CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

VERMES.

VERMES, in *Anatomy* and *Physiology*. We have explained, under **CLASSIFICATION**, the objections to which the Linnæan class of Vermes is liable, considered as one of the great divisions of the animal kingdom; and we have proposed, in place of it, an arrangement grounded on the distinctions of anatomical structure, and therefore better suited to the purposes of comparative anatomy, as well as more conformable to natural method. As the anatomical description of the **MOLLUSCA** (which order includes most of the Linnæan vermes) could not be prepared in time to appear under that word, it has been deferred to the present article, which will include also an account of the classes **VERMES** and **ZOOPHYTA**. In his "Handbuch der Naturgeschichte," Blumenbach retains the Linnæan term **VERMES**, dividing the class into, I. Intestina; II. Mollusca; III. Testacea; IV. Crustacea (Echino-dermata, Cuvier); V. Corallia (Zoophytes of most naturalists); and VI. Zoophyta (chiefly microscopic animals and the animalcula infusoria).

In the following article we shall employ the terms **MOLLUSCA**, **VERMES**, and **ZOOPHYTA**, not in the acceptation in which they are used by Linnæus or Blumenbach, but as they are explained in the article **CLASSIFICATION**;—the same sense in which they are used by the French naturalists generally, and by Cuvier particularly, in his most valuable and useful works, the "Tableau élémentaire" and "Leçons d'Anatomie comparée."

When, in descending along the scale of living beings, we arrive, after the class of fishes, at the invertebral animals, or such as have no vertebral column, we enter on an immense series of various creatures, the most numerous, and at the same time the most curious and interesting in respect to the difference of their organization and faculties.

At this point in the scale, the vertebral column is annihilated: as this column is the basis of the skeleton, the latter

no longer exists; and consequently the moving parts no longer have their points of action on internal organs.

Moreover, no invertebral animal breathes by means of cellular lungs: none have any vocal organ, nor consequently voice. They appear, at least for the most part, not to have true blood; that is, not to have a fluid undergoing a true circulation, and possessing, as one of its essential characters, the red colour. It would be an abuse of words to call the colourless fluid, which moves slowly in the cellular substance of polypes, blood. We might as well give that name to the sap of vegetables.

This constant and striking difference of colour in the nutritive fluids has been adopted, by some zoologists, as the basis of their first great division of the animal kingdom. The primary division into red-blooded and white-blooded corresponds with that into vertebral and invertebral animals.

The eye has no iris in invertebral animals. They have no kidney.

In the vertebral classes, and particularly in the first, or that of most complicated and perfect organization, all the essential organs are insulated, occupying distinct and separate situations; in the invertebral, they are all brought together.

In his "Tableau élémentaire," Cuvier introduces us to the Zoophytes as the last or most simple of the animal kingdom in their organization and faculties. The Mollusca possess nearly the same apparatus of organs for digestion, circulation, respiration, and sensation as red-blooded animals; and they even come very near in these points to fish. Insects, occupying a lower rank in the scale, have no distinct circulation, and respire by tracheæ. Yet they possess a spinal marrow, nerves, and organs of sense. In most vermes we recognise analogous parts, and they probably exist in all. But, in the zoophytes, we no longer discern these organic

apparatuses: there are, in a few, barely digestive viscera, and some indications of respiration. They have no circulation, no nerves, no centre of sensation: each part of the body seems to imbibe immediately the materials of its nutrition, and to possess, within itself, the power of sensation.

Hence most of these animals have very strong reproductive powers, quickly restoring injured or lost parts. Some of them indeed are multiplied by a simple division, like plants. There are however different degrees in this simplicity, which is common to all. We pass successively from beings, which have feet, tentacula, hard and soft parts, and distinct viscera (viz. the Echino-dermata), to others, whose whole body is a gelatinous mass variously shaped (Medusæ), or, when examined with the most powerful microscope, presents an apparently indivisible atom (Infusoria).

Stagnant water, infusions of vegetable substances, the recent seminal fluids of animals, &c. teem with animated points, round, oval, or of other figures, with or without a small appendix forming a tail, only visible, for the most part, by means of strong magnifying powers.

In the arrangement of Lamarck these creatures form a distinct class, with the name Infusoria. As they are merely microscopic objects, we can only say of them, that they are minute, gelatinous, semitransparent points, in some of which more opaque spots are visible, homogeneous, irritable throughout, and contracting in every direction; consequently changing their form frequently, but generally assuming, when at rest, a determinate figure in each species. We consider that these little bodies, which are mere animated points, and constitute, if we may use such an expression, the ultimate term of organization (ultimate at least to our means of research), are nourished by absorption from their whole surface, and are probably excited by the surrounding influences of caloric, electricity, &c. Thus they resemble vegetables, which live by absorption, executing no digestion, and performing organic motions in consequence of external excitation. But the infusoria are irritable and contractile, and execute sudden motions, which they can repeat: this characterizes their animal nature.

The genus *Monas* of Cuvier, or *Chaos* of Blumenbach, includes the simplest known animals. The latter author divides his *Chaos* into aquatic, infusorian, and spermatium, according as the animals are found in water, in vegetable infusions, or in animal semen. For a description of the latter, we refer to the article GENERATION; some of the former are noticed under ANIMALCULE. The *Volvox* is a round, yellowish or greenish, gelatinous, and nearly transparent animalcule, which swims round and round, and moves about without any visible organs of motion. It (*volvox globator*) abounds in summer in the water of marshes, and then has a reddish colour. In its interior we can distinguish globes similar to itself, which come out of its body, move about in the same way, and are seen to contain other smaller ones; so that the animal may be said to be pregnant at once with several successive generations. The *volvox confictor* is found in the water of dunghills, and moves by turning alternately to the right and left. It contains internally round moleculæ, which move about also.

The appearance of these animalcules, their motions, and the multiplication of some species, lead us to ascribe them to the animal kingdom; but doubts are entertained on the subject. In that sense, at least, we understand the remark of Cuvier, "On seroit même tenté de croire que plusieurs de ces animaux microscopiques ne se forment que de la décomposition des matières fournies à l'infusion." Tab. Element. p. 663.

They who believe them to be animals, are again divided

in opinion respecting the mode of their production; some arguing from analogy that they are produced by generation of some kind, while others admit of a spontaneous origin, or what has been commonly called *equivocal generation*. Spallanzani made several experiments to determine this point. Long boiling accelerated the production of the animalcules; which were also produced from the infusion of vegetable feeds burnt with the blowpipe. When boiling infusions were put into glass tubes, and these immediately hermetically sealed, no animalcules were produced. Electricity, tobacco-smoke, oleaginous, spirituous, and corrosive liquors destroy them. They will live a month in vacuo; but are not produced in that situation. Spallanzani's *Traacts on Animals and Vegetables*.

Respecting this doctrine of equivocal generation, we may observe, that the only argument in its favour is the indirect and unsatisfactory one arising from its opposers being unable to shew that the creatures in question are produced by a process of generation. The analogy of all nature, down to the minutest insects, which our microscopes enable us to investigate, affords a very strong presumptive proof against it, and leads us to conclude, that if our means of examination were more perfect, we should find that these creatures are produced and multiplied like all other animated beings.

There are numerous other species named after differences of form, or according to the circumstances under which they are produced. The *Proteus* has the singular property of changing its form, almost incessantly, into every possible modification of figure. The small animals found in vinegar and palse (*Vibrio aceti et glutinis*), generally called eels from their elongated figure, are almost large enough to be distinguished by the naked eye. Freezing does not destroy them; but evaporation does, unless they are protected by a little dust from the contact of the air. It is said that they change their skin, that they have different sexes, and produce young ones alive in spring, then lay eggs till autumn.

The genera just enumerated, viz. *Monas*, *Volvox*, *Proteus*, *Vibrio*, together with two others, *Bursaria* and *Kolpoda*, make up the order infusoria nuda of Lamarck; that is, such as have no external appendices. He has a second order of infusoria appendiculata, including such infusoria animalcules as exhibit any prominent part like hairs or tail, &c. The femal *vermiculi*, as they have been termed, (*cercarizæ*, Lamarck,) belong to this order, for they have a tail.

It includes also the genus or family of the *tricho-cercæ* and *trichodeæ*.

We come next to animalcules a little more complicated in their structure: they possess bellated organs, consisting of fine ciliated processes surrounding an opening, and susceptible of motion, with the supposed object of drawing their prey towards the aperture.

The following animals are formed by Lamarck into an order which he calls *Polypti*, and which we deem a very natural one. They are gemmiparous, or multiply by shoots. They have a small elongated body, homogeneous, gelatinous, very irritable, possessing wonderful reproductive powers, provided at its upper end with a mouth, which is surrounded by rotatory organs, or radiated tentacula, and serves as the entrance of an alimentary cavity which has no other opening. This cavity is the only organ they possess; it is usually an elongated bag, seldom folded on itself, or possessing any appendages. Such is the idea of a polype: when several of these little bodies are connected together, and participate a common life, they compose the animals of zoophytes.

The idea, which some have entertained, that the brain and nerves, the muscular system, &c. of which no trace can be discovered in the polypi, nevertheless exist, but are expanded and as it were melted down into the general mass of the body, so that every point is capable of sensation, muscular motion, &c. is a perfectly gratuitous and improbable supposition. On this view, it would follow that a fresh-water polype (hydra) has all the organs of a perfect animal in every part of its body, and consequently sees, hears, smells, &c. at all points. Thus it would be a more perfect animal than man, as each molecule would be equivalent, in the complement of its organization and faculties, to an entire individual of the human species. If we allow this to the polype, how can we refuse it to the monas, to vegetables? The study of nature teaches us in all cases, that when an organ ceases to exist, the faculty is no longer found.

The polypi are very irritable, and are acted on by external influences. Light attracts them towards the quarter whence it comes, as it does the branches, flowers, and leaves of plants. No polype pursues its prey; but when a foreign body touches its tentacula, they stop and convey it to the mouth; it is swallowed without distinction, digested if susceptible of that process, otherwise rejected.

Lamarck objects to the term zoophytes, or animal plants, because these are truly animals, and have nothing of vegetable nature. The only relations between polypi and plants are in the simplicity of their structure, in the connection of several polypi with each other, so as to communicate by their alimentary canal, and form compound animals; and in the external form of the masses which these united polypi compose, a form which for a long time caused them to be taken for true vegetables, since they are often ramified nearly in the same manner. Whether polypi have one or more mouths, we must always bear in mind that they lead to an alimentary cavity, that is, to an organ of digestion which does not exist in any vegetable.

The wheel animal of Spallanzani is a remarkable species of this kind (rotifer redivivus; vorticella rotatoria, Gmel.) It is found in stagnant water, and in the sand of sewers and tiles. It has a tail, and is forked in front; each portion bearing a kind of toothed wheel, which can be drawn in at pleasure. Internally an organ is perceptible with a slow and irregular motion, supposed to be a stomach.

The name of redivivus was given to this creature from its remarkable property, pointed out by Spallanzani, of recovering life after being long dried. This resuscitation will take place at the end of some years; but Spallanzani says, that the animal must be kept in the sand in which it is found. (See his Tracts.) Baker (on the Microscope) makes a similar representation with respect to the eels of blighted corn.

The vorticellæ of Cuvier, polypes à bouquet, (Brachionus, Blumenbach,) have small organs, like fine hairs, coming out of their anterior extremities, turning about rapidly and incessantly: their nature and use are unknown. Some have a tail; others a thread-like peduncle. The latter are united in an arborescent manner. They inhabit stagnant waters, and are so minute, that a mass of them appears only as a spot of film. They multiply by simple division, one of the small bodies splitting, and each half becoming an entire one.

The botrylli, corinae, and cristatellæ, or polypes à plumet of Cuvier, are allied to the latter: they possess tentacula or ciliated organs; and are either single or collected into arborescent masses.

In the fresh-water polypes (hydra), the organization is

rather more complicated, and the size of the animal increases, so that it is visible with the naked eye. They are gelatinous, semi-transparent, and therefore not easily recognised by a person unaccustomed to look for them. Their body is elongated, small at one end, by which it is attached to some aquatic plant, testaceous animal, &c. and larger at the other. It consists of a cavity terminating at the large end by a round orifice, surrounded by long tentacula. The animal indeed may be regarded as a stomach, provided with instruments for catching its food; the latter is the use of the tentacula. The substance of the body appears, under the strongest magnifying powers, a mere jelly, with more opaque portions interspersed. Blumenbach compares it to boiled fago. They live on naiades, monoculi, and other small aquatic animals, which they seize with their tentacula, and convey into the stomach, where they are digested, and from which the refuse is rejected by the same opening.

They perform locomotion, and seem very sensible to light, although nothing like muscle or nerve can be discerned in them. Neither have any vessels been seen in them: they are said indeed to receive a tint from the food they take, so that it must pass immediately from the stomach into the organs.

The most surprising circumstances, however, in these animals, are their mode of multiplication and their extensive power of reproduction. They propagate by buds from their own body. If cut into six or more pieces, each becomes a perfect animal: they may be inverted, and the external and internal surfaces will be changed and assume each other's functions. When they are partially divided in the longitudinal direction, the separated parts heal so as to form two heads or tails, &c. See the article POLYPE; also, Trembley Mem. pour servir à l'Histoire d'un Genre de Polypes d'Eau douce, &c.; Leid. 1744, 4to. Baker's Natural History of the Polype; Lond. 1743, 8vo. Rösel Historie der Polypen; in the third volume of his Insecten-belustigungen. Schäfer Armpolypen in den süßen Wassern um Regensburg, 1754, 4to.

From the fresh-water polypes, there is an easy transition to the animal of the West India islands described by Ellis, in the Phil. Trans. vol. lvii. tab. 19. fig. 1, and in his Natural History of Zoophytes, tab. 1. fig. 1, under the name of actinia sociata, or cluster animal flower. It is the zoonthe à dragons of Cuvier, hydra sociata of Gmelin. It is of a tender fleshy substance, consisting of many distinct tubular bodies, each of which swells above into a small bulb: at the top of this bulb is the mouth, surrounded by one or two rows of tentacula, which can be extended or withdrawn at pleasure: in the latter state they look like circles of beads. These bodies are connected below to a firm fleshy wrinkled tube, sticking fast to the rocks, and sending forth other fleshy tubes, which creep along in various directions, and give origin to similar bodies rising up irregularly in groups. Knobs are observed on the adhering tube, from its insinuating itself into the inequalities of the coral rock. When the animal is dissected lengthwise, a large cavity is exposed, into which a tube opens from the mouth. From this tube eight small cords arise, continued to the lower part of the animal, where they seem to be lost in the fleshy basis.

The small polypi will appear to us more wonderful, and will more powerfully engage our attention, when we find that they produce all those marine substances, formerly called zoophytes, from a notion that they partook both of the animal and vegetable natures, and including corals, corallines, madrepores, millepores, sponges, &c. &c. So active are these minute creatures in some parts of the ocean,

that their constructions form the basis of new islands, constitute extensive and dangerous reefs, block up harbours, create shoals, &c. All which effects are produced by animals not greatly exceeding in bulk the fresh-water polype.

It has been repeatedly found in the West Indies, that wrecks become covered universally and thickly with madrepoles and other corals within three-quarters of a year. The formerly excellent harbour of Bantam is now almost entirely occupied by corals. Several volcanic isles of the South-sea, and some even of the West Indian, as for example Barbadoes, are coated over with coral. The dangers to navigators from great coral banks rising out of the bottom of the sea, in unknown tracts, may be illustrated from what Cook and Flinders experienced on the coasts of New Holland.

These productions were formerly described with vegetables, and they will be found so classed by Tournefort: their vegetable nature was even defended by Pallas. Our countryman Mr. Ellis has the honour of demonstrating that they belong to the animal kingdom, and of shewing the animals by which they are formed. See his papers, accompanied by plates, in the 48th, 49th, 50th, 53d, 55th, and 57th vols. of the Phil. Trans.; also his admirable works, "Natural History of Corallines," &c. Lond. 1755, 4to.; "Natural History of many curious and uncommon Zoophytes," &c. 1786, 4to. See also Donati della storia Naturale Marina dell' Adriatico; Venez. 1750, 4to.; Cavolini Memorie per servire alla storia de Polipi Marini; Napol. 4to.

The animals belonging to these substances may be called compound polypi. The fleshy masses, which are differently circumstanced in different cases, exhibit numerous projecting heads, each of which has a mouth with radiated tentacula. These heads may be either extended or withdrawn. Thus all the polypi are connected into one mass, which is increased by shoots. In structure, these compound polypi do not differ from the simple ones, so far at least as our present knowledge of them goes.

Some zoophytes consist of a horny tube, branching out variously, and hollow internally. The axis of these zoophytes is occupied by a stem of animal substance, and at each of its branches a polype projects. The horny covering probably grows as the shells of the testacea do: and we may suppose, that the tentaculated heads of the animal serve to procure it nourishment. The stercularia is of this kind: the animal is not very intimately connected to the tube.

The tubularia occurs in fresh water as well as in the sea; there is a horny tube, sometimes simple, sometimes ramified. The polype at the end exhibits tentacula, or a bundle of hairs like a pencil. The capularia and fertularia are of the same kind.

In other instances, each polype, instead of being connected to a common stem, is contained in a horny or calcareous cell, with thin sides. In these there is not the same direct communication as in the former genera. Each polype is insulated, or, if they communicate, it must be by very fine filaments, traversing the cells.

In these and some other of the zoophytes, vesicles are occasionally seen, and have been supposed to be ovaries: the latter opinion, however, is inconsistent with the views entertained at present. Cellularia, flustra, and corallina, exemplify this: though, with respect to the latter, it must be observed, that its animals have not yet been demonstrated, and its pores are so small, that they must be extremely minute.

The zoophytes which have an axis of solid substance, covered by a soft fleshy layer, with hollows, which con-

tain tentaculated polypi, have been called ceratophyta. The axis is sometimes ligneous or horny, or stony, and covered by a fleshy substance capable of contracting. In this there are numerous hollow tubercles, from which there are projected and withdrawn at will, heads, or rather tentaculated mouths formed like polypi, all belonging to the same animal, like the branches of a polype: that is, the soft substance covering the solid axis is to be regarded as the animal, of which these are many mouths. It has the power of extending itself to form a basis of adherence to solid bodies. We also observe it extending over and forming a new stratum of coralline matter, inclosing foreign bodies that may be attached to the axis. That the coralline axis is formed by the fleshy covering cannot be doubted; we perceive in it concentric strata, indicating its successive depositions, and the surface is marked by longitudinal lines corresponding to the figure of the animal covering. When the trunk of the coralline tree contains ligneous or vegetable matter, probably this is an extraneous body, on which the coral is deposited. The branches are produced by an elongation of the soft flesh, which forms them in its interior: but their strata are not continuous with those of the trunk, as in the case of trees.

Cuvier (Tableau élémentaire, p. 671.) states, that the nourishment taken by any of the polype heads is converted to the use of the whole animal; to which, also, he ascribes a common will, as evidenced by its extension for the purpose of adhering to surrounding objects. We know no facts concerning the structure of the animal covering, at all sufficient to warrant these statements.

The *gorgonia nobilis* (fish nobilis), or red coral, is an example of this structure. The axis is the compact stony substance, of the hardness of marble, of which coral ornaments are made. The fleshy covering is of a bright red, containing calcareous molecules, which form a kind of incrustation when dried, and exhibiting numerous cavities in which polypi are lodged. Each of these has eight denticulated tentacula. The antipathes and isis belong to this division. See the excellent plates of Ellis in the Natural History of Zoophytes, exhibiting all the facts above enumerated; particularly tab. 3. fig. 1—5. for various views of the isis hippuris, or black and white coral: tab. 11. *gorgonia flamma*: tab. 12. figs. 1, 2. *gorgonia ceratophyta*: tab. 13. figs. 3, 4. *gorgonia pectinata*: tab. 14. figs. 1, 2. *gorgonia briareus*: fig. 3. *gorgonia pinnata*.

The pennatula, or sea-feather, belongs also to this division, and it is remarkable among the marine zoophytes, as being unattached, and possessing the power of locomotion. All the others are fixed by their trunks or bases to some other object, as rocks, shells, sea-weed, &c. &c.

The pennatula resembles a feather, and consists of a shaft and barbs. The former is cartilaginous and covered by a fleshy layer; from which, at its smaller half, forty, sixty, or more curved arms proceed on both sides, like the barbs of a feather. Ten, twelve, or more smaller processes are continued from one edge of each of these primary barbs; and in each of these is contained a delicate gelatinous polype, with eight tentacula.

"The stem of the suckers of this animal," says Mr. Ellis, "is of a cylindrical form: from the upper part proceed eight fine white filaments or claws to catch their food; when they retreat on the alarm of danger, they draw themselves into their cases, which are formed like the denticles in the corallines; but here each denticle is furnished with spiculae, which close together round the entrance of the denticle, and protect this tender part from external injuries." Phil. Trans. vol. liii. p. 424.

Thus,

VERMES.

Thus, in a feapen of a span long, there are at least above 500 of these polypes. (See Ellis, Zoophytes, p. 6. et seq. tab. 8.) They swim about in the sea by a common motion produced by their numerous polypi; and are remarkable for possessing phosphoric properties; hence one kind has been called pennatula phosphorea, and Linnæus says of it, "habitat in oceano, fundum illuminans." (Phil. Transf. vol. liii. tab. 19. fig. 1—5.) The pennatula rubra, or Italian feapen, is also strongly phosphoric. Dr. Shaw observes of it, that on the coast of Algiers it sends forth so great a light in the night, that the fishermen can distinguish the fish as they swim by it, so as to know where to cast their nets. See Phil. Transf. vol. liii. p. 21. figs. 1, 2.

The soft covering of the stem of the feapens consists externally of a strong coriaceous membrane, and internally of a thinner membrane; the cavity of the latter is occupied merely by the bone or cartilage. Between the two membranes are innumerable yellowish eggs, floating in a whitish liquor. The fins are also composed of two skins; the outer strong and leathery, the inner thin and clear. The cylindrical part of the fuckers is formed in the same way, except that their outward skins are softer. Both the fins and fuckers are hollow; so that the cavity of the fuckers may communicate with their fins, as their cavity does with the trunk.

— See an account of the feapen or pennatula phosphorea of Linnæus; likewise a description of a new species of feapen, found on the coast of South Carolina, with observations on feapens in general, by J. Ellis, in the Phil. Transf. vol. liii. with three plates representing various species, with magnified views of the fins and polypes.

The lithophytes are zoophytes with an axis or basis of a stony substance, in which receptacles for polypi are excavated. The madrepores and millepores belong to this division. See Ellis's Zoophytes, tab. 23. for views of the millepora truncata, in which the polypes are seen magnified. They are so numerous in some seas, as to form entire islands; several of those in the South-sea are a mere congeries of madrepores.

The last kind of zoophytes have a spongy friable or fibrous substance for their basis, covered by a fleshy incrustation, which sometimes contains polypes. There are only two genera; viz. alcyonium and spongia. The interior of the latter is light, friable when dry, composed of fine, diverging fibres. The animal covering is a soft incrustation, without calcareous particles, which becomes coriaceous by drying, and is pierced with cells from which the heads of polypes issue. See Ellis in the Phil. Transf. vol. liii. tab. 20. figs. 10, 11, and 13.

Whether the sponges are animals, is still doubted even by good naturalists: at all events, they possess the characters and faculties of animals in the lowest degree. They consist of a more or less dense and flexible fibrous tissue, covered in its recent state by a semifluid and thin kind of animal jelly. Regularly formed round apertures are observed, sometimes pierced in slightly prominent papillæ; but no polypes issue from these, nor has any thing of the kind ever been seen in them. The only circumstance mentioned about them, that can be deemed a sign of life, is a slight and hardly perceptible contraction or shrinking, when they are torn from their situation. After their death, the animal jelly dissolves and is removed, and the fibrous basis alone is left. See Ellis on the Nature and Formation of Sponges, Phil. Transf. vol. lv. pl. 10 and 11.

Next to the polypes, whether existing singly and unconnected, or connected with those constructions which con-

stitute the zoophytes, we may place, in respect to simplicity of structure, the actinize and meduse. The former possesses a coriaceous body, with considerable power of contraction, which enables the animal to change its figure very remarkably, from a half sphere, when the mouth is shut, and the tentacula withdrawn, to a cylinder when it is open. It adheres by a circular disk to the sand, rocks, &c. The opposite end forms a mouth, surrounded by several rows of long, conical, and moveable tentacula, which can be withdrawn or extended at pleasure. The mouth is round, and leads straight into a cylindrical stomach, with rugous sides. They live on small crabs principally, which they seize and envelop with their tentacula. The refuse is rejected by the same passage. Between the parietes of the stomach and the skin there is a vast number of very fine intestines, interwoven with each other, of which the communications and uses have not been found out.

The actinize are famous for their reproductive powers. When cut in two, each part becomes a perfect animal. The tentacula and other parts are easily restored. The young actinize are born alive, either at the mouth or through the side of the parent; in the latter case the cicatrix soon closes. They move sometimes on their basis, sometimes on the tentacula.

Lamarck's class of polypi terminates with the actinize. It includes the following orders:

I. Polypes rotifères (wheel-bearing), having ciliated and rotatory organs round the mouth. Urceolariz. Brachioni. Vorticellæ.

II. Polypes à polyplier, — polypes connected with hard substances; having radiated tentacula about the mouth, and connected to a hard substance, which does not float loose in the water.

1. With membranous or horny polyplier, without any distinct cortex. Critatella. Plumatella. Cellularia. Sertularia. Flustra. Cellepora. Botryla.

2. Polyplier with a horny axis, covered by an incrustation. Acetabulum. Corallina. Spongia. Alcyonium. Antipathes. Gorgonia.

3. Polyplier with an axis partly or entirely stony, and covered by a bark-like incrustation. Isis. Corallium.

4. Polyplier entirely stony, and without incrustation. Tubipora. Lunulite. Ovalite. Siderolite. Orbalite. Alveolite. Ocellaria. Eschara. Retepora. Millepora. Agarica. Pavonia. Meandrina. Aitrea. Madrepora. Caryophyllia. Turbinolia. Fongia. Cyclolite. Dactylopora. Virgularia.

III. Polypes flottans; loose polypi.

Polyplier loose, floating in the water, having a horny or osseous axis, covered by a fleshy investment, to which all the polypi are connected: radiated tentacula round the mouth of the latter. Funiculina. Veretilla. Pennatula. Encrinurus. Umbrellaria.

IV. Naked polypi; mouth with radiated tentacula, often multiplied; no polyplier. Pedicellaria. Corina. Hydra. Zoanthus. Actinia.

The substance of the medusæ is transparent and gelatinous (whence their common name of sea-blubber), and almost entirely destroyed by evaporation or boiling. In the state of rest, their body represents the segment of a sphere, with the convexity smooth, and the opposite surface furnished with various tentacula. Coloured lines are observed in their interior, but nothing which indicates circulation. Towards their edges, however, numerous vessels are observed, communicating apparently with the alimentary cavity. They inhabit the ocean, swimming very well by rendering their body

body alternately more and less convex. When the tide ebbs, many of them are left on the shore motionless. Although these creatures are very numerous, and in some instances of great bulk, their structure and economy are hitherto but little known. Messrs. Péron and Le Sueur devoted their attention to them very particularly in their voyage to the Southern islands; have delineated some species in their "Voyage aux Terres Australes;" and have announced a comprehensive work on the whole tribe, in which their natural history and structure are to be amply investigated. Perhaps this has even now appeared; but we have not seen it. In the notice of this publication, given in the *Annales du Muséum d'Histoire Naturelle*, tom. xiv. p. 218. et seq. they observe, "that the substance of the medusæ is resolved entirely, by a kind of instantaneous fusion, into a fluid analogous to sea-water; yet the most important functions of life are exercised in these bodies, which seem to be merely coagulated water. Their numbers are prodigious, yet we have no certain knowledge of their mode of generation; they are in some cases several feet in diameter, and weigh fifty or sixty pounds, yet their system of nutrition escapes us: they execute the most rapid and continued movements, yet we can discover no fibrous or muscular structure: their secretions are exceedingly abundant, yet we see nothing of the mechanism by which they are executed: they have respiration of a very active kind, but its seat is a mystery: they appear very feeble, yet fishes of some inches in length are their constant prey: their stomach seems incapable of any action on the latter animals, but they are digested immediately. Several of them contain air in their interior; we do not know how they can derive it either from the atmosphere or water, or develop it in their intestines. Several are phosphoric: they shine in the darkness of the night like so many globes of fire; yet the nature, the principle, and the agents of this striking property are so many problems. Some sting and numb the hand which touches them; the cause of this phenomenon is equally unknown." The latter property, being one of the most obvious, has influenced the name of these beings: they are called in all languages, sea-nettles.

In the same volume of the *Annales du Muséum*, the authors quoted above have given a view of the generic and specific characters of the medusæ, as they will be described in their great work. See p. 325, et seq.

The echino-dermata of Cuvier are the most complicated in their structure among the zoophytes: they have a coriaceous or calcareous covering, a distinct internal respiratory organ, and often numerous retractile feet. In many the skin is of a more or less crustaceous nature; or it may even be a true shell. The feet, passing through apertures of this covering, admit of being extended or withdrawn: they are often arranged with much regularity. There is a mouth, provided generally with five teeth arranged in a circle, and leading into an alimentary cavity in the interior of the body: there are also ovaries; and a very extensive ramified organ, which seems to establish a perpetual circulation of water through the bodies of these animals, and consequently a kind of respiration. Nothing is found like heart or brain. The holothuria (sea-cucumber), with its cylindrical body and thick leathery skin; the asterias, with its conical radiated processes and pliable calcareous integument; and the echinus (sea-hedgehog), with a complete calcareous shell, belong to this division.

The medusæ, star-fish, echini, &c. are formed by Lamarck into a distinct class, which he calls Radiaria, or radiated animals, because their bodies are distinguished, in

the arrangement both of their internal and external parts, by being formed into radii surrounding a centre; a formation of which the first sketch is seen in the polypes.

Their mode of generation is not exactly known, but they possess considerable powers of reproduction: they contain organs that seem like ovaries. The mouth is placed downwards, or on the inferior surface of the body: they have no head, eyes, nor articulated limbs, probably no nerves; and no circulating system.

This class comprehends two orders:

I. Radiaria mollusca (soft radiant animals). Gelatinous body, soft transparent skin, without any articulated spines; no anus. Genera: Stephanomia. Lucernaria. Physiphorus. Phyalia. Velella. Porpita. Pyrosoma. Beroc. Equorea. Rhizostoma. Medusa.

II. Radiaria echino-dermata. Opaque crustaceous or coriaceous skin, furnished with retractile tubercles, or spines articulated upon tubercles, and perforated by rows of holes.

1. Stelleria. Skin not irritable, but moveable; no anus. Genera: Ophiurus. Asterias.

2. Echinida. Skin not irritable, nor moveable; an anus. Genera: Clypeastrus. Cassidites. Spatangus. Ananchites. Galerites. Nucleolites. Echinus.

3. Fittulida. Body elongated; skin irritable and moveable; an anus. Genera: Holothuria. Sipunculus.

The vermes of Cuvier approach very much to the larvæ of insects. Perfect insects are distinguished, among all the white-blooded classes, by the perfection of their organs of motion, their members having distinct articulations, and the component parts being solid. The larvæ in some cases enjoy the same advantage: those of the orthoptera and hemiptera have as perfect legs as the perfect insects: in the larvæ of the lepidoptera and coleoptera, the members are generally very short, and not capable of prompt motion. The limbs disappear entirely in the larvæ of the diptera, and many of the hymenoptera, their place being supplied by hairs, bristles, or merely by the rings and transverse wrinkles of the trunk. The vermes resemble the last mentioned larvæ; but they undergo no change of form.

The largest have the body divided into distinct rings: a knotted nervous cord is found in their interior. Those which live in water, breathe by membranous or tufted branchiæ, like many aquatic larvæ. Others have along the sides of their body stigmata precisely similar to the openings of the tracheæ in insects. The organs of motion, in several instances, are stiff bristles or spines. Others crawl by successively wrinkling or contracting the different parts of the body. Some have even antennæ. In short, we cannot assign any general character, drawn either from external form or internal structure, which would be sufficient, in all cases, to distinguish worms from the larvæ of insects.

Most worms inhabit the interior of other animals, as the larvæ of some insects do: others live in the earth or water. Some of the latter construct solid habitations, either by agglutinating foreign substances, or by pouring out a calcareous matter, like that of the testaceous mollusca. But the shells of worms may always be distinguished from those of the mollusca, because they are always either straight or tortuous tubes, never regularly spiral, or an expanded cone, and more particularly because the animal is never attached, which it is almost invariably in the case of the mollusca.

This class of vermes has been divided by Lamarck into two; namely, worms, and annular animals (annelides). His class of worms contains the intestinal worms, and some others, whose organization is equally imperfect. The animals included in this class have a soft body more or less elongated,

VERMES.

gated, without head, eyes, or articulated limbs. They have no circulating vessels. No organ of fecundation has been hitherto discovered; so that sexual generation does not seem to exist in them. The parts supposed in some to be ovaries seem to be mere collections of reproductive molecules, which require no fecundation. Their intestinal canal is complete, or possesses two openings; and the mouth consists of one or more apparatuses for sucking.

The class is divided into three orders; *viz.* cylindrical, vesicular, and flattened worms, according to the form of the body.

The class of annelides or annulosa has a soft elongated body, covered by transverse rings, and no articulated limbs: seldom a head or eyes. They have a knotted spinal marrow; arteries and veins containing a fluid, which is generally red. They breathe by branchiæ, which are sometimes external and prominent, sometimes concealed.

The class consists of two orders:

I. Annulosa crypto-branchia (having concealed branchiæ).
Genera: Planaria. Hirudo. Lernæa. Clavala. Naias. Lumbricus. Tbalassema.

II. Gymno-branchia (having external branchiæ). Genera: Arenicola. Amphinomia. Nereis. Terebella. Amphitrite. Sabellaria. Serpula. Spirorbis. Siliquaria. Dentalium.

The mollusca have a muscular heart, to which the nutritive fluid is brought by the veins, and from which it is carried out by the arteries; they have organs nearly resembling the gills of fish, in which the fluid is exposed to the influence of the surrounding element, and glands which pour different secretions into the alimentary canal. They have a brain, nerves, and some organs of sense; but in the latter there is more variety than in the other points. Their body, or at least their limbs have no bone in the interior; but several of them are inclosed in very firm, even strong cases, which are called shells (*testæ*), whence the animals themselves have been denominated testacea or shell-fish in common language. These are comprehended, together with the entirely naked ones, under the name mollusca.

They have white and very irritable muscles. They are extremely tenacious of life; moving after being cut into several pieces, and reproducing very considerable portions of their body when destroyed in any way. Their skin is always soft, and generally lubricated by a viscid secretion: it is very sensible, and possesses organs, called tentacula, capable of elongation, for the purpose of touching. None have organs of smelling, but there are eyes in several, and ears in some. The body is generally enveloped, or at least covered in great part by a membranous investment, called in French *manteau*, which we shall term the mantle. Several have moreover a hard covering named a shell, composed of one or more pieces, called valves, and produced by calcareous matter transuding from the mantle. To this the body is fixed by means of muscles. Most mollusca inhabit the sea; some dwell in fresh water, and others live in the earth.

Lamarck removes four genera from the mollusca, to constitute a distinct class, which he calls cirrhipèdes: these genera are tubicinella, coronula, balanus, anatisa. Their principal distinguishing characters are articulated arms covered by a horny skin; two pairs of mandibles to the mouth; a knotted nervous cord.

It appears from the preceding review, if we join to it the consideration of the structure of insects, that the animals with white blood, as they have been called, have not so many common characters as the red-blooded. Their chief distinctions are of the negative kind, as the absence of a

vertebral column, and of an interior articulated skeleton, &c.

“Thus,” says Lamarck, “when we consider successively the various organic systems of animals, from the most compound to the most simple, we shall observe a *degradation* of the organization commencing even in the class which comprehends the most perfect animals, proceeding from class to class, though with anomalies caused by various circumstances, and terminating at last in the infusoria. The latter are the most imperfect, and most simply organized; the degradation in them has reached its term, the organization being reduced to a simple, homogeneous, gelatinous body, almost without consistence, possessing no distinct organs, and simply formed of a very delicate tissue, which seems to be affected by the surrounding subtle fluids.

“We have seen each organ, even the most essential, gradually degenerate, become less distinct, and at last entirely disappear long before we had reached the extremity of the series: and we may observe, that it is principally in the invertebral animals that the special organs are observed to be annihilated.

“Before we quit the division of vertebral animals, great changes are perceived in the perfection of the organs, and even some of them, as the urinary bladder, the organ of the voice, the eye-lids, &c. disappear entirely. The lung, which is the most perfect apparatus for breathing, degenerates in reptiles, ceases to exist in fishes, and is not found in any invertebral animal. The skeleton itself, which furnishes the basis of the four limbs possessed by most vertebral animals, begins to decline, particularly in reptiles, and ends altogether in fish.

“But in the invertebral animals, we see the most important parts annihilated, one after the other: the heart, the brain, the branchiæ, conglomerate glands, circulating vessels, the organ of hearing and of sight, those of sexual generation, and even those of sensation and motion. We should seek in vain among the polypes for the slightest trace of nerves or muscles: irritability alone supplies the place of sensation and voluntary motion. All the motions of a polype are the result of external excitation. Put a fresh-water polype (hydra) in a glass of water, and place this glass in a chamber, which receives light from one quarter only. It will slowly move itself towards the part on which the light falls, and will remain there. Vegetables turn themselves towards the light in an analogous manner.

“Undoubtedly, wherever a particular organ no longer exists, the faculty which it exercised ceases also: the latter is also more obscure in proportion to the deterioration of the organization. Insects are the last, in the scale of animated nature, possessing eyes; we have reason to suppose that they see very obscurely, and make but little use of their eyes.

“This degeneration may be observed, even in the nature and consistence of the essential fluids, and of the flesh of animals. The blood and muscles of the mammalia and birds are the most compound and animalized of animal productions. After fish, these substances are progressively changed to such a degree, that in the soft radiant animals, in the polypi, and particularly in the infusoria, the nutritive fluid has merely the colour and consistence of water, and the flesh is a soft jelly, scarcely animalized.” *Philosophie Zoologique*, tom. i. p. 212, et seq.

The following Table, extracted from the same work of Lamarck, p. 277, et seq. exhibits the invertebral animals, arranged according to their structure, with their principal characters, in a progressive series, from the most simple upwards.

VERMES.

Animals without Vertebrae.

Classes.		Degrees.
I. INFUSORIA.	{ Generation by splitting of the body, or by shoots; body gelatinous, transparent, homogeneous, contractile, and microscopic: no radiated tentacula, nor rotatory appendices; no special organ, not even for digestion.	1st. No nerves; no vessels; no internal and special organ, but for digestion.
II. POLYPI.	{ Generate by shoots; body gelatinous, with great powers of regeneration; no internal organ, except an alimentary cavity with a single opening. Mouth at one end surrounded by radiated tentacula, or by ciliated and rotatory organs. They compose, for the most part, compound animals.	
III. RADIARIA.	{ Suboviparous: great powers of reproduction; no head, eyes, nor articulated limbs; the form of the body radiated; mouth placed below.	2d. No knotted medullary cord; no circulating vessels; some internal organs besides those of digestion.
IV. VERMES.	{ Suboviparous; body soft, and highly reproductive; undergo no metamorphosis; no eyes, nor articulated limbs, nor radiated disposition of internal organs.	
V. INSECTA.	{ Oviparous; undergo metamorphosis; possess, in their perfect state, eyes in their head; six articulated limbs; tracheæ extending over the whole body; a single fecundation in the course of life.	3d. Nerves ending in a longitudinal, knotted, medullary cord; respiration by tracheæ, which convey air; circulation imperfect, or none.
VI. ARACHNIDA.	{ Oviparous; undergo no metamorphosis, but possess always articulated limbs, and eyes in their head. Tracheæ confined to certain parts; an attempt at circulation; several fecundations in the course of life.	
VII. CRUSTACEA.	{ Oviparous; body and limbs articulated; skin crustaceous; eyes on the head; and generally four antennæ; respire by branchiæ; a longitudinal knotted medullary cord.	4th. Nerves ending in a brain, or a knotted medullary cord; respiration by branchiæ; arteries and veins for circulation.
VIII. ANNELIDA.	{ Oviparous; body elongated and annulated; no articulated limbs; seldom eyes; respire by branchiæ; knotted nervous cord.	
IX. CIRRHIPEDA.	{ Oviparous; possess a mantle and articulated arms, with horny skin; no eyes; respire by branchiæ; knotted nervous cord.	
X. MOLLUSCA.	{ Oviparous; body soft, with its parts not articulated; mantle variable; respire by branchiæ, varying in form and situation; no spinal marrow, nor knotted longitudinal cord, but nerves ending in a brain.	

Structure and Formation of the hard Parts, which supply the Place of the Skeleton in the lower Orders.—The want of an internal articulated skeleton is the most striking character of the second great division of the animal kingdom, or the invertebral animals. Insects and crustacea have a species of external skeleton; they possess hard parts, which are at once instruments of motion, and means of support and protection for the included softer organs. (See INSECTS, in *Anatomy*.) The shells of the mollusca are to be regarded rather as provisions for defence, as habitations of the soft animals which they inclose, than, like the skeleton of the vertebral animals, or the hard external covering of crustacea and insects, as instruments of motion.

Shells are composed, like bones, of a calcareous matter, intimately connected with a gelatinous substance, from which it may be separated by means of acids. It is not disposed in laminae, or in fibres, but is distributed uniformly throughout the whole body of the shell.

It is only in some species that we find strata easily separated, and as it were agglutinated to each other, like the leaves of paper in the formation of pasteboard. We know from observation that these strata do not all exist in young animals; they have only the external, which are at the same time the smallest. In proportion as the animal increases in age, it forms a new stratum on the internal surface of the shell, which extends beyond the edges of all the preceding strata; so that each operation of this kind adds to the size

of the shell in length, breadth, and thickness. These are certain facts: to prove them, it is only necessary to compare some shells of the same species that have belonged to individuals of different ages; the fewest strata will always be found in the shells of the young. Muscles, which may be observed when they are very young, and even before they quit the body of the mother, have at that period one stratum only; but the shell is not therefore soft and gelatinous; it possesses the same firmness as the adult shell, and its greater fragility is merely owing to its thinness.

It has been a question among physiologists, whether these shells grow by development or intussusception, or by simple juxtaposition? That is, whether the shell, like our bones, contains nutritive vessels capable of increasing, diminishing or variously modifying it; or whether the gelatinous and calcareous component elements of the shell are simply deposited from the surface of the animal's body, and attached to the pre-existing mass? We conceive that the latter mode of formation has been incontrovertibly established; that the substance of the shell is inorganic, and consequently possesses no power in itself of increase, diminution, or any vital change.

This point was first investigated by Reaumur, whose researches are so clear and satisfactory, that they have left very little to be added by his successors. They are detailed in the *Memoires de l'Academie des Sciences* for 1709, under the title "De la Formation et de l'Accroissement des Coquilles

quilles des Animaux tant terrestres qu'aquatiques, soit de Mer, soit de Terre." He followed up the subject, in answer to some objections, in the Memoirs for 1716, p. 303: under the title "Eclaircissemens de quelques Difficultés sur la Formation et l'Accroissement des Coquilles."

"When (says the author) the animal, which filled its shell exactly, increases in size, and the shell is consequently insufficient to cover it entirely, a part of the surface must be exposed. This is the part nearest to the opening, for the animal's body can be augmented only in that direction. The inhabitants of a spiral shell, as snails, grow only in the direction of the head, or towards the opening of the shell; while those which occupy bivalve shells, as mussels, can increase in their whole circumference. In both cases it is the uncovered portion of the body that produces the shell." *Mém. de 1709*, p. 367.

"That the animal really grows before its shell, in the way just pointed out, may be easily seen in the garden-snails at their season of increase. We observe that the shell is too small. The animal fixes itself against a wall, or remains at rest, and a part of its body manifestly extends beyond the shell all round." *Ibid.* p. 370.

He illustrates the natural growth by the process employed for repairing injuries. "After breaking away a portion of the shell, which can be easily done without injuring the animal, as it adheres only at one point, we observe the creature soon attach itself to the sides of the vessel in which it is placed. A fine pellicle, which may be compared to the web made by the house spider in the angles of walls, covers the body in twenty-four hours, and forms the first stratum of the new shell. In a few days this is thickened by several strata produced under it; and, at the end of about ten or twelve days, the new portion of shell has nearly the thickness of the original part." P. 371.

"If," he observes, "the injury were repaired by means of materials furnished by the broken edge, as in the case of a fractured bone, we should observe a callus produced from that margin, and extending gradually into the centre of the aperture. But the edge, in fact, remains unaltered, and the matter deposited is on the surface of the body." P. 373.

That the body of the animal affords the materials by which the shell is formed, is rendered more evident by the following experiments. "I broke away a portion of the shell, and placed in the opening, between the animal's body and the shell, a portion of lamb-skin leather, such as is used to make what are called chicken gloves. I fastened this to the internal surface of the shell, so that it completely shut up the opening intervening between the shell and the animal's body. It is evident, that if the shell itself produced the materials of restoration, the new substance ought to be formed, in such circumstances, on the exterior surface of the leather. On the contrary, however, that side which was towards the animal's body became lined with shell, and none was deposited on the exterior surface.

"Again, I broke away a part of the shell at its opening, introduced a portion of the leather, and fastened it to the inner surface; then turned it down, and fastened it also to the outer surface, so that the circumference of the opening, with its broken edge, was completely covered. Now, if the shell grows by a principle of vegetation, either this covering should have prevented the growth, or the elongation of the shell should have pushed the leather forwards. On the contrary, the shell grew, and the leather remained where it was placed, being interposed between the old shell and the new piece, to the formation of which the former consequently could not have contributed." P. 374.

"It is a necessary consequence of the preceding facts, that

the shells of snails increase in size, only by an addition to the number of their spiral turns, and that the length of a turn, when once formed, continues always the same. The truth of this statement is easily shewn. If the shell of a full-grown snail be reduced to the same number of turns as that of a young one of the same species, the two shells are then of the same size. This holds true, even with respect to the shells of snails just produced. A turn more or less makes a great difference in the size of the shell; for the diameter of each is nearly double that of the preceding, and about one-half of the following: hence half, or even a fourth of a turn more increases considerably the size of the shell." P. 378.

The same point has been attentively examined by Mr. Carlisle, whose conclusions confirm in all respects those of Reaumur.

"The most apposite illustrations, and the most positive instances of union between vital and extra-vital parts, are to be found in the testaceous tribe of animals. After a long-continued and careful investigation, I am fully convinced, that the shells of all the vermes of Linnæus are extra-vascular from their commencement, and remain so during the whole of their connection with the living creature. The first production and the growth of those shells always depend upon a deposit of material thrown out from the surface of the body of the living animal. The figure and colours of the several parts of those shells, in every species, depend upon the shape and the colouring glands of the modelling organs. Fractures are repaired by spreading a crustaceous fluid over the inner edges, and never by any exudation from the fractured parts, since they retain always the squared broken surfaces after such repairs. Extraneous bodies are equally covered with shell, whether they are in contact with the parent shell or not. The first may be seen in the frequent envelopment of nerites in the common oyster; the latter has been often ascertained by the experiments made for the purpose of creating artificial pearls, and which might, if skilfully practised, yet prove very successful. The borings of parasitical vermes into shells are never filled up, or the bored surface altered, unless such borings penetrate into the cavity where the living animal dwells, and then the apertures are invariably plugged up or smeared over with pearly matter. The water-worn external surfaces of old shells, and other external abrasions, are never repaired, which is to be seen in old living oysters exposed to the moving friction of currents or strong tides, in the worn-off spines of the pholas dactylus, and in the convex points of the two valves of old mytili, especially the mytilus anatinus. I have fought in the most extensive collections of the metropolis for examples of fractures and other injuries which have occurred to the shells of living vermes, and I have collected many remarkable specimens. They all demonstrate the same results without any exception. I have made numerous experiments upon the garden-snail, (*helix nemoralis*), by fracturing and breaking away the shell in various parts, and have always found the repairs to be effected from within by first smearing over an epidermoid varnish, and then by plastering the inner surface of that film with successive calcareous laminae. I have in vain attempted to inject the shells of recent vermes from the vascular parts of their bodies; and am fully satisfied, that none of their albuminous or gelatinous testaceous membranes were ever at any time traversed by vessels; indeed, they do not possess any of the reticular texture or arborescent pores which are common to all vascular parts; but, microscopically examined, they resemble the exuvial or epidermoid membranes. To these may be added the notorious circumstance of the unchange-

ablens of the outer surfaces of testaceous shells during their growth, and the continued renewal of their other surfaces which admit of contact with the living inhabitant; next, the stains and coloured transudations which they often derive from metallic salts, and other colouring materials placed in their vicinity; and lastly, that such occurrences do not affect the living animal." See "Facts and Observations relative to the Connection between vascular and extra-vascular Parts, in the Structure of living organized Bodies." Lond. Med. Repository for August, 1814.

It is stated of some testaceous mollusca, that they quit their shell to form a new and larger one. Cuvier asserts this of the cypræas, and it is also supposed to be the case with the balani. (See *Annales du Muséum*, t. i. p. 470.) In these instances it is clear that the surface of the body must form the new shell.

The inhabitant of the paper nautilus (*argonauta argo*) does not adhere to its shell at any point; the additions to the shell cannot therefore possibly be made by the way of development. It grows, in all probability, by a secretion formed by its two palmed arms. Nautili are met with where extensive fractures have taken place, and have been consolidated by deposition from within. *Hist. des Mollusques*, par Denys Montfort, t. iii. p. 284.

The animal comes out of its egg with the shell ready formed; it possesses one turn, and sometimes rather more, but is very thin. Leeuwenhoek first ascertained the fact respecting oysters. Lister made the same observation, and extended it to other testacea, both terrestrial and aquatic. Marigli, Rumphius, Swammerdam, Reaumur, and Adanson, confirmed the discovery. The latter naturalist shewed that the viviparous testacea agree with the oviparous, in the circumstance of their young being covered by shells at the time of birth, and even before. *Encycl. Method.* t. vi. p. 549.

"As the animal grows after birth, its body advances constantly towards the mouth of the shell; the posterior end quits the bottom of the first turn, to which it does not adhere, and when the size of the shell is complete, it occupies a situation very distant from its original one. In some species of an elongated figure, as the bulime consolidé and decollé, and several others, where the end of the spire remains very thin and unsupported, it is liable to break: the animal stops the breach by a new calcareous exudation from the posterior end of its body. In other testaceous mollusca the end of the spire becomes solid, and presents a mass of laminated calcareous matter, sometimes as hard as marble. The successive layers are distinctly visible when a section is made. I have now before me a splendid specimen of the trochus Niloticus, in which six turns of the spire are solid, and filled with a calcareous substance equal to the finest Carrara marble. I can demonstrate the same fact in other shells.

"In some cases different phenomena are exhibited. The *murex tritonis* not only has the apex of its long spire consolidated, but, as the animal grows older, and abandons more rapidly the extremity of the spire, instead of filling up the whole tube, it forms only thick septa, which are constructed successively in the situations where the animal's body rests for a while." *Hist. des Mollusques*, par Denys Montfort, t. iii. p. 246, et seq.

Some white-blooded animals have hard parts internally; but they are not articulated so as to form the bases of moveable members, and their texture differs considerably from that of ordinary bones. The common cuttle-fish (*sepia officinalis*) contains in the flesh of the back an oval substance, convex before and behind, white, solid, friable, and of a calcareous nature. This substance is not attached

to the flesh, but has the appearance of a foreign body introduced into it. There is no indication of any vessel or nerve entering it; nor is any tendon affixed to it. It is composed of thin parallel lamellæ, which are not in immediate contact with each other. The intervals are occupied by an infinite number of small hollow columns, standing perpendicularly between one lamella and another, and arranged in very regular quincunces. As the superficies of the lamellæ are plane, and those of the bone itself convex, they necessarily intersect each other: the points of intersection are marked on the surfaces of the bone by regular curvilinear striæ. These bones have a kind of wings, which are of a less opaque nature, less brittle, and have a greater resemblance to thin elastic horn, than the body of the bone.

To this last substance the part called the sword of the calmar (*sepia loligo*) bears an analogy. It is transparent, elastic, and very brittle; its shape is sometimes that of a leaf, sometimes of a sword-blade. It bears the same relation to the soft parts, and occupies the same situation as the bone of the cuttle-fish.

There is a gradation in structure from this sword of the calmar and bone of the cuttle-fish, which are completely internal, to the external shells of the testacea. The *bulia aperta* (Linn.), *bullea* (Lamarck), has a shell contained in its cloak or outer integument, and not visible on the exterior of the body. It is extremely thin, and almost transparent; not attached to the body by any muscle, for it is so weak that the slightest muscular force would break it. It is striated, so as to indicate successive depositions; and so placed in the body as to cover the principal viscera. (Cuvier, *Annales du Muséum*, t. i. p. 159. pl. 12.) The *dolabella*, *testacella*, and *parmacella*, have analogous shells, called by Cuvier *coquilles cachées*. (*Ibid.* t. v.) There is a thin shell contained in the cloak of the pleuro-branchus. (*Ibid.* t. v. p. 270; pl. 18. B. fig. 3.) There is a small and thin calcareous plate in the back of the slug, analogous to the common shells. The fleshy covering of the branchiæ has a larger but thin, horny, transparent and flexible plate in the *aplysia*. *Ibid.* t. ii. p. 297.

The insulated bony or horny pieces just enumerated, particularly that of the cuttle-fish, strongly confirm the representation which has been already given respecting the growth of shells. They must increase by strata successively deposited; and they may thus be called internal shells.

The *asterias* and *echinus* have a kind of skeleton, the nature of which very much resembles that of the mollusca. In the *echinus* it is a solid calcareous envelope, frequently very hard. It has a number of little holes, through which pass membranous feet, furnished with tubercles and points analogous to the substance of the shell, which play freely on these tubercles.

In the star-fish, the calcareous part forms a stalk, composed of a number of small articulated vertebrae, which extend under the middle of each of the branches of the body, and to which is attached a kind of osseous grating, which supports the remainder of the envelope of the branch to which it belongs, and which is rendered remarkable, even externally, by its projection, and by the tubercles of different forms that cover the whole of its surface.

Their osseous stalk cannot be regarded as completely external, since it is covered outwardly by an epidermis and other soft parts. This is, perhaps, the most striking exception to the general rule that white-blooded animals have no internal articulated skeleton. The mode of growth of the skeleton of the star-fish has not yet been sufficiently investigated: the skeleton of some holothurix is exactly similar.

Coralz, other zoophytes, and lithophytes, have hard parts, which are sometimes horny, sometimes calcareous, and sometimes spongy; but which grow by simple juxtaposition, or at least like shells by the addition of successive strata. In some their growth takes place externally, and the sensible substance envelops the old strata by new ones, with which it again covers itself. Such is the case with the lithophyta and ceratophyta. In others, the parts which have once attained their proper hardness, no longer increase in thickness; but new shoots or branches are formed at their extremities. Such are all the jointed zoophytes.

There are some minute observations on the texture, course of the fibres, &c. of shells, and similar substances, in a paper by Mr. Boudant, entitled "Memoire sur la Structure des Parties solides des Mollusques, Radiaires, et Zoophytes." See *Annales du Muséum*, t. xvi. p. 66.

Chemical Composition of Shells, &c.—For our knowledge of the chemical composition of these substances, we are indebted principally to the excellent papers of Mr. Hatchett in the *Philosophical Transactions* for 1799 and 1800.

Shells, like bones, consist of calcareous salts united to a soft animal matter; but in the former the lime is united chiefly to carbonic acid, whereas in the latter it is united to phosphoric acid. The predominating ingredient in shells is carbonate, in bones, phosphate of lime. This constitutes the characteristic difference in their composition.

Mr. Hatchett divides shells into two classes. The first are usually of a compact texture, resemble porcelain, and have an enamelled surface often finely variegated. The shells belonging to this class have been distinguished by the name of porcellaneous shells; they are exemplified in the *voluta*, *cypræa*, &c. Those of the second class are usually covered with a strong epidermis, below which lies the shell in layers, and composed of the substance known by the name of mother-of-pearl: these he calls mother-of-pearl shells. The fresh-water muscle, the halyotis iris, and the turbo olearius, are examples. In the first class there is a small, in the second a large proportion of animal matter.

Porcellaneous shells contain little animal matter, that they emit no smoke nor smell, when exposed to a red heat, nor are they blackened; and they dissolve with effervescence in acids, without leaving any residue. They consist, therefore, of carbonate of lime, cemented together by a small portion of animal matter, which is soluble in acids, and therefore resembles gelatine.

Some patella from Madeira, examined by Mr. Hatchett, consisted also of carbonate of lime, but they emitted a smell like horn, when exposed to a red heat, and left a semi-liquid gelatinous matter behind, when dissolved in acids. They contain, therefore, less carbonate of lime, and more animal matter, which is also of a more viscid nature than that of porcellaneous shells.

The mother-of-pearl shells, when exposed to a red heat, crackle, blacken, and emit a strong fetid odour. When immersed in acids, they effervesce at first strongly; but gradually more and more feebly, till at last the emission of air-bubbles is scarcely perceptible. The acids take up only lime, and leave a number of thin membranous substances, which still retain the form of the shell. From Mr. Hatchett's experiments, we learn that these membranes have the properties of coagulated albumen. These shells, then, are composed of alternate layers of coagulated albumen and carbonate of lime, beginning with the epidermis, and ending with the last formed membrane. The animals which inhabit these shells, increase their habitation by the addition of a stratum of carbonate of lime, secured by a new membrane.

Different shells vary considerably in the proportion of their constituents, and in the consistency of the albuminous part. Some, as the common oyster-shell, approach nearly to the patella, the albuminous portion being small, and its consistence nearly gelatinous; while in others, as the halyotis iris, the turbo olearius, the real mother-of-pearl, and a species of fresh-water muscle, the membranes are distinct, thin, compact, and semi-transparent. One hundred parts of mother-of-pearl contain sixty-six of carbonate of lime, and thirty-four of membrane. Merat-Guillot in *Ann. de Chimie*, tom. xxxiv. p. 71.

Pearls, or the concretions formed in these shells, resemble them exactly in structure and composition. The substance consists of concentric and alternate coats of thin membrane and carbonate of lime. Hatchett, in *Phil. Transf.* 1799.

The bone of the cuttle-fish was found by Mr. Hatchett to be exactly similar, in its composition, to mother-of-pearl shells.

Mr. Hatchett compares the porcellaneous shells to enamel of teeth, (see CRANIUM), and mother-of-pearl shells to the bone of teeth, or other bone. (See BONE.) The only difference is, that in enamel and bone the earthy salt is phosphate of lime, whereas in shells it is pure carbonate of lime.

The shells of the echini, and the crusts of the alierias (star-fish), are made of carbonate, with a small quantity of phosphate of lime; and a greater or less proportion, according to their hardness or flexibility, of an animal, gelatinous, or albuminous matter.

Many of the substances which compose the basis, or hard part of zoophytes, have the hardness and appearance of shell or bone: others are soft, and belong rather to the class of membrane or horn. From Mr. Hatchett's admirable dissertation in the *Philosophical Transactions* for 1800, and the experiments of Merat-Guillot in the *Annales de Chimie*, tom. xxxiv., our knowledge of the chemical constitution of these substances is derived.

The hard zoophytes are composed chiefly of three ingredients; 1. An animal substance of the nature of coagulated albumen, varying in consistency, sometimes being gelatinous, and almost liquid, at others of the consistency of cartilage; 2. Carbonate of lime; 3. Phosphate of lime.

In some zoophytes the animal matter is very scanty, and phosphate of lime wanting altogether; in others, the animal matter is abundant, and the earthy salt pure carbonate of lime: in some, there is much animal matter, with a mixture of carbonate and phosphate of lime; and a fourth class is almost entirely destitute of earthy salts. Thus we have four classes; of which the first resembles porcellaneous shells, the second mother-of-pearl shells, the third the crusts of the crustacea and echino-dermata, and the fourth horn.

1. When the madrepora virginea is immersed in diluted nitric acid, it effervesces strongly, and is soon dissolved. A few gelatinous particles float in the solution, which is otherwise colourless and transparent. Ammonia precipitates nothing, but its carbonate throws down abundance of carbonate of lime. It is composed, therefore, of carbonate of lime and a little animal matter. The following zoophytes yield nearly the same results; viz. madrepora muricata and labyrinthica; millepora cærulea and alicornis; and tubipora musca.

2. The madrepora ramea effervesces in weak nitric acid; but when all the soluble part is taken up, there remains a membrane, completely retaining the original shape of the madrepora. The substance taken up is pure lime. Hence it is composed of carbonate of lime, and a membranaceous substance, which, as in mother-of-pearl shells, retains the figure of the madrepora.

The following zoophytes yield nearly the same results; *viz.* madrepora fascicularis; millepora cellulosa, fascialis, and truncata; and isis hippuris.

Merat-Guillot gives the following statement of the composition of three species, which must, according to this account, be referred to the present class.

	White Coral.	Red Coral.	Articulated Coralline.
Carbonate of lime	50	53.5	49
Animal matter	50	46.5	51
	100	100.0	100

3. Immersion in weak nitric acid does not affect the shape of the madrepora polymorpha: there remains a tough, opaque, membranaceous substance of a white colour, filled with a transparent jelly. The acid solution yields a slight precipitate of phosphate of lime, when heated with ammonia, and carbonate of ammonia throws down a copious precipitate of carbonate of lime. It consists, therefore, of animal matter, partly in the state of jelly, partly in that of membrane, hardened by carbonate, together with a little phosphate of lime.

The flustra foliacea, corallina opuntia, and isis ochracea, gave the same results; except that in the two latter, phosphate of lime could only be discovered in the solution of the burnt substance.

The colouring matter of the isis ochracea falls down in a fine red powder in weak nitric or muriatic acid; whereas that of the tubipora muscosa, and of the gorgonia nobilis, or red coral, is destroyed by these acids.

After the red coral has been immersed in acid, it is seen to consist of two parts, *viz.* an external tubulated membrane of a yellow colour, including a transparent gelatinous substance. The acid solution yields only carbonate of lime; but when the red coral is heated to redness, and then dissolved, the solution yields a little phosphate of lime also. Red coral then consists of an internal stem, composed of gelatinous matter and carbonate of lime; and an external covering or cortex, consisting of membrane hardened by the calcareous salts; and both coloured by some unknown substance.

The gorgonia ceratophyta and flabellum have a similar composition. The cortex of the gorgonia fuberosa contained a little phosphate and a large portion of carbonate of lime. The stem contained scarcely any earthy salt. The gorgonia fetosa and pectinata exhibited nearly the same phenomena.

4. Gorgonia antipathes has a horny stem, but is destitute of cortex. It gives out some gelatine to boiling water. When steeped in nitric acid, it becomes soft, and exhibits concentric coats of thin, opaque, brown membranes, of a ligneous aspect. With potash it forms an animal soap, and possesses nearly the properties of horn. The stems of the gorgonia umbraculum and verrucosa are similar; but they both possess a cortex, composed of membrane and carbonate of lime.

Mr. Hatched analysed many species of sponges; but found them all similar in their composition. They consist of gelatine, which they gradually give out to water, and a thin brittle membranous substance, which possesses the properties of coagulable albumen.

The alcyoniums resemble very much in their composition that of the gorgonia fuberosa. They yield a little gelatine to water. They are softened, and appear membranous in nitric acid, which takes up the carbonate of lime, and likewise a little phosphate, at least when the substance has been previously heated to redness.

In the Annales du Muséum d'Histoire Naturelle, we

have an account, by A. Laugier, of the earthy and saline matters contained in the liquor produced by the spontaneous decomposition of the medusa. This was procured by the melting of a blue medusa taken in the Channel. When left to spontaneous evaporation, a crystalline pellicle formed, and was removed, and so on successively, until no more crystals were formed. "The salt thus obtained," says the author, "was formed of carbonate and phosphoate of lime; these salts existing in exactly the same proportions as in all the calcareous concretions, produced by the hardening juices of the mollusca, the polyeps, and the crustacea, which I have examined, such as red coral, white coralline, oyster-shells, crab's-eyes, &c. *viz.* carbonate of lime 92, phosphoate of lime 7, animal matter uniting the molecules 1, in 100 parts. See p. 346.

The remaining liquor, being evaporated to dryness, gave a saline residue, of which the component parts, similar to the salts of the sea, were, in 100, muriate of soda 79, muriate of lime 4, muriate of magnesia 3, muriate of iron 2, phosphate of lime 1, water and loss 11. P. 349.

So complete, says Péron, is the spontaneous fusion of the medusa, that from an individual weighing several kilogrammes, hardly a few milligrammes of membranous residue remain in the filter. Ann. du Mus. t. xv. p. 43.

Organs of Motion.—In the cephalopodous mollusca.

The mollusca, which have the head furnished with long appendages for progressive motion, are called cephalopoda; and have two orders of muscles, one belonging to the body, the other to the feet or tentacula.

The sac which composes the body of these animals, stripped of the external skin, presents a muscular tissue of very compact fibres. Those of the outer layer appear to have a longitudinal direction; the middle layer is transverse; and the succeeding layers have different obliquities. They can flatten, elongate, twist, and bend the sac; but the action of each layer cannot be assigned in a positive manner, on account of their very complicated structure.

In the back of these animals, under the skin, there is found a body more or less solid. In the cuttle-fish it is a species of bone composed of different thin parallel plates one above another, and separated by little columns disposed in the form of quincunces. This bone is oval, thick towards the middle, and thin at the circumference. In other species, its form varies much, but its substance is generally elastic, and transparent like glass. Its surface is sometimes marked with longitudinal furrows.

The sepia octopus wants it entirely.

Two strong muscles arise from the inner surface of the sac, on each side of this bone. They run towards the head, and on their arrival there, divide each into two branches; one branch is inserted into the head, the other mixes its fibres with those of the sac, at the edge of which it ends. The cephalopoda have eight conical feet, of different lengths, arranged in a circle at the top of the head, round the mouth. The animal can turn and bend them in every direction, and fasten itself to bodies by help of the cups or suckers with which they are furnished. The muscles, which perform their motions, are very numerous; they may, however, be distinguished into those that are common to the whole foot, and those that are proper to the suckers.

Below the skin we find a very thin muscle, the fibres of which are united by a loose cellular substance. It accompanies the skin in all its different shapes, and may, perhaps, be regarded as a musculus cutaneous employed to corrugate the skin, and give greater force to the muscle situated within it, upon which it acts like a girdle. Between the feet, and under the skin, which unites them at their base,

two thin muscles are situated, one below the other, the fibres of which are transverse. One arises in the middle longitudinal line of the foot, on the side opposite to the suckers, and proceeds directly to its insertion in the same line of the adjacent foot on either side. The other arises below the suckers themselves, goes over the lateral parts of the foot, and at last forms a muscular membrane with transverse fibres, which passes under the preceding muscle, and proceeds to its insertion in the other foot, exactly in the same manner as it took its origin. This double muscular membrane bears some analogy to that which unites the toes of web-footed birds, such as ducks, geese, &c. It produces a circular plate, which occupies the intervals between each base of the feet. These two muscles probably serve to bring the feet nearer to each other; the second may besides separate the two rows of suckers. It reaches the whole length of the foot, but becomes thinner towards the extremity.

Below these three layers of muscles (the two transverse and the cutaneous), we find another pretty large one, the conical figure of which determines the shape of the foot. At the surface it seems entirely formed of transverse fibres; but on cutting it in different directions we find that it has longitudinal fibres. These fibres are interwoven like those of the human lingual muscle towards its centre. In the centre of this muscle there is a vacant space, in which we find very large vessels and nerves. The suckers are fastened to the inferior surface of this muscle, and to a layer of fibres still more evidently longitudinal, by little fleshy bands, differing in direction according to the species.

The suckers are formed by a muscular cup of radiated fibres, which, by their contraction, diminish its capacity. But at its edge, and close to the plate under the cylindrical muscle, there is another layer of circular fibres, like a sphincter, which renders the cup more convex. Finally, each sucker is retained and moved upon the foot by little muscular fasciculi interlaced together, and uniting at last in the inferior transverse muscle of the foot. At least, this is the case in the *sepia octopus*.

In the calmar (*sepia loligo*), and the cuttle-fish (*sepia officinalis*), the suckers are attached by very small muscular peduncles.

When an animal of this kind approaches any body with its suckers, in order to apply them more intimately, it presents them in a flat or plane state; and when the suckers are thus fixed, by the adaptation of surfaces, the animal contracts the sphincter, and forms a cavity in the centre, which becomes a vacuum. By this contrivance, the sucker adheres to the surface with a force proportioned to its area, and the weight of the column of air and water of which it forms the base. This force, multiplied by the number of suckers, gives that by which all or a part of the feet adhere to any body. The power of adhesion is such, that it is easier to tear off the feet than to separate them from the substance to which the animal chooses to attach itself.

In the cuttle-fish and the calmar, the mouth of the sucker is surrounded by a cartilaginous indented zone; in the *octopus* it is only a fleshy disk, flat, and perforated in the middle.

Besides the eight feet just described, which are all that are possessed by the *octopus*, the cuttle-fish and calmar have two others much longer and smaller, and without suckers, except at the extremity, which is enlarged. Their structure is in other respects the same as that of the other feet.

The organs of locomotion in the gasteropodous mollusca, reside principally in that inferior part of the body on which

they drag themselves forwards, and which is called their foot. It is a fleshy mass, formed of fibres which cross each other in several directions, and are capable of giving it every possible shape. Most commonly it has that of an oval, pointed behind; but, by the various contractions of which these fibres are susceptible, they extend or contract it in the whole or in part, so as to produce that slow progressive motion, which every body has remarked in the common snail or slug. The transverse fibres are easily seen in the foot of the slug, if it be opened by the back. They proceed from the edges of the foot to two longitudinal middle tendinous lines. Below these we meet with others in a contrary direction; but so interwoven, that it is difficult to trace the layers.

In the *scyllæa* the foot is only a longitudinal furrow, impressed in the whole length of the belly of the animal. By the help of this furrow it embraces the stalks of fucus, upon which it crawls. In other respects, the organization of its foot is nearly the same as that of the slug.

In the limpet (*patella*), the inferior layer is composed of transverse fibres, which are interlaced at the edge with numerous circular ones. The superior layer consists of two rows of fibres, meeting at an acute angle on a middle line, which corresponds to the long diameter of the foot. There are also some circular fibres at its edge. The inferior layer, by its contractions, lengthens the ellipsis of the foot, while it lessens the breadth; and the inferior diminishes the length, but increases the breadth. This is the mechanism which produces the progression of these animals. Lastly, the circular fibres diminish the surface on all sides, and render it convex above, thereby producing a vacuum, which makes the animal adhere firmly to the surface that supports it. So powerful is this adhesion, that we cannot separate a limpet from the rock by means of the fingers.

Reaumur tied a string round the limpet, called by the French *œil du bouc* (*patella Græca*), and suspended a weight from it perpendicularly. Thirty pounds were necessary to separate the shell; and this weight was supported by the animal for a short time. Reaumur conceives that the adhesion is not produced on the principle of forming a vacuum, but by a viscid fluid; and states, that when the shell and animal were split vertically, the divided portions still adhered. (*Mem. de l'Acad. des Sciences de Paris, 1711, p. 109, et seq.*) In this representation we are satisfied that this able observer was mistaken.

The gasteropodous mollusca, which are furnished with shells, possess, besides the muscles just described, others that enable them to retreat into the shell, and protrude their body from it again. These shells, or moveable habitations, vary much in their form. They are generally made of one piece, of different shapes, simple, without twisting, in the limpet; in a flattened spire, as in the planorbis; in a globular and pyramidal spire, as in the shell of the snail, bulimus, dipper-snail, &c. The chiton is the only genus of gasteropoda which has a shell formed of several pieces.

In the limpet the foot is fastened to the circumference of the shell by a ring of fibres attached all round the shell, and which, after piercing the outward covering or cloak, are inserted in the edges of the foot, and interlaced with its circular fibres. They leave a space in front, for the passage of the head. This muscle, by its contractions, brings the foot and the shell closer together, and compresses the body; on relaxing, it allows the shell to be raised up by the elasticity of the body.

In the garden-snail there are two strong muscles, which

draw

draw the foot and the whole body within the shell. They arise from the columella or axis of the shell, and, having penetrated the body below its spiral part, they run forward under the stomach, and spread their fibres in several dips, which interlace with those of the muscles proper to the foot, the substance of which they enter. From these attachments, their mode of action may be easily understood. When the animal wishes to protrude itself from the shell, its head and foot are forced out by circular fibres, which furround the body immediately above the foot.

The cephalous mollusca have the body enveloped by a membrane principally muscular, which is called the mantle or cloak. This integument is more or less complete in the different genera. It is generally covered by valves or shells of various forms and proportions. Few of the genera want this solid covering; among those, however, are the *acidia* and *salpa*.

The valves of the shells are so disposed, that they can move one upon the other, by means of ossific projections, which reciprocally receive each other, thus forming a real hinge. They are, besides, connected by an elastic ligament of a horny substance, which continually tends to open them. "This elastic substance," says Mr. Carlisle, "is wedged in at the hinge: its spring is excited by compression; but it does not possess the property of expansion beyond its passive state. When dried, it cracks into cubes. As the valves increase, this elastic ligament is augmented along the inner surface only, and must have been always deposited during the expanded state of the valves, since the limits of its elastic condition are exactly adapted to that state. As the laminae of the shells increase, there is a gap at the outside of the hinge, filled with soft crumbling and decomposing worn-out elastic ligament: this gap presents two inclined planes meeting at an acute angle, and that space is kept free from pebbles and hard extraneous bodies by the presence of the decomposing ligament; as such an accident would prove fatal, by preventing the opening of the valves." Monthly Repository for August, 1815.

The hinge of the shells presents so many varieties, that naturalists have drawn from it the characteristics of the genera. The oyster, *placuna*, scallop, *avicula*, &c. have no tooth in their joint. The piddocks and the *mya* or *gapers* have it in one of the valves only; but it is not received into a fossa. The razor-shells have the hinge strengthened by a tooth in each shell, which projects inward. These two projections meet and move upon each other. The *anomia*, *onio*, *chama*, *spondylus* or thorny oyster, and several others, have one or two teeth on one valve only, which are received into corresponding cavities, in the opposite valve. The *venus*, *cockle*, and *mastra*, have teeth on each shell, which are mutually received. Lastly, the *arca* has a multitude of little teeth, which are closely interlocked with each other. These different conformations either facilitate the motion of the hinges, or strengthen the joint; or they permit a greater or less opening of the valves.

The elastic ligament, which tends continually to open the valves, is not always situated at the same point of the shell. The muscles, for example, have it at one side of the valves. The *placuna* have a little ossific appendage, which forms a projection in the inside of each valve; and from this arises the ligament that holds them together. The *perna* has in each valve several little cavities, opposite to each other in pairs, in which an equal number of small ligaments are lodged.

The shells of the *acephala* present several other pe-

culiarities. We find the valves immoveable, and soldered together at the angle, in the *pinna*. The *teredo* or pipe-worm has the body inclosed in a calcareous tube, and is armed with two little moveable valves, which are used in penetrating wood. The *terebratula* has on the inner part of one of the valves two ossific appendages, which support the body.

The contractile membrane which covers all the body of the *acephalus mollusca*, and is called the mantle, is a real muscle, presenting many varieties. Sometimes, and indeed most commonly, it is open before, in the direction of the valves, as in the oyster, the muscle, &c.; in the shells that have two ends always open, as in the razor-shells, the *gapers*, the piddock, &c. it is perforated at both extremities. Lastly, the cloak may envelope the whole body of the animal, and be open at one end only, as in the *acidia*.

The cloak of the oyster is composed of two pieces of the same form as the shell; they are fixed to the body posteriorly, or on the side of the hinge, and extend to the edges of the valves. Their substance is soft, semi-transparent, and furnished with a number of muscular bands: they are perforated by the muscle, which closes the shell. One of the edges is in folds, like a flounce, and festooned; the other is furnished with small conical and contractile tentacula. The cloak of other *acephala* differs from this description in its general form; in the tentacula on its edge; in the tubes, which are prolongations of it; and, lastly, in the muscles which perforate it.

The aperture which serves for the expulsion of the feces, and that which receives water and the different aliments, are sometimes prolonged into a kind of tube, which is a continuation of the cloak: this is called a *proboscis* (in French "trompe.") The oyster, the muscle, the *onio*, the *anodontites*, have only one of these apertures, which is the anus. The water merely enters by the large slit in the cloak. In the *cockle*, each aperture is a few lines elongated; that which serves for respiration is longer and larger than the other. They are still more elongated and unequal in the *venus*, *tellina*, *mastra*, and some other genera. The razor-shell has likewise two; but in the piddock, both tubes are inclosed in a very thick fleshy *proboscis*, through the whole length of which they pass without uniting.

In the *acephala* that have the cloak open before, the tentacula are placed at its edge, and in particular towards the anus; but in those which have tubes, they are situated at the orifice of the *proboscis*. In the edible muscle (*mytilus edulis*, Linn.), they are branched.

The valves of shells having a continual tendency to open, in consequence of the action of the elastic ligament situated at the side of the hinge, it was necessary that the contained animal should have the power of closing them at pleasure. For this purpose they are furnished with muscles, passing between the valves at right angles. In the oyster there is only one muscle of this kind, situated near the centre of the shell, behind the liver, and in the middle of the cloak. It is equally inserted into both valves, passing in a straight line between them; and bringing them together, by its contraction, with an astonishing force. In the moderate separation of the valves, we observe the operation of the elastic ligament, when the muscle is relaxed: if we touch the animal, the shell is instantly closed; and we can estimate the power with which this is accomplished, by the amount of the force required for the forcible disruption of the valves. The same mechanism is seen in the *perna*, *avicula*, and *spondylus*.

There are two muscles for closing the shell in the *mytilus*,
8

VERMES.

foles, venus, maëtra, cardium, &c. They are always separate from each other towards the extremities of long shells, and generally approximate at the edge on which the hinge is situated, in order that a very small relaxation may produce a large opening on the opposite side.

The common oyster possesses its first pair of valves, consisting of single laminae, before it leaves the parental organs; the muscle passes between the centre of the concavity of each shell, adhering to each, and it acts on the valves nearly at right angles. The animal has no other continuity with the shell. As it grows, it augments the margin of its shells, and thickens them by adding new laminae on the inside; the muscular adhesion glides forward, still keeping to the centre of the valves.

Many of the testaceous mollusca have the power of removing themselves from one place to another, by means of a muscular appendix, which they can protrude or retract at pleasure, with which they fasten themselves to the sand and rocks, and thus drag themselves along. This appendix is called the foot of the animal.

The common oyster, the spondylus or thorny oyster, some species of the scallop, the anomia, and in general all the mollusca that have shells with unequal valves, have no foot, and are, therefore, deprived of the means of voluntary locomotion.

One of the most simple of these feet is that of the fresh-water muscle (*mytilus anatinus*, Linn.; *anodontites*, Cuv.) It is situated before the body, towards the margin of the shells. Its form is a compressed oblong. We observe on each side externally a layer of fibres, proceeding from the bottom of the shell. There are also some internal fibres, which cross each other at right angles; and others unite the two external layers, to which they are attached in a circular manner. From this disposition it will easily be understood, that the animal may, when it pleases, change the three dimensions of the foot, or of one of its parts: by this means, it is enabled to place its shell flat on the ground, and to crawl along like the snail by the help of its foot.

The muscle may be observed to open its shell, to put forth the foot, and elongate it, to feel about with it. The animal fixes it to some object, and drags the shell after it. The animal called by the French *lavignon*, also a bivalve, puts forth a broad flat foot, by which it makes its way into the sand or mud. It has two long tubes, which keep up its communication with the surface, for the purpose of respiration. The holes corresponding to them shew where the animal is. See Reaumur, "Du Mouvement progressif, et de quelques autres Mouvements de diverses Espèces de Coquillages, Orties, & Etoiles de Mer," in the Acad. des Sciences, 1710, with several figures, and detailed explanation of the subject, both so far as concerns the animals just mentioned, and some others.

We find this simple foot in the piddock. Its form is almost spherical, and truncated by a flat surface. The part which Linnaeus has observed in the razor-shells, and which he has compared to a glans in its prepuce, is the foot, by which the animal buries itself in the sand, or rises to the surface. In these two genera, the foot is protruded at the aperture of the shell, which is opposite to that through which the tubes pass. See Reaumur in the Acad. des Sciences, 1712, with figures.

The foot of the cardium or cockle is somewhat complex. It has a triangular appendix, which is capable of inflexion, of seizing with its point the glutinous matter, and drawing it out into threads. But the foot of the sea-muscle (*mytilus edulis*) is the most remarkable in its organization. It resembles a small tongue, marked with a longitudinal furrow,

susceptible of considerable elongation, and of being shortened into the form of a heart. This organ is moved by five muscles on each side. Two arise from the extremities of the shell, near those which close it; the other three come from the bottom of the shell, and the depression for the nates. They are all inserted into the foot, with the fibres of which they are interwoven, in the same manner as the external muscles of the human tongue join the lingual. The organ is completely enveloped in a sheath formed of transverse and circular fibres, of an obscure purple colour. This foot is employed both in spinning and crawling: the last office is performed as in all the other bivalves. It accomplishes the first by seizing with its point the gluten supplied by a gland situated under its base, and drawing it out into threads, in the above-mentioned furrow. The gland that secretes this humour, of which the thread is formed, will be described hereafter.

The organs of motion in worms are not so perfect as in the larvæ of insects; having neither scaly nor membranous feet, several of them crawl or drag themselves along by the help of stiff hairs or bristles, with which they are wholly or partly covered: of this description are the genera *aphrodita*, *terebella*, *nercis*, *lumbricus*, &c. Two kinds of muscles contribute to their motion.

The one extends the whole length of their body, and forms four principal fasciculi, two of which belong to the belly, and two to the back. These four muscles may be said to constitute the mass of the body. We find them immediately under the skin. Their fibres are parallel; but their length does not exceed that of the rings, being interrupted in the folds of each ring by a very compact cellular tissue. The structure of these muscles is, however, most distinctly observed in the inside. We there find that they are separated from each other by a longitudinal line, and enveloped in a kind of sac of a close cellular substance, which corresponds to each ring of the body. These four muscles produce the principal motions. Where those of the back contract wholly or partially, they raise the portion of the body to which they belong: the same effect, but in the opposite direction, is produced by the contraction of the ventral muscles.

The second order of muscles is appropriated to the motions of the spines or bristles. Their number is equal to that of the tufts of hairs. The description of one of them will be sufficient to give us a knowledge of the whole.

The hairs, bristles, spines, &c. which project from the bodies of these animals, are manifestly moveable. They are retracted, and pushed out at pleasure. The muscles which produce these motions are visible only when the animal is laid open, the intestinal canal taken out, and the skin stripped off. We then observe that each tuft of hair is received in the concavity of a fleshy cone, the base of which is attached to the longitudinal muscles, and the apex to the internal extremity of the hairs. All the fibres which form this cone are longitudinal, but enveloped by a compact cellular substance. They move the hairs outwardly, and in the direction which their contraction may determine. This first class of the muscles, which belong to each branch of hairs, may be called the protractors of the spines.

The spines are withdrawn within the body by another set of muscles, which may be called retractors. They have fewer fibres than the former; their action therefore is feeble. They are situated under the internal surface of the long muscles, at a short distance from the holes with which the latter are perforated for the passage of the hairs. They are inserted into the tufts of spines, nearly on a level with the point, which these reach, when completely retracted. It

may

may be conceived that the protractors, when they act, push the retractor outwards; but the latter, when contracting in its turn, tends to recover the parallel situation of its fibres, and thus draws the spines inwards. It is by the help of these muscles, and of the spines on which they act, that the imperfect locomotion of these worms is effected.

There are other worms, destitute both of spines and bristles; and therefore possessing a different muscular organization. Their manner of crawling differs considerably from that of the former. Their progression is accomplished by means of the two extremities of their bodies, which they apply alternately to the surface on which they crawl. They are fitted for this kind of motion by a peculiar structure. We may divide them into two orders.

The first, as the leeches, and several intestinal worms, have the head and the tail terminated by a kind of contractile fleshy disk, somewhat resembling those of the arms of the cuttle-fish. The structure of these two disks, which perform the office of suckers, cannot be easily ascertained; for when the skin which covers them is removed, we observe merely some very small fibres interwoven in different directions.

Though the worms with suckers possess a great power of contraction, it is extremely difficult to trace the muscles that move their bodies. Their whole skin may indeed be regarded as one muscle, or kind of fleshy sac, furnished with circular and longitudinal fibres, and containing the vessels, viscera, and glands. This muscular skin is thick, and lined with a very solid and compact cellular substance.

When the worm wishes to change its place, the body is fixed at one of the extremities, by means of the sucker that terminates it; the circular muscles of the skin then act, which elongates the animal's body by diminishing its diameter: when the free extremity has in this manner reached the place to which the worm chooses it should be extended, it is applied and made fast to that spot by the sucker, and becomes the fixed point of a new motion: the animal having detached the sucker first made use of, draws it by the operation of the longitudinal fibres of the skin towards the second sucker, and proceeds in this manner to fix each extremity alternately. This is the mechanism by which progression is effected in worms that have terminating disks.

The second order of worms, which move by fixing their extremities, includes the greater part of the intestinal kind. These possess less contractile power than the leeches, and their motions are therefore less extensive. Their head, instead of being terminated by a disk, is sometimes provided with hooks, by means of which they fix themselves to the parts they suck. Such are the common tænia, the tænia folium, the hydatigena, the hæruca, the echinorhynchus, the uncinaria, &c. &c. The disposition and number of the hooks, which vary considerably, have been described by naturalists.

The *Organs of Motion in Zoophytes* vary considerably in their nature, form, and action. It is necessary, therefore, in order to obtain a just notion of these organs, to take a particular and successive view of them in certain orders of those animals.

The chino-dermata are distinguished by numerous retractile feet, and a covering more or less solid. These feet are a kind of suckers, and have nearly the same organization in the three genera which compose this order. In their form, they resemble a globular phial or ampulla: they are filled with a fluid, and their parietes are formed of circular fibres. The elongated or tubular portion of the ampulla is the only part that appears externally, when the feet are extended. It is terminated by a kind of disk, which is convex in the middle. The spherical portion is situated within

the body. From this construction of the foot, the mechanism of its action will be easily understood. The liquor contained in the ampulla becomes, by a change of place, the cause of motion: when the foot is drawn into the body, the spherical portion of the ampulla is greatly enlarged: when the foot protrudes, the parietes of the ampulla contract, and impel the contained fluid into the tubular part, which consequently increases both in length and circumference. In the retractile motion of the foot, the tunic of the tube is contracted, and the liquor thereby forced back into the body of the ampulla. The number of these feet vary considerably in the different genera and species.

The holothurizæ are covered with a thick coriaceous skin, which the animal can lengthen or shorten at pleasure. These two motions are produced by longitudinal muscular bands, varying in length and breadth in different species, and smaller transverse bands extended over the whole internal surface of the body. The animals included in this genus have their feet disposed in different manners, and in some species they are even wanting. In others we find them either spread irregularly over the whole body, situated upon one side only, or placed in longitudinal rows.

In the asterizæ, or sea-stars, the covering of the body has a close fibrous texture, the interstices of which are filled with grains of calcareous matter of various forms and dimensions. This kind of crustaceous skin is however susceptible of a certain motion, which, though slow, is very remarkable. The body of the animal is commonly divided into five branches, to which the feet are attached. These last are ranged in several files throughout the whole length of the branches from the mouth. The branches are sometimes furnished with spines, their middle portion is frequently entirely calcareous, but articulated at its origin, and moveable upon the central part of the body.

Reaumur counted 1520 legs in a star-fish; yet their motion is extremely slow. These legs can be extended or withdrawn, or partly thrust out: when withdrawn, their extremity is visible. Mem. de l'Acad. des Sciences, 1710, p. 487.

The echini, or sea-eggs, are encrufted by a complete calcareous shell, the surface of which is covered by tubercles disposed in a very regular manner. Moveable spines of various shapes and sizes are articulated to these tubercles. It is very difficult to discover the fibres by which the spines are moved at the will of the animal; for in their joints we observe only a solid ligamentous substance, which cannot be easily cut. The feet are protruded through holes which perforate the shell with much regularity, and form uniform parallel lines, called by naturalists ambulacra. They are very numerous, but produce, as in the asterias, only a very slow motion.

The medusæ swim, by displacing the water with alternate motions, rendering their bodies now flat, now convex. Reaumur has a figure of one; Acad. des Sciences, 1710, p. 478, pl. 11.

"Although," says Péron, "the medusæ are composed of a homogeneous jelly, without any appearance of fibres, they possess a truly surprising power of contraction. Constantly active on the surface of the waters, we see them alternately contracted and developed. When the animal comes from below towards the surface, he strikes from above downwards, and thus raises himself in consequence of the resistance of the water to this motion of his umbrella. In order to change the direction of his course, he is inclined, so that the umbrella forms a more or less acute angle with the horizon: in this case the direction of the stroke, and consequently the resistance being oblique, he is urged forwards in the

the same direction. When he has reached the surface, the vertical position can have no other effect than that of retaining him in the same posture and place: to change it, he must again incline his body. In this way, all the medusæ with gelatinous and orbicular bodies swim: the umbrella remains parallel to the horizon only in the state of rest, or at least of relative repose. Descending in the water is accomplished very simply: their substance being specifically heavier than that of sea-water, it is only necessary that they should contract themselves powerfully, so as to contract their dimensions in every direction, and they sink of themselves. Sometimes, in order to go down more quickly, they turn themselves over; so that the upper convex part of the umbrella is downwards." *Annales du Muséum*, tom. xv. p. 41.

The coriaceous skin which covers the æginæ, possesses so extraordinary a power of contraction, that these animals can assume at pleasure the most dissimilar forms. Sometimes they are flattened into a disk; sometimes elevated into a cone; sometimes lengthened into a cylinder, &c. &c.

"They can walk," says Reaumur, "in two ways; first, by means of their basis, of which they can change the figure, dilating or contracting it in different directions, so as to move forwards the body slowly." Reaumur describes this at great length; *Acad. des Sciences*, 1760, p. 470, et seq. "I have also," says he, "seen them walk upon their tentacula. They were the kind that live in holes of rocks, and possess long tentacula in proportion to their size. In this case the animal is inverted, the basis being upwards. The tentacula are very viscid, and even rough to the touch, so as to be well calculated for the purpose." P. 475. He has represented them in the different forms which they can assume, in fig. 21—26.

In fresh-water polypes (hydra), we observe moveable tentacula about the mouth, which seem principally destined to seize their prey. The animal has the power of locomotion. The smallness and transparency of parts in the other genera do not allow of our discovering the mechanism by which motion is produced.

The two following memoirs of Reaumur, in the Academy of Sciences, contain the best account of the motions of these animals, and they are illustrated by several figures. "Du Mouvement progressif, et de quelques autres Mouvements de diverses Espèces de Coquillages, Orties, et Etoiles de Mer," 1710, p. 439; "Observations sur le Mouvement progressif de quelques Coquillages de Mer, sur celui des Herissons de Mer, et sur celui d'une Espèce d'Etoile," 1712, p. 115.

Nervous System.—Animals without vertebræ are not formed on a common plan, either with respect to the nerves or muscles; they present disparities so great, and indeed are so deficient in common characters, that we are obliged, without making any general observations, to consider the nervous system in the different classes and the principal genera.

Brain and Nerves of the Cephalopodous Mollusca.—In the sepia octopus, the cuttle-fish, and the calmar, the nervous system appears to resemble in some respects that of red-blooded animals. The brain is inclosed in a particular cavity of the cartilage of the head, which is pierced by a number of holes to give passage to the nerves. The cartilage of the head has the form of a hollow and irregular ring; its posterior part is the thickest, and contains the brain; its anterior part contains the ears, and a semicircular canal which communicates on each side with the cavity of the brain, and includes the medullary collar. The œsophagus passes through the centre of this cartilaginous ring, and is consequently, as in all white-blooded animals, surrounded by the medullary cord. The lateral parts of the carti-

luginous ring have eminences which form a kind of orbit on each side.

The brain is divided into two distinct parts; one next the œsophagus, the surface of which is smooth, and the other towards the back, which is round, and marked by longitudinal striæ. The medullary collar arises from the lateral parts of both portions: in the octopus it is in the form of a lamina, the anterior part of which produces four large nerves, which, with the four corresponding nerves, proceed forward into the eight feet, which crown the head. These laminae are joined inferiorly, and thus surround the œsophagus. Two other principal pairs of nerves arise on each side, near the origin of the collar. The first or optic pair extends directly into the orbit, passes after a short course through the sclerotic coat, and is there dilated into a ganglion larger than the brain, shaped like a kidney, with the concave side turned towards the brain. The substance of this ganglion appears to be the same as that of the brain: its convexity produces a multitude of small nerves, as fine as hairs, which pass through the choroïdes, by an equal number of small holes, to form the retina. The second pair belongs to the muscles of the fac; it originates a little above the preceding pair. These nerves descend obliquely, and after leaving the cerebral cavity, pass between the muscles, which sustain the head, to the lateral part of the fac, near its superior edge, between the body and the branchiæ. It then divides into two branches, one of which descends to the bottom of the fac, the other dilates into a roundish ganglion, which produces a multitude of nerves, disposed like radii. These are distributed to all the fleshy fibres of the fac and the fins.

The anterior and inferior part of the collar gives origin to two pairs of nerves. The first or auditory are very short, as they only traverse a cartilaginous lamina to penetrate the ear, where they are distributed. The second pair issues from the cartilage by two holes placed near each other, and beneath the ears: the two nerves which compose it descend within the peritoneum to the bottom of the fac. When they arrive near the heart, they form a complicated plexus, from which all the nerves of the different viscera proceed.

Each foot has a nerve, which passes from one extremity to another, like an axis, and occupies a canal, which we have described in speaking of the muscles. This nerve is enlarged, at different spaces, by numerous ganglia, which have the appearance of tubercles, and from each of which ten or twelve nervous filaments proceed: these diverge and penetrate the muscles of the interior of the foot, to which they distribute branchiæ; but the chief ramifications are spent on the suckers.

This description is taken from the octopus: the other cephalopoda differ only in having a brain less distinctly divided, and presenting less conspicuous furrows.

Nervous System of the Gasteropodous Mollusca.

In the Snail (Helix Pomatia).—The brain is situated upon the œsophagus, behind an oval mass of muscles, which envelop the mouth and the pharynx. Its shape is nearly semilunar, with the concavity backwards. The angles of the crescent are prolonged on each side into a branch, by which the œsophagus is encompassed in a collar. The salivary glands, and the muscle which retracts the mouth and brain, pass also through this collar. The two cords produced by the brain unite below the œsophagus and muscle in a large round ganglion, which is more than one-half the size of the brain. All the nerves proceed from one or other of these two masses. Those furnished by the brain proceed from the

VERMES.

lateral parts of its convex side. There are, first, two nerves for the fleshy part of the mouth; next, one on each side for the small horns; then two for each great horn, one of which proceeds to the base of that horn, and passes into its muscular substance; the other goes to the eye. The latter is folded considerably on itself, when the horn is drawn inward. There are besides some other filaments, which extend to the base of the parts of generation, and to the muscles which move the head. The large inferior ganglion produces at first three great nerves, one for the penis, another for the brain, and a third for the muscles, which draw the whole animal into its shell. The inferior surface of this ganglion afterwards produces two great fasciculi, which proceed backward, and which, after passing between the two muscles before mentioned, are distributed to all the fleshy parts of the foot.

Swammerdam's figure of the nerves of the snail appears to have been taken from the slug.

In the Slug (Limax Rufus).—The brain is also situated behind the œsophagus in this animal, but it has the form of a narrow ribbon lying crosswise. It enlarges a little at its lateral parts, each of which produces a filament to encircle the œsophagus. The ganglion, which is formed by the union of these two filaments, is larger than the brain.

Two principal trunks proceed, each on its respective side, in a straight line from this ganglion. They extend along the lower part of the body, throughout its whole length, preferring nearly a parallel direction. On the external side they each detach a number of filaments, which penetrate into the fleshy substance of the skin. A great number of other filaments also proceed immediately from the inferior ganglion to the skin. Further, the inferior ganglion sends off two nerves on each side, which go to the viscera, and follow the distribution of the arteries.

With respect to the brain, properly so called, it furnishes in the first place a nerve on each side for the fleshy mass of the mouth; then two for each of the great horns, one of which extends to the eye, and becomes the optic nerve. The nerves of the small horns arise more outwardly.

In the Aplysia.—This is a small marine animal, very like the slug, but respiring by means of branchiæ, which form a kind of tuft on the back, and are covered by a particular operculum. The brain is situated as in the snail; but the branches, which surround the œsophagus, produce two ganglia, one on each side, which are conjoined by a small filament.

The brain furnishes, at its anterior part, two slender filaments, which encircle the fleshy mass of the mouth, and unite under it in a small ganglion, whence the nerves of the lips are detached. The brain afterwards affords nerves to the horns and the eyes, which are in this animal situated between the horns, and to the parts of generation. The two lateral ganglia transmit a multitude of nerves to all the fleshy parts of the foot and skin; they also produce each a long cord, which unites to its corresponding cord on the aorta, near the part where it arises from the heart; there they form a ganglion, from which all the nerves of the viscera proceed.

In the Clit Borealis.—This small animal has no foot, and can only swim. It respire by two branchiæ, in the form of wings, situated on the neck; but in other respects it very much resembles the slug. Its nervous system is analogous to that of the aplysia.

Its brain is formed of two roundish lobes: it furnishes immediately nerves to the tentacula, and gives origin to a double collar. The anterior extends, as in the aplysia, under the mouth, to form a small ganglion. The posterior

has a ganglion on each side, which furnishes nerves to the muscular skin that surrounds the body; each of these produces one or two other ganglia, which send nerves to the viscera.

In the Doris.—This is also a small marine animal similar to the slug, but it respire by external branchiæ disposed like litars round the anus. The brain is very large in proportion to the rest of the body, and particularly in comparison with that of other gasteropoda. It is elongated transversely, and of a square form. It is situated immediately above the origin of the œsophagus, behind the orbicular mass of muscles, which form the parietes of the mouth.

Six nerves proceed from the brain on each side; one pair is defined for the muscles of the mouth, another for the tentacula. The third is a cord, which passes below the œsophagus, and is lost in the muscles of the foot, where it may be very distinctly observed on the lateral parts of the internal surface. The fourth and the fifth are directed above the mass of intestines, and proceed to the skin of the back. Lastly, the sixth terminates in the parts of generation.

In the Scyllæa.—This is another marine animal similar to the slug, but respiring by branchiæ in the form of wings arranged by pairs on the back: it crawls on a furrow in its belly. The collar surrounding the œsophagus is a simple cord, and does not enlarge into a ganglion as it proceeds downward. The brain, which is above it, is of an oval form; it sends nerves to the mouth and to the horns, but there are no optic nerves, as this animal has no eyes. The nerves of the viscera arise from the inferior part of the collar, and those of the muscles from its sides.

In the Sea-Ear (Halyotis Tuberculata).—This animal has no ganglion above the œsophagus to supply the place of the brain. We find merely a nervous filament, situated transversely above the œsophagus, behind the mouth. Four small ramifications proceed from the middle and anterior part of this filament, two on each side, and are lost in the parietes of the mouth. At each extremity of the transverse nervous filament there is a very large flat ganglion, from the circumference of which a number of nerves are detached to the adjacent parts. Three filaments pass off on each side from the external surface of this ganglion: one is sent to the setiform tentaculum, situated above the mouth, the other two proceed to the flat tentaculum, like a buckler, placed more posteriorly and on the sides. The most posterior appears to be intended for the eye: it is the thickest, the other seems lost in the muscular parts.

A very remarkable filament is detached from the superior parts: it proceeds above the œsophagus, and joins the corresponding one on the other side. There is a small enlargement at the point of union, from which four nerves proceed, two on each side of the middle line. The most external is lost in the muscles of the tongue; the other pursues the middle line of the œsophagus, and is ramified over the intestines. Several small branches are detached inferiorly, and terminate in the fan-like muscles that sustain the tongue.

Lastly, the ganglion is prolonged posteriorly into a thick nervous cord, situated on the sides and below the œsophagus, which becomes flat, as it proceeds backward: it describes a semilunar curve, so that the two nerves of the opposite sides are approximated, and finally touch each other at the basis of the tongue, and below the anterior part of the large muscle which attaches the animal to its shell. The union of these two nerves produces a ganglion, from which two very remarkable trunks, intended for the intestines, proceed; they can be followed to above the stomach, and we can perceive that some of their ramifications enter the liver. After

VERMES.

the formation of the ganglion, which furnishes nerves to the viscera, the two trunks penetrate by two different holes into the substance of the muscle of the foot. These two holes are the origin of two canals, which run throughout the whole length of the foot, on the sides of another middle canal, which appears destined to distribute the blood of the animal. The two nerves, lodged in the lateral canal, are distributed by a great number of lateral holes into the substance of the fleshy muscles of the foot, and of the shell, where they may be followed with facility.

In the *Helix Stagnalis* and *Helix Cornæ* (*Planorbis Cornæ*), the brain consists of two lateral masses, separated by a contraction. In the living animal they are of a lively red colour. The distribution of the nerves differs very little from what we observe in the common snail.

Nervous System of the Acephalous Mollusca.—It is formed on a plan far more uniform than that of the gasteropoda. In all the testaceous accephala, from the oyster to the pholas, and the teredo, there appears no essential difference: it consists always of two ganglia, one on the mouth representing the brain, and another towards the opposite part. These two ganglia are united by two long nervous cords, which take the place of the usual collar, but which occupy a much greater space at the foot where it exists, and the stomach and liver always pass in the interval between them. All the nerves arise from the two ganglia.

In the *Anadontites*, or *Fresh-water Mussels*, in *Cockles*, in the *Venus*, *Maëra*, and *Mya*.—In these, and generally in all the bivalves which have two cylindrical muscles, one at each extremity of their valves, for the purpose of bringing them together; the mouth is placed near one of those muscles, and the anus near the other. The foot appears about the middle of the shell; and the tubes for the excrements and respiration, when they exist, go out at the end of the shell opposite to that in which the mouth is situated. The brain is placed at the anterior edge of the mouth; it is oblong transversely; it sends off two cords anteriorly, which go to the adjacent muscles, and turning towards each side, penetrate the lobes of the cloak, passing through the whole extent of their edge. The brain furnishes also, on each side, some filaments to the membranous tentacula, which surround the mouth, and detaches, from its posterior edge, the two cords analogous to the medullary collar in other invertebral animals. These cords proceed, each on its side, under the muscular stratum which envelops the liver and the other viscera, and which becomes thicker as it is continued to form the foot, which is frequently constructed for spinning. When arrived at the posterior muscle which closes the valves, these cords approach each other, and enlarge as they unite to form the second ganglion. This ganglion has the form of two lobes. It is at least as large as the brain ganglion, and always much more easily distinguished. It detaches two principal nerves on each side, and the four together represent a kind of cross. The two anterior nerves, as they ascend, proceed a little towards the side of the mouth, and after having described an arc, penetrate into the branchiæ. The other two pass on the posterior muscle, precisely in the same manner as those of the brain on the anterior. After detaching some filaments they proceed into the cloak, the edge of which they follow until they join those of the brain; they thus form a continued circle. We do not yet know the origin of the visceral nerves in these animals.

The testaceous accephala, in which the foot is protruded by an extremity of the shell, that always remains open, and the tubes by the opposite extremities, that is to say, in razor-fish and piddocks, the mouth, and consequently the

brain, is always near one extremity. The nerves which proceed from the brain, take therefore a longer course before they diverge to join the cloak. The cords of the collar, however, have a much shorter distance to pass before they unite. There is a considerable space, particularly in the razor-fish, between the mass of the viscera situated in the base of the foot, and the posterior muscle. The second ganglion is situated in the middle of this space, between the branchiæ of each side: it is round, and much more distinct than in the other species; the nerves it produces are however exactly similar.

In the oyster, which has no mouth at the anterior part, the brain and mouth are situated under the kind of hood which the cloak forms towards the hinge. The nerves go directly into the cloak itself. The ganglion is situated on the anterior surface of the single muscle, immediately behind the mass of viscera. The nerves it produces are the same as in the preceding genera.

In the Ascidia.—These small marine animals are enveloped in an immoveable coriaceous or gelatinous case, which has two apertures; one for the expulsion of the excrement, the other for the admission of water to the branchiæ. The branchiæ are in the form of a large sac, and are inclosed, as well as the other viscera, in another membranous bag, of the same form as the external case, but smaller, and completely adhering to that case at the two apertures only. The inferior ganglion is situated on this membranous sac; its position is between the two apertures, but nearest that which corresponds to the anus; it produces four principal nerves: two ascend towards the superior or respiring aperture, the other two descend towards that of the excrements. There are smaller nerves dispersed through all the membranous sac. We have not yet discovered those produced by the brain, nor the brain itself, which is doubtless situated as usual on the mouth. The mouth is in the bottom of the branchial sac.

In the Tritons of Linneus, which inhabit the anatisferous and balanite Shells, (Lepas, Linn.)—These animals approach perhaps nearer to the crustacea, and particularly to the monocoela, than to the mollusca. Their nervous system is a sort of middle kind between that of the mollusca, and that of the crustacea and insects.

The brain is placed across the mouth, which is itself situated in the part of the body corresponding to the ligament, and at the bottom of the shell. It produces four nerves to the muscles situated in that place, and to the stomach, and two others which embrace the œsophagus, and proceed into that elongated portion of the body which bears the numerous articulated and ciliated horny tentacula which the animal protrudes from its shell. These two filaments approach, and form a ganglion, and then proceed close to each other among these tentacula, furnishing a corresponding pair of nerves for each pair of tentacula; but there are no apparent ganglia at the origin of these nerves.

The general result from the preceding statements is, that the nervous system of the mollusca consists in a brain placed on the œsophagus, and in a variable number of ganglia, sometimes approximated to the brain, and sometimes dispersed in the different cavities, or placed under the muscular envelopes of the body: that the ganglia are always connected to the brain and to each other by nervous cords, which establish a general communication between these different medullary masses: that the nerves all arise either from the brain or the ganglia: and lastly, that there is no part which can be compared to the medulla oblongata and medulla spinalis.

Nervous System of Worms.—Some genera present a very distinct

distinct nervous system, organized nearly like that of the crustacea and insects. In others, however, that system becomes so obscure, that we can scarcely recognize its existence. Thus the class of worms, which in several of its genera ranks above insects, with respect to the organs of circulation, is reduced almost to a level with the zoophytes, when considered with regard to the organs of sensation.

The *Apodite aculeata* has a very distinct nervous system. Immediately behind the tentacula, situated above the mouth, we observe a large nervous ganglion, which is the brain; it has the form of a heart, the broadest and bilobed part of which is directed backwards. The pointed anterior portion produces two small filaments for the tentacula, and the lateral parts some other filaments, which are still more slender, for the parietes of the mouth. This ganglion is situated immediately above the origin of the œsophagus. The two cords which arise from the brain, and from the collar, are very long and delicate; they gradually increase in thickness as they approach the point of their union. Each then produces a large filament, which we shall call the recurrent nerve; these nerves are very distinct: they are directed forward towards the part where the œsophagus, which is very short, joins the stomach. They may be easily followed by the naked eye to the lateral parts of that viscus, which is very long and muscular; before they reach the intestines that follow the stomach, they swell into a ganglion, which produces a great number of nervous fibrils.

The two curves of the collar produce a very large ganglion at their union; it is bifurcated anteriorly, and situated immediately behind the mouth, and above the œsophagus; it is the anterior extremity of the chief nervous cord. We do not observe any filaments proceeding from it. To this first ganglion another succeeds, which is distinguished from it only by a small contraction; the latter produces two nervous filaments, which go forwards into the muscles of the abdomen. A series of ganglia, the spaces between which are considerably greater, afterwards succeed; each of these sends off six nerves, three on a side, which are lost in the muscles. These ganglia are twelve in number. The nervous cord, which succeeds, and which occupies the posterior third of the body, no longer exhibits any apparent enlargement; but pairs of nerves are still detached at certain spaces. Finally, this cord may be followed to the extremity of the body.

In the *Leech*, the nervous system is a longitudinal cord, composed of twenty-three ganglia. The first is situated above the œsophagus; it is small and rounded; anteriorly it produces two slender filaments, which proceed above the disk of the mouth. The lateral parts furnish a thick pair of nerves, that form a collar round the œsophagus, as they proceed downward, and unite at the second ganglion. This ganglion is of a triangular figure, and appears to be formed by the union of two tubercles. Two of these angles are anterior and lateral; they receive the nerves that proceed from the first ganglion. The other is posterior; it is prolonged into a nerve rather more than half a line long, which produces the third ganglion: the anterior part of the triangular ganglion which we describe, detaches two small nerves that are lost on the œsophagus, around the mouth. The nine succeeding ganglia are precisely of the same form, and produce each two pair of nerves; they differ only in the greater or less distance at which they are placed from each other. The third, as we have observed, is very near the second. The three following are at the distance of nearly a line and a half: but those which succeed, from the seventh to the twentieth, are at the distance of three or four lines: finally, the three last are very close together.

All these ganglia are situated longitudinally below the intestinal canal, to which they furnish, from their superior surface, a number of nervous filaments; they produce on each side two nerves, which pass into the longitudinal and transverse muscles, in the substance of which they are lost. These nerves run in opposite directions, so that they represent the figure of an X. The coat of these nerves is black, and very solid, so that before the parts have been immersed in alcohol, they appear like a system of vessels.

The nervous cord of the *Earth-worm* derives its origin from a ganglion situated above the œsophagus: this ganglion is formed of two clove, but very distinct tubercles. It produces a pair of small nerves proceeding to the parietes of the mouth, and two large cords, which embrace the œsophagus in the form of a collar; these unite to form the nervous cord, the origin of which therefore appears bifurcated. Three pair of small nerves are detached at this place: one from the cord itself, and the others from its lateral parts. They all proceed into the muscles of the mouth. The nervous trunk is continued to the anus, along the inferior part of the intestine; its size is not sensibly diminished, and the contractions are not very remarkable: there are, therefore, no real ganglia. A pair of nerves arises between each of the rings of the body; these nerves pass under the longitudinal muscles, and disappear between them and the skin. When the nervous cord reaches the anus, it terminates by forming a plexus, which is lost on the parietes of that aperture.

In the *Gordius argillaceus*, there is only a single nervous cord, similar to that of the earth-worm, but its contractions are still less apparent.

The *Nereis* and *Terebella* have, within the skin of the belly, a longitudinal cord, which may be regarded as nervous: it has as many contractions as there are rings in the body. No nervous filament has been observed proceeding from this cord.

In the *Sea-worm* (*Lumbricus Marinus*, Linn.), which in its external characters approaches nearer to the nereis than to the lumbricus, the nervous system is the same as in the nereis, but the cord gradually increases in thickness towards the middle of the body, where it is much more distinct.

In the *Ascaris Lumbricoides* of Man and the Horse. — This animal appears to have two nervous cords; they are observable throughout the whole length of the body, on the lateral parts of the abdomen. They unite above the œsophagus, exactly at its origin on the mouth; they are very slender, and produce no remarkable ganglion: they are smaller at their origin than towards their extremity, that is to say, towards the anus; but they are equal, and precisely similar to each other with respect to their different parts. We observe at first some small granular points, which enlarge in proportion as the nerve descends. When it has reached the middle of the body longitudinally, it forms square ganglia, at a short distance from each other. Lastly, towards the termination, for the length of nearly six lines, the nerve becomes more and more slender, and ends in a very small filament, which unites with that of the other side.

Thus we find an evident analogy in the organization of the nervous system of crustacea, insects, and worms, no less striking than that which prevails in the external forms, in the disposition of the muscles, and the singular division, into a series of rings or segments, which we observe in these animals. This analogy prevents us from establishing between these three classes limits equally distinct with those which subsist between them and the mollusca. The uniform

distribution of nearly equal ganglia upon a cord, extending throughout the whole length of the body, seems designed to furnish each segment with a brain peculiar to itself. Thus we are gradually conducted to that general diffusion of the medullary substance, which seems to take place in zoophytes.

Animals in which no distinct Nervous System has been yet discovered.—We do not, says Cuvier, include in this division the animals of the class of worms, or the mollusca, in which the minuteness or softness of the parts have not yet permitted us to trace the nervous system. Analogy will not allow us to doubt its existence, when the parts which accompany it uniformly exist.

Thus the flukes (*fasciola*) having vessels, or liver, &c. must be supposed to have nerves also, though we have hitherto been unable to demonstrate them. We even doubt not the existence of a nervous system in several intestinal worms, particularly those which have a cylindrical form, which we suppose to have a medulla nearly similar to that described in the large ascariæ. It is found in the gordius; why should it not exist in the echinorhynchus, strongylus, &c. &c.?

But there are animals, in which analogy affords us no assistance, to whom we cannot ascribe a nervous system, unless we distinctly observe it: there are some intestinal worms, very different in form from those we have mentioned, and the greater part of zoophytes.

The ateriæ has parts very similar to nerves; but Galvanic experiments ought to be made on living individuals, to prove completely their nature. Round the œsophagus we observe a girth of a soft whitish substance, which produces ten filaments, two to each of the branches, which form the body of the star. The two filaments belonging to each branch having arrived at the base of the osseous and articulated stalk, which serves for the principal support of the animal, unite to form a short cord, which extends directly from one to the other: they afterwards both continue along the stalk to the extremity of the branch, diminishing always in thickness. At the place where they are united, each produces a fasciculus of filaments, which are distributed to the stomach, which, in these animals, is situated in the middle of the body, between the five branches. The appearance of all these filaments is rather tendinous than nervous, and that circumstance chiefly has hitherto prevented us from forming a decided opinion of their nature.

In the *Holothuria*, properly so called, among which we do not include either the thalia, or the holothuria physifer of Linnaeus, we find something similar to what we have described in the ateriæ; but the appearance of the cord is much more nervous, and this is a strong confirmation of our conjectures.

The parts we allude to are seen most distinctly in the species of holothuria which have five longitudinal pairs of muscles, as the priapus and pentacta. Between the two muscles, which compose each pair, there is extended a white cord, slightly serpentine, and marked by transverse rings, like common nerves. The five cords enlarge as they proceed towards the œsophagus, where they seem to unite and surround the canal.

The *Sipunculus* is more similar to the holothuria than to any other animal, though naturalists have hitherto placed them next the lumbricus. They have only a single whitish cord, but it completely resembles those of the holothuria, and it proceeds, in the same manner, to embrace the œsophagus by its anterior extremity.

If the parts now mentioned are real nerves, it will be

necessary to separate the echino-dermata from the other zoophytes, and establish them as a distinct class.

In the *Sea Urchins* (*Echinus*), nothing similar to nerves has been observed: the same remark may be extended to the actiniae and medusæ.

With respect to the polypes, both the fresh-water kind and those which belong to the corals, &c. we have already observed that their bodies exhibit only a gelatinous and homogeneous pulp, in which no particular arrangement of organs can be discerned. All these animals have however distinct sensations: their sense of touch is very delicate; they not only perceive the motions which agitate the water in which they live, but they completely feel the degrees of heat and light. The expansion of the actiniae corresponds precisely to the serenity of the atmosphere. The hydra perceives very distinctly the presence of light; prefers it, and constantly turns towards it. The microscopic animals appear to approach in some measure the nature of polypi, by their uniform and gelatinous structure. There are some, however, in which we observe a more complicated organization, and several kinds of internal viscera; but it will be obvious, that we have no means of ascertaining whether they possess a nervous system.

Organs of Sense.—The eye.

The cephalopodous mollusca have two eyes situated at the sides of the head, under the tentaculated arms. Most of the gasteropoda have also two eyes, but very small, and placed either on a level with the head, or on some of the fleshy and moveable tentacula. In some they are situated at the base of these tentacula; in others at the middle, or the point. In all this order, only the clio, scyllæ, and lerneæ, want eyes.

No eyes are found in the acephalous mollusca.

Among the articulated worms there are sometimes found small tubercles, which have been regarded as simple eyes, in consequence of their resemblance to those of insects. Some leeches have two, four, six, or eight; in some of the nereids we find two or four: in some naiades only two, &c. No parts that can be compared to eyes have hitherto been observed in any zoophyte.

The cephalopodous mollusca, particularly the calmar, have very large eyes; on the contrary, in such of the gasteropoda as possess eyes, they are scarcely visible.

The eye of the cuttle-fish has no cornea, nor aqueous humour: the anterior aperture of the sclerotic is not filled up, and the crystalline projects across it. Under the conjunctiva, however, a particular membrane is observed, dry, fine, and transparent, enveloping the sclerotic itself, and supplying, by its anterior part, the place of the cornea. This conjunctiva is easily separable from the eye, as in serpents. The crystalline is spherical, as in animals which see in water; and hard in consistence. The structure of the sclerotic is singular, being much removed posteriorly from the globe of the eye. The large ganglion of the optic nerve, and several other glandular parts, are situated between them. The sclerotic, therefore, forms posteriorly a truncated cone, the pointed part of which is directed to the bottom of the orbit: to this portion the muscles are attached. The anterior part nearly thins the globe of the eye. It is very soft and viscous; easily separated, and presents a coarse felt-like texture, which becomes firmer in spirits of wine. In some species it has a metallic brilliancy. As there is no cornea, the sclerotic is wanting opposite to the crystalline; but the hole is not sufficiently large to admit a view of the iris without dissection.

The internal surface of the choroid is of a purple-red colour. The use of the ciliary processes, in retaining the crystalline,

crystalline, is no where so distinctly seen as in the eye of the cuttle-fish. They form a large zone or diaphragm, in the aperture of which the crystalline is truly encased. A deep circular furrow passes completely round the crystalline, and divides it into two unequal hemispheres. The ciliary processes penetrate into this furrow, where they are so firmly fixed, that they cannot be removed without being torn. The process is not formed of projecting laminae, but of a continued membrane, the two surfaces of which are marked by a circle, consisting of a vast number of fine radiated fibræ, which present a very agreeable spectacle.

The sepia have glandular bodies between the sclerotica and the choroid; but none between the latter and the tunica Ruyfchiana. The separation of these two membranes is even sometimes difficult; the choroides is more thick, soft, and vascular, the Ruyfchiana thin and dry. There is no tapetum, all the eye being lined internally by a deep purple pigment. The pupil is shaped like a kidney.

After the numerous optic filaments have perforated the choroid, they are confounded in a single membrane, the retina.

The crystalline divides easily into two hemispheres, the limits of which are marked externally by a deep furrow: each hemisphere consists of a number of concentric cups, composed of radiated fibres.

As the conical sclerotic of the sepia is attached to the bottom of the orbit, the glandular bodies, which serve to support the globe, are situated, not between it and the orbit, but between it and the choroid. The part fixed to the edge of the optic hole is pointed; it preserves therefore some degree of mobility. There are only two small muscles, one superior and an anterior, the head being supped upwards.

The sepia and other mollusca, which have not the eyes at the extremity of their tentacula, have no eye-lid; the skin covers the eye, as in serpents and eels. But the slugs, snails, &c. have an organization, which is far more complicated, and much better calculated for the protection of their eye. This organ is situated at the extremity of a fleshy tube, called a horn or tentaculum, which may be drawn completely within the head, and protruded by a motion similar to the evolution of the finger of a glove. We have already described the muscles that draw the snail into its shell. The particular muscle of the eye is attached at the external edge of each of these muscles: this muscle penetrates to the inside of the horn, to the extremity of which it is fixed. When it contracts, therefore, but still more when assisted by the contraction of the great muscle of the body, it draws the extremity of the horn inwardly, in a manner which resembles the turning in of a flocking. The annular fibres, which encircle the horn throughout the whole of its length, unfold the internal part by successive contractions, and thus bring back the eye to its external position. In the slug, the retractors of the eyes are simply attached to the fleshy mass which forms the foot. In the inferior horns or tentacula, which have no eyes, the mechanism is also the same.

The gasteropodous mollusca are the only order, among the animals we are now considering, that possess an organ of hearing. No animals placed below these in the scale of being are known to possess such an organ, although there are proofs of the faculty in many. The ear of the sepia is very simple; it is entirely concealed in the body of the annular cartilage, which serves as the base of the great tentacula, or feet of these animals. Towards the back of the head there is an eminence of the cartilaginous ring, unperforated, and covered by the thick integument of the animal. The membrane of the labyrinth contained in this part is a simple purse of an oval or roundish form, containing a clear fluid.

In the common cuttle-fish (*sepia officinalis*), it has internally several conical eminences, disposed in an irregular manner: these eminences are wanting in the other species. In the pulp which fills the membrane there is a small body suspended, which is offensive in the cuttle-fish properly so called, and like starch in the octopus. In the *sepia officinalis* it resembles a small shell. See Scarpa de Auditu et Olfactu.

Organ of Touch.—We do not easily distinguish all the parts which compose the integuments of vertebral animals, in those that have no vertebrae: some of the strata are more distinct, others less so: there are also some species in which we do not find the whole of them. Of the animals we are now considering, different orders dwell in different situations, and are exposed to very different external circumstances: there are corresponding variations in their outward coverings. Some live in the intestines of other animals, the mucous fluids of which sufficiently protect them; others are enclosed in calcareous or stony habitations, necessary to ensure them from the agitations of the waves, and from the surrounding hard bodies. Others have a hard integument, covered sometimes with spines.

There is an epidermis in invertebral animals: those which live in water have it commonly mucous; it is of a very different thickness in the several species. It is nearly the same in the cephalopoda as in fishes. In the naked gasteropoda it very much resembles that of salamanders and frogs.

There is an epidermis on the shells of most testacea. In the land kind, as the snails, it is a dry pellicle, very easily detached, when the shell is, after the death of the animal, exposed to the action of the atmosphere, or plunged into boiling water. In the muscles, both of fresh and salt water, and in other bivalves, we observe a similar epidermis, which envelops the shell externally. This epidermis is always wanting on the surface of the projecting parts, on which the animal draws its shell along the sand, because it is there worn off. In some species of shells, the epidermis is thick and viscous, and on this account it has been named sea-cloth. This is very remarkable in several species of the genus *arca* of Linnæus; and to express this peculiarity, he has called one of them pilosa.

In all the testacea, the epidermis which envelops the shell is continued to produce the pellicle, which covers the animal, and it produces the same change as that which is prolonged within the body of vertebral animals. It is thin and mucous on all the parts which are not exposed to the action of the ambient fluid. In the species of gasteropoda, however, whose shell is concealed under the skin, and does not serve for defence, the epidermis does not change its nature. We have examples of this in some species of *aplysia* and *scyllæa*, as well as in the animal which produces the shell, called by Linnæus *helix halyotoidea* (figaret of Lamarck).

Worms have a distinct cuticle, which is easily separated from the skin in the earth-worm, when it has been immerged for a few hours in spirits of wine, or macerated some days in water: it is a pretty solid pellicle, which may be removed in a single piece. In the *pinunculus faceatus* this epidermis is even entirely separated from the body, which is unconnected and floating within it, as if it were enclosed in a sac. Leeches and some other worms have the cuticle mucous, like that of the gasteropodous mollusca.

It is very difficult to ascertain the nature of the epidermis in zoophytes, or even to discover whether it exists in some of them. The sea-stars (*asterias*), the urchins (*echinus*), and the actiniae, appear to possess it. The medusæ are covered with a pellicle, but so thin and transparent that it cannot be supposed to consist of strata. The other zoophytes,

VERMES.

phytes, as the polypes, &c. have a mucous surface, the festucels of which prevents us from distinguishing any membrane.

Moll mollusca have a rete mucosum below the epidermis. In the cephalopoda it is most commonly of a blue or red colour; but it forms a very thin layer. That of the gastropoda varies considerably, as we may observe particularly in the slug. It is thick and viscous; but dissolves completely in water. In situation, the shell is analogous to rete mucosum. It is found immediately under the epidermis, and, when some of the calcareous part is removed, it is a kind of crust without any apparent organization, and not a membrane. It is produced by successive strata. Finally, it is coloured, and its shades are infinitely various.

The rete mucosum is to be found in a small number only of zoophytes: and it cannot even be separated from the skin, as in the asteriæ and actiniæ.

It appears to be confounded with the calcareous shell, which forms the habitation of several other genera. This may be observed in some species of echini and corallines; and in the ceratophytes, and a number of lithophytes.

Nothing at all approaching to the appearance of nervous papillæ can be seen in white-blooded animals. In the cephalopodous mollusca some nervous filaments may be seen in the small globules, which seem glandular, and which cover the skin. In other mollusca, some nervous filaments may be traced into the substance of the skin; but they cannot be seen to form papillæ.

No real cutis is to be observed in the invertebral animals, excepting the cuttle-fish and the other cephalopoda. It is applied almost immediately to the muscles, by means of a very dense cellular substance: it is of a very coriaceous nature, and not easily lacerated. Its fibres are very slender.

In the other invertebral animals, there is no part which can be compared to the cutis. There is, indeed, a pellicle under the shell of the crustacea, but it is fine, transparent, and has very little consistence. The skin cast off by the larvæ of insects in moulting, is of the same nature and thickness as that below it, and which is destined to succeed it. Even the envelop of certain chrysalides, as those of the lepidoptera and diptera, cannot be regarded as cutis: it is rather a kind of horny epidermis. In the perfect state, there is no part of the teguments of insects that can be compared to the cutis. The same observation applies to the worms and zoophytes.

In the invertebral animals, that have soft bodies, almost all the muscles may be considered as cutaneous; for the greater number are attached to the skin. But as they are also employed in progression, they are described among the organs of motion.

Besides the skin in general, which is an universal organ of touch in man, and the red-blooded classes, there are particular organs possessing a much more acute power of discerning the tangible properties of bodies, and at the same time so constructed as to admit of easier application to their surface. The fingers exemplify this. It may be doubted whether the invertebral classes have any parts calculated to perform such an office; and we rather think that they have not. Some, however, regard the tentacula as organs of touch, and consider them analogous to the antennæ of insects, or to the fingers of man and the quadrumana.

We have already described the tentacula of the cephalopodous mollusca, under the head of *Organs of Motion*. They obviously serve for seizing their prey; but whether they enjoy any sense of touch is extremely doubtful.

The horns of the snail have been described in the account of the eye. Those of the other genera among the gastropo-

poda do not differ, except that they are incapable of that motion by which the former are retracted and protruded like the finger of a glove. They have muscular fibres, which may be contracted or relaxed.

Tentacula are found in many invertebral animals; but they are not so universal as the antennæ among insects. They are situated on the head; often at the opening of the mouth, as in the doris; above it, as in the slug; or round it, as in the terebella. Several species have similar appendices round the cloak. Such are the limpets, the genus halyotis, &c. Among the acephala, the greater part are provided with these appendices, and some have them in great numbers. In the species which have the cloak completely open they are placed around it, and particularly towards the anus: this may be observed in oysters, muscles, &c. In those in which the cloak opens by a tube only, the appendices are attached to the circumference of its orifice. Such are the genera venus, cardium, &c. The tube itself furnishes these animals with an excellent instrument of touch. The fleshy and ciliated arms of the genera lingua and terebratula are equally proper for this employment; but those of the anatifæ are very inferior, in consequence of their horny substance.

Cirri are found in several species of worms; and they sometimes appear to be formed of different articulations, like the antennæ of insects. Nerves proceed into those of the aphrodita and nereis. There are none in the lumbricus and leech; but their place is supplied in the latter by the two disks which terminate their bodies. Their number varies: generally there are two, the slug has four, the cuttle-fish eight, the pennatula forty to sixty or more. Many varieties of form are also observed, and described by writers in natural history. The tentacula of the polypes are said to be hollow, and to communicate with the stomach. Fine hairs are observed in them, by means of the microscope; they also possess numerous knots, which probably are of service in fixing them on animals which they seize for prey.

Throughout the invertebral classes, we find these instruments chiefly used for seizing the creatures on which the animal lives. The tubularia, hydra, brachyous, vorticella, &c. throw the water into motion by means of their arms. When any thing on which they can prey comes near, they instantly seize and convey it to the mouth. Trembley observed, that the tubularia sultana (polypes à bouquet) gave a rotatory motion to the water, and thus conducted the prey to their arms. Olivi observed, that the actiniæ and polypes (hydra) perceived their prey at a distance, put the water in motion, and thus brought it within the sphere of their arms.

Speaking of these organs, Cuvier says, "the anus, the tufts and the flowers of several zoophytes (polypi, Lamarck); the innumerable tentacula of the sea-lars, urchins and actiniæ, and the complicated branches of the medusæ, are excellent organs of touch."

Of the insensible parts, covering the skin, very little remains to be said; we have already described the formation of the shell, and have made some further remarks on it in speaking of the skin.

Many of the vermes clafs have the body furnished with bunches of hairs, which are sometimes stiff and retractile, and serve for feet, as we have pointed out in the genera nereis, terebella, lumbricus, &c. In the aphrodita, there are, besides these bristles employed in progression, an infinite number of other hairs, which are long, flexible, and of a changeable sea-green colour; there is also a tomentous felt-like substance, covering the branchiæ, through which the water is strained.

Organ of Smelling.—The faculty of smell is connected in

all animals, in which it has been hitherto discovered, with the respiratory apparatus; the air which enters the latter loaded with odorous effluvia acting on the olfactory nerves in its passage. This analogy would lead us to look for the nose in similar situations in invertebral animals. No such organ, however, has yet been discovered in this great division of the animal kingdom; although in some instances there are strong proofs that such a sense exists. (See *INSECTS*, in *Anatomy*.) In mollusca and worms we have still fewer direct arguments for the existence of the sense, than in insects. We should not perhaps expect it in intestinal worms, as it could answer no purpose; nor in such testaceous animals and corals, &c. as have no power of locomotion.

Organ of Taste.—The peizæ, snails, and most gasteropodous mollusca, have a cartilaginous tongue, the singular structure of which will be spoken of in describing the organs of mastication, &c. It has no motions except such as are connected with deglutition. Its anterior part is fixed below the mouth; and it is incapable of embracing sapid bodies. The acephalous mollusca do not appear to have any tongue; perhaps they exercise the sense of taste by those tentacula, so similar to papillæ, with which their cloaks are furnished at the parts, where the water, which is the vehicle of their aliments, enters.

There is no tongue, properly speaking, in worms; though some have given that name to the proboscis of the thalassema, echinorhynchus, &c. The zoophytes have also no tongue; but the tentacula, which surround their mouth, are frequently so fine, and of so delicate a substance, as to be very well calculated for the seat of taste.

Organs of Digestion.

Organs of Mastication in the Mollusca.—As this class hardly possesses in any instance an osseous or at all solid head, their jaws, when they have any, cannot be articulated with, or rest upon the head. Although the cephalopoda possess a kind of cranium, they do not constitute an exception to this rule; the parts composing their mouth are suspended in the ring formed by this cranium.

The jaws of the mollusca consist of horny, or sometimes stony substance, fixed in an oval fleshy mass, enveloping the mouth, and composed of the muscles of the jaws, and of those concerned in deglutition. The muscular fibres belonging to this mass are not very distinct, although we perceive in them different directions, by which they are calculated to approximate or separate the jaws. The latter differ considerably in form. All the cephalopoda possess two, which resemble exactly the horny mandibles of a bird. They are convex, hooked, and very sharp-pointed. They consist of a double plate of a thick hard horn, of a deep-brown colour, of which the edges, opposed to each other at the triturating part, become very thin, while they are hidden at their basis in the fleshy mass already mentioned. This instrument is employed to break the crabs and other testaceous animals which are used for food.

The form and number of the jaws are not so constant in the gasteropoda. The common slugs and snails have only one, which corresponds to the upper; it is crescent-shaped, and the concave edge is denticulated.

In the tritonia, the jaws may be best compared to the shears employed in shearing sheep. Instead, however, of playing on a common spring, the two plates move by a joint; and they are slightly curved, instead of being plane. These jaws are lateral, and move from right to left; the cutting-edge of one slides over that of the other, and they are very sharp.

We see nothing in the aplysia but a thin horny plate, of no great strength, covering the interior of each side of the mouth. Even this slight induration is not observed in the onchidium.

The gasteropodous mollusca, possessing a long or short proboscis, have no jaws at all; this is the case with the buccinum, murex, voluta, bullæa, &c.; and among the naked gasteropoda, with the doris, scyllæa, &c. We merely find in some cases, that the sides of the bottom of the proboscis are covered with cartilaginous plates; there are such in the doris. The oscabrio has no masticating organ: neither have the pteropoda, as the hyalæa, clio, pneumodermon, &c.

None of the acephalous mollusca have jaws, nor any thing subservient to mastication properly so called. The teredos employ, for piercing wood, the valves of their shells, which some naturalists have called their teeth; but about the true nature of which it is impossible to doubt, when the teredo is compared to the pholas, the genus most analogous to it. The valves of the former seem merely a miniature representation of those belonging to the latter; as Adanson observed long ago.

The naked acephala, as the salpa (biphore), ascidia, &c. have no apparatus for dividing their food. The cirropoda, as the balanus and lepas, have vestiges of jaws, disposed in pairs. The lepas, for example, has two denticulated pairs, and a thin one simply rounded.

Organs of Mastication in the Vermes.—Some of this class have lateral jaws as strong as those of any insect or crustaceous animal, and even very similar to them in form. In a large species of nereis, for example, the opening of the œsophagus is furnished with eight calcareous pieces, which seem to supply the place of mandibles, jaws, and lower lip. The two upper are flattened, arched, and pointed hooks, disposed like the branches of a pair of forceps, united behind, and articulated upon a horny, elastic, femular plate situated above the œsophagus. The two following are broader, but not so long; they have six denticuli directed backwards; they are articulated towards the posterior third and below the hooks, which rest upon them in their whole length. The third jaw on each side is placed below and exteriorly; it is shorter and embraces the first jaws, as in the bowl of a spoon. It is found, on attentive examination, to be composed of three small pieces placed near together; the internal has its edge denticulated with twelve small triangular points, like the teeth of a saw: the middle is placed forwards, and forms the posterior edge of a prominent rounded eminence, situated at the opening of the mouth; the last is external, and terminated by a single point. The two lower pieces, which seem to serve for a lower lip, are the longest, flattened horizontally, softer at their edge, which consists of a horny and rather flexible substance. All the parts just specified are surrounded by a stratum of muscular fibres destined to move them.

In other small species of nereis, the opening of the œsophagus is very muscular, covered with wrinkles and points of a horny firm texture, arranged in a circular manner, and on several lines, which are capable of rubbing on each other. Two principal rugæ, situated towards the upper part, support two larger horny pieces of a round form. At the lower and back part are two arched hooks, which come together like the branches of forceps. In other species we also observe two hooks; but the horny points are not arranged in the same manner. They are collected in six groups in muscular eminences, of which three are anterior and three posterior. It appears that the animal has the power of inverting this part of the œsophagus,

VERMES.

gus, so as to bring out the two hooks, which seize the food like a pair of forceps. When it is seized, they drag it in, and the muscular part of the œsophagus, acting on it by its contractions, and by means of the horny papillæ, divides and triturates it, and thus prepares it for the action of the intestinal canal.

The other marine vermes, arranged near the nereids, such as the arenicolæ, the amphinomizæ, amphitrite, terebellæ, and ferpillæ, have neither jaws nor teeth. At least we can hardly give that name to the pectinated processes of the amphitrite. They are scaly pointed pieces, of a brilliant golden colour, arranged in two rows, which represent two combs, but situated out of the mouth, on the surface of the head, and enabling the animal to fix itself, or to hook in various substances, but not to masticate or divide the food.

The aphroditæ have four small teeth at the bottom of a proboscis, which they can extend or withdraw at will.

Leeches have three small semi-circular prominences in the interior of the mouth: the edge is cutting, and finely denticulated, like a saw. With this instrument they pierce the skin. The lumbricus has no jaws.

Organs of Mastication in the Echino-dermata.—Amongst the invertebral animals, the echini are those which have the most surprising apparatus of this kind. Their external covering, which is bony and consists of a single piece, presents a large round hole, in which the mass of the mouth is suspended, attached indeed by ligaments and muscles, but moveable to a certain point. The bony part of this mass has some resemblance to a lantern with six divisions: the comparison was made as long ago as the time of Aristotle. The object of the apparatus is to support and move five teeth, which encircle the small round aperture, by which the food enters. These teeth are worn away by mastication, and are constructed on the same principle as the incisors of the rodentia; *viz.* very long, soft behind, and hardening towards the front, in which direction they advance in proportion to the effect of the attrition. They rest in an apparatus consisting of fixed and moveable pieces. The fixed pieces adhere within the shell, all round the hole: they consist of five bony arches, whose convexities are turned towards the cavity of the shell, or downwards; while their concavities are towards the edge of the circular opening, or upwards. The principal moveable pieces are five triangular pyramids, forming the principal body of the mass of the mouth, and dividing the great pyramid or pentagonal lantern of the mouth. Two faces of each pyramid correspond to those of the neighbouring pyramids: they are marked by five transverse striae. Their inner edges do not touch each other, but are separated by a small interval. The dorsal or external face of each pyramid is convex, thick, and perforated towards its base by a triangular or circular opening, differing in size according to the species. Its inner edge has a groove, in which the body of the teeth passes and can move longitudinally, but in no other direction. Its extremity passes out at the point of the pyramid; and the five points being approximated about the opening of the mouth, the five teeth end there also.

The pyramids are hollow, and their faces do not exactly touch those of the neighbouring pyramids; but they are united by a fleshy mass, which can approximate them. Its effect is that of bringing the five teeth together, and thus contracting the opening of the mouth.

The canal of the œsophagus passes between the five pyramids: the sides of their bases, by which they touch each other, are united, two by two, by five bony pieces disposed like radii, and approximating towards the œsophagus as

their centre. Each of these pieces unites the adjacent sides of the bases of two pyramids, being articulated to them in a loose manner. The third side of the basis of each pyramid, that which constitutes the basis of its dorsal or external surface, forms one of the planes of the general pyramid or pentagon. In the natural position these sides correspond to the intervals of the fixed bony arches, which consequently answer to the angles of the pentagonal pyramid.

Twenty muscles act from the fixed bony arches on this pentagonal pyramid, and can either move it entirely, or move on each other the five triangular pyramids which compose it. Ten of these muscles pass from the intervals of the arches to the external bases of the five pyramids. When they act all together, while at the same time the muscles joining the pyramids together contract, the whole mass of the mouth is carried forwards, or towards the outside of the body. If they act separately, they incline the mass and render its axis oblique, making the internal extremity of the axis converge towards the side of the muscles which act. If one acts alone, while the particular muscles joining its pyramid to the two neighbouring ones are relaxed, it carries the tooth of that pyramid further onwards than the others.

The ten other muscles go from the convexities of the arches like radii, to terminate at the points of the pyramids; so that each point receives the muscles of the two neighbouring arches. As the arches project inwardly, these muscles are inclined towards the outer surface of the shell; consequently their effect, when they act together, is that of making the mass of the mouth pass a little inward. When they act separately, while the muscles uniting the pyramids are contracted, they incline the mass of the mouth, by making the external extremity of its axis converge towards the side of the muscle which acts. When the muscles joining the pyramid to its neighbours are relaxed, the effect of the muscles we are now describing is to draw back the tooth corresponding to that pyramid, and move it away from the aperture of the mouth. Thus, in these three relations, the muscles coming from the arches are antagonists of those which come from their intervals.

If both sets act together, they become common antagonists of those which join the pyramids, and their operation will then be to separate the latter from each other, and to enlarge, not only the entrance of the mouth, but the whole of the passage left for the œsophagus through the axis of the great pentagonal pyramid.

Besides the twenty-five muscles, which act immediately on the pentagonal pyramid and its parts, there are ten others, which act on it through the intervention of five officula, which we must now describe. They are slender, and rather semi-circular or arched; and are placed each on the same level with one of the five bony radii which have been described.

One extremity of each arc is articulated to the internal extremity of the corresponding radiated piece: the other passes above and on the outside of its external extremity, and is bifurcated like the letter Y. A pentagonal membrane unites and strengthens their extremities towards the centre. Each of the two branches of the Y receives a muscle coming from the middle of the nearest interval of the fixed bony arches; so that each of the five intervals gives a muscle to the two nearest Ys.

The effect of the muscles, acting by such levers, in inclining the mass of the mouth in every direction can be easily conceived.

Each tooth may be considered as a long triangular prism; of which the two posterior faces make re-entrant angles. The part which comes out of the point of the pyramid is

E very

VERMES.

very hard; but it becomes gradually softer behind, and forms a long flexible tail. This soft part has a silky, or even metallic lustre, and is torn by the slightest effort.

The form of teeth just described, is that which we find in the echinus esculentus. In other species, as the echinus cidaris, instead of being prismatic, they are like half tubes, and their extremity, which is worn away obliquely, forms the bowl of the spoon.

All the echini, properly so called, and apparently all the subgenera, which have the body spherical and the mouth central, have a mouth constructed in the manner just described. Such as have the mouth central, and the body flattened (clypealter, Lamarck; echinus rosaceus), have an oval mass composed of five oleous pieces, each supporting a tooth; but this mass is quite flattened, like a circular cake divided into five sectors. The faces, by which the sectors touch each other, are not striated. Although there are fibres to unite them, they are merely perforated by fine and regular pores. The surface opposite to the opening is elevated at the sides into fine and prominent laminae; the other surface is sometimes like this. Their teeth do not slide in grooves, but are fixed, and have the shape of a compressed cylinder, worn obliquely at the end which is in action. The opposite end is soft, as in the preceding instance, but not prolonged into a flexible tail. The external muscles which act on this apparatus are very trifling.

Such echini as have the mouth oblique, and furnished with a plate of the shell advancing under it, as the spatangus and cassidula of Lamarck, have neither teeth nor oleous mass to support them. There is merely round the opening of the mouth a skin furnished with small scaly pieces, similar to those of the shell, but not so closely set as to render this part inflexible; it can, on the contrary, be extended and retracted to a certain point, at the will of the animal, like a proboscis.

The asteria have no teeth: their mouth is a round membranous aperture, leading to the stomach by a very short œsophagus, which is sometimes capable of being everted, particularly when the animal is hungry. Those spines of the external surface, which are nearest to the mouth, may serve, when inclined towards that opening, to retain the prey: but they cannot be regarded as teeth in the proper sense of the word.

The opening of the mouth in the holothuriz is surrounded by a ring composed of ten semi-oleous pieces; but they serve merely as points of support for the longitudinal muscles of the body and the tentacula. They are covered by the internal integument of the mouth, support no teeth, and are not concerned in the business of mastication.

The spunculi have no hard parts in the mouth, nor elsewhere; neither have any of the zoophytes, which come next in the scale.

Salivary Organs.

In the Mollusca.—They are very large in the cephalopoda and gasteropoda; more considerable indeed than in any other animals. In the former there are two pairs. The first and smallest is situated on the fleshy mass of the mouth: each gland has a short excretory duct, penetrating the mass laterally, a little in front of the origin of the œsophagus. The other pair is much larger, situated under the neck, behind the liver, and opposite the cross. The excretory ducts of the two glands unite into one tube, which ascends behind the œsophagus, and penetrates the mass of the mouth towards the posterior point of the small cartilage, which supplies the place of a tongue. These glands are whitish, flattened, and but little granulated. They are lo-

bulated, and have an angular outline; and they receive large branches from the principal artery.

In general, the gasteropoda have only a single pair of these glands. In the common snail (*helix pomatia*), they are oblong, placed close to the origin of the œsophagus, and produce two long canals, which increase in size as they are inserted in the mass of the mouth above. In the red slug they are less, and merely form a collar round the origin of the stomach.

In the aplysia, the salivary glands are two long, narrow, ribbon-like bodies, floating at the sides of the œsophagus. They are inserted in the mouth, near the origin of the stomach, without having any part of their excretory duct uncovered. Their posterior extremity is fixed to the second stomach by means of branches received from the stomachic artery.

The doris has salivary glands shaped like a long narrow ribbon, attached behind to the stomach. They are so slender in some species, that they might be taken for nerves, when they have passed through the nervous collar of the brain.

Animals of the genus *bullæa*, though very similar to the aplysia, have merely two short slender glands; but in the *cho borealis* they are nearly the same as in the aplysia.

In the pneumodermon they are elongated, and contracted where they pass under the brain: for in all these animals, without exception, either the gland, or at least its excretory canal, passes with the œsophagus through the cerebral ring.

In the tritonia they are very large and lobulated, situated at the sides of the œsophagus, and tolerably wide in their middle. The structure is similar in the onchidium. They are generally considerable in the aquatic univalves, as in the genera *bulimus*, *murex*, and *buccinum*, which is remarkable, inasmuch as in aquatic vertebral animals they are either small or entirely deficient. They are small in the halyotis.

In the Echino-dermata.—The holothurizæ have all round their mouth oblong blind pouches, which terminate in that cavity, and must be supposed to pour into it some liquor analogous to saliva. There are twenty of different lengths in the holothuria tremula. The pentactes has only two, much larger. Nothing of the kind has been discovered in the echini and asteria.

The medusæ and other radiaria, and the zoophytes properly so called, exhibit no salivary apparatus.

Organs of Deglutition.

In the Mollusca.—We must distinguish the external organs or lips from the internal or tongue. The former are again divided into two kinds; viz. short or proper lips, and tubular lips elongated into a proboscis.

1. Proper lips. In the cephalopoda, the opening of the mouth is surrounded by a fleshy and denticulated circle, which covers and entirely conceals, when the animal chooses, the two mandibles of the bill.

In the gasteropoda, which have no proboscis, the mouth is generally a longitudinal slit, whose fleshy margins hold the place of lips. Sometimes, as in the tritonia and onchidium, these lips have the form of thin plates, often divided into shreds, as in the tritonia arborefens; the inferior tentacula of the aplysia may also be considered as folds of its lips.

All the common bivalves have round their mouth four membranous folds, usually triangular, and more or less elongated, serving apparently by their motion to convey the food towards the mouth. One of their surfaces is, moreover, so vascular, that it probably has some connection with the business of respiration. Sometimes these folds are united, two by two, in part of their length, as in the pinna. In

other instances, the proper opening of the mouth is surrounded by a circle of fleshy fimbriæ, more or less divided, as in the spondylus.

The naked acephala, as the biphoræ, thaliæ, afdiæ, &c. have neither folds nor fringes. The mouth of the biphoræ has merely a circular and fleshy edge.

In the brachiopoda (terebratulæ and lingulæ) lips do not exist; but their place is advantageously supplied by two long ciliated arms.

2. Proboscis. Several naked mollusca, as the doris, and probably most of the testacea, as the buccinum, murex, volva, &c. have a fleshy cylindrical or conical proboscis, which they employ for seizing their food at a distance. The motions of this instrument are not confined to flexion and a limited elongation, as in the trunk of the elephant; but it is capable of being withdrawn into the body by folding inwards within itself, and of being extended again, like the finger of a glove, the horns of a snail, or many other parts of mollusca.

It may be represented as a cylinder folded inwards within itself, or as two cylinders, of which one includes the other, and the two superior edges are continuous, so that in drawing outwards the inner cylinder, it is elongated at the expense of the other, and in pushing it back again it is shortened, while the exterior is elongated. The latter effect takes place at the inside, because this outer cylinder has its inferior edge fixed to the parietes of the head.

There are several longitudinal muscles divided into many strands at their two extremities. They are fixed on one side to the parietes of the body; and on the other to the internal parietes of the inner cylinder in its whole length, and to its very end. It is obvious that they will have the effect of drawing inwards this cylinder, and the whole proboscis. When it is thus retracted, a large part of the inner surface of the internal cylinder comes to form part of the outer surface of the external cylinder: and the contrary takes place when the proboscis is elongated or extended. The insertions of the muscles undergo corresponding variations.

The elongation of the internal cylinder, by the unfolding of the external, is effected by the proper annular muscles of the proboscis. They surround its whole length; and by their successive contractions thrust it outwards. There is one stronger than the others where the external cylinder is attached to the parietes of the head. When the proboscis is elongated, its retractor muscles, by acting partially, can bend it to one side or the other; and the various portions in this way antagonise each other.

This description may serve also for the murex tritonis; but the proboscis is much shorter than in the buccinum.

In those mollusca which have a proboscis, the œsophagus is very long, and loosely folded, that it may follow all the motions of that instrument: it forms in a manner a third cylinder concentric to the two others.

None of the cephalopodous, pteropodous, or acephalous classes have a proboscis: the part which has been so named in the cirrhopoda (the auatizæ and balani) is the rectum. The supposed proboscis which some authors speak of in several bivalves, is the canal for the conveyance of water into the shell: it is placed opposite to the true mouth, and is an organ of respiration, not of deglutition.

The Tongue.—It is very singular in the cephalopoda and gasteropoda; and has nothing parallel in the animal kingdom. It is a membrane covered with prominent spines or ridges directed backwards, and capable of exercising a kind of peristaltic motion, in which the spines are alternately raised and depressed, so as gradually to propel the alimentary substances into the œsophagus.

The tongue of the cephalopoda is placed between the two mandibles: it is behind the jaws in such gasteropoda as have those organs. This is particularly observable in the tritonia, when the tongue immediately receives whatever passes the cutting edge of the jaws. Others have it near the opening of the mouth; and those which have a proboscis, have their tongue at the anterior extremity of that organ. In that case it serves, in some degree, as an organ of mastication; as it can cut the food more or less by means of its hooks.

The tongue varies much in length; and there are species in which we are at a loss to assign an explanation for its considerable extent. In the halotyis, for example, it is half as long as the body; in the patella and turbo pica it is nearly quite as long, and folded like the intestines; and, what is remarkable, these genera have no proboscis. In those which have one the tongue is short. The arrangement of the organ makes it impossible for the animal to employ more than the anterior part: but probably it may resemble some kinds of teeth, the posterior part coming forwards, and succeeding to the other in proportion as it is worn away in front. This conjecture receives confirmation from the soft and nearly gelatinous state of the posterior part: we may suppose that it becomes firm when it comes into use, as the teeth of quadrupeds which are to succeed. All this posterior part is rolled up longitudinally, like a horn.

In the cephalopoda the tongue is oblong, and prolonged posteriorly into a long horn. In the aplysia it is very broad, heart-shaped, and placed on two rounded eminences separated by a groove. In the bullæa it forms a small tubercle at the bottom of the mouth.

The hard covering of this tongue is disposed in a regular and constant manner in each species. It consists, in the cephalopoda, of hooked spines of equal length, arranged in two lateral rows, and of a middle series of scales with five points.

In the oscabrio, there is on each side a series of hooked scales, with three points, and of long, sharp, and hooked, but simple spines. In the middle there are small tubercles.

The turbo pica has transverse, cutting, and denticulated laminae.

The tongue of the aplysia is covered all over with small hooked spines, disposed in the quincunx order. In the onchidium there are very fine transverse grooves, themselves marked with still finer striæ of an opposite direction. The arrangement is nearly the same in the doris. A similar structure occurs in the snail and slug, but it is so minute that a strong glass is necessary to perceive it.

The acephala have no proper tongue; but there is a circular valve at the entrance of their œsophagus, directed towards the stomach, and capable of contributing powerfully to deglutition. It is very plain in the oyster. Generally these are mere transverse folds, which direct the food by their peristaltic motion.

The Alimentary Canal and its Appendages.—The alimentary canal of invertebral animals is composed of the same essential parts as in those which have vertebræ. There is an internal mucous surface, which in some instances assumes a callous nature, and sometimes becomes villous, or has a papillary texture; a cellular stratum external to this, analogous to what some have called the nervous coat of the mammalia; and a muscular covering of variable thickness. A leading difference is, that often the serous or mesenteric coat, and the mesentery itself, are wanting. There seems to be none in several mollusca, and in the class of insects, and we only meet with it again in the echino-dermata. Another difference is, that the cellular stratum is not always vascular: it is so

only in the mollusca, worms, and some echino-dermata. In no case have insects any thing more than tracheæ ramified in the parietes of their intestines, and most zoophytes have nothing at all. A third, but less general difference is, that the membranes of the stomach are often armed with hard parts, either simply in the form of plates, as in the bullæ; or of teeth, as in the crustacea; or of scales, as in the grylli; or hooks, as in the aplysia. This is a new analogy between the intestinal membranes and the skin; for we know, that in these animals, the shells and scales which cover them, are often produced by the induration of their rete mucosum.

In its relative length, in the size of its different parts, in the number and form of its dilatations, and particularly of the stomachs and cæca, and in its internal folds, the alimentary canal of invertebral animals exhibits varieties altogether analogous to those observed in the vertebral classes. Thus, for example, such as are carnivorous, have a simple and short canal, &c.

There is more variety in the position of the anus. The zoophytes, some echino-dermata excepted, have none at all, but void their excrement by the mouth. Insects, worms, and crustacea, always have an anus at the extremity of the body opposite to the mouth, and below. In the mollusca its position seems subject to no rule. In the doris we find it backwards and upwards; backwards and downwards in the onchidium. It is on the right side in the slug, snail, aplysia, and bullæ; in the head, in the patella; in front of the neck, in the cuttle-fish; on the side of the neck, in the clio: in the acephala it is usually found opposite to the mouth.

Alimentary Canal of the Mollusca.—Locomotion is performed in all the *cephalopoda* with the head downwards: as the mouth is in the centre of the feet, the food must ascend into the abdomen: the rectum descends and opens into a cartilaginous cloaca, or funnel, placed in front of the neck, and serving as a common receptacle for the semen, the eggs, and the inky fluid. The œsophagus passes behind the liver, or towards the back; and the rectum in front, or towards the abdomen: the rest of the canal is in the bottom of the sac or abdomen. In the middle of the œsophagus of the sepia octopus, there is a considerable dilatation, of which the parietes, though thin, are manifestly glandular: this is a true crop, analogous to that of birds; but they have nothing similar to the bulbous glandulosus of birds. The stomach is a gizzard in its general arrangement: the parietes are covered by two muscles nearly as strong as those of the gizzard of the gallinaceous birds; its internal membrane is equally thick, cartilaginous, and easily separated. The pylorus is near the cardia, and leads into a species of cæcum, or, if that name should be preferred, a third stomach which is a little bent on itself in a spiral form. Here the hepatic canals terminate. The second, or true pylorus, is near the other, and also near the cardia. A smooth canal lies along the concavity of the third stomach: the rest of its internal surface is plated transversely, and exhibits the orifices of an infinite number of small mucous follicles. The intestine itself has thin sides: it is large, and nearly of uniform diameter throughout. In the octopus it makes two nearly transverse convolutions, and a large longitudinal turn before it proceeds straight to the infundibulum. In the calmar it goes straight, without any convolution.

The alimentary canal presents numerous varieties in the *gasteropoda*. It is most simple in the snail and slug. The œsophagus, after being a little dilated to form a kind of crop, ends at the stomach, which is itself merely an oblong

membranous bag, with a large hepatic canal opening in it. The pylorus is near the same part: the intestine is cylindrical, and of uniform size; it makes two turns, and then goes forwards and to the right, to open close to the orifice of the lung, after having passed along the parietes of that cavity, and furnished numerous branches to the venous vessels which are distributed over those parietes. The same relation is observed in the other gasteropoda between the intestine and the pulmonary organ: hence the anus is always near the branchiæ, when the latter are of limited extent.

The parmacella differs only in having the anus, as well as the pulmonary opening further back; and the testacella, in having them quite at the posterior extremity.

There is a simple membranous stomach in the doris; it is an oval sac, into the bottom of which the bile is poured from numerous orifices. The pylorus is placed forwards, near the cardia; and the intestinal canal, which is large and short, goes directly backwards, almost without any turn, to open in the centre of the branchial circle, placed at the posterior part of the back.

In the tritonia and phyllidia, the stomach is as in the doris; but the intestine goes forwards to the right, where the anus ends under the edge of the cloak. The pylorus is nearer to the cardia, and the anus more anterior, and nearer to the generative orifice, in the phyllidia: it is separate, and placed further back, in the tritonia.

The halotyis has merely a membranous sac at the back of the body. The canal is uniform throughout, and runs twice and a half the length of the body, nearly in three straight lines. It opens by a fleshy tube in the cavity of the branchiæ, on the left of the body.

In the buccinum the œsophagus is long and slender, has a small lateral crop, and soon after ends in a rounded stomach. The intestine is very short. When it has reached the right side of the branchial cavity, it is dilated into a large tube with thick sides, of which the internal surface is plated longitudinally: it contracts suddenly before opening at the anus.

The stomach of the murex is a slight membranous dilatation. The rectum is not dilated, but situated as in the buccinum. The intestine is short.

The stomach of the patellæ is a scarcely sensible dilatation; the bile enters by numerous pores. In the oscabrio it is a rounded sac. The intestinal canal in both these genera is slender and long; and makes many convolutions.

In the helix itagnalis the stomach begins to be more complicated. It is furnished with two muscles united by common tendons, and radiated exactly as in the gizzard of birds. Immediately before entering it, the œsophagus is dilated into a kind of crop.

The onchidium also has a thick gizzard, preceded by a crop. Two hepatic canals open into the latter, and a third into the former. The gizzard is followed by two membranous but thick stomachs; one is pyramidal, with the broad part turned towards the gizzard, and parietes deeply plated into longitudinal ridges: the other is narrower, cylindrical, and more delicately plated.

There is some analogy between the stomach of the pleurobranchus and that of the onchidium; but the organ is weaker in the former. There is at first a membranous crop, which is a mere dilatation of the œsophagus, receiving, close to the opening of the second stomach, the biliary fluid: then comes a small gizzard, with muscular but weak parietes: this is followed by a third stomach, which resembles, by the thin longitudinal laminae of its inner surface, the third stomach (manyplus, feillet, Fr.) of the ruminantia. Lastly, there is a fourth stomach, simply membranous like the first,

but

but smaller. We observe in the gizzard a narrow groove, leading directly from the first stomach into the third, and probably subservient to something like rumination. The intestine is short and uniform. The aliment is moulded, in the third stomach, into long whitish cords.

The aplysia has a still more curious stomach: it is also four-fold. The œsophagus, at first narrow, dilates suddenly to form the first stomach or crop, which is a large thin membranous bag, making a nearly spiral turn, and having no glandular appearance. Then follows a short cylindrical gizzard, with muscular and very strong parietes: they are covered internally with a very extraordinary kind of armour, to which there is nothing exactly similar, although the ossæous pieces belonging to the stomach of the bullæ bear some analogy to it. Let us conceive pyramids with rhomboidal bases, whose irregular faces are united into an apex divided into two or three obtuse points. Their substance is semi-cartilaginous, and composed of strata parallel to the basis. There are about twelve large ones, arranged in quincunces on three rows, and some smaller, placed at the upper edge of the gizzard. These pyramids adhere so slightly to the mucous surface, that the slightest contact displaces them, no trace of membrane, or any other union, being perceptible. The places to which they adhered are, however, marked by smooth prominent surfaces, while the intervals are slightly hollowed and striated. The apices of these pyramids come together in the middle of the gizzard, and they must consequently comminute the food which passes along the space between them. The third stomach is broad, but not so long as the former, and has an equally singular covering, consisting of small pointed hooks attached to one side of the cavity, almost as slightly as the pyramids are to the preceding stomach. Their points are turned towards the gizzard, and no other use can be assigned to them but that of stopping the passage of the aliment when insufficiently triturated: here, indeed, the form of the alimentary substances is no longer recognizable. Near the pylorus are two small prominent membranous cristæ, between which the orifice of the fourth stomach is seen, and that of the hepatic vessels. The former, as in the cuttle-fish, might be called a cæcum. This cæcum is as long as the third stomach: its diameter is small, its sides simple, without any internal projections, and it is absolutely hid in the liver. The intestinal canal is of uniform diameter, with thin transparent sides, more so than those of the third stomach, and distinguished from it by this circumstance: it makes two great convolutions enveloped in the lobes of the liver, and terminates at the anus, in the middle of the right side of the body, by a rectum which passes transversely. Its internal surface exhibits neither papillæ nor valves; it has no sensible constriction nor dilations.

The most strongly armed of all known stomachs is that of the bulla lignaria and aperta; there are three flat stony pieces; two of similar form, triangular, broader and lateral, one narrower, rhomboidal and middle, united by muscular fibres, which have the power of approximating them. These hard substances are larger in the bulla lignaria, and rather differently made. Draparnaud found that this apparatus had been considered as a shell, and had given rise to the establishment of the genus *triclæ* or *gioëna*.

In the Pteropoda.—Two of the small genera which compose this order, *viz.* the *elio* and *pneumodermon*, have stomachs of the same kind: they are simple membranous bags, surrounded by the liver, and receiving bile from numerous organs. The third genus, *hyalæa*, has a dilatation of the œsophagus, followed by a short cylindrical gizzard: both have internal longitudinal plates. The two first genera

have a short straight intestine: the *hyalæa* has three convolutions included in the liver.

In the Acephala.—We generally find in this family a membranous stomach, following a very short œsophagus, surrounded on all sides by the liver, which adheres to it intimately, and in which it appears to be excavated. Its parietes are very irregular, forming several small cul-de-sacs, at the bottom of which the bile is received: for in all the order that fluid enters the stomach immediately. The biliary apertures have somewhat valvular edges, to prevent the food from entering the ducts. The intestine makes several convolutions, chiefly out of the liver, and most frequently in the substance of the muscles of the foot, in which it is in a manner incased. Towards its origin, in some species, the intestinal canal has dilations, which might be taken for second stomachs. In others there is a true second stomach, which is a kind of cæcum near the pylorus. The greatest singularity, which is also absolutely peculiar to some acephala, is a part long ago described by Willis, Swammerdam, and others, but more particularly by Poli, under the name of the crystalline filette. It is probably transparent and cartilaginous; elongated, pointed at one end, and obtuse at the other. It is composed of laminae, included one in the other, and contained in a sheath closely applied to the commencement of the intestine, but open towards the stomach, so as to allow the point of the filette to penetrate that cavity. On this point is articulated a body of similar texture, divided into some conical eminences, and occupying the entrance of the stomach: it is difficult to assign the use of such an organ.

The solen has a second stomach, long and slender, and occupying half the length of the foot, into which it penetrates: the intestine begins at the side of the origin of the latter, and proceeds parallel to it. The oyster has also a second stomach, situated between the branchiæ and the muscle that closes the shell: the intestine rises from it near its commencement, and proceeds in an opposite direction.

According to Poli, the intestinal canal is shorter in the genera fixed to one spot, as the oyster and spondylus, than in those which are capable of locomotion, as the cardium and venus. Yet the fresh-water muscle has it short; it makes a single fold in the foot, and returns backwards to descend to the anus. The same arrangement is found in the *mya pictorum*. On leaving the second stomach, in the oyster, the intestine ascends, furrows the liver, and then goes backwards. It is nearly the same in the spondylus. In the eatable muscle (*mytilus edentulus*), it descends along the back, ascends again, goes round the liver, and then descends to the anus. It is very short, making only two slight curves, in the *venus decussata*; but in the *cardium edule* (common cockle) it makes seven or eight spiral turns in the foot, and is more than five times the length of the body. It is equally long, but rather differently arranged, in the *maëtra piperata*, where its commencement is very large, and might easily pass for a second stomach. It is the same in some of the *genus venus*, and in the *orbicular tellinæ*: the common *tellinæ* have moreover a kind of cæcum at the end of this dilatation.

In most of the acephala the rectum passes through the middle of the heart, but the oyster is an exception.

There are some remarkable varieties respecting the anus. In those which have no tubes to the cloak, and which walk or spin like the fresh-water and sea muscles, it opens by a fleshy disk or sphincter, between the two edges of the cloak. In those which have these tubes, the anus itself makes another, situated more internally, projecting into the cavity

of the cloak, behind one of the muscles which close the shells. Such is the case in the selen, pholas, &c.

The naked acapala have a simple stomach and short intestine. In the acfidia, the latter makes only two convolutions; in the biphori (*falpa*), it turns twice round the liver, near which the anus is found. There is only one species (*thalia*) in which the canal is prolonged further, even to the opposite extremity of the body. The heart in this family is never traversed by the rectum.

The brachiopoda (*terebratulæ* and *lingulæ*) have a simple uniform canal. In the *lingula* it comes from the mouth, which is between the two arms, and makes two turns before reaching the anus, which is at the side. It is nearly twice as long as the body.

Alimentary Canal of Worms.—It is in general straight, without any considerable inequalities, extending from one end of the body to the other, and occupying nearly its whole capacity.

In the common sea-mouse (*aphrodite aculeata*), there is a fleshy part in front, holding the place of a proboscis, and capable of being extended out of the body: a mistake has been committed in considering this as a stomach. A cylindrical intestine follows, of small diameter, but giving origin on each side to twenty long blind processes, becoming larger towards their blind end, which is attached between the muscles of the feet and the lateral vessels. This organization is the more remarkable, as nothing like it is met with in the neighbouring genera.

The *amphinomia capillata* and *tetrædra* (*terebella* *flava* and *rostrata*) have first a fleshy mass of the mouth or a proboscis, rounder and shorter than that of the *aphrodite*, then a small œsophagus, and an enormously dilated stomach, with cellular parietes, like those of a colon, the folds of which are fixed by a tendinous line placed on the ventral side. It occupies two-thirds of the length of the body, and ends in a large short intestine.

The *arenicola*, or worm used as a bait by fishermen (*lumbricus marinus*, Linn.) has no fleshy proboscis; the œsophagus occupies one-eighth of its length; the stomach, which is more dilated, occupies a third. It is of a fine yellow, with the surface divided into lozenge-shaped sacculi, the separations of which are marked by vessels of a beautiful red. The rest of the canal is small, smooth, and straight.

In the leech of fresh water (*hirudo sanguifuga*), an œsophagus equal to one-eighth of the animal is followed by a stomach occupying one-half of its length: this organ is capacious, with thin sides, and divided by numerous membranous diaphragms, which contract it considerably, leaving only an opening in the middle. The intestine is narrower, and its internal membrane, which is opaque, exhibits an infinite number of small plaits; it enlarges towards the anus, which is very small, to that its existence has been erroneously denied by some anatomists. Two cæca arise from the pylorus, proceed parallel to the principal canal, and are nearly as long. In the sea-leech (*hirudo tuberculata*), the alimentary canal may be said to enlarge from the mouth to the opposite end; the existence of a stomach is marked merely by its septa, which are wanting in the intestine.

The common earth-worm has only a long canal, divided by numerous transverse septa, which are even strengthened by membranes attaching them to the exterior covering of the body. Some dilatations in front may represent a kind of stomach.

The canal of the nereis is equally simple, straight, and constricted at intervals: nothing more can be observed in the *amphitrite*, *terebellæ*, and *serpulæ*. The tail which

terminates the body of the genus *amphitrite*, contains the rectum. Cuvier has, however, observed in one species of *amphitrite*, which lives commonly on the oysters, a very thick and hard globular gizzard.

In the *lumbricus*, *thalassæma*, and *echinus*, the canal is five or six times longer than the body, of equal diameter throughout, with thin and corrugated sides. The posterior part is filled with excrement, moulded into small short cylinders.

Among the intestinal worms, the *ascaris* has a very simple canal with thin sides, of nearly uniform diameter, and scarcely longer than the body.

Alimentary Canal and Sac of Zoophytes.—In this class we meet with alimentary canals possessing both mouth and anus, and others like a simple sac, more or less complicated. The first are even supported by a true mesentery, which is not found in insects, mollusca, or worms. Such a structure is seen in the *echinus* and *holothuria*.

The canal of the *holothuria tubulosa* is four times the length of the body, in which it makes a double convolution, resembling the figure 8. It commences at the mouth by a slight contraction, then retains nearly the same diameter throughout. Its parietes are slender: the anus opens into the great cloaca situated at the back of the body, and separated from the cavity of the abdomen only by a valve: this circumstance will be further considered in speaking of the respiratory organs. A membranous mesentery attaches this whole canal to the external coverings of the body. A similar arrangement is observed in the *holothuria pentactes*.

The *sipunculus* has a small uniform canal, going first straight from one extremity of the body to the other; then returning in a spiral manner round this straight part, to terminate at a lateral anus very near the mouth. It is six or eight times as long as the body.

An alimentary cavity, constituting a complicated bag, is found in the *asterias*. It is a membranous sac, much folded when empty, placed in the common centre of the rays, and having no other opening but the mouth, so that the excrement is rejected by the passage which admits the food. This bag has ten blind appendices or intestines, minutely subdivided into branches and ramifications, which form a very beautiful object. These are lodged in the rays or branches of the body, two in each: when there are more than five branches, there are also more than ten of the ramified cæca. These trees, or kind of bunches of grapes, are fixed rays in their place by membranous mesenteries.

The *asterieæ*, whose rays have no feet, but resemble the tails of serpents, (*ophiuri*, Lamarck), have no such cæca. Their stomach is a simple bag, occupying merely the central disk of the animal: its membrane, however, exhibits in all parts an infinite number of small sacculi. Probably the same structure exists in the kind called *caput medusæ*.

The alimentary canal of the *medusæ* is as complicated as that of the *asterieæ*; but, instead of being suspended in the great cavity of the body, it seems to be excavated in its substance. The stomach, which is very large, fills the basis of what is called the pedicle or disk of the animal: tubcs proceed from it in a radiated manner towards the edges of the superior broad part of the body, which has the shape of a segment of a sphere. These vessels communicate together by lateral branches, and both furnish an infinite number of small ramifications, which form a very complicated net-work over the whole body, conveying the nutritive fluid to all parts, as blood-vessels do in other animals. This plexus is particularly discernible towards the edge of the umbella, where it resembles a species of lace.

The medusæ differ most widely in the manner by which the aliment enters the stomach. Some have a single mouth, a large round opening; others, instead of a mouth, have numerous branched tentacula, each perforated by a small opening. Each opening gives origin to a small canal, which joins the neighbouring one, and so on: in this way four large trunks are formed, which end in the stomach, and convey to it the matters absorbed by the small apertures of the tentacula. The number of the latter sometimes exceeds eight hundred.

It is from this structure, which is hitherto unique in the animal kingdom, that Cuvier has established the genus rhizostoma, from two Greek words (*ρίζα* and *σώμα*) signifying root and mouth. The rhizostoma, in fact, may be said to derive its nourishment from a kind of roots; and in it, as well as in all the medusæ, the stomach supplies the place of a heart.

The alimentary apparatus of the actiniæ consists of a simple bag, with a circular opening, serving both for mouth and anus. The aperture is placed in the centre of the superior surface of the animal, and is surrounded by the tentacula, which can seize the prey, and convey it immediately to the mouth. The animal has the power of contracting or dilating this orifice. The alimentary sac is suspended in the general cavity of the animal by a kind of membranous attachment. No intestine nor any vessel is known to proceed from this stomach. See *Memoire pour servir à l'Hist. de l'Acterie rouge*, &c. par Dr. Spix, *Annales du Muséum*, tom. xiii. pl. 33.

"It is surprising (says Reaumur), that a soft animal like this, not provided with claws, or any thing equivalent, should be able to devour others apparently well defended by their shells, such as muscles and other bivalves, and various species of univalves. It is however certain, that the actiniæ live on the flesh of these animals, though, as they swallow them whole, and then contract the entrance of the stomach over them, it is not easy to find out how they extract the animal from its shelly coverings. We can only see that after a certain time they expel the empty shells by the same orifice through which they had swallowed the whole animal. I have seen in this way the largest muscle-shells thrown out empty by moderate-sized actiniæ: while in some cases they are rejected without the animal having been extracted. In the same way I have seen them throw up entire buccina. I once saw a large muscle expelled entire through the basis of the actinia, where there is no natural opening. In getting rid of the shells, particularly when they are large, the animal not only dilates its mouth to the greatest extent, but absolutely inverts the whole cavity, as you would a stocking." See fig. 25. Reaumur, *Acad. des Sciences*, 1710. p. 475.

In the common polypes (hydra), the whole body appears to be a stomach; and the nutritive matter is imbibed apparently directly from the surface of the cavity into the substance of the animal. The most curious fact in relation to this stomach is, that if the animal be inverted, the external surface performs the office of stomach just as well as the original stomach did.

The pyrosoma, a large species of marine polypus, without arms, brought to France by Péron, seems, like our freshwater polypes, to be a mere stomach.

The polypes, which form by their aggregation compound animals, such as those which produce the various lithophytes, have a nutritive system nearly related to those of the common polype and medusa. Cuvier has examined this in the veretillæ (pennatula cynomorium), whose large and soft body, and transparent polypes, are more favourable to such researches than most other animals of this class. In the body of each polype, a small stomach with brownish parietes is

observed, from which proceed five tubes similar to those of the medusæ, that is, executing the functions both of intestines and vessels. These intestines are at first yellowish and undulated; having traversed two-thirds of the length of the polype, they become straight and smaller, and thus penetrate the general body or stem which supports all the polypes. They then separate to join corresponding vessels from the neighbouring polypi, and form with them a network occupying the whole mass of the stem. By means of this communication, the food taken by one polype is enjoyed by the whole animal, which may be considered as a single one with several mouths and stomachs.

The alcyonium exos exhibits an analogous structure. See Dr. Spix, in the *Annales du Muséum*, tom. xiii. p. 451, et seq. pl. 33; and it is probable that a similar organization prevails through the whole class.

Appendages to the Alimentary Canal.

Liver.—All the mollusca have a liver, which is generally very large, but never possesses a gall-bladder. It does not receive, as in the vertebral animals, the blood which has circulated through the intestines, and thus acquired a venous nature; but it derives from the aorta the necessary supply for its own nutrition, and the secretion of its peculiar liquor; and it returns this blood to the vena cava, which is the same with the pulmonary artery in these animals. In this arrangement we may perhaps find a reason for their having no spleen.

The liver of the cephalopoda is a large oval mass of a yellowish-brown, situated towards the back near the head, partly filling the interval behind the funnel, and partly descending into the abdomen. It may be divided into two lobes, between which the trunk of the aorta passes, giving to each a considerable branch. The bag, which produces the inky fluid peculiar to these animals, is inclosed between these two lobes; and in the calmar (*sepia loligo*), it is attached in front of them. Monro considered it to be a gall-bladder; he thought the ink was merely bile, consequently that that fluid was excrementitious in these animals. This is a gross error. In the common cuttle-fish the ink-bag is found in the bottom of the abdomen, far from the liver; and in those species, where the two organs are nearest together, they are not organically united. The bag contains its secreting apparatus in its own cavity, and the liver pours the bile into the alimentary canal. There are two excretory tubes, one for each lobe, penetrating together the third stomach, near its middle. Air impelled into the hepatic vein passes easily into these two canals; and they speedily inflate the third stomach. The bile which they pour out is of an orange-yellow: it remains for a considerable time mixed with the chyme, in the lateral and tortuous reservoir of the third stomach, where it can slowly exert its action.

All the gasteropoda have a large liver, divided into numerous lobes and lobules, and sometimes into several masses, each of which has a particular excretory canal. These lobes are interwoven with the intestinal convolutions, enveloping them, or being enveloped by them, and united by a cellular texture. The distribution of the artery and vein is easily seen, and even that of the proper vessels, which are distributed into the smallest lobules, the liver resembling a bunch of grapes more than a homogeneous parenchymatous mass, and extending usually through nearly the whole length of the body. In the aplysia, it pours out its secretion by several openings near the orifice of the cæcum, or fourth stomach; that is, nearly as in the cephalopoda. In the pleurobranchus and onchidium, which have several stomachs, there are differences. The bile is poured into the first stomach of the pleurobranchus. The onchidium has its

its liver divided into three distinct masses, of which the excretory ducts are not even united. The two first terminate in the first stomach by distinct orifices; the third opens into the bottom of the gizzard or second stomach.

In the testacea the liver is divided into two independent masses: their ducts are inserted opposite each other, in the beginning of the intestine, not in the stomach.

The doris and phyllidia, which have a simple membranous stomach, receive the bile in it by several openings. The liver of the former is remarkable, inasmuch as it gives rise to a second excretory vessel, terminating on the outside of the body, near the anus. The object of this structure is not known.

The snail and slug have enormous livers, divided into many lobes and lobules, all which pour their liquor by a common canal into the bottom of the cul-de-sac formed by the stomach behind the pylorus. The appearance of the liver is remarkable, particularly in the slug, from the contrast of its black surface with the fine opaque white of the blood-vessels. The testaceous gasteropoda have an equally voluminous liver, filling, together with the generative organs, the greatest part of the convolutions of the shell.

The liver of the acephala generally envelopes the stomach, like an incrustation on its surface: it pours the bile into that cavity by numerous orifices. The patella among the gasteropoda, and the clio and pneumoderon among the pteropoda, have the same structure; but the hyala, which belongs also to the latter order, has its liver placed as in the common gasteropoda, that is, interwoven with the intestine.

Even in the acephala, the intestine, after leaving the stomach, often returns to penetrate again the substance of the liver.

This form and disposition of the liver are found in the naked acephala (acidia and biphorii), as well as in the others. In the brachiopoda (lingula and terebratulæ), the liver is distinct, connected with the convolutions of the intestine, and even with the muscles.

In all the mollusca, as in the red-blooded animals, the bile is of a greenish-yellow, more or less strongly marked.

Nothing analogous to a liver is found in the worms, unless we consider the yellow substance in the parietes of the stomach of the arenicola as such. The echino-dermata and zoophytes have nothing which can be compared to this gland. The liver then seems to end with the mollusca, and some crustacea: insects have a kind of substitute for it, and zoophytes have nothing like it. In proportion as the function of respiration is less confined, and extends to more parts in the body, the liver ceases more completely.

Coverings and Supports of the intestinal Canal.

In the Mollusca.—We may assert in general, that the alimentary canal of the mollusca is not enveloped nor supported by a mesentery. The different convolutions are joined together, and to the lobes of the liver, by cellular tissue, blood-vessels, and nerves, but not fixed to a membrane. Yet all the viscera are contained in a true peritoneum, which even forms a distinct cavity for the heart, and also envelopes the lung, when the latter is not entirely exterior; but this peritoneum is not folded inwards to cover the intestine.

The peritoneum of the gasteropoda nearly lines the whole external integument of the body: the latter is thick and muscular, and, therefore, protects it effectually. In those which have a shell, the part of the body constantly covered by it is not surrounded by muscles; it is covered only by peritoneum and a thin layer of skin, and might almost be regarded as a natural hernia, formed by parts which have protruded from the muscular portion of the animal.

In the cephalopoda the peritoneum is a bag contained in another bag, namely, that which properly constitutes the body. But the latter does not entirely inclose the former; its opening leaves the peritoneum uncovered in front, where it is protected only by a thin continuation of the skin. The peritoneum of the cephalopoda is further remarkable from the circumstance of its being perforated by two openings, which communicate externally. There is no other example of such a structure, except in the rays. As the cephalopoda have a head, separated from the body by a neck, and a true cartilaginous cranium, their peritoneum, which does not stretch beyond the neck, does not cover the brain, nor the mass of the mouth, as in the other mollusca.

In consequence of the form of the body, the peritoneum of the acephala occupies a smaller space than that of the other mollusca. It is surrounded by the muscles, which go to the foot; and when there is no foot, it is simply covered by the skin. Nothing like an omentum has been seen in any animal of this class.

Some worms, as the arenicola, have their alimentary canal supported merely by blood-vessels; others, as the earth-worm, have small transverse membranes connecting the canal to the exterior covering of the body; but a mesentery, properly so called, exists in none. A thin membrane, forming an internal lining to the exterior integuments, may be regarded as a peritoneum.

In the echino-dermata we again meet with a perfect mesentery, and even sometimes with a kind of omentum. The mesentery of the echini is fixed to the shell, and makes turns exactly corresponding to those of the intestine, which it covers. In the star-fish there are as many mesenteries as ramified cæca in the branches of the body. They adhere also to the internal surface of the general covering, parallel to the axis of the branch. In the holothuria tremula, the mesentery is attached to the intestine from the mouth; it accompanies the tube to the other extremity of the body, following one of the longitudinal muscles; it then crosses, and returns to the mouth, following a second; crosses again, and re-descends to the anus along a third. Let it, however, be remarked, that the numerous vessels of this animal are not found in the mesentery, but on the opposite surface of the canal. The interweaving of these vessels with each other, and with the respiratory organs, forms a singular species of omentum, which respiration in the business of respiration.

The alimentary sac of the actinia is supported by several vertical membranes, which surround it like radii, and are fixed on the opposite side to the covering of the body.

The medusæ have no occasion for mesentery, their alimentary cavity being merely excavated in the gelatinous mass of their body: the fresh-water and other polypes still less so, inasmuch as their intestine and body are one and the same thing, that is, simply a bag formed of a gelatinous membrane.

Organs of Absorption.—No absorbing vessels can be discovered in the lower classes of animals now under our consideration. Cuvier thinks that the veins absorb in them; and he supports his sentiments by the following statement.

We are first, says he, led to this notion by observing that the blood of these animals does not differ from what is called lymph in the red-blooded classes: and also by the fact, that no anatomical method has hitherto enabled us to demonstrate the existence in these animals of any but blood-vessels. We have already observed that the parts, called by Poli lymphatic vessels, belong to the nervous system. There are, besides, some positive reasons; of which the principal is the natural communications of the great cavities of

VERMES.

of the body, in which there is always much fluid to be absorbed, with the trunks of the great veins.

These communications are particularly obvious in the cephalopoda, where the principal branches of the vena cava are furnished with a multitude of bodies resembling ramified glands, and floating loosely in the abdomen. They have tubes manifestly ending in the trunk of the vein. Fluids injected into the vein penetrate like a dew the extremities of these ramifications, and pass into the abdominal cavity. Sometimes air will pass in the same way. There must equally be a passage in the opposite direction.

Among the gasteropoda, the aplysia exhibits a communication no less free between its veins and the great cavities of the body. If we impel air from the lung into the venæ cavæ, which are continuous in these animals with the pulmonary artery, the abdomen will be distended. The orifices, through which the air escapes, are visible to the naked eye: they must admit liquids from the abdomen, as they allow air to pass from the vessels into that cavity.

The passage of the rectum through the heart in the cephalopoda is another point deserving attention. We cannot see what end this arrangement can serve, if the nutritive fluid does not find its way through the intestine into the heart, where it will be mingled with the blood, and set in motion.

This manner of viewing the subject coincides extremely well with the gradation of the organic systems, in the different classes of animals. Insects most probably have no vessel at all (see *INSECTS*, in *Anatomy*): it is, therefore, natural to find before them, in the scale, animals which have vessels of one kind only, and which, therefore, may be arranged between the vertebral division possessing the two kinds, *viz.* lymphatic and sanguineous, and the insects which have none; unless at least we regard the secretory tubes as a third order, the most essential, because common to all. The mollusca, vermes, and crustacea, seem destined to hold this intermediate rank. The echino-dermata, and particularly the holothurizæ, are of a doubtful kind: their place cannot be yet assigned.

In the zoophytes, properly so called, the substance of their body forming the sides of the alimentary cavity is immediately impregnated with the nutritive fluid. The meduse do not differ in this respect from the simplest polypes, except that their cavity has numerous tubular prolongations. If these intestinal tubes are to be considered as vessels, the stomach will perform, with respect to them, the functions of a heart.

Organs of Circulation and Respiration.—As both these kinds of organs exist together in all the vertebral classes, there can be no variety in their combinations; but one or the other may be wanting in invertebral animals, so that we may establish between them in this respect relations, which are very constant in the classes, in which these organs are perfectly understood. Thus, in the mollusca, the worms with red blood, and the crustacea, which have a complete circulation, we find circumscribed branchiæ. Insects have the body nourished by a fluid, which stagnates instead of circulating; and in them respiration is effected by means of tracheæ, which are distributed over the whole body. True zoophytes, meduse, and polypes, in which the body itself forms the sides of the intestinal canal, and directly absorbs its nourishment, have no particular organ for respiration. Probably the whole body respire.

The mollusca have a double circulation; that is, all their blood, after circulating through the body, passes through the lungs before it is fit to be circulated again.

The cephalopoda have three hearts, two composed of a ventricle and an auricle, and one of a ventricle only: the

gasteropoda have one, consisting of a ventricle and an auricle; the acephala one, of a ventricle with two auricles; and the brachiopoda two, of a ventricle without an auricle. This class alone, in fact, exhibits nearly as many modifications of the circulating organs, as all the four classes of vertebral animals: these modifications, however, have reference to the number and position of the auricles and ventricles, not to the course of the circulation, which is always double.

The cephalopodous mollusca have the most complicated system of circulating organs of all animals, possessing three distinct hearts, two pulmonary and one aortic.

The descending vena cava, formed by the union of branches which return the blood from the head and arms, passes from the neck, along the front of the liver, towards the bottom of the abdominal sac: it receives the hepatic vein in its course, and immediately afterwards, that is about the middle of the abdomen, it is bifurcated, each branch going transversely to one of the lateral hearts; but before they arrive, they receive various branches from other parts. Thus, directly after their origin from the common trunk, each receives a vein from the intestines and back of the body; and at the very point of entering the hearts, each receives another from the lower parts. All these veins are extremely thin and transparent: they are much more capacious and extensible than the arteries; no valve can be seen in them, except at the entrance of the hepatic vein.

The two great transverse branches, which end in the lateral hearts, and all the veins immediately ending in them, are perforated by openings leading into very singular appendices of a ramified or glandular appearance, such as are found in the nervous system of no other animal.

They are numerous, large, and of an opaque yellowish-white: only two offices can be ascribed to them; either that of secreting some fluid from the arterial blood, or of absorbing the liquids of the abdomen and conveying them into the veins. The small number of their arterial ramifications favours the latter idea: it is sufficient for their nutrition, but not for a secretion proportioned to their volume.

The two lateral hearts are placed at the root of the branchiæ; they are more or less rounded, with thick, muscular, though rather soft parietes, and large fleshy columns, intercepting numerous spaces of different size. In the sepia octopus they are of a very deep brown red, as in a red-blooded animal, while all the other viscera, the muscles, and the aortic heart, are whitish.

The entrance of the vein into each lateral heart is furnished with two membranous rectangular valves, fixed at their bases and extremities, and loose only at the inner edge: they allow the blood to pass in, but prevent its return. The pulmonary artery goes out at the extremity of the heart opposite to the entrance of the vein. There is no valve at its origin in the octopus, but in the cuttle-fish and calmar there are four, shaped like small fleshy tubercles, surrounding the orifice of the artery, and preventing the return of the blood. They are a little beyond the origin, and in the very trunk of the artery. The latter runs along the external and posterior edge of the gill, producing as many lateral branches, perpendicular to its trunk, as there are plates of the gill. Their ramifications and distribution will be described in the article on respiration. A branchial vein is found on the opposite or internal and anterior edge of the gill, from which it collects the blood. Reaching the lower end of the gill, the vein quits it, and runs transversely towards the middle of the body, a little below and behind the part where the vena cava bifurcates. Here it ends in the third, aortic, or intermediate heart. This heart receives then two pulmonary veins, one from each gill, which end each on its own

VERMES.

side, reaching the heart directly, and without any previous division. Their cardiac orifices are furnished with two membranous rectangular valves, analogous to those of the venæ cavæ in the pulmonary hearts.

The aortic heart is white, and of a firmer tissue than the two pulmonary hearts. Its form is oval in the longitudinal direction in the calmar; transversely in the octopus; and like the trefoil leaf in the officinalis. Its internal parietes exhibit numerous muscular columns, decussating in all directions. In the octopus it produces two principal arteries and some smaller ones, all arising immediately from the cavity, and not from a common trunk. The superior ascends nearly parallel to the venæ cava, giving branches to it, as well as to the surrounding parts. The inferior is the largest artery, and indeed analogous to the aorta: having given branches to the lower part of the sac, it turns upwards behind the viscera to the head, and sends ramifications to the intestines, liver, œsophagus, then terminates, near the fleshy mass of the mouth, by a circle which surrounds the œsophagus, and supplies the crop, the salivary glands, the mouth and feet.

Gasteropodus Mollusca.—In all these, without exception, the pulmonary system is exactly inverse of that of fishes: that is, the heart is composed of an auricle and a ventricle, and it receives the blood from the lung to distribute it over the body; while the heart of fishes sends the blood from the body to the lung. In other words, the gasteropoda possess always a simple aortic heart. All the veins of the body end in one or two venæ cavæ, which, as soon as they reach the respiratory organ, are changed into pulmonary arteries, without this change being marked by a ventricle, nor even by valves. It is exactly the same as the change of the trunk of the intestinal veins into that of the venæ portarum. The position and direction of these veins are determined by that of the pulmonary organ, which latter is usually found in the neighbourhood of the rectum, that they may receive more readily the veins of the intestines, which probably bring the chyle with them. Large trunks also come from the liver.

Thus, in the doris, where the branchiæ form a circle round the anus, the venæ cava having collected the blood from the whole body, and traversed the liver, arrives above the rectum, and divides into branches, which separate like radii to enter the bases of the branchial tufts. These branchiæ return the blood, which has undergone their action, by vessels corresponding to those which brought it. The auricle, which is shaped like a pyramid with a very broad base, has this basis disposed in a circular manner, and receives the blood from the pulmonary veins. It conveys this blood immediately into the heart, which is round, flat, and placed on the back of the liver. The heart has valves at its entrance and exit: the latter is the origin of a large artery divided immediately into four branches. One is turned back, and soon lost in the liver; two others also enter this gland; the fourth, which is the continuation of the trunk, goes directly forwards, giving branches to the intestine, stomach, salivary glands, organs of generation and mouth, and is lost ultimately in the fleshy mass of the foot.

The tritonæ and phyllidiæ have the lungs at the two sides of the body, and the heart consequently in the middle, towards the back. The auricle, placed at the back of the heart, extends transversely from one side to the other. It receives the blood from two or rather four pulmonary veins, which extend on the two sides of the body, from one end to the other, in the substance of the fleshy covering, and receive the blood from all the branchial tufts. The latter had received it from two arteries reaching in the same way

along the side of the body, and placed parallel to the veins. These pulmonary arteries collect the blood from the body by six large veins, three on each side, coming principally from the liver and intestines. The veins of the muscular covering end in these trunks without quitting its substance. Having thus received from the lung the blood, which has circulated through that organ, the heart distributes it over the body by three large arteries, one of which goes backwards into the ovary, another downwards to the liver and intestines, and the third forwards to the male organs of generation, the mouth, and the fleshy mass of the foot.

The onchidium has some resemblance to the tritonæ. Two vessels are formed in the same manner in the fleshy covering on the two sides, and they convey the blood of the body into the lung; but by their extremity only, since the lung itself is excavated in the back of the body. These vessels receive the blood from the viscera by many small veins entering separately, and that of the fleshy covering by others excavated in its thickness. The heart is near the lung behind on the right side. Its auricle is very large, and furnished with fleshy columns. The heart produces one great trunk, which first gives a branch to the liver and viscera, then a long retrograde one to the rectum and organs of generation, which are situated behind and on the right. It afterwards passes in the collar of the œsophagus, and gives two large branches to the general covering. The right sends an artery to the salivary gland of its side; the left does the same, and moreover one to the male organ of generation: the trunk is then lost in the mass of the mouth.

The aplysia possesses one of the most curious circulating systems. There is excavated on each side, in the fleshy covering, a large vessel surrounded by muscular bands decussating in every direction: these vessels receive the blood by ordinary veins from certain parts. Two come from the gland which surrounds the shell, and produces the purple liquor: but it is very clear that they communicate immediately with the abdominal cavity by several large holes. Are the latter shut during life by muscular contraction, or by any fine membrane? We do not hitherto know. However this may be, the two large vessels unite behind, and thus produce a third, which is the pulmonary artery. This is also very large, and runs forwards along one side of the membranous triangle which supports the branchiæ on its two surfaces. It distributes the blood to all the branchial plates by a corresponding number of branches: this blood returns by corresponding vessels into the pulmonary vein, situated also in the branchial triangle, and terminating in the auricle. The heart is situated crosswise, along the middle of the body, a little towards the left, inclosed in a pericardium. The auricle is large, thin, transparent, and strengthened by muscular fasciculi, which intercept lozenge-shaped spaces. The ventricle is oval and thick, and has strong muscular columns: it has valves only at its entrance, they are rectangular. The artery is divided at its exit into three principal trunks. The first goes to the left, for the liver and intestines: the second forwards to the stomach; the third and longest remains longer in the pericardium, inclining towards the right. It possesses in this situation a very extraordinary apparatus of unknown use; namely, a double criata filled internally with ramifications, arising from the artery itself, and filled by injecting the artery. They appear to have blind terminations; and the liquid they contain appears to pass back simply into the vessel, without entering any veins. After quitting the pericardium, this artery gives a branch for the corresponding part of the muscular covering, then goes directly forwards under the œsophagus. Arriving at the crop, it sends a retrograde branch

to the general covering; under the nervous collar of the œsophagus it produces a second, which goes backwards to the left in this covering; then immediately afterwards a third, which goes to the right for the penis. The trunk is then bifurcated, and lost in and about the mouth.

The lung lies on the front of the body in the slug, and the heart is placed immediately under it. The innumerable ramifications spread over the internal surface of the lung all end in the auricle, and the latter in the ventricle placed under it, and producing behind two large arteries. One suddenly turns forwards to the mouth, the generative organs and the general covering; the other goes directly backwards, and is distributed to all the viscera.

The circulation of the pleurobranchus much resembles that of the aplysia. But, as the heart is placed more forwards, the posterior artery is the largest of the three, since it has more parts to nourish.

In the testaceous gasteropoda, the heart and its auricle are situated in the bottom of the great pulmonary cavity, which occupies the upper part of the front of the body, towards the edge of the shell. The lung, whatever may be its form, receives the blood of the body, and a particularly large portion from the last part of the intestine, which runs close on the surface of the pulmonary cavity, opening sometimes within it, sometimes at its edge. Having passed through the lung, the blood enters the auricle, goes thence into the ventricle, from which it is sent over the whole body by arteries, which vary according to the general form of the animal.

The branchiæ form a series all round the body, under the cloak, in the patella. The pulmonary vein is also disposed in a circular manner, collects the blood from all the branchial plates by many small veins, and carries it to the heart, which is situated above the head, and distributes it over the whole body.

Acephalous Mollusca.—In such of these as have the heart in the back, and traversed by the rectum, it is perfectly symmetrical, oval, broader behind, and accompanied by an auricle on each side. Their branchiæ form four parallel plates: each auricle receives the blood from the two branchiæ of its own side, and transmits it to the heart. These auricles are triangular, broad towards the branchiæ, and pointed towards the heart: sometimes they have a kind of cristæ, susceptible of dilatation. Their sides are transparent, and possess few projecting threads. Their openings into the ventricle are furnished with valves, which allow the blood to pass only from the auricle to the ventricle. The latter is much stronger than the auricle: its sides are opaque, and furnished with numerous fleshy columns. The blood goes from it by two arteries situated at its two extremities; these follow the rectum, one ascending towards the head, the other descending to the anus. Such is the heart of the anodontites, or fresh-water muscle, of the venus, maëtra, cardium, solen, pholas, mya, and apparently of all the equivalve bivalves.

But the bivalves with unequal shells, at least the oysters and the peetens, have the heart differently placed: it occupies a cavity between the crabs of the liver and the muscle that closes the shell; and is directed from behind forwards, or from the back to the branchiæ, and not, as in other bivalves, from above downwards, or from the anus to the head. In this case the auricles, or rather the single bilobed auricle is situated before the heart, and not at the side. This is remarkable in the oyster on account of its thickness, and deep red colour. It receives the blood from the branchiæ, and the heart distributes it to the body by two vessels which pass out at the extremity opposite to the auricle, and go,

one upwards to the liver, the other downwards to the muscle.

Each branchia has an infinite number of small, straight, parallel vessels, terminating perpendicularly in a larger one at the back of the branchia: these dorsal trunks convey the blood to the auricle. But each branchia has at the same time another series of small vessels, similar and parallel to the first, and pouring the venous blood into their extremities. This blood is brought by another vessel at the back of each branchia, which vessel receives the veins of the body.

The circulation is carried on in the *pteropoda*, as in the gasteropoda, by a simple heart, with one auricle, which receives the blood from the lung, and transmits it to the body. These things may be seen in the hyalæa and pneumodermon.

Cuvier states, that he has dissected only one genus of brahiopoda, and found two distinct hearts, both aortic, that is to say, receiving blood from the lung, and sending it to the body.

Thus we find that the whole class of mollusca possesses a circulation as complete as any vertebral animal; and that this circulation is double. When there is only one ventricle, it is aortic, and not pulmonary; when more than one, they are separate, and form so many distinct hearts. The passage from the arteries to the veins, in the little as well as in the great circulation, is as evident as in animals of the higher classes.

Blood and Circulation of Worms.—The blood is transparent, or at most a little blueish, in mollusca and crustacea. The supposed red blood of some of the first class is merely a secretion. But the entire class of articulated worms, both marine and terrestrial, has the blood more or less red, and often of as deep a tint as in any vertebral animal. It may be seen in the genera lumbricus, hirudo, naia, nereis, aphrodite, amphionia, amphitrite, terebella, and ferpula. But the lumbricus marinus (*arenicola*) exhibits most plainly, not merely the colour of the nutritive fluid, but also its course and direction: the yellow colour of the intestine and the grey colour of the parietes of the body allowing all the vessels to be perfectly distinguished.

A large vessel, diminishing in size at the two ends, lies along the back, between the branchiæ. It flows forward the blood by its anterior origin, and receives fifteen lateral vessels on each side, one from each branchia. They bring the blood from those organs, and are to be regarded as pulmonary veins: when the branchiæ contract, the large vessel is distended. The blood is carried back to the branchiæ by vessels similar in number to the preceding, but not all arising from a single trunk. The nine first proceed from a large vessel situated upon the intestinal canal immediately under the one first described. The others come from the back part of a vessel parallel to the two first, but situated under the intestinal canal. These two great longitudinal trunks send all their blood to the branchiæ: they represent both venæ cavæ and pulmonary arteries; for those branches which do not go to the lungs are veins returning the blood from the various organs. These branches of the vena cava in the lumbricus marinus are spread over the yellow surface of the intestinal canal with an admirable regularity; and the beauty of the arrangement is heightened by the splendour of their purple colour.

All these branches arise, in the first instance, from two vessels, which proceed along the sides of the intestinal canal, and perform the office of an aorta. They ascend as far as the lower part of the œsophagus, and then are bent to communicate with the great pulmonary vein, with which the description began. At this communication there is a swelling, which exhibits to the naked eye more marked contrac-

tions and dilatations than any other part of the system: although their parietes are no thicker than those of the other vessels, their enlargements may be called hearts; but as they are not found in all worms, it would be more exact to say that the circulation is carried on in these animals by the vessels only, without a heart. If, however, the existence of a heart be admitted, at least in the *lumbricus marinus*, it must be considered as double, and, like that of the two preceding classes, aortic.

The aphrodite, amphinomie, and nereids, differ from the *lumbricus marinus*, only in having a greater number of pulmonary vessels corresponding to the greater number of branchiæ. But in the species which have their branchiæ on the neck, as the amphitrite, the pulmonary vessels form four trunks, two arterial and two venous, coming from the trunks, which extend the whole length of the body, upon the intestine, and similar to those which have been described in the *lumbricus marinus*.

The colour of the blood is more difficultly perceived in the leech, because it is paler and less contrasted with the ground of the body; yet the vessels may be easily distinguished, and injected with mercury. There is a large longitudinal vessel on each side, communicating together, both towards the belly and back, by transverse branches, the ramifications of which, distributed in the skin, probably serve for respiration, as no other organ can be found out. Along the back we observe a middle and slender vessel, not so immediately connected to the two others, as they are to each other, and producing branchiæ on each side. This probably belongs to the arterial, and the two others to the venous system; but their connection has not been hitherto discovered.

Longitudinal vessels, producing ramifications filled with a fine red blood, may be seen in the earth-worm.

Movements of systole and diastole are very manifest, and quickly performed in all these red-blooded worms.

Echino-dermata.—I have not, says Cuvier, been able hitherto to arrive at any clear notions concerning the arrangement of the vascular system in this order; but the following is the result of my researches.

The intestinal canal of the *holothuria tubulosa* is twice folded, and consequently forms three portions. The middle of these has a vessel at its side, diminishing towards the two ends. It receives numerous short vessels from another tube, which will be described last; and it produces from the opposite surface others, which are much subdivided, and whose branches are at last united into an equal number of small vessels to end in a second trunk, which will be described. The net-work produced by this subdivision of the branches of the first vessel, before they end in the second, is intimately interwoven with the small branches of a hollow ramified organ ending in the cloaca, and probably concerned in respiration. This organ can be distended with water, or emptied at the will of the animal, and thus probably admits of the blood being acted on by the air. The first vessel, then, would be a pulmonary artery, and receive the blood from the body to transmit it to the lung. We have seen the branches, by which it receives blood from the intestine: that of the rest of the body comes from a vessel, which will be described third in order, having been brought by veins which are perceived over the whole mesentery.

The second great trunk is divided into four great branches, united by a transverse one: two receive the blood from the lung, and run parallel to the first trunk, but at a distance suited to the subdivisions of branches which go from one to the other. These two branches are a kind of pulmonary veins: they convey the blood, which has undergone the

action of the lung, into the two other branches by the transverse canal, and by their extremities; for there is a visible communication between them. These other branches, which consequently perform the office of aorta, run along the first portion of intestine, sending blood to it by an infinity of small, but rather long arteries, which seem to terminate immediately in the body of the intestine. The superior branch, arriving at a certain height, is bifurcated, and its two ramifications are joined so as to form a circle round the œsophagus, from which five arteries go off to the mass of the mouth and the general covering of the body. The blood returns from this covering by veins, which fill the mesenteries: but there is also a general trunk, which seems to form a kind of vena cava. It is made up of four principal branches, united by a transverse one. Two of these branches, which run along the first portion of intestine, receive the blood from it; and the two others transmit it to the pulmonary vessel by the small branches already mentioned at the beginning of the description.

According to this representation, the arrangement would very closely resemble that of worms.

In the *alteria* and *echini* the same approximation is observed between the vascular and digestive systems. The principal vein and artery equally run along the intestinal canal in the latter; and they are multiplied in the former to follow the *cæca*.

Nothing like blood-vessels can be seen in the medusæ. "The substance of these zoophytes," says Péron, "presents at first view the appearance of a kind of jelly, more or less diaphanous, consistent, and agreeably coloured according to the species. Excepting the lines, lamellæ, and vessels of the lower surface of the umbella, their substance appears homogeneous, even when examined with the most powerful magnifiers. However it may be torn or cut, the appearance is the same, and no trace of internal vessels can be discovered. Such indeed are the density and homogeneity of this matter, that we can hardly conceive it to be penetrated and nourished by vessels." *Annales du Muséum*, t. xv. p. 42.

Organs of Respiration.—Cuvier observes that these exhibit, in vertebral animals, the same relations to the organs of motion, and particularly to the force which animates those organs, as in the vertebral classes, and thus confirm the theory which assigns the degree of motive power as a measure of the quantity of respiration. Thus, the only class in this division of the animal kingdom, in which most of the individuals have the power of flying, is that in which respiration takes place at all points of the body, in which the tracheæ convey air to all parts; in short, insects. In some of those which have no wings, and therefore do not fly, the power of the muscles is evinced by the rapidity of their other motions. Let any one observe the centipede running, or the flea jumping, and he will acknowledge that they belong to a class possessing great muscular power, as he would judge of the ostrich and callowary, although they are birds without wings.

The mollusca, superior to insects in their circulating organs, and particularly in the central parts of their nervous system, have a circumscribed respiration; they breathe only by the lungs, and no portion of air is admitted into the rest of the body. It is therefore only necessary to compare the slowness of their motions, with their rapidity in insects, to estimate the effects of those differences in organization.

Invertebral animals possess either lungs more or less analogous to those of reptiles; branchiæ, sometimes similar to those of fishes, sometimes to those of tadpoles; or lastly, tracheæ, a kind of organ not known in the vertebral division. The latter is peculiar to insects; the former to a small number

VERMES.

ber of mollusca; the second is the most common, and is found in most mollusca, in worms, and crustacea. The mode of respiration is not well known in the echino-dermata, so that their organs cannot be classed with certainty.

The effect of respiration cannot be estimated by the colour of the blood, except in red-blooded worms, where it is very obvious: it may be seen without ligature or incision in the branchiæ of the *limbicus marinus*. But the effect of this function on the respired air may be easily judged: the researches of Vanquelin and other naturalists have shewn that invertebral animals consume oxygen like others, and infect the residue with carbonic acid. See RESPIRATION.

Respiratory Organs of the Mollusca.—We meet in this class with lungs, with uncovered branchiæ, and with branchiæ contained in a cavity. In the cephalopoda and acephala they are always of the latter kind; the gasteropoda have all three sorts. A lung is found in the terrestrial gasteropoda, and in those aquatic kinds which are obliged to come to the surface of the water in order to take in air. The principal genera that have it are the snail (*helix*), slug (*limax*), the testacella and parmacella, among the terrestrial; in the onchidium, bulimus of pools (*helix stagnalis*), and planorbis, among the aquatic. This lung is a larger or smaller cavity, communicating externally by a narrow aperture, which can be opened or closed voluntarily, while the cavity, contracting or dilating at the same time, expels or admits air. As the parietes are muscular, and there is no bony structure, there is no other mechanism than muscular contraction. The parietes of the cavity are furnished with an almost infinite network of blood-vessels, ramified in a rather spongy substance. The cavity itself is placed on the neck, and opens at the right side of the chest, in the snail, slug, bulimus, and planorbis; on the back, and opens on the right side of the body, in the parmacella; on the back, and opens backwards, in the testacella; on the posterior part of the body, and opens behind, under the edge of the cloak, in the onchidium.

The branchiæ projecting externally, sometimes represent tufts or trees, as in the tritonis, where they form a kind of hedge all round the body, and in the doris, where they have a circular arrangement round the anus, at the posterior part of the back; sometimes in small laminae or scales, as in the eolides, where they are disposed like tiles on the back, in the phyllidæ, the oscabrio, the patellæ, where they form a cordon all round the body, under the edge of the cloak. In the scyllæ they are pencils of filaments, dispersed over fleshy plates, or a kind of wings placed on the back. In the glaucous they resemble fins, radiated like a fan: in the pleurobranchus they are small plates, arranged in transverse rows on the two surfaces of a prominent plate at the right side of the body.

Testaceous gasteropoda have prominent branchiæ, but situated in a cavity concealed under the edge of the shell. The opening is generally very free, and occupies all the upper part of the animal's neck. Often also a part of the fleshy edge of the cloak is prolonged into a small canal, lodged in a corresponding canal of the shell, and calculated to conduct the surrounding element into the branchial cavity, even while the animal is entirely inclosed in its calcareous habitation. These canals are found in all the genera made out of those united together by Linnæus under the names buccinum, murex, and strombus. In most of the genera the branchiæ form one or two long series of transverse plates, occupying the whole length of the cavity, but a part only of its breadth, and representing, sometimes a prism, sometimes a kind of pen fixed by the whole length of its stem. There is a single series in the murex tritonis; a large

and a small one in the buccinum undatum; two large ones in the halyotis.

Some genera however deviate from this general rule: the patella Hungarica, which seems so much like the other patellæ, has its branchiæ arranged in small long plates, placed within a cavity above the neck, but forming a transverse series round the edge of the cavity.

The course of the blood, however, is the same, whatever form the branchiæ may possess in the gasteropoda: each division and subdivision receives a pulmonary arterial branch from the vena cava, and sends a venous branch into the pulmonary vein, which terminates in the heart. The position of the branchiæ regulates that of the heart, as well as the course of the large vessels.

The branchiæ of the acephala are formed into plates, each composed of a double leaf: they have a double series of vessels, very regularly and closely arranged, like the teeth of a fine comb, the frizæ being at right angles to the length of the plate. An artery and a vein run along the basis of the plate. The testaceous acephala have four of these plates, inclosed between the two lobes of the cloak, and allowing the foot to pass between them when there is one. The internal surface of the four triangular plates surrounding the mouth, and occupying the place of lips or tentacula, is also striated with vessels similar to those of the branchiæ, and may probably assist in respiration.

Poli speaks of small air-vessels, commencing in the small tentacula, usually situated at the posterior edge of the cloak, or round the orifice of the branchial tube: he supposes that they penetrate to a certain reservoir, whence the air passes into the interior of the branchiæ. Cuvier has not found this structure, and thinks that respiration is carried on in the acephala, as in other mollusca and fishes, by the simple afflux of water over the external surface of the branchiæ.

Some genera bring this water to the branchiæ by simply opening the shell and the anterior edges of the cloak. It is expelled by again shutting the shell. In the muscle, which has the widest opening of the shell behind, the water passes in and out at this part. When the animal is placed in water, a slight motion of the fluid is perceived in this situation, produced by the process of respiration. In the genera which have the cloak prolonged behind into one or two tubes, the water enters, and is discharged by the tube farthest from the back, or by the analogous canal, when there is only one tube: for it is then divided into two canals. The cardium, venus, maetra, tellina, &c. &c. have two tubes; the pholas, solen, teredo, mya, &c. have only one. They can partly withdraw the tubes into the shell by means of two flat, fan-shaped, retractor muscles, attached to the lobes of the cloak: but they do not extend them simply by muscular action; for they may be seen to increase in length and breadth both at the same time in the pholades.

In the ascidæ, which are naked acephala, the branchiæ do not form four plates, but a single large sac, with an extremely fine vascular network. This bag is filled with water as often as the animal dilates it: the mouth is at its bottom. In the biphori, or salpæ, and the thalia, they form only a narrow ribbon, obliquely traversing the interior of the body: the water, in passing through this from before backwards, necessarily goes over this ribbon.

The cephalopoda also have their branchiæ inclosed in a cavity, that is, in the bag forming their body. They are separated from the other viscera by the peritoneum, and their cavity communicates externally by the funnel under the neck. The water is admitted and expelled by the dilatation

VERMES.

and contraction of the muscular parietes of the bag : thus it is renewed in the branchiæ. The latter are two large pyramids, placed at the side of the peritoneum, with their base towards the bottom of the sac, and the apex towards the infundibulum. Each is attached by a membranous ligament to a muscular column which adheres to the sac, and sends a process to each of the plates of which the pyramid is composed. The pulmonary artery, arising from the lateral heart of its own side, ascends along the external edge of the branchia, giving two arteries to each plate. The pulmonary vein, which terminates in the intermediate heart, descends along the internal side of the branchia, receiving two veins from each plate. The plates themselves are arranged one over the other, parallel to the basis of the pyramid : their figure is triangular, and the two surfaces exhibit rows of pencils, filaments, or minute ramifications, which are the ultimate divisions of the pulmonary vessels. Each branchial pyramid of the calmar has as many as sixty of these plates, while we find only nine in the octopus ; but in the latter the rows of filaments are more minutely ramified, and form much thicker strata.

Respiration must be effected by the admission of water to the branchia, and by its penetration among all the fine processes of their surfaces ; in the same way, in short, as in other inferences.

Instead of branchiæ, the brachiopoda have a circle of small triangular plates attached to each lobe of the cloak.

Among the pteropoda, the hyalæa has them concealed in the two folds of the cloak ; they represent vascular ramifications on the wings of the clo ; and in the pneumodermion they are small plates, forming various lines on the surface of the abdomen.

In the singular animals called anatifæ and balani, there are found, on each side, at the basis of the arms or tentacula, conical plates, equal in number to that of the arms, but having a contrary direction, namely, towards the back, and lying against the body under the cloak. Their relation to the vascular system has not yet been determined.

Thus we find, in all the mollusca, as complete an apparatus for respiration as for circulation. An extraordinary additional or secondary office of the branchiæ is that, which they perform in some acephala, of affording a receptacle, for a certain time, for the ova, and even for the young when hatched.

Organs of Respiration in Worms.—Leeches and earth-worms, as well as the thalassena, have no other apparatus for breathing but the skin and its vascular network : but in other genera there are ridges or tufts, in which the vessels are ramified. Those which swim freely in the water have the organs equally arranged on the two sides, along a more or less considerable portion of the back. Such as live in tubes have them usually placed on the head, that they may be more easily exposed to the water.

In the aphrodite aculeata they are small fleshy cristæ, slightly resembling that of the cock, situated above each of the tubercles, which support bristles. There are forty pairs. In the scaly aphrodite they are small bundles of filaments.

In the nereids there are small fleshy cones, amounting to two or three on each side of a ring ; the blood-vessels are ramified in them with wonderful delicacy. Sometimes, instead of these small cones, there are true filaments grouped into pencils, of three, or seven, or even in the form of tufts. Sometimes there are small thin plates.

In the terebella flava the branchiæ represent bipinnated leaves, and have a beautiful rose-colour. There are thirty pairs. In the tetrædra and carunculata there are merely

large fasciculi of filaments. Their number in all these genera is the same as that of the rings of the body.

The arenicola (*lumbricus marinus*) has only fourteen pairs occupying the middle of the back, and resembling small clove bushes, of the finest carmine when distended with blood, and becoming pale again when empty.

The terebella have branchiæ in the form of small clove trees ; there are only three pairs, situated in the back, near the head.

In the amphitrite there are two pairs in the same situation, but shaped like feathers, very thick.

They form, in the serpulæ, at the sides of the mouth, two beautiful fan-like processes, with feathery branches, having long stems and short barbs, and exhibiting the finest colours. The number of feathery processes, as well as the general curvature of the fan, varies according to the species.

The fabellæ (*amphitrite ventilabrum*, Linn., &c.) have fan-like branchiæ, as well as the serpulæ. Sometimes the fan has a spiral turn.

In these animals each branchia has a vascular, arterial and venous system, as in the higher classes. But we come to an end here of respiration by expansion of the vascular system.

Respiration of the Echino-dermata.—Monro regarded the feet, or those cylindrical and extensile tentacula, by means of which the echini, asteriæ, and holothuriæ walk, as organs for absorption of the surrounding fluid, at least in the first of these genera. Cuvier assigns this function, in the two first named genera, to organs much smaller and more numerous, which may be seen in a living asterias observed in water. Besides the great tentacula of the lower surface, the whole integument bristles with small fleshy tubes, which are withdrawn into small openings as soon as the animal is taken out of water. They form a beautiful spectacle in the large species, coming out at all points : the very spines produce them by small apertures along their stems ; and while the minute tubes are extended, they resemble small leaves of trees connected to their branches. There are species in which they form tufts, &c. round these spines. Those tubes which are situated on the sides of the feet, are generally longer than the others. It can hardly be doubted, that they have the office of conveying water into the interior of the body.

The holothuriæ, at least the tubulosa, have no tubes projecting externally, but they have an internal organ, which must be subservient, according to all appearance, to respiration. It is one or more membranous and hollow trees, of which the trunk opens into the same receptacle (cloaca) as the anus. It enters the body, dividing and subdividing, until it ends at last in small conical productions. The branches swell at intervals into vesicles, which are generally found more or less distended with water.

The holothuriæ tubulosa has a single trunk, divided from its origin into two principal branches, of which one proceeds along the general covering, adhering to it by a kind of mesentery ; the other runs among the intestines, interweaving its branches with the vessels already noticed. This connection is so intimate, that it cannot be detached without laceration : probably there is a communication at this point between the nutritive fluid and the surrounding element.

The holothuriæ pentactes has two distinct trunks, deeply divided into large branches ; other species have only one, which is not divided.

All animals situated below these in the scale, are destitute apparently of respiratory apparatus.

The genera medusa and rhizostoma, whose numerous vessels are expanded in the thin edge of their disk, may probably

bably respire by this part: but the zoophytes, properly so called, beginning with the armed polypes (hydra), breathe, if at all, by their whole surface.

If, as some have conjectured, the vibrating organs of the vorticellæ and rotifers are an apparatus for breathing, these animals ought to occupy a higher rank in the scale of being than they do now. Their extreme minuteness must oppose great obstacles to our acquiring any exact knowledge about them.

Physiology of Respiration.—The changes produced in the air by the respiration of the mollusca, &c. have been already spoken of in the article RESPIRATION, towards the end, under the head of *Respiration of Animals*. We have only to notice here the facts that have been ascertained respecting their temperature.

“Spallanzani observes,” says Mr. Ellis, “that when a snail or slug is insulated in a jar of atmospheric air, a thermometer placed in the jar will continue stationary; but when several are confined together, the mercury rises one-tenth, one-seventh, and even one-fifth of a degree, and in oxygen gas, one-third of a degree; from which he concludes, that snails and slugs, in decomposing oxygen gas, give out caloric enough to be sensible to the thermometer. (Memoirs on Respiration, p. 255, 258.) This experiment we repeated, by confining several snails in a pint jar of air, from the top of which a small thermometer was suspended, and at the bottom a glass of lime-water was placed. A film of carbonate of lime soon overspread the lime-water, the inside of the jar was dimmed by moisture, and the mercury in the thermometer rose at the same time nearly one degree. Dr. Martine says, that from the result of several trials which he made, snails were about two degrees warmer than the air. (On Thermometers, p. 141.) Mr. Hunter found the lungs of snails 38°, when the atmosphere was 34°; and, in other instances, snails were six and seven degrees above the atmosphere, when it was so low as 30°. Earth-worms he found 58.75, when the atmosphere was 56°; and, in other trials, the worms exceeded by four, leeches by three, and slugs by four degrees the temperature of the ambient air. (Treatise on the Blood, p. 298, et seq.) The temperature of a snail, which was 44°, sank, on exposure to a cold mixture, down to 31°, and then froze; and several leeches froze likewise when reduced to 31°. (Observations on the Animal Economy, p. 105.) In all these experiments, the animals, when thawed, were found to be dead; but Mr. Carlisle says, that the garden-snail may be frozen, during its state of dormancy, without destroying its muscular irritability. Philof. Transf. 1805, p. 18.” Inquiry into the Changes, &c. p. 215.

Generative Organs.

Generative Organs of the Mollusca.—Four combinations are met with in this class: *viz.* 1. Separate sexes with copulation; in several gasteropoda, as the buccinum. 2. Separate sexes without copulation; in the cephalopoda. 3. The sexes united with reciprocal copulation; in the snail, and most gasteropoda. 4. The sexes united, and fecundating each other in the same individual, or perfect hermaphroditism; in the acephala.

The Cephalopoda; Male Organs.—The testicle is a large, whitish, and rather soft gland, found in the bottom of the abdominal sac; its structure is remarkable, and easily developed. It is inclosed in a membranous capsule, united to it only by vessels passing between them, and that at one point only: it has a thin proper cellular tunic. Its surface exhibits an infinite number of small areolæ, which are the commencement of white, opaque, soft filaments, lying close to-

gether and composing the whole substance of the gland. In the cuttle-fish these filaments are small and numerous, so that the areolæ are mere points. In the octopus the filaments are larger, and like ribbons. They unite successively to form trunks, which terminate in the cuttle-fish, in vast numbers, in three or four large excretory canals passing through the gland in various directions, and ending ultimately in a large common circular opening, furnished with a valve which prevents the return of the fluid. In the octopus, which has fewer filaments, the large common canals do not exist, but the filaments end immediately at the common opening. These filaments are themselves small excretory vessels, surrounded by glandular parenchyma, and connected by blood-vessels, nerves, and cellular substance. The fluid they secrete is poured out through the opening into the membranous capsule, from which it is conveyed by a canal representing the epididymis, and tortuous, like that tube in the human subject. It ends in a larger canal, of which the interior has at first several projecting and ramified columns and ridges, and afterwards a single one extending through its whole length, and dividing it into two half canals. This canal, much shorter and less tortuous than that of the epididymis, contracts towards its end, and penetrates a tolerably large cylindrical glandular body, possessing a large excretory duct, which receives the termination of the canal just mentioned.

This body is large and solid in the octopus, much less and nearly membranous in the cuttle-fish. It is regarded as a kind of prostate. Its canal joins one of the two belonging to the cavity which contains the springing tubes, which will be spoken of presently.

This cavity or bursa, which is large and much folded, is capable of considerable extension, and contains the celebrated tubes, first imperfectly described in the cuttle-fish by Swammerdam, then more in detail by Needham in the calmar, and rendered famous by Buffon, who derived from them the principal support of his system, on the nature of the spermatic animalcules. The octopus has them larger than the two other species. The bursa, which contains them mixed up with a viscid liquor, is composed of two compartments communicating together, but each possessing a distinct orifice. One of these orifices is the commencement of a slender canal, which ends on the exterior of the penis at the side: the other also produces a canal, which, after having become still smaller, opens externally near the base of the penis.

The penis is a hollow, cylindrical, fleshy body, perforated at its point, and having a cul-de-sac behind the place where the canal just mentioned opens. Its cavity possesses fleshy columns internally.

The excretory canal of the prostate, which is to transmit also the feminal fluid of the testicle, communicates more particularly with that compartment of the bursa, whose duct opens externally on the penis. The communication indeed is very near its orifice. It is the other compartment of the bursa, whose duct opens in the penis. The name of penis is given to this part, because it projects externally, and has a cylindrical form: it does not seem, however, to be an organ of copulation, although it certainly is one of ejaculation.

All the canals now described, from the testicle to the penis, are situated on the left side of the abdomen, and the penis projects within the left branchia; but as the funnel placed under the neck closes the fleshy bag, it seems impossible for the penis to approach the part which gives issue to the oviduct of the female, so as to produce copulation. The feminal fluid thrown out by the penis must traverse the funnel, as the ova, the ink, and the excrements do.

VERMES.

Swammerdam and Needham took the bursa of the springing tubes for the testicle, from which it is considerably distant. They have been followed in this error even by modern authors.

The tubes themselves are membranous bodies like worms, terminated by a filament thinner than their body, six lines or more in length. While they remain in their viscous liquid, or if placed in spirits or oil, they continue at rest; but if they are put in water, they become agitated, twirl about, and throw out at one extremity an opaque matter. By means of a glass we can see in their interior an opaque whitish body, spiral like a cork-screw, terminating behind in a spongy mass, and before in a similar smaller one. It seems that this body is elastic, and retained by the external membrane of the tube; that water, by softening and dissolving the extremity of the tube, allows the spiral or spongy body to exert its natural elasticity; and that the twisting of the tube arises from the effort which the spiral body thus makes to escape. However the matters may be explained, the motion certainly is not a vital one, and may be seen in the tubes of a cuttle-fish, which has been preserved for years in spirits of wine, as soon as they are put in water.

But what purpose is served by these tubes? Are they, like the pollen of plants, capsules containing a femal aura, and not giving way to allow its escape, until they are in a proper situation? They seem to be developed only in the bursa, which contains them, and they are not found at all seasons. Are the ordinary spermatic animalcules to be considered analogous to these tubes, according to the notions of Buffon?

Female Organs.—They are more simple. The ovary occupies a situation analogous to that of the testicle, and is in the same manner enveloped by a membranous capsule, to which it is connected at one point only by vessels. The capsule is simple in the octopus, divided into two by a septum in the cuttle-fish.

The ovary has thousands of ramifications, and resembles the most complicated and beautiful tree. The ova enlarge unequally: at the end of a certain time we find them large, pressed together, and angular. Two tubes go from the capsule in the octopus, and the calmar *fagittatum* of Lamarck. In the former, when empty, they are small, and plaited internally. They end at the sides of the anus. At one-third of their length is a knot, which is a gland traversed by the ova, and furnishing them with their external covering. It is divided, like an orange, by longitudinal septa.

In the calmar *fagittatum* there are similar glands, much larger in proportion, oval, situated at the very end of the oviducts, and divided by very numerous, thin, transverse septa. The oviduct enters at the side, and contracts considerably before going out.

The cuttle-fish and common calmar have a single oviduct terminated by a gland of the same kind. The duct of the latter is larger, and makes two convolutions.

The ducts of the calmar *fagittatum* end at the inner side of the branchiæ: the single tube of the cuttle-fish and common calmar terminates near the left branchia, in the same situation as the penis of the male.

These three species have also three enormous oval glands, divided, like that of the oviduct, by transverse septa, and opening at the sides of the anus. Their use is unknown.

The eggs of the octopus and calmar are united by a gelatinous substance into small masses, while those of the cuttle-fish are united by a ductile matter into bunches, like those of grapes. The uniting medium is probably furnished by the glands which terminate the oviduct: perhaps the three

glands just mentioned may also be concerned in furnishing it.

Hermaphrodite Gasteropoda.—They must be arranged in two sections; those in which the organs of the two sexes have a common issue, as the snail; and those in which their issues are separate, or even distant, as the aplysia. Under the first are included the snail, slug, testacella, parmacella, doris, tritonia, and many univalves.

The slug may be described first, as being the most simply organized: it has only the organs common to the whole class; *viz.* an ovary, oviduct, testicle, vas deferens, penis, and bladder with a long neck.

The ovary is situated towards the back part of the body, between the lobes of the liver and the intestines. It forms a very complicated congeries, like a bunch of small grapes, of which each grain is an ovum, while the pedicles are tubes uniting together, and ending at last in the oviduct. The latter forms many zigzags, and adheres so closely to the testicle, that it may easily be supposed to penetrate its substance, and receive the secreted fluid; but this is not the case. Having followed the whole length of the testicle, become obviously larger, and even during the season of copulation swollen and plaited, the oviduct terminates in the bottom of the common cavity of generation.

The testicle is a white oblong gland, very large, particularly at the season of propagation. It may be divided into two parts: the posterior, behind the junction of the oviduct is oval, and swells most at the time just mentioned. The anterior is oblong. Its structure does not so much consist of filaments, like that of the cuttle-fish, as of grains. It produces an excretory canal, which opens at the bottom of the penis.

The latter is a cylindrical fleshy bag, possessing internally a prominent ridge in its whole length, and opening into the common cavity of the generative organs. It can be everted like the finger of a glove, and be extended by means of its own fibres, and withdrawn to its original position by a retractor muscle arising from the back of the animal, and inserted in the point of the bag, near the vas deferens. When this bag is unfolded, and is protruded externally, it forms a projecting penis, the internal ridge being unfolded so as to make the internal surface sufficiently broad to become external. The orifice of the vas deferens is now found on the very point of the penis, having been before at the bottom of the bag.

The bladder with the long neck, making the third principal organ, was called by Swammerdam the reservoir of the purple, believing that the murex formed in an analogous part the celebrated colouring matter of the ancients. This is not the case; though the real use of the part in question is not known. It sometimes contains, both in the slug and snail, a concrete reddish-grey substance: at other times merely a liquid. It is found in all gasteropoda, and may possibly be concerned in producing a fluid to cover the eggs.

The common cavity of generation is a fleshy sac, in which the three preceding organs terminate, and which has an external opening under the right superior horn.

When snails copulate, they evert this sac, which then presents three openings; *viz.* of the oviduct, bladder, and penis. The latter quickly comes out of its opening, and enters the oviduct of the other individual. In this way copulation is effected: the laying takes place some days after.

The intimate connection between part of the oviduct and part of the testis and vas deferens, deceived Swammerdam concerning the nature of these organs. He first conceived

VERMES.

the testicle to be the ovary: having afterwards found the true ovary, he called the testis the bag of glue. The large part of the oviduct adhering to the testis he called the uterus; and not seeing that the vas deferens belongs exclusively to the testis, and has only an external attachment to the oviduct, he admitted a communication between the uterus and penis.

The size of the penis varies in the different species of snails: some have it longer than the body, when extended.

These organs in the testacella do not differ remarkably from those of the snail.

The ovary of the tritonia is more voluminous, the oviduct larger in proportion, and the testicle irregularly lobed and shaped like a ball.

In the doris, the oviduct, after joining the testis, appears to unite with the canal of the bladder, and to form with it a common canal. In the doris solea, from the Indian seas, it seems even to enter the bladder itself; which would confirm the notion of this part being designed to furnish a covering for the ova. The testicle is rounded, and touches the common cavity. A small accessory bladder is connected to the canal of the bladder.

In the bulimus flagnalis (helix, Linn.) the connection between the oviduct and testicle is not so close. The vas deferens can be distinguished throughout, at first large and expanded into a reservoir much plaited, and capable of containing a large quantity of fluid. At passing out, the canal is small, enters the flesh near the end of the oviduct, then comes out again to end in the bottom of the sac of the penis, which is organized as in the slug.

The ovary and testicle of the snail are arranged as in the slug. The neck of the bladder is much longer, and connected to the broad portion of the oviduct, as far as the point of its union with the testicle. The lower part of its neck is broad, and receives the orifice of the oviduct. It moreover receives the apertures of two parts, which do not exist in the slug; viz. two ramified organs, each of which terminates in fifteen or twenty small cæca, containing a white milky liquor. This might be considered as femoral fluid, and the organs as vesiculæ feminales, but they have no immediate connection with the vas deferens. The latter terminates in the side of the penis, near its entry into the common cavity. The penis therefore is not perforated at its bottom, as in the slug: it is also much longer; but probably it cannot be unfolded in its whole length, perhaps only as far as the point at which the vas deferens enters: this would then become its external extremity.

The snail has another remarkable part, not found in the slug; viz. the sac of the dart. It is oblong, with thick muscular parietes: at the bottom there is a papilla, from which proceeds a pointed dagger-shaped dart, with four cutting edges. The substance of this singular part is calcareous: it is renewed when lost. Snails prick each other with it, at any part of the skin indifferently, when they are about to copulate. They seem too to dread it; for as soon as one perceives the other's dart, he withdraws immediately into the shell. The object of such a proceeding cannot be conjectured. Copulation does not take place, until after both individuals have brought out their darts: it resembles that of the slug.

The length of the penis protruded in copulation, and the number of cæca, vary in the different species of snails.

The parmacella has the same organs as the snails. Its vesiculæ are oval and undivided, and terminate directly in the common cavity. The sac of the dart is nearer to the

prepuce of the penis; and the vas deferens opens in the bottom of the latter.

The second section of hermaphrodite gasteropoda includes those, in whom the penis passes out at some point of the body distant from the oviduct. The vas deferens is still united to the oviduct, and communicates with the penis only by the intervention of a groove excavated in the external surface of the body. This groove is on the right side of the neck in the aplysia; under the right edge of the cloak in the onchidium, &c.

The ovary of the aplysia is an oval mass, occupying all the posterior part of the abdomen, and in its ordinary state of a whitish colour. The oviduct arises from it by several vessels, coming from the different parts of the mass, like the excretory tubes of a gland, and uniting into one canal. The latter, having run along the right side of the testicle, suddenly becomes smaller, turns round the apex of that gland, and forms a canal which, having been closely joined for some time to the vas deferens, terminates by opening in it, after receiving a small blind intestine, apparently analogous to the ramified organs of the snail.

The testicle is of a beautiful yellow, and resembles an elliptic spheroid surrounded by a spiral band. Its middle is tolerably compact, and seems nearly homogeneous. The spiral band is itself divided into a principal finely striated band, of which the striæ are probably so many vessels, and two smooth borders, which are excretory tubes. The superior is the vas deferens common to the whole testicle, serving to convey the seminal fluid.

The common cord going to the exterior of the body is at first divided into two canals. That which comes from the testis is formed of a thin membrane much plaited: the other, from the oviduct, has thicker parietes. From the first third of their length they communicate freely by means of a slit: yet the distinction between them is marked by a projecting membranous septum. The oval bladder opens, towards the second thread, by a small particular duct. Beyond this orifice, the double canal forms a prominence, visible externally, on the right side of the body: its opening is continuous with a deep groove formed in the right side of the neck, and continued into the body of the penis. Does this groove conduct the seminal fluid of one aplysia into the body of another? The solution of the mode of fecundation in these animals depends on the answer to that question.

The onchidium resembles the aplysia in the separation of the organs. The oviduct, after being joined to the testicle, is united to the canal of the bladder, near its neck; and the common canal goes out at the same point as the vas deferens. From their orifice a groove extends, on the right side, along the under part of the cloak, to that of the penis situated at the right side of the head. The latter communicates first with a cavity having two cul-de-sacs. In the bottom of one of them a cylindrical tube enters, which traverses an elliptical muscular enlargement, and extends beyond it to a length more than five times that of the body. Near its entrance into the cavity, this tube conceals a sharp horny point. The other cul-de-sac receives the end of a tube shorter and much slenderer than the preceding, without any enlargement. This has also a small horny point in the corresponding situation. The use of these organs is not known.

The oviduct is distinct throughout from the testicle and the canal of the bladder in the bullæa, although the three organs have their issue at the same point. There is also an accessory vesicula, coming out with them, and a smaller one

VERMES.

ending in the oviduct. The penis forms a tube nearly as long as that of the onchidium, but without any enlargement or accessory tube.

The openings of the sexual organs are remote from each other in the *hyalea* and *pneumodermon*, although united in the same individual; but the animals are too small for a detailed description.

Gasteropoda with separate Sexes.—This separation certainly exists in the *buccinum undatum*. The male is recognized, even externally, by a fleshy penis as large as a finger, compressed, broader at the end, and terminated by a small tubercle, which is perforated by the orifice of the vas deferens. It adheres to the right side of the neck, and folds back into the pulmonary cavity, but the animal often extends it, without any intention of copulating. The vas deferens traverses its whole length, making several folds and zigzags; it enters the right side of that part of the body which fills the shell, makes a large packet of tortuous turns, becomes gradually smaller, and ends at the testicle, a yellowish, soft, glandular mass, occupying with the liver the highest turns of the shell.

Nothing similar to this penis is found in the female; the neck is smooth, but on the right side of the pulmonary cavity, between the body and the rectum, a large canal is seen, the extremity of the oviduct. The orifice is small: on opening it we find a large tube with thick glandular parietes, calculated no doubt to furnish an exterior covering for the ova. It opens a little within the edge of the pulmonary cavity by a small aperture.

In the *murex tritonis*, there is a similar separation of sexes, and a penis equally fleshy and prominent. Instead, however, of having a complete vas deferens in its interior, there is a simple groove on the surface, continued on the body, as far as the portion which fills the shell. The penis is proportionally shorter and thinner than in the *buccinum*. The female has an oviduct similar to that of the female *buccinum*.

The *fitrombus* has a mere tubercle projecting slightly at the right side of its very small foot. The seminal fluid is conveyed to it also by a groove.

The penis of the *voluta* is fleshy, conical, always projecting, but not perforated: the semen arrives by a groove, which however ends at its basis, without going to the point.

In those genera with separate sexes, the oviduct is wanting when there is a penis with its groove; this groove occupies the place of the oviduct.

There is an hermaphrodite species; but it seems formed rather on the model of those just described, than on that of the species in the former division. It is the *helix vivipara* of fresh water. It has an oviduct and a groove, placed side by side, and ending respectively at the ovary and testicle. The latter is closely joined to the oviduct: its groove terminates externally at the very edge of the foot, under the right horn; and there is no penis but the prominence which this edge may form when extended. The oviduct is of great size and length when filled with small living individuals.

This animal is ovo-viviparous. In the upper part of its oviduct we find eggs not hatched, resembling small globules of a whitish glairy matter, in which with a glass the animal can be seen covered by its shell. In these ova the small pedicle may be still seen, by which they were attached to the ovary.

The *acephala* are all hermaphrodites, and impregnate themselves without any copulation. We discover no other generative organs but an ovary, extending over the two sides of the body, immediately under the skin, penetrating be-

tween the tendons of the muscles, and sometimes between the two membranes of the cloak. The size and colour vary according as the animal is more or less advanced in gelation. At a certain period a milky liquor is seen in it, which is probably a feminal fluid designed to fecundate the ova. When the latter are advanced, they pass into the spaces between the two vascular lamina, composing each of the four plates of the branchia, and sometimes distend them in an extraordinary manner, for the number is truly prodigious in some species. The eggs of the ovo-viviparous species, as the fresh-water muscle, are hatched in the branchia. When we observe the little muscles with a glass, we see them open and shut their valves with great activity.

No orifice has yet been discovered, by which they could pass out; probably they escape by lacerating the tissue at the edges of the branchia between their pulmonary vessels.

The organs of generation in the naked *acephala*, as the *biphoris* and *ascidiaz*, and in the *branchiopoda*, as the *terbratulæ* and *lingulæ*, have not been carefully investigated.

The *cirropoda*, or *balani* and *anatifæ*, differ very much from the *acephala*, and approach in their male organs, as in several others, to the crustacea. On each side of their intestinal canal there is a white serpentine tube, supposed to be the testicle, and ending towards the basis of the rectum. Yet these animals are hermaphrodites, and their ovaries are two masses placed between the trunk and the cloak, and connected in their situation only by vessels and cellular tissue.

Generative Organs of Worms.—This class exhibits the three combinations, which are found in the mollusca; some have the sexes separate; others united, so that they fecundate themselves in an insulated manner; in a third division they are united, but there is a reciprocal copulation.

The leech exemplifies the latter modification; it has a very considerable penis, composed of a thick and long muscular tube, hollow internally, which can be protruded like the penis of the snail, while it is prolonged backwards into a slender and merely membranous tube. There are two testicles, each composed of numerous convolutions of a single, soft, whitish canal, with glandular sides, and of a short, straight, and muscular vas deferens. These two tubes appear to terminate at the basis of the muscular part of the penis, and the feminal fluid probably flows along the grooves of its surface, when it is unrolled. Near it is a cavity opening externally, and serving apparently to receive the penis of the other individual. The orifices of these parts are near each other, and near the anterior extremity of the body.

The earth-worm exhibits two orifices on its under surface, near the anterior extremity, and not, as some have described, at the swelling in the middle of the body. They correspond internally to two or three soft, oval, glandular cavities. There are several smaller ones around them. These seem to be the organs of generation; but we cannot point out their functions. Willis mentions that the large cavities are sometimes filled with eggs; but we see true ovaries, in the form of small intestines, arranged in three or four pairs, and swelled by ova, so as to resemble rows of beads. No external or internal organ of copulation can be found; yet it is popularly known that earth-worms remain closely embraced for the purpose of fecundation.

In the anterior part of the body of the *lumbricus marinus* there are five greyish sacculi on each side, suspended by vessels and cellular substance, and appearing analogous to those of the earth-worm. The ova must escape from the sacculi

facculi in these animals, for we sometimes find the whole body filled with them.

The same thing is seen in the aphrodite, where the sexes are separate; in small individuals the body is filled with a whitish milt, while the large ones have it full of small ova in all the intervals of the viscera. If, as it seems probable, there are particular organs for the preparation of these substances, they have not yet been discovered or described. The same observation may be extended to the genera nereis, ferpula, and other red-blooded worms.

It is doubtful, whether or no there are distinct sexes in the intestinal worms. In the *ascaris lumbricoides*, the orifice of generation is found in the anterior third of the body; a small short vessel soon ends in two larger ones, which gradually diminishing extend to four or five times the length of the body, and are collected in irregular bundles, which may be easily developed. These tubes, which must be regarded as ovaries, contain a milky fluid, and an infinite number of small ova.

All the echino-dermata seem to be hermaphrodites, and to possess the power of fecundating themselves: their ovaries fill a large part of the body, when they are swollen in the season of laying. They are sometimes seen bathed as it were in a milky liquor, which seems to hold the place of feminal fluid: this may be observed in the common star-fish, where the ovaries form five large branches, one for each division of the body: the eggs are round and reddish.

The echini, properly so called, have from five to ten considerable ovaries, reddish, lying near the surface of the shell, and ending at the circumference of the anus. They form the eatable portion of the echini.

In the holothuriæ, a collection of numerous ramified small tubes is seen near the mouth, amazingly developed at particular seasons, when they are filled with a reddish powdery matter, sometimes collected in globules. These parts seem to be the ovaries; but we see also, near the anus, numerous whitish filaments, resembling worms, and each formed of a slender elastic thread, turned spirally, and capable of being unfolded.

The mode of generation in the actiniæ has been described by Reaumur: he states that "in producing its young, the actinia inverts its body as it does in rejecting the shells of animals, which it has swallowed for food. I have observed that these animals are viviparous, and have seen them come out, perfectly formed, from the body of the mother, as they are represented in fig. 25. It is necessary that the cavity should be turned inside out, as we have already described in speaking of the digestive process: the young ones then come out of a large transverse fissure. Although the parent may contain sometimes more than twelve (and this opening is large enough to allow several to pass at once), they come out one by one, and indifferently at all parts of the fissure. These little actiniæ, before their birth, are placed in the basis of the parent; and lodged in folds of the membrane." Reaumur, *Acad. des Sciences*, 1710, p. 477.

The process and the organs concerned in it have been described more in detail by Dr. Spix, in the *Annales du Muséum d'Hist. Naturelle*, tom. xiii. "The space left between the alimentary cavity and the external envelop of the animal is divided," he says, "into longitudinal cavities by folds of a membrane which lines it, and is analogous to peritoneum. Each longitudinal cavity contains an ovary, and communicates with two or three tentacula. Each ovary is composed of three or four cylindrical and united tubes, joining together at their basis into a common canal, and becoming slender towards the apex in proportion as the eggs become smaller, of which each ovary contains about

sixty. The common tubes of two neighbouring ovaries join into one, and this latter again joins the common tube of the two next ovaries. The oviduct thus formed belongs therefore to four ovaries, and terminates in the bottom of the stomach. This is the only point at which the young can come forth: hence all observers have found them in the stomach, without knowing how they came there. The eggs are round, yellow, and similar to grains of sand. The actiniæ are viviparous, according to the observations of Reaumur, Ellis, and Diquemarre, with which my own agree. I have often seen the young come out of the mouth, of a form perfectly similar to that of the mother. An actinia, which I have in spirits of wine, contains a great number of eggs marked with an opaque point, and apparently containing the embryo animal. I have even an individual about the size of a hempeed, which seems to quit its covering with difficulty, and whose mouth and tentacula are not yet distinct." P. 448. pl. 33.

The multiplication of polytes and zoophytes by buds or shoots is well known: this seems to preclude the existence of a particular organ of generation. Yet the author just quoted, has described and figured parts which he considers as generative organs in a species of alcyonium. See his *Memoir and plate* as above.

Peculiar Secretions.—The *inky fluid* of the sepia is produced in a membranous bag, expressly destined to that office. The secreting organ is a villous surface, with fine and long processes, adhering to one of the sides of the bag. The secretion is a very thick black substance; but its particles are so minute, that it admits almost of infinite dilution, and a small quantity will tinge a vast volume of water. This matter, when removed and dried, forms the colour named sepia by the painters; that of the common cuttle-fish is a black-brown. The octopus has it blacker; and the Indian ink which comes from China is certainly nothing more than the produce of some sepia of that country, so that it is useless to attempt imitating it by artificial mixtures. Chemical analysis has discovered in it a very minutely divided carbonaceous matter, mixed with animal gluten.

The ink-bag of the octopus is enveloped by the lobes of the liver, which has given rise to the erroneous idea of some moderns, that this part is analogous to the gall-bladder, and that the fluid is a biliary secretion.

It is in front of the liver in the calmar, but free, and not included in its substance. In the cuttle-fish it is much more deeply placed, before the intestines and the intermediate heart.

In all cases, its excretory duct terminates near the anus, pouring its liquor into the funnel, which is the general receptacle for all the excretions.

The *purple matter*, so celebrated among the ancients, is produced by several different gasteropoda: possibly, however, some species may furnish it of a more beautiful or durable kind. It transudes in some of the genus *murex* from the edges of the cloak; so that it is no doubt produced in them as in the *aplysia*, of which the organ will be described. Swammerdam suspected that the sac, adhering to the organs of generation, and described by the indefinite term of bladder, was the reservoir of the purple; but this supposition does not seem well founded.

In the *aplysia* the operculum of the branchiæ is analogous to the cloak of other univalves, and differs from it only because the shell does not entirely fill it. The edge is occupied, in all parts to which the shell does not extend, by a spongy substance, of which all the pores are distended by the purple matter. This is so thick, that when it is ex-

pressed without being diluted, its colour is a black violet; but it gives water the tint of claret wine. A single aplysia is capable of colouring in this way several buckets of water.

In spirits of wine this liquor becomes of a deep green. Some naturalists represent that the colouring liquor of certain animals of the genus *murex* comes out of the body green, and changes to purple by the action of light. But it may be squeezed out of the *murex brandaris* of a perfect violet colour.

Spinning Organs (Filières) of accephalous Mollusca.—The muscles of salt-water (*mytilus*), the limæ (*ostrea lima*, Linn.), *perna* (*ostrea*, Linn.), *aviculæ*, and *pectines*, are fixed to rocks by means of threads, which they make themselves. Those of the pinna are the most celebrated, for they have been actually employed in manufactures.

The matter, of which the threads are formed, is produced by a conglomerate gland, concealed in the body under the base of the foot. The latter, which has more or less resemblance to a tongue, with a groove along its under surface, seizes the viscid matter at the orifice of the excretory tube, draws it out, and models it in the groove. It fixes the end, still soft, to a rock, and returns to the orifice, to find the materials of another. Reaumur has minutely described the process, in the Memoirs of the Royal Academy of Sciences for 1710, from which we have taken the following particulars.

“From the root of this kind of tongue, or the part where it is attached to the body of the animal, several threads are observed to proceed to some neighbouring fixed object, and thus attach the animal in its situation. They are about equal in size to a pig’s bristle; vary in length from one to two inches, and pass out of the shell at the part where it naturally opens. Stones, fragments of shells, and very frequently the shells of other muscles, are the objects to which they are fixed: hence we often find large assemblages of these animals adhering together. I have sometimes reckoned more than 150 threads employed in fastening a single muscle: as they take different directions, we may regard them as so many cables keeping the animal firmly anchored.

“Having detached several, I inclosed them in boxes, and put them in the sea: in a few days, they were attached to the sides of the vessel, and to each other. I placed others in vessels of sea-water, and observed their proceedings. In a short time they opened their shell, and thrust out the part already described, which I have compared to a tongue. They elongated and then shortened it, and thus stretched it out farther: they would at last extend it to two inches in length, and then feel about with its extremity, as if to reconnoitre the ground. After these preludes, they fixed it for a time in one spot, and then withdrew it quickly, carrying it back completely into the shell. I now discovered that they were fixed to the spot by a thread. The repetition of this manœuvre multiplied the threads, until they were sufficiently numerous to fasten the animal. The new threads thus formed were whiter and more transparent than those which had existed for some time.” P. 114, et seq.

When a thread has been formed, the animal seems to try its strength, and sometimes it gives way. They will fix themselves to the surface of glass. They do not form more than four or five threads in a day. P. 122.

M. Reaumur could not discover whether they have the power of detaching themselves, after being once fixed. The youngest muscles spin these threads, such even as are smaller than millet seeds. The threads give way in time, either from the repeated shocks to which they are exposed, or from an alteration in their texture by time. P. 123.

The pinnae are very large animals, the valves of their shells measuring one or two feet, attached to rocks, &c. in a manner similar to that of the muscles, except that the threads are longer and more numerous. They almost equal, in fineness and beauty, the silk spun by the silkworm: hence the French name of *coquille porte-foie*, and the ancient name of *barba byssina* applied to this production, which has been generally called the *beard* of the animal. It has actually been manufactured in Sicily, and other parts of the Mediterranean, into gloves and other articles, which exactly resembled silk. As the individual threads are so fine, their number is immense. Ibid.

In the Memoirs for 1717, Reaumur speaks at greater length of the pinna or jambonneau, and the silk threads which attach the animal to surrounding objects. These animals are fished in the Mediterranean, in from fifteen to thirty feet of water. The tuft of silk is attached, as in the muscle, immediately to the animal’s body, and passes between the two valves, at four or five inches from the small end of the shell, in large pinnae. As they are torn up with an iron hook, you cannot be sure of seeing the whole length of the fastening; but Reaumur has found it seven or eight inches long, and weighing three ounces. The spinning organ is about two inches long in the dead animal, and must admit of extension to six or seven inches in the living, to form threads of the length we meet with. The end of the silk passes into a conical bag, which contains four membranous plates, and an equal number between them of thin silk plates, made of fine silk intricately interwoven. The silk fastening of the animal is secured to the latter. Observations sur le Coquillage appelé Pinne marine, ou Nacre de Perle, &c.

On the subject of the remarkable power, possessed by many animals of the lower orders, particularly in the genus medusa, of producing light, see the article LIGHT.

The source of that singular property, which many medusæ possess, of imparting a burning sensation to the skin, like that produced by the common nettle, (whence their names of *urtica marina*, sea-nettles, &c.) is not known. It may be in some fluid secreted by the animal.

We may observe, in general, of all the secretions in the lower orders, including the purple matter and silk, the biliary fluids, the luminous and stinging particles, the calcareous matter of shells, &c. that they are produced in structures much less complicated, and in animals much less perfectly organized, than the analogous products of the vertebral division.

We cannot pretend to give a complete enumeration of the works, from which information may be derived on the subject of the preceding article; but we shall mention a few of the most important.

On the anatomy of the lower orders, science is most deeply indebted to the learned, acute, and indefatigable Cuvier, who has contributed more than all others together to our accurate knowledge of these classes. His “*Lçons d’Anatomie comparée*” contain the results of most of his labours; and the greater part of our descriptions is derived from that work. He has also published numerous excellent papers, accompanied with very beautiful and valuable engravings, on the anatomy of several genera of mollusca, in the *Mémoires du Muséum National d’Histoire Naturelle*. They are as follow:

Mémoire sur l’Animal de la Lingule (*Lingula anatina*, Lamarck); tom. i. p. 69.

Mémoire sur la *Bulla aperta* (Lamarck), *Bulla aperta* (Linn.); tom. i. p. 156.

Mémoire sur le *Clio borealis*; tom. i. p. 242.

Memoire sur le Genre Tritonie, avec la Description et l'Anatomie d'une nouvelle Espèce, Tritonia Hombergii; tom. i. p. 480.

Memoire sur le Genre Aplysia, vulgairement nommé Lievre marin, sur son Anatomie, et sur quelques unes de ses Espèces; tom. ii. p. 287.

Memoire concernant l'Animal de l'Hyale, un nouveau Genre de Mollusques, intermediaire entre l'Hyale et le Clio, et l'Etablissement d'un nouvel Ordre dans la Classe des Mollusques; tom. iv. p. 223.

Memoire sur les Thalides (Thalia, Brown), et sur les Biplores (Salpa, Forskaohl); tom. iv. p. 360.

Memoire sur le Genre Doris; tom. iv. p. 447.

Memoire sur le Limace (Limax, Linn.), et le Colimaçon (Helix, ejusd.); tom. vii. p. 140.

Memoire sur le Linnée (Helix itagnalis, Linn.), et le Planorbe (Helix cornea, Linn.); tom. vii. p. 185.

Memoire sur l'Onchidie, Genre de Mollusques nus Voisins des Linnées, et sur une Espèce nouvelle, Onchidium Peronii; tom. v. p. 37.

Memoire sur la Phyllidie et sur le Pleurobranche, deux nouveaux Genres de Mollusques de la Famille des Gastéropodes, et Voisins des Patelles et des Océbrions, dont l'un est nu, et dont l'autre porte une Coquille cachée; tom. v. p. 266.

Memoire sur la Dolabelle, sur la Testacelle, et sur un nouveau Genre de Mollusques à Coquille cachée, nommé Parmacelle; tom. v. p. 435.

Memoire sur la Scyllée, l'Eolide et la Glaucus, avec des Additions au Memoire sur la Tritonie; tom. vi. p. 416.

Memoire sur l'Ianthine et la Phasianelle de M. Lamarck; tom. xi. p. 121.

Memoire sur la Vivipare d'Eau douce (Cyclostoma viviparum, Draparnaud; Helix vivipara, Linn.), sur quelques Espèces voisines, et Idée générale sur la Tribu des Gastéropodes péctinés à Coquille entière; tom. xi. p. 170.

Memoire sur le grand Buccin de nos Côtes (Buccinum undatum, Linn.), ainsi que sur les Buccins, les Murex, les Strombes, et en général sur les Gastéropodes péctinés à Syphon; tom. xi. p. 447.

Memoire sur le Genre Tethys, et son Anatomie; tom. xii. p. 257.

Memoire sur les Acères, ou Gastéropodes sans Tentacules apparens; tom. xvi. p. 1.

Sur les Ascidies, et sur leur Anatomie, Memoires du Muséum d'Histoire Naturelle; tom. ii. p. 10.

Sur les Animaux des Anatifés et des Balanes, Lamarck (Lepas, Linn.), et sur leur Anatomie; ibid. p. 85.

We may refer also to Péron, sur le nouveau Genre Pyrosoma, Ann. du Mus. tom. iv. p. 437.

Péron et Le Sueur sur les Meduses du Genre Equorée, tom. xv. p. 41; et Histoire de la Famille des Mollusques Pteropodes, p. 57.

Six Memoire pour servir à l'Histoire de l'Asterie rouge (Asterias rubens, Linn.), de l'Aétinie coriacée (Aétinia coriacea, Cuv.), et de l'Alcyon exos; Ann. du Mus. tom. xiii. p. 438.

Mery, Remarques sur la Moule des Etangs; Mem. de l'Acad. des Sciences, 1710.

Since this article was finished, new and valuable sources of information on the subjects comprehended in it have been opened to the public. Under this head we may enumerate Cuvier Histoire et Anatomie des Mollusques, 4to. 1817, containing all the memoirs specified above, and some new ones, particularly one on the cephalopoda.

Cuvier, Regne Animal, 4 tom. 8vo.

Savigny, Sur les Animaux sans Vertèbres, part 2.

Lamarck, Sur les Animaux sans Vertèbres, 2d edition, greatly enlarged.

Blainville, various memoirs on the Mollusca, published in the Bulletin des Sciences, 1814—1817.

Tiedemann, Anat. der Holothuria, des Seesterns, et des See-igels; fol. Landthut.

VERMICELLI, or VERMICHELLI, a kind of mixture, prepared of flour, cheese, yolks of eggs, sugar, and saffron; and reduced into little long pieces, or threads, like worms, by forcing it with a piston through a number of little holes in the end of a pipe made for the purpose.

The word, in the original Italian, signifies little worms: they also call it tagliarini, and millefanti.

It was first brought to us from Italy, where it is in great vogue. In effect, it is the great regale of the Italians. Other nations are not easily brought to relish the taste of it. It is chiefly used in soups and pottages, to warm, provoke venery, &c.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms, *vermiculi*.

Anatomists particularly apply it to the motion of the intestines and certain muscles of the body.

The *vermicular*, or *peristaltic*, motion of the intestines is performed by the contraction of the fibres thereof from above downward; as the unnatural, or antiperistaltic motion, is by their contraction from below upwards.

The contraction happening in the peristaltic, which others call the *vermicular* motion, as resembling the motion of worms, does not affect all the parts of the intestines at once; but one part after another.

VERMICULAR, or *Vermiculated Work*, *Opus vermiculatum*, in *Sculpture*, a sort of ornament, consisting of frets, or knots,

knots, in Mosaic pavements, winding, and representing, in some sort, the tracks made by worms:

“ Quam lepide lexis compositæ, ut tessellæ omnes
Arte pavimento, atque emblemate vermiculato.”
Cic. de Orat. lib. iii.

VERMICULARIA, in *Botany*, from *vermiculus*, a little worm, so named by Tode, on account of the arrangement of the seeds.—Tode Fung. Mecklenb. v. 1. 31. Perf. Syn. Fung. 110.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Capsule globose, sessile, filled with vermicular bodies, covered with seeds.

This genus appears to have been seen only by the lynx-eyed author of the *Fungi Mecklenbergenfes*. Perfoon has adopted it from him. Three species are all that we find described.

1. *V. pseudosphæria*. Black Granulated Vermicularia. Tode n. 1. t. 6. f. 46. Perf. n. 1.—Globose, aggregate. Capsule granulated, black. Seed-bearing filaments loose, naked, white.—On rotten oak-bark in March, found but once. The capsule is not larger than a grain of sand, slightly compressed, tender, not brittle as in *Sphæria*; full of short, flexible, crowded fibres, covered all over with extremely minute white seeds. Afterwards the fibres turn orange-coloured.

2. *V. pubescens*. Downy Vermicularia. Tode n. 2. t. 6. f. 47. Perf. n. 2.—Globose, scattered. Capsule downy, two-coloured. Seed-bearing filaments loose, naked, hoary.—Found in rainy weather, in July, on dry stalks, or dead branches. The size of cabbage-seed, of a deep orange-colour, covered with white cottony down. Fibres very slender, crowded together.

3. *V. hispidula*. Hispid Vermicularia. Tode n. 3. t. 6. f. 48. Perf. n. 3.—Cushion-like, scattered. Capsule black, beset with bristles, which disappear from its summit. Seed-bearing filaments whitish, loosely immersed in mealy pulp.—Found but once, on rotten elder-wood, in April. This is no larger than the first species. The capsule is orbicular, depressed; when young briefly all over; but at length the centre shows itself quite bare, very smooth, never bursting, slightly wrinkled as it advances in age. The fibres, though unconnected with any other part, are imbedded in rather soft pulp, which is peculiar to the present species.

VERMICULARIS. See **ASCARIS**.

VERMICULARIS Crusta, a term used by some anatomical writers to express the internal hairy and corrugated coat of the intestines.

VERMICULI SPERMATICI. See **GENERATION**.

VERMICULUM, a word used by some chemists to express a tincture or elixir.

VERMICULUS MARINUS, the *Sea-worm*, in *Natural History*, the name of a genus of shell-fish.

These shells are called *vermiculi*, sea-worms, from the fish contained in them, which is always a sort of worm. They usually are found in great clusters together, interwoven oddly with one another.

Bonani calls them sea-serpents, inclosed in shells, from the various twisted forms in which they adhere to ships and rocks. The author establishes them among the multivalves, because they are never found single, but always in these clusters. In this sense he looks upon the whole cluster as the shell-fish under consideration, not any one of the single tubes; though he acknowledges that each of these tubes is a perfect shell, independent of the rest, and has its proper

inhabitant. Strictness in natural history, therefore, would not bear him out, in arranging them among multivalves; for they are certainly an univalve shell, though many of them happen always to be found together.

Care must be had not to confound these with the *dentalia* and *entalia*; for these last are always found single; and the *vermiculi*, of the kind here treated of, are always found together in great numbers, forming clusters of ten inches, and often much more in diameter.

Of the *vermiculi*, which are straight, we have eight species; of the crooked kind, we have four species; and of those which are disposed in a sort of circles, we have nine species. Hist. Nat. Eclair. p. 354.

According to Da Costa's arrangement, the *vermiculi* or worm-shells constitute the third family of univalve shells; and he defines them to be tubular cylindrical shells, single, in masses together, or adherent to other shells or bodies; variously sinuous, by winding or twisting to and fro in a very irregular manner. Of these *vermiculi* he reckons two genera, *viz.* those which have no fixed or regular form, as the common *vermiculi*, of which, though they are found in great abundance, there are not many different species; and the *penicilli* or worm-shells, which, in the whole, or any particular part, have a determinate regular shape or structure. There are few species of this genus; the watering-pot from the East Indies is the chief kind, and, when perfect, is much valued. There are also *vermiculi* which have *comcamerations*, or are divided into chambers by a few or many transverse plates; but they are seldom regular, or set at equidistant intervals, and not pierced by a pipe or siphunculus, communicating from chamber to chamber, so as to permit the silt to penetrate more than one chamber or inclosure at a time; in which respect they differ from the *comcamerated* shells, as the *nautili*, &c. The *vermiculi* are frequently found in the fossil state; but there is no species, that is not known recent, or from the sea. Da Costa's Conch. p. 148. See **CONCHOLOGY**.

VERMIFORMIS Appendix Cæci, in *Anatomy*, a small blind process connected with the *cæcum*. See **INTESTINE**.

VERMIFORMIS Processus, of the cerebellum. See **BRAIN**.

VERMIFUGE SUBSTANCES, in the diseases of animals, are all such as are found capable of destroying or expelling insects or worms from their bodies. They are of many different sorts, as those of safin chopped fine, antimony, calomel, and many others. See **WORMS**.

VERMIFUGUS, the same with *anthelmintic*. See **WORM-Seed**, and **Worm-Powders**.

VERMILION, a bright, beautiful red colour; in great esteem among the ancients, under the denomination of *minium*.

There are two kinds of vermilion; the one *natural*, the other *fætitious*.

The *natural* is found in some silver mines in form of a ruddy sand; which they prepare and purify by several lotions and coctions. When this is used as a colour, no other preparation is necessary than a careful levigation with water on a stone.

The *fætitious* or *common* is made of artificial cinnabar, ground up, as some say, with white wine, and afterwards with the white of eggs: in this state it is made into cakes, and left to dry. And to fit it for use, they grind it up a second time with water, and whites of eggs. To purify and heighten its colour, some grind it up with urine, or spirits of wine, to which a little saffron is added.

Some also pretend to make vermilion of lead, burnt and washed; or of ceruss, rubified by fire. But these are

not properly denominated vermilion, but *red lead*. See MINIMUM.

It is this last, however, that seems to be the artificial minium, or vermilion of the ancients; and, accordingly, apothecaries and painters still give it that name.

The ancient Greek and Latin authors have given divers fabulous accounts of their minium; and several of the moderns have adopted their dreams; the most rational accounts are, that Theophrastus attributes the first invention of making it to Callias the Athenian; who hit upon it in endeavouring to draw gold, by fire, out of a red sand, found in the silver mines, in the year of Rome 249. But Vitruvius says, it was discovered in the Cilbian fields; where it was drawn from a red stone, called by the Greeks *anthrax*.

We have two kinds of vermilion from Holland; the one of a deep red, the other pale; but both are in reality the same matter, the difference of colour only proceeding from the cinnabar's being more or less ground: when fine ground, the vermilion is pale; and this is preferred to the coarser and redder.

It is of considerable use among the painters in oil, and in miniature; and likewise among the ladies, as a fucus, or paint, to heighten the complexion of such as are too pale.

VERMILION is sometimes also, though improperly, used for what we otherwise call *kermes*, or *scarlet grain*.

VERMILLION LAKE, in *Geography*, a lake of North America, which extends 6 or 7 miles N.N.W., and by a narrow strait communicates with lake Namaycan, that takes its name from a particular place at the foot of a fall, where the natives spear sturgeon. N. lat. 48° 40'. W. long. 93° 26'.

VERMILLION Point, or *Cape Townsend*, a peninsula in lake Michigan, which separates Green bay from the other part of the lake; 23 leagues long, and from 1 to 3 broad.

VERMILLION River, one of the principal rivers of Louisiana, in that part of the state which is called Attacapas, and which is bounded S. by the gulf of Mexico, N.W. by Opelousas, N.E. by the Atchafalaya, and on the E. by the Atchafalaya and the lakes belonging to that river. This district forms a scalene triangle, whose area amounts to 5100 square miles: the actual population, ascertained by the census of 1810, amounts to less than two persons to the square mile. The Vermillion river, like the *Teche* (which see), has its source in Opelousas, and enters Attacapas or Attakapas at the mouth of Carrion Crow; it then runs south about 16 miles, then winds to the west, and receives from the south the bayou (creek) Tortua, continues west eight miles, passes the ridge of hills, (a ramification of which winds along each bank to some distance,) and assumes a south-west course, which it maintains 25 miles. When it enters the hills, its magnitude justifies the title of river, though it has that appellation below the Carrion Crow. The tide in autumn is perceivable thus high, the current of the river being at all times rather gentle. When it has completed its south-west course, it winds south-east by south 20 miles: the whole length of its comparative course in Attacapas being 69 or 70 miles; but the distance, pursuing the windings of the stream, must exceed 100 miles. The two large prairies, known by the names of Opelousas and Attacapas, extend on each side of the Vermillion, from its entrance into Attacapas to its egress into the gulf of Mexico. Wood abounds more on the Vermillion than on the *Teche*; and though the soil may be less fertile, it is nevertheless excellent, and the quantity greater on an equal length of river. There are 80 miles on the banks of the

Vermillion, which have an extension backwards of two miles, that afford 320 superficial miles, or 204,800 acres. Some of the most beautiful settlements yet made in the Attacapas are upon this river. From the diversity of soil, and elevation, none can err in giving the preference, with regard to beauty of appearance, to the banks of the Vermillion, before any other river in Louisiana, south of bayou Bneuf. The lower part of the Vermillion will, without doubt, suit the culture of the sugar-cane; whilst the whole extent of its banks is well adapted to cotton and corn. The Vermillion, by its union with the gulf, forms the natural communication of its inhabitants with the sea. At present the depth of water through the inlet into the Vermillion will not admit vessels of very considerable burthen. Darby's Geog. Description of the State of Louisiana, Philad. 1816.

VERMILLION River, a river of America, which runs into the Wabash, N. lat. 40° 5'. W. long. 87° 40'.—Also, a river of America, which runs into the Theakiki, N. lat. 41° 10'. W. long. 88° 40'.—Also, a river of America, which runs into lake Erie, N. lat. 41° 45'. W. long. 82° 12'.

VERMILLION Sea. See CALIFORNIA.

VERMIN, in *Agriculture*, a collective term which includes all the various sorts of small animals, that are injurious to the corn, fruit, and other produce of the farmer. The vermin, rats and mice, stand foremost among those which are the most prejudicial. It has been stated, that one of the former eats and destroys more than a quart of corn, on the average, in the course of the week; which amounts to the vast quantity of upwards of twenty quarters in the year, for the support of an hundred of them; and this is probably fewer than the number to be met with, in most cases of large corn-farms; so that the real damage is perhaps considerably more. The injury sustained from the latter is, in all probability, nearly equal to that from the former. The losses, on a moderate calculation, cannot be less than forty pounds in the year to every large farmer, and half that amount to those of the smaller class.

In the field, the barn, and the dairy, these small vermin are equally disagreeable, troublesome, and destructive, and are supposed to be more mischievous than moles. Much care is bestowed, it is said, on the destruction of moles; and it might be worth while to endeavour to lessen the number of field vermin of this sort, which are in their nature, it is contended, more injurious to the farmer than moles are. In the rick-yard, the barn, the dwelling-house, and some other places too, their mischievousness is too obvious not to be noticed. In the dairy they not unfrequently commit great injuries, by spoiling and destroying the different products; and in the harness-rooms, and places where such articles are kept, they are not less destructive, by eating into and gnawing the different articles.

The barn and the stack-yard are, it is said, usually put under the care of the cat; but to set a trap for this vermin, in a barn full of corn, has perhaps been considered as a thing so unlikely to be effective, that it has seldom been tried. The success of traps, where they have been used, has been sufficient to recommend them; for although a total extirpation of the vermin, in cases where they have been tried, did not take place, an annual saving of some quarters of corn has been the consequence.

It is remarked, that while the number of these vermin is great, almost any kind of trap may be used, provided it be properly baited; but that for taking a remaining artful few, a common shaped round steel trap, suited to the size of the vermin, has been found to be the most effectual.

In order to the complete extirpation of these and other vermin,

VERMIN.

vermin, the author of a late Calendar of Husbandry has, however, advised that every farm should be well provided with a competent number of ferrets, and of true vermin-bred dogs, such as are usually kept for the purpose; and that an hour or two should be spared weekly, and reserved for executing the business in all accessible places. The holes and haunts of the vermin, in and about the premises, are to be diligently sought out and discovered; trifling rewards being given for the purpose, as an encouragement, by the master. Nothing of a reprieve is to be allowed to the delinquents, but a war of extermination is to be constantly kept up and carried on throughout the whole year. In aid of these means, others too may be adopted, when necessary; as those of the trap kind, which should be of the cage sort, and not such as to endanger the cats, a most useful sort of domestics, which are fully entitled to care and kindness; the qualifications of which in this situation are, that they do not touch young poultry, and hunt for mere sport, rather than from the impulse of hunger; as eating their prey injures them, and lessens their exertions. The ferrets in this view are, it is thought, best kept in huts, in the same manner as the rabbits: their food is well known to be any sort of offal of the flesh kind, with occasionally a little milk and bread boiled.

The same means of extirpation and removal apply equally, it is supposed, to the field vermin, polecats, weasels, and their different varieties; which, unless they be checked, commit such frequent considerable nightly depredations in and about farm-yards, as to become highly injurious, taking away various kinds of poultry in different fates, and sometimes even young pigs. But it is believed that neither these nor the fox would be heard of near such premises, if they were well furnished and guarded by vermin dogs.

A good method of trapping field vermin has been proposed by the author of the Rural Economy of the County of Kent, which is this: a wooden box, resembling a dog-kennel, divided in the middle by an open wire partition, running from end to end, and reaching from the ridge of the roof of it to the floor; one side of which partition is again divided into two parts or cages, one of them for a rabbit, and the other for a live fowl to be put into, to allure the vermin; the other half formed into a falling box-trap to take them in. But it is surely a most unnecessary piece of cruelty to expose a poor wretched fowl or rabbit to the fight and claws of their dreaded enemy. Kill the baits, and all is right; as the scent of the fresh blood is the greatest possible enticement to such vermin.

In regard to vipers, efts, lizards, toads, and different others of any sort of poisonous vermin of the reptile kind, which are troublesome and prejudicial to the farmer, it is suggested, that if country-people, who are engaged in this way, would be unanimous and steady in their endeavours, all these sorts of creeping little animals might in time be extinguished. Would a single parish but make the effort, it is said, of rooting out all such useless and dangerous vermin, they would soon find their account in it, and would undoubtedly be followed by their adjoining districts. The only mode is, it is thought, by the allowing of handsome premiums to those who shall produce the vermin, or who may discover their retreats, hiding-places, or their ova or eggs.

In respect to the destructive vermin birds of prey, and those of other kinds, it may be noticed, that the former, such as carrion-crows, ravens, magpies, kites, hawks, and some others, chiefly endanger the poultry, sometimes even attack lambs, and are often injurious to diseased sheep, by picking them in different parts; while the latter, as jays,

pigeons, rooks, and different sorts of small birds, are principally destructive of field produce. The first, as well as pies, bull-finches, and some others, are greatly destructive of fruit, and the jay often commits much injury on bean-crops near harvest-time. Pigeons are particularly injurious at feed-time and harvest, by destroying large quantities of grain, tares, and feeds, and doing much hurt to the crops. Rooks are a sort of vermin which do great injury to various kinds of field-crops as they rise, and at other times; but they are thought by some to be useful in devouring the grub-worm and other insects. Small birds do much mischief by the destruction of grain which they cause at the time of sowing, and when the corn becomes nearly ripe; besides that which they, in some cases, do to such buildings as are covered with thatch. In some places they quit the towns, villages, and single houses, and attack the corn-fields in flocks of thousands together, and would soon clear whole fields if not kept off by proper means. Some sorts of these birds feed upon animal as well as vegetable food, and do good by lessening the number of grubs, caterpillars, and butterflies, and much harm by destroying blossoms, fruit, and corn in the fields. Great numbers of caterpillars are said to have been found in the stomachs of some sorts of these small birds. The best and most effectual protection against their injuries and depredations, in all these cases, is probably the gun, though other means, such as rattles, and different contrivances, may be had recourse to against such vermin.

Vermin of the worm, grub, slug, and other similar kinds, are often very injurious to the farmer's crops. The earth-worm, the wire-worm, the grub of the cock-chaffer, the slug, the turnip-fly, the black canker caterpillar, the black insect, which destroys beans, and the yellow maggot, which feeds on the ears of wheat, are of numerous families, and not less mischievous than any of the above vermin. They not unfrequently cut off turnip, clover, tare, and other such crops, and do great damage to those of the corn-kind. There is a whitish sort of slug that often prevails much in bean and pea-stubbles, in strong land when sown with wheat, and in wheat after clover and beans. It is very destructive too to rye-crops in some districts and places. The destruction of these sorts of vermin may be attempted in different ways, as by having them devoured, in some cases, by the introduction of suitable birds for the purpose, and those of ducks and gulls in other cases. It has been stated that worms and slugs which feed on the new roots of corn, and other such matters, may mostly, perhaps, be destroyed by a clean fallow, continued so long as to occasion their death by want of food. It is probably a mistaken notion, it is said, that lime spread in such a quantity as to be beneficial to the soil, will destroy these reptile vermin. In Kent, near the chalk-hills, and even on a calcareous soil, they lime, it is said, frequently, and very liberally, without being at all relieved from the ravages of worms. The earth-worm feeds on herbs, and as its size is much larger, so it is probably more destructive than the wire-worm. See *BLACK CANKER*, *GRUB*, *SLUG*, *TURNIP-FLY*, and *WIRE-WORM*.

Vermin of the fly kind, such as hornets, wasps, and others, are often prejudicial to feeding and pasturing stock, and render team animals, in some instances, quite ungovernable; they and their nests should of course be as much destroyed as possible, in order to prevent such inconveniences and accidents. See *WASP*.

Game may be considered as a sort of vermin on farms, which feed upon the farmer's crops, and induce and encourage sportsmen to commit much injury and destruction

VERMIN.

on his property in the pursuit of such field-sport. This should be avoided and done away with whenever it can, as the damage is very considerable in many cases. See **CAME**.

The able writer of the Corrected Report of the Agriculture of the County of Middlesex has estimated, that the expences of guarding against, and the damage produced by vermin and game, on a farm of two hundred acres, half arable and half grass, without these walks, amount to fifty pounds in the year; which is nearly five shillings an acre on the whole quantity of land, which sum will perhaps, it is supposed, average the cultivated corn and grass land farms of Britain; and that, as there are nearly forty millions of acres in this state, these depredations amount to ten millions the year. This is an amount which would hardly have been suspected by many, and which it is important in different points of view to prevent as much as possible.

VERMIN, in *Gardening*, is a term applied to various small animals that are injurious to garden-crops in different cases, and as destructive as in the farm-yard.

Rats and mice are of this kind, and do much mischief in sheds and other places, where they frequently destroy beans, peas, and other feeds; they should therefore be extirpated as much as possible in all such cases.

And there are different modes of destroying them in these instances; as by traps, poison, &c. But Mr. Forsyth advises never to use arsenic, or corrosive sublimate for that purpose, except under particular circumstances, as they are deadly poison: nux vomica will, he thinks, generally answer the end as well, without the danger. He has suggested it as a very good plan to prevent accidents, to enclose the traps in cases, having holes in the ends of them large enough to admit rats, but small enough to exclude dogs, cats, &c.

And the following is recommended as a bait for rat-traps in these cases: Take a pound of good flour, three ounces of treacle, and six drops of the oil of carraways: put them all in a dish, and rub them well together till they are properly mixed; then add a pound of crumb of bread. The traps baited with this mixture should be set as near their haunts as possible; but, for two or three days, so as not to fall or strike on the rats going in, but letting them have free liberty to go in and out at pleasure, as this makes them fearless. Some of the bait should also be laid at the rat-holes, and a little of it scattered quite up to the traps, and so on to the bridge of each trap, where a handful may be placed. It may also, it is suggested, be proper to scent the traps with the following mixture, for the purpose of enticing the rats into them.

Take twenty drops of oil of rhodium, six or seven grains of musk, and half an ounce of oil of aniseed; put them in a small phial, and shake it well before using; then dip a piece of twisted paper or rag in the mixture, and rub each end of the trap with it, if a box-trap, and put two or three drops on the bridge, leaving the paper or rag in the trap. Of whatever kind the trap is, it should be scented; but once in a twelvemonth will be sufficient. Then throw some chaff mixed with a little wheat about the bottom of the trap, in order to deceive the rats; for they are very sagacious, and will not enter a suspicious place. This will be necessary to be done only at the first time of setting the traps; for after some rats have been caught, and have watered and dunged in them, rats will enter boldly when they find others have been there before them: do not, therefore, wash or clean out the trap, as some people do before they set it again, but let the dung and urine remain in it. Keep the places where the traps are set as private as possible; and when they are set

for catching, mix no bread with the bait, as the rats will in that case be apt to carry it away.

It is advised, that when the holes are found quiet, and that no rats use them, to stop them up with the following composition: Take a pint of common tar, half an ounce of pearl-ashes, an ounce of oil of vitriol, and a good handful of common salt, mix them all well together, in an old pan or pot. Take some pieces of paper, and lay some of the above mixture very thick on them; then stop the holes well up with them, and build up the mouth of the holes with brick or stone, and mortar; if this be properly done, rats will, he asserts, no more approach these, while either smell or taste remains in the composition.

In order to destroy the rats in places where traps cannot be set, he recommends us to take a quart of the above bait, then rasp into it three nuts of nux vomica, and a quarter of a pound of crumb of bread, if there was none before: mix them all well together, and lay it into the mouth of their holes, and in different places where they frequent; but first give them of the bait without the nux vomica, for three or four succeeding nights; and when they find it agrees with them, they will eat that mixed with the nut with greediness.

It is further observed, that rats are frequently very troublesome in sewers and drains. In such cases, arsenic may be used with success, as follows: Take some dead rats, and having put some white arsenic, finely powdered, into an old pepper-box, shake a quantity of it on the fore parts of the dead rats, and put them down the holes or avenues, by the sides of the sewers at which they come in; this puts a stop to the live ones coming any further; for when they perceive arsenic, they will, it is asserted, retire immediately: whereas, if they were put down without the arsenic, the live ones would eat them.

We have, however, found that these animals take arsenic best when it is prepared, by being finely levigated and mixed up with very strong old cheefe and oatmeal. In order to destroy mice, Mr. Forsyth advises persons to take a quart of the bait for rats before there is any bread mixed with it; then to take four nuts of nux vomica, and rasp them very fine, otherwise the mice will pick out the food from it, on account of its bitter taste; rub them well together; lay some of it upon a piece of paper, or, if without doors, on a piece of tile, removing all other food from the place, and it will kill all that eat of it. What is not eaten, should be taken away in the morning, and replaced at night. If this be in a garden, shelter it with boards or tiles, that it may not get wet.

Open traps should likewise be set, as mice are shy in entering close ones. And care should be taken not to convey these animals into gardens by the straw litter, or other similar materials.

Slugs are a sort of vermin that are frequently found harbouring about the foundations of walls, and about the roots of peas, lettuce, &c. They may, Mr. Forsyth thinks, be picked off, and killed, by putting them into a pot in which is a little fine unslaked lime: or the ground where they are should be well watered with soap-suds and urine, mixed with tobacco-water. When they are numerous on the surface of the ground, which frequently happens after rain, or in a dewy morning, fine unslaked lime thrown over the borders, &c. will, he contends, destroy them. But he prefers the above mixture, which, if the ground be well watered with it, will bring them up out of their holes, when they very soon die; it will also destroy their eggs, which they always deposit in the earth.

Snails, also, during the winter, the same writer assures us, gather themselves together in clutters; and in that season are frequently found in great numbers behind wall-trees, and in holes of the walls. They should be carefully picked off and crushed, which is the only effectual way of getting rid of them. If any should escape, they should be destroyed as they make their appearance in the spring. As they also deposit their eggs in the ground, the borders should be well watered in the above manner.

Wasps and flies are highly destructive of all sorts of fruit; therefore, as soon as the wasp and large flesh-fly make their appearance, it is proper to get ready several bottles or phials; then mix up grounds of wine or beer, with sweepings of sugar, honey, or grounds of treacle, and with this mixture fill the bottles half or three-quarters full; then place some of them at the bottom of the wall, and hang a sufficient number up by a piece of yellow willow, or pack-thread, on the nails against the walls in different places, observing to empty them frequently as they fill with flies and wasps; first pour the liquor into an empty bottle, and then shake out the dead insects, crushing them with your foot, that none of them may revive; then pour back the liquor into the bottles and phials as at first. In this manner a great many may be destroyed, it is supposed, before the fruit becomes ripe. If you begin to hang up the bottles as soon as you see the fly, which comes much earlier than the wasp, you will be able to destroy great numbers of them, and will have the bottles ready for the wasps when they make their appearance. The fly will be found as destructive as the wasp to grapes. And when the weather is hot, and the wasps are numerous, if they do not enter the bottles fast enough (which will happen when the fruit is very ripe), a little oil may be put in a cup, and with a feather dipped in it touch their backs, and they will instantly drop down; when you will find them turned black and green by the effects of the oil. See WASP.

Birds attack fruit much when it begins to ripen. The best preventive in this case is, Mr. Forsyth supposes, to cover the trees with nets, or bunting, a sort of cloth of which shippers' colours are made. See VITIS.

There are many other vermin of the insect tribe that are likewise highly destructive to fruits and garden-crops, but which are noticed under the articles which they are found to injure in most cases. In some they may be best destroyed, however, by gathering them by the hand as soon as they begin to appear in a small number, by plentiful steaming or watering; in others, by smoking and powdering with tobacco; and in others by different compositions, as those of soap-fuds and sulphur, or lime-water, and other such matters. Some are best taken by artifice, as ear-wigs and others of the same kind, as in the cases of wasps and flies. See CATERPILLAR, APHIS, COCCUS, THIRIPS, &c.

VERMIN, in *Sheep*, the different small animals which are troublesome and hurtful to them. The maggots produced from the ova or eggs of the flesh or sheep-fly, are a sort of vermin which are to be particularly guarded against in the later summer months, as they are then soon hatched in any wound, filth, or dirt, that may be in or hang about the skins of them, often producing great pain, uneasiness, and eating into the flesh and destroying the sheep, when not speedily removed. Consequently, when they are seen to be uneasy and disturbed, to frequent rubbing places, neglect their food, lie down frequently, and bite themselves with their teeth, they should be carefully examined; when, in some cases, large blisters may be discovered, under which the vermin are concealed; or the part is found of a dark colour,

and quite wet; and even sometimes large holes are eaten into the bodies of the sheep.

In all such cases the wool is to be carefully clipped off, the blisters, when present, opened, and the vermin picked out from the injured parts, which should then be gently washed, either with soap and water, with spirits and vinegar, with lime-water, with stle urine and black soap, or with infusion of tobacco, being afterwards anointed with tar, or the same substance mixed with butter and sulphur or red precipitate. In this way the vermin are soon removed and destroyed, and the sheep restored. In order to prevent the vermin, whenever sheep are wounded by the sheers in clipping, by the bite of dogs, or in any other way, a little tar ointment is to be applied to the parts.

Dirty layers or pastures are said to be liable to produce this kind of vermin, which most commonly attack lambs, and often appear about the hips of such as are affected with loofens.

There are other sorts of vermin which are very injurious to sheep. See TICK.

The fox too is an artful and formidable enemy of sheep and poultry, as well as the wild cat, which is extremely fierce and strong, and very destructive of lambs and fowls. The fountart is also very mischievous among weak lambs. Eagles are likewise frequent in the more northern districts, the strength and depredations of which are well known to sheep-farmers; but ravens are probably more destructive, being ready to attack sheep in all cases of distress, and exceedingly quick-sighted in discovering such instances. All these sorts of vermin should, consequently, be exterminated as much as possible, by offering premiums for their claws, skins, &c. and other proper means of different kinds.

VERMINA. See VERMINE, and VERMINATION.

VERMINATION, VERMINATIO, the act of breeding worms, and other vermin; particularly bots in cattle, &c.

VERMINATION is sometimes also used among physicians, for a fort of tormina ventris, or wringing of the guts; in which the patient is affected, as if worms were gnawing his intestines.

VERMINE, VERMINA, a collective name, including all kinds of little animals, or insects, which are hurtful or troublesome to men, beasts, fruits, &c. as worms, lice, fleas, bugs, caterpillars, ants, flies, &c.

VERMIS, WORM, in *Natural History*. See VERMES and WORMS.

VERMIS Aureus. See APHRODITA.

VERMIS Cereuleus. See CÆRULÆUS.

VERMIS Cerebri, the worm in the brain, a name given by some writers to an epidemical fever in Hungary, attended with terrible deliriums.

VERMIVOROUS ANIMALS, are such as feed upon worms.

VERMONETA, in *Botany*, Juss. Gen. 343; a manuscript name of Commerçon's, for a supposed genus of his, referred by Jussieu to their own *Blackwellia*, which we are much disposed to unite with *HOMALUM*; see the latter.

VERMONT, in *Geography*, one of the United States of America, situated between 40° 42' and 45° N. lat. and 3° 35' and 5° 27' E. long. from Washington; and bounded on the N. by Lower Canada, S. by Massachusetts, E. by Connecticut river, which divides it from New Hampshire, and W. by New York. Its extent from N. to S. is 152 miles, and its breadth from E. to W. 60 miles: its area is 8700 square miles, or 5,568,000 acres. It is divided into thirteen counties, containing the number of townships and inhabitants,

inhabitants, together with the chief towns, exhibited in the following

Topographical Table.

Counties.	Townships.	Population.	Chief Towns.	
Addison	24	19,993	Middlebury	715
Bennington	16	15,893	Bennington	611
Caledonia	24	18,730	Danville	771
Chittenden	23	18,120	Burlington	804
Essex	14	3,087	Guildhall	685
Franklin	19	16,427	St. Albans	729
Grand Isle	5	3,445	North Hero	82
Jefferson*			Montpelier.	
Orange	20	25,247	Chelsea	745
Orleans	23	5,830	Craftsbury	832
Rutland	27	29,486	Rutland	658
Windham	24	26,760	Brattleborough	786
Windfor	23	34,879	Windfor	893
	<u>242</u>	<u>217,895</u>		

* Laid out since the census was taken.

The number of inhabitants returned in the schedule of Mr. J. Willard, marshal, January 26th, A. D. 1811, is 217,913.

In each township is a reserve of two portions of land, each of 350 acres, one for the support of public schools, and the other to be given in fee to the first minister who settled in the township. An extensive chain of high mountains runs through the middle of this state, nearly S. and N., between Connecticut river and lake Champlain. The natural produce of this chain of mountains is hemlock, pine, spruce, and other evergreens; and on this account, as it has always a green appearance, it is denominated "Ver Mons," or "Green Mountain." On some high parts of it the snow lies till May or June. The country, on the E. side of the mountain, is watered by Paupanhoosak, Quechey, Welds, White, Black, and West rivers; and on the W. side by the La Moille and Onion rivers, and Otter creek, which discharge themselves by one mouth into lake Champlain, 20 or 30 miles S. of St. John's. The adjacent lands are excellent in quality, and annually enriched by the inundation of the water, occasioned by the melting of the snow on the Green mountains. The general aspect of the country is hilly, but it has many rich valleys, which furnish very good pasturage for cattle, and which, contrasted with the hills, afford beautiful scenery. Timber-trees of various kinds are abundant; wheat, rye, barley, oats, Indian corn, are cultivated by the inhabitants: though the corn on high grounds is sometimes liable to be damaged by the frosts. Flax and hemp are raised in considerable quantities: and potatoes, pumpkins, together with garden-roots and vegetables, are plentiful. The fugar-maple affords a large supply of excellent fugar. The metals and minerals of this country are iron, lead, coppers, flint, marble, pipe-clay, and vitriol. The trade of Vermont is principally carried on with Boston, Portland, Hartford, and New York; whither the inhabitants export horses, beef, pork, butter, cheese, wheat, flour, iron, nails, pot and pearl ashes. The climate resembles that of New Hampshire, and is upon the whole very healthy: the winters, however, are long and severe, and the summers hot. The inhabitants are for the most part emigrants from Connecticut and Massachusetts, and their descendants. The only foreigners are Scots, who have formed a settlement. As to the character, manners, customs, laws, policy, and

religion of the people in Vermont, we need only say that they are New-Englandmen.

Before the late war, this tract of country was claimed both by New York and New Hampshire; but upon the commencement of hostilities between Great Britain and her colonies, the inhabitants considered themselves as free from any legal jurisdiction, and associating together, formed for themselves a constitutional government; and before it was acknowledged by congress on the 4th of March, 1791, as the fourteenth state; they commenced their political independent existence as a separate government in the year 1777. On the 15th of December in this year, their representatives, in convention at Windsor, declared that the territory called Vermont, was and of right ought to be a free and independent state; and for the purpose of maintaining regular government in the same, they made a solemn declaration of their rights, and ratified a constitution, of which the following is an abstract.

Their declaration, which makes a part of their constitution, asserts that all men are born equally free—with equal rights, and ought to enjoy liberty of conscience—freedom of the press—trial by jury—power to form new states in vacant countries, and to regulate their own internal police: that all elections ought to be free: that all power is originally in the people: that government ought to be instituted for the common benefit of the community, and that the community have a right to reform or abolish government: that every member of society hath a right to protection of life, liberty, and property; and in return is bound to contribute his proportion of the expence of that protection, and yield his personal service when necessary: that he shall not be obliged to give evidence against himself: that the people have a right to bear arms, but no standing armies shall be maintained in time of peace: that the people have a right to hold themselves, their houses, papers, and possessions free from search or seizure; and therefore warrants without oaths first made, affording sufficient foundation for them, are contrary to that right, and ought not to be granted: that no person shall be liable to be transported out of this state for trial for any offence committed within this state, &c.

By the frame of government, the supreme legislative power is vested in a house of representatives of the freemen of the state of Vermont, to be chosen annually by the freemen on the first Tuesday in September, and to meet the second Thursday of the succeeding October: this body is vested with all the powers necessary for the legislature of a free state: two-thirds of the whole number of representatives elected, make a quorum.

Each inhabited town throughout the state has a right to send one representative to the assembly.

The supreme executive power is vested in a governor, lieutenant-governor, and twelve counsellors, to be chosen annually in the same manner, and vested with the same powers as in Connecticut.

Every person of the age of twenty-one years, who has resided in the state one whole year next before the election of representatives, and is of a quiet, peaceable behaviour, and will bind himself by his oath, to do what he shall in conscience judge to be most conducive to the best good of the state, shall be entitled to all the privileges of a freeman of this state.

Each member of the house of representatives, before he takes his seat, must declare his belief in one God, in future rewards and punishments, and in the divinity of the scriptures of the Old and New Testament, and must profess the Protestant religion.

Courts of justice are to be established in every county throughout the state.

The supreme court, and the several courts of common pleas of this state, besides the powers usually exercised by such courts, have the powers of a court of chancery, so far as relates to perpetuating testimony, obtaining evidence from places not within the state, and the care of the persons and estates of those who are *non compos mentis*, &c. All prosecutions are to be commenced in the name, and by the authority of the freemen of the state of Vermont. The legislature is to regulate entails so as to prevent perpetuities.

All field and staff-officers, and commissioned officers of the army, and all general officers of the militia, shall be chosen by the general assembly, and be commissioned by the governor.

Common schools and academies are liberally encouraged in Vermont; and in 1800 a college was incorporated in Middleburg, which is now in a flourishing state. See COLLEGE. Morfe. Melish.

VERN, a town of France, in the department of the Dordogne; 10 miles S. of Perigucux.—Also, a town of France, in the department of the Mayne and Loire; 6 miles S. of Segré.

VERN, or *Vernde*, or *Werna*, a town of Westphalia, in the bishopric of Paderborn; 2 miles W.N.W. of Salzkotten.

VERNACIA, *VENACIA*, *Venitica*, *Vernatia*, or *Veniana*, in *Ancient Geography*, a town of Spain, upon the route from Bracara to Aituria, between Complutica and Petavonium. Anton. Itin.

VERNACULAR is applied to any thing that is peculiar to some one country.

Whence, diseases which reign most in any particular nation, province, or district, are sometimes called *vernacular* diseases; though more frequently *endemic* diseases.

Such are the *plica Polonica*, *scorbutus*, *tarantism*, &c.

VERNAL, something belonging to the spring season. (See SPRING.) Hence, *vernal leaves* are those leaves of plants which come up in the spring, &c.

VERNAL Signs and Equinox. See SIGN and EQUINOX.

VERNAL Grass, in *Botany*. See ANTHOXANTHUM, and SWEET-scented Vernal Grass.

VERNAL, in *Geography*, a small island in the Pacific ocean, near the coast of Mexico. N. lat. 16° 35'. W. long. 95° 50'.

VERNAMO, a town of Sweden, in the province of Smaland; 35 miles N.W. of Wexio.

VERNANTOIS, a town of France, in the department of the Jura; 3 miles S. of Lons le Saulnier.

VERNASSA, a town of Genoa; 5 miles S.W. of Spezza.

VERNE, a town of France, in the department of the Doubs; 3 miles N. of Beaume les Dames.

VERNET, JOSEPH, in *Biography*, the best landscape painter of the French school, was born at Avignon in 1712. He was educated in his native country, and afterwards sent to Rome, where he studied under Adrian Manglard, a painter of sea-pieces and landscapes of some note. He soon surpassed his instructor, and the style which he adopted was as close an imitation of nature as he knew how to make; and his views of Rome and Naples, &c. will always please, from the freshness and spirit with which they are painted. His colouring, however, is not exactly true; the hues are too positive and crude, and lack the softness and delicacy of Claude or Wilson; but his compositions are excellently arranged, and he gave great truth of action to water; he

also adorned his pictures with groups of figures, arranged with taste and freely executed.

He remained many years in Italy, till at length the reputation he had acquired induced Louis XIV. to invite him to return to France, where he was engaged to paint a set of views of the sea-ports of that kingdom. However correct these views may be, it is evident that Vernet did not labour *con amore* at them, as they by no means rival the pictures he painted of other subjects, where he was more free to follow his own taste. He was very much employed and honoured, and enjoyed the exercise of his talents till he arrived at the age of 77, when he died, in 1786.

VERNET, in *Geography*, a town of France, in the department of the East Pyrenées; 4 miles S. of Prades.

VERNET *le Bas*, a town of France, in the department of the Allier; 13 miles N. of Digne.

VERNEUIL, a town of France, and principal place of a district, in the department of the Eure; 18 miles W. of Dreux. N. lat. 48° 43'. E. long. 1°.—Also, a town of France, in the department of the Allier; 15 miles E. of Montmarault.

VERNEY, GUICHARD-JOSEPH DU, in *Biography*, an eminent anatomist, was the son of a physician at Feurs in Forez, and born in 1648. From Avignon, where he studied medicine for five years, he removed to Paris in 1667, and there acquired high reputation, not only as an anatomical demonstrator, but as an eloquent lecturer. His manner was ardent and interesting, and this, together with his youth and agreeable person, rendered the study of anatomy fashionable. After his admission into the Academy of Sciences in 1676, he employed himself in an assiduous prosecution of the natural history of animals, and the result of his researches may be found in the Memoirs of the Academy. About this time he was engaged in communicating anatomical instruction to the dauphin and his learned attendants; and in 1679 he was nominated professor of anatomy at the Royal Gardens, where his auditors were very numerous, many of whom were foreigners. In this and the following year he was occupied in Lower Brittany and on the coast of Bayonne in the dissection of fishes. His work entitled “*Traité de l’Organe de l’Ouille, contenant le Structure, les Usages, et les Maladies de toutes les Parties de l’Oreille*,” was published in 1683, and translated into various languages. In his anatomical researches he was indefatigable, and he made many discoveries, the honour of which has been claimed by others. Having absented himself for a long time from the meetings of the Academy, he returned to it again, in his 80th year, on the republication of his History of Animals, and entered into its business with his former vivacity. In advanced age he undertook a work on insects and reptiles; and though he was afflicted with a pulmonary complaint, he exposed himself to the injurious effects of the damp and night air, in order to observe the actions of snails, with a view to the perfection of the work in which he was engaged. Although his health could not but be impaired by this practice, his life was prolonged to his 82d year, as he died in September 1730. He bequeathed his valuable anatomical preparations to the Academy, leaving a character held in high estimation by contemporary anatomists and physiologists, and by all who had enjoyed the benefit of his instruction in their youth. After his death, Senac published from his MSS. “*Traité des Maladies des Os*,” in 2 vols. 12mo.; and all his memoirs and posthumous papers were collected in his “*Œuvres Anatomiques*,” 2 vols. 4to. Paris, 1761, published by Bertin, to whom his MS. remains were entrusted by Senac. Haller. Gen. Biog.

VERNI,

VERNÉ, in *Geography*, a town of the republic of Lucca ; 12 miles N. of Lucca.

VERNIA, in *Ancient Geography*, a name which Eustathius gives to one of the British isles, supposed by Ortelius to have been Hibernia.

VERNÍCIA, in *Botany*, so called by Loureiro, from *vernix*, varnish, because the nuts of this tree afford by pressure a kind of oily varnish, either used by itself to protect wood from the weather, or employed to adulterate the true Chinese or Japan varnish.—Loureir. Cochinch. 586.—Clafs and order, *Monocœcia Monadelphica*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth tubular, in two rounded, erect segments. *Cgr.* bell-shaped, of five oblong spreading petals, longer than the calyx. *Stam.* Filaments ten, combined at the base, the inner ones longest ; anthers as many, arrow-shaped.

Female flowers few, on the same branch, *Cal.* and *Cor.* unobscured. *Pist.* Germen superior, roundish, three-lobed ; style none ; stigma obtuse, three-cleft. *Peric.* Drupa roundish, warty. *Seed.* Nut bony, bluntly triangular, rugged, of three cells, with an ovate-oblong kernel in each.

Eff. Ch. Male, Calyx two-lobed. Petals five. Stamens ten.—Female, Calyx . . . Corolla . . . Stigma obtuse, three-cleft. Drupa warty, with a triangular three celled nut.

1. *V. montana*. Cày dêu fon, of the Cochinchinese. Tong xù, of the Chinese.—Native of mountainous woods in Cochinchina, as well as in China. A large tree, with ascending branches. Leaves scattered, stalked, slightly heart-shaped, pointed, entire, undulated, smooth, perforated with two glands at the insertion of the footstalk. Flower-stalks terminal, many-flowered, short. Flowers white.

The wood is of little use for building. The nuts afford a copious expressed oil, which is yellow, viscid, transparent, moderately liquid, used as a sort of varnish for arrows, and any wood exposed to the weather. It also serves to increase the bulk of the far more valuable Chinese varnish, obtained from the *Augia* of Loureiro ; as well as to render that substance more fluid and manageable. For lamps it is useless, because it burns too fiercely and consumes too speedily.—We have not been able to reduce this plant to any known genus. All our knowledge respecting it is derived from Loureiro.

VERNIER, is a graduated index which subdivides the smallest divisions on any straight or circular scale, in the reading of which greater accuracy is required, than can be obtained by simple estimation of a fractional part, as indicated by a pointer, or fiducial edge. The vernier was first invented by Pierre Vernier of Frauche Comté, and made known to the world at Bruxelles (or Brussels) in the year 1631, through the medium of a pamphlet entitled “ La Construction, l’Usage, et les Propriétés du Quadrant nouveau de Mathématique,” &c. It soon gained the preference over the scale of Nonius, which was a circular diagonal scale, and which by some writers is yet confounded with a Vernier’s index, though there is no greater resemblance between the two, than exists between the dial of a clock and the hand that points to it. The vernier is applicable to any straight or circular line, provided the divisions be equal ; but the contrivance of Nonius was in the graduated line or scale itself, and required the aid of a fiducial edge as an index. We have given the representation of a *vernier* in several of our astronomical plates, when we were describing CIRCLE, EQUATORIAL, QUADRANT, TRANSIT-Instrument, and THEODOLITE, therefore it will not be necessary to introduce any other figure for the purpose of illustration ; particularly as the principle of its application can be made clearly intelligible by either arithmetical or algebraical notation. Let us suppose two lines, either straight or portions of circles, to

be exactly alike in dimensions, one called A, and the other B, and let one of them be divided into more equal parts than the other by *unity* ; then will the difference of any two of the equal parts of the two lines, or arcs respectively, be a fraction, the numerator of which is the common length of the equal lines, or arcs, and the denominator the product of the numbers of parts into which each is divided. For if we put A for the common length of the equal lines, or arcs, with n and $n + 1$ for the equal parts into which each is divided respectively, the length of the divisions of each will

$$\text{be } \frac{A}{n} \text{ and } \frac{A}{n + 1}, \text{ and their difference } \frac{A}{n} - \frac{A}{n + 1} = \frac{A}{n \times n + 1}.$$

To exemplify this principle in an arc of small radius, let each degree be divided by an engine into three parts, of each 20', and let it be required that the vernier shall read to the accuracy of one minute ; in this case the short scale of the vernier must be divided into 20 parts, and the equal arc on the limb of the instrument either into 21 or 19 parts, so that the difference of the two equal arcs, in divisions, may be = 1 ; if 21, the former number, is adopted, the reading will be in a backward direction ; but if the latter (*viz.* 19), it will be forward ; let the arc on the limb be 6° 20', and let each degree be divided into three parts, of 20' each ; also let 19 be the number of such parts or divisions ; and let the equal arc on the vernier be divided into 20 equal parts ; then $n = 19$, and $n + 1 = 20$ will make a difference between a single division of the limb, and one of the vernier

$$= \frac{6^\circ 20'}{19 \times 20} = \frac{380'}{380} = 1', \text{ as was required. This difference}$$

becomes the index for subdividing the smallest divided space of the limb, and it is ascertained how often it must be taken, by inspecting the place on the divided vernier, where a stroke on it exactly coincides with a dividing stroke on the divided limb of the instrument ; for instance, if the zero, or stroke marked 0, be the coincident one, the reading may be had from the divisions of the limb only, without any addition from the vernier ; but if the coincidence happens at any other place, say at stroke 5, stroke 8, or stroke 10, as numbered on the vernier, then 5', or 8', or 10', as the case may be, must be added, as the measure of a fractional part of a division, to the measure read from the divisions only, that are contained between zero on the limb and zero on the vernier : the difference, which we have said is = 1' when taken once, is 5' when taken five times, and 8' when taken eight times ; and as the point of coincidence can never be mistaken, wherever it may fall, it will always determine how many minutes must be added for the fractional portion of a division, that zero of the vernier has advanced into an entire division ; and as the eye will form a rough judgment at once, whether zero of the vernier is near $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, or $\frac{3}{2}$ of a space on the limb, this notice will at once guide the observer to that part of the vernier’s scale, where the coincidence will be immediately found ; for as zero of the vernier advances in any division of the limb, by the slow motion of the tangent-screw of any instrument, the point of coincidence of the strokes of the two arcs advances with it, till the stroke at zero becomes itself coincident with a new dividing stroke of the arc on the limb, which coincidence denotes the addition of another 20', in our example, without reference to the vernier : but should there be any doubt about the exactitude of the coincidence, 20'', 30'', or 40'', may be taken instead of the last minute, accordingly as the eye can best judge of the

the small quantity short of perfect coincidence; and examining the places of the preceding and following strokes will greatly assist in forming this judgment.

If we were to substitute 21 for 19 spaces on the limb, the result would be the same, with the inconvenience of reading backwards, and of subtracting instead of adding;

$$\text{for } \frac{7^{\circ}}{21 \times 20} = \frac{42^{\circ}}{420} = 1', \text{ as before; but instruments of}$$

modern construction are exempt from this inconvenience, by having always one more division on the scale of the vernier, than on the equal arc of the limb.

In Troughton's snuff-box sextant, which is a very convenient instrument for the pocket, the radius of the divided arc is only about $1\frac{3}{4}$ inch, and the degree is divided, therefore, into two spaces only, so that $30'$ are necessarily indicated by the vernier; and as 29 spaces on the limb are taken equal to 30 on the vernier, the smallest quantity indicated

$$\text{is } \frac{14^{\circ} 30'}{29 \times 30} = \frac{87^{\circ}}{870} = 1', \text{ as before; and the reading of the}$$

coincidences that indicate the last $30'$ is progressive, like the reading on the limb of the instrument.

In the common ebony sextant, the degree is sometimes divided into four parts, by reason of the increased length of the radius; consequently, when the reading is in a forward direction, fifteen divisions on the vernier occupy the same arc as fourteen on the limb; and the smallest quantity indicated thereby is

$$\frac{3^{\circ} 30'}{14 \times 15} = \frac{21^{\circ}}{210} = 1'; \text{ but the brass sextants made and}$$

divided by the best makers, have the minute subdivided into twenty, fifteen, ten, or even five seconds, according to the length of the radius, by means of a vernier with divisions and subdivisions, acting with divisions and subdivisions on the limb, which is a refinement of the original invention, introduced by Troughton, in consequence of the superior excellence of modern dividing. We have now before us one of

Ramfden's best brass sextants of $9\frac{1}{4}$ inches radius, on the limb of which the degree is divided into three parts, and 40 divisions on the arc of the vernier measure 39 divisions

$$\text{on the limb; therefore } \frac{13^{\circ}}{39 \times 40} = \frac{780'}{1560} = \frac{46800''}{1560} = 30''$$

is the smallest quantity that the vernier will indicate, and every alternate stroke thereon counts one minute as the coincidence advances. This mode of reading the vernier doubles its former accuracy. But on the limb of this same instrument, the late Mr. W. Walker prevailed on Mr. Troughton to divide a second arc, within the former, which by our measurement is only of nine inches radius: in this inner arc, which reads with the inner arc of the vernier, the degree is first divided into halves, and then each half is subdivided into five smaller divisions, by shorter strokes very delicately cut, so that the degree is divided into ten small spaces, of $6'$ each, which are to be read before the vernier's subdivision of one of these spaces is examined. On the scale of the inner vernier are 72 small divisions, co-extensive with 71 on the limb; and as each of these is $6'$, we have $71 \times 6' = 426'$, or $25560''$ for the whole arc of measurement: consequently

$$\frac{25560''}{71 \times 72} = \frac{25560''}{5112} = 5'' \text{ is the smallest quantity that can}$$

be indicated by such a vernier, and accordingly we observe on the scale of the Vernier twelve small or subdividing spaces between each minute stroke; i. e. every twelfth stroke is a long one, and they are numbered 1, 2, 3, &c. up to 6, which is the value of one of the smallest divisions on the limb, and

consequently the value of each subdivision on the scale is $\frac{1}{12}$ of $1'$, or $5''$: and yet, by the help of a high magnifier, placed in the centre of an illuminating reflector of plaster of Paris, this small quantity may be clearly discriminated. When Ramfden first saw this wonderful application of the powers of the dividing engine, he called his workmen together, to witness what he at first considered the folly of attempting greater accuracy than was practicable; but a close examination of the divisions convinced him, that his preconceived opinion had stood in the way even of his own improvements.

Sometimes a divided head or nut has been fixed on the end of the tangent-screw of flow motion, particularly by the older makers of pillar and mural astronomical quadrants, in order to subdivide the divisions of the vernier, as may be seen at Greenwich, Richmond, and other observatories; but when this apparatus has been in use some time, the parts become loose and inaccurate, even allowing that the measuring screw itself can be considered as perfect in all respects. On an examination of some of Graham's, the Sissons' and Bird's quadrants, we find that though the accuracy of $1'$ is professed by the construction, yet very little dependence can be placed on such professed accuracy after the parts have been for years in use. Of this conclusion Ramfden was no doubt sensible, when he introduced into his larger instruments the microscopic readings, with a good screw at the focus of the eye-piece of a compound microscope, where there is not so much stress on the screw as at the periphery of the arc, where the screw forms also a part of the clamping apparatus. To this adoption of the use of a compound microscope, in conjunction with the subsequent improvements in the art of dividing, much of the claim to superior excellence in our English astronomical instruments is to be attributed, which claim is still further supported by the invention of the achromatic object-glass and improved eye-pieces of the telescopic portion.

Hitherto we have considered the principle and application of a single vernier only, which is in itself an useful and beautiful contrivance; and, as we have said, may be applied with advantage to subdivide a straight line; as, for instance, the scale of a barometer into hundredth parts of an inch, or the scale of Dollond's divided object-glass micrometer into the five-hundredth parts, or more; but with an entire circle that is graduated all round, the accuracy of an observation is greatly augmented, may be ensured, by the use of different verniers reading at different parts of the limb at the same time. At first two diametrically opposite verniers were introduced, as has been asserted, by one of the Sissons, though, we understand, not with a view to reading at opposite sides of the circle, by way of correcting the observation by an average; seeing that the remote end of the vernier bar had only a single stroke answering to zero of the other; but subsequently, in transit and other instruments used with a spirit-level, the double vernier became a valuable appendage, particularly when the construction of the instrument admitted of inversion of the position of the axis, so as to procure a double observation; and thence the true zero of the graduation of the measuring limb. This useful property was extended, we believe, by Troughton, first by introducing four, and then, with equal advantage, three equidistant verniers of similar powers. We have shewn the great use of additional verniers, at considerable length, under our article CIRCLE, particularly with respect to the property that three possess of correcting for the excentricity as well as inequality of the divisions of a circular instrument; and that as great accuracy may be expected from one crossed observation with Troughton's reflecting circle, or from a pair of reversed observations with a theodolite, with either circle, that has three verniers, as can be obtained by

a repetition of observations on the repeating circle; for, by the mode in which Troughton's circular instruments are used, the readings will be had at six different points of the circle, though very little time is expended in making the observations. It is hardly necessary to add here, that when an instrument is of the reflecting kind, its divisions are doubly numerous for the same radius, when compared with an instrument that measures only by direct vision; and that therefore the divisions on the vernier must be calculated to have their dimensions accordingly. In Troughton's reflecting circle of five inches radius, the degree is divided into three parts, and fifty-nine of these are commensurate with sixty on the scale of each of the three verniers; therefore the excess of a space on the limb over one on the vernier is

$$\frac{19^{\circ} 40'}{59 \times 60} = \frac{70800''}{3540} = 20'', \text{ which is the smallest quantity}$$

that a single vernier will indicate; but as there are six readings in the crossed observation, which observation annihilates the errors of zero, and of the darkening glasses when used, it is to be inferred that the result will be accurate to $\frac{20''}{6}$, or little more than *three seconds*, if we disregard the

probable errors of reading, and of taking contacts in the observation, common to all instruments. The figures of the vernier scales in this circle count both ways, from each end, because the figures read both to the right and left of zero on the limb, but there can be no mistake if the figures of the vernier are counted the same way that the limb of the circle reads. Formerly the zero of the vernier was placed at the middle of its scale; and when it read out at one end, it commenced at the other, and finished again in the middle; but this method, being liable to misapprehension, is now discontinued.

In an eighteen-inch astronomical circle, by Troughton, at present under our examination, which has four verniers at equal distances, and turns in azimuth, the degree is divided by Engine into twelve divisions, of which 59 fill the same arc as 60 on the verniers respectively; hence we have $59 \times 5' = 295'$, or $17700''$ for the numerator, and $59 \times 60 =$

$$3540 \text{ for the denominator, and } \frac{17700''}{3540} = 5'', \text{ the smallest}$$

quantity that one vernier will indicate; and accordingly the space between zero and 1' on the vernier is subdivided in 12 smaller spaces, so that each successive coincidence will mark out 5'' on each separate vernier; but as there are four verniers, and as the circle will reverse in position by means of the azimuthal motion, there will be virtually eight readings from which to take an average of 5'', so that the probable accuracy resulting from such average comes *within the seconds*, and would have done so if there had been only three verniers. Hence the advantage gained over the average of the verniers by microscopic readings, is probably not so great as is generally supposed.

VERNIO, in *Geography*, a town of Etruria; 11 miles N.W. of Pistoia.

VERNIS MARTIN. See *Copal VARNISH*.

VERNISH. See *VARNISH*.

VERNISSON, in *Geography*, a river of France, which runs into the Loing, near Montargis.

VERNODUBRUM, in *Ancient Geography*, a river of Gallia Narbonensis. Pliny.

VERNOIL, in *Geography*, a town of France, in the department of the Mayne and Loire; 14 miles S.E. of Baugé.

VERNON, in *Biography*, an English singer, brought up

at St. Paul's under Savage, was selected from among the choristers of that cathedral, in 1750, to perform the part of Puck the fairy in *Queen Mab*. When his voice broke into a tolerable tenor, he was engaged at Drury-lane theatre to supply the place of Lowe, who was degraded into a singer at Sadler's Wells and Cuper's Gardens. Vernon, with a voice much inferior to that of Lowe at his best, was a much better musician and actor, and had not only all Lowe's parts assigned to him at Drury-lane, but succeeded him at Vauxhall, where, and at the theatre, he continued to perform till the time of his death.

Vernon was not only the professional successor to Lowe, but heir to his imprudence and debauchery.

VERNON, in *Geography*, a town of France, in the department of the Eure, on the south side of the Seine; 15 miles E.N.E. of Evreux.

VERNON, formerly *Hinfsdale*, a town of America, in Windham county and state of Vermont, on the W. bank of Connecticut river; containing 1159 inhabitants.—Also, a town of Suffolk county, in the state of New Jersey, 21 miles N.E. of Newtown; containing 1708 inhabitants.—Also, a town of Trumbull county, in the district of Ohio; containing 606 inhabitants.

VERNON, *Mount*. See *MOUNT Vernon*.

VERNONBURG, a town of the state of Georgia; 11 miles S. of Savannah.

VERNONIA, in *Botany*, was so named by Schreber, in memory of Mr. William Vernon, fellow of St. Peter's college, Cambridge, who towards the end of the seventeenth century made a voyage to Maryland, in company with Dr. David Kreig, a German physician, of which botany was the principal object. Their herbarium, consisting, it is said, of several hundred new plants, came into the possession of Sir Hans Sloane, and contributed to enrich the Supplement, or third volume, of Ray's *Historia Plantarum*. A North American genus therefore is peculiarly proper to commemorate Mr. Vernon; whose merits as an accurate and industrious English botanist are, moreover, recorded by Ray in the preface to his *Synopsis*, ed. 2d, and his name often occurs in the cryptogamic part of that work. We find no further mention of this gentleman, nor does he appear any where as an author.—Schreb. Gen. 541. Willd. Sp. Pl. v. 3. 1632. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 502. Michaux. Boreal-Amer. v. 2. 94. Pursh 511.—Clafs and order, *Syngeftra Polygamia-equalis*. Nat. Ord. *Compositæ capitata*, Linn. *Cinaræcephalæ*, Juss.

Gen. Ch. *Common Calyx* ovate, imbricated, with numerous, ovato-lanceolate, pointed, coloured scales. *Cor.* compound, uniform, all the florets, tubular, equal and perfect, of one petal, funnel-shaped; the tube inflexed; limb with five recurved segments. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen oblong; style thread-shaped, the length of the stamens; stigmas two, reflexed. *Peric.* none, the calyx remaining unchanged. *Seeds* solitary, ovate. Down capillary, coloured, sessile, longer than the calyx, surrounded at its base with a very short crown, of many chaffy bristles. *Recept.* naked, flat.

Eff. Ch. *Receptacle* naked. *Calyx* ovate, imbricated. Florets tubular, five-cleft. Seed-down double; the outer chaffy, short; inner capillary.

The species of this genus, as far as they were known to Linnæus or Jusseu, were referred by both to *SERRATULA*; see that article and *LIATRIS*. These genera differ very clearly from *Vernonia* in their scatheary seed-down, destitute of surrounding scales or bristles, and the first of them has, moreover, either a scaly or a villous receptacle. Seven spe-

cies of *Vernonia* have been determined, all of them, except one, natives of North America, and all herbaceous and perennial, except that one, which is annual and of East Indian origin.

1. *V. noveboracensis*. Long-leaved *Vernonia*. Willd. n. 1. Ait. n. 1. Pursh n. 5. Bigelow Bolt. 187. (*Serratula noveboracensis*; Linn. Sp. Pl. 1146. *S. noveboracensis maxima*, foliis longis ferratis; Dill. Elth. 355. t. 263. Pluk. Phyt. t. 109. f. 3; see Dill.)—Leaves lanceolate, rough, finely ferrated. Corymb level-topped. Calyx-scales with slender points.—By road-sides, and in old pastures, from Canada to Carolina, flowering from August to October. *Pursh*. Stem four or five feet high, erect, furrowed, purplish, clothed with abundance of scattered, nearly sessile, long and narrow leaves; paler underneath. Flowers numerous, dark purple, turning nearly black in decay. Scales of the calyx ending each in a fine slender awn. *Bigelow*.

2. *V. præalta*. Tall *Vernonia*. Willd. n. 2. Ait. n. 2. Pursh n. 4. (*Serratula præalta*; Linn. Sp. Pl. 1146. Mill. Ic. t. 234. *S. virginica*, pericæ folio, subtus incano; Dill. Elth. 356. t. 264. *Eupatoria virginiana*, ferratulæ noveboracensis latioribus foliis; Pluk. Almag. 141. Phyt. t. 230. f. 6.)—Leaves lanceolate, ferrated; downy beneath. Corymb level-topped. Calyx-scales ovate, pointed.—By road-sides and the borders of woods, from New England to Carolina, flowering from August to October.—A tall rough-looking plant. *Pursh*. Flowers purple. Calyx-scales with shorter points than the last; and leaves more downy beneath. Linnæus did not well distinguish these two species, nor have we been able to compare authentic specimens.

3. *V. glauca*. Glaucous-leaved *Vernonia*. Willd. n. 3. Ait. n. 3. (*Serratula glauca*; Linn. Sp. Pl. 1146. *S. marilandica*, foliis glaucis, cirsiî instar denticulatis; Dill. Elth. 354. t. 262.)—Leaves lanceolate, ferrated; glaucous beneath. Corymb repeatedly compound, level-topped. Calyx-scales ovate, acute.—Native of North America. This is omitted by Pursh, nor have we seen any certain specimen. Dillenius represents it with broader leaves than either of the former. A garden specimen communicated by sir Joseph Banks under this name, has smooth leaves, glaucous beneath; but the points of its calyx-scales are as long as in the first. Perhaps Willdenow's specific characters, almost entirely founded on the calyx, may be fallacious. The points of the scales appear variable in length, in all the specimens that have fallen in our way, all of which we should esteem one species, answering best, on the whole, to the characters of *V. noveboracensis*. The roughness of the leaves in any of them is but slight.

4. *V. fasciculata*. Tufted *Vernonia*. Michaux Boreal-Am. v. 2. 94. Pursh n. 3.—“Leaves linear, elongated, sparingly ferrated. Flowers corymbose, erect, crowded. Calyx ovate, smooth, with pointless scales.”—Native of meadows in the Illinois country. *Michaux*. In Virginia, flowering from August to October, the flowers small. *Pursh*. This, at least, should seem to be a distinct species.

5. *V. angustifolia*. Narrow-leaved *Vernonia*. Michaux *ibid.* Pursh n. 2. (*Chrysocoma graminifolia*; Walt. Carol. 196.)—Leaves crowded, linear, elongated, nearly entire. Corymb somewhat umbellate. Calyx-scales with little rigid points.—In barren sandy woods from Virginia to Georgia, flowering in August and September. Flowers the size and figure of *V. præalta*. *Pursh*. Considering how much some plants, nearly related to this, though of different genera, are liable to vary in the breadth of their foliage, we cannot but suspect this as a doubtful species, like some of the foregoing.

6. *V. oligophylla*. Few-leaved *Vernonia*. Michaux *ibid.*

Pursh n. 1. (*Chrysocoma acalis*; Walt. Carol. 196.)—“Stem simple, nearly naked. Leaves ferrated; radical ones oblong-ovate; the rest lanceolate. Corymb panicled.”—Native of South Carolina. Flowers purple, as in all the preceding. *Pursh*. Michaux distinguishes two varieties; one denominated *verna*, in which both flowers (of two that we presume stand together) are stalked; the other *autumnalis*, in which one of these flowers is nearly sessile.

7. *V. anthelmintica*. Worm-feed *Vernonia*. Willd. n. 4. Ait. n. 4. (*Conyza anthelmintica*; Linn. Sp. Pl. 1207. *Scabiofa conyzoides*, foliis latî, dentatis, femine amaro lumbicos enecante; Burm. Zeyl. 210. t. 95. *Cattu-ichiragam*; Rheede Hort. Malab. v. 2. 39. t. 24.)—Leaves elliptical, ferrated, roughish, tapering at each end; moist downy beneath. Flowers terminal, about three together.—Native of various parts of the East Indies. The seeds were sent to Kew, in 1770, by M. Richard, and have been received since from time to time. This species, well removed hither by Willdenow from *Conyza*, is annual, or, in our stoves, biennial, flowering in summer. The stem is branched, several feet high, bushy, downy. Leaves flat, coarsely ferrated, two or three inches long, veiny, more or less downy on both sides. Flowers pale purple, larger than any of the American species. Calyx-scales each tipped with a linear leafy point, very various in length. Seed-down exactly answering to the generic character, and well described by Burmann. The seeds powdered, and drank with warm water, are used in India to kill intestinal worms in children.

VERNOSOLA, in *Ancient Geography*, a place in Gallia Aquitannica; 15 miles from Aquæ Siccæ. Anton. Itin.

VERNOUX, in *Geography*, a town of France, in the department of the Ardèche; 14 miles S. of Tournon.

VERODUNUM, in *Ancient Geography*, a town of Belgic Gaul, on the route from Durocorvum to Divodurum, between Ad-Fines and Axuenna. Anton. Itin.

VEROFABULA, a town of Asia, in Phœnicia.

VEROLAMUM, or VERULAMIUM, a town of Great Britain, mentioned in several routes of Antonine, situated between Durocbrivæ or Dunstable, and Sullioniacæ or Brockley Hills. Antiquaries have no dispute about the situation of this town, which was undoubtedly at Verulam, near St. Albans. It was a very flourishing and populous city in the Roman times, and honoured with the title and privileges of a municipium or free city. Dion Cassius says that it was the capital of the Catuellani, whom Ptolemy calls Catyuechiani.

VEROLI, in *Geography*, a town of the Popedom, in the Campagna di Roma, the see of a bishop, under the pope; it contains eight churches and three convents; 3 miles S. of Alatri. N. lat. 41° 42'. E. long. 13° 20'.

VEROMANDUI, in *Ancient Geography*, a people of Belgic Gaul, according to Cæsar and Pliny. Their habitation was S. of the Nervii, N. of the Suefones, E. of the Ambiani, and W. of the forest of the Ardennes. They were able to furnish no more than 1000 men in a common war against the Romans.

VEROMETUM, a town of Great Britain, in the sixth Iter of Antonine, between Ratæ and Leicester, and Margidunum, near East Bridgeford; placed near Wiltoughby.

VERON, in *Geography*, a town of France, in the department of the Yonne; 5 miles S.S.E. of Sens.

VERONA, in *Ancient Geography*, a town of Italy, in Venetia, towards the W., upon the Athesis. It was founded by the Eugeniens, from whom it passed to the Cenomans, who driven from Brixia, settled here. Martial says, that Verona was no less indebted to the birth of Catullus than Mantua to that of Virgil. Under the reign of Vitellius, the partisans

partisans of Vespasian made it a place of arms. Towards the year 249 A.D., the emperor Philip was put to death in this city, or its environs, by order of Decius. Under the empire of Carus, in 284, Sabinus Julianus revolted and took possession of Verona, but he was defeated by the emperor near the walls of the city. It shut its gates against Constantine, when he took possession of the empire against Maxentius; but opened them after the defeat of the latter to the conqueror, who treated the inhabitants with moderation after his victory. In 568, Verona was transferred to the Lombards. See the next article.

VERONA, in *Geography*, a city of Italy, and capital of the Veronese, the see of a bishop, situated on the Adige. It is fortified in the ancient manner, and defended by three castles; two of which, namely, St. Felix and St. Pietro, stand on a hill; and the third, called Il Castello Vecchio, and a kind of citadel, lies in a plain along the river Adige, which runs through the city, and over which are four stone bridges, of which the principal, near the last-mentioned castle, is 348 feet long. The city makes a better appearance by its delightful outlets than within, most of the streets being narrow, crooked, and dirty, and the houses but mean. The number of its inhabitants is now computed to amount to nearly 50,000, but formerly was much greater. The best street is that called the Corso, which is pretty long. The cathedral is an old building. One of the finest churches is that of St. Giorgio, belonging to the Benedictines. The palace in which the society, or academy, of Philharmonics assemble, as also the society of the Philati, in order to the revival and improvement of martial exercises, is remarkable, particularly on account of the great collection of all the ancient inscriptions and monuments in the Etrurian, Punic, Egyptian, Greek, and Latin languages, found or brought here for a great many years past. The largest square in the city is the Piazza d'Armi, in which is a marble statue, representing the city of Venice. In the Palazzo della Regione, or the Guildhall, are the statues of five illustrious natives of Verona, *viz.* Catullus, Marcus Æmilius, Cornelius Nepos, the elder Pliny, and Vitruvius; but the most valuable piece of antiquity here is the celebrated Roman amphitheatre, (see AMPHITHEATRE,) which so far exceeds all others, the steps, or seats, on which the people sat, being still entire; though, in reality, but little of it appears ancient, having been carefully repaired, from time to time, at the city's expence. The learned count Maffei computed that it held 22,184 spectators: the outward wall and the upper story are wanting. Near this city is a delightful place, called Campus Martius, at present used for the annual fair; it is constructed in a quadrangular form, with four gates, and in the centre, along the stands and booths, which are placed in a direct line, one may see all the four gates. The trade of this city is not improved as it might be, by supplying other countries with the medicinal plants growing on Monte Balbo, olives, oil, wine, and very good linen, sewing silk, and woollen stuffs. The Scaligeri were lords of this city for 170 years; and one of them, for his greater security, and to keep the city in awe, built the Castello Vecchio, and the large stone bridge. In 1387, Galeazzo Maria, first duke of Milan, drove out the Scaligeri, and usurped the sovereignty of this city; but in the year 1409, the Venetians became masters of it. In 1796, Verona was taken by the French; 60 miles W. of Venice. N. lat. 45° 37'. E. long. 8° 9'.

VERONESE, ALESSANDRO, called *L'Orbetto*, in *Biography*, was born at Verona in 1582. He acquired the name of Orbetto, from having been, whilst a boy, the conductor of a blind beggar; from this condition he was rescued by Domenico Riccio, and instructed in the art of painting, for

which he had exhibited considerable ability. After passing some years with Riccio, of whom he became the rival rather than the scholar, he went to Venice, and there studied under Carlo Cagliari, and acquired an excellent idea of colouring. He then went to Rome, and drew attentively, and in the end composed a style of his own, in which he attempted to combine the excellencies of the two schools in which he had studied, and in a great degree succeeded.

He had a ready imagination, so that frequently he proceeded to paint his smaller works without any preparatory sketch. We seldom see in this country any other than small productions of this celebrated master, and those generally painted upon marble, but it is not upon them that his fame is founded. Lanzi, speaking of a picture of his in the church of S. Stefano in Verona, called the Forty Martyrs, says, "it is a work which, in the impart of colour, and the keeping, has the quality of the Lombard school; it partakes of the Roman in design and expression, and of the Venetian in colouring. It is the most studied, the most finished, the gayest, that he ever made, with a degree of beauty in the heads, almost rivalling those of Guido; and with so much art in the composition, that all is understood, even the multiplied circumstances which are introduced in the background of the picture."

There is also another fine picture by him at Verona, a Pietà, in the church of the Misericordia, which is esteemed one of the very finest in that city. He maintained himself fully in competition with Andrea Sacchi and Pietro da Cortona, in the church of La Concezione; and he painted several other pictures for public buildings in Rome. He died at Rome 1648.

VERONESE, PAOLO. See CAGLIARI.

VERONESE, in *Geography*, a province of Italy, so called from its capital, Verona, bounded on the north by the Trentino, on the east by the Vicentino, on the south and south-west by the Mantuan, and on the west by the lake of Garda; about 50 miles in length, and 25 in breadth. The soil is fertile, and produces plenty of silk, corn, wine, oil, and the most delicious fruits. The Veronese was anciently a Roman colony; afterwards it made a part of Lombardy. After divers revolutions, it became the property of the house of Este, from whence it fell to the dukes of Milan; and in 1409, to the Venetians.

VERONICA, a term abbreviated from *veronica*, of *vera-ikon*, *q. d.* true image, and applied to portraits, or representations of the face of our Saviour on handkerchiefs. Veronics are imitations of that celebrated original one, preserved with great veneration at St. Peter's in Rome; and imagined by some to be the handkerchief laid over our Saviour's face in the sepulchre.

The first mention we find of this famous relic is in a ceremonial compiled in 1143, dedicated to pope Celestine, by Benedict, a canon of St. Peter's; but there is no mention made of the time when it was brought to Rome. A feast is kept in honour thereof in most churches, on the Tuesday in Quinquagesima week.

It is to be observed, that the name veronica is only given to such handkerchiefs as represent no more of our Saviour than his face; for such as represent his whole body, as that of Besançon, which shews his fore-part at length; and that of Turin, which represents both his fore and hind-part, as having covered him all over, were never called by this name.

The painters sometimes represent the veronica as held up by an angel, but most commonly by a woman, which woman the common people imagine to be a faint, called St. Veronica; a person of that name having been sup-

posed, about the ninth century, to have presented her handkerchief to our Saviour as he went to Calvary, to wipe his face, when the picture was miraculously impressed upon it. This woman, it was added, was the person troubled with the flux of blood mentioned in the Gospel; and accordingly, she was soon joined with St. Fiacrius, and invoked together with him against the hemorrhoids. And hence the establishment of feasts in honour of St. Veronica, in the churches dedicated to St. Fiacrius.

The milliners have taken St. Veronica, or, as they call her, St. *Venisse*, or *St. Venecia*, or *Venisa*, for their tutelary saint.

VERONICA, in *Botany*, an old, but not classical, Latin name, whose derivation has occupied and perplexed etymologists as much as any upon record. Linnæus thought it a corruption of *Vetonica*, which, as professor Martyn observes, confounds it with *Betonica*. The same learned writer gives us a Greek etymology, from Hoffmann, *ἑρπονισ*, composed of *εἶπος*, to bear, and *νικω*, victory, or *distinction*, as if we should say in English, *bearing the bell*, on account of its beauty. But we doubt whether this be more than a pun. Its common etymology is of a mule kind, between Greek and Latin, from *verus*, or rather *vera*, true, and *ωνος*, a figure; and this, illiterate and barbarous as it is, has the sanction of the superstitious legend of St. Veronica, whose handkerchief is recorded to have received the impression of our Saviour's face, as he used it, in bearing his cross to the place of his crucifixion. But we find nothing analogous in any of the herbs which has borne this name, nor any character, true or false, stamped upon them, except that of their own peculiar beauty. Ambrosinus says the word is German, and originated in the druggists' shops of that country, though he favours the idea of its being corrupted from *Vetonica*, our *Betonica*, or *Betony*. The chief object of this controversy is to learn the true pronunciation of the name in question. If there be any truth in its Greek origin, the *i* must be long; but if otherwise, the analogy of *Betonica* may justify the usual practice, of throwing the accent on the *o*.—Linn. Gen. 12. Schreb. 15. Willd. Sp. Pl. v. 1. 54. Vahl Enum. v. 1. 55. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 15. Prodr. Fl. Græc. Sibth. v. 1. 5. Ait. Hort. Kew. v. 1. 26. Brown Prodr. Nov. Holl. v. 1. 434. Pursh 10. Tourn. t. 60. Juss. 99. Lamarck Dict. by Poiret, v. 8. 505. Illustr. t. 13. Gärt. t. 54. (Hebe; Juss. 105.)—Class and order, *Diandria Monogynia*. Nat. Ord. *Personate*, Linn. *Pedicularæ*, Juss. *Scrophularinæ*, Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four, rarely five, deep, lanceolate, acute, sometimes obovate, permanent segments. Cor. of one petal, wheel-shaped; tube almost as long as the calyx; limb flat, in four deep, ovate, unequal segments, the lowermost narrowest, the opposite one broadest. Stam. Filaments two, inserted into the tube of the corolla, spreading, ascending, tapering downwards; anthers roundish-oblong. Pist. Germen superior, compressed; style thread-shaped, the length of the stamens, declining; stigma simple, obtuse. Peric. Capsule inversely heart-shaped, or somewhat elliptical, compressed in the upper part, of two cells, and two, more or less cloven, valves. Seeds numerous, roundish.

Efl. Ch. Corolla four-cleft, wheel-shaped; its lower segment narrowest. Capsule superior, of two cells.

Obf. Linnæus remarks, that the tube of the corolla, though in most instances very short, in some spiked species is of considerable length. Mr. Brown particularly indicates *V. virginica* and *sibirica*, as having a tube longer than their five-cleft calyx, and hence belonging to PÆDEROTA,

if that genus, which moreover scarcely differs from WULFENIA, ought to be retained; see those articles. The calyx is five-cleft in some other species, as *multifida*, and several neighbouring ones, though others of the same tribe have a four-cleft calyx. Such a difference therefore furnishes merely, in this case, a specific, not a generic, distinction.

Veronica is a very natural genus. The stem, usually herbaceous, is in some few instances shrubby. Leaves opposite, simple, mostly undivided, sometimes many-cleft; in a few cases whorled; those which accompany the flowers, whether true bractæe, or the proper foliage of the plant, the flowers being axillary, are nearly all alternate. Partial flower-stalks alternate, single-flowered. Calyx more or less unequal. Corolla blue, rarely white or pale red, marked with simple, radiating lines, not reticulated. The species are very numerous, natives of the cold or temperate regions of Europe, America, New Holland, and New Zealand. Seventeen are wild in Britain; about twenty-five exotic ones are cultivated in the gardens, being mostly perennial and hardy. We have several to add to those of Linnæus and Willdenow, and even to the more copious catalogue of Vahl, amounting to sixty-eight species. The fourteenth edition of Linn. Syst. Veg. contains but forty. They are commodiously and naturally arranged by their inflorescence.

Sec. 1. *Clusters terminal. Leaves more or less whorled.*
1. *V. sibirica*. Siberian Speedwell. Linn. Sp. Pl. 12. Willd. n. 1. Vahl n. 1. Ait. n. 1. (*V. spicata altissima, foliis verticillatis*; Am. Ruth. 20. t. 4.)—Corolla dense, with nearly sessile flowers. Tube of the corolla twice as long as the five-cleft calyx. Leaves from five to nine in a whorl, lanceolate, sessile.—Native of Siberia; sent to Kew by professor Thunberg, in 1779. A hardy perennial, not rare in curious gardens, flowering in July and August, and rising to the height of five feet. The numerous whorled, finely serrated, smooth leaves, and the long, dense, upright spikes, rather than clusters, of innumerable pale blue, often white, tubular flowers, with long, projecting, capillary stamens and style, well mark this fine species.

2. *V. virginica*. Virginian Speedwell. Linn. Sp. Pl. 13. Willd. n. 2. Vahl n. 2. Ait. n. 2. Pursh n. 1. "Hoffm. in Comm. Goett. v. 15. 112. t. 1." (*V. virginiana procerior, foliis ternis, quaternis, &c.*; Pluk. Phyt. t. 70. f. 2.)—Clusters obscurely whorled, with nearly sessile flowers. Tube of the corolla twice as long as the five-cleft calyx. Leaves four or five in a whorl, elliptic-lanceolate, stalked.—On calcareous hills of North America, in sunny exposures, flowering from July to September. Perennial. Spikes long; white or bluish-coloured. On the mountains of Virginia, I observed a very tall-growing variety, with purple flowers, extremely beautiful. Pursh. This is usually of more humble stature than the preceding, and more frequent in gardens. The leaves are fewer in a whorl, broader, and, in our specimens, downy beneath. Clusters, or spikes, several at the top of the stem.

3. *V. foliosa*. Leafy Hungarian Speedwell. Vahl n. 3. "Waldst. et Kitaib. Hung. v. 2. 106. t. 102."—Leaves three in a whorl, ovate, doubly serrated. Calyx four-cleft. Native of Hungary. Stem about two feet high, erect, simple, hairy below. Leaves on short stalks, acute, veiny beneath; the lower ones downy, especially the rib and margin; uppermost rather lanceolate and smooth. Lower clusters three together; upper ones opposite or alternate. Bractæe linear. Corolla of a violet-blue. Capsule inversely heart-shaped. Vahl.

4. *V. maritima*. Sea-side Speedwell. Linn. Sp. Pl. 13. Fl. Lapp. ed. 2. 5. Vahl n. 4. Willd. n. 4. Fl. Dan. t. 374? (*V. mas surrecta clatior*; Barrel. Ic. t. 891. V. spuria;

VERONICA.

spuria; Poit. et Turp. Paris. 19. t. 18. *Lyfimachia cæruleo flore*; Cluf. Hist. v. 2. 52. *L. cærulea hortensis*; Lob. Ic. 344. Ger. Em. 477. f. 9.)—Clusters terminal, with nearly sessile flowers. Leaves stalked, three in a whorl, unequally and sharply serrated.—Native of barren dry ground, near the sea-coast, in the north of Europe. Linnæus observed it frequently on the confines of the Lapland Alps, near the North sea, though no where more abundantly than on the sea-coast near Tornea. We must take his plant as a fixed point, by which to determine this much-confused species; which, though often seen in gardens, flowering in the early part of summer, does not find a place in the *Hort. Kew.* The old wooden cut, which is the very fame in all the old authors above cited, represents the Linnæan plant most perfectly, even better than the plate of *Fl. Dan.*, whose leaves are too broad, and too finely serrated. The root of *V. maritima* is perennial, and somewhat creeping. Stems two feet high, erect, simple, leafy, round below, quadrangular above, finely downy, though occasionally smooth in a garden, the angles being the first part that becomes so. Leaves three or four in a whorl, on elongated rather slender stalks, spreading and rather dependent, linear-lanceolate, pointed, two and a half or three inches long, copiously, deeply, unequally, and very sharply serrated, either finely downy, or quite smooth, on both sides; accompanied by axillary tufts of a few linear, or awlshaped, small, serrated leaves. Flowers blue, in one large, central, dense spike, accompanied by several surrounding smaller ones, from the bosoms of the uppermost leaves, sometimes terminating small branches. Calyx unequally four-cleft, narrow, longer than the tube of the corolla.—A singular variety, as it is supposed, of this is described in Linn. Amoen. Acad. v. 3. 35. t. 2, by the name of *V. spuria*, and preserved in the Linnæan herbarium. The leaves are deeply and variously pinnatifid and jagged; flowers smaller than usual in *V. maritima*, and always barren. Linnæus conceived it to be a mule, from the pollen of *Verbena officinalis*, which grew near the *Veronica maritima* in his garden. We can neither confirm nor disprove this opinion. The plant must not be confounded with *V. spuria*, hereafter described.

Three dried specimens from Ehrhart's *Herbæ* are before us, *V. glabra*, n. 11; *nitida*, n. 21; and *clatior*, n. 31. The first is considered by Willdenow as the identical *V. maritima*, and indeed agrees well with *V. recta cærulea*, Bess. Eyt. vern. ord. 5. t. 10. f. 2. cited by C. Bauhin as the same with our *maritima*; but the leaves are shorter and more ovate, with far less taper serratures than the Linnæan specimen, or the authentic old wooden cuts; being more of the shape of *Fl. Dan.* t. 374, though with much broader serratures. The stem and leaves are very smooth; partial flower-stalks elongated and slender, nearly smooth; tube of the corolla about twice as long as the calyx, which last seems an important distinction, should it prove constant.—*V. nitida*, Ehrh. n. 21, is the top of a large luxuriant plant, whose very smooth leaves are opposite, or aggregate, not distinctly whorled, though its lower ones perhaps might; their form broad-ovate, strongly and sharply serrated, their length one and a half or two inches. Clusters numerous and long; the partial flower-stalks a little downy, longer than the calyx, which is full as long as the tube of the corolla. If these characters may be depended on, as in other plants, the two specimens in question must be distinct from each other and from *maritima*. *V. clatior*, n. 31, most unaccountably referred by Willdenow to *longifolia*, is more near *maritima* than either of the others, having merely broader, and less deeply serrated, leaves, and agreeing as nearly with *Fl. Dan.* t. 374, as a cultivated specimen usually does with a wild one.

Its inflorescence and flowers precisely resemble those of the Linnæan specimen of *maritima*. This is surely *V. spicata* of Rivin. Monop. Irr. t. 97.

5. *V. crenulata*. Notch-flowered Speedwell. "Hoffm. Phytogr. Blätt. fasc. 1. 95." Vahl n. 5.—"Leaves three in a whorl, or opposite, oblong-lanceolate, serrated, downy like the stem. Corolla finely crenate."—A garden plant, perennial, two feet high, with scattered branches in the upper part of the stem. Lower leaves stalked, opposite, rarely three together; upper nearly sessile, alternate, pretty equally and acutely serrated. Clusters hardly six inches long. Bractæes lanceolate. Calyx four-cleft, hairy at the edge. Corolla deep blue, hairy in the throat; its segments waved, minutely crenate. Capsule roundish-ovate, smooth, of four valves. Hoffmann, Vahl. We know nothing of this species, having seen no specimen answering to its name or character.

6. *V. spuria*. Spurious Speedwell. Linn. Sp. Pl. 13. Willd. n. 3. Vahl n. 6. Gmel. It. v. 1. 169. t. 39. (*V. spicata angustifolia*; Bauh. Pin. 246. *Herb. Sberard.* *V. recta vulgaris major*; Cluf. Hist. v. 1. 347. *V. recta verbariorum*; Lob. Ic. 473. *V. affurgens five spicata*; Ger. Em. 628, according to C. Bauhin; but the fame cut is in Clufius, v. 1. 346, who probably has the same species twice.)—Leaves three in a whorl, or opposite, on short stalks, lanceolate, equally serrated, somewhat downy; contracted at each end. Clusters lax.—Native of Siberia and the south of Europe. About the stature of the last, but the stem is round to the top; leaves shorter, equally, though strongly serrated, on much shorter stalks; never more than three in a whorl, often opposite only. Calyx the length of the tube. Vahl records an opinion of our learned friend Dr. A. Afzelius, that this may be a three-leaved variety of *V. longifolia*. Some botanists of the south of Europe, from whom we have specimens, have conceived the same idea. But the real *longifolia* is totally distinct, as we shall hereafter shew.

7. *V. paniculata*. Panicked Speedwell. Linn. Sp. Pl. 18. Willd. n. 45. Vahl n. 7. Ait. n. 31. ("V. dentata; Schmidt Bohem. v. 1. 31." *V. angustifolia, floribus paniculatis*; Amm. Ruth. 24.)—Leaves stalked, three in a whorl, lanceolate, equally serrated, smooth. Stem ascending, paniced with numerous simple clusters.—Native of Siberia, Tartary, and Bohemia. A hardy perennial in this country, introduced by Mr. Hunnemann, in 1797, yet it has never been figured. The herbage is smooth. Stem round, not quite erect. Leaves an inch or more in length, narrow, acute, rather distantly serrated, on shortish stalks. Clusters lax, many-flowered, smooth, on long, axillary, partly leafy, stalks, making a handsome terminal panice. Flowers blue. Vahl is certainly right in removing this species to the present section, near its most natural allies. It is, however, very distinct from the last.

8. *V. complicata*. Folded-leaved Speedwell. "Hoffm. Phytogr. Blätt. fasc. 1. 98." Vahl n. 8.—"Leaves whorled, or opposite, linear-lanceolate, folded, toothed; teeth thickened."—Native of Europe. Perennial. Stem two feet high, erect, slightly zigzag, round, downy in the upper part; the flowering branches nearly opposite. Leaves mostly opposite, rarely three in a whorl, spreading, reflexed; the radical ones elliptical, somewhat hoary, unequally toothed. Bractæes linear-lanceolate. Calyx four-cleft, downy. Corolla blue, hairy in the throat. Capsule inversely heart-shaped, smooth, with four valves. Hoffm. Vahl.

9. *V. brevifolia*. Short-leaved Speedwell. "Waldst. et Kitaib. Hung. t.—" March. à Bieberst. Taur.-Caucas.

VERONICA.

v. 1. 6.—“Leaves three in a whorl, broadly lanceolate, downy, sharply and finely serrated. Calyx and bractæa very short.”—Native of Ikon hills of Caucasus, flowering in May and June. Perennial. Whole herb clothed with fine, rather glaucous, pubescence. Akin to *V. spuria* in *flowers and inflorescence*, but the *leaves* are much shorter and broader, with sharper more copious serratures. *Marfeh.*

Seç. 2. *Clusters or spikes terminal. Leaves opposite.*

10. *V. longifolia.* Long-leaved Speedwell. Linn. Sp. Pl. 13. Fl. Suec. ed. 2. 4. Willd. n. 5, excluding Ehrhart's synonym. Vahl n. 9. Ait. n. 6? “Schrad. Veron. 26. t. 2. f. 1?” (*V. spicata* latifolia; Bauh. Pin. 246. Ger. Em. 628. *V. prima erectior latifolia*; Cluf. Hist. v. 1. 346. *V. major latifolia, foliis splendebus et non splendebus*; Bauh. Hist. v. 3. 283.)—Leaves opposite, ovate, pointed, doubly and sharply serrated, smooth, on very short stalks. Clusters aggregate, erect. Calyx ovate, shorter than the tube of the corolla.—Native of Sweden, Tartary and Austria. Perennial. *Stems* erect, two feet high, leafy, round, either smooth, or finely downy, with minute recurved hairs. *Leaves* two and a half inches long, and nearly one broad, with extremely numerous and sharp, unequal, and often double, serratures. *Footstalks* broad and very short; to the upper leaves scarcely any. *Clusters* rather dense, all erect and crowded, forming a sort of pyramidal panicle. *Partial flower-stalks* slightly downy, for the most part longer than the calyx, whose four segments are broad, ovate, and nearly equal. Tube of the corolla about twice as long as the calyx, and equal to the limb.—Such is the real *V. longifolia*, the Swedish plant of Linnaeus, for which, if we do not greatly err, authors have mistaken the *maritima* of Fl. Dan. t. 374. This latter is actually quoted for *longifolia*, by Mr. Dryander in Hort. Kew. on the authority, we presume, of Schrader, whose work is not within our reach, and therefore we refer to his plate with hesitation. That the above-mentioned plant of Fl. Dan. may be a distinct species from *maritima*, we are readily disposed to allow. But that both of them are perfectly different from our true *longifolia*, and essentially distinguished from it by the much narrower, and more unequal, segments of their calyx, to say nothing of the *leaves* and *footstalks*, is certain. A good figure of the *longifolia* is wanting, John Bauhin's being the best that we can find; as the others are very defective in their foliage. Vahl's description answers better to the so often mentioned *maritima* of Fl. Dan. than to the real *longifolia*. His variety β , *V. spicata urticae folio*, Amm. Ruth. 26, though cited likewise as a variety by Linnaeus, appears to be the true plant, the description agreeing precisely, except the “foliary spike.”

11. *V. incana.* Hoary Speedwell. Linn. Sp. Pl. 14. Willd. n. 6. Vahl n. 10. Ait. n. 3. “Hoffm. in Comm. Goett. v. 15. 123. t. 6.” *Marfeh.* Taur.-Caucas. v. 1. 7. (*V. spicata lanuginosa et incana, floribus cæruleis*; Amm. Ruth. 21.)

β . *V. neglecta*; Vahl n. 11.

Hoary and densely downy. Spike terminal, mostly solitary. Leaves opposite; lower ones stalked, crenate or serrated; uppermost entire, sessile, tapering at the base.—Native of the rocky summits of mountains in Siberia and Tauria, flowering in June. An elegant plant, a foot high, its white pubescence being strikingly contrasted with the dense spikes, rather than clusters, of dark blue flowers. Calyx cottony, with four oblong unequal segments. The leaves certainly vary in acuteness, as well as in the strength of their serratures, and we gladly profit of the hint given by the learned author of the *Flora Taurico-Caucasica*, to consider Vahl's *V. neglecta*, which is frequent in gardens, as a mere

variety. Still we do not concur with the same great authority in thinking the pubescence alone distinguishes this species from *V. spicata*; even though specimens of luxuriant *spicata*, as they appear to us, are pinned by Linnaeus in his herbarium to the genuine wild *incana*.

12. *V. spicata.* Spiked Speedwell. Linn. Sp. Pl. 14. Willd. n. 7. Vahl n. 12. Fl. Brit. n. 1. Engl. Bot. t. 2. Poit. et Turp. Paris. 19. t. 19. Fl. Dan. t. 52. (*V. spicata minor*; Bauh. Pin. 247. Vaill. Paris. t. 33. f. 4. *V. recta minima*; Cluf. Hist. v. 1. 347. Ger. Em. 627. *V. spicata recta minor*; Bauh. Hist. v. 3. 282.)

β . *V. altera erecta angustifolia*; Cluf. Hist. v. 1. 346. (*V. spicata recta major*; Bauh. Hist. v. 3. 282. *V. affurgens, five spicata*; Ger. Em. 628.)

Spike terminal, mostly solitary. Leaves opposite, stalked, bluntnish, with shallow serratures, somewhat downy; the extremity entire. Stem ascending, unbranched.—Native of open, chalky, mountainous, or alpine pastures, throughout moist parts of Europe, from Sweden to Greece, flowering from July to September. The root is creeping, perennial, a little woody. *Stems* from three to ten or fourteen inches high, each bearing usually a single dense spike of dark-blue flowers; but the luxuriant variety β has several spikes. The lower flowers are not sessile. The segments of the calyx are oblong and downy. The whole herb is more or less downy, or finely hairy, but by no means cottony, or hoary, in the manner of the last. The leaves vary in breadth, and are sometimes almost entire.

13. *V. hybrida.* Welsh Speedwell. Linn. Sp. Pl. 14. Willd. n. 8. Vahl n. 13. Fl. Brit. n. 2. Engl. Bot. t. 673. (*V. spicata cambrobritannica, bugulæ subhirfuto folio*; Raii Syn. ed. 3. 278. t. 11.)—Spikes terminal. Leaves opposite, elliptical, obtuse, roughish, unequally and bluntly serrated. Stem nearly erect.—Native of several parts of Europe, but rare. It is found in the Welsh county of Montgomery, as well as in Lancashire. Linnaeus suspected this might be a mule between *V. officinalis* and *spicata*, though surely without authority. It is most akin to the last, but twice as large in every part, with rougher leaves and stem, nor does it alter by culture. The spikes, or rather clusters, are very long and dense, seldom solitary, and consist of innumerable blue flowers.

14. *V. incisa.* Cut-leaved Speedwell. Ait. ed. 1. v. 1. 19. ed. 2. n. 9. Willd. n. 11. Vahl n. 14. “Schrad. Veron. 33.”—Clusters terminal. Bractæas as long as the calyx and flower-stalk. Segments of the calyx linear-lanceolate, longer than the tube of the corolla. Leaves lanceolate, deeply pinnatifid, smooth.—Native of Siberia. The whole habit of this species is very slender. Stem branched, about two feet high, leafy, round, slightly downy. Leaves linear-lanceolate, or variously pinnatifid and cut, very narrow, with axillary tufts of still narrower and much smaller ones. Clusters solitary at the ends of the branches, lax, many-flowered. *Partial stalks* capillary, a little downy, shorter than the calyx, which is four-cleft, unequal, smooth. Bractæas linear, channelled, smooth, various in length, but, in the lower part of the cluster at least, extending beyond the points of the calyx. Corolla tube, with acute segments.

15. *V. laciniata.* Jagged-leaved Speedwell. Ait. ed. 1. v. 1. 19. ed. 2. n. 8. Willd. n. 10. Vahl n. 15. “Schrad. Veron. 32.” (“*V. spuria*; Junghans Ic. Rar. cent. 1. fig. 2, excluding the synonyms.” Willd.)—Clusters terminal. Bractæas as long as the flower-stalk. Segments of the calyx ovato-lanceolate, as long as the tube of the corolla. Leaves linear, pinnatifid.—Native of Siberia. Akin to the last, but the shorter more ovate segments of the calyx afford a clear distinction. The clusters are very long, and their

VERONICA.

their lower *bractææ*, much longer than the upper, partake of the nature of leaves.

16. *V. pinnata*. Wing-leaved Speedwell. Linn. Mant. 24. Willd. n. 9. Vahl n. 16. Ait. n. 7. "Schrad. Veron. 32. Laxmann in Act. Petrop. ann. 1770. 553. t. 29. f. 1. Hoffm. in Comm. Goett. v. 15. 130. t. 10."—Clusters terminal. Segments of the calyx lanceolate. Leaves pinnatifid, with linear, acute, divaricate, entire or toothed, segments.—Found by Laxmann in Siberia, and by Dr. Sibthorp on mount Athos.—Like the two last, this is a hardy perennial in the gardens, flowering in June and July; but though they have been introduced about forty years, they are not become common. The *foliage* of the prefest species abounds with copious, narrow, often capillary, segments. *Clusters* numerous, from a span to a foot long, consisting of a profusion of handsome sky-blue *flowers*, whose *calyx* is smooth, almost equally four-cleft. *Bractææ* linear, various in length. *Capfulæ* inversely heart-shaped, a little longer than the permanent calyx, tumid, with four valves.

17. *V. bellidioides*. Daify-leaved Speedwell. Linn. Sp. Pl. 15. Mant. 316. Willd. n. 21. Vahl n. 17. Ait. n. 12. (V. n. 543. t. 15. f. 1; Hall. Hist. v. 1. 235. V. alpina, bellidis folio, hirsuta; Bauh. Prodr. 116.)—Cluster corymbose, terminal, hairy, of few flowers. Leaves obovate, crenate. Stem simple, ascending. *Capfulæ* elliptical, abrupt, emarginate.—Native of the Alps and Pyrenæes, flowering in June and July. This is one of those numerous alpine plants, which were first introduced to the knowledge of British cultivators by Dr. Pitcairn and Dr. Fothergill, who in 1775 sent a skilful gardener abroad for that purpose. *V. bellidioides* is perennial, with a creeping *stem*, throwing up perfectly simple flowering-branches, a finger's length, bearing two or three pair of opposite spatulate *leaves*, smaller than the more numerous radical ones. The whole of the herbage is more or less hairy. *Flowers* pale greyish-blue, from five to eight in a terminal viscid *corymb*, afterwards elongated and racemose.

18. *V. gentianoides*. Gentian-leaved Speedwell. Vahl n. 18. Symb. v. 1. 1. Willd. n. 22. Ait. n. 13. Sm. Tr. of Linn. Soc. v. 1. 194. Fl. Græc. Sibth. v. 1. 5. t. 5. Curt. Mag. t. 1002. Venten. Malmaif. t. 86. (V. orientalis erecta, gentianellæ foliis; Tourn. Cor. 7. V. erecta, blattariæ facie; Buxb. Cent. 1. 23. t. 35.)—Cluster corymbose, terminal, hairy. Radical leaves lanceolate, somewhat crenate, smooth.—Native of Cappadocia, and the mountains of Taurida and Caucasus, as well as of the Bithynian Olympus. Hardy, perennial, and not uncommon in gardens, flowering in May and June. But this little alpine plant, originally four or five inches high, by culture rises to the height of two feet, with a lax habit, and long cluster of numerous *flowers*. It may always be known by its thick, smooth, acute *leaves*, with a pale cartilaginous edge, resembling the foliage of *Gentiana acaulis*. The *corolla* is large, beautifully streaked; purplish-blue in a wild state; bluish-white in gardens.

19. *V. thymifolia*. Thyme-leaved Speedwell. Sm. Fl. Græc. Sibth. v. 1. 5. t. 6. Prodr. n. 19.—Cluster terminal, corymbose. Leaves revolute, hoary. Stems somewhat shrubby, diffuse. Lobes of the *capfulæ* divaricate.—Discovered by Dr. Sibthorp on the summits of mountains in Crete, flowering on the first melting of the snow. A shrubby little plant, whose *stems* are only three or four inches high, slightly branched, clothed with thyme-like, opposite, hoary, elliptical, entire, revolute *leaves*, tapering down into short *foxystalks*. *Flowers* blue, very pretty, in *clusters* not an inch long. *Capfulæ* hairy, inversely heart-shaped, with distant lobes.

20. *V. fruticulosa*. Flesh-coloured Shrubby Speedwell. Linn. Sp. Pl. 15. Mant. 316. Willd. n. 24. Vahl n. 19. Fl. Brit. n. 5. Engl. Bot. t. 1028. Wulf. in Jacq. Coll. v. 4. 229. t. 5. (V. n. 545; Hall. Hist. v. 1. 235. t. 16. f. 1.)—Cluster terminal, elongated, many-flowered. Leaves elliptic-lanceolate. Stems erect, somewhat shrubby. *Capfulæ* ovate, of four valves. Native of the mountains of Austria, Scotland, Switzerland, and the Pyrenæes, flowering in July. The *stems*, at least their flowering *branches*, are quite erect, from four to six inches high. *Leaves* above an inch long, a little downy at their edges and veins, sometimes quite entire, sometimes crenate or serrated. *Flowers* numerous, in a spiked rather than corymbose *cluster*, pink or flesh-coloured, never blue. *Capfulæ* abrupt or rather acute, soon splitting into four valves.

21. *V. saxatilis*. Blue Rock Speedwell. Linn. Suppl. 83. Willd. n. 25. Vahl n. 20. Fl. Brit. n. 4. Engl. Bot. t. 1027. Bauh. Hist. v. 3. 284. Dickf. Crypt. fasc. 2. 29. (V. fruticulosa; Sm. Tr. of Linn. Soc. v. 1. 191. Fl. Dan. t. 342. V. n. 545 β ; Hall. Hist. v. 236. V. tertia fruticans; Cluf. Hist. v. 1. 347. V. fruticans ferpyllifolia; Ger. Em. 628.)—Cluster terminal, corymbose, of few flowers. Leaves elliptical. Stems spreading, somewhat shrubby. *Capfulæ* ovate, of four valves.—Native of the mountains of Norway, Scotland, Austria, Switzerland, and the Pyrenæes, more frequent than the preceding, flowering in July. This is akin to the last, with which many botanists, even the greatest, have confounded it. The *stems* however are diffuse; *leaves* shorter and rounder; *flowers* of a rich ultramarine blue, and much fewer in each short corymbose *cluster*. The *bractææ* too are rounder and shorter in proportion to the *partial stalks*. The flowering branches of both these species are herbaceous and annual, though the main stem of both is shrubby and perennial, forming woody entangled tufts.—*V. nummularia*, Gouan. Illust. 1. t. 1. f. 2, appears by original specimens from the author to be, as Willdenow and Vahl make it, a dwarf variety of the *saxatilis*, with small, rounded, crowded *leaves*. *V. pygmaea*, Schranck Salisb. n. 11. t. 1. f. 1, seems scarcely different from the *nummularia*.

22. *V. alpina*. Alpine Speedwell. Linn. Sp. Pl. 15. Fl. Lapp. ed. 2. 7. t. 9. f. 4. Willd. n. 26. Vahl n. 21. Fl. Brit. n. 6. Engl. Bot. t. 484. Fl. Dan. t. 16. (V. pumila; Allion. Pedem. v. 1. 75. t. 22. f. 5. Spec. 19. t. 3. f. 3. V. integrifolia; Willd. n. 27. V. n. 544; Hall. Hist. v. 1. 235. t. 15. f. 2.)—Cluster terminal, dense, corymbose. Leaves ovate, smoothish, somewhat serrated. Calyx fringed. Stem ascending, simple.—Native of the alps of Europe, from Lapland to Savoy, flowering in July and August. Vahl thinks this *Teucurium sextum* of Cluf. Hist. v. 1. 350, with the description of which it well agrees, but there being no figure, we cannot absolutely decide. In general, though not unfrequent in boggy alpine spots, among trickling rills, in Switzerland and Savoy, it seems to have almost totally escaped the notice of the earlier writers. The *root* is perennial, rather creeping. *Stems* procumbent at the base, then ascending obliquely, a little zig-zag, round, leafy, from two to five inches long. *Leaves* about an inch long, more or less broadly elliptical, rarely hairy. *Flowers* small, of a bright light blue, with a white tube, shorter than the four ovate, nearly equal, hairy segments of the *calyx*. *Capfulæ* oval-heartshaped, of two compressed valves.—We reduce to this species, on the authority of Vahl, the *V. integrifolia* of Schranck and Willdenow, of which no specimen has fallen in our way; but we find among those of indubitable *V. alpina* many that answer to their descriptions.

VERONICA.

23. *V. serpyllifolia*. Smooth Speedwell, or Paul's Betony. Linn. Sp. Pl. 15. Willd. n. 28. Vahl n. 22. Fl. Brit. n. 7. Engl. Bot. t. 1075. Curt. Lond. fasc. 1. t. 3. Pursh n. 4. Fl. Dan. t. 492. (V. humifusa; Dickf. Tr. of Linn. Soc. v. 2. 288. V. minima repens; Rivin. Monop. Irr. t. 99. f. 1. V. minor; Ger. Em. 627. V. minor serpyllifolia; Lob. Ic. 472.)—Cluster terminal, somewhat spiked. Leaves ovate, slightly crenate, three-ribbed, smooth. Capsule inversely heart-shaped, shorter than the style.—Native of Europe and North America, in pastures, and by road-sides, very frequent, flowering in May and June. The herbage in moist situations is smooth, shining, and rather juicy; in dry open or hilly ground it becomes downy or hairy. The roots are perennial. Stems from two to twelve inches long, erect or prostrate. Clusters elongated, lax, with ovate bractees. Corolla small, elegantly variegated with bright blue and white, streaked with dark blue.

24. *V. tenella*. Little Round-leaved Speedwell. Allion. Pedem. v. 1. 75. t. 22. f. 1. Willd. n. 29. Vahl n. 23. Synb. v. 3. 5.—“Leaves roundish, somewhat rugged and crenate, all stalked. Stem creeping, villous as well as the calyx.”—Native of the Pyrenean mountains, and the Alps of Savoy. This is said to differ but little from the last. Indeed Plukenet's t. 233. f. 4, cited for the present, can hardly be any thing else than the *serpyllifolia*. Allioni describes the leaves as less firm and even than that species, but the creeping stem and less dense cluster, are characters of no moment. We have not examined the plant.

25. *V. telephifolia*. Orpine-leaved Speedwell. Vahl n. 24. (V. orientalis, telephii folio; Tourn. Cor. 7.)—“Leaves obovate, nearly entire. Stem creeping.”—Gathered in Armenia by Tournefort, and described by Vahl from his herbarium. Stems thread-shaped, smooth. Leaves stalked, hardly half the length of the nail, very obtuse, smooth, with one or two obscure notches about the extremity; acute at the base. Flowers (and we presume inflorescence) wanting in the specimen. Vahl.

26. *V. ruderalis*. Round-leaved Peruvian Speedwell. Vahl n. 25. (“V. serpyllifolia; Fl. Peruv. v. 1. 6.”)—“Leaves roundish, crenate, obscurely five-ribbed; the upper ones slightly fringed and entire. Stem creeping.”—Native of waste ground, borders of fields, and cool watery situations, in Peru. Perennial. Stems many, diffuse, thread-shaped, purplish; downy in the upper part. Lower leaves on short stalks, spreading; upper sessile. Partial flower-stalks thread-shaped, the length of the bractees. Corolla violet; its smallest segment white. Vahl. This is evidently very near *V. serpyllifolia*.

Seet. 3. Clusters lateral.

27. *V. parviflora*. Small-flowered Shrubby Speedwell. Vahl n. 26. Symb. v. 3. 4. Willd. n. 16.—Clusters axillary, about the ends of the branches. Segments of the calyx ovate, fringed. Leaves linear-lanceolate, entire, pointed. Stem shrubby.—Gathered by Sir Joseph Banks and Dr. Solander in New Zealand. They gave a specimen to the younger Linnæus, by the name of *V. floribunda*. The stem is perhaps several feet in height, with forked, twisted, round, scarred, woody branches, leafy only while young. Leaves crowded, sessile, crossing each other in pairs, from one to two inches long, very smooth and even, single-ribbed, deciduous. Clusters axillary, and somewhat terminal, stalked, dense, many-flowered, nearly smooth, longer than the leaves. Flowers small, we believe them to be white. Bractees minute, fringed. Calyx the length of the tube of the corolla, and only one-third as long as the ovate, smooth, finally four-valved and quadrangular capsule. The style is remarkably long and capillary, deciduous.

This is one among many shrubby or arborecent white-flowered species, referrible to Jusliciu's and Commerlon's genus of *Hebe*, which are indeed so unlike most *Veronica* in habit, that one could wish their fructification afforded any generic distinction. They serve to approximate the present genus, by some points of resemblance, to the *Jasminæ*.

28. *V. macrocarpa*. Large-fruited Shrubby Speedwell. Vahl n. 27. Symb. v. 3. 4.—Clusters axillary, about the ends of the branches, erect. Segments of the calyx lanceolate. Leaves lanceolate, entire, flat. Stem shrubby.—Native of New Zealand. The leaves are four inches long, smooth and even, without lateral ribs, or veins. Tube of the corolla twice, and capsule thrice, the length of the calyx. Vahl.

29. *V. salicifolia*. Willow-leaved Shrubby Speedwell. Forst. Prodr. 3. Vahl n. 28. Symb. v. 3. 4. Willd. n. 15.—Clusters axillary, about the ends of the branches, drooping; partial stalks aggregate. Segments of the calyx lanceolate. Leaves lanceolate, entire; tapering at each end. Stem shrubby.—Gathered in New Zealand by Sir Joseph Banks and Dr. Solander. This appears to be nearly related to the last, but the leaves are narrower at the base. In our specimen they are little more than two inches long, scarcely perceptibly undulated at the very edge. Clusters longer than the leaves, their capillary partial stalks very numerous, several from the same point, each accompanied by its own little short lanceolate bractea. Tube of the corolla twice the length of the calyx; segments of its limb elliptic-lanceolate, acute; not, as in the two preceding, obtuse. Capsule, according to Vahl, oblong and acute, twice as long as the calyx.

30. *V. elliptica*. Elliptic-leaved Shrubby Speedwell. Forst. Prodr. 3. Vahl n. 29. Willd. n. 13.—Clusters axillary, about the ends of the branches, simple, of few flowers. Segments of the calyx ovate, acute. Leaves elliptic-lanceolate, pointed, entire, slightly revolute. Stem shrubby.—Native of New Zealand, from whence Mr. Menzies has favoured us with a specimen in seed. No writer has yet given any detailed description of this species. Its woody branches are rough with very protuberant scars, where the leaves have been, and when young are quadrangular. Leaves crowded, crossing each other in pairs, about an inch long, acute at each end, single-ribbed, smooth, very slightly revolute, or reflexed at the margin. Clusters of not more than six or eight flowers, at first probably short and dense; when in fruit hardly longer than the leaves; their stalks all angular and smooth. Bractees minute, acute, permanent. The corolla we have not seen. The permanent calyx is smooth, acute, half the length of the ovate, acute, tumid, four-valved capsule.

31. *V. deussifata*. Cross-leaved Shrubby Speedwell. Ait. n. 20. Vahl n. 31. Willd. n. 19. Curt. Mag. t. 242.—Clusters axillary, about the ends of the branches, simple, of few flowers. Segments of the calyx ovate. Leaves elliptical, obtuse, entire, slightly revolute. Stem shrubby.—Native of Falkland islands, and the straits of Magellan; yet it requires the shelter of a greenhouse in this country. Dr. Fothergill is said to have first cultivated this shrub in 1776. It flowers, but not freely, in July and August, and the foliage is evergreen. This species is so nearly related to the last, that they must necessarily be placed next to each other, nor are we well assured of a specific distinction between them. The leaves of the present are indeed much shorter, rounder, and less pointed, but their figure is not invariable. The inflorescence is precisely similar. The flowers are white, large and elegant, observed by Mr. Curtis to have a most delicious fragrance, similar to that of *Olea fragrans*; another

VERONICA.

another point of resemblance to the *Jasminea*, see n. 27. The same writer justly observes, that the segments of the corolla are more equal than is usual in *Veronica*, and sometimes vary to five. The capsule is oval, scarcely emarginate.

32. *V. formosa*. Elegant Shrubby Speedwell. Brown n. 1.—Clusters corymbose, axillary, of few flowers. Leaves lanceolate, entire; acute at the base. Stem shrubby. Branches with two opposite hairy lines.—Gathered by Mr. Brown in Van Diemen's island. The leaves are evergreen, in pairs crossing each other, very smooth. *Brown*.

33. *V. catarrhæa*. Water-fall Shrubby Speedwell. Forst. Prodr. 3. Vahl n. 30. Ait. n. 12.—Clusters axillary, elongated, lax. Leaves stalked, lanceolate, distantly serrated. Stem somewhat shrubby.—Gathered by Forster in New Zealand, we presume near some remarkable cascade. The leaves are an inch long, acute at each end, smooth; paler beneath. Clusters from the bosoms of the upper leaves, four inches long, with smooth flower-stalks in distant pairs. Calyx with four awl-shaped segments, shorter than the oblong capsule. *Vahl*.

34. *V. labiata*. Labiated Speedwell. Brown n. 2. Ait. Epit. 376. Curt. Mag. t. 1660. (*V. Derwentia*; Littlejohn in Andr. Repof. t. 531.)—Clusters axillary, elongated. Leaves sessile, ovato-lanceolate, taper-pointed, unequally serrated.—Native of Van Diemen's island, and the south coast of New Holland, flowering with us most part of the summer. It is perennial and herbaceous, increased by parting the roots, but hitherto treated as a greenhouse plant; though, not being shrubby, it will probably bear our climate. The stems are simple, erect, about two feet or more in height, round, leafy, very smooth. Leaves opposite, clasping the stem by a sort of dilatation, scarcely to be termed a footstalk, veiny, quite smooth, three or four inches long, acutely and copiously serrated. Clusters numerous, opposite, about the top of the stem, ascending, stalked, many-flowered, rather dense, a little downy; their partial stalks sometimes aggregate. Bractæes awl-shaped. Segments of the calyx four, lanceolate: those of the pale blue corolla elliptic-lanceolate, unequal, acute. Capsule of four valves.

35. *V. aphylla*. Naked-stalked Speedwell. Linn. Sp. Pl. 14. Willd. n. 20. Vahl n. 32. Ait. n. 11. (*V. n. 541*; Hall. Hist. v. 1. 234. *V. alpina pumila*, caule aphylo; Bocc. Mus. 17. t. 1, and t. 9. *V. faxatilis parva*, caulibus nudis; Pluk. Phyt. t. 114. f. 3. Segu. Veron. v. 1. 241. t. 3. f. 2. *Teucrium minimum*; Clus. Hist. v. 1. 350.)

β. *V. Kamtchatica*; Linn. Suppl. 83. (" *V. grandiflora*; Cært. Nov. Com. Petrop. v. 14. p. 1. 531. t. 18. f. 1." *Vahl*.)

Leaves obovate, crenate, hairy. Flower-stalks erect, naked, thrice as long as the branches, about three-flowered.—Native of alpine situations in the south of Europe, and north of Asia; not uncommon on the mountains of Switzerland and the north of Italy, flowering in July; but it has never been found in Britain or Ireland. The perennial trailing stems throw up several short leafy branches, about an inch in length. Leaves crowded, opposite, stalked, usually an inch long, sometimes much less, bluntish, with numerous shallow notches; their pubescence finely jointed. Flower-stalks solitary, near the top of each branch, two or three inches long, each bearing two or three light-blue flowers, on slender downy partial stalks, accompanied by oblong obtuse bractæes. Calyx hairy, in four obovate segments. Capsule twice the length of the calyx, obovate, emarginate, thin, compressed, hairy. The variety β differs merely in the somewhat larger size of every part; the pubescence being not more articulated in this than the common *V.*

aphylla, as we have long ago remarked; Tr. of Linn. Soc. v. 1. 190.

36. *V. Beccabunga*. Brooklime Speedwell. Linn. Sp. Pl. 16. Willd. n. 30. Vahl n. 33. Fl. Brit. n. 8. Engl. Bot. t. 655. Curt. Lond. fasc. 2. t. 3. Woodv. Med. Bot. t. 7. Pursh n. 5. Fl. Dan. t. 511. (*Beccabunga*; Rivin. Monop. Irr. t. 100. *Anagallis seu Beccabunga*; Ger. Em. 620. Sium; Fuchf. Hist. 725.)—Clusters lateral. Leaves elliptical, flat. Stem creeping.—Native of clear ditches, and limpid streams, throughout Europe, from Sweden to Greece, as well as in North America, flowering in June and July. Perennial. Stems procumbent or floating in their lower part, sending out long fibrous radicles from the joints; round, succulent, smooth and shining, like every other part of the herb, and extending two or three feet. Leaves slightly serrated, of a bright rich green, from one to two inches long, on short broad stalks. Clusters axillary, opposite, stalked, longer than the leaves, of several, not very brilliant, blue flowers. Segments of the calyx ovate, as long as the roundish, emarginate capsule. De Théis says, the old name *Beccabunga* is corrupted from *Bach-pungben*, the German appellation of this plant; *bach* meaning a rivulet; from whence comes the word *beck*, used for a brook in Yorkshire and Norfolk. However this may be, Dr. Sibthorp found *Beccabunga* the Turkish name of this *Veronica*; adopted perhaps from some European doctor.

37. *V. Anagallis*. Water Speedwell, or Long-leaved Brooklime. Linn. Sp. Pl. 16. Willd. n. 31. Vahl n. 34. Fl. Brit. n. 9. Engl. Bot. t. 781. Curt. Lond. fasc. 5. t. 2. Pursh n. 6. Fl. Dan. t. 903. (*Anagallis aquatica major*; Ger. Em. 620.)—Clusters lateral, opposite. Leaves lanceolate, serrated. Stem erect.—Native of ditches, the borders of rivers, and other watery situations, throughout Europe; more general in North America than the foregoing; and found also in Japan. Perennial, and agreeing in habit with *V. Beccabunga*, but taller, more erect, and readily known by its long, acute, lanceolate leaves. The clusters also are longer and more pointed, and the flowers smaller, occasionally flesh-coloured.

38. *V. scutellata*. Narrow-leaved Marsh Speedwell. Linn. Sp. Pl. 16. Willd. n. 32. Vahl n. 35. Fl. Brit. n. 10. Engl. Bot. t. 782. Curt. Lond. fasc. 5. t. 3. Pursh n. 7. Fl. Dan. t. 209. Poit. et Turp. Paris. 15. t. 13. (*V. palustris angustifolia*; Rivin. Monop. Irr. t. 96. f. 1. *Anagallis aquatica quarta*; Lob. Ic. 467. Ger. Em. 621.)—Clusters lateral, alternate; partial flower-stalks divaricated. Leaves linear, slightly indented.—Native of watery places, especially on spongy bogs, or a sandy soil, in various parts of Europe and North America; much less common in England than the two last; flowering in July and August. A slender, weak, often purplish, perennial herb, with long narrow leaves, occasionally downy. Flowers pale flesh-coloured, with purple veins; their stalks bent quite back as the capsule ripens. The clusters are axillary, rarely opposite. *V. parvularia*, Poit. et Turp. Paris. 16. t. 14. is only the hairy variety of this species, mentioned in Fl. Brit., which is rather of a smaller size, and hairy or downy in every part of the herbage; but even the authors cited esteem it only a variety.

39. *V. gracilis*. Slender New-Holland Speedwell. Br. n. 4.—"Corymbs lateral, of few flowers. Leaves linear-lanceolate, nearly entire, very smooth as well as the nearly simple stem."—Native of Port Jackson, New South Wales. Partition of the capsule contrary to the valves. *Brown*.

40. *V. persfoliata*. Perfoliate Speedwell. Br. n. 3. Curt. Mag. t. 1936.—Clusters lateral, stalked, many-flowered. Leaves entire, very smooth, ovate, pointed; combined at the

VERONICA.

the base. Capsule of four valves.—Native of Port Jackson, New South Wales. *Flowers* dark blue.

41. *V. Billardiæ*. Sharp-leaved Syrian Speedwell. Vahl n. 36.—Clusters axillary, many times longer than the lanceolate-oblong, entire, hoary leaves. Stems prostrate, hoary.—Gathered in Syria by M. Labillardière. The stems are several, thread-shaped, somewhat branched, hoary and villous, like the foliage and flower-stalks. Leaves nearly sessile, hardly the length of the nail, sharpest, without ribs or veins, and accompanied by axillary rudiments of linear leaves. Clusters after flowering two or three inches long. Bractæes linear, the length of the partial stalks. Calyx in four linear, equal segments, the length of the fame. Capsule inversely heart-shaped, compressed, as long as the calyx, becoming smoother as it ripens. Vahl.

42. *V. macrostachya*. Blunt-leaved Syrian Speedwell. Vahl n. 37.—Clusters axillary, many times longer than the linear-oblong, obtuse, deeply ferrated, hoary leaves. Stems prostrate, hoary.—Native of Syria. Labillardière. Every part of the herb is villous and hoary. Stems several, a span long, thread-shaped, somewhat branched. Leaves sessile, the length of the nail; a little dilated, and deeply ferrated, towards the extremity. Clusters long. Bractæes linear. Calyx in four linear segments. Capsule as in the last. In a garden the stem becomes eighteen inches, and each cluster two feet, in length; with very soft downy leaves. Vahl.

43. *V. pectinata*. Pectinated Speedwell. Linn. Mant. 24. Willd. n. 36. Vahl n. 38. Sm. Prodr. Fl. Græc. Sibth. n. 25. (*V. constantinopolitana incana, chamædryos folio*; Tourn. Cor. 7. Buxb. Cent. 1. 25. t. 39. f. 1.)—Clusters lateral, on leafy stalks. Leaves oblong, with deep parallel ferratures. Stems prostrate.—Gathered by Buxbaum, and since by Sibthorp, on craggy shelvy mountains, bordering both shores of the Bosphorus, flowering in spring. Mr. Hawkins met with this plant on the highest summits of the Sphaciot mountains of Crete. It has a woody perennial root, and several woody stems, a finger's length, chiefly hairy on two opposite sides. Leaves rather sessile, not an inch long, with parallel, blunth, rather deep incisions. Flowers blue, in long, loose, downy clusters, whose stalks bear several, alternate, partly entire, leaves. Segments of the calyx linear, obtuse, hairy, two of them much longer than the other two.

44. *V. orientalis*. Various-leaved Speedwell. Willd. Dict. ed. 8. n. 10. Ait. n. 27. Willd. n. 39. Vahl n. 39. Marfch. Taur.-Cauc. v. 1. 12. (*V. austriaca* β; Linn. Sp. Pl. 17; the specimen marked *V. cappadocica, foliis laciniatis*; Tourn. Cor. though no such name occurs there. *V. heterophylla*; Salisb. Ic. 7. t. 4. *V. montana, folio vario*; Buxb. Cent. 1. 24. t. 38.)—Clusters lateral, lax, on partly leafy stalks. Leaves pinnatifid, smooth, acute; tapering at the base; the uppermost linear-lanceolate, nearly entire. Partial stalks capillary, longer than the bractæes.—Native of grassy pastures in Armenia, Georgia, and Tauria, flowering in June and July. Miller cultivated it in 1748, and it is still preserved in the gardens; but there was no reason for retaining his unmeaning name, which had not come into general use, instead of the expressive one of *heterophylla*. This evil it is now too late to remedy. The plant is hardy and perennial, bushy, of a pale and smooth appearance, the leaves variously cut, thin, flat, and pinnatifid. Flowers copious, rather large, light blue, prettily fringed. Calyx and bractæes linear, rather downy. Capsule kidney-shaped.

45. *V. taurica*. Narrow-leaved Taurian Speedwell. Willd. n. 42. (*V. orientalis* β; Vahl n. 39. Marfch. Taur.-Cauc. v. 1. 12.)—Clusters lateral, lax, on naked stalks. Leaves

linear, revolute, downy, tapering at the base; entire, or somewhat toothed. Partial stalks longer than the obtuse bractæes.—Native of Tauria, on chalky stony hills, flowering from June to August. We cannot agree with Vahl in reducing this to *V. orientalis*. Our wild specimens, from the Chevalier de Steven, shew it to be a more firm and rigid plant, with woody roots. The decumbent stems are not a finger's length. Leaves almost coriaceous, bright green, an inch long, somewhat downy on both sides, very narrow and revolute in their lower part; some of them cut into two, rarely more, strong, lateral, tooth-like segments. Clusters axillary, greatly overtopping the branches, as in the foregoing; but the lower part of their long firm stalks is naked, never leafy. The bractæes, and segments of the calyx, are obovate and obtuse, not linear. Flowers but half the size of the last; according to Willdenow rose-coloured, as they seem in our specimen. Capsule abrupt, scarcely lobed.

46. *V. parviflora*. Small-flowered Oriental Speedwell. Vahl n. 40. (*V. orientalis minima, foliis laciniatis*; Tourn. Cor. 7. Buxb. Cent. 1. 26. t. 41. f. 2.)—Clusters several, lateral, on naked stalks. Leaves pinnatifid, linear, revolute. Bractæes linear, obtuse, as long as the partial stalks.—Native of Cappadocia and Armenia, in grassy hilly pastures, flowering in June. Linnæus confounded it with *V. pectinata*, though nothing can be more distinct; nor can there be less difficulty in distinguishing this species from the two last. The stems are hardly a finger's length. Leaves deeply and regularly pinnatifid, thick, obtuse, revolute, and in our specimen rather downy, as in *taurica*; Vahl says smooth. Clusters from four to six about the top of the stem, and rising far above it, downy all over, on long, round, downy, leafless stalks. Partial stalks rather shorter than the bractæes. Flowers blue, much smaller than even the last. Calyx with four linear, obtuse, very unequal segments. Capsule inversely heart-shaped, more deeply divided than in *taurica*.

47. *V. rosea*. Rose-coloured Speedwell. Desfont. Atlant. v. 1. 13. Vahl n. 41.—Clusters dense, axillary, nearly terminal, on naked stalks. Leaves unequally pinnatifid, minutely hairy; lower ones wedge-shaped, obtuse, toothed. Bractæes linear, nearly as long as the partial stalks.—Found by Desfontaines, on mount Atlas, near Tlemcen. The stems are shrubby, numerous, ascending, from four to eight inches high. Leaves an inch long, acute, tapering at the base into a short footstalk. Calyx in four linear-lanceolate unequal segments. Corolla rose-coloured, the size of *V. Teurium*, hereafter described.

48. *V. austriaca*. Austrian Speedwell. Linn. Sp. Pl. 17. Willd. n. 41. Vahl n. 42. Ait. n. 28. (*V. multiâta et austriaca*; Jacq. Austr. v. 4. 15. t. 329. *Chamædryis spuria, tenuissimè laciniata*; Bauh. Hist. v. 3. 287. Morif. scét. 3. t. 23. f. 17.)—Clusters lateral, on long naked stalks. Leaves slightly hairy, variously pinnatifid, or bipinnatifid; most deeply towards the base. Partial stalks capillary. Calyx very unequally five-cleft, somewhat hairy.—Native of Austria, Silesia and Carniola, a hardy perennial in our gardens, flowering from June to August. The herbage is more or less downy, but scarcely hoary, except the stems, which are round, leafy, a span or more in height. Leaves various in their divisions, the segments generally broader upwards, all decurrent, sometimes as narrow and compound as in *V. multifida*, with which most botanists have always confounded the present species. Flowers light blue, in several long, lax, axillary clusters, rising high above the stem. Segments of the calyx acute, the two lowermost very long, the fifth opposite to them, between the two others, much smaller than

VERONICA.

than either, but, as far as we can discern, always present. Divisions of the *corolla* elliptic-oblong, acute. *Capsule* small, shorter than the calyx, elliptic-obcordate.

49. *V. multifida*. Fine-cut Speedwell. Linn. Sp. Pl. 17, excluding the synonym. Willd. n. 40. Vahl n. 43. Sm. Tr. of Linn. Soc. v. 1. 191. Marfch. Taur.-Caucas. v. 1. 12. Curt. Mag. t. 1679. (V. n. 38; Gmel. Sib. v. 3. 222; excluding the synonym of Tournefort.)—Clusters lateral, on long naked stalks. Leaves deeply and doubly pinnatifid, downy, with linear revolute segments tapering downwards. Calyx very unequally five-cleft. Segments of the corolla rounded.—Native of open fields and hills, in Siberia, Tauria, and about mount Caucasus, flowering in April and May. A much smaller plant, more delicate in its herbage, than the last, as well as more downy. The narrow revolute spreading segments of the leaves, resembling some kinds of *Artemisia*, readily distinguish it. The flowers are bright blue, with rounder broader divisions than in *V. austriaca*. The calyx is very smooth in every flower of the original Linnaean specimen, but in most others, from various quarters, it is more or less downy. The fifth segment is minute, scarcely half so long as the shortest of the others. Baron Marfchall à Bieberstein observes, that all this tribe of *Veronica*, with cut leaves, have a five-cleft calyx.

50. *V. tenuifolia*. Slender-leaved Georgian Speedwell. Marfch. Taur.-Caucas. v. 1. 13.—“Clusters lateral. Leaves pinnatifid, with linear-threaded divisions. Segments of the calyx awl-shaped; three upper ones very short. Stems ascending.”—Gathered in Georgia, by the Chevalier de Steven. Perennial. Akin to the last, but the stems are more elongated; leaves less subdivided; their segments, especially those of the lower ones, longer; partial stalks equal to the bractæ, or longer; three upper segments of the calyx minute. May this be *V. parviflora* of Vahl? (see n. 46.) The flowers however are by no means smaller than *multifida* or *orientalis*. Marfchall.

51. *V. caucasea*. Slender-leaved Caucasian Speedwell. Marfch. Taur.-Caucas. v. 1. 13.—“Clusters lateral. Leaves doubly pinnatifid, with lanceolate or linear segments. Partial stalks capillary. Segments of the calyx lanceolate, nearly equal. Stem almost erect.”—From the same country. Perennial. The leaves are like *multifida*, but the divisions of the lower ones are broader. Partial stalks longer than the bractæ. Segments of the calyx four, almost equal, broader than in the neighbouring species. Lobes of the corolla rounded. Marfchall.

52. *V. Allionii*. Shining-leaved Speedwell. Villars Dauph. v. 2. 8. Sm. Tr. of Linn. Soc. v. 1. 190. Willd. n. 18. Vahl n. 44. Ait. n. 19. (V. pyrenaica; Allion. Pedem. v. 1. 73. t. 46. f. 3. V. repens, ex alis spicata, &c.; Spec. 21. t. 4. V. officinalis β ; Linn. Sp. Pl. 14. V. n. 2; Ger. Galloprov. 332. V. mas repens pyrenaica, folio longiori glabro; Sherard Schol. Bot. 46. Tourn. Inf. 143. Pluk. Phyt. t. 233. f. 1.)—Clusters lateral, very dense, obtuse, on long smooth stalks. Leaves roundish-oblong, crenate, rigid, shining, smooth as well as the creeping items.—Native of mount Cenis, and the alps of Switzerland, Dauphiny and Savoy, flowering in August. Root perennial, creeping. Stems round, procumbent, leafy, creeping also to a great extent. Leaves roundish, or obovate, firm and coriaceous; paler beneath: on short broad footstalks. Clusters axillary, solitary, scarcely more than one to each branch, on a round, naked, firm, ascending stalk, thrice the length of the leaves; the cluster itself an inch long, downy, elliptic-oblong, obtuse, of numerous, crowded, violet-blue flowers, with very short partial stalks, not half the length of the obtuse bractæ. Calyx in four oblong,

unequal segments. Villars mentions a hairy variety. This species, confounded by Linnaeus with the following, is of a much more rigid, compact, and smooth habit, of a darker hue, and unquestionably very distinct. Its infusion, used medicinally in the fourth of France, for colds, coughs, debility of the stomach, &c. is said to be more fragrant and aromatic than that of *V. officinalis*, a popular medicinal tea in the northern parts of Europe.

53. *V. officinalis*. Common Male Speedwell. Linn. Sp. Pl. 14. Willd. n. 17. Vahl n. 45. Fl. Brit. n. 3. Engl. Bot. t. 765. Curt. Lond. fac. 3. t. 1. Pursh n. 2. Woodv. Suppl. t. 219. Rivin. Monop. Irr. t. 93. Fl. Dan. t. 248. Poit. et Turp. Paris. 12. t. 8. (V. mas; Fuchf. Hist. 166. V. vera et major; Ger. Em. 626.)—Clusters lateral, stalked, slender, acute, rather lax. Leaves elliptic-oblong, ferrated, rough, stem procumbent.—Native of dry sandy banks, heaths and woods, on a barren soil, throughout Europe and North America, flowering in May and June. Perennial. Stems trailing, branched, forming broad tufts or scattered patches. Whole plant hairy. Leaves more oblong, acute, pliant, paler, and more deeply ferrated, than in the former. Flowers pale blue, or light pink, striated, in long, rather lax, alternate, axillary clusters, on hairy stalks, about twice the length of the leaves. Capsule inversely heart-shaped, splitting into four valves.

The late Mr. Mackay has sent us from the mountains above Blair in Athol, and from Ireland, a sort of intermediate variety between this and *V. Allionii*, partaking of the rigidity and smoothness of the latter, but even more strongly ferrated than *officinalis*. We scarcely hesitate to which species to refer it, though we have never compared living specimens.

54. *V. reniformis*. Kidney-leaved Speedwell. Pursh n. 3.—Spikes lateral, stalked. Leaves kidney-heart-shaped, deeply crenate, smooth. Stem creeping.—Collected by Messrs. Lewis and Clark, in boggy soil, on the banks of the Missouri, flowering in June. Perennial. Stem creeping, thread-shaped, taking root at the joints. Leaves opposite, on long stalks, deeply cut and notched. Flower-stalks axillary, alternate, round, smooth, the length of the leaves, bearing towards the top a single, oblong, crenate bractæ. Spike oblong, short. Flowers large, crowded, pale blue. Calyx four-cleft; the two upper segments oblong; two lower linear, much smaller. Corolla flat, with oblong acute segments, thrice the length of the calyx; the lower one linear. Filaments the length of the corolla.

Pursh.

55. *V. prostrata*. Trailing Germander Speedwell. Linn. Sp. Pl. 17. Willd. n. 35. Vahl n. 46. Ait. n. 24. Ehrh. Herb. n. 71. Roth in Sims and Kon. Ann. of Bot. v. 1. 137. (V. angustifolia minor; Rivin. Monop. Irr. t. 95. f. 2. Chamaedrys spuria minor angustifolia; Bauh. Hist. v. 3. 287.)

β . *V. satuzraizifolia*; Poit. et Turp. Paris. 18. t. 17.

Clusters lateral, mostly opposite, corymbose. Leaves elliptic-oblong, variously ferrated, nearly sessile; upper ones narrower and entire. Stem ascending, partially naked at each side. Calyx five-cleft, very unequal.—Native of Germany, Switzerland, Italy, France, and the Levant. A hardy perennial, flowering in May and June. The herbage is light green, more or less downy, slightly hoary. Stems not a span long, clothed with short dense recurved pubescence, which is partly smoothed away, here and there, in opposite lateral lines. Leaves three-quarters of an inch long, rarely more, rather blunt, crenate or deeply ferrated for the most part; the upper ones only being linear, revolute and entire; but in the variety, as we judge it, most of the

the leaves are of the latter description. The *flowers* are bright blue, rather showy, in corymbose dense tufts, subsequently lengthened out into long lax *clusters*. The *calyx* seems to vary in acuteness, but is generally smooth.

56. *V. pilosa*. Hairy-stalked Germander Speedwell. Linn. Sp. Pl. 1663, excluding the description. Willd. n. 34. Vahl n. 47. (*Chamædrys falva* species, *Teucrium fecundum* aut quintum Clusii; Bauh. Hist. v. 3. 286.)—"Clusters somewhat spiked. Leaves ovate, obtuse, plaited. Stem prostrate, hairy."—Native of Austria. *Linnaeus*. This is a very doubtful species, not to be found in the Linnaean herbarium; and the description in Sp. Pl. 1664. is erased by *Linnaeus* himself, from his own copy.

Willdenow's description of a Bohemian specimen, in his possession, answers very nearly to one of those passed together as the *prostrata*, in the Linnaean herbarium, whose *leaves* are more cut, and *calyx* rather sharper than the three others; but we cannot think there is any specific distinction between them. The *calyx* of this specimen has five segments, though that character is not invariable. Willdenow describes four.

57. *V. Teucrium*. Upright Germander Speedwell. Linn. Sp. Pl. 16, synonyms confuted. Willd. n. 33. Vahl n. 48. Ehrh. Pl. Off. 51. Poit. et Turp. Paris. 16. t. 15. (*V. montana*; Rivin. Monop. Irr. t. 95. f. 1. *Chamædrys spuria major angustifolia*; Bauh. Pin. 249. Bauh. Hist. v. 3. 285. chap. 58. Ch. sylvestris; Dod. Pempt. 45. Ch. vulgaris mas; Fuchf. Hist. 871. *Teucrii quarti tertia* species; Clus. Hist. v. 1. 349.)—Clusters lateral, opposite, cylindrical, on long stalks. Leaves sessile, oblong-lanceolate, bluntly serrated, rough. Stem ascending, hairy. Fifth segment of the *calyx* very minute.—Native of Germany, Bohemia, and France, on a dry soil, flowering in May. The root is perennial. Stems seldom quite erect, a foot long, round, hairy, partly smooth on two opposite sides, leafy. Leaves an inch and a quarter long, veiny, hairy, strongly serrated, but not cut; a little dilated at the base. Clusters axillary, usually two near the top of the stem, rising high above it, on long, parallel, naked, downy stalks. Flowers copious, rather crowded, large, handsome, of a fine blue. Segments of the *calyx* oblong, the fifth minute, various, often obsolete.

Mr. Sieber has sent as a variety of this species the *V. dentata* of Schmidt, whose *leaves* are narrow, linear, and nearly all entire. Yet it is probably not specifically distinct.

58. *V. latifolia*. Great Germander Speedwell. Linn. Sp. Pl. 18. Willd. n. 44. Vahl n. 49. Ait. n. 30. Marfch. Taur.-Caucas. v. 1. 10. (*V. Teucrium*; Roth in Sims and Kon. Ann. of Bot. v. 1. 137. *V. pseudo-chamædrys*; Jacq. Austr. t. 60. *Chamædrys spuria major* altera, five frutescens; Bauh. Pin. 248. *Teucrium majus pannonicum*; Ger. Em. 659. *T. quartum*; Clus. Hist. v. 1. 349.)—Clusters lateral, opposite, tapering, on long stalks. Leaves sessile, ovate, somewhat heart-shaped, rough, deeply serrated and cut. Stem erect, hairy. Calyx unequally five-cleft. Native of Austria, Bohemia, Germany, and the Levant; a common hardy perennial in gardens, flowering in June and July. We have long supposed this not specifically distinct from the last. Vahl and Roth confound them; Willdenow seems to have been acquainted with their differences, and the old authors were clearly so. The present is a more robust plant, with broader more jagged *leaves*. The stem is quite smooth on two opposite sides, densely and equally hairy on the intermediate ones. Flowers large, copious, very brilliant, in dense more tapering clusters. Fifth segment of the *calyx* half as long as the two next, but on this mark we have little reliance. *Linnaeus* has led Jacquin and

others astray, by citing synonyms of *V. urticifolia* for his *latifolia*, of which latter, as above described, the original specimen is preserved in his herbarium, nor can we concur with the learned Dr. Roth in transferring this name to the *urticifolia*: see his excellent remarks in Ann. of Bot. above cited. Neither do we by any means assert our *Teucrium* and *latifolium* to be more than varieties of each other, Schmidt's *dentata* perhaps excepted, which is too unlike the latter. We have only aimed at collecting their synonyms, and indicating what distinctions we could find, for future inquiry.

59. *V. pedunculata*. Long-stalked Germander Speedwell. Marfch. Taur.-Caucas. v. 1. 11. Sims and Kon. Ann. of Bot. v. 2. 401. (*V. pedunculata*; Vahl n. 50. *V. chamædrys foliis parvis*; Buxb. Cent. 1. 26. t. 41. f. 1.)—Clusters lateral, opposite; with long capillary partial stalks. Leaves stalked, ovate, deeply serrated and cut; their segments toothed. Calyx in four, nearly equal, bluntish segments.—Native of shady thickets and groves of mount Caucasus, flowering in May. Perennial. Akin to *V. Chamædrys* hereafter described, but the stems are hairy almost all round; leaves stalked, smaller, and yet more cut, in an unequal or compound manner. The partial *flower-stalks* are also longer; the *bractæas* and segments of the *calyx* broader and more obtuse. The variety γ of *Fl. Taur.-Caucas.* sent by the Chevalier de Steven, is of a very different and diminutive aspect; the *leaves* scarcely stalked, or cut.

60. *V. umbrosa*. Wood Germander Speedwell. Marfch. Taur.-Caucas. v. 1. 11.—"Clusters lateral, of few flowers. Leaves oblong, obtuse, distantly serrated, rough; uppermost linear-lanceolate, entire. Stems creeping. Calyx as long as the corolla."—Native of the dense shady forests of Tauria, about the town of Karassubasar, flowering in April and May. Perennial, forming loose tufts. Partial *flower-stalks* thread-shaped. Segments of the *calyx* linear.

Specimens sent by the Chevalier de Steven from Tauria, under this name, have smooth *leaves*, except the edges; clusters of rather numerous, though distant, large and handsome blue flowers; bractæas ovate, as well as the segments of the *calyx*, which last is but half the length of the corolla.

61. *V. Michauxii*. Michauxian Speedwell. Lamarck Illustr. v. 1. 44. Dict. v. 8. 532. Vahl n. 51.—"Clusters lateral. Flowers somewhat crowded. Leaves ovate, toothed, sessile. Herbage hairy and glutinous."—Brought from the East by Michaux to the Paris garden. Stems four to six inches long, clothed with whitish viscid hairs. Leaves opposite, obscurely toothed, bluntish, an inch and a half long, six lines broad, without ribs. Stalks axillary, opposite, some of them at the ends of the short lateral leafy branches all downy, hardly so long as the leaves. Flowers on very short downy stalks, crowded. Bractæas lanceolate. Segments of the *calyx* four, oval, sharpish, scarcely downy.

62. *V. Chamædrys*. Wild Germander Speedwell. Linn. Sp. Pl. 17. Willd. n. 38. Vahl n. 52. Fl. Brit. n. 12. Engl. Bot. t. 623. Curt. Lond. fasc. 1. t. 2. Mart. Ruft. t. 66. Poit. et Turp. Paris. 13. t. 9. Fl. Dan. t. 448. (*V. pratensis latifolia*; Riv. Monop. Irr. t. 94. *Chamædrys*; Brunf. Herb. v. 1. 125. Ch. vulgaris fœmina; Fuchf. Hist. 872. Ch. sylvestris; Ger. Em. 657.)—Clusters lateral. Leaves ovate, sessile, rugged, deeply serrated. Stem diffuse, with a narrow hairy line at each side. Calyx four-cleft, lanceolate.—Native of grassy pastures, groves, and banks throughout Europe, and even in Japan, perennial, flowering in May. Few of our wild flowers can vie with this in elegance and brilliancy, nor can the pencil easily do

VERONICA.

do it justice. The wavy stems spread in every direction, and are merely fringed at each side with a line of longish hairs, not only partially naked, as in *V. Teurium* and *latifolia*. The foliage is akin to the latter, but less cut. Clusters numerous, generally opposite, on hairy stalks, taper-pointed, many-flowered. Bracts lanceolate, usually rather shorter than the partial stalks. Flowers large, bright blue, most elegantly veined; paler at the back. Capsule inversely heart-shaped, small.

63. *V. urticifolia*. Nettle-leaved Speedwell. Linn. Suppl. 83. Willd. n. 43. Vahl n. 53. Ait. n. 29. Jacq. Austr. t. 59. (V. n. 535; Hall. Hist. v. 1. 232. V. pratensis, omnium maxima; Buxb. Cent. 1. 23. t. 34. V. maxima; Dalech. Hist. 1165; Chamædryis spuria major latifolia; Baulh. Pin. 248.)—Clusters lateral, lax, with capillary stalks. Leaves sessile, heart-shaped, pointed, sharply serrated. Stem quite erect. Calyx four-cleft, ovate.—Native of woods in Austria, Bavaria, Switzerland, and Bithynia, flowering in May and June. This species was not known to Linnæus, till Jacquin, who originally took it for *latifolia*, sent him a specimen. Under this latter name it is described by Dr. Roth, in Sims and Kon. Ann. of Bot. v. 1. 137, but was never what Linnæus intended. No species is better defined nor better named. The large nettle-like leaves at once determine it. The roots are perennial, moderately creeping. Stems erect and straight, slender, eighteen inches or two feet high, quite simple, marked with a slight hairy line. Clusters numerous, axillary, opposite, erect, loose and slender. Flowers small, flesh-coloured, with crimson lines. Capsule of two semi-orbicular lobes.

64. *V. Pona*. Rock Germander Speedwell. Gouan Illustr. 1. t. 1. f. 1. Willd. n. 23, excluding the variety. Vahl n. 54. (V. petrea; Pon. Bald. 1792? Clus. Hist. v. 2. 336?)—Cluster nearly terminal, lax, of few flowers. Leaves sessile, heart-shaped, obtuse, coarsely serrated. Stem erect. Calyx five-cleft, smooth.—Native of the Pyrenees, and perhaps of mount Baldus. Perennial. Stem four or five inches high, quite simple and upright. Lower leaves smallest, roundish, crenate; the rest an inch long, very blunt, coarsely serrated, entire at the extremity, besprinkled with distant close-pressed hairs. Bracts linear, the length of the partial stalks. Flowers distant, the size of *V. Chamædryis*. Such is Vahl's description of Gouan's plant, which he received from that author, and found himself also on the Pyrenees. He asserts it to be a distinct species, nor do we doubt his accuracy. We nevertheless have great doubts respecting Pona's plant, which may be a Linnæan *Paderota*, as Linnæus supposed; for the figure very closely agrees with Micheli's *Bunorota*, t. 15. Gouan himself seems not quite certain of Seguiet's plant, from mount Baldus; nor do we implicitly confide in Gouan's learning with regard to synonyms. The references to Plukenet, *Phyt.* t. 233. f. 2. and 3, are best omitted. Willdenow is surely wrong in referring hither Allioni's *V. pumila*, which Vahl more judiciously confiders as *V. alpina*; see our n. 22.

65. *V. montana*. Mountain Germander Speedwell. Linn. Sp. Pl. 17. Suppl. 83. Willd. n. 37. Vahl n. 55. Fl. Brit. n. 11. Engl. Bot. t. 766. Curt. Lond. fasc. 4. t. 2. Jacq. Austr. t. 109. Hoffm. Germ. ann. 1791. t. 1. Fl. Dan. t. 1201. (V. procumbens; Rivin. Monop. Irr. t. 93. Alyssum Dioficoidis montanum; Column. Ephem. v. 1. 286. t. 288.)—Clusters lateral, elongated, lax, of few flowers. Leaves ovate, stalked, serrated. Stem diffuse, hairy all round. Native of shady rather mountainous woods, especially on a calcareous soil, in Denmark, England, Germany, and Italy, flowering in May and June.

A very distinct perennial species, which some botanists have incautiously confounded with *V. Chamædryis*. Scopoli, still more unaccountably, united them both with *V. Teurium*. Sherard, who first noticed the *montana* in England, and Curtis, have been more exact in their observations. The stem being hairy in every direction, and the large capsule formed of two orbicular lobes, not orbiculate, are abundantly sufficient distinctions. The leaves are thinner, and more shining, than in *Chamædryis*; flowers smaller, paler, much less beautiful; segments of the calyx obovate. We regret that a mistake of the late very accurate Mr. W. Brunton is recorded in Turner's and Dillwyn's Botanist's Guide 666. He seems to have taken up a portion of the root of *Chamædryis* along with *montana*, and thought the latter was, in the following season, transformed into the former. His specimens are before us; and of the obvious and absolute distinctness of the species there can be no doubt, however they came together.

66. *V. calycina*. Long-cupped New Holland Speedwell. Br. n. 5.—Clusters lateral, of few flowers. Leaves stalked, ovate, rugose, unequally crenate, hairy as well as the creeping stem. Calyx hairy, fringed, longer than the capsule. Observed by Mr. Brown, in Van Diemen's island, and on the south coast of New Holland.

67. *V. distans*. Distant-flowered New Holland Speedwell. Br. n. 6.—Corymbs lateral, stalked, of few flowers. Leaves ovate, broadly fringed, smooth. Footstalks fringed. Stem decumbent, with a hairy line at each side.—Gathered on the south coast of New Holland, by Mr. Brown.

68. *V. arguta*. Sharp-toothed New Holland Speedwell. Br. n. 7.—Clusters lateral, lax. Leaves ovato-lanceolate, smooth, unequally serrated. Stem downy on two opposite sides. Lower footstalks one-third the length of the leaves.—Gathered by Mr. Brown at Port Jackson, New South Wales. A specimen from the same country, communicated by Mr. Lambert, answers in every respect to the above definition, except that the leaves are triangular-heartshaped; but perhaps it may be a variety only. The calyx has four obovate segments, rather longer than the nearly orbicular capsule.

69. *V. plebeia*. Common New Holland Speedwell. Br. n. 8.—Clusters lateral, lax. Leaves ovate, unequally and deeply serrated, smooth. Stem very finely downy. Lower footstalks half as long again as the leaves.—Gathered at Port Jackson, by Mr. Brown, who speaks of it as very closely related to the last.

SECT. 4. Stalks single-flowered, axillary.

70. *V. biloba*. Two-lobed Speedwell. Linn. Mant. 172, excluding the synonyms of Columa and Bauhin. Sm. Tr. of Linn. Soc. v. 1. 193. Willd. n. 46. Vahl n. 56. (V. orientalis, ocymi folio, flore minimo; Tourn. Cor. 7. V. arvensis annua, chamædryos folio; Buxb. Cent. 1. 24. t. 36.)—Flower-stalks thread-shaped. Leaves ovate, acute, serrated, nearly smooth. Calyx of the fruit in four deep, ovate, three-ribbed, almost equal, segments.—Gathered by Tournesort in corn-fields in Cappadocia; and by the Chevalier de Steven on the eastern mountains of Caucasus. The root is annual. Stems two to four inches high, erect, branched, downy. Leaves somewhat heart-shaped at the base, half or three-quarters of an inch long, on short stalks. Flowers axillary, solitary, alternate, about the top of the stem and branches, the leaves which accompany them being more entire, and sessile, than the rest. Segments of the calyx lanceolate while in flower, the two uppermost shortest; afterwards they become much larger, ovate, fringed, marked with two evident lateral ribs besides the central one. Corolla small, white. Capsule hairy, of

VERONICA.

two distinct, divaricated, rounded lobes, much shorter than the permanent calyx. Linnæus seems to have taken his specific character from Columna's *Epiphrafi*, t. 290, which represents a widely different species, akin to *Chamædryis*, possibly the *Pona* of Gouan; see n. 64.

71. *V. amoena*. Handsome-flowered Annual Speedwell. *Marfch. Taur.-Caucas. v. 1. 14.*—"Flowers solitary. Leaves ovate, crenate; floral ones oblong, entire, much shorter than the flower-stalks. Segments of the calyx linear. Stem spreading."—Gathered by the Chevalier de Steven, in the fields of Georgia, flowering early in spring. *Root* annual. *Herb* the size of *V. arvensis*. The floral leaves are minute and entire, so different from the rest, as to cause a doubt whether they be other than *bracteas*, and the *inflorescence* racemose. This is the most beautiful species of the present section, on account of its very large blue flowers, white in the middle. *Marsch.*

72. *V. glauca*. Glaucous Three-cleft Speedwell. *Sm. Fl. Græc. Sibth. v. 1. 6. t. 7.*—Flowers solitary. Leaves heart-shaped, deeply serrated. Stems procumbent. Segments of the calyx three-cleft.—Native of the summit of mount Hymettus, above Athens. *Mr. Ferdinand Bauer. Root* annual. Stems spreading on the ground in every direction, much branched, reddish, with a dense hairy line at each side. Leaves glaucous, stalked, more or less deeply cut, scarcely an inch long, most hairy at the base and underneath; the lower ones opposite; upper alternate. Flower-stalks capillary, smooth, shorter than the leaves. Calyx in four very deep, nearly equal, wedge-shaped segments, remarkable for being three-cleft, which well marks the species. Corolla deep blue, white in the centre.

73. *V. agrestis*. Procumbent Field Speedwell. *Linn. Sp. Pl. 18. Willd. n. 47. Vahl n. 58. Fl. Brit. n. 13. Engl. Bot. t. 783. Curt. Lond. fasc. 1. t. 1. Fl. Dan. t. 449. (V. folio chamædryis; Rivin. Monop. Irr. t. 99. f. 2. Alfine foliis trifraginis; Ger. Em. 616.)*

β. *Sm. Fl. Græc. Sibth. v. 1. 6. t. 8. (V. perfica; Poir. in Lam. Dict. v. 8. 542. V. stoculis oblongis pediculis infidentibus, chamædryos folio, major; Buxb. Cent. 1. 26. t. 40. f. 2.)*

Flowers solitary. Leaves ovate, deeply serrated, shorter than the flower-stalks. Stems procumbent. Segments of the calyx ovate. Seeds cupped.—Native of cultivated and waste ground, throughout Europe, annual, flowering from April to the end of autumn. β was gathered by Dr. Sibthorp, in Prince's islands, near Constantinople. *Root* small. Stems prostrate, simple, except at the base, round, leafy, hairy, from six to twelve inches long. Some of the lower leaves are opposite, but the greater part are alternate, all stalked, roughish. Flowers deep blue, rather small. Segments of the calyx ovato-lanceolate, fringed, generally quite entire, now and then irregularly toothed; becoming broadly ovate as the fruit advances. Capsule rough, of two round swelling lobes. Seeds about six in each cell, externally rugged, hollowed out underneath, where their stalk is inserted.—We would gladly, if possible, have made a distinct species of the *V. byzantina* of Sibthorp's manuscripts, our variety β; but no difference is to be found, except the greater size of every part. The corolla is much larger, paler, more elegantly streaked. The form of the calyx, tumid capsule, and curious structure of the seeds, are all the same as in our common kind.

74. *V. arvensis*. Wall Speedwell, or Speedwell Chickweed. *Linn. Sp. Pl. 18. Willd. n. 48. Vahl n. 59. Fl. Brit. n. 14. Engl. Bot. t. 734. Curt. Lond. fasc. 2. t. 2. Fl. Dan. t. 515. Pursh n. 8. (Alfine foliis veronicæ; Ger. Em. 613. Alyssum; Column. Phytob.*

t. 28.)—Flowers solitary, nearly sessile. Leaves ovate, deeply serrated; the floral ones lanceolate, entire. Stem erect. Seeds flat.—Native of Europe, North America and Japan, on walls, banks, and dry gravelly or sandy ground, flowering in May. The *herbage* is of a pale green, rough. Stem about six inches high, branched from the bottom. Lowest leaves on short stalks; the rest sessile; the floral ones so small, as to seem like bracteas only, but their true nature appears from the analogy of other annual species. Flowers small, pale blue; their very short stalks more or less elongated as the fruit advances. Segments of the calyx lanceolate, somewhat unequal. Capsule inversely heart-shaped, compressed. Seeds elliptical, flat, with a little dimple in the centre of one side.

75. *V. rotundifolia*. Round-leaved Peruvian Speedwell. "Fl. Peruv. v. 1. 6." *Vahl n. 60.*—"Flowers solitary, stalked. Leaves orbicular-kidney-shaped, crenate. Stem three-shaped, creeping."—Plentiful in boggy situations in Peru. Hairy. Stem slender, branched, round, purple. Leaves two or three, often but one, from each joint, on long stalks, somewhat peltate, deeply notched. Flower-stalks twice the length of the footstalks. Segments of the calyx lanceolate. Corolla of a rosy purple, with ovate segments. Stamens three, the length of the tube. The flowers are occasionally five-cleft, with four stamens. Vahl from the *Fl. Peruv.* There is no figure, and having seen no specimen, we are very ready to concur with Vahl, in his opinion, that the genus of this plant is doubtful.

76. *V. cymbalaria*. White Oriental Speedwell. *Sm. Fl. Græc. Sibth. v. 1. 7. t. 9. (V. cymbalariaefolia; Vahl n. 61. V. cymbalarifolia; Gmel. Tubing. 6. V. hederifolia β; Linn. Sp. Pl. 19. Willd. n. 49. V. chia, cymbalariz folio, verna, flore albo umbilico virescente; Tournef. Cor. 7. Buxb. Cent. 1. 25. t. 39. f. 2.)*—Flowers solitary. Leaves heart-shaped, deeply crenate. Segments of the calyx rounded. Seeds cupped, nearly smooth.—Native of fields about Constantinople, and in the Greek islands, as well as in Morocco. Annual. Stems spreading or procumbent, branched at the base only, a span long, square, with a hairy line at two opposite sides. Leaves all stalked, opposite, rounded, obtuse, with two or three deep notches at each side, but scarcely lobed. Flowers white with a yellow centre, on long, opposite, capillary stalks, reaching beyond their corresponding leaves. Segments of the calyx obovate, obtuse, fringed, entire. Capsule turgid, of two round lobes, hairy. Seeds only two in each cell, large, hollow at one side, nearly smooth externally, chiefly wrinkled at the margin. Very distinct in its calyx from the following.

77. *V. hederifolia*. Ivy-leaved Speedwell. *Linn. Sp. Pl. 19. Willd. n. 49. Vahl n. 62. Fl. Brit. n. 15. Engl. Bot. t. 784. Curt. Lond. fasc. 2. t. 1. Poit. c. Turp. Paris. 23. t. 26. Fl. Dan. t. 428. (V. folio hederæ; Rivin. Monop. Irr. t. 99. Alfine hederacea; Ger. Em. 616. Alfine quantum genus; Fuchf. Ic. 13.)*—Flowers solitary. Leaves heart-shaped, flat, five-lobed. Segments of the calyx heart-shaped, acute. Seeds cupped, wrinkled.—Native of fields and waste ground throughout Europe, flowering in April and May. Annual, in habit like the last, but the leaves are more decidedly lobed, and ivy-like, though of a pale green. They are also, except a very few of the lowermost, all alternate, mostly longer than their footstalks. Flowers pale blue, on long, solitary, axillary stalks. Segments of the calyx nearly equal, pointed, three-ribbed, with a very broad heart-shaped base. Seeds much more wrinkled at the outside than the last, but agreeing with that species and *agrestis* in their reversed cup-like form.—The late Mr. Crowe observed to the writer of this, after the

VERONICA.

the present species had appeared in *Engl. Bot.*, that it is scarcely to be found with us in flower later than May, and that the Norfolk farmers call it Winter-weed.

78. *V. filiformis*. Capillary-stalked Speedwell. Sm. Tr. of Linn. Soc. v. 1: 195. Willd. n. 50. Vahl n. 63. March. Taur.-Caucas. v. 1. 15. (*V. orientalis*, foliis hederæ terrestris, magno flore; Tourn. Cor. 7. Buxb. Cent. 1. 25. t. 40. f. 1.)—Flowers solitary. Leaves heart-shaped, crenate, much shorter than the long slender flower-stalks. Segments of the calyx lanceolate.—Native of the Levant; found by the Chevalier de Steven in mountainous fields of Georgia, flowering early in the spring. We have compared his specimens with Tournefort's, nor is there any difference, though the reference to this author is directed in the *Fl. Taur.-Caucas.* to be struck out. The root is annual. Stems long and trailing. Leaves a quarter of an inch long, alternate, on short stalks, and shaped more like those of *arvensis* or *agrestis* than of *hederifolia*. Flower-stalks four times as long as the leaves. Segments of the calyx elliptic-lanceolate, obtuse, slightly three-ribbed. Capsule inversely heart-shaped, reticulated with veins. Seeds somewhat cupped.

79. *V. Crista-galli*. Crested Speedwell. Stev. Tr. of Linn. Soc. v. 11. 408. t. 31.—Flower-stalks solitary, as long as the ovate, ferrated, nearly sessile, leaves. Calyx of the fruit divided to the base into two heart-shaped, cloven, ferrated, compressed leaves.—Found by the Chevalier de Steven, to whom we are obliged for a specimen, very plentifully in the dense shady forests of Eastern Caucasus, above Kuban, flowering in May. The root is annual. Stem a span high, ascending, simple, or alternately branched, slender, downy, on two opposite sides. Leaves most like *V. agrestis*, uniform; the floral ones alternate, the rest opposite. Stalks axillary, slender, downy. Flowers extremely minute and fugacious, blue. Calyx greatly enlarged after flowering, of two flat, parallel, strongly ferrated, veined, heart-shaped valves, each with two points, being altogether peculiar in this genus, and about the diameter of the leaves. Capsule of two nearly orbicular lobes, shorter than the permanent calyx, very minutely fringed. Seeds solitary in each cell, black, rugged; concave, or umbilicated, at one side; inserted at the top of the cell.

80. *V. triphyllus*. Blunt-fingered Speedwell. Linn. Sp. Pl. 19. Willd. n. 51. Vahl n. 64. Fl. Brit. n. 16. Engl. Bot. t. 26. Sm. Fl. Græc. Sibth. v. 1. 8. t. 10. Curt. Lond. fasc. 6. t. 2. Fl. Dan. t. 627. (*V. folio ruta*); Rivin. Monop. Irr. t. 96. Aline recta; Ger. Em. 612.)—Flowers solitary. Upper leaves in deep, finger-like, obtuse segments. Flower-stalks longer than the calyx. Seeds flat.—Native of sandy fields, here and there, throughout Europe; rare in England, occurring chiefly in the sandy confines of Norfolk and Suffolk, flowering in April. Dr. Sibthorp found it, very luxuriant, in fields bordering on the Euxine sea. A small upright annual plant, more or less branched, leafy, downy, a little viscid and hoary. Lower leaves opposite, undivided, scarcely lobed; upper alternate, in three deep segments, the lateral ones often cloven. Flowers of a rich dark blue. Two segments of the calyx sometimes notched. Capsule almost orbicular, emarginate. Seeds numerous, obovate, flat. This plant turns black in drying, like most of the following species.

81. *V. verna*. Vernal Speedwell. Linn. Sp. Pl. 19. Willd. n. 52. Vahl n. 65. Fl. Brit. n. 17. Engl. Bot. t. 25. Rofe Elem. app. 444. t. 2. f. 1. Fl. Dan. t. 252. Poit. et Turp. Paris. 21. t. 22. (*V. Bellardi*; Willd. n. 56. Allion. Pedem. v. 1. 77. t. 85. f. 1. *V. succulenta*; *ibid.* 78. t. 22. f. 4.)—Flowers solitary. Leaves pinnatifid. Flower-stalks shorter than the calyx. Stem erect.—Native

of dry open sandy fields in various parts of Europe, flowering in April. In England it chiefly occurs about Bury, Thetford, and the same sandy country as the last, but there in the greatest abundance, though soon disappearing after the feed is shed. This diminutive species is most akin to *V. arvensis*, in the flat elliptical form of its seeds, general habit and colour; not turning black in drying, like *triphyllos* and most of its allies. But the leaves, unless starved, are deeply fingered, or pinnatifid, their terminal lobe often large and rounded, like *triphyllos*; even the floral ones are deeply three-cleft. The stem, whether branched or not, is stiff and erect, from one to four inches high. Calyx in four nearly equal, lanceolate, acute segments. Capsule inversely heart-shaped. The herb varies so much in luxuriance, and consequently in the divisions of its leaves, that scarcely two representations of it are alike.

82. *V. digitata*. Slender-fingered Speedwell. Vahl n. 66. Symb. v. 1. 2. (*V. verna*; Cavan. Leccion. 22. *V. acinifolia*; Ait. n. 37. *V. chamæpithyoides*; Lamarck Illustr. v. 1. 47.)—Flowers solitary, sessile. Leaves all in deep, finger-like, linear segments. Stem erect. Capsule wedge-shaped.—Native of the south of Europe. We have gathered it in Lombardy, and received it from near Araujuez in Spain, by favour of the late abbé Cavanilles, who has described this species for *verna*. The plant is annual, flowering in April. Stem branched from the bottom only, from three to six or eight inches high, rigid, round, downy, leafy, rather woody. Leaves alternate, sessile, generally cut, more than half way down, into three, five, or seven, linear, obtuse, fleshy, somewhat rough or hairy, entire segments; the base narrow and linear, which Vahl considers, perhaps justly, as a *footstalk*. Flowers small, axillary. Calyx in four deep, lanceolate, fringed segments, the length of the capsule, two of them shorter than the rest. Capsule inversely heart-shaped, but with straight sides, rough, abrupt, rigid. Seeds pale, roundish, not compressed.

83. *V. præcox*. Early Jagged Speedwell. Allion. Auctuar. 5. t. 1. f. 1. Vahl n. 57. Poit. et Turp. Paris. 22. t. 24. (*V. acinifolia*; Willd. Prodr. Berol. 11. *V. minor* annua, ocyimi caryophyllati folio, subtus rubro; Vaill. Paris. 202.)—Flowers solitary, stalked. Lower leaves opposite, stalked, heart-shaped, deeply ferrated and notched; uppermost oblong, alternate, nearly entire. Stem erect. Style longer than the lobes of the capsule.—Native of fields about Turin, Paris, and Berlin, flowering in March and April. Mr. Davall found it also in the Lower Valais, in April, 1787. An annual upright plant, about the size of *V. arvensis*, but with more of the habit and red hue of *triphyllos*, much larger and stronger than *verna*. Stem chiefly branched from the bottom, round, downy all over, but most densely on two opposite sides. Leaves rough, rather fleshy; the largest half an inch long, and nearly as broad, obtuse; variously toothed or jagged; floral ones hardly so long as the flower-stalks. Flowers blue or purplish. Segments of the calyx obovate-oblong, hairy, two of them rather the shortest. Capsule inversely heart-shaped, hairy, tumid, rounded at the sides, so as to be somewhat orbicular, the permanent style extending far beyond its lobes. Seeds numerous, roundish, cupped and umbilicated.—No wonder that those botanists, who had not seen both species, have always taken this for the following, and yet they are essentially distinct.

84. *V. acinifolia*. Basil-leaved Early Speedwell. Linn. Sp. Pl. 19. Willd. n. 54. Vahl n. 67. Dickk. Dr. Pl. n. 1. Poit. et Turp. Paris. 22. t. 23. Allion. Ped. v. 1. 79. (*V. romana*; *ibid.* t. 85. f. 2. *V. minima*, clinopodii minoris folio; Vaill. Paris. 201. t. 33. f. 3. *V. minima*, clinopodii minoris folio glabro, romana; Bocc. Mus. 19. t. 102.)—Flowers

—Flowers solitary, stalked. Leaves opposite, ovate, slightly crenate; lower ones opposite, partly stalked; upper sessile, alternate, entire. Stem erect. Style about as long as the lobes of the capsule.—Native of France, Italy, Turkey, and, as it is reported, of Germany; though we have never received from that country any thing but *arvensis* or *præcox* under this name. In shady neglected garden walks, and gravelly ground, about Rome, nothing is more common than this little annual, flowering in April. What Mr. Davall sent to Kew for *acinifolia*, in 1788, was certainly the *præcox*. The present is by far the most delicate and slender plant of the two, though nearly of the same height. Leaves smoother, paler, ovate, and much more entire. Flowers much smaller, on rather longer, more capillary, stalks. Segments of the calyx ovate, or obovate. Capsule short, broadly obovate, with round distant lobes, between which the permanent style is situated, scarcely, if at all, extending beyond them. Seeds numerous, oval, flat. The authors of the splendid, but too soon discontinued, *Flore Parisienne*, have well distinguished these two last species, by the proportion of the styles to their respective, very differently shaped, capsules. It is curious to observe how authors have erred and copied each other's errors, in their citation of Boccone. See Linnæus, Willdenow, Vahl, and Poiret in Lamarck.

85. *V. peregrina*. Purslane-leaved Speedwell. Linn. Sp. Pl. 20. Willd. n. 55. Vahl n. 68. Ait. n. 38. Sm. Tr. of Linn. Soc. v. 1. 192. Pursh n. 9. Fl. Dan. t. 407. (*V. romana*; Linn. Sp. Pl. 19. Mant. 317. *V. marilandica*; Linn. Sp. Pl. 20. "Murr. in Comm. Goett. for 1782. 11. t. 3." *V. caroliniana*; Walt. Carolin. 61. *V. terrestris* annua, folio polygoni, flore albo; Morif. v. 2. 322. sect. 3. t. 24. f. 19.)—Flowers solitary, sessile. Leaves oblong, smooth, obtuse, toothed or entire; the lower ones opposite. Stem erect. Style shorter than the lobes of the capsule.—Native of cultivated ground in several parts of Europe, Britain excepted, as well as of North America, Lima, and the Brazils, flowering in summer. The root is annual. Herb very variable in habit and size, sometimes partly decumbent; it is branched from the base, smooth in every part, rather succulent, vastly more like Purslane, than any species of *Polygonum*. Leaves an inch or more in length, for the most part sessile, some of them coarsely and distantly toothed, the upper or floral ones generally entire. Flowers nearly or quite sessile. Segments of the calyx oblong, bluntish, a little unequal. Corolla small, white. Capsule inversely heart-shaped, with a very short style, not reaching quite so far as the lobes. Seeds numerous, small, oval, flat.—Linnæus was singularly unfortunate with respect to this species and the *acinifolia*. His original specimen of *V. romana*, answering to the character, as well as the number, in Sp. Pl. ed. 1, is, notwithstanding Vahl's doubts, precisely the same as his *peregrina*, of which a third specimen is marked *acinifolia*; but this last specimen is not an original one. The synonyms of *romana* are properly referred in Sp. Pl. ed. 2. to *acinifolia*, so that the Linnæan *romana* is to be entirely excluded. Whether the *V. erecta acini folio glabro, floribus cæruleis*, Dill. Giff. app. 39, be the *acinifolia*, as commonly supposed, or the *præcox*, we have some doubts. *V. marilandica*, adopted from Gronovius, is universally allowed to be the *peregrina*, which therefore embraces three Linnæan species, none of them entitled to rank even as varieties of each other.

VERONICA, in Gardening, comprises plants of the herbaceous, perennial, and shrubby kinds, among which the species cultivated are, the Siberian speedwell (*V. sibirica*); the Virginian speedwell (*V. virginica*); the bastard speedwell (*V. spuria*); the sea speedwell (*V. maritima*); the long-leaved speedwell (*V. longifolia*); the Welsh speedwell

(*V. hybrida*); the cut-leaved speedwell (*V. incifa*); and the cross-leaved speedwell (*V. decussata*).

In the second sort the stems are terminated by long slender spikes of white flowers, which appear late in July; and it varies with the bluish-coloured flowers. The third is perennial in root, having the stems terminated by long spikes of blue flowers, which appear in June and July. A variety of this has a flesh-coloured flower. The fourth has the stalks of less length than those of the preceding, but the flowers are of a bright blue, and appear in July. There are varieties with leaves opposite, in threes or in fours, with blue, blueish, flesh-coloured, and with white flowers. The fifth has the stems a foot and a half high, which are terminated by long spikes of blue flowers, which appear in June. The sixth has very white and woolly stalks about a foot high, the flowers of which are deep blue in terminating spikes. A variety has white flowers. The last sort is a bushy shrub, about two feet in height.

Method of Culture.—These plants may be raised by seed and parting the roots. In the annual sorts the seeds should be sown in the autumn, or very early spring, in the borders or places where the plants are to grow, being lightly covered in: if the seeds be permitted to scatter, good plants may be raised: sometimes they are sown on beds, to be afterwards removed. In the perennial sorts the roots may be parted in the autumn or early spring, and planted out where they are to grow, or in nursery rows to be afterwards removed. They should not be parted too small, or oftener than every two years: the large-growing sorts are proper for the borders, clumps, &c. and the trailing kinds for banks and shady slopes, or other similar places: they are hardy, and require only to be kept clean afterwards. The eighth sort is readily increased by cuttings in the spring and summer, being managed as a hardy greenhouse plant, in the same way as the myrtle. In very mild winters it sometimes stands secure in the open air. The annual and perennial sorts afford variety in the borders, clumps, and other parts of pleasure-grounds, and the last among plants of the hardy potted greenhouse kinds.

VERONICA, in the *Materia Medica*. The *Becabunga* was formerly used in several diseases, and applied externally to wounds and ulcers; but its supposed efficacy must depend on its antiscorbutic quality. As a mild refrigerant juice, it is deemed serviceable in an acrimonious state of the fluids; and it is ordered in the Lond. Ph. as an ingredient in the fucus cochliariæ compositus. Its benefit depends on taking the juice in large quantities, or eating the fresh plant as food. The leaves of the *officialis* have a weak, not disagreeable, smell, and a bitterish taste: an extract from them by rectified spirit is moderately bitter and astringent. About a century ago, this plant was much recommended as a substitute for tea: as a medicine, it had considerable reputation in coughs, asthma, consumptions, &c.; but, as it is a less powerful astringent than many others, it is now disregarded. Lewis. Woodville.

VERONUS, in *Ichthyology*, a name given by many to a small river-fish, well known in England by the name of the *minnow*.

VEROVITZA, in *Geography*, a town of Slavonia. This is a strong town, situated near the Drave; 36 miles S.S.E. of Cambrach.

VERPILLIERE, LA, a town of France, in the department of the Ière; 5 miles S.E. of Lyons.

VERPLANK'S POINT, a fortified spot in the State of New York, on the left bank of Hudson's river, in West Chester county, which was taken, in 1779, by the British troops; 34 miles N. of New York. N. lat. 41° 15'. W. long. 74°.

VERRANA, a town of Naples, in the province of Otranto; 10 miles S.S.E. of Oria.

VERREGINUM, or VERRUGO, in *Ancient Geography*, a town of Italy, in Latium, in the country of the Volsci.

VERRETZ, in *Geography*, a settlement of the island of Hispaniola; 30 miles N.E. of St. Marc.

VERREZ, a town of France, in the department of the Dora, or in Piedmont, situated at the foot of a hill, on a stream of water, which divides into three branches, traversing the town on both sides, and the centre. The inhabitants have no other ramparts than the neighbouring mountains, and no other fosses than the beds of the rivers, made by nature: the houses are about 150 in number. In the most elegant part is a square fortress, built on a sharp rock, surrounded with a wall of stone, a parapet, and a good rampart, which surrounds the fortress and the gate of entrance, so that no one can arrive at this gate till they have passed the rampart and a drawbridge upon the fosse. When the bridge is up, the fortress is supposed to be impregnable, being surrounded on all sides with frightful precipices, while the access is only by narrow passes in the valley, which a small garrison can obstruct and annoy the enemy far and near; 15 miles S.S.E. of Aosta.

VERRIÈRES, a town of France, in the department of the Vienne; 13 miles S.E. of Poitiers.—Also, a town of France, in the department of the Marne; 3 miles S. of St. Menehould.—Also, a town of Neuchâtel, on the borders of France, the environs of which are famous for cheese. Near it is a narrow pass of only five feet wide, with inaccessible rocks on both sides; so that a few men could defend it against great numbers.

VERRIO, ANTONIO, in *Biography*, was born at Naples in 1634. After he had acquired the management of the pencil, he went to Toulouse, and there was engaged to paint the high altar in the church of the Carmelites. He was invited by Charles II. to England, the king intending to engage him in designs for tapestry, to be made here; but he changed his mind, and ordered him to paint most of the ceilings of Windsor castle, the great hall, and the chapel; all which he loaded with heterogeneous compounds of gods and goddesses, vices and virtues, and all the emblematic imagery which scholastic pomposity could muster up, to supply the place of common sense; and this he executed with great freedom and great freshness of colour, but in a manner devoid of any other good quality of art. For these labours he was paid nearly 6000*l*.

The Revolution was not to his mind: he declined to serve king William, and went to the earl of Exeter at Burlington, where he painted several apartments, which are esteemed his best works. He afterwards painted at Chatsworth, and at Lowther: at length he was persuaded by the earl of Exeter to engage to paint for the king the great staircase at Hampton-Court; and Walpole observes, "he painted it as ill as if he had spoiled it out of principle." His eyes failing him, queen Anne gave him a pension of 200*l*. per annum for life; but he did not long enjoy it, dying at Hampton-Court in 1707.

VERRO, in *Geography*, a town of Russia, in the government of Riga; 124 miles N.E. of Riga. N. lat. 58° 10'. E. long. 27° 24'.

VERROCHIO, ANDREA, in *Biography*, was among the early Florentine artists who prepared the way for the greater talents of subsequent painters. He was born at Florence in 1432, and distinguished himself both as a sculptor and painter. He had the honour to be the instructor of P. Perugino and Lionardo da Vinci, and was much employed; till, as Vasari reports, being engaged by

the monks of St. Salvi, at Valombrosa, to paint a picture of the Baptism of Christ, he set Lionardo da Vinci, then his pupil, to put in the figure of an angel from his design, and he executed his task in a manner so superior to the work of his master, that Verrochio, in disgust, resolved to paint no more, but apply himself entirely to sculpture and drawing. His style of design was grand and free, and Lionardo took great pleasure in copying his drawings, particularly a battle-piece, on account of the peculiar airs of the heads, the disposition of the hair, and the actions of the figures. He died in 1488, aged 56.

VERRUA, in *Geography*, a town of Piedmont, or lately of France, in the department of the Tanaro, on a high hill, near the Po, opposite Crescentin: the fortifications were once very strong, and the castle was called impregnable; 18 miles N.E. of Turin. N. lat. 45° 14'. E. long. 8°.

VERRUCA, in *Medicine*. See WART.

Hence, verrucous is applied to any excrescences which have a resemblance to warts. There are also verrucous ulcers, &c.

VERRUCARIA, in *Botany*, so called by Perfoon, from *verruca*, a wart, in allusion to the protuberant form of its fructification. The same name had been previously applied by Wiggers in his *Primitiæ El. Hist.* 85, in an extremely vague manner, to many of the crustaceous Lichens of Linnæus; but it is now limited, as Perfoon intended, to a very natural genus.—Perf. in *Ust. Annal. fasc. 7. 23.* Schrad. *Spicil.* 108. *Achar. Prodr.* 13. *Meth.* 113. "Lichenogr. 51. t. 4. f. 2, 3." *Syn.* 87.—Class and order, *Cryptogamia Algæ. Nat. Ord. Lichenes.*

Gen. Ch. Frond crustaceous, expanded, flat, uniform, closely attached. *Receptacles* nearly globose, or somewhat hemispherical; their base sunk in the frond; their coat double; outermost rather cartilaginous, thick, black, clothing the upper, or exposed, half, and furnished with a small prominent mouth; inner very thin and membranous, entirely inclosing a globular, cellular nucleus.

Ess. Ch. Frond crustaceous. *Receptacles* half-immersed, globose, concave, black, with a cellular nucleus.

We have, under ENDOCARPON, adverted to the near agreement between the fructification of that genus and the present. Their habits and fronds however are very different, and Schrader has long ago indicated another distinction, that the *receptacle* is always closed in *Verrucaria*, while in *Endocarpion* its contents are discharged, he says "exploded," by a small, but distinct, orifice. On these characters this great cryptogamist would found his generic distinctions, regardless of the nature of the frond, and the greater or less degree of prominence of the *receptacles* sunk therein. But the learned Acharius, so peculiarly devoted to this difficult department of botany, has defined *Verrucaria* by more obvious, and as we think more natural limits, by which we have pointed above. He defines forty-five species of this genus, in his latest publication, the *Synopsis Methodica Lichenum*. They are distributed into four sections, according to the nature of the crust, or frond.

SECT. 1. Frond membranous, or somewhat cartilaginous, contiguous and smooth. Twenty-one species.

These all grow on the smooth barks of various trees, in Europe, Africa or America, in the form of a thin inseparable membrane, generally of a different colour from the cuticle of the bark, by which, more than the black dot-like fructification, these plants are generally rendered conspicuous. Examples of this section are

V. punctiformis. Ach. *Syn.* n. 1. (Lichen punctiformis; Engl. Bot. t. 2412. L. mycoproides; Ehrh. *Crypt.* 264.)—Crust determined, very thin, smooth, rusty-brown. *Receptacles*

ceptacles minute, black, hemispherical, umbilicated.—Found by Mr. W. Borrer, on the smooth bark of ash-trees.

V. analepta. Ach. n. 2. (Lichen analeptus; Engl. Bot. t. 1848.)—Differs from the foregoing chiefly in the central depression of the *receptacles* being more minute.

V. gemmata. Ach. n. 12. Meth. 120. t. 3. f. 1. (*V. melaleuca*; *ibid.* 117. *V. alba*; Schrad. Spicil. 109. t. 2. f. 3.)—Cruft undefined, thin, smooth, of a hoary white. Receptacles scattered, hemispherical, polished, beaked; nucleus globular, pellucid.—Found on the barks of the taller kinds of trees. *Acharius*. Mr. D. Turner has met with this species in England. The black and shining prominent *receptacles* are strongly contrasted with the white, somewhat mealy, cruft.

SECT. 2. *Fruond rather solid, more or less gelatinous*. Three species.

V. mucosa. Ach. n. 22. Meth. suppl. 23. “Wahlenb. Lapp. 466.”—Cruft gelatinous and slimy, very smooth, blackish-green. Receptacles minute, nearly globular, funk, with a prominent beak; dirty white internally.—Found by Mr. Wahlenberg, on rocks and stones washed by the mountain streams of Lapland and Sweden. When dry it is hard and almost black, but moisture restores the *cruft* to a slimy state, and the *fructification* is visible, in both states, to a careful observer.

The other species of this section are named *gelatinosa* and *ceuthocarpa*.

SECT. 3. *Cruft somewhat tartareous and friable, uninterrupted, cracking into small portions, or powdery*. Seventeen species.

V. Schraderi. Ach. n. 25. Meth. 114. (*V. rupestris*; Schrad. Spicil. 109. t. 2. f. 7. Lichen Schraderi; Engl. Bot. t. 1711. *L. immerfus*; Hoffm. Enum. Lich. 24. t. 3. f. 5. *fuco-ater* β ; Hag. Lich. 49.)—Cruft tartareous, hard, whitish, smooth. Receptacles minute, crowded, nearly globular, umbilicated, funk; semitransparent within.—This is often to be seen on chalk or lime-stone. The cavities in the very hard *cruft*, seem formed by the growth of the *receptacles*, and remain empty and unclosed after the latter fall out; just as happens in the true *Lichen immerfus*, or *Lecidea immerfa*. In this state our present *Verrucaria* may frequently be observed, on wrought stones in exposed situations; its hard *cruft* being scarcely distinguishable from the stone, except by its internal green hue when rubbed.

V. Harrimanni. Ach. n. 26. Lichenogr. v. 1. 284. (Lichen Harrimanni; Engl. Bot. t. 2539.)—Cruft tartareous, contiguous, limited, moufe-coloured, with very minute depressed dots. Receptacles minute, immerfed, globose, with a prominent bordered orifice; brownish within.—Native of hard, grey, calcareous rocks, in the county of Durham, where it was discovered by the Rev. Mr. Harriman, a very skilful British botanist. The *cruft* of this is thicker, with a more defined black edge than usual in *Verrucaria*, yet it cannot be separated in any entire portions from the stone. The dotted surface is peculiar. The dilated rim of each *receptacle* is all that is visible of the fructification.

V. maura. Ach. n. 36. Meth. suppl. 19. (Lichen maurus; Engl. Bot. t. 2456.)—Cruft thin, continued, imperfectly circumscribed, coal-black, smooth, with innumerable minute cracks. Receptacles black, immerfed, swelling under the cruft, marked by an umbilicated point; nucleus blackish.—Mr. W. Borrer has noticed this frequently on rocks on the Scottish coast, and his specimens agree with those sent by Mr. Wahlenberg, the original discoverer of the present species, on the rocky shores of Sweden. It composes foaty inseparable blotches, on stones exposed to the flux and reflux of the tide; but when examined, will be found as distinct in characters as any of its tribe.

SECT. 4. *Cruft soft, fibrous, somewhat spongy, or like a thin cobweb*. Four species.

V. epigea. Ach. n. 43. Meth. 123. (*Sphæria epigea*; Perf. Syn. Fung. append. 27. Lichen terrestris; Engl. Bot. t. 1681.)—Cruft somewhat fibrous, gelatinous, uneven, pale greenish-grey. Receptacles minute, globose, immerfed, with a prominent orifice; internally black.—Not unfrequent on earthy or muddy banks. When dry the *cruft* is smooth and even, without any sign of the fibrous texture, which becomes visible on the admission of wet. The *receptacles* are scattered like little black dots over the surface, being most prominent in a dry state.

V. byssacea. Ach. n. 45. Meth. 116. (*Sphæria byssacea*; Weigel Obs. Bot. 42. t. 2. f. 9. Perf. Syn. Fung. append. 27.)—Cruft somewhat leprous and fibrous, dirty white. Receptacles minute, nearly globular, half immerfed, perforated; black within.—On the trunks of old oaks, and other trees. This seems to be a very doubtful *Verrucaria*. We have never examined it, but the *cruft* is described more of a leprous than fibrous texture, resembling *Byssus laevis* of Linnæus. Receptacles full of black powder. It is one of those ambiguous productions, partly allied to the *Lichenes*, partly to the *Fungi*, which the students of each tribe press into their own service. From an attention to the fibrous bases of some other *Sphæriae*, we should incline to think this a fungus, especially if the *receptacles* be really full of powder; but on the other hand, the mealiness of the *cruft* is much more of the nature of the genus under consideration. *Acharius* now considers as a variety of this, his *V. sititica*, Meth. 118; and indeed they appear very nearly akin.

VERRUCINI, in *Ancient Geography*, a people of the Maritime Alps, N.W. of the Suelteri, mentioned by Pliny. They are placed at Verignon.

VERRUCOLA, LA, in *Geography*, a town of Etruria; 4 miles E. of Pisa.

VERRUCOSUS, *Warty*, in *Botany and Vegetable Physiology*, is a term applied to any part of the surface of a plant when furnished with scattered protuberances from its own substance. *Euonymus verrucosus* of Scopoli and Jacquin has a warty bark. The young branches are first besprinkled with little black shining oblong specks, which soon enlarge, crack longitudinally, and become tumid rough warts, having much more of the appearance of a parasitical fungus, than many productions that are so denominated. In *Aloe perlata* the cuticle of the leaves is studded with hard cartilaginous smooth warts, exhibiting a most genuine example of a *solum verrucosum*. So in *Echium*, several species bear hard, almost bony or fleshy, warts, sometimes elegantly stelled, from which the brittle clothing of the herbage originates. These are all less strong and remarkable, the more luxuriant the plant. The papillary coat of the Ice-plant, *Mesembryanthemum crystallinum*, can scarcely come under the above denomination; being an assemblage of cuticular bladders full of a watery fluid, without any cuticular or fleshy solidity.

VERRUYE, in *Geography*, a town of France, in the department of the Two Sevrès; 7 miles N.N.W. of St. Maixens.

VERRY, in *Heraldry*. See VAIRY.

VERS du Gard, in *Geography*, a town of France, in the department of the Gard; 6 miles S.E. of Uzès.

VERS en Montagne, a town of France, in the department of the Jura; 18 miles N.E. of Lons le Saunier.

VERSA. See VICE Versa.

VERSAILLES, in *Geography*, a city of France, and capital of the department of the Seine and Oise. In the beginning of the last century, it was a small village, when

Louis XIII. built here a hunting feat, which Louis XIV. enlarged into a palace, in a forest 30 miles in circumference, which became a place of frequent residence of the royal family till the revolution. The palace is magnificent, with beautiful gardens, adorned with statues, canals, fountains, &c. and a park five miles in circumference, surrounded with a wall. Since the revolution, it has been erected into a bishop's see; 3 posts S.W. of Paris. N. lat. 48° 49'. E. long. 2° 11'.

VERSAILLES, a township of Pennsylvania, in the county of Alleghany; containing 883 inhabitants.—Also, a town of Woodford county, in the state of Kentucky; containing 488 inhabitants.

VERSAK, a district of Asiatic Turkey, in the S. part of Caramania, so named from a mountain, 60 miles S.E. of Cogni.

VERSAMEYRA, a town of Hindoostan, in Cutch; 20 miles E. of Boogebooge.

VERSARA, a town of Hindoostan, in Guzerat; 32 miles S. of Amedabad.

VERSAUL, a town of Hindoostan, in Guzerat; 6 miles N. of Pernalla.

VERSCHORISTS, in *Ecclesiastical History*, a religious sect, deriving its denomination from Jacob Verschoor, a native of Flushing, who, in the year 1680, out of the tenets of Coccius and Spinofa, produced a new form of religion; for the leading tenets of which see HATTEMISTS.

The disciples of Verschoor were also called Hebrews, on account of the zeal and diligence with which they applied themselves to the study of the Hebrew language.

VERSE, VERSUS, in *Poetry*, a line or part of a discourse, consisting of a certain number of long and short syllables, which run with an agreeable cadence; the like being also reiterated in the course of the piece.

This repetition, according to F. Bossu, is necessary to distinguish the notion of verse from that of prose; for in prose, as well as verse, each period and member are parts of discourse, consisting of a certain number of long and short syllables; only, prose is continually diversifying its measures and cadences, and verse regularly repeats them.

This repetition of the poets appears even in the manner of writing; for one verse being finished, they return to the beginning of another line to write the verse following: and it is to this return that verse owes its name; *versus* coming from *vertere*, to turn or return.

Accordingly, we find the same word used to signify any thing that is placed in a certain regular order: Cicero uses *versus* for a line in prose; Virgil for a row of trees, and even of oars in a galley. But as the regularity of verse carries with it more charms, and requires a greater degree of exactness, the word has, in time, become appropriated to poetry.

To make verse, it is not enough that the measures and quantities of syllables be observed, and fix just feet put, one after another, in the same line; there are farther required certain agreeable cadences, particular tenes, moods, regimens. and even sometimes words unknown in prose.

But what is chiefly required, is an elevated, bold, figurative manner of diction; this manner is a thing so peculiar to this kind of writing, that, without it, the most exact arrangement of longs and shorts does not constitute verse so much as a sort of measured prose. See POETRY.

Dr. Blair (Lectures, vol. iii.) observes, that nations, whose language and pronunciation were of a musical kind, rested their versification chiefly upon the quantities, that is, the length or shortness of their syllables. Others, who did not make the quantities of their syllables to be so distinctly per-

ceived in pronouncing them, rested the melody of their verse upon the number of syllables it contained, upon the proper disposition of accents and pauses in it, and frequently upon that return of corresponding sounds which we call *rhyme*; which see. The former was the case with the Greeks and Romans; the latter is the case with us, and with most modern nations.

The Greek and Latin verses consist of a certain number of feet, disposed in a certain order; so that every syllable, or the greatest number at least, was known to have a fixed and determined quantity; and their manner of pronouncing rendered this so sensible to the ear, that a long syllable was counted precisely equal in time to two short ones. Upon this principle, the number of syllables contained in their hexameter verse was allowed to vary. The musical time, however, was precisely the same in every such verse, and was always equal to that of twelve long syllables. In order to ascertain the regular time of every verse, and the proper mixture and succession of long and short syllables which ought to compose it, were invented what the grammarians call metrical feet, dactyles, spondees, iambs, &c. And the hexameter verse was scanned or measured by six metrical feet, either dactyles or spondees, with this restriction, that the fifth foot was regularly to be a dactyle, and the last a spondee. And some have attempted to make French and English verses on the same foundation, but without success.

The introduction of these feet into English verse would not suit the genius of our language, which does not correspond, in this respect, to the Greek or Latin. Hence mere quantity is of little effect in English versification. The only perceptible difference among our syllables is owing to that stronger percussive of voice, called accent, with which some of them are uttered: and accordingly, the melody of our verse depends much more upon a certain order and succession of accented and unaccented syllables, than upon their being long or short.

If we take any of Mr. Pope's lines, and, in reciting them, alter the quantity of the syllables as far as our quantities are sensible, the music of the verse will not be much altered; but if we do not accent the syllables as the verse dictates, its melody will be totally destroyed. (See Lord Monboddo's Treatise of the Origin and Progress of Language, vol. ii.) In the constitution of our verse, the cæsural pause is an essential circumstance, and this falls towards the middle of each line. In the French heroic verse this is very sensible. This is a verse of twelve syllables, and in every line, just after the sixth syllable, there falls, regularly and indispensably a cæsural pause, dividing the line into two equal hemistichs. Thus the one-half of the line always answers to the other, and the same chime returns incessantly on the ear, without intermission or change; which is, without doubt, a defect in their verse, and renders it unfit for the freedom and dignity of heroic poetry. For the difference of the English verse in this respect, see PAUSE. See also ACCENT, PROSODY, and QUANTITY.

Vossius is very severe on the modern verse, and makes it altogether unfit for music: our verses, says he, run all, as it were, on one foot, without distinction of members or parts, and without regard to the natural quantities of syllables. We have no rhythmus at all; and we mind nothing, but to have a certain number of syllables in a verse, of whatever nature, and in whatever order.

Mr. Malcolm vindicates our verse from this imputation. It is true, he says, we do not follow the metrical composition of the ancients; yet we have such a mixture of strong and soft, long and short syllables, as makes our verse flow smoothly

smooth or rumbling, slow or rapid, agreeable to the subject. Instances of all which we have in the following lines.

“ Soft is the strain when Zephyr gently blows.
The hoarse rough verse should, like the torrent, roar.
The line too labours, and the words move slow.
Flies o'er th' unbending corn, and flims along the main.”

By making a small change, or transposition of a word or syllable in any of these verses, any body who has an ear will find, that we make a great matter of the nature and order of the syllables.

Vossius adds, that the ancient odes were sung, as to the rhythmus, (see RHYTHMUS) in the same manner as we scan them; every *pes* being a distinct bar, or measure, separated by a distinct pause, though, in reading, that distinction was not accurately observed.

Lastly, he observes, that their odes had a regular return of the same kind of verse; and the same quantity of syllables in the same place of every verse; whereas, in the modern odes, to follow the natural quantity of our syllables, every stanza would be a distinct song.

It is next to impossible to write prose without sometimes intermixing verse with it; so that Vaugelas's rule, which enjoins us to avoid them, is next to impracticable. This may be farther said, that for short verses they are so little perceived, that it is scarcely worth one's while to strain one's self to avoid them; and as to long verses, they are chiefly to be avoided in the ends of periods, for, in the middle, they are scarcely felt. In the general, rules of this kind must be considered as principally regarding numerous verses, and such as are readily distinguished by their cadence: thus, in Latin, it is scarcely possible to avoid iambic verses; but hexameters must, by all means, be avoided, their cadence being more sensible and more studied.

Verses are of various kinds; some denominated from the number of feet of which they are composed; as the *monometer*, *dimeter*, *trimeter*, *tetrameter*, *pentameter*, *hexameter*, *hendecasyllabum*, &c. Some from the kinds of feet used in them; as the *pyrrhician*, *proceleusmatic*, *iambic*, *trochaic*, *daelylic*, *anapestic*, *spondaic* or *mollosian*, *choriambic*, *iambic-daelylic*, or *daelylotrochaic*. Sometimes from the names of the inventors, or the authors who have used them with most success: as the *Anacreontic*, *Archilochian*, *Hippocratic*, *Phecratian*, *Glyconian*, *Alemanian*, *Aclepiadean*, *Alcaic*, *Stesichorian*, *Phaliscan*, *Aristophanian*, *Callimachian*, *Galliambic*, *Phalacian*, and *Sapphic*. Sometimes from the subjects, or the circumstances of the composition; as the *heroic*, *elegiac*, *Adonic*, &c. See HEXAMETER, PENTAMETER, IAMBIC, &c.

In reckoning the feet of iambs, trochaics, and anapestics, each meter is a dipody, or comprehends two feet. In other verses, a meter is but a single foot. Hence it is that the iambic trimeter is also called *senarium*, because composed of six feet. See VERSIFICATION, *infra*.

The ancients invented various kinds of poetical devices in verse, as *centos*, *echoes*, and *monorhymes*.

VERSE, *Alexandrin* or *Alexandrian*. See ALEXANDRIN.

VERSE, *Blank*, is a noble, bold, and disencumbered species of versification; free from that full close which rhyme forces upon the ear at the end of every couplet, and allowing the lines to run into each other, with as great, if not greater, liberty than the Latin hexameter. Accordingly it is suited to subjects of dignity and force, which demand more free and manly numbers than rhyme. The constraint and strict regularity of rhyme are unfavourable to the sublime, or to the highly pathetic strain. An epic poem or a tragedy would be fettered and degraded by it. As this kind of verse is naturally read with less cadence or tone than rhyme,

the pauses in it, and the effect of them, are not always so sensible to the ear. It is constructed, however, entirely upon the same principles, with respect to the place of the pause. See PAUSE.

VERSES, *Concordant*, *Daelylic*, and *Elegiac*. See the adjectives.

VERSES, *Equivocal*, those where the same words contained in two lines carry a different sense.

VERSES, *Fiscentine*. See FISCENNINE.

VERSE, *Heroic*. See HEROIC.

Our English heroic verse is of that kind which may be denominated iambic structure; that is, composed of a nearly alternate succession of syllables, not short and long, but unaccented and accented. The line often begins with an unaccented syllable, and sometimes, in its course, two unaccented syllables follow each other. But, generally, there are either five or four accented syllables in each line. The number of syllables is ten, unless an Alexandrian verse be occasionally admitted. In the Italian heroic verse employed by Tasso in his *Gierusalemme*, and Ariosto in his *Orlando*, the pauses are of the same varied nature with those that belong to English versification. See PAUSE, and VERSIFICATION, *infra*.

VERSES, *Metrical*. See METRICAL.

VERSES, *Reciprocal*, are those which read the same backwards as forwards. See RETROGRADE.

VERSES, *Rhopalic*, *Serpentine*, and *Technical*. See the adjectives.

VERSE is also used for a part of a chapter, section, or paragraph, subdivided into several little articles.

The whole bible is divided into chapters; and the chapters are divided into verses.

The five books of the law are divided into fifty-four sections. See PARASCHE and PENTATEUCH.

Many of the Jews maintain, that this was one of the constitutions of Moses from mount Sinai; and some modern Christian writers, such as Buxtorf, Leusden, Pfeiffer, and their admirers, insist upon it, that the division of the verses of the Old Testament was not a work merely human, but had the peculiar privilege of being fixed by the inspired author of each book, or at the latest by Ezra. Others, with greater probability, ascribe it to Ezra, and say that it was made for the use of the synagogues, in which one section was read every Sabbath-day, and thus the whole law read over every year. When the Jews were forbidden, in the time of the persecution of Antiochus Epiphanes, to read the law, they substituted in its room fifty-four sections out of the prophets, which were afterwards continued; and when the reading of the law was restored by the Maccabees, the section which was read every Sabbath out of the law, served for their first lesson, and that out of the prophets for their second lesson; and so it was practised in the time of the apostles.

These sections were divided into verses, which the Jews call *pesukim*. They are marked out in the Hebrew bibles by two great points at the end of them, called *soph-pasuk*, *i. e.* the end of the verse. If Ezra was not the author of this division, it is certainly very ancient, and was probably invented for the sake of the Targumists, or Chaldee interpreters. Mention is made of these verses in the *Mishna*. Pridaux's *Conn.* vol. ii. p. 479. For the more modern division, see CHAPTERS.

That the modern division could not be of inspired authority is undeniable, for no inspired author could separate words which the sense determines to be inseparable, several instances of which occur.

It is probable, says Dr. Kennicott (State of the printed Hebrew

Hebrew Text, vol. i.), that the division of the verses of the Old Testament has been different at different times; and it seems certain, that verses were not the same in St. Jerom's time as at present: for that learned father, in his preface to the book of Job, observes, that there were seven or eight hundred verses (some think the true reading to be seventy or eighty) wanting in the ancient Latin translation of that book; which cannot be easily supposed of such verses as the present, the whole book containing no more than one thousand and seventy of our verses. But the nature of verses having varied, and the present verses, as terminations of, or pauses in the sense, having been probably fixed in the Hebrew text, or in the Greek version, some ages after the publication of the books of the Old Testament, as they confessedly were with regard to the New Testament; we shall the less wonder that some of the wiser Jews made no scruple to alter the received division where they found it to be erroneous. F. Simon tells us that Elias Levita, the best Jewish critic, affirms, the present distinction of verses was made by the Masoret Jews, after the Talmud; and that Aben-Ezra mentions amongst others, R. Moses Cohen, a learned grammarian, who took the liberty of joining some verses of the bible otherwise than they were joined by those who had marked them; affirming that they were mistaken in those places.

The division of chapters into verses has been found so convenient, that it has been used in all the editions of the bible, ever since it was first introduced. It is not, however, without its disadvantages. By this division the sense is often interrupted, and the reader may be thus led into mistakes, by fancying that every verse completes the sense. Besides, some persons are hence led to conceive, that every verse contains a mystery, or some essential point, though there is frequently no more than some incident or circumstance recorded in that place. Moreover, it has proved the occasion of that wrong method which sometimes prevails among preachers. Many imagine that one verse is a sufficient subject for a sermon; and when they find that it does not furnish solid and instructive reflections enough, they are constrained to wander from their point, and in order to fill up their discourse, display their wit and learning, which often administer but little edification to their hearers, and is undoubtedly contrary to the end of preaching.

It is then much to be wished, that some judicious person would divide the chapters otherwise than they are at present divided. If the verses were suffered to remain, they should be so divided, as to make always a complete sense, though on this account they might happen to be longer or shorter than they now are. But perhaps it would be better to suppress the verses entirely, and to divide the chapters into certain articles, which should contain such a number of verses as would complete the sense. When any word or passage of scripture is quoted, it would be no great trouble to look over a whole article, which could not require much time. To which we may add, that such a method of division would much assist the memory, which is now overburdened with such a great number of verses as preachers are, occasionally, obliged to remember.

The division of verses in the New Testament was first made by Robert Stephens; and so negligently was it done, that his son, Henry Stephens, assures us, he worked at it as he travelled from Paris to Lyons. Many learned men found great fault with this division, and yet it is every where followed.

F. Simon observes, that the Greeks and Latins meant by verse, a line, containing a certain number of words. He adds, that the authors of those days, to prevent any thing being added or taken away from their works, used to mark, at the end, the number of verses they contained; but the

books themselves were written all running, without any division, points, or the like.

VERSE, *Neck.* See NECK-VERSE.

VERSE, in *Church Music*: as, a verse anthem is distinct from a solo anthem, an anthem for two or three voices, and from a full anthem. A verse anthem consists of chorusses, with solo movements between them, for one, two, or three voices, so that in this sense verse is equivalent with solo.

VERSED *Sine of an Arch.* See VERSED SINE.

Co-VERSED *Sine.* See Co-VERSED SINE.

VERSHIRE, in *Geography*, a town of Vermont, in the county of Orange, containing 1311 inhabitants; 16 miles N. of Hanover.

VERSHOCK, or WERSHOCK, a Russian measure equal to $1\frac{1}{2}$ of an English inch. An arsheen is divided into 16 vershocks, or werhocks, and equals 28 Eng. inches: thus 9 arsheens = 7 Eng. yards, and 4 vershocks = 7 Eng. inches. A face, fath, or fathom, is = 3 arsheens, or 7 Eng. feet.

VERIFICATION, the art or manner of making verse; also the tune and cadence of verse.

Verification is properly applied to what the poet does more by labour, art, and rule, than by invention, and the genius, or *suor* poeticus. See POETRY.

The matter of verification is long and short syllables, and feet composed of them; and its form is the arrangement of them in correct, numerous, and harmonious verses; but this is no more than a mere translator may pretend to, and which the Catilinarian war, put in measure, might merit.

It is with reason, therefore, that these simple matters are distinguished from the grand poetry, and called by the name verification.

In effect, there is much the same difference between grammar and rhetoric, as there is between the art of making verses, and that of inventing poems.

History of Verification.—It appears that verse has been cultivated from the earliest period of literature, and among all people, from the most barbarous to the most refined; and to it principally we are indebted for most of the original accounts we have of the ancient nations of the earth. Equally measured lines, with an harmonious collocation of expressive and sometimes highly metaphorical terms, the alternate lines either answering to each other in sense, or ending with similar sounds, were easily committed to memory, and easily retained. As these were often accompanied with a pleasing air or tune, the subject being for the most part a concatenation of striking and interesting events, histories formed thus, became the amusement of youth, the palliative of labour, and the solace even of old age. In such a way, the histories of most nations have been preserved. The interesting events celebrated, the rhythm or metre, and the accompanying tune or recitative air, rendered them easily transmissible to posterity; and by means of tradition, they passed safely from father to son, through the times of comparative darkness, when the various tribes of mankind had no method more effectual of communicating to their descendants the principles of their worship, their religious ceremonies, their laws, and the renowned actions of their sages and heroes, till they arrived at those ages in which the *pen* and the *press* have given to them, by multiplying the copies, a sort of deathless duration.

The propriety of assigning the priority to Hebrew verification is obvious. The most intelligent consider the Hebrew to have been the primeval language, or at least the most ancient of which we have any knowledge; and, therefore, it is here that we must look for the earliest dawn of the poetic art. The address of Lamech (Gen. iv. 23.), which is in hemistichs in the original, is doubtless the most ancient verse in the world.

VERSIFICATION.

Of the same kind is Noah's prophecy concerning his sons (Gen. ix. 25—27.), Jacob's blessing to the twelve patriarchs (Gen. xlix. 2—27.), the song of Moses (Exod. xv.); and the book of Job, of Psalms, the songs of Solomon, Isaiah, &c. afford ample proof not only of the existence of verse among the ancient Hebrews, but that in its origin and earlier history it was intimately connected with music; that is, it was frequently set to some air or tune, for vocal or instrumental performance.

Having thus pointed out the origin of verse, at an early period, among the Hebrews; we shall now endeavour to trace its rise amongst other nations, assigning the precedence chiefly to those where we are most likely to find it in a *native*, rather than in a *borrowed* or *ingrafted* state.

Tcho-Yong, the sixteenth emperor of the ninth period, is the first on record among the Chinese for his attachment to the Muses. Feu-Hi composed verses on the pifcoratorial art. Chin-Nong, a succeeding emperor, wrote verses on the fertility of the earth. Here we find what is frequently remarkable in the early history of the ancients, the office of a chief or legislator and bard or poet united in one person: for many of the ancient poems were of a legislative cast, and contained, in verse, the most essential parts of their religious, moral, and political systems. The last emperor whom we find to have retained the poetical character was Chao-Hao. After him the complex office seems to have separated, as the next bard we meet with is in the person of the philosopher Confucius, who lived about six hundred years before the Christian era. (See *Extraits des Hist. Chinois, et Du Halde Hist. Chinois.*) The Chinese ode, therefore, translated by sir William Jones, must be of high antiquity, as Confucius considered it as very ancient in his time. About one century before the same epoch, Calidas, who has been termed the Shakespeare of India, wrote his poems. Such being the state of oriental verse at these early periods, it is not more than we might expect, that the Portuguese missionaries should meet with it on the coast of Proper India, where they found the natives possessed of a species of rude verse set to music. They composed, in the Malabar tongue, a long ode, containing a history of the Portuguese prelate, and a descriptive detail of what had passed at his synod. This nation had preserved the ancient custom of transmitting to posterity, by this kind of poem, all the most remarkable events. (*La Croze's Hist.*) The missionaries, who visited the opposite coast of Coromandel, give us sufficient proof that the culture of verse was not inconsiderable at that early period. (*Lettres Edifiantes, rec. xviii. p. 28.*) With respect to Egypt, the origin of the belles lettres is so lost in the antiquity of that famous kingdom, that we know nothing of the first advances made there in verse. We naturally expect that it met with the fate of its kindred science, music; which, in an early period, had all its forms unalterably fixed by law, and, therefore, improvement and corruption were alike prevented.

In adverting to those points of the poetic horizon, where we are most likely to descry the early dawn of the art of verse, it is now incumbent on us to notice the Arabs, whose language, from its manifest affinity, unquestionably had a common origin with the Hebrew and Chaldaic; and, consequently, is one of the most ancient in the world. Count Reviczki, however, was of opinion, that with respect to the metrical art of the Arabs, it was an invention of a date much later than that of the Hebrews, and that it assumed its form only a short time before Mohammed. At the beginning of the seventh century, the Arabic language was brought to a high degree of perfection, by a sort of poetical academy, that used to assemble at stated times in a place called *Ocadh*, where every poet produced his best composi-

tion, and met with the applause which it deserved. The most excellent of these poems were transcribed in characters of gold upon Egyptian paper, and hung up in the temple of Mecca, whence they were named *mozahebat*, or *golden*, and *moallakat*, or *suspended*. The poems of this sort were called *caffaidas*, or *eclogues*, seven of which are preserved in our libraries, and are considered as the finest that were written before the time of Mohammed. Concerning the Arabic and oriental verse in general, count Reviczki remarks, that he "anticipates the mortification of all our European poets, when they discover that the oriental dialects had a greater variety of feet, and consequently the true science of metre and prosody." After the above-mentioned period, however, the Muses disseminated their gifts with a prolific hand, and many were signified with their favours. Amongst the rest, the caliph Almamoun, sometimes termed the Arabian Augustus, for the protection he afforded to the belles lettres, bore an early and a distinguished rank. We have only to consult the abbé Andres, in his luminous work "*Dell' Origine, de' progressi e dello Stato attuale d'Ogni Letteratura,*" to assure ourselves, on the authority of the authentic manuscripts which he cites, that the Arabs had now become pre-eminent for their cultivation of the Muses. Scoppa affirms that there is no exaggeration in the expression of the "*Histoire de la Poésie Française,*" which, from undoubted evidence, asserts "that there had been more poets amongst the Arabs than in all the rest of the world." Abilabba-Abdalla, son of the caliph Motaz, recapitulates the lives of an hundred and twenty-one poets of the first rank. Another work, entitled "*Théâtre des Poètes,*" forms a library of twenty-four volumes. Casiri, the celebrated author of the "*Bibliothèque Arabico-Hispana de l'Escurial,*" does not hesitate to maintain that the excellencies of the Arabian poets rose as high in the scale of merit as those of the Greeks and Latins.

In our endeavour to trace the history of versification, where it is more likely to be found in its native and unborrowed state, we now turn to the northern nations of Europe. Tacitus mentions the verse and hymns of the Germans, at a time when that rough people inhabited the woods, and whilst their manners were yet savage. The Arthur of Teutonic romance is the hero Dietrich of Berne, who lived about the year 450 A.D. It is thought that his deeds of high enterprise were sung in the ancient and barbarous verses, some of which were collected by Charlemagne. The flight of Theodoric to the Huns is related in an exceedingly curious fragment, from the language and metre of which we infer, it must have been composed in the eighth century. We learn from a Latin fragment, written by Du Chesne, that Lewis the Pious, son of Charlemagne, being desirous that all his subjects speaking the Theotic language should be enabled to read the scriptures, "ordered a Saxon, who was reputed to be no vulgar bard, to make a *poetical* translation of the Old and New Testament into the German tongue." It is supported by Eccard and the German philologists, that the "Harmony of the four Evangelists," in the Cottonian library, forms a part of this translation. Otfried's Paraphrase of the four Gospels, made about the year 870, affords a proof that alliteration had fallen into disuse, and presents us with the earliest specimen of German rhyme.

Nor is this early production uninteresting. The infant Saviour is described as growing amongst men as a lily amongst thorns.

The victory gained in the year 883 over the Normans, by Louis III., was recorded, as is stated by a contemporary chronicle, "not only in our annals, but also in our national songs." The Franks had not yet adopted the language of

VERSIFICATION.

their vassal Gauls; and one of their national songs, which has been singularly preserved, is written in the pure Franco-Theotic dialect, and consequently belongs to the history of German poetry. From these scanty remains we pass on to the period (from 1136 to 1254) during which the imperial dignity was held by the house of Hohen-Staufen. Upon the accession of Conrad III., the founder of the Swabian line, the banquet-hall suddenly unfolds its portals, and we behold the fathers of romantic verse, in the persons of "kings and dukes, mailed knights and trusty squires," each of whom

" — took the harp in glee and game,
And made a lay, and gave it name."

Under this new race of rulers, the dialects of the fourth and west of Germany obtained a decided preponderance. The Swabian or Allemannic became blended with the Franco-Theotic, and thus formed the basis of the language of the present day; which, as in the parallel instance of the "Vulgar illustre" of Italy, has superadded its sister idioms, and became the sole vehicle of information.

Whatever literary impulse may have been given by the first crusade, it appears that the second produced a more decided effect, by generally diffusing the cultivation which had been maturing in the more propitious regions of the south. The population of the empire was brought into closer connection with the songsters of Provence and Catalonia, and their polished strains were soon re-echoed in the harsher tones of the "Minne Singers," or bards of love, as they were pleased to call themselves, of the Swabian era. A noble author is now considered as a rare occurrence. But in the age of the "Minne Singers," hardly any one dared to cultivate the art of versification, unless he could prove his sixteen quarters. The sovereigns of Germany themselves, emulating perhaps the example of our captive Richard, shared in the same fervour. The collection in the volume of Rudiger Manis is headed by the poems of the emperor Henry; the next place is held by Wenceslaus, king of Bohemia. A ballad, distinguished for its tenderness, is given as the production of the duke of Breisau. The verse of Henry, duke of Anholt, is by no means devoid of taste and elegance; and a single lay bears witness to the talents of the unfortunate Conradine. The "Geste" of king Rother connects itself both with the Helden-buch and the Cycle of Charlemagne. This poem, and a fragment of the history of the expeditions of the French monarchs against the Saracens, are the earliest specimens now extant of the German metrical romance.

The Swabian era produced upwards of two hundred poets, many of whom are deserving of attention. Under Rodolph of Hapzburg (1273) and his successors, they began to lose ground; and the brilliancy which had distinguished the preceding era gradually died away.

It is difficult to establish a definite boundary for the different periods of literary history; they melt into each other, like the colours of the rainbow. In Conrad of Würzburg, who flourished towards the conclusion of the 13th century, we find the glow of better days united to some of the peculiarities of the later "Maler-Singers" of Augsburg and Nuremberg. At this time a few princes and high-born lords, amongst whom Otto the marquis of Brandenburg, and the count of Leiningen, may be named as the most distinguished, still continued to imitate the style of the Swabian poets. But they had no successors. The art expired amongst the nobility, and the scene was suddenly changed. Poetry certainly never had so singular a fortune in any other country as in Germany. It actually

became one of the incorporated trades in the German cities; and the burghers obtained the freedom of it, as of any other corporation. By M. Grimm the "Minne-Singers" and the "Maler-Singers" are supposed to have originally formed but one class of poets. At all events, these societies offer a most singular phenomenon. Composed entirely of the lower ranks of society, they obtained a monopoly of verse-craft, and extended their tuneful fraternity over the greater part of the empire. The candidate for admission into these societies was introduced with prescribed formalities. The four "merkers," or examiners, sat behind a silken curtain, to pass judgment on his qualifications. One of these had Martin Luther's translation of the bible before him, it being considered as the standard of the language. His province was to decide whether the diction of the novice was pure, and his grammar accurate. The others attended to the rhyme and metre of the composition, and the melody to which it was sung. And if they united in declaring that the candidate had complied with the statutes and regulations, he was decorated with a silver chain and badge, and admitted into the society.

Bouterwick remarks, that the rude inferiority of the German poetry, during the 16th century, forms an unpleasing contrast to its state in Italy and Spain. In the age of Ariosto and Cervantes, Hans Sach continued to rank as the first German poet; and the only dignified epic which Germany possessed was the stiff allegory of Melchior Pfuitzing.

Having traced the rise and progress of the art of versification in Germany, we shall now still pursue the same system, in noticing, first, those places where its early dawn was unmingled with the rays of neighbouring constellations. Sheringham and Bartholine inform us, that the scaldi or bards were highly honoured among the Danish tribes; that their verse was of the legislative cast; and that they sung the great actions of their ancestors, and kindled the flame of war by the influence of poetic recitation. The "Welkina" and "Nifunga Saga" were compiled in the 13th century from the songs of the Danes and Swedes. We also meet with the poetical and musical office united in almost every northern clime. The union of the legislator's and bard's character is exemplified in the person of Snorro Sturluson, who, about six hundred years since, was at once the chief legislator and most eminent bard in the isle of Iceland. Odin, the Scythian legislator, boasted that the Runic songs had been handed to him by the gods. Strabo tells us, that throughout the whole district of Gaul, there were three kinds of men held in high estimation, the Bards, the Vates, and the Druids. Diodorus Siculus adds, that "the bards sung to instruments, praising some and satyrizing others." The British bards, about the same time, were of the same character; and their genius is sufficiently evinced by their verse yet extant under the name of Ossian, if Ossian's work be genuine. In Ireland they were endowed with estates, and lived by public patronage, independent and free from temporal care. Orlamb Fodlah, one of their kings, summoned them to a triennial festival, for the purpose of transmitting to posterity the authentic records contained in their verse; which were from them selected and preserved in the custody of the king's antiquary. In the year 558, the Irish bards, being extremely numerous, and insolently powerful, had attained the summit of their influence. Even in the time of Spenser, they were the subject of serious complaint. (Keating's History, and Spenser's View of the State of Ireland.) Nor are we without instances of the native and ungrafted state of verse in the transatlantic world. In the ancient empire of Peru, Garcilasso de la Vega informs us, that their songs were innumerable;

VERSIFICATION.

numerable; that he had heard many, and learned some from his ancestors, who were the last of the royal family of the Incas. Their Incas or chiefs had been poets or musicians in the early periods of their history. The same author presents us with some specimens of their verse, which bear every character of aboriginal texture. Father Lafuta (Mœurs des Sauvages, tom. ii. p. 213.) has given a circumstantial account of the festivities of the Iroquois, Hurons, and some less considerable tribes of North American Indians, in which verse and song bore an essential part. These, for the most part, consist of the fables of ancient times, and are composed in a style so antiquated as to differ materially from their colloquial dialect. They were observed also to retrench or strike off some syllables from their words, to produce the requisite measure: and the audience beat the time with a corresponding motion of the head, accompanied with shouts, repeated at certain intervals with such accuracy that they never err.

It is easy to perceive that our remarks have hitherto been confined to trace the earliest source and rise of versification amongst those nations only, where we were most likely to discover it in a state unmixed with borrowed streams. The talk is evidently not a little difficult, to say exactly where it can be contemplated in a stage purely nascent. Its distant course has gradually receded from our view, and ultimately lost itself in the remote and visionary forms of aboriginal tradition. Nor do we mean to affirm that the subsequent meanders, which, from each insulated fountain, we have for a while been led to pursue, has, in every instance, remained unblended with the confluence of adventitious channels. It is sufficient if, by the preceding remarks, we have, in any degree, developed those features which appear to be uniformly peculiar to its infant state. This, however, will not only apologize for, but even warrant, our omitting, until this, to mention the Greek and Roman versification, where we can contemplate it only in an engrafted predicament. It is admitted, that knowledge and useful arts the Greeks received from the East; yet it is the opinion of some, that since "the Greeks studied no foreign language, it was impossible that any foreign literature should influence their's. Not even the name of a Persian, Assyrian, Phœnician, or Egyptian poet is alluded to by a Greek writer. The Greek poetry was, therefore, wholly national. The Pelagic ballads were infensibly formed into epic, tragic, and lyric poems; but the heroes, the opinions, the customs mentioned in them, are exclusively Grecian; as they had been, when the Hellenic minstrels knew little beyond the Adriatic and the Egean." This argument, however, is not so conclusive as to lead to the inference, that the Greeks had no preceding example from which to copy. No more can we suppose that Homer was the most ancient poet: for as the Paradise Lost of Milton plainly implies that other epic poems existed prior to this, and that Milton had read them; so do the Iliad and Odyssey of Homer. It is contrary to all the phenomena of the human mind, that so finished a work should have been the *first* essay of the kind. There can be no room to doubt but many poets flourished before Homer. As the Paradise Lost necessarily supposes Spenser's Fairy Queen; that, Tasso's Gerusalemme Liberata; that, Virgil's Æneid; and the Æneid, the Iliad of Homer; so the Iliad itself may stand in reference to as many preceding poems as the Paradise Lost does. As the Æneid never could have existed, had not the Iliad gone before, after the model of which it is entirely constructed; and as the Jerusalem Delivered is a proceed from the Æneid, as the Fairy Queen is from the poem of Tasso, and the Paradise Lost from the whole; so we may con-

jecture, that the Iliad is from the works of preceding poets, and that we are left to lament the irreparable loss of a vast mass of intellect in the destruction of the works which preceded and gave birth to those of Homer.

In the art of versification, the Greeks and Romans claim that eminent and distinguished rank, which has already secured to their memory that renown and celebrity to which they were so unquestionably entitled. But as they possessed this art only in an engrafted state, and as their success in this department of literature is so universally known, and as we shall have a future opportunity to notice it, our limits compel us here to pass to that which is more reconducive and less generally understood.

According to the testimony of the abbé Andres, and the authentic MSS. which he cites, it is to the Arabs that Spain, France and Italy, were not a little indebted for the cultivated state of their versification. These nations had for a long time groaned under the yoke of the barbarians of the North; and according to the testimony of the abbé Andres, it is chiefly to the instrumentality of the Arabs that we owe the return of the sciences into Europe. Amongst the French and the Spaniards who have cultivated with the greatest success the poetry of which the Arabs gave them the example, the Troubadours of Provence, for the harmony of their enchanting verse, which has been received with such éclat through Western Europe, stand pre-eminently distinguished. The history of the Troubadours is replete with the names of those exalted personages, to whom it had become a delightful recreation to compose verse in the Provençal dialect. We may mention, amongst others, William, duke of Aquitania, whose verses were composed in the year 1100 A.D.; Peter I.; Alphonse I.; James the Conqueror; James I.; Thibaut, king of Navarre; Charles of Anjou, brother of St. Louis, king of Naples and Sicily; Henry, duke of Brabant; Peter Mauclerc, earl of Brittany; Raoul, count of Soissons. There exists yet at the Escorial a code, of which Casiri (tom. i. p. 126.) makes mention, and which notices the literary dispute between Abu-Jahia, son of the king of Toledo, and Almotemed, king of Cordova, to obtain the poetic prize. Neither must we omit to mention the name of Frederic II., who patronized the Muses, and was himself a poet. Nor the poems composed by king Alphonse X. son of St. Ferdinand, who signalized himself for the protection he afforded to the Troubadours.

The encouragement which the Provençal poets enjoyed under the auspices of the great, induced them to traverse Europe in every direction. They resorted to the castles and palaces of kings, they were received with transport, and their melodious strains were listened to with enthusiastic plaudits. Nor was England without some share of the general fervour. It was by the aid of the Troubadours, says Dryden, that Chaucer enriched and polished that language, which the same Dryden calls "sterile." Richard I. was surrounded by the Troubadours and cultivated their verse. In short, says the same Andres, every king and emperor accounted it an honour to become accomplished in Provençal poetry.

From the intercourse of the Provençals throughout Italy, their verse obtained the honour of becoming the mother of Italian poetry. This is asserted by Bembo, Equicola, Varchi, and by many other Italian authors, and especially by Bastero (Prefaz alla Crusca Provenzale.) There is no Italian author who has more frankly pronounced his opinion in favour of the Provençals than Bembo. (Prof. I.) He favours us with a long detail of all that the Italians had borrowed from the Provençals. Redi also enumerates those amongst the Italians, who had blended in their Tuscan composition, a multitude of words and phrases peculiar to the Provençals.

VERSIFICATION.

The celebrated Tiraboschi, in his History of Italian Literature, speaks also of the rhyme and the different kinds of poetic composition which the Italians had borrowed from the Provençals. On this subject may be read the work of Vicenzo Gravina della Ragion Poetica, liv. ii. p. 132, and L'istoria della volgar Poesia del Crescimbeni. The three fathers of Italian literature, Dante, Boccaccio and Petrarca, were eminently conversant with this exotic verse. The last lived a long time in Provence, and studied for a while at Paris; and Tassoni assures us, "il Petrarca molto prese da' rimatori Provenzali." As to Boccaccio, it is generally acknowledged, that in his Decameron, he excels by the riches he has culled alike from the Roman and Provençal poets. But of the three, it is more especially Dante who has clearly decided, that it is Italy which has borrowed from the French, and more particularly from the Troubadours.

It is not without foundation that the count Caylus accuses the Italians of plagiarism; and it is not without reason that Millot says, that the Provençals opened the road to the Italians and furnished them with models for imitation.

Nevertheless, whatever may be the degree of plagiarism of which the ancient Italian poets are accused; whatever may have been the anteriority of the time in which the belles lettres flourished among the Provençals; and the time when it passed to the Italians; we cannot refuse to the latter the honour of being pre-eminently distinguished for the peculiar care they have bestowed on the superstructure, and for their advancing to the acmé of cultivation those arts and sciences which had been sepulchred under the ruins of the Roman empire. The Arabs, the Spaniards, the French, the English, and all other nations, says Andres (tome i. c. 12. p. 339. édit. de Parme), have been as the Egyptians and the Asiatics who claim the right of originality in the invention and culture of their verse; but the Italians may be regarded as the Greeks, who with the industrious bee culled their honey from every surrounding flower.

We must not forget, however, that with regard to this right of priority, the Provençals have formidable rivals in the Sicilians. The authorities on each side of the question seem paradoxically equal. Sicily has always boasted herself to have been the cradle of Italian poetry. She encircles herself with a cloud of authorities, which serve as a shield to protect her from the design to rob her of that title of which she desires the exclusive enjoyment. To this end, she frequently offers to consideration the following passage of Dante. (Volg. Eloq.) "Ex acceratis, quodammodo, vulgaribus Ital, inter ea quæ remanserunt in cribro comparationem facientes honorabilibus ac honorificentibus, breviter seligitur: et primò de Siciliano examiniemus ingenium: nam videtur Sicilianum vulgarem sibi famam præ aliis adficeræ, eò quòd quiddam poetantur Itali Sicilianum vocatur."

Petrarch, who in the next age succeeded Dante, both in his prose and poetic works, confirms the same opinion. Nor does he express himself with less decision in the epistle which he composed about the year 1360.

Petrarch also informs us, that in his poems, he had followed that species of versification, which had made its re-appearance some ages before in Sicily, or at least two or three hundred years before the twelfth century.

But to afford the clearest light in the discussion of this subject, it is necessary to transport our ideas to the period of the decline of the Roman empire. The Italian language took its radical elements from the nature of the Latin. Even before the splendour and the authority of the emperors had been impaired, the language was adulterated by that admixture of barbarisms which seemed the necessary consequence of foreign intercourse. But all limits to this cor-

ruption were overthrown, when the Goths, the Huns, the Greeks, the Lombards, the Franks and Germans in rapid succession inundated the empire. Hence arose a new jargon which served the vulgar and the plebeian tribes in their colloquial intercourse, whilst the learned and the polite circles of society endeavoured to maintain the dignity and purity of the Latin language. The former, however, composed the majority, and carried the day. This, according to Muratori, happened about the 11th century.

But whilst this revolution happened in Italy, France and Spain, where the Latin language, the common genus, branched into three kindred species, each receiving such modifications as were suited to the circumstances and temper peculiar to each nation, Sicily had also been long subject to a similar revolution by the frequent invasions of the Saracens from the year 649 to 827; and again to 1060. And besides this, the Latin language had been already corrupted by the influence of the Vandals, who made a descent on this isle in 440, and by the dominion of the Goths, who governed it from 493 to 535, when Belisarius defeated the island. The Sicilians had also their plebeian dialect; and they had, from the dominion of the Arabs, imbibed a predilection for that peculiar species of versification, which the latter had been equally successful in communicating to the Spaniards. The Sicilians, guided by that delicacy of the ear for which they are always remarkable, discovered themselves to be the first that had in their native language a certain melodious order, resulting not from that prosodial quantity which defines merely syllables to be long or short, but rather from another measure, which is the effect of the acute accent, artificially distributed within the limits of a definite number of syllables. They were thus enabled, without any other effort, to imitate the taste and the versification of the Arabs their conquerors; and the example of the latter was a spark to set on fire what till this was but latent in their imagination, and thus the genius and natural disposition of their minds received an unexpected and brilliant development.

It is, at least, affirmed, that the Sicilians have far exceeded the Spaniards and the French in the culture of this modern versification. And Castelvetro and Muratori maintain, that it was not Italy and Sicily that received from the Provençals the elements of this new species of verse, but that the latter were indebted for it to the Sicilians. We learn, however, from the authority of incontestible witnesses, that the Sicilians made great progress in the culture of the fine arts either during the 9th or 10th century; whilst Fauchet could not find among the poetry of the French a writer more ancient than Eutaché, who flourished about the middle of the 12th century. And Galland (Acc. Infer. tom. iii.) could not quote an author anterior to the fame. And whilst the learned Andrews could not fix the birth of the fame art amongst the Spaniards earlier than the 11th century.

The Sicilian versification, at first rude, uncultivated, and barbarous, became, by degrees, a studied and polished art, replete with brilliant images, and with thoughts noble and sublime. It was, in short, the verse of the year 1220 that was seen to shine with peculiar lustre in the mind of Frederic II., who, after he had received the investiture from pope Celestin, came to reign in Sicily. The Sicilians preserve even yet his poems, those of Enzo his son, king of Sardinia, and those of Pier delle Vigne, secretary to the fame. From the centre of Sicily, this art diffused itself over all Italy. The more learned Italians, attracted by the virtues of a generous prince, came in a crowd to Sicily, frequented the court of Frederic, became themselves poets, and carried the taste of the novel versification into their native country.

Cresf.

VERSIFICATION.

Crescimbeni dates the commencement of this art about the year 1189. But Quadrio fixes its origin about the year 1135. And this he proves by an inscription in verse, which he found in the cathedral church of Ferrara.

It is not improbable, however, that when Frederic II. arrived in Sicily, which happened nearly a century after this, he was already well instructed in this new species of versification, which he had learned in Provence, his native country; and also that he possessed an art which he had derived from the Arabs established in Spain, whilst the Sicilians boasted the possession of the same art, which they had originally received from the Saracens.

These two points of history being reduced to these parallel terms, it will become easy to resolve what would otherwise appear to be contradictory and paradoxical in those apparently opposite opinions, of which the one attributes to the Sicilians, the other to the Provençals, the honour of having been the first who communicated to Italy the knowledge of this modern species of versification. The fact doubtless is, that both the one and the other, nearly at the same time, received from the Arabs that new acquisition for which their own dialects were found to possess a certain innate congeniality, and subsequently became reciprocally instrumental in confirming and maturing that art, which soon became celebrated throughout Europe, under either the Italian epithet “*lettere amene e legiadre*,” or the Provençal “*guai faber*,” i. e. *the gay science*.

Having now, perhaps, executed the most difficult part of our task, in tracing from this remote and obscure period, the earliest source of this new species of versification, our limits and our readers will exempt us from entering into a long detail of the subsequent progress of this art amongst two neighbouring nations, especially as this part of the subject is more accessible through the medium of the pens of the literati of France and Italy.

Before we proceed to treat on the nature of verse, it will be necessary to premise the following explanations of such technical terms as will occur in the sequel.

A SYLLABLE.

By a reference to the article QUANTITY, the reader will discover that we have already had an opportunity of distinguishing between a short and a long syllable, and of stating that the former is usually denoted by a small curve, as “;” and the latter by a dash, as “-”

FEET.

A *foot*, (so called from the ancient custom of beating time by the foot,) is a part of a verse, and consists of two or more syllables, as here exemplified.

I. TWELVE SIMPLE FEET.

1. Four feet of two syllables.

1 } A spondee	--
2 } A pyrric	^-
3 } A trochee, or choree.....	-^
4 } An iambus	^-

2. Eight feet of three syllables.

5 } A molossus	---
6 } A tribrach	-^-
7 } A dactyl	-^^
8 } An anapest	^-^
9 } A bacche	^-^-
10 } An antibacche	-^-^-
11 } A cretic, or amphimacer	-^-^
12 } An amphibrach	-^-^-

II. EIGHTEEN COMPOUND FEET.

“*Quidquid enim supra tres syllabas habet, id ex pluribus est pedibus.*” Quintil. 9. 4.

1. Four of the same foot doubled.

13 } A dispondee, or two spondees	----
14 } A proceleusmatic, or two pyrrics.....	----
15 } A dichoree, or two chorees, or trochees...	----
16 } A diiambus, or two iamбусes	----

2. Four of contrary feet.

17 } A great ionic, or a spondee and a pyrric ...	-^-^-
18 } A small ionic, or a pyrric and a spondee ...	^----
19 } A choriambus, or a choree and iambus.....	-^-^-
20 } An antispall, or an iambus and a choree ...	^-^-^-

3. Four feet in which long times exceed

21 } First epitrit, or an iambus and spondee.....	-^----
22 } Second epitrit, or a choree and spondee ...	^----
23 } Third epitrit, or a spondee and iambus ...	^-^-^-
24 } Fourth epitrit, or a spondee and choree ...	^-^-^-

4. Four feet in which short times exceed

25 } First pæon, a choree and pyrric	-^-^-
26 } Second pæon, an iambus and pyrric.....	^-^-^-
27 } Third pæon, a pyrric and choree.....	^-^-^-
28 } Fourth pæon, a pyrric and iambus	^-^-^-

5. Compound feet of five syllables.

29 } Dochmius, an iambus and cretic	-^-^-^-
30 } Mesomacer, a pyrric and a dactyl.....	^-^-^-^-

METRE.

A *metre* is composed of two adjacent feet. In Greek verse of the dactylic species, one foot constitutes a metre, according to Hephæstion;

“*Κατὰ Μονοπόδιαι μετρηταὶ τὰ Δακτυλικά.*”

In Greek verse of double feet, a metre is also said to consist of only one foot; but since, in this case, each foot comprises two simple feet, it forms no exception to the general rule. Metre is divided into nine species; *iambic, trochaic, anapestic, dactylic, choriambic, antispastic, ionic à majeure, ionic à minore, pæonic*.

RHYTHM

Is a series of similar feet, continued until the ear perceives the order of the series, and is able to anticipate the peculiar nature of the verse. To render this more plain, we add, that rhythm in verse is analogous to as many terms of an infinite series in mathematics, as are necessary to render the law of the rising order apparent, and from which we can easily anticipate the sequel; or, more exactly, if we

have the compound circulate $\overset{1}{1} \overset{1}{2} \overset{1}{3} \overset{1}{4}$ given to evolve the series, we easily write or repeat $1 \overset{1}{2} 2 \overset{1}{3} 3 \overset{1}{4} 4$, &c. to as many periods as necessary.

Now, a metre is said to be the commencement of this series. A rhythm is that portion of the series, which brings the whole under the recognizance of the ear. Metre respects both the *time* and *order* of the syllables. The rhythm of a dactylic and anapestic measure is the same; the metre different.

VERSE.

A *verse* is an assemblage of a definite number of feet, and contains one, two, or more metres; and is accordingly termed

VERSIFICATION.

termed either a *monometer*, *dimeter*, *trimeter*, *tetrameter*, *pentameter*, or *hexameter*, &c. Verse sometimes receives its name from a reference to the number of feet, not of meter, which composes it; as, the *senarius*, *astionarius*, *novenarius*, &c.: sometimes from a noted author who was particularly attached to that species; as, *Sapphic*, *Anacreontic*, *Alcaic*, *Hippocratic*.

A verse is also said to be *acatalectic*, if it be neither defective nor redundant; *catalectic*, if it want a final syllable; *brachycatalectic*, if it want two; *hypercatalectic* or *hypermeter*, if it exceed the regular measure; *acephalous*, if it want an initial syllable.

Hence the complete name of a verse necessarily consists of three terms; the first referring to the species, the second to the number of metres, the third to the apothesis or ending. See **VERSE**.

Schmidius and Tricinius, in their Analysis of the Metres of Pindar and Sophocles, generally recite first the general name, consisting of the three terms above-mentioned, and then subjoin the particular feet.

A *hemijch* is, properly speaking, a half verse: yet the name is commonly applied to either portion of an hexameter verse divided at the penthemimer.

The *trienemimer* is that portion of a verse (measured from the beginning of the line) which contains three half feet, or a foot and a half; *penthemimeris*, five half feet, or two feet and a half; *hepthemimeris*, seven half feet, or three feet and a half; *enemimeris*, nine half feet, or four feet and a half.

A *distich* is a couplet of two verses.

A *stanza*, or *strophe*, is such a series of two or more verses of different kinds, as comprises every variety employed in the composition.

When only one sort of verse is used throughout the ode or poem, such an ode, &c. is called *monocolos*; when several sorts, *polycolos*: or more precisely, if there are two sorts of verse in a poem, it is called *dicolos*; if three, *tricolos*; if four, *tetracolos*.

When the *stanza*, or *strophe*, is composed of two verses, it denominates the ode *distrophos*; when of three, *tristrophos*; when of four, *tetrastraphos*, &c.

By a complex use of these terms, the ode is *dicolos distrophos*, when in a stanza there are two verses of different kinds; it is *dicolos tristrophos*, when the stanza contains three verses, but only of two kinds, one sort being twice used; *dicolos tetrastraphos*, when the stanza has four verses, but of only two sorts, one sort being used thrice. Again, the ode is *tricolos tristrophos*, when the stanza consists of three verses, each of a different kind; and *tricolos tetrastraphos*, when in the stanza there are four verses, but of only three kinds, one being used twice.

Hebrew Versification.

On the very first attempt to elucidate the nature of this versification, a question presents itself uncommonly difficult and obscure. If it be essential to the existence of verse that it be measured by a definite number of feet or syllables, it appears absolutely necessary to demonstrate that those parts at least of the Hebrew writings which we term poetic are in a metrical form, and to inquire whether any thing be certainly known concerning the nature and principles of this versification or not.

It is well known, that an hypothesis was invented by bishop Hare concerning the Hebrew metres; and the arguments which he had advanced in its favour appeared so conclusive to some persons of great erudition, as to persuade them, that the learned prelate had fortunately retrieved the knowledge of Hebrew verse, after an oblivion of more than two thousand years. The following are the rules or canons of bishop Hare.

1. In Hebrew verse all the feet are disyllabic.
2. No regard is paid to the quantity of the syllables.
3. When the number of the syllables is even, the verse is trochaic, placing the accent on the first syllable.
4. If the number of the syllables is odd, the verse is iambic, and the accent is to be placed on the second syllable.
5. The periods mostly consist of two verses, often three or four, and sometimes more.
6. The verses of the same period, with few exceptions, are of the same kind.
7. The trochaic verses mostly agree in the number of feet; there are, however, a few exceptions.
8. In the iambic verses the number of feet are mostly unequal, though in some instances they are equal.
9. Each verse does not contain a distinct sense.

One of the examples given by bishop Hare for the illustration of these rules, is the 111th Psalm, which the learned reader may consult in any pointed Hebrew bible.

The same example is alluded to by bishop Lowth, in the following confutation of the principles of bishop Hare.

1. In the first place, the feet are not all disyllables.
2. Attention must always be paid to the quantity of the syllables, for the same word, as often as it occurs, is always of the same quantity.
3. The verses are either trochaic which admit a dactyl, or iambic which admit an anapaest. But it by no means follows, that a verse is either the one or the other, from its consisting of an even or odd number of syllables. Those, indeed, which consist of an even number of syllables, are, for the most part, iambic; but they are also sometimes trochaic. And those which consist of an odd number of syllables are mostly trochaic; but they are, however, sometimes iambic, contrary to the third and fourth canons.
4. The verses of the same period are of different kinds, a few only excepted; and those which are of the same kind seldom agree in the number of syllables and feet; and these facts are contrary to the sixth, seventh, and eighth canons.
5. All the periods consist of only two verses: this is contrary to the fifth canon.
6. Each verse has one particular sense; contrary to the ninth canon.

And in the same manner, perhaps, may every hypothesis, which pretends to state the laws of Hebrew verse, and to prescribe the numbers, the feet, the scansion of the lines, be confuted. For to that hypothesis another directly contrary, yet confirmed by arguments equally forcible, may be successfully opposed.

Subsequently to bishop Hare, John Robertson, M.D. published his treatise on the Hebrew versification. To give any idea of his method, it is requisite to premise, that he, in common with the antimetereotics, supplies the pointed vowel by ; to ך he gives the power of U or V, and to ם, O. His rules are as follow:

- “ 1. Every syllable is long in which there is a written vowel. 'Tis true that I and U are sometimes joined in one syllable with the vowel *before*, but *ostener* with that *after* either of them. But in that case the I and U are not vowels, but consonants.
- “ 2. Every syllable having the inserted or implied vowel *e* is short, if only one consonant follows it before another expressed or implied vowel occurs.
- “ 3. Every syllable having only an inserted vowel in it is long, if two or more consonants intervene between it and the next expressed or implied vowel, either in the same or following word.

VERSIFICATION.

“ 4. In all Hebrew verses, every alternate syllable must be long; the others may be long or short.

“ 5. The last syllable of every verse is common; *i. e.* either long or short.”

On laying down these preliminaries, it was easy for Dr. Robertson to reduce Hebrew verse to the iambic or trochaic metre. But so long as the true Hebrew pronunciation and the quantity of their vowels remain unknown, to attempt the analysis of Hebrew verse by iambic, trochaic, anapæstic, or any other metre, is to lay a superstructure without a foundation. But whilst we prefer to prosecute the sequel rather with bishop Lowth; we do not in the mean time withhold from our readers the pleasure of perusing Dr. J. Robertson's “ Treatise on the true and ancient Manner of Reading Hebrew, and on Hebrew Versification,” Lond. 1757.

As to the real quantity, the metre and rhythm, these from the present state of the language seem to be altogether unknown; which is the necessary consequence of our uncertainty of the ancient pronunciation. To some of those, indeed, who have laboured in this matter, thus much of merit is to be allowed, that they have rendered the Hebrew metre, which, without their methods, founded uncommonly harsh, in some degree polished and more agreeable. They indeed have furnished it with a sort of versification and metrical arrangement, when baffled in their attempts to discover the real. That we are warranted in attributing to them any thing more than this, is neither apparent from the nature of the thing, nor from the arguments with which they attempt to defend their conjectures.

It is, however, undeniably apparent, that certain of the Hebrew writings bear not only evident signs of poetic animation, but also such characteristics of verse, as leave us little difficulty in pronouncing them of the poetic class. There existed, amongst the Hebrews, a kind of verse, intended, perhaps, for the memory; in which, when there was little connexion between the sentiments, an alphabetic order was preserved by the initial letters of each verse or stanza. Of this there are several examples, where the verses are so exactly marked and defined, that it is impossible to mistake them for prose, especially if we compare the corresponding words of the proximate verses, where word answers to word, and almost syllable to syllable. This being the case, though no appeal can be made to the ear, yet the eye remains competent to perceive the poetic symmetry and arrangement.

Hebrew versification also exhibits another property peculiar to metrical composition. Writers confined to the limits of verse, are generally indulged with the licence of using words in a sense and manner remote from their common acceptation, and of retrenching or adding a syllable for the purpose of reducing the line to their assigned limits. Next to the Greeks, none, perhaps, have admitted those liberties more freely than the Hebrews, and especially by the use of certain particles peculiar to metrical composition, so as to form to themselves a dialect distinctly poetical. There may be further observed a certain conformation of the sentences, so that a complete sense is almost equally infused into every component part, and every member constitutes an entire verse. So that as the poems divide themselves in a manner spontaneously into periods, for the most part equal, so the periods themselves are divided into verses, most commonly couplets, though frequently of greater length. The Hebrew verse too was adapted to their custom of singing corresponding parts by alternate and opposite choirs. (See Nehem. xii. 24. 31. 38. 40. and the title of the 88th Psalm.) Verse constructed in this manner, is similar to the Grecian

proasm or epode. And it was thus, it is thought, that Moses with the Israelites chanted the ode at the Red sea. (Exod. xv.) For “ Miriam the prophetess, the sister of Aaron, took a timbrel in her hand; and all the women went out after her, with timbrels and with dances. And Miriam answered them, sing ye to the Lord, for he hath triumphed gloriously: the horse and his rider hath he thrown into the sea.” (Exod. xv. 20, 21.) On some occasions, one of the choirs sung a single verse to the other, which was answered by the other by a verse in some respect correspondent to the former.

The 135th Psalm is obviously adapted to *three* choirs; the high priest with the house of Aaron constituting the *first*; the Levites, the *second*; and the congregation, the *third*; each having its distinct part, and all at stated intervals uniting in full chorus.

From an analysis of this psalm it might easily be shewn, that the Hebrew hymn is a composition not less regular than the Grecian ode. One cannot but observe too, that it was from the Jewish, that the Christian church derived the custom of singing in alternate chorus. Pliny (l. x. epist. 97.) observes of the primitive Christians, that “ they repeat alternate verses to Christ as to a god.” And the remains of this ancient custom are yet evident in the alternate or responsive parts of the liturgy of the established church. See Bingham's Antiq. xiv. 1.

The peculiar conformation, already alluded to, in the structure of Hebrew verse, consists chiefly in a certain equality, resemblance, or parallelism between the members of each period; so that in two verses, or members of the same period, things for the most part shall answer to things, and words to words, as if fitted to each other by a kind of rule or measure. This parallelism consists of three species. See PARALLELISM.

Greek Versification.

It is necessary, before we present the reader with a system of the Greek versification, to apprise him, that the second, fourth, and sixth foot, &c. of a verse are commonly called the *even* places; and the first, third, and fifth foot, &c. the *odd* places.

I. Iambic Metre.

1. An iambic verse admits in the even places an iambus, in the odd, an iambus or a spondee.
2. An iambus in the odd places may be resolved into a tribrach; the spondee, into a dactyl or anapæst.
3. An iambus in the even places (except the last) may be resolved into a tribrach. An anapæst is substituted for it in the case of a proper name only.
4. A dactyl must be avoided in the fifth place; and resolved feet must not concur.

Dimeters catalectic.

Οὐδ' αἰετι μο χενστος,
Οὐδ' φθοᾶ τυραννις.
Ἐμοι μελι μερσι
Καταβριχιν υπηνη·
Ἐμοι μελι εσοσι
Καταστηφιν καρμα.

Beginning with an anapæst.

Ἀπολοιο πρῶτος αυτος
Ο του αρχυουσι φιλιασας.
Δια τουτου ουκ αδιλ·οι,
Δια τουτου ου τοκεις·—ΑΝΑΚΡΟΝ.

Trimeters

Trimeters or senarii.

Εἰ παντὶ πράξει δ' αὐτὸ ἔμμελος κκεῖ·
Κακίῳ οὐδὲν, καρπὸς οὐ κομισθεῖσσι.
Αἴτις ἀρούρα θανάτου ἐκκατάρτισται·
Ἡ γὰρ ζυμίσθαις πλοῖον ἰσθμῶς ἀπὸς
Ναυτῆς ἰερέως καὶ πανουργῆς τινὸς
Ὀλλεῖν ἀνδρῶν σὺν θιοπύσιω γένει.—Æschylus.

II. Trochaic Metre.

1. A trochaic verse admits trochees in the odd places, trochees and spondees in the even places.
2. The trochee may in any place be resolved into a tribrach; and the spondee into a dactyl or anapaest.
3. A dactyl in the odd places occurs only in the case of a proper name.
4. In trochaic tetrameters, the second metre should always end with a word.

Dimeters catalectic.

Ταῦτα τις ταχῶς ἀν πατρὸς
Ἡ τεκοσὰ νοσητήν;
Οἰκτὸς οἰκτισάτω· ἐπι-
-δὴ τίτις δόμος Δίκαια.—Æschylus.

Tetrameters catalectic.

Ὅυ γὰρ ἐν ξυμβαίμεν ἀλλως, ἢ πρὸς ἁρμονίαν;
Ὅστε μὲ σκηπτέρῳ κρατοῦντα, τῶσδ' ἀνακτ' ἐκαστὸν χῆνον;
Τῶν μακρῶν δ' ἀπαλλαγῆναι νοσήτηματων μ' ἐσσι.
Καὶ σὺ τῶσδ' εἴω κομίζω τεύχεων, ἢ κατθανόν.

III. Anapaestic Metre.

1. An anapaestic admits either in the even or odd places an anapaest, a spondee, or a dactyl.
2. Except the dimeter catalectic, called paræmiacus, which requires an anapaest only in the last place but one.
3. Anapaestic verses are sometimes intermixed with other species.
4. A system is chiefly composed of dimeters, and is most correct when, first, each foot, or at least each fuzzyg, ends with a word; secondly, when the last verse but one, is monometer acatalectic; and the last, dimeter catalectic; with an anapaest in the second metre.
5. In a system, the last syllable of each verse is not (as in other species) common; but has its quantity regulated by the foot of which it is a part.
6. The monometer acatalectic is termed an anapaestic base. This, in a system, is sometimes dispensed with. In the paræmiacus rarely.
7. A series of anapaestic verses, consisting of one or more sentences, must be constructed as if each sentence were only a single verse. Therefore, if the last foot of a verse, in the middle of a sentence, begin as an anapaest or spondee, its last syllable must be long; but as a dactyl, short. This rule, however, may be dispensed with, when a tribrach, cretic, or trochee, supplies the place of an anapaest, dactyl, or spondee.
8. An anapaestic verse has sometimes in the last place a proceleusmatic, which foot is isochronal to an anapaest; as,

Πρὸς ἔμον ο | μογεστω | εα.—Eur. Ph. 169.

Anapaestic system with the base.

Διπλὸν μοῖα γ' ὡς φοβῆς χρεῖα
Στεφὸν ὀργμῆναι τοῖδε πύλας πού.
Ταῦτη γὰρ ἔχειν βίωσις αὐτοῖ
Λόγος· ἰσθ' ὕψισι, θεοδόλουσιν
Πτῆνος· κῆς σπύργον σπύργωσ.
Ὅσθι τῶ αὐτῶ
Παιῶνα κακῶν ἐπιμῆμαίν.

Anapaestic system without the base.

Ὁ δειπὸν ἰδεῖν παθὸς ἀνθρώπων,
Ὁ δεισοτάτου πάντων ὄσ' ἐγώ
Προσεκμεσ' ἴδη. Τίς σ' ὡ τλήμων,
Προσέθη μαγία; τίς δ' ἔπθησας
Δαίμων μὲνίονα τῶν μακίστων
Πρὸς τῆ σὴ δυσδαίμων μοῖρα
Φεῦ, φεῦ, δύσταν· ἀλλ' οὐδ' ἴσθιδεν
Δυναμίαι σὲ θύλον πολλ' ἀνεσθῆναι,
Πολλὰ πύθῆσθαι, πολλα δ' ἀθῆσθαι.
Τοῖαι φεῖναι παρῆχίαι μοι.—Sophocles.

System of paræmiaci.

Σίγαθ' ἢν ἀπας ἔχει σῆγας·
Καὶ πάντα λόγον ταχὰ πεισῶ·
Ἥμιν δ' ἴθακῃ πατρὸς ἴσσι.
Πλαίμεν δ' ἀμ' Ὀδυσσεῖ βασι.—Cratin.

Tetrameters catalectic.

Ὅπου τ' ἀπείχει καὶ γυμνασίῳ καὶ τῶν ἀλλῶν ἀνεστῆναι,
Καὶ βέλτεῖσθαι. τοῦτο νομίζεις, σπῆρ κῆος δέξῃον ἀνδρῶν,
Νίκην πρᾶττων καὶ βουλήν καὶ τῆ γλωττῆ πολίμικῶν.
Aristoph.

IV. Dactylic Metre.

1. A dactylic verse consists only of dactyls and spondees.
2. The common heroic is hexameter acatalectic, having in the fifth place a dactyl, in the last, a spondee.
3. In the heroic verse, several licences are allowed, which are not admitted in iambic metre; as, first, the lengthening a short final syllable not only at the place of the œsural pause, but sometimes even on other final syllables, whose emphasis is increased by their beginning a foot; as,

Τὸς' ὠμοῖσιν ἔχων ἀμφιφρέσας, τὲ θάρσῃον.—Il. 4. 45.

Secondly, the hiatus, or the concurrence of two vowels in contiguous words; as when the word ends with a short vowel, Ἀλλ' ἀκείσασ κἀθῆσασ, ἐμῶ δ' ἐπιπύθεισ μῆδων. Il. 4. 565. Or when the word ends with a long vowel or diphthong, in which cases the syllable may either be long without elision, or short, on the supposition that the latter of the component vowels is cut off; as,

Κεῖρῆος ἀλοχῆ, εἴτε εἰ ἔθεν ἐστὶ χρεῖων
Ὅκῃ ἐθέλον δέξασθαι· εἴτε πολὺ βουλομαι αὐτῆ.

4. The Ionic dialect affords great variety in the form of epic verses. And that irregular sort of dactyls, called œolic, admits in the first place any foot of two syllables: the rest must be all dactyls, except when the verse is catalectic, and then the catalectic part must be a trochee.
5. Hephæstion terms that species of dactyls, logœadics, which requires at the end a trochaic fuzzyg; but every where else a dactyl.

Dactylic trimeters.

Αἰ Μούσαι τοῖν Ἐρωτά
Δύσασσι σὺφρακῆσι,
Τῶ Καλλίῳ παρὶδάκων
Καὶ ἢν ἢ Κυβερναία
Ζητεῖ, λυτὰ φερούσασ,
Αὐσασθῆναι τῶν Ἐρωτά.—Anacr.

Dactylic hexameters.

Ἐν δ' ἔπεισ', ὡς εἶτε κῆρα βοῆ ἐν τῆ πεισσι
Δαθῶν ὕπαι νεφύων ἀνεμοστρέφεις· ἢ οἱ τε πασσα
Ἀχρῆ νηκερῆσθαι, ἀνεμῶ δὲ οἰῶσ ἀπῆσι
Ἰσθῶν ἐμῆμερῆται, τρομεροῖσ δὲ τε φέτα καυταῖ
Δεινότατι τῶσθον γὰρ ὕπ' ἐκ θανάτω φερούται.—Hom.
M 2 Elegiac.

VERSIFICATION.

Elegiac.

Πενήσο, μηδ' ἀσχετοῦ ἐρ' ἐρημισί μηδ' ἀδικοῖσι
 Τίμας, μηδ' ἀρετᾶς ἔλκος, μηδ' ἀφίνος.
 Ταυτα μὲν αὐτὸς ἐσθ'· κακοῖσι δὲ μὴ τροστομίηι
 Λόδοσιν, ἀλλ' αἰσι τῶν ἀγαθῶν ἔχειο.—Theogn.

Ὅσις, τοῦ πλοῦτος μέρους.
 Χρηζῆι τοῦ μετρίου παρις
 Ζῆτι, σκαιοστον φύλασσαν
 Ἐν ἑμοῖ καταπόδος ἰσθαι.—Sophi.

V. Choriambic Metre.

1. A choriambic verse requires in every place but the last a choriambus, and in the last, an iambic fzyzgy, entire or catalectic.

2. Sometimes the iambic fzyzgy occurs in the first place, and in long verses in other places; but this happens less frequently.

3. Either two iambic feet, or a spondee and iambus, or the third epitrite, form the iambic fzyzgy: it is used here for the former case.

4. Any other foot of four syllables joined with a choriambic constitute the epichoriambic verse.

Dimeter catalectic.

Οὐκ ἐτος, ἠ γυραικίς,
 Πάσι κακοῖσι ἦμας
 Φλώσι ἐκαστ' ἀνδρῆς.
 Δέννα γὰρ ἔργα θρασυῖ
 Λαμῶναίτ' ὑπ' αὐτῶν.—Aristoph.

Sapphic system; consisting of epichoriambic and Adonic verses.

Ποικιλοφρον' ἀνεκίτ' Ἀφροδίτα,
 Παι Διὸς δολοπλοκῆ, λίσσεται σέ,
 Μη μ' αἰαίσι, μηδ' ἀνεκίτ' ἄδικον
 — Ἐλθε μοι καὶ νῦν, χαλιπὸν δὲ λυτὸν
 Ἐκ μερμηγῶν ὅσα δὲ μοι τέλεισαι
 Θῆμος μίθρῃι τέλεισσι, σὺ δ' ἄνικα
 Ἐνιμπαχορῆ ἴσσο.

VI. Antisphalic Metre.

An antisphalic verse admits in the last place, an iambic fzyzgy complete, or catalectic, or an incomplete antisphalus; and in the first place, besides the proper foot, is admitted any foot of four syllables ending like an antisphalus in the two last syllables; i. e. either $\text{---} \text{---} \text{---} \text{---}$. But in the intermediate places only an antisphalic.

The following are the most usual varieties in this species of verse.

1. In short verses, the proper foot frequently vanishes, and the verse is composed of one of the above-mentioned feet, and an iambic fzyzgy.

2. Every epitrite, except the second, is occasionally substituted in the different places of the verse, especially the fourth epitrite in the second place.

3. If an antisphalic begins the verse and three syllables of any kind remain, the verse is antisphalic; because the remaining syllables may be considered as a portion of some of the admissible or resolved feet.

4. Long verses sometimes contain an iambic fzyzgy in the second place, and then the third place admits the same varieties as the first.

Dimeter acatalectic and hyperacatalectic.

Μη Φύαι τον ἀπαταν η-
 κά λογι' πο δ' ἐπι Φανη,
 Βναι κίθεν ὀθιν περ ἦκει,
 Πολυ δευτερον, ὡς ταχιστα.
 Ως εντ' αν το νον παρῆ,
 Κουφας ἀφροσινικς Φιροῖ,
 Τις πλαγχθη πολυμυχῶς ἔξω:

An Ionic verse à majeure admits a trochaic fzyzgy promiscuously with its proper foot.

Var. 1. The second pæon is sometimes found in the first place.

2. A molossus in an even intermediate place, followed by a trochaic fzyzgy.

3. The second pæon is sometimes joined to a second or third epitrite, so that the two feet together are equal in time to two Ionic feet. This is called an *Ανακλασις*, the defect in time of the preceding foot being supplied by the redundant time of the subsequent. And the verse so disposed is called *Ανακλαμένος*.

4. Resolutions of the long syllables are allowed in all possible varieties.

If the three remaining pæons, or the second pæon in any place but the first, without an *ανακλασις*; or if an iambic fzyzgy, or a third epitrite, a choriambus, or any of the discordant feet of four syllables, be found in the same verse with an Ionic foot, the verse is then called Epionic.

Trimeters brachycatalectic.

Πληρῆς μὲν ἔρανετ' ἠ σίτανα,
 Ἀδ' ὡς περὶ βῆμον ἰσθαιβαν.—Sapph.

Tetrameters brachycatalectic.

Σωκράτην ὁ κοσμος πεποικισεν σοφῶν ἐναι,
 Καὶ κακῶς ἀνιδεν τον Σωκράτην ὁ κοσμος,
 Ἐν τη φύλακῃ, κωνον οτι πῶν θῆρῆκε.—Sotad.

VII. Ionic Metre à Minore.

1. An Ionic verse à minore is often composed entirely of its proper feet. It begins sometimes with the third pæon, followed by one of the epitrites, for an *ανακλασις*. And it admits an iambic fzyzgy promiscuously.

2. In the odd places, a molossus preceded by an iambic fzyzgy sometimes occurs: and in the first a molossus alone.

3. In the intermediate places, a second or third pæon is prefixed to a second epitrite, and this construction is also called *ανακλασις*.

4. The long syllables admit of resolutions, as in the other Ionic metre.

5. An epionic verse à minore is formed by intermixing with the Ionic foot a double trochee, second epitrite, or pæon without an *ανακλασις*.

6. When a choriambus precedes or follows an Ionic foot of either kind, the verse is called profodiæcus: which name is applied to a verse consisting of an alternate mixture of choriambic and Ionic feet, or of their respective representatives.

7. The two species of Ionic feet are not to be intermixed in the same verse.

Dimeters.

Δοκίμος δ' οὐτις ὑπόστις
 Μεγαλῶν ἔρματι Φωτῶν,
 Ἐχρῶσις ἔρκεισιν ἐφρῶν
 Ἀμῶσιν κυμα θαλασσις·
 Ἀφροσιστος; γὰρ ὁ Πιερων
 Στρατος, ἀλκιφρῶν τε λαος.—Ανακλαμ.

Δολομητιν δ' ἀπαταν βιο
 Τις ἀνη βιατος ἀλυξῆς;
 Τις ὁ κεραιφρῶν ποδὶ πῶθη-
 ματος ἐπιτιος ἀναισταν.—Alchylus.

VERSIFICATION.

IX. Pæonic Metre.

1. A pæonic verse requires all the admissible feet to have the same rhythm with the proper foot, *i. e.* to consist of five times.
2. The construction is most perfect when each metre ends with the several words of the verse.
3. Verses called Bacchiac and Cretic are referrible to this head.

Tetrameters catalectic.

*Εἶσα τινες οἱ μ' ἔλεγον, ὡς καταδιλλὰ γάρ νιν,
 Νῆκα Κλεων μ' ὑπὲρταρατῆν επικυμῆμος.
 Καί με κακιστῆαις ἐκνεσε' καθ', ὃ τ' ἀπειδείροισιν
 Οὐκ οἶτος, ἐγέλωσ' ἄνευ κερκαράτα με θρωμῆμοι,
 Οὐδὲν ἄρ' ἔμην μέλον. ὅσον δὲ μόνον εἶδεναι,
 Σκωμμάτιον εἰ ποτε τι βλιθόμενος ἐκβάλλω.—Aristoph.*

X. Of the Pause.

Besides the division of a verse into metres and parts, writers have taken notice of another division into two parts only, arising from the natural intermission of the voice in reading it. This is called the *pause*, which necessarily ends with a word. Heroics and trimeter iambs are esteemed most harmonious, when the pause falls upon the *first syllable of the third foot*. In iambic and trochaic tetrameters, its place is *at the end of the second metre*. These rules, which are far from being general, are more observed by the Roman than the Greek poets. In anapaestic and pæonic verses, and the verse Ionic à minore, no place is assigned to the pause; because the effect of a pause will be produced at the end of each regularly constructed metre.

XI. Of the different Combinations of Metre.

1. The first is a long syllable between the parts of a verse, as in the common pentameter; thus,

2. In some species, the portions of an admissible foot of four syllables are separated by the intermediate metres.
3. It frequently happens that two species totally dissimilar are united in the same verse, which is then denominated *Ασυναρτητος*. We shall employ the mark + to connect the dissimilar portions, in the following instances.

1. Dactyl. tetram. + troch. hemihol.
2. Iambic penth. + troch. hemihol.
3. Dactyl. dim. + troch. monom. or logocædic verse.
4. Dactyl. comma prefixed to an iambic dim. which is called elegiambus.
5. $\left. \begin{array}{l} \text{Iamb. dim.} \\ \text{or} \\ \text{Iamb. penth.} \end{array} \right\}$ prefixed to a dactylic comma, the converse of the former, and called iambelegus.
6. Dactyl. comma + iamb. hemihol.
7. Iamb. penth. + dactyl. dim.

4. When the parts thus united are an iambic and trochaic syzygy, the verse is called periodic or circulating; the quantity being the same as if scanned from the end.

5. A verse agreeing with none of the preceding institutes is termed *Πελοσχηματιστος*, or anomalous; to which class we may refer,

1. A verse, otherwise iambic, having a spondee in the second or fourth place.

2. An iambus in a trochaic, &c.
3. Scæzon.

“Fit scæzon, si spondeo prior exit iambus.”

“Ἄκουσάθ' ἱππιδάκτῶ; οὐ | γὰρ ἄλλ' ἦκα.”

Of the Figures used in Versification.

The syllables composing a verse are affected seven different ways: by *cæfura*, by *synalæpha*, by *ecthlypsis*, by *synærisis*, by *diæresis*, by *lytote*, and by *diastole*.

Of Cæfura.—When, after finishing a foot, there remains one syllable of the word, this circumitance is called *cæfura*; a term which is also sometimes applied to the syllable itself thus *cut off*, and which forms the first part of the following foot.

There are four species of *cæfura*; the *triemimeris*, *penthemimeris*, *hepthemimeris*, and *enemimeris*.

The *triemimeris* is when, after the first foot, or two half feet, there remains a syllable terminating a word, or a *third* half foot.

The *penthemimeris* is when, after two feet, or four half feet, there remains a terminating syllable, or *ffifth* half foot.

The *hepthemimeris* is when, after three feet, or six half feet, a syllable remains, which is the *seventh* half foot.

The *enemimeris* is when, after four feet, or eight half feet, a syllable remains, which is the *ninth* half foot.

The first three *cæfurae* are in the following line:

Silvef-|trem tenu|³i Mu-|⁷fam med|taris a|vena.—Virg.

All are in the following line:

Ille la|²tus nive|⁵um mol|⁹li ful|³l⁹ hya|cintho.—Virg.

Ου χερσ| πανουργ|⁶ον ευ|⁹θην βελ|²φορον ἀνδρα.
Hom. Il. β. 24.

Ἄλλα με|³γαλ³ω|⁷χων φλογο|⁹ικηλα τευχε|⁹α παλλων.
Hesiod. Suet. 451.

The preceding are named syllabic *cæfuras*. To these may be added the trochaic *cæfura*, which is formed either by a trochee remaining at the end of a word, after the completion of a foot, or by a word consisting of a trochee; as,

Cuncta pri|us ten|³tatâ; sed | immedicabile vulnus.—Ovid.
Per cor|nubia | *nâfrâ* per | incæptos Hymenæos.—Virg.

And the monosyllabic *cæfura*; as,

De grege | *nunc* tibi | *vir* nunc | *de* grege | *natus* ha|
bendus.—Ovid.

The principal effects of *cæfura* are, first, to impart smoothness and elegance to a verse, by connecting the different words harmoniously together; secondly, to cause a short syllable to become long, especially after the first, second, or third foot; as,

Pectori|bûs inhians, spirantia consulit exta.—Virg.

Of Synalæpha.—Synalæpha cuts off the final vowel or diphthong of a word, when the following word begins with a vowel or a diphthong; as,

Terra ân|³tiqua, potens armis atque ubere glebæ.—Virg.

As though it were,

Terr' ân|³tiqua, &c.

VERSIFICATION.

The Greeks never employ the *synalæpha*, unless they join the apotrophe; as,

Ω; εφάτ', | εδδεις|σει δ' ο γη|εως, και ε|πειθελο | μωβο.
Iliad, α 33.

Synalæpha is sometimes omitted. First, regularly, as in the interjections O, heu, ah, proh, vœ, vah, hei; as,

Heu ubi pacta fides, ubi quæ jurare solebas.—Ovid.

Secondly, by poetic licence; as,

Et fuccus pecori, et lac subducitur agnis.—Virg.

Long vowels and diphthongs, when they are not cut off, become common; as,

Insula Ionio in magno qua dira Celæno.—Virg.

Ante tibi Eoæ Atlantides abcondantur.—Virg.

Of Ecclipsis.—*Ecclipsis* cuts off the final *m*, and the preceding vowel, when the following word begins with a vowel; as,

Dice puer, virtutem ex me, verumque laborem Fortunam ex aliis.—Virg.

This figure is not employed in the Greek language. The ancients sometimes retained the *m*, and its preceding vowel, which they made short; as,

Corporum officium est quoniam premere omnia deorsum.
Lucret.

But the *um* of officium is elided.

S was formerly elided, not only before a vowel, with the loss of a syllable; but also before a consonant, without the loss of a syllable; as,

Vicimus, O focii! et magnam pugnavimu' pugnam.—Enn.
Nam, si de nihilo fierent, ex omnibu' rebus.—Lucret.

Both *synalæpha* and *ecclipsis* are found in the last syllable of a verse, when the following verse begins with a vowel, provided no long pause intervene to suspend the sense; as,

*Jamque iter cemenſi, turres ac tecta Latinorum
Ardua cernebant juvenes murosque fubibant.*—Virg.

*Sternitur infelix alieno vulnere cœlumque
Afpicit, et dulces moriens reminiscitur Argos.*—Virg.

Of Synæresis.—*Synæresis* is the contraction of two syllables in the same word into one syllable; as τειχεῖ for τεῖχεῖ; ἦ for ῆ, dœinde for dœinde; abiete pronounced abyête for abiete, &c.

And in the following verses for parietibus, tenuis, vindemiator, pronounce pâr-yêtibus, tén-wiûs, vindêm-yâtor.

Hærent pâriêtibus scæle; posteqve sub ipſos.—Virg.

Quæ nec mobilis quidquam neque tènuiûs exiſtat.—Lucr.
Vindêmîator et invictus cui sæpe viator.—Hor.

Of Diæresis.—*Diæresis* is the division of one syllable into two; as τειχῆς for τεῖχῆς, aurai for auræ, fũefco for fũefco, filæ for filvæ, solvit for solvit, subiecta for subiecta, Jüpiter for Jupiter, &c.

Of Syftole.—*Syftole* is the shortening of a syllable, otherwise long by nature or position; as ται; τεχνῆς ἡγεῖται, Theor.; vidên. for vidēs ne, hodie for hœc die, ôbiciſ for ôbiciſ, &c.

Of Diastole.—*Diastole* is the lengthening of a syllable, otherwise naturally short; as Ηρωῦ αυτῆς δ' ἰλαρῆ τευχῆ

κυσσῶν, Hom. Il. α. 4. So are the first syllables in Priamides, Arabia, occasionally lengthened; without which licence, these and some similar proper names would scarcely be admissible in heroic verse.

There are other figures which may affect a verse, but these belong to etymology.

Latin Versification.

I. An hexameter or heroic verse consists of six feet, of which the fifth is usually a dactyl, the sixth a spondee: the rest may be either spondees or dactyls, at the option of the poet. The following scale exhibits the construction:

1.	2.	3.	4.	5.	6.
· · ·	· · ·	· · ·	· · ·	· · ·	· ·
· ·	· ·	· ·	· ·	· · ·	· ·

Āt tūbā | tērritū-|lēm sōnī|tūm prōcūl|zrē ca-|noro.
Virg.

Sometimes when the description is grave, slow, majestic, mournful, &c. a spondee is admitted in the fifth place, and the verse is called *spondaicæ*. In this case, a dactyl usually occupies the third place, and the verse terminates with a word of three or four syllables. It is but seldom otherwise; as,

Constitit atque oculis Phrygia | agmina | circū-
ſpexit.—Virg.

Hexameters abounding too much in spondees may appear to drag, as it were, heavily; and those in which dactyls prevail seem sometimes to have a light and fluttering effect. An equal admixture, therefore, has been thought to afford the just and most harmonious medium.

A proper regard to the *cæſura*, in the structure of an hexameter, is indispensably necessary. The term *cæſura* is used by grammarians in two senses. In the former, it signifies the division of a verse into two portions, affording a little pause or rest for the voice, at some convenient place, where the pause may take place without injury to the sense or harmony of the line. This kind of *cæſura* is sometimes called a *tome*, which term, for distinction's sake, we shall in this former sense exclusively employ.

Tantæ molis erat ♀ Romanam condere gentem.—Virg.

Errabant, acti fati ♀ maria omnia circum.—Virg.

From these examples, it is evident that the *tome* is not exclusively confined to a particular part of the hexameter, as in the pentameter, which, like the English and French Alexandrine, is invariably divided into two equal portions.

But the *tome* most approved in heroic verse was the *penthemimeral*; as,

Lūctān-|tes vên-|tos, ♀ tempestatesque sonoras.—Virg.

Instead, however, of the *tome* at the exact *penthemimeris*, a different division was admitted after a *trœchee* in the third foot; as,

Effigī-|ēm stātū-|rē, ♀ nēſas quæ triste piaret.—Virg.

This, however, is generally censured, as the ear seems to require that there should be no pause immediately after a *trœchee* in this place, especially as the voice, which would find an agreeable rest on a long *semifoot*, is disagreeably suspended on a short syllable.

VERSIFICATION.

The heptemimeral tome was also approved as heroic ; as,
Clāmō-rēs simūl | hōrrēn-|dōs ☞ ad sidera tollit.—Virg.

The tome after the third foot has been the subject of critical censure, though Virgil, the princeps faciliē poetarum, has on a few occasions employed it. The penthemimeral or heptemimeral tome is, however, unquestionably preferable.

The tome between the fourth and fifth feet has been considered as peculiarly adapted to pastoral verse, and therefore called tome Bucolica ; as,

Stānt vītū-|li, ēt tēnē-|ris mū-|gītībūs | ☞ aëra com-
plent.—Nemesian.

But this pause occurs as frequently in heroic as in pastoral verse.

In the second acceptation, the cæsura means the division or separation which takes place in a foot, when that foot is composed of syllables belonging to different words.

A verse in which this cæsura is neglected, in which the insulated and unconnected feet seem to thum all society with each other, is held to be stiff and uncouth in the extreme, and devoid of all poetic elegance ; as,

Spārsis | hāstis | latē | cāmpūs | splēndēt ēt | hōrrēt.
Ennius.

On the contrary, those verses are the most pleasing in which this figure abounds ; and this effect is equally produced, whether the division take place before a semifoot or before a solid trochee.

N. B. By a *solid* trochee is meant a trochee consisting of a single word, or the last two syllables of a word ; not a semifoot joined with a short monosyllable.

Tē spēc-|tēm, fū-|prēmā mē-|hī quum | vēnērīt | hōrā.
Tibullus.

But two successive trochees of this kind occurring in the second and third, or in the third and fourth feet, should be avoided ; but in the first and second, or in the first, third, and fifth, they are unobjectionable.

After the first foot, the neglect of the cæsura is no blemish, provided that foot be a dactyl ; as,

Rēgā | folis erat sublimibus alta columnis.—Ovid.

Nor after a spondee is it much felt, especially if it be an emphatic word ; as,

Tāndēm | progreditur, magnā stipante catervā.—Virg.

Nor is the want of the cæsura felt after the second foot, if it be a spondee concluding with a monosyllable ; as,

Ah quoties per | faxa canum latratibus acta est.—Ovid.

The cæsura, at the third foot, is held to be, if not absolutely necessary, highly desirable. When the tome, however, takes place at the penthemimeris, and there is no pause at the close of the third foot, no objection can be made to its terminating, either with a long monosyllable, two short monosyllables, or a dissyllabic word ; as,

Contem-|nuntque fa-|vōrē, ☞ et | frigida tēta relinquunt.
Virg.

Scindit | fe nu-|bēs, ☞ et in | æthera purgat apertum.
Virg.

Et semel | emif-|sum ☞ vōlūt | irrevocabile verbum.
Hor.

The cæsura is seldom introduced after the fourth foot ;

it is then generally unnecessary, and when it occurs the verse is not harmonious ; as,

Omnes innocuē ; sed non pup-|pis tua Tarchon.—Virg.

Vertitur interea cælum, et ruit ocean-|o nox.—Virg.

When formed by a monosyllable, and when the verse is spondaic, it is unobjectionable ; as,

Explorare labor : mihi iusta capeffere fas est.—Virg.

Perfolvit pendens e vertici-|būs præruptis.—Catul.

II. Neglected Hexameters.

In the epistles and satires of Horace are hexameters, which, from their studied *negligence*, and their want of all the characteristic majesty of the heroic, have received this appellation. They are not, however, devoid of either beauty or simplicity ; and Horace has successfully employed them in occasionally drawing the portrait of the foibles and passions of mankind ; as,

Rure ego viventem, tu dicis in urbe beatum :
Cui placet alterius, sua nimerum est odio fors.
Stultus uterque locum immeritum causatur inique
In culpā est animus, qui fe non effugit unquam.

The following verse consists either of the beginning or latter part of an hexameter.

1. The Archilochian penthemimer or dimeter, named from Archilochus, its inventor, consists of two dactyls and one syllable, and therefore named hypercatalectic ; as,

Pūlvīs ēt | umbrā fū-|mus.—Hor.

2. The Alcmæian dactylic trimeter, first used by Alcmæon, consists of three dactyls and a hypercatalectic syllable ; as,

Nōstrā dē-|ūs canēt | hārmōn-|a.—Prudent.

This verse, like the hexameter, of which it is a part, admits a spondee in the first, second, and third places.

3. The Alcmæian dactylic tetrameter catalectic admits in the first, second, and third places, either a dactyl or spondee ; in the fourth, a dactyl only ; as,

Lūmīnī-|būsqūe pī-|ōr rēdī-|it vīgōr.
Nimbōf-|isqūe pō-|lūs stētīt | imbrībūs
Dēsūpēr | in tēr-|rām nox | funditūr.—Boët.

Sōlvitūr | acris hū-|cems grā-|tā vicē.—Hor.

4. The Alcmæian tetrameter acatalectic contains the last four feet of an hexameter, of which, of course, the third is a dactyl, and the last foot a spondee ; as,

Ibimūs | ō fōci-|ī cōmī-|tēfquē.—Hor.

A spondee may precede the last foot, provided a dactyl precede it ; as,

Mēnō-|rēm cōbī-|bēt Ā-|r-|chytā.—Hor.

5. The Alcmæian tetrameter catalectic contains one long syllable, or two short syllables, then a dactyl or spondee ; afterwards a dactyl ; and lastly a spondee.

Quī | se vōlēt | cēfē pō-|tētēm

Ān-|mōs dōmēt | illē fe-|rōces.—Boët.

6. The Alcmæian tetrameter hypercatalectic contains an heroic penthemimer and an adonic (see N^o VI.) ; as,

Hēū quām | prēcīpī-|tī || mērsā prō-|fundo.—Boët.

VERIFICATION.

7. The tetrameter acatalectic consists of three dactyls and a pyrric, or iambus; as,

Qui fērē-|re ingēnū-|ūm vōlēt | āgrum.—Boët.

8. The Bucolic hexameter has in the fourth place a dactyl; as,

Ab Jove principium, Musæ; Jōvis omnia plena.—Virg.

Fortunatianus observes, that Theocritus adhered to this rule in his pastorals, and that Virgil often neglected it.

9. The hexameter, which is named miurus or teliambus, having for its last foot an iambus instead of a spondee; as,

Dirige odoriferos ad cæca nubilia canes.—Liv. Andron.

The two alcaics will be noticed hereafter.

III. Of the Pentameter.

The pentameter verse consists of five feet, of which the first two may be either dactyls or spondees, the third must always be a spondee, the fourth and fifth anapaests.

It appears from Quintilian that this was the ancient mode of scanning the pentameter. (Inst. ix. 4.) But among the moderns it is scanned otherwise. By dividing the verse into two hemistichs or penthemimers, the first hemistich must contain two dactyls or two spondees, or one of each indiscriminately, and a long syllable, or cæfura; in the latter hemistich, two dactyls with another cæfura; thus,

Cārminī-būs vī-|vēs || tēmpūs īn | omnē mē-|is.—Ovid.

1. The first hemistich ought to end with the entire word, that the cæfura belonging to the penthemimer may take place; otherwise it will not be a legitimate pentameter, according to Quintilian, ix. 4. "In medio pentametri spondeo, qui nisi alterius verbi fine, alterius initio consistet, versum non efficit." Therefore Terentianus condemns the following line.

Īntēr | nōstrōs | gēn-||tilis ō-|berrāt ē|quus.

2. An elision immediately after the penthemimer is harsh; as,

Mī mīse-|ro eripu-|i-|i || omnia | nostra bo-|na.

which verse is rendered still more harsh by the elision in the preceding foot.

3. Neither hemistich should end with a monosyllable, except it be preceded by another monosyllable, or an elision.

4. The most eligible conclusion of a pentameter is a disyllable, or a word of four or five syllables. But the verse of Ovid, Propertius, or Tibullus, seldom ends with a trisyllable.

5. A pentameter subjoined to an hexameter constitutes an elegiac distich; as,

Flebilis indignos, elegeia. solve capillos.
Ah nimis ex vero nuuc tibi nomen erit!

6. Every distich should terminate with a period, or colon.

7. Rhyming must be avoided in this and every other kind of Latin verse; as,

Quærebant flavos per nemus omne favos.

Such verses are called Leonine, or monkish, from Leoninus, a Benedictine monk, who is censured by Vossius and others for affecting this mode of verifying.

IV. Of the Asclepiadic, or Choriambic.

This verse, invented by the poet Asclepiades, consists of four feet, a spondee, two choriambi, and a pyrric; or, considering the last syllable of the verse as long, an iambus; thus,

Mæcē|nās atāvīs | ēditē rē|gibus.—Hor.

1. Sometimes the first foot was a dactyl; as,

Eflūgē-|ūm ēt miserōs | liberā mōrs | vehit.—Seneca.

2. Sometimes, but seldom, a spondee was admitted into the second and fourth places; as,

Tēndit īn | ēxtēr-|.nas ire tenebras.—Boët.

3. Single feet are elegantly composed in this verse of complete words; as,

Quāssās | indōcīlis | pāuperiēm | pāti.—Hor.

4. The first choriambus, or a cæfura, falls inelegantly in the middle of a word; as,

Non in-|cēndā Cārthāgīnis īm-|piæ.

Unless there be an ecchipsis, a synalapha, or the word be a compound; but even then the lines lose not all their harshness, and are but seldom to be imitated.

There are, likewise, the following varieties in choriambic verse.

1. The Aristophanian choriambic dimeter acatalectic, consisting of a choriambus and a bacchic, or an amphibrac; as,

Lydā dic | pēr omnes.—Hor.

2. The Alcaic pentameter acatalectic, consisting of a spondee, three choriambi, and a pyrric; as,

Sēu plūrēs liēmēs | sēu tribūt | Jūpitēr ūl-|timam.
Hor.

3. The Alcaic epichoriambic tetrameter acatalectic, consisting of the second epirrite, (a choree and a spondee), two choriambi, and a bacchic; as,

Tē Dēōs ō-|ro Sībārīn | cūr prōpērēs | amando.—Hor.

V. Of the Glyconic.

The Glyconic verse, so named from the poet Glyco, consists of a spondee, a choriambus, and an iambus; as,

Sic tē | divā potēs | Cypri.—Hor.

But the first foot was sometimes varied to an iambus, or a trochee: but Horace, who was partial to the Glyconic, invariably adheres to the spondic commencement, except in one solitary instance; viz. ode i. 15. 36.

VI. Dactylic Dimeter, or Adonic.

The Adonic verse consists of two feet, the first a dactyl, the other a spondee; as,

Vīfērē | mōntēs.—Hor.

We seldom find this verse employed alone. Terentianus Maurus (De Metr. 439.) informs us that Sappho wrote entire poems in this short measure. Terentianus himself has also left us a short piece of the kind; and another of thirty-one successive adonics occurs in Boetius, lib. i. metr. 7.

VII. Of the Sapphic Pentameter.

The Sapphic verse, so named from the poetess Sappho, consists of five feet; the first a trochee, the second a spondee,

VERSIFICATION.

spondee, the third a dactyl, and the fourth and fifth trochees; as,

Dēfū-'.-it fax-'.-is āgīt-'.-tātūs | hūmōr.—Hor.

1. The penthemimeral cæfura adds that elegance to Sapphic verse, without which it does not flow harmoniously.

2. Sappho and others admitted sometimes, in the first place, a spondee, or a pyrric; as,

ΔιΨ' ἀλλ' | εἰζικαστο τυ δ' α μιχαλιας.—Sappho.

Pōsi-'.tis tandem levibus fagittis.—Seneca.

3. Sappho, Catullus, and Seneca, sometimes made the second foot an iambus, a trochee, or a dactyl; as,

Χρυσι-'.-ῥέμῃ-'.-τηζ δαίφρον ασασσα.—Erimua.

Παι Δι-'.-ῶ; δδ-'.-λοτλοκε, λισσημαι σε.—Sappho.

Quæque ad | Hēlpēri-'.-as jacet ora metas.—Seneca.

Horace, however, who in many instances improved upon the invention of Sappho, invariably adheres to that form which has the second foot a spondee; and the young poet, if he be prudent, will not pass beyond his limits.

4. Sapphic verse appears sometimes to be hypercatalectic, but in this case the final vowel of the line suffers the elision consequent on the following verse beginning with a vowel.

5. Instances occur in Sappho, Catullus, and Horace, of the division of a word between two lines; as,

Grofphe, non gemmis, neque purpura ve-'.-nals, nec auro.—Hor.

It has been conjectured, however, that the cause of this peculiarity in the Sapphic is, that neither Sappho, Catullus, nor Horace, intended the stanza to consist of four, but of three separate verses; viz. two sapphics, and one verse of seven feet; as,

Otium bello furiosa Thrace,

Otium Medii pharetrâ decori,

Grofphe, non gemmis, neque purpura venale, nec auro.

Hor. Od. ii. 16. 5.

6. However, we moderns usually consider the strophe to consist of three sapphics and an adonic: see No. VI.; as,

Quid brevi fortes jaculamur ævo

Multa? Quid terras alio calentes

Sole mutamus? Patræ quis exul

Se quoque fugit.—Hor. Od. ii. 16. 17.

VIII. Of the Phalæcian Verse.

The Phalæcian verse, denominated from the poet Phalæcius, consists of five feet, viz. a spondee, a dactyl, and three trochees; as,

Nōn est | vivēre, | fēd vā-'.-lērē, | vitā.—Martial.

1. This verse neither rejects nor requires a cæfura.

2. Sometimes the first foot was made an iambus or a trochee by Catullus, but by the poets posterior to Catullus, not more than two or three solitary instances of this anomaly can be proved from an analysis of some thousand verses.

3. The same poet has in some instances also spoiled the elegance and harmony of his measure by introducing a heavy spondee into the second place, but his example was not imitated by his more polished successors.

4. The term hendecasyllabic (as employed by some) is not applicable exclusively to the Phalæcian verse, since

Vol. XXXVII.

the epithet is equally suitable to the Sapphic and to the Alcaic verse.

IX. Of the Pherecratic Verse.

This verse, invented by Pherecrates of Athens, consists of what may be the three last feet of an hexameter; viz. a spondee, a dactyl, and a spondee; as,

Nigris | æquora | ventis.—Hor.

1. Boëthius sometimes admits an anapaest in the first place; as,

Sīmili | fūrgit ab | ortu.

2. Catullus sometimes admits in the first place a trochee, or an iambus, and at others, in the last place, a dactyl; as,

Prōdē-'.-as nova | nupta.

Pūcl-'.-læque cæ-'.-namus.

X. Of the Iambic Verse.

Iambic verses take their name from the iambus, which in pure iambics was the only foot admitted. The two most common kinds are the dimeter and the trimeter; as,

I.	II.	III.
Īnar-'.-sīt æ-'.-flūō-'.-sītis	Stūs ēt ip-'.-sā Rō-'.-mā vi-'.-ribūs rūit.—Hor.	

1. But in order both to facilitate and dignify the composition, spondees were admitted into the odd places; as,

Fōrti sēquē-'.-mūr pē-'.-tōre	Pārs sã-'.-nitã-'.-tis vcl-'.-lã sã-'.-nãri fūit.—Seneca.	Hor.
---------------------------------	---	------

2. The former of these makes two thirds epitrits, and the latter three.

3. And instead of an iambus and a spondee, their isochronal feet were admitted instead of them, i. e. in the odd places, an anapaest, a dactyl, and sometimes a tribrac; and also in the even places, (except the last, which always requires an iambus,) a tribrac: the scale of the mixed trimeter iambic is, therefore, as follows:

1.	2.	3.	4.	5.	6.
∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨
∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨
∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨	∨ ∨ ∨

4. The comic poets not only admitted these feet, but also the amphibrac, proceleumatic, and bacchiæ into the even as well as the odd places, the last always excepted; and almost all the fables of Phædrus are written in the following manner:

Āmit-'.-tīt mēri-'.-tō prōpri-'.-ūm, qui āli-'.-ēnum

āp-'.-pētīt

Fāciť | pāren-'.-tēs boni-'.-tās nōn | necēs-'.-cītās.

The following are the varieties of the iambic.

1. The iambic monometer, or binarius, consisting of two iambs; as,

Cāvē | mālūm
Tēnē | bōnūm.

2. The iambic dimeter consists of two metres, or four feet, properly

N

VERSIFICATION.

properly all iamboes; it admits, however, the same variations as the trimeter; as,

Förtü-|nā nōn || mutāt | gēnus.—Hor.
 Añt ěgō | vīcis-||sīm rī-|sērō.—Hor.

Prudentius, and several posterior authors, wrote entire poems in this metre.

3. The Archilochian trimeter catalectic, which in the first place has an iambus or spondee, in the second an iambus, in the third a spondee, in the fourth and fifth an iambus with a common syllable; thus,

Trāhūnt-|quē sic-|cās mā-|chīnæ | cārī-|nas
 Nēc prā-|ta cā-|nis āl-|bicānt | prūi-|nis.—Hor.

4. The Archilochian trimeter catalectic differing from the last in this, that it admits a spondee or iambus in the third place; as,

Mēā | rēnī-|dēt īn | domo | lacū-|nar.
 Premūt | colum-|nās ūl-|timā | recif-|as.—Hor.

5. The Galliambic trimeter (so named from the Galli or priests of Cybele) acatalectic consists of six feet, of which the first is an anapaest, the second and third an iambus, the fourth and fifth a dactyl, and the sixth an anapaest; as,

Super	al- ta	vec- tus	ā- tys	ēle- ri	ratē	māria
Phrygiūm	nemus	cita- to	cupi- dē	pede	tetigit	
Adiit-	que opa- ca	fil- vis	redi- mita	lo-	ca	Dez.
						Catullus.

This verse has always an iambus in the third verse place, in the fifth a dactyl, and in the sixth a spondee. In the second, however, it admits an anapaest or a tribrac; and in the fourth, a spondee. It is but seldom that other feet are admitted, *viz.* in the first place a spondee, a cretic, or a proceleusmatic; in the second, a spondee and its isochronal foot, a dactyl; in the fourth an iambus.

6. The Saturnian trimeter hypercatalectic, which has a spondee in the fourth place, and in the other five iambs, with the hypermeter syllable at the close; as,

Dabunt | mālum | M⁷tel-|li N⁴x-|vio | Poē-|tæ.
 Ter. Maur.

7. The Hipponactic tetrameter catalectic consists of seven iambs and a long syllable, and sometimes admits a spondee into the odd places; as,

Et īn | solen-|ter æf-|tues | velut | minu-|ta mag-|no.
 Depren-|sa na-|vis in | mari | vōsā | nien-|te ven-|to.
 Catullus.

8. The tetrameter, or octonarius acatalectic, contains eight feet, of which the last is always an iambus; in the other even places are iamboes or tribracs; in the odd places, iamboes or spondees, or their isochronal feet, tribracs, anapaests, or dactyls; as,

Sufpi-|cio-|si ad¹ con-|tūme-⁴liam⁵ om-|niā ac-
 |cipiunt | magis.—Terence.

Comic writers admit not only in this, but also in the trimeter and catalectic tetrameter, such feet, in the even places, as are generally used in the odd places, and *vice versa*; the last place excepted, in which there is always an iambus.

Of the Scazon, or Choliambus.

The scazon or choliambus (*i. e.* lame iambic), so named,

because in it the cadence is inverted, or maimed, by the change of feet in the two last places, consists of six feet, of which the fifth is invariably an iambus, and the sixth a spondee, the others being the same as in the iambic trimeter; as,

Ō quīd | solū-|tis est | bēā-|tūs | cūrīs?—Catul.

Of the Anacreontic.

The name of the celebrated lyric poet Anacreon forms the distinguishing epithet that characterizes this verse; which is nothing else but the iambic dimeter catalectic. The first foot is an iambus, often a spondee or anapaest, sometimes a tribrac or a cretic; the second and third are iamboes, with an additional syllable at the end; as,

Ὅπῶσ' | φερον-|ται λαι.—Anac.

Lēx hęc | dāta est | cadū-|cis.—Prudent.

Hābēt om-|nis hōe | vōlūp-|tas.—Boët.

Of the Trochaic.

The trochaic verse admits, in the odd places, a trochee or a tribrac; but in the last place a trochee only; in the even places, besides the trochee and tribrac, a spondee, a dactyl, or an anapaest, but a proceleusmatic was seldom admissible. It rejects the iambus, as the iambus does the trochee.

The most common trochaic verse is the tetrameter catalectic, which consists of seven feet, (properly all trochees,) followed by a catalectic syllable; as,

Jūfūs | est īn-|cērmis | irē : | pūrūs | irē | jūfūs est.
 Catullus.

1. Although iambic and trochaic verses seem opposite in their nature, yet as in each, single short and long syllables alternately recur, the retrenchment of the initial syllable of either, transforms it into the other, *i. e.* the iambic into the trochaic, and the trochaic into the iambic. This circumstance has induced some, particularly the author of the Port Royal grammar, to deny the existence of trochaic verse, and to denominate them accephalous iambs.

2. In the trochaic tetrameter, the caesura ought to be altogether avoided *after* the fourth foot, which divides the verse into two hemistichs.

3. The comic writers use, in trochaic verse, the same liberties in regard to the choice of the feet as in iambs, planting promiscuously, in the odd places, such feet as others admit in the even places, the seventh foot alone excepted.

Of trochaic verse we have the following species.

1. The trochaic monometer hypercatalectic contains two trochees and the hypermeter syllable; as,

Nūllā | jān fī-|les.—Scalig.

2. The trochaic dimeter brachycatalectic contains three trochees; as,

Huc a-|des Ly-|æc.—Scalig.

3. The Euripidean dimeter catalectic consists of three trochees, (in the second place sometimes a spondee or a dactyl,) with a catalectic syllable; as,

Dōmā | cōfey-|ēntī-|.æ.—Prudent.

Vītā | decūr-|rēns vi-|ā.—Seneca.

Lēnis | æ modī-|cūm flū-|ens.—Idem.

4. The Alemanic dimeter acatalectic contains four trochees;

VERIFICATION.

chees; but it admits, in the second place, a spondee, or its isochronal feet, a dactyl or anapæst; as,

Nōn fā-|cīt quōd | ōptāt | ipsē.—Boët.

Āēre | tōrvō | cōmmi-|nāntēs.—Boët.

Cōnfcī-|s scēlē-|ris nē | fāndi.—Buch.

5. The Anacreontic dimeter acatalectic has, in the first place, a pyrric, in the other three trochees; as,

Rēdi-|mita | vere | tellus.—Claud.

6. The Hipponætic tetrameter acatalectic consists of eight trochees; but it admits in the even places a spondee and its isochronal feet, an anapæst, a dactyl, and sometimes a proceleusmatic, and in the odd places a tribrac; as,

Appē-|tente | vere | primo | cum te-|ner vi-|refcīt
| annus.—Scalig.

But the comic writers reserved to themselves the same licence which characterizes their catalectic iambic tetrameters, and introduce all the above-mentioned indiscriminately in any place.

Of the Anapæstic.

Anapæstic verse is so named, because in any place of it an anapæst may be used. It admits, however, so freely the isochronal feet, (the spondee and the dactyl,) that there is frequently not one anapæst in an anapæstic verse.

1. The anapæstic dimeter acatalectic is seldom found in its pure state; as,

Phārētræ-|quē grāvēs | dātē fā-|vā fērō.—Seneca.

But the sweetest and most common kind, is that which is named the Aristophanian or Pindaric, which consists of an admixture of dactyls, spondees, and anapæsts, excluding, however, generally the dactyl from the second and fourth places; as,

Quānti | cāsūs | būmā-|nā rotant :

Mīnūs īn | pārvīs | fōrtū-|nā fūrit,

Lēviūs-|quē fērit | lēviō-|rā Dēūs.—Seneca.

The pyrric, the trochee, and the tribrac, were occasionally substituted for the anapæst. The young poet must here observe, that those anapæstics are the most harmonious which are without the cæfura; and next to these in elegance are the lines in which each dipodia terminates with a word.

2. The Simonidian dimeter acatalectic consists of an anapæst, a dactyl, or a spondee, in the first place, and in the last an anapæst or spondee; as,

Dēflē-|tē vīrūm

Quō nōn | aliūs

Pōtūit | citiūs

Difcēre | cāsūs

Ūnā | tāntūm

Pārte aū-|ditā

Sēpe ēt | nēutrā.—Seneca.

3. The Parthenic tetrameter catalectic, having in the first and second places either an anapæst or a spondee; in the third only an anapæst; and, lastly, the catalectic syllable; as,

Ūtīnām | mōdō nōf-|trā rēdi-|rent

Īn mō-|rēs tem-|porā prif-|cos.—Boët.

4. The Archebulian pentameter acatalectic, (denominated from the inventor Archebulus,) consists of four anapæsts and a bacchic; thus,

Gēnēri | dātūr aūc-|tōr hūic | vētūs Ār-|chēbulūs.

Terent.

Of the greater Alcaic.

The greater Alcaic is an hypercatalectic tetrameter, consisting of an iambic penthemimer, followed by a choriambus and an iambus; as,

Cālēf-|tīs ār-|cīs | nōbilis īn-|cōla.—Prudent.

The cæfura more frequently occurs in the last syllable of a word at the catalectic syllable, as above. In Horace, however, the cæfura is sometimes found in the beginning of a word, sometimes in the middle, and sometimes it is a monosyllable.

In the first place, Horace has *seldom* an iambus, but generally, and Prudentius *always*, a spondee.

Of the less Alcaic.

This metre consists of two dactyls, followed by two trochees; and is, therefore, a dactylic-trochaic tetrameter; as,

Lēviā | pērsōnū-|ērē | fāxā.—Horace.

Of the Pyrric.

In Terentianus and Aufonius we find a pyrric tetrameter catalectic; as,

Pērit | ābit | avī-|pēdis | ānī-|mūlā | lēpō-|ris.

Terent.

Of the Ionic à Majore.

1. The pure great ionic tetrameter acatalectic consists of four great ionics; as,

Fēcīt fatīs | ægrūm rābī-|ēm qui dōmū-|īt fēmīnæ.

Scalig.

2. The mixed great ionic, (or Sotadic, from the poet Sotades,) consists of three great ionics and a spondee; as,

Vōcālīā | quædām mēmō-|rānt cōnsōnā | quædām.

Terent.

This kind of verse oftener admits, in the third place, a dichoree instead of a great ionic; thus,

Has cum gemi-|na compede | dedicat ca-|tenas.

Mart.

It admits also, in all the places but the last, the second pæon, the second epitrite, and the dichoree; and in almost every place a long quantity may be resolved into short syllables.

Of the Ionic à Minore.

This verse receives its name from the foot, the ionic à minore, which it employs in every place. It is more usually either a trimeter or tetrameter. Thus Horace, Carm. iii. 12. after two trimeters places a tetrameter; as,

Mifērārūm ēst, | nēque amōri | dātē ludūm.

Nēque dūlci | mālā vinō | lāvare aut ēx-

ānīmāri | mētūentēs | patrūæ vēr-|berā linguæ.

The learned Bentley was, however, of opinion, that this composition of Horace's consists of ten small ionics, without any pause, and that, therefore, the whole of the ode is finished in four decapodia of this kind.

VERSIFICATION.

Of Mixt Verses.

Verſes are ſaid to be mixt, when two of different kinds are united. Amongſt the Latin poets we find the following variety.

1. The Archilochian pentameter conſiſts of two members, the firſt a dactylic tetrameter *à priori*, the latter is a trochaic dimeter brachycatalectic; as,

Solvitur | acris hi-|cems grā-|tā vicē || vērīs | ēt Fa-|
vōni.—Hor.

2. The Archilochian elegiac; of which the firſt member is the latter part of an elegiac pentameter, or the Archilochian dactylic penthemimer, (conſiſting of two dactyls and a ſyllable,) the ſecond member, the iambic dimeter acatalectic; as,

Scribēre | vēsīcū-|Jos, || amō-|re per-|cuſſum | gravi.
Hor.

which is commonly thus divided into two verſes :

Scribere verſiculum
Amore percuffum gravi.

3. The dactylic hexameter acatalectic conſiſts of two diviſions of an hexameter, each of three feet, but in ſuch a manner, that in the firſt place of each there is a ſpondee, or a trochee, or iambus; in the ſecond and third place of the firſt diviſion, there is a dactylus; in the ſecond place of the ſecond diviſion a dactyl, and the third or laſt a ſpondee. In this kind of verſe the laſt ſyllable of the firſt diviſion is accounted common; as,

Nām tē | præcipū-|e in ſūs || ūrbi-|būs cōlit | ōra.
Catul.

4. The iambelegiac (the converſe of No. 2.), in which the firſt diviſion is iambic, and the ſecond elegiac; thus,

Nivēs-|quē dē-|dūcūnt | Jōvēm: || nūnc mārē | nūnc
ſilū|x.—Hor.

Commonly thus divided,

Niveſque deducunt Jovem:
Nunc mare nunc ſiliās.

5. The choriambic dactylic; in which the firſt diviſion is the Glyconic, having generally in the firſt place a trochee; the ſecond diviſion is the Pherecratic, with a trochee alſo in the beginning; thus,

Ō Cōllōniā quæ | cūpīs || pōntē | lūdērē | lōngō.—Catul.

6. The choriambic trochaic; of which the firſt diviſion is the choriambic dimeter, or two choriambuses; the ſecond, the trochaic dimeter brachycatalectic, of which the firſt foot is a dactyl, the other two trochees; thus,

Vēſtiāt Al-|pinūs apēx || ēt rūbē-|ānt prū-|inæ.
Claud.

7. The trochaic dactylic; of which the firſt diviſion is a trochaic penthemimer; that is, in the firſt place there is a trochee, in the ſecond a ſpondee or dactyl, with an additional ſyllable; and the ſecond part is an adonic; as,

Sī quis | Ārētū-|ri || ſidērē | nefcit.
Cūm ni-|mis cēlē-|rēs || explicēt | ortus.—Boët.

8. The iambic dactylic; of which the firſt is an iambic penthemimer, conſiſting of two iambs, with a long ſyllable, but oftener in the firſt place a ſpondee, and ſometimes

in the ſecond a tribrac; and in the laſt part an adonic; thus,

Prōpīn-|quā ſum-|mō || cārdinē | lābi
Mērgāt-|quē ſē-|ras || æquōrē | flammās.—Boët.
Stūpēt-|que ſūbī-|tis || mōbile | vulgus.

Of Compoſitions in which the Verſe is varied.

From what has been already ſaid, it appears that there are five different ſpecies of compoſition, conſiſting of a combination of various kinds of verſes, and in each there are generally ſeveral varieties.

I. *of the Carmen Dicolon Diſtrophon.*

1. The elegiac diſtich is already explained. See Pentameter, Obf. 5.

2. An hexameter with an Archilochian dactylic penthemimer; as,

Diffugere nives; | redeunt jam gramina'campis
Arboribusque comæ.—Hor.

3. An hexameter with an Alcmæian dactylic tetrameter catalectic; as,

Tunc me diſcuſſa liquerunt nocte tenebræ,
Luminibusque prior rediit vigor.—Boët.

4. An hexameter with an Alcmæian dactylic tetrameter catalectic; as,

Laudabant alii claram Rhōden, aut Metylenen,
Aut Ephēſum, bimariſve Corinthi.—Hor.

5. An hexameter with an Alcmæian dactylic tetrameter catalectic; as,

O qui perpetuis orbem moderaris habenis
Placidus bonus exere vultus.—Buchan. Pſal. 68.

6. An hexameter with an iambic dimeter catalectic; as,

Nox eras, et cælo fulgebat luna fereno
Inter minora fidera.—Hor.

7. An hexameter with an iambic trimeter; as,

Alterā jam teritur bellis civilibus ætas;
Suis et ipſa Roma viribus ruit.—Hor.

8. An hexameter with an Archilochian elegiac ſyſtē; as,

Horrida tempeſtas cælum contraxit; et imbres
Niveſque deducunt Jovem: nunc mare, nunc ſiliæ.—Hor.

9. An Alcmæian dactylic trimeter hypercatalectic, with a Pherecratic dactylic trimeter acatalectic; as,

Omne hominum genus in terris
Simili fargit ab ortu.—Boët.

10. The Alcmæian dactylic tetrameter acatalectic, with an Archilochian dactylic dimeter hypercatalectic; as,

Quam thalamo, tedifque jugalibus
Invida mors rapuit.—Aulon. Parent 2.

11. The Alcmæian dactylic tetrameter acatalectic, with an iambic dimeter acatalectic; as,

Sunt etenim pennæ volucres mihi
Quæ cæſa conſecundant poli.—Boët.

12. The Anacreontic iambic dimeter catalectic, with the Pherecratic dactylic trimeter acatalectic; as,

Quifquis volet perennem
Cantus ponere ſedem.—Boët.

VERSIFICATION.

13. The iambic trimeter acatalectic, with the elegiac pentameter; as,

Quamvis fluente dives auri gurgite
Non expleturas cogat avarus opes.—Boët.

14. The iambic trimeter acatalectic, with the iambic dimeter catalectic; as,

Ibis liburnis inter alta navium,
Amice, propugnacula.—Hor.

15. The iambic trimeter acatalectic, with the Archilochian elegiac; as,

Petti, nihil me, sicut antea, juvat
Scribere vericulos, amore percussum gravi.—Hor.

16. The scazon iambic, with an iambic dimeter acatalectic; as,

Verona docti syllabas amat vatis
Marone felix Mantua est.—Martial.

17. The Euripidean trochaic dimeter catalectic, with an iambic dimeter acatalectic; as,

Orbis omnes incolæ
A sole Eoo ad Hesperum.—Buchan.

18. The Euripidean trochaic dimeter catalectic, with an Archilochian iambic trimeter catalectic; as,

Non ebur, neque aureum
Mea renidet in domo lacunar.—Hor.

19. The Alcmanian trochaic dimeter acatalectic, with a Pherecratic dactylic trimeter acatalectic; as,

Quos vides federe celfos
Solii culmine reges.—Boët.

20. The trochaic tetrameter catalectic, with an iambic trimeter acatalectic; as,

Ore pulchro, et ore muto, scire vis quæ sim?
Imago Rufi rhetoris Pictavici.—Aufon.

21. The Sapphic pentameter acatalectic, with an iambic dimeter acatalectic; as,

Gentis humane pater atque custos
Quam sancta majestas tui.—Buchan.

22. The Sapphic pentameter acatalectic, with the Glyconic choriambic trimeter acatalectic; as,

Cum polo Phæbus røfeis quadrigis
Lucem spargere cæperit.—Boët.

23. The Phalæcian pentameter acatalectic, with an elegiac pentameter; as,

Quid tantos juvat excitare motus
Et propriâ fatum sollicitare manu.—Boët.

24. The Phalæcian pentameter acatalectic, with an Alcaic dactylic tetrameter acatalectic; as,

Quamvis se Tyrio superbus ostro
Comeret, et niveis lapillis.—Boët.

25. The Phalæcian pentameter acatalectic, with a Sapphic pentameter acatalectic; as,

Hic partus placidâ manens quiete,
Hoc patens unum miseris asylum.—Boët.

26. The Aristophanian choriambic dimeter acatalectic, with an Alcaic epichoriambic tetrameter acatalectic; as,

Lydia dic per omnes
Te deos oro, Sybarin cur properes amando.—Hor.

27. The Glyconic choriambic trimeter acatalectic, with the Afelepiadic choriambic tetrameter acatalectic; as,

Sic te diva potens Cypri,
Sic fratres Helenæ lucida fidera.—Hor.

28. The Afelepiadic choriambic tetrameter acatalectic, with the Pherecratic dactylic trimeter acatalectic; as,

Si quantas rapidis flatibus incitus
Pontus verfat arenas.—Boët.

29. The Afelepiadic choriambic tetrameter acatalectic, with an iambic dimeter acatalectic; as,

Eheu, quæ miseros tramite devios
Abducit ignorantia.—Boët.

30. The dactylic-trochaic septenarius, with an Archilochian iambic trimeter catalectic; as,

Solvitur acris hiems gratâ vice veris et Favoni,
Trahuntque ficcas machine carinas.—Hor.

31. The trochaic dactylic, with an iambic dactylic; as,

Si quis Arcturi fidera nefcit
Propinqua summo cardine labi.—Boët.

II. Of the Carmen Dicolon Tristrophon.

1. Two Aristophanian anapaestic tetrameters acatalectic, and an Adonic dimeter acatalectic; as,

Tu quoque in ævum, Crispe, futurum
Mælti venies commemoratus
Munere threni.—Aufon.

2. Two Alcmanian trochaic dimeters acatalectic, and an Euripidean trochaic dimeter catalectic; as,

Incolæ terrarum ab ortu
Solis ultimum ad cubile,
Eia Domino pfallite.—Buchan.

3. Two small Ionic trimeters acatalectic, and a small Ionic tetrameter acatalectic; as,

Miserarum est, neque amore dare ludum
Neque dulci mala vino lavere; aut ex-
animari metuentes patriæ verbera lingue.—Hor.

III. Of the Carmen Dicolon Tetrastrophon.

1. Three Anacreontic trochaic dimeters acatalectic, and a choriambic trochaic quinarius; as,

Age cunctâ nuptiali
Redimita vere tellus
Celebra toros heriles
Omne nenus cum fluvii, omne canat profundum.—Claud.

2. Three Sapphic pentameters, and an Adonic dimeter; as,

Jam fatis terris nivis, atque diuæ
Grandinis niist pater, et rubente
Dextera sacras jaculatas arces
Terruit urbem.—Hor.

VERSIFICATION.

3. Three Glyconic Choriambic trimeters acatalectic, and a Pherecratic dactylic trimeter acatalectic; as,

Dianæ fumus in fide
Puellæ, et pueri integri:
Dianam pueri integri,
Puellæque canamus.—Catull.

4. Three Afelepiadic choriambics and a Glyconic; as,

Aurum per medios ire fatellites,
Et perumpere amat faxa potentius
Ictu fulmineo. Concidit auguris
Argivi domus ob lucrum.—Hor.

IV. Of the Carmen Tricolon Tristrophon.

1. An hexameter, an Archilochian dactylic dimeter hypercatalectic, and an Iambic dimeter acatalectic; as,

Te regem Dominumque canam, dum lucida volvet
Lucidus astro polus,
Et unicum colum Deum.—Buchan.

2. An hexameter, an Iambic dimeter acatalectic, and an Archilochian dactylic penthemimer; as,

Horrida tempesta cælum contraxit; et imbres
Nivesque deducunt Jovem;
Nunc mare, nunc filivæ. Epod. 13.

Thus Heinsius scans the 13th Epod.

3. An Iambic trimeter acatalectic, an Archilochian dactylic penthemimer, with an Iambic dimeter acatalectic; as,

Petti, nihil me, sicut antea juvat
Scribere versiculos—
Amore percussum gravi.—Hor.

But others term this a carmen dicolon distrophon.

4. A Glyconic choriambic trimeter, an Afelepiadic choriambic tetrameter, and an Alcaic choriambic pentameter; as,

Per quinquennia jam decem
Ni fallor, fuimus; septimus insuper
Anno cardo rotat, dum fruimus Sole volubili.—Prudent.

V. Of the Carmen Tricolon Tetraistrophon.

1. Two great alcaics, an Iambic dimeter hypercatalectic, and a small alcaic; as,

Odi profanum vulgus et arceo:
Favete linguis: carmina non prius
Audita, Musarum sacerdos,
Virginibus purisque canto.—Hor.

2. Two Afelepiadic choriambics, a Pherecratic dactylic trimeter, and a Glyconic choriambic; as,

Prima nocte domum claude, neque in vias
Sub castu querulæ despicere tibias:
Et te sæpe vocanti
Duram, difficilis mane.—Hor.

There is likewise a third kind formed by a certain arrangement of ode 12. lib. 3. of Horace; for which see the Carmen Diocolon Tristrophon, No. III.

As the literature of Italy and France is allowed to hold such distinguished rank and importance in the republic of

letters, it is now incumbent on us to offer such remarks as may tend to develop the nature and principles of

Italian and French Versification.

I. If the reader will take the trouble to consult the abbé d'Olivet on the French Language, (edit. of 1807, p. 6—10.) he will find a detail of those who attempted the composition of verse after the principles of the ancient Greeks and Romans. This practice, however, has long since become quite obsolete, and syllabic quantity has been superseded, in the structure of verse, by accentuation, and therefore the definition of modern verse may be given in the following words.

II. A verse is an assemblage of such a definite number of syllables or feet, and comprises such a series of regularly recurring accents, as may be easily remarked by the ear; whose pleasing succession is regulated by our innate perception of what is musical and harmonious; and it, therefore, admirably serves to delight the ear, to expand the soul, to solace the heart, to aid the memory, and to adapt the language of discourse to that of song and music.

The extent or the measure of verse ought to be such, that it may be easily and sensibly felt by the ear; otherwise verse differs not from prose. For if the number of feet or syllables constituting the verse be such, as to prevent the early recognition of the same returning series, the ear fails to be delighted, or the memory to be assisted by the recurrence of what it is only fatigue or difficulty to anticipate.

That an intimate analogy exists between verse and music is manifest to the most superficial observer. They receive their existence from the same laws, and their object is to gratify and delight the same organ. Amongst the ancients, music lent its numbers to poetry. It was to the lyre that Apollo, Orpheus, and Homer sung their verse. "Illud quidem certum," says Vossius, "commem poemum olim cantatum fuisse." It is, therefore, to music that we must refer for the basis, the rationale, of versification.

It is affirmed too, by the definition just given, that verse admirably serves to delight the ear, to expand the soul, and to aid the memory. Verse aims to render the truths and sentiments expressed by its language, amiable and interesting. And this it effects by the medium of an accurately measured and agreeable succession of accented and unaccented sounds, which address the ear; and by the means of such images and sentiments as delight and affect the soul: and the memory is powerfully assisted as well by the one as by the other.

III. To explain the nature of Italian verse, it is necessary to remark, that they divide all the words contained in their language into three classes, termed words *tronchi*, *piani*, and *sdruccioli*. Words having the accent on the last syllable are called *tronchi*; as *bontà*, *virtù*, *fa*, *senti*. Those having the accent on the penultimate are termed *piani*; as *uómo*, *animále*, *impéro*, &c. And those that are accented on the antepenultimate are named *sdruccioli*; as *dócile*, *ábito*, *án-cora*, &c. The first are denominated *tronchi*, (*tronqués coupés*, *cut short*;) because they were originally entire, as *bontàde*, *virtutede*, *face*, *sentis*. The second class, *piani*, receives this distinction from the circumstance of the words composing it being pronounced (*pianamente*) more gently than those of the other two classes; and the last, the *sdruccioli* (*coulans* or *glissons*), because the words of this kind seem to flow or slide swiftly from the antepenultimate syllable to the end.

IV. Hence also it follows, that a verse also receives its denomination, according as it is terminated by a word of one or the other of these kinds: consequently, verses termed *tronchi* are terminated by an acute accent; those called

VERSIFICATION.

piani have a syllable after this accent; and the *sdrucciuti* have two; to which some add the *più che sdrucciuti*, which have four syllables after the accent.

The last accent decides the nature and the completion of every verse. The ear measures the extent of a verse from its commencement to the last accent. The ear is naturally sensible at the occurrence of this last accent, that the harmony of the verse is accomplished: it is satisfied, and demands nothing more. It is equal, whether the last accented syllable be itself the last syllable, or followed by one, two, or four syllables; for the measure of the verse is comprised between its commencement and this last accented syllable. The syllables remaining after this accent are redundant, with respect to the measure and harmony of the verse. (See Aristotle, Poet. cap. 8.) This consideration will render it evident, that if a verse be piano, (which species the Italians select for their regular measure,) it will have the precise number of syllables which the nature of the verse assigns to it; if it be tronco, it will have one less; if *sdrucciuto*, one more. Therefore, the verse piano is acatalectic; the verse tronco, catalectic; the verse *sdrucciuto*, hypercatalectic.

V. The French in a similar manner divide their words chiefly into two classes, the masculine and the feminine. The masculine (corresponding to those which the Italians term *tronchi*) have the accent on the last syllable; as *vertù, nouveau, il parlá*, and are generally of the masculine gender. The feminine (analogous to the Italian *piani*) have the accent on the penultimate; as *honnète, ils parlèrent, il parle, France*, &c.: and these are so called, because that nouns of this description are generally terminated by the *e* mute, a characteristic of the feminine gender. The words called *sdrucciuti* by the Italians (glissant by the French) can only be found in such phrases as *garde-le, dites-le, montrelc*, &c.

The same epithets are also applied to their verse, according to the characteristic of the word which terminates it.

These preliminary observations, well understood, will reconcile the anomalies which, until the present, have produced an apparent difference between the nature of the Italian and that of the French versification. For since the Italians select the verse piano for their common measure, and the French the masculine (or tronco), which, between the commencement of the verse and the accented syllable, will contain one syllable less than the former; it follows that the Italian verse will always exceed the French verse of the same kind by one syllable. For example, the Italian hendecasyllable piano has eleven syllables, and the French hendecasyllable masculine (tronco) ten; and the French hendecasyllable piano will have the same, for they do not reckon, as the Italians, the redundant syllable.

The only simple feet admitted in the composition of French and Italian verse are the trochee, the iamb, the dactyl, and the anapaest. It is unnecessary to repeat here the definition we have already given of a metre and a rhythm, in a former part of this article. We shall, therefore, now proceed to state all the possible combinations that can result from these four feet in the composition of a hemistich, which is, by a late French writer, considered as a simple or primitive verse.

An iambic hemistich may consist of three, four, or five feet; so may the trochaic, the anapaestic, or the dactylic hemistich: therefore, from hence we have twelve varieties, or all the possible combinations of the hemistich. For each of the four feet cannot produce more than three varieties, the smallest of which cannot consist of less than three, nor the greatest of more than five feet. Hence, then, we have

at once the *minimum* and *maximum* of their extent. At the former, we assert that an hemistich cannot consist of less than three feet. We have already remarked, that the extent or measure of a verse ought to be such as to admit of its being easily and sensibly remarked by the ear, otherwise it is not verse, but prose. And every verse or hemistich contains more or less of the rhythmical order; and, as we have already observed, a rhythm is a series of similar feet continued until the ear perceives the order of the series, and is able to anticipate the peculiar nature and recurrence of the verse. But one foot cannot be a series, therefore a foot cannot be a hemistich. We have already affirmed, too, that the succession of two similar feet constitute a metre; and a metre is the commencement of a series. But the commencement of a series is not the series itself: the series supposes a continuation; therefore, the succession of two feet, or a metre, cannot be a hemistich or primitive verse. For the union of two feet form a metre; but a metre is not a rhythm; therefore, two feet are not a hemistich. But if to two similar feet succeed another of the same nature, then the series is decided. An hemistich, then, cannot have less than three feet. What is smaller than this is only the element of an hemistich. Let us further inquire, in what consists the harmony of a verse? Doubtless in the regular order of the accents in its rhythm or series. But one foot has only one accent; therefore, it has no harmony, and cannot be an hemistich or radical verse. So we reply concerning two feet; they are not an order or series, but only the commencement of a series. We may, with M. J. J. Sulzer, illustrate these remarks by repeating the following series, *un deus, un deus, un deus, un deus, un deus, &c.* Here we can easily perceive the rhythmical order. But no one can suppose that the first foot, *un deus*, is an order or series; nor in the first two feet, *un deus, un deus*, do we perceive more than the commencement of a series. But if we include the third, *un deus, un deus, un deus*, we see at once the order, the series, the rhythm, and, lastly, the metrical hemistich precisely decided. Three feet, then, is the smallest number which can constitute the hemistich or primitive verse.

In the same manner we may determine the maximum of the hemistich. We have said that it cannot exceed five feet; for the number must be such as may be distinctly remarked by the ear. Suppose, for example, an hemistich of six feet; since it may be divided into two equal parts of three feet each, and since three feet form an hemistich, it is evident that the line of six feet is not one but two hemistichs, *i. e.* a verse. But the hemistich of five feet is incapable of being thus divided. If it be, let the one part consist of three feet, which, as we have just proved, is an hemistich; the other of two feet, which is only a metre; and a metre, as we have just observed, is not an hemistich; consequently, the line of five feet is an hemistich or primitive verse. And because a verse of six feet is composed of two hemistichs, the line of five feet is the maximum or greatest hemistich or primitive verse; and lines consisting of more than this, after the redundant syllables are cut off, contain two or more hemistichs of a verse.

VI. Some writers on versification are in the habit, however, of treating on verse, which they term disyllabic, trisyllabic, quadrisyllabic, the quinarius, and the senarius. But these are not verses, but only the elements of a regular and complete verse. We shall, however, in conformity to their custom, and to omit nothing essential, especially in what must be admitted to form the basis of this art, proceed to treat on the elements here enumerated.

1. The disyllabic member cannot have more than one accent.

VERSIFICATION.

cent. If it is *tronco*, it has but one syllable (see obs. 3. and 4. supra); if *piano*, two; if *sdruciolò*, three; as,

Tronco	-	-	-	Là.
Piano	-	-	-	Láffo!
Sdruciolò	-	-	-	Pénfaci.

2. The trisyllabic member, if it has but one word, has only one accent; if it consist of two words, it has two accents. If it is *tronco*, it has only two syllables; if *piano*, three; if *sdruciolò*, four; as,

Tronco	-	-	-	Potrà Chi fù ?
Piano	-	-	-	Potránne Si disse.
Sdruciolò	-	-	-	Rísvéglíati ³ No, dissero ⁴ .

3. The quadrisyllabic member *tronco* has only three syllables; *piano*, four; *sdruciolò*, five; as,

Tronco	-	-	-	Io men vò ³ .
Piano	-	-	-	Belle róse ⁴ Porporine ⁴ .
Sdruciolò	-	-	-	I di volàno ⁵ .

We may here remark, that the Italians call that the accent (*commun*), which is placed at the end of each verse, and which accomplishes the measure of the same. They assign this epithet to it, in consequence of its being essential and *commun* to all verse. And this accent is placed on the last syllable, if the verse is *tronco*; on the penultimate, if *piano*; on the antepenultimate, if *sdruciolò*. Now, in the above quadrisyllabics, we may observe that this accent uniformly falls on the third syllable.

3. The *quinarius*, besides the common accent, has also an accent on the second syllable, sometimes on the first, and not infrequently it has only the common accent. It contains four, five, or six syllables, according to the laws already prescribed; as,

Tronco	-	-	-	Porgilo a mè ⁴ .
Piano	-	-	-	Terli deh fórgi ⁵ .
Sdruciolò	-	-	-	Ah non ti pérdere ⁶ .

The disyllabic member, when it is *tronco*, does not contain even the image of a foot; but if it is *piano*, it is a trochee, as *lássò*; and if it is *sdruciolò*, it is a *daçtyl*, as *pénfaci*. The trisyllabic, of whatever kind it be, can have only an iamb, as *potrà*, *potránne*, *ríscéglíati*. Example:

Sè cèrca,	S' io vò'
Se dice :	" Colla forte
L'amico	Cangiando
Dov' e	Sembianza ;
L'amico	Virtu
" Infelice	" L'incostanza
Rispondi	Diventa
Mori	Per me, &c.—Metaft.

The quadrisyllabic is a monometer, consisting of two trochees, which form a metre; and two of these united form the regular octonarius.

1. Dámfgèllà	Tutta bella,
Verfa verfa — quel bel vïno	
Fa che cada	
La ruggiada	
Distillata — di rubígio.	

2. O' nel feno	Río vençno
Che vísparfe	Amor profundo,
Ma gíttarlo	E lafcíarlo
Vò' fommerfo in-	questo fondo.

The *quinarius* is an iambic monometer, and consequently not a rhythmi. Example:

Oh quánto e facile	Si fcuote il laccio,
Nella catena	Ma non fi spezza,
D'amor languir !	E amor fi vendica
Quanto e difficile	Con piu fíerezza
Poterne ufir !	Del folle ardir.—Zeno.

VII. Every species of French verse is the same as the Italian. In each we discover the same number of syllables, the same accents, the same caesura, the same feet, the same harmony. To evince this, we shall now state, in the same order as we have done for the Italian verse, the following elements or members of a verse.

1. The disyllabic	Tronco	-	-	Èft.
	Piano	-	-	Ètre.
				Dönnè.
	Sdruciolò	-	-	Dönnè-lè.
2. The trisyllabic	Tronco	-	-	Sèrà ² .
	Piano	-	-	Facile ³ .
	Sdruciolò	-	-	Règàrdè-lè ⁴ .
3. Quadrisyllabic	Tronco	-	-	Còmbattèz ⁵ .
	Piano	-	-	Cònsidèrè ⁶ .
	Sdruciolò	-	-	Cònsidèrè-lè ⁶ .

VIII. The *Senarius*.

The *senarius* is an anapestic monometer catalectic, having only an iamb for the first foot. Besides the accent *commun*, (which is on the fifth syllable,) it generally requires an accent on the second syllable; though sometimes the accented syllables are the first, third, and fifth. It contains five, six, or seven syllables, according as the verse is *tronco*, *piano*, or *sdruciolò*; as,

Tronco	-	-	-	Ufáte pietà ³ .
Piano	-	-	-	Begli àltri d'amòre ⁶ .
Sdruciolò	-	-	-	Dà qui tu quel càlice ⁷ .

The French, according to the rule which we have already explained, call this verse of five syllables. The difference is merely nominal: the verses are virtually the same.

Tronco	-	-	-	Toujòurs eè zèphir.
Piano	-	-	-	L'amòur à dès chîrmes.
Sdruciolò	-	-	-	(no example exists).

IX. The *Septenarius*.

If to each of the monometers, of which we have just treated, we add one, two, or three other feet, these monometers become, according to the principles we have prescribed, regular and legitimate verse.

The *septenarius* is composed of iambic feet, and contains six, seven, or eight syllables, according as the verse is *tronco*, *piano*, or *sdruciolò*; as,

Tronco	-	-	-	Che vino è quel colà ?
Piano	-	-	-	In un gravòlo affanno ⁷ .
Sdruciolò	-	-	-	O liqur dólce e amabile ⁸ .

This verse, besides the *commun* accent, which constantly falls

VERSIFICATION.

leſtic, acataleſtic, or hypercataleſtic, according as it is tronco, piano, or ſdruciolò; as,

Tronco - Contra morte non val freſca età.
 Piano - Vaſto incendio ſe bolle riſtretto.
 Sdruciolò I bon vini fon quelli che acquietano.¹⁰

There is another variety of the decasyllabic verſe, of which Chiabrera has given us an example. It has the accent on the firſt, the third, the fifth, the ſeventh, and on the ninth ſyllables.

The rhythm of this verſe is eſſentially different from either of the preceding; it conſiſts of five trochaic feet.

XIV. The Hendecasyllabic Verſe.

The hendecasyllabic verſe is alſo called *heroic*; for it is that rhythm * which, from its harmony, its grave and maſtetic movement, and the variety of which it is ſuſceptible, offers to the poet peculiar advantages for the expreſſion of ſublime and elevated ſubjects. It is, in common with every other, capable of three kinds; as,

Tronco - Monte-pulciano d'ogni vino è ib re¹⁰.
 Piano - T'Alzò natura in verſo al ciel la fronte¹¹.
 Sdruciolò Celebri l'acqua, e fe la bea pur Pindaro¹².
Redi.

Tronco - Le printems fuit, hàtons-nous d'être heureux.
 Piano - Qui n'en ferait en effet idolâtre.—Petr.

This verſe is generally accented on the ſecond, the fourth, the ſixth, the eighth, and on the tenth ſyllable, which laſt is the accent common, or invariable.

And the verſe thus accentuated is the moſt harmonious: but as an unvaried recurrence of the ſame luxuriant rhythm would become eventually monotonous, it admits of the following varieties.

1. It is ſufficient, if, beſides the common accent, the ſixth ſyllable ſhould be accented.

2. The ſecond variety has, independently of the common accent, the fourth and eighth ſyllables only accented.

3. The third variety, beſides the common accent, has only the fourth and the ſeventh ſyllables accented.

With regard to the *apparent* difference in the number of ſyllables between the Italian and French hendecasyllabic, the reader is referred to what has been already obſerved at § V.

Concerning the Intermixture of different Verſe.—Whatever harmony may ariſe from the ſucceſſion of verſes of the ſame kind, they often acquire a new excellency when the ſeries is compoſed of an *appropriate* admixture of verſe of a different rhyme.

It may now be reaſonably inquired, why is the intermixture of different verſe productive, at one time, of an agreeable effect, and at another of the contrary? In anſwer to this inquiry it is here only neceſſary to remark, that we have already ſaid that the hendecasyllabic verſe and the ſeptenarius, together with the two members of which the hendecasyllabic is compoſed, the ſeptenarius and the quinaris, are of the iambic rhythm. Hence we clearly perceive, that the tranſition from the hendecasyllabic to the ſeptenarius, and

vice verſà, from the latter to the former, preſerves the ſame rhythmical order and movement. And the ſame principle will ſanction the intermixture of an octonarius and a quadriſyllabic verſe, ſince the rhythm of each is trochaic. It often happens however, that notwithstanding the exact identity of the rhythm in the alternation of different verſes, the effect is not agreeable. But this only happens when we connect verſes, for example, of four feet, with others of five or three feet. And here it is evident, that although a verſe of five feet and another of four are of the ſame rhythm, yet they preſent an eſſential difference. The verſe of five feet is indiviſible, but that of four feet, which is an even number, may be divided into two equal parts, which are in rhythmical quantity perfectly equivalent and reciprocal to each other. The impreſſion, therefore, reſulting from this verſe, is different from that of the verſe which can only preſent to the ear the rhythm of two unequal parts. And here we may add, once for all, that all which we have ſaid concerning the combination of verſe of the ſame or of different kinds in the Italian language, is perfectly applicable to that of the French alſo.

I. Of the Sonnet.

The regular ſonnet contains fourteen hendecasyllabic verſes, divided by the rhythm into four ſtanças, or ſtrophes, of which two are tetraſtrophs, and two triſtrophs.

The ſonnet, which the Italians call *colla coda*, '*caudato*,' receives this appellation from the circumſtance of its having, after the fourteenth verſe, a train of one or more ſtanças of three verſes each, or triſtrophs. The fifteenth verſe muſt in this caſe be a ſeptenarius, and rhyme with the fourteenth.

Sonnets may be alſo compoſed of the verſe octonarius, ſeptenarius, or quinaris.

The two rhymes of the tetraſtroph ſtança are ſuſceptible of four different combinations, according to the following table. Any of which, but legitimately no other, the poet may adopt freely at his choice.

1ſt. Tetraſtrophon: rhyme cloſed (*ſerſe*).

1	-	-	ano	5	-	-	ano	}	moſt in uſe.
2	-	-	ore	6	-	-	ore		
3	-	-	ore	7	-	-	ore		
4	-	-	ano	8	-	-	ano		

2d. Tetraſtrophon: rhyme alternate.

1	-	-	aſto	5	-	-	aſto
2	-	-	era	6	-	-	era
3	-	-	aſto	7	-	-	aſto
4	-	-	era	8	-	-	era

3d. Tetraſtrophon: rhyme reciprocally alternate.

1	-	-	idi	5	-	-	ezzo
2	-	-	ezzo	6	-	-	idi
3	-	-	idi	7	-	-	ezzo
4	-	-	ezzo	8	-	-	idi

4th. Tetraſtrophon: rhyme alternate and cloſed.

1	-	-	ente	5	-	-	eme
2	-	-	eme	6	-	-	ente
3	-	-	ente	7	-	-	eme
4	-	-	eme	8	-	-	ente

The rhyme of the triſtroph may have, at the option of the poet, the following varieties.

1ſt. Triſtrophon: rhyme connected (*enchainée*).

1	-	-	ice	4	-	-	ante	}	moſt in uſe.
2	-	-	ante	5	-	-	ice		
3	-	-	ice	6	-	-	ante		

2d. Trif-

* *Rhythm* and *rhyme* are two diſtinct things: the former is defined in the preceding pages of this article, it is derived from *ῥυθμός*; the latter is only the correſpondence of the laſt ſound of one verſe, to the laſt ſound of the next. And on account of this material diſtinction, not generally underſtood, even by *English* lexicographers, the recent writers on this ſubject thus orthographically diſtinguiſh the former,—*rhythm*.

VERSIFICATION.

2d. Triftrophon : rhyme tertian (*alternata*).

1 - - etto	4 - - etto
2 - - ente	5 - - ente
3 - - ogno	6 - - ogno

Or,

1 - - etto	4 - - ente
2 - - ente	5 - - etto
3 - - ogno	6 - - ogno

3d. Triftrophon : rhyme duplex.

1 - - ate	4 - - oria	}	feldom ufed.
2 - - oria	5 - - ate		
3 - - oria	6 - - ate		

There is no essential difference between the Italian and French sonnet. In addition, however, to the above, they also employ the following rhymes.

4th. Triftrophon : rhyme tertian (à la manière Française).

1 - - ufe	4 - - eme
2 - - ufe	5 - - eme
3 - - net	6 - - net

Or,

1 - - eux	4 - - crit
2 - - eux	5 - - erre
3 - - erre	6 - - crit

We may, in the reading of poets, discover other methods ; but every series differing from the above, is pronounced, by the connoisseurs, to be not “ *ad unguem*.”

II. Of the Ode.—*Canzone, or Chanfon.*

The ode is a composition formed of an indefinite number of stanzas, which, with respect to the rhyme and the measure of the verse, are uniformly the same to the conclusion of the poem. We may except, however, those concluding stanzas which have been called *congé* (*congedo, or commiato*), as if the poet, by this concluding strophe, shorter than the rest, took his *leave* of the poem, or person to whom it is addressed. Our limits will not admit of examples.

III. Of the Canzonetta.

The canzonetta (*chanfonette, or the Anacreontic ode*) is an imitation of the characteristic, the simplicity, and the artless style of the odes of Anacreon. Of this species of composition, the celebrated Tasso was the inventor ; but the praise is due to Chiabrera for that acmé of perfection to which he has advanced it.

The canzonetta differs from the ode in the following particulars.

1. Generally, though not always, the stanzas of which they are composed are less, and contain a smaller number of verses.

2. The stanzas consist of small verses of different kinds.

3. They are not adapted to that elevated and sublime style which the ode requires. The characteristic of their style should be simple, artless, and familiar ; and they are, therefore, very well suited to what is of an agreeable and humorous nature, to fables, and to allegories, of which the fable or moral is usually given at the close.

The number of stanzas of which the canzonetta consists is indefinite, at the discretion of the poet. The strophes are usually composed of four or six verses, in their measure either mixed or uniform, but always agreeing together by the *closed* or *alternate* rhyme. (*Rime serrée ou alternée.*) See the table of rhyme under the *Sonnet*. Sometimes the stanzas contain ten verses, and then, as well as when they have

six verses, the two first and the two last should rhyme together.

When the strophe contains verses *tronchi, piani, and fdrucchioli*, we may perceive a disagreement in the rhyme. But of whatever nature the first stanza may be, the subsequent stanzas should strictly conform thereto. In lyric poems, on the contrary, we are at liberty to vary the stanza, *pro re natâ*, as circumstances and the taste and discretion of the poet may require.

IV. The Sapphic Ode.

This ode, of which the Grecian poets Sappho was the inventress, is, when regular, composed of several tetrastrifrophons, of which the three first verses are hendecasyllabic, the last a quinaris. Frequently, however, the septenarius is substituted for the quinaris ; in which case the strophe has less elegance, and less conformity to the Grecian original, of which they should be an exact imitation. The rhyme most employed is the *alternate* or the *closed* (*alternée* or *serrée*).

Among the several forms of the French ode, the following is much admired. The reader must be content with a single stanza for illustration ; our limits forbid more.

Puiffantes Détés, qui peupler cette rive,
Préparer, leur dirais-je, une oreille attentive
Au bruit de mes concerts.
Puiffent-ils amollir vos superbes courages
En faveur d'un Héros digne des premiers âges
Du naiffent Univers !—Rouffseau.

We are compelled, for want of appropriate epithets, to borrow the following terms with which the Italians and the French denominate certain strophes of their composition.

Terza Rima.—This species of composition contains several triftrophons, each consisting of three hendecasyllabic verses. The rhyme is connected together in such a manner, that the first verse of each stanza agrees with the third, and the second rhymes with the first and the third of the stanza following. And this order is preserved to the end.

There is no example of this species of composition in the French language, for, by a transposition of the verses, they convert the triftrophon into the tetrastrifrophon, and then call the *terza rima* the

Quarta Rima.—By the *quarta rima*, that species of poem is denominated which contains several tetrastrifrophons, of which each verse is an hendecasyllabic in Italian, and an Alexandrine in French ; the rhyme is either *serrée* or *alternée*. See table of rhyme under *Sonnet, supra*.

Sesta Rima et Ottava Rima.—Compositions of this kind receive their name from the number of verses of which their stanzas are composed ; the former of six, the latter of eight. The two last verses agree together in rhyme (*plate*) i. e. *unmixed* ; the rest in rhyme (*alternée*) *alternate* ; see table, *supra*.

The French do not adhere to any regular standard in the composition of the *sista rima*, which they call *les fixains, ou les stances de six vers*.

But with regard to the “ *Ottava rima*” of the Italians, and the “ *Stances de huit vers*” of the French, there is, both as it respects the rhyme and the nature of the verse, which in either case is hendecasyllabic, a perfect similarity. This species of composition has prevailed much since the time of Thibaut, who lived a hundred years before Boccace.

V. The Madrigal and the Epigram.

The madrigal is a small poem consisting generally of not less than six nor more than twelve verses, which are either octonarii, or more commonly septenarii or hendecasyllabic.

VERSIFICATION.

The number of verses, however, of which the madrigal consisted, was amongst the poets of the sixteenth century arbitrary. The rhyme is yet *ad libitum*; sometimes only the two last verses rhyme together.

The character of the madrigal is not essentially different from the epigram of the Latins. It is contradistinguished, however, by its style, which, though simple, is so elevated as to become equally unadapted to the satire, or to humorous and trivial subjects.

The epigram is a small poem consisting of an indefinite number and kind of verses, and terminating in a point of wit. Generally, however, it contains not less than two nor more than eight verses, which are frequently hendecasyllabic, and rhyme together by couplets.

VI. *The Dithyramb.*

The dithyramb is a species of poem composed in honour of Bacchus: or, in fact, it is any poem written with a degree of unusual wildness and enthusiasm. It employs verse of every kind, piano, tronco, sdrucciolo, great and small, with or without rhyme, andanzas of any magnitude. And the whole is written with that liberty and freedom from restraint, as indicates it to be the indigenous production of the devotee of Bacchus. Its style at one time is elevated, at another low. The metaphors it employs are bold; its phraseology excentric and whimsical, and words are admitted either purely exotic, or oddly compounded of others; as *erisefotof*, *egidarmato*, *capribarbicornipede*, &c. The reader will find many examples of the Italian dithyrambic in the works of Crecimbeni, Quadrio, and Andrucci, and in the “*Bacco in Toscana*” of Francesco Redi.

VII. *The Idyl.*

This species of poem consists of an indefinite number of septenarii or hendecasyllabic verses, and free from all restraint as it respects the rhyme. The word *idyl* (*idillio*) is derived from *ιδύλλιον*, the diminutive of *ιδύω*, a figure or representation; and the *idyl*, in fact, is nothing but the painting or image of some natural object.

There is no difference between the Italian and the French *idyl*.

The Cæsura.

We have now to notice what is peculiar to the cæsura in the French and Italian versification. Amongst the moderns, it is said to be that pause between one word and another, which divides the verse into two equal or unequal parts. A verse is said to be so much the more harmonious, in proportion as it abounds in cæsurae which give redoubled energy to the accented syllables. The use and design of this pause, Boileau very appositely mentions in the following lines.

Que toujours dans vos vers,—les sens coupant les mots,
Suspende l'hémistiche,—en marque le repos.

In the hendecasyllabic verse, the cæsura should occur between the fifth and sixth syllable, and between the ninth and the tenth, or between the seventh and the eighth only; as in the following verses of Ariosto.

Il collo è tondo, il petto colmo e largo.
Da render molle ogni cor rozzo, e scabro
Quindi escon le cartesi-paulette.

By adverting to the principles of accentuation already explained, we shall discover that when the hendecasyllabic is accented on the fourth and eighth syllables, it ought to have

the cæsural pause between the fifth and the sixth, and between the ninth and the tenth syllables. And when the principal accent is on the sixth only, it ought to have the cæsura between the seventh and the eighth syllables; *i. e.* when the verse is *piano*. But if the words on which the principal accents fall (*i. e.* *accent commun*) are *troubés*, the cæsura must follow immediately after each accented syllable.

We may, from these observations, easily infer what are the most suitable places for the cæsura in every other verse; as the cæsura ought to take place immediately after the principal or characteristic accent (*accent commun*) of the entire verse, the hemistich, or of any constituent member.

To the above remarks, which are perfectly applicable to the versification of the French language, we may add the following. If at the place of the cæsura, the preceding word be feminine, (*i. e.* end with *e* mute,) the following word ought to commence with an initial vowel, in order that the elision or synalapha may take place. For example, in the hendecasyllabic verse, which consists of a quinarius and a septenarius, when the former ends with an *e* mute, the latter must commence with a vowel; otherwise the verse will have a syllable too much, since a quinarius and a septenarius conjointly make twelve syllables.

English Versification.

All the different feet used in English versification are reducible to eight kinds, four of two and four of three syllables; as,

Disyllabic Feet.

1. An iambus, - - ; as, bêtrây, consist.
2. A trochee, - - ; as, c'xtört, g'illdeks.
3. A spondee, - - ; as, the pâle mōon.
4. A pyrric, - - ; as, ðn the tall tree.

Trisyllabic Feet.

5. An anapaest, - - - ; as, cōntrivēue, acquiesce.
6. A dactyl, - - - ; as, labōurer, possible.
7. An amphibrac, - - - ; as, delightful, domestic.
8. A tribrach, - - - ; as, numérâblé, cōnquerable.

Those feet of which verse may be wholly or chiefly formed are termed *principal feet*. Such are the trochee, iambus, dactyl, and anapaest. The others are denominated *secondary feet*, because their use in English versification, is merely to diversify the rhythm and to improve the verse.

I. *Iambic Verse.*

1. *Iambic Monometer Catalectic.*—This verse, which is the shortest form of the English iambus, consists of an iambus and an additional short syllable. It is only found in stanzas: we have no poem, (or monocolon,) formed exclusively of this measure.

Åfsälling,
Åvälling,
Relënting,
Rëpënting.

2. *Iambic Monometer Acatalectic.*—This verse, which is also too short to be continued through any great number of lines, contains an iambic metre, or two iambic feet; as,

With räptür'd ears
Thë mōnârch hears.—Dryden.

3. *Iambic Monometer Hypercatalectic.*—This verse is the same as the former, with an additional short syllable, as,

Ûpōn a mōuntâin
Beside a fōuntain.

VERSIFICATION.

4. *An Iambic Dimeter Brachycatalectic.*—This form consists of three iambic feet; being one foot less than the iambic dimeter; as,

Though in the utmost peak
A while we do remain,
Amongst the mountains bleak,
Expos'd to fleet and rain,
Nor sport our hours shall break,
To exercise our vein.—Drayton.

5. *An Iambic Dimeter Catalectic.*—This verse is only one syllable less than the iambic dimeter; as,

Our hearts nõ länger languish.

6. *An Iambic Dimeter Acatalectic.*—This form contains exactly, without redundancy or defect, two iambic metres, or four feet; as,

The spacious firmament on high
With all the blue ethereal sky
And spangled heav'ns, a shining frame,
Their great original proclaim.—Addison.

7. *An Iambic Trimeter Brachycatalectic.*—This species of verse contains one foot, (or two syllables,) less than the iambic trimeter; as,

Dèfèr nõt till tõ möröw tõ bë wifè;
To-morrow's fun to thee may never rise.

The cobwebb'd cottage with its ragged wall
Of mould'ring mud is royalty to me!
The spider's most attenuated thread
Is cord, is cable to man's tender tie
On earthly bliss; it breaks at every breeze.—Young.

This is also termed the heroic measure. In its pure or unmixed state it consists of five iambic feet only. But here we may remark, once for all, that not only this, but most of the English common measures admit, for the sake of variety, of the occasional introduction of other feet, as the trochee, dactyl, anapaest, &c.

8. *An Iambic Trimeter Acatalectic.*—This verse is commonly called the Alexandrine. It consists of six iambic feet; as,

Èspècial aùdiènce crävès, öffèndèd with thè thröng,
Drayton.

The Alexandrine verse is now used only to diversify heroic lines; as,

Thè sèas shall wäste, thè skies in smöke dècäy.
Rocks fall to dust, and mountains melt away;
But fix'd his word, his saving pow'r remains;
Thy realm för övèr lasts, thy öwn Mèfjünåh rèigns.

9. *An Iambic Tetrameter Brachycatalectic.*—This last iambic form consists of one foot less than four iambic metres, *i. e.* of seven iamboles; as,

And äs thè mind öf süch ä män, thät häth ä löng wäy göne,
And èithèr knöwèth nõt his wäy, ör ölfè wöuld lèt älonè.
Chapman.

But it is more usual now to break this verse into a lyric measure, or into two verses, consisting alternately of eight and six syllables; as,

Whèn in thè slipp'ry päths öf yöuth,
With hëödlèss stèps, I rän,
Thine arm unseèn, convey'd me safe,
And led me up to man.—Addison.

II. Trochaic Verse.

1. *A Trochaic Monometer Catalectic.*—This, which is the shortest trochaic verse in the English language, consists of one trochee and a long syllable; as,

Öthèr jöys
Äre büt töys.—Walton.

2. *A Trochaic Monometer Acatalectic.*—This verse consists of one trochaic metre, or two trochaic feet; but both this and the last verse are too brief to form a monocolon; as,

Ìn thè gräfjy
Mèädwö verdänt.

3. *A Trochaic Monometer Hypercatalectic.*—This form of trochaic verse contains one syllable more than the exact trochaic monometer; as,

Häppý färmíng äge,
Heälthý, blithe änd säge.

4. *A Trochaic Dimeter Brachycatalectic.*—This species of trochaic verse contains two syllables, or one foot less than two trochaic metres; *i. e.* three trochees; as,

Blööm yè súmmèr röfès.

5. *A Trochaic Dimeter Catalectic* consists of one syllable less than two trochaic metres; or of three trochees with an additional long syllable; as,

Fäirèst pièce öf wèll-förm'd èärth
Urge not thus your haughty birth.—Waller.

6. *A Trochaic Dimeter Acatalectic* contains two trochaic metres or four trochaic feet; as,

Röund üs shine thè sün-beäms bríghtèr.

7. *A Trochaic Dimeter Hypercatalectic* contains a long syllable more than the last verse; as,

Sèè yön clöüds thät nõw dispèrse änd clèär.

8. *A Trochaic Trimeter Brachycatalectic* is, as well as the last, seldom employed; it contains five trochaic feet, and, of course, one foot less than three trochaic metres; as,

Äll thät wälk ön fööt, ör ríde in chäriöts,
Äll thät dwell in paläces or garrets.

9. *A Trochaic Trimeter Acatalectic* contains six trochees, or three trochaic metres; as,

Ön ä müuntain strèth'nd bënèth ä höärý willöw
Lay ä shepherd swain, and view'd the rolling billöw.

III. Anapaestic Verse.

The reader will recollect that we have already said, that in dactylic and anapaestic measure one foot forms a metre, but in every other case, two feet form a metre.

1. *The Anapaestic Monometer Acatalectic* contains, without redundancy or defect, one anapaestic foot; as,

Nöw ägäin
They remain.

But as by laying the stress of the voice on the first syllable, we reduce the verse into trochaic rhythm, this measure is ambiguous; hence the simplest form of our regular anapaestic verse is the

2. *Anapaestic Dimeter Acatalectic*, or verse of two anapaestic feet; as,

För nõ ärt cöüld äväil.

3. *The Anapaestic Dimeter Hypercatalectic* contains two anapaestic feet, with an additional short syllable; as,

 In thē cāve | ōf thē moūn-|tain.

4. *The Anapaestic Trimeter Acatalectic* contains three anapaestic feet; as,

 Ō yē wōōds, sprēad yōur brānchēs āpāce;
 To yōur deēpest recesses I fy;
 I wōuld hide with the beats of the chafe
 I wōuld vanish from every eye.

5. *The Anapaestic Tetrameter Acatalectic* consists of four anapaestic feet; as,

 Māy Ī gōvēm mý pāsšōns with ābsōlūte swāy;
 And grow wiser and better as life wears away.—Pope.

6. *The Anapaestic Tetrameter Hypercatalectic* adds to the end of the last verse a short syllable; as,

 Ōn thē tōp | ōf thāt hīll | fēē thē sūn | nōw āfcēnd-|ing.

Of the Cæsura.

The same advantages result from a suitable and appropriate use of the cæsura in English verse, as in that of the French and Italian, which we have just noticed. What is peculiar to this pause amongst us may be briefly comprised under the following particulars.

1. In heroic verse the cæsura may take place on the fourth syllable; as,

 Child of the sun^o, refulgent summer comes.

2. Or on the fifth syllable; as,

 He comes attended^o by the sultry hours.

3. Or on the sixth syllable; as,

 But should he hide his face^o, th' astonish'd fun.

4. Or, two cæsuras may divide a verse into three portions; as,

 Some love to stray^o; there lodg'd^o, amus'd and fed.

5. Some lines admirably admit that subdivision of the cæsural pause, which may be called a *demi cæsura*; as,

 Glows^o while he reads^o, but trembles^o as he writes.

 Rides^o in the whirlwind^o and directs^o the storm.

 Warms^o in the sun^o refreshes^o in the breeze,

 Glows^o in the stars^o and blossoms^o in the trees;

 Lives^o through all life^o extends^o through all extent,

 Spreads^o undivided^o, operates^o unspent.

As we have now treated minutely on every point essential to Hebrew, Greek, Latin, French and Italian versification, our readers will permit us, in accommodation to the limits of our work, to refer them, for further information on English versification, to what has been said at the article ODE, EPIGRAM, SONNET, &c. in other parts of this work.

VERSIO CHEMICA, a term used by chemical writers to express a change, wrought by their art, of manifest forms into occult ones, which, they say, is done by a corruption of the specific form, and the generation of a more general one; that is, by a conversion of decomposed elements into compound bodies, and of impure into such as are perfectly pure.

VERSION, a translation of some book, or writing, out of one language into another.

The chief objects which ought to be regarded by every translator, and more especially by a translator of sacred scripture, are the following: *viz.* to give a just and clear representation of the sense of his original; to convey into his genius as much of his author's spirit and manner as the genius of the language, in which he writes, will admit; and, as far as may be consistent with these two ends, to express himself with purity in the language of the version.

The ancient versions of the New Testament, in particular, have been justly considered as affording an important evidence of its antiquity, and presumptively of its authenticity. Some of these are supposed to have been made so early as the first century; such as the Syriac, and several Latin versions, the latter of which, abounding in Hebraisms and Syriacisms even in a greater degree than the original, were manifestly made by native Jews, and must have been productions of the first century. A book, therefore, so early and universally read throughout the East in the Syriac, and throughout Europe and Africa in the Latin translation, must be able to lay claim to a high antiquity. To the strange and trivial hypothesis, that the New Testament was forged in the fifth century, after the conquest of Italy by the Goths, the Gothic version of Ulphilas, which was made in the preceding century, will serve for a sufficient answer. For an account of the *Anglo-Saxon, Arabic, Armenian, Coptic or Egyptian, Ethiopic, and Gothic* versions, see BIBLE. See also ARMENIAN and COPTIC.

VERSION of Aquila. See AQUILA and HEXAPLA.

VERSIONS, Greek. See SEPTUAGINT, and GREEK BIBLES.

VERSION, Italian, called by St. Jerom the *common and vulgar*, and by Gregory the Great the *ancient*, was made in Italy, and for the service of the Latin Christians. As it was used in the church till the sixth century, there are several fragments of it extant in the quotations of those Latin fathers, who wrote before that time. As this version continued, partly from the influence of custom, partly from respect to antiquity, to be regarded and used by many, there is reason to believe that a part of that version still remains in the Vulgate, and is in a manner blended with it. (See VULGATE.) From what remains of the old Italian, it appears to have resembled almost all the Jewish translations, and to have been very literal, and consequently, in a great degree, obscure, ambiguous, and barbarous. Dr. Mills supposes, that this version was the work of several persons in the second century, by order of pope Pius I., who was an Italian. This learned writer, in his "Prolegomena," has given an account of the qualities of this version; and how far it may be of use for discovering the true reading of the original Greek. St. Jerom, in his translation, has deviated from this version without sufficient reason.

VERSION, Latin, includes not only the *Italian*, (see the preceding article,) but other versions made before and since the time of Jerom, as well as that which he corrected and published. (See VULGATE.) It appears from the testimony of Augustin (*De Doctrinā Christianā*, lib. ii. c. 11.), that the Latin church had a great number of translations of the bible, that they were made at the first introduction of Christianity, but that the authors are totally unknown. Some of these Latin versions were probably written later than the first ages of Christianity. The style of these ancient versions, still perceivable in the Vulgate, though amended by Jerom, is not only devoid of classical elegance, but inaccurate and impure. False Latin frequently occurs, and such as no native Roman could have written. Errors of this kind, and a too servile attention to the idiom of the Greek, betray a translator, who was neither a native Italian, nor had learned the language by the rules of grammar.

At other times, we find expressions that seem to be improper, and that nevertheless are justifiable according to the usage of the Italian language. Words are also used in a sense that is very rare in the classic writers. Moreover, these versions contain very numerous Hebraisms, or rather Syriaisms, that are diametrically opposite to the genius of the Latin: from which circumstance we may infer, that some of these versions were made by Jewish converts, whose native language was the Syriac. The language of these versions has materially influenced the Latin of the church, which is not only unclassical, but has a tincture of the oriental idiom, though in a much lower degree than the versions themselves.

Michaelis differs from Mills, who refers the origin of the oldest Latin version no higher than to the time of pope Pius, in the middle of the second century, and who supposes that the Latin version was made by public authority, or under the direction of the bishop of Rome. It is, says the professor, very improbable, if a translator had been appointed by a bishop or a council, that a writer would have been chosen, who was so little master of the Latin. He therefore supposes, that the real state of the case was as follows. The New Testament was read in the Christian churches, in the same manner as the Old Testament in the Jewish synagogues; and as the Jews, after reading the original Hebrew, explained it by a Chaldee paraphrase, the Christian bishops and public teachers expounded the passages in Latin, which they first read in the Greek. At first this was done extempore; but by degrees, in order to facilitate the public service, these translations were committed to writing, and at length communicated to the different members. By these means we may account for their great variety, and the confusion, which might have been avoided by a version ordained by the public authority of the Christian church.

As it cannot be denied, that the oldest Latin versions are of very high antiquity, though some of their readings are false, their principal use in the criticism of the New Testament is, that they lead us to a discovery of the readings of the very ancient Greek MSS. that existed prior to the date of any that are now extant. The great confusion which prevailed in the copies of the old Latin version induced pope Damasus to employ Jerom in correcting it; and among all the Latin fathers, before and after his time, it seems that no one was better qualified for the task. Jerom finished this work about the year 384; but F. Simon observes, that the Vulgate, after the time of Jerom, was manifestly different from the old version, in all the books of the New Testament. He partly expunged the spurious readings, and partly corrected the translations, which appeared to be erroneous; but it must be acknowledged, that, with the best intention, he has sometimes altered for the worse. See *VULGATE*, and *Latin BIBLES*.

The learned and ingenious Eichorn, in his Introduction to the Old Testament, supposes, not improbably, that the first Latin version of the bible was made in Africa, where Latin alone being understood, a translation was more necessary, where the Latin version was held in the highest veneration, and where the language being spoken with less purity, barbarisms might have more easily been introduced, than in a provincial town in Italy. But the Greek Testament could not have been translated into Latin before the canon had been formed, which was certainly not made in the first century. Michaelis by Marsh.

Of the modern Latin versions, the first we shall mention is that of Erasmus, who translated the New Testament from the Greek; following not only the printed copies, but also four Greek MSS., and varying very little from the Vulgate.

The first edition appeared in 1516, and dedicated to pope Leo X.

Arius Montanus undertook, by order of the council of Trent, as some pretend, a version of the Old and New Testaments; following, in his translation of the Old Testament, Pagninus, keeper of the Vatican library, who had translated the Old Testament from the Hebrew, by order of Clement VIII. As for the New Testament, he only changed some words in it, where he found that the Vulgate differed from the Hebrew. See *BIBLE*.

A Latin version of the whole New Testament, except the Revelations, is ascribed to Thomas de Vio, a Dominican, commonly styled cardinal Cajetan; but not understanding Greek, he probably procured some person to perform the work in his name. This was printed at Venice in 1530 and 1531, with the cardinal's commentaries. Another Latin version was published by an English writer in 1540, and dedicated to Henry VIII.

The Zurich version is one of the most ancient Latin translations made by Protestants. Part of it was done by Leo Juda, one of the ministers of that city, aided by some of his learned brethren; but being prevented by death from completing it, he left it to the care of T. Bibliander, professor at Zurich, who, aided by Conradus Pellican, professor of Hebrew in the same place, translated the rest of the Old Testament. The New Testament was continued by Peter Cholin, professor in divinity, and by Rodolph Gualterus, Leo Juda's successor in the ministerial office. This version was published in 1544. The seventh verse of the fifth chapter of the first epistle of St. John is omitted in this version, and placed in the margin. This passage was not inserted by Erasmus in his first editions of the New Testament, because he did not find it in the Greek copies; but having afterwards found it in a MS. in England, he introduced it into subsequent editions. In the following years, Robert Stephens printed this edition, with a few alterations; joining to it the Hebrew text and the Vulgate, and notes from the public lectures of Vatablus. See *Latin BIBLES*.

Sebastian Castalio published a Latin bible, which has been both censured and admired. See *Latin BIBLES*, and *CASTALIO*.

Theodorus Beza's Latin version has been much approved by Protestants, but depreciated by the Roman Catholics. It has been also censured by bishop Walton and Dr. Mills. See *BIBLE*.

VERSION of Origen. See *HEXAPLA* and *TETRAPLA*.

VERSION, Persian. See *BIBLE*.

VERSION, Peshito and Philoxentan. See *SYRIAC Version*.

VERSION, Slavonian or Russian. See *BIBLE*.

VERSION, Sabidic. See *BIBLE*.

VERSION, Syriac. See *SYRIAC Version*, and *BIBLE*.

For an account of *English, Flemish, French, Gaelic, Georgian, German, Indian, Irish, Italian, Rhenish, Saxon, Spanish, and Welsh* versions, see *BIBLE*. See also *POLYGLOTT*.

VERSTITZ, or *VERSEZ*, in *Geography*, a town of Hungary. It is the see of a Greek bishop, and contains some extensive barracks, with about 12,000 inhabitants. Near it are the ruins of a castle; 20 miles N.N.W. of Vapalanka.

VERSMOLD, a town of the county of Ravensburg; 10 miles N.W. of Bielefeld. N. lat. 52° 2'. E. long. 8° 5'.

VERSO. See *FOLIO Verso*.

VERSOIX, in *Geography*, a town of France, in the department of the Ain, at the mouth of a river of the same name, on the side of the lake of Geneva; 6 miles S.E. of Gex.

VERSOIX, La, or *Verfoy*, a river which rises in France, and runs into the lake of Geneva at Verfoy.

VERSOU, Le, a town of France, in the department of the Ière; 6 miles N. of Grenoble.

VERSOY, a town of France, in the department of Mont Blanc; 4 miles N. of St. Maurice.

VERT, or WERT, a Russian measure, containing 500 fathes or 1500 arsheens = 3500 English feet. Hence 264 *verts* = 175 English miles; so that a *vert* is nearly two-thirds of an English mile, and a degree of the meridian is reckoned to be about 104 *verts*. The Russian foot is = 13½ English inches, and the Moscow foot = 13½ English inches; but the English foot is generally used at Peterburg, and also the Rhineland foot = 12½ English inches. See MEASURE.

VERTSTEGAN, RICHARD, in *Biography*, a descendant of an ancient family in Guelderland, and the son of a cooper in London, enjoyed the advantage of a liberal education at Oxford, and distinguished himself by his literary acquirements; but becoming a Catholic, he left the university without a degree, and removed to Antwerp. About the year 1585, he there published a work, entitled "Theatrum Crudelitatum Hereticorum nostri Temporis," adorned with engravings, and intended as a counterpart to the Protestant Martyrologies. In this work he treated queen Elizabeth with great severity; and when Vertegan removed to Paris, complaint was preferred against him by the English ambassador to Henry III., who, from motives of policy more than from a disapprobation of his book, caused him for some time to be imprisoned. After his release, he returned to Antwerp, where he employed himself as a printer, and published, in 1592, a second edition of his *Theatrum*. He also entered with much acrimony into a dispute between the regular and secular Roman Catholic clergy in England, taking part with the former. But he was more honourably and usefully employed in preparing his "Restitution of decayed Intelligence in Antiquities concerning the noble and renowned English Nation," which was first printed at Antwerp in 1605, 4to. Bishop Nicolson's character of this work is as follows: "The writer had several advantages for making of some special discoveries on the subject whereon he treats, which is handled so plausibly, and so well illustrated with handsome cuts, that the book has taken, and sold very well. But a great many mistakes have escaped him." Some of these are stated by the bishop; and he adds, they have been carefully corrected by Mr. Somner. The last of three editions of this work that issued from the press in England was that of 1674. Among some other works of Vertegan, we find mentioned his "Antiquitates Belgicæ," Antwerp, 1613. He is supposed to have died about the year 1625. *Biogr. Brit.*

VERT, DOM CLAUDE DE, was born at Paris in 1645, and at the age of 16 entered into the order of St. Benedict, in the Congregation of Cluni. In the Jesuits' college at Avignon he studied philosophy and theology; and after his return from a journey to Rome, he devoted himself to the study of the rule of St. Benedict, and contributed by his influence to the establishment of general chapters. In 1676 he and another monk were appointed to the office of reforming the breviary of the order. The result of their labour appeared in 1686; and in 1689 he published a translation of the rule of St. Benedict, with a preface and learned notes. In 1690 he wrote a letter to Jurien, who had expressed himself contemptuously of the ceremonies of the church; and in 1690 he was rewarded for his services, by the dignity of vicar-general to the cardinal de Bouillon, and the priory of St. Peter in Abbeville. His work oft

known is entitled "Explication simple litterale et historique des Ceremonies de l'Eglise," 4 vols. 8vo. The writer died at Abbeville in 1708, aged 63, leaving the character of a pious, as well as a mild and polished man. *Moreri*.

VERT, in *Heraldry*, the term for a green colour.

It is also called *vert* in the blazon of the coats of all under the degrees of nobles; but in coats of nobles it is called *emerald*; and in those of kings, *Venus*.

In engraving, it is expressed by diagonals, or lines drawn athwart, from right to left, from the dexter chief corner to the sinister base.

In lieu of *vert*, the French heralds use *synople*, or *synople VERT*, or *Green Hue*, in *Forest Law*, any thing that grows and bears a green leaf, within the forest, that may cover a deer.

This is divided into *over-vert* and *nether-vert*. The former is the great woods, which, in law-books, are usually called *hault-bois*; and the latter is the under-woods, otherwise called *sub-bois*.

We sometimes also meet with *special vert*, which denotes all trees growing in the king's woods within the forest, and those which grow in other men's woods, if they be such trees as bear fruit to feed the deer.

VERT, in *Geography*, a river of France, which runs into the Gave of Oleron.—Also, a river of France, which runs into the Lot, near Cahors.

VERT St. Denis, a town of France, in the department of the Seine and Marne; 3 miles N.W. of Melun.

VERTACOMEÇORI, in *Ancient Geography*, a people to whom Pliny ascribes the foundation of Navarre, in Gallia Cisalpina, and who formed a part of the Vocontii.

VERTÆ, a people of Asia, allies of the Persians, and found at the siege of Amida.

VERTAISON, in *Geography*, a town of France, in the department of the Puy de Dôme; 4 miles N.W. of Billon.

VERTE BAY, or *Green Bay*, a bay of the Atlantic ocean, between Nova Scotia and New Brunswick, on the north coast. N. lat. 46°. W. long. 63° 54'.

VERTE Bay, a bay on the north-east coast of Newfoundland. N. lat. 50° 10'. W. long. 56°.

VERTEBRÆ, in *Anatomy*, the bones composing the spine. They are distinguished by their situation into *vertebræ colli, dorſi,* and *lumborum*; or *cervical, dorsal,* and *lumar*. See *SPINE*.

The cartilages between the *vertebræ* of the back yield considerably to the pressure of the body, in an erect posture, and expand themselves in the night, when persons lie down. Hence arises a very singular phenomenon, but a very true one; which is, that a man is considerably taller at his rising in the morning, after the expansion of these cartilages, during the absence of the pressure for several hours, than at night, when they have been pressed down all the day.

The reverend Mr. Wasse seems to have examined this difference more strictly than any other person. He found that several persons, enlisted as soldiers in a morning, had been discharged for want of height, on their being measured again before the officers in the evening; and on this occasion measured several other people, and found the difference, in many cases, to be not less than an inch. This gentleman observed in himself, that fixing a bar of iron where he just reached it with his head on getting first out of bed in the morning, he could lose near half an inch in an hour, or less, if he employed that time in rolling his garden, or any other exercise of that laborious kind. He observed also, that riding often took off the height very suddenly; and what was more particular, that in sitting close to study five or six

fix hours without any motion, he lost often a whole inch in height.

People who use hard labour sink rather less in the whole than those of sedentary lives; and the height once lost is never to be recovered that day, not even by the use of the cold bath; but a night's lying down can alone restore it. Phil. Trans. N^o 383, p. 87.

This difference in height takes place only in the human species, as they are the only creatures who walk erect, and throw the pressure of their whole weight upon the backbone. This gentleman measured horses before and after riding, and could find no difference even after the longest journeys.

The alteration in height is much greater in young people than in those who are more aged. It is evident from this change happening to persons when they sit, as well as when they stand, that it is brought about merely by the backbone; and we must admire the structure of that part of the body, which owes its giving way thus to its being formed together in that manner, which alone could suit it to the several purposes it was intended for. The thickness and shortness of the bones, with the intervening cartilages, assisted by the bony processes, dispose it to a motion peculiar to itself; whereas, had the bodies been of any considerable length, upon bending the body, the articulations must have made a large angle upon their inmost edges, and the spinal marrow would have been continually liable to be injured; and had the cartilages been entirely wanting, it would have been as useless as if it were but one bone, by which the trunk of the body, being rendered incapable of bending, must have remained for ever in an erect posture. Another particular, which bespeaks the utmost wisdom and design in the contrivance of this part is, the remarkable difference there is in the cartilages placed between the several bones of the spine.

The vertebræ of the back require but little motion, and the cartilages there are for that reason small and thin, in comparison with those of the loins, which being very thick, the lowest more especially, the motion is much greater there, and much better to be borne. This being the state and disposition of the parts during the whole space of time in which we are usually employed about our several businesses, till the time that we dispose ourselves to rest, the cartilages of the spine will, by their compressible and yielding properties, become more close and compact for the pressure they sustain, and consequently the spine, which is the only support of the trunk of the body, will become shorter; but when this superior weight shall be entirely removed, by placing the body in an horizontal posture, as it always is when we are in bed, the compressed cartilages will, by their natural elastic power, begin gradually to enlarge themselves, till they, by degrees, recover the expanded state they had before they gave way.

The cartilages between the several vertebræ are twenty-four in number, and every one of these is pressed somewhat in our daily employments, so that when they all come to expand, the aggregate of their several expansions cannot be supposed less than about an inch. Now, if this be the difference occasioned by the pressure of the common weight of the body alone upon itself, it must necessarily be much greater in those persons whose constant employment is to carry heavy burdens. The compression and expansion of the cartilages in older people being less than in younger, is a necessary consequence of the cartilages in time of age growing harder, and less capable of compression; for they often grow almost bony in length of time: and hence it is, that old people are observed to lose somewhat of their former

height, the cartilages in them shrinking to a somewhat smaller compass as they grow bony; and this shortening is, therefore, not imaginary, as many have believed, but real, and owing to this plain cause. Phil. Trans. N. 383, p. 90. See CARTILAGE and SPINE.

VERTEBRÆ, *Disease of the*. See SPINE.

VERTEBRÆ, *Dislocations of*. See LUXATION.

VERTEBRÆ, *Fractures of*. See FRACTURE.

VERTEBRÆ of *Fish*. The vertebræ of fish are extremely different in shape in the several kinds, and even vary in number in the different species of the same genus. The anterior vertebræ in some have three apophyses, as in the cypriini, efoces, pleuronecti, &c.; and in the clupeæ they have no less than seven of these apophyses, but they are slender and capillary. Artedi Ichthyol.

VERTEBRAL *Artery and Vein*, in *Anatomy*, branches of the subclavian vessels. See ARTERY and VEIN.

VERTEBRAL *Canal*, the canal of the spine, which contains the medulla spinalis. See SPINE.

VERTEBRAL *Nerves*, the nerves sent off from the medulla spinalis, and passing out at the lateral holes of the spine. See NERVE.

VERTEBRAL *Theca*, the sheath of dura mater inclosing the medulla spinalis. See BRAIN.

VERTEILLAC, in *Geography*, a town of France, in the department of the Dordogne; 7 miles N. of Ribercac.

VERTENEGGI, a town of Istria; 11 miles S. of Capo d'Istria.

VERTERIS, in *Ancient Geography*, a town of Great Britain, in the second route of Antonine, between Brovonacæ or Kirbythure and Lavatræ or Bowes, and in the fifth route between Lavatræ and Brovacum or Brougham Castle, placed at Brugh under Stanemore.

VERTEUIL, in *Geography*, a town of France, in the department of the Charente; 3 miles S. of Ruffec.—Alfo, a town of France, in the department of the Lot and Garonne; 6 miles N.N.E. of Tonneins.

VERTEX, in *Anatomy*, the crown of the head, or that uppermost and middle part situated between the finciput and occiput. See HEAD.

Hence, also, vertex is figurately used for the top of other things. Thus, the vertex of a cone, pyramid, conic section, &c. is the point of the upper extremity of the axis, or the top of the figure.

VERTEX of an *Angle*, is the angular point, or the point A, (*Plate II. Geometry*, fig. 15.) in which the legs meet.

VERTEX of a *Figure*, is the vertex of the angle opposite to the base.

Such is the point M (*Plate XV. Geometry*, fig. 17.) opposite to the base A B.

VERTEX of a *Curve*, is the point A (*Plate XV. Geometry*, fig. 18.) from which the diameter is drawn; or it is the intersection of the diameter and the curve.

VERTEX of a *Glass*, in *Optics*, the same with the pole of it.

VERTEX is also used, in *Astronomy*, for the point of heaven perpendicularly over our heads, called the *zenith*.

VERTEX, *Path of the*. See PATH.

VERTIBULUM, a word used by some writers to express the round head of a bone, which, in its articulation, is inserted into the sinus, or cavity of another bone.

VERTICAL, in *Botany*, is technically used to express the perpendicular position, or insertion, of certain parts of a plant. Vertical Leaves are such as stand *fo erect*, that neither of their surfaces can properly be called the upper or under, of which nature are all sword-shaped leaves, *folia ensiformia*. (See LEAF.) But the term is usually restricted

to such leaves as have properly an under surface, different in nature from the upper one, and yet stand upright; witness *Lactuca Scariola*, and perhaps several succulent leafed plants.

Vertical Anthers, as in the Tulip, terminate the filaments, and being inserted by one of the extremities, stand no less upright than the filaments themselves, being opposed to incumbent anthers, whose insertion is generally lateral, and whose position is more or less horizontal, over the stigma, as in the Passion-flower. In both these instances the anthers are remarkably versatile, *anthera versatilis*; allowing themselves to be turned round many times without separating from the filament. Vertical stalks, &c. readily explain themselves.

VERTICAL Circle, in *Astronomy*, is a great circle of the sphere, passing through the zenith and the nadir, and any other given point on the surface of the sphere.

The vertical circles are also called *azimuths*; which see. The meridian of any place is a vertical circle. All the vertical circles intersect each other in the zenith and nadir.

The use of the vertical circles is to measure the height of the stars, and their distances from the zenith, which is reckoned on these circles; and to find their eastern and western amplitude, by observing how many degrees the vertical, in which the star rises or sets, is distant from the meridian.

VERTICAL, *Prime*, is that vertical circle, or azimuth, which passes through the poles of the meridian; or which is perpendicular to the meridian, and passes through the equinoctial points.

VERTICALS, *Prime*, in *Dialling*. See PRIME Verticals.

VERTICAL of the Sun, is the vertical which passes through the centre of the sun at any moment of time.

Its use is, in dialling, to find the declination of the plane on which the dial is to be drawn, which is done by observing how many degrees that vertical is distant from the meridian, after marking the point, or line of the shadow, upon the plane at any time.

VERTICAL Dial. See Vertical DIAL.

VERTICAL Line, in *Conics*, is a right line drawn on the vertical plane, and passing through the vertex of the cone.

VERTICAL Line, in *Dialling*, is a line in any place perpendicular to the horizon.

This is best found and drawn on an erect and reclining plane, by holding up a string and heavy plummet steadily, and then marking two points of the shadow of a thread on the plane, a good distance from one another; and drawing a line through those marks.

VERTICAL Line, in *Perspective*. See Vertical LINE.

VERTICAL Plane, in *Conics*, is a plane passing through the vertex of a cone, and parallel to any conic section.

VERTICAL Plane, in *Perspective*. See PLANE and PERSPECTIVE.

VERTICAL Point, in *Astronomy*, the same with vertex or zenith.

Hence a star is said to be vertical, when it happens to be in that point which is perpendicularly over any place.

VERTICILLARIA, in *Botany*, Fl. Peruv. 69, a Peruvian genus of plants, so called because its branches are disposed in regular whorls, one above the other. *De Theis*. See VERTICILLUS.

VERTICILLATÆ, Whorled-flowered plants, form the 42d natural order in Linnæus's natural system, being precisely analogous to Jussieu's LABIATÆ (see that article); as well as to the order of *Didymia Gymnospermia* in the Linnæan artificial system, except that it includes also several diandrous genera of the latter arrangement. Ray

first established this order, under the above name, and distinguished it, though not by a very clear or infallible definition, from his own *Asperifolia*. Hermann injudiciously combined these two orders. Linnæus first clearly defined their differences. Both have four naked seeds, and a monopetalous corolla; which is regular in all the *Asperifolia*, except *Echium*; irregular in all the *Verticillata*, and also ringent, or at least two-lipped, except *Mentha* and *Lycopus*; see those articles. The *Asperifolia* have, moreover, alternate or scattered leaves; the *Verticillata* opposite ones; the former are more of a mucilaginous quality; the latter more aromatic. Linnæus however detected the true characters of the orders in question in their *stamens*. These in the *Asperifolia* are five, all of equal length; in the *Verticillata* either four or two; if four, two are longer, or more perfect, than the rest.

For the genera which compose this order of *Verticillata*, and their general characters and properties, the reader is referred to the article LABIATÆ. Their particular mode of inflorescence is explained under VERTICILLUS; though in many instances their whorls are so crowded together as to form a spike, or cluster, the foliage diminishing, or changing, into *bractæas*. Of this, examples occur in *Salvia*, *Mentha*, and *Origanum*, with some other genera.

This being one of the most natural of all the orders in the whole vegetable kingdom, few botanists have succeeded in defining its genera. Linnæus has been eminently successful in this point, having happily seized some essential character by which each genus is clearly marked, in one part or other of the fructification; such characters being, on the whole, as well supported by the habit as can be expected in so natural an order.

VERTICILLUS, a Whorl, is a mode of inflorescence, in which the flowers surround the stem in a sort of ring. There is seldom a perfectly whorled insertion of the flowers, around a stem or stalk, independent of the leaves, though the rare genus *GNETUM*, (see that article,) may afford an instance. It is most usual for each flower to be axillary, or accompanied by a leaf, as in *Hippuris*. Nevertheless the natural order of VERTICILLATÆ, so denominated from this circumstance, is considered as having truly whorled flowers, though inserted on two opposite sides of the square stem; as they, being commonly very numerous and crowded, spread into one dense uninterrupted mass. Such may, or may not, be accompanied by leaves or bractæas.

Folia verticillata, whorled leaves, are when more than two leaves surround the stem at one point, or articulation. Examples occur in *Galium* and its allies, thence called by Ray and following authors *plante stellate*; as well as in a few of the first species of VERONICA. Peruvian shrubs are remarkably inclined to bear three or four leaves in a whorl, though the genera, or natural orders, to which they respectively belong, have merely opposite leaves. See under the article LEAF, *folia, bina, ternata*, &c.

Whorled *Cotyledons* are very rare, but they do occur in PINUS and DOMBEYA.—Even if such were, as Jussieu suggests, merely opposite cotyledons in numerous deep segments, they might perhaps, according to the analogy of the above-described inflorescence, be called *cotyledones verticillata*.

VERTICITY, is that property of the load-stone by which it turns or directs itself to some particular point.

The attraction of the magnet was known long before its verticity.

VERTICORDIA, in *Mythology*, one of the epithets of Venus. See VENUS.

VERTIGO, in *Medicine*, from *verto*, I turn, *giddiness*, *dizziness*, or *swimming of the head*, a well-known affection, in which

VERTIGO.

which external objects appear to move in various directions, though stationary, and there is a difficulty of maintaining the erect posture, often accompanied with sickness.

Philosophers have differed in their opinions respecting the cause of *vertigo*, when it is produced under various circumstances, independently of internal disease: as from swinging, turning round rapidly, looking from a high station, riding across a broad undulating stream, or over a plain covered with snow, or looking at the walls of a room painted with equal small figures, at a whirling wheel, &c. &c.; circumstances which might appear upon a casual view not explicable upon one common principle. Dr. Darwin, however, has very ingeniously explained the origin of giddiness from these various causes. He observes, that in learning to walk, we judge of the distance of the objects which we approach by the eye, and by observing their perpendicularity determine our own; and that at all times we determine our want of perpendicularity, or inclination to fall, by attending to the apparent motion of the objects within the sphere of distinct vision. Hence, when we are placed upon the summit of a high cliff or tower, and look down, we become dizzy, because the objects below are out of the sphere of distinct vision, and we are obliged to balance ourselves by the less accurate feelings of our muscles. Hence also, on going into a room hung with a paper which is covered all over with similar small black lozenges, many people become giddy; for the objects around being so small, that they do not perceive their minute parts, or so similar, that they do not distinguish them from one another, they begin to lose their balance; for on inclining to one side or the other, the next and the next lozenge succeeds on the eye, which they mistake for the first, and they are not aware that they have any apparent motion; but if you fix a sheet of paper, or draw any other figure in the midst of the lozenges, the charm ceases, and no giddiness is produced. Giddiness is occasioned in a similar way in riding over an extensive plain of snow or sheet of water, in which no distinct object presents itself by which we can ascertain our perpendicularity.

But the circumstance which occasions *vertigo* in the other cases, is the difficulty of distinguishing our own real motions from the apparent motions of external objects; and the difficulty is still greater, when both ourselves and the circumjacent objects are in motion. Our daily practice of walking and riding soon instructs us with accuracy to discern the modes of motion, and to ascribe the apparent motion of the ambient objects to ourselves; but those which we have not acquired by repeated habit continue to confound us. Hence whirling round, swinging, skating on the ice, sailing, riding backwards in a coach, and a thousand other movements, produce giddiness, which, if long enough continued, bring on sickness and vomiting. When first an European mounts an elephant sixteen feet high, and whose mode of motion he is not accustomed to, the objects seem to undulate as he passes, and he frequently becomes sick and vertiginous. And when we first go on ship-board, where the movements of ourselves, and the movements of the large waves are both new to us, the *vertigo* is almost unavoidable, with the terrible sickness which attends it. Yet in persons habituated to these motions, no *vertigo* occurs; even the most continued whirling, as practised by the dervises in Turkey, as a religious ceremony, and by European waltzers, may be learnt to be performed without giddiness.

Dr. Darwin mentions several other circumstances, which prove that we require experience in the motions of surrounding objects, even while we are ourselves at rest, in order to determine our own perpendicularity by them. Whence some people become dizzy at the sight of a whirl-

ing wheel, or by gazing on the undulations of a river, if no steady objects are at the same time within the sphere of their distinct vision. And he mentions the following curious experiment, illustrating this fact. When a child first can stand erect upon his legs, if you gain his attention to a white handkerchief steadily extended like a sail, and afterwards make it undulate, he instantly loses his perpendicularity, and tumbles on the ground. See *Zoonomia*, vol. i. sect. 20.

Vertigo, however, arising from any of these causes, is not properly the subject of medical treatment; and it is only when it occurs independently of external circumstances, that it becomes the object of pathological inquiry. It is not in itself, indeed, considered as a distinct disease, but is always symptomatic of some other morbid affection, against which our remedies must be directed. Whence Dr. Cullen has excluded it altogether from his classification of diseases.

Vertigo occurs under three different states of the constitution, or is a symptom of three different species of disease, which it is necessary to distinguish, in order to apply the appropriate remedies. The first, and the only variety of *vertigo* that is accompanied with danger, is that which arises from an over-fullness of the vessels of the head, and which is sometimes the precursor of apoplexy or palsy. The *vertigo* from intoxication is probably chiefly produced in this way, though it may be partly explained upon the principle of debilitated muscular energy, by which the person is disabled from directing the eye steadily upon surrounding objects, and which even occasions double vision.

The *vertigo* originating from a plethoric state of the vessels of the brain will be indicated by the presence of certain other symptoms. If it occurs in a person of sanguine temperament, of a full habit of body, florid complexion, in the meridian of life, or past that period, and in one accustomed to free living; and if it is accompanied by occasional head-ache, throbbing of the vessels of the head, noise in the ears, and drowziness; little doubt can remain that it originates from a plethoric condition of the vessels, and that the proper remedies will be, the abstraction of blood, either from the system at large, or by opening the temporal artery or jugular vein, or by the application of leeches to the temples; at the same time administering moderate purgative medicines, and enjoining an abstinence from fermented liquors, and high-seasoned food, as well as great moderation in respect to the quantity of the latter. If these remedies are not resorted to, and these precautions not adopted, the result may be a sudden attack of apoplexy, which may prove immediately fatal, or leave behind it a *hemiplegia*, or palsy of one side.

The second variety of *vertigo*, to which we have alluded, is attended with little hazard, though sometimes very distressing. It occurs in an opposite condition of the body, a state of nervous debility, and accompanies many of those anomalous affections which are comprehended under the appellations of *hysteria* and *hypochondriasis*. This *vertigo* occurs in persons of a different temperament from that above described; in thin and spare habits, or in those of a certain degree of corpulency, but pale and relaxed constitution. It is accompanied also by other symptoms characteristic of the hysterical and hypochondriacal diseases; and cannot easily be mistaken for the plethoric *vertigo*. The cure, of course, will depend upon the general features of the whole complaint, of which the *vertigo* is but a passing symptom, and we need not here enlarge upon the subject. See *HYPOCHONDRIASIS* and *HYSTERIA*.

There is a third variety of *vertigo*, which is also transient and void of danger; which is a symptom of indigestion; and

is connected with particular conditions of the stomach. This is not permanent, but comes on suddenly for a few seconds or minutes, and then goes off; but during this short interval, the person, if walking, will seize a rail, or post, or fix himself against a wall, to preserve his perpendicularity; or even if sitting, will be obliged to hold the back of his chair firmly, or to lean forward on the table for the same purpose. This slight attack is generally attended with a feeling of beginning nausea, which subsides with the vertigo.

As this occurs in persons who are neither plethoric nor hypochondriacal, is unaccompanied by head-ache, and generally attended by flatulence, irregularity of bowels, or some other symptom of disturbance in the digestive organs, so it is easily distinguished from the preceding species. It is generally soon removed by the use of an absorbent, and gentle laxative, in some moderately cordial vehicle; as by a little carbonate and sulphate of magnesia in mint-water, or in an infusion of chamomile, or orange-peel; or by a portion of magnesia and rhubarb, or similar medicines.

VERTIGO, in *Animals*. See APOPLEXY and STAGGERS.

VERTILLAGE, in *Agriculture*, the tilling or preparing of ground to receive the seed, by turning, stirring, or tilling it.

VERTINÆ, in *Ancient Geography*, a small town of Italy, in the interior of Lucania, according to Strabo.

VERTORIGÈ, a town of Hispania, in Beticæ. Pliny.

VERTON, in *Geography*, a town of France, in the department of the Lower Loire; 4 miles N.E. of Nantes.

VERTOT D'AUBGUF, RENÉ AUBERT DE, in *Biography*, a French historian, was born in 1655, at the seat of Bennetot in Normandy. Inclined to retirement, he entered, at the early age of 15 or 16, among the Capuchins, whose austerities he impaired his constitution, that he was under a necessity of obtaining a brief for exchanging this order for that of the regular canons of Prémontré, with which he connected himself in 1677. Some disputes, however, occurred in this order, which occasioned his abandoning it. After several changes of situation, humorously called the "Abbé de Vertot's revolutions," he settled at Paris in 1701, where he was employed in compiling the memoirs for the house of Noailles, engaged in a contest with that of Bouillon, for which service he obtained a pension. In 1705 he became a pensioner of the Academy of Inscriptions and Belles Lettres, which was revived in 1701; and afterwards occupied several posts in connection with the duke and duchess of Orleans. In 1715 he was appointed, by the grand-master of Malta, historiographer to that order, with its attendant privileges, and the right of wearing the cross; and the commandery of Santeny was added to his other preferments. Some have said that he was sub-preceptor to Lewis XV., but he was deprived of this honour. As he advanced in life, his infirmities increased, so that he died in 1735, at the age of 80. His disposition and character were highly estimable. His principal works were, "L'Histoire des Révolutions de Portugal," 1689, 12mo., much commended by Bouhours for its style, though the memoirs upon which it was founded were not worthy of confidence:—"L'Histoire des Révolutions de Suède," 2 vols. 12mo. 1696, which is characterized as an interesting performance; though in this, as well as some other works, the author inclines to the romantic:—"L'Histoire des Révolutions Romaines," 3 vols. 12mo., considered as his principal performance:—"L'Histoire de Chevaliers de Malthe," 4 vols. 4to., and 7 vols. 12mo. 1727, less esteemed than the preceding:—"Traité de la Mouvance de Bretagne,"—"Histoire critique de l'Établissement des Bretons dans les Gaules," works that have not been popular:—"Origine de la Gran-

deur de la Cour de Rome, et de la Nomination aux Evêchés et aux Abbâyes de France," a posthumous publication. Several of his learned dissertations were inserted in the Memoirs of the Academy of Belles Lettres. The abbé Mably appreciates Vertot highly as an historian, from a preconceived notion that perfect history corresponds very much with epic poetry; but by others he has been deemed a pleasing and eloquent writer, and denominated "The French Quintus Curtius," whilst his style has been extolled, and his manner of treating his subject has been regarded as interesting. Some of the best judges have disputed his thorough knowledge of mankind, and the accuracy of his research. Moreri.

VERTUE, GEORGE, an eminent artist and antiquary, of whom we have given an account under the article ENGRAVING.

VERTUMNALIA, among the *Romans*, a festival celebrated in honour of the god Vertumnus, in the month of October.

VERTUMNUS, in *Mythology*, a god who presided over gardens and orchards, honoured among the Etruscans, from whom the worship of this deity was transmitted to the Romans.

Ovid (Met. lib. xiv.) has described the various forms assumed by this deity, in order to obtain the love of Pomona. Some have supposed that Vertumnus, whose name they derive à *vertendo*, because he had power to change his form at pleasure, marked the year and its variations; and thus, they say, he pleased Pomona, by bringing the fruits to maturity. Accordingly, Ovid says that he assumed the form of a labourer, reaper, vine-dresser, and old woman, to represent the four seasons, spring, summer, autumn, and winter.

Vertumnus had a temple and a statue near the market-place at Rome, being represented as one of the tutelary deities of the merchants. To this Horace is supposed to allude, where, addressing his book, he says, "Methinks, my book, you often turn your eye towards Vertumnus and Janus;" that is, you are longing to be handsomely bound, and exposed to sale.

Accordingly Vertumnus, says an ancient scholiast on Horace, "deus est preses vertendarum rerum," i. e. "venderandarum ac emendarum."

At the feast instituted in honour of him, he was represented as a young man crowned with different sorts of herbs, dressed in a robe, which reached to his middle; holding fruit in his left hand, and in his right a cornucopia.

The commentators on Ovid say, that he was an ancient king of Etruria, who, by his diligent and successful cultivation of fruits and gardens, obtained the honour of being ranked among the gods. In proof of this, they refer to Propertius, eleg. l. iv. At Rome, in the street called "Vicus Thufcus," was a statue of Vertumnus, of which Cicero speaks, on occasion of Verres' avarice; "who is there but has traced thy avarice all along the way that leads from Vertumnus's statue to the great Circus?"

VERTUS, in *Geography*, a town of France, in the department of the Marne; 15 miles S.W. of Châlons-sur-Marne.

VERU, a comet according to some writers, resembling a spit, being nearly the same as the lonchites, only its head is rounder, and its train longer and sharper pointed.

VERVA, a word used by some authors to express an ivory amulet to be worn for the epilepsy.

VERVAIN, in *Botany*. See VERBENA.

The common vervain, or *verbena officinalis* of Linnæus, is very common on the sides of roads, foot-paths, and farmyards,

yards, near habitations; for although there is scarcely any part of England in which this is not found in plenty, yet it is never found above a quarter of a mile from a house; which occasioned its being called *simples joy*, because, wherever this plant is found growing, it is a sure token of a house being near; this is a certain fact, says Miller, but not easy to be accounted for. It is rarely cultivated in gardens, but is brought to the markets by those who gather it in the fields. It is annual, and flowers in July or August.

Vervain was used among the ancients at their sacrifices, and was thought to contain something divine. The Romans, in the beginning of the year, made a perfume of this herb to their friends. It appears to be the *lego Bolam*, or *περιστερανα* of Dioscorides. It is destitute of odour, but manifests a slight degree of astringency. The root, worn at the pit of the stomach, an infusion, and an ointment prepared from the leaves, are said to produce good effects in scrophulous cases. Morley's *Ess.* on Scrophula.

But this, says Dr. Withering, wants confirmation from the more rational and less enthusiastic practitioner.

Its sensible qualities, says Dr. Lewis, afford little or no foundation for the abundance of virtues for which it has been celebrated. Its use in medicine seems to have originated from some superstitious idea of its efficacy, when suspended about the neck as an amulet. In order to obtain its virtues more effectually, the vervain was directed to be bruised before it was appended to the neck; and of its good effects thus used for inveterate head-aches, Forestus relates a remarkable instance. In still later times it has been employed in the way of cataplasm, by which we are told the most severe and obdurate cases of cephalalgia have been cured; for which we have the authorities of Etmuller, Hartmann, and more especially De Haen.

Notwithstanding these testimonies in favour of vervain, it has deservedly fallen into disuse in Britain; nor has the pamphlet of Mr. Morley, written professedly to recommend its use in scrophulous affections, had the effect of restoring its medical character. This gentleman directs the root of vervain to be tied with a *yard of white satin ribbon* round the neck, where it is to remain till the patient recovers. He also has recourse to infusions and ointments prepared from the leaves of the plant; and occasionally calls in aid the most active medicines of the *Materia Medica*. Woodville's *Med. Bot.*

VERVAIN, *Mallow*. See MALVA and URENA.

VERUDA, in *Geography*, a small island in the Adriatic, near the coast of Istria; 4 miles S. of Pola.

VERUES, in *Ancient Geography*, a people of Africa, in Mauritania Tingitana, S. of the Succosii and of the Macanite, according to Ptolemy.

VERVIC, in *Geography*. See WERWIC.

VERVIERS, a town of France, in the department of the Ourthe, situated on the river Weze. It was anciently walled, but when the French were masters of Limburg, they compelled the inhabitants of Verviers to demolish the walls. The body of citizens is represented by seven commissaries, appointed by the magistrates, whose office is for life, independent of the bishop. The inhabitants carry on a very considerable traffic in cloth, which they export to Germany, the northern parts of Europe, Italy, and Turkey; 17 miles E.S.E. of Liege. N. lat. 50° 36'. E. long. 5° 53'.

VERVINS, a town of France, and principal place of a district, in the department of the Aisne; 4 points N.N.E. of Laon. N. lat. 49° 50'. E. long. 3° 58'.

VERULÆ, or VERULANUM, in *Ancient Geography*, a

town of Italy, in Latium, in the country of the Hernici, according to Florus. Frontinus reckons it in the number of Roman colonies.

VERULAM, in *Geography*. See St. Alban's.

VERULAMIA, in *Botany*, received this appellation from the learned Decandolle, now botanical professor at Geneva, in memory of our immortal BACON, baron of Verulam; see that biographical article. That lord Bacon's speculations in natural knowledge may allow us to claim him as a botanist, we are too much interested in the honour of our science to dispute; but we must deeply regret that his real name, so universally known and venerated, was not preferred, to one which serves but to perpetuate the remembrance of his lamentable disgrace. We should, on any future occasion, presume to establish *Baconia*, in preference to the above, as being, in addition to the above reasons, authorized by Linnæan rule and custom. The characters of this genus, in a paper read before the French *Institute*, were communicated by the above author to M. Poiret, from whom we adopt them.—Poiret in *Lam. Dict.* v. 8. 543.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, in four obtuse segments. *Cor.* of one petal, funnel-shaped, longer than the calyx; tube cylindrical, shorter than the limb, its orifice beset with hairs; limb in four spreading segments. *Stam.* Filaments four, short, inserted into the upper part of the tube; anthers prominent, linear, twisted after discharging their pollen. *Pist.* Germen superior, nearly globular, umbilicated at the top; style thread-shaped, hardly to long as the anthers; stigma simple, cylindrical. *Peric.* Berry somewhat globular, compressed at the summit, nearly dry, of two cells. *Seeds* solitary, hemispherical, with a cartilaginous albumen, and straight cylindrical embryo.

Ess. Ch. Corolla funnel-shaped, bearded in the mouth. Calyx four-cleft, inferior. Berry of two cells. Seeds solitary.

1. *V. corymbosa*. Decand. Mem. t. 1. unpublished. Poiret n. 1.—Found by Mr. Stadman, in Africa, near Sierra Leone. A *shrub*, differing from all the known genera of this order besides, in having a superior *germen*. It is said to be most akin to GÆRTNERA, but we know not what these writers intend under that name; certainly not what we, in its proper place, have described. The *branches* are cylindrical and smooth. *Leaves* opposite, stalked, crossing each other in pairs, elliptical, entire, smooth on both sides, six or seven inches long, two or more in breadth. *Stipulas* in pairs, entire, scarcely pointed, permanent. *Flowers* in terminal branched *corymbs*, without *bractæas*. *Calyx* wide, obtuse. *Berry* the size of a pea.

VERULUM, VEROLI, in *Ancient Geography*, a town of Italy, in Latium, at a small distance from Alatrium; exhibiting some relics of antiquity.

VERU-MONTANUM, in *Anatomy*. See GENERATION and URETHRA.

VERURIUM, in *Ancient Geography*, a town of Hispania, in Lusitania. Ptolemy.

VERUS, LUCIUS, in *Biography*, a Roman emperor, son of L. Verus, who had been adopted by Adrian, was born about A. D. 131; and on his father's death, in 138, adopted by Titus Antoninus, at the same time with M. Aurelius. In early life Verus neglected all serious studies, and attached himself to amusement and frivolous pursuits; and, therefore, T. Antoninus, at his death in 161, devolved the imperial power solely on M. Aurelius; but this emperor, with an almost unexampled generosity, declared Verus to be an

associate

associate in the empire, with the titles of *Cæsar* and *Augustus*, and other appendages of imperial authority; consolidating the union by marrying his daughter *Lucilla* to *Verus*; nor was the new emperor inensible of the condescension and kindness of his father-in-law. Upon an invasion of *Armenia* and *Syria* by *Vologeses*, king of *Parthia*, *Aurelius*, with a view of refusing *Verus* from the temptations of the capital, appointed him to the command of an army which marched against this formidable foe. His attachment to licentious pleasure and dissipating amusements disqualified him for a service so important; his march was slow; and on reaching the voluptuous capital, *Antioch*, in the year 162, he totally neglected all military operations, and for four years devoted himself to almost every species of licentious gratification and idle amusement. At the conclusion of the war, rendered successful by subordinate Roman commanders, he returned to *Rome*, and partook of a triumph with *Aurelius*. Such, however, was the pernicious effect of the course he pursued in *Syria*, that he addicted himself, without restraint, to all the follies and excesses which have disgraced the most profligate and contemptible of the Roman emperors. Cruelly excepted, he vied in vice and folly with *Nero* and *Caligula*, or any of the imperial monsters that had preceded him. His virtuous colleague beheld his conduct with regret, and used every effort which wisdom could suggest for restraining and reforming him. With this view, he took *Verus* with him in the war against the *Marcomanni*, which commenced in the year 166. The two emperors wintered together at *Aquileia*; but *Verus* was soon tired of the war, and when the frontiers were secured from the barbarians, he determined to return to *Rome*. But upon their route from *Aquileia*, in the year 169, he was seized with an apopleptic fit, which terminated his life in three days, in the 39th year of his age, and the ninth of his partnership in the empire. *Aurelius* interred him with magnificence, and culpably lavished all kinds of divine honours upon his memory, whilst in his speech to the senate he expressed his satisfaction that death had removed an impediment to his designs and efforts for promoting the public welfare. *Crevier*.

VERY LORD and **VERY Tenant**, are those that are immediate lord and tenant to one another. See **LORD** and **TENANT**.

VERZELLINO, in *Ornithology*, the name of a bird common in *Italy*, and kept in cages for its singing, called by authors *citrinella*, and *thraupis*.

VERZINO, in *Geography*, a town of *Naples*, in *Calabria Citra*; 3 miles S.W. of *Umbriatico*.

VERZUOLO, a town of *Piedmont*, late *France*, in the department of the *Stera*, situated in a fruitful foil and salubrious air, near the *Vratis*. The country about it seems an agreeable garden, covered with fruit-trees, vines, pulse, &c. It is surrounded with an ancient wall, and flanked with towers. It has two parish-churches, besides several chapels and religious houses. It has also a castle or palace; 2 miles S. of *Saluzzo*.

VERZY, a town of *France*, in the department of the *Marne*; 9 miles S.E. of *Rheims*.

VESALIUS, ANDREW, in *Biography*, a very eminent anatomist, was born at *Brussels* in 1513 or 1514; pursued his classical studies at *Louvain*, and with a view to medicine and anatomy, frequented the schools of *Cologn*, *Montpellier*, and *Paris*, attending, in the last-mentioned capital, the lectures of *Gunther* and *James Sylvius*. Upon occasion of the war between *Francis I.* and *Charles V.* he was obliged to quit *Paris*, and in the *Low Countries* he served as physician and surgeon in the imperial troops from 1535 to

1537. In the latter year he removed to *Padua*, and taught anatomy there with great applause till the year 1543. He afterwards delivered lectures in the schools of *Bologna* and *Pisa*, and in the beginning of 1544, he became physician to *Charles V.*, and resided chiefly at the imperial court. In the midst of his career of professional reputation, a singular circumstance occurred. Being summoned to examine by dissection the body of a Spanish gentleman who died in 1564, and too precipitately commencing the operation, a palpitation was observed in the heart of the subject. This incident being known to the family, *Vesalius* was accused before the *Inquisition*, and in order to avert some dreadful sentence, *Philip II.* interposed, and procured injunction of a pilgrimage to the *Holy Land* as an expiatory penance. Accordingly the unfortunate anatomist went first to *Cyprus*, and from thence to *Jerusalem*. During his abode in that city, he received an invitation to occupy the chair of anatomy at *Padua*. Having, as it is supposed, accepted this invitation, the vessel in which he was returning to *Europe* was wrecked on the coast of *Zante*, on which island he died in 1564, about the 50th year of his age. A jeweller of the island procured an honourable interment for his remains in the church of the *Holy Virgin* at *Zante*.

Vesalius has been represented as the first person who refused anatomical science from the slavery imposed upon it by deference to ancient opinions, and who led the way to modern improvements. His first publication of note was a set of anatomical tables, entitled "Suorum de Corporis Humani Anatomie Librorum Epitome," *Basil*, 1542, fol. max. The plates were for the most part given again in his great work, "De Corporis Humani Fabrica, Lib. VII." *Basil*, 1543, fol. which has been frequently reprinted in several countries. He is most correct, says one of his biographers, in the bones, muscles, and viscera; the muscles, says *Haller*, he describes more accurately than any other writer, to the time of *Winflow*. The earliest impressions of the plates are considered as the most valuable; but the author corrected his explanations in the second *Basil* edition, 1555. His treatise "De Radicis Chinæ uti Epitola," published in 1546, contains a severe critique on the anatomy of *Galen*, and a correction of his errors; and his reply to the defence of *Galen* by *Fallopio* is the subject of his "Anatomicarum Gabriëlis Fallopii Observationum Examen," 1561. The medical and chirological writings of *Vesalius* are held in no high estimation. His paraphrase on the 9th book of *Rhazes*, published in 1537, is a compendium of medical practice. After his death, his disciple, *Borgarucci*, published "Chirurgia Magna" under his name, a work scarcely worthy of its alleged author. An edition of all the anatomical and chirological works of *Vesalius*, with fine plates, was published under the care of *Boerhaave* and *Albinus* at *Leyden*, 1725, 2 vols. folio. *Haller*. *Tiraboschi*. *Eloy*. *Gen. Biog.*

VESBOLA, in *Ancient Geography*, a town of *Italy*, in the vicinity of the *Ceraunian mountains*, about 60 stadia from *Trebula*, and 40 from *Suna*, attributed by *Dionysius Halicarnassus* to the *Aborigines*.

VESCAVATO, in *Geography*, a town of the island of *Corfica*; 9 miles N.E. of *La Porta*.

VESCI, in *Ancient Geography*, a town of *Hispania*, in the interior of *Betia*, at the foot of mount *Ilipula*, belonging to the *Turduli*.

VESCIA, a town of *Italy*, in *Aufonia*. *Steph. Byz.* *Livy* mentions this town and its territory.

VESCIS, a port of *Hispania Citerior*.

VESCONTE, in *Geography*, a town of *Naples*, in *Calabria Ultra*; 3 miles N.W. of *St. Severina*.

· VESCOVATO, a town of Italy, in the department of the Upper Po; 8 miles N.N.E. of Cremona.

VESCOVIO, or VESCOVIO DI SABINA, a town of the Popedom, in the province of Sabina; 12 miles S. of Narni.

VESCOVO, LA, a town of Naples, in Principato Citra; 14 miles W.S.W. of Amalfi.

VESERIS, in *Ancient Geography*, a place of Italy, in Campania, on the plains at the foot of mount Vesuvius. Livy says that it was in this place that Decius devoted himself to the gods Manes, on occasion of a battle between the Romans and Latins.

VESICA, in *Anatomy*, a bladder; a membranous or skinny part in which any humour is contained.

VESICA Biliaria. See GALL-Bladder.

VESICA, among *Chemists*, is a large copper vessel tinned on the inside, used in distilling ardent spirits; so called, as resembling the figure of a blown bladder.

VESICÆ Sp̄in̄æ, in *Anatomy*. See SPHINCTER.

VESICARIA, in *Botany*, a genus of Tournefort's, thus named from the bladdery appearance of its very large inflated seed-vessel.—Tourn. Cor. 49. t. 483.—Linnæus reduces this plant to *Alyssum*; see that article, n. 16. Tournefort makes a singular remark, that "if the root were fleshy, it would belong to the same genus as *Leontopetalon*;" see LEONTICE. He subsequently perhaps discovered it to be a true cruciform flower, as it undoubtedly is. No other botanist seems to have met with this plant; though Willdenow, like ourselves, had seen a dried specimen, and he finds fault, we think unjustly, with the figure. Tournefort met with this species in a bare and uncultivated valley of Armenia, not far from Baïboul, early in June. The root is woody, and appears to be perennial, crowned with tufts of linear, channelled, toothed, nearly smooth, bright-green leaves, not an inch long. Stems three or four inches high, simple, clothed with smaller, more entire, leaves. Flowers corymbose, small, yellow. Pouch somewhat ovate, inflated, four-sided, an inch long, and nearly as broad, membranous, smooth, with four longitudinal angles and ribs, and many reticulated veins, pale-green, purplish on one side, crowned by the permanent style. It consists of one cell, with two opposite, linear, marginal, membranous receptacles, into which the three or four oval seeds are inserted.—All things considered, we cannot but think this plant entitled to rank as a genus by itself, nor is the name exceptionable. Though not furnished with materials to draw up its full generic character, we can give the essential distinctions.—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Cruciferae*, Juss.

Ess. Ch. Pouch inflated, quadrangular, acute, of one cell, with two linear marginal receptacles. Seeds several.

1. *V. dentata*. Toothed Bladder-crefs. (*V. orientalis*, foliis dentatis; Tourn. Cor. 49. Voyage, v. 2. 109, with a plate. *Alyssum Vesicaria*; Linn. Sp. Pl. 910. Willd. Sp. Pl. v. 3. 470. Mill. Dict. ed. 8. n. 9.)—Native of Armenia. It is scarcely necessary to remark, that Miller merely adopted this plant from Tournefort, without having seen it alive, nor can we discover his authority for saying the stems spread on the surface of the ground. They appear by our specimen, as well as by Tournefort's figure, to be upright.

VESICATORY, VESICATORIUM. See BLISTER, CANTHARIDES, and EMPLASTRUM.

Vesicatories are a stronger sort of sinapisms, and a kind of topical cauteries.

VESICULA, VESICLE, a diminutive of *vesica*; signifying a little bladder.

The lungs consist of vesiculæ, or lobules of vesicula, ad-

mitting air from the bronchiæ; and not only air, but also dust, &c.

There are several parts in the body which bear this appellation; as,

VESICULA Fellis, Cistula Fellis. See GALL-Bladder.

VESICULÆ Seminales. See GENERATION.

VESICULÆ Seminales. These vessels are very evident in fish; the females of most fish have double ovaria, though in some they are single, as in the osmerus, and *perca fluviatilis* of Bellonius; but the vesiculæ feminales in the males are two in number in all fish, not excepting the males of those here mentioned. They differ, however, very much in regard to their figure and situation. As to their situation, they in some fish occupy almost the whole length of the abdomen, as in the spinose kinds in general, and in the petromyzum, acipenser, and many of the other cartilaginous kinds. In some fish, they are placed only in the lower part of the abdomen, as in the cetaceous kinds, &c. As to figure, in the generality of fish they are oblong and compressed, but in some they are round, as in the cetaceous kinds. The other parts of generation are wanting in most fish. Artedi's Ichthyology.

VESICULÆ Adiposæ. See ADEPS, and CELLULÆ Adiposæ.

VESICULAR GLANDS. See GLANDS.

VESIDIA, or VERSIGLIA, in *Ancient Geography*, a small river of Italy, in Etruria.

VESINNE, in *Geography*, a town of France, in the department of the Yonne; 10 miles S.E. of St. Florentin.

VESIONICÆ, in *Ancient Geography*, a place of Italy, in Umbria, S.W. of Iguvium.

VESIRE, in *Geography*, a river of France, which runs into the Lignon, near its union with the Loire.

VESLE, a river of France, which runs into the Aisne, near Veilly.—Also, a river of France, which runs into the Saône, opposite Varenne-le-Grand.

VESLING, JOHN, in *Biography*, a physician, anatomist, and botanist, was born at Minden, in Westphalia, in the year 1598; and having studied medicine at Padua, he travelled into Egypt, and upon his visit to Jerusalem, he became a knight of the Holy Sepulchre. Upon his return, he was appointed, in 1652, to occupy the first chair of anatomy at Padua, lecturing also in surgery and botany, and in 1638 superintending the botanical garden. In order to enrich this garden, he travelled to Candia, and other parts of the Levant, where he collected a large number of rare plants. At length, exhausted by his labours, he died at Padua in 1649, at the age of 51 years. As an anatomist, he published "Syntagma Anatomicum publicis Dissectionibus diligenter aptatum," Patav. 1641, and again with additions and figures, Patav. 1647; a work which has been often reprinted and translated into various languages, and which, though for the most part a compilation, contains new observations, especially pertaining to the organ of hearing. A posthumous work, entitled "De Pullitione Ægyptiorum, et aliæ Observationses Anatomicæ, et Epistolæ Medicæ posthumæ," Hafn. 1664, is highly commended by Haller, and contains some curious observations on the hatching of eggs in Egypt, and evolution of parts of the chick, the anatomy of the viper, crocodile, and hyæna, the human lacteals and lymphatics, &c. His principal publications in botany were, "De Plantis Ægypti Observationses, et Notæ ad P. Alpinum," Patav. 1638; "Opobalsami Veteribus cogniti Vindicis," Patav. 1644; and "Catalogus Plantarum Horti Patavini," Patav. 1642-1644. Haller. Eloy.

VESLY, in *Geography*. See VELLY.

VESOUL, a city of France, and capital of the department

ment of the Upper Saône, situated on a mountain, called Mott de Vesoul: near it is a medicinal spring; $5\frac{1}{2}$ poits N. of Befançon. N. lat. $47^{\circ} 38'$. E. long. $6^{\circ} 14'$.

VESPA, *Wasp*, in *Entomology*, a genus of the Hymenoptera order of insects, the characters of which are these: the mouth horny; the jaw compressed, without proboscis; the palpi or feelers four, unequal, filiform; the antennæ filiform, the first joint being longer and cylindrical; the eyes lunated; the body smooth; the sting concealed; and the upper wings plicated. This is a very extensive genus, comprehending, in Gmelin's System of Linnæus, 159 species; but in the history and arrangement of this species there remains much confusion. We may observe in general, that they are remarkable, like those of the apis, or bee, for the dexterity with which they construct their nests, which in those of many species is of considerable size. We shall confine ourselves, in this article, to a description of two species; *viz.* the *Vulgaris* and *Crabro*.

VULGARIS; or Common Wasp. This has an interrupted small line on both sides of the thorax; a four-spotted scutellum, and the incisions of the abdomen marked with black spots. It is suggested by Dr. Shaw, that the *V. vulgaris* of Linnæus, which he represents as building its nest under projecting roofs, may not be the same with the common English wasp, so well known to us, which builds its nest under ground; as under the surface of some dry bank. M. Reaumur (*Hist. Acad. Sc. Paris, 1719*), and Dr. Derham (*Phil. Transf. N° 382. p. 53. or Abr. vol. viii. p. 404.*), agrees in distinguishing three sorts of wasps; *viz.* the queens or females, the males, and the common labouring wasps, called mules, which, according to Reaumur, are neither males nor females, and consequently barren. The queens, of which there is a considerable number, though fewer than the males, and of course much fewer than the neutral or labouring wasps, are much longer in the body, and larger than any other wasp: they have a large heavy belly, corresponding in size to the prodigious quantity of eggs with which they are charged. The males are less than the queens, but longer and larger than the common wasps, which are the smallest of the species: they have no stings, with which both the queens and common wasps are furnished. There are in one nest two or three hundred males, and as many females; but their number depends on the size of the nest; and Dr. Derham observed that the males were bred, or at least mostly reared, in the two cells or partitions, between the combs, next to the uppermost cell. The antennæ or horns of the male wasps are longer and larger than those of either of the other sorts; but the chief difference, says Dr. Derham, consists in their parts of generation, which are altogether different from those of other wasps.

The mules are the labourers belonging to the nest, and are employed in procuring materials for the nests, and in constructing them, and also in furnishing the other wasps, and the young, with provisions.

M. Reaumur has observed, that when the females that have survived the winter begin, at the return of spring, to lay their eggs, they first lay those which hatch mules, and at this time they build cells of a smaller size to lodge the eggs from which they are produced: they afterwards build larger cells, and fill them with the largest eggs, which are those of the males and females. This writer says, that the copulation of the males and females is visible, and he has given a particular account of it; observing that it is performed in October, like that of all other flies.

At the beginning of winter the wasps destroy all the eggs, and all the young ones without exception; all the mules and males which have been employed in this work, being unfur-

nished with provisions, perish; and none survive, except some few females, which, according to Reaumur, were fecundated in October, and raise a new colony in the beginning of spring.

The wasps construct regular combs, and rear their young in the cells of these combs, in the manner of bees: wherever there is a young worm in a cell, the old wasps frequently thrust their heads into it, and cast up the food, being a coarse kind of honey, for the young one out of their mouths: their cells are hexagonal; and when they have a mind to enlarge their habitations, and make more or bigger combs in them, they are seen very busily coming out of the mouth of the hole, every one loaded with a parcel of earth, till they have carried out as much as is necessary for the intended enlargement.

They support their combs, one over another, by cross-pieces of about an inch long, so that there is ample room for the wasps to pass in their several businesses. Those cells which stand in the centre of a comb are always perpendicular; the others all stand more or less obliquely; and in the centre, the comb is somewhat hollowed and depressed on the face, and convex on the back; and in this part is inserted the principal cross-piece that serves for a support.

A wasp's nest is commonly round, or oval, measuring about ten or twelve inches in diameter, and made of materials resembling the coarser kinds of whitish-brown paper. These materials consist of the fibres of various dry vegetable substances, agglutinated by a tenacious fluid, discharged from the mouths of the insects during their operations. The common covering of it, which is formed of several leaves or layers, with intermediate spaces, is pierced by two holes at a distance from one another, one of which is used for the entrance of the wasps, and the other only for their exit. The space within this covering is cut by a number of horizontal planes, with intervals between them of the size of about half an inch; they are suspended from one another by ligaments, and attached to the covering by their edges; they all have hexagonal cells in their lower surface.

The eggs, larvæ, or maggots of the wasp are of an oblong form, and resemble those of a common fly, but they are larger; they are always fastened to the angles of a cell, never to the sides of it. They are usually placed single: it is very rare to find two in one cell; and, if they are laid so, it seems that only one succeeds; for there is never found more than one worm in a cell.

The heads of all the nymphs are turned toward the centre of the comb, and their tails go obliquely downward toward the base of the cell. They are continually seen opening their mouths, and moving their forceps, seeming ever hungry, and impatiently waiting for food from their parents. The cells are left open till the nymph is at its full growth; then the wasps cover it over with a thin lid, under which the worm undergoes its transformation; and as soon as it arrives at the wasp state, it eats its way through this thin cover, and comes to work with the rest.

The wasps do not, like bees, prepare and lay up a store of honey for winter use, but the few which survive the season of their birth remain torpid during the colder months. Wasps in general are both carnivorous and frugivorous.

CRABRO; or Hornet. This has its thorax black on the fore part, and unspotted, having the incisions of the abdomen marked with a double contiguous black spot. This species is of a much more formidable nature than the common wasp, and of considerably larger size: its colour is a tawny yellow, with ferruginous and black bars and variegations. The nest of this species is generally built in the cavity of some decayed tree, or immediately beneath its roots; and not un-

frequently in timber-yards, and other similar situations. It is of smaller size than that of the wasp, and of a somewhat globular form, with an opening beneath; the exterior shell consisting of more or fewer layers of the same strong paper-like substance with that prepared by the wasp: the cells are also of a similar nature, but much fewer in number, and less elegantly composed. The hornet, like the wasp, is extremely voracious, and preys on almost any kind of fresh animal substances which it can obtain, as well as on honey, fruit, &c. &c. Its sting is greatly to be dreaded, and is often productive of very serious consequences.

A highly elegant wasp's-nest is sometimes seen during the summer season, attached, or hanging as it were, by its base to some straw or other projecting substance, from the upper part of unfrequented buildings or outhouses. It does not much exceed the size of an egg, but is of a more globular form, and consists of several concentric bells, with considerable intervals between each, the interior alone being entire, and furnished with a small round orifice; the rest reaching only about two-thirds from the base of the nest. In the centre of the complete or entire bell is situated the congeries of cells, built round a small central pillar attached to the base: the cells are not very numerous, and their orifices look downwards. This nest is attributed by M. Latreille, in the work entitled "Annales du Muséum National d'Histoire Naturelle," No. 4. to the *Vespa Holstatica* of Fabricius, and appears to be found both in England and France, as well as in many other parts of Europe. *Shaw's Zoology*, vol. vi.

Mr. Ray mentions a peculiar species of wasp, which builds a much smaller nest. This is usually fixed to a beam of some old building, and has only one aperture, which is about half an inch wide, and serves for the wasps to go in and out at. This aperture is always exactly opposite to that part of the hive where it adheres to the beam. The hive or nest is covered with a thin membranaceous substance resembling paper, of a brown colour, with streaks of white, disposed in regular circles. The whole nest is about three inches in diameter, and is usually composed of about nine combs; when these are cut away, there appears a round comb in the centre, and a smaller above it, fixed up by a pedicel arising from the centre of each. In every one of these cells, which are hexagonal, as those of the common wasp, is reared one worm, which, in fine, becomes a wasp.

The species of wasp which builds in this manner differs from the common wasp in that it is somewhat larger; it is smoother also, and has rings of a deeper yellow on the back: the black spots are not so regular in this as in the common wasp; and the forehead in this is of a perfect yellow, without any spots. These marks, with the difference of hanging a small nest against a beam, and building a large one in the ground, are sufficient to distinguish this as an absolutely different species. Besides these two, Mr. Ray mentions four other species of wasps.

We have an account in the *Philosophical Transactions*, No. 476, of some wasp-nests made of clay in Pennsylvania.

M. Reaumur, in his *History of Insects*, vol. vi. mentions clay-nests from St. Domingo, somewhat different from these.

The common wasp has four wings and six feet; its body is yellow, with black triangular spots: the common wasp breeds in the ground.

There is another kind much more fierce, but very rare: these breed in woods and mountains; they are larger, and have broader bodies, and much more black about them;

their sting is so large, that it seems disproportioned to the size of their bodies. The application of vinegar is said to be good against their stinging.

To these are to be added the ichneumon wasps, which are smaller than the others, and have very slender bodies, but of the same colours with the common kind; these usually live in the holes of mud-walls, and make a sort of porch of mud before the doors of their habitations.

Of this insect, Mr. Ray mentions not less than thirty-two species; the greater part of which are common on the sides of mud-banks in the borders of fields. These have all slender bodies, and are armed with stings.

The origin of this creature is very strange; it is usually found issuing from the body of the common cabbage caterpillar; the occasion of which is this: the parent fly strikes her tail through the skin of the back of this caterpillar, and deposits her eggs in the creature's flesh. The eggs hatch into small maggots of the carnivorous kind; and these prey upon the flesh of the caterpillar till they arrive at their full growth: the creature that supports them keeping itself alive all this time by the vast quantities of nourishment it is continually taking in. At length, when these worms are arrived at their full growth, they spin themselves a web, under which they change into chrysalides, and soon after come out in form of the fly that laid the egg. This is not peculiar to this single species of fly; but many are formed thus in the bodies of caterpillars of several kinds: some of these spin their webs under the skin of the caterpillar, and eat their way through it, when arrived at their perfect state; but others crawl out while yet in their worm state, after having eaten their full time, and bury themselves under ground in order to spin their webs.

There is also another wasp common about Vienna; this is three times as large as the common kind, and seems of two different species, the one having rough antennæ, and the other smooth: they are both variegated with black and a bright yellow. *Mouffet's Hist. Insects*, p. 6.

VESPA-Ichneumon. See the preceding article.

VESPASIE, in *Ancient Geography*, a place of Italy, in the country of the Sabines, on the summit of a mountain, six miles from Nursia. Many monuments indicating the antiquity of the Vespasian family, are found in this place, according to Suetonius.

VESPASIAN, TITUS FLAVIUS VESPASIANUS, in *Biography*, a Roman emperor, was born near Reate, in the country of the Sabines, A. D. 7, and brought up by his paternal grandmother near Cosa, in Tuscany. In the year 38 he was edile, and disgraced himself by his adulation of the tyrant Caligula: actuated by the same mean spirit, he married Domitia or Domitilla, the mistress of a Roman knight. In the reign of Claudius he distinguished himself by the command of a legion, obtained for him by the interest of Narcissus, first in Germany, and afterwards in Great Britain, and he was rewarded for his services by the triumphal ornaments, a double priesthood, and at last a consulate. During the early years of Nero's reign he lived in retirement, but at length he was appointed proconsul of Africa; and in this office he incurred the detestation of the people, according to Tacitus, whereas Suetonius says, that he discharged his duties with integrity and dignity. By way of reconciling these contradictory accounts, it has been stated, that in levying the public impositions on the province he was rigorous, whilst he exacted nothing for himself, and that he administered justice with impartiality. Upon his return he was reduced to pecuniary embarrassments, from which he was relieved by mortgaging his landed property, and by some mean practices. In the attentions expected from a

courtier he was deficient; for he is said to have fallen asleep during one of Nero's public musical performances, and to have thus hazarded his ruin. He accompanied this emperor in his tour to Greece, and A.D. 66, he was appointed imperial lieutenant in the Jewish war. In this station he had full scope for exhibiting his good qualities as a military commander. With three legions, a body of cavalry, and ten auxiliary cohorts, he invaded Judæa, his son Titus serving under him as lieutenant. His progress was irresistible; and after capturing Jotapa and Joppa, and reducing almost the whole of Galilee, he withdrew to Cæsarea, where he witnessed the conflict of two Jewish parties, who were destroying one another. Whilst he was preparing for the siege of Jerusalem, the death of Nero, A.D. 68, presented to him new prospects. As soon as he received intelligence of the accession of Galba, he sent his son Titus to pay homage to the new emperor; but on his journey Titus received an account of the murder of the emperor. This event produced a contest between Otho and Vitellius for the imperial throne. Vespasian declared for Vitellius, who, by Otho's death, was left in possession of the throne. But the new emperor was both hated and despised; and Vespasian's reputation was so generally acknowledged in the East, that in the year 69 he was proclaimed emperor by the legions of Judea, Syria, and Egypt, and his sovereignty was every where recognized. When Italy submitted to his name, Vespasian was at Alexandria; and as the senate and people concurred in his elevation to the imperial throne, he left this city A.D. 70, and hastened to Rome, where his arrival was eagerly expected. He was received with general congratulation and rejoicing; and his conduct confirmed the hopes that were entertained at the commencement of his reign. To the revival of the ancient discipline of the army his first attention was directed; and as soon as he assumed the censorial office, he revised the list of senators and knights, displacing the unworthy, and augmenting the number by the admission of several meritorious citizens. Whilst he restrained luxury by his example and authority, and administered justice with impartiality, he manifested in his general conduct the clemency and mildness of his disposition. He avoided every kind of parade, nor did he ever attempt to disguise the meanness of his origin. With the senators he lived upon easy and familiar terms, receiving and returning their visits; and, as an historian observes, acting the emperor only by his vigilance for the public welfare. The principal blemish of his character was his avarice. Accordingly, he had recourse to various mean and oppressive expedients for raising money. Nevertheless, the wealth which he accumulated by forcible methods was distributed with munificence, in improving the capital and the country, and in providing for poor senators, for literary professors, and for the encouragement of the arts.

If we advert to the public events of his reign, the first year was distinguished by the termination of the rebellion of the Gauls under Civilis, and the capture of Jerusalem by Titus; and in the following year he shut the temple of Janus, and erected a magnificent temple to Peace. In the year 72, Comagene was reduced to a Roman province by the deposition of its king Antiochus. The liberty granted to the people of Greece by Nero, in recompence of their adulation, was restricted A.D. 73, on account of some tumults which occurred, and they were again subjected to tribute and the Roman government. The islands of the Ægean sea were likewise constituted a Roman province, and Rhodes was made the metropolis. The honour of this reign was justly reproached for the death of the virtuous patriot Helvidius Priscus, who, for freedom of speech, and action scarcely

compatible with monarchical government, was first banished and afterwards sentenced to death by the senate, a sentence which, it is said, was executed by the contrivance of Murcianus, contrary to the orders of Vespasian. The tragical fate of Sabinus, and his wife Eponina, was very derogatory to the character for clemency by which he was distinguished. (See SABINUS.) Vespasian has also been blamed for the banishment of the Stoic and Cynic philosophers from Rome, under an apprehension that they were enemies to absolute power. This emperor, having enjoyed the benefit of a good constitution to advanced age, was attacked with a fever in the insalubrious climate of Campania, and having drank too copiously of a cold mineral water, he was seized with a complaint in his bowels, which soon reduced him to a state of perilous debility. Apprised of his danger, and jesting upon the usual imperial apotheosis, he said, "In my opinion, I am going to become a god." Afterwards, as he found himself fainting, he attempted to rise out of his bed, observing, that "an emperor ought to die standing." He expired in the arms of his attendants, in June A.D. 79, in the seventieth year of his age, and tenth of his reign; lamented by the Roman people, who under his government had enjoyed several years of peace. Titus, one of his sons, was the great support of his father's throne, and the other, Domitian, was the cause of much trouble and vexation to him. Tacitus. Suetonius. Crevier.

VESPER, in *Astronomy*, called also *Hesperus*, and the *evening star*, is the planet Venus, when she is eastward of the sun, and consequently sets after him. See VENUS.

VESPER, in *Geography*, a small island in the Pacific ocean, about 36 miles in circumference, discovered by Roggewin in 1722; about 60 miles W. of Pernicious island.

VESPERIES, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Varduli; situated N.E. of Flaviobriga.

VESPERS, in the *Romish Church*, *Evening Song*, that part of the office which is rehearsed after noon; answering to our *evening prayers*; except that it differs more from the office of the morning, called *matins*.

VESPERS, *Sicilian*, denote a famous era in the French history; or a general massacre of all the French in Sicily, in the year 1282, to which the first toll that called to vespers was the signal.

Some will have it to have happened on Easter eve; others on the day of the Annunciation; but most authors assign it to Easter day. It is ascribed to one Prochites, a Cordelier, at the time when Charles of Anjou, count of Provence, was king of Naples and Sicily. The women with child by Frenchmen were not spared.

After the like manner we say, *the matins of Moscow*, speaking of the Muscovites assassinating their prince Demetrius, and all the Poles, his adherents, at Moscow, the 27th of May, 1600, under the conduct of their duke Choutky, at six o'clock in the morning; and *French matins* to the massacre of St. Bartholomew, in 1572.

VESPERTILIO, *Bat*, in *Zoology*, a genus of the order Primates, in the class of Mammalia; which, though ranked by Linnæus in the order of Primates, differs greatly from the rest. The characters of this genus are, that the teeth are erect, sharp-pointed, and approximated; and that the hands are palmated with a membrane surrounding the body, and giving the animal the power of flight. Dr. Shaw observes, that the curious formation of these animals cannot be contemplated without admiration; the bones of the extremities being continued into long and thin processes, connected by a most delicate membrane or skin, capable, from its thinness, of being contracted at pleasure into innumerable wrinkles,

VESPERTILIO.

wrinkles, so as to lie in a small space when the animal is at rest, and to be stretched to a very wide extent for occasional flight. The species of this extraordinary genus are numerous, and may be divided into the *tailed* and *tailless* bats. Gmelin, in his edition of the Linnæan System, enumerates twenty-three species, and distributes them into several divisions, according to the number of the fore-teeth in the upper and lower jaw.

* *Bats with four Fore-teeth in both Jaws.*

VAMPYRUS. Tailless bat, with the nose simple, or without any appendage, and the flying membrane divided between the thighs. This is the ternate bat of Pennant; and this, or the variety α of Gmelin, the colour of which is chiefly black, is the *V. ingens* of Clusius, the *V. volans* of Bontius, the *chien volant* of Daubenton, and *rouffette* of Buffon. Gmelin enumerates two other varieties, differing in size and colour; one the great bat of Edwards, or *rouffette* of Buffon; and the other the lesser ternate bat of Pennant. See **VAMPYRE**.

SPECTRUM. Tailless bat, with a funnel-shaped, sharp-pointed membrane on the nose. This is the *andira guacu*, *vespertilio cornutus* of Pifo, the *vampyre* of Buffon, or *spéctre* bat of Pennant. See **VAMPYRE**.

PERSPICILLATUS. A tailless bat, with a nose furnished with a plane leaf acuminate. This is found in South America, and is supposed by some to be the *javelin* bat of Pennant.

SPASMA. A tailless bat, with a doubly heart-shaped leaf-like membrane on the nose. This is the *glis volans ternatanus* of Seba, and cordated bat of Pennant. The colour is reddish-brown; the extent of wing about fifteen inches, and length of body nearly four inches: it is a native of Ceylon and the Molucca islands.

HASTATUS. A tailless bat, with a trefoil-shaped upright membrane on the nose. This is the *javelin* bat of Pennant, with large pointed ears, a membrane at the nose in the form of an ancient javelin, with two upright processes on each side, cinereous fur, and of the size of the common bat: synonymous, according to Pennant, with the *V. perspicillatus* of Linnæus, and inhabiting the warmer parts of America.

SORICINUS. A tailless bat, with lengthened snout, furnished with a heart-shaped, leaf-like membrane. This is the leaf bat of Pennant, and bat from Jamaica of Edwards; with small rounded ears, a web between the hind-legs; fur of a mouse-colour, tinged with red, and size of the common bat. Found in South America.

LEPORINUS. Tailed bat, with the upper lip bifid. This is the Peruvian bat of Pennant. It has a head resembling that of a pug-dog; the ears are large and fraight, sharp at the ends, and pointing forwards; tail inclosed in the membrane which joins to each hind-leg, and supported by two long cartilaginous ligaments, involved in the membrane; colour of the fur iron-grey; body of the size of a middling rat, and extent of wing two feet five inches.

* * *Fore-teeth in the upper Jaw four, in the lower six.*

AURITUS. Tailed bat, with simple or inappendiculated mouth and nose, and double ears larger than the head. This is the long-eared English bat of Edwards, the *oreiller* of Buffon, and the long-eared bat of Pennant. This very much resembles the next species, but is rather smaller, and the fur has less of the reddish tinge; but it is distinguished by the very large size of the ears, which are more than an inch long, and furnished internally with a kind of secondary auricle or internal flap, so placed as to serve by way of a valve or guard to the auditory passage.

MURINUS. Tailed bat, with simple nose, and ears smaller than the head. This is the *chauve-fouris* of Buffon, the short-eared English bat of Edwards, and the common bat of Pennant. It is about two inches and a half from the nose to the tip of the tail, and the extent of the wings, fully expanded, is about nine inches: it is of a mouse-colour, tinged with reddish; the wings and ears black, the latter being small and rounded.

This and the former bats are the two most common species in this country; and they are those which are seen fluttering about in the evenings of summer and autumn; often uttering a sharp, frigidulous note or scream during their flight, and pursuing the various insects on which they feed, particularly moths. They are sometimes taken by throwing up the heads of burdock whitened with flour, being thus caught by the hooked prickles and brought to the ground. The bat is, like the mouse, capable of being tamed to a certain degree. Insects are its favourite food, though it will not reject raw flesh when offered; so that the notion that bats go down chimneys and gnaw men's bacon is not improbable. The vulgar opinion, that bats, when on a flat surface, cannot get on the wing again, is erroneous. Bats are commonly supposed to produce two at a birth, which they suckle for a considerable time. When recently born, they adhere so tenaciously to the breast of the parent, as not to be removed without great difficulty: they lodge in great numbers in the cavities of old buildings, under the projections of walls, in the hollows of trees, in rocky places, &c. &c. In these recesses they lie torpid during winter, till the warmth of the vernal atmosphere invites them abroad to make their evening excursions. When taken torpid, and brought into a warm situation, they awake from their slumber, and again expand their wings. During their state of torpidity, the circulation of the blood is not perceivable in the smaller vessels, but when awakened by warmth, it becomes visible by the microscope. Bats are said to drink on the wing by sipping the surface, like swallows, as they play over pools and streams. They are fond of frequenting waters, not only for the sake of drinking, but on account of the insects that hover over them. The general appearance of the bat, together with its nocturnal flight, excites the idea of something that is hideous and dismal; and therefore the ancients consecrated it to Proserpine, and conceived it as one of her dusky regions; and hence painters, in their representations of fiends and demons, usually exhibit them with the leathern wings of the bat. It is also no less evident, that the larger bats of India and Africa might, by a little poetical exaggeration, serve very well in a general description of the fabulous Harpies. Spallanzani, having found that bats would fly in the darkest chamber with precision, and without touching the walls, discovered also the same exactness in their motions, when their eyes were closely covered; and he even destroyed the eyes and covered their sockets with leather; and in this state they were equally accurate in all their movements. Similar experiments were tried by several other naturalists with the same result. In order to account for these phenomena, professor Jurin of Geneva makes a variety of pertinent observations. Neither the touch, nor ear, nor smell, nor taste, is sufficient in his opinion to supply the want of sight; but from some anatomical investigations of these animals, he concluded that a very large proportion of nerves is expanded on the upper jaw, the muzzle, and the organ of hearing; and these appeared to him, in a great degree, to account for the extraordinary faculty above-mentioned. Mr. Carlisle's observations on this subject led us to conclude that the sense of hearing in the bat is extremely delicate, and that this is one of the principal causes

VESPERTILIO.

of the dexterity with which these animals, even when blinded, avoid objects which would impede their flight. Mr. Carlisle found, that when the external ears of the *V. auritus* in a state of blindness were closed, it struck against the sides of the room, without being at all aware of its situation. These bats refused every kind of food for four days, as was also the case with others which were preferred in a dark box for above a week. During the day-time they were very desirous of retirement and darkness; and, while confined to the box, never moved nor endeavoured to get out during the whole day, and when spread on the carpet, they crawled slowly to a dark corner or crevice. At sun-set the scene was quite changed; every one of them then endeavoured to scratch its way out of the box; a continued chirping was heard, and no sooner was the lid of their prison opened than each was active to escape, either flying away immediately, or running nimbly to a convenient place for taking wing. When these bats were first collected, several of the females had young ones clinging to their breasts in the act of sucking. One of them flew with perfect ease, though two little ones were thus attached to her, which weighed nearly as much as their parent. All the young were destitute of down, and of a black colour.

NOCTULA. Tailed bat, with nose and mouth simple; oval ears, and very small valves. This is the noctule of Buffon, and great bat of Pennant. This species is larger than the *V. auritus*, its extended wings measuring from fourteen to fifteen inches; the length from the nose to the tip of the tail being about four inches and a half; the nose is slightly bilobed; the eyes are small and rounded; the body is fleshy and plump; the shoulders very thick and muscular; the fur very soft and glossy, and of a bright chestnut-colour. This is an inhabitant of Britain and France; and is said to be common in some parts of Russia, sheltering in caverns. It flies high in the air in search of food, and does not skim near the surface, like the smaller bats. It has been found occasionally in great numbers under the eaves of old buildings, and its smell is generally strong and unpleasant.

SEROTINUS. Tailed yellowish bat, with short emarginated ears. This is the serotine of Buffon; its length from nose to rump two inches and a half. A native of France, and found in Russia.

PIPISTRELLUS. Tailed blackish-brown bat, with convex front and ovate emarginated ears, scarcely longer than the head. The pipistrelle of Buffon and of Pennant. This is a small species, and found in France. The length from nose to rump scarcely an inch and a quarter; the extent of wings somewhat more than six inches.

BARBASTELLUS. Tailed bat, with elevated hairy cheeks, and large ears angulated on the lower part. The barbastelle of Buffon and of Pennant. Length about two inches from nose to tail; extent about ten inches; upper part of the body dusky-brown, lower part ash-coloured; ears broad and long; nose short; cheeks full; and end of the nose flattened. Found in France.

HISPIDUS. Tailed hairy bat, with channelled nostrils, and long narrow ears. The bearded bat of Pennant; a small species: above reddish-brown; beneath whitish, tinged with yellow; nostrils open; hair on the forehead and under the chin very long; tail included in a very veiny membrane.

*** *Fore-teeth in the upper Jaw four, in the lower eight.*

PICTUS. Tailed bat, with simple nose, and funnel-shaped appendiculated ears. The autre chauve-fouris of Buffon, and striped bat of Pennant. A Ceylonese species, measuring from nose to the end of the tail two inches; above

brown; wings striped with black, or with tawny and brown; changing in colour of the body, which is reddish-brown, with the under parts whitish; the nose small and short; the ears short, broad, and pointing forwards.

**** *Fore-teeth in the upper Jaw two, in the lower six.*

NIGRITA. Tailed yellowish-brown bat, with the fore-part of the head, the feet, and the tail black. The Senegal bat of Pennant, with a long head, nose a little pointed, ears short and pointed, head and body tawny-brown, mixed with ash-colour; under parts paler; the two last joints of the tail extending beyond the membrane; length from nose to rump above four inches; extent of wing twenty-one inches. A native of Senegal.

**** *Fore-teeth in the upper Jaw two, in the lower four.*

MOLOSSUS. Tailed bat, with pendulous upper lip, and long tail, stretching beyond the connecting membrane. This is the bull-dog bat of Pennant, which has a thick nose; broad and round ears; the upper part of the body of a deep ash-colour, the lower paler; the five last joints of the tail disengaged from the membrane; length above two inches; extent of wings nine and a half. Found in the West Indies.

Gmelin reckons two varieties, one greater, the autre chauve-fouris of Buffon, and the other lesser, the autre chauve-fouris of Buffon. Found in the American islands.

***** *Fore-teeth in the upper Jaw two, in the lower none.*

CEPHALOTES. Tailed yellowish-grey bat, with large head, extended lips, spiral nostrils, subocular warts, and small ears without valves. This is a native of the Molucca Isles: the end of the tail reaches beyond the membrane; the tongue covered with papillæ and minute spines; the claw or thumb joined to the wing by a membrane, and the first ray of the wing terminated by a claw; the head and back of a greyish-ash colour; length from nose to rump three inches and three-quarters; extent of wings about fifteen.

***** *Fore-teeth in the upper Jaw none, in the lower four.*

LEPTURUS. Tailed bat, with tubular nostrils, slender tail, and a purse-shaped cavity on the interior part of each of the wings. This is the pouched bat of Pennant. The colour of the body is cinereous-brown; the under parts paler; length an inch and a half. A native of Surinam.

FERRUM EQUINUM. Bat with horse-shoe shaped nose; ears without valves; and tail half the length of the body. This is the fer-a-cheval of Buffon. The upper part of the body is deep cinereous; the lower part whitish. Gmelin mentions two varieties, greater and smaller, which may be the male and female, the greater above three inches and a half long from the nose to the tip of the tail, and extent of the wings above fourteen. Found in France, very rarely in England; also about the Caspian sea.

***** *No Fore-teeth.*

NOVERORACENSIS. Long-tailed ferruginous bat, with short sharp nose, short round ears, and white spot at the base of each wing. This is the New York bat of Pennant; $2\frac{1}{2}$ inches long from nose to tail; tail $1\frac{1}{3}$ inch; extent of wings $10\frac{1}{2}$ inches; head shaped like that of a mouse; tip of the nose bifid; tail included in a conic-shaped membrane; head, body, and upper side of the membrane inclosing the tail, covered with long soft hair of a bright tawny colour; the wings thin, naked, and dusky, and the

bones of the hind legs very slender. A native of North America, and also found in New Zealand.

***** *Number and Order of Fore-teeth unknown to Gmelin.*

LASIOPTERUS. Tailed bat, with the membrane connecting the feet very broad, and covered on the upper part with hair. The forehead of this species, which is one of the largest, is very prominent and rounded; nose short; general colour ferruginous; the upper part of the wings of a paler cast; the ends and lower parts black.

LASIURUS. Tailed bat, with tumid lips, and broad hairy tail. A small species, of unknown native country, with upright small ears; tail broad at the base, terminating in a point thickly covered with hair; colour reddish-brown.

Dr. Shaw adds the following species, *viz.*

AURIPENDULUS. Tailed bat, with obtuse nose, and large pendent ears, with pointed tips. This is the fouchereed bat of Pennant; tail long, included in a membrane, and terminated with a hook; colour above deep chestnut, lighter on the belly, cinereous on the sides; length three inches and four lines; extent of wing fifteen inches. Native of Guiana.

NASUTUS. Tailless ferruginous bat, with long nose, flogging at the tip; and long upright rounded ears. This is the great serotine of Pennant; colour of the upper parts a reddish-chestnut; sides of a clear yellow; remainder of a dirty white; length five inches eight lines; extent of wings two feet. A native of Guiana, assembling in great numbers in meadows and other open places; flying in company with goat-suckers in such multitudes as to darken the air.

SPEORIS. Tailed bat, with a transverse frontal cavity. This is the pit-nose bat, and from Schreber's description appears to be about the size of the common bat, and to resemble it in its general aspect, but differing in colour, which is a pale yellowish ash-brown. Its principal character, though not peculiar to it, is a remarkable transverse concavity situated on the forehead, lined with a naked blackish skin; the nostrils seated in a similar concavity at the tip of the nose. A native of India.

VESPERTILIO, in *Conchology*, the name of an elegant species of voluta, supposed to have some resemblance to the colour of a bat.

VESPERTILIONUM ALÆ, *Bats' Wings*, among *Anatomists*, two broad membranous ligaments, with which the bottom of the womb is tied to the bones of the ilium; they are so called from their resembling the wings of a bat.

VESPERTINE, VESPERTINUS, in *Astronomy*, is when a planet is seen descending to the west after sun-set.

VESPIVORUS BUTEO, in *Ornithology*, a name given by some authors to the bird, called in English the honey-buzzard, from its feeding its young with the maggot worms out of honey-combs. See **APIVORUS**.

VESPOLA, in *Ancient Geography*. See **VESBOLA**.

VESPOLATE, in *Geography*, a town of Italy, in the department of the Gogna; 6 miles S. of Novara.

VESPRIN, a town of Hungary, the see of a bishop; 16 miles S.W. of Stuhl Weissenburg. N. lat. 47° 4'. E. long. 17° 49'.

VESPUCCI, AMERIGO, in *Biography*, was the son of a Florentine of noble family, and became famous by giving name to the largest quarter of the world. He was born in 1451, and having been educated under a paternal uncle, he was sent by his father, in the year 1490, to conduct a com-

mercial concern in Spain. At Seville he was informed of the discoveries made by Columbus, and imbibed the desire of distinguishing himself by a similar pursuit. Whether he had been previously engaged in any nautical expeditions has been a subject of controversy, since he has claimed the honour of being the first discoverer of the American continent. Of himself he says, that having been engaged by Ferdinand, king of Spain, to prosecute the discoveries in the New World, he sailed from Cadiz in May 1497, and after touching at the Canaries, arrived in thirty-seven days at a land which he conceived to be Terra Firma; and if this account be true, he must have anticipated Columbus's view of the coast of Paria by a whole year. But this expedition depends merely on his own statement; and if we consider the high estimation in which Columbus was held, in the year 1497, at the court of Ferdinand and Isabella, and that he possessed the privileges of viceroy and governor of all the newly discovered countries, we cannot suppose it credible, that any other person should be employed to prosecute the object above stated. Accordingly it has been generally believed, that Vespucci's account of his first voyage is a mere fiction, or that it is antedated, in order to support his own claims. It has also been disputed, whether in the voyage which he really made in 1499, Vespucci was a commander or merely a passenger. It is most probable that he was a passenger, and that being skilful in astronomy, a science at that time imperfectly understood, he was very useful to the navigators, and much esteemed by them. After his return he resided for some time at Seville; and upon being repeatedly invited to the court of Manuel, king of Portugal, he secretly quitted Spain, and went to Lisbon, where the king engaged him to undertake a voyage of discovery. With this view he had the command of three vessels, and sailed in May 1501, making land 5° S. of the equinoctial line, which must have been Brazil, though he has not mentioned it. Herrera, however, asserts, that at this time he was with Ojedo in the gulf of Darien, and the discovery of Brazil is attributed by the Portuguese to Cabral in the year 1500. But it appears from the testimony of Peter Martyr, a contemporary writer, that Vespucci really sailed in the service of Portugal some degrees to the south of the line. In May, 1503, he proposed in another voyage pursuing his course to the East Indies, but was thrown on the coast of Brazil, and moored in the bay of All-Saints, to which he gave name; and from thence he returned to Lisbon in 1504. Being again taken into the service of Spain, he resided at Seville in 1507, with the title of pilot-major and a yearly pension, in consideration of marking out the tracks to be followed by navigators, with the power of examining all pilots. This employment afforded him an opportunity of connecting his own name with new discoveries; and as he drew charts for mariners, he distinguished the newly discovered countries by the name of "America," as if it were "Amerigo's Land;" so that the true discoverer, notwithstanding the complaints of the Spaniards, was defrauded of the honour that belonged to him. Vespucci, however, cannot vie in the public estimation with Columbus. He is supposed to have died in 1516, and to have been buried on one of the Azores. Vespucci drew up a compendium of his four voyages, which was first published by Simon Grineus, in his "Novus Orbis," at Basil, in 1537, and afterwards in Ramusio's Collections. The Italian originals were afterwards discovered and published by Bandini. Tiraboschi. Gen. Biog.

VESSA, in *Ancient Geography*, a large and flourishing town of Sicily. Phalaris is said to have taken possession of it by stratagem from Tautus, its prince.

VESSAUX,

VESSAUX, in *Geography*, a town of France, in the department of the Ardèche; 9 miles S.W. of Privas.

VESSEL, *VAS*, *Vafe*, a thing proper to hold or contain liquor. See *VAS*.

Thus, a ton, or hoghead, &c. are vessels fit to contain ale, wine, &c.

The chemists use a great diversity of vessels in their operations; as copper alembics, with their refrigeratories; worms and receivers; alembics of glass, stone, and earthen-ware; adopters, or small receivers with two necks; aludels, balloons, bottles, glass jars and basons of various sizes; cap-sules, or dishes of glass, stone-ware, crystal glass, crucible earth, and plate-iron; the cone, crucibles, glass funnels, ingot moulds, matrasles, mortars, muffles, pelicans, retorts, receivers, circulatory vessels, lubrifying vessels, &c. See each article. See also *LABORATORY*.

Among anatomists, &c. all the tubes or canals in which the blood, and other juices or humours, are secreted, conveyed, deposited, &c. as the veins, arteries, lymphatics, spermatics, &c. are called vessels.

Some even extend the word vessel to the nerves; as supposing them the conduits of the animal spirits.

VESSEL, a general name given to the different sorts of ships, from the first-rate man-of-war to the smallest, which are navigated with masts and sails. It is, however, more particularly applied to those of the smaller kind. *Plate VI.* will represent most European vessels, with little description. The *first-rate* is a ship of the line, of one hundred guns and upwards, having three decks or tiers of guns; and the *seventy-four* is also of the line, with two decks or tiers of guns. The *gun-vessel* is rigged like a sloop of war, which is the sixth or smallest rate. The *brig* has only two masts, which are rigged like the main and fore masts of a ship, but has a fore and aft main-sail. A *sloop* only differs from a brig by having a try-sail, which hoists upon a small mast abaft the main-mast, and thereby can carry a square main-sail. A *ketch* has two masts, similar to the brig, but has no fore-mast, but a main-mast and a mizen-mast rigged as a ship's. The *lugger* has two masts, with square sails that are hoisted by their yards, not in the middle, as vessels in general, but at one-third of their length. *Schooners* are vessels of a similar size to luggers, having two masts, whose main-sail and fore-sail are suspended from gaffs at the head; and the foot stretched out by a boom, like a man-of-war's long-boat. Both luggers and schooners sometimes carry top-sails, as the brig. *Sloops*, or vessels having one mast, have a main-sail, fore-sail, and jib, as the man-of-war's long-boat. Foreign vessels, not rigged like the above, are mostly like the *xebec*; which see.

A vessel is said to be of *three or four hundred tons*; meaning, that it will carry three or four hundred times two thousand weight; or that, when immersed in water, it possesses the space of three or four hundred tons of water; which are equal to the weight of the vessel, and all the loading it can carry.

A vessel is said to *draw ten or fifteen feet of water*; meaning, that when laden, it sinks to deep under water.

The figure of vessels is an object of great importance, with regard to their motion, sailing, &c.; and in the determining what form is most commodious, the new doctrine of infinites becomes of apparent service to navigation and commerce.

A body moving in an immoveable fluid, is obliged to sever the parts thereof: and they resist such separation.—Now, setting aside a certain tenacity, by which they are, as it were, glued together, and which is different in different fluids; the whole force of the resistance depends on that of

the shock, or impulse: for a body that is struck, strikes at the same time; but a perpendicular stroke is that which a liquid resists the most, as being the greatest; and for a body to move freely therein, it must be of such figure, as to present itself as obliquely as possible. If it were triangular, and moved with the point foremost, it is certain all its parts would strike the fluid obliquely; but they would all strike it with the same obliquity; and it were more advantageous that each should strike more obliquely than the next adjacent.

Now, such a perpetual augmentation of obliquity can no where be had in a curve line; each point of which is considered as an infinitely small right line, always inclined to the other little right lines contiguous to it.

To find what curve it is, whose perpetual change of obliquity, or inclination in all its parts, renders it, of all others, the fittest to divide the fluid easily, is a problem much more difficult than it appears to be, and, in effect, is only to be solved by the new geometry; the solution was first given by sir Isaac Newton, in his investigation of the solid of the least resistance.

That author, however, did not publish his analysis; yet the marquis de l'Hôpital hit upon it; and afterwards M. Fatio resolved the same problem, though by a much longer, and more perplexed way. See *Solid of the least RESISTANCE*, *SHIP*, and *SHIP-BUILDING*.

VESSELS, *Book of*. See *BOOK*.

VESSEL *Bay*, in *Geography*, a bay on the E. coast of lake Champlain.

VESSIEGONSK, a town of Russia, in the government of Tver; 48 miles N.N.E. of Tver. N. lat. 58° 20'. E. long. 37° 34'.

VESSION, a term formerly applied to the puffy swelling termed *wind-gall* on the legs of animals. It is sometimes written *veffion*.

VEST, and VESTITURE. See *INVESTITURE*.

VESTA, in *Astronomy*, one of the new planets, which was discovered by Dr. Olbers in March 1807, and observed by S. Groombridge, esq. at Blackheath, near London, in April of the same year. For an account of this planet, see *PLANET*, *Planetary NUMBERS*, and *Solar SYSTEM*.

VESTA, in *Mythology*, one of the principal deities of the Pagans.

Those who have diligently investigated the religion of the Pythagorean philosophers pretend, that by Vesta they meant the universe, to which they ascribed a soul, and which they worshipped as the sole divinity, sometimes under the name of *το πᾶν*, the *universe*, and sometimes under the appellation of *μονο*, *unity*. However, fabulous history records two goddesses under the name of Vesta; one the mother of Saturn, and wife of Caelum, and the other the daughter of Saturn, by his wife Rhea. The first was Terra, or the Earth, called also Cybele, and derived her name Vesta, according to some, from clothing, because the earth is clothed, *vestitur*, with plants and fruits, or, according to Ovid, from the stability of the earth, because *stat vi terra sua*, or it supports itself. Hence the first oblations in all sacrifices were offered to her, because whatsoever is sacrificed springs from the earth; and the Greeks both began and concluded their sacrifices with Vesta, because they esteemed her the mother of all the gods. The second was fire, and Vesta, whose power was exercised about altars and houses, derives her name, according to Cicero, from *iva*, *fire* or *heart*. Accordingly the poets frequently use Vesta for fire or flame; as they do Jupiter for air, Ceres for corn, &c. An image of Vesta, to which they sacrificed every day, was placed before the doors of the houses at Rome; and the places where these statues

were erected were called *vesfibula*, from *Vesta*. This goddess was a virgin, and so great an admirer of virginity, that when Jupiter her brother gave her leave to ask what she would, she besought that she might always be a virgin, and have the first oblations in all sacrifices.

This goddess is called by Horace *ætæna Vesta*, and it was in honour of her that Numa erected a temple at Rome, and dedicated virgins to keep a perpetual fire upon her altars, "ut ad simulacrum cœlestium siderum cultus imperii flamma vigilaret," as Florus says. One way of representing this goddess, it is said, was in the habit of a matron, holding in her right hand a flambeau or lamp, and sometimes a Palladium, or small Victory. Mr. Spence, however, doubts, whether the figures, that are generally looked upon as *Vestas*, do really represent that goddess or not. There is nothing, he says, which he has seen, that would not be as proper for one of the vestal virgins, as for the goddess who presided over them. To this purpose Ovid expressly says (*Fast.* vi. ver. 298.) they had no representations of this goddess: "effigiem nullam Vesta nec ignis habent." And he explains away another passage in the third book of his *Fasts*, ver. 46. where he speaks of a figure of *Vesta*. (*Polymetis*, p. 82.) The titles that are given to *Vesta* upon medals and ancient monuments are, *Vesta* the Happy, the Mother, the Saint, the Eternal, &c. The worship of *Vesta* and of fire was brought from Phrygia into Italy by *Æneas* and the other Trojans who resorted thither. To this purpose Virgil observes (*Æn.* lib. ii.) that *Æneas*, before he left the palace of his father, had taken away the fire from the sacred hearth: "Æternunque adytis effert penetralibus ignem."

Vesta was one of the eight great gods of the Egyptians, often mentioned by Herodotus.

The name *Vesta*, called by the Greeks *Ἥστια*, was synonymous with the Chaldee and Persian *Avesta*; and hence, according to the learned Hyde, Zoroaster gave to his famous book on the worship of fire, the name of *Avesta*, or *Avesta*, *i. e.* the custody of fire.

VESTALIA, feasts held in honour of the goddess *Vesta*, on the fifth of the ides of June; *i. e.* on the ninth day of that month.

On that day, banquets were made before the houses; and meats were sent to the Vestals, to be offered by them to the goddesses. See VESTALS.

The asses, that turned the mills for grinding corn, were, on this occasion, led about the city, crowned with flowers, and chaplets formed of pieces of bread; and the mill-stones were likewise decked with garlands and crowns.

The ladies went barefooted in procession to the temple of *Vesta*; and an altar was erected to Jupiter the Baker, *Jovi Pistori*, in the Capitol.

The Vestalia had their names from that of their goddesses *Vesta*.

VESTALS, VESTALES, in *Antiquity*, virgins in ancient Rome, consecrated to the service of the goddess *Vesta*; and particularly to watch the sacred fire in her temple.

Numa first instituted four Vestals; and Plutarch tells us, Servius Tullius added two more; but Dionysius Halicarnassus and Valerius Maximus ascribe this augmentation to Tarquinius Priscus; which number, six, lasted as long as the worship of the goddess *Vesta*. The Vestals made a vow of perpetual virginity; their employment was, the sacrificing to *Vesta*, and keeping up the holy fire in her temple. If they violated the vows of chastity, they were punished with remarkable severity; being shut up, or buried, in a deep pit, or cavern, in a place called "agger et sceleratus campus," with a lighted lamp, and a little water and milk, and there left to be devoured by hunger. If they let out

the fire, they were whipped by the pontifex maximus; and the fire was rekindled by the fun-beams. It is said, that they always lighted it anew on the first of March in every year, whether it had gone out or not.

To be secure of their virginity, at their admission, it was provided, that they should not be under six, nor above ten years old. They were chosen by lot, out of twenty virgins, carried by the pontiff to the comitia, for that purpose.

They were only consecrated for thirty years; after which time they were at liberty to go out, and be married. If they continued in the house after that time, they were only to be assistants, in point of advice, to the other Vestals.

The first ten years they were to employ in learning their functions; the ten following they were to exercise them; and the last ten, to teach them to others.

Their order was very rich; both on account of the endowments of the emperors, and of legacies of other persons.

The Vestals had a particular place allotted them at the amphitheatres and games of the Circus. Their vehicle was the carpentum, or plentium. The veil in which they sacrificed was called *stibulum*.

At first, they were nominated by the kings; but after the extinction of monarchy, by the pontifex maximus, or high-priest. The eldest of them was called *maxima*, as the first pontiff was *maximus*.

They had divers privileges; disposed of their effects by testament, in their father's life-time; had the same gratification as a mother of three children; and whenever they met a criminal going to execution, they had a power to pardon him. Whenever they went abroad, they had the fables carried before them, a consul, or the prætor, being obliged to give way to them.

The fire which the Vestals were to watch, was not on an altar, or an hearth, but in little earthen vessels with two handles, called *capuduncula*.

This fire was held a pledge of the empire of the world. If it went out, it was judged a very unlucky prognostic, and was to be expiated with infinite ceremonies. Among the Romans, Festus tells us, it was only to be rekindled by the rubbing a kind of wood, proper for the purpose. But among the Greeks, Plutarch, in the life of Numa, observes, it was to be rekindled by exposing some inflammable matter in the centre of a concave vessel held to the sun. For it is to be noted, the Romans were not the only people who kept the perpetual fire of *Vesta*, in imitation of the celestial fires; but the Greeks were possessed with the same superstition; particularly the Delphians, Athenians, Tenedians, Argives, Rhodians, Cyziceniens, Milesians, Ephesians, &c.

This order of Vestals is said to have subsisted about a thousand years, *i. e.* from the time of Numa to that of the emperor Theodosius. See SIBYLS.

VESTALS Ferry, in *Geography*, a town of Virginia, on the Shennando; 18 miles N.W. of Leesburg.

VESTED LEGACY. See CONTINGENT Legacy.

VESTED Remainder. See REMAINDER.

VESTIARIUS, VESTIARY, in *Antiquity*, master of the wardrobe; an officer under the Greek empire, who had the care and direction of the emperor's apparel, robes, &c.

The *proto-vestiarius*, or first vestiary, was the grandmaster of the wardrobe. But among the Romans, *vestiarius* simply was only a fileman, or taylor.

VESTIBULE, VESTIBULUM, in the *Ancient Architecture*, a large open space before the door, or entrance, of a house.

Martinus derives the word from *vesta stabulum*; because the fore-part of the house was dedicated to *Vesta*. Daviler derives

derives it from *vestis* and *ambulo*; because people there begin to let their trains fall.

The Romans had places called vestibules, at the entrance of their houses, to shelter people obliged to stand at the door from the weather; and we have still vestibules of the like kind, in many old churches, houses, &c. called *porches*.

Vestibules only intended for magnificence, are usually between the court and the garden: these are sometimes *simple*; that is, have their opposite sides equally enriched with arches; and sometimes their plan is not contained under four equal lines, or a circular one, but forms several van-corps, and rear-corps, furnished with pilasters.

VESTIBULE is also used for a kind of little anti-chamber before the entrance of an ordinary apartment.

VESTIBULE is also an apartment in large buildings, which presents itself at the entrance into a hall or suite of rooms, or offices. The area, in which a magnificent staircase is carried up, is sometimes called a vestibule. And also when the ends of corridors, or passages, terminate in a room, without being separated from them by doors, either to receive light or air, or for appearance; such rooms are called vestibules.

VESTIBULUM, in *Anatomy*, a cavity belonging to the labyrinth of the ear. See EAR.

VESTIGIA, a Latin term frequently used by English writers, to signify the traces or footsteps any thing has left behind it.

The word is particularly applied to the marks remaining of something antique, gone to ruin by time.

VESTINCH, in *Geography*, a town of Bosnia; 44 miles S. of Bihacs.

VESTINI, in *Ancient Geography*, a people of Italy, regarded as Samnites; but being of Sabin origin, they were sometimes comprehended under the name of Marfi. They were situated between the Prætulii, Marracini and Peligni.

VESTINUS, a mountain of Italy, in the environs of Minturna.—Also, a river of Italy, in Campania, which discharged itself into the Sarnus.

VESTIS ANGELIA. See ANGELIC Garment.

VESTITZA, in *Geography*, a town of European Turkey, in the Morea; 44 miles E.N.E. of Chiarenza.

VESTMENT. See VESTURE.

VESTRY, VESTIARIA, a room adjoining to a church, where the priests' vestments, and the sacred utensils, are kept, and parochial assemblies are held.

Hence the term vestry is applied to the parochial assembly itself. On the Sunday before a vestry is to meet, public notice ought to be given, either in the church, after divine service is ended, or else at the church door, as the parishioners come out, both of the calling of the said meeting, and also the time and place of assembling it, and sometimes of the business for which it is convened. And it is usual, for half an hour before it begins, to give notice, by tolling one of the church bells. Anciently, at the common law, every parishioner who paid to the church rates, or foot and lot, and no other person, had a right to come to these meetings, the minister excepted, who is responsible to the bishop, whether he be rector or vicar, for his attendance, and who presides in every parish meeting. Out-dwellers also, occupying land in the parish, have a vote in the vestry, as well as the inhabitants; and when they are met, the major part present will bind the whole parish. The power of adjourning the vestry is not in the minister or any other person as chairman, nor in the churchwardens, but in the whole assembly, to be decided by a majority of votes. Every vestry act, in order to prevent disputes, should be entered

in the parish-book of accounts, and every man's hand consenting to it be set thereto. Burn's Eccl. Law, art. *Vestry*.

VESTRY-Men, a select number of the principal persons of every parish within the city of London, and elsewhere; who yearly choose parish-officers, and take care of its concerns.

They are thus called, because they usually meet in the vestry of the church.

By these select vestries, the parishioners have in some places lost not only their right to concur in the public management as often as they would attend, but also the right of electing the managers. And yet such a custom of the government of parishes hath been adjudged a good custom, as the churchwardens accounting to them has been adjudged a good account. In some parishes, these select vestries have been thought oppressive and injurious, and great struggles have been made to set them aside. Prescription and constant immemorial usage seem to be the basis and only support of these select vestries. In the act of the 10 Ann. c. 11. for building fifty new churches, the commissioners are empowered to appoint a convenient number of sufficient inhabitants to be vestry-men; and from time to time, upon the death or removal, or other avoidance, of any such vestryman, the rest, or majority of them, may choose another. In the several private acts for building particular churches, sometimes the minister, churchwardens, overseers of the poor and others, who have served or paid fines for being excluded from serving these offices; sometimes the minister, churchwardens, overseers of the poor, and all who pay to the poor rate; sometimes only all who pay a certain sum to the poor rate; sometimes all who rent houses of so much a year, are appointed to be vestry-men within such parishes, and no other persons.

VESTRY-Clerk, an officer chosen by the vestry, who keeps the parish accounts, and who has the custody of all books and papers relating to them. The beadle is also chosen by the vestry; and his business is to attend the vestry to give notice to the parishioners when and where it is to meet, and to execute its orders as their messenger or servant.

VESTURE, VESTMENT, a garment or clothing.

In our law-books, it is also used metaphorically; as in *vestura terre*, i. e. *segetes quibus terra vestitur*; the corn with which the earth is clothed, or covered.

VESTURE of an Acre of Land, is the produce on it; or the wood, corn, &c. growing on it. It shall be enquired how much the vesture of an acre of ground, and how much the land, &c. 4 Ed. I. 14 Ed. III. &c.

VESTURE, *Vestura*, also signifies a possession, or seisin.

In which sense it is borrowed from the feudists; with whom *investitura* signifies a delivery of possession by a spear, or staff; and *vestura*, the possession itself. See INVESTITURE.

VESUBIA, in *Geography*, a river of France, which runs into the Var; 8 miles N. of Nice.

VESUBIANI, in *Ancient Geography*, a people belonging to Italy, though they were inhabitants of Liguria.

VESULIO, in *Geography*, a mountain of France, in the department of the Stru. It is a part of the Alps.

VESULUS MONS, *Mount Viso*, in *Ancient Geography*, a mountain of Gallia Transpadana, in which was the source of the Padus or Po.

VESUNI, a people of Africa, in Mauritania Tingitana. Pliny.

VESUNNA, afterwards *Petrocorii*, the capital of the Petrocorii, according to Ptolemy. The vestiges of the ancient town, still subsisting at Perigucux, are called *La Visone*.

VESUVIAN, in *Mineralogy*, (*Idocrase*, Hauy,) a mineral originally found in the vicinity of Vesuvius, and classed by some mineralogists with the garnet family, of which it forms a distinct species. It is generally crystallized in four-sided prisms, the edges of which are truncated, forming prisms with eight, fourteen, or sixteen sides, differently terminated by low planes. The sides of the crystals are streaked longitudinally; the terminating planes are smooth. The crystals are generally middle-sized; they occur in groups, or lining cavities of other minerals. Vesuvian sometimes occurs massive. The colour of this mineral is either a liver-brown or reddish-brown, or blackish or yellowish-green. The lustre of the crystals is splendid or vitreous. The fracture is small-grained and uneven. It is more or less translucent. It is sufficiently hard to scratch glass, but is brittle. Vesuvian melts before the blow-pipe into a yellowish translucent glass. The specific gravity varies from 3.35 to 3.42.

The analysis of Vesuvian gives its constituent parts as under :

	From Vesuvius.	From Siberia.
Silex - -	35.5	42

Vesuvian has been found in various parts of Europe as well as near Vesuvius : the opinions respecting its formation will be referred to under *VOLCANIC PRODUCTS*.

VESUVIANÆ ΔΟΥΞ, in *Ancient Geography*, the name given by Tacitus to a small river of Campania, which watered the town of Neapolis.

VESUVIUS, in *Geography*, a celebrated volcanic mountain in Italy, situated in the kingdom of Naples, about six miles S.E. of the capital. Vesuvius appears an isolated mountain, standing in the middle of a plain, but is considered as connected with the Apennines. The base of the mountain is about 40 miles in circumference; the height is stated at from 3700 to 3900 English feet. Vesuvius has two summits; the most northern is called Somma, the other is properly called Vesuvius. Somma is supposed, with much reason, to have been part of the cone of a larger volcano, in which the present volcanic cone of Vesuvius was formed. "It is impossible," says Sir James Hall, "to see the mountain of Somma, which in the form of a crescent embraces Vesuvius, without being convinced that it is a fragment of a larger volcano, nearly concentric with the present cone; which in some great eruption has destroyed all but this fragment. In our own times, an event of no small magnitude has taken place in the same spot : the inner cone of Vesuvius having undergone so great a change during the eruption in 1794, that it now bears no resemblance to what it was in 1785." *Transactions of the Royal Society of Edinburgh*, vol. vii.

From the building of Rome to the year 79 of the Christian era, a period of seven centuries, Vesuvius appears to have been in a state of profound repose, as no mention is made of any eruption during the whole of that time; and the ancient writers who refer to this mountain always speak of its extraordinary beauty and fertility. There were, however, certain appearances near the summit which left no doubt of its prior volcanic state, and the cities in its vicinity were paved with the lavas of ancient eruptions.

Vitruvius, who flourished in the reign of Augustus, says (*lib. ii. cap. 6.*) "that Vesuvius had formerly been burning, and had covered all the adjacent country with its fires." Diodorus Siculus, who wrote at the latter end of the same reign, refers to a tradition of a volcanic eruption of Vesuvius seen by Hercules. Strabo, a contemporary writer, describing this mountain, says, "here rises Vesuvius, inhabited through all its delicious fields, the summit alone excepted, which spreads into a barren plain, displaying ashes and caverns formed of burnt rock;" whence it may be conjectured, that this summit was formerly in a state of conflagration, and presented fiery craters, which became extinguished when the materials were exhausted. Silius Italicus, in the time of Nero, says, "Vesuvius, by its fires, had formerly caused great ravages both on the land and at sea."

The first great eruption on authentic record took place in the reign of Titus, on the 24th of August, A.D. 79; and on the same the towns of Herculaneum, Pompeii, and Stabie were buried under showers of volcanic sand, stones, and scorizæ. Such was the immense quantity of volcanic sand (called ashes) thrown out during this eruption, that the whole country was involved in pitchy darkness; and according to Dion, the ashes fell in Egypt, Syria, and various parts of Asia Minor. The particulars of this eruption are described in a letter from the younger Pliny to Tacitus : his uncle, the elder Pliny the naturalist, lost his life by this event. He had the command of the Roman fleet on the coast of Campania, and wishing to succour those persons who might desire to escape by sea, and also to observe this grand phenomenon more nearly, he left the cape of Misenum, and approached the side of the bay nearest to Vesuvius. He landed and advanced towards it, but was involved in whirlwinds of sulphureous vapour, in which he expired.

After this period, Vesuvius continued a burning mountain for nearly a thousand years, having eruptions of lava at intervals. The fire then appeared to become entirely extinct, and continued so from the beginning of the 12th century to the beginning of the 16th, a period of about 400 years. Woods were growing on the sides of the crater, and pools of water were collected in its centre. Since the eruption of 1506, it has remained burning to the present time, having violent eruptions of lava and ashes at intervals. There have been more frequent during the last century and the beginning of the present, than at any former period. Of twenty-nine eruptions which took place from the time of Titus to 1800, fourteen occurred in the last century : several have taken place since the commencement of the present century, and the volcano is at this time (1817) in a state of activity.

The eruptions of Vesuvius are always preceded by earthquakes more or less violent and extensive, and by a succession of subterranean explosions, growing louder before the stones or lava are ejected. Sir William Hamilton, the English ambassador to the court of Naples from the year 1766 to the latter end of the century, has given several interesting descriptions of the eruptions that took place under his own observation, which are published in the *Transactions of the Royal Society*. From 1769 to 1779 there were nine eruptions, many of them considerable. Most of the eruptions of Vesuvius take place from the crater at the summit, but the eruption of 1794, which destroyed Torre del Greco, a city containing 10,000 inhabitants, flowed from a large opening made near the bottom of the cone.

The volcanic products of Vesuvius differ considerably from those of *Ætna*, and still more from those of the volcanoes in the Lipari islands, more immediately in its vicinity. White pumice and obsidian, a volcanic glass, have not been

VESUVIUS.

found among the lavas of Vefuvius; but they contain imbedded crytals of leucite, vefuvian, and fommite, which are almost peculiar to this volcano. The lavas of Vefuvius, besides iron, contain alfo copper, and fome of them are faid to contain a portion of gold, filver, and other metals. See *VOLCANIC Produâs*.

Breifak, an Italian geologift, has given an account of the prefent ftate of Vefuvius, and an interefting defcription of the very remarkable eruption of 1794; the moft important particulars of which we fhall felect. This eruption was fo great as to change the very form of Vefuvius, as we have before obferved.

“The prefent cone of Vefuvius is truncated, fo as to form an inclined plane, floping from the N.E. to the S.W. The circumference of the fummit, which forms the brim of the cauldron, is about 3000 feet; and at the bottom is diftinguifhed an oblong plain, the greateft diameter of which is from E. to W. Having fince afcended feveral times to the top of the cone, I perceived that its depth had gradually diminifhed, and that the bottom of the crater became higher daily, owing to the different matter which falls down, efppecially from the almoft perpendicular fides on the E. and N. One can at this time eafily fean the extent and depth of its mouth, but occasionally it is much encumbered, and fometimes totally clogged. In 1755, the bottom of the funnel rofe fo confiderably, that it prefented a vault plain only twenty-three feet beneath the brim, and in the middle of this plain was another cone from eighty to ninety feet high, with a fmall crater, from which the eruptions proceeded.

“Bracini has left us a curious defcription of the ftate of Vefuvius, after a long period of reft, and before the great eruption of 1631. The whole of it, or at leaft the greater part of it, had become acceffible. Having himfelf defcended into the crater, he fays, he found it covered with plants and trees, and that a road down it was practicable for the fpace of a mile; at this depth a very deep cavern was feen, which having paffed, the way was again open for two miles by a very fteep but at the fame time very fafe road, owing to the trees growing near to each other. At length a large plain prefented itfelf, furrounded by a number of grottoes and caverns, which might be entered, but which the party were deterred from on account of their darknefs. This plain, which was not acceffible otherwife than by a very rapid flope, nearly three miles in length, muft affuredly have been much beneath the level of the fea.

“When the volcano is at reft, vapours are feen to arife from the cauldron’s brim, or from the interior of its fides, which are very perceptible.

“When the mouth of Vefuvius is obferved from any diftance, and during the prevalence of moifture in the atmofphere, a mafs of vapour feems to rife from it which mingles with the clouds.

“The weftern portion of Somma muft be confidered as connected with the cone of Vefuvius by a hill of fmall eminence, denominated Monte Cantaroni, on which is the hermitage del Salvatore. This hill is interfeated by three valleys, that deferve to be examined with attention, on account of the quantity of primitive fubftances which the volcano has thrown thither during old eruptions. The northern valley is that termed La Foffa di Pharaone, near the plain, and Vallone della Vetrana, in its more elevated part, where the current of lava flowed in 1785. This vale, hollowed by rains, is the only interval between mount Somma and mount Cantaroni. South of this vale are two others, nearly parallel, the firft called Rio Cupo, the fecond Foffa Grande, which, taking a direâion from eaft to weft, emerge in the plain of

St. Jorio. Its northern fide, nearly perpendicular, rifeſ to a confiderable height above the valley, and being compoſed only of cemented fragments of porous lava, called capillo, of maſſes of ſpongy lava, and other fubſtances of an inadheſive quality, is ſubject frequently to crumble and fall in large quantities. Along the whole extent of the fouthern fide, at its upper part, is feen an ancient current of lava, which at firſt fight appears to be feveral ſtrata of lava impoſed one on the other, but which a little attention ſhews is but one current, in which horizontal chafms have been occaſioned by refrigeration, and into which the wind has ſince introduced a ſlight quantity of vegetable earth. This lava is hard and compact; it contains but few fragments of augite or pyroxene, and ſeems to be an aſſemblage of leucites, the ſuperficial cryſtalline luſtre of which having been impaired by decomposition, makes it reſemble variolite in its exterior. Many detached maſſes of this current have fallen to the bottom of the valley. Each fall of matter brings down calcareous ſtones, mica, and mixtures of felpar and vefuvian. The lava of 1767, which threatened the villages of La Barra and St. Jorio, diſcharged itſelf into this valley, which it filled to a certain height, and afterwards flowed further, ſpreading itſelf to the plain. As it is already covered by the crumblingſ from the flank, in order to examine it, the enquirer muſt repair to the plain of St. Jorio, in the neighbourhood of the chapel of St. Vito. Its grain is cryſtallized but fine, and oftentimes ſo cloſe as to be nearly equal to petro-flex, or horn-ſtone. It contains many ſmall cryſtals of pyroxene and fragments of leucite, which is rarely found in its perfect form of cryſtallization.

“The lava of La Scala paſſes beneath the garden of La Favorita. It is of the colour of aſhes, whitifh, and of a cryſtallized grain. It contains many cryſtals of pyroxene, few of leucite, and ſmall pieces of felpar, in groups in its cavities. This lava, where it is hewn on the ſea-ſhore near La Cavalleria, is worthy of attention. Under an uniform bed, from fifteen to twenty feet in thickneſs, the lava is found divided into ſtrata of from three to four feet: theſe diviſions are formed by parallel and horizontal lines; and where theſe are dug down to, the lava is found to have ſeparated itſelf ſpontaneouſly into beds. Below them are large priſms, commonly hexagonal, which are diſjoined with great eaſe: in ſome places theſe priſms, inſtead of the lower, are found in the upper part of the current.

“The ſame tendency to a baſaltic conformation, which is noticed in the lava of La Scala, is obſerved again in the neighbouring current of Calaturo. This, after paſſing through a deſile below Vallongia, ſpreads to a broad front on reaching the ſea. What moſt deſerves obſervation in the lava here are the ſmall cryſtallizations it preſents, which ſeem to be the olivine of Werner. It is moreover of a deeper colour than the lava of Scala, more porous, and like that contains many cryſtals of augite and fragments of felpar.

“Next to this lava is found that of the eruption of 1794. Of the different eruptions of Vefuvius, this is the moſt recent, and was one of the moſt confiderable.

“Vefuvius had continued tranquil for a long time. On the 12th of June, 1794, towards eleven in the evening, a very violent ſhock of an earthquake was felt, which induced many of the inhabitants of Naples to leave their houſes for the night. The tranquillity of the mountain did not, however, appear diſturbed, either on the 13th, 14th, or 15th, nor did it exhibit any ſymptom of an approaching eruption; but towards nine in the evening of the laſt day many ſymptoms were manifeſted. The houſes about the mountain experienced violent ſhocks, which gradually increaſed in force: a very powerful one was felt at ten o’clock in Naples and

VESUVIUS.

its environs. At this instant, on the western base of the cone, at the spot called La Pedamentina, and from the middle of ancient torrents, a new mouth disgorged a stream of lava. This opening was 2375 feet in length, and 237 in breadth. Scarcely had the stream of lava begun to flow, before four conical hills, each having its small crater, (the third alone excepted, which had two distinct mouths,) arose out of the stream itself. From these different mouths stones were darted into the air with great noise, and in a state so highly ignited, that they resembled real flames; the explosions indeed were so quickly repeated, that they seemed but one, and formed a continued sheet of fire in the air, which received no other interruption than what was occasioned by the inferiority of force of some of the ejections. They sometimes vomited substances, I may say, in a fluid state, for they expanded in the air like a soft paste, so that one may imagine they were either a part of the running lava, or masses of old lava fused and projected. Some of these hills were contiguous one to the other; and it seems as if the force by which they were produced had met with obstruction to the disengagement of the substances at one point, and consequently effected several issues in the same line. The lava flowed in one body for some time, and at intervals flashes of light arose from the surface of it, produced by jets of hydrogenous gas, which disengaged itself from the lava, precisely in the same manner as the gases expand from the surface of a fluid. Its first direction was towards Portici and Resina, so that the inhabitants of Torre del Greco already bewailed the fate of their neighbours, and began their thanksgivings to the Almighty for their escape. Collected together in the church, they were still singing hymns of joy, and expressing their gratitude, when a voice announced to them the fatal news of their altered destiny. The stream of lava, on flowing down a declivity it met in its way, divided itself into three branches; one, bearing towards Sta Maria de Pngliano, traversed a space of 2063 feet; another, directing its course towards Resina, flowed to the distance of 3181 feet; while the remainder of the stream, falling into the valley of Malomo, flowed towards La Torre. On reaching the chapel of Bolzano, it formed a branch towards the south-east, which terminated in the territory of Aniello Tirone, after having run the length of 1490 feet; the residue of the lava pursuing its course flowed upon Torre, presenting a front from 1200 to 1500 feet in breadth, and filling several deep ravines.

“On reaching the first houses of the town, the stream divided according to the different slopes of the streets, and the degrees of opposition presented by the buildings. An idea may easily be formed of the accidents consequent on such a flood of fire; accidents which bear relation to the site of the manufactories, the thickness of their walls, and the manner in which they were assailed by the lava. Had not the mass of the stream suffered a diminution from the different divergencies noticed, not a single house would have been left standing in Torre del Greco. The lava, after a serpentine course through the town, at length reached the sea-shore. The contact with the water diminished the speed of its course: still the current flowed into the sea in a body 1127 feet in breadth, and advanced into it a distance of 362 feet. Its entrance into the sea was not marked by any singular phenomenon; it began to issue from the volcano at ten at night, and reached the sea-shore by four in the morning; continuing a very slow progressive movement into the sea throughout the whole of the 16th, and the following night. The main stream, from the point where it issued from the volcano to that at which it stopped in the sea, measured 12,961 feet. Its breadth varied greatly; in some places it

scarcely exceeded 322 feet, but in the plain it spread to 1111; and at a medium, without risk of any great error, it may be computed to have been 725 feet broad. In thickness also it differed according to the depth of the hollows it filled; in the plain it was constantly from twenty-four to thirty-two feet thick: and if its mean thickness be reckoned at the latter number of feet, it may possibly be near the truth. According to these data, the mass of molten matter is 1,869,627 cubic fathoms. During the eruption the convulsion of the mountain was so great, that even the houses in Naples were shaken by it. Still it was not constantly alike. At the beginning the trembling was continual, and accompanied by a hollow noise, similar to that occasioned by a river falling into a subterranean cavern. The lava, at the time of its being disgorged, from the impetuous and uninterrupted manner in which it was ejected, by striking against the walls of the vent, occasioned a continual oscillation of the mountain. Towards the middle of the night this vibratory motion ceased, and was succeeded by distinct shocks. The fluid mass, diminished in quantity, now pressed less violently against the walls of the aperture, and no longer issued in a continual and gushing stream, but only at intervals, when the interior fermentation elevated the boiling matter above the mouth. About four in the morning the shocks began to be less numerous, and the intervals between them rendered their force and duration more perceptible. One might compare them to the thunder heard in Italy during storms in summer, the loudest claps of which are succeeded by rumbling sounds, which gradually die away.

“While I was making my observations on this grand eruption at the foot of Vesuvius, its summit was tranquil, and no phenomena were visible about its crater. I passed the night at sea, between Calastro and La Torre, to have a nearer view of this great operation of nature, and to prove the truth of the opinion generally received, that great eruptions are accompanied by extraordinary phenomena in the sea. A more grand spectacle there could not be. On one of those serene and brilliant nights, known only in the delightful climate of Naples, a majestic stream of fire, 11,868 feet in length, and 1483 in breadth, was seen at the foot of Vesuvius; its reflected surface formed in the atmosphere a broad and brilliant aurora borealis, regularly spread and terminated at its upper part by a thick and dark border of smoke, which, dilating itself in the air, covered the disc of the moon, the shining silvery light of which was enfeebled and obscured. The sea again reflected the illuminated sky, the surface of it corresponding with this portion of the atmosphere appearing as red as fire. At the source of this river of fire, inflamed matter was incessantly spouted out to a prodigious elevation, which, as it diverged on all sides, resembled an immense fire-work. On the sea-shore, finally, the mournful spectacle of the conflagration of La Torre completed the picture. The vast clouds of thick black smoke which rose from the town, the flames which occasionally crowned the summits of the houses, the ruins of the buildings, the noise of the falling palaces and houses, the rumbling of the volcano,—these were the principal incidents of this horrible, yet sublime scene. The ruins of Pompeii, buried beneath heaps of drosses and powders, did not certainly present a spectacle near so striking. To these objects, so powerfully calculated to fix the senses, was added another, which forcibly touched the heart: this was a doleful group of fifteen thousand persons, bewailing the destruction of their city and property, who had had but a moment's notice to flee and abandon their homes for ever, and were reduced to become wanderers, and dependent on the world for refuge.

VESUVIUS.

"About dawn, the fummit of Vefuvius ceased to be visible: it was covered with a thick cloud, frequently furrowed with lightning. This cloud gradually spread itself, and in a little time overhadowed the gulf, the city of Naples, and its vicinage. It was formed of a large quantity of that fine sand called ashes, and prevented all light of the fire of the volcano. The sun, as it appeared above the horizon, presented a still more dismal picture. From the abundance of ashes in the air, it seemed more pale than during the strongest eclipse; and a black fear appeared to be spread over the whole of the gulf and the country. At the extremity of the horizon, towards the west, the day was more clear, while the light at Naples was fainter than twilight; and, with Pliny the younger, one might have said, "Jam dies alibi illic nox omnibus nigrior deniorque."

"During this mournful night the air was perfectly unagitated, and the sea calm: it was not disturbed even in the slightest degree, at least in the gulf of Naples. The slightest action of the volcano on it would have been perceptible at the base of the mountain, and I was within a distinct view of this part of the sea; but its influence on that element was absolutely null.

"While one current of lava flowed over the western flank of Vefuvius, spreading ruin and desolation; another fell down its eastern slope, from an opening of inferior height, and a greater distance from the fummit. This current was not visible at Naples: all that was perceived of it was a great light in the atmosphere, produced by reflection from the rolling fire. At first it took an eastern direction, turned afterwards to the south, and descended to the spot called Cognolo. There it fortunately found the valley of Sorienta, 65 feet wide, 121 deep, and 1627 long. This valley the lava filled; but as the volcano still continued to emit fresh matter, the current afterwards spread into the plain of Forte, near to Pozzelle, where it divided into three branches: one proceeded towards Bosco, another towards Mauro, and the third to the plain of Mulara. The length of this current of lava was not less than an Italian mile; but as it flowed constantly over old lavas, it did but little harm, merely laying waste and occupying a small extent of vineyard. From the spot where it diverged from its first direction, it projected a small branch in a continued line: falling to this point over a very rapid slope, the speed with which it flowed must have been considerable; and a portion of its mass preserving its first impulse, naturally fell in this small stream, in which were four mouths in the shape of an inverted cone, the base of which is in the surface of the lava. This stream terminates in a small and regular hill of a conical figure, on the fummit of which are two mouths in form of inverted cones. The dimensions of this second current are nearly half those of the first: consequently the mass of the whole is adequate to 2,804,440 cubic fathoms.

"The coincidence and perfect resemblance of these two currents of lava sufficiently prove that they had but one common origin, and but one cauldron in which the matter was fused of which they were composed. How great then must that recipient be in which such an enormous mass could be contained! And what powerful exertion of strength must have been required to break through the mountain in such opposite directions! The lava agitated by the expansion of elastic fluids made its first efforts to liberate itself on the eastern flank, and found a passage; but the resistance it met with from the mountain no doubt occasioned its reflux or rebound against its opposite flank.

"The western current, taking its departure from a more elevated mouth, more quickly terminated its course; but the cauldron chiefly emptied itself by the eastern opening.

The lava issued from it very slowly, compared with the celerity with which that flowed which proceeded from the eastern mouth, because it was no longer driven forward, or compressed by the total mass, which was already greatly diminished.

"On the morning of the 16th, the lava ceased to flow over the western side, and the mouth of the volcano began to resume activity. The whole of its cone was covered with a very thick rain of ashes or powders, which totally hid it from sight, so that nothing could be distinguished on Vefuvius, which was wholly inaccessible. In this state it continued four days, during which many shocks of earthquakes were felt, and loud claps of thunder were heard. Thunders raged in every part of the adjacent country, and the flashes of lightning by which they were accompanied at intervals, for an instant allowed a view of the mountain through the darkness in which it was involved by the rain of powders. This darkness was so prodigiously great, that at Caserto, and other places ten or twelve miles from Vefuvius, it was impossible to walk the streets at mid-day without torches, and that circumstance was renewed which is related by Pliny on the occasion of the eruption in the time of Titus, "faces multe, varique lumina solvebant obscuritatem." It is utterly impossible to determine with precision the quantity of ashes or powders that fell in the course of these days, as it was different in different places, according to the direction of the wind; it is, however, computed, on the base of observations at different places, that fourteen inches and six lines in depth fell on an area, the radius of which is three miles, the fummit of Vefuvius being the centre."

It would be erroneous to conclude, that all this mass of matter proceeded from the entrails of the mountain, the greater part was the offspring of the ruins of the crater, which during the three last days fell into the abyss. For, after the rain of volcanic sand had ceased, and the mountain became visible, its appearance excited much surprize, the fummit had fallen, and its mouth was considerably enlarged.

Incessant rains followed this eruption, which continued to the 3d of July. Whenever a cloud appeared above the horizon, it seemed attracted by the volcano, and scarcely did it reach its fummit, ere immense streams were visible, precipitating themselves with horrible roarings to the base of the mountain. These impetuous torrents of water, mingled with volcanic powders, overturned the bridges, harrowed up the roads, tore up the trees, and utterly devastated the fields of one of the most rich and flourishing countries in the world. Mephitic vapours were also exhaled, which destroyed all other vegetation, except the olive and the pear-trees, which retained their verdure and strength. It is remarkable, that during the whole of this eruption the barometer at Naples was not sensibly affected, and exhibited no change, although the temperature and moisture of the atmosphere experienced considerable variation.

Though the quantity of matter thrown out of Vefuvius, during any single eruption, is not so great as from *Ætna*, Vefuvius being of diminutive size, compared with the latter mountain; yet the magnitude of some of the stones ejected is truly surprising, and the quantity prodigious. According to sir William Hamilton, during the eruption of 1779, the town of Ottacano, at the foot of Somma, was half buried under the showers of sand and fragments of volcanic matter. A stone, measuring one hundred and eight feet in circumference and seventeen feet in height, was thrown a quarter of a mile clear of the mouth of the volcano. One of ninety-two feet in circumference was thrown much farther,

ther, and lay in the valley between Vefuvius and the Hermitage. From the fragments which furrounded this mafs, it appeared to have been much larger when in the air. For further obfervations on the volcanic phenomena of Vefuvius and the adjacent country, fee VOLCANO.

VETAS, a town of South America, in New Grenada; 15 miles E.S.E. of Pamplona.

VETAVELUM, a town of Hindooftan, in the Carnatic; 12 miles N. of Tricalore.

VETCH, in *Botany*, a word of one common origin with VICIA; fee that article, as well as LATHYRUS, OROBUS, and ASTRAGALUS.

VETCH, in *Agriculture*, a well-known wild plant of the fodder kind, which in fome of its forts promifes, from the few trials that have yet been made with it, to be beneficial when cultivated in the field. In this view, it has been fuggested, that fome of the plants of this kind may be useful to the farmer either as affording a good full paffurage for live-flock, or as fupplying large quantities of green food to be confumed in other ways; though nothing fatisfactory has hitherto been done in afcertaining how far they may be of fuperior utility in feeding or fattening, paffuring, and being eaten green in the cut itate by animals, to fully juftify any decifion as to their particular merits in any of thefe modes of application. They are, however, in general, plants that are, in their nature, not only very productive as to the quantity of food, but from many trials, extremely nutritious and fattening in their properties. In addition too, they have moftly the very defirable quality of being fed upon by almoft all forts of live-flock with great avidity; and it is not by any means to be concluded in confequence of their appearing of a coarfe nature and quality, that they may not be of advantage even as paffure herbage, as it is now well known that clofe, hard, judicious feeding or eating down is capable of bringing the coarfeft and rougheft kinds of herbage into a fine graffy ftate of produce. Of thefe wild plants, that which is ufually known by the name of bufh vetch, is a fort which would feem capable of being introduced as a paffure plant with confiderable benefit in different cafes. It is afferted by fome, that its roots fpread much in a lateral manner juft under the furface of the foil of the land, and fend forth numerous ftems or fprouts at the fpring of the year, clofe to each other, which, as they have a broad bufhy top, covered with many leaves, a clofe pile or furface grafs is formed without the affiftance of any other plant. It is a plant which is not found to rife to any great height of growth; but from its fpringing up rapidly, after being cut over or cropped and eat off by animals, it would feem not ill fited to the purpose of paffurage. On fuch lands as are of the more rich and fertile kind, it, however, grows to a good height for the production of hay; but as the ftalks rife fo clofely together, there is fome danger of its rotting at the bottom in moift rainy feafons. It affords great abundance of feed, but which is very liable to be deftroyed in the pod by infefts while in their vermicular or worm ftate. It is contended by fome, that it would appear to fucceed beft in lands of the clayey kind, where it abounds in foliage preffy much, affording feeds very fimilar to thofe of the cultivated plants of this nature. It is ftated too in the Tranfactions of the Bath Society, that it has been found to fhoot earlier in the fpring than any other plant that is eaten by cattle, and to vegetate late in the autumn, continuing green all the winter. In good rich land, when cultivated in the drill manner, it may, in the fecond year, it is faid, be cut five times, producing at the rate of twenty-four tons the acre of green food, which would be nearly four and a half tons when dry and made into hay.

It is noticed, that the principal difficulty in introducing this plant into field culture, would arife from the feed being fo apt to be devoured by the larvæ of a fpecies of atteleobas, as Mr. Swayne has fully fhewn.

Another fort of this wild plant which might be useful to the farmer in fome what the fame way, is that of the kind ufually called the tufted vetch, which, in confequence of its riling to a confiderable height in the ftem, and affording much foliage, is capable of yielding a large proportion of green fodder for cattle-flock; and from its being eafily cultivated, might alfo be made to afford a great deal of hay. It is therefore equally applicable in paffures and meadows. Plott, in his *History of Staffordfhire*, has indeed long fince remarked it to improve the condition of poor lean cattle, more than any other plant then known. There are probably fome other forts of thefe wild plants that might be usefully grown in the field, if properly attended to by the farmer.

The cultivated plants of this nature are confidered under their proper heads. See TARE.

VETCH, *Axe, Securidaca*. See CORONILLA.

VETCH, *Bitter or Pea*. See OROBUS.

VETCH, *Bitter, and Corn Vetch*. See ERVUM.

VETCH, *Bindweed-leaved*. See LATHYRUS.

VETCH, *Chickling*. See LATHYRUS.

VETCH, *Grafs*. See GRASS.

VETCH, *Crimfon-grafs*. See LATHYRUS.

VETCH, *Hatchet, Securidaca*. See CORONILLA.

VETCH, *Clufus's Foreign Hatchet*. See BISERRULA.

VETCH, *Horse-Shoe*. See HIPPOCREPIS.

VETCH, *Kidney*. See ANTHYLIS.

This is a plant of the weed kind, and is common in lands of the chalky and calcareous forts, of which fheep are very fond. It affords a yellow dye.

VETCH, *Liquorice, or Wild Liquorice*. See ASTRAGALUS.

VETCH, *Knobbed-rooted Liquorice*. See GLYCINE.

VETCH, *Milk*. See ASTRAGALUS.

VETCH, *Baglard Milk*. See PHACIA.

VETCH, *Venetian*. See OROBUS.

VETCHLING, in *Botany*, is the Englifh name of *Lathyrus Aphaca*, expreffive of its diminutive fize. The fame appellation is fometimes given, though improperly, to one or two of the fmalleft fpecies of *Vicia*.

VETCHLING, *Meadow*, in *Agriculture*, a wild plant common in meadow lands, for the cultivation of which a premium has been offered. It bears a large number of fucculent leaves, and feems well fited as an addition to the meadow graffes. As it makes good hay, it is probably the moft useful in mixture with graffes for this purpose; for though cattle and horfes eat it, they do not feed upon it with avidity. It is very prevalent in fome diftricts.

VETCHLING, *Yellow*. See APHACA.

The feeds of this, and of all the other fpecies of vetchling, are nutritious, either eaten in broth, or made into bread. Withering.

VETERAN, VETERANUS, in the *Roman Militia*, a foldier who was grown old in the fervice; or who had made a certain number of campaigns; and, on that account, was entitled to certain benefits and privileges.

Thefe privileges confifted in being abfolved from the military oath; in being exempted from all the functions of a foldier; and in enjoying a certain falary or appointment, &c.

The time of fervice fixed by the Roman laws was from feventeen to forty-fix years; and among the Athenians forty years. The ufe of the term veteran was not introduced

duced till about the close of the republic; but its origin may be traced to the first distribution which Servius Tullius made of the Roman people into classes and centuries; under which the *centuria seniorum*, or old soldiers, were appointed to guard the city. They were afterwards employed to guard the camp, whilst the *centuria juniorum* fought in the field of battle. After they had served some years, they were called *veteres*, in contradistinction to the *novitii* or *titones*. In process of time, those who had served a certain number of campaigns were called veterans, and were exempt from the obligation of military service, except on urgent occasions. See *EVOCATI*.

The rewards conferred on veterans were at first very inconsiderable, *e. gr.* a few acres of land in a foreign country, where they established colonies; but at length they became immense. Tiberius Gracchus distributed among them the treasures of Attalus, who had made the Roman people his heirs. Augustus also bestowed upon them pecuniary recompense, and almost all his successors augmented their privileges.

In France, the term veteran is still retained for such officers as have held their post twenty years, and who enjoy certain of the honours and privileges affixed thereto, even after they have laid them down.

A veteran counsellor has a voice and seat at audiences, though not at process by writing. A veteran secretary of the king acquires the privilege, &c. of nobility, to himself, and his children.

VETERINARIA, *MULO-MEDICINA*, or medicine applied to the diseases of cattle. Whence,
VETERINARIUS, a farrier, or horse-leech.

VETERINARY, a term applied to and signifying that part or department of cattle-medicine, which relates to the treatment and cure of morbid animals of the domestic kind.

Veterinary College, an institution first established, in this country, in the year 1792, at St. Pancras, in the vicinity of the metropolis. It is stated in "Boardman's Dictionary of the Veterinary Art," that the public are indebted for this truly national foundation to the humanity, discernment, and patriotic exertions of a country agricultural society, that of Odiham, in Hampshire; and that the first professor of it was a Frenchman of the name of St. Bel, who had previously distinguished himself as a veterinary anatomist and writer in this country, by dissecting and describing different parts of the famous race-horse Eclipse, so much known and admired for his swiftness.

It is added, that the college is supported by public subscription; that the annual contribution is two guineas, but the payment of twenty guineas at one time constitutes a subscriber for life. In some recent instances, too, the institution has shared, it is said, the bounty of parliament; an important favour having resulted to the nation from the appointment of veterinary surgeons to the different regiments of British cavalry, in consequence of it.

The different views and objects of the college or establishment appear in the statement, printed by the authority of the governors, and given below.

It is said, that the grand object is the improvement of veterinary knowledge, in order to remedy and obviate the ignorance and incompetency of farriers, so long and so universally complained of. For this end, a range of stables, a forge, a theatre for dissections and lectures, with other necessary buildings, have been erected; and a gentleman, properly qualified for the purpose, has been appointed professor, with other requisite officers.

The anatomical structure of quadrupeds and other ani-

mals, such as horses, cattle, sheep, dogs, and others, the diseases of which they are subject, and the remedies proper to be applied, are investigated and regularly taught; by which means, enlightened practitioners of liberal education, whose whole study has been directed and devoted to the veterinary art in all its branches, may be gradually prepared, provided, and dispersed over the whole kingdom, on whose skill and experience confidence may be securely placed.

That the pupils to the college, in addition to the lectures and instructions of the professor, and the practice of the stables, at the present enjoy, in consequence of the great liberality of some of the most eminent of the faculty of medicine in London, the advantage of free admission to their medical and anatomical lectures. These pupils, previous to leaving the college, are strictly examined by a medical committee, from whom they receive a proper certificate; and several, examined and approved, have, it is said, already left the college, and are at this time practising in various parts of the country with great success.

That subscribers have the privilege of sending their diseased animals to the college, without further expence than that of their daily food; and that these, in general, form a sufficient number of objects for the practice of the professor and pupils to be tried and exercised upon. That on fixed days, the professor prescribes for animals belonging to subscribers, who find it inconvenient to spare them from home, provided the necessary medicines be furnished and compounded at the college. Subscribers' horses are there also shod at the ordinary price, and new improved modes of shoeing practised in different cases.

And that his royal highness the commander-in-chief having been pleased to appoint a board of general officers to take into consideration the objects of this institution, they have reported the continual loss of cavalry to have been very heavy, in consequence of the almost total ignorance of those who have hitherto had the veterinary department in the army. This report his majesty has approved; and henceforward, to qualify for the military service, a veterinary surgeon must be provided with a regular diploma from the college. A number of gentlemen, subscribers to the institution, attend once a fortnight, for the purpose of inspecting the discipline of the stables, and seeing that the regulations are duly complied with.

These form the most material objects and regulations of the establishment; from which it is evident, that it is capable of being of great use and advantage, if properly directed, and confined to the points which it has principally in view.

VETERNA, in *Geography*, a town of European Turkey, in Bulgaria; 9 miles S.W. of Driftra.

VETERNITZA, a river of Servia, which rises in the Karadagh mountain, and runs into the Morava.

VETERNUS is used, by some physicians, for a lethargy, or other drowsy disease.

VETERSEN, in *Geography*, a town of the duchy of Holstein; 15 miles N.W. of Hamburg.

VETIL, **NEDER**, a town of Sweden, in the province of Wafa; 16 miles E. of Jacobstadt.

VETIL, *Ofvers*, a town of Sweden, in the province of Wafa; 32 miles E.S.E. of Jacobstadt.

VETINA, in *Ancient Geography*, a town of Italy, in Magna Græcia, supposed to lie between Sybaris and Metapontum; but its exact situation is not known.

VETITUM NAMIUM, in *Law*, imports a forbidden distress. See **NAMIUM**.

VETTITZA, in *Geography*, a river of Walachia, which runs into the Kotmana, 10 miles N. of Rufei.

VETLIANSKOI, a fort of Ruffia, on the Volga; 32 miles S.E. of Tchernoiyar.

VETLUGA, a river of Ruffia, which runs into the Volga, near Kozmodemianfk, in the government of Kazan. —Also, a town of Ruffia, in the government of Koltrom, on a river of the fame name; 140 miles E. of Koltrom. N. lat. 58°. E. long. 45° 44'.

VETO, in *Roman Antiquity*, was the folemn word ufed by the tribunes of the people, when they inhibited any decree of the fenate, or law propofed to the people, or any act of other magiftrates. See INTERCESSION.

VETOLA, in *Ornithology*, a name ufed by the Venetians, and from them by many others, for a water-bird of the scolopax kind, called by Aldrovand the *totano*, and by Gefner the *fedoa fecunda*. In the Linnæan fyftem it is the *scolopax limofa*.

It ufually weighs about nine ounces; its beak is fhaped like that of the woodcock, and is red all over, except at the end, where it is blackifh; its neck is grey; its belly and breast white; its head of a brownifh-grey, and its back brown; but its rump has a white ring on it; its tail is compofed of black and white feathers. Ray's *Ornithology*, p. 216.

VETRALLA, in *Geography*, a town of the Popedom, in the Patrimonio; 9 miles S. of Viterbo.

VETSCHAU, a town of Lufatia; 28 miles S.W. of Guben. N. lat. 51° 47'. E. long. 14°.

VETTICUTTY, a town of Hindooftan, in the Carnatic; 22 miles W.N.W. of Trichinopoly.

VETTINGEN, a town and abbey of Switzerland, in the county of Baden; 2 miles S. of Baden.

VETTONA, in *Ancient Geography*, a town of Italy, in Umbria.

VETTONES, a people of Hifpania, in Lufitania, who extended themfelves from the fouth towards the north, in the eaftern part.

VETTONIANA, a town of Vindelicia. Itin. Anton. VETTONICA, in *Botany*, the ancient way of fpelling the word *betonica*, the name of a plant, called in Englifh *betony*.

It is called *vettonica* by Pliny, who fays it obtained that name from a people of Italy fo called, among whose woods it grew.

If any thing certainly can be judged of the betonica of the ancients, it is that it was our *feratula*.

VETTORI, PIETRO, (Lat. VICTORIUS,) in *Biography*, a defendant of a noble family at Florence, was born in 1499. Educated at his native city and at Pifa, he vifited Spain, and returned to Italy with a collection of ancient infcriptions. At Rome he complimented Clement VII. on his acceffion to the pontificate; and fettling at Florence, joined the party oppofed to the houfe of Medici, and fupported it with his eloquence and arms. Upon the affaffination of Alessandro di Medici in 1537, he withdrew to Rome. In the following year, duke Cosmo appointed him public profefor of Greek and Latin eloquence at Florence, and he fufained this office with diftinguifhed reputation for many years. He was much efteemed by feveral popes, and Marcellus II. drew him to Rome; but upon the death of this pontiff, he refufed the chair at Florence, and held it nearly to the clofe of his life. He died in 1585, regretted and eulogized by the learned, on account of his virtuous and amiable manners, as well as his extenfive erudition. Vettori took great pains in improving the editions of the ancient Greek and Latin writers. Of the latter we may mention Cicero, Terence, Varro, and Salluft; and of the former, Euripides, Porphyry, Demetrius Phalereus, Plato,

Xenophon, Dion. Halicarn., Aristotle, Æfchylus, and Clemens Alexandrinus. His commentaries upon the rhetoric, poetics, ethics, and politics of Aristotle, and upon the elocution of Demetrius Phalereus, are much valued. He was alfo the author of many Italian and Latin letters, and of fome poems, of an elegant Latin tract on the culture of the olive, and of other pieces in MS. Tirabofchi. Gen. Biog.

VETULA, in *Ancient Mythology*, a goddefs who profided over pleasures.

VETULONIA, or VETULONIENSES, in *Ancient Geography*, a town of Italy, in Etruria, fituated towards the weft, on the fea-coaft. It was one of the cities of the Etruscans, and defcribed by Silius Italicus as one of the moft pleafant of their cities; but it was destroyed at the commencement of Rome.

VETULONIUM, a town of Italy, in the interior of Etruria, according to Ptolemy; called *Vetulonia* by Silius Italicus.

VETUSSALINA, or VETUSALINÆ, a town of Valeria Ripenfis, fituated, according to Anton. Itin., on the route from Taurunum in the Gauls, purfuing the fhore of Pannonia, between Anamafia and Campona.

VEVAY, in *Geography*, the ancient *Vibifcum*, a town of Switzerland, in the canton of Bern, and the principal town of the bailliege, fituated near the lake of Geneva. This town is clean and well-built, ftands on a fmall plain at the foot of the mountains, on the margin of the water, and is one of the few places in the canton of Bern which carry on any trade. The chief manufacture is that of hats, and the trade in cheefe is confiderable. The borders of this part of the lake are much more contracted, wild, and picturefque, than thofe about Geneva; the mountains of the Vallais and Savoy projecting boldly into the water, and forming a femicircular chain inclofing the lake, except where they are divided by the Rhone, a few leagues from Vevay. This town was taken from the houfe of Savoy in the year 1474, but foon after reftored. In 1536 it was again taken, and from that time has been attached to Bern. It has a college for the inftruction of youth, and two churches, one for the French, and the other for the German language. Vevay was diftinguifhed as the refidence of Edmund Ludlow, the famous parliamentary general; and here he found an afylum from the attempts of his enemies, under the protection of Bern. Here he was interred, and his monument is a plain grave-ftone of black marble, on which is a Latin infcription. Over the door of the houfe which he inhabited is ftill preferred, from refpect to his memory, the following uncouth motto:

“ Omne folum forti patria eft, quia patris.”

Vevay is 10 miles E. of Laufanne. N. lat. 46° 30'. E. long. 6° 48'.

VEULLES, a town of France, in the department of the Lower Seine; 9 miles N.E. of Cany.

VEURDRE, LA, a town of France, in the department of the Allier; 13 miles N.W. of Moulms.

VEUVEY, a town of France, in the department of the Côte d'Or; 12 miles N.W. of Beaune.

VEXALA, in *Ancient Geography*, an eftuary of Britain, which is probably the bay at the mouth of the river Brent, in Somerfetfhire.

VEXES, See *NE injufte vexes*.

VEXILLARIJ, among the Romans, were veteran foldiers, the fame with thofe the old Romans called *striarii*. There were fix hundred of them in every legion.

VEXILLUM, a pair of colours belonging to each century

tury of a Roman legion, for the preservation of which, ten of the best soldiers in the century were allotted; and all those, in the different centuries of a legion, (ten centuries composing a cohort, and ten cohorts constituting a legion,) formed a very choice body of men, which was called the vexillation of that legion, and was sometimes separated from it, and sent upon particular services. The vexillation of a legion was equal in number of men to a cohort, and had an equal proportion allotted to it in the execution of all public works.

VEXILLUM, in *Botany*. See **STANDARD** and **PAPILIONACEOUS**.

VEXIN, in *Geography*, before the revolution a country of France, situated along the river Epte, which divided it into two parts, called "Vexin François," and "Vexin Normand." The principal towns of the former are Pontoise, Chaumont, and Magny, included in the department of the Oise. The capital of the latter was Gisors, in the department of the Eure.

VEOXE, a small island of Denmark, near the north coast of the island of Laland. N. lat. $54^{\circ} 58'$. E. long. $11^{\circ} 41'$.

VEYNE, a town of France, in the department of the Higher Alps; 12 miles W. of Gap.

VEZ DE MARBAN, a town of Spain, in the province of Leon; 8 miles N. of Toro.

VEZEDERINA, a town of European Turkey, in Bulgaria; 36 miles S.E. of Viddin.

VEZELAY, a town of France, in the department of the Yonne. Theodore Beza was a native of Vezelay; 7 miles W. of Avallon.

VEZELIZE, a town of France, and principal place of a district, in the department of the Meurthe; 12 miles S. of Nancy. N. lat. $48^{\circ} 30'$. E. long. $6^{\circ} 11'$.

VEZENOBRE, a town of France, in the department of the Gard; 6 miles S.S.E. of Alais.

VEZERE, LE, a river of France, which runs into the Dordogne, at Limeuil.

VEZINES, a town of France, in the department of the Yonne; 4 miles N. of Tonnerre.

VEZINS, a town of France, in the department of the Mayne and Loire; 7 miles N.E. of Collet.—Also, a town of France, in the department of the Aveyron; 6 miles S.W. of Severac le Château.

VEZIRKAR, a town of Asiatic Turkey, in Natolia; 25 miles S.E. of Ifnik.

VEZOUZE, a river of France, which runs into the Meurthe, about 3 miles below Luneville.

VEZZANO PIETROSO, a town of the island of Corfica; 13 miles S.E. of Corte.

UFALÉ, a town of the state of Georgia, on the Oak-fulkee. N. lat. $32^{\circ} 55'$. W. long. $85^{\circ} 57'$.

UFENS, or **OUFENS**, in *Ancient Geography*, a river of Italy, in New Latium, east of the Pontine marsh, which discharged itself into the sea; mentioned by Virgil and Silius Italicus.—Also, a river of Gallia Cispadana, mentioned by Livy.

UFFENHEIM, in *Geography*, a town of Germany, in the principality of Anspach; 18 miles S.S.E. of Wurzburg. N. lat. $49^{\circ} 37'$. E. long. $10^{\circ} 19'$.

UFFINIAC, a town of France, in the department of the North Coasts; 3 miles S.E. of S. Briec.

UFFUGUM, in *Ancient Geography*, a pretty considerable town of Italy, in Brutium. Livy.

UFHOLZ, in *Geography*, a town of France, in the department of the Upper Rhine; 17 miles S.S.W. of Colmar.

UFNAU, an island of Switzerland, in the lake of Zurich; about a mile in circumference.

UFTER GERFEN, a mountain of Switzerland, in the canton of Bern; 23 miles S. of Thun.

UFVERSO, a small island in the Baltic, east of Aland. N. lat. $60^{\circ} 7'$. E. long. $20^{\circ} 20'$.

UGAB, a very ancient instrument of the Hebrews, mentioned by Moses before the deluge. Many wild conjectures have been formed concerning this instrument. It has been construed into an organ by some, who did not recollect that *organ* was the general name for instruments of all kinds; and it is very improbable that a machine, so complicated as a modern organ of the most simple kind, should have been invented before the deluge. Don Calmet, whose ideas concerning Hebrew instruments are not always happy, thinks the ugab was only a syrinx, similar to Pan's pipe; for all the descriptions tell us that the ugab was a wind-instrument with many pipes. See **SYRINX**.

UGARA, in *Geography*, a town of Asiatic Turkey, in the government of Sivas; 7 miles W. of Tocat.

UGENA, in *Botany, so named by Cavanilles, *l.c. Plant. v. 6. 73. t. 594, 595*, is the same genus of *Filices*, which Willdenow, in his *Sp. Pl. v. 77*, has called *Hydroglossum*, from *ὕδωρ*, *water*, and *γλωσσα*, *a tongue*, alluding to its damp place of growth, and the tongue-like shape of the fructifying parts of the frond. Cavanilles meant to commemorate an excellent Spanish draughtsman, employed to delineate the new plants of the Madrid garden. Whether Willdenow's authority may restore *Hydroglossum*, we cannot here venture to foretell; but the genus in question is established by Swartz under the name of **LYCOPODIUM** (see that article); and Mr. Brown has sanctioned this last appellation, both in his *Prodr. Nov. Holl. v. 1. 162*, and in *Ait. Hort. Kew. v. 5. 497*, which we presume will decide the question.*

UGENTO, in *Geography*, a town of Naples, in the province of Otranto; 16 miles S.W. of Otranto. N. lat. $40^{\circ} 12'$. E. long. $77^{\circ} 8'$.

UGERNUM, in *Ancient Geography*, or, as Strabo has it, *Gernum*, a place which lay on the way from Nimces to Aqua Sextie, or Aix.

UGEST, in *Geography*, a town of the duchy of Warfaw, in the palatinate of Rawa; 6 miles S.E. of Rawa.

UGGADE, in *Ancient Geography*, a place marked in the Itinerary of Antonine between Rotomagus and Mediolanum Aulercorum, which is Evreux.

UGGER-ZEHM, in *Geography*, a town of the duchy of Courland, in the gulf of Riga; 33 miles E.N.E. of Goldingen.

UGGIATE, a town of Italy, in the department of the Lario; 5 miles W. of Como.

UGGIONE, or **OGGIONE**, **MARCO DA**, in *Biography*, was a native of Oggione, in the Milanese, and was born about the year 1480. He was one of the most able scholars of Lionardo da Vinci. Avoiding the minute elaborate finish of his master's smaller works, which was imitated by his fellow pupils generally, and attaching himself to the study of the great principles of the art, he became a skilful painter in fresco. He must have been greatly aided in his progress, by having copied the most renowned and the greatest of Da Vinci's works, the Last Supper, painted in the refectory of the Dominican convent at Milan. Uggione's copy is of the same size as the original, near 30 feet long, and was painted on canvas for the refectory of the Carthusians at Pavia, where it remained till the revolution, when it was removed and sold to a rich grocer at Milan; and is lately brought to this country for public exhibition, and for sale. Lanzi says of it, "that in measure it com-

penfates for the lofs of the original," and is juftified by the merit of the work. The characters of the heads appear to have been well rendered, except that of the Saviour. Thofe of St. John, St. Simon, and St. James, are excellently wrought, the former efpecially: indeed it appears fo diftinctly more complete than any other in colour and character, that one might think the great matter's hand had been employed upon it. The hands, however, are ill drawn, and tamely executed; and the feet much too large, and out of keeping. The draperies alfo are laboured, and a part is cut off the top of the picture, which injures the perfpective of the room in which the figures are feated.

His *frecco* pictures in the church of La Pace at Milan ftill preferve their lines and colours unimpaired: fome of them are in the body of the church itfelf; but the Crucifixion, his moft copious compofition, is in the refectory; a work, Mr. Fufeli has obferved, "which furprifes by its variety and fpirit: few Lombards have reached that degree of expreffion which ftrikes here, for the art of its compofition, and the fancy of its draperies." Of his oil pictures, two of the moft efteemed are at Milan, one at St. Paolo in Compito, the other in St. Eufemia; but they are inferior to his *freccos*. He died in 1530, aged about 50.

UGGLIBO, in *Geography*, a town of Sweden, in Geftricia, on a lake; 16 miles N.W. of Gefco.

UGH, a town of Hungary, near the Theiffe; 32 miles N. of Zegedin.

UGHELLI, FERDINANDO, in *Biography*, an ecclefiaftical hiftorian, was born of a good family at Florence in 1595; in his youth entered into the Ciftercian order, and finifhed his ftudies at Rome. After having paffed through various offices in different monafteries, he was elected abbot of St. Vincent, &c. at Rome, theologian to cardinal Carlo de Medici, and confultant of the congregation of the Index. He was alfo domeftic prelate to pope Alexander VII., who gave him a penfion, augmented by Clement IX. He declined accepting any bifhopric, though feveral were offered him, becaufe he preferred purfuing his ftudies at Rome. Having undertaken to give a feries of the bifhops of all the churches in Italy, with an illuftration of each church, deduced from documents in their refpective archives, he employed feveral perfons to affift him; and the work was printed at Rome in 9 vols., from 1642 to 1648, under the title of "*Italia facra, five de Epifcopis Italiae et Infularum adjacentium, rebufque aliis praeclare gefitis, deducta ferie ad nofttram ufque Aetatem, Opus fingulare.*" A new edition of this work was begun at Venice in 1717, and completed in 1733, in 10 vols. folio, with confiderable additions. Ughelli alfo made additions to the lives of the popes by Ciacconius, and publifhed eulogies of the cardinals of the Ciftercian order, and thofe of the Colonna family, and genealogies of the Marfciano and Capifuechi families. He died at Rome in 1670, at the age of 75. Moreti. Gen. Biog.

UGIA, in *Ancient Geography*, a town of Hispania, in the interior of Betica, belonging to the Turdetani, according to Ptolemy; marked in the Itin. Anton. between Afta and Orippe.

UGIE, in *Geography*, a river of Scotland, which runs into the German fea, about a mile N. of Peterhead. N. lat. 57° 27'. W. long. 1° 47'.

UGINE, a town of France, in the department of Mont Blanc; 20 miles E.S.E. of Chambéry.

UGLIANI, a town of France, in the department of the Dora; 16 miles E.S.E. of Aofta.

UGLIANO, a fmall rocky ifland in the Adriatic, near the coaft of Dalmatia, about 3 miles W. from Zara. The

VOL. XXXVII.

inhabitants fuffer confiderably from the want of *fresh water*. Illyrian fruits, efteemed by the Romans as one of the moft delicate luxuries of their table, abound here. N. lat. 40° 18'. E. long. 15° 16'.

UGLICH, a town of Ruffia, in the government of Jarofflav, on the Volga. The principal trade is in leather and foap; 60 miles W. of Jarofflav. N. lat. 57° 30'. E. long. 38° 22'.

UGLUM, a town of Sweden, in Weft Gothland; 16 miles S. of Uddevalla.

UGOD, a town of Hungary; 14 miles N.W. of Stuhl Weiffenburg.

UGOGNA, or VOGOGNA, a town of Italy, in the department of the Gogna, on the river Tofa; 15 miles N.W. of Arona.

UGONE, MATTIA, in *Biography*, was a native of Brefcia at the commencement of the 16th century, a doctor of laws, and bifhop of Famagotta, in the ifland of Cyprus. His principal performance is a treatife on councils, entitled "*Synodia Ugonia*," approved by a bull of Paul III. in 1543, and printed at Venice in 1565. Dupin pronounces it one of the beft and full eft treatifes written on that fubject in the 16th century. This writer maintains, that a council is fuperior to the pope, and may depofe him, not only for herefy and fchifm, but for any notorious crime, perfifted in after admonition; and that, in matters of faith, and fuch as concern the ftate of the church, or its head, the judgment of the council is to be preferred to that of the pope. He died in 1616. Dupin. Gen. Biog.

UGROČZ, in *Geography*, a town and caftle of Hungary; 16 miles N. of Topoltzan.

UGUALE, Ital., in *Mufic*, equal; as, *à parti uguale*, two vocal or instrumental parts, of equal confequence.

UHERCE, in *Geography*, a town of Auftrian Poland, in Galicia; 64 miles S.W. of Lemberg.

UHLERSDORF, a town of Saxony, in the circle of Neufadt; 5 miles S.W. of Weyda.

UHLFELD, a town of Germany, in the principality of Bayreuth; 19 miles N.W. of Nuremberg.

UHRTSCHUTA, a town of Moravia, in the circle of Olmutz; 10 miles S.W. of Olmutz. N. lat. 49° 23'. E. long. 17°.

UL, a river of Ruffia, which runs into the Irtifch, near Malanova, in the government of Toboltk.

U *et Armis*, q. d. *by force and arms*, a law-term ufed in an indictment; to denote the forcible and violent commiffion of any crime.

U *Laica Removenda*, in *Law*, a writ lying where debate being between two parsons, or provifors, for a church, one of them makes a forcible entry into it, with a number of laymen, and holds the other out.

VIA, *Way*. See *WAY*, and *ROAD*.

VIA *Lactea*, in *Aftronomy*, the milky way, or *galaxy*; which fee.

VIA *Militaris*, in our *Law-Books*, is ufed for a highway. "*Quae publica dici poterit, et ducit ad mare, et ad portum, et quandoque ad mercata.*" Bracon, lib. iv. c. 16.

VIA *Militaris*, in *Roman Hiftory*. See *MILITARY Ways*, and *WAY*.

VIA *Regia*, the *King's Highway*, is defined in Leg. Henry I. to be "that which is always open, and which nobody may fhut by any means, as leading to a city, port, or town."

Its breadth the fame laws prefcribe to be fuch, as that two carts may pafs each other, and fixteen horfemen armed may go abreast. See *HIGHWAY*.

VIA SOLIS, the *Sun's Way*, in *Astronomy*, is used, among some astronomers, for the ecliptic line; so called, because the sun never goes out of it.

VIA TURRATA CHICA, in *Ancient Geography*, a place of Africa, in the eastern part of Mauritania Caesariensis, situated on the sea-coast, some miles W. of Icofium, in which are the remains of some Roman walls and cisterns.

VIA, ULLA, a river of Hispania Citerior, which ran from the N.E. to the S.W., passed by Iria Flavia, and discharged itself into the sea.

VIA APPIA. See *APPIAN WAY*, and *VIA ROMANA*.

VIA DOMITIANA, took its name from Domitian, by whose orders it was executed. It detached itself from the Appian way at a small distance from Sinuessa, on the spot now called Mont-Dragone. This way opened under a triumphal arch, which was richly ornamented with marbles and metals, and passed along the sea by Vulturum, Litemum, Cumeæ, and Bayæ to Puteoli.

VIA CURIA, a Roman way marked by Dionysius of Halicarnassus in the Sabine territory, on which were the following towns, *viz.* Curfula, 80 stadia from Reatè, and Iffa near Curfulin. Some have represented this as the same with the Latin way.

VIA QUINTIA, which, according to Dion. Hal., belonged to the Sabines. Holitenius suggests that it was the same with the *Via Salaria*. Dion. Halic. places upon this way Palatium, 25 stadia from Reatè; Trebula, 60 stadia from Palatium; Vespola, 60 stadia from Trebula; Sima, 40 stadia from Vespola; Mephyle, 30 stadia from Suna; and Orviniun, 40 stadia from Mephyle.

VIA ROMANA, or *Roman Ways*, were public roads on which the ancient Romans impressed marks of grandeur and celebrity, as well as of utility, that have not been altogether effaced during an interval of more than 2000 years. In the construction of these roads they began with making a deep excavation, on each side of which they erected walls, and on these walls formed a parapet. The space between the walls was filled with layers of different materials, one of which was mortar made of the volcanic produce called puzzolano. Above these they placed the hardest stones which they could procure, and which they fastened together by an intermediate cement; and the salient angles were so constructed as to form a large mass. The elevated parapet served not only to give solidity to the way, but to afford a convenient seat for those who travelled on foot; and at certain intervals they placed stones of a greater height, which served for the convenience of horsemen. On these ways they had temples and monuments, which contributed to their ornament; and the distances were marked on columns of stone. Originally they marked the distance of any place from a column in the city of Rome; but in process of time they noted the distance from the capital of the province, or from any other town which they selected for this purpose. The first of these Roman ways was the *Appian way*, which commenced at the gate of Rome bearing this denomination, and took a S.S.E. direction. To the right commenced the *Via Ardeatina*, which proceeded from the south as far as Ardea, almost perpendicularly to the meridian. Within the compass of Rome, at the foot of mount Cælius, and to the left of the Appian way, commenced the *Via Latina*, the direction of which was to the S.E. At seven miles and a half commenced, to the left of the Latin way, the *Via Tusculana*. To the E. commenced the way, which, in the city, bore the name of *Via Sacra*. From this way, in the interior of the city, proceeded the *Via Campana* towards the S.E. The *Via Labicana* has an almost S.E. direction. Towards the E. is the *Via Praenestina*. To

the left of this way, about the fifth mile from Rome, is the *Via Collatina*. Towards the N.E. the first way is the *Via Tiburtina*, passing, as its name indicates, to the Tiber. The second is the *Via Nomentana*, proceeding towards the N.E. to the tenth mile, and then turning directly northwards to Nomentum. The third is the *Via Salaria*, which is detached to the Colline gate from the left of the Nomentane way, and proceeding directly towards the N. as far as the eighth mile, rejoins the same way at Eretum. It is called *Salaria*, from the salt which the Romans used to bring to Rome along this way from the sea. It was through the gate *Salaria* that the Gauls entered Rome, under the command of their leader Brennus, when that city was first taken by them. Towards the N.W. the first way is the *Via Lata*, which formerly turning by the Capitoline mount, passed by the ancient triumphal gate. This way afterwards assumed the name of *Flaminia*. The second is the *Via Claudia*, which advanced towards the N.W.; and at the sixth mile proceeded the third way in this direction, or the *Via Cassia*, which proceeded to Veii. The fourth way is the *Via Triumphalis*, which at the ninth mile joined the *Claudian way*. The fifth bore the name of *Via Cornelia*, which proceeded by the W. $\frac{1}{4}$ N. to the tenth mile; and the sixth was the *Via Aurelia*, which left Rome at the gate of Janiculum, and proceeded a little towards the S.W., but changing its direction towards the N.W. it gained the sea-coast, along which it pursued its course.

Towards the S.W. the first way was the *Via Portuensis*, so called, as well as the gate by which it left the city, from their leading to the place called Portuensis, now called by corruption "Villa Portese." It passed by the S.E. and joined the route which followed the windings of the Tiber under the name of *Via Littoralis*, which last advanced to the "Portus Augusti." The second was the *Via Ufrensif*, which passed N.W. of the Circus Maximus, and crossing the Almo at the gates of Rome, it turned to the S.W. towards Ostia. The third way commenced five miles and a half on this way towards the left, under the name of *Via Laurentina*, which proceeded to the S. as far as Laurentum. We have above enumerated twenty-one ways or roads, which separating at the centre of Rome extended more or less to different parts of Italy. Bergier, to whom we are indebted for this detail on the Roman roads, proceeds, after having surveyed them at and near Rome, to trace their length and direction in various parts of Italy.

The military ways proceeding immediately from the gates of Rome, according to the table of Peutinger, and recorded in history, are eleven, agreeably to the following arrangement: *viz.* *Via Flaminia, Salaria, Numentana, Tiburtina, Praenestina, Labicana, Latina, Appia, Hostiensis, Aurelia, and Triumphalis*.

The construction of the Flaminian road is ascribed by some authors to Flaminius, who was killed at the battle of the lake of Thrasymene, under the consulate of Lucius Veturius and Caius Lutatius, in the year of Rome 533; but Strabo ascribes this work to the son of this Flaminius, and he says expressly that he formed two grand roads in Italy, one from Rome to Ariminum (Rimini), called *Via Flaminia*; and another from Ariminum to Bononia (Bologna), and to Aquileia, which was denominated *Via Emilia*. The distance from Rome to Rimini, according to the Itinerary of Antonine, was 222 Roman miles; but according to the table of Peutinger, 194 miles. History records nine military ways which parted from the *Via Flaminia*; and of all these ways, that called *Via Æmilia* was the most ancient, the most known, and the grandest of all; its length surpassed that of the Flaminian way, and

it was equally ancient. As to its antiquity, Strabo says that it was made at the same time with the Flaminian way, and Palladio ranks it among the three most renowned and most excellent, viz. *Via Appia*, *Via Flaminia*, and *Via Emilia*. This latter extended from Ariminum to Bononia, and thence to Aquileia, a distance, according to Antonine's Itinerary, of 485 miles, and according to the table of Peutinger of 527 miles. The poet Martial, speaking of this famous way, and of one of the cities which he found upon it, (lib. iii. ep. 4.) says,

“ Romam vade, liber, si veneris undè requiret,
Emiliae dicas de regione viae,
Siquibus in terris, qua finis in urbe rogabit,
Corneli referas me licet esse fero.”

The second branch of the Flaminian way is that called *Cassian*. It commenced at pons Milivius (or Ponte Mole), built upon the Tiber, two miles from Rome. From thence it took its direction by the town of Sutri.

The third branch, which detached itself from the Flaminian way, was the Claudian way, of which Ovid (l. i. de Ponto) says,

“ Nec quos pomiferis positos in collibus hortos
Spectat Flaminiae Claudia juncta viae.”

According to the Itinerary, the distance from Lucca to Rome was 239 miles, and according to the chart of Peutinger 145 miles.

Besides these, the Annienne, Augustan, Cimine, Ameniense, Sempronian, and Posthumian, commencing at different parts of the Flaminian way, extended themselves across the different regions of Italy, between the city of Rome and the Po. Of all these ways, that called the Annienne is known by an ancient inscription found in the ruins of the town of Axuma. The Cimine way was between a mountain and the lake of its name near Viterbo. Virgil thus speaks of it, (*Æn.* vii.)

“ Cimini cum monte Lucum, Lucosque Capenos.”

The Ameniense way took its name from the town of Amelia, near Spoleto. The Sempronian way had its name from the town of Forum Sempronii, whence it extended as far as Fulginia or Fulcinium in Umbria. The Posthumian passed into Gaul, called by the Romans Togata; and Tacitus thus speaks of it: “ Sistere tertiam legionem in ipso viæ Posthumiae aggere tubet.”

The *Via Salaria* commenced at the Colline gate, and extended towards the N. across the country of the Sabines, receiving the Nomentane way at the village of Hercolum, eighteen miles from Rome, on the bank of the Tiber. Its route, indicated by the Itinerary from Eretum to Hadria, was 166 miles, and according to Peutinger's table 168 miles. Near this way were built the temples of Ericina and Venus Verticordia, and also several magnificent tombs. From the *Via Salaria* branched out two other ways, viz. the Quinctian and the Junian.

The Nomentane way took its origin at the Viminal gate, and extended N.E. as far as Nomentum, a town of the Sabines, in ancient Latium. Ovid thus speaks of it, (*Fast.* l. iv.)

“ Hæc mihi Nomento Romam cum luce redirem
Obstitit in media Caudida Turba via.”

Two miles from the city, on the Nomentane way, was a temple of Bacchus, which afterwards became the tomb of the family of the Constantines. On this way were also several temples and sepulchres.

It has been said by some authors, that the Porta Tiburtina and the Porta Gabina or Gabiosa were the same, and also the *Via Tiburtina* and *Via Gabina* or *Gabiosa*. Others have maintained that they were different, issuing from the same gate; the Gabiana being more to the east than the Tiburtina; the former taking its course to the right, towards the Prænestine way, and the latter to the left, towards the N.E., passing by delightful places near the Tiber. From the Esquiline gate proceeded the two grand roads, called Prænestina and Lavicana. The Prænestine, according to Bergier, commenced at Rome, not far from the Forum; and at Anagnia, joined the *Via Latina*. The Lavicana also commenced in Rome; and having passed between two aqueducts, joined the Latin way at Anagnia. Strabo does not conduct the Lavicana so far; and the table of Peutinger terminates it at Lanuvium, twenty-nine miles from Anagnia. The *Via Latina* commenced at the gate of this name, and proceeded between the W. and the S. to join the grand Appian way, nineteen miles from Capua. The Appian, Latin, and Valerian ways were the most considerable in Latium: the Valerian way, upon leaving Rome, proceeded towards the left, the Appian towards the right, and the Latin way between the two. We may here observe, that there were two ways under the name of Valerian, the ancient and the new. The Itinerary mentions one, and Strabo the other. The Latin way was called by the ancients the Aufonian way; accordingly Martial has given it these two names. On this way was found the temple of female Fortune, with her statue, which married women only were allowed to touch without committing sacrilege. Of the *Appian* way we have given a brief account under that article: and for a farther account of other ways, we refer to the preceding part of this article; our limits allowing of no farther enlargement. The Romans extended their ways through the whole extent of their empire, and it would fill a volume to trace them in Europe, Asia, and Africa. The Itinerary of Antonine, and the table of Peutinger, will afford the curious in this research great assistance. For an account of the Roman roads in Britain, see *WAV.*

In connection with the Roman roads, it may not be improper to enumerate, as briefly as possible, the gates of Rome. When Rome was founded, it comprehended only mount Palatine and the neighbouring valley, where was the Forum; and it had only three gates. When the Sabines were admitted by Romulus into a participation of the freedom of the city, it was enlarged, and the Capitol inclosed; and for admission on the side of the Capitol, a fourth gate was added. The first gate had the name of *porta Munitionis*, from the bellows of the horned beasts which were sent through it to the adjoining pastures; the next called *Romula*, from the name of the city; and the third *Janualis*, from the god Janus, who inhabited this quarter. The fourth had the name of *porta Carmentalis*, from Carmenta, wife of Evander, who had his abode in that quarter, at the foot of the Capitol: which last gate is mentioned by Solinus, Plutarch (Life of Camillus), and Virgil (*Æneid.* viii.). In subsequent ages Rome was several times enlarged, and it became necessary to construct new gates; the four first serving merely for the fortrefs and the inclosure of the city. Numa, the successor of Romulus, added to the city a part of the Quirinal mount; and as the inhabitants multiplied, Tullus Hostilius joined to it mount Cælius; Ancus Marcius, the Janiculum; Servius Tullius, the rest of the Quirinal and the Viminalis. A long time afterwards, Sylla, Julius Cæsar, Augustus, and Tiberius, enlarged the compass of the city, so as to include a variety of magnificent edifices.

edifices. Nero having set fire to it, added to its former grandeur; Trajan also augmented it, as did also Aurelian, who inclosed the Campus Martius; and, finally, Constantine the Great enlarged it on the side of the Viminal and Tiburtine gates. Authors have differed as to the number of gates which belonged to the city of Rome. Pliny, in his time, reckoned twenty-four; but Procopius states them at fourteen, besides those less considerable gates, which he calls portule. In order to reconcile these discordant statements, it has been said that Rome had fourteen royal and principal gates, which might be denominated imperial and military, and to which all the military ways of Italy were directed; and besides these it had, in Pliny's time, ten others of inferior importance. The first fourteen, with their ancient and modern names, were the following, viz. *P. Flamentana*, afterward *Flaminia*, now the gate of the people, or del Popolo, from a church built near it by pope Pascal II., dedicated to the Virgin Mary, under the appellation of Sta. Maria del Popolo:—*Collatina*, so called because it led to a town of that name in the country of the Sabines, not far from Rome, since *Pinciana*:—*Agonensis*, bearing that name from the Agonalia celebrated just without it; since *Quirinalis*, from a chapel sacred to Romulus (Quirinus), which stood near it; also *Collatina*, or *Collina*, from its situation at the junction of the hills Quirinalis and Viminalis; and last of all, *Salaria*:—*Viminalis*, so called on account of the officers that grew near it, and because it was situated on the declivity of mount Viminalis; called also *Nomentana*, or *Numentana*, because the road through it led to Numentum; and now the gate of St. Agatha, or St. Agnes:—*Gabiosa*, so named from its leading to a road called Gabina; called by St. Gregory *Metroni*:—*Esquilina*, originally so called from its situation on mount Esquiline; *Taurina*, from the head of an ox engraved upon it; *Tiburina*, from its leading to Tibur, now Tivoli; *Libitensis*, on account of the dead bodies that used to be carried through it to be interred in the Campus Esquilinus, the burying place of the common people; *Laticana* and *Præstina*, because the roads passing through it led to these places; now, as some say, the gate of St. Lawrence, to whose magnificent church it leads; but others ascribe the name of St. Lawrence to the *Gabiosa*, and say this is the Porta major or greater gate; hence it is said that this name, as well as that of *Sancti Crucis*, or of the *Holy Cross*, is applied to *P. Nevia*, so called, says Varro, from the *nemoribus* or woods that formerly stood near it, or from an adjacent wood belonging to one Nævius; and it is observed that the Claudian aqueduct runs close by it:—*Calimontana*, so denominated from its situation on mount Cælius; since *Afinaria*, so called either from a road of that name to which it led, or from gardens, called the Afinarian, situated near it, or from Afinius Pollio or Afinius Gallus, consuls under Augustus, who built or repaired it; its oldest name was *Querquetulana*, under which name it is mentioned by Cicero; now *St. John's* gate, because it leads to St. John Lateran:—*Ferentina*, a name derived from Ferentinum, a place on the Latin way; since *Latina*, from its leading to Latium, now the Campagna di Roma; near it is now a chapel dedicated to *St. John the apostle*, from whom the gate is at present called:—*Capena*, so called from Capua, an old city of Italy, the way to which led through this gate; since *Appiana*, from its leading to the Appian way; or *Triumphalis*, from some triumphs in which the procession passed through it; it was also, as some say, called *Foninalis*, from the aqueducts which were raised over it; now the gate of *St. Sebastian*, from a church dedicated to that saint, which stands near it:—*Trigemina*, anciently so named from the three Horatii,

who went out at this gate to fight the Curiatii; called also *Appia*, from its being near the Appian aqueduct; *Foninalis*, from its being near a number of springs; and *Ofstiensis*, on account of the road to Ostium, which began there; now the gate of *St. Paul*, from a noble church dedicated to that apostle, to which it leads, without the walls:—*Navalis*, so called from its being near the river; and *Portuensis*, from its leading to the city of this name:—*Janiculensis*, named probably from a bridge of that name which led to this gate; sometimes called *Trajana*, as having been repaired by the emperor Trajan; and *Aureliana*, from the emperor Aurelian, who either built or repaired it; now *St. Paucras's* gate:—*Foninalis*, called also *Septimiana*, from the emperor Septimius Severus, who built it, and whose baths are just without this gate; it was repaired by pope Alexander VI.:—and *Aurelia*, near the gate of Adrian. The other ten gates were of less importance; they were called *Portula* by Procopius, but there is a confusion in their names, which are as follow, compared with those of the other class: viz. *Querquetula*, or *Querquetulana*, on mount Viminal:—*Picuaris*:—*Catularia*:—*Minutia*:—*Mugiona*:—*Sanguis*:—*Nævica*:—*Rauduscula*, or *Raudusculana*:—*Lavernalis*:—and *Libitensis*. Besides these twenty-four gates, there is yet one which served for an entrance into the city of Rome, on the side of mount Vatican, and on this side of the Tiber, not comprehended under those which we have already recounted. It is the most celebrated of all, and bore the name of *P. triumphalis*, ascribed by some to *Capena*, already mentioned.

VIA, in *Geography*, a town of Persia, in the province of Segestan; 15 miles S.E. of Ferah.

VIA REGGIA, a sea-port town of the state of Lucca, and the only port of the republic; 20 miles W. of Lucca.

VIACHA, a town of Peru, in the diocese of La Paz; 8 miles S.W. of La Paz.

VIACIENSES, or VIATIENSES, in *Ancient Geography*, a people of Hispania Citerior, comprehended under the general name of Oretani.

VIADANA, LODOVICO, in *Biography*, the inventor of the expedient of expressing chords by figures in accompaniment or thorough-bass, which the Italians call *basso continuo*, was born at Lodi, in the Milanese, the latter end of the sixteenth century. His first preference was that of maestro di cappella of the cathedral of Fano, and the second that of Mantua. He was one of the most distinguished ecclesiastical composers of his time. The indication of chords by figures in accompanying on keyed instruments, lutes, harps, and, in recitatives, even violoncellos, has been doubted, as several instances of the minute beginnings of this expedient have been observed previous to the time of Viadana; but he was, doubtless, the first who drew up general rules for expressing harmony by figures over the bass in 1615. Draudius, in an ample list of his ecclesiastical compositions, which were very numerous, tells us of one that authenticates his claim to this invention, which was a collection of all his choral pieces, of one, two, three, and four parts; "with a continued and general bass, adapted to the organ according to a new invention, and useful for every finger as well as organist; to which are added short rules and explanations for accompanying a general bass, according to the new method." Viadana was therefore the first who composed an organ bass different from the voice-part, in the execution of which the new invented figures enabled the performer to give the fingers the whole harmony of the several parts of a full composition, without seeing the score.

As the construction of perpetual fugue, or canon, required more meditation and science than any other species

of composition, there were several musicians during the seventeenth century, who, from an ambition to excel in such difficult undertakings, seem to have devoted as great a portion of their lives to these labours as holy men ever did to severe acts of piety and devotion, in order to be canonized.

Though the learned and elaborate style in which both the music of the church and chamber continued to be cultivated at this period, till near the middle of the seventeenth century; yet a revolution in favour of melody and expression was preparing, even in sacred music, by the success of dramatic composition, consisting of recitation and melodies for a single voice, which now began to be preferred to music of many parts, in which canons, fugues, and full harmony, were the productions which chiefly employed the master's study and hearer's attention. And this rendered the art of accompaniment or thorough-bass more necessary. See **CHORDS, ACCOMPANIMENT, and THOROUGH-BASS.**

VIADANA, in *Geography*, a town of Italy, in the department of the Mincio, on the Po; 23 miles S.S.W. of Mantua.

VIADUS, or **VIADRUS**, in *Ancient Geography*, a river of Germany, which had its source in Suevia, and discharged itself into the Suevian sea, or Codanus Sinus. This river is called *Gustallus* by Pliny.

VIE PRIMÆ, the first passages; a technical term for the stomach and intestines.

In this sense we say, an obstruction in the primæ viæ. Purging and emetic medicines operate chiefly on the primæ viæ. And sudorifics, alteratives, cardiacs, &c. suspend their action till after they have passed the primæ viæ.

VIAL, or **PHIAL**, a small and thin glass bottle. See **PHIAL.**

VIALA du Tarn, Le, in *Geography*, a town of France, in the department of the Aveyron, near the Tarn; 9 miles S.W. of Milhaud.

VIALES, in *Mythology*, a name given, among the Romans, to the gods who had the care and guard of the roads and highways. Such were Mercury and Hercules.

The Dii Viales, according to Labeo, were of the number of those gods called Dii Animales; who were supposed to be the souls of men, changed into gods: these were of two kinds; viz. the Viales and Penates.

The Viales were the same with those otherwise called Lares; at least, some of the Lares were denominated Viales; viz. such of them as had the more immediate superintendency of the roads.

Hence the two names are sometimes joined, and those highway-deities are called Lares Viales; witness that inscription in Gruter:

FORTUNÆ
REDUCI LARI
VIALI ROMÆ
ÆTERNÆ
Q. ANIUS AELIA
NUS—VE. PROC.
AUG.

IONI.

VIAMON, in *Geography*, a town of Brasil, in the jurisdiction of Rio de Janeiro.

VIANA, in *Ancient Geography*, the name of a town of Norica. Pliny.

VIANA, in *Geography*, a mountain of Portugal, in the province of Alentejo; 3 miles S. of Evora.—Also, a town of Portugal, in the province of Alentejo; 12 miles S. of Evora.—Also, a town of Spain, in Galicia; 30 miles E.S.E. of

Orense.—Also, a town of Spain, in Navarre, on the Ebro; 16 miles S.W. of Estella.

VIANA de Foz de Lima, a sea-port of Portugal, in the province of Entre Duero e Minho, situated on the N. side of the Lima, near its mouth, containing two parishes, an hospital, seven convents, and about 7000 inhabitants; the harbour is choaked up, and only capable of receiving small vessels; 9 miles W.S.W. of Ponte de Lima. N. lat. 41° 41'. W. long. 8° 26'.

VIANDEN, or **WYANDEN**, a town of France, in the department of the Forests, late the duchy of Luxemburg, called by the Germans Vyenthal, situated on the river Uren, which divides it into New and Old Town, in the midst of rocks and mountains. In the Old Town is a castle, situated on a rock of prodigious height, where a garrison was kept. Vianden is a very ancient and illustrious comté, which comprehends forty villages and hamlets, that belonged to the house of Nassau. The inhabitants carry on a considerable trade in manufacturing cloth and the tanning of leather; 18 miles N.N.E. of Luxemburg.

UJANDINSKOE YASASCHNOE, a town of Russia, in the government of Irkutsk, on the Indigirda; 148 miles N.N.E. of Zashiversk. N. lat. 68° 40'. E. long. 132° 14'.

VIANEN, or **VIANEN**, a town of Holland, situated on the S. side of the Leck; 7 miles S. of Utrecht.

VIANINA, a town of the duchy of Piacenza; 20 miles S. of Piacenza.

VIANO, a town of the duchy of Piacenza; 13 miles S. of Piacenza.

VIANOS, a town of Spain, in New Castile; 3 miles S. of Alcazar.

VIAREDEN, a town of Brandenburg, in the Ucker Mark; 1 mile N. of Schwedt.

VIAS, a town of France, in the department of the Herault; 6 miles N.W. of Agde.

VIASDUM, a town of Poland, in the palatinate of Rawa; 16 miles W. of Rawa.

VIAST. See **VIEST**.

VIATICUM, among the ancient Romans, was the allowance or appointment which the republic gave to such of its officers as were sent into the provinces to exercise any office, or to perform any service or commission; as also to the officers of the army, and even the soldiers, &c.

Tacitus makes mention of it, *Annal. lib. i. c. 37. Viaticum amicorum, ipsiusque Cesaris*; meaning the appointments which the republic paid to Germanicus and his officers.

This viaticum, however, did not consist altogether in money; the ring given to the magistrates and officers sent into the provinces was part of it; so were the clothes, baggage, tents, and the rest of the equipage.

Some have also given the name of viaticum to the piece of gold, silver, or copper, which the ancients used to put into the mouths of the dead, to pay Charon for their passage.

In the Romish church, viaticum is still the allowance made a religious, to defray the expences of a journey, mission, &c.

VIATICUM is also used for the communion, or eucharist, which is given to the people in the pangs of death, or who are about to make the voyage of the other world.

The viaticum is not to be given to persons executed in course of justice.

VIATKA, in *Geography*, a town of Russia, and capital of the government of Viatskoe: the environs of this city abound in excellent pasture for sheep, of which great numbers were sent hither from Germany, and a woollen manu-

manufacture was established by the great Peter. Some tanners likewise were brought by him from England, to teach the art of tanning leather; 624 miles E. of Peterburg. N. lat. $58^{\circ} 25'$. E. long. $50^{\circ} 22'$.—Alfo, a river of Ruffia, which paffes by Viatka, Orlov, Kotelnitch, &c. and runs into the Kama, 40 miles E. of Kazan.

VIATOR, in *Antiquity*, an officer of juftice among the Romans. The term, originally, had no other fignification than that of a public meffenger, or fervant, fent to advertife the fenators and magiftrates when afsemblies were to be held, where their prefence was required.

Hence, becaufe, in the firft ages of that empire, the Roman magiftrates lived moftly at their country houfes; thefe officers being obliged to be frequently upon the road, were called *viatores, travellers*; from *via, highway*.

In procefs of time, the name *viator* became common to all officers of the magiftrates, lifitors, accenfi, fcribes, ftatores, and criers; either by reafon thefe names and offices were confounded in one; or becaufe *viator* was a general name, and the reft particular ones, fpecifying the particular functions they difcharged, as A. Gellius feems to infinuate, when he fays, that the member of the company of viatores who binds a criminal condemned to be whipped, was called *liſtor*.

Be this as it will, the names *liſtor* and *viator* are often ufed indifferently for each other; and we as often meet with *Send to ſeek, or advertiſe him by a liſtor, as by a viator*.

None but the confuls, pretors, tribunes, and ædiles, had a right to have viatores. They were not to be Roman citizens, and yet they were required to be free.

VIATORE, in *Geography*, a town of Hindooftan, in the country of the Nays; 25 miles N.E. of Tellichery.

VIATSKOE, a government of Ruffia, bounded on the N. by the government of Vologda, on the E. by Permiſkoe. on the S. by Uphiuſkoe and Kazanſkoe, and on the W. by Koſtromſkoe; 260 miles long, and from 80 to 180 broad. N. lat. $55^{\circ} 40'$ to $60^{\circ} 25'$. E. long. 46° to 54° .

VIAZMA, a town of Ruffia, in the government of Smolenſk. This town is fituated on an eminence, and covers a great extent of ground; it is irregularly built, chiefly of wooden houfes, a few only of the more modern being of brick. It contains more than twenty churches, a great number for the town, which is far from being populous; 76 miles E.N.E. of Smolenſk. N. lat. $55^{\circ} 20'$. E. long. $24^{\circ} 26'$.

VIAZNIKI, a town of Ruffia, in the government of Vladimir, on the Kliazma; 52 miles E. of Vladimir. N. lat. $56^{\circ} 10'$. E. long. $41^{\circ} 50'$.

VIAZOVSKOI, a town of Ruffia, in the government of Upha, on the Ural; 26 miles E.S.E. of Orenburg.

VIBANTANARIUM, or VIBANTAVARIUM, in *Ancient Geography*, a town of European Sarmatia. Strabo and Ptolemy.

VIBELLI, a people of Italy, in Liguria. Pliny.

VIBEX is ſometimes ufed, by *Physicians*, for a black and blue ſpot on the ſkin, occaſioned by an afflux or extravafation of blood.

VIBI FORUM, in *Ancient Geography*, a place of Italy, in Gallia Cifalpina.

VIBINUM, a place of Italy, in Apulia, making a part of Magna Græcia.

VIBISCUS, a town of Gallia Celtica, or the Lyonneſe, among the Helvetians. Anton. Itin.

VIBO, VIBONA, or *Vinoba*, a town of Italy, in Brutium, upon the route from Rome to Colonne, by the Aprian way, between Ad Turres and Nicotera. Cicero calls it Vibo.

VIBORG, or WIBORG, in *Geography*, a city of Denmark, capital of a dioceſe, and all North Jutland, ſituated near the centre of the province, on a lake, called Afmild, which abounds in fiſh. It is one of the moſt ancient towns of the kingdom, and was formerly large and rich, containing, prior to the reformation, twelve churches and fix convents. At preſent it is about two miles in circumference, and contains three pariſh churches. It is ſtill the reſidence of a governor, and the ſee of a biſhop; and a provincial court is held here every month for all North Jutland. In 1528, the reformation firſt began in this town; 186 miles N. of Hamburgh. N. lat. $36^{\circ} 32'$. E. long. $9^{\circ} 18'$.

VIBORG, or *Wyborg*, a ſea-port town of Ruffia, and capital of a government, to which it gives name, in the gulf of Finland; the ſee of a biſhop. This town was built in the year 1293, and was heretofore the capital of Carelia. It was founded by Birger Jahl as a military hold, that ſhould enable him to check the increaſing power of the republic of Novgorod, ſo famous in thoſe days. Peter the Great having taken this town by capitulation in the year 1710, improved its fortifications, which have ever ſince been kept in tolerable good condition, ſo that Viborg was looked on as the bulwark of Ruffia againſt Sweden. They are now, however, in a ſomewhat dilapidated ſtate, and not regarded as of much uſe. The principal exports are planks, tallow, pitch, and tar, for which the Engliſh are the greateſt customers: their imports are moſtly purchaſed from France and Holland, and are chiefly wine, ſpices, and ſalt; 360 miles S.W. of Archangel. N. lat. $60^{\circ} 50'$. E. long. $28^{\circ} 50'$.

VIBORGIA, in *Botany*, erroneouſly written *Wiborgia*, received its name in honour of Mr. Eric Viborg, a learned and acute Daniſh botaniſt, author of ſeveral botanical and economical treatiſes in his own language, publiſhed eighteen or twenty years ago at Copenhagen.—Thunb. Prodr. n. 45. Willd. Sp. Pl. v. 3. 919.—Clafs and order, *Dialdelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Eſſ. Ch. Stamens all connected. Calyx five-toothed, with rounded interſices. Legume turgid, furrowed, winged.

1. *V. obcordata*. Thunb. Prodr. 121. Willd. n. 1.—Leaflets ſmooth, obtuſe. Branches elongated, lax.—A ſhrub, found at the Cape of Good Hope.

2. *V. ſufca*. Thunb. ibid. Willd. n. 2.—Leaflets ſmooth, pointed. Branches wand-like, erect.—A ſhrub, from the ſame country.

3. *V. ferricea*. Thunb. ibid. Willd. n. 3.—Leaves downy, as well as the wand-like branches.—This is alſo a Cape ſhrub. We have ſeen none of the ſpecies. The genus feems well defined, though we lament the meagreneſs of its hiſtory.

VIBORSKOI, in *Geography*, a government of Ruffia, of which Viborg is the capital; bounded on the N. and W. by Finland, on the S. by the gulf of Finland and the government of Peterburg, and on the E. by lake Ladoga and the government of Oloœt; its form is very irregular. Its extent from N. to S. about 152 miles, where longeſt, in other places ſcarcely 60; its breadth from 60 to 100. N. lat. $60^{\circ} 15'$ to $62^{\circ} 40'$. E. long. 26° to 32° .

VIBRAIS, or VIBRAYE, a town of France, in the department of the Sarte; 9 miles N. of St. Calais.

VIBRANT, or VIBRION, in *Natural Hiſtory*, the name of a claſs of flies, commonly known by the name of the *iechnumons*.

The word is derived from the Latin *vibro, to ſhake or quiver*, and is applied to theſe flies, from the continual vibrating motion obſerved in their antennæ.

VIBRATION, in *Mechanics*, a regular, reciprocal motion

VIBRATION.

tion of a body, *e. g.* a pendulum; which, being suspended at freedom, (twings, or vibrates, first this way, then that. For the bob being raised, falls again by its gravity; and with the velocity thus acquired, rises to the same height on the other side; whence its gravity makes it fall again: and thus its vibrations are continued.

Mechanical authors, in lieu of vibration, frequently use the term *oscillation*; which see.

The vibrations of the same pendulum are all isochronal; that is, they are performed in equal time, at least in the same climate: for, towards the equator, they are found somewhat slower. See PENDULUM.

A pendulum 3 feet $3\frac{1}{8}$ inches, according to Huygens, or 39.25 inches, according to sir J. Moor and lord Brouncker, vibrates seconds, or makes 3600 vibrations in an hour.

The vibrations of a longer pendulum take up more time than those of a shorter one, in a subdupple ratio of the lengths. Thus, a pendulum three feet long will make ten vibrations, while another nine inches long makes twenty. For 10 is the half of 20, and 3 feet, or 36 inches, are the square of 6 inches; which is double of 3, whose square is 9; so that 10 is to 20 in a subdupple ratio of 36 to 9.

The same thing is meant when we say, that the number of vibrations of pendulums, in a given time, is in a reciprocal subdupple ratio of their lengths.

The following table shews the number of vibrations in a minute, corresponding to pendulums of different lengths, expressed in inches.

Length.	Vibrations.	Length.	Vibrations.	Length.	Vibrations.
4	187	10	118	35	63
5	167	12	107	40	59
6	153	15	97	50	53
7	142	20	84	60	47
8	132	25	75		
9	125	30	68		

M. Mouton, a priest of Lyons, wrote an express treatise to shew, that, by means of the number of vibrations of a given pendulum, in a certain time, one might establish an universal measure throughout the whole world; and fix the several measures in use among us, in such manner, as that they might be recovered again, if at any time they should chance to be lost, as is the case of most of the ancient measures; which we now only know by conjecture. See *UNIVERSAL MEASURE AND STANDARD*.

The vibrations of a *stretched chord*, or *string*, arise from its elasticity; which power being of the same kind with that of gravity, the vibrations of a chord follow the same laws as those of pendulums: consequently, the vibrations of the same chord equally stretched, though they be unequal in length, are equidurnal, or are performed in equal times; and the squares of the times of the vibrations are among themselves, inversely, as the powers by which they are equally bent and inflected. (See CHORD and STRING.) On this subject, see Young's *Philos.* vol. ii. p. 546.

The sounding body in action quits its tranquil state by slight, but sensible and frequent undulations, each of which is called a *vibration*. These vibrations, communicated to the air, convey to the ear, by that vehicle, the sensation of sound; and this sound is grave or acute, in proportion as the vibrations are more or less frequent in the same time. See SOUND.

The vibrations of a *string* (which see), too, are proportionable to the powers by which it is bent: these follow the same laws as those of the chord, or pendulum; and, conse-

quently, are equidurnal; which is the foundation of spring watches.

For Pythagoras's account of the doctrine of vibrations, see PYTHAGORAS.

VIBRATIONS are also used in *Physics*, &c. for divers other regular alternate motions. Sensation is supposed to be performed by means of the vibratory motion of the contents of the nerves, begun by external objects, and propagated to the brain.

This doctrine has been particularly illustrated by Dr. Hartley, and extended farther by him than by any other writer, in establishing a new theory of our mental operations. The doctrine of vibrations, and its use in explaining our sensations, are comprised by this writer in the following propositions: that the whole medullary substance of the brain, spinal marrow, and the nerves proceeding from them, is the immediate instrument of sensation and motion: that this white medullary substance of the brain is also the immediate instrument by which ideas are presented to the mind; or, in other words, whatever changes are made in this substance, corresponding changes are made in our ideas, and *vice versa*: that the sensations remain in the mind for a short time after the sensible objects are removed: that external objects impressed upon the senses occasion, first in the nerves on which they are impressed, and then in the brain, vibrations of the final, and, as one may say, infinitesimal, medullary particles: that these vibrations are excited, propagated, and kept up, partly by the ether, *i. e.* by a very subtle and elastic fluid, and partly by the uniformity, continuity, softness, and active powers of the medullary substance of the brain, spinal marrow, and nerves; which Dr. Hartley supposes are rather solid capillaments, according to sir Isaac Newton, than small tubuli, according to Boerhaave: and that the phenomena of sensible pleasure and pain, and also those of sleep, appear to be very suitable to the doctrine of vibrations. Hence he proceeds to establish the agreement of the doctrine of vibrations with the phenomena of ideas. Sensations, he says, by being often repeated, leave certain vestiges, types, or images of themselves, which may be called simple ideas of sensation; because the most vivid of these ideas are those where the corresponding sensations are most vigorously impressed, or most frequently renewed; whereas, if the sensation be faint or uncommon, the generated idea is also faint in proportion, and, in extreme cases, evanescent and imperceptible. The exact observance of the order of place in visible ideas, and of the order of time in audible ones, may likewise serve to shew, that these ideas are copies and offsprings of the impressions made on the eye and ear, in which the same orders were observed respectively: and though it happens that trains of visible and audible ideas are presented in fallies of the fancy, and in dreams, in which the order of time and place is different from that of any former impressions; yet the small component parts of these trains are copies of former impressions; and reasons may be given of the varieties of their compositions. Sensory vibrations, by being often repeated, beget, in the medullary substance of the brain, a disposition to diminutive vibrations, which may be also called *vibratuncles* and miniatures corresponding to themselves respectively: so that if it be allowed that original impressed vibratory motions leave a tendency to miniature ones of the same kind, place, and line of direction, this author infers, that sensations must beget ideas, not only in the senses of sight and hearing, where the ideas are sufficiently vivid and distinct, but in the three others, since their sensations are also conveyed to the mind by means of vibratory motions.

Any sensations, says Dr. Hartley, by being associated with
one

one another a sufficient number of times, get such a power over the corresponding ideas, that any one of the sensations, when impressed alone, shall be able to excite in the mind the ideas of the rest: and any vibrations, by being associated together a sufficient number of times, get such a power over the corresponding miniature vibrations, that any of those vibrations, when impressed alone, shall be able to excite the miniature of the rest. Hence he argues, that simple ideas will run into complex ones, by means of association, and that when this is the case, we are to suppose, that the miniature vibrations corresponding to those simple ideas run, in like manner, into a complex miniature vibration, corresponding to the resulting complex idea; some of which complex vibrations, attending upon complex ideas, may be as vivid as any of the sensory vibrations excited by the direct action of objects. See ASSOCIATION and Mental PHILOSOPHY.

Dr. Hartley also applies the doctrine of vibrations to the explication of muscular motion, which, he thinks, is performed in the same general manner as sensation, and the perception of ideas. For a particular account of his theory, and the manner in which it is largely illustrated, and the arguments by which it is supported, we must refer to his Observations on Man, vol. i. passim.

The several forts and rays of light fir Isaac Newton conceives to make vibrations in the ether of several magnitudes or velocities; which, according to those magnitudes or velocities, excite sensations of several colours; much after the same manner as vibrations of air, according to their several magnitudes or velocities, excite sensations of several sounds. See COLOUR and SOUND.

Heat, according to the same author, is only an accident of light, occasioned by the rays putting a fine, a subtle, ethereal medium, which pervades all bodies, into a vibrative motion, which gives us that sensation. See ÆTHER and HEAT.

From the vibrations or pulses of the same medium, he accounts for the alternate fits of easy reflection and easy transmission of the rays. See REFLECTION and UNDULATION. See also LIGHT.

In the Philosophical Transactions, it is observed that the butterfly, into which the silk-worm is transformed, makes one hundred and thirty vibrations, or motions of its wings, in one coition.

VIBRATIUNCLES. See VIBRATIONS, *supra*.

VIBRATO, in Geography, a river of Naples, which runs into the Adriatic, 2 miles N.N.E. of Giulia Nova.

VIBRISSÆ, a word used by medical writers to express the hairs in the nostrils.

VIBURNUM, in Botany, reckoned by Linnæus, *Phil. Bot.* 174, among the Latin names whose origin cannot be ascertained, is traced by Vaillant, Ainsworth, and Martyn to the verb *vico*, to bind; which is perfectly consistent with Virgil's expression of *lenta viburna*, but does not decide the old doubt, whether the poet meant our *Viburnum*, or any shrub of the willow or osier kind. Matthioli has led modern botanists to apply this name to the genus before us, one of whose species, *V. Lantana*, he conceives to be Virgil's plant, on account of its great pliability and humble flexible growth, well contrasted with the tall and upright cypress.—*Linn. Gen.* 147. Schreb. 107. Willd. Sp. Pl. v. 1. 1486. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 334. Prodr. Fl. Græc. Sibth. v. 1. 206. Ait. Hort. Kew. v. 2. 166. Pursh 201. Juss. 213. Tourn. t. 377. Lamarck Illustr. t. 211. Gærtn. t. 27. (Opulus); Tourn. t. 376. Tinus; Tourn. t. 377.)—Class and order, *Pentandria Trigynia*. Nat. Ord. *Dumoseæ*, Linn. *Caprifolia*, Juss.

Gen. Ch. Cal. Perianth superior, very small, in five

deep permanent segments. Cor. of one petal, bell-shaped, cut half way down into five obtuse, reflexed or spreading segments. Stam. Filaments five, awl-shaped, the length of the corolla; anthers roundish. Pist. Germen inferior, roundish, crowned with a turbinate gland; styles scarcely any; stigmas three. Peric. Berry roundish, of one cell. Seed solitary, roundish, bony.

Eff. Ch. Calyx superior, deeply five-cleft. Corolla in five segments. Berry with a solitary seed.

Viburnum is technically distinguished from *Sambucus*, (see that article,) by having one seed instead of three. The stem is shrubby, scarcely arborescent, with tough and pliant branches. Leaves simple, opposite, stalked, mostly elliptical, undivided, except in the *Opulus* of Tournefort and its nearest allies. Flowers generally terminal, cymose, copious, whitish. Berry red, blue, or black; in some cases eatable. The plants are hardy, natives of Europe, America, or Japan.

1. *V. Tinus*. Common *Laurus-Tinus*. Linn. Sp. Pl. 383. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 38. (Tinus, n. 1, 2, and 3; Clus. Hist. v. 1. 49. *Laurus Tinus*; Ger. Em. 1409.)—Leaves ovate, entire; their veins furnished with axillary tufts of hair underneath. Cymes smooth.—Native of Spain, Portugal, and Italy, especially about the coasts of the Mediterranean. In our gardens it is a valuable evergreen, thriving best near the sea, seldom injured, except by very hard and lasting frosts, which sometimes destroy it nearly to the root. In a pure air it flowers all winter long, even when partially covered with snow; but in close or smoky situations, the plant is easily killed, and never blossoms. The berries are seldom perfected but in a greenhouse. At Vienna this shrub, like the *Prunus Lauro-cerasus*, is always treated as a greenhouse plant. We have lately seen what is now become the English name, affectedly accented *Laurisstinus*. But it is a compound word, meaning *Laurus*, which is called *Tinus*; and Ovid teaches us that the first syllable of *TINUS* is long; see that article. The species before us is very bushy, spreading widely, seldom above five feet high; the twigs smooth, dark red; angular when young. Leaves two or three inches long, acute, veiny; dark shining green above; paler beneath, with glandular hairs at the origin of each large vein. Flowers tinged with red. Berries blue, like burnt feel, very beautiful. The leaves are occasionally more or less hairy, whence Clusius and Aiton distinguish three or four varieties.

2. *V. tinoides*. Mexican *Laurus-Tinus*. Linn. Suppl. 184. Willd. n. 2.—Leaves elliptical, entire; the origin of their veins slightly hairy underneath. Cymes and young branches hairy.—Sent by Mutis from Mexico. Like the preceding, but the leaves have shorter footstalks, and are elliptical rather than ovate; the young branches, and all the flower-stalks, are clothed with bristly hairs.

3. *V. villosum*. Downy Jamaica *Viburnum*. Swartz Ind. Occ. 564. Willd. n. 3.—Leaves ovate, acute, entire; hoary and downy beneath.—Gathered by Maffion and Swartz on hills in the southern part of Jamaica, flowering in autumn. A shrub about six or eight feet high, with a grey bark. The young branches, like the footstalks, cymes, and backs of the leaves, are clothed with soft, itarry, hoary pubescence, particles of which are also scattered over the green upper surface of each leaf. Flowers white.

4. *V. scandens*. Climbing *Viburnum*. Linn. Suppl. 184. Willd. n. 4. (V. virens; Thunb. Jap. 123.)—Stem twining. Leaves lanceolate, serrated. Cymes lax. Styles twice as long as the calyx. Outer flowers radiant.—Native of Japan. A slender climbing shrub, with short, leafy, opposite branches. Leaves two inches long, thin, tapering at each

VIBURNUM.

each end, bright green, smooth. *Cymes* slender, hairy, of three unequal branches. *Flowers* white; a few of them imperfect, with large, dilated, unequal, radiant *calyx-leaves* instead of *petals*, as in the Guelder-rose, &c. Thunberg describes ten *stamens*, but this is an accident, or error, his own specimen before us having but five. The three elongated *styles*, with club-shaped *stigmas*, are remarkable. Nothing is known respecting the *fruit*. The *germen* is turbinate, encircled with the *calyx*, as in *Hydrangea*.

5. *V. nudum*. Smooth Oval-leaved Viburnum. Linn. Sp. Pl. 383. Willd. n. 5. Ait. n. 2. Pursh n. 4. (*V. foliis ovato-lanceolatis integerrimis; subtus venosis*; Mill. Ic. 183. t. 274.)—Leaves elliptical, bluntish, somewhat revolute, nearly entire, very smooth, as well as the *cymes*, branches, and footstalks.—Native of North America, in swamps, particularly on a sandy soil, from Canada to Georgia, flowering in May and June. Every part is very smooth. *Leaves* three or four inches long; evergreen in the southern states of North America, but not in our gardens. The *cymes* are large, on long terminal *stalks*. *Flowers* copious, white. *Berries* black.

6. *V. obovatum*. Smooth Obovate Viburnum. Walt. Carol. 116. Poiret in Lam. Dict. v. 8. 658. Pursh n. 5.—Leaves obovate, obtuse, smooth, entire or somewhat notched. *Cymes* sessile. *Berries* roundish-ovate.—In shady woods of Carolina and Georgia, flowering in May and June. *Pursh*. *Flowers* white, small. *Berries* blackish. This is supposed to be *V. californoides* of Michaux, *Boreal-Amer.* v. 1. 179, though not that of Linnaeus.

7. *V. prunifolium*. Plum-leaved Viburnum. Linn. Sp. Pl. 383. Willd. n. 6. Ait. n. 3. Pursh n. 1. (*V. Lentago*; Moench Hort. Weissenf. 140. t. 8. *Mespilus prunifolia virginiana*; Pluk. Phyt. t. 46. f. 2.)—Smooth, with wide-spreading branches. *Leaves* roundish-obovate, finely serrated. Footstalks even. *Cymes* sessile. *Berries* roundish.—Common in hedges and fields, from New England to Carolina, flowering in May and June. A hardy shrub, cultivated by Miller. The *leaves* are scarcely an inch and a half long, full an inch broad, minutely and sharply serrated. *Flowers* white. *Berries* dark blue.

8. *V. pyriformis*. Sharp-leaved Viburnum. Poiret in Lam. Dict. v. 8. 653. Pursh n. 2.)—Smooth. *Leaves* ovate, pointed, serrated. *Cymes* somewhat stalked. *Berries* elliptic-oblong.—On the banks of rivers, in Pennsylvania, New Jersey, &c. flowering in May and June. Resembles the former, but is not so fragrant in its growth. *Berries* black. *Pursh*. Our wild Pennsylvanian specimen has copiously serrated *leaves*, two inches and a half long, with taper entire points. The *fruit* seems rather obovate. This may perhaps be *V. arboreum*, Muhlenb. Catal. 32. n. 12, our specimen having been sent by that excellent botanist, without a name, and formerly referred by us to *prunifolium*, to which it is certainly near akin.

9. *V. dauricum*. Siberian Viburnum. Pallas Ross. v. 1. p. 2. 30. Willd. n. 7. Ait. n. 4. (*Lonicera mongolica*; Pall. Ross. v. 1. p. 1. 59. *L. daurica*; *ibid.* t. 38. L. n. 8; Gmel. Sib. v. 3. 135. t. 25.)—Leaves ovate, serrated, dotted and hairy. *Cymes* of few flowers.—Found in the fissures of rocks, in various parts of Siberia. The late Mr. Bell, to whom our English gardens are so much indebted for plants from that country, introduced this in 1785. It flowers in June and July, but is not ornamental. The *leaves* are an inch and a quarter long, about half as broad. *Flowers* white, very few in each *cyme*, compared with most of the species. *Corolla* with an elongated tube. In his first account of this plant, above cited, Pallas attributes five, six, or seven *seeds* to the *fruit*; in the second he says one of his

pupils imposed upon him with a wrong specimen, and that the real fruit of this shrub is an oval *berry*, red at first, then black, like *V. Lantana*, but more oblong, with a solitary, compressed, ribbed *seed*. He gives figures of these parts, with the *leaf* of a smaller variety, in his tab. 58. fig. F, G; which he calls tab. 7. Pallas further remarks, that the scattered pubescence of this species is stellated, and that a portion of such is found on the *flower-stalks*; all which brings it nearer to the *Lantana*, a circumstance hardly to be divined from his figure.

10. *V. dentatum*. Shining Tooth-leaved Viburnum. Linn. Sp. Pl. 384. Willd. n. 8. Ait. n. 5, e. Pursh n. 9. Jacq. Hort. Vind. v. 1. 13. t. 36.—Leaves roundish-ovate, acute, furrowed and somewhat plaited, strongly toothed, nearly smooth on both sides. *Cymes* stalked. *Berries* almost globular.—In mountainous woods frequent, from New York to Carolina, flowering in June and July, and known by the name of Arrow-wood. *Berries* dark blue. *Pursh*. The *leaves* of this species are three inches long, and nearly as broad, somewhat heart-shaped at the base; besprinkled on the upper side with fine, simple, distant hairs; paler and smoother beneath. They are strongly ribbed. *Flowers* rather small, hairy in the middle. *Calyx* white as well as the *petals*.

11. *V. pubescens*. Downy Tooth-leaved Viburnum. Pursh n. 10. (*V. dentatum* β ; Ait. n. 5. Willd. n. 8.)—Leaves ovate, pointed, furrowed and somewhat plaited, strongly serrated; soft and downy beneath. *Cymes* stalked. *Berries* oblong.—In the lower parts of Virginia and Carolina, flowering in June. The whole of the shrub smaller than the preceding. *Pursh*. We have a specimen of this from the Paris garden, marked *V. dentatum longifolium*, *Juss.* The *leaves* are downy on both sides, but particularly soft at the back; their form oblong-ovate; length two or two and a half inches; margin sharply serrated; transverse veins numerous, divided. *Flowers* much like the last.

12. *V. platicum*. Plaited Japanese Guelder-rose. Thunb. Tr. of Linn. Soc. v. 2. 332. Willd. n. 9. (*V. dentatum*; Thunb. Jap. 122, excluding the reference to Linnaeus. Fundan, vulgò Te Mariqua; Kämpf. Am. Exot. 854.)—"Leaves ovate, obtuse, with tooth-like serratures, plaited."—Found by Thunberg near Fammamoto, in Fakona, and other parts of Japan, flowering in April and May. The *flowers* are radiated, like our Guelder-rose; but the *leaves*, as Kämpfer observes, are rounder than in that species, with crowded ribs, and a serrated margin. Thunberg says the *leaves* are plaited, especially before they fully expand; their form rounder, and their teeth finer, than in the true *V. dentatum*, n. 10.

13. *V. erosum*. Jagged Japanese Viburnum. Thunb. Jap. 124. Willd. n. 10.—Leaves obovate, pointed, sharply notched, nearly smooth. Footstalks downy, as well as the *cymes*.—Native of Japan. *Branches* grey, somewhat spreading, smooth, except when young. *Footstalks* slender, near an inch in length; Thunberg calls them very short; we suspect he wrote *petiolus* for *pedunculus*, (the common flower-stalk,) which is very short, and downy like the *cyme*, (not *panicle* nor *umbel*), which it supports. The *flowers* are numerous and crowded, but not radiated. *Leaves* pliant, strongly veined, two or three inches long, dilated upwards.

14. *V. Lantana*. Mealy Guelder-rose; or Way-faring Tree. Linn. Sp. Pl. 384. Willd. n. 11. Fl. Brit. n. 1. Engl. Bot. t. 331. Jacq. Austr. t. 341. (*Viburnum*; Matth. Valgr. v. 1. 194. Camer. Epit. 122. *Lantana*, five *Viburnum*; Ger. Em. 1490.)—Leaves heart-shaped, sharply serrated, veiny; downy beneath, with hoary hairs. *Cymes* stalked, downy.—Native of hedges and thickets, in the more temperate

VIBURNUM.

temperate parts of Europe, on a chalky or marly soil, flowering in May, and not rare in various parts of England, especially Oxfordshire. It has justly been described by Ray, as of a taller stature in the northern counties than in the south. In general it is a tufted bush, with round, pliant, mealy twigs. (See the explanation of the generic name.) All the *stalks*, the backs of the elliptic-heart-shaped veiny *leaves*, and in some measure their upper surface, are clothed with dense, hoary, itarry hairs, often loaded with dust from the road, which scarcely adds to the powdery aspect of the plant. *Flowers* white, in large, rather convex, stalked *cymes*. *Stigmas* sessile, very short and thick. *Berries* roundish, abrupt, compressed; when young red on the outermost side, yellow on the other; finally quite black, mealy and astringent, with a large, flat, furrowed *seed*. The *foliage* turns in autumn to a dark red.

14. *V. grandifolium*. Large-leaved, or American, Way-faring Tree. (*V. Lantana* β , *grandifolium*; Ait. ed. 1. v. 1. 372. ed. 2. n. 6, β , by mistake called *grandiflorum*. Willd. n. 11, β . *V. lantanoides*; Michaux Boreal.-Amer. v. 1. 179. Pursh n. 11.)—Leaves roundish-heart-shaped, abruptly pointed, unequally and obtusely serrated; their ribs and stalks downy, with itarry hairs. *Cymes* quite sessile. *Berries* ovate.—In shady woods, on high mountains, from Canada to Virginia, principally in the forests called Beech-woods, flowering in June and July. Known by the name of *Hobble-bush*. *Berries* red; but when ripe, black. *Pursh*. Of more humble growth than the last, with more trailing *branches*, and larger greener *leaves*. Michaux has well separated it from the European *Lantana*, but we cannot adopt his barbarously-formed specific name, though too many such illiterate deformities are unaccountably introduced daily by more classical writers. The error of *grandiflorum*, for *grandifolium*, is one of those very few which escaped the late supremely accurate Dryander. It were an injury to his memory not thus to correct him.

15. *V. tomentosum*. Downy Japanese Viburnum. Thunb. Jap. 123. Willd. n. 12. (Sijo, vulgo Adai, &c.; Kämpf. Am. Exot. 854.)—Leaves ovate, pointed, serrated, veiny; downy beneath. *Cymes* lateral.—Observed by Thunberg, in various woods between Miaco and Jedo, as well as cultivated, in Japan, flowering in April and May. The *branches* are round, smooth, reddish, divaricate, subdivided. *Leaves* ovate, (not heart-shaped,) ribbed; the upper ones most downy beneath. The youngest *branches*, and all the *stalks*, are downy. *Cymes* axillary, at the extremities of the small branches. *Flowers* radiant. Thunberg. Kämpfer says the *flowers* are blue, composing a large dense ball, the outer ones largest.

16. *V. hirtum*. Hairy Japanese Viburnum. Thunb. Jap. 124. Willd. n. 13.—Leaves ovate, serrated, villous. Footstalks hairy.—Native of Japan. *Stem* ascending in a zigzag manner, round, smooth; its *branches* alternate, round, smooth at the base, hairy at the extremity. *Leaves* opposite, resembling those of a nettle, acute, deeply and equally serrated, an inch long, veiny; the veins clothed with white close hairs. *Footstalks* and *flower-stalks* covered with horizontally spreading hairs. *Flowers* minute, not radiant. *Stigma* two-lobed. Thunberg.

17. *V. acerifolium*. Maple-leaved Viburnum. Linn. Sp. Pl. 384. Willd. n. 14. Ait. n. 7. Pursh n. 12. Venten. Jard. de Cels, t. 72.—Leaves three-lobed, pointed, sharply serrated; downy beneath. Footstalks hairy, without glands.—In rocky mountainous situations, from New England to Carolina, flowering in May and June. *Berries* black. *Pursh*. The *branches* are round, finely downy, with itarry hairs. Such are found also on the *footstalks*, but in-

termixed with simple much coarser ones. The *leaves* are rather acutely lobed, and strongly serrated, very much resembling those of the Common Vine. *Stipulas* fetaceous, in pairs on the base of each footstalk. *Cyme* of many downy branches, on a long terminal common *stalk*. *Flowers* not radiant. This appears by the manuscripts of the celebrated Peter Collinson, to have been imported by him in 1736.

18. *V. orientale*. Oriental Guelder-rose. Pallas Ross. v. 1. p. 2. 31. t. 58. f. H. Willd. n. 15. *Opulus orientalis*, folio amplissimo tridentato; Tourn. Cor. 42.)—Leaves three-lobed, pointed, coarsely and rather bluntly toothed. Footstalks smooth, without glands.—Native of rather alpine situations in Imiretta. *Pallas*. Differs from the last, to which it is very nearly akin, in having *leaves* strongly toothed, not serrated, and an oval *seed*, with three ribs and two furrows at each side, as in *V. Lantana*, instead of the heart-shaped seed of the *acerifolium*. Willdenow. *Berries* red. *Pallas*.

19. *V. Opulus*. Common Guelder-rose, Water Elder, or Snow-ball Tree. Linn. Sp. Pl. 384. Willd. n. 16. Fl. Brit. n. 2. Engl. Bot. t. 332. Fl. Den. t. 661. (*Sambucus aquatilis* sive *palustris*; Ger. Em. 1424. *S. aquatica*; Camer. Epit. 977.)—Leaves three-lobed, sharply toothed. Footstalks smooth, furnished with glands. *Cymes* radiant.—Native of watery thickets and hedges throughout Europe, flowering in June. A small bushy tree, smooth in all its parts, only the backs of the *leaves* being occasionally downy. Their three lobes are unequally toothed or serrated. The *footstalks* bear, towards the top, several cup-like glands, and towards the base, a pair or two of linear *stipulas*. *Cymes* large, smooth, stalked, of numerous white *flowers*, the marginal ones abortive, dilated and radiant. *Berries* oval, drooping, scarlet, very succulent, not eatable. *Seed* heart-shaped. A variety with globose *cymes*, composed entirely of radiant *flowers*, is commonly cultivated in gardens and shrubberies, as a companion to the lilac and laburnum. The foliage turns in autumn to a beautiful pink or crimson, as in many genera of trees and shrubs that are principally American.

20. *V. mollis*. Soft-leaved American Guelder-rose. Michaux Boreal.-Amer. v. 1. 180. Pursh n. 13. (“*V. alnifolium*; Marsh. Arb. 162.”)—Leaves roundish-heart-shaped, plaited, furrowed, toothed; downy beneath. Footstalks slightly glandular. *Cymes* radiant. Berry oblong-ovate.—In hedges in Kentucky, near Danville, as well as in Tennessee and Upper Carolina, flowering in June and July. *Berries* red. This species resembles the following. *Pursh*. The *leaves* are undivided, not three-lobed. The *flowers* are radiant. The bark falls off every year in thin shreds. Michaux.

21. *V. Oxycoctus*. Cranberry Guelder-rose. Pursh n. 14. (*V. Opulus* β ; Ait. n. 8. Michaux Boreal.-Amer. v. 1. 180. “*V. trilobum*; Marsh. Arb. 162.”)—Leaves three-lobed, acute at the base, three-ribbed; lobes divaricate, elongated, pointed, sparingly toothed. Footstalks furnished with glands. *Cymes* radiant.—In swamps and shady woods of Canada, and on the mountains of New York and New Jersey, flowering in July. *Berries* red, of an agreeable acid, resembling that of Cranberries, *Vaccinium macrocarpon*, for which they are a very good substitute. *Pursh*. We have never examined this species, though it probably may be found in the London nurseries. If the fruit answers to the above character, and is plentiful, it would be worth cultivating for the table. The twigs are described of a shining red.

22. *V. edule*. Smaller Eatable Guelder-rose. Pursh n. 15.

VIBURNUM.

n. 15. (*V. Opulus*; Michaux Boreal-Amér. v. 1. 180.)—Leaves three-lobed, bluntish at the base, three-ribbed; lobes very short, serrated with minute pointed teeth. Footstalks furnished with glands. Cymes radiant.—On the banks of rivers, from Canada to New York, flowering in July. A smaller and more upright shrub than the preceding species. *Berries* of the same colour and size, but, when completely ripe, more agreeable to eat. *Pursh*.

23. *V. dilatatum*. Spreading Japanese Viburnum. Thunb. Jap. 124. Willd. n. 17.—Leaves obovate, pointed, unequally toothed, villous. Cymes axillary.—Gathered by Thunberg in Japan. *Stem* shrubby, erect, somewhat angular, grey, villous. *Leaves* two inches long, stalked, ribbed, jagged at the margin, villous on both sides; the lower ones smaller. *Footstalks* round, villous, three-quarters of an inch long. *Cyme* axillary, repeatedly compound, four-cleft and three-forked, very widely spreading, with downy stalks. *Flowers* not radiant. *Thunberg*. The learned author uses the terms *panicle*, *umbel*, and *cyme* indifferently in his descriptions of this genus; but from what we have seen, even of his own species, we, without scruple, substitute the latter throughout.

24. *V. macrophyllum*. Large-leaved Japanese Viburnum. Thunb. Jap. 125. Willd. n. 18.—Leaves obovate, pointed, toothed, smooth. Cymes radiant, terminal.—Native of Japan. The whole plant is smooth. *Stem* and *branches* round. *Leaves* ribbed, paler beneath, four inches in breadth, and somewhat more in length. *Footstalks* one-third the length of the leaves. *Thunb*.

25. *V. cuspidatum*. Pointed-leaved Japanese Viburnum. Thunb. Jap. 125. Willd. n. 19.—Leaves ovate, pointed, serrated, villous. Cymes radiant.—From the same country as the two last. *Leaves* equally and acutely serrated, of the size of the preceding species, clothed with feathered hairs. *Cymes* terminal, repeatedly compound. *Thunb*.

26. *V. Lentago*. Pear-leaved Viburnum. Linn. Sp. Pl. 384. Willd. n. 20. Ait. n. 9. Pursh n. 3.—Leaves smooth, broad-ovate, pointed, finely and sharply serrated. Footstalks bordered, crisp. Cymes sessile.—Frequent in hedges, and on the borders of woods, from New England to Carolina, flowering in July. More inclined to grow to a tree than any of the rest of the American species. *Berries* black. *Pursh*. Cultivated in England, by Mr. James Gordon, in 1761. *Aiton*. The leaves are three inches long, and nearly half as broad, rather coriaceous, very smooth, with many transverse ribs. *Footstalks* channelled, with a curled dilated border at each side. *Buds* large, ovate, with a long point. We never saw the flowers.

27. *V. squamatum*. Scaly Viburnum. Willd. Enum. 327. (*V. nudum*; var. *squamatum*; Muhlenb. Catal. 32.)—"Leaves oblong, bluntly and finely serrated. Footstalks and flower-stalks clothed with scaly pubescence."—Native of Pennsylvania. A hardy shrub in the open air at Berlin. *Leaves* two inches long, with a very short point; their base somewhat contracted; their edges unequally, distantly, bluntly, and very slightly serrated; smooth, except the under side of the younger ones, which is besprinkled with small, brown, very distant, scales. *Footstalks*, as well as the long lanceolate *buds*, thickly covered with minute, brown, hairy scales. *Cyme* terminal, as in *V. nudum*, n. 5, which the present species greatly resembles; but it is distinguished by the scales of all the stalks, and the finely-serrated, less coriaceous, leaves, which are neither shining nor revolute. *Willdenow*.

28. *V. cassinoides*. Thick-leaved Viburnum. Linn. Sp. Pl. 384. Willd. n. 21. Ait. n. 10. Pursh n. 6.—Leaves ovato-lanceolate, acute at each end, smooth, crenate, slightly

revolute. Footstalks keeled, without glands.—In swamps from New York to Carolina, flowering in June and July. *Berries* bluish-black. *Pursh*. The whole plant is smooth. *Leaves* two inches long, more or less, and one broad, coriaceous; paler beneath; and the transverse ribs scarcely visible. *Footstalks* angular, gibbous at the base, but not decurrent. *Cymes* terminal, on short stalks.

29. *V. levigatum*. Caffioberry Viburnum, or Paraguay Tea. Ait. n. 12. Willd. n. 23. Pursh n. 7. (*Cassine* Peragua; Linn. Mant. 22c. *C. foliis ovato-lanceolatis ferratis oppositis deciduis, floribus corymbosis*; Mill. Ic. 55. t. 83. f. 1. *C. ver perquam filibus arbutula, phyllyrea foliis antagonistis*; Pluk. Mant. 40. Hortul. Angl. 16. t. 20.)—Leaves lanceolate, smooth, unequally serrated; entire at the base. Branches two-edged.—Found near the sea-coast, in Virginia and Carolina, flowering in June and July. *Berries* black. *Pursh*. The smooth wand-like branches are marked at each side with a narrow prominent line, running down from the insertion of the *footstalks*, which are rather short and thick, carinated, bordered, and somewhat crisp. *Leaves* scarcely two inches long, bluntish. *Cymes* at the ends of short lateral branches. *Flowers* white, not radiant. *Berries* globular, red.

30. *V. nitidum*. Shining Narrow-leaved Viburnum. Ait. n. 11. Willd. n. 22. Pursh n. 8.—"Leaves linear-lanceolate, very smooth, entire, or slightly serrated; shining above. Branches quadrangular."—In sandy barren woods of Carolina and Georgia. A low shrub, with small leaves. *Pursh*. Mr. Aiton speaks of it as hardy, flowering in May and June; cultivated in 1758, by Mr. Christopher Gray, who had at that time, and long before, a well-furnished nursery-ground at Fulham.

VIBURNUM, in Gardening, contains plants of the deciduous and evergreen flowering kind, among which the species cultivated are, the plant mealy or wayfaring tree (*V. lantana*); the water elder or guelder rose (*V. opulus*); the pear-leaved viburnum (*V. lentago*); the thick-leaved viburnum (*V. cassinoides*); the shining-leaved viburnum (*V. nitidum*); the caffioberry bush (*V. levigatum*); the oval-leaved viburnum (*V. nudum*); the plum-leaved viburnum (*V. prunifolium*); the tooth-leaved viburnum (*V. dentatum*); and the laurustinus, or laurustine (*V. tinus*).

The first is a thickly-branched shrub, the flowers of which are whitish, in large terminating, solitary, many-flowered cymes. It is sometimes known by the name of plant mealy tree; and according to Withering, the bark of the root is used to make bird-lime.

There is a variety in North America with larger leaves, of a bright green; and with variegated leaves in nurseries.

The second sort is a small bushy tree, with numerous white flowers, smooth in all its parts, and very much branched.

There is an American variety, which is a shrub, that has the twigs of a shining-red colour, and which rises eight or ten feet high, with many side-branches, covered with a smooth purple bark; the leaves cordate-ovate, ending in acute points, deeply serrate, having many strong veins, and standing upon very long slender footstalks.

There is also another beautiful variety common in plantations, under the name of guelder-rose, bearing large round bunches of abortive flowers only, which rises to the height of eighteen or twenty feet, if permitted to stand; the stem becomes large; and the branches grow irregular, and are covered with a grey bark; the leaves are divided into three or four lobes, somewhat like those of the maple; they are about three inches long, and two and a half broad, jagged on their edges, and of a light green colour: the

flowers come out in a large corymb, are very white, and being all neuters, are barren: from their extreme whiteness, and swelling out into a globular form, some country people have given this shrub the name of *snow-ball tree*. It is also sometimes called *elder rose*, and *rose elder*.

In the seventh fort there are varieties with deciduous and evergreen leaves.

The eighth fort has a woody stalk ten or twelve feet high, and is commonly called *black bar* in North America.

The ninth has the stalks soft, pithy, and branching, with white flowers.

There are varieties with the leaves smooth on both sides, and with the leaves downy underneath, and drawn out to a point.

In the tenth fort there are several varieties; as the smaller hairy-leaved, in which the umbels (cymes) of flowers are smaller, and appear in autumn, continuing all the winter. The plants are much harder than in the original fort.

The shining-leaved, in which the stalks rise higher, and the branches are much stronger: the bark is smoother, and turns of a purplish colour: the leaves are larger, of a thicker consistence, and of a lucid green colour: the umbels (cymes) are much larger, and so are the flowers; these seldom appear till the spring, and when the winters are sharp, the flowers are killed, and never open unless they are sheltered.

There is a sub-variety of this with variegated leaves, with gold-striped and silver-striped; in which the branches are warted, the younger ones four-cornered; the leaves opposite, ovate, on short petioles, rigid, shining, perennial; the younger ones hirsute, with short ferruginous villose hairs: flowers in crowded cymes, with little bractees between them: the corolla white; and the berries, when ripe, blue.

The common, with narrower leaves, hairy only on the edge and veins underneath: the fruit smaller.

And the upright laurustinus.

Method of Culture.—These plants may some of them be increased by seeds, most of them by layers, many by cuttings, and a few by suckers.

The seeds in the deciduous kinds should be sown in the autumn or spring in beds of light fine mould, being well covered in. The plants appear in the first or second year; and when they are of a twelvemonth's growth, they should be planted out in nursery rows, to be continued till of proper growth to plant out in the shrubberies or other parts of pleasure grounds, as from two to five feet.

In the laurustinus kinds, the seeds, after being mixed with mould in the autumn, soon after they become ripe, and exposed to the air and rain in the winter, should in the spring be sown on a gentle hot-bed, or in pots plunged into it; the plants being continued in the bed till the autumn, when they should be removed and managed as in the layer method. The plants raised in this way are said to be harder than those raised from layers.

The first fort is tedious in being raised from seeds.

In the layer, which is the most expeditious mode of raising most of these plants, the young lower branches should be laid down in the autumn or spring, being pegged down in the usual manner in the earth, when they mostly become well rooted in a twelvemonth, and may then be taken off and planted out where they are to remain, or in the nursery; and sometimes, in some of the kinds, a few are put in pots.

The best season for removing the tenth fort is in the early autumn, that they may be well rooted before the winter sets in.

The first fort succeeds best by layers put down in the autumn; and the striped variety may be increased by budding it upon the plain fort.

The cuttings may be made in the autumn from the strong young shoots being planted in a moist border in rows, when in the following summer many of them will be rooted, and form little plants. Most of the deciduous forts may be raised in this way.

The suckers should be taken up in the autumn or spring with the root-fibres, and be planted out in nursery rows to have a proper growth. The guelder-rose may be readily increased in this way, and sometimes the laurustinus.

The fourth fort is rather tender in winter while in its young growth, as well as the sixth, and should have protection in that season. A plant or two should be constantly laid in pots under shelter. This last fort is easily increased by layers.

These plants afford much variety and effect in shrubbery and other parts of pleasure-grounds, when planted out in a mixed order. The evergreen fort are often used to cover disagreeable objects. The flowering evergreens are likewise often set out in pots. They are sometimes trained to a single stem, to the height of one or two feet, being encouraged to branch out into a close bushy round head. They should all mostly be permitted to take on their own natural growths, except the occasional retrenching of their lower straggling branches, and pruning the long shoots from their heads.

VIBURNUM-Galls, in *Natural History*, the name of a species of galls, or small protuberances, frequently found on the leaves of the viburnum. These are of a very singular nature, and seem to be composed of a different substance from that of the leaf. They appear in form of brown circular spots, of which there are sometimes forty or more on one leaf: they are about the fifteenth of an inch in diameter, and rise a little above the surface of the leaf, as well on the under as the upper side; each of them has also a small prominence in the centre, on each side of the leaf, looking like a nipple standing on the breast.

These are found in great plenty in the months of June, July, and August, and, when opened, each contains one insect, which is a small worm of a white colour, with six legs, and two hooks of a brown colour at the head.

M. Reaumur found that these worms became, in time, a very small species of beetle. They were of a cinnamon colour, and had conic and granulated antennæ of a beautiful figure. Reaumur's Hist. Insectes, vol. vi. p. 209.

VIC, in *Geography*, a town of France, and seat of a tribunal, in the department of the Meurte; 15 miles E. of Nancy.—Also, a town of France, in the department of the Vienne, on the Gartempe; 18 miles N. of Montmorillon.

Vic, or *Vieq*, a town of France, in the department of the Indre; 18 miles N. of Châteauroux.

Vic. See *VIQUE*.

Vic Bigorre, a town of France, and principal place of a district, in the department of the Upper Pyrenées; 18 miles E. of Pau. N. lat. 43° 22'. E. long. 8'.

Vic en Carladéz, or *Vic sur la Cère*, a town of France, in the department of the Cantal, situated at the foot of the Cantal, with a medicinal spring; 21 miles W.S.W. of St. Flour.

Vic le Comte, a town of France, in the department of the Puy de Dôme. About half a league from the town is a medicinal spring; 6 miles S.W. of Billom.

Vic Dessot, a town of France, in the department of the Arriège; 6 miles S.W. of Tarascon.

Vic Fexenjac, a town of France, in the department of the Gers; 12 miles S. of Condom.

VICAR, *VICARIUS*, a person appointed as deputy of another,

VICAR.

another, to perform his functions in his absence, and under his authority.

The word is formed from *vicarius, qui alterius vires gerit*. The pope pretends to be vicar of Jesus Christ on earth. He has under him a *grand vicar*, who is a cardinal; and whose jurisdiction extends over all priests, both secular and regular; and even, in many cases, over laymen.

Apostolical vicars are those who perform the functions of the pope in churches or provinces which he has committed to their direction.

Among the ancient Romans, *vicarius*, vicar, was a legatus, or lieutenant, sent into the provinces where there was no governor; so that the vicarii were properly the emperor's vicars, not those of governors. Cod. de Offic. Vicar.

Italy, in the time of the eastern empire, was governed by two vicarii: the one *vicar of Italy*, who resided at Milan; the other *vicar of the city*, who resided at Rome.

Cujas observed, that the word vicar was sometimes, though rarely, attributed to the lieutenant-generals of provinces, or governors of Roman provinces.

VICAR, in the *Canon Law*, denotes a priest of a parish, the predial tithes of which are impropriated or appropriated; that is, being either to a chapter, religious house, &c. or to a layman, who receives them, and only allows the vicar the smaller tithes, or a convenient salary, anciently called *portio congrua*.

He is thus called, *quasi vice fungens rectoris*, as serving for, or in lieu of, rector, who would be entitled to the great tithes.

Hence, the part or portion of the parsonage allotted to the vicar, for his maintenance and support, or the promotion or living which he has under the parson, is called a *vicarage*. This part or portion is, in some places, an annual sum of money certain; but in most places, it is a part of the tithes in kind, which most commonly is the small tithes; and in some places he has a part of the great tithes, and also of the glebe.

The stipend of vicars was formerly at the discretion of the appropriators; but, on account of their neglect, it was enacted by 15 Rich. II. c. 6. that in all appropriations of churches, the diocesan bishop should ordain (in proportion to the value of the church) a competent sum to be distributed among the poor parishioners annually, and that the vicarage should be sufficiently endowed. However, the vicar was liable to be removed at the pleasure of the appropriator; and, therefore, by 4 Hen. IV. c. 12. it is ordained, that the vicar shall be a secular person, not a member of any religious house; that he shall be vicar perpetual, not removable at the caprice of the monastery; and that he shall be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary, for these three express purposes, to do divine service, to inform the people, and to keep hospitality. Institution and induction seem to be the specific difference between a vicar and a perpetual curate; both can only be in a church that was appropriated. But this must be understood, only where the curacy is parochial; for as to curates of chapels, there seems to be no similitude between them and curates of parishes. In appropriated churches, where no vicar has been endowed, the officiating minister is appointed by the appropriator or impropiator, and is called perpetual curate. The endowments in consequence of these statutes have usually been by a portion of the glebe, or land belonging to the parsonage, and a particular share of the tithes, called small or vicarial tithes; which see. Some, however, were made liberally, and some more scantily endowed; and hence many things,

as wood in particular, is in some countries a rectorial, and in some a vicarial title. The distinction therefore of a parson and vicar is this: that the parson has generally the whole of all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, entitled to the best part of the profits, to whom he is in effect a perpetual curate, with a standing salary. Though in some places the vicarage has been considerably augmented by a large share of the great tithes; which augmentations were greatly assisted by the statute 29 Car. II. c. 8. enacted in favour of poor vicars and curates, which rendered such temporary augmentations (when made by the appropriators) perpetual. See AUGMENTATION. Blackst. Comm. book i.

A vicar who has a part of the great tithes, and also of the glebe, is called a *vicar endowed*.

These vicars were anciently called *perpetui vicarii*; because not appointed by the impropiator, and licensed by the bishop to read service; but presented by the patron, and canonical institution given them by the hands of the ordinary; and so having constant succession, or corporations, and never dying.

The act of endowment by the bishop might be made either in the act of appropriation, or by a subsequent act or separate instrument. Upon the making of an appropriation, an annual pension was reserved to the bishop and his successors, commonly called an indemnity, and payable by the body to whom the appropriation was made. See APPROPRIATION and IMPROPRIATION.

A vicarage by endowment becomes a benefice distinct from the parsonage. As the vicar is endowed with separate revenues, and is now enabled by the law to recover his temporal rights without aid of parson or patron; so hath he the whole cure of souls transferred to him, by institution from the bishop. It is true, in some places, both the parson and the vicar do receive institution from the bishop to the same church as it is in the case of sinecures; the original of which was thus: The rector (with proper consent) had a power to entitle a vicar in his church to officiate under him; and this was often done; and by this means two persons were instituted to the same church, and both to the cure of souls, and both did actually officiate. So that however the rectors of sinecures, by having been long excused from residence, are in the common opinion discharged from the cure of souls (which is the reason of the name); and however the cure is said in the law-books to be in them *habitualiter* only; yet in strictness of law, and with regard to their original institution, the cure is in them *actualiter*, as much as it is in the vicar. Gibb. 719. Cro. Jac. 518. 1 Sid. 426.

The parson, by making the endowment, acquires the patronage of the vicarage. For in order to the appropriation of a parsonage, the inheritance of the advowson was to be transferred to the corporation to which the church was to be appropriated; and then, the vicarage being derived out of the parsonage, the parson of common right must be patron thereof. So that if the parson makes a lease of the parsonage (without making a special reservation to himself of the right of presenting to the vicarage), the patronage of the vicarage passeth as incident to it. (2 Roll. Abr. 59.) But it was held in the 21 Jac. that the parishioners may prescribe for the choice of a vicar. And before that, in the 16 Ja. it was declared by the court, that though the advowson of the vicarage of common right is appendant to the rectory, yet it may be appendant to a manor; as having been reserved specially upon the appropriation. Gibb. 719. Moore, 894. 2 Roll. Rep. 304.

Sometimes, upon appropriation, the right of presenting the

the vicar was given to the bishop, probably to induce his consent: as appeareth from divers instances.

There were no vicarages at common law; or, in other words, no tithes or profits of any kind do *de jure* belong to the vicar, but by endowment or prescription; which cannot be presumed, but must be shewn on the part of the vicar. For which reason, the payment of tithes to the parson is *prima facie* a discharge against the vicar. Gibf. 719. Palm. 113. Yelv. 86. 4 Mod. 184.

The first endowment of the vicars cannot be prescribed against by the parson. Which original endowments therefore being of such authority as no time can destroy; and such causes between parson and vicar as relate to them, or depend on them, being also cognizable in the spiritual court: it were much to be wished, says Dr. Gibfon, for the sake of the poor vicars, that diligent search were made after them in the ecclesiastical offices, and other repositories of records; in order to bring to light as many as can possibly be found. Especially, since it hath been also adjudged, that if a vicar hath used time out of mind, or for a long time, to take particular tithes or profits, he shall not lose them, because the original endowment is produced and they are not there: but inasmuch as every bishop had an indisputable right to augment vicarages as there was occasion, and this, whether such right was reserved in the endowment or not; the law will presume, that this addition was made by way of augmentation. Gibf. 720.

The loss of the original endowment is supplied by prescription; that is, if the vicar hath enjoyed this or that particular tithe by constant usage, the law will presume that he was legally endowed with it; by the same reason that it presumes some tithes might be added, by way of augmentation, which were not in the original endowment. Gibf. 720. 2 Keb. 729. Hardr. 328.

It is said that all compositions for the endowments of vicarages shall be expounded by the judges of the common law; and if the spiritual court meddle with that matter, they are to be prohibited. Watsf. c. 39. Lit. Rep. 263.

But where the dispute is between rector and vicar, being both spiritual persons, it seemeth that the proper cognizance of the cause belongeth to the ecclesiastical judge. 2 Bröwnl. 36. See, however, Moore, 457.

But the courts of equity frequently determine upon the interpretation of endowments.

The canonists mention four species of vicars: some *perpetual*; others, appointed for a certain time, and on some special occasion, called *mercenarii*: others, called *speciales*, appointed not for the whole cure, but for some certain place, article, or act: others, *generales*, neither perpetual, nor appointed for any certain act, but for all things in the general.

VICAR-GENERAL was a title given by Henry VIII. to Thomas Cromwell, earl of Essex; with full power to oversee the clergy, and regulate all matters relating to church-affairs.

VICAR-GENERAL is now the title of an office, which, as well as that of official principal, are united in the chancellor of the diocese. The proper work of an official is to hear causes between party and party, concerning wills, legacies, marriages, and the like; which are matters of temporal cognizance, but have been granted to the ecclesiastical courts by the concessions of princes: whereas that of a vicar-general is the exercise and administration of jurisdiction purely spiritual, by the authority and under the direction of the bishop, as visitation, correction of manners, granting institutions, and the like, with a general inspection of men and things, in order to the preservation of discipline and good government in the church. These two offices have been

ordinarily granted together; but Dr. Gibfon wishes they might be still kept separate; and the office of vicar-general to be vested in the hands of some grave and prudent clergyman, usually resident within the diocese; and that of official (as being conversant about temporal matters) in the hands of a layman, well skilled in the civil law.

VICARDI, the name of an office in the island of Candia. The word is probably a corruption of the Latin *vicarii*. The vicardi is the governor of a village, and is sometimes the parish priest; his office is to levy the public taxes, and to send offenders to the cadic. This office is always appointed yearly. Pococke's Egypt, vol. ii. part ii. p. 12.

VICARELLO, in *Geography*, a town of the Popedom, in the Patrimonio, near the lake of Bracciano, celebrated for its baths; 3 miles N.W. of Bracciano.

VICARIO deliberrando occasione cufusdam recognitiouis, &c. in *Lavo*, an ancient writ that lies for a spiritual person imprisoned.

VICARO, in *Geography*, a town of Naples, in Capitanata; 9 miles S.E. of Volturara.

VICE, VITIUM, in *Ethics*, is ordinarily defined an elective habit, deviating either in excess, or defect, from the just medium in which virtue is placed.

It is called a *habit*, to distinguish it from *sin*, which is only an act: hence, a *sin* is looked upon as something transient; and a *vice*, as something permanent.

In the common use of the terms vice and sin, there is no ground for this subtle distinction. *Vice*, as opposed to virtue, is better defined the disagreement of the actions of any intelligent being with the nature, circumstances, and relation of things; hence called the moral unfitness of such actions. See *VIRTUE*.

Some authors distinguish three states of vice: the first *incontinentia*, of incontinence, in which a person sees and approves the good, but is hurried to evil by the violence of his passions. The second *intemperantia*, of intemperance; in which even the judgment is depraved and perverted; the third *feritas*, of obduracy; in which the person is totally immersed in vice, without any sense or feeling of it.

The state of incontinency is considered as infirmity, in which the person feels the sharpest stings of conscience: that of intemperance, as malice, in which the remorse is not so lively. In that of obduracy there is none.

VICE, in *Smithery*, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it be to be filed, bent, or rivetted, &c.

The parts of the vice are, the *face*, or *plane*, which is its uppermost part; the *chaps*, which are cut with a bastard-cut, and well tempered; the *screw-pin*, cut with a square, strong worm; the *nut*, or *screw-box*, which has a square worm, and is braised into the round box; the *spring*, which throws the chaps open; and the *foot*, on which the whole is mounted.

VICE, Hand, is a small kind of vice, serving to hold the lefs works in, that require often turning about.

Of this there are two kinds, the *broad chapt hand-vice*, which is that commonly used; and the *square-nas'd hand-vice*, seldom used but for filing small round work.

VICE is also a machine used by the glaziers, to turn, or draw lead into flat rods, with grooves on each side, proper to receive the edges of the glass.

This machine consists of two iron chaps, or cheeks, joined with two cross iron pieces. In the space between the chaps are two steel wheels, and their spindles, or axcs, passed through the middle, each of which has its nut or pinion with teeth, that catch into each other; and to the lowest is fitted a handle, by which the machine is turned.

There are some of these vices double, and that will draw two leads at once: these have three wheels. Some glaziers will turn lead of different sizes in the same vice; by changing their cheeks for each size.

With another pair of spindles, whose nuts almost meet, they turn lead for *tiers*; which, when it comes out of the vice, is almost cut asunder, in two thicknesses, easy to be parted. Before the invention of this vice, they used a plane: accordingly, in all the ancient windows, we find the lead planed and grooved that way.

VICE is also used in the composition of divers words, to denote the relation of something that comes instead, or in the place, of another.

In this sense the word is Latin, *vice*, stead, place, turn, &c.

VICE-Admiral. See ADMIRAL.

VICE-Chamberlain, called also, in ancient statutes, *under-chamberlain*, is an officer in the court, next under the lord-chamberlain; and who, in his absence, has command and controul of all officers belonging to that part of the household called the *chamber* above stairs.

VICE-Chancellor of an university is an eminent member, chosen annually to manage affairs in the absence of the chancellor.

VICE-Comes, in Law. See VISCOUNT.

VICE-Comitem, *Accedas ad*. See ACCEDAS.

VICE-Comitis, *Respectu habendo computi*. See RESPECTU.

VICE-Consul, an officer who discharges the duty of a consul, under his orders or during his absence.

VICE-Doge is a counsellor of Venice, who represents the doge when sick, or absent; that the signory may never be without a chief.

The vice-doge never takes the ducal chair, nor bears the horn, nor is addressed under the title of *serenissimo*: yet the foreign ambassadors, speaking to the college, use the common apostrophe of *serenissimo principe*; and he performs all the offices of doge, and gives answers to ambassadors, without moving his cap.

VICE-Dominus, a viscount, sheriff, or vidame.

VICE-Dominus Abbatie, or Ecclesie, in the *Canon Law*, an advocate, or protector, of an abbey or church. See ADVOCATE.

VICE-Dominus Episcopi, in the *Canon Law*, is the commissary or vicar-general of a bishop.

VICE-Gerent, *Viceregens*, a vicar, deputy, or lieutenant.

VICE-Legat, an officer whom the pope sends to Avignon, and some other cities, to perform the office of a spiritual and temporal governor, at a time when there is no legate, or cardinal, to command there.

All the Gaul Narbonnoise, as Dauphiné, Provence, &c. has recourse to the vice-legate of Avignon, for all ecclesiastical dispatches; in like manner as the other provinces address themselves to Rome. See LEGATE.

VICE-Roy, a governor of a kingdom, who commands therein in the name and stead of a king, with full and sovereign authority.

Thus, when Naples and Sicily were subject to Spain, vice-roys were sent thither; and the name is now given to those who govern in Mexico and Peru.

The lord-lieutenant of Ireland is also sometimes called the vice-roy.

VICE-Versa, a Latin phrase, frequently retained in English writings; signifying as much as *on the contrary*.

Thus, as the sun mounts higher and higher above the horizon, insensible perspiration increases; and, *vice versa*, as he descends lower, it diminishes.

VICEGRAD, or VISSEGRAD, in *Geography*, a town of

Hungary, near the Danube, with a castle, formerly the residence of the kings of Hungary. It was enlarged, and magnificently fitted up by Charles I., who, in 1310, ordered the royal crown to be deposited here. In this castle likewise he entertained John, king of Bohemia, and his son Casimir, king of Poland, and Nemagna, king of Bosnia and Servia. After the death of Louis II. it was taken by the Turks, since which it has been neglected; 9 miles S.S.E. of Gran.

VICENNALIS, in *Antiquity*, something of twenty years, or that returns after twenty years.

Among the Romans, *vicennalia* particularly denoted the funeral feasts, held on the twentieth day after a person's decease.

VICENNALIA, or *Vicennales Ludi*, were also games, feasts, and rejoicings, held every twentieth year of the reign of a prince.

On medals we frequently meet with *vicennalia vota*; the vows put up on that occasion for the safety of the emperor and the enlargement of the empire.

These are expressed by VOT. X. & XX, in the medals of Tacitus, Gallienus, and Probus; VOT. X. M. XX, in those of Valerius Maximianus and Galerius Maximianus; VOT. X. MUL. XX, in those of Constantine, Valentinian, and Valens; VOT. X. MULT. XX, in those of Dioclesian, Constantine, Julian, Valentinian, Theodosius, Arcadius, Honorius; VOTIS X. MULT. XX, in those of Julian, Valentinian, Gratian; VOT. X. SIC. XX, in those of Valerius Constantius; VOT. XII. FEL. XX, in the younger Licinius; VOT. XV. FEL. XX, in Constantine.

VICENTE, or VINCENT, *St.*, in *Geography*, a province of Brasil, containing the noted republic of *St. Paul* (which see); and as this is the first province in which the Portuguese established themselves, so it was one of the most fertile, till the discovery of the mines diverted the channels of commerce. It is now chiefly remarkable for hams, esteemed equal to any in Europe; and, if Eitalla may be credited, for tanned hides of large wine.

VICENTIA, VICENZA, in *Antient Geography*, a town of Italy, in Venetia, upon the Medoacus Minor (the Barchiglione). Of its foundation nothing is known; but it appears to have been a Roman colony, and municipal. The partisans of Vespasian took possession of it, A.D. 69. Tacitus, Hist. l. iii. c. 8.

VICENTIN, in *Geography*, a country of Italy, bounded on the north by the Tyrolése, on the east by the Trevisan and the Paduan, on the south by the Paduan, and on the west by the Veronese and Tyrolése; about 45 miles in length, and from 10 to 24 in breadth. This territory was formerly a part of Lombardy. It is partly hilly, and partly flat; but in general uncommonly pleasaunt and fertile. The plains abound in all kinds of corn, fruit, and mulberry-trees; and the mountainous parts afford good pastures, and most excellent wine, called "vino santo." The breeding of cattle is so very considerable here, that the country of Vicenza is proverbially called the stables of Venice. The sheep are in tolerable plenty, and the wool is excellent. The culture of silk is so important, that it produces annually upwards of 200,000 pounds of that article; there are also silver and iron mines, medicinal springs, paper, and saw-mills, which are abundantly provided with timber from the forests. Fish and venison are in abundance. The hill Summano is celebrated on account of the great variety of salubrious herbs which grow there; and on the other hills petrified shells and fish are found, some of which differ entirely from those that live in the Adriatic sea. The larger rivers and rivulets are the Astico, Agno or Gua, the Temonchio,

monchio, the Cerifon, and Tergola, all which run into the river Baghiglione, and difcharge themfelves afterwards into the Po. The territory of Vicenza belonged formerly to ancient Venetia, and in the fequel raifed itfelf to the rank of one of the thirty duchies of Lombardy, and was incorporated by Charlemagne with the Marca Trevifana. In the progrefs of time, the country of Vicenza afumed again a republican form; and in the 13th century, fell under the dominion of the tyrant Ezzelin. After his death, it came under the government of Padua, from which it was taken by the family of Scala, who were again difpoffeffed of it by John Galeazzo Visconti, duke of Milan. It did not, however, remain long in his hands; for in the year 1404, it refused itfelf from the government of Milan, and fubmitted voluntarily to the republic of Venice. In the year 1796, it became part of the Auftrian monarchy, in virtue of the peace of Campo Formio. This province comprehends one city, 13 fmall towns and boroughs, and upwards of 300 villages. The whole population amounts, according to the laft enumeration made by the French, to 286,000 fouls.

VICENTINO, DON NICOLÒ, in *Biography*, published at Rome, 1555, a work in quarto, entitled "L'Antica Musica ridotta alla moderna Pratica," or "Ancient Music reduced to modern Practice," with precepts and examples for the three genera and their fpecies; to which is added, an account of a new inftrument for the moft perfect performance of mufic, together with many mufical fecrets.

During the 16th century, and a great part of the next, many of the moft eminent mufical theorists of Italy employed their time in fubtle divifions of the feale, and vifionary purfuits after the ancient Greek genera; nor was this rage wholly confined to theorists, but extended itfelf to practical muficians, ambitious of aftonifhing the world by their deep fcience and fuperior penetration, though they might have employed their time more profitably to themfelves, and the art they profefled, in exploring the latent refources of harmonic combinations and effects in compofition, or in refining the tone, heightening the expreffion, and extending the powers of execution, upon fome particular inftrument. Thefe vain inquiries certainly impeded the progrefs of modern mufic; for hardly a fingle tract or treatife was prefented to the public, that was not crowded with circles, fegments of circles, diagrams, divifions, fubdivifions, commas, modes, genera, fpecies, and technical terms, drawn from Greek writers, and the now unintelligible and ufelefs jargon of Boethius.

Vicentino, by the title of *Don* prefixed to his name, feems to have been an ecclefiaftic of the Benediftine order. He was a practical mufician, and appears to have known his bufinefs. In his treatife he has explained the difficulties in the mufic of his time, with fuch clearnefs, as would have been ufeful to the ftudent, and honourable to himfelf, if he had not fplit upon enharmonic rocks, and chromatic quick-faunds. He gives a circumftantial account of a difpute between him and another mufician at Rome, Vicentio Lufitanio, who maintained that modern mufic was entirely diatonic; while Vicentino was of opinion, that the prefent mufic was a mixture of all the three ancient genera, diatonic, chromatic, and enharmonic. This difpute having produced a wager of two gold crowns, the fubject was difcuffed in the pope's chapel, before judges appointed by the difputants, and determined againft Vicentino; whether juftly or unjuftly, depends upon the precise fenfe affigned to the term *chromatic* by the feveral difputants.

What ufe was made of the enharmonic genus in the mufic of the 16th century, we know not; but whenever other founds are ufed than thofe of the feale, ftrictly diatonic, by

introducing F, C, or G fsharp, or any flat, except that of B, which the Greeks themfelves allowed in the fynemomen tetrachord, and the moft fcrupulous writers upon canto-fermo, in the modes of the church, the diatonic is mixed with the chromatic; and to this licence the firft contrapuntifts were reduced, at a cadence in D and A minor, as well as G major.

Though Vicentino loft his wager by the decifion of the judges againft him, he recovered his honour fome time after, by his antagonift, Lufitanio, recanting, and coming over to his opinion. According to Kircher, Vicentino was the firft who imagined that the proportions or ratios of the ancient diatonic genus were inadmiſſible in our counterpoint; and tried in his work to eftablifh the tetrachord to confift of a major, femitone, and two tones, one major and one minor; which forms the diatonic fyn-tonas of Ptolemy, which Zarlino has propagated, and which is now in general ufe.

VICENZA, in *Geography*, a city of Italy, and capital of the Vicentino, fituated at the union of two fmall rivers, in a plain, between two hills. The celebrated architect, Andrea Palladio, was born and lived here. Among the buildings are feen feveral regular ftately palaces, and other elegant edifices, particularly the council-houfe, the grandeur of which is heightened by two very lofty columns, with St. Mark's winged lion on one of them, and on the other the image of our Saviour. The Monte della Pietà is a ftately fabric, and has a very fine library. Of the churches, which are 57 in number, 14 are parochial, and 29 conventual, with feveral good hofpitals. The cathedral ftrikes the eye with nothing particular. The great altar of the Dominican church is a moft auguft piece of Palladio's architecture, as is alfo the beautiful convenient theatre in the building where the Academia Olympicorum meets. The feats are difpofed in the manner of the ancient amphitheatre, and the perſpective is furprifingly beautiful, chiefly by reafon of the many ftatues of Roman emperors, and fome philofophers. This academy is a fociety of men of learning, who meet at ftated times, for the improvement of the Italian language. By the fame fkilful architect is likewife the copy of the triumphal arch of the Campo Martio, without the city, erected for the embellifhment of the public walk. The church della Madonna di Monte, on a mountain, without the city, is much frequented by pilgrims, and poffeffes a fine front-piece, with a convent built clofe by. The Scaligeri were once for a confiderable time lords of this city; afterwards it paffed through feveral hands, and, in 1304, fubmitted to the republic of Venice; 35 miles W. of Venice. N. lat. 45° 31'. E. long. 11° 22'.

VICES, a term ufed by the dealers in horfes to exprefs certain faulty habits or cuftoms in that creature, which render him troublefome to the rider, and are never to be worn off, but by attention to the regular methods.

The following are the tricks generally underftood as vices by dealers, and their methods of preventing, correctng, and curing them.

1. If a horfe carry his head or neck awry, ftrike him twice or thrice with the ſpur on the contrary fide; but if he be very ftiff-necked on the right fide, and very plying or bending on the left, the rider is to hold the right rein ſhorter than the other, and give him fudden checks every time he inclines that way, having a fsharp wire faftened in the reins, that ftriking in his neck, he may be compelled to hold it ftraight; but in this, care muft be always taken to check him upwards, for otherwife he will get a habit of ducking his head, which will prove very troublefome.

2. If a horfe is apt to ſhake his head and ears upon the leaft occaſion, or move his ears when he is going to kick or bite,

bite, or cast his rider; the way of curing this is to strike him on the head with a wand, as soon as he shews the first attempt to it; and, at the instant of striking him, he is to be checked with the bridle, and struck with the spur on the contrary side: this will put him out of his pace, and he is then to be stopped, that he may have leisure to understand the rider's meaning. Every time that he starts or winces, which are signals that he is going to bite, or to strike with his heels, the same is to be done, and he will, by degrees, be broke of these habits.

3. If a horse is subject to ducking down his head frequently, the rider must, every time he is guilty of it, check him suddenly with his bridle, and at the same time strike him with the spurs, in order to make him sensible of his fault. If he be standing, he is thus to be made to bring his head in the right place as he stands; and when he does so, he is to be cherished, that he may understand the rider's meaning, which, in time, he will certainly do.

4. If a horse be skittish, and apt to start, so that the rider is never free from danger while on his back, the cause of the malady is first to be carefully inquired into: if it be found to proceed from a weak sight, which represents objects to him other than they really are; the method of curing him is, every time he does it, to give him leisure to view the things, and see what they really are; he must have time to view them well, and then be rid gently up to them. If, on the contrary, his skittishness depends on his being naturally fearful, and alarmed at every noise, he is to be cured of it by the inuring of him to loud noises of many kinds, as firing of guns, drums, trumpets, and the like; and he will, in time, come to take delight in that of which he was before afraid.

5. If a horse be restive, and refuse to go forward, the rider is to pull him backwards, and this will often occasion his going forward: this is using his own fault as a means of reclaiming him. The rider is first cautiously to find whether this vice proceeds from real stubbornness, or from faintness: if from the latter, there is no remedy but rest; but if actual stubbornness be the fault, the whip and spur, well employed, and persisted in, will at length be found a certain cure.

6. If a horse rear up an end; that is, if he rises so high before as to endanger his coming over the rider, the horseman must give him the bridle, and bear forwards with his whole weight. As he is going down, he should have the spur given him very roundly; but this must by no means be done as he is rising, for then it will make him rise higher, and probably come over.

7. If a horse be subject to lie down in the water, or upon the ground, there is no better remedy than a pair of sharp spurs resolutely applied. But there is some caution to be used in the application of them, for bad horsemen generally are the occasion of the faults in horses, by correcting them out of due time.

The proper moment of spurring is just when he is going to lie down; but when this has diverted him from the thought of it, he is not immediately to be spurred again. For the doing this frightens the creature, and puts him into confusion to that degree, that he at length becomes restive, and thus one fault is only changed for another, and that perhaps a worse.

8. If a horse be apt to run away, very cautious means must be used to break him of it. The rider must be gentle, both with a slack curb, and keeping an easy bridle-hand. He is first to be walked without stopping him; but only slaying him, by degrees, with a steady, not a violent hand, and always cherishing him when he obeys: when he is thus made very manageable in his walk, he is to be put to

his trot, and finally to his gallop; and from these he is to be brought into a walk again, always by degrees, and slaying him with a steady hand. By using this method from time to time, with judgment and patience, it is probable he may at length be cured.

9. If a horse is apt to fly out violently, it is certain, that the more the bridle-rein is pulled, and the more he is hurt by tugging the curb, the faster he will run: the best method is therefore, if there be field-room enough, to let him go, as soon as he is going, by slackening the bridle, and giving him the spur continually and sharply, till he slacken of his own accord. Thus, by degrees, he will find that himself is the sufferer by all his flights, and he will then leave them off, though he could be never broke of them any way else.

10. Some horses will not endure the spurs when they are given them, nor ever go forwards; but fastening themselves to them, they will strike out and go back; and if they are pressed more hard, they will fall to italing without ever going out of the place. If the horse who has this vice be a gelding, it will prove very difficult to cure him of it. A stone-horse, or mare, are much easier cured; but even these will be trying at it again afterwards; and if they ever get the better of their rider, they will not fail to keep it up in this particular.

Every horse, of whatever kind, that has this fault of cleaving to the spurs, as the jockeys call it, and not going forwards with them, is to be rejected, in the buying for any gentleman's riding, for it is a sign of a restive nature, and is a fault generally accompanied with many others.

VICESIMATIO, in *Roman Antiquity*. See DECIMATION.

VICH, in *Geography*, a river of Russia, which runs into the Oby, N. lat. 61° 20'. E. long. 76° 14'.

VICHEREY, a town of France, in the department of the Vosges; 9 miles E. of Neufchâteau.

VICHNOU, or VISNE, in *Mythology*, a deity in the East Indies, of whom the Brachmans have a tradition, that he was metamorphosed into a tortoise; and they explain this fable by saying, that by the fall of a mountain the world began to stagger and to sink down gradually towards the abyss, where it would have perished, if their beneficent god had not transformed himself into a tortoise to bear it up. See VISHNU.

VICHY, in *Geography*, a town of France, in the department of the Allier, on the Allier; near it are some medicinal springs; 3 miles S.W. of Cusset.

VICIA, in *Botany*, the Vetch, an old Latin name, is by some etymologists derived from *vincio*, to bind together, as the various species of this genus twine, with their tendrils, round other plants. De Theis traces this word to its Celtic synonym, *Gauig*, whence also, according to him, comes the modern Greek name of the vetch, *βίαιον* or *βίαια*.—*Linn. Gen.* 376. *Schreb.* 497. *Willd. Sp. Pl.* v. 3. 1093. *Mart. Mill. Dict.* v. 4. *Sm. Fl. Brit.* 768. *Prodr. Fl. Græc. Sibth.* v. 2. 69. *Ait. Hort. Kew.* v. 4. 310. *Pursh* 471. *Juss.* 360. *Tourn.* t. 221. *Lamarck Illust.* t. 634. *Gærtn.* t. 151. (Faba; *Tourn.* t. 212.)—Class and order, *Diadelphia Decandria*. *Nat. Ord. Papilionaceæ*, *Linn. Leguminosæ*, *Juss.*

Gen. Ch. Perianth inferior, of one leaf, tubular, erect, cloven half way down into five acute segments; the upper ones shortest, converging; all of equal breadth. *Cor.* papilionaceous. Standard oval, with a broad oblong claw; its summit emarginate with a small point; the sides reflexed; the back marked with a longitudinal, compressed, elevated line. Wings two, oblong, erect, half-heartshaped, shorter than the standard, with oblong claws. Keel shorter than

the wings, half-orbicular, compressed, with a divided oblong claw. *Stam.* Filaments in two sets, one simple, the other in nine divisions; anthers erect, roundish, with four furrows. A nectariferous gland, short and pointed, arises from the receptacle, between the compound filament and the germen. *Pist.* Germen linear, compressed, long; style shorter, thread-shaped, bent upwards at a right angle; stigma obtuse, transversely bearded underneath. *Peric.* Legume long, coriaceous, of one cell and two valves, terminating in a point. *Seeds* several, roundish.

Obf. *Faba* of Tournefort has oval compressed seeds. *Vicia* of that author and Rivinus has roundish seeds.

Eff. Ch. Stigma transversely bearded on the under side.

An extensive genus of herbaceous, perennial or annual plants, climbing by means of tendrils, which terminate the common footstalk of their abruptly pinnated leaves. It is nearly akin to *LATHYRUS*, (see that article,) differing essentially in the *stigma*, and in a generally more slender habit, with smaller, more oblong, flowers. The species are mostly natives of Europe, a few of Barbary, and North America, scarcely any occurring in tropical climates. The flowers are axillary: either racemose on a longish common stalk; or nearly sessile, solitary or two or three together; their colour crimson, purplish, or pale yellowish, rarely white or blue.

SECT. 1. Flower-stalks elongated.

1. *V. pisiformis.* Pea Vetch. Linn. Sp. Pl. 1034. Willd. n. 1. Ait. n. 1. Jacq. Austr. t. 364. (*Pisum sylvestris*; Clus. Hist. v. 2. 229. *P. perenne sylvestris*; Ger. Em. 1220. *Cracca flore ochroleuco*; Rivin. Tetrap. Irr. t. 52.)—Stalks many-flowered. Leaflets ovate; the lower pair close to the stem.—Native of woods in Hungary, Austria, Germany, Switzerland, and near Constantinople; a hardy perennial, flowering in July and August in our botanic gardens. The stem is angular and striated, branched, climbing to the height of several feet. Leaves of three or four pair of not quite opposite, broad, blunt, smooth leaflets, about an inch long, all on very short partial stalks, attached to a straight footstalk from three to five inches in length, which ends in a branched tendril; the lowest pair largest, and close to the stipulas, which are ovate, acute, with an awl-shaped descending lobe. Flower-stalks half as long as the leaves, each bearing a dense cluster of numerous, oblong, pale-yellowish flowers, all drooping one way. Legume an inch and half long, near half an inch broad, smooth, veiny, of a rusty brown.

2. *V. caroliniana.* Carolina Vetch. Walt. Carol. 182. Willd. n. 2. Pursh n. 5. (*V. parviflora*; Michaux Boreal-Amer. v. 2. 69.)—Stalks with many distant flowers. Leaflets numerous, elliptic-lanceolate, nearly smooth. Stipulas ovato-lanceolate, entire. Stem smooth.—Native of mountians in North America, from Pennsylvania to Carolina, flowering in July and August. Resembles *V. Cracca*, but the flowers are white, with a black-tipped standard, and a great deal smaller. *Pursh*. The stem is angular, furrowed. Leaflets eight or ten, not quite opposite. Stipulas small. Clusters three inches or more in length, of above twenty flowers, hanging all one way. *Walters, Willdenow.*

3. *V. pontica.* Euxine Vetch. Willd. n. 3. (*V. multiflora fipicata*, floribus albidis, calyce purpureo; Tourn. Cor. 27.)—Stalks with many crowded flowers. Leaflets numerous, lanceolate. Stipulas lanceolate-sword-shaped, entire. Stem downy.—Native of the country near the Euxine sea. Stem angular and furrowed. Tendrils of the leaves three-cleft. Leaflets from twenty to twenty-seven, elliptic-lanceolate, an inch or more in length, bearing, on the under side especially, many scattered close-pressed hairs. Stipulas almost

half an inch long, hairy, ribbed. Clusters six inches, the lower ones a foot, in length. Flowers drooping, crowded, the size of *V. Cracca*. *Willdenow.*

4. *V. dumetorum.* Great Wood Vetch. Linn. Sp. Pl. 1035. Willd. n. 4. Ait. n. 2. (*V. n. 427*; Hall. Hist. v. 1. 185. *Cracca sylvatica*; Rivin. Tetrap. Irr. t. 51.)—Stalks many-flowered. Leaflets reflexed, ovate, pointed. Stipulas somewhat toothed.—Native of France, Switzerland, Germany, and the neighbourhood of Constantinople; a hardy perennial, flowering in May or June, but seldom cultivated here, except for curiosity. The leaflets are smaller, more numerous, and more alternate than in the first species, the lower one only situated near the base of their common footstalk. Flowers fewer, and much larger, purple, not yellow. Legumes lanceolate, tapering at each end.

5. *V. sylvatica.* Common Wood Vetch. Linn. Sp. Pl. 1035. Willd. n. 5. Fl. Brit. n. 1. Engl. Bot. t. 79. Fl. Dan. t. 277. (*V. n. 426*; Hall. Hist. v. 1. 185. t. 12. f. 2. *V. multiflora maxima perennis*, tetro odore, floribus alben-tibus, lineis caruleis striatis; Pluk. Phyt. t. 71. f. 1.)—Stalks many-flowered, longer than the leaves. Leaflets numerous, elliptical. Stipulas lunate, with capillary teeth.—Native of rather mountainous woods and thickets, in Sweden, Germany, France, and England, flowering in July and August. An elegant plant, with a branching perennial root. The stems are much branched, climbing over bushes, which they decorate with long-stalked clusters of white flowers, delicately striated with purplish-blue. The leaflets are feathered, smooth, blunt, or emarginate, with a small point; their length from a quarter to half an inch. Legume lanceolate, pointed, smooth, with about four seeds. This species is well worthy of a place in gardens and shrubberies. In the north of England it often makes a beautiful appearance in hedges and mountain thickets, flowering copiously for several weeks.

6. *V. americana.* American Wood Vetch. Muhlenb. Cat. 65. Willd. n. 6. Pursh n. 3.—Stalks with several flowers, shorter than the leaves. Leaflets elliptic-lanceolate, obtuse, smooth. Stipulas half-arrow-shaped, deeply toothed.—Discovered in Pennsylvania, by the late Rev. Dr. Muhlenberg, from whom we have a specimen. It flowers in May, and is perennial. Pursh compares this species with *V. sylvatica*, as to the size of its flowers and general resemblance. But the leaflets are rather larger, somewhat toothed. Stipulas with deep, but not capillary segments. Flowers much fewer, their common stalks never longer than the leaves.

7. *V. grandiflora.* Large-flowered Vetch.—Stalks with several flowers, shorter than the leaves. Leaflets ovate, smooth. Stipulas lunate, with sharp teeth. Calyx-teeth taper-pointed.—Gathered by Mr. Menzies, at the upper edge of the forest, on the mountain called *Moona-rooa*, in Owhyhee, which is 6000 feet high. This magnificent species is much larger than any of the preceding. Its leaflets, near an inch and half long, are the shape of *V. dumetorum*, but twice as large. Flowers pale purple, full thrice the size of *dumetorum*; their standard and other petals all strongly recurved. Calyx half as long as the corolla, with long, very finely pointed, teeth. The clusters are lax, with slender, somewhat downy, partial stalks, three-quarters of an inch in length. We have not seen the legume.

8. *V. variegata.* Parti-coloured Oriental Vetch. Willd. n. 7. Prodr. Fl. Græc. n. 1700. (*V. orientalis multiflora argentea*, flore variegato; Tourn. Cor. 27.)—Stalks with many imbricated flowers. Leaflets elliptical, villous. Stipulas deeply divided at the base, ovato-lanceolate.—Native of

of the Levant. *Tournefort*. Found by Dr. Sibthorp in the Peloponnesus. His specimens answer well to Willdenow's description, except that the *leaves*, though clothed with shining hairs, are scarcely "whitish, or silvery." The *stems* are about a foot high, square, striated, villous. *Leaflets* from fourteen to twenty, obtuse; those of the lower *leaves* obovate, emarginate, pointed, crowded. *Tendrils* short, cloven. *Common stalk* dilated, semi-cylindrical. *Stipulas* pointed. *Clusters* rather longer than the leaves. *Flowers* the size of *V. sativa*, turned all one way.

9. *V. caffubica*. Caffubian Vetch. Linn. Sp. Pl. 1035. Willd. n. 8. Ait. n. 4. (V. Gerardi; Jacq. Auftr. t. 229. V. pedunculata multifloris, petioli polyphyllis, folioli villosis, stipulis acutis integris appendiculatis; Gerard Galop. 497. t. 19, excellent. V. multiflora caffubica frutescens, lentis filiquâ; Pluk. Phyt. t. 72. f. 2.)—Stalks many-flowered, shorter than the leaves. *Leaflets* elliptic-oblong, slightly downy. *Stipulas* lanceolate, entire, with a divaricated awl-shaped spur at the base.—Native of mountainous woods and meadows, in Provence, Pomerania, and Aultria. Perennial, flowering in June, and ripening seed in August. This, it seems, has been formerly confounded with *V. sylvatica*, but the *stems* are only about eighteen inches high, erect, not climbing. The whole of the herbage is somewhat downy. *Leaflets* very numerous, opposite or alternate, obtuse or emarginate. *Stipulas* narrow, with a capillary point. *Flowers* light purple, from six to twenty, drooping, the size and shape of *V. sylvatica*. *Legumes* ovate, hardly an inch long, likewise resembling those of the *sylvatica*. The name *caffubica*, taken from a province of Pomerania, is extremely exceptional, for a plant found in so many different countries.

10. *V. atropurpurea*. Dark-purple Vetch. Desfont. Atlant. v. 2. 164. Willd. n. 9.—Stalks many-flowered, shorter than the leaves. *Calyx*-teeth bristle-shaped, very villous. *Leaflets* lanceolate, villous. *Stipulas* half-arrow-shaped, deeply toothed. *Legume* hairy.—Native of the isles of Hyeres, and of Algiers. Annual. The whole plant is villous. *Stem* square, striated. *Leaflets* from eight to twelve, bluntish, pointed. *Stipulas* ovate, with deep, linear-lanceolate, pointed teeth. *Calyx* clothed with long spreading hairs. *Corolla* of a deep blood-red. *Legume* covered with short reddish hairs. Very different from the following species. *Willdenow*.

11. *V. villosa*. Villous Vetch. Roth Germ. v. 2. part 2. 182. Hoit. Syn. 399. Willd. n. 10.—"Stalks longer than the leaves, with many imbricated flowers. *Leaflets* oblong-ovate, villous. *Stipulas* half-arrow-shaped, ovate; bluntly toothed at the base."—Native of Germany, Aultria, and Hungary. Resembles *V. Cracca*, but the *root* is annual; *flowers* larger; *stem* weaker; *herbage* more villous; *legumes* twice as broad, and half as long again, as in that species, with *seeds* twice as large, grey covered with sooty powder, not black and smooth. *Roth*.

12. *V. polyphylla*. Many-leaved Vetch. Desfont. Atlant. v. 2. 162. Willd. n. 11. Sm. Fl. Græc. Sibth. t. 699, unpublished. (V. orientalis multiflora incana, angustiflora folio; Tourn. Cor. 27. Buxb. Cent. 5. 46. f. 35.)—Stalks longer than the leaves, many-flowered. *Leaflets* linear-lanceolate, acute, downy. *Stipulas* half-hastate, lanceolate, entire.—Native of Hungary, Greece, mount Hymettus, and Barbary. Perennial. *Stems* branched, angular, climbing, clothed, like the rest of the herbage, with soft silky hairs. *Leaflets* very numerous, near an inch long. *Stalks* rather longer than the leaves, each bearing a cluster of larger, less numerous and crowded *flowers*, than in the following. *Calyx*-teeth very unequal. *Standard* sky-blue, with purple

veins. *Wings* and *keel* white; the latter tipped with violet. *Legume* oblong, smooth.

13. *V. Cracca*. Tufted Vetch. Linn. Sp. Pl. 1035. Willd. n. 12. Fl. Br. n. 2. Engl. Bot. t. 1168. Pursh n. 4. Curt. Lond. fasc. 5. t. 54. Mart. Ruft. t. 117. Fl. Dan. t. 804. (Cracca; Rivin. Tetrap. Irr. t. 50.)—Stalks the length of the leaves, with many imbricated flowers. *Leaflets* lanceolate, bluntish, downy. *Stipulas* half-arrow-shaped, mostly entire. Found in thickets, hedges, and fields throughout Europe, as well as in North America, flowering in July and August, when the dense *clusters* of numerous blue *flowers* make a handsome appearance. The *petals* are all blue; *flowers* more crowded; *leaflets* shorter and rather blunter than in the last. In the *stipulas* we find no permanent difference, the lower lobe being more or less divaricated or deflexed. Curtis justly remarked that the *stigma* is hairy all round.

14. *V. tenuifolia*. Slender-leaved Vetch. Roth Germ. v. 2. pt. 2. 183. Willd. n. 13. Ait. n. 6. Donn Cant. ed. 5. 176.—"Stalks longer than the leaves, with many imbricated flowers. *Leaflets* linear, three-ribbed, smoothish. *Stipulas* linear, entire."—Native of sandy hills in Germany, as well as in Tauris. Said to be very like the preceding; but of a more humble and upright growth. The lower *stipulas* only are half-hastate; the upper ones simple and linear. *Flowers* fewer in each cluster, always violet-coloured. *Legumes* about half as large. *Roth*.

15. *V. onobrychioides*. Saint-foin Vetch. Linn. Sp. Pl. 1036. Willd. n. 14. Ait. n. 7. Allion. Pedem. v. 1. 325. t. 42. f. 1. (V. onobrychidis flore; Bauh. Prodr. 149.)—Stalks longer than the leaves, with many distant flowers. *Leaflets* linear, rather abrupt, smooth. *Stipulas* lanceolate, deeply toothed at the base.—Native of Switzerland, Italy, the south of France, Greece, Cyprus, and the Archipelago, flowering in summer. The *root* is annual. *Herb* branched, climbing, with the habit of *V. Cracca*, but smooth, and much more variable in size, as well as in the breadth of the *leaflets*, which are moreover sometimes acute, sometimes obtuse or abrupt, always tipped with a bristly point. *Flowers* thrice as large as in *Cracca*, fewer and more remote, parti-coloured with crimson and white. *Legume* an inch and half long, lanceolate, pointed, with many small seeds.

16. *V. biennis*. Biennial Vetch. Linn. Sp. Pl. 1036. Willd. n. 15. Ait. n. 8. (V. n. 9; Gmel. Sib. v. 4. 10. t. 2.)—Stalks much longer than the leaves, with many scattered flowers. *Leaflets* elliptic-lanceolate, smooth. *Common footstalks* angular, furrowed. *Stipulas* half-arrow-shaped, stalked.—Native of Siberia. A tall, smooth, biennial plant. *Leaflets* ribbed, an inch and quarter or inch and half long. *Flowers* half the size of the last, whitish, with a blue standard.

17. *V. altissima*. Tall Vetch. Desfont. Atlant. v. 2. 163. Willd. n. 16.—"Stalks many-flowered. *Leaflets* about twice, elliptical, abrupt, smooth. *Stipulas* toothed."—Native of Barbary, in hedges near Arzeau. Akin to the foregoing, but the abrupt *leaflets*, and toothed *stipulas*, distinguish it. *Desfontaines*. We would observe that nothing is more variable than the termination of the *leaflets* in this tribe; yet we do not dispute the distinctness of the present species. The *herb* is perennial, perfectly smooth throughout, six feet high. *Flower-stalks* longer than the leaves, angular. *Flowers* numerous, pale blue, scarcely larger than in *V. scipium*; see the second section.

18. *V. Bivona*. Blue Sicilian Vetch.—Stalks as long as the leaves, about three-flowered. *Leaflets* elliptical, obtuse, hairy. *Stipulas* lunate, deeply toothed. *Legume* oblong,

reticulated, smooth.—Native of Sicily, from whence it was sent us by the baron Bivona Bernardi. Akin to several of the foregoing, but decidedly distinct. *Root* perennial. *Stems* several, climbing, eighteen inches or more in height, sharply angular, hairy like the rest of the herbage. *Leaflets* half or three quarters of an inch long, pale green, rather silky. *Flowers* two, three, or four on each stalk, light purplish-blue, much shorter than those of *V. Cracca*. *Calyx-teeth* all remarkably long, tapering, finely fringed. *Legume* an inch and quarter long, half an inch broad, flat, with four or five seeds.

19. *V. nissoliiana*. Red Oriental Vetch. Linn. Sp. Pl. 1036. Willd. n. 17. Ait. n. 9.—Stalks shorter than the leaves, with few flowers. *Leaflets* elliptic-oblong, obtuse, downy. *Stipulas* lanceolate, entire. *Legumes* compressed, ovate-oblong, silky.—Native of the Levant. A hardy annual, said to have been first introduced at Kew, in 1773, by the celebrated earl of Bute. The whole plant is downy, or somewhat silky. *Leaflets* an inch long, tapering at the base into little partial stalks. *Stipulas* narrow, undivided. *Flowers* five or six, dark purple, the size of the last. *Calyx-teeth* long and slender, but not quite so long in proportion to the tube as in that species. *Legume* above an inch long, flat, very silky, with four or five large prominent seeds. Linnæus cultivated this species at Upsal. We have never observed it in any collection here.

20. *V. benghalensis*. Bengal Vetch. Linn. Sp. Pl. 1036. Willd. n. 18. Ait. n. 10. (*V. benghalensis*, *hirsuta* et *incana*, *siliquis pisi*; Herm. Lugd.-Bat. 623. t. 625. *Cracca benghalensis*; Rivin. Tetrar. Irr. t. 50.)—Stalks shorter than the leaves, about three-flowered. *Leaflets* elliptic-oblong, obtuse, downy. *Stipulas* lanceolate, entire. *Legume* turgid, oblong, silky.—Native of Bengal, from whence Sir Joseph Banks procured seeds for the Kew garden, in 1792. An annual stove-plant, flowering in June and July. This is nearly related to the last, in general habit, pubescence, *stipulas*, and *calyx*; but the *flowers* are scarcely more than three; their *petals* longer, said to be of a very deep scarlet, at least their upper half, the *keel* tipped with black. We have not seen them, except dried. The *legume* differs essentially from the foregoing, having concave valves, like a *Pisum*, with five large round seeds.

21. *V. canescens*. Hoary Syrian Vetch. Billard. Syr. fasc. 1. 17. t. 7. Willd. n. 19. Ait. n. 11.—Stalks many-flowered, about the length of the leaves, which scarcely bear tendrils. *Leaflets* elliptic-lanceolate, downy. *Stipulas* half-arrowshaped. *Legume* turgid, oblong, silky.—Gathered by La Billardiere, towards the summit of mount Lebanon, and by Sibthorp in Greece. Sir Joseph Banks sent seeds to Kew in 1800. If this and the two preceding exist at present, in any garden, they ought to be figured in one, not both, of our periodical works. The present is marked as a hardy annual, flowering in July and August. The whole *herb* is hoary with soft down. *Stem* erect, a foot or more in height, square, striated. Lower leaves numerous pinnate, with an odd leaflet, in whose place the upper ones have only a short straight point, or abortive tendril. *Flowers* blue, full as large as the last, and more numerous. *Legume* welling as in that, downy, but with fewer seeds.

22. *V. capensis*. Cape Vetch. Berg. Cap. 215. Willd. n. 20. Thunb. Prodr. 125.—Stalks elongated, many-flowered. Leaves pinnate with an odd leaflet, without tendrils; silky beneath. *Stipulas* lanceolate, undivided.—Native of the Cape of Good Hope. Perennial. *Stem* a span high, erect, angular, smooth; branched at the base; the branches short, procumbent. *Leaflets* about twenty-one, linear, abrupt with a point, or slightly emarginate; smooth above;

scarcely half so long as the finger-nail. *Stipulus* membranous, ovate or lanceolate, simple and entire. *Clusters* roundish, hairy, rather dense, on long stalks. *Calyx-teeth* lanceolate, acute, nearly equal. *Bergius*. Linnæus has made a manuscript note in this author's book, saying "this plant resembles *Hippocrepis comosa*, but it has a *racemus*, not an *umbella*. It cannot be a *Vicia*, because of the odd leaflet."—The last remark is invalidated by *V. canescens*, n. 21. We have seen no specimen, on which to found any opinion.

23. *V. pellucida*. Transparent Vetch. Jacq. Hort. Schoenbr. v. 2. 50. t. 222. Willd. n. 21.—Stalks shorter than the leaves, with several flowers. Leaves pinnate with an odd leaflet, without tendrils, downy. *Stipulas* lanceolate, undivided. *Legume* falcate, many-seeded.—Native of the Cape of Good Hope. Jacquin's figure answers so well to the remark of Linnæus under the last species, that we are much inclined to think the present is the very same plant. Willdenow indeed, who had seen a dried specimen of the former, thought them distinct; but he indicates no material difference. The *flowers* of Jacquin's plant have a roundish, elegantly striated, *standard*, with purple *wings* and *keel*. The *legume* is compressed, curved, near two inches long, with ten or more seeds, separated by transverse stricures. *Bergius* has not described the fruit of his plant.

24. *V. fraticosa*. Willd. n. 22. (*Lathyrus tomentosus*; Cavan. Ic. v. 1. 58. t. 84. *Orobus tomentosus*; Desfont. Tabl. 224.)—Stalks shorter than the leaves, two-flowered. Leaves abruptly pinnate, without tendrils, downy. *Stipulas* awl-shaped, undivided. *Legume* straight, downy, many-seeded.—Found on hills near Huanuco, in Peru. A shrub, flowering in the Madrid garden from July to November. The *stem* is two feet high, with numerous, drooping, downy, round *branches*. *Leaflets* about twenty pair, elliptical, uniform, entire, a quarter of an inch long, without an odd one, or any terminal point. *Flowers* yellow, in shape and size not unlike the last, nor is the *legume* very dissimilar, except being straight, and gradually dilated upwards.—We feel little confidence as to the genus of this plant, but a certain resemblance to the two last, notwithstanding the want of an odd leaflet, induces us to retain it here. Perhaps they might all three, if all distinct, be removed from *Vicia*, and on more complete examination and comparison, might form a genus.

25. *V. biflora*. Two-flowered Sharp-leaved Vetch. Desfont. Atlant. v. 2. 166. t. 197. Willd. n. 24. Ait. n. 13.—Stalks two-flowered, shorter than the leaves. *Leaflets* linear, tapering at each end. Tendrils divided. *Stipulas* half-arrowshaped.—Native of Algiers. A hardy annual, sent to Kew, by M. Thouin, in 1801, flowering from June to August. The *stem* is slender, angular, procumbent. *Leaflets* eight or ten, alternate, very narrow. *Stipulas* minute, occasionally toothed. *Stalks* slender, bearing one or two rather large, oblong, blue *flowers*, and tipped with a small point. *Calyx-teeth* rather short. *Corolla* most like *V. benghalensis*, or *biennis*, in shape and dimensions.

26. *V. ciliaris*. Fringed Vetch. Sm. Prodr. Fl. Græc. Sibth. n. 1706. Fl. Græc. t. 700, unpublished.—Stalks single-flowered, pointed, as long as the leaves. *Leaflets* emarginate. *Stipulas* many setaceous segments.—Gathered by Dr. Sibthorp in Asia Minor, probably near Smyrna. We know not whether the *root* be annual or perennial. The *stems* are weak, climbing, two or three feet long, branched, angular. *Leaflets* about seven pair, half an inch long, smooth. *Tendrils* many-cleft. *Stipulas* lunate, very remarkable for their numerous, spreading, almost capillary, segments. Point of the *flower-stalk* elongated three-quarters of an inch beyond the *flower*, which is therefore lateral,

lateral, about the size of the last, pale blue streaked with purple. *Legume* an inch long, elliptical, acute, compressed, with two seeds.

27. *V. graminea*. Grass-leaved Vetch.—Stalks about four-flowered, shorter than the leaves. Leaflets linear, pointed, smooth. Stipulas ovate, entire, slightly half-arrow-shaped.—Gathered by Commerlon, at Buenos Ayres. We do not find any account of this species, a specimen of which was given by Thouin to the younger Linnaeus. The whole herb is nearly or quite smooth. *Stem* two feet or more in height, slender, angular, furrowed, scarcely branched. *Leaves* remote, each of three pair of very narrow leaflets, above an inch long, with a simple or divided tendril at the end of their common stalk. *Flowers* very small, pale, apparently tinged with purple. *Calyx* a little downy, the teeth shorter than the tube. *Legume* smooth, compressed, not an inch in length, elliptic-oblong, with an oblique incurved point, and six or seven small round seeds.

28. *V. longifolia*. Long-leaved Vetch. Poir. in Lam. Dict. n. 15.—Stalks much longer than the leaves, with many distant flowers. Leaflets numerous, linear, elongated, smooth. Stipulas lanceolate, half-arrow-shaped, entire.—Gathered in Syria, by La Billardiere. *Stems* straight, angular, striated, stiff, smooth, branched. *Leaflets* from sixteen to twenty, alternate, distant, very narrow, an inch and a half long, ribbed, entire. *Stipulas* narrow and acute. *Tendrils* in two or three divisions. *Flowers* yellowish-white, drooping, in very loose clusters. *Legume* not observed. Poir.

29. *V. oroboides*. Four-leaved Vetch. Wulf. in Jacq. Coll. v. 4. 323. Willd. n. 25. Hofst. Syn. 399. (*Orobis pannonicus quartus*; Clus. Hist. v. 2. 231.)—Stalks about four-flowered, shorter than the leaves. Leaflets two pair, ovate, pointed, without a tendril. Stipulas half-arrow-shaped, toothed at the side.—Found by Wulfen, in the mountainous woods of Carinthia and Carniola, flowering in May and June. We have specimens from Jacquin. The root is perennial, tuberous. *Stems* erect, a foot and half high, simple, leafy, angular, strongly furrowed, smooth. *Leaves* of two pair of large, smooth, reticulated leaflets, an inch, or inch and half, long, with a small awl-shaped stipulaceous point in the place of a tendril. Clusius's figure erroneously represents an odd leaflet here and there. *Flowers* an inch long, yellow, with a purplish calyx, about four together, in short, lax, axillary clusters.

For *V. Ervilia*, Willd. n. 23. see ERVILIA and ERVUM. We are now convinced that this plant is an *Ervum*.

See 2. *Flowers axillary, nearly sessile.*

30. *V. sativa*. Common Vetch. Linn. Sp. Pl. 1037. Willd. n. 26. Fl. Brit. n. 3. Engl. Bot. t. 334. Pursh n. 2? Mart. Ruit. t. 116. Fl. Dan. t. 522. (*Vicia*; Rivin. Tetrap. Irr. t. 54. Ger. Em. 1227. Lob. Ic. v. 2. 75. Camer. Epit. 320.)

β. Fl. Brit. *V. angustifolia*; Willd. n. 28. Rivin. Tetrap. Irr. t. 55. (*V. lathyroides*; Hudf. 318, α. Dickf. H. Sicc. fasc. 4. 12. *V. sylvestris*, five Cracca major; Ger. Em. 1227. *V. globosa*; Retz. Obs. fasc. 3. 39? Willd. n. 27?)

γ. Fl. Brit. (*V. sylvestris*, flore ruberrimo, siliqua longa nigra; Raii Syn. 321. *V. angustifolia*; Sibth. Oxon. 224. *V. folio angustiore*, flore rubro; Dill. Giff. append. 47.)

Legumes sessile, solitary or in pairs, nearly erect. Lower leaves with abrupt leaflets. Stipulas toothed, marked with a dark depression.—Native of cultivated ground, and grassy pastures, throughout Europe, flowering in May and June. A very variable annual plant, more or less hairy, distinguished by a brown or blackish depressed

mark on each stipula, which is visible in all the supposed varieties; but we are not sure that those varieties may not be specifically distinct; at least our γ, which is characterized by its long, cylindrical, black legumes, and very elegant crimson solitary flowers. The leaflets of *V. sativa*, usually from four to six pair, vary much in breadth; those of the lower leaves are shorter, abrupt, or even inversely heart-shaped; the rest lanceolate or linear; all tipped with a bristle. *Tendrils* of the common stalk long and branched. *Flowers* variously shaded with red and blue. *Legume* compressed, rough, or a little downy, with many globose, or slightly lenticular, very smooth seeds. The use of this plant for fodder is well known. The seeds are the favourite food of pigeons.

31. *V. amphicarpa*. Subterraneous Vetch. Dorthes in Journ. de Phys. v. 35. 131. Willd. n. 29. (*Aracus ipsover*; Clus. Exot. 87. t. 88.)—*Legumes* solitary, sessile; the lower ones subterraneous, ovate. Leaflets linear, abrupt, three pair. Stipulas half-arrow-shaped, toothed.—Native of Provence. Root annual. *Stems* a span long, diffuse, angular. *Leaves* slightly hairy, with more or less of a tendril. *Flowers* crimson, most like *V. sativa* γ. *Legume* lanceolate, acute, above an inch long, with many seeds. Such is the ordinary fructification; but several flowers are produced from subterraneous leafless stalks. These are very small, consisting of a closed colourless calyx, in which, when examined against the light with a magnifying glass, stamens may distinctly be seen. Each of these flowers produces an oval-pointed legume, with one very perfect seed. *Orobis fasciatis*, Venten. Jard. de Cels, t. 94, may possibly be this plant, though the author did not observe its two-fold fructification. Many persons have taken the present *Vicia* for *Lathyrus amphicarpos*, which exhibits a similar phenomenon, but is widely distinct in other respects.

32. *V. pusilla*. Small American Vetch. Muhlenb. Cat. 65. Willd. n. 30. Pursh n. 1.—Stalks solitary, capillary, single-flowered. *Legumes* oblong, smooth. Leaflets about six, linear-lanceolate, bluntnish. Stipulas half-arrow-shaped, entire.—Found by the Rev. Mr. Muhlenberg, in Pennsylvania, and New Jersey. Mr. Pursh says, it grows in low grassy grounds, from Pennsylvania to Virginia, flowering in July and August. The flowers are exceedingly small, white, with a tinge of red. *Pursh*. Root annual. *Stem* four or five inches high, ascending. *Tendrils* of the lower leaves simple, of the upper divided, and very long. *Legume* small. *Willdenow*.

33. *V. lathyroides*. Spring Vetch. Linn. Sp. Pl. 1037. Willd. n. 31. Fl. Brit. n. 4. Engl. Bot. t. 30. Jacq. Misc. Austr. v. 2. 299. t. 18. Fl. Dan. t. 58. Hudf. 319, γ. (*V. minima*; Rivin. Tetrap. Irr. t. 55. *Ervum solonense*; Linn. Sp. Pl. 1040.)—*Legumes* sessile, solitary, smooth. Leaflets about six; the lower ones abrupt. Stipulas half-arrow-shaped, nearly entire. Seeds cubical, tuberculated. Native of France, Britain, Norway, and the Levant. With us it grows in fallow fields, or grassy pastures, on a gravelly or chalky soil, flowering in April and May; at which time of the year it may always be found in Hyde-park, near Kennington gardens. The root is annual, though beset with red fleshy tubercles. *Herb* downy, or rather silky. *Stems* procumbent, spreading, from three to six inches long. *Tendrils* simple, generally very short, or wanting. *Leaflets* mostly inversely heart-shaped; those about the top of the stem more oblong and narrower. Stipulas not marked, and seldom toothed. *Flowers* small, bluish. *Legume* erect, very smooth, by which, and especially the cubical rough seeds, this long-obscure species is at any time to be known from all the varieties of *V. sativa*. Sometimes the flowers

are white, or striated. The *tendrils* are never divided, nor the *leaflets* more than fix.

34. *V. lutea*. Rough-podded Yellow Vetch. Linn. Sp. Pl. 1037. Willd. n. 32. Fl. Brit. n. 5. Engl. Bot. t. 481. (V. flore ochroleuco, filiquis hirsutis propendentibus; Morif. fect. 2. t. 21.)—Legumes solitary, nearly sessile, reflexed, hairy. Stems diffuse. Stipulas coloured. Standard smooth.—Native of the pebbly sea-shores of the south and east of England, as well as of France, Spain, Italy, Barbary, Greece, and the Levant, flowering in July and August. The *root* is perennial and creeping, much divided. *Stems* diffuse, not much branched, smooth, angular, striated, from one to two feet long. *Leaflets* numerous, elliptic-oblong, hairy beneath; sometimes abrupt. *Tendrils* much branched. *Stipulas* triangular, brown or reddish. *Flowers* long, pale yellow, streaked or stained with grey or purple. *Legumes* ovate, pointed, an inch and half long, rough with hairs springing from small tubercles. *Seeds* from five to eight. Some of the *flowers* and *legumes* are often subterraneous, as in *V. amphicarpa*, n. 31.

35. *V. hybrida*. Hairy-flowered Yellow Vetch. Linn. Sp. Pl. 1037. Willd. n. 33. Fl. Brit. n. 6. Engl. Bot. t. 482. Jacq. Austr. t. 146.—Legumes solitary, nearly sessile, reflexed, hairy. Standard villous. *Leaflets* emarginate.—Native of bushy places in Austria, the south of France, and of England. Found chiefly in Somersetshire, about Glastenbury, flowering in June. This is nearly related to the last, but the *stems* are taller and more upright. *Leaflets* generally more obtuse than in *lutea*, though variable, as in that and other *Vicia*. *Stipulas* always entirely green. Back of the *standard* clothed with yellow silky hairs. We presume not to say how far this is really a distinct species, though we have little faith in its being, as the name indicates, a mile production.

36. *V. melanops*. Black-eyed Yellow Vetch. Sm. Prodr. Fl. Græc. Sibth. n. 1711. Fl. Græc. t. 701, unpubl.—Legumes solitary, reflexed, linear, smooth. Stems diffuse. Stipulas marked. Wings of the corolla depressed, incumbent.—Found by Dr. Sibthorp in Laconia. The *root* seems perennial. *Herb* very like the last, but rather smoother, and the *legumes* differ essentially in their long narrow figure, and smooth surface. *Flowers* of a dull greenish-yellow; their *wings*, which converge horizontally, tipped with a very dark brown, almost black.

37. *V. pannonica*. Hungarian Yellowish Vetch. Jacq. Austr. t. 34. Willd. n. 34. Ait. n. 19. (V. sylvestris albo flore; Cluf. Hist. v. 2. 235.)—Legumes stalked, about three together, hairy as well as the standard. Stipulas marked. Native of meadows in Austria and Hungary. Annual. Said to have been cultivated in the Oxford garden, in 1658. We have a specimen from Jacquin's own herbarium, by which this species appears to be very like *V. hybrida*, especially in its hairy *standard*; but the *flowers* are paler, and grow two or three together. The *calyx* is reddish. *Legumes* dark brown when ripe, hairy, and shaped like *V. lutea* and *hybrida*. Willdenow speaks of a variety with violet-coloured *flowers*, the *Vicioides uncinata*, Moench. Method. 136, which may be a distinct species, as the colour is not altered by culture. We have no knowledge of any such plant.

38. *V. levigata*. Smooth-podded Sea Vetch. Fl. Brit. n. 7. Engl. Bot. t. 483. Willd. n. 35. Ait. n. 18. (V. hybrida; Hudf. 319.)—Legumes sessile, solitary, reflexed, ovate, smooth. Stems nearly upright. *Leaflets* elliptical, very smooth.—Found on the stony sea-beach at Weymouth, Dorsetshire, flowering in July and August. We have never met with a specimen from any other country,

yet there is no doubt of the species being perfectly distinct. The *root* is perennial, with many fleshy knobs. Whole plant entirely smooth, especially the *legume*, which differs in that respect from *V. lutea*, *hybrida*, and *pannonica*, with all which it agrees in shape. The *seeds* are rarely more than five. The *stems* are from six to twelve inches long, much less spreading than those of *lutea*. *Leaflets* elliptic-lanceolate, hardly ever abrupt or emarginate. *Tendrils* branched. *Stipulas* green, or pale brown. *Calyx-teeth* nearly equal. *Flowers* the size of *V. lutea*, varying between pale purplish-blue and yellow. Both Hudson and Lightfoot knew this species well, but could not agree about its synonyms.

39. *V. fordida*. Dingy Vetch. "Waldit. et Kitaib. Hung." Willd. n. 36.—Legumes nearly sessile, in pairs, reflexed, linear-oblong, reflexed at the point, smoothish. *Leaflets* obovate-oblong, emarginate. Stipulas marked.—Native of meadows in Hungary. Communicated by M. Thouin to the writer of this. It flowered in Mr. Mackie's garden, near Norwich, in 1813. The *root* is annual. Plant totally distinct from the last, notwithstanding Willdenow's doubts, being larger, with emarginate *leaflets*, seldom quite smooth: twin *flowers* of a dull or dirty yellow; but particularly a much longer, linear, not ovate, *legume*, which, though not hairy, is somewhat roughish to the touch, and curved upwards, not downwards, at the point.

40. *V. peregrina*. Broad-podded Vetch. Linn. Sp. Pl. 1038. Willd. n. 37. Ait. n. 20. (V. peregrina, angustifolium foliis, filiqua latâ glabrâ; Pluk. Phyt. t. 233. f. 6.)—Legumes solitary, on short stalks, reflexed, ovate, smooth. *Leaflets* linear, very narrow, smooth, abrupt, emarginate.—Native of the south of France, from whence Linnæus received specimens in the herbarium of Sauvages. Dr. Sibthorp found it in Caria. M. Thouin sent seeds to Kew garden, in 1779. The plant is annual, flowering in July, of a slender smooth habit. *Leaflets* extremely narrow in a wild state, with two divaricated terminal points; in a luxurious cultivated specimen they are rather wider, and more obtuse, but scarcely exceeding an inch in length; they are from seven to ten, scattered, on a stalk ending in a divided tendril. *Flowers* stalked, pendulous, of a reddish-purple, shorter and thicker than several of the preceding, and more like those of *Orobis tuberosus*. *Legume* shaped like *V. lutea*, *hybrida*, &c. with a deflexed point, but longer, flatter, and quite smooth. *Seeds* six in our specimens. A very distinct species, little known to modern botanists, of which a good figure is wanted.

41. *V. monantha*. Single-flowered Spur-stalked Vetch. Retz. Obs. fasc. 3. 39. Willd. n. 38. Ait. n. 21. (V. calcareata; Desfont. Atlant. v. 2. 166; Willd. now.)—Stalks much shorter than the leaves, spurred under the solitary flower. *Leaflets* lanceolate, obtuse. Stipulas divided. *Legumes* smooth, drooping.—Native of Barbary. A hardy annual, flowering in July and August. *Herb* smooth. *Stem* angular, decumbent, two feet long. *Leaflets* twelve or thirteen, gradually decreasing, obtuse with a point. *Flower* the size of *V. sativa*, red with blueish veins. *Seeds* six or seven. *Revisus*. The description of Desfontaines answers very well to this, except that he speaks of the *leaves* as slightly villous, and of the *flowers* as pale blue, half the size of *sativa*, to which species nevertheless he thinks his plant related; but the *stipulas* are not marked.

42. *V. sepium*. Common Bush Vetch. Linn. Sp. Pl. 1038. Willd. n. 39. Fl. Brit. n. 8. Engl. Bot. t. 1515. Fl. Dan. t. 699. Rivin. Tetrap. Irr. t. 56. (V. maxima dumetorum; Ger. Em. 1227. Aphace; Fuchs. Hist. 110.)—Stalks about four-flowered, much shorter than the upright smooth *legumes*. *Leaflets* numerous, ovate, obtuse,

VICIA.

tuse, gradually smaller upwards.—Common in hedges and bushy places throughout Europe, flowering with us in May and June. The root is perennial, somewhat creeping. Stems about two feet high, weak, but little branched, furrowed, clinging to other plants by the tendrils of their leaves. The whole herb is clothed with scattered short hairs. Leaflets twelve to fifteen, of a dull greyish-green; the lowest an inch in length, the uppermost half as much. Stipulas ovate, acute, marked with a brown depression; the lower ones generally half-arrowshaped. Flowers crowded, dull purplish-blue, rather short and thick. Legumes nearly erect when ripe, linear-lanceolate, an inch and a half long, blackish, minutely dotted, not hairy. Seeds about six or eight globular, smooth.

43. *V. bithynica*. Rough-podded Purple Vetch. Linn. Sp. Pl. 1038. Willd. n. 40. Fl. Brit. n. 9. Engl. Bot. t. 1842. Jacq. Hort. Vind. v. 2. t. 147. Allion. Pedem. v. 1. 325. t. 26. f. 2. (Cracca floribus albis, foliis circa caulem denticulatis; Buxb. Cent. 3. 25. t. 45. f. 2.)—Legumes stalked, solitary, erect, rough. Leaflets two pair, elliptic-lanceolate, or nearly linear. Stipulas toothed.—Native of Greece, Italy and Bavaria, in cultivated fields; as well as of bushy places in Yorkshire and Worcestershire, and of fields, or rocky situations, near the coast of Hampshire, Dorsetshire, and Devonshire, flowering from May to July. The root is perennial, branching, with many small fleshy knobs. Stems angular, trailing or climbing, two feet long, smooth. Leaflets from one to two inches long, varying from a line to one-third of an inch in breadth, acute; rather hairy underneath. Stipulas large, half-arrowshaped, very deeply, but variously, toothed. Flower-stalks various in length, from half an inch to an inch and a half, hairy as well as the long-toothed calyx. Flowers nearly as large as *V. lutea*, purple, occasionally white. Legume oblong-lanceolate, an inch and half long, half an inch broad, reticulated, rough with tawny hairs. Seeds five or six, speckled. The keel and wings of the flower, pure white, tipped or tinged with blue or violet, when fresh, turn greenish or brownish twelve hours after gathering.

44. *V. platycarpus*. Flat-podded Vetch. "Roth. Abhandl. 10. t. 1." Willd. n. 41. Ait. n. 24. (Aracus fabaceus, et Fabæ Kayrina, cui femina minoræ; Bauh. Hist. v. 2. 286.)—Legumes solitary, nearly sessile, compressed, somewhat inflated. Leaflets ovate, toothed at the end. Stipulas with fringe-like teeth.—Native of Germany. Annual. Cultivated in Chelsea garden in 1723, flowering in July and August. Aiton. Stem a foot and half high, thick, angular, hollow, a little hairy. Leaflets four, like those of *V. Fabæ*, hairy, dark green, with a long branching tendril. Stipulas broad. Flowers purple. Legumes large, longish, hairy. Seeds the size of peas, of a strong disagreeable taste and smell; black when ripe. Baubin.

45. *V. narbonensis*. Broad-leaved Narbonne Vetch. Linn. Sp. Pl. ed. 1. 737. Willd. n. 42. Ait. n. 25. "Roth. Abhandl. 10. t. 2." Rivin. Tetrap. Irr. t. 57. (Faba sylvestris; Matth. Valgr. v. 1. 381. Ger. Em. 1209.)—Legumes about three together, nearly sessile, compressed. Leaflets ovate, obtuse, entire. Stipulas fringed; toothed at the base.—Native of the south of Europe. Annual. The size of the last. Leaflets one or two pair, with a divided tendril, obtuse, quite entire, an inch and a half long, one broad, hairy at the rib and margin. Flowers solitary; in a cultivated state two or three, dark purple. Germen fringed. Legume oblong, rather hairy. Seeds globose.

46. *V. Fabæ*. Common Garden Bean. Linn. Sp. Pl. 1039. Willd. n. 43. Ait. n. 26. (Faba; Matth. Valgr. v. 1. 380. Rivin. Tetrap. Irr. t. 23. F. major, hortensis;

Ger. Em. 1209.)—Stalks with several flowers, very short. Legumes ascending, tumid, coriaceous. Leaflets elliptical, acute, entire. Tendril abortive. Stipulas half-arrowshaped, toothed at the base.—Native of the borders of Persia, near the Caspian sea, according to Lerche. Commonly cultivated throughout Europe, for the food of men and horses; there being many varieties, differing in the size, roundness or flatness, as well as quality, of the seeds. Annual, flowering in June and July. The stem is from three to five feet high. Leaflets smooth, larger, more acute at each end, and more alternate than in the two last. Flowers from six to ten or more, on a short racemose stalk, deliciously fragrant, white, with a broad black velvet-like spot on each wing. Calyx whitish, with ovate taper teeth. Legume large, thick, oblong, pulpy within while unripe, containing four or five seeds.

The *Faba minor* five equina; Bauh. Pin. 338. F. minor; Rivin. Tetrap. Irr. t. 24; is the variety called the Horse Bean, known by its small pod and roundish seeds. Of this also cultivators observe many subordinate varieties, and perhaps *V. narbonensis* is often confounded among them.

47. *V. ferratifolia*. Saw-leaved Vetch. Murr. in Linn. Syst. Veg. ed. 14. 665. Jacq. Austr. append. t. 8. Willd. n. 44. Ait. n. 27. (V. narbonensis; Sm. Prodr. Fl. Græc. Sibth. n. 1715. V. lupina, latissimo folio ferrato; Tourn. Inst. 397. Aracus fabaceus ferratus; Bauh. Hist. v. 2. 287.)—Legumes about three together, nearly sessile, fringed. Leaflets elliptical, obtuse, serrated throughout, as well as the stipulas.—Native of Hungary, Greece, and the island of Cyprus, in moist cultivated ground. A hardy annual with us, flowering in June and July. This is nearly related to the two last, and still more perhaps to *V. platycarpus*; but differs from all in the copious sharp serratures of the leaflets, which are usually four pair, with a branched tendril. Stipulas broad, sharply and copiously toothed. Flowers three or four, on a very short stalk, dark purple. Legume compressed, with seven or eight globular seeds.

We believe the Linnæan synonyms, as here arranged, are correct; and yet Linnæus, like other botanists from time to time, certainly confounded these four last species more or less together. His specimen marked *narbonensis*, from the Upsal garden, answers to the character of *platycarpus*, the leaflets being toothed towards the extremity. Hence, in the second edition of Sp. Pl. he altered the specific character, to stipulifuge denticulatis. But this is not an original specimen, answering to the first edition of Sp. Pl. which latter we take as the most certain authority; and it is in this case consonant with the sentiments of all authors, as above quoted. The plant of the Prodr. Fl. Græc. therefore, by mistake called there *narbonensis*, is really *ferratifolia*, with which its synonyms agree. Possibly *platycarpus* may be a variety of *ferratifolia*; but for want of an authentic specimen, from some author who has written upon it, we decline any decision upon that point. These two, and the real *narbonensis*, agree in hairiness; the blunt rounded shape of their leaflets; the presence of tendrils; the dark purple of their flowers; and the strong bristly fringe of their germens and legumas; in all which points they differ from *V. Fabæ*.

VICIA, in Gardening, furnishes plants of the biennial, perennial, and annual hardy kinds, among which the species cultivated are, the common vetch or tare (*V. fativa*); the Narbonne vetch or tare (*V. narbonensis*); the many-flowered Siberian vetch (*V. biennis*); the wood many-flowered vetch (*V. sylvatica*); the tufted vetch (*V. cracca*); the Cassubian ligneous vetch (*V. cassubica*); and the common bean (*V. faba*.)

The first sort does not rise to any great height, but is a plant that varies with common purple flowers; with white flowers. And there is the early summer vetch; the black-seeded vetch; and the white-seeded vetch.

It is the sort which is commonly cultivated in the field for the purpose of green fodder, &c. as well as the production of feed. Sometimes also in pleasure-grounds, &c. as a low climbing plant. See **TARE**.

The second has long climbing stalks, with dark purple flowers.

The third sort also rises to some height, with numerous light blue flowers coming from the sides of the branches.

The fourth rises with climbing stalks to the height of five or six feet, having many pale blue flowers. It is a twining plant among trees or bushes.

The fifth has the same sort of stalks and flowers.

The sixth sort has lower trailing woody stalks, and pale blue flowers.

The last sort has an annual root, with an upright stalk from two to three or four feet in height in the larger garden varieties.

There are several varieties of garden beans; as the Mazagan bean, which is the first and best sort of early beans at present known. It is brought from a settlement of the Portuguese on the coast of Africa, just without the straits of Gibraltar, and is smaller than those of the horse-bean kind.

The early Portugal or Lisbon bean, which is the next, and appears to be the Mazagan sort sowed in Portugal, as it is very like those which are the first year sowed in this country. It is the most common sort used by the gardeners for their first crop, but they are not near so well tasted as the real Mazagan.

The small Spanish bean, which comes in soon after the Portugal sort, and is rather a sweeter bean.

And of the small early varieties, there is one which is chiefly planted for curiosity. It is a dwarf, six or ten inches in height, with branches spreading like a fan, and flowers succeeded by small pods, both in clusters; whence it is called the dwarf fan or cluster bean.

Further also of the middle-sized later beans, a sort now very commonly cultivated is the long-podded bean, a yard or more in height, a great bearer, the pods long and narrow, closely filled with oblong middle-sized seeds. Of this there are several sub-varieties, as the early, the tall, the Turkey, &c.

The broad Spanish, which is a little later than the other, but comes in before the common sorts, and is a good bearer.

The white-blossomed bean, which has none of the black mark on the wings. The seed is semi-transparent, and having less of the peculiar bean flavour, when young, than any of the others, is by many in much esteem. It bears abundance of smallish, long, narrow pods, and the seeds are almost black when ripe.

And there is a red-blossomed bean, with smallish pods and seeds, but which is not near so palatable as that with white blossoms.

There are also some other varieties, as the Mumford, the green Venetian, &c.

In the large late kinds, the Sandwich bean, which comes soon after the Spanish, and is almost as large as the Windsor bean, but, being hardier, is commonly sown a month sooner. It is a plentiful bearer, but not very delicate for the table.

The Toker bean, which comes about the same time with the Sandwich, and is a great bearer.

The white and black blossom beans, which are also by some much esteemed; the beans of the former, when boiled,

are almost as green as peas; and being a tolerable sweet bean renders it more valuable. These sorts are very apt to degenerate, if their seeds are not sowed with great care.

The Windsor bean is allowed to be the best of all the sorts for the table: when these are planted on a good soil, and are allowed sufficient room, their seeds will be very large, and in great plenty; and, when they are gathered young, are the sweetest and best tasted of all the sorts; but these should be carefully sowed, by pulling out such of the plants as are not perfectly right, and afterward by sorting out all the good from the bad beans.

This sort of bean is seldom planted before Christmas, because it will not bear the frost so well as many of the other sorts; so it is generally planted for the main crop, to come in in June and July.

Method of Culture in the Vetch Kind.—All the sorts of vetches may be propagated by sowing the seeds in the autumnal or spring seasons, but chiefly in the latter, and mostly where the plants are to remain and grow, as in the large open flower borders, in those of the shrubberies and pleasure-grounds, as well as in the woody walks, wilderness parts, and in the thickets; or in any other place where they are to run and climb up any sort of wood. They should be sown in patches near to shrubs or bushes on which they may climb, and sometimes in the open spaces, to climb upon sticks set for the purpose.

Method of Culture in the Bean Kind.—These crops are raised with much facility by sowing them at different times from October to March, or later. The small sorts are mostly sowed for the earliest crops, and the first two or three of the above sorts are the most proper for the purpose; but the Mazagan kind is the earliest of all, and most proper to plant for the first crop, and the Portugal and small Spanish bean next, all of which should be planted early on warm south borders, or other sheltered sunny exposures, under or near walls, pales, or hedges, or other warm defended quarters, every month from October till the beginning of February; in order that if the first planting should fail by inclement weather in winter, the others may succeed; and if all the crops should survive the frost, they will succeed one another regularly in bearing. The planting should be performed in rows, ranging south and north, two feet and half asunder, an inch and half deep, and two or three inches apart in each row. They may also be planted in one row lengthways close along under a south wall, &c.

The dwarf bean is not proper to be planted for any general crop, only a few for variety; for which purpose it may be put in in autumn or winter; or in any of the spring or summer months till June or July, in rows two feet asunder, or in patches about the borders.

Of the middle-sized sorts, the long-pods, broad Spanish, and white-blossomed bean are the best for general culture; though some of all the others may be planted occasionally; and the season for these sorts being put in, is for the first crop in November or December, on a broad warm border, or in any of the most sheltered kitchen-garden quarters, in rows two feet and a half or a yard asunder, three inches distance in the row, and two or three inches deep; repeating the planting every month till March, in the open quarters.

Of the large kind, the Sandwich and Toker bean, being generally more plentiful bearers, and of somewhat less succulent growth than the Windsor, are rather hardier to resist the frost, and may be planted earlier, as before Christmas for the first crop; and any time after till May, if required; and of the Windsor, a small or moderate crop may be planted in December, in open mild weather, and a dry soil; in a larger supply in January; and a first full crop in February; and

and thence in full supplies, of these or any of the other larger sort, every three or four weeks, till the end of April, for the main crops; continuing planting them till the end of May, to have successions as long in the season as possible. These should constantly be planted in open exposures, in rows a yard asunder, or three feet and a half for the large Windsor fort; four or five inches asunder in each row, and three deep.

They succeed in any common soil, but where the land is manured for them it is the best.

The general method of planting them is by the dibble, or in drills; for early planting in dry ground, a shallow drill may be first made, then planting the beans in a row along the bottom, allowing from two to four or five inches distance in the row, according to the size or growth of the different varieties, and from one and a half to three inches deep in the small and large beans; and when the plants are come up about three inches high, they should be earthed up on each side of the row with a drawing hoe, keeping them clear from weeds by occasional hoeing in dry weather; and after having advanced nearly to full growth, and in bloom, it is proper to top the plants in general, which throws all the nourishment to the embryo pods, and greatly promotes their setting, and forwards their growth; and in the latter crops prevents their being so much annoyed with the small black fly.

As the use of garden beans is very considerable for some length of time, a pretty large portion of kitchen-garden ground should be allowed for the different crops each year, in order to have a proper succession. They succeed well, as has been seen, in any common soil, but the best where manure is employed, and in free open situations, where they are not injured by the shade or droppings of trees, selecting the driest and warmest places for the early crops, and the strongest moist ground for the late ones.

In gathering the crops, avoid pulling up the stems, especially when the land is moist.

The plants of the vetch kind are, for the most part, introduced for the purpose of variety and ornament in their climbing growth and the curious appearance of the flowers.

VICIOLA, in *Geography*, a river of Naples, which runs into the Trentino, at Teramo.

VICIOSAS, a cluster of small islands, near the coast of Honduras. N. lat. 15° 12'. W. long. 83° 4'.

VICIS at *Venellis Mundandis*, in *Lava*, a writ lying against a mayor, bailiff, &c. for not taking care that the streets be well cleaned.

VICISSITUDE, VICISSITUDO, the succeeding of one thing after another. As, the vicissitude of seasons, fortune, &c.

VICKY, in *Geography*, a town of Sweden, in West Gothland; 37 miles N. of Uddevalla.

VICKERYVANDY, a town of Hindoostan, in the Carnatic; 18 miles W.N.W. of Pondicherry.

VICO, ENEA, in *Biography*, a native of Parma in the 16th century, was one of the first persons who illustrated the medallie science. By profession he was an engraver of copper; and at his death in Ferrara, among other remains, he left copper-plates of all the coins in Europe, with their weight, standard, and value. See ITALIAN School of Engraving.

Vico, in *Geography*, a town of Naples, in Principato Citra, the see of a bishop, suffragan of Sorrento; near the sea. Its situation is delightful, on the brow of a hill,

backed by an amphitheatre of mountains. The strata of these eminences incline contraryways to one central point, as if there had originally existed a similar mass in the centre, torn asunder and swallowed up by one of those shocks which must have often overturned this unfavourable country. Charles II. and Joan I. raised Vico out of obscurity, on account of the charms of its situation. In 1694, it was almost destroyed by an earthquake; 3 miles E.N.E. of Sorrento.—Alfo, a town of Naples, in Capitanata; 10 miles W. of Vieste.—Alfo, a town of Corsica, in which is the cathedral of the bishop of Sagonia; 30 miles S. of Calvi. N. lat. 43° 3'. E. long. 8° 56'.—Alfo, a village of Dalmatia, near the river Norin, in a marshy spot, where the ancient Narona once stood. The inhabitants, who go often to cut reeds in the marsh, say that the vestiges of that large city may still be seen under water. It must have been extended over the plain a great way, and undoubtedly above three miles in length, at the foot of the hills. The ancient roads are now under water, and the present passage over a very steep and craggy hill, on which, probably before the Roman times, the fortifications were erected. Along the path are to be seen traces of ancient inscriptions on the rock. A poor hamlet now occupies the spot where temples and palaces of the conquering Romans once stood; and grand vestiges still remain of baths, aqueducts, walls, and noble edifices; even the wretched cottages of the Morlack inhabitants are all built of fine ancient hewn stone; 5 miles N.W. of Citluc.

Vico di Pantano, a town of Naples, in Lavora; 12 miles S.W. of Capua.

VICOMAGISTER, among the Romans, an officer whose business it was to take care of the streets, that nothing might obstruct, or render them any wise inconvenient.

VICONTIEL. See VICOUNTIEL.

VICOVARO, in *Geography*, a town of the Popedom, in the Sabina, on the Teveroni; 20 miles E.N.E. of Rome.

VICOUNT, VICE-COMES, in our *Law-Books*, signifies the same with sheriff; between which two words there seems to be no other difference, but that the one came from our conquerors, the Normans; and the other from our ancestors, the Saxons.

VICOUNT, or *Vifcount*, is also used for a degree of nobility, next below a count or earl, and above a baron.

Camden observes, that this is an ancient name or office, but a new one of dignity never heard of among us till Henry VIth's days, who, in his eighteenth year, created, in parliament, John lord Beaumont, *vicount Beaumont*; but it is much more ancient in other countries.

Du-Cange, indeed, will have the dignity to have had its first rise in England; but it is much more probable it was first brought over hither by the Normans.

The privileges of a vicount are, that he may have a cover of assay held under his cup when he drinks, and may have a traver in his own house. And a vicountess may have her gown borne up by a man, out of the presence of her superiors; and, in their presence, by a woman.

VICOUNTIELS, VICONTIELS, *Vicecomitalia*, in our *Law-Books*, denote things belonging to the sheriff; particularly certain farms, for which the sheriff pays a rent to the king, and makes what profits he can of them.

VICONTIEL, *Writs*, are such as are triable in the county or sheriff's court, and which are not returned to any superior court, till finally executed by him. Of which kind are divers writs of nuisance, the writ of ADMEASUREMENT of Pasture, &c. which see.

VICONTIEL or *Vicontiel Jurisdiction*, is that jurisdiction belonging

belonging to the officers of a county; as sheriffs, coroners, escheators, &c.

VICQ, in *Geography*. See VIC and VIO.

VICQ-D'AZYR, FELIX, in *Biography*, was born at Valognés, in Normandy, in 1748, and distinguished himself both as a physician and a man of letters. Settling at Paris in 1765, he pursued with diligence every branch of study connected with medicine, and paid particular attention to the physiological part of anatomy. In 1773 he commenced a course of lectures on human and comparative anatomy, in which pursuit he was very popular; but he was interrupted by a spitting of blood, which made it necessary for him to return to his native place. Here he applied to the anatomical examination of fishes, the result of which he communicated to the Academy of Sciences, which associated him as a member. When a murrain appeared among the cattle in Languedoc in 1775, Vicq-d'Azyr was commissioned by the minister Turgot to discover means for restraining it, which charge he executed with success. A medical society was formed at Paris about this time, which he zealously promoted, and of which he was secretary. He also, in connection with this society, performed the office of eulogist, very much to his own reputation, and to the honour of many considerable persons, whose talents and services he commemorated. In his private character he exhibited, with gentle manners, a very considerable degree of ardour and sensibility; so that he is represented as a warm friend and philanthropical citizen. He obtained both fame and fortune, employing the latter liberally in collecting a costly apparatus and a well-chosen library. Agitated and exhausted by the disastrous effects of the revolution, he died in June 1794, at the age of forty-six. His "Eloges Historiques" were collected and published, with notes, and a memoir on the author, by J. L. Moreau, three vols. 8vo. 1805. His other writings were communicated to the Memoirs of the Academy of Sciences and of the Medical Society. *Nouv. Dict. Hist.*

VICTIM, VICTIMA, so called, either because *vincta percussa cadebat*, or because *vincta ad aras ducbatur*, a bloody sacrifice, offered to some deity, of a living thing; either a human person, or a beast, which is slain to appease his wrath, or to obtain some favour. See SACRIFICE.

It is not certain who was the first person that introduced bloody sacrifices among the Pagans. If the authority of Ovid be at all regarded, he alleges that the fow was the first animated victim which was offered to Ceres, on account of the ravages which that animal makes in the field. (*Fast. l. l.*) From Homer we learn, that the use of such sacrifices was common in the time of the Trojan war. Whenever they were introduced, it is certain that they were very ancient in the Pagan world. It may be observed, however, that when victims of this kind were offered, they blended with them herbs, salt and meal. Pliny informs us, that Numa prohibited the Romans from using bloody victims, or any other sacrifice, besides those in which they employed fruits, salt, and corn. Dion. Halic. ascribes this prohibition to Romulus; and he adds, that this usage subsisted in his time, although they had inperaded to it that of bloody sacrifices. At length, however, superstition prevailed to such a degree, that they offered to their deities human victims; and this barbarous custom, the origin of which is not satisfactorily ascertained, was propagated to almost every known nation. These horrid sacrifices, prescribed even by the oracles of the gods, were known in the days of Moses, and constituted a part of those abominations with which this legislator reproached the Amorites. The Moabites sacrificed their children to Moloch, and burned them in the cavity of

the statue of that god. According to Dionysius of Halicarnassus, they offered men in sacrifice to Saturn, not only at Tyre and Carthage, but even in Greece and Italy. The Gauls, if we may believe Diodorus Siculus, sacrificed to their gods their prisoners of war; those of Tauris, all the strangers who landed upon their coasts: the inhabitants of Pella sacrificed a man to Pelcus. Those of Temessa, as Pausanias has it, offered every year a young virgin to the Genius of one of Ulysses' associates, whom they had stoned; and Aristomenes, the Messenian, sacrificed three hundred men at one time. Strabo mentions those abominable sacrifices offered by the ancient Germans. Athanasius gives the same account of the Phœnicians and Cretans; and Tertullian of the Scythians and Africans. In the Iliad of Homer we see twelve Trojans sacrificed by Achilles to the manes of Patroclus. In sine, Porphyry gives a long detail of all the places where, in old times, they offered up human sacrifices; among which he enumerates Rhodes, the island of Cyprus, Arabia, Athens, &c.

From all these testimonies put together, and from several others, which it is needless to quote, it follows, that the Phœnicians, the Egyptians, Arabians, Canaanites, the inhabitants of Tyre and Carthage, those of Athens and Lacedæmon, the Ionians, all Greece, the Romans and Scythians, the Albanians, the Allemans, the Angles, the Spaniards, and the Gauls, were equally guilty of this horrid superstition.

For the public sacrifices there were authorized ministers or priests who made a choice of victims; and several names were given to these victims from some circumstances that attended the oblations. Such as were offered up the day before the solemnity, were called "præcidaneæ hostiæ;" as the fow, sacrificed to Ceres before harvest, was called "præcidaneæ porca." Again, they gave the name of "saccedaneæ hostiæ" to such sacrifices as they offered up, when the former ones had been neglected; and thus it was they atoned for the omission. There were others named "eximiaz hostiæ;" meaning not that these victims had any peculiar excellence, as the word properly signifies, but that they were separated from the flock in order to be sacrificed, "eximbantur grege." The ewes that had two lambs, which they sacrificed with the mother, were termed "ambiguaræ oves," and the victims whose entrails were adherent, "harungæ" or "harugæ;" such as were confumed, "prodigiz;" and such as had two teeth higher than the rest, "bidentes."

Of whatever nature the victims were, great care was to be taken in the choice of them; and the same blemishes, that excluded them from sacrifices among the Jews, rendered them also imperfect among the Pagans; whence it would seem that they borrowed several rites from the Hebrews.

All sorts of victims were not offered indiscriminately to every divinity, or for every purpose. It was commonly a fow, big with young, that they offered to Cybele and to the goddess Tellus; the bull to Jupiter; to Juno, heifers, ewe-lambs, sheep; and at Corinth they sacrificed to her a she-goat. To Neptune, a bull and lambs, as appears from Homer; to Pluto, likewise, a bull; and to Proserpine a cow, both of them black: and when that goddess was taken for Hecate, they sacrificed to her a dog, an animal whose barking they thought drove away the apparitions sent by that goddess. The most acceptable victims to Ceres, were the boar and the fow: they made her likewise an offering of honey and of milk. To Venus the dove, the he-goat, the heifer, a white she-goat, &c.: to Bacchus, a he-goat. They sacrificed the cow and the bull to Hermione, as we learn from Ælian, who adds, that in these sacrifices, a bull, which

ten men had much ado to master, of his own accord followed an old priestess to the altar. To the Sun sometimes honey; but the Armenians and Massagetes sacrificed to him horses. To Apollo (for frequently he was distinguished from the Sun) they offered the ram, the she-goat, the ewe, and the he-goat; and when they confounded him with the Sun, a young bullock, with gilded horns, as an emblem of his beams: they offered to him likewise a raven. To Mars, the horse, the bull, the boar, and the ram. The Lusitanians sacrificed to him he-goats, she-goats, and sometimes their enemies; the Scythians offered to him asses; and the Carians, dogs. We learn from Homer, that the victims most grateful to Minerva were the bull and the lamb; or, according to Fulgentius Planciades, oxen which had never known the yoke. To Diana, stags, she-goats, more especially among the Athenians; and, in some places, cows. To the Dii Lares, a bullock, or an ewe-lamb, according to the ability of those who offered. To them they also sacrificed cocks and swallows, and the hog, whence they got the name of Grundiles.

In fine, every god had his favourite animal, tree, or plant. Among the animal kind, the lion was consecrated to Vulcan; the wolf to Apollo and Mars; the dog to the Lares and to Mars; the dragon to Bacchus and Minerva; the griffins to Apollo; the serpents to Esculapius; the stag to Hercules; the lamb to Juno; the horse to Mars; the heifer to Isis. Among the birds, the eagle was sacred to Jupiter; the peacock to Juno; the owl to Minerva; the vulture and the wood-pecker to Mars; the cock likewise to Mars, to Esculapius, Apollo, and Minerva; the dove and sparrow to Venus; the king's-fisher to Tethys; the phoenix to the Sun; and the cicada, a sort of flying insect, to Apollo. Among the fishes, which belonged also to Neptune, the concha marina, and the small fish named apua, which Festus says is produced by the rain, were acceptable to Venus, and the barbel to Diana. Among the trees and plants, the pine was consecrated to Cybele, for the sake of Atys; the beech to Jupiter; the oak, and its different species, to Rhea; the olive to Minerva; the laurel to Apollo, from his amour with Daphne; and the reed to Pan, from the story of Syriax: the lotos and the myrtle were likewise consecrated to Apollo and Venus; the cypress to Pluto; the narcissus and the maiden-hair, termed likewise capilli veneris, to Proserpine; the ash-tree and dog's-grass to Mars; purslane to Mercury; the myrtle and the poppy to Ceres; the vine, and its leaves, to Bacchus; the poplar to Hercules; dittany and the poppy to Lucina; garlic to the Dii Penates; the alder-tree, the cedar, the narcissus, and the juniper-tree, to the Furies; the palm to the Muses; the plane-tree to the Genii; the alder to the god Sylvanus; the pine to Pan, &c. The Greeks offered Iphigenia, at Aulis, for a victim to obtain a favourable wind.

As there were different sorts of victims, the mode of offering them was also different. Some were wholly burnt, and others consumed only in part: and it belonged to the diviners among the Greeks, and to the aruspices among the Romans, to order the time, form, and manner of the sacrifices. We may further remark with Lucian, that the sacrifices differed according to the quality of the persons. "The husbandman," says he, "offers up an ox; the shepherd, a lamb; the goat-herd, a goat: there are some who make only a simple offering of cakes or incense; and he that has nothing, makes his sacrifice by kissing his right hand."

Artificial or *falsitious* victim, denotes a victim made of baked pastes in the form of an animal, which was offered to

the gods, when they had no natural victims or no opportunity of offering them. Thus, according to Porphyry, Pythagoras offered a sacrifice of an ox in paste; Empedocles is also said by Athenæus to have done the same. Pythagoras derived the practice from Egypt, where it was very ancient, and where it was used in the time of Herodotus.

VICTIMARIUS, a minister, or servant of the priest, whose office was to bind the victims, and prepare the water, knife, cake, and other things, necessary for the sacrifice. See SACRIFICE.

To the victimarii also belonged to knock down, and kill, the victims: in order to which, they stood close by the altar, naked to the waist, but crowned with laurel; and holding a hatchet or a knife up, asked the priest leave to strike; saying, *Agone? Shall I strike?* Whence they were called *agones*, and *cultellarii*, or *cultrarii*.

When the victims was killed, they opened it; and, after viewing the entrails, took them away, washed the carcass, and sprinkled the flour on it, &c.

The same victimarii also lighted the fire in which cows were condemned to be burnt. See Liv. lib. xl. cap. 29. and A. Gellius, lib. i. cap. i. extr. 12.

VICTOIRE, or *Woody Island*, in *Geography*, a small island in the Chinese sea. N. lat. 1° 33'. E. long. 106° 18'.

VICTOPHALI, or VICTOBALI, in *Ancient Geography*, a people of Dacia, according to Eutropius and Ammianus Marcellinus. This country was subjugated by Trajan.

VICTOR I., pope, in *Biography*, succeeded Eleutherius in 192. During his pontificate several circumstances occurred which render it difficult to maintain his infallibility. He first appeared and afterwards anathematized the heretical doctrine taught at Rome by Theodotus of Byzantium concerning the person of Christ. He also recognized a prophetic spirit in Montanus; and gave to two of his female followers, Prisca and Maximilla, letters of peace to the churches of Asia and Phrygia, which he afterwards revoked. As his infallibility was impeached, his pontifical authority was also vigorously opposed in the controversy between the Eastern and Western churches concerning the celebration of Easter. The former had been accustomed to observe the rule established for the Jewish paschal, whereas the latter disapproved the observance of Easter on any day except Sunday, and they had, accordingly, adopted a different method of computation. The dispute was of no great importance, and had occasioned no discord and separation between these churches. But Victor arrogantly interposed, and enjoined the Asiatic prelates to observe the custom that prevailed among the Western Christians. These prelates resisted his mandate, and Victor menaced Polycrates, bishop of Ephesus, who took the lead on this occasion, with exclusion from his communion. The prelate convened a council of all the bishops of Asia Minor, and they were unanimous in their resolution not to abandon the ancient practice. The pope was exasperated, and declared the Asiatic prelates unworthy of the title of brethren, and excluded them from all fellowship with the church of Rome. But his violence was disapproved, and he was regarded as a disturber of the peace and union that subsisted among Christians. Irenæus, bishop of Lyons, remonstrated against his conduct in a letter written to him with a spirit of wisdom and moderation: and the Asiatics retained their custom till the Western practice was authoritatively established by the council of Nice. These proceedings sufficiently shew that the supremacy of the see of Rome was not acknowledged at this period. Victor, after a pontificate of ten years, closed his life towards the

end of the year 201, or the beginning of 202. None of his writings are extant, though, according to St. Jerom, he was the first ecclesiastical author who used the Latin language. His zeal for the church has caused him to be enrolled among the saints of the Roman calendar. Dupin. Bower.

VICTOR II., pope, was the successor of pope Leo IX., and elevated to the papal chair by the influence of Hildebrand, afterwards pope Gregory VII., and by the special appointment of Henry III., emperor of Germany. The person chosen was Gebhard, bishop of Eichstat, a relation of the emperor, who against his own inclination was consecrated in April 1055, and assumed the name of *Victor*. Soon after his promotion he held a general council at Florence, for the correction of various abuses, and the condemnation of Berengarius's doctrine concerning the Eucharist. Hildebrand maintained his influence during this pontificate, and availed himself of an opportunity that offered for extending the civil authority of the papal see. This was the recognition of Henry III. as the only true emperor, against the claims of Ferdinand, king of Castile and Leon. The pope's requisition, though at first vigorously opposed in Spain, ultimately prevailed. In 1056 a council was held at Touloufe, which passed several canons against simony, and the incontinence of the clergy. Whilst this council was sitting, Victor was summoned by a special message from the emperor Henry to attend him in his last moments. The pope, in compliance with his dying intreaty, recognized his son, Henry IV., for his successor in the empire. After his return to Italy he held a council at Rome, and then retired to Tuscany, where he died in July 1057. A single letter of this pope remains: and superstition has recorded some miracles that were wrought during his pontificate. Dupin. Bower.

VICTOR III., pope, one of three persons named by Gregory VII. in 1085, when he was dying, and recommended to the cardinals as his successor. The person chosen was Desiderius, abbot of Monte Cassino, descended from the family of the dukes of Benevento, and born about 1027. He had embraced a monastic life in 1050, and was chosen abbot of Monte Cassino in 1058, and in the following year created cardinal. It was with great reluctance that he consented, in 1086, to accept the pontificate, and as soon as the attendant ceremonies were completed, he withdrew to his monastery. In the following year a council was held at Capua, which constrained him to accept the popedom in March 1087, and he was solemnly consecrated in the church of St. Peter by the name of Victor III. His election was contested by the antipope Guibert and his adherents; but he was zealously supported by the countess Matilda, who by force of arms established him at Rome, though he was not long after obliged to withdraw to Monte Cassino. Here he engaged the Italian princes to form a league against the African Saracens. Soon afterwards he summoned a council at Benevento, at which Guibert was anathematized, and the decrees of Gregory against lay investitures and simony were renewed. During the session of this council he was taken ill, and after recommending Otho, bishop of Ostia, for his successor, he retired to Monte Cassino, and died in September 1087. Whilst he was abbot he wrote four books of dialogues on the miracles of St. Benedict, and the other monks of Monte Cassino, three of which are published in Mabillon's "Acta Sanctorum." Dupin. Bower.

VICTOR-AMADEUS II., duke of Savoy, and first king of Sardinia, was born in 1666, and succeeded his father,

Charles-Emanuel II., in 1675. In 1684 he married Anna-Maria of Orleans, daughter to the duke of Orleans, brother of Lewis XIV., by Henrietta-Anne of England, which marriage would have conveyed to the house of Savoy the next hereditary right to the British throne, after the house of Stuart, if it had not been set aside by its profession of the Roman Catholic religion. The first military transaction of this prince, which is not very honourable to his memory, was the expulsion, by much slaughter, of his Protestant subjects of the Vaudois. In 1687, however, he joined the grand alliance against France, in which treaty the restoration of the Vaudois was a secret article. Voltaire characterizes him as a wife, politic, courageous prince, understanding the art of war, and practising military discipline; but chargeable with faults, both as a sovereign and as a general. In the first war against France he was a severe sufferer; but in 1696 a treaty was concluded, by which all the places he had lost were restored, and a sum of money was granted to him by way of indemnification; and a contract of marriage was settled between his eldest daughter and the duke of Burgundy, heir apparent to the crown of France. The duke of Savoy then joined his troops to those of his new ally, and he soon after became generalissimo of Lewis XIV. Soon after these events, another connection was formed between the house of Bourbon and the duke of Savoy, by the marriage of Philip, duke of Anjou, grandson of Lewis XIV. called to the throne of Spain, to the duke's second daughter: and thus he had the rare fortune of seeing the two principal kingdoms of Europe occupied by his immediate descendants. Nevertheless, at the commencement of the succession-war, in 1702, the duke abandoned the interest of these courts, and entered into secret negotiations with the allied powers. The French court, having found that he had signed a treaty with the emperor, adopted hostile measures, and took from him a number of towns, and in 1706 laid siege to his capital, Turin, which he bravely resisted, until he was effectually succoured by prince Eugene, who attacked the French in their trenches, and raised the siege. The duke, having recovered the towns which he had lost, assisted the Imperialists in driving the French from Lombardy. The duke afterwards had some disagreement with the emperor, and remained inactive till the treaty of Utrecht, in 1713. In this general pacification, such was the high estimation in which he was held by all parties, that he was restored to the possession of the duchy of Savoy, the county of Nice, and all their dependencies. The king of France yielded to him two strong fortresses, and several valleys among the mountains; and the ridge of the Alps was made the boundary between France on one side, and Piedmont and Nice on the other. The emperor confirmed to him that part of Montserrat which had belonged to Mantua, with several provinces and territories in Italy; and his Catholic majesty resigned to him the kingdom of Sicily, which gave his house the royal title; and it was moreover agreed, that in default of heirs to the king of Spain, that crown should pass to the house of Savoy, in preference to that of Bourbon. Victor-Amadeus and his spouse were crowned at Palermo, in the clove of that year, and the Spaniards evacuated Sicily: but some differences occurring between him and the court of Spain, it was required that he should send his eldest son to Spain, as a kind of hostage. Upon his non-compliance with this requisition, Alberoni, the prime minister of Spain, made preparations for conquering Sicily from Victor, and Sardinia from the emperor. France and England interposed in the dispute; and it was finally determined, that Victor should resign Sicily,

Sicily, and as an indemnity receive Sardinia, with the royal title annexed to it, which measure was accomplished in 1718, and the dukes of Savoy have thenceforth ranked among the monarchs of Europe as kings of Sardinia.

VICTOR-Amadeus from this time devoted himself to the arts of peace; and after a reign of fifteen years, as duke and as king, abdicated his titles and government, in 1730, in favour of his son, Charles-Emanuel, contenting himself with an annual pension. But afterwards repenting of his conduct, and incited by an ambitious mistress, to whom he was privately married, he attempted to resume his royalty. The new king resisted his inclinations, and placed him under a degree of restraint, in which state he died, at the castle of Rivoli, near Turin, in 1732, in his 67th year. Mod. Un. Hist. Gen. Biog.

VICTOR, AURELIUS. See AURELIUS.

VICTOR, in *Geography*, a town of Peru, in the jurisdiction of Arequipa; 15 miles S. of Arequipa.

VICTORIA, VICENTE, in *Biography*, was a Spanish artist, a native of Valencia, and born in 1658. He went to Rome when young, and there became a scholar of Carlo Maratti, and distinguished himself sufficiently in historical painting to be taken into employment by the grand duke of Tuscany. His portrait is in the Florentine gallery. He painted several pictures for churches in his native country, and died at Rome in 1712.

VICTORIA, *Masjar*, in *Ancient Geography*, a town of Africa, in the interior of Mauritania Cæsarensis, S.E. of Arfanaria: mentioned by Ptolemy.

VICTORIA, a town of ancient Britain, belonging to the Damni, which Camden supposes may be the ancient British town mentioned by Bede, called Caer-Guidi, and situated in Inch-Keith, a small island in the Firth of Forth. Baxter earnestly contends for Ardoah, in Strathearn, while Horsley prefers Abernethy. Its situation cannot be ascertained.

VICTORIA, in *Geography*, a town on the south-west coast of the island of Amboyna, situated in a large bay. N. lat. 3° 42'. E. long. 128° 23'.—Also, a small island in the Atlantic, near the coast of Brasil. S. lat. 23° 40'.—Also, a town of South America, in the province of Caraccas; six leagues E. from Tulmero, and on the road that leads to the city of Caraccas. It was founded by the missionaries, and composed solely of Indians, until industry fixed her seat in the valleys of Aragoa, and drew thither a number of whites, of whom part settled at Victoria. The lands in its vicinity were cultivated, and their produce placed decent houses in the room of Indian huts. A very handsome church, vying in beauty and size with the principal cathedrals in America, has lately been erected in this place, and the number of inhabitants of all colours is reckoned to amount to 7800.

VICTORIÆ Mons, in *Ancient Geography*, a mountain of Hispania Citerior, near the river Hebrus.

VICTORIÆ *Julio Brigenfum Portus*, a port and town of Hispania Citerior, belonging to the Varduli.

VICTORIAN PERIOD, in *Chronology*. See PERIOD.

VICTORIATUS, among the *Romans*, a coin with Victory represented on one side, equal in value to half the denarius.

VICTORINUS, CAIUS, or FABIVS MARIUS, in *Biography*, an African philosopher, was a convert to Christianity, and flourished in the fourth century. He gained such a degree of reputation by teaching rhetoric at Rome, that a statue was erected in honour of him in one of the public places. He was led to the perusal of the Scriptures by the study of Plato's works, and thus convinced of their

truth, after some hesitation, he publicly declared himself a Christian, and was baptized in the presence of all the people. He was the author of several works, some of which are published in the *Bibliotheca Patrum*; but as they are of no great value, it is needless to enumerate them. The time of his death, though not precisely ascertained, is supposed to have been previous to the year 386. Dupin.

VICTORIOLA, in *Botany*, a name used by some authors for the hippoglossum, called in English the *Alexandria-laurel*, *horle-tongue*, or *double-tongue*.

VICTORIUS, in *Biography*. See VETTORI.

VICTORY, VICTORIA, the overthrow, or defeat, of an enemy, in war, combat, duel, or the like. See WAR, COMBAT, DUEL, CHAMPION, &c.

Among the Romans, crowns, triumphs, &c. were decreed to their generals, for the victories they gained.

VICTORY, *Ælian*, denotes the victory which Augustus, or rather his general, gained over Mark Antony after the capture of Actium; in commemoration of which he built the city of Nicopolis, and re-established with peculiar magnificence the Actian games.

VICTORY, *Games of*, were public games celebrated on account of a victory; they were called by the Greeks *επινοικιαστων αλωνες*, and in Latin inscriptions they are denominated *ludi victoria*. Of these, the Roman history recites those in honour of Augustus, after the battle of Actium; those of Septimius Severus, after the defeat of Pescennius Niger; those in honour of Lucius Verus and Marcus Aurelius, on their return from the expedition against the Parthians, recorded on the marble of Cyzicus, &c.

VICTORY, in *Mythology*, called *ΝΙΚΗ* by the Greeks, was personified and made a deity both by the Greeks and Romans. According to Varro, she was the daughter of Cælum and Terra; but Hesiod makes her the daughter of Styx and Pallas. Temples, statues, and altars were consecrated to this deity. Sylla, according to Cicero, instituted games in honour of this goddess. At Athens there was a temple dedicated to Victory, in which was placed her statue without wings. The first temple built in honour of her by the Romans was during the Samnite war, under the consulate of L. Posthumus and M. Attilius Regulus. With them she was represented as a winged deity, sometimes almost in the attitude of flying, and with her robe carried back with the wind; holding a laurel crown in her hand, which was anciently the peculiar reward of successful generals and great conquerors. The Egyptians represented her under the figure of an eagle, a bird always victorious in its combats with other birds. The poets inform us that her wings were white, and her robe of the same colour. They sometimes describe her hovering between two armies engaged in battle, as doubtful which side she shall choose, and sometimes standing fixed by one she is resolved to favour, as she is often seen on the medals of the Roman emperors. This goddess is often represented in a chariot, drawn rapidly along by two horses. Pliny speaks of a picture of Victory in Rome, in which she was ascending to heaven, in a chariot with four horses, as she appears on the Antonine pillar, carrying thither some hero, and with a palm-branch in her hand. This, and the crown of laurel, were her general attributes; and a third was a trophy, and sometimes two, one on each side of her. Sometimes she is seen mounted on a globe, as she appears upon the medals of the emperors, because they reckoned themselves masters of the world. When a naval battle was designed, she was drawn mounted on the prow of a ship; and when she holds a bull by the muzzle, it points out the sacrifices that were offered after any advantages that were gained. It appears from the ancients that no bloody

victim was offered to her, but that her sacrifices were the fruits of the earth. She was called by various names; by the Egyptians, Nepthe; by the Sabines, Vacuna; by the Greeks, Apteris, without wings; by others, Vitula. Among her epithets were Eteralcea, which Homer uses to denote that she inclined to both sides; that of Prapes and Volacris, to denote her swiftness; and that of Cæligena by Varro, because Victory comes from heaven. A Victory at Rome, whose wings were burnt by lightning, gave rise to the following epigram: "Rome, great queen of the world, thy glory shall never fade, since Victory, now stripped of her wings, can never fly away."

VICTORY, in *Geography*, a town of America, in the district of Vermont, and county of Essex, containing six inhabitants; 75 miles N. of Norwich.

VICTORY, *Cape*, the extreme N.W. point of the Straits of Magellan, at the opening to the South Pacific ocean. S. lat. 52° 15'. W. long. 76° 40'.

VICTUALLER, one that sells victuals; and we now call all common alehouse-keepers victuallers. See **ALEHOUSE**.

Vicuallers shall sell their victuals at reasonable prices, or forfeit double value; and vicuallers, fishmongers, poulterers, &c. coming with their victuals to London, shall be under the regulation of the lord-mayor and aldermen; and sell their victuals at prices appointed by justices, &c. (23 & 31 Edw. III. c. 6. 7 Rich. II. 13 Rich. II.) If any vicuallers, butchers, brewers, poulterers, cooks, &c. conspire and agree together not to sell their victuals, but at certain prices, they shall forfeit for the first offence 1*ol.*, for the second 2*ol.*, and for the third offence 4*ol.* (2 & 3 Edw. VI. c. 15.) See **FORESTALLING**.

VICTUALLER, *Agent*. See **AGENT**.

VICTUALLING-OFFICE, an office formerly kept on Tower-Hill, now in Somerset-House and Deptford, for furnishing his majesty's navy with victuals.

It is managed by seven commissioners, who have their inferior officers, as secretaries, clerk, &c.; besides agents in divers parts of Great Britain, Ireland, &c.

VICTUS RATIO, among *Physicians*, a particular manner of living, for the preservation of health, and prevention of diseases.

VICUNNA, in *Zoology*, a name given to the *pacos*.

VICUS AQUARIUS, in *Ancient Geography*, a very considerable town of Hispania, in Lusitania, towards the north, in the country of the Vettones.

Vicus Augyssi, *Kair-Wan*, a town of Africa, on a large plain, S. of Adrumetum, marked in the Itin. of Antonine between Aquilianæ and Cloacaria.—Also, a town of Africa Propria, upon the route from Carthage to Sufetula, between Adrumetum and Aquæ Regiæ. Anton. Itin.

Vicus Badius, a place of Italy, on the route from Rome to Adria, between Palacrinum and Centesimum. Anton. Itin.

Vicus Cuminarius, a place of Hispania Citerior, belonging to the Carpetani, at a small distance upon the left of the Tagus. It is marked in the Itin. Anton. on the route from Emerita to Cæsar-Augusta, between Alces and Tiltule.

Vicus Judæorum, a place of Egypt, on the other side of the Nile, between Thou and Scenæ Veteranorum, according to the Itin. of Antonine.

Vicus Novus, *Vico*, a small place of Italy, in Campania, at some distance to the S.E. from Calatia and Capua.—Also, a place of Italy, in Umbria, on the route from Rome to Adria, between Eretum and Reate. Anton. Itin.

VID, in *Geography*, a river of Bulgaria, which runs into the Danube, 10 miles W. of Nicopolis.

VIDA, MARCO-GIROLAMO, in *Biography*, a modern Latin poet of reputation, was born at Cremona of parents nobly descended, but in humble condition. The date of his nativity is differently assigned; some fixing it in the year 1470, and others in 1490. His education was liberal at Padua and Bologna, in the latter of which cities two of his poems were published in 1504, under the name of Marc-Antonio, which he changed for Marco-Girolamo, when he took orders as a canon regular of Lateran. For assistance in the study of theology and philosophy, to which in early life he was devoted, he went to Rome in the latter years of Julius II. His poems were much applauded, and gave him rank among the principal geniuses of the age. He was indebted to the early patronage of Ghiberti, bishop of Verona, for an introduction to Leo X., who bestowed upon him both wealth and honours. Besides other benefices, he presented him to the priory of St. Silvestro, in Frascati, where he enjoyed a favourable opportunity for pursuing his studies, and especially the completion of his "Christiad," in which Leo had engaged him. Of his more considerable poems, his work entitled "De Arte Poetica" is supposed to have been first written; and the first known edition of it is dated in 1527. This was soon followed by his "Bombyx," or art of rearing silk-worms, and his "Scacchiæ Ludus," or poem on the game of chess. Clement VII. became his second patron, and promoted him first to the office of apothecary prothonotary, and in 1532 to the bishopric of Alba. After the death of this pope, he retired to his diocese, and established the character of a zealous and affectionate pastor; and when, in 1542, Alba was invested by the French, he contributed by his exhortations and example so to animate the citizens, as to preserve it from the enemy. His two books "De Republica" contain dialogues, which are the substance of a conversation that passed between him, and some cardinals and learned men, at the council of Trent. These dialogues are excellent, with respect to the correctness and elegance of their style, and evince that the author was no less extensively conversant with politics and philosophy than with polite literature. In 1551 Vida retired to Cremona, on account of the wars which desolated his diocese; however, he was not unmindful of his pastoral charge, but effectually interceded with Don Ferdinand Gonzaga, governor of Milan, and thus prevented his marching, as he threatened to do, to Alba, and putting all the inhabitants to the sword. In 1563 he was still at Cremona, but soon after removed to Alba, and died there in 1566. As a Latin poet, Vida acquired a very high reputation; to which he was justly entitled, partly on account of the subjects which he selected, and partly for the singular classic purity and dignity of his style, formed on the model of the most admired productions of antiquity. Virgil was the object of his admiration and imitation, whom he respected, and after whom he copied, as Cicero was the model of the prose Latin writers of that age. "Vida's works," says a judicious biographer, "do not so much give the impression of a writer of original and fervid genius, as of one possessing taste, elegance, and ingenuity." Besides the poems already mentioned, Vida was the author of Eclogues, of Sacred Hymns, and of other small pieces, which are marked with his purity of diction and classical refinement. The fame of this poet in England has been greatly promoted by the well-known lines in Pope's Essay on Criticism, which place him on a parallel with Raphael, and entitle Cremona to boast of him, as much as Mantua of Virgil; but this was the hyperbolic eulogy of a juvenile writer, which his maturer judgment would scarcely have

have confirmed. The candid Tiraboschi is contented with saying of him, that his qualities, if not sufficient to rank him in the number of first-rate poets, at least give him a title to be placed much above the vulgar tribe of old writers. Roscoe's Life of Leo X. Gen. Biog.

VIDAME, VICE-DOMINUS, was anciently used for the bishop's deputy in temporals; as *comes*, or *vice-comes*, was the king's.

The word, according to Nicod, comes from *vicarius*; or according to Pasquier, from *vice-dominus*; *dom* signifying *dominus*, or *lord*. See *DOM*.

The original institution of vidames was for the defence of the temporalities of bishoprics, while the bishops themselves were taken up in prayer and other spiritual functions. They also led the bishop's forces when they were obliged to go to war, either to defend their temporalities, or for the arrier-ban.

They also managed, and pleaded, their cause in courts of justice; distributed justice among their tenants; and prevented any body's pillaging, or damaging, the houses of deceased bishops, &c. In effect, they represented the bishop, considered as a temporal lord.

In some ancient charters, the vidames are called *advocates*, or *advocates*.

VIDAME continued to be a title of signory, or lordship; attributed to several gentlemen in France: as the vidame of Chartres, of Amiens, &c.

The ancient vidames, Pasquier says, were the bishops' temporal judges; and they had the same privileges as the viscounts.

By degrees, the vidames converted their office into a fee; and the bishops their vidames, or judges, into vassals; as kings did their counts, dukes, &c. Accordingly, the vidame of Chartres, &c. held lands of the bishops of those places. See VALVASOR.

VIDDIN, in *Geography*, a town of European Turkey, in Bulgaria, on the Danube, the see of a Greek archbishop; 356 miles N.W. of Constantinople. N. lat. 44° 25'. E. long. 22° 26'.

VIDE, in *Fr. Music*, is equivalent to *open*, in English: as *corde à vide*, an open string, on instruments with a neck, such as a violin or violoncello; or the sound produced by the whole length of a string from the nut to the bridge, without the pressure of a finger.

The sound of open strings is not only more grave or lower in tone than when pressed by the finger, but more sonorous and full; which arises from the softness of the finger which impedes its vibrations: on which account good players on the violin avoid using open strings as much as possible, in order to preserve an equality of tone. But to do this, the performer must know all the *sfists*, and be well acquainted with the finger-board. See SHIFT and FINGER-BOARD.

VIDEO, MONTE, in *Geography*. (See MONTEVIDEO.) This, says Mr. Mawe, is a tolerably well-built town, situated on a gentle elevation, at the extremity of a small peninsula, and is walled entirely round. Its population amounts to between 15,000 and 20,000 souls. The harbour is the best in the Rio de la Plata, and has a very soft bottom of deep mud, but cannot be called a good one for vessels above 300 or 400 tons. The houses are generally of one story, paved with brick, and furnished with few conveniences. In the square is a cathedral, and opposite to it an edifice, divided into a town-house, or *cabildo*, and a prison. The streets are unpaved, and the well that supplies the town with water is at the distance of two miles. Provisions are abundant and cheap, particularly beef. The inhabitants, especially

the Creolians, are humane and well-disposed, when not actuated by political or religious prejudices. Their habits, like those of their brethren in Old Spain, proceed from the opposite extremes of indolence and temperance. The ladies are generally affable and polite, and in their persons neat and clean. Abroad they usually appear in black, and always covered with a large veil, or mantle; and at mas they always appear in black silk, bordered with deep fringes. The chief trade of Monte-Video consists in hides, tallow, and dried beef; the two former being exported to Europe, and the latter to the West Indies, especially to the Havannah. Coarse copper from Chili, in square cakes, is sometimes shipped here, and an herb called "metta," from Paraguay, the infusion of which is used as tea in England. The climate is humid; in the winter months (June, July, and August) the weather is occasionally boisterous, and the air piercing. In summer, the serenity of the atmosphere is often interrupted by tremendous thunder-storms and lightning, and also deluges of rain, which sometimes destroy the harvest.

The heat is troublesome, and the mosquitoes are peculiarly injurious. The town stands on a basis of granite: and the high mount on the opposite side of the bay, on which is a light-house, and which gives name to the town, is principally composed of clay-slate in laminae, perpendicular to the horizon. The vicinity of Monte-Video is agreeably diversified with low gently sloping hills, and long valleys watered by beautiful rivulets, but traces of cultivation are rarely observed.

VIDERØE, one of the Faroer islands. N. lat. 61° 59'. VIDICINORUM OPPIDUM, in *Ancient Geography*, a town of Italy, in Picenum, destroyed by the Romans.

VIDIGAL, in *Geography*, a town of Portugal, in the province of Algarve; 18 miles N. of Sagres.

VIDIGUEIRA, a small market-town of Portugal, in Alentejo; 12 miles N.E. of Beja, and 5 leagues from Serpa, in a very charming country. On one side is a fertile plain, on the other, close to the town, rise mountains, intersected with valleys, that are adorned with quintas and orange-gardens, with a large Gothic church on the fore-ground. The place is small, having little more than 2000 inhabitants. Its oranges are small, but well-flavoured, and the best in the country, as is also the wine, from the neighbouring Villa de Tradas, much celebrated at Lisbon.

VIDIMARUM, in *Botany*, the name of the tree which bears the febeffens, a medicinal plum, of Asia and Ægypt.

VIDIMUS, in *Law*, the same with *innofcimus*; being letters patent of a charter of feoffment, or some other instrument, not of record.

VIDINI, in *Ancient Geography*, a people of European Sarmatia. Ammian. Marcell.

VIDOTARA, a bay on the northern side of Great Britain, near the mouth of the river which runs by Aire.

VIDOURELLE, in *Geography*, a river of France, which runs into the lake of Than, near Aignes Mortes.

VIDRA, a town of Spain, in Catalonia; 12 miles N. of Vique.

VIDROPUSK, a town of Russia, in the government of Tver; 12 miles N. of Torzok.

VIDRUS, in *Ancient Geography*, a river of Germany; its mouth, according to Ptolemy, being between Marmanis Portus and the mouth of the river Anafus.

VIDUA, a river on the northern coast of Hibernia. Ptol.

VIDUCASSES, the name of a people who occupied a part of that country which is now the diocese of Bayeux. The capital of these people was near the river Orne, a little above Caen, probably Vieux.

VIDUCHOVA, in *Geography*. See FIDDICHOW.

VIDUITATIS PROFESSIO, the making a solemn profession of living a chaste widow; a custom heretofore observed in England, and attended with divers ceremonies.

VIE. See *CESTUE qui Vie*.

VIE, in *Geography*, a river of France, in the department of the Vendée, which runs into the sea near St. Gilles.—Also, a river of France, in the department of the Calvados, which runs into the Dive, 3 miles N.W. of Crevecoeur.

VIECHTACH, a town of Bavaria; 13 miles S.E. of Cham.

VIEDAM, or VEDAM, the name of a sacred book of law and religion, written, according to M. de Sainte-Croix, by the Samaneans, in the Samscritan, or Shanfcrit language, and held in great veneration by the Brahmins of Hindoostan, from a notion that Brahma, their legislator, received it from the Deity himself. See VEDA.

VIEDENBRUCK, or VIDENBRUGGE, in *Geography*. See WIEDENBRUCK.

VIEJO, one of the small Bahama islands.

VIELBRUN, or FELBRUN, a town of Germany, in the county of Wertheim; 17 miles W. of Wertheim.

VIELLA, a town of France, in the department of the Gers; 10 miles S.W. of Nogaro.—Also, a town of Spain, in the province of Catalonia; 38 miles W.N.W. of Urgel.

VIELLE, a musical instrument, often confounded with the *viola*, or *viol*. It is not, indeed, a bowed instrument, like the viol, but its tone is produced by the friction of a wheel, which performs the part of a bow. The strings are pressed on the wheel by the fingers, and sometimes by keys. It is at present a mere street instrument every where but at Paris, where it is much in use with other instruments at the Boulevards and Guinguettes; and even ladies sometimes condescend to learn to play upon it. Kircher gives it no better title than that of *lyra mendicorum*, the beggar's lyre. It is so loud in the open air, that it seems impossible to bear it in a room. The itinerant performers on this instrument are generally Savoyards.

The name of the instrument seems a corruption of *viola*, if it is not the eldest of the two. The Dict. Etymol. says; *Viole, Violon*, from the Spanish *viola* and *violone*. The Spaniards also say *viuela*, whence we (the French) have *Vielle*. It has a neck or finger-board fretted, and two strings, always sounding as drones, tuned fifths or eighths.

VIELLE, *La*, in *Geography*, a town of France, in the department of the Lower Pyrenées; 21 miles N. of Pau.

VIELLE Ridee, the *Wrinkled old Woman's Shell*, in *Conchology*, a name given by the French authors to a species of chana of the mutilated kind, very much resembling the famous concha Veneris, but longer, and without that peculiarly-shaped oval aperture to which that shell owes its name.

It has several spines about the lips, as the concha Veneris has, but they are shorter, and more obtuse, than in that shell. The whole surface of this species is deeply and irregularly wrinkled. It is of a whitish colour, variegated with brown.

VIELLEUR, in *Natural History*, the name of a species of fly common in Surinam, and some other places. It is moderately large, though less so than the lantern-fly, so common in that place, and has a long head, and some other particulars, in which it resembles that creature. Mrs. Merian has given a figure of it, and reports it as the opinion of the natives, that it changes at length into a lantern-fly.

VIELMUR, in *Geography*, a town of France, in the department of the Tarn, on the Agout; 9 miles W. of Castres.

VIELSK, a town of Ruffia, in the government of Vologda, on the Vaga; 156 miles N.N.E. of Vologda. N. lat. 61° 40'. E. long. 41° 44'.

VIENENBURG, a town of Westphalia, in the bishopric of Hildesheim; 7 miles S. of Schladen.

VIENNA, or VIENNENSIVM CIVITAS, in *Ancient Geography*, one of the most opulent towns of Gaul, and the capital of the Allobroges. This town enjoyed the rights of a Roman city, and the prerogative of furnishing subjects for the senate of Rome, granted to it, according to Tacitus, under the consulate of Rutilius, in the year of Rome 664. This place is mentioned by Strabo as the most considerable among the Allobroges. Mela ranks it among the most opulent in the Narbonnensis, and it is cited by Pliny under the denomination of a colony. By the first division of ancient Narbonnensis, Vienna became the metropolis of that district, which was distinguished by the name of the Viennois, and this province was formed at the beginning of the fourth century, since it is mentioned in the acts of the council of Arles, held A.D. 314. See VIENNE.

VIENNA, in *Geography*, a city and capital of Austria, the see of an archbishop, on the W. side of the Danube, on a fertile plain, where it receives a small river, called *Vien*, which passes through the city and suburbs; near the place where stood the ancient *Vindobona*. The situation is pleasant, for to the east and north the country around is entirely level, but to the west and south is seen a range of mountains, which are thickly planted with trees and vines; and the Danube, which is here very wide, divides itself in that part of the town into several arms, forming many islands, which are stocked with wood. The circumference of that which is properly the fortified city of Vienna is not large, and only contains about 60,000 souls; but the suburbs are therefore the more ample; and, according to the estimate of a late traveller, the city and the suburbs together contain 230,000 (others say 254,000) inhabitants, without including the garriſon. In 1795, the whole population of Vienna was computed at 231,105 inhabitants; of whom 1231 were ecclesiastics, 3253 nobility, 4256 public functionaries, and persons living upon their private fortune, and 7333 citizens belonging to the corporation. In the city itself there are numerous and beautiful palaces; but the streets are not spacious, and are, in part, crooked. The houses are generally of brick, covered with stucco. There is but one street in Vienna that can be called magnificent, and this is a continued line of splendid houses and palaces. It is called the "Nobles'-street." The suburbs are constructed on a better plan, and would be very elegant, if the houses were larger and richer in architectural ornaments. Most of the streets are regular, level and wide, but they are chiefly inhabited by manufacturers and workmen of various trades. Near the centre of the town is a bridge thrown across a deep low street, which admits of the passage of carriages, whilst the usual thoroughfare is below, resembling our canals over navigable rivers. Those people of fashion who have no country-seats, or who are prevented by their public employments from leaving Vienna, generally reside in the suburbs during summer. The second floor of all burghers' houses is allotted for the residence of the officers of the imperial court; and the owners can only purchase an exemption by paying a sum of money for the erection of barracks. It is divided into four quarters, which contain fifteen squares or public places; that of the court is large and beautiful; in it, between two fountains, is a superb monument, built by the emperor Leopold; in the high market-place is a marble monument, representing the marriage of Joseph and the Virgin, erected in the year 1732. Vienna contains fifty churches

VIENNA.

churches or chapels, and twenty-one convents. The chief edifices are the metropolitan church of St. Stephen, the imperial palace, library and arsenal, the house of assembly for the States of Lower Austria, the council-house, the university, and some monasteries. The metropolitan church is a dark Gothic building, richly adorned on the outside with sculpture, and within with thirty-eight altars, mostly of beautiful marble; a great number of relics, jewels, &c. and an ancient vault, in which the archdukes are interred. Here is a mausoleum of Frederic III. which cost 40,000 ducats, and a monument in honour of prince Eugene of Savoy. Near it is a palace of the archbishop. In a chapel belonging to the Capuchins, the princes of the royal family are buried, without pomp, with hardly their names over their tombs. The university of Vienna was instituted in the year 1365, from a college founded about a century before, and is divided into four faculties and four nations, Austrian, Saxon, Hungarian, and Rhenish. It has been much improved since the year 1752. The books in the library are not very numerous; it is open two or three hours morning and afternoon. The imperial library contains about 5000 or 6000 volumes, printed in the 15th century, rare manuscripts, and a very extensive and valuable collection of prints, and is well furnished with useful modern books. It is open three or four hours every morning to the public. The imperial cabinet is very rich in medals, and still more so in natural history. The Academy of Arts is divided into seven classes, each of which has its own professor. A taste for music is likewise very general; and the theatre at Vienna has been liberally encouraged. It must be acknowledged, however, that liberty does not flourish here. It is said that the list of prohibited books is scarcely exceeded by that of the Index Expurgatorius at Rome. Nevertheless it has an university, as we have already mentioned, and some considerable schools, principally with a view to commerce. Education needs or demands greater encouragement. The people are in general honest, and simple in their manners. Their ruling propensity is that for luxurious living, both as to food and drink. The women are handsome, and mild in their manners. They love dress, and are addicted to luxury. Music is the principal object of their attention. The Augarten and the Prater are the principal promenades. The police of Vienna is so well conducted, that the streets are remarkably quiet and orderly, so that as early as ten o'clock at night silence prevails. The suburbs are far larger than the city itself. They are adorned with a great number of spacious gardens, and many of the buildings occupy a large space of ground. They lie round it, but are removed to the distance of 500 or 600 common paces from the works of the fort. The line which incloses them and extends on both sides to Leopoldstadt, was, in the year 1794, thrown up against the Hungarian rebels, and afterwards lined with bricks, the gates and entries to it being always kept by regular guards. These suburbs stand for the most part under the jurisdiction of the town-council, to whom an appeal lies from the sentence of the judge and his assessors, with which each suburb is provided. Of them, Leopoldstadt is the largest and chiefest. It lies next the town, on an island in the Danube, being formerly called the Jews' town; but the emperor Leopold, in 1670, having driven that people from thence, it took its name from him. It contains one parish church, two cloisters, the old imperial favorita, a citadel, which, in 1683, was miserably laid waste by the Turks, and but a small part of it repaired; together with the adjoining extensive au-garden, and many considerable fine houses and gardens. On an island in the Danube, well planted with wood, is the Prater, or imperial park, and to the S. is the chapel of Herenthartz, much frequented in

Lent for the sake of amusement as well as of devotion. In one of the suburbs is the palace of Belvidere, which formerly belonged to prince Eugene; and at the distance of a few miles stands Schombrun, another imperial palace. The garrison of Vienna consists of one regiment of foot. Provisions are brought to Vienna from the different parts of Austria, and other countries belonging to the emperor, in the greatest plenty and variety. The police pays particular attention to the supply of provisions, and often inspects the markets, and the weights and measures of the dealers. A modern traveller says, he has seen a score of wild hogs and a dozen stags in the game-market at the same time, and hares, literally, by cart-loads, with abundance of pheasants and partridges. Every kind of bird seems to be an article of food, and none rejected; hawks, jays, magpies, are brought to market, and even the bulfinch and robin are not spared. The livers of geese are esteemed a great delicacy; and in the fish-market are found, with sturgeon, carp, pike, tench, and trout, tortoises, frogs, and snails. The manufactures of Vienna are numerous; that of cotton on the increase, that of silk much regarded, and embroidery encouraged. The people of Vienna, upon the whole industrious, excel in manufactures of steel, carriages of all sorts, silk, ribbands, harness, saddles, &c. The inland commerce, carried on by the Danube, is not inconsiderable. The people delight in the combats of wild beasts and of bulls. Vienna owes its first aggrandizement to Henry I. duke of Austria, who, about 1142, made it the place of his residence; it was then a town, and in 1158 was surrounded with walls. In 1198 it obtained its municipal privileges, and was better fortified. The mortality of this city is thought to be greater than that of any other place in Europe; and it is commonly said that one in twenty dies annually: a late traveller, Küttner, supposes the mortality much greater. Although Vienna be much exposed to the N. and E. winds, yet the southern hills serve as a fence against the rain, so that the traveller rather complains of dust than of moisture. The summer heats, on account of its situation in the midst of hills and mountains, which collect much snow and ice in winter, last only about two months, and in winter the cold is often very severe. The pleasantness of the environs is said to be much enhanced by the happy aspect of the Austrian peasantry of this city. The number of those who fall victims to pulmonary diseases is very large, and many have been carried away by the small-pox, the ravages of which, it is hoped, will be restrained by the introduction of the practice of inoculation for the cow-pox. The establishments for the relief of the sick are very numerous; such are the Great Hospital, which in 1796 received 11,860 patients; and within its walls is contained a pathological museum; the hospital for lying-in-women, which in the above-mentioned year received 1904 women; the lunatic hospital, which in the same year accommodated 261 insane persons; a military hospital; and an hospital for Jews, excellently managed. The suburbs of the town, according to a singular and useful institution founded by Leopold, are divided into eight districts, each of which has its physician, surgeon, and midwife, all paid by government, whose office it is to visit the poor at their own houses. In the year after its establishment this institution was extended to the whole city. Another institution has the charge of diseased children under ten years of age. In 1796 it was ordained, with a view to the public health, that no new-built house should be inhabited before the physician of the district had examined whether the walls were sufficiently dry; 175 miles S. of Prague. N. lat. 48° 13'. E. long. 16° 23'.

VIENNA, a port of entry and post-town of the eastern shore

shore of Maryland, in Dorchester county, on the W. side of Nanticoke river, about fifteen miles from its mouth. It contains about thirty houses, and carries on a brisk trade with the neighbouring sea-ports, in lumber, corn, wheat, &c.; 15 miles N.W. of Salisbury, and 120 from Washington.—Also, the capital of Greene county, Kentucky, on the N. side of Green river; about 158 miles W.S.W. of Lexington.—Also, a town of Kennebeck county, in the district of Maine, incorporated in 1802, including the late plantations of Goshen and Wyman: the number of inhabitants is 417.—Also, a post-town in Abbeville county, South Carolina; 651 miles from Washington.—Also, a town in Ohio county, Kentucky, containing 26 inhabitants.

VIENNE, a town of France, and principal place of a district, in the department of the Iere, situated on the left side of the Rhône, over which was formerly a stone-bridge, built in the year 1265, now destroyed. A Roman colony was established here, and called Vienna Allobrogum. In the fifth century it was taken by the Burgundians, and the kings made it their place of residence. In the ninth century it was the capital of the kingdom of Provence. It was afterwards erected into an archbishopric, and became the capital of a province called Viennois, in which state it remained till the revolution, when the archbishopric was suppressed. In 1311, a council was held here by order of pope Clement V. in which, among other matters, the suppression of the knights Templars was determined; 10 posts N. of Valence. N. lat. $45^{\circ} 32'$. E. long. $4^{\circ} 58'$.

VIENNE, a town of France, in the department of the Loir and Cher, on the fourth side of the Loire, opposite Blois.

VIENNE, a river of France, which rises about three miles E. of Tarnac, on the borders of the departments of the Correze and the Creufe, passes by or near to Tarnac, Aimoutier, St. Leonard, Limoges, Aix, St. Julien, Chabanois, Confolent, St. Germain fur Viennne, Availle, Isle Jourdain, Luffac, Chavigny, Châtellerault, Ile Bouchard, Chânon, &c. and joins the Loire, in the department of the Indre and Loire, about five miles above Saumur.

VIENNE, one of the nine departments of the western region of France, formerly a part of Poitou, in $46^{\circ} 30'$ N. lat., bounded on the N. and N.E. by the department of the Indre and Loire, on the E. by the department of the Indre, on the S. by the departments of the Charente and Upper Vienne, and on the W. by the department of the Two Sevres. The department of the Maine and Loire joins it a little to the N.W. The territorial extent of this department is 7340 kilometres, or 364 square leagues, and it contains 250,807 inhabitants. It is divided into 5 circles or districts, 31 cantons, and 344 communes. The circles are Loudun, comprehending 32,256 inhabitants; Châtellerault, 46,518; Montmorillon, 48,570; Civray, 38,971; and Poitiers, 84,492. Its capital is Poitiers. According to Haffenfratz, its extent in French leagues is 21 in length, and 13 in breadth; its circles are 6, its cantons 49, and its population 257,953. Its contributions in the 11th year of the French era amounted to 1,979,952 fr.; and its expences, administrative, judiciary, and for public instruction, to 280,570 fr. 35 cents. This department is diversified with hills, plains, heaths, and cultivated lands, yielding grain, wine, fruits, flax, and good pastures. It has considerable forests.

VIENNE, *Upper*, one of the nine departments of the upper region of France, formerly Limosin, in 46° N. lat., bounded on the N. by the departments of the Vienne and Indre, on the E. by the department of the Creufe, on the S.E. by the same department, on the S.W. by the

department of the Dordogne, and on the W. by the department of the Charente. The territorial extent of this department is 6002½ kilometres, or 288 square leagues, and its population consists of 259,795 inhabitants. It is divided into 4 circles, 26 cantons, and 224 communes. Its circles are Bellac, including 85,388 inhabitants; Limoges, 92,637; St. Yrioux, 38,251; and Rochecourat, 43,519. Its capital is Limoges. According to Haffenfratz, it is in length 26 French leagues, and in breadth 12; its circles are 5, and cantons 40, and the number of its inhabitants 266,910. The contributions of this department, in the 11th year of the French era, amounted to 1,641,147 fr.; and its expences, administrative, judiciary, and for public instruction, were 241,803 fr. 33 cents. The soil of this department is, in general, of an indifferent quality; yielding rye, little wheat, and tolerable pastures. The hills are covered with chefnut-trees and woods. Here are mines of iron, lead, copper, coal, and quarries of marble.

VIENNE le Château, a town of France, in the department of the Marne; 6 miles N. of St. Menehould.

VIENS, a town of France, in the department of the Mouths of the Rhône; 3 miles E.N.E. of Apt.

VIEPREZ, a river of Poland, which rises 16 miles W. of Lublin, and runs into the Vistula near Stezicza, in the palatinate of Sandomirz.

VIEPRIE, a town of the Popedom, in the duchy of Spoleto; 5 miles N.E. of Todi.

VIERINGEN, or WIERINGEN, an island in the Zuyder Sec, of an oval form; about six miles in length, and, where widest, rather more than two in breadth; 6 miles S.E. from the Texel.

VIERRADEN, a town of Brandenburg, in the Ucker Mark, on the Welfe, near its union with the Oder; 24 miles S.E. of Prenzlau.

VIERUEDRUM, or VERVEDRUM, in *Ancient Geography*, a promontory of the isle of Albion, according to Ptolemy.

VIERZON, in *Geography*, a town of France, and principal place of a district, in the department of the Cher, near the conflux of the Eure and Cher; 11 posts S. of Orleans. N. lat. $47^{\circ} 13'$. E. long. $2^{\circ} 9'$.

VIESCAS, a town of Spain, in the kingdom of Aragon; 10 miles from Jaca.

VIESCHORN, a mountain of Switzerland, in the canton of Bern, and bailiwick of Grindelwald.

VIEST, or UJEST, or *Oyssl*, a town of Silesia, in the principality of Oppeln; 14 miles W.N.W. of Gleiwitz.

VIESTI, a town of Naples, in Capitanata, on the coast of the Adriatic, the see of a bishop, suffragan of Manfredonia; 29 miles N.N.E. of Manfredonia. N. lat. $41^{\circ} 56'$. E. long. $33^{\circ} 52'$.

VIETA, FRANCIS, in *Biography*, a very eminent mathematician of the 16th century, was born at Fontenai, in Poitou, in the year 1540. Although he occupied the post of master of requests at Paris, and his time and attention were much engaged by the duties of his office, he was indefatigable in his application to mathematical studies; so that he is said to have remained in his apartment for three days, without either eating or sleeping. In his writings he manifests great originality of genius, as well as invention. For a brief account of his improvements in *algebra*, we refer to that article. On other branches of the mathematics, besides those that may be denominated analytical, he bestowed much attention and labour; and whilst he collected and detailed what others had done before him, he enlarged the boundaries of science, and made some important and useful additions

additions to the flock of knowledge which had been amassed by his predecessors. In this respect he was not a mere labourer, but original and ingenious in his communications. His treatise on "Angular Sections" is a performance which enabled him to resolve a curious problem, propofed by Adrian Romanus to mathematicians, and which amounted to an equation of the 45th degree. Romanus was so impressed by his sagacity, that he travelled from Wirtemberg in Franconia, where he resided, as far as France, in order to visit Vieta, and cultivate friendship with him. His "Apollonius Gallus," or restoration of Apollonius's tract on Tangencies, not to mention other pieces that may be found in his works, displays powers of invention, eminently adapted to the more sublime geometrical speculations. His tracts on trigonometry, plane and spherical, with the tables annexed to them, were important and valuable at the time when they were published, and without doubt led the way to farther modern improvements. We have no reason for believing that Vieta was irritable and querulous; but his disputes with Scaliger and Clavius, more especially with the latter, did him no honour. Scaliger pretended to quadrature the circle, an operation for which he was altogether incompetent, and Vieta evinced his incapacity. With Clavius he had a contest about the emendation of the Gregorian calendar, charging him with ignorance and error; whilst he himself committed mistakes, which Clavius detected. The loss of Vieta's "Harmonicon Celeste," entrusted with father Merenne, and surreptitiously taken from him, has been much deplored. Others of his works have also been lost, which has been probably owing to his causing few to be printed, and retaining them in his own custody, those excepted which he distributed among his friends and persons of science. Vieta was profoundly skilled in the art of deciphering, which he employed with advantage to his country. Vieta, notwithstanding the intemperate and assiduity of his application, passed his grand climacteric, and died at Paris in December, 1603. After his death, some of his MSS. were published by Alexander Anderfon, an ingenious Scots mathematician, a native of Aberdeen; and in 1646, Schooten gave an edition of all his works which he was able to collect. Montucla. Hutton.

VIETRI, in *Geography*, a town of Naples, in Principato Citra; 2 miles N.N.E. of Cangiano.—Also, a town of Naples, in Principato Citra. In 1694 it was destroyed by an earthquake; 2 miles W. of Salerno.

VIEUSSENS, RAYMOND, F.R.S., in *Biography*, was born at a village in Rouvergue, and having commenced his education at Rhodéz, he pursued the study of physic at Montpellier, where he graduated. In 1671 he was chosen physician to the hospital of St. Eloy. The result of his anatomical researches in this situation was published under the title of "Neurology," and gained him great reputation. His name became known at court, and Mad. de Montpenfer, in 1690, chose him as her physician. After her death he returned to Montpellier, and directing his attention to chemistry, he found an acid in the caput mortuum of human blood; and on this imagined discovery founded a theory, which he communicated to the different schools of medicine. In advanced life his writings were multiplied, without augmenting his reputation. He died in 1726. His most valuable work is his "Neurologia Universalis," Lyons, 1685, folio, which is commended by Haller, and which exhibits a more accurate dissection of the brain than that of any preceding writers. After his death appeared "Histoire des Maladies internes," 4to., containing many practical observations. Haller. Eloy.

VIEUSSEUXIA, in *Botany*, was so called by Dr.

Daniel de la Roche, in his inaugural dissertation, published at Leyden in 1766, in honour of his countryman and friend M. Vieuffeux, an excellent botanist; of whom, however, we know not that the world has heard any thing further, or that he has written any thing relative to this science. The genus in question was thought, by its truly intelligent and ingenious author, to be intermediate between *Iris* and *Ferraria*. It has not been adopted by Thunberg, Ker, or any of our popular botanists, who have declined separating it from *Iris*, there appearing no distinctive character, except the flames being united into a tube. The learned Decandolle, on the contrary, has adopted *Vieuffeuxia*, in Ann. du Mus. v. 2. 141. t. 42. He is followed by Redouté, who figures the same species, *V. glaucopis*, in his *Liliacées*, v. 1. t. 42, and mentions seven species in all; as well as by Desfontaines, in his recently-published Tableau de l'École de Botanique du Jardin du Roi, ed. 2. 37. Most, if not all, of the plants supposed to constitute the above genus, are, we believe, comprehended as varieties by Thunberg under his *Iris triculpis*. See his dissertation on *Iris*, p. 15; also Willd. Sp. Pl. v. 1. 231.

VIEUX MAISONS, in *Geography*, a town of France, in the department of the Aisne; 6 miles W. of Montmirail.

VIEUX Marché, a town of France, in the department of the North Coast; 8 miles S. of Lannion.

VIEVY, a town of France, in the department of the Côte d'Or; 6 miles S. of Arnay le Duc.

VIEW, VISUS, in *Law*, the act of *viewers*, or *viewers*.

This is called by Bracon, "Res quasi sacra, quia solam personam regis respicit, et introducta pro pace, et communi utilitate."

When a real action is brought, and the tenant knows not well what the land is, that the demandant asks; he may pray the view: which is, that the jury may see the land which is claimed.

This course of proceeding we received from the Normans, as appears by the Grand Customary. It is used in various cases; as in affize of rent-services, rent-charge, rent-sec; in a writ of nuisance; in a writ quo jure; in the writ de rationabilibus divisis, &c. See JURY.

VIEW of Frank Pledge, *Vifus Franci Plegii*, is the office which the sheriff in his county-court, or the bailiff in his hundred, performs; in looking to the king's peace, and seeing that every man be in some pledge. See COURT-LEET, and FRANK-PLEDGE.

VIEW, in matters of *Optics*, *Perspectiue*, &c. See VISION.

VIEW, *Point of*. See POINT.

VIEW, among *Hunters*, the track, or print of the feet, of a fallow deer on the ground.

VIEW a Place, *To*, in the *Military Art*, is to ride about it, before the laying of a siege, in order to observe the strength or weakness of its situation and fortification.

VIEWERS, or VEIORS, in *Law*. See VEIORS.

VIEYRA, ANTONY, in *Biography*, a Portuguese writer, was born at Lisbon in 1608, and in early life accompanied his father to the Brasils. His genius at the age of fourteen began to display itself to a degree that excited the astonishment of his tutors. In 1623 he entered into the society of Jesus, and having carefully read the scriptures, the works of the fathers, and the Summa Aquinatis, he composed some tracts, and gave lectures in the college of Bahia. At this time he was tutor to the son of the viceroy of Brasil, the marquis of Montalvan; and in 1641 accompanied him to Europe. At Lisbon he distinguished himself in the pulpit, and was appointed by John IV. preacher to the court. The king, discovering also his talents for public affairs, deputed him, in 1646, on important business to

England, Holland, and France, and also to the court of Rome. For the services rendered in these missions he was offered a bishopric, which he declined accepting, and requested only to be employed as a missionary among the savages in the forests of Maraganan. The king demurred against acceding to this proposal, but urged him to accept a bishopric, which he still refused; but with some other Jesuits he embarked in a ship, in order to proceed to Maraganan. Soon after his arrival there in 1653, he was sent to Portugal, in order to obtain an order from the king, that the Portuguese settled in the Braffils should treat the Indians with less cruelty. He succeeded in the object of his mission, but he was not allowed to return to America, though he went thither some time after; and in less than six years, in a district more than 600 miles in extent, he formed an establishment similar to that in Paraguay. There the Indians were instructed, and availing themselves of their knowledge, began to live like men, and to practise the virtues which Christianity taught them. The Portuguese residing in Brazil were alarmed, and could not bear that the Indians, whom they treated as slaves, should enjoy the blessings of liberty: they, therefore, seized Vieira and his attendants, and transported them to Portugal, under a charge of their joining the Dutch in forming a plan for expelling all the Portuguese from Brazil. Vieira and his associates were able to prove their innocence, and succeeded in obtaining the reinstatement of all their brethren in the colleges and other establishments of Maraganan. Vieira remained in Portugal, and, at the desire of the queen and ministers of state, drew up a remonstrance, which was presented to king Alphonso, respecting the irregularities and abuses that prevailed in the kingdom. The king's favourites were incensed, and, in 1663, those who were attached to the queen, and who wished to promote the welfare of the nation, were sent into banishment. Vieira was first conveyed to Oporto, and soon after to Coimbra; and for the more certain and speedy decision of his fate, he was committed into the hands of the inquisition. Many charges were alleged against him; however, in 1667, when the influence of the favourites terminated, he was freed from the inquisition, and sent to Lisbon. He was merely forbidden to preach; but this prohibition was revoked, when the queen, Maria Isabella of Savoy, and the infant Don Pedro, then regent of the kingdom, expressed a wish to hear him. In 1669 he was called to Rome, and preached before queen Christina of Sweden, who was so much pleased that she invited him to the conversaciones held in her palace, and requested him to become her confessor. But finding the air prejudicial to his health, he returned to Lisbon, after having obtained from pope Clement X. a letter of exculpation, freeing him from the jurisdiction of the inquisition, and rendering him immediately amenable to the college of cardinals. Vieira, upon the recovery of his health, set sail for Brazil; and being incapable, on account of his advanced age, of superintending the mission of Maraganan, of which he had been long superior general, he spent his time in revising his writings, and preparing for the termination of his life, which happened at Bahia in 1697, when he had attained nearly the 90th year of his age. His interment was conducted with great pomp, his coffin being borne to the grave by the viceroy and his son, and other persons of distinction. The Portuguese consider Vieira as the best writer their country ever produced. His works were published at Lisbon between 1679 and 1718, in 14 quarto volumes. Gen. Biog.

VIF, Fr., in *Music*, lively. See VIVACE. This word, says Rousseau, implies a movement, gay, cheerful, and animated; and requires a bold execution, full of fire.

VIF, in *Geography*, a town of France, in the department of the Isere; 9 miles S. of Grenoble.

VIFALU, a town of Hungary; 16 miles S.S.E. of Ketskemet.

VIG, a lake of Russia, in the government of Olonetz. N. lat. 63° 30'. E. long. 34° 14'.—Also, a river of Russia, which passes through lake Vig, and runs into the White sea, 20 miles S. of Kemi.

VIGAN, LE, a town of France, in the department of the Lot; 17 miles N. of Cahors.—Also, a town of France, and principal place of a district, in the department of the Gard; 36 miles W.N.W. of Nîmes. N. lat. 43° 59'. E. long. 3° 40'.

VIGANONI, GIUSEPPE, in *Biography*, a tenor singer in the Italian opera, first arrived in England in 1782, as first man in the comic opera, in which part Lovatini had rendered us very difficult to be pleased. Trebbi, his immediate successor, was a very useful performer, as he occasionally had a part assigned him in the serious opera; but he excited no raptures in either serious or comic parts. And Jerolmi and Tafca, his successors, were still less interesting. The same might perhaps be said of Viganoni, with a small diminution of praise. His singing did not appear to us in a style of expression that was genuine Italian; it seemed to favour of German or French expression, or of both.

On his second arrival in London, he had less voice than when he came here first; but more knowledge of music, a greater variety of embellishments, and more use of the stage. His voice was never powerful, and now he had more falset than real notes in his scale; and such a rage for gracing and changing passages, that he scarcely ever let the audience hear a single passage as it was written by the composer. He certainly knew his business, and was a good musician; but his style of singing was what painters would call *manière*: for with all his *fioreamenti*, or embellishments, of which he was so lavish, his performance seemed monotonous.

VIGASIO, in *Geography*, a town of Italy, in the Veronese; 10 miles S. of Verona.

VIGENNE, a river of France, which runs into the Saône, at Talmey.

VIGEOIS, a town of France, in the department of the Corzeze, on the Vezere; 4 miles S. of Uzerches.

VIGER, an island in the North sea, on the coast of Norway; 10 miles round. N. lat. 62° 35'. E. long. 6° 30'.

VIGESIMA, among the Romans, a tax of the twentieth part of the yearly incomes of all inheritances. It was first established by Augustus.

VIGESIMA was likewise a custom paid for slaves sold, as also for one made free.

VIGESIMARIUS, among the Romans, an officer who had the management of collecting the vigesima.

VIGEVANO, in *Geography*, a town of Italy, in the department of the Gogna, capital of a small district, in the principality of Piedmont, lying between the Novaresa and the Lumellina, on the Tefin, the see of a bishop, suffragan of Milan; 13 miles S.E. of Novara. N. lat. 45° 19'. E. long. 8° 53'.

VIGGIANO, a town of the island of Corsica, in the district of Tallano.

VIGHIZZOLA, a town of Italy, in the Paduan, near a lake which abounds in fish, especially eels; 16 miles S. of Padua.

VIGIA, a town of Brazil, in the government of Para; 50 miles N.N.E. of Para.—Also, a rock near the south coast of Cuba. N. lat. 21° 32'. W. long. 84° 32'.—Also, a rock

a rock near the fourth coast of Cuba. N. lat. 20° 53'. W. long. 80° 55'.

VIGIL, or **EVE**, in *Church Chronology*, the day before any feast, &c.

Though the civil day begins at midnight, yet the ecclesiastical or scriptural day begins at six o'clock in the evening, and holds till six in the evening the ensuing day.

Hence, the collect for every Sunday and holiday, by order of the church, is to be read, at the preceding evening service, that is, at six o'clock the day before; from which time the religious day was supposed to begin.

And this first part of the holiday, from six o'clock the day before, was, by the primitive Christians, spent in hymns, and other devotions; and, being often continued till late in the night, was called *vigil*.

These vigils came by degrees to be so enlarged, that, at last, all the day preceding the holiday was called by the name.

The origin of vigils is deduced by Forbes from a custom in the ancient church, for the people, both men and women, to meet together in the evening before Easter-day, and watch and pray, as expecting the coming of our Lord, who was to rise early in the morning. This practice, Tertullian observes, *ad uxorem*, afterwards got to other feasts, and saints' days. But abuses creeping in, they were forbidden by a council, in 1322, and, in lieu of them, fastings were instituted on the day before, though still called by the ancient name of vigils. See **WAKES**.

VIGIL. Coma. See **COMA**.

VIGILANTIUS, in *Biography*, an ecclesiastical of the fifth century, was born in Gaul, and removing to Spain, became a parish priest in the diocese of Barcelona. He is said to have written treatises on religious subjects in a polished style; but he incurred the censure of Dupin, because he exposed several superstitions of the time in which he lived. After his return from a voyage to Palestine and Egypt, he propagated opinions that were hostile to the corrupt state of Christianity at that period. He denied that the tombs and remains of the martyrs are entitled to any kind of adoration, and censured pilgrimages to holy places. He derided the miracles pretended to be wrought at the shrines of martyrs, and condemned the nocturnal assemblies held at such places. He affirmed that the practice of burning tapers by day-light at the tombs of holy persons was a superstition, borrowed from the Pagans; that prayers addressed to departed saints were of no avail; and he spoke with contempt of fastings and mortifications, the celibacy of the clergy, and the austerities of monastic life. He also asserted, that the voluntary poverty of those who distribute all their substance to the poor, and the practice of sending donations to Jerusalem for pious purposes, are in no respect acceptable to the Deity. These opinions were favourably received by several of the bishops in Gaul and Spain; but Jerom, the great advocate for monkish discipline, censured them with severity, and rancorously abused Vigilantius for adopting and propagating them. His opposition, and that of persons of similar sentiments prevailed, and prevented every kind of reform. The repentment and hostility of Jerom, to whom Vigilantius had been recommended by Paulinus, seem to have commenced with his declaring himself an enemy to superstition. Bayle. Dupin. Molsheim.

VIGILIA, in *Ancient Chronology*. See **WATCH**.

VIGILIA, that state of an animal which is opposite to sleep, and is popularly called *waking* or *watching*. See **SLEEP** and **WATCHING**.

VIGILIE, in *Antiquity*, denote the watches and guards among the Roman soldiers, who performed duty by night,

in contradistinction to the *excubie*, who kept guard by day, either in the camp, or at the gates and intrenchments: of these last there seem to have been assigned one company of foot and one troop of horse to each of the four gates every day; and it was a most unpardonable crime to desert their post, and to abandon their corps of guards. In the camp, there was allowed a whole manipulus to attend before the prætorium, and four soldiers to the tent of every tribune. The night-guards assigned to the general and tribunes were of the same nature as those in the day. But the proper vigils were four in every manipulus, keeping guard three hours, and then relieved by four others; so that there were four sets in the night, according to the four watches, which took their name from this custom. The night-guard was set by a tally or tessera, with a particular inscription given from one centurion to another through the army, till it came again to the tribune who first delivered it. Upon the receipt of this, the guard was immediately set. But because this regulation was not sufficient, they had the *circuito vigillum*, or a visiting of the watch, commonly performed about four times in the night by some of the horse. Upon extraordinary occasions, the tribunes and lieutenant-generals, and sometimes the general himself, made these circuits in person, and took a strict view of the watch in every part of the camp. Kennet's *Ant. Rom.* p. 206.

VIGILÆ Florum, in *Botany*, a term used by Linnæus to express a peculiar faculty, belonging to the flowers of several plants, of opening and closing their petals at certain hours of the day. Previous to the explanation of this phenomenon, it is necessary to observe, that the flowers of most plants, after they are once opened, continue so night and day, until they drop off, or die away. Several others, which shut in the night-time, open in the morning sooner or later, according to their respective situation in the sun or shade, or as they are influenced by the manifest changes of the atmosphere. But the class of flowers, to which this article refers, open and shut regularly at certain hours, exclusive of any manifest changes in the atmosphere. This property is so evident in one of our common English plants, the *trapsagopon luteum*, that our country people have called it *John-go-to-bed-at-noon*. Linnæus's observations in the *Philosophia Botanica*, p. 273, extend to near fifty species, which are subject to this law: such are the male pimpernel, the blue-flowered pimpernel with narrow leaves, the little blue convolvulus or bindweed, the day-lily, the profliferous pink, the common purflain, the white-water-lily, the garden lettuce, the dandelion, the rough dandelion, several species of hawkweeds, wild fucerry, wild marygold, &c. See an account of this phenomenon by Dr. Pulteney, in *Phil. Transf.* vol. I. p. 506, &c. See also **SLEEP** of *Plants*.

VIGILIUM PREFECTUS. See **PREFECT**.

VIGILIUS, in *Biography*, a pope, was raised to the pontificate by the empress Theodora, when his predecessor Silverius did not answer her purpose, on certain stipulated conditions, to which a person like him, destitute of principle, could have no objection. He was, therefore, sent from Constantinople to Italy with a sum of gold, and an order to Belisarius, then master of Rome, to depose Silverius, and to elect Vigilus. Accordingly the measure was accomplished in November 537: Silverius was banished, and Vigilus, a Roman by birth of a noble family, was ordained to the see of Rome. Silverius appealed to the emperor Justinian, and obtained an order for a rehearing; but upon his return to Rome, he was banished to a distant island, in consequence of the intrigues of Vigilus, and there died in 538. After the death of Silverius, the church of Rome acknowledged Vigilus as lawful pope. Although he punctually

punctually fulfilled his engagements to the emperors, he wrote a letter to the emperor, in which he solemnly professed the orthodox faith; and in another letter to the patriarch of Constantinople, he commended him for his zeal in favour of the council of Chalcedon, which by his engagement to Theodora he condemned, and anathematized as heretics those persons whom he had lately admitted to his communion. The emperor Justinian, fond of exercising authority in matters of faith, was induced, in 542, to issue an edict, condemning the writings of certain prelates who were inclined to the Nestorian tenets, famous under the appellation of "The Three Chapters;" and his edict was received by almost all the Eastern bishops. Vigilus, at the head of those of the Western churches, refused to concur in what they conceived to be an assumption of authority in matters of faith, which belonged only to a general council. Upon this resistance, Vigilus was summoned by the emperor to repair to Constantinople. He left Rome amidst the curses of the people, who charged him with enormous crimes, and arrived at Constantinople in the beginning of the year 547. At first he declared against the imperial edict, and excluded from his communion the patriarch and all the bishops who had subscribed it. The emperor's measures, however, caused him to waver; and at a council held at Constantinople, he issued a decree, entitled "Judicatum," in which the "Three Chapters" were formally condemned. But when he found that this decree excited a great opposition on the part of the Western bishops, he got it revoked, under a pretence of referring the matter to a general council. Without stating the violence and coercion of the emperor on the one hand, or the resistance and tergiversation of the pope on the other, it will be sufficient to observe, that after Vigilus had a fourth time changed his declaration relating to the "Three Chapters," which he finally condemned by a solemn constitution, he was permitted to return to Rome, which had been in the mean time sacked by Totila, and recovered by Narfes. But during his voyage he was seized with a fit of the stone, and obliged to land in Sicily, where he died in 555. A summary of the letters of this pope, still extant, is given by Dupin. Bower. Dupin. Mosheim.

VIGINTIVIRATE, a dignity among the ancient Romans, established by Cæsar.

This dignity comprehended four others; for of the vigintiviri, or twenty men which composed the company, there were three who sat and judged all criminal affairs; three others had the inspection of the coins and coinage; four took care of the streets of Rome; and the rest were judges of civil affairs.

VIGLES, in *Geography*, a town and castle of Hungary; 5 miles S.S.E. of Altsof.

VIGNACOURT, a town of France, in the department of the Somme; 9 miles N.W. of Amiens.

VIGNAIS, or VINHAES, a town of Portugal, in the province of Tra los Montes; 15 miles W. of Bragança.

VIGNE, ANDREW DE LA, in *Biography*, a French writer of the 15th century, bore arms under Charles VIII., and was secretary to his queen, Anne of Brittany. In conjunction with Jaligni, he composed a "History of Charles VIII.," folio, printed at the Louvre, under the care and with the notes of Denis Godefroy. He also wrote "Vergier d'Honneur," Paris, 1495, containing an exact account of the expedition of Charles VIII. against Naples, at which he was present. Nouv. Dict. Hist.

VIGNE, ANNE DE LA, a French poetess, was born in 1634 at Vernon-sur-Seine. Her talent for poetry appeared

so soon, that Pelisson said of her, she seemed to have been suckled by the Muses. Menage compliments her with having surpassed the ancients, and excited the jealousy of the moderns, by the beauty and sonorousness of her verse. She is said to have united the study of philosophy with that of polite literature, and her character is represented as no less estimable than her talents. Huet speaks highly of her cheerfulness and amenity, notwithstanding the feebleness of her constitution, and the pains she suffered. She closed life under the anguish of a calculous complaint in 1684, at the age of 50. Her principal pieces are an ode, entitled "Monseigneur le Dauphin au Roi," for which she received from a person unknown a lyre in gold enamelled, with a copy of verses in her praise; "Ode à Mademoiselle de Scudery;" "Reponse à Mademoiselle Descartes;" and several other "Pièces de Vers," collected in a small octavo. Moreri. Huet. Gen. Biog.

VIGNE, PIERRE DELLE, a celebrated minister of the emperor Frederic II., was born of mean parentage in Capua, at the end of the twelfth century; and having pursued his studies to good effect as a mendicant scholar at Bologna, he was introduced to Frederic II., and ingratiated himself with this prince to such a degree, that he gave him a lodging in his court, and the opportunity of further improvement. He became a proficient in civil and canon law, and acquired an elegant style of writing, so that he was advanced by the emperor to the posts of protonotary of his court, judge, and chancellor; and he became the confidant of all his designs. His ability and learning raised him to the highest reputation, and his influence in the court of Frederic was boundless. The emperor afforded him opportunity of amassing immensurable treasures, and employed him in a variety of the most important embassies, which our limits will not allow us to recount. But before the close of his life, he lost the emperor's attachment and confidence, for which various reasons, none of which are satisfactory, have been assigned. To the jealousy and envy of court attendants, the fall of favourites may often be justly ascribed. Whatever was the cause in this instance, Vigne suffered severely under his master's displeasure: he was deprived of sight, and shut up in prison; and sinking into despair, he put an end to his life. The time of his death is not known. The chronicle of Placentia dates his being blinded in 1248. Six books of letters remain, which Tiraboschi regards as one of the most valuable monuments of the 13th century. The last edition of them is that of Basil, in 1740. He also collected and arranged the laws of the kingdom of Sicily; and to him are attributed a work "Concerning the Imperial Authority," and a book "On Consolation," in imitation of that of Boethius. He also composed some Italian poems. Gen. Biog.

VIGNETTE, in the art of *Printing*, is a French word, now often used among English artists and writers, to denote the flourish or ornament placed at the beginning of a book, preface, or dedication. These vignettes or head-pieces are very various in their form and size. See the description of *PRINTING-Prefs*.

VIGNIER, NICHOLAS, in *Biography*, an historian and chronologist, was born at Bar-sur-Seine in 1530, and brought up a Protestant. Having lost his property in the civil wars, he withdrew to Germany, and practised physic with reputation and advantage. Upon his return to France, he conformed to the established religion, and was appointed physician to the king, as well as historiographer-royal. One of the most curious of his works is his "Traité de l'Origine et Demeure des anciens François," 1582, 4to., which was translated into Latin by Andrew du Chesne. His other works may be consulted with advantage by those who

who wish to acquaint themselves with French history. This writer died in 1595. Moreri.

VIGNIER, JEROM, grandson of the preceding, was born at Blois in 1606. He was the son of a Protestant minister, educated in that profession, and designed for the law; but in 1628 he abjured Calvinism, and entered into the congregation of the Oratory. He became superior of several houses in his society, and acquired high reputation for piety as well as for extensive erudition. He was more particularly conversant with the oriental and other languages, with medals and antiquities, and with the genealogy of the foreigner houses of Europe. He died at St. Magliore, in Paris, in 1661. His writings of various kinds were numerous. Moreri.

VIGNOLA, a name commonly given to JAMES BAROZZI, from the place of his birth, a small town in the duchy of Modena, an eminent architect, was born in 1507; and as he discovered an early inclination for the arts, he was sent for education to Bologna. From painting, to which he was first attached, he directed his attention to architecture. By various designs, upon the principles of Vitruvius, some of which he communicated to the historian Guicciardini, he acquired early reputation. With a view to further improvement he went to Rome, and was there admitted into the academy of design, newly founded, and employed by it in measuring the most celebrated remains of antiquity. The abbat Primaticcio, who was sent to Rome in 1537, by Francis I. of France, to procure designs of the ancient buildings and casts of statues, availed himself of the assistance of Vignola; and on his return, took him to France. After two years' residence in France, he returned to Bologna, and was employed in forming a plan for the facade of the church of St. Petronius, which, through the envy of his competitors, was not executed till some years afterwards. In and near this city he built some palaces, and constructed the canal of Naviglio, running thence to Ferrara. Unduly recompensed for this work, he went to Placentia, and planned a palace for the duke of Parma. After his return to Rome in 1550, he built several churches there; and by the interest of Vafari, pope Julius III. appointed him his architect. For him he built a villa, and near it the small church of St. Andrew, in form of an ancient temple; and by his command he brought the Acqua Vergine to Rome. After the death of Julius, he was employed by cardinal Alexander Farnese in the construction of his magnificent palace or castle of Caprarola; and he had also the charge of building the church belonging to the professed house of Jesuits at Rome, which is an edifice of extraordinary beauty and grandeur. It was raised only to the cornice before the death of Vignola, and finished by his disciple James della Porta. After the decease of Michael Angelo, Vignola was appointed to succeed him as architect of St. Peter's, in conjunction with Pirro Ligorio, a Neapolitan. This engagement and his advanced age obliged him to decline accepting an invitation from Philip II. to the court of Spain. He was consulted, however, with regard to the different plans given for the Escorial; and one which he furnished was highly approved, though not adopted. His other professional labours were interrupted by a commission from Gregory XIII. to settle the limits between the territories of the church and those of the duke of Tuscany; which commission he executed to the pope's satisfaction. Upon his return from this service, he was seized with a fever, of which he died in 1573, aged 66. His remains were solemnly interred in the church of Sta Maria della Rotonda, the ancient Pantheon. Vignola acquired reputation as an author no less than as a practical artist.

His "Rules for the five Orders of Architecture" were formed on the purest taste of antiquity, and have been always reckoned classical and original. This work has been often reprinted, and translated into almost all the European languages. The French translation, with the commentaries of Daviler, is most esteemed. Vignola also wrote a treatise on "Practical Perspective," which has passed through many editions. Tiraboschi. D'Argenville. Gen. Biog.

VIGNOLES, ALPHONSO DE, a learned Protestant minister, was born in 1649 at Aubais, in Languedoc, and received his education chiefly under domestic tutors; and for the study of theology he went to Saumur. He officiated as minister, first at Aubais, and then at Cailar. On the revocation of the edict of Nantes, in 1685, he removed to Brandenburg, and served several churches for 14 years. In 1701 he was elected a member of the Royal Academy of Sciences at Berlin; and in 1703, by the recommendation of Leibnitz, the king ordered him to quit his church, and reside at Berlin, that he might be thus more useful to the Academy. He preached, however, for some years at a church in the vicinity of Berlin. Upon the distribution of the members of the Academy into classes, Vignoles was placed first in that of historians, and afterwards in that of mathematicians. In 1727 he was chosen director of the Royal Academy, which post he occupied with distinguished reputation. He died in 1744, at the advanced age of 95. He contributed a variety of essays and dissertations on history, chronology, and antiquities, to the "Bibliothèque Germanique;" the "Memoirs of the Berlin Academy;" and the "Histoire Critique de la Republique des Lettres." His principal separate work, the result of labour and much erudition, was "Chronologie de l'Histoire sainte, et des Histoires étrangères qui la concernant, depuis la Sortie d'Egypte jusqu'à la Captivité de Babilon," Berlin, 1738, 2 vols. 4to. Moreri.

VIGNOLY, in *Geography*, a town of Naples, in Basilicata; 5 miles S.E. of Potenza.

VIGNORY, a town of France, in the department of the Upper Marne; 10 miles S. of Joinville.

VIGNOT, a town of France, in the department of the Meuse, on the Meuse; 17 miles E. of Bar le Duc. N. lat. 48° 46'. E. long. 5° 41'.

VIGNUOLA, or VIGNOLA, a town of Italy, in the department of the Panaro; 15 miles S.E. of Modena.

VIGNY, a town of France, in the department of the Seine and Oise; 8 miles W. of Pontoise.

VIGO, GIOVANNI DA, in *Biography*, an eminent surgeon, born in Genoa, and in 1503 invited to Rome by pope Julius II. to be his first surgeon. He also received a considerable pension from the pope's nephew, cardinal della Rovere. His work, entitled "Practica in Arte Chirurgica copiosa," first published at Rome in 1514, folio, became very popular, and was often reprinted. It is a very full compendium of the art of surgery, (as then known and practised), and contains also a system of anatomy and of materia medica, and was long regarded as a standard work. Another of his works, entitled "Chirurgia Compendiosa," 1517, is a kind of summary of the former, and some new observations. Haller. Eloy.

Vigo, in *Geography*, a sea-port town of Spain, in the province of Galicia, situated on a bay of the Atlantic, defended by a fort on an eminence, but not capable of great resistance. It has also an old castle, and stand in a very fruitful country. In 1589, Vigo was plundered by sir Francis Drake. In 1702, the English and Dutch fleets forced their passage in, and made themselves masters of the Spanish plate-fleet, when just returned from America. In

1719, the English again took possession of the place, but relinquished it after raising contributions; 12 miles N.N.W. of Tuy. N. lat. $42^{\circ} 14'$. W. long. $8^{\circ} 43'$.

VIGOER, a town of Norway, in the province of Bergen; 25 miles E. of Bergen.

VIGOLO, a town of the duchy of Piacenza; 15 miles S. of Piacenza.

VIGOLZANO, a town of the duchy of Piacenza; 8 miles S. of Piacenza.

VIGONE, a town of France, in the department of the Po; 14 miles S.S.W. of Turin.

VIGORETZKOI, a town of Russia, in the government of Olonetz; 20 miles E. of Povenetz.

VIGOROSO, or VIGORASAMENTE, in the *Italian Music*, is used to direct a performer to sing or play with vigour, strength, and firmness.

VIGTEN, in *Geography*, an island in the North sea, near the coast of Norway. N. lat. $64^{\circ} 55'$. E. long. $11^{\circ} 10'$.

VIGULONE, a town of the duchy of Parma; 15 miles S.S.W. of Parma.

VIHEL, a town of Hungary; 10 miles N.E. of Patak.

VIHIERS, a town of France, and principal place of a district, in the department of the Mayne and Loire; 20 miles S. of Angers. N. lat. $47^{\circ} 9'$. W. long. $27'$.

VIJAR, a town of Spain, in the province of Grenada; 13 miles N.E. of Almeria.

VIJAYA, in *Hindoo Mythology*, is the name of a granddaughter of Brahma, her father being Daksha. The name Vijaya, like Sarvajaya, means *victorious* or *all-conquering*, and is given to Parvati in some of her martial characters. In some books it is related, that in the process of churning the ocean, as described in our article KURMAVATARA, a flower or plant was produced, called Vijaya, or ever victorious, which Siva kept for his own use.

VIJBO, in *Geography*, a town of South America, in the jurisdiction of Guayaquil.

VIKA, a town of Sweden, in Dalecarlia; 6 miles S.E. of Fahlun.

VIKRAMA, or VIKRAMADITYA, in *Biography*, a celebrated astronomer and legislator of the Hindoos. The era named after him, corrupted into Bickermajit or Becker-majet, is in very extensive use in the East, both among Hindoos and Mahometans; though the latter, of course, generally among themselves adopt that of the Hegira. In the ninth volume of the Asiatic Researches is a learned essay by Mr. Wilford on the era named after this celebrated astronomer, who was a monarch also. His capital was *Ongin*, under which article we have given some account of that very interesting city, and some notice of its royal patron, and his era.

VILAINE, in *Geography*, a river of France, which rises near Ernée, in the department of the Mayenne, passes by Vitré, Châteaubourg, Rennes, Redon, Rieux, la Roche Bernard, &c. and runs into the Atlantic, 9 miles below the last town.

VILAINES, a town of France, in the department of the Côte d'Or; 8 miles S. of Châtillon sur Seine.

VILAR de Belle, a town of France, in the department of the Aude; 12 miles S. of Carcassonne.

VILASAR, a town of Spain, on the fourth coast of Catalonia; 2 miles W. of Matara.

VILASK, a town of Hungary; 8 miles N. of Libeten.

VILBEL, a town of Germany, in the county of Hanau-Munzenbourg, on the Nidda; 4 miles N. of Frankfort on the Maine.

VILBESTRE, a town of Spain, in the province of Leon; 43 miles S. of Salamanca.

VILCABAMBA, a town of Peru, in the diocese of Cusco; 60 miles N.N.W. of Cusco.—Also, a town of Peru; 70 miles S.S.E. of Cusco.—Also, a town of South America, in the province of Quito; 15 miles S. of Loxa.

VILCAS CUAMAN, or BILCAS, a town of Peru, and principal place of a jurisdiction of the same name, in the bishopric of Guamanga. The air is temperate, and the soil produces corn and fruit, and feeds abundance of cattle. The Indians are industrious, and employed in manufactures of different kinds of stuff.

VILEMERITZ, a town of Croatia; 6 miles S. of Sluin.

VILEPATTY, a town of the island of Ceylon; 12 miles W.N.W. of Trinkamaly.

VILEVO, a town of Sclavonia; 34 miles N.W. of Etzek.

VILFA, in *Botany*, an arbitrary name of Adanson's, in his *Fam. des Plantes*, v. 2. 495, adopted by Mr. Kunth, in Humboldt's *Nov. Gen. et Sp. Pl. v. 1. 137*. We cannot account for this adoption, there being nothing to recommend the name. Happily the genus which it designates is Mr. Brown's *SPOROBOLUS*. See that article.

VILILLA, in *Geography*, a town of Spain, in the province of Aragon, on the left side of the Ebro; 27 miles S.E. of Saragoña.

VILKIOT, a town of Sweden, in the province of Smaland; 23 miles N.W. of Calmar.

VILL, VILLA. See VILLAGE.

VILLA, a town of Etruria; 13 miles S.S.E. of Pontremoli.—Also, a town of South America, in the province of Paraguay; 90 miles E. of Assumption.—Also, a small island in the Atlantic, near the coast of Brasil. S. lat. $20^{\circ} 9'$.

VILLA, La, a town of New Grenada, on the Madalena; 16 miles N. of Neyba.—Also, a town of Mexico, in the province of Veragua, situated on the river Veragua, with a harbour fit to receive vessels of forty tons.

VILLA Bella, a town of Brasil, in the government of Matto Grosso.

VILLA Boa, a town of Brasil, and capital of the government of Goyas; 450 miles N.W. of Rio Janeiro. S. lat. 17° . W. long. $51^{\circ} 24'$.

VILLA Baim, a town of Portugal, in Alentejo; 4 miles S.W. of Elvas.

VILLA Boa, a town of Spain, in Guipuzcoa, on the Oriz; 6 miles from Tolofa.

VILLA do Carmo, a town of Brasil, in the government of Minas Geraes; 20 miles E.N.E. of Villa Rica. S. lat. $20^{\circ} 20'$. W. long. $44^{\circ} 30'$.

VILLA Cham, a town of Portugal, in the province of Beira; 11 miles E. of Coimbra.

VILLA Chan, a town of Portugal, in the province of Entre Duero e Minho; 5 miles N.W. of Barcelos.

VILLA Clara, a town of the island of Cuba; 20 miles N.W. of Spiritu Santo.

VILLA de Conde, a sea-port town of Portugal, in the province of Entre Duero e Minho, situated on the N. side of the river Ave; 9 miles E.S.E. of Barcelos. N. lat. $41^{\circ} 23'$. E. long. $8^{\circ} 21'$.

VILLA Diego, a town of Spain, in Old Castile, on the Pisuerga; 8 miles N.N.W. of Burgos.

VILLA Falter, a town of France, in the department of the Stura; 5 miles N.N.W. of Coni.

VILLA Faujini, in *Ancient Geography*, a town of Great Britain, in the fifth Iter of the route of Antonine, between Colonia

Colonia or Colchester, and Ictanos or Chesterford. This station is placed by Camden, Gale, and Baxter, at St. Edmund's Bury, in Suffolk; but Mr. Horsley prefers those copies of the Itinerary which have xxv for the numerals, and fixes it at Dunmow. Wherever it was situated, it probably derived its name from some great Roman called Faustinus having a country seat there.

VILLA Fernanda, in *Geography*, a town of Portugal, in Alentejo; 14 miles E. of Estremoz.

VILLA Flor, a town of Portugal, in the province of Trallos Montes; 12 miles S.E. of Mirandela.—Also, a town of Portugal, in the province of Alentejo; 7 miles N.N.W. of O Crato.

VILLA de Frades, a town of Portugal, in the province of Alentejo; 4 miles N. of Beja.

VILLA Franca, a town of Italy, in the department of the Benaco; 13 miles N. of Mantua.—Also, a town of Spain, in the province of Cordova; 13 miles N.E. of Cordova.—Also, a town of Spain, in Old Castile, on the Tormes; 25 miles S. of Avila.—Also, a town of Spain, in Old Castile; 9 miles S. of Frias.—Also, a town of Spain, in Old Castile; 10 miles E. of Burgos.—Also, a sea-port, and capital of St. Michael, one of the Azores islands. It is the most ancient town in the whole island; and so called from its being at first a free port. Before its harbour lies an island, about a mile in circumference, and towards the sea the town is defended by a fort and some other works. It consists of 1813 hearths, has two parish churches and two convents.—

Also, a town of Spain, in the province of Leon; 12 miles N.W. of Ponferrada.—Also, a town of Spain, in the province of Leon; 35 miles W. of Astorga.—Also, a town of Italy, in the Trevisan; 14 miles W. of Treviso.—Also, a town of France, in the department of the Dora; 3 miles S.E. of Aosta.—Also, a town of France, in the department of the Po; 16 miles S.S.W. of Turin.—Also, a sea-port town of France, in the department of the Maritime Alps, late the county of Nice, with two castles. The harbour is sheltered by some lofty hills, founded in 1295 by Charles II. king of Naples, who was earl of Provence: the citadel was built by duke Emanuel Philibert; 3 miles E. of Nice.

VILLA Franca de Panades, a town of Spain, in Catalonia, and principal place of a viguery; 20 miles S.W. of Barcelona.

VILLA Franca de Xira, a town of Portugal, in Estremadura, on the N. side of the Tagus; 15 miles N.E. of Lisbon.

VILLA Frechar, a town of Spain, in the province of Leon; 7 miles W.N.W. of Riofeco.

VILLA Gaba, a town of Brazil, in the government of St. Paul; 95 miles N.N.E. of St. Paul. S. lat. 22° 15'. W. long. 46° 6'.

VILLA Garcia, a town of Spain, in Estremadura; 4 miles N. of Llerena.

VILLA Haria, a town of Spain, in New Castile, on the left side of the Guadiana; 36 miles W. of Ciudad Real.

VILLA Hermosa, or *Dilla de Mofa*, a town of Mexico, in the province of Tabasco, on a river navigable by boats to Tabasco; chiefly inhabited by Indians; 56 miles S.W. of Tabasco. N. lat. 17° 40'. W. long. 94° 16'.

VILLA Hermosa, a town of Spain, in New Castile; 15 miles W.S.W. of Alcaraz.—Also, a town of Spain, in the province of Valencia; 24 miles N. of Segorbe.

VILLA de Horta, the chief town of Fayal, one of the Azores islands. It is situated in the bottom of the bay of Fayal, or De Horta, close to the edge of the sea, and is defended by two castles, one at each end of the town, and a wall of stone-work, extending along the sea-shore, from

the one to the other. But these works are in a state of decay, and seem more for show than strength. They brighten the prospect of the city, which makes a fine appearance from the road; and if we except the Jesuits' college, the monasteries, and churches, there is not another building that has any thing to recommend it, within or without. There is not a glass window in the place, except those of the churches, and in a country-house which lately belonged to the English consul; all the others being latticed, which to an Englishman has the aspect of prisons. This little city is crowded with religious buildings; it has three convents of men, and two of women, and eight churches. The Jesuits' college is a fine structure, and is seated on an eminence in the pleasantest part of the city. Since the expulsion of that order it is sinking into decay, and will probably soon be completely ruined. The Fayal wine, as it is called, is raised on the island Pico, and shipped abroad from De Horta, chiefly to America; from which circumstance it derives its name. Its bay or road of Fayal is situated at the E. end of the isle before the Villa de Horta, and facing the W. end of Pico. It is two miles broad, three-quarters of a mile deep, and has a semicircular form. N. lat. 38° 31' 55". W. long. 28° 38' 56".

VILLA d'Iglesias, or *Villa di Glesia*, a town of the island of Sardinia, and see of a bishop, in 1513 united to Cagliari; 36 miles S.W. of Cagliari. N. lat. 39° 28'. E. long. 8° 42'.

VILLA Imprenta, a town of Italy, in the department of the Mincio, on the Tione; 9 miles E. of Mantua.

VILLA Joiosa, or *Joyosa*, a town of Spain, in Valencia, on the coast of the Mediterranean; 18 miles N.N.E. of Alicante.

VILLA de Laguna, or *Lagoa*, a town of Brazil, in the jurisdiction of Rio de Janeiro.

VILLA Magna, or *Villa Privata*, in *Ancient Geography*, a place of Africa Propria, upon the route from Carthage to Alexandria, between Pontezita and Fisdia Vicus. Anton. Itin.

VILLA Magna, in *Geography*, a town of Naples, in Abruzzo Citra; 51 miles S.E. of Civita di Chieti.

VILLA Major, a town of Spain, in Galicia, on the coast of the Atlantic; 27 miles S.W. of St. Jago.—Also, a town of Spain, in Aragon; 12 miles S. of Saragozza.

VILLA Martin, a town of Spain, in Seville; 12 miles N.E. of Arcos.—Also, a town of Spain, in Leon; 22 miles E. of Leon.

VILLA Mayor, a town of Spain, in Leon; 30 miles S. of Leon.

VILLA de la Monclova, or *Le Coagula*, a town of New Mexico, in the province of New Leon.

VILLA Mofa. See *VILLA Hermosa*.

VILLA de Motta, a town of Istria; 3 miles S. of Capo d'Istria.

VILLA Nova, a town of France, in the department of the Sesa; 3 miles S. of Vercelli.—Also, a town of France, in the department of the Dora; 4 miles W. of Aosta.

VILLA Nova d'Alvio, a town of Portugal, in Alentejo; 18 miles N. of Beja.

VILLA Nova d'Anjos, a town of Portugal, in Estremadura; 5 miles S. of Montemor o Velho.

VILLA Nova d'Asli, a town of France, in the department of the Tanaro, so called because it was built by the inhabitants of Asli, from the ruins of some neighbouring villages; and when they understood the advantages of its situation, they surrounded it with walls, bastions, ramparts, deep fosses filled with water, half-moons, and other works.

It has besides two ancient towers, and two churches; 11 miles E. of Turin.

VILLA Nova de Barcarota, a town of Spain, in Estremadura; 27 miles S. of Badajoz.

VILLA Nova da Cerveira, a town of Portugal, on the S. side of the Minho, near its mouth, in the province of Entre Duero e Minho; 27 miles N.N.W. of Braga. N. lat. 41° 55'. W. long. 8° 27'.

VILLA Nova de Ficalho, a town of Portugal, in Alentejo, on the confines of Spain; 24 miles S.E. of Beja.

VILLA Nova de Fossa, a town of Portugal, in the province of Beira; 12 miles S.E. of St. Joao da Pefqueira.

VILLA Nova de Meyá, a town of Spain, in Catalonia; 13 miles N.N.E. of Balaguer.

VILLA Nova de Milfontes, a town of Portugal, in Alentejo; 11 miles S. of Sines.

VILLA Nova de Moncarros, a town of Portugal, in the province of Beira; 16 miles W. of Montemor o Velho.

VILLA Nova de Portimão, a sea-port town on the S. coast of Portugal, and province of Algarve. It is a fortified town, built in the year 1463, and contains about 500 mostly small and poor houses, surrounded by a high wall, beyond which is a small suburb, and is garrisoned by two companies. The river of Villanova flows close to the walls, is here considerably broad (next to the Guadiana, which is the largest in Algarvia), and discharges itself half a league from thence between high downs into the sea. The bar is dangerous, and the sand-banks shifting, so that the harbour cannot be very important; 9 miles E.N.E. of Lagos. N. lat. 37° 5'. W. long. 8° 28'.

VILLA Nova de Porto, a town of Portugal, in the province of Entre Duero e Minho, on the left side of the Duero, opposite Oporto, built in the year 1255, and containing about 3000 inhabitants.

VILLA Nova del Principe, a town of Brazil, in the jurisdiction of Bahia. N. lat. 17° 10'. W. long. 42° 34'.

VILLA Nova del Rio, a town of Spain, in the province of Seville, near the Guadalquivir; 18 miles N.N.E. of Seville.

VILLA Nueva, a town of Spain, in Catalonia, on the coast of the Mediterranean. It has no harbour, but a good road; 24 miles W. of Barcelona.—Also, a town of Spain, in Asturia; 43 miles W. of Oviedo.

VILLA Nueva de Gallego, a town of Spain, in Aragon, on the Gallego; 6 miles from Saragossa.

VILLA Nueva de Jaro, a town of Spain, in the province of Cordova; 27 miles N.N.E. of Cordova.

VILLA Nueva de los Infantes, a town of Spain, in Galicia; 12 miles S. of Orenfe.

VILLA Nueva de la Serena, a town of Spain, in Estremadura; 63 miles N. of Seville.

VILLA Nuova, a town of Istria; 9 miles E.S.E. of Umago.—Also, a town of the island of Sardinia; 10 miles S. of Algeri.—Also, a town of Italy, in the department of the Upper Po; 18 miles E. of Cremona.—Also, a town of the Popedom, in the marquisate of Ancona, on the coast of the Adriatic; 10 miles E. of Macerata.

VILLA Obleda, a town of Spain, in New Castile; 28 miles N. of Alcaraz.

VILLA Ombrosa, a town of Etruria; 14 miles E. of Florence.

VILLA del Ovo, a town of Brazil, in the jurisdiction of Matto Grosso.

VILLA do Ponte Trappa, a town of Portugal, in the province of Beira; 18 miles N.E. of Viseu.

VILLA del Principe, a town of the island of Cuba; 145 miles N.W. of St. Jago. N. lat. 21° 17'. W. long. 77° 45'.

VILLA do Principe, a town of Brazil, in the government of Minas Geraes; 360 miles N. of Rio Janeiro. This town is situated on the declivity of a lofty hill, the base of which is washed by a rivulet called Corvinha de quatro Vergtems. It was established as a comarço, or district, in the year 1730, when the gold-washings were most productive; though it dates its origin about fifteen years earlier, when the place was discovered by the Paupists, at the commencement of their migration from Villa Rica and the adjacent settlements. At present the town contains about 5000 inhabitants, most of whom are shop-keepers, and the rest artificers, farmers, miners, and labourers. As this town is situated very near the confines of the Diamond district, and on the high road leading to it, the passage of all persons thither is subject to the strictest regulations. The country round is very fine and open, being free from those impenetrable woods, which occur so frequently in other parts of the province. Its soil is in general very productive, and the climate mild and salubrious. N. lat. 17° 6'. W. long. 42° 44'.

VILLA Real, a town of Portugal, in the province of Algarve, built by Pombal, four leagues from Tavira. It is situated at the mouth of the Guadiana, which is here a broad and fine stream. It is built with perfect regularity, the streets in which are the handsomest houses being situated on the bank of the river, and the smaller houses at a greater distance. The pavement is good, and in the middle of the town is a handsome square, in which the town-house stands. But it is in a lamentable degree destitute of inhabitants, and without a company of soldiers, the place would be quite empty. Poverty every where appears, the adjacent country being very sandy, and the soil in many places consisting entirely of quicksand: the downs are planted with fig-trees. The entrance of the harbour is broad but not very deep. The town derives all its supplies, even of bread, from Ayamonte, the destruction of which was aimed at by the founder of this town.—Also, a town of Portugal, in the province of Tra los Montes, containing two churches, two hospitals, three convents, and about 2400 inhabitants; 9 miles N. of Lamego.—Also, a town of Spain, in the province of Valencia; 20 miles E. of Segorbe.—Also, a town of Spain, in Guipuzcoa; 6 miles S.S.W. of Paelencia.

VILLA Real de Conceição, a town of Brazil, in the government of Minas Geraes; 40 miles N.W. of Villa Rica.

VILLA del Rey, a town of Spain, in Estremadura, on the borders of Portugal, taken by the allies in the year 1706; 12 miles N. of Badajoz.—Also, a town of Spain, in Galicia; 22 miles S.E. of Orenfe.

VILLA de la Reyna, a town of Spain, in Estremadura; 12 miles E. of Llerena.

VILLA Rica, a town of Brazil, and capital of the jurisdiction of Minas Geraes; 150 miles N. of Rio Janeiro. S. lat. 20° 25'. W. long. 44° 36'. The town stands on a steep and lofty eminence, connected with others forming an immense chain, of which it is one of the highest. Most of the streets, irregular and badly paved, range in steps from the base to the summit, and are crossed by others which lead up the acclivity; but its environs exhibit few traces of cultivation. This town has been denominated the rich village; it is the capital of the province and the seat of its government, and has for many years been reputed the richest in Brazil, as it was the depository of all the gold found in the extensive surrounding district. This town is admirably supplied with water, which is conducted in a very convenient manner into almost every house; and in the streets are many fountains that are well constructed. One cistern contains water having a strong

strong taste of sulphate of iron, which the natives consider as serviceable in the cure of cutaneous diseases, and in which they often bathe.

The town is divided into two parishes, and contains a population of about 20,000 inhabitants, of whom there are more whites than blacks. The climate is delightful, and supposed to be equal to that of Naples; and though the latitude is only $20^{\circ} 3'$, yet on account of its elevated situation, the temperature of the air is generally moderate. The thermometer never exceeds 82° in the shade, and is rarely below 48° ; but its usual range is from 64° to 80° in summer; and from 48° to 70° in winter. The greatest heats prevail in January. Here are frequent showers of rain, and thunderstorms are common, but not violent. The sun is sometimes clouded by dews and mist so dense, as not to subside until the forenoon is far advanced. The gardens in the vicinity of the town are laid out with great taste, and present a curious spectacle, by their arrangement on the declivity of the mountain. They furnish an ample supply of vegetables of every kind, as artichokes, aparagus, spinach, cabbage, kidney-beans, and potatoes. The peach, which is the only exotic fruit hitherto introduced, flourishes in an astonishing degree.

The town is of considerable extent, but not so well peopled as when the mines were rich. The shop-keepers are a numerous class, and they are plentifully supplied with all sorts of English merchandize, except earthenware, hams, porter, and butter, which articles are dear. The market is ill supplied, notwithstanding the fertility of the surrounding district. Poultry might be had at a moderate price, from *3s. 6d.* to *4s. 6d.* per couple; beef was tolerable; pork very fine; but mutton utterly unknown. When Mr. Mawe visited this town in the year 1809, some of the inhabitants told him that it ought now to be termed "Villa Pobra," instead of "Villa Rica." Of above 2000 habitations which the town contained, a considerable proportion were untenanted, and the rents of the rest were continually lowering.

The mountain on which the town stands appeared to be eight or nine miles in length, narrow and almost insulated, being surrounded by deep ravines. It is composed of argillaceous schistus in almost every gradation, migrating from the compact blue slate into micaceous schistus. The first discovery of this once rich mountain was owing to the enterprising spirit of the Paulists, who, of all the colonies in Brazil, retained the largest portion of that ardent and indefatigable zeal for discovery which characterized the Lusitanians of former days. They penetrated from their capital, St. Paul's, through impervious woods, and disputed every inch of their progress with the barbarous Indians. Following the course of rivers, they occasionally found gold; till arriving at this mountain, its riches arrested their progress, and erecting temporary houses, they began their operations. They were soon joined by other adventurers from St. Paul's and other places. Their wealth proved the occasion of contests between the first settlers and new adventurers. When tranquility was re-established, a regular town began to be formed in 1711, and a code of laws enacted for the regulation of the mines. A fifth in weight of the gold-dust that was found was taken for the king, and the remainder purified, melted into ingots at the expence of government, then assayed, marked according to their value, and delivered to the owners, with a certificate to render them earnest: and for the convenience of trade, gold-dust was allowed to circulate for small payments. Smuggling, however, gained ground, and new regulations and provisions were adopted for restraining it. Villa Rica soon enjoyed a considerable

trade with Rio de Janeiro: the returns were negroes, iron, woollens, salt, provisions of various kinds, and wine, which then bore very high profits. About the year 1713, the royal fifth amounted to half a million sterling annually. Antonio Dias, the leader of the Paulists, who discovered this source of wealth, and became very rich, built a fine church, and at his death endowed it with considerable funds: it still bears his name: five or six others were begun and soon finished. The town also underwent many improvements; its streets were more regularly built, and the side of the mountain levelled for the site of new houses and gardens; reservoirs and fountains of water were constructed in different parts; and the mint and smelting-houses were enlarged. The number of inhabitants at this time amounted to 12,000, or upwards. Between the year 1730 and 1750, the mines were in the height of their prosperity; the king's fifth, as it is said, amounting to at least a million sterling.

At the present day, Villa Rica scarcely retains a shadow of its former splendour. Its inhabitants are unemployed, and the culture of the adjacent country neglected. Almost every trade is now occupied either by mulattoes or negroes, both of which classes seem superior in intellect to their masters, because they make a better use of it. However, the vicinity furnishes the means of acquiring wealth by its mines of gold, iron, and porcelain clay, &c. if the inhabitants had understanding or application to convert them into real value.

At the distance of eight miles from Villa Rica is Mariana, separated from it by a tremendous and almost impassable road, along a ridge of mountains. The Rio del Carmen runs through this town. This was made a bishop's see about the year 1715, and called Cidade de Mariana, in honour of the then reigning queen of Portugal. This is a small, neat, well-built town, containing from 6000 to 7000 inhabitants. It has a college for the education of young men designed for the church. This place has little trade, and depends chiefly on the mines and seams in its vicinity. Mawe's Travels.

VILLA Rica, a town of South America, in the province of Paraguay; 100 miles N.E. of Assumption.—Also, a town of Chili; 60 miles N.E. of Valdivia. S. lat. $38^{\circ} 50'$. W. long. $73^{\circ} 10'$.

VILLA Rodrigo, a town of Spain, in the province of Leon; 40 miles E. of Leon.

VILLA Rubia, a town of Spain, in New Castile; 6 miles E. of Ocana.

VILLA Rubia de los Ojos, a town of Spain, in New Castile; 12 miles N. of Calatrava.

VILLA de los Santos. See SANTOS.

VILLA de Sagra, a town of Italy, in Friuli; 15 miles W. of Gemona.

VILLA Savary, La, a town of France, in the department of the Aude; 14 miles W. of Carcassonne.

VILLA de Sul, a town of Portugal, in the province of Beira; 5 miles W. of Viseu.

VILLA del Valle, a town of South America, in the province of Chiquitos.

VILLA de Valle Fertile, a town of South America, in the province of Cuyo; 80 miles S.E. of Juan de la Frontera.

VILLA Vecchia, a town of the Ligurian Republic; 12 miles N. of Genoa.

VILLA Veja, a town of South America, in the government of Bahia, at first called St. Salvador.

VILLA Vella de Rodao, a town of Portugal, in Estremadura; 17 miles S.S.W. of Castel Branco.

VILLA Vicento, a town of Spain, in the province of Leon; 30 miles S. of Leon.

VILLA Vicoça, or VILLA Vizoça, or VILLA Vicioça, a town

of Portugal, in Alentejo, containing two parish churches, eight convents, and about 3700 inhabitants. In the neighbourhood is dug some beautiful green marble. Near it is a royal palace, with a park; 97 miles N.E. of Evora. N. lat. 38° 39'. W. long. 7° 12'.

VILLA *Viciofa*, a town of Spain, in the province of Cordova; 25 miles N.N.W. of Cordova.—Also, a town of South America, in the province of Quito; 10 miles S.E. of Quito.—Also, a sea-port town of Spain, in the province of Asturias, situated at the bottom of a bay of the Atlantic; 30 miles N.E. of Oviedo.

VILLA *Vieja*, a town of Spain, in Old Castile; 34 miles E. of Burgos.

VILLA *Regis*, or *Regia*, a title anciently given to those villages where the kings of England had a royal seat, and held the manor in their own demesne; having there commonly a free chapel exempt from the bishop's jurisdiction.

VILLABAR, in *Geography*, a town of Portugal, in the province of Tras os Montes; 15 miles S.E. of Miranda.

VILLACANAS, a town of Spain, in New Castile; 32 miles E.S.E. of Toledo.

VILLACASTIN, a town of Spain, in Old Castile; 18 miles W.S.W. of Segovia.

VILLACERF, a town of France, in the department of the Aude; 8 miles N.W. of Troyes.

VILLACH, a town of the duchy of Carinthia, on the right side of the Drave. Near the town are some medicinal baths; 18 miles W. of Clagenfurt. N. lat. 46° 43'. E. long. 13° 39'.

VILLACO, a town of the island of Corfica, in the district of Corte.

VILLACURI, a town of Peru, in the audience of Lima; 12 miles E.S.E. of Pisco.

VILLADA, a town of Spain, in the province of Leon; 27 miles N.W. of Palencia.

VILLÆ PREPOSITUS. See PREPOSITUS.

VILLAFAPILA, in *Geography*, a town of Spain, in the province of Leon; 20 miles N.N.E. of Zamora.

VILLAFELICHE, a town of Spain, in the kingdom of Aragon; 3 miles N. of Daroca.

VILLAFREDDA, a town of Naples, in Lavora; 9 miles N.N.W. of Sezza.

VILLAFRIA, a town of Spain, in Guipuzcoa; 12 miles E.S.E. of Trevigno.

VILLAGE, *Villa*, or *Vill*, an assemblage of houses, inhabited chiefly by peasants and farmers, having usually a church, but no market.

The word is French, formed of *vil*, or *vilis*, *low*, *mean*, *contemptible*: or rather, from the Latin *villa*, a *country-house*, or *farm*.

The want of a market distinguishes a *village* from a *town*, as the church does from a *green*, *street*, &c. Among our Saxon ancestors, *vill*, or *village*, was used in the sense of the Roman *villa*; *viz.* for a country farm, or seat, furnished with convenient outhouses, &c. for repositing the fruits thereof. Afterwards it came to be taken for a manor; and then for part of a parish, or the parish itself.

Hence, in several ancient law-books, *vill* and *parish* are the same thing: accordingly, Fortescue de Laudibus Leg. Ang. writes, "That the boundaries of villages are not by houses, streets, or walls; but by a large circuit of ground, within which may be divers hamlets, waters, woods, &c."

Fleta makes this difference between a *manſion*, a *village* and a *manor*; that a manſion may consist of one, or more houses; though there is only to be one dwelling-place, without any other very near it: for if other houses be conti-

guous, it is then a village. A manor may consist of one or more villages.

For the better government of villages, the lord of the soil has usually a power to hold a court-baron every three weeks.

The statute of Exeter, 14 Edw. I., makes frequent mention of entire-vills, demi-vills, and hamlets.

Entire-vills, fir H. Spelman conjectures to have consisted of ten freemen, or frank-pledges, demi-vills of five, and hamlets of less than five. See TOWN.

VILLAGE *Bay*, in *Geography*, a bay on the west coast of Africa. S. lat. 14° 25'.

VILLAGRA, a town of Spain, in the province of Leon; 17 miles N. of Rio Seco.

VILLAIN, or VILLEIN, *Villanus*, in our *Ancient Customs*, the same with *bondman*: called also, in Domesday-book, *seruus*, *ſlave*.

A villain was one who held lands in *villanage*, or on condition of rendering base services to his lord.

Under the Saxon government, there was, as fir William Temple speaks, a sort of people in condition of downright servitude, employed in the most servile works, and belonging, they, their children and effects, to the lord of the soil, like the rest of the cattle or stock upon it. These seem to have been those who held what was called the *ſolk-land*, from which they were removable at the lord's pleasure. On the arrival of the Normans here, it seems not improbable, that they, who were strangers to any other than the feudal state, might give some sparks of enfranchisement to such wretched persons as fell to their share, by admitting them, as well as others, to the oath of fealty, which conferred a right of protection, and raised the tenant to a kind of state superior to downright slavery, but inferior to every other condition.

This they called *villanage*, and the tenants *villains*, either from the word *vilis*, or else, as fir Edward Coke tells us, à *villa*, because they lived chiefly in villages, and were employed in rustic works of the most fordid kind: hence they were also denominated *pauperes* and *ruffici*. These villains, belonging principally to lords of manors, were either villains *regardant*, by the civilians called *glebe additi* or *ascriptitii*, that is, annexed to the manor or land; or else they were *in groſſi*, or at large, that is, annexed to the person of the lord, and transferrable from one owner to another. They could not leave their lord without his permission; but if they ran away, or were purloined from him, might be claimed and recovered by action, like beasts or other chattels. They held indeed small portions of land by way of sustaining themselves and families; but it was at the mere will of the lord, who might dispossess them whenever he pleased; and it was upon villain services, that is, to carry out dung, to hedge and ditch the lord's demesnes, and any other the meanest offices; and their services were not only base, but uncertain both as to time and quantity. A villain could acquire no property either in lands or goods; but if he purchased either, the lord might enter upon them, oust the villain, and seize them to his own use, unless he contrived to dispose of them again before the lord had seized them; for the lord had then lost his opportunity. In many places also, a fine was payable to the lord, if the villain presumed to marry his daughter to any one without leave from the lord; and by the common law, the lord also might bring an action against the husband for damages in thus purloining his property. For the children of villains were also in the same state of bondage with their parents; whence they are called in Latin *nativi*, whence the female appellation of a villain, who was called a *neife*. In case of a marriage between a freeman and a neife, or a villain and a free-woman, the

The issue followed the condition of the father, being free if he was free, and villain if he was villain; but no bastard could be born a villain. The law, however, protected the persons of villains, as the king's subjects, against atrocious injuries of the lord; for he might not kill, or maim his villain; though he might beat him with impunity, since the villain had no action or remedy at law against his lord, but in case of the murder of his ancestor, or the maiming of his own person. Neives indeed had also an appeal of rape, in case the lord violated them by force.

Villains might be enfranchised by manumission. Hence, and by other means, they gained in process of time considerable ground on their lords; and in particular strengthened the tenure of their estates to that degree, that they came to have in them an interest in many places full as good, in others better than their lords. For the good-nature and benevolence of many lords of manors having, time out of mind, permitted their villains, and their children, to enjoy their possessions without interruption, in a regular course of descent, the common law gave them title to prescribe against their lords; and, on performance of the same services, to hold their lands, in spite of any determination of the lord's will. For though, in general, they are said to hold their estates at the will of the lord; yet it is such a will as is agreeable to the customs of the manor; which customs are preserved and evidenced by the rolls of the several courts-baron in which they are entered, or kept on foot by the constant immemorial usage of the several manors in which the lands lie. And, as such tenants had nothing to shew for their estates but these customs, and admissions in pursuance of them, entered on those rolls, or the copies of such entries witnessed by the steward, they now began to be called *tenants by copy of a court-roll*, and their tenure itself a *copyhold*. Copy-holders are, therefore, in truth no other but villains, who, by a long series of immemorial encroachments on the lord, have at last established a customary right to those estates, which were before held absolutely at the lord's will. These encroachments at length became so universal, that when tenure in villenage was virtually abolished (though copy-holds were reserved) by the statute of Charles II. there was hardly a *pure* villain left in the nation. To this purpose Sir Thomas Smith testifies, that in all his time (and he was secretary to Edward VI.) he never knew any villain in grofs throughout the realm; and the few villains regardant that were then remaining, were such only as had belonged to bishops, monasteries, and other ecclesiastical corporations, in the preceding times of popery. By several means, the generality of villains in the kingdom have long ago sprouted up into copy-holders; their persons being enfranchised by manumission, or long acquiescence; but their estates, in strictness, remaining subject to the same servile conditions and forfeitures as before; though, in general, the villain services are usually commuted for a small pecuniary quit-rent. Blackst. Com. book ii. See VILLENAGE.

VILLAIN *Estate, or Condition*, is contradicting with the *free estate*. See *BASE TENURE*, and VILLENAGE.

VILLAINAGE. See VILLENAGE.

VILLAINNE, in *Geography*, a town of France, and principal place of a district, in the department of the Mayenne; 12 miles E.N.E. of Mayenne. N. lat. 48° 21'. W. long. 0° 11'.

VILLAINOUS JUDGMENT, is that which casts the reproach and stain of villainy and shame on him against whom it is given. As that against a conspirator, &c. See CONSPIRACY.

Lambard calls it *villainous punishment*; and says, it may well be called *villainous*, in regard the judgment, in such

case, shall be like the ancient judgment in attain, viz. that the criminals shall not be of any credit afterwards: nor shall it be lawful for them, in person, to approach the king's court; that their lands and goods shall be seized into the king's hands, their trees rooted up, their bodies imprisoned, &c.

This villainous judgment is now become obsolete; it not having been pronounced for some ages; but instead of it, the delinquents are usually sentenced to imprisonment, fine, and pillory.

VILLALAR, in *Geography*, a town of Spain, in the province of Leon; 12 miles N.N.W. of Rio Seco.

VILLALBA, a town of Spain, in Estremadura; 32 miles S.E. of Badajoz.—Also, a town of Spain, in Galicia; 18 miles S.W. of Mondonedo.

VILLALON, a town of Spain, in the province of Leon; 25 miles W.N.W. of Palencia.

VILLALPANDA, JOHN-BAPTIST, in *Biography*, a native of Cordova, entered the society of Jesus in 1571, and distinguished himself by a learned and diffuse commentary on the book of Ezekiel, in three vols. fol. Rome, 1596. It contains an elaborate description of the city and temple of Jerusalem. He also published, in 1598, "Explanatio Epistoliarum Sancti Pauli," under the name of Remi of Rheims, to whom he found it ascribed in a manuscript dated in 1067. This Jesuit died in 1608. Dupin.

VILLALPANDO, in *Geography*, a town of Spain, in the province of Leon; 33 miles S. of Leon.

VILLALTA, a town of Italy, in the country of Friuli; 5 miles W. of Udina.

VILLALVA, a town of Spain, in Galicia; 15 miles S. of Mondonedo.

VILLAMBEA, a town of Spain, in New Castile; 25 miles S.S.E. of Madrid.

VILLAMEA, a town of Portugal, in the province of Beira; 4 miles S. of Lamego.

VILLAMEDO, a town of Spain, in Estremadura; 12 miles W.S.W. of Talavera la Vieja.

VILLAMENA *de la Jarra*, a town of Spain, in the province of Cordova; 27 miles N.N.E. of Cordova.

VILLAMIEL, a town of Spain, in the province of Leon; 43 miles S. of Ciudad Rodrigo.

VILLANDRAUT, or VILLANDRADE, a town of France, in the department of the Gironde; 8 miles W.N.W. of Bazas.

VILLANDRY, a town of France, in the department of the Indre and Loire; 9 miles W.S.W. of Tours.

VILLANELLA, in *Italian Music*, rustic airs that were sung about the streets of Naples in the 16th century, in three and four parts, as serenades. They are sometimes called *villotte* and *villanesche alla Napolitana*.

VILLANI, GIOVANNI, in *Biography*, a native of Florence, was old enough in 1300 to visit Rome at the jubilee, and is supposed to have afterwards travelled into France and Flanders. In 1316 and 1317 he was one of the magistrates called priors at Florence, and also in the latter year official of the mint, to whom was due an exact register, still extant, of all the money coined at Florence in and before his time. He served in the Florentine army in 1323, and in 1328 contrived means for relieving his poor countrymen at a period of distressing scarcity. On occasion of the failure of the company of Bonaccorsi, in which he had a share, in 1345, and to which he was not accessory, he was committed to the public prison, and his life was terminated by the plague, which severely visited Florence in 1348. Villani bears the character of one of the most polished writers of his age, and the most conversant in the history of his country. His History

History records, in twelve books, the events occurring in Florence from its foundation till the year of his death, and comprehends also the principal changes that happened in the other Italian provinces. The early part of this History abounds with errors and fables; but in describing the occurrences of Tuscany in his own time, he is deemed a safe guide, allowing for his partiality to the Guelph interest, and for his unacknowledged extracts from the History of Ricordano Malaspini. This History, which has been always much esteemed, both for its matter and the elegance of its style, was first printed by the Giunti of Florence in 1537, and the latest of several editions of it was that of Milan, in the collection of Italian historians. It was continued after his death by his brother, MATTEO VILLANI, who brought it down to 1363, in which year, whilst he was writing the 11th book, he was carried off by the plague. His History is not held in equal estimation with that of his brother, its style being too diffuse; but he was contemporary with the events which he relates. Tiraboschi. Gen. Biog.

VILLANI, FILIPPO, son of *Matteo*, was educated for the law, and was for many years chancellor to the municipality of Perugia. But he chiefly devoted himself to literary pursuits, and in 1404 delivered lectures on the *Commedia* of Dante. He added forty-two chapters to his father's History of Florence, thus completing the 11th book. He also composed the "Lives of illustrious Florentines," originally written in Latin, but translated into Italian, and published in 1747 by Mazzuchelli, with copious annotations. The first book of this work treated of the origin and antiquities of Florence. Tiraboschi. Gen. Biog.

VILLANTERIA, in *Geography*, a town of Italy, in the department of the Upper Po; 9 miles S.W. of Lodi.

VILLAR, a town of France, in the department of Mont Blanc; 9 miles W. of Conflans.

VILLAR *Mayor*, a town of Portugal, in the province of Beira; 5 miles N. of Alfayates.

VILLAR de *Canas*, a town of Spain, in New Castile; 25 miles S. of Huete.

VILLAR de *Toro*, a town of Portugal, in the province of Beira; 10 miles N. of Alfayates.

VILLARA, a town of Spain, in the province of Biscay; 13 miles S. of Bilbao.

VILLARCAYO, a town of Spain, in Old Castile; 12 miles N. of Frias.

VILLARD de *Lans*, *Le*, a town of France, in the department of the Isere; 8 miles S.S.W. of Grenoble.

VILLARD *St. Pancraee*, a town of France, in the department of the Higher Alps; 3 miles S. of Briançon.

VILLAREJORUBIA, a town of Spain, in New Castile; 35 miles S.E. of Cuenca.

VILLARESIA, in *Botany*, a genus named after Matthew Villares, a Spanish botanist, in the Flora Peruviana, p. 28, according to De Theis. We have no account of its characters.

VILLARET, CLAUDE DE, in *Biography*, was born at Paris in 1715, and liberally educated, but prevented, by the pernicious influence of youthful passions, from duly availing himself of his acquisitions. After writing a novel and a piece for the theatre, he quitted Paris in 1748, and went upon the stage at Rouen, and other places. But renouncing this mode of life at Liege in 1756, he returned to Paris, and becoming first clerk in the chamber of accounts, he was reclaimed from his dissipated course, and made himself acquainted with those sources of French history to which his office gave him access. On the death of the abbé Velly in 1759, he was selected for continuing his History; and at the same time was made secretary to the peerage. His early

imprudence and his subsequent application to business terminated his life in 1766. His continuation of the "Histoire de France" commences in the 8th volume, with the reign of Philip VI. and concludes in the 17th volume: it abounds with interesting remarks and curious anecdotes, but the reader is diverted from the main object by prolixity of detail in prefaces and digressions. The style however is elegant and animated, but too rhetorical for the simplicity of history. Villaret was also the author of "Confidérations sur l'Art du Theatre," 1758; and "L'Esprit de Voltaire," 1759. Nouv. Dict. Hist.

VILLARIA, in *Botany*, was intended by Schreber to commemorate the excellent author of the "Histoire des Plantes de Dauphiné," M. Villars, formerly physician to the military hospital at Grenoble, who died professor of botany at Straßburg, two or three years ago, where his bier was elegantly decorated with wreaths of his own *Rosa rubrifolia*; see ROSA, n. 44. He published there, in 1807, a "Catalogue Méthodique du Jardin de l'Ecole de Médecine de Straßburg," in French, according to Jusseu's system, with a historical, critical and practical preface. Villars was an excellent and indefatigable observer of nature, well worthy of commemoration, which makes us regret our total want of information respecting his genus, except the generic characters given by Schreber. As this author did not live to write a work on the species of plants, and has left no account of the native country, number of species, nor any other circumstance in the history of his *Villaria*, the genus can never be properly adopted. We shall only here remark, that the name ought certainly to be VILLARSIA; see that article.—Class and order, *Diocia Pentandria*. Nat. Ord. perhaps *Rhamnii* or *Sapindi* of Jusseu.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in five deep, spreading, roundish, obtuse, concave, coriaceous, nearly equal, segments, thinner at the margin, permanent; two of them interior. *Cor.* Petals five, oblong, obtuse, flat, spreading, coriaceous, thinner at the margin, twice the length of the calyx, permanent. *Stam.* Filaments five, awl-shaped, erect, half as long as the calyx; anthers roundish, two-lobed. *Pist.* Germen orbicular, depressed (we presume imperfect); style very short; stigma capitate.

Female, *Cal.* and *Cor.* as in the male. Nectary of five ovate, obtuse, erect, permanent leaves, alternate with the petals, and not so long. *Pist.* Germen turbinate, somewhat ovate; style very short, scarcely any; stigma capitate, slightly three-cleft. *Peric.* Berry nearly globular, pointed with the permanent style, three-celled. *Seeds* solitary.

Obf. This description is materially defective, inasmuch as there is no mention of the germen being inferior or superior, nor indeed any useful information with regard to the respective insertion of the parts; except the leaves of the nectary being alternate with the petals, which, if true, militates against our conjectures as to the natural order of this genus. Nevertheless, we shall attempt an essential character, in hopes that those who have access to the learned Schreber's herbarium, may discover, and communicate to the world, a complete history of the plant in question.

Eff. Ch. Male, Calyx in five deep segments. Corolla of five petals. Nectary none. Germen orbicular, imperfect.

Female, *Cal.* and *Pet.* like the male. Nectary of five leaves, alternate with the petals. Style one. Berry of three cells. Seeds solitary.

VILLARINO, in *Geography*, a town of Spain, in the province of Leon, on the E. side of the Duero, and confines of Portugal; 38 miles W. of Salamanca.

VILLARLUENGO, a town of Spain, in Aragon; 21 miles S.W. of Alcaniz.

VILLAROYA, a town of Spain, in the kingdom of Aragon; 15 miles N.W. of Calataud.

VILLARRAMEL, a town of Spain, in the province of Leon; 16 miles W. of Palencia.

VILLARS, LOUIS-HECTOR, duke of, and marshal of France, in *Biography*, was born at Moulins, in Bourbonnois, in 1653, and commenced a military life in his youth. He served in Holland in 1672, signalized his courage at the siege of Maestricht in 1673, and was wounded at the battle of Senef in 1674. We cannot follow him through all his gradations of advancement and displays of military talents; but we find, at the famous battle of Blenheim, that he was defined by Lewis XIV. to check the progress of Marlborough. With an inferior army he kept the victors at bay, so that the campaign of 1705 passed off without any further loss to France. After various other services, in which he distinguished himself, he was appointed to command in Flanders against the allies in 1709; and marching to the relief of Mons, he was attacked by Marlborough and Eugene at Malplaquet. The engagement was long and bloody, and though the French were driven from the field, the greatest loss of men was sustained by the victors. To a wound which compelled Villars to withdraw from the field, he attributed the loss of the battle. In reference to this gaffade (as some would be disposed to call it), Voltaire observes, "I know that the marshal himself was persuaded of it, but I also know, that few others were so." As a further reward for his services, he was made a peer of France, and lieutenant-general of the bishoprics of Metz and Verdun. Although France was relieved by the separation of England from the alliance in 1712, Eugene produced consternation at Paris by besieging Landrecy with a superior force. On this occasion, Villars attacked a part of the allied army at Denain, which he entirely broke up, and this success led to the recovery of all the places lost by the French in that quarter, at the restoration of their superiority. The peace of Utrecht followed; and the emperor having refused to be comprehended in it, marshal Villars and Eugene held conferences at Radstadt in 1714, for a treaty between their respective sovereigns, which they conducted with the frankness of military men, and soon brought to a conclusion. Villars, who had experienced the attacks of envy and jealousy at his own court, said to Eugene on this occasion: "Sir, we are not enemies; your enemies are at Vienna, and mine at Versailles."

After the death of Lewis XIV., Villars for some time maintained his credit at court; being made president of the council of war in 1715, and one of the council of regency in 1718. But when Lewis's system was in agitation, he thought it his duty to state to the regent the evils which, in his apprehension, would result from it; and he thus contributed to the discharge of that financier, and to the appointment of his successor. When the regency devolved upon the duke of Bourbon, Villars was always consulted, who was then at the height of his fortune:—a marshal of France, a duke and peer, governor of Provence, a grandee of Spain, a knight of the golden fleece, and a member of the council. What more was wanting to gratify ambition? When France was excluded from the treaty that was brought about by the intrigues of the principal courts of Europe between the emperor, Spain and England, a war broke out in 1733; and Villars, with the title of general of the camps and armies (dormant since Turenne), was sent, at the age of eighty, to command in the Milanese. But though he met with some success, age and infirmities would not allow him to make more than one campaign. On his return to France, he was seized with a disorder that terru-

nated his life at Turin. When his confessor observed to him, that God had favoured him with more time to prepare for death than marshal Berwick, who had just been killed by a cannon-ball at the siege of Philipsburg, "What! (said he) has he ended his life in that manner? I always said that he was more fortunate than I." He soon after expired, in June 1734, in the eighty-first year of his age.

The character of Villars is thus delineated by one of his biographers. "Marshal Villars was a true military genius, full of courage and confidence, who raised himself by persisting in always doing more than his duty. He was reproached with having less modesty than valour, and with speaking of himself as he had deserved that others should speak of him. Nor was he sparing of censures on others, and he employed rather defiance than conciliation towards his enemies. Though possessing integrity and lively parts, he was therefore never able to render himself popular, or to acquire friends. In action he was always present where the danger was greatest; and he held it as a maxim, 'that a general ought to expose himself as much as he exposes others.'" Villars was admitted into the French Academy in 1714. "Memoirs of the Marshal de Villars" were printed in Holland, in three vols. 1734-36, the first of which alone was written by himself. A more interesting publication appeared in 1784, entitled "La Vie du Maréchal de Villars, écrite par lui-même, et donnée au Public par M. Anquetil," four vols. 12mo. This work contains the letters, recollections, and journal of the marshal, properly arranged by the editor. Moreri. Gen. Biog.

VILLARS DE MONTFAUCON DE, a relation of the celebrated father Montfaucon, was educated for the church, and came from Toulouse to Paris in order to obtain distinction as a preacher. He was received into the best company, and made himself known by several works, especially by his "Comte de Gabalis, ou Entretiens sur les Sciences secretes," first printed at Paris in 1670. This work is a kind of jocoseries view of the Rosycrucian philosophy, rendered amusing as a romance. From this source Pope derived his machinery of the "Rape of the Lock." Villars, in consequence of this work, which was thought to contain heretical notions, was forbidden the pulpit. He added to it a second part, and it has been several times reprinted; the last time in 1742, two vols. 12mo. He was also the author of several other works. He was killed by a pistol-shot, by one of his relations, on the road from Paris to Lyons, in 1675, when he was about thirty-five years of age. Bayle. Moreri.

VILLARS, in *Geography*, a town of France, in the department of the Ain; 8 miles S.E. of St. Trivier.

VILLARSIA, in *Botany*, a genus more correctly named, as to its orthography, than VILLARIA, (see that article,) but with respect to its distinctive character, we fear, less certain. It consists of such species of the Linnean *Mentanthes*, as have the corolla only partially covered with hairs, and the margin of whose segments is thin, inflexed in the bud. The leaves moreover are simple, not ternate. Gmelin had long ago established this same genus, in the Petersburg Transactions for 1760, by the name of *Limnanthemum*; and Wiggers in his *Primitive Floræ Holstatiæ*, p. 20, published in 1780, by that of *Waldschmidia*. Yet in spite of these prior claims, Ventenat, in his *Choix de Plantes*, t. 9, has followed a more recent authority, if it may be called, in naming these plants *Villarfa*, and he is followed by Mr. Brown, in his *Prodr. Nov. Holl.* v. 1. 456. The authority to which we allude is that of another Gmelin, late professor at Gottingen, who in his compiled edition of Linneus's Systema, took upon him to bestow gratuitously appellations

appellations on numerous genera, which the modest unpretending Walter, in his *Flora Caroliniana*, had left for the future examination and decision of more experienced botanists. His *Anonymos*, n. 109, is the *Villarfa* of this professor Gmelin, in Linn. Syst. Nat. v. 2. 447; neither of these authors seeming to have the least idea of the plant being already described or named.—Notwithstanding what these writers have done, Mr. Dryander, in *Ait. Hort. Kew.* v. 1. 312, has followed the example of Linnæus, Jussieu, Schreber, Willdenow, and the writer of this in his *Fl. Brit. and English Botany*, in keeping all the species, which constitute *Villarfa*, in the genus *MENYANTHES*; see that article. There we trust they may safely remain, and perhaps the above authorities may at least neutralize each other, with respect to botanical discrimination, as well as nomenclature. We must not omit that Mr. Pursh, in his *Flora Amer. Sept.* 139, has adopted the present *Villarfa*, but without throwing any new light upon its characters.

VILLARUM NOMINA. See NOMINA.

VILLASANDINO, in *Geography*, a town of Spain, in Old Castile; 20 miles N.W. of Burgos.

VILLASECA, a town of Spain, in Catalonia, on the coast of the Mediterranean; 6 miles W. of Tarragona.

VILLASIDRA, a town of the island of Sardinia; 10 miles N.E. of Villa d'Iglesias.

VILLATTE, a town of France, in the department of the Creuse; 11 miles N.W. of Gueret.

VILLAVANEZ, a town of Spain, in the province of Leon; 12 miles S. of Palencia.

VILLAYER FERTANS, a town of France, in the department of the Doubs; 5 miles S.S.W. of Ornans.

VILLAZIM, a town of Portugal, in the province of Beira; 23 miles S.S.E. of Viseu.

VILLE, a town of France, in the department of the Lower Rhine; 8 miles N.W. of Schleitstätt.—Also, a town of France, in the department of the Marne; 9 miles S.W. of Rheims.—Also, a town of France, in the department of the Marne; 9 miles N.N.W. of St. Menehould.

VILLE aux Cleres, La, a town of France, in the department of the Loire and Cher; 24 miles N.W. of Blois.

VILLE Comtal, a town of France, in the department of the Gers; 11 miles S.W. of Mirande.—Also, a town of France, in the department of the Aveyron; 18 miles W. of St. Genies de Rivedolt.

VILLE Franche, a town of France, and principal place of a district, in the department of the Aveyron; 24 miles W. of Rhodéz. N. lat. $44^{\circ} 21'$. E. long. $2^{\circ} 7'$.—Also, a town of France, in the department of the Lot and Garonne; 6 miles E. of Castel Jaloux.—Also, a town of France, and principal place of a district, in the department of the Upper Garonne, on the Garonne; 18 miles S.E. of Toulouse. N. lat. $43^{\circ} 24'$. E. long. $1^{\circ} 49'$.—Also, a town of France, and seat of a tribunal, in the department of the Rhône and Loire, on the right bank of the Rhône. It is surrounded with walls and ditches; $3\frac{1}{2}$ posts N. of Lyons. N. lat. $46^{\circ} 7'$. E. long. $4^{\circ} 48'$.—Also, a town of France, in the department of the Allier; 15 miles S.W. of Moulins.—Also, a town of France, in the department of the Dordogne; 15 miles S.W. of Mucidan.

VILLE Franche d'Albigois, a town of France, in the department of the Tarn; 8 miles E.S.E. of Alby.

VILLE Franche d'Astarac, a town of France, in the department of the Gers; 14 miles S. of Auch.

VILLE Franche de Conflans, a town of France, in the department of the Eastern Pyrenées; defended by a fort, erected in the reign of Louis XIV.; 27 miles W.S.W. of Perpignan.

VILLE Franche de Panat, a town of France, in the department of the Aveyron; 6 miles W. of Milhaux.

VILLE Franche de Perigord, a town of France, in the department of the Dordogne; 36 miles S.S.E. of Périgueux.

VILLE sur Ilon, a town of France, in the department of the Vosges; 9 miles W. of Epinal.

VILLE en Tardenois, a town of France, in the department of the Marne; 10 miles S.W. of Rheims.

VILLE sur Tourbe, a town of France, in the department of the Marne; 8 miles N.N.W. of St. Menehould.

VILLE Vaucance, a town of France, in the department of the Ardèche; 14 miles N.N.W. of Tournon.

VILLE Vieu, La, a town of France, in the department of the Vienne; 8 miles S. of Poitiers.

VILLEBERNIER, a town of France, in the department of the Mayne and Loire; 3 miles E. of Saumur.

VILLEBOIS, a town of France, in the department of the Ain; 6 miles S. of St. Rambert.

VILLEBOURG, or VILLE BOUREAU, a town of France, in the department of the Indre and Loire; 18 miles N.N.W. of Tours.

VILLEBRUMIER, a town of France, in the department of the Upper Garonne; 15 miles S.E. of Castel Sarafin.

VILLECROSE, a town of France, in the department of the Var; 9 miles N.N.W. of Draguignan.

VILLEDEIU, a town of France, in the department of the Mayne and Loire; 9 miles N.W. of Chollet.—Also, a town of France, in the department of the Vienne; 12 miles S.E. of Poitiers.—Also, a town of France, in the department of the Loire and Cher; 18 miles W. of Vendôme.—Also, a town of France, in the department of the Channel; 8 miles N.N.E. of Avranches.

VILLEFAGNAN, a town of France, in the department of the Charente; 6 miles S.S.W. of Ruffec.

VILLEFLEUR, a town of France, in the department of the Lower Seine; 2 miles N. of Cany.

VILLEFORE, JOSEPH-FRANÇOIS-BOURGOIN DE, in *Biography*, was born of a noble family at Paris in 1652, and liberally educated. In 1706 he was admitted a member of the Academy of Inscriptions; but withdrew from it in 1708, because he did not choose to perform its burdensome exercises. He passed the remainder of his life in the cloister of the metropolitan church, and died in 1737, at the age of 85. His historical and biographical works, the latter being chiefly religious, were numerous. He also made several translations from St. Augustine, St. Bernard, and Cicero, which are faithful, and occasionally elegant. He was likewise the author of some smaller pieces in classical literature. Moreri.

VILLEFORT, in *Geography*, a town of France, and principal place of a district, in the department of the Lozère; 20 miles E. of Mende. N. lat. $44^{\circ} 27'$. E. long. $3^{\circ} 59'$.

VILLEHARDOUIN, GEOFFROI DE, in *Biography*, was marshal of Champagne, an office held by his father and his descendants. He took a principal part in the fourth crusade of 1198, which produced the capture of Constantinople by the French and Venetians in 1204; and of this expedition he wrote or dictated a narrative, which is curious and interesting. The best edition is that of Du-Cange, fol. 1657, with many notes. Moreri.

VILLEIN FLEECES, in our *Statutes*, are bad fleeces of wool, shorn from scabby sheep. 31 Edw. III. cap. 8.

VILLEJUIF, in *Geography*, a town of France, in the department of Paris; 3 miles S. of Paris.

VILLEL, a town of Spain, in New Castile; 17 miles N.N.W.

N.N.W. of Molina.—Also, a town of Spain, in New Castile; 15 miles S. of Molina.

VILLELOIN, or VILLELOUP, a town of France, in the department of the Indre and Loire; 9 miles E.N.E. of Loches.

VILLEMAUR, a town of France, in the department of the Aube; 14 miles W.S.W. of Troyes.

VILLEMONTAIS, a town of France, in the department of the Rhône and Loire; 8 miles S.W. of Roanne.

VILLEMUR, a town of France, in the department of the Upper Garonne; 17 miles N. of Toulouse.

VILLENA, a town of Spain, in the province of Murcia. In the neighbourhood is a morafs, from which they manufacture falt; 41 miles N.N.E. of Murcia. N. lat. $38^{\circ} 35'$. W. long. $1^{\circ} 2'$.

VILLENAGE, or VILLAINAGE, *Villania*, the quality or condition of a *villain*; which fee.

Villanage is more particularly ufed for a servile kind of tenure of lands or tenements; by which the tenant was bound to do fuch services as the lord commanded, or were fit for a villain to perform: which Bracton expreffes by “*Ciri non poterit vefpere, quale fervitium fieri debet manere.*”

Villanage is divided into that *by blood*, and that *by tenure*. Tenure, in villanage, could make no freeman a villain, unlefs it were continued time out of mind; nor could free land make a villain free.

Villanage is alfo divided, by Bracton, into *pure villanage*, where the services to be performed were bafe in their nature, and indeterminate and arbitrary as to the time and quantity, as above expreffed; from which ancient tenures have sprung our prefent copyhold tenures: and *focage or privileged villanage*, where the service was bafe in its nature, but reduced to a certainty: which was to carry the lord’s dung into his fields, to plow his ground on certain days, to fow and reap his corn, &c. and even to empty his jakes: as the inhabitants of Biçton were bound to do to the lord of Clunçatle, in Shropfhire; which was afterwards turned into a rent, now called *Biçton filver*; and the villainous service excufed.

This laft fpecies of villanage, fays Bracton, is fuch as has been held of the kings of England from the Conqueft downwards; that the tenants herein *villana faciunt fervitia, fed certa & determinata*; that they cannot alien or transfer their tenements by grant or feoffment, any more than pure villains can; but muft furrender them to the lord or his steward, to be again granted out and held in villanage. From thefe circumftances, fays judge Blackftone, we may collect, that what he thus defcribes is no other than an exalted fpecies of copyhold fubfifting at this day, *viz.* the tenure in *ancient demefne*: to which, as partaking of the bafenefs of villanage in the nature of its services, and the freedom of focage in their certainty, he has given the compound name of *villanum focagium*. This ancient demefne, or demain, confifts of lands or manors, which, though now perhaps granted out to private fubjects, were actually in the hands of the crown in the time of Edward the Confeffor, or William the Conqueror; and fo appear to have been by the greaturvey called Domesday-book. Some of the tenants of thefe lands continued for a long time pure and abfolute villains, dependent on the will of the lord; and thofe who fucceeded them in their tenures now differ from common copyholders in a few points. Others were in a great meafure enfranchifed by royal favour; being only bound in refpect of their lands to perform fome of the better fort of villain services, and thofe determinate and certain; as, to plough the king’s land, to fupply his court with provifions, and the like; all of which are now changed into pecuniary rents;

and in confideration of them they had many privileges and immunities granted to them; as to try the right of their property in a peculiar court of their own, called a court of ancient demefne, by a peculiar procefs, denominated a writ of *right clofe*; not to pay toll or taxes; not to contribute to the expences of knights of the fhire; not to be put on juries, and the like. Thefe tenants, though their tenure be abfolutely copyhold, have an intereft equivalent to a freehold; for their services were fixed, and they could not be compelled (like pure villains) to relinquifh thefe tenements at the lord’s will, or to hold them againft their own; and *ideo*, fays Bracton, *dicuntur liberi*. Britton alfo, from this their freedom, calls them abfolutely *fokemans*, and their tenure, *fokemanries*. The fame name is alfo given them in Fleta. Lands holden by this tenure are a fpecies of copyhold, and as fuch, preferved and exempted from the operation of the ftatute of Charles II.; yet they differ from common copyholds, principally in the privileges before-mentioned: as alfo they differ from freeholds by one fpecial mark and tincture of villanage, noted by Bracton, and remaining to this day, *viz.* that they cannot be conveyed from man to man by the general common law conveyances of feoffment, and the reft; but muft pafs by furrender to the lord or his steward, in the manner of common copyholds: yet with this difference, that, in the furrenders of thefe lands in ancient demefne, it is not ufed to fay “to hold at the will of the lord” in their copies; but only “to hold according to the cuftom of the manor.” Blackftone’s Com. book ii. &c.

VILLENEUVE, in *Geography*, a town of Switzerland, in the canton of Berne, fituated at the eaftern extremity of the lake of Geneva, about three miles from the mouth of the Rhône; celebrated for its trout fifhery; 15 miles E.S.E. of Lauffanne. N. lat. $46^{\circ} 25'$. E. long. $6^{\circ} 46'$.—Also, a town of France, in the department of the Allier; 8 miles N.W. of Moulins.—Also, a town of France, in the department of the Tarn; 8 miles N.W. of Alby.—Also, a town of France, in the department of the Herault, on the Grand Canal; 3 miles S.E. of Beziers.—Also, a town of France, in the department of the Aveyron; 6 miles N. of Villefranche.—Also, a town of France, in the department of the Seine and Oife; 9 miles S.E. of Paris.

VILLENEUVE *d’Agen*, a town of France, and principal place of a diftrict, in the department of the Lot and Garonne; 12 miles N. of Agen. N. lat. $44^{\circ} 24'$. E. long. $48'$.

VILLENEUVE *l’Archevêque*, a town of France, in the department of the Yonne; 21 miles W.S.W. of Troyes.

VILLENEUVE *lez Avignon*, a town of France, in the department of the Gard, on the weft fide of the Rhône, oppofite Avignon; 21 miles N.E. of Nîmes.

VILLENEUVE *de Berg*, a town of France, and feat of a tribunal, in the department of the Ardèche; 12 miles S. of Privas. N. lat. $44^{\circ} 32'$. E. long. $4^{\circ} 35'$.

VILLENEUVE *la Garenie*, a town of France, in the department of Paris; 3 miles N. of Paris.

VILLENEUVE *la Guyard*, a town of France, in the department of the Yonne; 15 miles N.N.W. of Sens.

VILLENEUVE *de Marfan*, a town of France, in the department of the Landes; 9 miles E. of Mont-de-Marfan.

VILLENEUVE *le Roy*, or *Villeneuve-sur-Yonne*, a town of France, in the department of the Yonne, on the Yonne; 2 pofts N.W. of Joigny.

VILLENEUVE *St. George*, a town of France, in the department of the Yonne, on the Yonne, oppofite Villeneuve-le-Roy.

VILLENOCÉ, a town of France, in the department of the Aube; 10 miles N.E. of Provins.

VILLENORE, a town of Hindoostan, in the Carnatic; 10 miles W. of Pondicherry.

VILLENOUVETTE, a town of France, in the department of the Hérault, on the Orb, anciently considerable, and surrounded with walls. It at one time contained three parishes, now only one; 3 miles N.W. of Beziers.

VILLENTROIS, a town of France, in the department of the Indre; 18 miles N.E. of Châtillon-sur-Indre.

VILLEPEYS, or VILLEPAIS, a town of France, in the department of the Var, on the coast of the bay of Frejus; 3 miles S.S.W. of Frejus.

VILLEPINTE, a town of France, in the department of the Aude; 6 miles S.E. of Castelnaudary.

VILLEPREUX, a town of France, in the department of the Seine and Oise; 5 miles W. of Versailles.

VILLEQUIER, a town of France, in the department of the Lower Seine, on the right bank of the Seine; 3 miles S.W. of Caudebec.

VILLEQUIERS, a town of France, in the department of the Cher; 18 miles E. of Bourges.

VILLEREAU, a town of France, in the department of the Lot and Garonne; 7 miles N. of Monflanquin.

VILLEREST, a town of France, in the department of the Rhône and Loire, on the Loire; 5 miles S. of Roanne.

VILLERS, a town of Brabant; 9 miles E. of Nivelles.

VILLERS Bocage, a town of France, in the department of the Somme; 7 miles N. of Amiens.

VILLERS le Bocage, a town of France, in the department of the Calvados; 12 miles S.W. of Caen.

VILLERS sous Chalamont, a town of France, in the department of the Doubs; 12 miles W. of Pontarlier.

VILLERS Cotterets, a town of France, in the department of the Aisne; 12 miles S.W. of Soissons.

VILLERS Farlay, a town of France, in the department of the Jura; 6 miles N. of Arbois.

VILLERS la Montagne, a town of France, in the department of the Moselle; 3 miles S.E. of Longwy.

VILLERS sous Perny, a town of France, in the department of the Meurthe; 3 miles N.W. of Pont-à-Mousson.

VILLERSEYSEL, or VILLERSACEY, a town of France, in the department of the Upper Saône; 9 miles S. of Lure.

VILLESHEIM, a town of the duchy of Wurzburg; 5 miles S.E. of Kitzingen.

VILLETERTRE, a town of France, in the department of the Oise; 6 miles S.E. of Chaumont.

VILLETTE d'Anton, a town of France, in the department of the Hère, on the Rhône; 12 miles E. of Lyons.

VILLETTE d'Issins, a town of France, in the department of the Hère; 10 miles N.N.E. of Vienne.

VILLEVIEILLE, a town of France, in the department of the Higher Alps; 12 miles S.E. of Briançon.

VILLI, *Coarse Hair*, in *Anatomy*, is sometimes used in the same sense as fibres, or fibrille. See FIBRE.

VILLI, in *Botany*. See VILLOSUS.

VILLIE, in *Geography*, a town of France, in the department of the Rhône and Loire; 12 miles N. of Villefranche.

VILLIERS, GEORGE, in *Biography*, the first duke of Buckingham, was descended from an ancient family in Leicestershire, and born at Brookby in that county, A.D. 1592. His attention was directed by his mother, who undertook the charge of his education, to his maternal rather than solid accomplishments, which were further improved by a resi-

dence of three years in France, whither he was sent at the age of eighteen. His graceful person and gay disposition recommended him at court, to which he was introduced by sir John Graham, a gentleman of the king's privy-chamber. In 1613, James I. conferred upon him the office of his cup-bearer. Upon the fall of the earl of Somerset, Villiers took his place in the affection and confidence of the king, who knighted him in 1615, and made him gentleman of the bed-chamber, with a pension of 1000*l.* a-year. He soon after became master of the horse, and in 1616 was honoured with the garter, created a baron and viscount, and in the following year advanced to the earldom of Buckingham, and admitted into the privy-council. After his return from Scotland, whither he accompanied the king in 1617, he was created a marquis, and promoted to the dignities of lord high-admiral of England, chief justice in eyre fourth of the Trent, master of the king's-bench office, steward of Westminster, and constable of Windsor Castle. He also employed his powerful interest with the king for the advancement of his family and connections. His character was that of an ardent friend and implacable enemy, insolent and arrogant to those who opposed him, and regardless of real merit in those whom he patronised. To his pusillanimous sovereignty and to prince Charles he manifested his arrogant disposition; but in order to engage the prince's attachment, he proposed a visit of respect to his intended bride, the infanta of Spain. The king, at first averse from this journey, at length granted to his impertunity a reluctant consent. His manners, however, disgusted the Spanish court, and he returned avowing his enmity to the prime minister Olivarez. Such was his powerful influence at home, that he was appointed lord warden of the Cinque Ports. By misrepresenting the negotiations with Spain relating to the proposed marriage, he inflamed the nation against the Spaniards, and became popular; and dreading the return of lord Bristol from his embassy, and a true statement of this business, he joined the opposers of the court and promoted popular measures. Upon the accession of Charles his influence was augmented, and he was sent to France, in order to conduct into England the royal bride, Henrietta-Maria. During his visit to France, he had the assurance to declare his affection for Anne of Austria, queen of Lewis XIII., and to prosecute his addresses; and with this view, he determined to pay her a private visit. The consequence would probably have been his assassination; but forewarned of his danger, he declined the execution of his purpose; swearing, at the same time, that he would see and speak with that lady in spite of the strength and power of France. To this circumstance lord Clarendon imputes his enmity against the French court, and his attempt to alienate the affection of Charles from his queen. At length, his inordinate use of the power with which he had been entrusted rendered him an object of national jealousy and abhorrence; and in May 1626, the earl of Bristol, who at his infatigation had been committed to the Tower, and afterwards banished from the court, exhibited against him a charge of high-treason. He was also accused by the commons of high crimes and misdemeanours; but his master averted the stroke that was aimed against him by the dissolution of parliament. In the war now subsisting with Spain, he went to the Hague to concert a treaty with the States-general for the recovery of the Palatinate: but his conduct towards France soon produced a war with that country. At his solicitation, France was invaded in 1627 by an expedition under his command; and he landed on the isle of Rhé, whence he was obliged to withdraw with great loss. In order to recover his reputation after this disgrace, he advised the calling of a new parliament; which, so far from answering his purpose, charged him with being the author of

all the evils and dangers brought upon the king and kingdom, and drew up a remonstrance, containing a statement of the grievances of which he had been the cause. These proceedings were staid by a prorogation, and in the mean while he made an effort for recovering the good-will of the country, by fitting out an expedition for the relief of the Rochellers, then under close siege, in whose fate the zealous Protestants felt great interest. Whilst he was at Portsmouth, preparing for this expedition, Felton, who had served under him as a lieutenant in the army, moved by discontent and a fanatical spirit, gave him a stab, which proved almost instantly mortal, and of which he expired August 23, 1628, having just completed his 36th year. His tragical death, unpopular as he was, occasioned general commiseration. His public character has been sufficiently delineated in the preceding sketch of his conduct. Possessing some qualities that excite vulgar applause, a high spirit, personal courage, ready elocution and generosity, he had no other title to the appellation of a great man, which some have bestowed upon him, besides his advancement, by the erroneous judgment and partial favour of his sovereign, to place and power. He married lady Catharine Manners, daughter and sole heiress of Francis, earl of Rutland, by whom he left two sons and a daughter. In domestic life, he was an affectionate, though not a faithful husband, and kind to his family. With him, it is said, all-powerful favouritism at the English court terminated. Biog. Brit. Clarendon. Hume, &c. &c.

VILLIERS, GEORGE, second duke of Buckingham, was the son of the preceding, and born A.D. 1627, at Wallingford-House, Westminster. He and his brother Francis received the rudiments of education under the same tutors with the king's own children, and were both entered at Trinity college, Cambridge, and afterwards sent upon their foreign travels. Upon their return the civil war had commenced; and after having been presented to the king at Oxford, they engaged in military service under prince Rupert and lord Gerard. Upon this their estates were seized, but restored on account of their nonage. They afterwards renewed their travels in France and Italy. In 1648, when the king was prisoner in the Isle of Wight, they returned to England, and joined the earl of Holland, who was in arms in Surrey; but in an engagement with the parliamentary troops at Nonfuch, lord Francis, who fought valiantly, was slain. The duke escaped to St. Neot's, and surrounded by the enemy, made way with sword in hand through the guard, and joined prince Charles in the Downs. By adhering to the royal cause he forfeited his estates, which were then amongst the most considerable belonging to any English subject. Whilst he was abroad, his chief support was derived from a sale at Antwerp of his father's noble collection of pictures, which a faithful servant had secured. He attended the exiled Charles in Scotland, and accompanied him at the fatal battle of Worcester, when his escape was no less extraordinary than that of his master. He afterwards served as a volunteer in the French army, and occasionally visited the king's little court in Flanders. When the duke was informed that lord Fairfax had retired from the army and resided on part of his estate, which parliament had allotted to him, that he had acted generously with regard to other forfeitures, and that he had an only daughter, he determined to venture into England and try his fortune. He soon gained the affection of the daughter, and they were married in 1657, at his lordship's feat of Nun-Appleton, near York; and Cowley is said to have written an epithalamium on the occasion. He was seized, however, in 1658, and committed to the Tower, very much to the displeasure of his father-in-law. After the death of Cromwell, he was allowed to confine himself at Windfor

Castle, and upon the abdication of Richard he obtained his liberty. The Restoration put him in possession of all his estates, and he lived in splendour and magnificence, indulging in a profusion of expence, which was very injurious to his fortune, and which was not counterbalanced by the poiss of a lord of the bed-chamber, lord-lieutenant of Yorkshire, and master of the horse, which the king assigned him. Reduced to desperate circumstances, or inclined to faction and intrigue, he was charged, as early as the year 1662, with treasonable designs; so that in 1666 it became necessary for him to abscond; and a proclamation was issued for apprehending him. However, he voluntarily surrendered himself, and contrived so to ingratiate himself with Charles, as to be restored to his place in the bed-chamber and in the council. Always an adversary to lord chancellor Clarendon, he used his influence to accelerate his fall. In 1668 he joined sir Orlando Bridgeman and sir Matthew Hale in the laudable scheme of relaxing the severities against the Non-conformists; but their plan for this purpose was defeated by the house of commons. Destitute of steady principle, the duke was selected, in 1670, to form one of the infamous party denominated the *Cabal*, (which see,) and he was deputed as ambassador to the court of France, in order to dissolve the triple alliance, concerted by Temple and De Witt; and being a favourite with the French king, he concurred in all the measures of that court. He was suspected, on account of his profligate character, with being accessory to the attempt made upon the life of the duke of Ormond, by Blood; and his cowardice was so contemptible, that he tamely bore from the duke's spirited son, lord Ossory, the imputation of this villainy, accompanied with a menace, in the royal presence. He was elected, however, in 1671, by court-interest, to the chancellorship of Cambridge; and in the same year was exhibited his comedy, called the "Rehearsal," which is said to have been a joint production. The satire levelled against Dryden, then made poet-laureat, was thought to be just, but illiberal; and it was retorted by the poet in the character of the duke, under the name of Zimri, in "Abalom and Achitophel."

In 1672, the duke was sent to France to concert measures for the war which was intended to ruin the Dutch commonwealth. In 1674, the conduct of the Cabal being attacked in the house of commons, a motion was made for his impeachment, and he was questioned at the bar of the house. The result of this business was, that the commons voted an address for his removal. But as he was directed and restrained in his conduct by no kind of principle, he joined the opposition to the court with the earl of Shaftesbury. In 1680, having sold Wallingford-House, he removed to the city, and there concurred in the politics of the opposition. Hume has delineated his character very justly, when he says of him, "the least interest could make him abandon his honour; the smallest pleasure could seduce him from his interest; the most frivolous caprice was sufficient to counterbalance his pleasure. By his want of secrecy and constancy, he destroyed his character in public life; by his contempt of order and economy, he dissipated his private fortune; by riot and debauchery he ruined his health; and he remained at last as incapable of doing hurt, as he had ever been little desirous of doing good to mankind." Such, notwithstanding this appropriate character, was his inconsistency, that in 1685 he published a popular work, containing some just and liberal sentiments, and entitled "A short Discourse upon the Reasonableness of Men's having a Religion, or Worship of God." Upon his retirement, in declining health, to his manor of Helmley, in Yorkshire, and whilst he was amusing himself with rural sports and company, he wrote a short essay, entitled "A Demonstration of the Deity." At length, in a

fox-chace, he caught cold, which brought on a fever, that confined him in a tenant's house at Kirkby-moor-side, where he was visited by some friends, and at their suggestion he received the sacrament according to the rite of the church of England. On the third day of his illness he died, in April 1688, in the 61st year of his age, and was interred in the family-vault at Westminster Abbey. He was an unfaithful husband, and had no issue by his wife. His amours were numerous; and of these, the principal was that with the countess of Shrewsbury, who held his horse while he killed her husband in a duel. His writings, consisting of essays, poems, &c. have been collected in 2 vols. 8vo. and have passed through four editions. He is said to have devoted himself to chemical, or rather alchemical pursuits, in which he was the dupe of interested and designing persons; and it is added, that he introduced the art of making crystal-glasses from Venice. Biog. Brit. Hume.

VILLIERS DE L'ISLE ADAM, PHILIP DE, was a descendant of an ancient French family, born in 1464, and elected grand-master of the order of St. John of Jerusalem in 1521. In the year after his election, the island of Rhodes, where he resided, was invaded by 200,000 Turks, against whom he defended it with such vigour, that sultan Solyman came in person to superintend the attack; and after a siege of six months, in which the Turks are said to have lost 100,000 men, he found it necessary to surrender it. Solyman treated him with great respect, declaring to one of his officers, that it was not without regret he obliged this Christian to leave his house at his age. Abandoning Rhodes in 1523 with fifty vessels, his remaining knights, and about 4000 of the inhabitants, he arrived at Rome during the papacy of Clement VII.; who assigned to him for a present residence the town of Viterbo. In 1527 the emperor Charles V. offered the island of Malta, which in a general chapter it was determined to accept. He then went to Syracuse, and in 1530 received the donation by letters-patent of Malta, Gozo, and Tripoli in Barbary. In this year he fortified Malta; and from that period, the knights of St. John assumed the title of knights of Malta. After a life distinguished by piety, courage, and prudence, he died in 1534, at the age of 70. Upon his tomb was inscribed this appropriate eulogy, "Here reposes Virtue victorious over Fortune." Moreri.

VILLIERS, in *Geography*, a town of France, in the department of the Côte d'Or; 6 miles N.N.W. of Clâtillon-sur-Seine.—Also, a town of France, in the department of the Loire and Cher; 4 miles W. of Vendôme.—Also, a town of France, in the department of the Mayne; 6 miles N. of Château Contier.

VILLIERS *en Vexvre*, a town of France, in the department of the Eure; 15 miles E. S.E. of Evreux.

VILLIERS *St. Benoît*, a town of France, in the department of the Yonne; 15 miles W. of Auxerre.

VILLIMPENTA, a town of Italy, in the department of the Mincio; 10 miles E. of Mantua.

VILLINGEN, a town of the duchy of Baden, in the Brisgau. This place, by means of the mountains and narrow access leading to it, is extremely well secured, and also somewhat fortified by art. It has always served the Austrians as a magazine for these parts, as well for provisions as military stores. In it is an abbey of Benedictines; and its neighbourhood contains a good bath; 52 miles S.S.W. of Stuttgart. N. lat. 48° 4'. E. long. 8° 26'.

VILLOA, a town of the duchy of Piacenza; 10 miles S. of Piacenza.

VILLOISON, JOHN-BAPTIST GASPARD D'ANSE DE, in *Biography*, was the descendant of a family originally Spanish,

and born in 1750 at Corbelle-sur-Seine, and after receiving the rudiments of literature at several colleges, attended the Greek lectures of M. le Beau at Paris, and enjoyed the higher instruction in this department of M. Capperonier, Greek professor in the royal college of France. Such were his talents and application, that with these advantages he became acquainted, at the age of fifteen, with almost all the writers of antiquity in every class. In his researches among MSS. in the library of St. Germain-des-Prés, he found a Greek lexicon of Homer by Apollonius, which he published in 1773, with prolegomena and notes, that displayed a very surprising extent of erudition, considering his early age, and that introduced him, out of the usual form, into the Academy of Inscriptions and Belles Lettres. His next considerable undertaking was an edition of the Pastoral of Longus, which was published in 1778. In 1781 he obtained a mission, at the king's expence, to examine the library of St. Mark in Venice, where he found several inedited works of rhetoricians, philosphers, and grammarians, a collection of which he published in 2 vols. 4to. under the title of "Anecdota Græca." He also found a very valuable MS. of Homer's Iliad, with scholia by ancient grammarians, which he committed to the press in 1788, accompanied with learned prolegomena. About this time he received an invitation from the duke and duchess of Saxe-Weimar, to visit their court, the most literary in Germany; and here he collected various readings and emendations of the text of several Greek authors, which he printed at Zurich, under the title of "Epistolæ Vimarïenses." Another of his publications is that of a translation of part of the Old Testament, by a Jew of the ninth century, which he had found in the library of St. Mark; and of this he gave an edition, with notes, at Strasburgh in 1781. Soon after his return to Paris, and his marriage of an interesting young woman, he formed the purpose of searching for MSS. in the East, and in 1785 he visited Constantinople, and afterwards Smyrna, and several islands in the Archipelago, and Greece; and the result of his researches and observations was read before the Academy of Belles Lettres, on his return to Paris in 1787. At the commencement of the Revolution he retired to Orleans, for the pursuance of his literary plans; and the fruits of his consultations of ancient and modern authors were 15 large volumes in 4to. He also contemplated a larger work, which was a new edition of father Montfaucon's "Paleographia Græca." When the revolutionary tempest subsided, he returned to Paris, with literary treasure, in amassing which he had expended three-fourths of his moderate fortune; and he was therefore under a necessity of commencing a course of lectures in the Greek language, which proved unsuccessful. He therefore gladly accepted the professorship of modern Greek, which the government established, and discharged its duties till it was suppressed by Napoleon. From respect to his merit, a professorship of ancient and modern Greek was created for him alone in the college of France; but he was carried off by a lingering malady in April 1805, at the age of 55 years. In verbal knowledge Villosus was deemed a profound scholar; but to the higher qualities of intellect he is said to have had no just pretensions. Gen. Biog.

VILLONA, in *Geography*, a town of Spain, in the province of Leon; 13 miles E. of Salamanca.

VILLOSLADA, a town of Spain, in Old Castile; 20 miles S.E. of Najera.

VILLOSUS, in *Botany and Vegetable Physiology*, expresses that kind of hairiness which is longish, soft, and shaggy, like wool, yet does not amount to the thick entangled coat of many plants, which is properly termed woolly,

woolly, as in *VERBASCUM*; see that article: see also *PURSCENCE* and *LEAF*.

VILLOUS, *VILLOSA*, is particularly applied to one of the coats or membranes of the stomach, called *crusta villosa*.

It takes its name from innumerable villi, or fine fibrillæ, with which its inner surface is covered.

VILLURBANNE, in *Geography*, a town of France, in the department of the Ière; 4 miles E. of Lyons.

VILMANSTRAND, or **WILMANSTRAND**, a town of Russia, in the government of Viborg, on the south coast of the lake Saima; 40 miles N.N.W. of Viborg. N. lat. 61° 20'. E. long. 27° 26'.

VILMAR, a town of Germany, in the circle of the Lower Rhine; 24 miles N. of Mentz.

VILMINOREU, a town of Italy, in the department of the Adda and Oglio; 28 miles N.E. of Bergamo.

VILMNITZ, a town of the island of Rugen; 7 miles S.E. of Bergen.

VILOVATOSTANOVITSCH, a fortress of Russia, in the government of Archangel, near the Frozen ocean; 180 miles E.S.E. of Kola. N. lat. 68° 50'. E. long. 40° 14'.

VILS, a river of Bavaria, which passes by Amberg, &c. and runs into the Nab, at Kalnzuz.—Also, a river of Wurttemberg, which rises near Wiefenstug, passes by Geitingen, Coppingen, &c. and runs into the Neckar, 2 miles N. of Wendlingen.

VILS, or *Gros*, a river of Germany, which runs into the Danube at Villhofen.

VILS *Biburg*, a town of Bavaria; 8 miles S.E. of Landshut.

VILSECK, a town of Bavaria, on the Vils; 20 miles S.E. of Bayreuth. N. lat. 49° 36'. E. long. 11° 48'.

VILSEN, a town of Germany, in the county of Hoya; 5 miles W. of Hoya.

VILSHOFEN, a town of Bavaria, at the conflux of the Vils with the Danube; 11 miles W. of Passau. N. lat. 48° 29'. E. long. 13° 11'.

VILTRUM, a word used sometimes alone to express a filtre, instead of the word *filtrum*. But *vitrum* is more commonly joined with the word *philosophorum*, and then expresses the common alembic for distillation.

VILUI, in *Geography*, a river of Russia, which runs into the Lena, at Ust Viluiskoi. N. lat. 64°. E. long. 126° 14'.

VILUISKOI, *NIZNEI*, a town of Russia, in the government of Irkutsk, on the Vilui. N. lat. 63° 45'. E. long. 122° 44'.

VILUISKOI, *USSI*, a town of Russia, in the government of Irkutsk, at the conflux of the Vilui and Lena; 128 miles N.W. of Yakutsk. N. lat. 63° 50'. E. long. 126° 14'.

VILUISKOI, *Verchnei*, a town of Russia, in the government of Irkutsk; 200 miles N. of Oleminsk. N. lat. 63° 44'. E. long. 120° 24'.

VILVORDE, or **VILLEFORTE**, a town of France, in the department of the Dyle, situated on the river Senne; 6 miles S. of Malines.

VIM, a river of Russia, which rises in the government of Archangel, and runs into the Vitcheгда, near Lialkoi, in the province of Ustiug.

VIMERCATO, a town of Italy, in the department of the Olona; 13 miles N.N.E. of Milan.

VIMIEIRO, a town of Portugal, in the province of Alentejo; 10 miles W. of Estremoz.

VIMINIACIUM, or **VIMINIATUM**, in *Ancient Geogra-*

phy, a town of Hispania Citerior, belonging to the *Vaccæi*; marked in the Itin. Anton. between Palentia and Lacobriga.

VIMINALIS, in *Mythology*, an epithet of Jupiter.

VIMINARIA, in *Botany*, was so named by the writer of this article, from *vimen*, a slender rod, or twig, in allusion to the habit of the plant.—Sm. in Sims and Kon. *Annals of Botany*, v. 1. 507. Brown in Ait. *Hort. Kew.* v. 3. 13.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, simple, of one leaf, bell-shaped, angular, with five short equal teeth, permanent. *Cor.* papilionaceous. Standard inversely heart-shaped, ascending, with a short claw. Wings oblong, obtuse, converging, shorter than the standard, each with a tooth at the base, on the lower side, and a short slender claw. Keel nearly equal to the wings, of two combined petals, with distinct claws, concave, with a blunt tooth at each side of the upper edge, at the base. *Stam.* Filaments ten, awl-shaped, distinct, rather ascending, the lower ones gradually longest, the upper one shortest; anthers roundish, two-lobed. *Pist.* Germen superior, oval, smooth; style capillary, ascending, as long as the stamens; stigma simple. *Peric.* Legume oval, half inverted by the calyx, acute, slightly compressed, smooth, coriaceous, of one cell, not burbling. *Seed* solitary, oval-kidney-shaped, without any appendage.

Ess. Ch. Calyx angular, simple, five-toothed. Corolla papilionaceous. Style capillary. Stigma simple, acute. Legume leathery, of one valve, not burbling, entirely filled with a single seed.

1. *V. denudata*. Leaflets Rush-Broom. Sm. in *Ann. of Bot.* as above. *Exot. Bot.* v. 1. 51. t. 27. *Tr. of Linn. Soc.* v. 9. 261. *Ait. n. 1.* (*Daviesia denudata*; Venten. *Choix de Plantes*, t. 6. *Sophora juncea*; Schrad. *Sert. Hannov.* v. 3. *Pultenaea juncea*; Willd. *Sp. Pl.* v. 2. 506. *Donn Cant. ed.* 5. 101.)—The only known species, a native of New Holland and Van Diemen's island, said to have been introduced at Kew by Sir Joseph Banks, in 1789. It is a rather hardy greenhouse shrub, flowering in July. The *stem* is branched, round and smooth. *Leaves* only to be seen on the lower part of seedlings, or young plants, alternate, on long smooth stalks, ovate, entire, three-ribbed, smooth, either acute or emarginate; at first sometimes ternate. The *footstalks* on the greater part of the plant are leafless, cylindrical, smooth, with two or three minute scales at the point; the lower ones six inches, or more, in length; the upper gradually shorter. *Clusters* terminal, solitary, simple, of many pretty yellow flowers, the silk of whose standards is red. Each partial stalk has a small bractæa at the base.

VIMINIATUM **LEGIO**, in *Ancient Geography, a town of Higher Mæcia, on the banks of the Danube, marked in the Itin. Anton. on the route from Mount d'Or to Constantinople, between Municipium and Ideuminacum.*

VIMIOSO, in *Geography, a town of Portugal, in the province of Tra los Montes; 15 miles W.N.W. of Miranda de Duero. N. lat. 41° 29'. E. long. 6° 14'.*

VIMMALA, in *Natural History*, a name given by the people of the East Indies to a kind of pyrites, of a brassy appearance, and of a cubic figure.

They also give it in the same place to the pyritæ in general, when small, and of a simple internal structure.

VIMOUTIER, in *Geography*, a town of France, in the department of the Orne, on the Vic; 15 miles N.E. of Argentan.

VIMY, a town of France, in the department of the Straits of Calais; 5 miles N. of Arras.

VINA,

VINA, or VENA, in *Hindoo Mythology*, is the father of Prithu, who is fabled to have been an incarnation of the god Vishnu. Vina is the correct mode of writing the name of a musical instrument of the East, commonly called *Been*; under which word we have given a description, and referred to one of our plates for a representation of it.

VINAGO, in *Ornithology*, a name given by some authors to the wood-pigeon, from the colour of its breast, shoulders, and wings, resembling that of red wine. Its more usual name among authors is *oenos*.

VINALHAVEN, in *Geography*, a town of America, in the district of Maine and county of Hancock, containing 102 inhabitants; 60 miles E.N.E. of Brunswick.

VINALIA, in *Antiquity*, a name common to two feasts among the ancient Romans; the one in honour of Jupiter, and the other of Venus.

The first was held on the 19th of August; and the second on the 1st of May. The Vinalia of the 19th of August were called *Vinalia rustica*; and were instituted on occasion of the war of the Latins against Mezentius; in the course of which war, that people vowed a libation to Jupiter of all the wine in the succeeding vintage.

On the same day likewise fell the dedication of a temple of Venus; whence some authors have fallen into a mistake, that these Vinalia were sacred to Venus. But Varro L.L.L.V. and Festus, in *verbo Rustica*, distinguish between the two ceremonies; and expressly assert the Vinalia to be a feast of Jupiter.

VINARA, in *Geography*, a town of South America, in the province of Tucuman; 56 miles N.N.W. of St. Yago del Estero.

VINARAZ, a town of Spain, in the province of Valencia, on the coast of the Mediterranean; 5 miles N. of Peniscola.

VINATA, in *Hindoo Mythology*, is the parent of the eagle of the Indian Jove, called Garuda, or Saperna. He is also parent of the Aurora of Eastern fable, who is called Aruna, the driver of the car of Phœbus, or Surya. Under SURYA we have spoken of Vinata as the paternal ancestor of Superna and Aruna, but it is rather an equivocal parentage, as Kasyapa is sometimes said to be their father, and Diti their mother. (See *KASYAPA*.) The name of Vinata, or Vinava, seldom occurs in Hindoo books; though that of Vinateya, as a name of Superna, marking his parentage, is not very uncommon.

VINATEYA, a name of the Hindoo mythological eagle, more commonly called *Superna*; which see, and VINATA.

VINAY, in *Geography*, a town of France, in the department of the Iferé; 4 miles S. of St. Marcelin.

VINAZA, in *Ancient Geography*, a town of Africa Propria, upon the route from Tacapæ to Grand Leptis, between Aurus and Thalamus. Anton. Itin.

VINCA, in *Botany*, originally *Pervinca*, whence its English and French names, Periwinkle and Perwenche, is not satisfactorily explained by any etymologist. The best derivation of the word may perhaps be from *vincio*, to bind or wrap up, because its long trailing or twining branches wind themselves round, and entangle, every other plant in their way.—Linn. Gen. 115. Schreb. 163. Willd. Sp. Pl. v. 1. 1232. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 269. Prodr. Fl. Græc. Sibth. v. 1. 164. Ait. Hort. Kew. v. 2. 66. Juss. 144. Lamarck Illustr. t. 172. Gertn. t. 117. (Pervinca); Tourn. t. 45.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apo-cinæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five

deep, erect, acute segments, permanent. Cor. of one petal, falver-shaped. Tube longer than the calyx; cylindrical in the lower part; dilated and grooved with five lines in the upper; five-angled at the mouth. Limb horizontal, in five deep equal segments, attached to the top of the tube, dilated outwards, obliquely lopped at the extremity, and slightly twisted. Stam. Filaments five, inserted into the tube, very short, inflexed and then bent backward; anthers membranous, obtuse, erect, incurved, bearing pollen at each margin. Pist. Germens two, roundish, at whose sides are two roundish bodies; style common to both germens, simple, cylindrical, the length of the stamens; stigma of two parts, the lower orbicular, flat, the upper capitate, concave. Peric. Follicles two, long, cylindrical, pointed, erect, each of one valve bursting lengthwise. Seeds numerous, oblong, cylindrical, furrowed, without down or wing.

Efl. Ch. Corolla of one petal, contorted, falver-shaped, inferior. Follicles two, erect. Seeds naked.

1. *V. minor*. Lesser Periwinkle. Linn. Sp. Pl. 304. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 917. Curt. Lond. fasc. 3. t. 16. (*V. pervinca minor*; Ger. Em. 894. Clematis; Camer. Epit. 694, 695. Matth. Valgr. v. 2. 305.)—Stems procumbent. Leaves elliptic-lanceolate, smooth at the edges. Flowers stalked. Calyx-teeth lanceolate.—Found in bushy places, groves, and about hedges, in Germany, England, France, Switzerland, and various parts of Greece. There can be little doubt of this being the *αμυρανός* of Dioscorides, as all authors have thought. He speaks of it as a native of Egypt. Dr. Sibthorp met with it in Arcadia, as well as in the countries of Elis and Argolis. In England this pretty plant is seldom found wild, though in gardens and shrubberies nothing is more commonly planted, particularly the double-flowered purple, and the white-flowered variegated kinds. They are all perennial, flowering in May. The root creeps extensively. The stems, erect while in flower, become trailing, creeping very fast, and are round, smooth, leafy. Leaves evergreen, opposite, stalked, entire, smooth, shining, about an inch long. Flowers axillary, solitary, alternate, stalked, erect, scentless, deep blue, white in the centre. We have never seen the fruit of this species.

2. *V. major*. Greater Periwinkle. Linn. Sp. Pl. 304. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 514. Curt. Lond. fasc. 4. t. 19. (*Pervinca vulgaris*; Garidel Aix; t. 81. Clematis daphnoides major; Ger. Em. 894.)—Stems nearly erect. Leaves ovate, fringed. Flowers stalked. Calyx-teeth bristle-shaped, elongated.—Native of thickets and groves, in rather moist situations, in England, France, Spain, Switzerland, and Carniola, flowering in May, being less rare with us than the former, and no less commonly cultivated for ornament in extensive shrubberies, that will admit of its rambling mode of growth. There this species composes light, convex, evergreen tufts under trees and hedges. The leaves are thrice the size of *V. minor*, of a lighter green, and more ovate, or somewhat heart-shaped. Flowers larger, and rather more blue, with less of a violet tint. Seed-vessels an inch and a half long, recurved, pointed, with seldom more than two roughish seeds, one above the other.

3. *V. lutea*. Yellow Periwinkle. Linn. Sp. Pl. 304. Am. Acad. v. 4. 309, not 307. Willd. n. 3. ("Apocynum scandens, falcis folio, flore amplo plano; Cateb. Carol. v. 2. 53. t. 53.")—"Stem twining. Leaves oblong."—Native of Carolina. This has the habit of an *Echites*. We are quite unacquainted with the plant, nor did Linnæus ever see a specimen.

4. *V. rofea*. Madagafcar Periwinkle. Linn. Sp. Pl. 305. Willd. n. 4. Ait. n. 3. Curt. Mag. t. 248. (Vinca; Mill. Ic. 124. t. 186.)—Stem shrubby, erect. Flowers sessile, in pairs. Leaves elliptic-oblong.—Native of the East Indies. Cultivated here by Mr. Thomas Knowlton, before the year 1756. It is now become a very popular stove-plant, flowering most part of the year, and recommending itself to general admiration, by the beautiful colour of its ample blossoms, whose corolla is either of a bright rose-colour, or pure white, the centre always of a peculiarly rich crimson, with a yellow eye. The stem is bulky, quite erect, about a yard high. Leaves entire, rather downy, two inches long, bluntish. This species is propagated easily, either by seed or by cuttings, but will not endure much cold or wet, though it requires a free air in summer.

5. *V. parviflora*. Small-flowered Periwinkle. Retz. Obs. fasc. 2. 14. Ait. n. 4. Willd. n. 5. (*V. pusilla*; Murray in Comm. Goett. for 1772. 66. t. 2. f. 1. Linn. Suppl. 166.)—Stem erect, herbaceous. Leaves lanceolate, acute.—Native of the East Indies. An Annual stove-plant, flowering in August, whose seeds were imported by Sir Joseph Banks in 1778. The stem is about a span high; slightly branched. Leaves as long as the last, being about two inches, but much narrower, and acute. Flowers foliary or in pairs, small, with not much pretension to beauty; their corolla white, with a yellow eye, not ill compared by Willdenow to *Litbosperrum officinale*.

VINCA, in Gardening, comprehends plants of the shrubby, evergreen, upright and trailing kinds, among which the species cultivated are, the small periwinkle (*V. minor*); the great periwinkle (*V. major*); and the Madagafcar periwinkle (*V. rofea*).

The first has a perennial creeping root, and it varies in the colour of the flowers; with pale blue, with purple, and white, and with double flowers of these different colours; and the foliage is sometimes variegated either with white or yellow stripes.

The second sort is larger in all its parts than the preceding, having flowers of a purple-blueish colour. It varies with white flowers.

The third has an upright branching stem, three or four feet high, having a long succession of pale flesh-coloured flowers.

It varies with flowers with purple eyes.

Mabod of Culture.—These plants are all capable of being increased by layers, cuttings, and suckers.

In the first method, when the layers of the trailing branches are put down into the ground, they readily take root at almost any season. This is very much the case with the first sort, as almost every joint furnishes plants in the course of the summer ready to be put out in the autumn.

The cuttings may be made from the stalks and branches, and be planted in shady borders in the autumn or early spring, when they will become well rooted by the following autumn.

All the sorts succeed in this way.

In the third sort, the cuttings should be made from the young shoots and be planted in pots, plunging them in a hot-bed, or the bark-bed, where they will become perfectly well rooted in the same year, and may be potted off separately, being placed in the stove, and shifted as may be necessary into large pots.

This sort may likewise be raised from seed, which should be sown in pots in the early spring filled with light rich earth, covering them well in, and plunging the pots in the hot-bed, or the bark-bed of the stove; and when the plants have a few inches growth, they should be pricked

out into separate pots, re-plunging them in a hot-bed, giving proper shade and water, managing them afterwards as the cuttings.

The suckers may be taken off with root-fibres in the autumn or spring, and planted where they are to grow.

The two first sorts afford variety in the borders, clumps, &c. and they may be planted in thickets and wildernesses under trees with perfect success; while the last has a fine effect in stove collections as an elegant evergreen and flowering shrub.

VINCAC, in Geography, a town of France, in the department of the East Pyrenées; 4 miles E.N.E. of Prades.

VINCELLES, a town of France, in the department of the Jura; 6 miles S.S.W. of Lons le Saunier.

VINCENNES, a town of France, in the department of Paris, in which was a royal palace, originally begun by Philip de Valois, but repaired and finished by Louis XIV.: the ancient towers served as a state prison. At this place the duke d'Enghien suffered death; 1 post E. of Paris.

VINCENNES, a town of America, the capital of the territory of Indiana and county of Knox, on the bank of the Wabash, 150 miles from its mouth; in a delightful situation, surrounded by a prairie four miles long and one broad, mostly cultivated, and the remainder being a fine meadow which produces good grass. The soil, which is not inferior to any in the United States, yields corn, rice, wheat, tobacco, hemp, hops, grapes, &c. The Wabash is navigable, almost through the whole year, as far as this place. Commerce centres here, as the merchants bring their goods from Canada down the Wabash, from Orleans up the Mississippi, and from the eastern states, down the Ohio and up the Wabash. The fort, erected in 1787, stands on the E. side of Wabash river. It is garrisoned by a major and two companies. The inhabitants, principally of French extraction, amount to 670. It is a post-town; 743 miles from Washington.—Also, a town-ship in the same territory and county, containing 223 inhabitants.

VINCENT, WILLIAM, D.D. in Biography, dean of Westminster and vicar of Islip, Oxon, was a descendant of a race of ancestors who officiated as clergymen of the established church, and belonged to that class of ecclesiastics usually denominated the "High Church Party." They were seated at Shepey, in the county of Leicester. The dean was the last surviving son of Mr. Giles Vincent, who acquired a fortune as a packer under Spanish and Portugal merchants; but afterwards, by losses and disappointments in his commercial connections, retired from trade without being enriched by it. He was born in London, November 2, 1739, and being designed for the church, was entered at Westminster school in September, 1748, and in 1753 was admitted on the foundation. In 1757 he was elected to Trinity college, Cambridge, and supported there by his elder brother, who continued the business of a packer. He took his first degree of B.A. in 1761, and in the following year was appointed teacher at Westminster school. In 1764 he was graduated M.A.; in 1771 he became second master; in 1776, D.D. and one of his majesty's chaplains; in 1788, head-master of the school; and in 1798, president of Sion college. Having married in early life, his family rapidly increased, and some of his children were arrived at maturity before he obtained any considerable preferments in the church, notwithstanding the favourable situation which he occupied. In 1777 he was nominated by Dr. Markham, upon his elevation to the see of York, sub-almoner to the king, an office which he held until his demise;

and in 1778 he was advanced to the rectory of Allhallows, which in 1803 he resigned in favour of his eldest son. In 1801 he obtained a prebendal stall in the collegiate church of St. Peter, Westminster, which preferment enabled him to resign the laborious office of head-master of the school; and in 1802 he became dean. In 1807 he took possession of the rectory of Ilip. On the parsonage-house, rebuilt by Dr. South, he expended between two and three thousand pounds, 1000*l.* of which arose from dilapidations, and the remainder furnished by himself, so as to render it a convenient and comfortable residence. It is mentioned as a remarkable circumstance in the life of this learned divine, that he passed twice, with great applause, through Westminster school; first, from the lowest form to the highest as a scholar, and secondly as an usher: nor is it less singular, that he almost constantly resided within the precincts of the Abbey, from his eighth to his seventy-sixth year, or during the interval of sixty-eight years, allowing for his temporary absence at Cambridge during his education, and on occasion of taking a degree. Notwithstanding his assiduous application to the duties of a sedentary profession, his life was prolonged to an advanced age; and after a fortnight's illness, he died at his favourite residence of the deanery, December 21st, 1815, in the 77th year of his age; leaving behind him two sons, both of whom are married and have children.

While he was unremitting in his attention to his office as tutor, and to his various clerical duties, he devoted a portion of his time to compositions which have issued from the press. Of these, the first we shall mention was "A Letter to Dr. Richard Watton (afterwards Bishop of Llandaff), King's Professor in the University of Cambridge," 8vo. 1780, in reply to some observations introduced by this learned prelate into a sermon preached before the university of Cambridge, which was afterwards printed under the title of "The Principles of the Revolution vindicated," and into another discourse "On the Anniversary of His Majesty's Accession." In 1787 he published his tract on "Parochial Music;" in 1789, a sermon delivered before the sons of the clergy; and in 1792, a sermon preached at St. Margaret's, Westminster, for the Grey-coat school of that parish. In the latter discourse he noticed opinions, which were then prevalent, respecting the doctrines of natural liberty and equality; and more than 20,000 copies of it were printed and dispersed in and near the metropolis, and a great number was circulated through different parts of the kingdom. The next publication of Dr. Vincent was "The Origination of the Greek Verb, an Hypothesis," 8vo.; the title of which was altered in the second edition to "The Greek Verb analysed." This work was criticized with some humour, and not without a degree of asperity, in a piece entitled "Hermes unmasked." Our author's next publication was an elaborate dissertation on military affairs, entitled "De Legione Manliana Quæstio, ex Livio desumpta, et Rei Militaris Romanæ studiosius propolita," 1795. Six years afterwards appeared his principal performance, evincing his acquaintance with both ancient and modern geography and navigation, under the title of "The Voyage of Nearchus to the Euphrates; collected from the original Journal preserved by Arrian, and illustrated by Authorities ancient and modern, containing an Account of the first Navigation attempted by the Europeans in the Indian Ocean," 4to. 1799; and this was soon after followed by "The Periplus of the Erythrean Sea; containing an Account of the Navigation of the Ancients from the Red Sea to the Coast of Zanzibar, with Dissertations, Part I.," 4to. 1800. Our learned author was next engaged in a controversy with Dr. Rennell, prebendary of Winchester and master of the Tem-

ple, occasioned by some reflections on the neglect of religion in our public institutions, which were introduced in a sermon preached in 1799, before the Society for promoting Christian Knowledge, at the annual meeting of all the charity-schools of the metropolis, in the cathedral of St. Paul's. To this sermon was annexed a note, in which the preacher declares his opinion, "that there is scarcely any internal danger which we fear, but what is to be ascribed to a *Pagan education*, under Christian establishments, in a Christian country." Dr. Vincent, then master of the only great public school in the metropolis, seemed at first to think that this attack was personal; but in order to avoid public contention, he commenced a private correspondence with Dr. Rennell, in the course of which ample and satisfactory explanations were made. But at the next anniversary, in 1800, Dr. O'Beirne, bishop of Meath, delivered a sermon, which was printed at the request of the Society, accompanied by a note, containing the same obnoxious assertions, together with additional remarks of his own. Dr. Vincent applied to the Society for permission to inclose in the parcels, containing its annual communications, a justification of the public instructors of England; but the Society declining to take a part in the controversy by complying with this request, the author committed to the press his "Defence of Public Education," addressed to the bishop of Meath, in which he makes an apology for the present system, and expresses himself in a high and indignant tone, in respect to the distinguished individuals whose supposed indiscretion had incurred his censure. As no reply was made, the contest terminated; and in order to prevent the recurrence of a similar event, the Society resolved, that the notes as well as the text of the annual sermon should for the future be submitted to its revision and approbation.

In 1802, our author published his thanksgiving sermon, preached at St. Margaret's, Westminster, before the honourable house of commons; in 1805, the second part of "The Periplus of the Erythrean Sea;" in 1809, "The Voyage of Nearchus, and the Periplus of the Erythrean Sea," translated from the Greek; and in Mr. Valpy's classical Journal, No. 18. "Observations on the Geography of Sufiana." The dean also reviewed several articles in the British Critic, particularly that relating to the controversy about the Troad, and occasionally contributed articles to the Gentleman's Magazine. By such literary lucubrations Dr. V. amused himself in the intervals of his more laborious employments, passing a long and honourable life by devoting his mornings to reading and his evenings to the society of his friends; and towards the close of life, dividing his time between his deanery and his living of Ilip. "In the bosom of his family," says one of his biographers, "Dr. Vincent was seen to the greatest advantage." In the tranquil and peaceful circle above briefly delineated, "he endeared himself to all around him, by the benignity of his disposition, the affability of his demeanour, and the charms of his conversation. Here were laid open that singleness of heart and simplicity of mind, which none could appreciate justly, but those who saw and were conversant with him in the free and familiar hours of domestic privacy. With qualifications which would have conferred dignity on the highest station in the church, and with an ambition, perhaps, not wholly averse from rank and elevation, Dr. V. nevertheless loved quiet and retirement." We shall close this article with some extracts from a biographer who has duly appreciated his talents and character. "As a clergyman," says this writer, "Dr. Vincent was regular and exemplary in the discharge of his duties; strictly orthodox in point of faith; and a firm supporter of all the doctrines,

doctrines, tenets, and practices of the church of England. His person, as well as enunciation, were well fitted for pulpit oratory: his voice, in particular, was sonorous; his animation produced a lively interest in the hearts of his auditors, while a certain dignity of manner commanded their implicit attention."—"As a writer, he possessed all the necessary requisites to gain the approbation of intelligent critics; he was indefatigably industrious; addicted to research; and learned in no common degree. While his literary labours evinced his intimate acquaintance with the ancients, his sermons were admirably adapted to the abilities and understandings of an ordinary audience. In both capacities his language was chaste; his composition elegant: in short, he continually reflected the images of a mind, richly imbued with learning, both human and divine."

"As a controversial writer, he sometimes bordered on asperity, and this, too, in respect of minor points; while with certain persons, from whom he differed in essentials, he exhibited no common share of moderation and liberality. Accordingly he did full justice to the talents of a Tooke, a Porson, and a Gibbon."

"As a school-master, he must be allowed to have had a number of distinguished pupils," among whom we may reckon the late and present dukes of Bedford, sir Francis Burdett, and his successor, as head-master, Dr. Carey; and in this capacity he is said to have been the acute, able, indefatigable, and strenuous assertor of the ancient discipline. Annual Biography and Obituary, for 1817, vol. i. Gent. Mag.

VINCENT, THOMAS, a celebrated performer on the hautbois, was a scholar of the admirable San Martini; and, after his master had ceased to perform in public, and had furnished him with concertos, was an unrivalled favourite on his instrument, till the arrival of Fischer.

In 1765 he became joint impresario of the Opera with Gordon.

Vincent, after the decease of San Martini, had been in great favour with his royal highness Frederic, prince of Wales, father to his present majesty; had acquired a considerable sum of money in his profession, which he augmented by marriage. However, the ambition of being at the head of so forward a family as an opera vocal and instrumental band, turned his head and his purse inside out; in short, he soon became a bankrupt, and his colleagues, though they escaped utter ruin, were not enriched by the connection. He ended his days in the evening of life, of which the morning had been so brilliant, in poverty and obscurity, and paid dear for his ambition and imprudence.

VINCENT, RICHARD, who performed the first hautbois at Vauxhall Gardens from the beginning of musical performances there, and at Covent-Garden theatre more than thirty years. He was the father of the young musician who married the celebrated Miss Birchell, possessed with one of the finest treble voices that was ever heard in public. After performing at Vauxhall with great and constant applause, on the death of her husband she went to the East Indies, where she was still more applauded than in England, and where she was married a second time to John Mills, esq., a gentleman of fortune and consideration, with whom she returned to her native country, and lived happily in a splendid manner. She was buried in St. Pancras church-yard, where there is an honourable and affectionate epitaph inscribed on a tablet dedicated to her memory, by her surviving husband.

VINCENT of Beauvais, a Dominican monk of the 13th century, was appointed by St. Lewis, king of France, inspector of the education of his children. About the

year 1244, he compiled a kind of encyclopædia, entitled "Speculum Majus," which consisted of four parts, viz. "Speculum Naturale, Doctrinale, Morale, et Historiale." Notwithstanding all its errors, it passed through many editions; the first at Straßburg in 1476, and the last at Douay in 1624. He was also the writer of a "Letter to St. Lewis on the Death of his eldest Son," and of a "Treatise on the Education of Princes;" and died in 1624. Brucker by Enfield.

VINCENT FERRIER, or FERRER, a Dominican, was born at Valencia, in Spain, in 1357; and having entered into the order of preachers in 1374, obtained the degree of doctor in theology at Lerida in 1384. He was the chosen companion of cardinal de Luna, the pope's legate to France; and on his return was summoned to Avignon, in 1394, by the same cardinal, when he rose to the papal chair under the name of Benedict XIII. Yielding to an imagined impulse for preaching the word of God, he became a missionary in 1397, and travelled through several countries, not excepting Britain and Ireland. He also exerted himself in terminating the discord of the Romish church with regard to the papacy, and finding Benedict unrelenting, he abandoned him, and assisted at the council of Constance. In 1407 he accepted the invitation of John, duke of Brittany, and fixed the seat of his mission at Vannes, where he died in 1410. After his death, miracles were said to have been wrought at his tomb, and he was canonized by pope Calixtus III. He was the author of many devotional tracts; and his "Treatise on the Spiritual Life, or interior Man," was frequently reprinted. Dupin. Moreri.

VINCENT of Lerins, was a native of Gaul in the fifth century, who abandoning the military profession, and adopting a religious life, retired to the monastery of Lerins in Provence, where he became a priest. He was held in high estimation for his piety and learning; and after his death, in the reign of Theodosius and Valentinian, was canonized by the Roman church, to which he was thought to be entitled for his "Commonitorium adversus Hæreticos," which was neatly written, and much applauded by the Roman Catholics. Of this work Dr. Maclaine, deviating from the article of Mosheim, says, that he can see nothing in it but a blind veneration for ancient opinions. It has been printed in the "Bibliotheca Patrum," and has been published separately, particularly at Cambridge, in 1687. Dupin. Mosheim.

VINCENT DE, PAUL, founder of the congregation of the "Priests of the Missions," (see MISSION,) was born at Poui, or Poy, in the diocese of Acqs, in the year 1576, and advanced, on account of his extraordinary talents, and by a course of education at Acqs and Toulouse, from the humble condition of a shepherd to the office of priest in 1600. Having occasion soon afterwards to visit Marseilles, for the purpose of receiving a small property which devolved upon him by inheritance, he was, upon his return by sea to Narbonne, taken captive by a Barbary corsair, and sold for a slave at Tunis. Here he served several masters, the last of whom, who was a Savoyard renegade, he was successful in reclaiming. They both determined on making their escape, and arrived safely in a small boat at Aignes Mortes, in 1607. Upon his return to his native country, he was deputed by Peter Montorio, vic-legate of Avignon, on business of importance to the court of Rome; and here he was intrusted by the minister of Henry IV. with a commission to that monarch in 1608. In return for this service, Lewis XIII. conferred upon him the abbey of St. Leonard de Chaume. Having been introduced as tutor to the family of M. de Goudy, general of the galleys, he conceived the design of

founding the congregation above-mentioned; and in the mean while, wishing to serve the miserable objects that were under the care of his patron, he applied to court for the appointment of almoner-general of the galleys, and obtained it in the year 1619. His assiduity in the discharge of the duties of his office, as well as the piety and benevolence of his disposition, engaged the general esteem and respect of the inhabitants of Marfeilles. Devoted to acts of compassion and beneficence, he was entrusted, in the year 1620, with the direction and government of the order of the "Daughters of Charity." His next object was the accomplishment of his purpose with regard to a new community, in which he obtained the concurrence of some priests, who made choice of him as their principal. This institution was prosperous, and the number of the society having increased, he accepted the great house of St. Lazarus, in the suburb of St. Denis, which became the principal house of his order; and in 1632, its utility was acknowledged by pope Urban VIII., who formed it into a regular congregation, and appointed its founder as the first superior general. The rule prescribed to the society enjoined, independently of attention to their own religious exercises, the appropriation of eight months in the year to the instruction of the common people in the neighbouring parishes, to the relief of the sick and indigent, to inspection of seminaries in which young persons were educated for holy orders, and to other acts of private and public service. The superior conducted himself with so much zeal and activity, that he obtained encouragement in the prosecution of his plan, not only in all parts of France, but also in Italy, Scotland, Barbary, Madagascar, &c. Not satisfied with the single object to which his benevolent attention was first directed, he took a very active part in the conduct and support of many other institutions of a benevolent and useful kind. So highly was he esteemed on account of his piety and prudence, and his zeal for doing good, that he was engaged in regular attendance on Lewis XIII. during his last sickness; and under the regency of Anne of Austria, mother of Lewis XIV., he was the chief adviser in all the ecclesiastical affairs of the kingdom. For a period of ten years, during which he possessed this influence, he maintained the most exemplary character in the discharge of his public duties, as well as in his private conduct. He died in 1660, at the age of nearly 85 years. He was beatified by pope Benedict XIII. in 1729, and canonized by Clement XII. in 1737; and it must be allowed, that he occupies a distinguished rank among the saints in the Romish calendar. Moreri. Mosheim.

VINCENT, GREGORY *St.* See GREGORY ST. VINCENT.

VINCENT, in *Geography*, a township of America, in the state of Pennsylvania, and county of Chester, containing 1630 inhabitants; 25 miles W. of Philadelphia.

VINCENT, *St.*, one of the Cape Verd islands, being one of the four situated towards the north-west, about 30 miles in circumference; the land of which is generally elevated, but towards the north-west low and sandy; so that it is unproductive, and the island probably still uninhabited. It has good fresh water, which springs up on digging a little way into the soil of the valley, but the hills are totally destitute of it; and, therefore, the island is improper for cattle. It has a fine large road called Porto Grande, with a rock like a tower in the centre. The bay, which is about a league and a half broad at the mouth, is surrounded with high mountains, and stretching into the middle of the island, is thus sheltered from the west and north-west winds; and, therefore, it is deemed the safest harbour in all the Cape Verd islands; but difficult of access, on account of the im-

petuous winds that blow off the mountains along the coast, so as to endanger ships before they can arrive at this place of security. Besides this bay, there are several others on the fourth side, in which ships may anchor; and these are generally chosen by the Portuguese for landing their hides. The fish are numerous and excellent. The fourth part of the island is situated in N. lat. 16° 50'. W. long. 25°. See *Cape Verd*.

VINCENT, *St.*, one of the Charibbee islands in the West Indies, about 40 miles in length, and 10 in breadth. Dr. Campbell says, that the Spaniards called it by this name, because they discovered it upon the 22d of January, which, in their calendar, is St. Vincent's day; but it does not appear that they ever, properly speaking, had possession of it; as the Indians were very numerous here, on account of its being the rendezvous of their expeditions to the continent. At length, however, ambition and avarice effected an establishment for a clats of intruders, who were long distinguished by the name of the black Charibes, whom the native Charibes regarded at first with contempt and pity. Of the origin of these intruders Campbell gives the following account. In 1672, king Charles II. divided the governments in the West Indies, and, by a new commission, appointed lord Willoughby governor of Barbadoes, St. Lucia, St. Vincent, and Dominica; and sir William Stapleton governor of the other Leeward islands, which separation has ever since subsisted. On the demise of lord Willoughby, he was succeeded by sir Jonathan Atkins, who continued governor until the year 1680, when the government was transferred to sir Richard Dutton; who, being sent for to England in 1685, appointed colonel Edwin Stade lieutenant-governor; and he, with a view of asserting and maintaining the British rights, by constituting deputy-governors for the other islands, exerted himself in preventing the French from wooding and watering in this island without permission. At this time it was intimated to him, that the king had signed an act of neutrality, and that commissioners were appointed by the two courts to settle all differences relating to these islands. Some years after, a ship from Guinea, with a large cargo of slaves, was either wrecked or run ashore upon the island of St. Vincent, into the woods and mountains of which great numbers of the negroes escaped, whom the Indians suffered to remain. Partly by the accession of runaway slaves from Barbadoes, and partly by the children they had by the Indian women, these Africans became very numerous; so that about the beginning of the 18th century, they constrained the Indians to retire into the north-west part of the island. These people, as may be reasonably supposed, were much dissatisfied with this treatment; and complained of it occasionally both to the English and to the French, that came to wood and water amongst them. The latter at length suffered themselves to be prevailed upon to attack these invaders. After much deliberation, in the year 1719, they came with considerable force from Martinico, and landing without much opposition, began to burn the negro huts, and destroy their plantations, supposing that the Indians would have attacked them in the mountains; which, if they had done, the blacks had probably been extirpated, or forced to submit, and become slaves. But either from fear or policy, the Indians did nothing, and the negroes falling in the night, and retreating to inaccessible places by day, destroyed so many of the French, that they were forced to retire. When by this experiment they were convinced that force would not do, they had recourse to fair means; and by dint of persuasion and presents, patched up a peace with the negroes as well as the Indians, from which they received great advantage.

tags. Things were in this situation, when captain Uring came with a considerable armament, to take possession of St. Lucia and this island, in virtue of a grant of king George I. to the duke of Montague. When the French had dislodged this gentleman, by a superior force, from St. Lucia, he sent captain Braithwaite, in the year 1723, to try what could be done at the island of St. Vincent, in which he was not at all more successful. After this, the country became a theatre of savage hostilities between the negroes and the Charaibes, in which it is believed that the former were generally victorious: it is certain they proved so in the end, their numbers, in 1763, being computed at 2000; whereas of the red or native Charaibes, there were not left more than 100 families, who retained only a mountainous district, and most of these are by this time said to be exterminated. It is, however, worthy of remark, that the African intruders have adopted most of the Charibbean manners and customs: among the rest, the practice of flattening the foreheads of their infants; and it was perhaps from this that they acquired the appellation of black Charaibes. St. Vincent being ceded to the English by the peace of Paris, in the year 1763, as well as Dominica and Tobago, St. Lucia being assigned to France, (the Charaibes not being mentioned in the whole transaction,) the first measure of the English government was to dispose of the lands, without any regard to the claims of the Charaibes of either race; which, in truth, were considered as of no consequence or validity. This gave rise to a war with the Charaibes, in the course of which it became the avowed intention of government to exterminate those miserable people altogether; or by conveying them to a barren island on the coast of Africa, consign them over to a lingering destruction. By repeated protests and representations from the military officers employed in this disgraceful business, and the dread of parliamentary inquiry, administration at length thought proper to desist; and the Charaibes, after surrendering part of their lands, were permitted to enjoy the remainder unmolested. On the 19th of June 1779, St. Vincent shared the common fate of most of the British West India possessions, in that unfortunate war with America, which swallowed up all the resources of the nation, being captured by a small body of troops from Martinico, consisting only of 450 men, commanded by a lieutenant in the French navy. The terms of capitulation, however, were favourable, and the island was restored to the dominion of Great Britain by the general pacification of 1783. It contained at that time 61 sugar estates, 500 acres in coffee, 200 acres in cacao, 400 in cotton, 50 in indigo, and 500 in tobacco, besides land appropriated to the raising of provisions, such as plantains, yams, maize, &c. All the rest of the country, excepting the few spots that had been cleared from time to time by the Charaibes, retained its native woods. St. Vincent contains about 84,000 acres, which are every where well watered; but the country is very generally mountainous and rugged: the intermediate valleys, however, are fertile in a high degree, the soil consisting chiefly of a fine mould, composed of sand and clay, well adapted for sugar. The extent of country at present possessed by the British subjects is 23,605 acres; and about as much more is supposed to be held by the Charaibes. All the remainder is thought incapable of cultivation or improvement. The island, or rather the British territory within it, is divided into five parishes, of which only one had a church, and this was blown down in the hurricane of 1780. There is one town called Kingiton, the capital of the island, and the seat of its government; and three villages that bear the name of towns, but they are inconsiderable hamlets, consisting each of a few houses only.

The botanic garden of St. Vincent consists of 30 acres, of which no less than 16 are in high cultivation. In the frame of its government, and the administration of executive justice, St. Vincent seems not to differ from Grenada. The council consists of twelve members, the assembly of seventeen. The salary of the governor is 2000*l.* sterling, half of which is raised within the island, the other half being paid out of the exchequer of Great Britain. The military force, according to Mr. Edwards, consisted in his time of a regiment of infantry, and a company of artillery, sent from England, and a black corps raised in the country. The militia includes two regiments of foot, serving without pay. The number of inhabitants, says Mr. Edwards, amounts to 1450 whites, and 11,853 negroes. The several smaller islands dependent on the St. Vincent government are Bequia, containing 3700 acres, a small island, valuable for the commodiousness of its bay, called Admiralty bay; Union, containing 2150 acres; Canouane, containing 1777 acres; and Mustiqua, containing about 1200 acres. The negroes employed in the cultivation of these islands, being about 1400, are supposed to be included in the 11,853 before mentioned. There are likewise the little islets of Petit Martinique, Petit St. Vincent, Maillereau, and Bellefau, each of which produces a little cotton. N. lat. 13° 10'. W. long. 61°. Edwards's West India Islands, vol. i.

VINCENT, *St.*, a town of United America, in the western territory of the Wabash. N. lat. 38° 44'. W. long. 88° 6'.

VINCENT, *St.*, a town of France, in the department of the Lot; 6 miles W. of Cahors.

VINCENT, *St.*, a sea-port town of Brazil, in the government of St. Paul, situated on the sea-coast; 150 miles W. of Rio Janeiro. See SANTOS, *St. Vincent*, and VICENTE.

VINCENT, *St.*, a river of Madagascar, which runs into the Indian sea, on the east coast, S. lat. 21° 48'. E. long. 44°.

VINCENT, *St.*, a town of Peru, in the diocese of La Plata; 40 miles N.E. of Lipas.

VINCENT *d'Ardenes*, *St.*, a town of France, in the department of the Indre; 7 miles S.E. of Châteauroux.

VINCENT, *Cape St.*, the south-west point of Portugal, where commences a chain of lime-stone mountains, which terminates at Tavira, N. lat. 37° 2'. W. long. 6° 5'. Towards this cape the hills become flatter, and this promontory itself is a desert plain, consisting of a grey lime-stone, so naked and rough near the front, that it is very difficult to travel over it. In other parts it is nearly covered with sand. Toward the sea the rock is every where fractured, about 50 to 80 feet high, being of equal height with Cabo de Roeca, which it somewhat resembles. At the utmost extremity in this desert country is a monastery of Capuchins. Ships can approach very near the rock, so that in fine weather the monks can speak to the persons on board. The famous naval engagement between the Spaniards and lord St. Vincent was distinctly seen from this monastery. On another point of the rock, separated by a creek from the extreme end, is the small fort of Sagres, within which nothing is seen but the commandant's dwelling, the soldiers' barracks, and the works which are not allowed to be surveyed. Without the fort are only two houses. At the time when the earthquake of 1755 destroyed Lisbon, the sea swelled here, and pouring from the creek over the land, laid the country waste. At Sagres a great quantity of fish and muscles is taken, and small fishing-smacks lie at anchor under the rock in the creek. Five small leagues from Cape St. Vincent is the city of Lagos, which is properly the chief town of Algarve, though it be no longer the residence of the governor of that province.—Also, a cape on the west coast

coast of Madagascar. S. lat. $25^{\circ} 38'$. E. long. $43^{\circ} 50'$.—Alfo, a cape on the east coast of Terra del Fuego. S. lat. $54^{\circ} 25'$.

VINCENT DE CONNOZAL, *St.*, a town of France, in the department of the Dordogne; 14 miles W. of Perigueux.

VINCENT DE BEIRA, *St.*, a town of Portugal, in the province of Beira; 15 miles W.N.W. of Castel Branco.

VINCENT DE LA BARQUERA, *St.*, a sea-port of Spain, in the province of Asturia; 9 miles W.S.W. of Santillana.

VINCENT DE RIVEDOT, *St.*, a town of France, in the department of the Dordogne; 6 miles S. of Riberae.

VINCENT'S BAY, *St.*, a bay on the north coast of Terra del Fuego, a little to the east of Cape St. Vincent. Before the anchorage ground, says captain Cook, lie several rocky ledges that are covered with sea-weed; but not less than eight and nine fathoms over all of them. It appears strange that where weeds, which grow at the bottom, appear above the surface, there should be this depth of water; but the weeds which grow upon rocky ground in these countries, and which always distinguish it from sand and ooze, are of an enormous size. The leaves are four feet long, and some of the stalks, though not thicker than a man's thumb, above 120. Mr. (sir Joseph) Banks and Dr. Solander examined some of them, over which we founded and had 14 fathoms, which is 84 feet; and as they made a very acute angle with the bottom, they were thought to be at least one half longer. The footstalks were swelled into an air-vessel, and these eminent naturalists called this plant *fucus giganteus*. They went on shore, and in about four hours returned with above a hundred different plants and flowers, all of them wholly unknown to the botanists of Europe. They found the country about the bay to be in general flat, the bottom of it in particular was a plain, covered with grass, which might easily have been made into a large quantity of hay; they found also abundance of good wood and water, and fowl in great plenty. Among other things, of which nature has been liberal in this place, is Winter's bark, *Winteranea aromatica*; which may easily be known by its broad leaf, shaped like the laurel, of a light green colour without, and inclining to blue within; the bark is easily stripped with a bone or a stick.

VINCENT DE LA PASSES, *St.*, or *Onda*, a town of Popayan, in Terra Firma, about 25 miles E. of St. Sebastian's, with a port, where canoes from Carthage and St. Martha unload their merchandize.

VINCENT, *Port St.*, lies on the coast of Chili, in the South Pacific ocean, 6 miles N.N.E. of the mouth of the river Bobio, with a safe harbour, secure against all winds but that from the west, which blows right into it. Talca-guana port is six miles to the north of it.

VINCENT'S ROCKS, *St.*, rocks on each side of the river Avon, about three miles below Bristol; at the bottom of which is the spring from which rise what are called the Bristol waters.

VINCENT ISLAND, a small island in the North Pacific ocean, at the entrance into Portlock's harbour. N. lat. $57^{\circ} 48'$. W. long. $136^{\circ} 30'$.

VINCETOXICUM, in *Botany*, from *vinco*, to conquer, and *toxicum*, poison, a name which first occurs in Dodonæus, *Pempt. 407*, and which he says had been recently given to the official *Alepias*, (*A. Vincetoxicum*, Linn. Sp. Pl. 314. *Cynanchum Vincetoxicum* of Brown, in Ait. Hort. Kew. v. 2. 77.)—The plant thus denominated was supposed destitute of the dangerous and acrid properties of the rest of its tribe, because its juice is not milky. The root, whose flavour and scent resemble Valerian, has been used as a counter-poison, in the place of Contrayerva, whose name

has the same meaning, and each may have its use as a tonic, or stimulant, however erroneous the idea may seem of a specific, against any poison whatever, except by a chemical alteration of its qualities. Among plants, at least, no such marvellous power has hitherto been ascertained. The above root is scarcely ever used in this country.

VINCETOXICUM, in the *Materia Medica*. As a medicine, this root has been chiefly used in dropical disorders, but its good effects are not sufficiently established; which is also the case with respect to Stahl's pulvis antihydropsicus, in which the vincetoxicum is an ingredient. It has been also recommended in malignant fevers, and even in the plague, by some German authors; and hence called "Contrayerva Germanorum." It is said likewise to be useful in small-pox, scrophula, and uterine obstructions. The dose, in powder, is from a scruple to a drachm, or an infusion of three or four drachms. Woodville.

VINCI, LIONARDO DA, in *Biography*, the illegitimate son of Piero da Vinci, a notary of the signoria of Florence, distinguished himself during his life as a man of science and of literature, a philosopher, poet, painter, and musician of the most profound study, and the most exalted taste. He was born at the castle of Vinci, in the lower vale of the Arno, in 1452. From his earliest years he testified a more than ordinary share of ingenuity, and particularly exhibited an ardent desire for drawing. This at length became so decided a preference above all other pursuits, that it determined his father to indulge and cultivate it; and for this purpose he placed him under the tuition of Andrea Verocchio, a skilful designer, and eminent as a sculptor, an architect, and a painter. The progress of Lionardo equalled the sanguine expectation his intellectual abilities had excited; and whilst a youth, he surpassed his master in the practice of the art he had learnt of him. Verocchio had been employed by the monks of S. Salvi at Valombroso, to paint the Baptist of Christ, as an altar-piece for their church, and having made his designs, he entrusted the preparation of the parts to his disciples. Among them, the young Da Vinci was ordered to paint the figure of an angel, which he did with so much taste and skill, and so far surpassing the work of his master, that Verocchio, mortified at being excelled by a youth, abandoned the art, and from that time confined himself to sculpture.

The career of this extraordinary man, thus begun in honour, was pursued with enthusiasm in all things relative to art and science. Nature had endowed him with the beauties of body and of mind, and he cultivated the useful exercise of both. His person was finely proportioned, and his features beautiful and expressive; he was dexterous in feats of arms, the management of the horse, and all the favourite amusements of the time. He was admirably skilled in mechanics, was an able anatomist, and an architect; was learned in natural philosophy, optics, and geometry; in short, he had steadily applied himself to acquire a thorough knowledge of the operations of nature; and was besides an excellent poet and musician.

Thus endowed, and constituted to apply these endowments with energy to every useful and ornamental purpose, fame crowned his portion of human felicity by spreading the renown of his uncommon talents throughout Italy. His various application of them had however one evil attending it,—a certain portion of infatigability: the impetuosity of his nature, leading him too rapidly to new projects, often prevented the completion of those already commenced. In his youth, Vafari says, he invented mills and engines to go by water for various purposes, and contemplated schemes for making the Arno navigable from Pisa to Florence; he; made

plans for roads, for raising water, &c. : yet amidst these occupations he cultivated drawing most assiduously from all kinds of objects of animated nature, in a style of the most laboured and exquisite finishing, as if he never could attain too close an imitation of the object he had selected. He always strove to make them appear as strongly relieved as possible ; their defect is, that not having hit upon the true nature of relieving objects, such as has been exemplified in the Dutch school since his time, he laboured his works to blackness ; and whilst his principal objects appeared illuminated by the light of the day, his shadows partook of the blackness of night.

He delighted in observing those whose character was strongly marked, who had any thing extravagant in the style of their beards, their hair, or dress, and would follow them till he had fixed their form fully in his mind, and then go home and draw them. By studies of this nature he became possessed of strong ideas of expression and of character, and employed himself actively in the use of them in designs ; though the finished works of his hand, which conjecture places at this period of his life, are not of a kind to exhibit much of their application.

His life, Lanzi observes, " may be divided into four periods, the first of which was, as we have seen, spent in prosecuting his studies in art, and occasionally applying them to practice in Florence : to this belong not only the head of Medusa, and the few works mentioned by Vasari, but probably all those paintings of his which have less energy of shade, less complicated drapery, and heads of forms rather delicate than exquisite, seemingly derived from the school of Verocchio. Such are the Maddalenas of the Pitti palace at Florence, and the Aldobrandini at Rome ; some Madonnas or holy families in various galleries, as the Justiniani and Borgese ; some heads of the Saviour and of the Baptist ; though the multitude of his imitators must render all decision on their originality ambiguous. Of a different class, however, and without a doubt of his hand, is the Bambino, who lies in a little ornamented bed, richly dressed and adorned with necklaces, which is in the apartment of the *Confalonière* at Bologna."

After this first period of his life, when he was forty-two, viz. in 1494, he was invited to Milan by the duke Ludovico Sforza, to whom Leonardo rendered himself more particularly acceptable by playing upon the lyre, and upon one of a peculiar form, which he himself had made. To this instrument he sung also admirably, and recited verses extemporaneously, surpassing all who attempted that species of amusement. But the more effective cause assigned for his going to the duke, was a design entertained by that prince of erecting a monument of bronze to the memory of his father. Among the manuscripts still existing of Leonardo, is a memorial presented by him to the duke about 1490. In it he offers his services in various military mechanical contrivances, for the purpose of aiding in sieges, passing rivers, &c. and also for the conducting water-courses, sculpture in bronze or marble, and painting ; and in conclusion remarks, " that at the same time that these things are going on, the equestrian statue to the memory of the duke's father need not be neglected." So that it appears by this, that the modelling and erection of this statue were the primary objects for which he was carried to Milan ; and it was executed by him in bronze, and erected in the city, where it remained till it was demolished on the incursion of the French, after the defeat of Ludovico. The duke appointed him director of the academy of painting and sculpture, which he had recently revived with additional splendour ; and under his instructions many pupils arose, who increased the love and

renewal of the arts, as he in great measure banished the remains of the Gothic style, and introduced his own new and more elevated one in its stead.

Here, by desire of the duke, he painted a Nativity, which was sent by him as a present to the emperor of Germany ; but if we except this, the portraits of the duke and duchess, and his grandest work in the art, the Last Supper, painted on the walls of the refectory of the Dominican convent of the *Madonna delle Grazie*, he does not appear to have occupied much of the time he spent at Milan (which was about five years) in painting. Indeed he scarcely could devote more time to it, as the duke engaged him as an engineer to conduct the waters of the *Adda* to the walls of Milan : an immense operation, in which, after much study and labour, he had nearly succeeded, when it was interrupted by the French. He also made many models of ingenious mechanical contrivances, and among them a lion, in compliment to the king of France, on his arrival at Milan, which, after advancing by itself many paces to meet the monarch, suddenly stopped when it came near him, reared upon its hinder legs, and threw open its breast, which was filled with lilies.

Whilst these various inventions shewed the versatility of his powers, the picture above alluded to, the Last Supper, gave immortality to the fame of the moment. Of this picture, one only character is given by all who have written or spoken of it,—that of superior excellence in all the most admirable and exalted qualities of the art. Unfortunately, his knowledge in chemistry was not equal to his love of novelty, or he would not have painted it with a vehicle and a ground totally discordant, which necessarily led to a speedy destruction of the surface. He painted it with oil colours upon the plastered wall, and in consequence the colour cracked and peeled off ; so that in fifty years after it was painted, when Armenini visited it, he says " it was already half spoiled ;" and Scannelli, who saw it in 1642, says, that " the subject was scarcely discernible." Lanzi, in speaking of it recently, observes, that " what with the attempts to restore it by oils and varnishes, and with the repainting which has accompanied these attempts, there now remain only three heads of the apostles by the hand of Da Vinci, and those rather drawn than coloured." The assent, therefore, which may be now given to the high testimony of contemporary authorities as to the merit of this great work, rests with the copies which were made when the picture was perfect, (and they are many,) and the general character of Leonardo's talent.

There has lately been introduced into England, and is now exhibiting, (1817,) a copy as large in length as the original, said to be the one painted by M. Uggione, a pupil of Da Vinci, for the convent of the *Carthusians* at Pavia ; which in 1793, upon the breaking up of that order, was sold with the other effects of the convent, and is now brought here. In it there remains sufficient of the grandeur of style adopted by its great author to satisfy every beholder of the justice fame has done to his talents. The selection of matter, the general treatment of the subject, the unequalled truth and variety of expression, the close attention paid to character and to nature, the depth, richness and brilliancy of its colour, with the high degree of finish to which it was carried,—all are manifested in this copy, though in some parts imperfectly. In it also are seen the want of many points in chiaro-scuro and in colour, which, if they could have been combined with the matter it contains, (and they have since then been combined by Titian and others,) would place the original of this picture in every respect at the head of all the pictures which ever were painted.

During

During his residence at Milan, Du Fresne says he composed his very useful work "Il Trattato della Pittura," for the use of the pupils in the academy under his care; and his studies for the equestrian statue doubtless gave rise to the curious and learned memoranda of the structure of that animal, as his former studies did to those concerning the human figure, which are found in the manuscript in the library of Buckingham-House. It appears to have been his customary practice to write his thoughts constantly, and accompany the passages by appropriate illustrations in drawing; and it would have been well for the art, if every eminent professor had adopted the same habit: we should then have been in possession of a mass of information which would much alleviate the necessities involved in practice, and enable men to express their thoughts and inventions without encountering the difficulties which not unfrequently flit the most beautiful and sublime conceptions in their birth.

The activity and exertions of Lionardo, supported by such uncommon talents, had already formed many skilful artists, who afterwards became renowned, and who would probably have rendered Milan the rival of Florence as a school of art, but for the disastrous issue of a contest between the duke and the king of France, in which, in 1500, the former was defeated, captured, and carried into the country of his enemy, where about ten years afterwards he died.

By this event the progress of the arts at Milan was broken up, with its academy for a time, and its illustrious president returned to Florence, where the arts were encouraged by the house of Medici. In this third period of his life, his first work was a design for an altar-piece for the chapel of the college of the Annunciate, the subject of which was a group, of our Saviour with the Virgin and St. Anne, which was universally approved and admired; yet it does not appear that the picture was ever painted, at least to remain in Italy. It is said, that by the desire of Francis I. he made a picture from it, and certainly one is shewn in the royal collection at Paris, painted from the design, though in a heavy and low tone of colour.

He employed himself also about this time on a portrait of Mona Lisa, known by the name of La Gioconda, a Florentine lady, wife of Francisco del Gioconda, for whom it was painted. This picture he is said to have employed himself upon during four years, but we must conceive it to mean only that it remained unfinished that length of time. It is in possession of the king of France, and attests, by its exquisite finish, the laborious attention of its author. It has a very beautiful expression, particularly about the mouth; but is black and heavy in the shadows: in fact it is overlaboured, and had probably been far better had it left his study sooner.

In 1503, the council of Florence having determined to decorate their chamber with works of art, Lionardo was appointed to execute one side of it; and M. Angelo, then only twenty-nine years of age, but whose gigantic powers were already matured, was selected, as his competitor, to undertake the other. A most unfortunate coalition, as the emulation it excited, aided and strengthened to bitterness by the mistaken affection of admiring partisans of either master, produced in the end the most confirmed jealousy, and even hatred, between these two great men, and divided Florence into parties, who embittered their disputes, without being able to reconcile their differences. Lionardo chose for his subject the battle of Nicolo Piccinino against Attila. He had prepared his cartoon, and proceeded in a certain degree with his picture in oil colours, when to his great mortification he found, that owing to some imperfection in the pre-

paration of the ground, his colours began to peel from the wall, and he abandoned the work.

The cartoon, however, of which we have one group preserved to us in the Battle of the Standard, engraved by Edelinck, had exalted his name highly among artists and connoisseurs, who flocked to Florence to see it and its rival, which had been prepared by M. Angelo; and among others Raffaele, in 1504, was drawn there, allured by the desire of improving the taste he had imbibed in the school of Perugino; and there, with the benefit he derived from these great works, and the instruction of Bartolomeo della Porta, he shook off in a great degree the dry and Gothic manner of his master, and laid the foundation of his future fame.

Lionardo appears to have divided his residence at Florence and at Milan till 1513, during which time he probably painted his own portrait, which is in the gallery at Florence, a head whose energy leaves all the rest in the room far behind, and that perhaps which in many cabinets is called the portrait of Raffaele. The half figure also of a young nun in the palace Nicolini; Christ among the doctors, formerly in the Doria palace; the supposed portrait of queen Giovanna, adorned with beautiful architecture; that picture in the Barberini of Vanity and Modesty, the beauty and finish of which no one has ever been able to convey in a copy;—these appear, with many others, to belong to this period, when, free from other serious occupations, he was at liberty to attend to painting with increasing power.

No work, however, of any consequence like his Last Supper, was entrusted to him after the failure in the Hall at Florence, so that his great and deserved renown in the art is principally upheld by that work, and the remnant of the cartoon above-mentioned, to which his minor works, though beautifully wrought, are but trifles.

The election of cardinal Giovanni di Medici to the tiara under the title of Leo X. induced Lionardo to visit Rome, which he had never seen: and from his previous knowledge of the pontiff, he hoped for honour and employment. He went there with his patron Giuliano di Medici, and was graciously received by Leo, who soon after signified his intention of employing his pencil. Upon this Lionardo began to distil his oils and prepare his varnishes, which the pope seeing, and being unacquainted with the necessities of the painter's style, he exclaimed with surprise, that nothing could be expected of an artist who thought of finishing his works before he had begun them. This unlucky *bon mot* disconcerted the painter, and prevented him from proceeding: and probably he found the ground too firmly occupied by Raffaele and M. Angelo, (who as the pope said produced works while Lionardo gave words), to leave room for the expectation of honourable employment for himself. He therefore accepted an invitation from Francis I., king of France, to visit his court, and left Rome in 1514 for that purpose, having spent his time there principally in the production of various fantastic and diverting mechanical contrivances, but in nothing of importance.

This change of circumstances marks the fourth period into which Lanzi divides the life of this most extraordinary man, and with its commencement terminated his career in art, as he appears to have been so exhausted by anxiety and sickness on his arrival in France, that he was never more able to use the pencil. For the five years that he continued to exist, it was but to struggle under an incurable complaint, during the continuance of which the king frequently visited him; and it has been said, that in one of these visits Lionardo, exerting himself beyond his strength to shew his sense of his majesty's condescension, was seized with a fainting fit, and that the king stooping forwards to support

support him, he expired in his arms. This event occurred on the 2d of May, 1519, at a place called Cloux, near Amboise, and in the 67th year of his age.

There are so many imitators of the style of Da Vinci, that it is extremely difficult to know what to regard as his among the numerous minor productions which are presented to us as the product of his easel. Among those imitators, Bernardino Luini holds the first rank, and his pictures are constantly imposed upon us as those of Lionardo. Lorenzo di Credi is another who copied Lionardo with great exactness. Antonio Sogliani also imitated and copied him as well as others; so that no wonder there are so many works brought to sale under the high pretension of his name, by which our connoisseurs are duped and our picture-dealers are enriched.

The real character of Lionardo da Vinci as a painter is of the highest quality, as we have before observed. He is the parent of the chiaro-scuro, upon which the fame of Correggio principally depends; and he first attempted to combine high finish with selection of parts and grandeur of style, particularly aiming to give intelligence to character and expression to features; in fact, to pourtray the mind: and in this no one has ever surpassed him, not even Raffaele, who followed in this respect the road opened by Da Vinci. What is commonly called the beau-ideal, was not exactly the form he appears to have sought; but he had so much the feeling which generated it, that he always took from his model the essential and characteristic, leaving out the mean and useless. Hence we find in his picture of the Last Supper so great a variety of character and of expression, which those who have attached themselves to the antique as their guide have never given; the imitation having, as we conceive, always superseded the original spirit of selection which dictated the taste of the ancients.

Two different manners are observable in his painting; one with dark shades, strongly contrasting with the lights, the other more placid, and conducted with more of middle tint. Grace of design, expression of the mind, and subtle management of the pencil, triumph in and adorn each; all is gay in his pictures, but especially the heads of his women and children. In these he constantly repeated one idea, giving a smile to them which it is impossible to behold without experiencing a sympathetic impulse. Yet, if one may judge from the labour of his pictures, he rarely reached the point at which he aimed, having an impression in his own mind more full and complete than he could render by his pencil; and, like Protogenes of old with his Jadyfus, knew not, as Apelles said of him, when to leave off, nor could be contented with good, when he aspired after the best.

As an author, Lionardo da Vinci has rendered essential service to art, particularly in his Treatise on Painting, which is the only one of his numerous compilations that has been given to the public, and which has been recently (in 1802) translated into English by a member of our Royal Academy, J. F. Rigaud, esq. Venturi speaks of this work as having been compiled from various of his manuscripts, which were doubtless the product of his every-day reflections, set down as they occurred, and without attention to order or arrangement. It treats of proportion, anatomy, motion and equipose of figures, perspective, composition, expression, light and shade, colouring, &c. in 365 precepts, some of which are confused and not easily to be unravelled, others are common place, but most are learned, ingenious, and useful. The rest of his miscellaneous works, treating of the anatomy of the horse and of the human subject, of perspective, optics, hydraulics, botany, &c. were left by him in his will to his friend and pupil Francisco Melzi, and consisted of fourteen

volumes, large and small, which by various means found their way into the national library at Paris, and one is in possession of our own sovereign. Venturi, who saw these at Paris, says "that they contain speculations on those branches of natural philosophy nearest allied to geometry, are extremely miscellaneous, and entered without regard to method or arrangement." Whether the change of events in the political world since his time has reconveyed these remains to the Ambrosian library at Milan, we know not, but most probably they are again returned there. The one in the library at Buckingham-House was the property of Pompeo Leoni, who obtained it, with two others since returned, from H. Melzi, and it is probable it was acquired by the earl of Arundel for Charles I. It was found, soon after his present majesty's accession, in the same cabinet where queen Caroline found the portraits of the court of Henry VIII. by H. Holbein.

VINCI, LEONARDO, an admirable opera composer of the Neapolitan school, is said to have run away from the conservatorio of Gli poveri in Giesù Cristo in that city, where he was the scholar of Gaetano Greco, on account of a quarrel with Porpora, a student of the same seminary. He began to distinguish himself in the year 1724, when he set the opera of Farnace for the Aliberti theatre at Rome. So great was the success of this drama, that he was called upon to furnish at least one opera every year till 1730, when he composed two, "Artaserse," and "Alessandro nell' Indie," both written by Metastasio. These, as we were informed at Rome, he set for half price, to gratify his enmity to Porpora, who was then his rival, in that city.

The vocal compositions of Vinci form an era in dramatic music, as he was the first among his countrymen who, since the invention of recitative by Jacopo Peri, in 1600, seems to have occasioned any considerable revolution in the musical drama. The airs in the first operas were few and simple; but as singing improved, and orchestras became more crowded, the voice-parts were more laboured, and the accompaniments more complicated. In process of time, however, poetry seems to have suffered as much as ever from the pedantry of musicians, who forgetting that the true characteristic of dramatic music is clearness; and that sound being the vehicle of poetry and colouring of passion, the instant the business of the drama is forgotten, and the words are unintelligible, music is so totally separated from poetry, that it becomes merely instrumental; and the voice-part may as well be performed by a flute or violin, in the orchestra, as by one of the characters of the piece, on the stage. Vinci seems to have been the first opera composer who saw this absurdity, and, without degrading his art, rendered it the friend, though not the slave to poetry, by simplifying and polishing melody, and calling the attention of the audience chiefly to the voice-part, by disentangling it from fugue, complication, and laboured contrivance.

In 1726, he set Metastasio's "Didone Abandonata" for Rome, which established his reputation; for in this exquisite drama, not only the airs were greatly applauded, but the recitative, particularly in the last act, which being chiefly accompanied, had such an effect, that, according to count Algarotti, "Virgil himself would have been pleased to hear a composition so animated and so terrible, in which the heart and soul were to be as often assailed by all the powers of music." Saggio sopra l'Opera in Musica.

We shall mention the rest of this pleasing and intelligent composer's operas, the airs of which long served as models to other masters, and are not yet become either ungraceful or inelegant.

In 1727, he composed "Gismondo, Re di Polonia;" in 1728,

1728, "Catone in Utica;" in 1729, "Semiramide Riconosciuta;" and in 1730, "Alessandro nell' Indie," and "Artaferse," all for the theatres in Rome. The celebrated air at the end of the first act of Artaferse, "Vo folcando un mar crudele," originally composed for Caretini, is well known, and is perhaps the only production of Vinci by which his merits have been favourably estimated in England. In the printed book of the words, Vinci is called "Pro-vince maestro della Real Capella di Napoli."

We have been able to find no more of his works after this period; so that he must either have begun late, or been cut off early in life, as his great and durable renown seems to have been acquired in the short space of six years of his existence.

Vinci began that free and truly dramatic style of composition, which Haffé and Pergolesi afterwards, perhaps, improved; but it is a style which no good composer, except Gluck, has abandoned. It has been, indeed, embellished and rendered more elegant by the disciples of Durante: Piccini, Sacchini, Traetta, and Anfossi; but they have all been guided by the outline of Vinci.

This justly admired composer died at Rome in 1731, during the first run of his Artaferse. Metastasio, in a letter to the Romanina, makes a melancholy reflection on the subject: "Poor Vinci! Now that merit will be known, which during his life was blatted by his enemies.

"What a miserable being is man! He thinks fame the only good that can render him happy; but alas! he must die ere he is allowed to enjoy it; and if he does not die, envy will make him wretched for attempting to acquire it."

One of our own poets has made a similar reflection on the vanity of human wishes for any other than posthumous fame.

"For such the frailty is of human kind,
Men toil for fame, which no man lives to find;
Long rip'ning under ground the *china* lies:
Fame bears no fruit, till the vain planter dies."

Earl of Mulgrave.

VINCIA, VENCE, in *Ancient Geography*, a town of Gallia Narbonensis, N. of Antipolis, and the capital of the Narusci. The town seems to have been consecrated to the god Mars, and Cybele was worshipped there.

VINCULO *Matrimonii, Divorce* à. See DIVORCE.

VINCULUM, in *Algebra*, a character in form of a line, or stroke drawn over a factor, divisor, dividend, when compounded of several letters, or quantities; to connect them, and shew that they are to be multiplied, or divided, &c. together, by the other term.

Thus, $d \times a + b - c$, shews that d is to be multiplied into $a + b - c$.

VINCUM, in *Ancient Geography*, a town of Lower Germany. Anton. Itin.

VINDALIUM, VÉDÈNE, a village of Gallia Narbonensis, upon the left of the Rhone, N.W. of Cypréseta.

VINDANA, a port of Gallia Lyonnensis. Ptol.

VINDELICIA, a country of Europe, N. of the Alps and S. of the Danube, near Rætia. It has been conjectured that this name is formed of two words, which are the names of two rivers that water the country; one called *Vindo* (the Wertach, which passes to Augsburg), and the other *Licibus* (the Lech). Strabo and Ptolemy differ in their assignment of the bounds of this country. According to Strabo, the Vendelicians lived near the Salasses, and inhabited a part of the mountains which regarded the east and turned towards the S. He adds that they were the limitrophes of the Helvetians and Boians. According to this author, the Rætians

did not touch the lake of Constance, except in a part of their borders, that is, between the Rhine and Bregentz; but this town, which Ptolemy assigns to the Rætians, really belonged to the Vendelicians. The Helvetians and Vendelicians occupied a great part of the banks of the lake. Upon the whole we may conclude, from the observations of Strabo, Pliny, Tacitus, and Sextus Rufus, who have all taken a part in settling the boundaries of Vendelicia, that in its ancient state it had the Danube to the N., and that the river *Ænus* separated it from Norica on the E. side, and that on the W. it extended from the lake of Constance to the Danube. Its boundaries on the S. are less satisfactorily ascertained. Strabo says that the Vendelicians possessed mountainous plains at the extremity of the Alps; and he represents this country as contained between the Licus and the *Ænus*. M. D'Anville, in his *Ancient Geography*, says that the country of the Vendelici extended from the town of Brigantia (Bregentz), on the lake of Constance, to the Danube; and that the lower part of the course of the *Ænus* or of the Inn separated it from Morbihan. A powerful colony was established in the angle formed by the two rivers Vindo and Licibus, whence the nation seems to have derived the appellation of Vendelici; and Augusta, given to this colony, preserves its name in that of Augsburg, between the two rivers Lech and Wertach, the first of which actually separates Suabia from Bavaria.

Vindelicia, when it was subjugated by the Romans, was joined to Rætia, and the whole country, contained between the lake of Constance, the Danube, the Inn, and the country of the Carni, the Insures and Venetians, was always called Rætia, or Provincia Rætia. Nevertheless, the Rætians and Vendelicians formed two separate people, although they inhabited the same province. Accordingly Horace calls the inhabitants of Vendelicia, Rætii Vindelii, to distinguish them from the inhabitants of Rætia properly so called.

VINDELIS, or VINDILIS, an island placed by the Itinerary of Antonine between the Gauls and Great Britain; but this is done in so vague and indefinite a manner, that it is not possible to say what island is meant. Some authors think that it is the isle of Portland.

VINDEMIATING, formed of *vindemia*, *vintage*, the gathering of grapes, or other ripe fruits; as apples, pears, cherries, &c.

VINDEMIATRIX, or VINDEMIATOR, a fixed star of the third magnitude, in the northern wing of the constellation Virgo.

VINDENUTA, VINDUNITA, *Vindimita*, or *Vindonitenfis insula*, in *Ancient Geography*, an island of France, in dependence on the town of Nantes. It was to this island Friard is supposed to have retired in 560, to pass the life of an indolent and useless hermit; and he thus acquired the name of St. Friard.

VINDERIUS, a river of Hibernia, having, according to Ptolemy, its mouth on the eastern coast, between the promontory Iamnius and the mouth of the river Logia. Camden thought that it is the present bay of Knockfergus.

VINDIA, or VINDA, a town of Asia, in Galatia, upon the route from Pessuntine to Ancyra, between Germa and Papira. Anton. Itin.

VINDICATION, CLAIMING, in the *Civil Law*, an action arising from the property a person has in any thing; or a permission to take or seize a thing, as one's own, out of the hands of a person, whom the law has doomed not to be the true proprietor.

VINDICATORY *Part of a Law*. See LAW.

VINDICTA, among the Romans, the prætor's rod or switch, with which he touched a slave's head when he was enfranchised.

VINDINATES, in *Ancient Geography*, a people of Italy, in Umbria.

VINDINUM, a town of Gallia Lyonenfis, belonging to the Auleri or Cenomani. Ptol.—Also, a town of Italy, in Umbria.

VINDIUS or VINNIUS Mons, one of the most considerable mountains in Hispania Citerior, according to Ptolemy and Florus. The name is applicable to the chain of mountains which, detaching itself from the Pyrenees, traverses Biscay and the Asturias, and forms, at the entrance of Galicia, two branches, one extending itself to Cape Finisterre, and the other, turning to the S., traverses the country of the ancient Bracones.

VINDUS Mons, a mountain of India, on this side of the Ganges. Ptol. It extends from the S.W. to the N.E., S. of the country called Sandrabatis.

VINDO, a river of Germany. See VINDELICIA.

VINDOBONA, *Vienna in Austria*, a town of Superior Pannonia, six miles from Cætum, according to the tables of Peutinger. It is marked in the Itinerary of Antonine upon the route from Sirmium to Trèves, between Motanum and Comagenes.

VINDOGLADIA, VINDUGLADIA, or *Vindocladia*, a town of Great Britain, in the 12th Iter of Antonine, on the route from Calleva to Uriconium, between Sorbiodunum (Old Sarum) and Durnovaria (Dorchester); supposed to be near Cranburn. Dr. Stukeley traced the Roman road all the way from Old Sarum, for 13 miles, to near Borof-ton, where he places Vindocladia.

VINDOMAGUS, one of two towns mentioned by Ptolemy, as belonging to the Volæz Arecomici: the other being Nemausus. Although the precise situation of Vindomagus is not certainly known, the presumption lies in favour of Vigan, because it affords many monuments of antiquity, and has been mentioned under the name of Vicanus for 600 or 700 years. It is in the same parallel with Nimes, and only about half a degree differing in longitude, and corresponds in a variety of respects to the place marked out by Ptolemy.

VINDOMIS, VINDOMUM, or *Vindonium*, a town of Great Britain, in the 12th Iter of Antonine, on the route from Calleva to Uriconium, between Calleva (Silchester) and Venta Belgarum (Winchester). If Mr. Horsley has rightly placed Calleva at Silchester, it is probable that he has fixed justly on the site of Vindomis at Farnham.

VINDOMORA, a town of Great Britain, in the 1st Iter of Antonine, on the route from the limit, vallum or wall to Prætorium (Broughton), between Corstoptum (Cowbridge) and Vinovia (Binchester). The situation of this place, fixed at Ebchester, is evidently mistaken by Gale and Camden, the former fixing it at Dolande, within less than five miles of Cowbridge, and the other at Wall's-End, which is altogether out of the way of this Iter, that proceeds from N. to S. along the famous military road called *Watling-street*. See Horsley's *Brit. Rom.* p. 396.

VINDONISSA, the station of the 21st legion, according to Tacitus, the position of which unites many Roman ways. The distance marked xxii in the Theodosian table, with respect to Augusta Rauracorum, is more suitable than that of xxvii in the Itinerary of Antonine. Vindonissa is named Vindo in a panegyric of Constantine by Eumenius; and Castrum Vindonissenle in the notitia of the provinces of Gaul lies in Maxima Sequanorum. This town had been an episcopal see; but having been ruined towards the

end of the sixth century, or the commencement of the seventh, this bishopric became that of Constance, and Mayence was recognised as the metropolis, although Vindonissa, included in the Sequanois, should have acknowledged Befançon under this dignity. The place which it occupied upon the bank of the Ruſ, near its junction with the Aar, is denominated Windſch.

VINE, in *Botany and Gardening*. See VITIS.

It is said that vines were first planted about the rivers Rhine, Maine, and Moselle, and also in Hungary, and the northern part of Gaul, about the year 276. But with respect to the provinces of Gaul and Spain, which border on the Mediterranean sea, as well as to Italy, many are of opinion that vines grew spontaneously there. Julius Cæsar found vines growing in Gallia Narbonensis, *i. e.* Languedoc and Provence; and Strabo remarks, that the said province produced all the kinds of fruit which Italy afforded. The Phœnicians are said in early times to have planted vines in the isles of the Mediterranean sea, as well as in several parts of the continent both of Europe and Africa. It appears that there were real vineyards in England in 1140 and 1230. *And. Com.* vol. i. p. 16, and p. 81.

VINE, *Black*. See *TOURNEFORTIA Volubilis*.

VINE, *Climbing fusc-leaved*, of *Canada*, a species of *Hedera*; which see.

VINE, *Spanish Arbor*, a species of *Ipomœa*; which see.

VINE, *Wild*, or *White Vine*. See *CISSUS Sicyoides*, and *Acida*.

VINE, *Culture of, in the Field or open Ground, in Rural Economy*, the growth and management of it in such situations for the use of the grapes in making wine. It would seem probable that the cultivation of this plant might be conducted with advantage in this intention, in many situations in the southern parts of this country; especially as some of them are well known to be nearly within the vinous latitude, which is found to extend between the twenty-fifth and fifty-first degree in the northern hemisphere: and, as in Germany, it is found by experience, that all such vineyards as are situated within the latter of these limits, are capable of being cultivated with considerable profit; though where they stretch much beyond it, their success is extremely doubtful. Proper cultivation and management are, therefore, all which appear necessary in raising crops of this sort.

In speaking of the means of establishing vineyards in this country, Mr. Speechly has remarked, in his useful work on the subject, that there are four things which ought to be materially considered; namely, the situation; the soil; the kinds of vines which are the most fit and proper to be planted; and the mode of their management.

In regard to the first, it is said that an elevated situation, where there is a gentle declivity to the south or south-east, is esteemed preferable to low grounds, which are generally subject to damps and spring-frosts, even at times when the adjoining high grounds are entirely free from both. Vineyards or grounds of this kind, too, should be well protected and sheltered to the north, as well as to the north-west and north-east. In a hilly country there are generally many favourable spots, where nature has given important advantages, and which should be still further improved by art for this purpose. Plantations of forest-trees, judiciously formed, would, it is supposed, contribute much to give warmth and shelter; but these should not be placed too near the vineyards, so as to confine the air, as that would prove very injurious to them.

In wine countries it is well known, that vineyards are often not only confined to gentle declivities, but that they are frequently formed on slopes, on the sides of

VINE.

hills and rocks, which are sometimes so steep as even to border upon precipices; and that vineyards thus situated produce grapes uncommonly rich, yielding wines of the most excellent quality. Consequently, from the hills which border upon the English Channel having declivities which tend towards the south, they would appear, it is thought, to be highly proper for the growth of the vine. And that the excavations in them, from which chalky materials have been taken, where they have a southern exposure, would likewise seem well calculated to answer the same purpose.

In what respects the nature of the ground, it has been observed that the vine delights in such gravelly and rocky soils as are frequently found on the sides of steep hills and rocks, and that it has sometimes been known to flourish among mere stones and gravel. It grows most favourably in a light, dry, sandy, or gravelly soil, which is perfectly free from stagnant moisture: consequently it may be noticed, that the introduction of the vine into this country would have no bad effect in respect to agriculture, as all strong and deep lands, which are best adapted for tillage, are the most unsuitable for the cultivation of the vine.

But besides gentle declivities and light soils, vines, it is said, grow in situations and soils where the land could hardly be rendered profitable in any other way. And thus, though vines would not grow robust on the steep slopes of poor, gravelly, and rocky soils, still they would be more productive than when planted on rich lands, and the fruit be greatly preferable. All such hills as have the above aspect or exposure, and are composed of either slate, gravel, scaly rock, or lime-stone, are of course highly proper for being planted upon. It is therefore evident, that there is a considerable portion of soil in the southern districts of this kingdom that is well adapted for the growth of vines.

However, the success of a vineyard in this country would, it is thought, most essentially depend on the kinds of vines which are propagated and cultivated. It is believed that it has been a prevailing, though certainly an erroneous notion, that the sweet early kinds of grapes are the best to plant for the purpose of making wine in this country. And that most or all of the modern trials in this way have been made from vines brought from France. It is not doubted by the above writer, but that there are, among the abundant variety of grapes, peculiar sorts, which are by nature singularly suited to make wines in different climates and situations. Thus the different sorts of grapes propagated and grown in the Madeira and Canary islands, might not, it is thought, be found, if tried, to make good wines in France. It is hence concluded, that as the southern part of this island is almost on the verge of the vinous latitude, it should seem reasonable to suppose, that there would be the greatest probability of success from those kinds of grapes which have been known to thrive and prosper best in the most northern latitudes. On this account, therefore, the kinds of vines cultivated in Germany are recommended, and particularly the sort producing the grapes of which the Rheinisch wine is made, in preference to any kind cultivated in France.

It is noticed above, that the early sweet kinds of grapes are improper for making of wine in this country: the reason of which is this, it is supposed, that though such grapes yield a sweet juice, it is not calculated to undergo fermentation in a proper manner. It is found by experience, that good bodied, or generous wines, can be made from grapes of an aultere taste, and that too even before they are quite arrived at a state of maturity. But then wine from such crude grapes requires to be kept to a good age. The case is similar, it is said, in respect to apples. It is well

known that the sweet kinds of them, which ripen in the summer months, are very unfit for making cyder. And that the noblest liquor of this sort, such as that of the styre and cockage, is made from apples not much better than wildings. Mr. Loudon, however, remarks, in speaking of the culture of the vine in other intentions, that the general imperfection of English grapes is their defect of saccharine matter and want of sweetness. This is, perhaps, it is thought, in part owing to the humidity of the atmosphere, more than to its coldness, as very sweet grapes grow, and spirituous wines are made, in much colder and more northern latitudes than a great part of England. Another reason why the fruit of English vines possesses considerable acidity, is the general taste for large globular grapes, without regard so much to the delicacy of their flavour as the grandeur of their appearance. This species of vine does not produce delicious grapes in the hottest climates, it is said, and consequently should not be so generally cultivated in this. But the appearance in this intention is of little importance. The grapes most abundant in saccharine matter, are, it is said, always round, as those of the currant grape. It must be confessed, however, that the more exposed the vine is to the intense meridian sun, so much the sweeter will be the grape, and the greater the quantity of saccharine or spirituous juice that it will contain.

The sorts of vines most suitable for this purpose may probably be, the chassilas, or common white muscadine, the berries of which are not large, or very sweet. The morillon, noir hatif, a good sort of grape in this intention, which has a small round black berry, of a fugary juice, is much esteemed, as being early, ripening in September. The Malmsey muscadine, which somewhat resembles the above, the juice of which is very sweet, and of a high flavour, is a good bearer, and a fine grape. The black sweet-water has a small roundish berry, of a sweet taste; but which, being apt to crack, is not in much repute. Birds are fond of it. It ripens in the same month as the above. The small black cluster, which has small oval berries, and the leaves covered with a hoary down, is a very pleasant fruit. The early white grape from Teneriffe; the berries of which are of a middling size, and the flesh remarkably sweet and juicy: the Auverna, or true Burgundy grape, sometimes called the black morillon, which is an indifferent fruit for the table, but esteemed one of the best for making wine from: and the white sweet-water, which has a large berry of a white colour, and very agreeable juice, is esteemed an excellent grape, and ripens in the above month:—it is supposed that from some of these, and perhaps a few others, the cultivator may probably find a proper grape for cultivating in the intention of making wine in this country.

In regard to the culture of the vine with this design, as even the most southern parts of this island are but nearly on the verge of the vinous latitude, as has been seen, every possible advantage should be consulted and had recourse to in the formation and management of vineyards. Those abroad, it is said, are formed by planting the vines in rows, and by training them in a perpendicular direction. The first of the above writers would, however, in this country, greatly prefer the mode of training the vines in a lateral or horizontal form, similar to the method which is practised in Holland with vines in frames. There would, it is thought, be little difficulty in this method, as the vines might readily be trained along small poles, not thicker than those used for hops; these poles being fixed nearly parallel to the ground. Vines thus trained, it is apprehended, would derive many advantages, not only by means of warmth and shelter, but that they would most easily be protected also from spring-frosts,

VINE.

frosts, by applying the boughs of trees, particularly those of the evergreen kind. The grapes too, it is observed, would be greatly benefited by the reflection from the foil of the ground underneath them.

It is suggested, that when vines are intended to be planted on the steep hills, and on the sides of rocks, the ground should be prepared and formed in the manner of steps, which it is particularly necessary should be lower at the inner angles, as without this the vine-plants would lose the advantage of such rains as fall hastily and perpendicularly. It is easy to conceive that much advantage would be gained from a situation thus formed, as the back would be nearly equal to a wall. And the expence attending the formation of the ground could not be very considerable. The work should be begun at the top, and the foil taken out be thrown down the hill. It would likewise be further beneficial to have a little good foil or earth put in at the angles, before the vines are planted.

In respect to the plants, they may be provided either by seeds, cuttings, or layers, but the two last are mostly the best methods. When they are raised from seed, after they have had a year's growth, they should be planted out, about the latter end of March, or beginning of the following month, against the poles or treillis to which they are to be trained, if from seeds ripened in this country; but when from such as are imported from the vine countries, too many should not be planted till their value be known. When they have been thus planted, they should be cut at the third eye, if strong, but at the second, if weakly; at the same time rubbing off the lower end with the finger and thumb.

When by cuttings, they should be chosen from shoots that are best ripened, and have the shortest joints; always having one or two joints of the last year's wood to them, cutting each perfectly smooth, and a little rounding at the lower end, and as near to a joint of the old wood as possible. The upper end too should be cut smooth, and sloping towards the treillis or poles. They should afterwards be trained as circumstances may direct. It has been advised too by some, that choice should be made of cuttings after a warm and dry season, when the wood ripens well; each cutting having two inches of the old wood with one eye of the new. When the old vines are pruned, there is mostly great choice, they should therefore be then selected of a middling size, and the wood round.

In raising vines for this purpose in the layer manner, a method very usually made use of is to lay the stools down in an open situation, in the same mode as for forest-trees and shrubs; though the best way, in the opinion of some, is to take layers from such vines as have been trained.

They should be cut so as to leave one or two strong eyes on each, and when the shoots begin to run, be trained to the treillis or poles. Those which have the strongest and most vigorous shoots should be selected and preserved for this purpose. They should afterwards be carefully trained and pruned, as circumstances may require, always considering that much of the goodness of the grapes in these cases depends upon the living wood being strong and well ripened.

In planting the grounds, the vines may be set in rows at suitable distances, according to the soil, situation, and mode of training which is to be practised, but mostly about three or four feet distant in the rows, and five, six, or more from row to row. The intervals between the rows are to be kept quite clean and free from weeds, by frequent hoeing and digging them over. After the vines have been thus raised, and carefully pruned and trained for three years, they mostly produce crops of fruit, which, when for wine,

should be well ripened before it is used, especially in this country.

The mode of the culture of vines in Madeira may probably suggest some hints for their growth in the open grounds in this country. It is stated, that the best season for planting them there, is from the middle of the month of November to the end of February; that the slips or cuttings are made from a foot and a half to two feet and a half in length; they are set two feet in the ground, about three feet distant, in straight rows or trenches, about four or five feet asunder. After one trench is opened, and the earth taken out and laid on one side of it, so as to form a bank, the butt ends of the vines are put into the bottom of the trench, and the small ends extended sloping up the bank; the trench is then filled with earth dug from the found land the depth of it, breaking the clods, taking out the stones, hawling all the earth towards the vines, and thus making a second trench, at the distance noticed above, from the first; proceeding to plant the whole vineyard or ground in the same manner. By this means the ground is lightened all over, as well as where it touches the vines, and is cleared of stones, the roots of trees, plants, shrubs, and grass, which are all carefully picked out. A vineyard or ground planted in this manner will, it is said, last there fifty or sixty years.

Afterwards the young vines are not pruned until they have been two or three years planted. The season for pruning is nearly as above; in doing which, no part of the vine is cut but the new shoots, which are cut off every year at the end of every second or third joint. The largest of these cuttings are saved for planting, and will keep for several weeks above ground; but if cut early, and not planted till late, it is better to cover the butt-end with earth.

The supporting of the vines, and other such matters, is done to the height of three or four feet, by sticking stakes in the ground from end to end of the rows, then lashing long slender poles near the heads of them; and across the poles are laid, both ways, reeds or canes, at the distance of two or two and a half feet, which are tied to one another, and to the poles where they cross, with split-willow twigs: these, if full grown and hard, will last two or three years. In the second or third year after planting, the vines are raised and fastened to the stakes and poles by means of twigs, and the branches spread open, and loosely tied to the poles or canes, so that they may not be too thick in some places and too thin in others.

In the third year after the vines have been planted out, they commonly produce a pretty good crop of grapes fit for making wine. In which cases, when they are almost come to their full size, they are gradually exposed to the sun, by frequently thinning the leaves till every branch lies open to the sun some part of the day. But if this should be done while the fruit is green, or, all at once, when nearly ripe, it would wither the grapes, and the juice would never be rich. The grapes are here to hang until they are very ripe, and many, on almost every branch, begin to turn to raisins, otherwise the wine will be weak, harsh, and rough, and without much flavour; hence it is evident the grapes should not be promiscuously gathered all at once, but two or three gatherings made, taking only what are ripe each time.

It is likewise found, that in soils which are hot, dry, and poor in quality, the culture of vines in this country in the open ground may be conveniently accomplished in another manner; as by their growth being greatly limited and restricted in such cases, their tendency to fruiting is con-

siderably increased and expedited, they can, of course, be managed by being kept in a dwarf state, in somewhat the manner of the currant, and in this way produce much fruit for the purpose of wine. It is a method which seems to have answered well in some cases, and which is perfectly suited to many situations, where the vine might be cultivated for the making of wine in the southern parts of this country. See *VITIS* and *WINE*.

It is evident from a variety of circumstances, that the cultivation of the vine in the open ground of this country, in the view of procuring wine from the fruit, should be more attended to than has hitherto been the case. In some situations it would probably afford a better profit and advantage than the hop, and with much less expence of cultivation; while in others it is almost the only plant that could be introduced with any chance of success.

VINE Gall-Insect, an insect of the gall-insect class, principally found on the vine, though capable of living on some other trees, and sometimes found on them. It is much of the same shape, figure, and manner of life, with the other animals of this class; but differs from them in this, that as they lay their eggs all under their body, and continue absolutely to cover them till they are hatched, these produce them from their body, and they are found in prodigious abundance, lodged in a sort of cottony or silken bags, all over the stalks and branches of the vines: the dead animal is sometimes found covering them in part, but more frequently they are absolutely naked, and often are so numerous, as to appear like thin cobwebs hung one over another all over the vine.

These eggs might be easily mistaken for those of small spiders; they always hatch well, and come to maturity on the vines they are found on; but if removed to others, they seldom come to any thing, which is very singular, since the gall-insects of almost all other trees may be removed and propagated either on the same or on different trees.

These vine-insects are of the boat-fashioned kind; but beside these, there are some other species which lodge their eggs in a cottony nest of the same kind. The common thorn affords a shorter and more convex kind than this does; these are a very small species; others are something larger; but the oak affords a sort equal in size, if not exceeding those of the vine; some of these are brown, others blueish, and others reddish; and there are some minute differences in their shape. Reaumur, Hist. Inf. tom. iv. p. 61.

VINE-Grubs, a name given by some authors to the pucerons, or little insects which are usually of a green colour, and are found, often in prodigious numbers, sticking to the leaves of trees and plants, and to their young stalks.

M. Reaumur has been very curious in his investigation of the nature of this insect; but the manner of propagating its species was never clearly observed, till Mr. Bonet discovered it.

Reaumur observes, that in every family of pucerons, there are some that have wings, and some that have not; and that, according to the usual course of nature, the winged ones should be males, and the others females; but, on the contrary, that both the winged and the unwinged vine-grubs are females, all being viviparous, and each kind producing a number of living young; so that the males of these pucerons were never discovered, even by that careful observer; nor could he ever find out what it was that impregnated the one and the other kind. He leaves us queries on this subject, whether there is no copulation among them?

and whether they are all hermaphrodites, each having in itself the organs of both sexes, as is the case of the river muscles?

Mr. Bonet, in order to inform himself of the process of nature in these creatures, brought up one of them in perfect solitude from its birth; he had an opportunity of observing it in the place where it was kept, and watched it very strictly for many months together. At the end of twelve days this creature, without having had any copulation with a male, began to breed. She produced in the whole ninety-five young ones, all alive, and constantly under the eye of the observer. This experiment was repeated several times with the same success: and, at length, repeated upon the young ones produced in this manner, and they were found to breed at the same period, and in the same manner with their parent, without having had any copulation with a male, as far as to the fourth generation.

A hasty observer would immediately conclude from this, that there was no copulation among the pucerons; but farther enquiry proves that this is not the case; for the same observer has found a species of them in which there is copulation; so that both the winged and the unwinged kinds are truly females, and the male is a small fly, of a very different shape, as is the case in regard to many other insects. This male is the most falacious creature imaginable, copulating a vast many times successively, with the same, and with different females. As this is the case in regard to one species of this creature, it doubtless is so also in regard to the rest, though that has not yet been observed: and the singularity seems to be this, that after the male has copulated with the female, she not only becomes prolific, but her young ones are born ready impregnated, as far as the fourth generation; after which, probably, there is a necessity for the copulation with the male again.

There is another very singular observation also in the production of the young pucerons; the females are properly viviparous, and usually bring forth live young; but they sometimes produce only a sort of fetuses, which are laid in a long series one beside the other, as the caterpillar eggs are laid by the butterfly; and they are left to hatch, as it were, afterwards, by the heat of the sun. Phil. Trans. N^o 469.

VINE or *Bine Hop*, in *Rural Economy*, a term often applied to the shoot of the hop-plant. After picking the hops, it is mostly the best practice to tie up the vines, bines, or binds, into small bays while perfectly dry, in order to preserve them in some way or other as fuel for different uses, and to clear the ground for future operations. The work usually costs about sixpence the hundred.

VINE-Press, a sort of press and vat constructed for the purpose of squeezing and receiving the liquor from the grapes, where wine is to be made from them. It may be formed of different sizes, as from six to nine feet square, or more, according to the extent of the vineyard, being made of planks which are about eighteen or twenty inches in breadth, and two and a half or three inches in thickness, so fixed to a bottom of the same kind, or of greater thickness, that they may be capable of being pressed close to it, and to one another, at the corners, by the help of posts or studs, with wedges and levers; it being caulked, where necessary, in order to prevent the waste of the liquor. On one side a spout is to be placed, on which a wicker basket is to be hung during the operation, to strain the liquor through as it runs into a tub, which is often put half way in the ground, to accommodate it to the height of the vat. When the grapes are gathered, they are thrown into the vat of the
press,

press, and the spout being stopped, receive a gentle pressure; and then the spout is opened, and the juice drawn off as long as it will run without further pressing; when the spout is again stopped, the grapes are again subjected to a stronger pressure, somewhat in the manner of the cyder-press, and the liquor afterwards drawn off as before. In this manner the work proceeds until the liquor is wholly drawn off.

These presses are perfectly simple in their nature, being merely so contrived as to afford a proper degree of pressure, without doing too much injury to the grapes, which would probably hurt the flavour and quality of the wine. See *VINE*.

VINEÆ, in the *Roman Art of War*, were defensive engines, composed of wicker hurdles, laid for a roof on the tops of posts, which the soldiers who went under it for shelter bore up with their hands. Some say that they had two roofs; the first and lower of planks, and the upper roof of hurdles, to break the force of any blows, without disordering the machine. See *MANUELS*.

VINEGAR, *ACETUM*, an agreeable, acid, penetrating liquor, prepared from wine, cyder, beer, and other liquors, and varying in hue from light red to brown straw-colour, malt vinegar being more highly coloured than that of wine; and of considerable use, both as a medicine and a sauce; or, vinegar is a vegetable acid liquor, produced by the second degree of fermentation, or that which succeeds the spirituous, and is called the acid or acetous fermentation. Every liquor, which has completely undergone the spirituous fermentation, is spontaneously and necessarily disposed to the acid fermentation. Accordingly, every vinous liquor does continually tend to become vinegar, and is actually changed into it, sooner or later, according to circumstances; unless this change be prevented by some obstacle to fermentation in general. If vinegar be long kept, and particularly if it be exposed to the air, it will become muddy and ropy, acquiring an unpleasant smell, losing its acidity, and putrefying. In order to preserve it for a longer time, it should be boiled for a few minutes, so that the gluten may coagulate and separate, on the presence of which these changes depend, and also kept in well-corked bottles.

The word is French, *vinaigre*; formed from *vin*, *wine*, and *aigre*, *four*.

The method of making vinegar has long been kept a secret among the people of that profession; who, it is said, oblige themselves to each other by oath not to reveal it; but, notwithstanding this, the Philosophical Transactions, and some other late writings, furnish us with approved accounts of it. Whatever be the materials used in the preparation of the liquor for producing vinegar, it is merely necessary to admit air into the vessel in which it is kept, and to preserve it in a temperature somewhat higher than that of the atmosphere in this climate, that is, from about 75° to 80°. When a liquor already fermented is used, it is also of almost indispensable importance that yeast, or some other ferment, be added, in order to hasten the fermentation, or else the change will be too gradual to obtain vinegar in perfection, and the first acidified portion will turn mouldy before the last has become sour. But if the material employed has not undergone fermentation, the whole process of the vinous and preceding acetous fermentation will go on without interruption, with the same ferment which first set it in action, as, *e. g.* in making vinegar from malt, or from sugar and water. It is necessary also to stop the process of the manufacture in that stage of it, in which the acid has attained to its highest degree of strength and perfection,

after which the liquor would then speedily be deteriorated, the acetous acid would gradually disappear, and an offensive mouldy watery liquor remain, with scarcely any acidity. It depends upon the skill and experience of the manufacturer to determine when his vinegar is in a fit state to be drawn off and closely barrelled.

VINEGAR, Method of making Cyder. The cyder (the meanest of which will serve the purpose) is first to be drawn off fine into another vessel, and a quantity of the must, or pouze of apples, to be added; the whole is then to be set in the sun, if there be a conveniency for the purpose; and, at a week or nine days end, it may be drawn off.

VINEGAR, Method of making Beer. Take a middling sort of beer, indifferently well hopped; into which, when it has worked well, and is grown fine, put some rape, or husks of grapes, usually brought home for that purpose; mash them together in a tub; then, letting the rape settle, draw off the liquid part, put it into a cask, and set it in the sun as hot as may be; the bung-hole being only covered with a tile, or slate-stone; and in about thirty or forty days it will become a good vinegar, and may pass in use as well as that made of wine, if it be refined, and kept from turning musty.

Or, vinegar may be made thus: To every gallon of spring-water, add three pounds of Malaga raisins; which put into an earthen jar, and place them where they may have the hottest sun from May till Michaelmas; then pressing all well, tun the liquor up in a very strong iron-hooped vessel, to prevent its burbling: it will appear very thick and muddy, when newly pressed; but it will refine in the vessel, and be as clear as wine. Thus let it remain untouched for three months, before it be drawn off, and it will prove excellent vinegar.

VINEGAR, To make Wine. Any sort of vinous liquor, being mixed with its own faeces, flowers, or ferment, and its tartar first reduced to powder; or else with the acid and austere stalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar: and the whole being kept frequently stirring in a vessel which has formerly held vinegar, or set in a warm place full of the steams of the same, will begin to ferment anew, and conceive heat, and will grow sour by degrees, and soon after turn into vinegar.

The remote subjects of acetous fermentation are the same with those of vinous; but the immediate subjects of it are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine; for it is absolutely impossible to make vinegar of must, the crude juice of grapes, or other ripe fruits, without the previous assistance of vinous fermentation.

The proper ferments for this operation, by which vinegar is prepared, are, 1. The faeces of all acid wines. 2. The lees of vinegar. 3. Pulverized tartar; especially that of Rhenish wine, or the cream or crystals of it. 4. Vinegar itself. 5. A wooden vessel well drenched with vinegar, or one that has long been employed to contain it. 6. Wine that has often been mixed with its own faeces. 7. The twigs of vines, and the stalks of grapes, currants, cherries, or other vegetables of an acid austere taste. 8. Bakers' leaven, after it is turned acid. 9. All manner of ferments, compounded of those already mentioned.

Vinegar is no production of nature, but a mere creature of art: for verjuice, the juices of citrons, lemons, and the like native acids, are improperly said to be *natural* vinegars; because, when distilled, they afford nothing but rapid water; whereas it is the property of vinegar to yield an acid spirit by distillation.

VINEGAR.

The wine which is generally converted into vinegar, and which for its cheapness is commonly employed for this purpose, is such as has already become four; although the better and the more spirituous the wine, and also the more of the vinous spirit that can be retained in the vinegar, the better and stronger it will be. Becher says, in his "Phyfica Subterranea," that having digested wine in order to convert it into vinegar, in a bottle hermetically sealed, he found, that although a longer than the ordinary time was required, the vinegar produced was much stronger than when free air is admitted. Mr. Cartheuser also affirms, that the strength of vinegar may be much increased by adding some aqua vitæ to the wine, before it is exposed to the acetous fermentation. Nothing more seems requisite in the preparation of good vinegar than to employ good wine, and to conduct the fermentation in the most advantageous method; the principal part of the operation being performed by nature.

VINEGAR in France, Method of making. The French use a method of making vinegar different from that above described. They take two very large oaken vessels, the larger the better, open at the top; in each of which they place a wooden grate, within a foot of the bottom: upon these grates they first lay twigs, or cuttings of vines, and afterwards the stalks of the clusters of grapes, without the grapes themselves, or their stones, called the *rape*, till the whole pile reaches within a foot of the brim of the vessels; and then they fill one of these vessels with wine to the very top, and half fill the other; and with liquor drawn out of the full vessel, they fill up that which was only half full before; daily repeating the same operation, and pouring the liquor back from one vessel to the other; so that each of them is full and half full by turns.

When this process has been continued for two or three days, a degree of heat will arise in the vessel which is then but half full, and will increase for several days successively, without any appearance of the like in the vessel which happens to be full during those days; the liquor of which will still remain cool; and as soon as the heat ceases in the vessel that is half full, the vinegar is prepared; which, in the summer, happens on the fourteenth or fifteenth day from the beginning; but, in the winter, the fermentation proceeds much slower; so that they are often obliged to forward it by artificial warmth, or the use of stoves.

When the weather is exceedingly hot, the liquor ought to be poured off from the full vessel into the other twice a day; otherwise the liquor would be over-heated, and the fermentation would prove too strong; whence the spirituous parts would fly away, and leave a vapid wine, instead of vinegar, behind.

The full vessel is always to be left open at top; but the mouth of the other must be closed with a cover of wood, in order the better to keep down and fix the spirit in the body of the liquor; for, otherwise, it might easily fly off in the heat of fermentation. The vessel that is only half full seems to grow hot, rather than the other, because it contains a much greater quantity of the vine-twigs and stalks than that, in proportion to the liquor; above which the pile rising to a considerable height, conceives the heat more, and so conveys it to the wine below. Boerhaave's Elem. of Chemistry, part iii. p. 143, &c. Phil. Trans. vol. ii. p. 657.

There is another method, by which a very good vinegar is commonly made at Paris from the lees of wine. A quantity of wine-lees is put into a large tun, and worked up with wine sufficient to render it very fluid. This is then put into cloth sacks, which are arranged in a large

iron-bound wooden vat, the heavy cover of which is laid over them, and serves as a press, that is gradually screwed down till all the liquor is pressed out. The wine, thus loaded with the extractive and tartareous matter of the lees, is distributed in large casks set upright, through the heading of which a hole is cut, which is constantly left open. In summer these casks are simply set in the sun; but in winter they are arranged in a stoved room. The fermentation comes on in a day or two, and when it has got to its height, so much heat is excited, that sometimes the hand can hardly be borne in it. In this case, it must be checked by a cooler air, and by adding some fresh wine to the casks; and, indeed, it is in a due regulation of the heat that most of the practical skill of the maker consists. The process goes on in this way till the whole of the wine is thoroughly acidified, which requires about a fortnight in summer and a month in winter; after which the new vinegar is put into barrels, at the bottom of which are laid a good many chips of beech wood. Here it remains for about a fortnight, during which time it clarifies, and the clear part is then drawn off and kept in well-closed casks. These beech chips may be used over and over again for several years.

The natural colour of good wine-vinegar is a very pale red, but a higher colour is given, if desired, by the addition of elder-berries.

There are several slight variations in the mode of making wine-vinegar, but which need not be detailed. They all consist in exciting a fresh fermentation in wine, and keeping it up in a moderate degree till acetification is complete. Many refuse parts of the vine are of use for this purpose, such as the husks, the four succulent twigs, the marc or cake left in the wine-press, and the like; and after they have once served, they are still more valuable, as the acid which they naturally contain, or which is evolved by them, is more readily produced.

Wine may also be converted to good vinegar without these additions, simply by adding wine, especially when on the fret, to vinegar already made, and exposing it to a proper heat. In this way many manufacturers proceed, keeping their casks always full, by taking out of them at intervals about a third or fourth part, replenishing them with wine, and again bringing the contents to the state of vinegar.

In this country vinegar is chiefly made from malt. The following is the usual process in London. A mash of malt and hot water is made, which, after infusion for an hour and a half, is conveyed into a cooler a few inches deep, and thence, when sufficiently cooled, into large and deep fermenting tuns, where it is mixed with yeast, and kept in fermentation for four or five days. The liquor (which is now a strong ale without hops) is then distributed into smaller barrels, set close together in a stoved chamber, and a moderate heat is kept up for about six weeks, during which the fermentation goes on equally and uniformly till the whole is soured. This is then emptied into common barrels, which are set in rows (often of many hundreds) in a field in the open air, the bung-hole being just covered with a tile to keep off the wet, but to allow a free admission of air. Here the liquor remains for four or five months, according to the heat of the weather, a gentle fermentation being kept up, till it becomes perfect vinegar. This is finished in the following way. Large tuns are employed, with a false bottom, on which is put a quantity of the refuse of raisins or other fruit left by the makers of raisin and other home-made wines, called technically *rape*. These rape-tuns are worked by pairs; one of them is quite filled with the vinegar from the barrels, and the other only three-quarters full, so that the ferment-

VINEGAR.

fermentation is excited more easily in the latter than the former, and every day a portion of the vinegar is laded from one to the other, till the whole is completely finished and fit for sale.

Vinegar, as well as fruit-wines, is often made in small quantity for domestic uses, and the process is by no means difficult. The materials may be either brown sugar and water alone, or sugar with raisins, currants, and especially ripe gooseberries. These should be mixed in the proportions which would give a strong wine, put into a small barrel, which it should fill about three-fourths, and the bung-hole very loosely stopp'd. Some yeast, or, what is better, a toast fopp'd in yeast, should be put in, and the barrel set in the sun in summer, or a little way from a fire in winter, and the fermentation will soon begin. This should be kept up constant, but very moderate, till the taste and smell indicate that the vinegar is complete. It should be pour'd off clear and bottled carefully, and it will keep much better if it is boiled for a minute, cooled and strained before bottling.

In both the vinous and acetous fermentations, an intestine motion, a swelling, a hissing noise, and an ebullition, may be perceived; but the heat produced by the former is scarcely sensible, whereas that produced by the latter is very considerable. Moreover, the vapour which exhales from vinegar, during fermentation, is not noxious, like that of fermenting wine: on the contrary, as the acid of vinegar disengages itself, it seems to acquire more power to bind and retain the inflammable principle, which is the truly dangerous part of these vapours. Besides, vinegar does not deposit tartar as wine does, even though it has been made with wine that had not deposited its tartar; but the sediment of vinegar is a viscid, oily, and very putrescent matter; which is used to cover the grape-stalks that are employed in the making of vinegar, in order to promote the fermentation. The acid of the grape-stalks, which are washed clean and preserv'd to promote the fermentation of more vinegar, acts powerfully as a leaven or ferment. The casks which have been used are also to be cleans'd from the viscid matter just mentioned, and kept for the same use, as they are fitter for the purpose than new casks. When the acetous fermentation is finished, the nature and character of the liquor that has undergone it are totally changed. The taste and smell of wine are partly spirituous and partly acid; though in good wine the latter is scarcely perceptible: the taste and smell of vinegar are also acid and spirituous; but the former quality prevails so much, as almost totally to conceal the latter. The properties of wine and vinegar prove, that the acetous fermentation unfolds in a very singular manner the acid parts of wine, and intimately combines them with the inflammable spirit; so that by changing wine into vinegar, the ardent spirit is no longer perceptible, so that it cannot affect the head and intoxicate; and if it be distilled, the first liquor that rises with a heat less than that of boiling water is not an ardent spirit, as when wine is distilled, unless the vinegar be too new, and the acetous fermentation has not been completely finished; but when old vinegar is distilled, the liquor that first rises is a slightly acid phlegm, which contains the most volatile, the most odoriferous, and the most spirituous part of the vinegar.

When vinegar has run a little beyond the acetous state, and begun to enter on the putrefactive, the putrefaction may be stopp'd by quenching a red-hot iron in the liquor; and the acid, which has been lost, may in some measure be restored, by the addition of a little spirit of wine, rye-bread, mustard-seed, &c. The putrefaction of vinegar may also be prevented, by racking it off from the feculencies, and keeping

it in a close-stopp'd vessel, in a cool place. However, such as has once suffered a considerable heat, cannot long be preserv'd from corruption.

In England, the excise laws relating to vinegar are as follow:

Every maker of vinegar for sale shall take out a licence, for which he shall pay 1*o*l.; and shall renew the same annually ten days at least before the end of the year; on pain of 5*o*l. 43 Geo. III. c. 69. Sched. (A.) 24 Geo. III. c. 41.

But persons in partnership need only take out one licence for one house.

By 43 Geo. III. c. 68. for all vinegar or verjuice imported, a certain duty shall be paid *per* ton (quantity 252 gallons).

By 43 Geo. III. c. 69. Sched. (A.) for every barrel of vinegar, vinegar beer, or liquors preparing for vinegar, which shall be brewed or made in Great Britain for sale, shall be paid by the maker a certain other duty.

And upon every hoghead of verjuice which shall be made in Great Britain for sale, shall be paid by the maker a certain duty.

And by 49 Geo. III. c. 98. a duty is impos'd in lieu of all former duties of customs.

By 10 & 11 W. c. 21. thirty-four quarts shall be accounted a gallon of vinegar, according to the standard ale quart.

Every vinegar-maker shall make entry with the officer of excise of the house or place where he intends to carry on the business; and whether he intends to make vinegar from malt or corn, or molasses or sugar, or from any and what other materials. 26 Geo. III. c. 73.

Such officer may at all times by day and night (but if in the night, in the presence of a constable), enter into any places used by such persons, and take an account of such liquors therein, and shall make a report thereof in writing to the commissioners, leaving a true copy thereof under his hand, with such maker, if demanded, in writing, under the penalty of 1*o*l. 7 & 8 W. c. 30. 12 Geo. c. 28. 12 Ch. c. 24.

By 10 & 11 W. c. 21. no vinegar-maker shall receive into his custody any liquors for making vinegar, nor deliver out any vinegar in casks, or by the gallon, without notice first given to the officer, unless from Sept. 29, to Mar. 25, yearly, between seven in the morning and five in the evening, and from Mar. 25, to Sept. 29, between five in the morning and seven in the evening; on pain of 5*o*l.

On receiving such liquors into his custody, he shall shew the same to the gauger before he mixes them with any other liquors, rape, or other materials; on pain of 2*o*l.

If any vinegar-maker shall, without giving notice at the next excise-office, or to one of the commissioners, use any store-house, warehouse, cellar, or other place, for making or keeping any vinegar beer, or liquor preparing for vinegar, he shall forfeit 5*o*l.

If any maker of vinegar for sale shall conceal any vinegar, or liquor preparing for vinegar, from the view of the gauger, he shall for every barrel forfeit 4*o*s. 7 & 8 W. c. 30.

If such maker shall, on demand made by such gauger in the day-time (or if by night, in the presence of a constable), refuse to permit him to enter his house, store-house, or other place used by him, and to take an account of the said liquors, he shall forfeit 15*l*.

No person carrying on the trade of a vinegar-maker from molasses or sugar, or other materials, (except malt or corn,) shall carry on (either alone or in partnership) the trade of a distiller

VINEGAR.

distiller or rectifier of spirits in the same premises, or within two miles thereof; and all entries made by such person shall be void. 26 Geo. III. c. 73.

All stale beer, returns of beer or ale, cyder, verjuice, or any other liquor proper to be made into vinegar, which shall be found in the possession of any common vinegar-maker, except such as are to be drunk in his family, and which shall be kept separate for that purpose, shall be deemed vinegar or liquors preparing for vinegar. 10 & 11 W. c. 21.

Every such vinegar-maker shall make entry once a month at the next excise-office of all liquors made within that month, and also within a month after such entry, shall clear off the duties, on pain of double duty. 12 Ch. II. c. 24.

All penalties and forfeitures are to be recovered, levied, and mitigated as by the excise laws. 43 Geo. III. c. 69.

VINEGAR, *Chemical Properties of the pure Acid of the different Kinds of.* See ACETOUS Acid.

The quantity of fixt alkaline salt which vinegar is capable of saturating, is one of the surest criterions of its strength. The best of the German vinegars, according to Stahl, saturate little more than $\frac{1}{4}$ th of their own weight; the French vinegars, examined by Geoffroy, above $\frac{1}{2}$ th; and some of them no less than $\frac{1}{7}$ th; the common distilled vinegar of our shops about $\frac{1}{7}$ th. By congelation, and distillation from alkalies, and from some metallic bodies, particularly copper, the acid may be so far concentrated as to saturate nearly equal its own weight. The best way of judging of the saturation, according to Dr. Lewis, is by trying the liquor from time to time with certain coloured vegetable juices, or on paper stained with them. For this purpose, a thick writing paper may be stained pale blue on one side with the blue preparation of archil, commonly called lacmus; and pale red on the other side, by a mixture of the same infusion with so much diluted spirit of salt as is just sufficient to redden it. If a small slip of this paper be dipped occasionally into the liquor to be tried, or a drop of the liquor be applied on both sides of the paper, the red side turns blue as long as any of the alkali remains unsaturated; the blue side turns red, when the acid begins to prevail; and no change at all is produced, when the saturation is complete. Where lacmus cannot be procured, the paper may be coloured with the juices of violets, iris, cyanus, &c. or with the blue juice pressed out from serapings of the cortical part of common radish roots; with which it is sufficient to stain the paper on one side; this one colour discovering both acidity and alkalescence, the former changing it red, and the latter green.

The acetous acid differs essentially from all the others: from the native vegetable acid, in subtilty and volatility; not being obtainable in the form of a concrete salt, which most, perhaps all, of the native ones are, and rising in distillation with a moderate heat, which very few of the native ones have been found to do: from the mineral acids, in its habitude to different bodies, and the nature of the compounds which it forms with them, being much weaker than the mineral acids: thus, whatever alkaline, earthy, or metallic substance the acetous acid be combined with, the addition of any mineral acid will disjoin them, the mineral taking the place of the acetous; neutral salts, composed of the acetous acid and fixed alkalies, dissolve totally and plentifully in rectified spirit of wine, whilst those composed of the same alkalies and mineral acids are not at all soluble in that menstruum: in this property, the acetous acid differs also from most, perhaps from all, of the acids of its own kingdom; and from all acids in general, in its peculiar odour.

The acid of vinegar dissolves all substances upon which other acids can act, and forms with them neutral salts, all which may be called acetous salts. With calcareous earth it forms salts, which in crystallizing shoot into silky ramifications and vegetations: these salts are named, from their earthy bases, salt of chalk, salt of crabs' eyes, &c. (See ACETITE of Lime, &c.) The solubility of calcareous earth in this acid, and its precipitability by that of vitriol, afford a ready method of discovering the sophistication of vinegar, laid to be sometimes practised, with vitriolic acid. If a saturated solution of any calcareous earth, as chalk, made in strong vinegar, be added to such as is suspected of containing vitriolic acid, no change will ensue, if the vinegar was pure; but if it contained even a minute portion of that acid, the mixture will immediately become milky, and, on standing for a little while, deposit a milky sediment: if the calcareous solution be gradually dropt in, so long as it produces any milkiness or cloudiness, all the vitriolic acid will be absorbed by the chalk; and as this new compound is very sparingly dissoluble, nearly the whole of it will precipitate, so as to leave the vinegar almost pure. Its adulteration with vitriolic or sulphuric acid may also be detected by a solution of nitrate of barytes, which forms a white precipitate, when dropped into the suspected vinegar, insoluble in nitric acid, after having been exposed to a strong heat. With fixed vegetable alkali the acid of vinegar forms a very pungent and very deliquescent salt, called *Regenerated TARTAR*, or *TERRA foliata tartari*; which see. (See also ACETITE of Potash.) With fixed mineral alkali it forms a neutral crystallizable salt. With volatile alkali it forms an acetous ammoniacal salt, called *spirit of Mindererus*. See ACETITE of Ammonia.

Vinegar dissolves, among metallic bodies, zinc and iron; and the rest with difficulty, if at all. (See ACETOUS Acid.) United with copper, it forms a verdigris and crystals of Venus. With lead it forms cerusse, and salt or sugar of lead; dissolving it more easily when reduced to a calx than in its metallic state; boiled even with the glass of lead, or in the common glazed earthen vessels, in the glazing of which this metal is a principal ingredient, it extracts so much as to become strongly tainted with the pernicious qualities of the lead. Gold, platina, silver, and quicksilver, are not affected by vinegar in their metallic state; the two first have not been observed in any state to be affected by it. Silver precipitated from the nitrous acid, and thoroughlyedulcorated with water, and mercury treated in the same manner, or changed by fire into a red powder, slowly and sparingly dissolve in it. Of the affinities of this acid to different metals, or its forsaking one to unite with another, few experiments have been made. Dr. Lewis observes, that it deposits lead and copper upon adding iron. (See TABLES of AFFINITY.) It dissolves the vegetable infusated juices, and several of the gummy resins, and extracts the virtues of sundry plants in tolerable perfection, superadding at the same time a virtue of a different kind. However, it excellently assits and coincides with some drugs, as garlic, squills, and ammoniacum; and in many cases, where this acid is principally to be depended upon, it may be advantageously impregnated with the flavour of certain vegetables. Vinegar very much concentrated, as the rectified spirit of Venus, or radical vinegar, being distilled with equal parts of highly rectified spirit of wine, furnishes a liquor which has all the essential characters of ether, and is called *acetous ether*. It was discovered by the count de Lauraguais. (See Hist. Acad. Scienc. Par. 1759.) It mingles equally with blood and its serum, and with most of the fluids of animals; not thickening or coagulating them, like the acids

VINEGAR.

of the mineral kingdom, but tending rather, as Boerhaave justly observes, to attenuate and resolve coagulations. It is likewise, when taken internally, less stimulating than the mineral acids, and less disposed to affect the kidneys. Professor Cullen observes, that it is less liable to undergo changes in the first passages than the native vegetable acids, which have yet to go through the process of fermentation. The use of vinegar as a condiment, and as an antiseptic for pickling and preserving dead animal and vegetable matter, is well known.

VINEGAR, Medicinal Properties of. This mild, unctuous acid is a medicine of great use in the different kinds of inflammatory and putrid distempers, both internal and external. Nothing is more extolled in many cases of putrefaction, and as an antidote against venomous bites, by Dioscorides and Hippocrates, than oxycrate; and vinegar, when applied to sores in animal bodies, is known to stimulate and resist putrefaction. When weak, it possesses the virtues of water; when strong, its effects approach to those of salts and acid spirit. Med. Ess. Edinb. vol. v. art. 24.

It is one of the most certain antiphlogistics and sudorifics in high fevers, and one of the best preservatives against peffential and other putredinous contagions. Accordingly Boerhaave informs us, that Franciscus de la Boe Sylvius visited his patients in the plague with safety, by drinking first an ounce or two of vinegar. And it is now a common practice to wash and sprinkle the rooms of hospitals, the decks of ships, &c. with vinegar, in order to purify the air. Dr. Hales (Ventilators, part i. p. 46.) recommends dipping many cloths in vinegar, and hanging them up in all proper vacancies between the decks of ships, and in the chambers of sick persons, by which great quantities of vinegar would intermix and float in the air; and he found by an experiment, mentioned in his Statical Essays, vol. i. p. 266, that an air which passes through such cloths, could be breathed to and fro as long again, as the like quantity of air which was not impregnated with vinegar. Fainting, vomiting, lethargic and hysterical paroxysms, are likewise frequently relieved by vinegar, applied to the mouth and nose, or received into the stomach. Lethargic persons are often found to be excited more effectually by vinegar blown into the nose, than by the far more pungent volatile spirits. Boerhaave observes, that this acid counteracts, in a peculiar manner, the effects of spirituous liquors. The daily use of vinegar with food is salutary in hot, bilious dispositions, and where there is a tendency to inflammation or putrefaction. It is prejudicial to children, to aged, hysterical, and hypochondriacal persons; in cold, pale, phlegmatic habits, where the vessels are lax, the circulation languid, and the power of digestion weak. It tends in all cases, if used freely, to prevent corpulence. Hoffman suspects that it produces this effect by impeding the formation of chyle, or destroying the union of the unctuous and ferous fluids of which chyle is composed; an effect common to all acids, as appears from their coagulating milk and artificial emulsions. Dr. Lewis observes, that he has known great corpulence reduced by the liberal use of vinegar, but not with impunity: diseases succeeding, which eluded the power of medicines, and proved at length fatal.

Combinations of vinegar with different earthy bodies, differ in virtue according to the nature of the earth. A solution of the aluminous earth in this acid is strongly astringent; of vegetable earth, or magnesia alba, bitterish and gently purgative: both these solutions are milder, and less ungrateful, than those of the same earths made in the mineral acids; and, though as yet unknown in practice, certainly deserves, as Dr. Lewis says, to be introduced. Solutions

of different animal and the calcareous mineral earths are bitterish and subausteric, in various degrees, and supposed to act as mild resolvents, subastringents, or diaphoretic. Combinations of vinegar with fixed alkaline salts are useful aperients, diuretics, and cathartics. Dr. Lewis has known two drachms of the alkali, dissolved in as much vinegar as was sufficient to saturate it, occasion ten or twelve copious watery stools, and a plentiful discharge of urine, without griping or fatiguing the patient. Mixtures of alkali and distilled vinegar, evaporated to a dry salt, are kept in the shops; either in a brownish oily state, as obtained by simple evaporation, or purified to perfect whiteness, by gentle fusion or solution in water. These preparations are given in doses of ten or twenty grains as mild aperients, and to a drachm or two as purgatives and diuretics. See TARTAR, Regenerated, SAL Diureticus, TERRA Foliated, and ARCANUM Tartari.

Combinations of vinegar with volatile alkaline salts, commonly made with distilled vinegar, added gradually to the salt, till the effervescence ceases, scarcely yield any solid salt; the saline matter evaporating with the watery fluid, or even before it: on distilling the mixture in a retort, a salt sometimes concretes about the sides of the receiver, but liquefies again as the vessels grow cold. These mixtures, called *Spiritus Mindereri*, have little purgative virtue, but operate powerfully as aperients; by urine, if the patient walks about in the cool air; by perspiration or sweat, if kept warm in bed. They are principally made use of in this last intention, in doses of half an ounce; and, as they act without irritation, they have place in inflammatory cases, where the warm sudorifics, if they fail of exciting a sweat, aggravate the distemper. Vinegar and honey, or oxymel, of the consistence of a syrup, swallowed warm, is very good in many cases of sore throats arising from colds. A very important medicinal virtue has been attributed to vinegar, namely, that of curing the canine madness. See HYDROPHOBIA, and MADNESS from the Bite of enraged Animals.

M. Buchoz, in a work, entitled "An historical Treatise of Plants growing in Lorraine, &c." affirms, that several successful trials have ascertained the efficacy of vinegar against the ill effects arising from the bite of mad dogs, when it is given in the quantity of a pound each day, divided into three doses; one to be taken in the morning, another at noon, and a third in the evening. Upon the whole we shall here observe, that vinegar, taken into the stomach, acts as a refrigerant, promotes diaphoresis and the discharge of urine; and is a powerful antinarcotic: externally its action on the living fibre is moderately stimulant and astringent. In inflammatory fevers it may be used to acidulate the ordinary beverage. It is given as a remedy in putrid diseases and scurvy; and is the most easily procured, and the best means of counteracting the fatal effects of over-doses of opium, and other narcotic poisons; for which purpose it should be administered in table spoonfuls, frequently repeated, after the stomach has been emptied by a proper emetic. It is employed as a glyster in obstinate costiveness; and externally, in the form of fomentation, or of lotion, is applied in burns, bruises, sprains, and chronic ophthalmia; and diluted with water, it is the best lotion for clearing the eye of small particles of lime, when they adhere to any part of the ball, or the lids. Its vapour is inhaled in putrid fore-throat; and diffused through sick rooms, with the view of neutralizing peffential effluvia; but as a fumigation it has little efficacy. The dose of vinegar is ℥j to ℥ij; and the quantity given in clysters ℥j to ℥ij. See on the subject of this article, Boerhaave's Elem. Chem. by Dallowe, part iii. p. 146, &c. Neumann's Chem. by Lewis, p. 458, &c.

VINEGAR.

Dict. Chem. Lewis's Mat. Med. Thomson's Lond. Disp. See also ACETIC Acid, ACETITE, ACETOUS Acid, and ACETUM.

VINEGAR, in *Rural Economy*, is an acid or cooling liquid that may be made use of with considerable benefit in different sorts of field labour, in mixture with water or other fluids, as quenching thirst very effectually, without stimulating or increasing the heat of the body too greatly. It has been stated, on the authority of a manuscript paper found in possession of Sir William Pulteney on the use of vinegar, by the writer of the Corrected Report of the Agriculture of the County of Middlesex, that during the first American war, the interruption given by our cruizers to the trade of that country, and some other circumstances, prevented the inhabitants of it from procuring proper supplies of molasses for their distilleries, and a distress was experienced, particularly in harvest-time, from the want of rum to mix with water, which was the drink of their labourers. It is commonly known, the writer thinks, that cold water is dangerous, when used by persons heated with labour, or by any severe exercise; and yet it is necessary to supply the waste and exhaustion of perspiration in some mode or other. When rum or wine is added in small quantity to water, it may be used, even if cold, with little danger: it would, however, be safer, it is supposed, if a little warm water were mixed and employed in such cases.

On this account, Dr. Rush, of the same country, after making proper experiments on the subject, recommended in a publication, that instead of rum, which could not then be had, the labourers in harvest should mix a very small proportion of vinegar with the water they made use of as drink. Some years afterwards, in another publication, the same writer mentioned that the practice had been adopted, and had succeeded even beyond his expectations; indeed so much so, that in many places vinegar was still continued to be used, though rum could easily be had. The preference of vinegar to rum is accounted for in this manner: severe labour or exercise excites a degree of fever; and that fever is increased by spirits or fermented liquor of any sort; but vinegar, at the same time that it prevents mischief from drinking cold water during the heat and perspiration occasioned by exercise, allays the fever; and the labourers found themselves more refreshed and less exhausted at night, when vinegar was used instead of rum.

The exact proportion of the vinegar is not known by the writer, but it is supposed that it was not more than about a tea-spoonful to half a pint of water.

The discovery, it is said, was not altogether new, as the Romans used vinegar to mix with water for the drink of their soldiers.

The writer of the above agricultural report adds to this, that M. Denon, a celebrated French draughtsman, who accompanied their army while it was in Upper Egypt, experienced the advantage of vinegar mixed somewhat in this way in that burning climate, which he relates in this manner: "I cooled the heat of my blood with vinegar, which I mixed with water and sugar, and drank of it largely."

Independently of this, however, the same writer states, that the quality of water, which produces the ill effects above described to persons drinking it cold, when under any considerable degree of perspiration, may probably be corrected by the simple addition of skim-milk. The labourers in some districts of this kingdom, it is said, during harvest, make use of no other beverage than milk and water, which is found to allay the fever, and quench the thirst, much more than beer. At the same time, the labourers are

glad when they can get beer or ale, though they confess that they are much sooner thirsty after drinking either, than they are after drinking milk and water, or it would seem than vinegar and water.

As it is necessary to have good and well-kept vinegar in this intention, as well as for some domestic and other purposes, it may be proper to consider the nature of it, and the means of preserving and preventing the decomposition and injury of it in any way. Where good vinegar is wanted, wines of good quality are necessary, as the best kinds of it are those that have been made from generous wines. The more spirituous the wine is, and the more of this vinous spirit that can be retained in the vinegar, of course the better and stronger it will be, and consequently the more fit for the above uses. In regard to the means of its preservation, they principally consist in defending it well against the action or influence of the external air, by keeping it in proper vessels, well closed, and placed in cool situations. Its alterations and injuries may likewise be further retarded, where necessary, by depriving it of a portion of the water which it contains; for which purpose, nothing more is wanted than to just let it boil for an instant; but the vessels which are employed in this kind of business should obviously not be made of copper. The process too, which has been proposed by some with a similar intention, is quite simple; it consists in filling with this acid glass vessels of a proper kind, which are to be then placed in boilers full of water; the water being in this case made to boil for a full quarter of an hour, after which the vinegar in the vessels is taken out, when it may be kept for several years without undergoing any alteration or decomposition. Distillation, too, has been advised as a means of preserving vinegar; but besides the circumstance of its being a tedious and difficult process, it is apt to deprive the acid of the agreeable smell and taste which are peculiar to it in its natural state, and which is always desirable, but more especially when for use in the above intention. And the same is the case with vinegar that has been concentrated by freezing. The acid by this simple operation becomes much stronger, and capable of being kept for a much greater length of time; but it acquires something of a burnt smell and taste, which render it unfit for being employed for many domestic purposes, as well as that above stated.

There is another manner of accomplishing this business by a saline substance, which is that of sea-salt, or muriate of soda, which is advised by some to be added to vinegar, as being able to preserve it, and which succeeds well enough in some cases, though it is not without its inconveniences; for the vinegars that contain this material grow turbid, and at length lose their primitive qualities. But though it may not succeed quite so perfectly as might be wished, it may still be employed in certain cases with advantage, especially if the quantity of salt that is necessary to be added to the vinegar be not in too large a proportion.

What respects the signs by which vinegar may be known to be good, adulterated, or spoiled, deserve considerable attention, as nothing is more common than to meet with vinegars that are of bad quality. Two causes principally contribute to their being in that state: the first of which is, that they have been manufactured or prepared with weak wines, or such as are already in a spoiled condition; the second, that they have been mixed with acid substances, such as pimento and others; or that mineral acids, such as the sulphuric or muriatic, have been added to them. Nothing is, however, more easy than to detect such frauds and impositions, it being sufficient for the purpose to merely saturate a given quantity of potash with the vinegar which is suspected

liable to spontaneous decomposition, it is fitter for pharmaceutical purposes. Thomson's Disp.

VINEGAR, Concentrated. See CONCENTRATION.

VINEGAR of Lead, is a liquor formed by digesting ceruse or litharge, with a sufficient quantity to dissolve it perfectly. This is called the *acetum lithargyrites*, and is prepared by digesting four ounces of litharge about three days in a sand heat, with a pint of strong vinegar, now and then shaking the vessel. The liquor, filtered, will receive a strong impregnation from the litharge, and will be found to have dissolved about one-tenth of it. When a saturated solution is required, the ceruse is preferred to the litharge. This vinegar is of the same nature with solutions of saccharum saturni, and when diluted with a large quantity of water, it abates external inflammations, the itching and other uneasinesses in cancerous ulcers; and before Mr. Goulard's practice, it was used for bathing inflammations in scirrhous tumours, to prevent their becoming cancerous. Inflammations and inflammatory tumours, in general, are dispersed by it. Dr. William Saunders has observed, that the acetum lithargyrites, or Goulard's extract, is not the same in its operation and powers as the saccharum saturni, as medical practitioners have generally supposed. In the preparation of the former, the acid is fully saturated with lead; but in that of the latter, the acid is in a much greater proportion to the lead. The former, when diluted by the purest distilled water, gives out a copious precipitation, which he finds, by experiment, to be ceruse. The latter remains dissolved in distilled water, and is, therefore, applied topically in a state more immediately active, both on account of its greater proportion of acid, and its preserving its solubility under high degrees of dilution. He has also found by experiment, that, by adding a very small proportion of distilled vinegar to the aqua saturnina of Goulard, the white precipitate is redissolved, and that the solution procured in this manner is more active, but less adapted to remove inflammation, and abate irritation, as a sedative, than the aqua saturnina itself. Dr. Saunders, however, is perfectly convinced that no degree of dilution of saccharum saturni will answer the many valuable purposes obtained from the use of the acetum lithargyrites. Water alone, in the case of the aqua saturnina, proves a precipitant of lead, by attracting the acid, and reducing the preparation to a state of ceruse, an intermediate state between lead and the saccharum saturni; so that ceruse dissolved in water more nearly resembles the aqua saturnina of Goulard, than a solution of the saccharum saturni does. The saccharum saturni may be considered as an union of ceruse with vinegar; whereas Goulard's acetum lithargyrites is an union of lead with vinegar. See Percival's Phil. Med. and Exp. Ess. 1776. Append. p. 323, &c. See also LEAD.

VINEGAR of Meadow Saffron, Acetum Colchici, is ordered by the London College to be prepared by taking of the meadow saffron root (bulb) sliced, 1 oz.; of acetic acid, a pint; and of proof-spirit, a fluid-ounce; macerating the root with the vinegar in a covered glass vessel for twenty-four hours, then expressing, and setting the liquor aside, that the feculencies may subside, and adding the spirit to the clear liquor. This is given as a diuretic in ascites and hydrothorax, but is less to be depended on than the squill. The dose is from fʒs to fʒj, united with honey, or any bland fluid. See COLCHICUM and MEADOW SAFFRON.

VINEGAR, Portable, a name given by the chemists to a sort of vinegar-powder, or vinegar in a dry form. It is a preparation of tartar with vinegar, and is made in this manner: Take white tartar, half a pound; let it be carefully washed, then dried and powdered; infuse this powder in the

strongest wine-vinegar; then dry it, and infuse it again, repeating this operation ten times: after this the dry powder is to be kept for use. At any time, a sort of extemporaneous vinegar may be made by dissolving a small quantity of this powder in any proper liquor.

VINEGAR, Prophylactic. See ACETUM Prophylacticum.

VINEGAR, Radical, is a name given to the acid of vinegar, highly concentrated, by distilling verdigris, or crystals of verdigris, &c. See ACETIC Acid.

M. de Laffone has lately found, that in the process of distilling verdigris for this purpose, a fluid escapes of the nature of those called by the ancient chemists *gas*, and by the moderns *fixed air*; and he also observed, that if the distillation be suspended the moment before the acid concentrated vapours appear under a white form, copperish flowers are obtained; before this period, the radical vinegar contains no copper; it only begins to contain some, when the copperish flowers, carried along by the acid vapours, mix themselves with this vinegar: if it is then rectified by a new distillation, these flowers are no more sublimed, and, therefore, a radical vinegar, exempt from copper, may be extracted from verdigris. The copperish flowers are in a high degree caustic, and may be considered as a violent poison. Hist. Acad. Sc. Par. 1777.

VINEGAR of Roses. See ACETUM Rosatum.

VINEGAR of Squill. See SQUILL.

VINEGAR, Edis in. The common opinion, from the discovery of eels in vinegar, that its sharpness to the taste was occasioned by these animals, caused the accurate Leeuwenhoek to attempt a careful examination of it by the microscope.

Some of the strongest and sharpest vinegar, after having been exposed for some hours to the air, and afterwards examined by the microscope, entertains the sight with a number of corpuscles, called the salts of vinegar, which are acute at both extremities, and have many of them in the middle an oblong figure of a brownish colour, and others were altogether clear, pellucid, and bright as crystal. Others of these particles appeared of an oval figure, and some of the half of such a figure, hollowed like a small boat, or the half of a nut-shell. The more perfect figures, pointed at both ends, and pellucid, are so very minute, that some thousands of them are comprehended in a small drop.

These seem to be what affect the tongue with the acid sharpness, when we taste vinegar; and it is very probable, that beside these, minute as they are, there are multitudes of others, equally pointed, and infinitely smaller than these.

If vinegar be placed in an open glass, and suffered to remain some weeks, the surface of it will be found, on examination with good glasses, to be full of the same figures, double-pointed, and very pellucid; and in these, very often, there may be cavities plainly discovered; but examining the liquor a little deeper down, there are found numbers of minute eels; yet these, though minute, are prodigiously larger than the salt particles, and can never be supposed to be the occasion of the sharpness of vinegar to the taste, by any who rightly consider, since it is not all vinegar that contains them; nay, the much greater part of vinegar is wholly without them, and in winter they all die; yet vinegar is not less sharp at that season than in the summer.

Mr. Mentzelius was so lucky as to see these undergo their last metamorphosis, and change into small flies; and though this is a single instance, in regard to the microscopical world of animalcules, yet it is highly probable that the whole race of those, whose appearance in medicated fluids we have been so long puzzled to account for, may, like these, be the worm-state of some winged aerial insect, and have owed
their

their origin, where we see them, to the eggs of parent flies, too small for our sight. Reaumur, Hist. Inf. vol. iv.

If vinegar be impregnated with crab's-eyes, or any other alkaline substance, which blunts, and in a great measure destroys its acidity, these double-pointed figures are no longer found in it, on a microscopical inspection; but in their places we find others with an oblong quadrangular base, from which they shoot up into pyramids, and appear like polished diamonds. These are also very minute, that six thousand of them are computed to be contained in a drop of the liquor, no larger than two corms of barley; and these will be usually found all of the same size, or very nearly so, which is by no means the case with the other sorts of vinegar in its natural state. See *Microscopic EELS*.

VINEGAR-Hill, in *Geography*, an eminence near the town of ENNISCORTHY, famous for being a station of the rebels in 1798.

VINER'S ISLAND, a small island in the south-west part of James Bay, Hudson's Bay.

VINERY, in *Gardening*, a sort of garden erection, consisting of a wall twelve or fourteen feet in height, extending from east to west, furnished with flues, and proper flues, with roof and lights of glass, covering a border of some extent; as ten feet or more in width. When vines are to be forced at an early season, upright glasses, two and a half or three feet in height, are often employed in front, to support the roof, and to admit sun and light to the border, which is frequently occupied with low-growing vegetables; but when they are not wanted early, a low wall will answer equally well. In forcing vines, the following dimensions are supposed to form an improved vinery, or house of this kind, and one that has been found to answer well in actual practice. In houses of this sort, if the wall be twelve feet high, the breadth ten feet, and the height of the upright wall in front three feet, the roof will form an angle of about forty-three degrees; which experience has shewn to be a suitable pitch for forcing vines with advantage.

These sorts of buildings may likewise be constructed on a plan somewhat similar to that of a single-pitted pine-flue, having the back wall fourteen feet high; the roof slanting, and covering an extent of about sixteen feet; with a flue running from east to west near the front wall. This is well suited, not only for grapes, but early crops of melons, strawberries, and other similar kinds of fruit.

To save the expence of glass; where there are peach-houses, the glass frames may also be employed for the vinery, when constructed with this intention, and good grapes may be obtained from vines trained against walls about six feet high, by means of melon-frame glasses, where a small slanting roof is made proper to receive them. But a small degree of fire-heat is of great advantage, and might be applied either by a flued wall, the flue running through the house, or by cast-iron pipes for the purpose.

These sorts of houses, Mr. Nicol remarks, vary exceedingly in their construction; and although some lay great stress on this article, (and there are extremes which ought not to be followed,) he is convinced the failure of success in the production of the grape, is much less a consequence of bad construction in the house, than in the preparation of the border, the choice of the kinds, and the general management. It has fallen to his lot to have the construction and management of three several and differently constructed grape-houses in the same garden, under his care for years, which have equally and uniformly produced excellent crops. This, in his opinion, is a proof of the necessity of a greater niceness in the formation of the border being observed, than in the construction of the house; the fire-place and

flues excepted, which should always be particularly attended to.

He also thinks that the site of a vinery is an object of such consequence to the welfare of the plant, and successful cultivation and production of well-flavoured fruit, that the greatest care should be taken in the choice of it. A gentle hill, having a south aspect, and considerable declivity that way, the soil a strong brown loam of two feet, over a bottom of dry sand, gravel, or soft clay, is, he thinks, the most desirable, and would be the least expensive of all situations. In this case the border requires no paving or draining; and admits of a proper mixture of sandy loam, vegetable mould, marle, and dung, by the removal of two feet of the natural bottom, with the natural soil, to form a border, perfectly adapted to the growth of the vine, in the following proportion; viz. one half strong brown loam, a quarter light sandy loam, an eighth vegetable mould of decayed tree-leaves, and an eighth stable-dung; to which add about a fiftieth part of shell-marle. This is the composition of the vine-borders at Wenys Castle, none of which are less than four feet deep, and one (owing to the accidental situation of the house) is six. See FORCING, HOT-HOUSE, and STOVE. See also VITIS.

In order to form borders against these hot-walls in other cases, they should have the earth taken out two feet deep where the ground is dry, but in other cases one foot will be sufficient, as in wet soils the borders should be raised at least two feet above the level of the ground, to prevent the roots of the vines from being injured by the wet. The bottom of this trench should be filled with stones, lime-rubbish, &c. a foot and a half or two feet in thickness, which should be levelled and beaten down pretty hard, to prevent the roots from running downward. The trenches should be made five feet wide at least, otherwise the roots will, in a few years, extend themselves beyond the rubbish, and, finding an easy passage downwards, run into the moist ground, and be thereby much injured, or destroyed; but before the rubbish is filled into the trench, it is a better method to raise a nine-inch wall at that distance from the hot-wall, which will keep the rubbish from intermixing with the neighbouring earth, and also confine the roots to the border in which they are planted. This wall should be raised to the height of the intended border, and may be useful to lay the plate of timber of the frames upon, which will be necessary to cover the vines with when they are forced; and where the borders are raised to any considerable height above the level of the ground, these walls may preserve the earth of the borders from falling down into the walks; but in carrying them up, it will be proper to leave little openings, about eight or ten feet distant, to let the water pass off by. As soon as the walls are finished and thoroughly dry, the rubbish should be filled in, as directed above, when there should be fresh light earth laid upon it two feet thick, which will be a sufficient depth of mould for the vines to root in. The borders should be prepared in this manner at least a month or six weeks before the vines are planted, in order that they may have time to settle. See VITIS.

Improved and more economical modes of heating and steaming the plants in vineries have lately been had recourse to by Mr. Loudon and others, as by the ordinary fires, and the use of cast-iron plates, &c. Vineries have sometimes steam-vaults under the ground, for supplying occasional warmth to the roots of the vine plants. Houses of these kinds are sometimes called *graperies*, and *grape-houses*. See STOVE.

VINET, ELIAS, in *Biography*, a learned man of the sixteenth century, was born at Vinets, a village of Saintonge, and

and having gained a small fund of money by tuition, he went to Paris for the study of mathematics and improvement in classical literature. He was invited to Bourdeaux in 1541, and appointed to a professorship by Govea, principal of the college in that city. He accompanied his patron to Coimbra in 1547, but after his death returned to Bourdeaux, where he was appointed principal of the college in 1558. Having performed the duties of this office for twenty-five years, he was released from service in his advanced age, but retained his salary, and died in 1587, at the age of 78. Vinet edited various ancient authors; and besides his translations into French, he published some original works, such as "The Art of making Dials;" a treatise "On Moderation;" the "Antiquities of Saintes and Barbefieux," 4to. 1571; and "Antiquities of Bourdeaux and Bourg," 4to. 1574. Moreri.

VINEUIL, in *Geography*, a town of France, in the department of the Loir and Cher, on the Couffon; 3 miles E. of Blois.

VINEYARD, VINETUM, a plantation of vines. See VINE.

Vineyards were formerly common in England, but for a considerable time the cultivation of them has been altogether neglected. There was a famous vineyard at Bath, planted with white Muscadine and black cluster grapes, which, at one time, yielded sixty hogheads of wine at a vintage, though, in 1721, it only yielded three hogheads.

Bradley also mentions a small vineyard of a private person at Rotherhithe, consisting only of a hundred vines, which yielded at a vintage ninety-five gallons of wine, that had the true Burgundy flavour, as being made of that sort of grape, and exceeded any made on this side of Paris.

VINEYARD, in *Geography*, a town of America, in the district of Vermont, and county of Grand Isle; containing 338 inhabitants.

VINEYARD, *Martha's*. See *MARTHA'S Vineyard*.

VINEYARD, *New*, a township in the district of Maine, and county of Somerset; containing 484 inhabitants; 60 miles N.W. of Brunswick.

VINEYARD *Sound*, a narrow sea, on the north-west coast of Martha's Vineyard, separated from Buzzard's bay by Elizabeth islands.

VINFELD, a place of Westphalia, in the county of Lippe, near Horn.

VINGENNA, in *Ancient Geography*, a river of Gaul, which discharges itself into the Loire.

VINGER, in *Geography*, a town of Norway, in the province of Aggerhus; 12 miles S.E. of Berga.

VINGORLA, a town of Hindoostan, in the country of Concan, where the Dutch had a settlement, from which they were driven by the natives in 1696. About ten miles to the west-north-west are some rocks, in the Indian sea, called Vingorla Rocks. The town of Vingorla is situated near the mouth of a river; 22 miles N.N.W. of Goa. N. lat. 15° 53'. E. long. 73° 27'.

VINHAES, a town of Portugal, in the province of Tra los Montes; 12 miles W. of Bragança.

VINJA CUTARIA, a town of Hindoostan, in Cutch; 16 miles S. of Tahej.

VINIE LAKE, a lake of Norway, in the government of Aggerhus; 45 miles W. of Conberg.

VINIOLÆ, in *Ancient Geography*, a place in the isle of Sardinia, on the route from Portus Tibulis to Caralis, between Fanum Carisi and Sulci. Anton. Itin.—Also, a place of Spain, belonging to the Carpetani, between Accatucci and Mentefa Baitia.

VINITZA, in *Geography*, a town of Croatia; 12 miles W. of Varadin.

VINIUS, in *Ancient Geography*, a river of Italy, in the vicinity of the town of Casinum, according to Varro, supposed to be now known by the name of Fiume di San Germano.

VINKATTY CHILLUM, in *Geography*, a town of Hindoostan, in the Carnatic; 10 miles S. of Nellore.

VINKENBOOMS, DAVID, in *Biography*, a landscape painter, born at Mechlin in 1578, was the son of an obscure painter in dittemper. His landscapes, which are in the style of Roland Savery and of John Breughel, are sometimes adorned with stories from the Bible, but more frequently are convivial; being fairs or merry-makings. He ventured occasionally on history, with landscape backgrounds; such is the picture of Christ bearing his Cross, in the collection of the elector palatine, and of Christ healing the Blind, at Frankfort. His compositions are ingenious, but his touch is petite and hard.

VINKISH, the name of a disease in sheep. See VANQUISH.

VINMARSUCK, in *Geography*, an island near the coast of East Greenland. N. lat. 60° 40'. W. long. 45° 45'.

VINNA, a town of Hungary; 2 miles N.W. of Ungvar.

VINNAS, a town of Peru, in the diocese of Guamanga; 50 miles W. of Guanaca Velica.

VINNEBERG, a town of Germany, in the bishopric of Munster; 10 miles N.E. of Munster.

VINNET, in our *Statutes*, is used for a flower or border, which printers use to ornament printed leaves of books. See VIGNETTE.

VINNIUS, (VINNEN,) ARNOLD, in *Biography*, an eminent jurist, was born in Holland in 1588, studied at Leyden, and taught the classics at the Hague till the year 1633, when he became law-professor in the university of Leyden. Whilst he occupied this office, he acquired distinction by various works of jurisprudence, in an elegant and ornamented style. The principal of his publications are, "Commentarius Academicus et Forensis in quatuor Libros Institutionum Imperialium," Amst. 1642, often reprinted, and particularly by Heinecius, with a preface and notes, Lugd. Bat. 1726, 4to.; "Notæ ad Institutiones," accompanying the preceding; "Introductio ad Praxin Batavam," &c. &c. He died at Leyden in 1657, or, as some say, in 1668. Moreri.

VINNY, in *Agriculture*, a term signifying mouldy and stufy, when applied to hay and other such substances. We have thus vinny hay, &c.

VINOVIA, VIONIA, or *Viconia*, in *Ancient Geography*, a town of Great Britain, in the 1st Iter of Antonine, on the route from Vallum to Prætorium, is fixed at Binchester on the Were, in the bishopric of Durham, between Vinodomora (Ebechester) and Cataractori (Cataract), on the fourth side of the river Swale. Ptolemy assigns it to the Brigantes.

VINOUS, VINOSUS, something that relates to wine; or that has the taste and smell of it.

All vegetables, by a due treatment, afford a vinous liquor; as corn, pulse, nuts, apples, grapes, &c.

A second fermentation, duly managed, turns any vinous liquor into an acetous one.

The proper character and effect of fermentation are, to produce either a vinous, or an acetous quality in the body fermented.

Some of our countrymen, bound on a voyage to the East Indies, having filled several casks with Thames water, to carry

carry along with them, observed an intestine motion in it when they came to the equator; and found it afterwards turned into a kind of vinous liquor, capable of affording an inflammable spirit by distillation. See *PUTREFACTION of Water*.

VINSOBRES, in *Geography*, a town of France, in the department of the Drôme; 4 miles S.E. of Nions.

VINTAGE, the crop of wine, or what is got from the vines each season.

The word is also used for the time or season of gathering or pressing the grapes.

In France, a decree or ordinance of the proper judge, and a solemn publication of it, are required, before the vintage can be begun.

VINTAIN, or **BINTAIN**, in *Geography*, a town of Africa, and capital of the kingdom of Fonia, on a river of the same name, which runs into the Gambia. This town is much frequented by Europeans for the purchase of wax, ivory, and skins.

VINTIMIGLIA, a sea-port town of Genoa, defended by a castle. It is the see of a bishop, under the archbishop of Milan; 13 miles N.E. of Nice. N. lat. 43° 48'. E. long. 7° 33'.

VINTIUM, in *Ancient Geography*, a town of the Nerufi, according to Ptolemy, recognized by inscriptions in honour of Gordian and Trajan-Decius, in which are read *CIVIT. VINT.* In the Notitia of the provinces of Gaul, Civitas Vintuntium is one of those of the Maritime Alps. In later times it was called Vincium, and this name is preserved in that of Venice.

VINUESA, in *Geography*, a town of Spain, in Old Castile; 13 miles N.W. of Soria.

VINUM, a liquor, or drink, popularly called *Wine*; which see.

VINUM, in *Medicine*, *Vinum Medicamentum*, is particularly applied to several medicated wines, *i. e.* medicinal preparations, of which wine is the basis. Wine, as a solvent, is liable to the objection of inequality of strength; and on account of its spontaneous decomposition by exposure to the air, it is more objectionable, this change being more likely to occur sooner when it is imbued with principles which tend to hasten the fermentative process. In order to obviate these disadvantages, Parmentier (*Annales de Chimie*, lii. 46.) proposes, that instead of preparing medicated wines in the usual way, the alcoholic tinctures well prepared should be added to wine in given quantities; by which means, he says, the preparations are less nauseous, and always of a determinate strength. By the general term wine, the London College designates cherry wine. These medicated wines should be kept in very well-corked bottles, and in a cool situation. Some of these are denominated from the ingredients used in them; and some from the intentions with which they are prescribed; and some from their qualities, &c. Such are the

Vinum Absinthites, or *Wormwood Wine*; made of the great or little absinthium, by taking the apices, or tops, with the flowers, putting them in a facculus, or bag, and suspending it in the middle of a vessel of wine; which, fermenting, extracts the taste, smell, and virtues, of the wormwood. See *ABSINTHITES*.

Vinum Aloes, *Wine of Aloes*, is prepared, according to the Lond. Ph., by rubbing eight ounces of extract of spiked aloes to powder with white sand previously freed from any impurities, and also rubbing two ounces of canella bark into powder, and on these, mixed together, pouring six pints of wine and two pints of proof-spirit; macerating for fourteen days, frequently shaking the vessel containing the mixture, and afterwards straining. The Dub. Ph. directs four

ounces of focotorine aloes and one ounce of canella alba to be separately reduced to powder, and mixed together, and then to pour over it three pints of Spanish white wine, mixed with a pound of proof-spirit; then to digest for fourteen days, with frequent agitation, and lastly to strain the solution.

Vinum Aloes Socotorina, *Wine of Socotorine Aloes*, of the Edin. Ph., commonly called *Sacred Tincture*, is prepared by taking one ounce of focotorine aloes in powder, lesser cardamom-seeds bruised, and ginger-root bruised, of each a drachm, and two pounds of Spanish white wine; digesting for seven days, with frequent agitation, and then straining. This medicated wine is an excellent warm purgative and stomachic; and has been employed, largely and beneficially in cold phlegmatic habits, paralysis, gout, dyspepsia, and chlorosis; the dose is from fʒj to fʒij as a stomachic, and from fʒj to fʒij as a purgative.

Vinum Aloceticum Alkalinum, a form of medicine in the late London Dispensatory, intended to stand in the place of Helmont's elixir proprietatis. It is prepared in this manner: Take of bay fixed alkaline salt, eight ounces; aloes, myrrh, and saffron, of each an ounce; purified fix ammoniac, six drachms; white wine, a quart; infuse them together without heat for a week, or longer, and then filter the wine through paper for use.

Vinum Amarum, *Bitter Wine*, is an infusion of certain bitter, stomachic herbs, as gentian-root, juniper-berries, tops of centaury, orange and lemon-peel, in wine. This wine may be made by infusing for a week, without heat, gentian-root, and yellow rind of lemon-peel, of each one ounce, and two drachms of long-pepper, in two pints of mountain-wine, and straining out the wine for use.

The *Vinum Gentiane Compositum*, vulgò *Vinum Amarum*, or compound wine of gentian, commonly called *bitter wine*, is obtained by slicing or bruising half an ounce of gentian-root, one ounce of cinchona bark, two drachms of orange-peel dried, one drachm of canella alba, and pouring upon them four ounces of proof-spirit, and, after twenty-four hours, adding two pounds and a half of Spanish white wine; then macerating for seven days and straining. This wine, newly prepared, is stomachic and tonic, but by keeping becomes acerbent. The dose is from fʒiv to fʒvi, given two or three times a day. For other preparations, see *GENTIAN-ROOT*.

In complaints arising from weakness of the stomach, or indigestion, a glass of this wine may be taken an hour before dinner and supper.

Vinum Antihelminthicum, *Anthelmintic Wine*, may be made by infusing, without heat, half an ounce of rhubarb, and an ounce of worm-seed, bruised, in two pints of red Port wine, for a few days, and straining off the wine. As the stomachs of persons afflicted with worms are always debilitated, red wine alone will often prove serviceable: it must, however, have still better effects when joined with bitter and purgative ingredients, as in the above form. A glass of this wine may be taken twice or thrice a day.

Vinum Antimoniale, *Antimonial Wine*, is made by digesting, without heat, half an ounce of glass of antimony, reduced to a fine powder, in eight ounces of Lisbon wine, for three or four days, occasionally shaking the bottle, and afterwards filtering the wine through paper. The dose of this wine varies according to the intention. As an alterative and diaphoretic, it may be taken from ten to fifty or sixty drops. In a larger dose it generally proves cathartic, or excites vomiting.

The *Liquor Antimonii Tartarizati*, or solution of tartarized antimony of the Lond. Ph., is obtained by dissolving a scruple

of tartarized antimony in four fluid-ounces, of boiling distilled water, and then adding six fluid-ounces of wine. The *Vinum Tartritis Antimonii*, formerly *Vinum Antimoniale*, is had by mixing twenty-four grains of tartrate of antimony in one pound of Spanish white wine, so that the tartrate may be dissolved. These solutions are of equal strength; ℥ʒj of either containing two grains of tartarized antimony. They are diaphoretic or emetic, according to the extent of the dose. In doses of ℥x to ℥ʒj, in any proper vehicle, repeated every three or four hours, diaphoresis is usually excited; but this solution is principally used as an emetic for infants, a tea-spoonful being given every five minutes till it produces full vomiting. See ANTIMONY.

Vinum Aromaticum, is made by infusing aromatics, or spices, in new wine, or must.

Vinum Benedictum, *Blessed Wine*, is made of crocus metallorum and mars infused in wine. This was formerly a celebrated emetic, but is now almost out of use, on account of its roughness.

Vinum Chalybeatum, *Chalybeate Wine*, is thus prepared: Take filings of iron, four ounces; cinnamon and mace, of each half an ounce; of Rhenish wine, two quarts; infuse a month without heat, often shaking the vessel; then filter it off for use. Some superadd a reddish colour, by using a small quantity of cochineal.

Fine iron wire, cut in pieces, is more eligible than the filings, as we may always depend on the wire being pure iron; and as it exposes a larger surface to the fluid, it is more easily acted upon.

This wine is an excellent stomachic and aperient; it may be drank in the quantity of a common spoonful, or even of a moderate glass, once or twice a day, or mixed in apozems of the aperient vegetables.

In obstructions of the menses, this preparation of iron may be taken in the dose of half a wine-glass twice or thrice a day. Dr. Buchan says, that the medicine would probably be as good if made with Lisbon wine, sharpened with half an ounce of cream of tartar, or a small quantity of the spirit of vitriol.

The *Vinum Ferri*, or *Wine of Iron*, is by the Lond. Ph. directed to be prepared by mixing two ounces of filings of iron with two pints of wine, and setting the mixture aside for a month, occasionally shaking it; and filtering it through paper. The Dub. Ph. orders four ounces of iron wire cut in pieces, and four pints of white Rhenish wine; and directs to sprinkle a little of the wine over the iron filings, and exposing them to the air, until they be covered with rust, then to add the remainder of the wine; to digest for seven days, with frequent agitation, and lastly to filter. This is a vinous solution of tartrate of iron and potash, and when prepared as the London College directs, each pint contains about twenty-two grains of oxyd of iron. It is the least unpleasant of the preparations of iron; chiefly employed in chlorosis, and the relaxed habits of young females. The dose is from ℥ʒj to ℥ʒvj, given twice or thrice a day.

Vinum Cydonites, *Quince Wine*; made of slices of that fruit, steeped in must, or new wine.

Vinum Emeticum, *Emetic Wine*, is wine in which the galls or regulus of antimony, or crocus metallorum, has been steeped. See EMETIC.

This only takes a certain degree of efficacy from the matters; nor is it found any stronger at three months end, than at the end of three days. It purges both upwards and downwards.

Vinum Enulatum, *Eletcampane Wine*, is an infusion of the root of that plant, with fugar and currants, in white Port. It cleanses the viscera, prevents disorders and obstructions

of the lungs, and is good in asthmatic cafes, cachexies, &c. See ELECAMPANE.

Vinum Hippocraticum. See HIPPOCRAS.

Vinum Ipecacuanhe is prepared, according to the Lond. Ph., by macerating for fourteen days two ounces of the root of ipecacuanha bruised in two pints of wine, and filtering; according to the Ed. Ph., by macerating for seven days one ounce of the root bruised in fifteen ounces of Spanish white wine, and filtering through paper; and according to the Dublin Ph., by digesting for seven days two ounces of the bruised root in two pints of Spanish white wine, and then filtering. As an emetic, this is equally efficacious, and milder in its operation than antimonial wine, and, therefore, better adapted for infants: for this purpose, a tea-spoonful, or ℥ʒs, is given for a dose, and repeated every ten minutes till it operates. In smaller doses it answers the same purposes as the powder, and is given in coughs, diarrhoea, dysentery, and other complaints in which a determination to the skin is indicated.

Vinum Marinum, *Sea-wine*, is made by casting sea-water on the grapes in the vat.

Vinum Millepedum. See MILLEPEDES.

Vinum Nicotiana Tabaci, *Wine of Tobacco*, of the Edinb. Ph., is prepared by macerating for seven days one ounce of tobacco-leaves in one pound of Spanish white wine, and filtering through paper. This is the only form in which tobacco can be conveniently administered as an internal remedy. It is given to produce diuretic and antispasmodic effects in dropsies, colica pictonum, and ileus. The dose is from ℥x to ℥xxx, in any proper vehicle.

Vinum Opii, *Wine of Opium*, is obtained, according to the Lond. Ph., by taking an ounce of extract of opium, cinnamon bark bruised and cloves bruised, of each a drachm, and a pint of wine; macerating for eight days, and filtering. Mr. Ware introduced the use of this tincture as a local application in the second stage of ophthalmia, when the inflammatory symptoms have subsided, and the vessels of the conjunctiva remain turgid with red blood. Two or three drops are dropped into the eye every morning, until the redness be removed.

Vinum Peccorale, *Peccoral Wine*, is prepared by liquorice, saffron, coriander-seeds, caraway, anise, salt of tartar, pennyroyal, and hyssop leaves, digested with Canary wine, and strained. It is a good expectorant, helping to deterge and cleanse the lungs, &c.

Vinum Picatum, *Pitched Wine*, is made of pitch infused in must.

Vinum Rhei Palmati. See RHUBARB.

Vinum Rosatum, *Rose Wine*, is made by steeping roses for three months in wine.

Vinum Scilliticum. See SQUILLS.

Vinum Stomachicum, *Stomachic Wine*, is prepared by infusing an ounce of Peruvian bark, grossly powdered, cardamom-seeds, and orange-peel, bruised, of each two drachms, in a bottle of white Port or Lisbon wine for five or six days, and straining off the wine. This wine is not only of service in laxity and debility of the stomach and intestines, but may also be taken as a preventive, by persons liable to the intermittent fever, or who reside in places where this disease prevails. It will be of use to those who recover slowly after fevers of any kind, as it assists digestion, and helps to restore the tone and vigour of the system. A glass of it may be taken two or three times a day.

Vinum Strabites, denotes pine-apple wine.

Vinum e Tartaro Antimoniali, is made by dissolving tartar emetic in white wine, in the proportion of twenty-four grains to a pound.

VINUM *Viperinum*. See VIPER-WINE.

VINUM *Essatum*, in *Chemistry*. See ESSENCE OF WINE.

VINUM *Extemporaneum*, a name given by Dr. Shaw and others to a sort of extemporaneous vinous liquor, made without fermentation, from the melasses spirit, lemons, water, and fugar, in the following manner. Some good found lemons are to be cut in slices, rind and all, and put into a quantity of pure and fine melasses spirit; when they have stood in infusion three or four days, the liquor is to be strained clear off, and filtered; and having before prepared a very thin syrup of the finest fugar dissolved in spring-water, the two liquors are to be mixed together. The proportions of this mixture can only be hit by repeated trials; but when once found, it will be easy to continue them; and a vinous liquor will thus be prepared not inferior to many foreign wines.

VINZELA, in *Ancient Geography*, a town of Asia, in Galatia, belonging to the Tectosages. Ptolemy.—Also, a town of Asia, in Pisidia. Ptolemy.

VIO, in *Biography*. See CAJETAN.

VIO, in *Geography*, a town of Spain, in Aragon; 11 miles N.W. of Ainh.

VIOL, VIOLA, a musical instrument, of the same form with the violin, but larger, and having six strings; and struck, like that, with a bow.

The viol played with a bow was very early in favour with the inhabitants of France, and is very different from the *vielle* (which see), whose tones are produced by the friction of a wheel, which performs the part of a bow.

There are viols of divers kinds. The first and principal among us is the *base-viol*, called by the Italians *viola di gamba*, or the *leg-viol*; because held between the legs. (See GAMBA.) It is the largest of all, and is mounted with six strings. Its neck is divided in half-notes, by seven frets fixed thereon. Its sound is very deep, soft, and agreeable. The tablature, or music for the *base-viol*, is laid down on six lines, or rules.

What the Italians call *alto viola*, is the counter-tenor of this; and their *tenore viola*, the tenor. They sometimes call it, simply, the *viol*: some authors will have it the lyra, others the cithara, others the chelys, and others the testudo, of the ancients. See VIOLA.

2. The *love viol*, *viola d'amore*, which is a kind of triple viol, or violin; having six brads or steel strings, like those of the harpsichord. This yields a kind of silver sound, which has something in it very agreeable. See VIOL *d'Amour*.

3. A large viol, with forty-four strings, called by the Italians *viola di bardone*; but little known among us.

4. *Viola bastarda*, or bastard viol of the Italians; not

used among us. Broffard takes it to be a kind of *base-viol*, mounted with six or seven strings, and tuned as the common one.

5. What the Italians call *viola di braccio*, arm viol; or, simply, *braccio*, arm; is an instrument answering to our counter-tenor, treble, and fifth violin. See VIOLA.

6. Their *viola prima*, or first viol, is really the counter-tenor violin; at least, they commonly use the clef *c-fol-ut* on the first line, to denote the piece intended for this instrument.

7. *Viola secunda* is much the same with our tenor violin; having the clef of *c-fol-ut* on the second line.

8. *Viola terza* is nearly our fifth violin; the clef *c-fol-ut* on the third line.

9. *Viola quarta*, or fourth viol, is not known in England, or France; though we frequently find it mentioned in the Italian compositions; the clef on the fourth line.

Lastly, their *violetta*, or little viol, is, in reality, our triple viol; though strangers frequently confound the term with what we have said of the *viola prima*, *secunda*, *terza*, &c.

VIOL d'Amour, an instrument played with a bow, like the violin, of which it has the form. The only one we ever examined was many years ago in the hands of Giardini. It had but four strings, tuned fifths like those of the violin; but underneath these there were four metalline strings of small brass or iron wire, which were called sympathetic strings. These were never touched by the bow, but were caused to vibrate by the sound of the strings over them, when played upon by the bow.

In the Supplement to the first Encyclopædia in folio, another viol d'amour is mentioned with twelve strings, six upon the great bridge, and six upon a smaller bridge below. The six inferior strings are of metal, and tuned octaves to the superior.

VIOL d'Amour is also an instrument with seven strings, in the shape of a violin, but larger; it is played with a bow, but the finger-board is fretted. Its tone is sweet, but more feeble than the violin.

VIOL is a term used by mariners, when a hawser, or strand-rope, is bound fast with nippers to the cable, and brought to the jeer-captain, for the better weighing of the anchor, where the main-captain proves insufficient.

VIOLA, and *Alto Viola*, the tenor violin. What the *contralto* is in vocal music, the *alto viola* is in instrumental. The same clef is used for both: the tenor on the third line. The instrumental tenor, or *viol da braccio*, as it is often called by the Italians, from its resting on the arm or shoulder, to distinguish it from the *viol da gamba*, which rests on the leg, is an octave above the violoncello, and five notes below the violin.

Scale of the Tenor.

These, with the semitones, are all the notes that were given to the tenor during the first fifty years of the last century, in the concertos of Corelli, Geminiani, and Handel; and the tenor was the instrument to which great violinists retreated, when the hand, and perhaps the eyes, failed. But during the last fifty years of the preceding century,

when quartets, *à parti equali*, came into favour, the tenor was made an important instrument; and when played by a Hindmarsh, a Shields, a Stamitz, and by Giardini himself, was as much and as deservedly applauded as the violins and violoncello.

VIOLA, in *Botany*, the common and well-known Latin

VIOLA.

name of a charming flower, most probably originated in its Greek synonym *ion*. At least, the vague and forced etymologies of this word, for which Latin authors have ransacked their own language, prove it not to have come from thence. Nor are the explanations of the Greek much more satisfactory, though the fable of this plant having sprung up on purpose to be the food of the metamorphosed Io, is too poetical to be forgotten. The names of the Violet in modern languages all proceed from the Latin, or from the same source, whatever it may be. The poetry, the romance, the scenery, of every country, is embroidered with the violet, from Caledonia to Arcadia, and the very same individual species is, or has been, the object of homage in both those distant countries. Yet it must be remembered, that *ion*, *Viola*, and even the English *Violet*, are names of more wide-extended and indefinite application, than those of perhaps any other flower, even the Rose not excepted; so as to be nearly synonymous with the word *flower* itself; nor can any thing be more dissimilar from the true kind, or from each other, than the Calathian Violet, a *GENTIANA*, or the Dame's Violet, *HESPERIS*; the Dog's-tooth Violet, *ERYTHRONIUM*, or the Water Violet, *HOTTONIA*. (See those articles).—Linn. Gen. 457. Schreb. 597. Willd. Sp. Pl. v. 1. 1159. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 244. Prodr. Fl. Græc. Sibth. v. 1. 145. Ait. Hort. Kew. v. 2. 43. Pursh 171. Juss. 294. Tourn. t. 236. Lamarck Illustr. t. 725. Poiret in Lam. Dict. v. 8. 623. Gærtn. t. 112.—Class and order, *Syngenesia Monogamia*, Linn. *Pentandria Monogynia*, Smith, Willd., &c. Nat. Ord. *Campanaceæ*, Linn. *Cistifl.* Juss.

Gen. Ch. Cal. Perianth inferior, short, permanent, of five ovate-oblong, erect leaves, most acute at the summit, inserted above their base, which is obtuse; they are equal, but variously disposed; two of them subtending petal α , one each of the petals β and γ , and the fifth the two petals δ and ϵ together. Cor. irregular, of five unequal petals; of which petal α is at the top of the flower, the broadest and most obtuse of all, straight, looking downwards, emarginate, ending at the base in a horn-shaped, obtuse Nectary, projecting betwixt the calyx-leaves; β and γ are lateral, both alike, opposite, obtuse, straight; δ and ϵ are the lowest of all, both alike, larger than the two former, reflexed upward. Stam. Filaments five, very small, two of them adjoining to petal α , are furnished with two combined appendages, which enter the nectary; anthers converging, hardly connected, obtuse, with a terminal membrane to each. Pist. Germen superior, roundish; style thread-shaped, projecting beyond the anthers; stigma oblique, pointed or concave. Peric. Capsule ovate, triangular, obtuse, of one cell and three valves. Seeds several in each cell, ovate, polished, inserted into the valves. Recept. linear, running along the centre of each valve.

Obs. The *stigma*, in the Common March Violet, *V. odorata*, and its allies, is a simple reflexed hook; in the *tricolor*, or Panfy, tribe, it is a hollow knob, perforated at the summit, and more or less gaping occasionally. In the European species, the flower is always inverted; in the Indian ones, mostly erect; hence the different aspect of the two.

Eff. Ch. Corolla of five petals, irregular, spurred behind. Anthers somewhat connected. Capsule superior, of three valves and one cell. Calyx of five leaves, extended at their base.

Viola is a very numerous, almost entirely herbaceous genus, for the most part of humble stature, though of great elegance. The *stem* is either trailing, or erect; sometimes wanting. *Leaves* alternate, rarely opposite, stalked, simple,

crenate, or ferrated, occasionally deeply divided. *Stipulas* various and remarkable. *Flowers* on simple stalks, blue, or rather purplish, whitish, or yellow; in one instance, at least, green; very often fringed in a radiant manner, like those of *Veronica*. The species abound in cold or cool countries, such as Europe and North America, though some are of tropical origin; but the habit of these latter is peculiar. One species has but two perfect Stamens.

The discoveries of North American botanists have, of late, greatly enriched this genus. New Holland likewise has contributed several new and curious species; but of these we shall probably learn much more than is at present known, from Mr. Brown, whenever he continues his valuable *Prodromus*.

Two sections are most commodious for the distribution of the species, others, which have been proposed, proving problematical or obscure.

SECT. 1. *Without stems.*

1. *V. palmata*. Palmated Violet. Linn. Sp. Pl. 1323. Willd. n. 1. Ait. n. 1. Pursh n. 3. Curt. Mag. t. 535. (*V. alba*, folio fœnicris amazoniz effigie, Floridana; Pluk. Amalth. 208. t. 447. f. 9.)—Downy. Leaves heart-shaped, lobed in a haltate or palmate manner, more or less notched. Calyx-leaves lanceolate, smooth. Two lateral petals bearded at the base.—Native of North America, on dry hills and pasture ground, generally in a sandy soil. Perennial, flowering from April to June. *Pursh*. Hardy in our gardens, but rarely cultivated. The first leaves are kidney-shaped, ferrated; the subsequent ones deeply and variously palmate, five-lobed, an inch and a half or two inches long, occasionally smooth. *Footstalks* erect, from two to four inches long. *Flower-stalks* rather taller, simple, and single-flowered, as in the whole genus, with a pair of opposite awl-shaped bractæ below the middle. *Flowers* an inch broad, light blue, whitish at the base, inodorous.

2. *V. pedata*. Cut-leaved Violet. Linn. Sp. Pl. 1323. Willd. n. 2. Ait. n. 2. Pursh n. 1. Curt. Mag. t. 89. Andr. Repot. t. 153. (*V. virginiana tricolor*, foliis multifidis, cauliculo apyllo; Pluk. Phyt. t. 114. f. 7.)—Leaves pedate, smooth, with seven or nine lanceolate, nearly entire, lobes.—Native of dry sandy hills and fields, from New England to Carolina. Perennial, flowering in May and June. Rare in our gardens. According to Mr. Curtis, it should be planted in a pot of loam mixed with bog earth, plunged into a north border, and kept in a frame through the winter. The truly pedate leaves distinguish this species. The flowers are larger than the preceding, pale blue, with prominent orange-coloured tips to their anthers. Pursh mentions a variety, whose petals are very handsomely ornamented with a dark purple velvet at the bottom, similar to *V. tricolor*. This may be Plukenet's plant, so meanly figured, as usual with him.

3. *V. digitata*. Finger-leaved Violet. Pursh n. 2.—“Leaves palmate, tapering down into the footstalk, of five or seven undivided lobes.”—Native of Virginia. *Leconte*. Perennial, flowering in May. Flowers pale blue. *Pursh*. May not this be nearly akin to the entire-lobed variety of the following?

4. *V. pinnata*. Wing-leaved Violet. Linn. Sp. Pl. 1323. Willd. n. 3. Ait. n. 3. Allion. Ped. v. 2. 97. (*V. aculis*, foliis pinnatifidis; Gmel. Sib. v. 4. 101. t. 49. f. 4. *V. n. 561*; Hall. Hist. v. 1. 241. *V. montana*, laciniato folio; Cluf. Hist. v. 1. 309.)

β . *V. aculis*, foliis digitatis; Gmel. Sib. v. 4. 100. t. 49. f. 3. (*V. montana*, folio multifido; Bauh. Hist. v. 3. 544.)

Leaves in many deep, toothed or jagged, segments, tapering

VIOLA.

tapering at their base, somewhat downy.—Native of Siberia, as well as of the mountains of Switzerland and Savoy, flowering in the spring. Cultivated by Miller in 1752, but we know not that it exists at present in the English collections. This species is rather smaller than *V. pedata*. *Leaves* generally, as deeply divided, into about five segments, which are either unequally three-cleft, or pinnatifid, as well as jagged, and very narrow; or, in the variety β , lanceolate and only somewhat notched. Their ribs and edges are more or less downy. *Flowers* pale blue, with darker veins. Sometimes the *leaves* are less deeply divided, in a pedate manner, with bluntish lobes; but this variety does not seem confined to any particular country.

5. *V. sagittata*. Arrow-leaved Violet. Ait. n. 4. Willd. n. 4. Pursh n. 4.—Downy. *Leaves* oblong, acute, somewhat ferrated; heart-shaped, cut, a little elongated, at the base. *Calyx* linear, smooth. Three lower petals bearded at the base.—On dry hills, from New England to Virginia. Perennial, flowering from April to June. Dr. Fothergill imported it from Pennsylvania in 1775. Linnaeus confounded this species with his *hirta*, an European plant, distinguished by its uniformly heart-shaped, regularly crenate, *leaves*. The *sagittata* has remarkably elongated *leaves*, very obscurely ferrated, except towards the base, where they are more or less deeply toothed. *Flower-stalks*, in our specimens, much shorter than the leaves; Mr. Pursh says longer. He describes the *flowers*, which we have not seen fresh, “blue; lower *petal* white towards the bottom, with purple veins; the rest longer, narrower, and white towards the base.”

6. *V. dentata*. Toothed-leaved Violet. Pursh n. 5.—Smooth. *Leaves* oblong, acute; abrupt, dilated, with large ascending teeth, at the base. *Flower-stalks* shorter than the leaves. *Calyx* linear, smooth. Three lower petals bearded at the base.—Native of wet meadows and woods in Pennsylvania. Perennial, flowering in May and June. *Flowers* nearly the same as the last. *Pursh*. The *leaves* are of a hastate figure, two to three inches long, somewhat shorter than the preceding.

7. *V. betonicifolia*. Betony-leaved Violet.—Rather downy. *Leaves* linear-oblong, obtuse, crenate; heart-shaped, and slightly dilated, at the base. *Flower-stalks* taller than the leaves. *Calyx* lanceolate, smooth. Petals all bearded at the base.—Native of New South Wales. *Dr. White*. The *root* is somewhat woody, and doubtless perennial. *Leaves* the size of the last, but smooth or slightly downy only, regularly crenate throughout; not toothed, nor much dilated, at the bottom. *Stalks* generally, but not always, densely downy for an inch and a half below the *flowers*. *Calyx-leaves* broader than in the two last. *Petals* apparently light purple, not much veined.

8. *V. lanceolata*. Spear-leaved Violet. Linn. Sp. Pl. 1323. Willd. n. 5. Ait. n. 5. Pursh n. 6. Forst. Tr. of Linn. Soc. v. 6. 310.—Smooth. *Leaves* lanceolate, obscurely crenate; tapering at the base; rather shorter than the *flower-stalks*. *Petals* beardless.—In overflowed meadows, from Canada to Pennsylvania, flowering in June and July. Perennial. The *leaves* are an inch and half long; their *footstalks* nearly twice as much. *Flowers* the size of *V. palustris*, white; three of their *petals* marked with purple ribs.

9. *V. jussiformis*. Tap-rooted Siberian Violet. (*V. acaulis*, foliis lanceolatis, crenatis, hirsutis; Gmel. Sib. v. 4. 99. t. 49. f. 2.)—*Leaves* ovato-lanceolate, crenate, downy, longer than their *footstalks*, much shorter than the *flower-stalks*. *Root* tap-shaped.—Native of Siberia, in rather dry places, flowering in autumn. *Gmelin*. Mr.

Forster, in Tr. of Linn. Soc. v. 6. 310, has long ago pointed out this Siberian *Viola* as a distinct species from the North American *lanceolata*. We have never seen a specimen. The *leaves* in the figure cited are above an inch long; the *flower-stalks* near three inches, with two lanceolate *bracteas*, rather above the middle. *Flowers* larger than the last, blue or purplish.

10. *V. microphylla*. Small-leaved Yellow Violet. Poir. in Lam. n. 11.—*Leaves* ovato-lanceolate, crenate, somewhat downy, shorter than their *footstalks*. *Root* scaly. *Flower-stalks* taller than the leaves, smooth, with two awl-shaped *bracteas* near the top.—Gathered by Commerçon on hills on the Patagonian coast, in the straits of Magellan. *Poir.* *Leaves* several, radical, four or five lines long, and three broad. *Stipulas* two, narrow, membranous, at the base of each *footstalk*. *Flowers* yellow; *lip* twice the size of the other petals, emarginate, marked with purple lines, and ending behind in a short blunt spur; two lateral petals bearded at the base. This seems nearly akin to *V. magellanica* of Forster; see n. 18.

11. *V. pygmaea*. Dwarf Linear-leaved Violet. Poir. in Lam. n. 18.—*Leaves* sessile, linear, entire, somewhat fleshy, smooth, rather longer than the *flower-stalk*. *Root* tap-shaped.—Gathered in Peru, by Joseph de Jussieu. A very distinct species, according to the description of Poir. hardly an inch high, with thick fleshy roots, crowned by tufts of narrow, linear, obtuse leaves, having scaly, oval, pointed *stipulas* at their base. *Flowers* small, drooping, pale blue, striated; the petals obtuse, scarcely longer than the sharp, lanceolate, white-edged leaves of the *calyx*.

12. *V. obliqua*. Oblique-flowered Violet. Ait. n. 6. Willd. n. 6. Pursh n. 8.—Smooth. *Leaves* heart-shaped, acute, flattish, acutely crenate, taller than the *flower-stalks*. *Flowers* erect. Petals obliquely twisted; the lateral ones narrowest and longest, bearded below the middle.—In shady wet places, from Pennsylvania to Virginia, flowering from April to June. Perennial. *Flowers* white, with purple and yellow veins. *Pursh*. *Leaves* an inch and half long; their *stalks* twice or thrice as much. *Flower-stalks* thread-shaped, usually the length of the *footstalks*. *Calyx* smooth. Petals oblong-ovate, straw-coloured; blue at the base; the uppermost half an inch long, with blue streaks, beardless; two lateral ones rather narrower and longer, bearded below their middle; two lowest as long as these, and rather broader, beardless. *Solander in Ait. H. Kew*.

13. *V. cucullata*. Hollow-leaved Violet. Ait. n. 7. Willd. n. 7. Pursh n. 10. Curt. Mag. t. 1795.—Smooth. *Leaves* heart-shaped, acute, ferrated; involute at the base. Petals twisted, obtuse; the lateral ones bearded at their lower part.—Common in North America, in grassy wet places, flowering in May and June. A hardy perennial with us. *Root* tuberous. *Leaves* rather larger than our Sweet Violet, erect and smooth, remarkably rolled in at their base, so as to form a sort of cup. *Flowers* also larger than in that species, light purplish-blue, with dark veins; the centre white. The late Mr. Curtis, as Dr. Sims records, observed the spring *flowers* to bear no seed; though later ones, on very short stalks, without petals, were all prolific. Such is, more or less, the case with many of this section, as well as with the caulescent *V. mirabilis*, hereafter described.

14. *V. sororia*. White-rooted Violet. Willd. Hort. Berol. t. 72. Ait. n. 8. Pursh n. 11.—*Leaves* heart-shaped, crenate, obtuse; downy beneath. Petals oblong; the lower one bearded at the base.—Found in overflowed meadows of Pennsylvania, and other parts of North America.

VIOLA.

America. Perennial, flowering from April to June. *Flowers* blue, white at the bottom; lower *petal* veined. *Pursh*. This species was sent to Kew garden, in 1802, by the late Mr. Masson, during his last botanical expedition to North America.

15. *V. primulifolia*. Cowslip-leaved Violet. Linn. Sp. Pl. 1324. Willd. n. 8. Ait. n. 9.—Smooth. Leaves ovate-heart-shaped, obscurely crenate, obtuse, running down to the bordered footstalks. Calyx naked.—Native of Pennsylvania and Virginia, flowering in the spring. We have specimens from the late Dr. Muhlenberg, exactly agreeing with those of Linnæus. The root seems to be perennial and creeping. Leaves an inch and half long, on footstalks half as long again, and sometimes slightly downy, furnished with a narrow, leafy, entire border, gradually dilated upwards, till it unites with the leaf; hence the foliage of this plant is compared by Linnæus to that of the Cowslip, not the Primrose. The flowers are rather small, pale flesh-coloured or bluish; the lower *petal* strongly and copiously veined with dark purple; the lateral ones bearded at the base. *Calyx-leaves* linear-lanceolate, unequal in breadth, always, as it appears to us, quite smooth.

16. *V. fimbriatula*. Fringed Violet. (*V. primulifolia*; *Pursh* n. 9).—Leaves heart-shaped, crenate, fringed, acute, running down into the bordered footstalks; moist downy beneath. Calyx mostly ciliated.—Sent from North America, by Mr. Francis Boott, as the *V. primulifolia* of *Pursh*, with whose definition it agrees. That author speaks of it as growing on dry hills, from Canada to Virginia; perennial, flowering from April to June. The appearance of this plant is very different from the last. Root rather tuberous, not creeping. Leaves more heart-shaped and acute, fringed, and somewhat downy on both sides, their length, like that of their bordered footstalks, about an inch. Flowers numerous, blue, thrice the size of the preceding, with obovate petals, two of which are loosely bearded at the base. *Calyx-leaves* lanceolate, unequal in breadth, dilantly but strongly fringed; occasionally naked.

17. *V. hirta*. Hairy Violet. Linn. Sp. Pl. 1324. Willd. n. 9. Fl. Brit. n. 1. Engl. Bot. t. 894. Curt. Lond. fasc. 1. t. 64. Fl. Dan. t. 618. (*V. martia* major hirsuta inodora; Morif. sect. 5. t. 35. f. 4).—Leaves heart-shaped, hairy as well as their footstalks. Calyx-leaves obtuse. Lateral petals marked with a hairy central line.—Native of groves and bushy places, principally on a chalky lime-stone soil, in various parts of Europe, from Denmark to mount Athos, flowering in April and May. The whole herb is of a hoary green, clothed with soft pubescence. Stem none, except very short leafy scyons, which do not throw out roots, but compose a dense leafy tuft, lasting many years if undisturbed. Flower-stalks taller than the leaves, smooth, with a pair of lanceolate smooth bractees below their middle. Flowers light greyish-blue, streaked with black, scentless. Calyx smooth. Anthers distinct. *V. campestris*, March. à Bieb. Tauro-Caucas. v. 1. 171. may possibly be a sweet-scented variety of this.

18. *V. magellanica*. Magellanic Violet. "Forst. Comment. Soc. Goett. v. 6. 41. t. 8." Willd. n. 10.—"Stem none. Leaves kidney-shaped, wavy, villous."—Native of boggy situations, in Terra del Fuego. Perennial. Flowers large, yellow, streaked with brown veins. *Foyster*. Perhaps not distinct from *V. microphylla*, n. 10. We have not seen either.

19. *V. papilionacea*. Butterfly Violet. *Pursh* n. 12.—"Leaves triangular-heart-shaped, acute, crenate, somewhat hooded, nearly smooth. Flower-stalks the length of the leaves. Petals obovate: three lower ones converging,

bearded below the middle; two upper reflexed."—Near Philadelphia, in wet places. Perennial, flowering in May and June. Flowers blue, elegantly striated, bearded with yellow down. *Pursh*.

20. *V. clandestina*. Subterraneous Violet. *Pursh* n. 13. (*V. rotundifolia*; Michaux Boreal.-Amer. v. 2. 150? Muhlenb. Cat. 26?)"—"Nearly smooth. Leaves almost orbicular, bluish; heart-shaped with converging lobes at the base; with blunt glandular serratures at the margin. Flowers from lateral shoots. Petals linear, hardly longer than the calyx."—On the high mountains of Pennsylvania, in shady beech woods, among rotten wood and rich vegetable mould. Perennial, flowering from June to September. This singular species differs from all the rest, in producing its flowers as it were under ground, they being always covered with rotten wood or leaves. They are very small, of a chocolate-brown. The seed-vessel buries itself still deeper in the ground, and is large in proportion to the plant. The inhabitants know it by the name of *Heal-all*, being used by them to cure all kinds of wounds or sores. *Pursh*.

21. *V. palustris*. Marsh Violet. Linn. Sp. Pl. 1324. Willd. n. 11. Fl. Brit. n. 3. Engl. Bot. t. 444. Abbot Bedf. 190. t. 3. Curt. Lond. fasc. 3. t. 58. Fl. Dan. t. 83. (*V. palustris* rotundifolia glabra; Morif. sect. 5. t. 35. f. 5).—Leaves kidney-shaped, smooth. Root creeping. Two lateral petals bearded.—Native of mossy bogs, in the colder parts of Europe, flowering in April or May. More frequent in Scotland, and the north of England, than in the south, growing on the moist parts of sandy or turfy heaths. The root is thread-shaped, rather fleshy, creeping considerably. Herb smooth. Leaves shining, obscurely crenate, generally abrupt, or emarginate, often purple beneath, on stalks exceeding their own length. Flower-stalks longer than the leaves, with a pair of lanceolate bractees about the middle, not always below that part. Flowers scentless, smaller than the Sweet Violet, of a very pale blue or flesh-colour, streaked partly with red, partly with dark purple; the two lateral petals marked at the lower part with a central downy line. This is a very pretty species, not easily to be cultivated. Ray's *V. rubra* striata Eboracensis, *Syn. ed.* 3. 365, is scarcely to be deemed a variety.

22. *V. blanda*. White-flowered American Violet. "Willd. Hort. Berol. t. 24." Ait. n. 12. *Pursh* n. 7.—Leaves heart-shaped, bluish, crenate, smooth. Root creeping. Petals beardless.—In wet places, or boggy meadows, from New York to Carolina. Perennial, flowering from April to June. Flowers yellowish-white; lower *petal* marked with blue stripes and veins. *Pursh*. Nearly akin to the last, but the leaves, though variable in acuteness, are not at all kidney-shaped. The roots are very slender. Petals marked with similar veins to the foregoing species, but they appear not to be hairy in any part.

23. *V. hederacea*. Ivy-leaved Violet. Labillard. Nov. Holl. v. 1. 66. t. 91.—Leaves heart-shaped, wavy, nearly smooth, running down into the slightly bordered footstalks. Root creeping. Flower-stalks solitary, much taller than the leaves. Two lateral petals bearded below the middle.—Found by Labillardiere, at the Cape of Van Diemen. We have the same, or a very similar species, from New South Wales, in which the flowers seem to be pale pink, with a purple eye; the petals obovate, veiny, the lateral ones densely hairy in their lower half. The leaves however are larger, more kidney-shaped, and more toothed, than in the figure above cited; but it may be only a luxuriant variety. M. Labillardiere describes his with a trailing root, or runners, throwing up here and there solitary tufts of numerous heart-shaped, or rather kidney-shaped, long-stalked leaves, half an inch

VIOLA.

each broad, with copious awl-shaped radical *stipulas*. Each tuft bears one *flower-stalk*, three inches high, with two awl-shaped *bracteas* towards the middle, and one small erect *flower*, the size of *V. palustris*, whose two lateral *petals* are villous near the base. The *calyx-leaves* project but very little at the base, which is the case with our specimens above-mentioned, from New South Wales, and indeed with *V. palustris* and *blanda*. Yet they all have enough of that character to prove them true *Viola*.

24. *V. odorata*. Sweet Violet. Linn. Sp. Pl. 1324. Willd. n. 12. Fl. Brit. n. 2. Engl. Bot. t. 619. Curt. Lond. fasc. 1. t. 63. Fl. Dan. t. 309. Bulliard t. 169. Rencalm. Spec. 141. t. 140. (*V. nigra*, five purplea; Ger. Em. 850. *V. purpurea*; Matth. Valgr. v. 2. 522. Camer. Epit. 910.)—Scyons creeping. Leaves heart-shaped, crenate, smoothish as well as the footstalks. Calyx obtuse. Two lateral petals with a hairy line.—Native of thickets, groves, and banks, throughout Europe, from Sweden to Greece, flowering in March. It appears, by Dr. Muhlenberg's catalogue, to be cultivated, not wild, in North America. There can be no doubt of this being the *un purpuræ* of Dioscorides, who speaks of the ivy-like leaves, and very sweet-scented purple flowers, which he recommends for sore throats, and for children in the falling-sickness; hence syrup of violets is still kept in the shops. The long trailing leafy runners, by which the plant is widely increased, characterize this species. These seldom bear flowers till the second year. Leaves truly heart-shaped, dark green; slightly downy beneath. *Stipulas* lanceolate, toothed, pale. *Flower-stalks* taller than the leaves, with two lanceolate narrow *bracteas*, more than half way up. *Flower* nodding, twice the size of *V. palustris*, and about equal to that of *hirta*, whose cent resembles Orrice-root, or the flowers of Mignonette, or the Vine, and indeed is too generally known and esteemed to require description. The colour is that dark purplish-blue, peculiarly called a violet colour. There is a white variety, frequently found wild; and a very double one cultivated in gardens, which requires a pure air. Whether the more early pale grey, and very sweet double Violet, be a variety, or a distinct species, we have had no opportunity of enquiring. The *stamens* of *V. odorata* are quite distinct. *Cap'sule* soft, pale green, minutely dotted with red, like an unripe Cranberry. Leers, in his Fl. Herb. 189, mentions having once found a curious flower of this species which had five regular petals, all spurred, resembling the nectaries of an *Aquilegia*, stripped of its own petals. This was, as he says, an instance of PELORIA in *Viola*; see that article. The petals are often wanting in our wild, as well as garden, Violets.

25. *V. pyrenaica*. Pyrenean Violet. "Decand. Franc. v. 4. 803." Poir. in Lam. n. 19.—Leaves slightly heart-shaped, crenate, smooth. Footstalks dilated at the summit. Calyx obtuse. Spur very short.—Found by M. Ramond, on the Pyrenees, in stony ground. Perennial. This is said to differ from *V. odorata* in having more woody roots, without runners. *Stipulas* greener, and narrower. Leaves scarcely heart-shaped. Nectary shorter, straighter and more obtuse. Flowers smaller, less fragrant, the lip more strongly radiated. Decandolle and Poir.

SECT. 2. With leafy stems.

26. *V. canina*. Dog's Violet. Linn. Sp. Pl. 1324. Willd. n. 13. Fl. Brit. n. 4. Engl. Bot. t. 620. Curt. Lond. fasc. 2. t. 61. (*V. canina sylvestris*; Ger. Em. 851. *V. canina carulea inodora sylvestris ferotina*; Lob. ic. v. 1. 609. *V. inodora major*; Rivin. Pentap. Irr. t. 119.)—Stem at length ascending, channelled. Leaves oblong-heart-shaped. Calyx acute. *Stipulas* serrated.—Even more common throughout Europe than the Sweet Violet, being

as abundant in Greece, and its neighbouring islands and mountains, as it is in England or Sweden, flowering from April throughout most part of the summer, when very thick, grove, bank, and barren heath abounds with its pale purple scentless blossoms. The root is woody, though slender. The first flowers are radical; but several branched, angular or furrowed, smooth, leafy stems soon spring forth, extremely variable in length, direction, and luxuriance, which continue growing, and bearing numerous, axillary, stalked flowers, for several weeks. The leaves vary no less in size, and somewhat in figure, but are always crenate, smooth, heart-shaped; more or less oblong. Footstalks slightly dilated upwards. *Stipulas* not very deeply toothed. *Bracteas* above the middle of the *flower-stalks*. *Cap'sule* more oblong than in the *V. odorata*. See a species nearly related perhaps to this at n. 63.

Several varieties are mentioned by authors. That with a white flower is less frequent than in *V. odorata*. Can this be *V. neglecta* of the Fl. Taur.-Caucas. v. 1. 172? The γ of Fl. Brit., found by M. Du Bois about Mitcham, is smaller in all its parts, and said by Dillenius to have a yellowish, not a whitish spur, a very trifling difference indeed! We have in Norfolk a diminutive, though truly shrubby plant, first noticed by the late Mr. Crowe, in which we cannot discern any specific difference from *V. canina*, except size, and perhaps a thicker texture of leaf. Yet it has remained unchanged in a garden, where the soil is manured, for above twelve years. This cannot be the δ of Fl. Brit. (*V. alpina*; Hudl. ed. 1. 379. *V. martia alpina*, folio tenello circinato; Raii Syn. 366.) The leaves are exactly heart-shaped, obtuse, smooth, coriaceous, minutely crenate. Flowers like *canina*, but not half so large. *V. farnetosae*, Fl. Taur.-Caucas. v. 1. 172, we have not seen, and therefore must leave it in doubt.

27. *V. laeta*. Cream-coloured Violet. Fl. Brit. n. 5. Engl. Bot. t. 445. Ait. n. 15. (*V. canina*, var. 3; With. 262. *V. Ruppii*; Allion. Ped. v. 2. 99. t. 26. f. 6. *V. flore albo*; Rivin. Pentap. Irr. t. 120.)—Stem ascending, round. Leaves ovate-lanceolate. *Stipulas* deeply serrated.—Native of moist rather mountainous heaths, in the south of England. Mr. T. F. Forster found it first on the wolds at Tunbridge; Mr. Stackhouse at Pendarvis, Cornwall. M. Reynier gathered specimens, now before us, in the bogs of Switzerland, but rarely, and he has indicated Rivinus's figure, which, though taller and larger, resembles our plant. Nevertheless we much doubt the permanency of the species, and were only led by the great authority, in this genus, of our friend Mr. Forster, to adopt it. The whole plant is smaller than the ordinary *canina*, but the chief difference consists in the leaves being lanceolate or ovate, decurrent at the base, not heart-shaped. The *stipulas* are supposed to be more deeply cut, and *bracteas* broader. The petals are narrower than in *canina*, obtuse, whitish, streaked with purple lines exactly like *canina*. They even vary often to a light blue.

28. *V. montana*. Long-leaved Mountain Violet. Linn. Sp. Pl. 1325. Willd. n. 14. Ait. n. 16. (*V. flore caruleo longifolia*; Rivin. Pentap. Irr. t. 121. *V. affurgens tricolor*; Ger. Em. 854. *V. arborescens*; Camer. Epit. 911. Matth. Valgr. v. 2. 523, bad. *V. erecta*, flore caruleo et albo; Morif. sect. 5. t. 7. f. 7.)—Stems erect. Leaves ovate-oblong, somewhat heart-shaped. *Stipulas* pinnatifid at one side.—Native of the mountains of Lapland, Germany, Switzerland, and the north of Italy; a hardy perennial in our gardens, flowering in May and June. The name of *arborescens*, given first by Matthioli, has been justly thought absurd. The numerous stems are herbaceous

VIOLA.

and annual, twelve or eighteen inches high, erect, straight, smooth, leafy, but little branched. Leaves two inches and a half long, and one broad, bluntly serrated, smooth. *Foot-stalks* an inch long. *Stipulas* for the most part longer than the footstalks, lanceolate, obtuse; half-ovate at the base, and more or less pinnatifid at the outer, more rounded, margin. *Flower-stalks* axillary, shorter than the leaves, each with two awl-shaped *bracteas* above the middle, and a large, greyish-blue, inodorous flower. *Calyx-leaves* acute, unequal in breadth; most elongated and toothed at the base. *Cap-
sule* oblong, triangular. *Seeds* oval.

29. *V. concolor*. Green-flowered Violet. Forster Tr. of Linn. Soc. v. 6. 309. t. 28. Ait. n. 24. Pursh n. 21. Muhlenb. Cat. 26.—Stem erect, downy. Leaves elliptic-lanceolate, tapering at each end. *Stipulas* linear-lanceolate, entire.—Native of lime-stone rocks in Pennsylvania, flowering in June and July. *Pursh*. Mr. Forster received living plants from America before the year 1788. The root is fibrous, perennial. *Stems* simple, erect, leafy, from one to two feet high, angular and furrowed, most hairy in the upper part. *Leaves* three inches long, more or less, and above one broad, entire or somewhat toothed, taper-pointed, ciliated, running down into shortish bordered *footstalks*. *Stipulas* four, two smaller than the rest. *Flowers* very small, green, on axillary stalks, two together, one of them imperfect. The flowers are very rarely produced in a garden. Their diminutive size, and green petals, are very peculiar, as is indeed the whole habit of this curious species; yet we see no possible reason for separating it from *Viola*. The *capsule*, figured, but not described, by Mr. Forster, appears rather large in proportion to the flower, elliptical, acute, with large, oval, not numerous, seeds.

30. *V. canadensis*. Canadian Violet. Linn. Sp. Pl. 1326. Willd. n. 17. Ait. n. 18. Pursh n. 14.—Stem nearly erect, partially hairy, almost round. Leaves heart-shaped, pointed, serrated, smooth. *Stipulas* slightly notched. *Cap-
sule* downy.—In shady woods, in rich moist situations, on the mountains, from Canada to Carolina; perennial, flowering from June to August. *Flowers* sweet-scented; on the outside purplish-blue; on the inside white, elegantly veined. *Pursh*. The habit of the plant is somewhat akin to *V. canina*. *Stem* a span high, simple, most leafy in the upper part; often marked partially, more or less distinctly, with a downy lateral line. *Leaves* stalked, broad at the base, somewhat deltoid, with about seven ribs; their length an inch and a half; breadth nearly as much. *Stipulas* ovato-lanceolate, rarely notched. *Flower-stalks* about equal to the leaves, angular, with one or two minute *bracteas* towards the bottom. *Calyx-leaves* linear-lanceolate, smooth; heart-shaped, very little elongated, at the base. *Corolla* often white on both sides. *Cap-
sule* globular, densely villous, especially in an early state; which we do not find noticed, but it appears to distinguish the species very satisfactorily.

31. *V. striata*. Streaked Violet. Ait. n. 19. Willd. n. 18. Pursh n. 15.—Stem nearly erect, semi-cylindrical. Leaves heart-shaped, pointed, smooth, serrated. *Stipulas* with fringe-like ferratures. *Cap-
sule* smooth.—In shady woods, from Pennsylvania to Virginia; perennial, flowering from May to July. *Flowers* white, with purple veins. *Pursh*. This resembles the last, but the *stipulas*, and if we mistake not, the smoothness of the *capsule*, afford a clear specific distinction between it and the last. The *flower-stalks* bear a pair of very narrow awl-shaped *bracteas* towards the top. The *calyx* is considerably elongated at the base.

32. *V. debilis*. Weak-stalked Violet. Michaux Boreal-Amer. v. 2. 150. Pursh n. 16.—Stem ascending. Leaves kidney-heart-shaped, scarcely pointed, smooth, crenate. *Sti-*

pulas with fringe-like ferratures. *Flower-stalks* twice the length of the leaves.—In low grounds, from Pennsylvania to Carolina; perennial, flowering from May to July. About half the size of the two preceding, with light-blue flowers. *Bracteas* linear, on the upper part of the stalks. *Calyx* decidedly elongated at the base. *Cap-
sule* quite smooth. Most akin to *V. striata*, but apparently distinct.

33. *V. rostrata*. Larkspur Violet. Pursh n. 17.—Stem ascending. Leaves roundish-heart-shaped, serrated, smooth. *Stipulas* deeply fringed. *Flower-stalks* twice the length of the leaves. *Nectary* longer than the petals.—On shady rocks, near Eastown, Pennsylvania; perennial, flowering in May and June. *Flowers* blue. *Pursh*. About the stature of the last. The leaves have a small blunt point. *Stipulas* often rather pinnatifid than fringed, almost as long as the *footstalks*. *Bracteas* awl-shaped, above half way up the stalks. *Flowers* large, very much like *Delphinium Consolida* in size, colour, and general aspect. *Nectary* an inch long, obtuse, slightly recurved.

34. *V. pubescens*. Downy Yellow Violet. Ait. n. 20. Willd. n. 19. Pursh n. 18. (V. penylvanica; Michaux Boreal-Amer. v. 2. 149.)—Stem erect, simple, downy, leafy at the top. Leaves triangular-heart-shaped; most downy beneath. *Stipulas* ovate, notched at the extremity.—In shady woods among rocks, particularly lime-stone, from New York to Virginia; perennial, flowering in May and June. *Pursh*. Sent to Kew garden in 1772, by Mr. W. Young. We are indebted to Mr. Francis Boott, a young botanist of great zeal and intelligence, for finer specimens of this, and many other North American plants, than have ever before been seen in Europe. The root has many long, stout, simple fibres. *Herb* rather succulent, more or less clothed with fine short silky pubescence. *Stem* simple; naked in the lower part; with three or four leaves at the top, which are two inches wide, serrated, bright green, many-ribbed. *Stipulas* shorter than the lowest *footstalk*, longer than the others. *Flower-stalks* downy, rather shorter than the leaves, destitute, as far as we can discern, of *bracteas*. *Flowers* nearly as large as *V. canina*, yellow, with brown veins. *Calyx* scarcely elongated at the base.

35. *V. hastata*. Halberd-leaved Yellow Violet. Michaux Boreal-Amer. v. 2. 149. Pursh n. 19. Ait. Epit. 376.—Stem erect, simple, leafy at the top, smooth as well as the hastate, nearly sessile, leaves. *Stipulas* minute, finely toothed.—On high mountains, from Pennsylvania to Carolina; perennial, flowering in May and June. *Flowers* yellow. *Pursh*. Introduced at Kew, we presume by Mr. Masson, in 1803. This seems nearly related to the last, and indeed to the following, though all are sufficiently well discriminated. We have not seen specimens of this or the *V. Nuttallii*. It is much to be wished that such as are not yet figured, might find a place in some periodical work.

36. *V. Nuttallii*. Yellow Mifflour Violet. Pursh n. 20.—Downy. *Stem* simple, erect. Leaves ovate-oblong, acute, ribbed, slightly toothed; tapering down into long footstalks. *Stipulas* lanceolate, undivided. *Flower-stalks* the length of the leaves.—Found by Mr. Nuttall, on the banks of the Mifflour; perennial, flowering in June. *Flowers* yellow. *Pursh*.

37. *V. mirabilis*. Broad-leaved Violet. Linn. Sp. Pl. 1326. Willd. n. 20. Ait. n. 21. Jacq. Auftr. t. 19. Fl. Dan. t. 1045. (V. montana latifolia, flores ex radice, femina in cacumine crevens; Dill. Elth. 408. t. 303.)—Stem erect, triangular, leafless in the middle. Leaves kidney-heart-shaped, acute, crenate, smooth. Upper flowers without petals. *Calyx* much dilated at the base. *Stipulas* lanceolate, entire.—Native of woods and bushy places in Sweden

VIOLA.

den and Germany. A hardy perennial, flowering in July and August. The *stems* are a foot high, leafy at the bottom and top only, smooth. *Leaves* two or three inches broad, acute; the radical, or lower, on very long stalks; the upper on very short ones. Radical *flowers* the size of *V. odorata*, light reddish-purple, with a veiny lip; axillary ones about the top of the stem, on shorter stalks, generally without petals, but alone, for the most part, perfecting seed. The base of the *calyx-leaves* in all is much dilated, abrupt, one-third as long as the rest of the calyx. *Capsule* large, rigid, veiny, smooth. The specific name alludes to the fruit being produced by apparently imperfect *flowers*, not, as De Theis imagined, to their great size or admirable beauty. Such a circumstance in the fructification of Violets occurs in several other species.

38. *V. biflora*. Two-flowered Yellow Violet. Linn. Sp. Pl. 1326. Willd. n. 21. Ait. n. 22. Fl. Dan. t. 46. (*V. flore luteo*; Rivin. Pentap. Irr. t. 121. *V. montana prima*; Clus. Hist. v. 1. 309. *V. alpina rotundifolia minor*; Pluk. Phyt. t. 233. f. 7.)—Stem erect, about two-flowered. Leaves kidney-shaped, serrated, nearly smooth. Stipulas ovate, entire.—Native of the mountains of Lapland, Austria, Switzerland, and Savoy, but not of Britain. Sometimes kept, with other alpine plants, in pots, under a frame, in our gardens, flowering in the spring. This is a pretty delicate species, three or four inches high, allied to several of the preceding, but perfectly distinct. The slender simple stem bears three or four stalked leaves, an inch or inch and half in diameter; and usually two distant, axillary, slender-stalked, small, yellow flowers, whose lip is streaked with black. *Bractæas* minute, about the middle of each stalk. *Calyx-leaves* scarcely dilated or elongated, but rather gibbous, at the base. *Capsule* smooth, rigid. *Seeds* few, large.

39. *V. uniflora*. Siberian Yellow Violet. Linn. Sp. Pl. 1327. Willd. n. 22. Ait. n. 23. (*V. n. 67*; Gmel. Sib. v. 4. 101. t. 48. f. 5.)—Stem single-flowered, leafy at the top only. Leaves heart-shaped, toothed.—Native of Siberia. Said to have been cultivated in 1774, by the late Mr. James Gordon; but we presume it would be as easy to find one of the artificial golden flowers of the ancient Mexicans in our gardens at present, for its name does not even appear in Mr. Donn's Cambridge catalogue. The root of this rare and very curious species is thread-shaped, toothed, perennial, with long simple fibres. *Herb* about the size and habit of the Winter Aconite, *Helleborus hymalis*, but rather downy, especially the stem. *Leaves* two or three, crowded at the summit of the stem, on very short stalks, ovate or heart-shaped, an inch long, scarcely downy, coarsely toothed, with a blunt point; their base entire. Stipulas small, lanceolate, with glandular teeth. *Flowers* yellow, larger than any of the preceding; their petals rounded, an inch long; two lateral ones bearded at the base. *Calyx-leaves* oblong, somewhat heart-shaped at their insertion, but hardly dilated or elongated. Gmelin's figure is very incorrect.

40. *V. decumbens*. Narrow-leaved Cape Violet. Linn. Suppl. 397. Willd. n. 23. Thunb. Prodr. 41.—Stems procumbent, round. Leaves linear, crowded, acute, entire. Calyx smooth. Petals of nearly equal length.—Native of the Cape of Good Hope. *Stems* smooth, somewhat branched, rather shrubby, a span long. *Leaves* numerous crowded about the ends of the branches, alternate, an inch and half long, hardly a line broad; tapering at the base, where they are united to a pair of minute lanceolate stipulas. *Flower-stalks* axillary, solitary on each branch, and rising above its summit, twice the length of the leaves, slender,

with two awl-shaped *bractæas* about the middle. *Flower* blue, far more like *V. canina* than *tricolor*, to which Linnaeus compares it; but the *calyx-leaves* are very slightly extended at the base. *Nectary* pale green.

41. *V. arborescens*. Shrubby Dwarf Violet. Linn. Sp. Pl. 1325. Willd. n. 30. Ait. n. 30. (*V. hispanica fruticans*; Barrel. Ic. t. 568.)—Stem ascending, shrubby, branched. Leaves lanceolate, downy, entire. Calyx minutely fringed. Petals of nearly equal length.—Native of the fourth of Spain, about Conil and Tariffa, flowering in February. Durand. A greenhouse plant, cultivated by the late Mr. Blackburne, in his rich garden at Orford, Lancashire, in 1779, as appears by his Catalogue; but scarcely now, probably, existing in any collection. The root is long and woody, as are also the stems, whose extremities terminate in many dense, crowded, leafy branches. *Leaves* resembling those of a *Cheiranthus*, more or less hoary, an inch long, tapering down into slender footstalks, each accompanied by two longish very narrow stipulas. *Flowers* somewhat like the last, but the nectary is very short, and *calyx-leaves* more elongated at the base, each marked with three ribs. Possibly *V. cheiranthifolia*, Poir. in Lam. n. 43, may not be distinct from this.

42. *V. capensis*. Hoary Cape Violet. Thunb. Prodr. 40. Willd. n. 29.—Stem shrubby, erect, downy. Leaves obovate, crenate, hoary. Calyx-leaves ovate, hairy. Lower petal abrupt, thrice as long as the rest.—Gathered at the Cape of Good Hope by Thunberg, from whom we have an unnamed native specimen, which can belong to no other species. It is more or less downy in every part, especially the flower-stalks, and calyx, which is not at all extended at the base. *Leaves* alternate, stalked, an inch long. Stipulas extremely minute, lanceolate. This is one of those species of which the lower petal, or lip, is so much extended, or rather the other four petals fo diminished, as to have a very peculiar aspect; added to which, the base of the calyx is quite simple, not protracted beyond the insertion. Such species have given occasion to the late M. Ventenat to establish his genus *Ionidium*, in Jard. de la Malmaison, t. 27, of which the distinctive characters are, the want of a spur to the corolla, and of appendages, or elongations, to the calyx-leaves. These characters should seem to indicate a distinct genus from *Viola*; but there are so many gradations, some of which we have noted in their proper places, with respect to the calyx, and no less with regard to the nectary, that we cannot rely on either part; especially as the habit does not always concur with these differences. Several of the supposed species of *Ionidium* have as evident a spur, though short, as any *Viola*. Their calyx, it must be allowed, is more constant, but several undoubted *Viola* have as little of a projection there. Ventenat was, moreover, but imperfectly conversant with the species of his supposed genus, as will appear in the course of our history of them.

43. *V. busifolia*. Box-leaved Madagascar Violet. Poir. in Lam. n. 56. (*Ionidium busifolium*; Venten. Malmaison, t. 27.)—Stems ascending, smooth, herbaceous. Leaves obovate, smooth, revolute, entire. Calyx-leaves ovate, naked. Lower petal abrupt, twice as long as the rest.—Gathered by Commerçon in Madagascar. *Thoin*. Allied very nearly to the last, but smooth, and less shrubby. The leaves are rather smaller, and greatly resemble Box, or rather *Polygala Chamæbusus*. The root is woody. Stems six inches long, spreading every way, leafy, scarcely branched. Stipulas minute, awl-shaped. *Flower-stalks* twice the length of the leaves, with two small awl-shaped bractæas towards the top. *Calyx-leaves* broad at the base, especially the two lowermost, which have membranous edges, and embrace the rounded

rounded spur of the *nectary*, which is extended a little beyond them. Here a material character of *Ionidium* fails us. Lateral *petals* veined, half as long as the spatulate lip. *Calyx* ovate, smooth. *Seeds* four in each cell, pale, oval, abrupt, beautifully striated longitudinally.

44. *V. enneasperma*. Nine-seeded Violet. Linn. Sp. Pl. 1327. Willd. n. 33, excluding the synonym of Burmann. (*Ionidium enneaspermum*; Venten. Malmaif. under t. 27. I. heterophyllum; ibid. according to the characters and synonym. *Viola fureccta maderafatensis*, lini facie, rotundioribus imis foliis; Pluk. Phyt. t. 120. f. 8. "Nelandrapenda; Rheede Hort. Malab. v. 9. 117. t. 60.")—Stem erect, much branched from the bottom. Leaves lanceolate or linear, somewhat revolute, smoothish, slightly toothed. Calyx-leaves lanceolate, naked. Lower petal twice as long as the rest.—Native of Ceylon, Tranquebar, and Madagascar. The root is long, simple, woody, perennial. Stems several, branched chiefly in the lower part, erect, six inches high, angular, smooth. Leaves rather glaucous, various in length and breadth, stalked; the lower ones shortest and roundest; none more than an inch, or an inch and half, long. Stipulas minute, awl-shaped, spreading, like little prickles. Flower-stalks shorter than the leaves. Flowers purplish, very like the last; but the calyx-leaves are much narrower and more acute; lip obovate, not so abrupt. Seeds only three in each cell, striated in the same manner, but rather larger. Such is the plant of the Linnæan herbarium, which must be n. 317 of Linn. Fl. Zeyl. 149, though its leaves are certainly not quite entire, nor in any sense linear; neither are the stipulas wanting. Ventenat rightly finds fault with Willdenow for citing a plant of Burmann's Fl. Zeyl. t. 85, which he also cites, more correctly, for *Polygala theezans*; but the error is Linnæus's, and Willdenow copies him without examination. *V. lini-folia*, Poir. in Lam. n. 61, from Madagascar, has perfectly linear, very narrow, leaves, but is certainly a mere variety.

45. *V. suffruticosa*. Madder-leaved Violet. Linn. Sp. Pl. 1327. Fl. Zeyl. n. 318. 150. Willd. n. 34. (*Rubra zeylanica*, foliis latioribus, ramulis dicta; Burm. Zeyl. 208.)—"Stem procumbent. Leaves lanceolate, crowded, somewhat serrated. Calyx even at the base."—Native of Ceylon. Herb procumbent, much branched, hard, like *Cistus Helianthemum*. Leaves acute, scarce evidently serrated, tapering down into foot-stalks. Stipulas awl-shaped, hardish, permanent; hence the plant becomes rough, and in a manner prickly. Flowers as in the last. Linn. in Fl. Zeyl.

We have seen no specimen of this. However the stipulas may be, the procumbent stem seems the most striking difference between these two species.

46. *V. verticillata*. Whorl-leaved Violet. "Ortega Decad. 4. 50." Ait. n. 25. (*Ionidium polygalæfolium*; Venten. Malmaif. t. 27.)—Stems procumbent. Leaves opposite, lanceolate, entire, with lanceolate stipulas, one-third of their length. Flower-stalks drooping, as long as the leaves. Corolla without a spur, nearly equal.—Native of South America. A greenhouse perennial herbaceous plant, brought from Spain, in 1797, by the late marchioness of Bute. The inconspicuous reddish flowers are produced during summer. This is related to several of the last described, inasmuch as the calyx is not extended at the base; but the corolla is also nearly, or quite, destitute of a spur, without any great disproportion between the several petals. The opposite leaves are almost unparallelled in this genus. They are erroneously called whorled, though the large stipulas, resembling leaves, give that appearance. The seeds are smooth, black, two in each cell.

47. *V. striata*. Stiff Opposite-leaved Violet. Poir. in Lam. n. 66. (*Ionidium strictum*; Venten. Malmaif. under t. 27.)—"Leaves opposite, lanceolate, entire. Stipulas very short. Flower-stalks erect, shorter than the leaves."—Found in Hispaniola by M. Poiteau. Ventenat. Stems above a foot high. Leaves an inch long. Flowers whitish, with narrow obtuse petals. Poir. It is said to be related to Poir. V. *linariaefolia*, a species concerning which we have not sufficient information.

48. *V. labiata*. Large-lipped Violet.—Stem erect. Leaves opposite, linear, revolute, smooth. Stipulas minute. Flowers racemose. Lower petal obovate, very large, with a short spur.—Sent by Dr. White from New South Wales, among the first specimens collected in that country. This very remarkable species is evidently akin to *V. enneasperma* and *verticillata*, with their allies, but nevertheless so distinct in many important characters, that we are at a loss which to select for discrimination. The stems are from nine to twelve inches high, angular, erect, rigid, smooth like the rest of the herbage. Leaves an inch and half or two inches long, very narrow, acute, entire; tapering at the base, sessile; some of the lower ones scattered, but the greater part opposite. Stipulas hardly discernible. Flowering branches like the rest of the stem in thickness, but destitute of leaves, bearing several rather distant flowers, on short, drooping, partial stalks, so as to constitute a true cluster. Calyx very small; its leaves lanceolate, acute; the two lower ones gibbous at the base, clasping the spur. Four of the petals ovate, pointed, very little longer than the calyx, pale, with dark veins; the two lateral ones much dilated and rounded at the lower side: the fifth petal, or lip, is disproportionately large, an inch long, broadly obovate, abrupt or emarginate, veiny, apparently rose-coloured; its claw channelled, the length of the other petals, ending behind in a rounded spur, extending beyond the base of the calyx. Capsule ovate, smooth. Seeds two in each cell, large, orbicular, black and smooth, as in *V. verticillata*; not furrowed, as in *enneasperma* and *buxifolia*.

49. *V. thibisifolia*. Toad-flax-leaved Violet. Poir. in Lam. n. 69.—Leaves alternate, linear, entire, smooth, very long. Stipulas awl-shaped. Flowers axillary, nearly sessile.—Gathered by Adanson, in Senegal. Roots slender. Stem erect, herbaceous, scarcely branched, cylindrical, or a little compressed, smooth. Leaves two or three inches, or more, in length, a line or two broad. Stipulas very acute. Flowers very small. Calyx-leaves narrow, acute. Petals whitish, hardly longer than the calyx. Capsule roundish-oval, obtuse. Poir.

50. *V. longifolia*. Long-leaved Cayenne Violet. Poir. in Lam. n. 68.—Stem shrubby. Leaves lanceolate, serrated, very smooth. Flowers solitary or aggregate, on capillary stalks, hardly so long as the awl-shaped nectary.—Native of Cayenne. Preserved in the herbarium of professor Desfontaines. Remarkable for the great size of its leaves, which are four or five inches long, finely serrated, and the smallness of its flowers, which grow on capillary axillary stalks, six lines at most in length, either solitary, or several together. The calyx is smooth, minute. Petals whitish, with a straight awl-shaped spur, at least as long as the stalk.

We presume, from Poir. V. authority, that this last species has no posterior elongation of the calyx, though the spur is to be considered. It may therefore, considering the leaves, serve to connect the foregoing species with the following.

51. *V. glutinosa*. Clammy Violet. Poir. in Lam. n. 63. (*Ionidium glutinosum*; Venten. Malmaif. under t. 27.)

VIOLA.

t. 27.)—Stem branched. Leaves ovate, serrated, smooth; tapering at the base; the lower ones opposite. Stipulas lanceolate, acute. Flower-stalks the length of the leaves. Lip twice the length of the calyx, without a spur.—Gathered by Commerçon, on rocks at Monte-Video. The stem is perhaps shrubby, apparently two feet at least in height, our specimen having several opposite, angular, leafy branches, each a foot long, somewhat downy. Both the stem and leaves are said to be covered with a glutinous moisture. The upper leaves are chiefly alternate, an inch long, stalked, veiny. Flowers numerous, axillary, solitary, not bigger than a large pin's head, drooping, whitish, without bracteas. Calyx-leaves ovate, acute, combined at the base, a little gibbous, but not elongated, in that part. Four of the petals rather longer than the calyx: lip twice as long, abrupt, with no protruding spur. Capsule globose. The form and proportion of the petals appear similar to *V. verticillata*, n. 46.

52. *V. parviflora*. Small-flowered South American Violet. Linn. Suppl. 396. Willd. n. 32. Poir. in Lam. n. 60. Cavan. Ic. v. 6. 21.—Stem branched, diffuse, downy. Leaves ovate, serrated, smooth; obtuse at the base. Stipulas awl-shaped. Flower-stalks the length of the leaves. Lip twice the length of the calyx, without a spur.—Native of Mexico. The root is woody. Stems several, shrubby, branched, leafy, a foot or more in length. Leaves about half as long as the last, but of a broader, more ovate, form, not at all tapering at the base; their serratures few and large. The lower ones are sometimes opposite. The flowers are so much like the preceding, that we can scarcely find any difference. Their stalks, about half an inch long, remain after the capsules are fallen off. The lip has perhaps a slight rounded protuberance at its base, but not extending beyond the calyx.

53. *V. oppositifolia*. Lanceolate Opposite-leaved Violet. Linn. Sp. Pl. 1327. Willd. n. 36. (Calceolaria, n. 1; Læfl. It. 183.)—Stem shrubby, cross-branched, smooth. Leaves opposite, lanceolate, nearly sessile, acutely serrated. Flowers racemose.—Gathered by Læfing, in South America. Many circumstances, indicated by that author, shew an affinity between this and ten or eleven of the foregoing species, especially perhaps the two last. They all, in some particular or other, form exceptions to the characters or habit of a *Viola*. The stems of that before us are described as erect, from a span to eighteen inches high, woody below, round, smooth, with opposite branches. Leaves on very short stalks; their serratures long, not deep; the extremity entire. Flowers white, in solitary spreading clysters (see n. 48.), their stalks partly permanent. Calyx gibbous below. Lip scarcely so broad as its claw, bent upwards, and revolute, at the end. Capsule triangular. Seeds somewhat angular. This plant has something of the habit of *Veronica Anagallis*, or *V. scutellata*. Læfing.

54. *V. Calceolaria*. Shaggy Slipper Violet. Linn. Sp. Pl. 1327. Willd. n. 35. (V. Itoubou; Aubl. Guian. 808. t. 318. Calceolaria, n. 2; Læfl. It. 184.)—Stems hairy, herbaceous. Leaves scattered, nearly sessile, ovate, serrated, very hairy as well as the lanceolate stipulas and bracteas. Calyx shaggy with branched hairs. Lip kidney-shaped.—Native of South America. Gathered by Aublet in Cayenne and Guiana, in sandy ground, flowering at various seasons. This is distinguished by the copious, silky, shaggy hairs, covering every part of the herbage. The stems are a foot high, simple or branched, leafy. Leaves an inch long. Flowers solitary, stalked, white or blue. Four petals small, convoluted. Lip very

large, bristly underneath. Capsule hairy. Seeds oval, smooth.

55. *V. Ipecacuanha*. Ipecacuanha Violet. Linn. Mant. 484. Suppl. 397. (V. grandiflora, veronica folio villoso, Ipecacuanha alba dicta; Barrere Fr. equinox. 113. Pombalia Ipecacuanha; Vandelli Fasc. 7. t. 1.)—Stem shrubby, erect. Leaves scattered, ovate, crenate; hairy underneath and at the margin. Calyx hairy. Lip very abrupt, twice as broad as long.—Native of Brazil. Cultivated by Vandelli at Lisbon, where it flowered in October, in the greenhouse. The root is white, woody, with many cylindrical branches, and is reported to possess the qualities of the true IPECACUANHA (see that article); though in a weaker degree. The stem is two feet high. Leaves stalked, an inch or inch and half long. Flowers fragrant, pale red, with a very short but broad lip, near an inch wide, involute at each side. Seeds roundish, five or six in each cell.

56. *V. diandra*. Diandrous Climbing Violet. Linn. Syst. Veg. ed. 13. 669. Willd. n. 39.—Stem herbaceous, trailing. Leaves oblong, remote. Stalks single-flowered. Nectary very long and twisted. Three of the stamens abortive.—Native of Guiana. Stem thread-shaped, climbing up hedges. Leaves alternate. Flower-stalks axillary, solitary, with a joint; swelling upwards. Bracteas two, minute. Calyx not at all prominent behind. Corolla white. Lip uppermost, very large, with a long twisted spur. Lateral petals ascending; two lower ones smaller, deflexed. Two hinder stamens only perfect. Allamand.

57. *V. Hybanthus*. Gibbous Climbing Violet. Linn. Sp. Pl. 1328. Willd. n. 37, excluding Aublet's synonym. (V. n. 209; Læfl. It. 282? Hybanthus havanensis; Jacq. Amer. 77. t. 175. f. 24, 25.)—Stem shrubby, climbing, prickly. Leaves oblong, slightly serrated, smooth, aggregate. Flowers several on a stalk. Lip somewhat longer than the other petals, without a spur.—Native of uncultivated hills about the Havannah. An elegant branching shrub, seven feet high, erect. Leaves several from one bud, an inch and half long, emarginate; each tapering at the base into a short footstalk. Flower-stalks one or two from the same bud with the leaves, short, divided in the upper part, each bearing a few minute whitish flowers, about the size of *V. glutinosa* and *parviflora*, and nearly agreeing with those species in structure, except that the lip appears shorter in proportion. Capsule the size of a pea. Seeds few, globose. We take our description from Jacquin, having seen no specimen of his plant, or of Læfing's; so that we have no means of determining whether the *Viola* of the latter author, cited as above by Linnæus, be the plant in question, or whether Jacquin's conjectural reference to Læfing's *Calceolaria frutescens*, It. 184, be more correct. We are only certain that Aublet's *V. Hybanthus* is extremely different from the above; see the following species.

58. *V. laurifolia*. Laurel-leaved Climbing Violet. Linn. fil. MSS. (V. Hybanthus; Aubl. Guian. 811. t. 319; excluding Læfing's synonym.)—Stem shrubby, climbing. Leaves ovate, pointed, very obscurely crenate, smooth, alternate. Flowers corymbose. Nectary cylindrical, obtuse, thrice as long as the petals.—Found by Aublet, on the banks of waters in Guiana, flowering in April. The main trunk is three inches in diameter, and three or four feet high, sending forth long, round, twining branches, which climb the neighbouring trees. Leaves from four to six inches long, veiny, very smooth, entire, or slightly crenate towards the end, which Aublet's figure expresses too strongly. Footstalks stout, half an inch long, smooth.

Flower-stalks axillary, long, corymbose, rarely simple and solitary, each bearing, about the middle, two minute opposite bractæes. *Flowers* pale yellow, sweet-scented, not unlike some species of *Impatiens*, the *nectary* being full an inch long. Two lateral *petals* much larger than the others. The structure of the parts of *fructification* answer well to *Viola*, so far at least as we can examine them. The *calyx-leaves* are, in some degree, gibbous, or extended at their base, though Aublet notices it not.

59. *V. stipularis*. Trailing Fringed Violet. Swartz Prodr. 117. Ind. Occ. 1956. Willd. n. 31. (*V. perfoliata*; Poir. in Lam. n. 39.)—Stem creeping, round, simple. Leaves ovate, crenate, smooth; tapering at each end. *Stipulas* fringed, longer than the footstalks. *Flowers* solitary, without a spur. *Calyx* dilated at the base.—Gathered by Mr. Francis Masson, on a lofty mountain called mount Misery, in the island of St. Kit's. *Stem* rather shrubby, trailing probably to the extent of several feet, smooth, taking root, and sending up short leafy branches, not above an inch long, from each joint. *Leaves* with their *footstalks* an inch and half or two inches long. *Stipulas* near an inch in length, crowded, ovato-lanceolate, taper-pointed, membranous, deeply fringed with fine, long, capillary teeth. *Flower-stalks* few, axillary, slender, shorter than the leaves, each with two awl-shaped bractæes above the middle. *Calyx-leaves* awl-shaped, long and slender, gibbous or dilated at the base, and apparently longer than the small blue corolla. No spur is discernible. Poir. has taken an inadmissible liberty, in changing the original name of this species, in compliance with an error of Cavanilles; see the following.

60. *V. setosa*. Upright Fringed Violet. (*V. stipularis*; Cavan. Ic. v. 6. 21. t. 531. f. 2. Poir. in Lam. n. 38.)—Stem erect, round, much branched. Leaves ovate, acute, serrated, unequal at the base. *Stipulas* fringed, longer than the footstalks. *Flower-stalks* solitary, twice the length of the leaves.—Native of the neighbourhood of Talcahuano, in Chili. The stem is shrubby, a foot high; we presume it, from the plate, to be erect, though nothing is said by the author upon that subject, nor whether the leaves be smooth, the *calyx* dilated at the base, or the corolla furnished with a spur. By the figure, the two latter characters seem wanting, and the petals are drawn obovate, the lip being broader, and rather longer, than the rest. The *stipulas* are fringed with long prominent bristles, much like the preceding. Cavanilles did not perceive that the specific name he chose had been long pre-engaged.

We shall here introduce some new species of this author, which, according to the incomplete information afforded by his work, seem naturally to follow what have just been described; though some essential particulars are neglected, especially the structure of the *calyx-leaves* at their base. If the figures be faithful, these are not at all dilated beyond their insertion. The figure and description of *V. philippica*, t. 529. f. 2. are such, that we dare not adopt that species at all.

61. *V. rubella*. Little Red Violet. Cavan. Ic. v. 6. 20. t. 531. f. 1. Poir. in Lam. n. 37.—Stem erect, shrubby. Leaves ovate, acute, serrated. *Stipulas* shorter than the footstalks, with bristly serratures. *Flower-stalks* solitary, shorter than the leaves. Spur half as long as the petals.—Native of Chili, flowering in February. This appears to be smooth, and the stem round. Leaves thrice the size of the last, obtuse and equal at the base, on footstalks an inch long. *Stipulas* scarcely half so long. *Flowers* reddish, much like the last in size and shape, except the *nectary*, which is obtuse, projecting beyond the base of the *calyx*.

62. *V. maculata*. Dotted-leaved Violet. Cavan. Ic. v. 6. 20. t. 530. (*V. pyrrolzifolia*; Poir. in Lam. n. 32.)—Stem simple, erect. Leaves elliptical, crenate; acute at each end; dotted beneath. *Stipulas* pinnatifid. *Flower-stalks* longer than the leaves.—Native of the Falkland islands, flowering in December. This is certainly remarkable in its tribe for having yellow flowers. The dots on the leaves occur in some other species, even in *canina*, yet surely the name ought not to be arbitrarily changed. The stem is six inches high. Leaves an inch and half long; their stalks still longer. *Stipulas* hardly an inch in length, deeply and copiously pinnatifid. *Flower-stalks* axillary, rising much above the stem. *Flowers* drooping, the size of *V. odorata*, but yellow, their spur projecting beyond the base of the *calyx*, whose lanceolate taper-pointed leaves are represented a little gibbous at that side.

63. *V. adunca*. Hooked Violet.—Stems simple, ascending. Leaves ovate, somewhat heart-shaped, obtuse, crenate, downy, dotted. *Stipulas* loosely fringed. *Flower-stalks* longer than the leaves. Nectary hooked.—Brought by Mr. Menzies from the west coast of North America. This species has the size and habit of *V. canina*, and their *stipulas*, *flower-stalks*, and bractæes are similar. The *calyx-leaves* too are extended, in like manner, at the base. The whole of the herbage is minutely speckled, as in our last species, as well as in *canina*. But the plant is more or less downy, and clearly distinguished by the strongly recurved form of the spur, which if straight would be as long as the lip. The two lateral petals are downy at the base. Perhaps this species is more akin to *canina* than to any other, and ought to stand near it; at least if the *rubella* and *maculata* have no elongation at the base of their *calyx*.

64. *V. tricolor*. Pansy Violet, or Heart's-Ease. Linn. Sp. Pl. 1326. Willd. n. 24. Ait. n. 26. Fl. Brit. n. 6. Engl. Bot. t. 1287. Curt. Lond. fasc. 1. t. 65. Woodw. Suppl. t. 252. Fl. Dan. t. 623. Ger. Em. 854. Reinealm Spec. 144. t. 140. Rivin. Pentap. Irr. t. 122. Ehrh. Pl. Off. n. 278. (V. n. 568; Hall. Hist. v. 1. 244. Jacea, five Flos Trinitatis; Camer. Epit. 912.)

β . *V. arvensis*; Murray Prodr. Gotting. 73. Sibth. Oxon. 84. Sym. Syn. 61. (*V. bicolor*; Rivin. Pentap. Irr. t. 122. Ehrh. Pl. Off. n. 359. Pursh n. 22. V. n. 569; Hall. Hist. v. 1. 244. *V. tricolor* petræa; Ger. Em. 854. Jacea altera; Camer. Epit. 913. Corn Panfie; Petiv. Herb. Brit. t. 37. f. 9.)

Stem angular, diffuse, divided. Leaves oblong, deeply crenate. *Stipulas* lyrate, pinnatifid. Bractæes obsolete.—Native of cultivated ground throughout Europe, from Sweden to Greece, as well as in North America, flowering all summer long. Root annual. Stems more or less branched, especially from the bottom, angular, most hairy on one side, extremely variable in luxuriance, when simple nearly erect. Leaves stalked, usually ovate, deeply crenate; sometimes more oblong; and in the more starved plants of variety β merely undulated. *Stipulas* always deeply pinnatifid, with narrow tongue-shaped segments; the terminal one very large, ovate, crenate. *Flower-stalks* axillary, solitary, firm, longer than the leaves, bearing towards the top a pair of extremely minute, close-pressed, scarcely visible bractæes. *Calyx-leaves* greatly and unequally dilated at the base, lanceolate in front, acute, entire. *Petals* extremely variable in size and colour, from the large, splendid, velvet-like Pansy of the gardens, which if allowed to sow itself without attention, soon becomes scarcely different from the wild plant; to the small pale-yellowish variety β , whose ultimate state of degeneracy, among the scorie of mount *Ætna*, is the *V. ætica erecta bicolor hirta*

VIOLA.

futa minima, of Cupani's Hort. Cath. 130, sent us by Baron Bivona. In general, however, there are two tolerably dissimilar wild varieties, as above indicated; one with the *petals* longer than the *calyx*, the two uppermost purple; two lateral whitish, ribbed with purple, hairy at the base; *lip* yellow, inversely heart-shaped, streaked with purple, ending behind in a short *spur*; the other variety (β) has *petals* of a pale yellow, or cream-colour, hardly so long as the *calyx*, but little marked with blue. The hairiness of the *calyx*, like that of the herbage in general, is certainly variable.

65. *V. pilosa*. Blue Hairy Heart's-Ease. Donn Cant. ed. 3. 40. ed. 5. 52. (*V. hispida*; Lamarck Franc. v. 2. 679. *V. rothomagensis*; Poirlet in Lam. n. 45. "Decand. Franc. v. 4. 809." Desfont. Tabl. 178. Sims in Curt. Mag. t. 1498. Ait. Epit. 376.)—Stem angular, zigzag, hairy, diffuse, branched. Leaves ovate, crenate, fringed. Stipulas pinnatifid, somewhat lyrate. Bractæas lanceolate, toothed at the base.—Native of stony hills near Rouen, as well as in other parts of France, and on the downs near Dunkirk; perennial, flowering in the spring. This plant has long been universally known in our gardens, under the apt name of *V. pilosa*, given by the late Mr. Curtis, who gave us a specimen, so named, from his garden at Lambeth marsh, in May 1781. The date of its introduction is, therefore, anterior, even to what the late Mr. Donn has recorded, 1783. We had a specimen also of the same as his *V. pilosa*, from the Cambridge garden in 1803; and we regret that Dr. Sims has followed less classical authority and example, in the appellation he has retained, to the disparagement, though undesigned, of his old friends and our's. The plant in question is not very easily distinguishable, by a definition, from *tricolor*, though unquestionably a different species. The root is perennial. Herb much more hairy. Flowers bright blue, the side *petals* and *lip* striped with black. *Calyx* and *spur* much like *tricolor*. Bractæas nearer the top of the *flower-stalks*, and much larger, lanceolate, with two very evident teeth on each side at the base. This character seems material, though not yet mentioned. The reader of M. Poirlet's description may, at first sight, suppose it to have been found out by him, but a slight examination will discover that author to have written bractæas for *stipulas*.

66. *V. lutea*. Yellow Mountain Pansy. Hudf. ed. 1. 331. Fl. Brit. n. 7. Engl. Bot. t. 721. Ait. n. 27. Poirlet in Lam. n. 46. "Decand. Franc. v. 4. 809." Great Yellow Pansy; Petiv. Herb. Brit. t. 37. f. 10. (*V. grandiflora*; Hudf. ed. 2. 380. Lightf. 508. Ait. ed. 1. v. 3. 291; but not of Linnaeus. *V. bore luteo majore*; Rivin. Pentap. Irr. t. 121. *V. n.* 566 β ; Hall. Hist. v. 1. 243.)—Stem triangular, unbranched. Leaves ovate-oblong, crenate, fringed. Stipulas lobed, palmate. Bractæas minute, scarcely toothed. Spur the length of the *calyx*.—This plant is found in grassy mountainous pastures, flowering from May to September. It is frequent in such situations, from Sweden, if we mistake not, (see Linn. Lapland Tour, v. 1. 41.) to Britain, Switzerland, and France. A specimen before us, from the son of the great Haller, shews it to have been confounded, amongst other things, by that author, under his n. 566. The root is perennial. Stem weak and decumbent at the base, scarcely ever branched, three or four inches high, a little downy, especially at one side, leafy. Leaves stalked; the lowermost small, nearly orbicular. Stipulas large, deeply cut, their middle segments largest. Flowers one or two, on long solitary axillary stalks, rising high above the leafy top of the stem, larger than in the common *tricolor*, to which their

calyx is similar; but their *spur* is smaller, not extending beyond the posterior lobes of that part. *Petals* mostly yellow; the two lateral ones, and the *lip*, streaked with black, and all more or less downy at the base; two upper ones sometimes also streaked with black or purple, or partly spotted with the latter colour; not unfrequently they are purple all over; as in Engl. Bot. The *stigma* is club-shaped, hairy, hollow, with a purple line underneath. M. Poirlet has shewn great practical knowledge in his remarks under this species, adverting to *V. grandiflora*. We hope to remove his doubts in the next paragraph.

67. *V. grandiflora*. Great Mountain Pansy. Linn. Mant. 120. Willd. n. 25, excluding all the synonyms. (*V. altaica*; Pallas Herb. according to Dr. Sims. "Ker. Bot. Regist. 54." Sims in Curt. Mag. t. 1776.)—Stem angular, unbranched. Leaves ovate-oblong, crenate. Stipulas pinnatifid, somewhat lyrate. Bractæas minute, scarcely toothed. Spur twice the length of the hind lobes of the *calyx*.—Native of Siberia. Pallas is said to have gathered it on the Altay mountains. The Linnaean specimen seems of older date than the discoveries of this eminent traveller, but has no mark to indicate where it grew. This species is certainly more akin to the preceding than to the following, both which have been confounded with it. The habit and mode of growth agree with *V. lutea*, but every part is twice as large. The stem, weak and decumbent at the base, is about a span high, smooth, except a roughness on some of the angles, or at one of the sides. Leaves on longish stalks; the upper ones ovate, or ovate-lanceolate, a little hairy, not fringed; lower orbicular or heart-shaped, smooth. Stipulas very different from *V. lutea*, being oblong, pinnatifid in their lower half only, not palmate. Flower-stalks two or three on each plant, axillary, solitary, erect, five inches long, rising high above the stem. Bractæas an inch or more below the summit, opposite, membranous, lanceolate, extremely small, with a tooth on each side at the base. Flowers pale yellow, above twice the size of *V. lutea*, and of a rounder figure; their lateral *petals* hairy at the base, and marked, like the *lip*, with a few black lines. *Calyx* much dilated and toothed at its base, but not reaching half the length of the *spur*, which is cylindrical, rather slender, slightly curved, affording the most decisive distinction. The specimen represented in the Bot. Mag. seems to be the top of a plant, with rounder upper leaves than our wild specimens exhibit. The flower is unfortunately drawn so as not to shew the *calyx* or *spur*, but the description answers to our plant, except that the dried *petals* are not remarkably undulated. The Linnaean description is good, except that the stem is not branched. Some naked flower-stalks caused this error. The remark that this and *calcarata* are the offspring of *V. tricolor*, is perfectly unauthorized.

68. *V. calcarata*. Dwarf Mountain Pansy. Linn. Sp. Pl. 1325. Willd. n. 27. Ait. n. 28. (*V. n.* 566 α ; Hall. Hist. v. 1. 243. t. 17. f. 1. *V. alpina purpurea*, exiguis foliis; Bauh. Pin. 199. *Mclanium montanum*; Dalech. Hist. 1204.)

β . *V. n.* 566 β , n. 2; Hall. Hist. v. 1. 243. (*V. Palafii*; Forst. Tr. of Linn. Soc. v. 6. 311. *V. montana lutea*, subrotundo crenato folio; Barrel. Ic. t. 691, et *V. montana cerulea tricolor*, folio subrotundo crenato; *ibid.* t. 692.)—Stems quite simple, hardly so long as the foot-stalks. Leaves ovate, crenate. Stipulas three-cleft. Bractæas toothed at the base, somewhat haltate. Spur thrice as long as the hind lobes of the *calyx*.—Native of the mountains of Siberia, Austria, Switzerland, Savoy, and the south of France, flowering in July and August. Generally known in gardens by the name of *grandiflora*, at least

the variety β ; which is confounded by Linnæus in his synonyms with the true *grandiflora*; by Haller with *lutea*. M. Poiret justly observes, that a specific character of the variety β , when it was announced in Tr. of Linn. Soc. by the name of *V. Pallasi*, ought to have been given. That name, however, is now superfluous, for we are perfectly satisfied that no specific difference exists between the plant there intended and the original *calcarata*. The root is perennial, much branched under ground, and creeping extensively, each shoot crowned with a short leafy stem, much overtopped, not only by the generally solitary *flower-stalk*, but by its own crowded *leaves* or their stalks. The *leaves* are smaller, thicker, blunter, more glaucous, and more uniformly ovate, than in either of the two last, with a few, slight and rounded, notches. *Stipulas* usually longer than the *footstalks*, in three deep segments, scarcely more, the middle one obovate, varying in breadth. They are well represented by Barrelier. The herb is often smooth, occasionally more or less downy. *Flower-stalks* rising high above the leaves, two or three inches long, more or less. *Braçtes* above the middle, lanceolate, with several lateral teeth, as if palmate, or hastate. *Flower* generally light purple, with black lines at the bottom, larger than *V. lutea*, sometimes parti-coloured like that; in β almost the size of *grandiflora*, with more remarkable black lines, and either yellow, parti-coloured, or all over violet. The *calyx* in both varieties is elongated, dilated, and toothed, at the base. *Spur* long, slender, cylindrical, slightly curved. Haller's figure is characteristic, but shews no part with critical precision. We have endeavoured to be explicit on the subject of the three last species, as no plants have been less understood.

69. *V. Zoysii*. Dwarf Carinthian Pansy. Wulf. in Jacq. Coll. v. 4. 297. t. 11. f. 1. Willd. n. 26, excluding the synonym.—Stems quite simple, hardly so long as the *footstalks*. *Leaves* ovate, crenate, smooth. *Stipulas* elliptic-lanceolate, undivided, nearly entire. *Braçtes* toothed at the base. *Spur* thrice as long as the hind lobes of the *calyx*.—Native of the mountains of Carniola and Carinthia, communicated by Mr. Sieber. Wulfen received it from the Baron de Zoys, whom he commemorates in the name. His description and figure are complete, except that we cannot account for his citing, without scruple, t. 69 of Barrelier. M. Poiret makes *V. Zoysii* a variety of *calcarata*; but they are clearly distinguished by their *stipulas*, which in the present are always oval, never lobed, though in one or two instances we find a slight lateral notch. The plant moreover is smaller, more perfectly smooth, green, not at all glaucous. *Flower-stalks* two or three inches high, angular. *Braçtes* minute. *Petals* large, yellow, with black lines at the bottom; sometimes partly tinged with blue. *Spur* ascending, rather thicker than in *calcarata*, and not quite so long. Wulfen might well be puzzled with the determination of this plant, *grandiflora*, &c.

70. *V. cenifolia*. Violet of Mount Cenis. Linn. Sp. Pl. 1325. Willd. n. 16. Ait. n. 17. Allion. Pedem. v. 2. 98. t. 22. f. 6. Spec. 14. t. 3. f. 4. Poiret in Lamarck n. 26. (V. n. 565; Hall. Hist. v. 1. 242.)

β . Poiret *ibid.* (*V. valderia*; Allion. Pedem. v. 2. 98. t. 24. f. 3.)—Stems simple, procumbent. *Leaves* ovate, entire. *Stipulas* obovate, stalked, undivided, unequal. *Spur* thrice as long as the hind lobes of the *calyx*.—Native of the hill called Ronce, above the hospital on Mount Cenis, where we gathered specimens, with Dr. Bellardi, in August 1787. It also grows on the alps of Savoy and Switzerland. The roots are creeping. The whole plant bears a resemblance to *V. calcarata* and its allies, but has decumbent

stems, two or three inches long; fleshy entire *leaves*, either smooth, or rough with short reflexed hairs; and very different *stipulas*, on long stalks. *Flowers* nearly the usual size of *calcarata*, blue. *Braçtes* small, hardly toothed. *V. valderia* is surely a most trifling variety. The *leaves* are falsely described finuated; and the *stems* are not more erect than in the original *cenifolia*.

71. *V. arenaria*. Sand Violet. Poiret in Lam. n. 25. "Decand. Franc. v. 4. 806."—Stems simple, diffuse, somewhat downy. *Leaves* roundish-heartshaped, smoothish, slightly crenate. *Stipulas* lanceolate, toothed. *Calyx* acute.—Native of sandy places, in the Lower Valais. *Root* scaly at the crown, sending out two or three spreading *stems*, two or three inches long. *Flower-stalks* three or four times as long as the leaves. *Flowers* pale blue, or whitish, with a thick obtuse spur. *Braçtes* linear, acute, four or five lines long, about an inch below the flower. *Decandolle*. Poiret.

72. *V. minuta*. Minute Basil-leaved Violet. Marsch. à Bieberst. Fl. Taur.-Cauc. v. 1. 173. (*V. orientalis minima*, ocymi folio; Tourn. Cor. 30?)—Stems simple, flaccid, single-flowered. *Leaves* roundish, crenate, nearly smooth. *Stipulas* ovate, entire.—Native of the Georgian region of Mount Caucasus. *Root* apparently creeping. *Stems* as long as the finger-nail. *Leaves* only two or three lines in length and breadth, broadly but slightly crenate. *Footstalks* about as long. *Stipulas* rough with hairs at the edges. *Flower* the size and shape of *V. odorata*, with a spur the length of the *petals*. *Braçtes* remote, very minute. Akin perhaps to *V. cenifolia* and *alpina*. Marsch. à Bieberst. It may possibly be more related to the following, though the *stipulas* do not agree.

73. *V. nummularifolia*. Money-wort-leaved Violet. Allion. Pedem. v. 2. 98. t. 9. f. 4. Willd. n. 15. (*V. alpina minima*, nummularis folio; Bocc. Mus. 163. t. 127.)—Stems tufted, simple. *Leaves* orbicular-heartshaped, nearly entire, smooth. *Stipulas* lanceolate, membranous, three-cleft. *Spur* rounded, rather longer than the dilated base of the *calyx*.—Native of the rocks of Corsica, Dauphiny, and Piedmont. The long, slender, branching roots divide at the top into tufts of little, smooth, leafy stems, erect or decumbent, not branched. *Leaves* fleshy, a quarter of an inch in length and breadth, obtuse, occasionally crenate, on slender stalks about twice as long. *Stipulas* half or quarter the length of the *footstalks*, sessile, unconnected with them, pale, acute, with one or two taper teeth at each side. *Flowers* blue, rather smaller than *V. odorata*, not unlike that species in shape. Very distinct from *V. cenifolia*.

74. *V. alpina*. Alpine Radical Violet. Jacq. Obs. part 1. 21. t. 11. Fl. Austr. v. 3. 24. t. 242. Poiret in Lam. n. 15. (*V. montana fecunda*; Clus. Hist. v. 1. 309.)—Stem scarcely any. *Leaves* nearly radical, orbicular-heartshaped, slightly crenate, nearly smooth. *Stipulas* lanceolate, membranous, entire, united to the base of the long *footstalks*. *Spur* rounded, twice as long as the dilated base of the *calyx*.—Native of the summits of the loftiest mountains of Austria, flowering in July and August. Mr. Sieber, to whom we are obliged for wild specimens, exactly agreeing with some from Jacquin, justly observes, that botanists in general have unaccountably neglected this species. It is not to be found in Linnæus, Murray, nor Willdenow; yet none can be more distinct. It ought perhaps to stand in the first section, as having much less of a stem than some which are placed there; but its affinity to several we have just described is so great, that it more naturally ranges with the Pansy tribe, of which it has the large concave oblique stigma. The *stipulas*, being laterally united to the *footstalks*, like

VIOLA.

like those of a rose or bramble, though hitherto unnoticed, afford a most striking and clear character. The flowers are deep blue, striped or spotted with black, or dark violet, nearly the size of *V. calcarata*, but with a shorter spur, and much shorter flower-stalks.

75. *V. tenella*. Little Syrian Violet. Poir. in Lam. n. 53.—“Lower leaves opposite, roundish, minute; upper somewhat alternate, oblong, obtuse; all smooth and entire. Flower-stalks rather longer than the leaves.”—Native of Syria; preserved in the herbarium of professor Desfontaines. A very small plant, two inches high at the utmost. Roots simple, thread-shaped, whitish. Stems erect, very smooth, simple, slender. Leaves stalked. Flower small, on a solitary almost capillary stalk. Poir. Nothing is said of the stipules, bractææ, calyx, or spur, so that our knowledge of this species is very incomplete, and, for the remarkable circumstance of the partly opposite leaves, we should scarcely have ventured to admit it without examination of a specimen.

76. *V. tridentata*. Three-toothed Magellanic Violet.—Stems procumbent. Leaves crowded, wedge-shaped, with three terminal teeth. Flower-stalks much longer than the leaves. Calyx obtuse.—Gathered by Mr. Menzies, in February 1787, on the mountains of Staten Land, growing among the snow. This little species is so different in habit from all the rest, that we know not where to place it. The numerous stems, an inch or two in length, compose dense tufts, and are thickly covered with alternate, closely crowded, or imbricated, fleshy, shining, smooth leaves, a quarter of an inch long, more resembling a *Saxifraga* than a *Viola*, each ending in three broad blunt teeth, and sometimes notched aloft at the sides; the base tapers down into a short broad footstalk. We can discern no stipules, except the imbricated scales on the lower part of each branch may be called. Flowers small, drooping, on thick stalks an inch high, rising above the top of each stem. Calyx-leaves ovate, obtuse, thick, somewhat gibbous at the base. Spur scarcely any.

77. *V. gracilis*. Slender Mountain Violet. Sm. Prodr. Fl. Græc. Sibth. n. 511. Fl. Græc. t. 222, unpublished.—Stem branched, angular, diffuse. Leaves lanceolate, somewhat crenate; the upper ones crowded, opposite. Stipules deeply three-cleft. Spur much longer than the base of the calyx.—Gathered by Dr. Sibthorp, on the summit of the Bithynian Olympus. We have also specimens from mount Ætna, collected by Baron Bivona. The roots are perennial, creeping, long and very slender, much divided at the top. Stems slender, angular, hardly a span long; subdivided at the base; leafy in the upper part; simple, either quite smooth or very finely downy. Leaves on longish stalks, lanceolate or obovate, very rarely and obscurely crenate, smooth or a little downy, scarcely an inch long at the most; the lower ones alternate; upper opposite, and much crowded at the top of the stem. Stipules like the leaves, but about one third as large, in three deep, stalked, obovate, entire segments, the middle one rather the largest. Flower-stalks axillary, few, three or four inches long. Bractææ rather above the middle, small, lanceolate, membranous, toothed at the base in a bastate manner. Flowers about the size of *V. lutea*, but somewhat more oblong, of a dull purplish-blue, occasionally yellow. Calyx-leaves bluish; much elongated and toothed at the base. Spur slender, about the length of the petals. Capsule oblong.

This is allied to the Pansy tribe, and perhaps more akin to *V. canifera* than any other, but very distinct, and remarkable for the opposite leaves; a character occurring here and there in species otherwise little related to each other.

78. *V. cornuta*. Horned Violet. Linn. Sp. Pl. 1325. Willd. n. 28. Poir. in Lam. n. 48. Ait. n. 29. Curt. Mag. t. 791. (V. n. 570; Hall. Hist. v. 1. 244. V. pyrenaica, longidis caudata, teucuri folio; Tourn. Inft. 421.)—Stem ascending, angular, branched. Leaves heart-shaped, crenate. Stipules sessile, pinnatifid. Calyx-leaves awl-shaped, taper-pointed; elongated and abrupt at the base, much shorter than the spur.—Native of the Pyrenées, and of mount Atlas. Ray is reported to have found this species on the Jura; but Haller asserts there is no record of any person besides having met with it in Switzerland. Professor Ortega is said to have first introduced it at Kew in 1776. The plant is hardy and perennial, now frequent in gardens, flowering in May. The stems form large lax tufts, producing abundance of sky-blue, or pale purple, inodorous flowers, of the Pansy kind. Their lip has a small point. The spur is slender, ascending, near an inch long. Calyx-leaves remarkably long, slender, and acute. The whole herb is somewhat downy, of a greyish-green. Stipules broad, variable in size, usually about as long as the footstalks. Ray in his Hist. Plant. v. 3. 510, seems to indicate that some of the leaves, at least, are opposite. We have seen no instance of this.

The arrangement of the species of this ample and interesting genus might, doubtless, be greatly improved, provided any able botanist could compare the leading ones together, in a sufficiently perfect state. The flower being reversed in position, as in most European and American Violets; in other words, the lip being turned downwards, seems the natural posture, though many of Indian growth are supposed to have erect flowers. This character is not easy to ascertain in dried specimens, the only ones possible to be obtained of several of the most singular or curious kinds. We have, therefore, scarcely adverted to it. The intelligent reader will trace out the leading circumstances which have made us swerve, in part, from Willdenow's distribution, though we are conscious that much more remains to be done. In the admission of new species, we have passed over many American ones, mentioned by M. Poir. because they are probably superseded by the labours of Mr. Pursh. We could not, therefore, undertake, nor did it appear requisite, to settle their synonymy; especially as we have reason to think the American *Viola* are not yet all well known.

We regret that the elaborate treatise on this genus, which, for near thirty years, has been meditated by our accurate friend Mr. Forster, and which is, in fact, promised in the sixth volume of the Linnæan Society's Transactions, has never been accomplished. We are aware of the difficulty of the subject, and those who have studied it more deeply, are perhaps still more so; but we do not scruple to declare, that a full scientific botanical essay on *Viola*, might display as much skill and learning, and be made subservient to as much philosophical illustration of Botany, as any monographical subject that could be chosen.

VIOLA. See CHEIRANTHUS, LUNARIA, and TROX-OLUM.

VIOLA Aquatilis. See HOTTONIA.

VIOLA Mariana. See CAMPANULA.

VIOLA Matronalis. See HESPERIS.

VIOLA Palustris. See HOTTONIA and PINGVICULA.

VIOLA, in Gardening, contains plants of the herbaceous, fibrous-rooted, perennial kind, among which the species cultivated are, the sweet-scented March violet (*V. odorata*); the palmated violet (*V. palmata*); the multifid-leaved violet (*V. pedata*); and the pansy violet, or heart's-ease (*V. tricolor*).

The first sort is a low creeping flower plant, which is in general very highly esteemed for its fragrance. There are different varieties of it, as the single blue and white, the double blue and white, and the pale purple; it is also found with white flowers; and it has been seen wild with double flowers. This variety is in much esteem, both for the superior size of the flowers, and their extreme fragrantcy; and as they appear later, they keep up the succession.

The second sort is curious, and rare in this country, having no sweet scent to recommend it.

The last sort varies with more than two colours, as purple, blue, yellow, white, improved and enlarged by garden culture. There is the low growing, with small flowers; the larger upright, with large flowers; large Dutch, with largest flowers; variegated, yellow; purple and white flowered; yellow-flowered, with purple spots; purple, with yellow or white spots; white, with yellow and purple spots; entire yellow; deep and pale yellow; purple-flowered; scentless flowered; sweet-scented flowered.

Method of Culture.—The first sort may be increased by seeds, or parting the roots. The seeds may be sown in a bed of light earth, soon after they become ripe, in the beginning of autumn; and when they have some growth, be removed into a shady border, until the autumn, when they may be set out where they are to grow. The double-flowered sorts afford no seed. The best mode is, however, by parting the roots in the early autumn, or after they have flowered, and planting them out in the borders, or in beds at good distances; at the latter season watering them well. When intended for flowers, they should not be parted oftener than once in three or four years.

The second and third sorts succeed best by being planted in pots filled with loam and bog-earth well mixed, plunging them in the mould of a north border, where they should be protected in winter, or removed under a common hot-bed frame.

The fourth sort rises readily from scattered seeds, and may be raised by sowing the seed where the plants are to grow, in the autumn or spring.

They may likewise be increased by planting out the offset slips of the large bushy plants, taken off with root-fibres, in the autumn or spring, in the borders, or in beds for increasing their growth. The varieties may be preserved in this way with safety.

These plants afford much variety in the borders, and other parts; and the first sort is useful for the flowers. It is proper to be planted out on the verges of shrubberies and wood-walks, as well as in tufts and patches in the borders, clumps, and other parts of pleasure-grounds; but when cultivated for the purpose of its flowers, it is best planted out in rows in beds, or in the borders, at the distance of a foot.

VIOLA, in the *Materia Medica*. The common sweet violet, or *viola odorata* of Linnæus, is perennial, grows wild in hedges and shady places, and flowers in March. The flowers of the *V. hirta*, or hairy, scentless March violet, are often substituted for the other in our markets: but this sort may be easily distinguished; the herb, by its having stalks, which trail on the ground, and bear both leaves and flowers, and by the young leaves being hairy; the flower, by the three lower petals being spotted with white, and by their want of smell. The officinal violet is the *ἰω μάλισιν* of Theophrastus, and the *ἰω ποικίλιν* of Dioscorides; it was also well known to the Arabian physicians, as Mesue commends its use highly in various inflammatory diseases. *Viola* is likewise frequently mentioned by the Latin poets, who allude to its effects as a vulnerary. The recent flowers only

are now received in the catalogues of the *Materia Medica*: they have an agreeable sweet smell, and a mucilaginous bitterish taste; when chewed, they tinge the saliva blue; to water they readily give out both their virtue and their fine flavour, but scarcely impart any tincture to rectified spirit, though they impregnate the spirit with their flavour. These flowers, taken in the quantity of a drachm or two, are said to be gently purgative or laxative; and according to Bergius, and some others, they possess an anodyne and pectoral quality. The officinal preparation of these flowers is a syrup, which to young children answers the purpose of a purgative. This syrup is usually prepared from the petals of the cultivated violet; and Dr. Withering tells us, that at Stratford-upon-Avon, large quantities of the violet are cultivated for this purpose; but the London herb-shops are chiefly supplied from Kent. (See *SYRUPUS*.) This syrup is also found useful in many chemical inquiries, to detect an acid or an alkali; the former changing the blue colour to a red, the latter to a green. The seeds of violets are reported to be strongly diuretic, and useful in gravelly complaints. The root powdered, in the dose of a drachm, proves both emetic and cathartic.

That species of violet called pansy, or heart's-ease, the *viola tricolor* of Linnæus, grows in corn-fields, waste and uncultivated grounds, flowering all the summer months. By the vivid colouring of its flowers, it often becomes very beautiful in gardens, where it is distinguished by various names. To the taste, this plant, in its recent state, is very glutinous or mucilaginous, accompanied with the common herbaceous flavour and roughness. By distillation with water, according to Haæe, it affords a small quantity of odorous essential oil, of a somewhat acrid taste. The dried herb yields about half its weight of watery extract; the fresh plant about one-eighth. It was formerly reckoned a powerful medicine in epilepsy, asthma, ulcers, scabies, and cutaneous complaints; but its present character is owing to its having been recommended by Dr. Starck, a German physician, and others, as a specific in the crusta lactea of children. He directs a handful of the fresh, or half a drachm of the dried leaves, to be boiled two hours in half a pint of milk, which is to be strained for use. This dose is repeated morning and evening. Bread, with this decoction, is also to be formed into a poultice, and applied to the part. He observes, that when it has been administered eight days, the eruption usually increases considerably, and the patient's urine acquires a smell like that of cats. When the medicine has been taken a fortnight, the scurf begins to fall off in large scales, leaving the skin clean. The use of the remedy is to be persisted in, till the skin has resumed the natural appearance, and the urine ceases to have any particular smell. Lewis. Woodville.

VIOLA, FRANCISCO DELLA, in *Biography*, maestro di cappella to Alfonso d'Este, duke of Ferrara, a disciple of Adrian Willaert, the master of Zarlino, and one of the interlocutors in his "Ragionamento." He was the editor of a curious work by his master Willaert, published at Ferrara, 1558, under the title of "Musica Nova."

VIOLA, in *Geography*, a river of Spain, in Guipuscoa, which rises in the mountains of Adrian, and runs into the sea, at Cumaja.

VIOLA, in *Ichthyology*, a name by which some authors have called the smelt.

VIOLA Serotina, the late violet, in *Botany*, a name given by the ancients to a garden-flower, not properly of the violet kind, but to which we, as well as they, have connected the name violet, though with a distinctive epithet, we call it *viola matronalis*, or *dame's violet*.

Pliny is very express in this distinction, but is not sufficiently attended to in it; and by this means is misunderstood in some other parts of his works, where he alludes to this flower in his description of the colour called by the Romans *eonchylis*, or *conchylaceus color*; he says that the deepest degree of it was that of the flower of the *viola ferotina*. The commentators on his work have generally explained this into his saying, that the deepest colour of this name was a blue purple, like that of the violet; but he only means that it is of a deeper red than the colour of the mallow flower, and with a proportionate mixture of purple, as there is in that flower.

VIOLARIS LAPIS, in *Natural History*, a fossil body, called by the Germans *violstein*, and by many authors *lapis odore violarum*, from its having a sweet smell when fresh broken, which has been supposed to resemble that of the violet.

The Germans have many stones which have more or less of a sweet smell when fresh broken, as they have many which stink very strangely; the latter of these they call all by the common name of *foveine-stone*, and the former, all by that of *violet-stone*. The substance, however, which possesses this quality in the highest degree of all others, and is, therefore, most proper to be called distinctly by this name, is a species of talc, of the genus of the bractearia, called by Dr. Hill *bractearium niveum lucidissimum bracteis undulatis*, or the snow-white shining bractearium, with undulated scales. This is found in masses of an extremely rude and irregular structure, but very compact and firm, usually of a roundish or oblong figure: these are of various sizes, from an inch or two, to a foot in diameter, and are composed of almost an infinite number of thin, extremely beautiful, and snow-white plates, which are all broad, thin, and flaky, and of various sizes, and perfectly irregular in shape and figure, and are naturally waved, bent, and curled: its smell, when broken, is not like that of any of the known perfumes, but is a sort of mixed one, resembling that of roses and violets together: it is very heavy, and will neither give fire with steel, nor ferment with acid menstruums. It is common on the shores of rivers in Italy, and in the mountains of Germany. Hill's *Hist. of Fossils*.

VIOLATION, the act of *violating*, i. e. forcing a woman, or committing a rape upon her.

Amnon, David's son, violated his sister, who was avenged by Abalom: Tereus violated his sister-in-law Philomela. To violate the queen, the king's eldest daughter, or the princess of Wales, is high-treason.

VIOLATION is also used, in a moral sense, for a breach or infringement of a law, ordinance, or the like.

Thus, we say a violation of the law of nature, of the law of nations, of a treaty of peace, of one's oath, &c.

VIOLATION is also used for a profanation. In which sense we say, to violate a church, &c.

VIOLENT, in the *Schools*, a thing done by force. In which sense it stands opposed to spontaneous.

A thing is said to be violent, when affected by some external principle; the body that undergoes it contributing nothing thereto, but struggling against it.

The body, in such case, is said to struggle, because whatever is violent, discomposes and distracts a thing from its natural constitution, and tends to destroy it.

The schoolmen all allow, that man, as being endued with reason, is capable of suffering such violence; but brute and inanimate bodies are not: *in brutum*, &c. *violentum non cadit*.

VIOLENT Motion. See **MOTION**.

VIOLENT Purging, or *Cling*, a disease in sheep of the

more inveterate bowel kind, which not unfrequently attacks them in some situations.

It is said not to be peculiar to any soil, but appears most frequently, and spreads most rapidly, where the pasture is of a soft grassy nature. It is constantly produced by improper management, such as working among the flocks inconsiderately in hot sultry weather, and in crowded folds. It is thought by some to break out most frequently in milking time, where that practice is carried on, when the sheep lie, for six or seven weeks in the later warm summer months, upon the same spot for some time, during the morning and evening at the *bought* or milking-place. Indeed, when sheep, from whatever cause, lie upon the same spot until the ground turns foul, if the weather be soft, sultry, and warm, with thunder, or showers of that kind, this disease is much to be apprehended, and is often very spreading and fatal.

The appearances of the disease are, that the sheep affected with it acquires a sickly look, the ears of it drop and hang low down, the eyes are languid, and the wool claps to the body of it. It continues for some time to follow the flock, but mostly stands in the same position, looking to the ground. It often lies down, but soon rises up again, and walks to a short distance, during which it commonly voids feces. The skin is hot, dry, and scaly, and the pulse and respiration quick. It eats very little, and does not chew the cud, but seems to have an unquenchable thirst. There is frequent rumbling heard in the bowels, followed by the discharge of feces, which are thinner than ordinary, having little or no resemblance to the hard purl of healthy sheep. As the disease advances, the purging increases, the discharge becomes thinner, is first mixed with blood, then slime and blood, and at last is black and fetid, accompanied clearly with severe gripes and straining. After a wet summer, the discharge is sometimes green, the grass seeming to pass with little change of colour. In the mean time, the sheep rapidly wastes away, and in a few days is reduced to a perfect skeleton, with its belly drawn up to its back; it separates from the flock, wanders about in an unsteady manner, and hides itself among fern, heath, or bushes, when they are present. Its eyes are suffused with red, its breathing becomes more laborious, an unpleasant smell exhales from every part of its body, its feces are absolutely putrid, it is quite overcome by the disease, and it continues straining and purging until it expires.

It is said, in the third volume of the *Transactions of the Highland Society of Scotland*, to be distinguished from the ordinary diarrhoeas and loosenesses in these animals, by their chiefly attacking hogs, weak-gimmers and dimonts, while this disease is frequent among older sheep; by their mostly occurring in the spring and ceasing in the summer, when this disease only commences; by their having no fever, straining, or pain before passing the stools, as is the case in this disease; by the feces in them being loose, but natural in other respects, and without blood or slime, while in this disease they consist of hard lumps occasionally passed, the rest being blood and slime; by there not being that degree of fetor in the feces in them, that takes place in this disease; by the appetite being rather sharper than usual in them, while in this disease it is wholly gone; by there being nothing infectious in them, while this disease is often greatly so; by there being only a temporary stop put to the thriving of the sheep, which afterwards becomes rapidly strong and vigorous in them, while in this disease the animal wastes suddenly; and by their having little danger in them for the most part, except where there is much debility, while this disease is very commonly fatal.

According to some, if a sheep survives this disease for a

fort-

fortnight, or even for a few days, it mostly recovers. In this case, there is either very little or no blood in the feces, the slime dries up, and becomes mixed with hardened balls, the feverish heat abates, the skin gets moist, the vigour of the eye returns, the appetite increases, and the wool rises slowly, and assumes its natural appearance, though a great part of it frequently comes off. However, it grows again, and sheep which have had this disease commonly become very healthy and sound, being seldom attacked by any other disease. In some cases there is the feverish appearances without any flux at all, which is a less fatal and of course more favourable state of the disease.

Notwithstanding the disease is always originally produced by improper management, it is often greatly infectious, and spreads rapidly among the same flocks and to different ones. It is a very dangerous sort of disorder, which on soft soils destroys the greater number of sheep attacked with it, but which on dry hard land is less fatal and less infectious.

In preventing the disease, which is more certain and beneficial than any thing that can be done in the cure of it when it is formed, the principal circumstances to be regarded are, the dispersing the sheep as equally as possible over the land; the preventing their collecting together in clumps and fouling the land; the having the situations for the *boughs* in milking time, high, dry and airy, shifting them often, and dividing the sheep equally among them, to prevent their being too much thronged and heated; the changing those situations frequently, where they lie, before they become foul; the removing the diseased sheep immediately as they become affected to some considerable distance; the using of tar to the noses and tails of the sheep, as well as in tubs where they are confined; and the salving of many of the sheep, and putting them in clean pastures, to lie at their ease. The disease however sometimes continues, in spite of these means, until the frost sets in, when it disappears slowly with much loss.

The cure of the disease is to be attempted, when the sheep are strong and in good condition, by cutting the tails across, and afterwards causing them to perspire in some way or other freely, not letting them be suddenly exposed to cold after it. At the same time the bowels are to be cleared by the use of a little rhubarb, as about half a drachm, or, what is better, by about four grains of ipecacuanha in powder, given until they purge freely. A quantity of thin flour-porridge well boiled, and barley or oatmeal, may then be given with a pint of sweet milk two or three times a day. If the disease be not soon removed by these means, remedies of the powerful astringent kind must be had recourse to, with opium in small quantities, such as a decoction of logwood, bark, Japan earth, and chalk made with milk, and given in the proportion of a gril two or three times a day. Fifteen or twenty drops of the tincture of opium may be put in each dose of the decoction. And it is often very useful when taken alone in a very little cold water.

VIOLET, in *Botany, Gardening*, and the *Materia Medica*. See **VIOLA**.

VIOLET, *Bulbous*, a name sometimes given to the snow-drop, a plant which Linnæus makes a distinct genus under the name *galanthus*; but which Tournefort comprehends among the *narcisso-leucocimus*.

VIOLET, *Calathian*. See **GENTIANA PNEUMONANTH**.

VIOLET, *Corn*, a name sometimes applied to the *Campanula hybrida*.

VIOLET, *Damask*. See **HESPERIS**.

VIOLET, *Dame's*, *Rocket*, or *Queen's Gilliflower*. See **HESPERIS**.

This plant is an antiscorbatic and diaphoretic, and is very serviceable in the asthma, coughs, and convulsions. The outward use of it is recommended in inflammations, cancers, gangrenes, sphacelus, and contagious diseases. Bruised, it very potently resists putrefaction; and applied to pestilential buboes in the arm-pits, it ripens and softens them. James from Boerhaave.

VIOLET, *Dog's-tooth*, the name by which some call the *dens canis* of botanical writers. See **ERYTHRONIUM**.

VIOLET, *Water*. See **HOTTONIA**.

VIOLIN, an instrument of four strings, tuned fifths, and played by a bow. It has a neck like the treble viol, but the finger-board has no frets. This may be pronounced the most powerful, the most perfect, and the most useful instrument that has ever been invented. It is in the power of the performer on this sovereign of the orchestra, to make the intonation of all keys equally perfect. We have not been able to trace its antiquity higher than the 16th century. In the beginning of the 17th century it was hardly known to the English in shape or name; and, therefore, that superior power of expressing almost all that a human voice can produce, except the articulation of words, seemed at this time so utterly impossible, that it was not thought a gentleman's instrument, or one that should be admitted into good company. Viols of various sizes, with six strings, and fretted like the guitar, began indeed to be admitted into chamber-concerts: for when the performance was public, these instruments were too feeble for the obtuse organs of our Gothic ancestors; and the low state of our regal music in the time of Henry VIII. 1530, may be gathered from the accounts given in Hall's and Hollinghead's Chronicles, of a masque at cardinal Wolsey's palace, Whitehall, where the king was entertained with "a concert of drums and fifes." But this was soft music compared with that of his heroic daughter Elizabeth, who, according to Henxner, used to be regaled during dinner "with twelve trumpets and two kettle-drums; which, together with fifes, cornets, and fide-drums, made the hall ring for half an hour together." Itinerarium, edit. 1757, Strawberry-Hill.

It has long been a dispute among the learned, whether the violin, or any instrument of that kind, as now played with a bow, was known to the ancients. The little figure of Apollo, playing on a kind of violin, with something like a bow, in the grand duke's tribuna at Florence, which Mr. Addison and others supposed to be antique, has been proved to be modern by the abbé Winckelmann and Mr. Mings. So that as this was the only piece of sculpture reputed ancient, in which any thing like a bow could be found, nothing more remains to be discussed relative to that point. With respect to an instrument with a double neck, besides that on the broken obelisk at Rome, and one from a sepulchral grotto in the ancient city of Tarquinia, there is an antique painting in the collection of William Locke, esq. which consists of a single figure, supposed to be a muse, with an instrument nearly in the form of a modern violin, but the neck is much longer, and neither bow nor plectrum are discoverable near it. This, as Dr. Burney apprehends, may have been a chelys, which was a species of guitar, either thrummed by the fingers, or twanged with a quill. The ancients had, indeed, instead of a bow, the plectrum; but in all the representations which painting and sculpture have preserved of this implement, it appears too clumsy to produce from the strings tones that had either the sweetness or brilliancy of such as are drawn from them by means of the bow or quill. Dr. Burney supposes, though it is represented so massive, that it was a quill, or piece of ivory in imitation of one, rather than a rick or blunt piece of wood

VIOLIN.

or ivory; and, indeed, Virgil tells us, *Æn.* vi. 647, that it was made of ivory. Burney's *Hist. Mus.* vol. i.

The origin of the violin, according to the French account, is unknown. It is only supposed to have been invented about the ninth or tenth century, to which opinion we should have subscribed, had not some ancient monuments remained with an exact representation of its form. In the pictures of Philostratus, p. 85, in an ancient grotto, may be seen many violins which are represented much like those of the present times, except that the neck is shorter.

Amphion is there represented, p. 76, playing upon a kind of viol or violin with five strings, and with a bow like our's, and quite different from the plectrum of the ancients. It is believed that Athenæus means the bow, when he says, "the sceptre is one thing and the plectrum another." It is imagined that by the sceptre he means the bow, which is very probable, especially after the ancient monuments of which we have preserved the figure. The pit or grotto, on the walls of which we see violins like the present, is found on silver medals which were struck by order of Scribonius Libo, a very considerable personage at Rome. An account of these may be seen in Pierre Valerien, author of the *Hieroglyphics*, book 47.

This is all that antiquity has preserved concerning the violin, and, says the author, it is so little, that we learn nothing from it.

The rebec is the most ancient violin in France; it had but three strings, and the romancers and troubadours frequently mention it. A figure of the mirlitré Colin Mufet, is still preserved at the entrance of the church of St. Julien des Menestriers, at Paris, playing on the rebec.

The time is not known when a fourth string was added to this instrument. It is still used in its primitive state as a trichord in Turkey and other Eastern countries; the oldest violins we have in France are not more ancient than the time of Charles IX. made at Cremona by the famous Amati, which are still of the best model possible. Laborde, tom. i.

The violin seems to have been brought into favour at the court of France before any honourable mention is made of it elsewhere, by the arrival of Baltazarini, a great performer on that instrument; who, at the head of a band of violin-players, was sent from Piedmont by marshal Brissac to Catharine de Medicis, and appointed by that princess her first valet de chambre and superintendent of her music. Gallei (*Dial.* p. 147.) says, that "both the violin and base, or violoncello, were invented by the Italians, perhaps by the Neapolitans;" and we are unable to confute that opinion. Corelli's violin, long in the possession of Giardini, was made in 1578, and the case painted by Annibal Caracci, probably several years after the violin was finished, at which time Anib. Caracci was but eight years old. Montagne, who was at Verona in 1580, says that there were organs and violins to accompany the masques in the great church. *Journ. du Voyage.*

The restoration of monarchy and episcopacy seems to have been not only favourable to sacred music, but secular; for it may be ascribed to the particular pleasure which king Charles II. received from the gay and sprightly sound of the violin, that this instrument was introduced at court, and the houses of the nobility and gentry for any other purpose than country-dances, and festive mirth. Hitherto there seem to have been no public concerts; and in the music of the chamber, in the performance of *fancies* on instruments, which had taken place of vocal madrigals and motets, the violin had no admission, the whole business having been done by viols.

VOL. XXXVII.

After Charles had, in imitation of Lewis XIV., established a band of twenty-four violins, tenors, and basses, instead of the viols, lutes, and cornets, of which the court band used to consist, the violin family began to rise in reputation, and had an honourable place assigned it in the music of the court, the theatres, and the chamber; and the successions of performers and compositions with which the nation was afterwards supplied from Italy and elsewhere, stimulated the practice and established the character of that class of instruments, which have ever since been universally acknowledged to be the pillars of a well-ordered orchestra. A general passion for this instrument, and for pieces expressly composed for it, as well as a taste for Italian music, seem to have been excited in this country about the latter end of Charles II.'s reign, when French music and French politics became equally odious to a great part of the nation. The Hon. Mr. North, brother of the lord keeper North, who listened critically to every kind of music, and left manuscript memoirs of the music of his time, still in the possession of his family, says, that the decay of French music, and favour of the Italian, came on by degrees. Its beginning was accidental, and occasioned by the arrival of Nicola Matteis.

During the last century, almost all the great violinists of Europe, except Sonis and Tartini, have visited this country; but Giardini, at one time perhaps the best performer in Europe, residing here for many years, formed a school which furnished our orchestras with a greater number of able performers on that instrument, than can be found in the capital of any other kingdom in Europe. And we may venture to assert from our own knowledge, that the lowest ripieno in the opera orchestra at present, has more hand, and is a better sight's-man, than the leader of that band in Felling's time.

The violin consists, like most other instruments, of three parts; the *neck*, the *table*, and the *soundboard*.

At the side are two apertures, and sometimes a third towards the top, shaped like a heart.

Its bridge, which is below the apertures, bears up the strings, which are fastened to the two extremes of the instrument; at one of them by a screw, which stretches or loosens them at pleasure.

The style and sound of the violin are the gayest and most sprightly of all other instruments; and hence it is, of all instruments, the fittest for dancing. Yet there are ways of touching it, which render it grave, soft, languishing, and fit for church or chamber music.

It generally makes the treble, or highest parts in concerts. Its harmony is from 5th to 5th. Its play is composed of base, counter-tenor, tenor, and treble; to which may be added a fifth part: each part has four 5ths, which rise to a greater 17th.

In compositions of music, violin is expressed by V: two V V denote two violins.

The word violin, alone, stands for treble violin: when the Italians prefix *alto*, *tenore*, or *basso*, it then expresses the counter-tenor, tenor, or base violin.

In compositions where there are two, three, or more different violins, they make use of *primo*, *secondo*, *terzo*, or of the characters I^o II^o III^o, or i^o 2^o 3^o, &c. to denote the difference.

The violin has only four strings, each of a different thickness, the smallest of which makes the *e si mi* of the highest octave of the organ; the second, a fifth below the first, makes the *a mi la*; the third, a fifth below the second, is *d la re*; lastly, the fourth, a fifth below the third, is *g e re sol*.

Most nations, ordinarily, use the clef *g e re sol* on the second line, to denote the music for the violin; only, in France,

G g

France,

France, they use the same clef as the first line at bottom: the first of these methods is best, where the song goes very low; the second where it goes very high.

Merfennus speaks of the tenor and contra-tenor violin, which, he says, differ only in magnitude from the treble violin. But we have at present no such instrument in use as the contra-tenor violin; the part proper to it being with ease performed on the violin; and accordingly in concertos, overtures, and other instrumental compositions of many parts, the second violin is in reality the counter-tenor part. It is

much to be doubted, says sir John Hawkins (Hist. Mus. vol. iv. p. 115.) whether the counter-tenor violin ever came into England. Anth. Wood, speaking of the band of Charles II., makes no mention of the contra-tenor violin. Before the restoration of Charles II. says he, and especially after, viols begun to be out of fashion, and only violins used, as treble violin, tenor and base violin; and the king, according to the French mode, would have twenty-four violins playing before him while he was at meals, as being more airy and brisk than viols.

Natural Scale for the Violin.

VIOLINO PICCOLO, Ital. a kit, or the pocket-violin of dancing-masters.

VIOLINO SCORDATO, Ital., a fiddle out of tune.

VIOLONCELLO, the diminutive of *violone*, *contrabasso*, or double-bass. The violoncello is the natural base to the violin and tenor, and has been very much cultivated throughout Europe, and no where more successfully than in England, during the last century, in proportion as the base-viol or six-stringed base lost its favour. The last English performer on the viol di gamba, who was favourably noticed, was Miss Ford, afterwards Mrs. Thicknes; but she made little more use of it than in accompanying her voice, which she did with great expression and effect. But Abel, in spite of the natural defects of the instrument, the tone of which every one disliked, by his exquisite taste, prodigious execution when he pleased, genius, and profound knowledge of composition, delighted all hearers, and made them forget, or at least forgive, its querulous and nasal quality of tone. The instrument now is as dead as this great musician, and seems to have departed this life at the same time.

The first performer on the violoncello in our memory, who was always heard with pleasure, was Caporale, whose chief excellence was his fine tone. Gordon and Paxton had considerable merit of that kind. The elder Cervetto and Paqualino, both defective in tone, had what was then thought considerable execution and knowledge of the finger-board; but Crofdil and the younger Cervetto became in all respects the most complete and delightful performers on the violoncello, which not only England but all Europe can boast. So equally perfect in all things else are these admirable artists, that the fire of the one, and the vocal tone of the other, can alone distinguish them. But, to the great regret of the public, they have retired from all professional exercise of their talents. We have however many performers on the violoncello for general business, who would have been thought wonderful players formerly; and to console us a little for the loss of Cervetto and Crofdil, a Linley, who in every requisite of a great player, may be pronounced wonderful at present (1804).

Diatonic Scale of the Violoncello, without Shifts.

VIOLONE, a double-bass, almost twice as big as the common base-violin, and the strings bigger and longer, in proportion; and, consequently, its sound an octave lower than that of our base-violin; which has a noble effect in great concertos; but this depends upon the number of strings, and the manner of tuning them; some performers using four strings, and others three; and in the tuning of these there is a considerable difference. The true use of the violone is to sustain the harmony, and in this respect it has a noble effect: divided basses are improper for it, the strings not answering immediately to the percussion of the bow: these can only be executed with a good effect on the violoncello, the sounds of which are more articulate and distinct.

VIOLONISTA, Ital., a performer on the violin.

UJON, in *Geography*, a town of Persia, in the province of Chusikan; 35 miles N.N.W. of Eitachar.

VIOTTI, —, in *Biography*, a good composer and great performer on the violin. He is a native of Turin, and said to be the son of the prince de Carignan's gardener, and intended by his father to be brought up to his own profession, discouraging as much as possible his passion for music, which he early discovered; and even complaining to the prince that he should never make a gardener of him, as he was always scraping upon a bad fiddle. The prince advised his father to send him to Pagnani, and if he discovered in him the seeds of genius and promising talents, he would prevail on him to take the boy as a scholar or an apprentice.

Pagnani immediately discovered, that with proper cultivation, he would soon distinguish himself among professors of the first class; an opinion which a few years confirmed.

In 1783 he went to Paris, and first performed at the concert spirituel, was extremely applauded, and increased in favour

favour till the time of the Revolution, when the Convention invited foreigners to assist them with their counsel in framing a new government, and elected as deputies many strangers; among the rest, Viotti was chosen a member of the senate, who had mounted to great eminence in his profession, and was a favourite of the public.

He continued to act as a deputy till Danton, Marat, and Roberfpierre had disgraced the cause of liberty, and excited such horror as well as terror in every humane breast, that he emigrated to England, where he was received as his professional merit deserved; till an information was lodged against him at the duke of Portland's office (perhaps by jacobinical emissaries from Paris), that he attended by jacobinical clubs, and was caballing against the state. He was ordered to quit the kingdom; but at the peace returned, though not as a musician or a politician, but established himself in London as a wine-merchant, and has never been heard in public since his second arrival, which is much lamented by the lovers of music. Yet, though he is no longer a public performer, we may, perhaps without impropriety, give our sentiments concerning his abilities as a composer; and confess, that it has often struck us, in the midst of our sincere admiration of Viotti's great abilities, that his style of composition was a *mescolanza dell' antica e moderna*; writing sometimes with all the solidity of the great Italian masters of the old school, and sometimes with the levity and frivolity of the French in modern times. He may perhaps have done this insensibly, in trying to please in a style which was the most certain of applause. We have sometimes, in his grave and elaborate movements, thought he resembled Geminiani more than any other old master, with more rhythm and pathos, and indeed with more decided and meditated plans and subjects; but in his latter movements and finales, he generally degenerates into French *naïveté*, or rather *niaiserie*, which makes us forget that Viotti is a native of Italy, and a disciple of Pugnani, whom he greatly surpasses, when he does his best, both in hand and genius.

He has been a considerable publisher of pieces for his instrument, which, though every one cannot play, yet all admire, when played.

In 1786, he published at Paris, Berlin, and Amsterdam, twelve violin concertos, in nine and twelve parts; and the next year six violin quartets. Most of his pieces have been adapted to the piano-forte by other masters. The last work which he published at Paris, was six duets for violins.

VJOP, or DJOP, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana, according to Pliny and Ptolemy. Hardouin says that it is now named Sus; a river of which name is known on the confines of the kingdom of Morocco.

VIORNA, in *Botany*, an old synonym of our common Traveller's Joy, *Clematis Vitalba*, and evidently of a similar meaning, being derived from *via*, a road, and *orno*, to adorn. Gerarde, who thus explains the word, declares himself the author of the English name. *Viorna* is transferred by Linnæus to another species of *Clematis*, with which it had originally no connexion. See CLEMATIS.

VIPACH, in *Geography*. See WIPACH.

VIPALANKA, or UJ PALANKA, a fortress of Hungary, in the banat of Temesvar, on a small river which runs into the Danube; 50 miles S. of Temesvar. N. lat. 45°. E. long. 21°.

VIPAO, a river of Carniola, which runs into the Lisonzo, in the county of Goritz.

VIPATORE, a town of Hindoostan, in Baramaul; 28 miles E. of Darampourey.

VIPER, VIPERA, in *Natural History*, the *coluber berus* of

Linnæus, famed not only for the exceeding venomousness of its bite, which is one of the most dangerous poisons in the animal kingdom, but also for the great usefulness of its flesh in medicine; whence vipers come to make a considerable article in the materia medica.

We have described the common viper, as well as some other species, under the article COLUBER, and have detailed some of the most interesting particulars relating to this animal. Under the article POISON, we have considered the nature of its venom, and some of the usual remedies applied as antidotes to its pernicious and usually fatal effects. We shall not here repeat the observations that may be found under those articles.

The method of catching vipers is by putting a cleft-stick on or near their head, after which they are seized by the tail, and put into a bag.

Dr. Mead observes, that the ancients esteemed the viper sacred; and that the kings of the East Indies caused cottages to be built for their entertainment, and their killers to be punished with death. On medals, the viper is frequently represented as a symbol of divine power; and, as such, given by way of attribute to the ancient physicians.

The story of the rattle-snake's charming its prey has been seriously discredited or ridiculed by many, and by others the effects of the animal's fear have been supposed the result of a previous bite; but we have reason to be less incredulous, if we advert to an experiment mentioned in the Philosophical Transactions, of a like thing in regard to a viper. It is well known that no viper will feed while in confinement, except a female which is with young, but that such a one will. A viper-catcher, who had more than sixty living vipers in a chest, put a living mouse in among them; there happened to be one female big with young among these, none of the others at all regarded the mouse, but she raised up her head a little, and looked furiously at it. The mouse was terrified, and stood still for a considerable time, though the viper continued rolled up in a spiral, only raising up its head and looking at it, and vibrating its tongue; the mouse at length recovered from its fright, and began to move, but without running away, only walking in a terrified manner round and round the viper, and often squeaking; at length she came before the head of the creature, which was still raised, and the mouth open. The mouse, after some time, went up to the creature, and crept into its mouth, where she was gradually swallowed without the viper's altering its posture.

By Mr. Boyle's experiments made upon vipers *in vacuo*, it appeared, that on the withdrawing of the air from the vessel where the viper was put, she began to swell, and after some time, she opened her mouth very wide, and frequently; but on continuing two hours and a half in the receiver, she did not appear to be quite dead. The gaping of the jaws was attended with a loss of the swelling, observed at first in her whole body; but after every time closing them she swelled again, and thus became lank and plump reciprocally many times in an hour. During the first moments this creature crawled about, as if in search of air, and afterwards foamed at the mouth.

The neck and body continued swelled longer in a second experiment with another viper, and a blister appeared on the back. This creature lived an hour and a half. The mouth remained vastly distended after death, and the internal parts of it were much distorted, and thrust forwards. After the admission of the air the mouth closed, and opened again after a time; and, in fine, on pinching the tail there was some motion perceived in the body that seemed to argue life. The common snake bears the exhausted receiver

better than the viper, and, after many hours remaining in it, and seeming dead, will give signs of life on being warmed by bringing the glass to the fire; but a longer continuance in the rarefied air absolutely kills it, as it does all other creatures. Phil. Transf. No. 62.

As to the manner in which the viper conveys its poison, authors are a little disagreed. Francisco Redi, and Moïse Charras, have each of them written very curious pieces on the subject; but their result is very different.

Redi maintains, that all the venom of the viper is contained in the two vesiculae, or bags, which cover the base of the two canine teeth; whence, upon biting, a yellowish liquor is squeezed out into the wound; where, mixing with the blood, and other juices, it produces those dreadful symptoms. This hypothesis he maintains by a great number of experiments; as of animals, *viz.* cocks, &c. being bit with vipers, after these vesiculæ and their juice had been taken out, without any signs of poison, or any ill consequence at all.

Charras, on the other hand, maintains, that this yellow liquor is not poisonous; that he has given it to pigeons as food, without their being at all disordered by it; that the viper's bite he has always found mortal to animals, even after the bag has been taken clear out, as well as before; and lastly, that the poison must lie in the irritated spirits of the viper, which it exhales in the ardor of its biting, and which are so cold, that they curdle the blood, and stop the circulation.

The controversy between these two ingenious authors is very extraordinary; their systems are opposite, yet both are maintained by a great number of well-attested experiments.

Dr. Mead supposes the sentiment of Sig. Redi to be the true one, in his essay on the poison of the viper, and adds to Redi's account, that the poison in the viper's bag is separated from the blood by a conglomerate gland, lying in the lateral interior part of the os scapicis, behind the orbit of the eye; from which gland there is a duct that conveys the poison to the bags at the teeth. The teeth, he adds, are tubulated, for the conveyance and emission of the poison into the wound; but their hollowness does not reach to the apex, or tip of the tooth, but ends in a long slit below the point, out of which slit the poison is emitted.

These slits, or perforations of the teeth, Galen tells us, the mountebanks of his days used to stop with some kind of paste; after which they would publicly expose themselves to be bitten without danger.

The abbé Fontana, in a treatise on the poison of the viper, first published in Italian, in 1765, and, in 1776, translated into French by M. Darcet, who has made several additions to it, has given the result of no less than six thousand experiments, in which upwards of four thousand animals were bitten, and most of them killed by the vipers.

The viper, he says, has sometimes four, seldom three, but generally two canine teeth in each jaw, falcated and inserted and fixed in a socket; at their bases, and behind them, are six or seven smaller teeth, adhering by a membrane, which, it is thought, are intended to supply the place of the larger teeth, sometimes lost in the act of biting. A similar conjecture, with respect to the use of the same kind of teeth in the rattle-snake, was made by Dr. Bartram. Phil. Transf. No. 456. p. 358; or Abr. vol. ix. p. 60.

Each of these has two cavities; one tubular, beginning near the base, and proceeding along the convex side nearly

to the end, and open at each end; the aperture near the base being almost elliptical, and the other longitudinal; the other cavity, situated behind the former, and never before observed, is broad at the base, and diminishes as it approaches towards the point. It has only one aperture at the insertion in the gum, through which the nerves and blood-vessels of the tooth are admitted. The fibrous sheath, that covers all these teeth, seems to be a continuation of the external membrane of the palate, being always open near the points of the teeth. The receptacle of the venom is a small bladder, a spongy gland, situated under the muscles of the side of the upper jaw, and seldom containing more than three or four drops of a yellow fluid, which is conveyed thence by an excretory duct to the socket of the canine teeth, whence it enters the lower aperture of the tube, and finds its way out again at the longitudinal orifice, near the point, into the internal part of the wound occasioned by the bite: this fluid receives its impulse from a constrictor muscle, which, however, never propels at once the whole of the contents of the gland. For an account of the effects of the viper's bite, we refer to COLUBER, BERUS, and POISON. See also WOUNDS.

The cure of the venomous bites of vipers seems very unsettled: Mr. Boyle found a hot iron held near the place very successful; but it proved otherwise with M. Charras. Again, the snake-root from the East Indies, immediately applied to the place, is much commended; but signor Redi and M. Charras found it of no use; yet Baglivi and Dr. Havers give instances of its good success.

Dr. Mead adds, that the snake-stone, directly applied to a pigeon when bitten, saved its life four hours; whereas most of the other pigeons bitten died in half an hour.

This stone is not natural, but factitious; its virtue lies in its porosity, which is supposed to imbibe the virus.

The viper-catchers, Dr. Mead adds, have a specific, in which they can so far confide as not to be afraid of being bitten.

That specific is, the axungia of the viper presently rubbed into the wound; which, consisting of clammy, viscid, penetrating and active parts, sheathes the salts of the virus.

The same author applying it to the nostrils of a dog bitten, found the creature well the next day: when this is not timely applied, and the virus has insinuated into the blood, the sal viper is excellent, given and repeated till sweats be produced. This succeeded well with M. Charras; and Dr. Mead relates, that it recovered one after the virus had induced an universal icterus.

The bite of the viper having been supposed certainly curable by oil of olives, vulgarly called salad-oil, alone; and a viper-catcher in England having suffered himself to be bitten by one of these creatures, and having recovered, after many dangerous symptoms, and the cure being attributed to the oil alone, though other medicines were given him internally; in consequence of which, Dr. Vater tried the same remedy with success at Dresden: Messrs. Geoffroy and Hunauld, of the Royal Academy of Sciences at Paris, made a number of experiments, in which this oil proved ineffectual; and added to their accounts, some other persons bitten, in which all the dreadful consequences of that poison are shewn, and the remedies by which they were cured are mentioned. Philof. Transf. N^o 443, 444, 445; or Abr. vol. ix. p. 60.

Two instances are mentioned, in which the symptoms of the bite appeared much in the same manner with those of the man who suffered himself to be bitten in England, in order to be cured by the oil. The sleep came on in all the same circumstances, and they were all cured, as well he who

VIPER.

who used no unctuous application at all, as he who used the fat of the vipers, or the Englishman who depended upon oil. The internal medicines given to them all were of much the same kind; and all that can be concluded from the whole is, that either these bites would not have proved mortal in themselves, or that the cordial medicines which they took internally, were the remedies that prevented the mischief that would have ensued; and these seem to have acted not as specifics against the bite of this animal, but merely as medicines that would stop the spreading of a gangrene; the unprevented increase of which is the thing that proves fatal from the creature's bite.

The dissections of the animals which had died by the bite of the viper, whether they had or had not been rubbed with oil, afforded all the same appearances. The limb which had received the wound was in all swelled and livid, and these symptoms were usually carried along the thigh to the belly, and sometimes up to the breast. Incisions made along these parts always discovered the cellules of the membrana adiposa full of bloody-coloured water, and the membrane itself was swelled, blackish, and gangrened. And this appeared always more plainly in the belly than in any other part: the membrana adiposa in all other parts of the body was in its natural state. The injured parts often had a cadaverous smell; the muscles of the wounded limb were also found of a brownish colour, and their fibres had lost their consistence, and seemed ready to give way to the approaching gangrene. Nor is this effect confined to the external parts alone: a goose that had been bitten had three gangrenous spots on its heart, and all the indications of a beginning gangrene in other parts of it; the concave side of the liver was also gangrened, and had wholly lost its consistence; and the lungs of a fowl, that had been bitten on the wing, were found in part gangrened. The effects, however, were different in degree, from the bite of the several vipers; and there seems no reason to doubt, but that the bites of different animals, though of the same species, under different circumstances, either in regard to the creature wounding, or the creature wounded, may be followed with very different consequences; so that remedies are not to be depended on from their success in one or two trials. Mem. Acad. Scienc. Par. 1737.

The poison of the viper is only noxious when immediately conveyed into the blood. Nor is it mortal to eat the flesh of creatures killed by vipers, or to drink the wine in which they have been drowned, or to suck the parts they have wounded. On the contrary, signor Redi says, sucking the wound is a sovereign remedy against the bite of vipers. This author denies what has been affirmed by Aristotle and Galen, that the spittle of a falling person kills vipers. Phil. Trans. N^o 9. p. 160.

The practice of sucking out poisons is very ancient, and indeed nothing can be more rational. Where the bite cannot be cut out, this is the most likely way for extracting the poison. There can be no danger in performing this office, as the poison does no harm, unless it is taken into the body by a wound. The person who sucks the wound ought, however, to wash his mouth frequently with salad-oil, which will secure him from the least inconvenience.

The Pfylli in Africa, and the Merfi in Italy, were famed for curing the bites of poisonous animals, by sucking the wound; and we are told that the Indians in North America practise the same at this day.

When the wound is well sucked, it should be afterwards rubbed with warm salad-oil. A poultice of bread and milk, softened with salad-oil, should likewise be applied

to it, and the patient should drink freely of vinegar-why, or water-gruel with vinegar in it, to make him sweat. Vinegar is, indeed, one of the best medicines which can be used in any kind of poison, and ought to be taken very liberally: If the patient be sick, he may take a vomit. This course, says Dr. Buchan, will be sufficient to cure the bite of any of the poisonous animals of this country.

Dr. Brookes says, that the following remedy, which was the invention of a negro, who for the discovery obtained his freedom and a pension for life of 100*l. per annum*, from the general assembly of Carolina, has been found effectual for the bite of the rattle-snake. The prescription is as follows: Take of the roots of plantain and horhound in summer, roots and branches together, a sufficient quantity; bruise them in a mortar, and squeeze out the juice, of which give, as soon as possible, one large spoonful; if the patient be swelled, force it down his throat. This generally will cure: but if he finds no relief an hour after, give him another spoonful, which is said never to fail. If the roots are dried, they must be moistened with a little water. To the wound may be applied a leaf of good tobacco moistened with rum.

Messrs. Jussieu and Le Sage strongly recommend the use of the volatile fluor alkali as an antidote against the venom of vipers; but if the proofs alleged by the abbé Fontana, that the poison of vipers is not of an acid nature, be admitted, the utility of the alkali must be precluded. The abbé adds, that cantharides, applied outwardly, always did mischief by increasing the inflammation; when given inwardly, they operated as an emetic, which is sometimes beneficial. Scarifications produced the same effects with the external application of cantharides: Peruvian bark, theriaca, oils, the suction of leeches, and of the mouth, were all found ineffectual. He also explodes, in this case, the boasted virtue of the Piedra de Cobras, as an alexipharmic. Quicklime also, when applied to the wound in pigeons, has sometimes been of use, but not so as to justify any confidence in the remedy.

Upon the whole this writer infers, that the greatest security we have against the bite of vipers in one species, is the little probability of its being poisonous to the degree that has been always imagined, and that has caused such dreadful alarms, which alone are sufficient to irritate a tainted habit. He also doubts whether the bite of the rattle-snake is actually so venomous as is generally imagined. See Fontana for les Poisons et sur le Corps Animal, &c. in 2 vols. 4to. Florence.

Vipers make a considerable article in medicine. Most authors agree, that there is no part, humour, or excrement, not even the gall itself of a viper, but may be swallowed without harm. Accordingly the ancients, and, as several authors assure us, the Indians, as well as many other people at this day, both of the East and West, eat them as we do eels.

Caro viperina, viper's flesh, either roasted or boiled, the physicians have unanimously prescribed as an excellent restorative; and it has been particularly recommended in the elephantiasis, incurable consumptions, leprosy, &c.: and Dr. Mead thinks they might be less sparing in the quantity than they are: instead of a little viper's flesh, he recommends the broth or jelly of vipers; or, as the ancients did, to boil and eat them as fish, or at least to drink vinum viperinum, *i. e.* wine in which they have been long infused.

Viper's flesh, indeed, appears to be very nutritious, and therefore an useful restorative in some kinds of weakness and emaciated habits; but in scrophulous, leprous, and other like distempers, the good effects which have been ascribed

ascribed to it are more uncertain. Dr. Lewis says, that he has known a viper taken every day for above a month, in disorders of the leprosy kind, without any apparent benefit.

The form in which they are used to the best advantage, is that of broth, or jus viperinum.

Viper's flesh used to be an ingredient in several of our best antidotes, as the theriaca Andromach. &c.

The apothecaries also formerly sold the pulvis viperinus, which is only dried vipers pulverized, heart, liver, and all, and passed through a sieve. This, to heighten the price, we suppose, they call *animal bezoard*.

The salts of vipers, whether volatile or fixed, also their fat, or axungia, and their oil, chemically drawn, are drugs that have been in considerable repute.

The fat of the viper is accounted particularly useful in disorders of the eyes; but what advantages it has above other soft fats, is by no means clear. It was formerly supposed to have some specific power of resisting the poison of the viper's bite, by being rubbed immediately on the wounded part; but experience has now shewn, that common oil is, in this intention, of equal efficacy. Lewis. See COLUBER *Berus*.

VIPER, *Bites and Stings of*, in *Animals*, the affections which it produces in these ways. The bites of such reptiles should constantly be guarded against as much as possible, as they are not infrequently attended with dangerous consequences. Animals of the neat-cattle kind are more liable to be bitten and stung by these reptiles, than those of any other sort of live-stock. Instances have been known where the tongues of such cattle have even been bitten or stung while grazing or feeding, which have proved fatal. Such stock are, however, seldom attacked by reptiles of the adder kind, except in cases where these are disturbed by the animals in pasturing or feeding; which is the main reason why so many of them are bitten or stung about the head, and occasionally the feet. There are mostly such pain, inflammation, and swelling produced by these bites and stings; the progress of which may commonly be checked or stopped, and the complaint removed, by the use of such means as are directed below.

A sort of soft liquid of the liniment kind may be prepared by mixing strong spirit of hartshorn, saponaceous liniment, spirit of turpentine, and tincture of opium, with olive-oil; the former in the proportion of about two ounces each to three of the last, incorporating them well together by shaking them in a phial, which will be found very useful in many cases. A proper quantity of it should be well rubbed upon the affected part, two or three times in the course of the day, until the inflammation and swelling begin to disappear, after the bottle has been well shaken.

In the more dangerous cases, it may often be advantageous to use fomentations to the affected parts, especially when about the head, with the above application; such as those made by boiling white poppy-heads with the roots of the marshmallow, the leaves of the large plantain, and the tops of wormwood, in the quantities of a few ounces of the first, and a handful of each of the latter, when cut small, and bruised in five or six quarts of the stale grounds of malt liquor. They may be applied frequently to the diseased parts, rubbing them afterwards each time well with the above soft liquid liniment. Where there are feverish appearances, as is often the case in the summer season, a proper quantity of blood may sometimes be taken away with great benefit, and a strong purge be afterwards given of the cooling kind with much use.

In slight cases of this kind, some think the continued free use of spirit of hartshorn, given internally, and applied ex-

ternally to the affected parts, is the best remedy of any that is yet known.

As they are so dangerous, these reptiles should always be destroyed as much as possible in all pastures and grazing grounds.

VIPER *Wine*, *Vinum Viperinum*, is a preparation of vipers infused in wine. It is commonly made by macerating for a week, with a gentle heat, two ounces of the dried flesh in three pints of mountain. This has been deemed a great restorative, and provocative to venery, and also good against cutaneous eruptions, &c.

But Dr. Lewis observes, that it cannot perhaps be affirmed from fair experience, that this wine has any great virtue.

VIPER's *Buglossi*, in *Botany*. See ECHIUM.

The flowers of the viper's bugloss are supposed to possess the virtue of cordials, in the same degree with the borage and bugloss. Some authors greatly recommend a decoction of the dried plant in epilepsies. It is said that very singular cures have been done by it.

VIPER's *Grafts*. See SCORZONERA.

The roots of the common viper's grafts, or *scorzonera Hispanica* of Linnæus, have been employed indifferently as alexipharmics, and in hypochondriacal disorders and obstructions of the viscera; but at present are more properly considered as alimentary articles, in general salubrious, and moderately nutritious. They abound with a milky juice, of a soft, sweetish taste, but which, in drying, contracts a slight bitterness. Extracts made from them by water are considerably sweet and mucilaginous: extracts made by rectified spirit have a less degree of sweetness, accompanied with a slight grateful warmth.

In Cartheuser's experiments, the spirituous extract amounted to one-third the weight of the root, and the watery to above one-half. Lewis.

VIPER *Key*, in *Geography*, one of the Tortugas islands.

VIPERA *Pileata*, or *Vittata*, in *Zoology*, a name by which some authors have called a remarkable species of Indian serpent, more usually known by the name of *Cobra de capella*.

VIPERARIA, in *Botany*, a name given by some authors to the *scorzonera*, or viper's grafts.

VIPITANUM, in *Ancient Geography*, a town of Germany, between Veldidana and Sublavio, thought to be the present Stortzingen, or rather Amoluz, a village at the foot of mount Brenner.

VIPPACH, in *Geography*, a town of Germany, in the territory of Erfurt; 8 miles N. of Erfurt.—Also, a river of Thuringia, which runs into the Gram; 3 miles S. of Sommerda.

VIPPACH, *Mark*, a town of Germany, in the principality of Eisenach; 7 miles N.E. of Erfurt.

VIPULZAN, a town of Austria, in the county of Goritz; 6 miles W. of Goritz.

VIQUE, or VICQ, a town of Spain, in Catalonia; the see of a bishop, suffragan of Tarragona; 22 miles W.S.W. of Gerona. N. lat. 41° 54'. E. long. 2° 8'.

VIR, in *Ancient Geography*, a river of Spain, the mouth of which, according to Ptolemy, is near the promontory on which was the altars of the sun.

VIRABADRA, in *Hindoo Mythology*, a warlike character, usually spoken of as a son of Siva, the *avenging* form of the trimurti, or divine triad of that polytheistic race. (See SIVA and TRIMURTI.) Sometimes he is said to be an incarnation of Siva. He is usually represented four-armed; holding a sword, shield, bow, and arrow; and in a threatening pursuing posture, accompanied by Sivean attributes;

attributes; such as collar of skulls, lingua, &c. (See LINGA and SAIVA.) A human figure with a ram's head, and a handsome female figure, are commonly seen beside him, in the act of adoration. Some account of Virabadra; with representations of him from metallic casts, may be seen in the Hindoo Pantheon.

Virabadra is a personage of extensive and ancient celebrity. His exploits, parentage, &c. are recorded in the Sivpurana, and his name frequently occurs in other Sanscrit works. (See PURANA.) In the sacred poem just named, it is said that he was produced from a drop of Siva's sweat. He is understood, as one of the offspring of Siva, to be included in the denomination of Bhairava; a word derived from *bheru*, meaning terrific or tremendous. It is written, and we believe more correctly pronounced, Vairava; which name is given to another supposed son or incarnation of Siva. See VAIRAVA.

Sonnerat mentions Virabadra as a Carnatic deity; calling him, in his inaccurate mode of writing Eastern names, Virapatin. He calls him Siva's fourth son, produced with a thousand heads and a thousand arms, by the sweat of his body, to avert the effects of a sacrifice. He is sometimes called also Bhir Bhadr.

The other three sons of Siva, mentioned by Sonnerat, are, we suppose, *Kartika*, *Pollear*, and *Vairava*. See those articles.

VIRACELLUM, in *Ancient Geography*, a town of Italy, in Liguria, S.E. of Apua.

VIRAGO, a woman of extraordinary stature and courage, and who, with the female sex, has the mien and air of a man, and performs the actions and exercises of men.

The word is pure Latin, formed from *vir*, man, and is seldom used but in the way of diversion.

Such were Semiramis and Penthesilea among the ancients; and Jeanne la Pucelle, commonly called *The Maid of Orleans*, among the moderns.

In the Vulgate version of the bible, Eve is called *virago*, because made of the rib of man. The Latin translator by this, aimed to preserve the etymology as it is in the Hebrew, and of *vir*, formed *virago*; as Adam, in the Hebrew text, called *Eve* *Ischa*, and *ischa*, man.

VIRAGUE, in *Geography*, a town of Hindoostan, in Dowlatabad; 25 miles E. of Perinda.

VIRAJ, in *Hindoo Mythology*, a very mysterious personification, originating immediately from the godhead, in a manner not reconcilable to minds which have happily shaken off the trammels of idolatry and superstition. In the early portion of the Institutes of Menu (ch. i. v. 32.) it is said, "Having divided his own substance, the mighty power became half male, half female (or, says the commentator, *nature adive and passive*); and from that female he produced Viraj." Menu next tells us that he himself was the person produced by the male power Viraj, and that he produced her lords of created beings eminent in holiness. These are usually called Brahmadikas, or offspring of Brahma; but the Puranas do not agree as to their number: sometimes nine, seven, and three only are mentioned. Considerable difficulty is found in the attempt to reconcile the apparent contradictions in the histories of these early personages; who, it may be reasonably imagined, have had historical existence, though so much obscured by the fictions of mythology.

All travellers who have visited the cavern temple, called by the English Elephanta, have been struck with a colossal one-breasted figure; and various have been the conjectures as to its allusion. The author of the Hindoo Pantheon, who has examined the temple in question, reasonably judges

it to be a representation of Viraj, or nature active and passive; and he gives several representations of similar subjects from original pictures. (See SIVA.) In our article ELEPHANTA we have noticed the supposition of some travellers, that the one-breasted armed female alluded to the fable of the Amazons. It is now found that the Hindoos also have fables of islands inhabited only by warlike women, who are called, in the Persian translations of these stories, Hamazen; which word means, in that language, *all-women*. (See on this curious subject, Moor on Hindoo Infanticide, p. 82.) The whole ground-work of the Amazonian fable may, therefore, have come from India to the embellishing Greeks, as well as the notion of male and female deities; all originating possibly in the mysterious sexual union, the subject of this article.

In the Hindoo mythology, the co-equality of the male and female power is asserted. There is less sexual confusion among the Hindoo than among the Greek deities. Among the latter, the sex of several is very dubious; while others were both male and female. Authority can be produced among western mythologists, making both Minerva and Venus male as well as female. These goddesses correspond with the Parvati and Lakshmi of the Hindoos: the former of whom is seen in the biune figure Viraj; and the latter in her character of Sukra, or the planet Venus, is of the male sex. Soma, the moon of India, is also male, as he was among the Germans and Saxons. The Parthians said that Venus was the moon, and a male deity; as, according to Macrobius, did some western mythologists. See SOMA.

There are fables connected with the history of Krishna, in which he and his mistress, to conceal the shame of the amorous deity from his enraged consort, were variously metamorphosed. On one occasion, as related in a Purana, "when detected dallying in a grove of sandal with Viraja, the figure of a quadruped concealed his shame; and she was changed into a river." This fable is noticed in our article RADHA. We know not if the nymph of the sandal grove have any connection with the subject of this article.

VIRAMSHAMPETTA, in *Geography*, a town of Hindoostan, in the Carnatic; 9 miles S.W. of Terriore.

VIRANDJIK, a town of Asiatic Turkey, in Natolia; 16 miles W. of Kiutaja.

VIRANSHEHR, a town of Asiatic Turkey, in Natolia; 42 miles E.N.E. of Boli.

VIRATARUPA, in *Mythology*, a name of the Hindoo god Vishnu; and given also to his warlike incarnation in the person of Rama. See RAMA and VISINU.

VIRBIUS MONS, in *Ancient Geography*, part of a mountain, now called "Mont Albano." The name Vir-bius (from *vir*, man, and *bis*, twice) is said to have been given to this mountain in honour of Hippolytus, who, having been put to death by a monster, had been restored to life by Diana. From the Appian way another was detached, which led to a temple of Diana on this mount. This mountain was on the Appian way, from which diverged two other ways, one of which led to the temple of Jupiter Latialis, on mount Albano, and the other to the temple of Diana, at the bottom of the centre of the lake of Armenia.

VIRE, in *Geography*, a river of France, which rises near Calvados, and runs into the English Channel, to the north of Igigny, between the departments of the Channel and the Calvados.—Also, a town of France, and principal place of a district, in the department of the Calvados; 27 miles S.W. of Caen. N. lat. 48° 51'. W. long. 48'.

VIRE, or *Malraça*, a cape of Arabia, on the coast of the Indian sea; 16 miles N.N.E. of Hafek.

VIREA, in *Botany*, Adanson Fam. des Plantes, v. 2.

112, a name which seems to allude to the more green, and less hoary, herbage of the plants to which it is applied, compared with many of the same tribe; like *Vireo*, the Latin name of the Green-finch. See APARGIA, under the article THRINCIA.

VIRECTA, a word derived from *vireo*, to be verdant, alluding to the verdure of the plant, which however is not peculiarly striking, except in the dried specimens; whose colour, being better preserved than in some of the same natural order, might perhaps suggest to Linnæus the idea of the name. *Virectum* occurs in some copies of Virgil, for a green retreat; but *virectum* is generally supposed the true reading.—Linn. Suppl. 17. Schreb. Gen. 125. Willd. Sp. Pl. v. 1. 972. Mart. Mill. Dict. v. 4. Juss. 200. Poir. in Lamarck Dict. v. 8. 676. (Sipanea; Aubl. Guian. 147. t. 56. Juss. 201, under *Muffenda*. Lamarck Illustr. t. 151.)—Clas and order, *Pentandria Monogynia*. Nat. Ord. *Stellata*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. Cal. Perianth superior, of five narrow-awhaped, erect, equal, permanent leaves, with as many solitary, glandular or bristly, intermediate teeth. Cor. of one petal, funnel-shaped; tube thrice as long as the calyx, erect, even; slender below; dilated in the upper half; limb horizontally spreading, in five ovate, or lanceolate, entire, equal segments, not half so long as the tube. Stam. Filaments five, various in length, inserted into the middle of the tube; anthers terminal, very long, linear-awhaped, converging, either contained within the tube, or prominent. Pist. Germen inferior, globose, crowned with an elevated rim within the calyx; style thread-shaped, smooth, the length of the tube; stigma in two short, acute, divaricated segments. Peric. Capsule globose with five furrows, hispid, crowned with the upright calyx, of two cells and two valves; the partitions transverse, from the centre of each valve. Recept. central, globose, meeting the partitions. Seeds numerous, small, angular, dotted with minute depressions.

Ess. Ch. Corolla funnel-shaped. Stamens inserted into the tube. Calyx of five leaves, with intermediate teeth. Stigma deeply divided. Capsule inferior, of two cells and two valves, with contrary partitions. Seeds numerous.

Obs. Though Linnæus described this genus with great care and minuteness, he erred in attributing to it a capsule of only one cell. Hence M. Poir. justly doubted the propriety of referring hither the *Sipanea* of Aublet, which has two cells, and if compared with the above description will be found to answer in every material point. The only difference indeed is, that *Sipanea* has five bristles between the calyx-leaves, instead of the minute glands of the original *Virectæ*. A circumstance which confirms, rather than invalidates, that part of the generic character.

1. *V. biflora*. Twin-flowered *Virectæ*. Linn. Suppl. 134. Syst. Veg. ed. 14. 197. Willd. n. 1. (*V. virens*; Vahl Symb. v. 2. 38. *Rondeletia biflora*; Rottb. Surin. 7. t. 2. f. 2.)—Stem creeping. Flower-stalks unequal, terminal, in pairs. Corolla smooth. Stamens within the tube. Leaves ovate, twice as long as their footstalks.—Native of Surinam, in rather moist situations, where it was gathered by Dalberg and Rolander. The root is fibrous, annual. Stems a foot or more in length, decumbent, throwing out roots from their lower joints, ascending at the extremity, square, a little hairy, leafy, forked. Leaves stalked, opposite, near an inch long, smooth, or nearly so, resembling some *Parietaria*, or *Urtica*. Stipulas small, triangular, opposite, connecting the bases of the footstalks. Flower-stalks from the forks of the stem, some of them terminal, each bearing two reddish flowers, about an inch

long, white in the centre; the lowest of them nearly sessile. Germen bristly. Calyx and Corolla quite smooth.

2. *V. procumbens*. Procumbent *Virectæ*.—Stem procumbent. Flowers terminal, aggregate. Corolla bristly. Stamens prominent. Leaves ovate, thrice as long as their footstalks.—Discovered at Sierra Leone, by Mr. Afzelius, to whom we are obliged for a specimen, and for the determination of the genus. This is about the size of the preceding, but is more procumbent, and rather more hairy, especially the stem and footstalks. Leaves similar, but somewhat smaller, and more tapering from their broad base into the footstalk. Flowers in some measure capitate, at the end of the stem or branches, not numerous, smaller than the first species; their corolla with narrow, almost linear, segments, and clothed externally with shining, bristly hairs. Filaments as long as the limb of the corolla, with short purplish anthers.

3. *V. pratensis*. Savanna *Virectæ*. Vahl Eclog. fasc. 2. 11. Schrad. Journ. v. 2. 333. (Sipanea *pratensis*; Aubl. Guian. 148. t. 56.)—Stem erect. Flowers terminal, aggregate. Corolla smooth. Stamens within the tube. Leaves ovate-lanceolate, stalked.—Abundant in the meadows round the town of Caienne, where it is almost always to be found in flower and seed. Aublet says this herb serves to make astringent decoctions, useful for washing wounds and ulcers, as well as in the gonorrhœa. The root is fibrous; whether annual or otherwise we are not informed. Stems two feet or more in height, roundish, with many opposite branches. Leaves about an inch and a half long, acute, rather tapering at the base, a little hairy, especially their ribs beneath. Footstalks rather short. Stipulas membranous, abrupt. Flowers five, six, or seven, together, in little terminal tufts, white or rose-coloured, about the size of the first species. The corolla appears to be smooth; its segments broad, rounded or obovate. The short filaments, inserted into the middle of the tube, with their anthers of the same length, are altogether concealed therein, and do not reach near so high as the mouth. Calyx fringed with bristles, and furnished with small solitary hairs between its segments; but these do not appear quite so long in Aublet's own specimen as in his figure. The capsule resembles *V. biflora*.

4. *V. multiflora*. Many-flowered *Virectæ*.—Stem erect. Flowers terminal, aggregate, numerous. Corolla bristly. Stamens and style longer than the limb. Leaves ovate-lanceolate, nearly sessile.—Found by Mr. Afzelius at Sierra Leone. Very like the last in size and habit, but the stem is rather more quadrangular, and purplish. Leaves an inch and a half or two inches long, deflexed, rounded at the base, hairy, on short stalks. Stipulas lanceolate, hairy. Flowers many together, almost sessile, in dense, hairy, terminal heads. Calyx densely fringed with long bristly hairs, such as clothe the outside of the corolla. The segments of the latter are very narrow, almost linear. The filaments extend beyond them, and are quite capillary, smooth, with shortish terminal anthers. The style is slender, still longer than the filaments, with a small divided stigma. We have not seen the fruit.

VIRELAY, the name of a song among the Provençal poets, which succeeded the *chants royaux*, or royal songs, so called either because Thibaut, comte de Champagne, and king of Navarre, was author of so great a number, or to give them the dignity of poems the most worthy to be sung at court. For different from the Vaudevilles which pass from mouth to mouth, they were produced for the most delicate ears, and performed by the most able musicians of those times. From the chant royal, and from the balade, came the lay and virelay, the rondeau, the triolet, and

and all those little poems, of which the refrain, or burden, is the most agreeable part.

VIRET, PETER, in *Biography*, a famous Calvinistic divine, was born in 1511, at Orbe, in the canton of Berne, and during his studies at Paris formed an acquaintance with Farel, with whom he co-operated in propagating the doctrines of the Reformation in several towns of Switzerland, and particularly at Geneva, whither he accompanied Farel in 1534. At Lausanne he exercised his ministry with great satisfaction, so that he declined the offer of being colleague with Calvin at Geneva. He is said, in one of his visits to Geneva, to have escaped death by poison, administered to him by the infliction of some of the popish canons of that church, which, though it did not prove instantly fatal, injured his constitution, which was delicate, and shortened his life. From Lausanne he removed to Nîmes and Montpellier, and at length settled at Lyons. But in 1633 he was obliged to quit his station, in consequence of the edict of Charles IX., which prohibited his subjects of the reformed religion from having ministers that were not born in the kingdom. He then retired to Orange, and from thence, by the invitation of the queen of Navarre, to Berne. In 1569 he was in prison, and exchanged for the governor of a town. His death happened, probably at Pau, in 1571, at the age of 60.

Viret possessed a considerable share of learning, and was an eloquent preacher. His works were numerous; of these, several upon the doctrines and superstition of the Romish church were written in a style of ludicrous sarcasm, but others were serious. His work "On True and False Religion," published at Geneva in 1560, displays much reading on the subject of superstition: but his largest work is "An Exposition of the Doctrine of the Christian Faith," which Dupin depreciates, as he does his small tracts of controversy. Bayle. Dupin.

VIRGA. See YARD.

VIRGA is particularly used in law for *verge*, or rod, such as sheriff's and bailiffs carry, as a badge of their office.

"Ranf. ap Howell, præpositus de Lantiffin americiatus pro eo quod habuit in manu sua eorum iudicialis hic virgam nigram & inhonestam, ubi habere debuisset virgam album et honestum certæ longitudinis, prout decet." In fess. Itin. de Cardiff. 7 Hen. VI.

VIRGA Aurea, in *Botany*. See SOLIDAGO.

VIRGA Pistoris, a name given by some authors to *dipsacus*; which see.

Where the name *virga pistoris* occurs in the translation of the Arabian writers, it is not to be supposed to mean the plant we call *virga patoris*.

It is, indeed, the literal translation of the hassalerheir of Serapion and Avicenna; but they called the common horsetail by this name, when they applied the adjective female to it; and when they added the male, they meant by it the common knot-grass.

VIRGA Sanguinea, a name given by Matthioli, and some other authors, to the cornus fœmina, or dogberry-bush, common in our hedges. See CORNUS.

VIRGÆ Lateralis Minimus, in *Anatomy*, a name given by some writers to a muscle, called by others levator ani parvus, and by some transversus ani. It is called by Albinus the transversus perinæ, and by some transversus penis.

VIRGÆ, in *Physiology*, a meteor, called also *columnæ*, and *funes tentorii*; being an assemblage of several streams of light, representing a bundle of rods or ropes.

It is supposed owing to the streaming of the sun-beams through certain rimulæ, or chinks; at least through the

more lax and open parts of a watery cloud, happening chiefly in the morning and evening.

There is also another kind, consisting not of streams of mere white light, but, as it were, painted of various colours, like those of the rainbow.

VIRGANTIA, in *Ancient Geography*, a town of the Segusians, according to Ammianus Marcellinus. Strabo names it Brigantium: it is fo called by Ptolemy and Anton. Itin.: it is the present Briançon.

VIRGATO ALBA, a town of Hispania Citerior, called in Anton. Itin. Urcao, Vircao, and Virgao, and marked between Calpurniana and Iliturgis.

VIRGATA SUTURA, a term used by some anatomists for the sagittal suture of the cranium.

VIRGATA Terra, or *Virga Terra*, a yard-land.

VIRGATORES SERVIENTES, in Fleta, are vergers, or tip-staves, who attend the judges. See VERGER, and SERJEANT at ARMS.

VIRGI, or URCA, in *Ancient Geography*, a town of Spain, upon the gulf Virginitanus Sinus.

VIRGIL, PUBLIUS VIRGILIUS MARO, in *Biography*, a celebrated Roman poet, whose name is familiar to every classical scholar, was born in the year B.C. 70 at Andes, a village near Mantua, and liberally educated at Cremona, Milan, and Naples. His teacher in philology was named Syro, and the philology in which he was instructed was the Epicurean. From his first eclogue, in which he is supposed to have related his own adventures under the appellation of Tityrus, it appears that he first visited Rome in his 30th year for the purpose of recovering lands that were in the possession of the military belonging to Octavius and Antony, after the war against the republicans; and having been introduced to Octavius by Pollio, or some other person, and to his subsequent patron Mæcenas, he succeeded in the object of his visit by their influence. His life, however, was endangered by the violence of the veteran who occupied his farm, and who resisted the surrender of it, so that he was obliged to seek redress by another visit to Rome, and to obtain an order for his reinstatement. His eclogues, which were completed in his 33d or 34th year, were very favourably received; and in his 34th year he was induced by Mæcenas to commence his *Georgics*; and during a period of seven years, which he employed in the prosecution of them, he resided chiefly at Naples. The latter years of his life were devoted to the *Æneid*. At this time he was ranked among those friends, who were particularly distinguished by the attention and confidence of Augustus. After the death of Marcellus, in the year B.C. 23, he paid that admirable tribute to his memory, which occurs in the sixth book of the *Æneid*, and concerning which Donatus says, that when it was recited before Augustus, in the presence of Octavia, the mother of the deceased, as soon as the words "Tu Marcellus eris" were pronounced, she fainted away; and afterwards rewarded the poet with ten sesterces (above 8*ol.*) for each line of the passage. After the completion of his *Æneid*, Virgil went to Greece, with the view of further polishing it; and on this occasion Horace is supposed to have addressed him with the third ode of his first book, beginning "Sic, te Diva potens Cyprî," in which he expresses the warmest affection for his brother poet. At Athens he met with Augustus, and proposed returning in his company; but at Megara he was seized with a disorder, which detained him, as some say, at Brundisium, or, according to others, at Tarentum, and which soon terminated his life in the year B.C. 19, in the 52d year of his age. His remains were conveyed, in pursuance of his request, to Naples, and interred

tered on the Puteolan way. On his death-bed he is said to have expressed a wish that his *Æneid*, which he regarded as an imperfect work, might be committed to the flames; but it was saved either by the interposition of his friends Tuca and Varus, who prevailed upon him to bequeath it to them, on the condition that they should make no alteration in it, or by the injunctions of Augustus to his executors. His modesty, indicated by this wish, was combined with other similar qualities. "He was mild and gentle in his manners, unassuming in conversation, sincere and faithful in friendship, so that he was singularly beloved by Augustus, Mæcenas, and all the most distinguished persons of that period." His poetical talents, as well as general character, were highly appreciated by his contemporaries, inasmuch that whenever his verses were recited in the theatre whilst he was present, the audience rose up and paid him the respect which was usually manifested to the emperor. His eminent merit has been also acknowledged by ancient and modern critics, and though they have differed in opinion as to his peculiar and distinguishing excellencies, they have generally agreed, as one of his most judicious biographers has said, "in placing him upon one of the highest seats in Parnassus." Of the faculty of invention he seems to have possessed a very moderate share, inasmuch that his *Bucolics*, *Georgics*, and *Æneid*, abound with traces of imitation, and even of transflation; but it is "in the diction and phraseology of poetry, in all that constitutes the artist, that his chief excellence consists; and his admirers will not allow that the Virgilian splendour and majesty of style have ever been equalled."—"In two species of composition Virgil has afforded models to almost all succeeding poets, the didactic and the epic." His fame has been testified by the numerous editions of his works, as well as the commentaries and translations which they have produced. The learned professor Heyne has given an account of the various MSS. and editions of Virgil in his edition of Leipzig, 1788, which has been considered by competent judges as the most complete and valuable. For a description and character of the *Æneid*, see *ÆNEID*. Vita Virgilii Ruzii et Heynii. Gen. Biog.

VIRGIL, in *Geography*, a post-township of America, in the province of New York, and S.W. corner of Courtland county; 10 miles S. of Homer, and 155 miles W. of Albany. It is ten miles square, well watered, and furnished with good roads; the soil is excellent; the timber is maple, beech, bals, elm, butter-nut, &c. with some pine and hemlock. In 1810, the population was 913; the senatorial electors 77; and the whole amount of taxable property 84,351 dollars.

VIRGILIA, in *Botany*, a genus dedicated by Lamarck to the great Latin poet, whose *Georgics* may well claim for him this sort of commemoration, has taken place of the *Virgilia* of L'Heritier, Sm. Exot. Bot. v. 1. 71, called by Lamarck and others *Galardia*. We shall submit to the general determination; for though L'Heritier thought M. Gaillard unworthy of distinction, he may be screened by a host of names, which certainly confer less honour upon their authors than their owners, however small the merits of the latter may be.—Lamarck Illustr. t. 326. Poir in Lamarck Dict. v. 8. 677. Brown in Ait. Hort. Kew. v. 3. 4. Pursh 309.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, two-lipped; upper lip in two lefs deeply separated segments; lower in three spreading ones; the tube breaking off circularly just above the base. *Cor.* papilionaceous; standard oval, ascending, not reflexed at the sides, emar-

ginate: wings oblong, direct, rather shorter than the standard; keel of two elliptic-oblong petals, nearly the length of the wings. *Stam.* Filaments ten, awl-shaped, distinct, ascending, converging, the length of the keel which enfolds them; anthers oval, notched. *Pist.* Germen superior, oblong, compressed; style curved, the length of the stamens; stigma obtuse, beardless. *Peric.* Legume oblong, compressed, of one cell and two valves. *Seeds* several, orbicular, compressed.

Effl. Ch. Calyx two-lipped, with five unequal teeth. Corolla papilionaceous, nearly equal; standard not reflexed at the sides. Stigma beardless. Legume compressed, oblong, with many seeds.

1. *V. capensis*. Vetch-leaved *Virgilia*. Poir in Lam. n. 1. Lam. fig. 2. Ait. n. 3. (*Podalyria capensis*; Willd. Sp. Pl. v. 2. 501. *Sophora capensis*; Linn. Mant. 67. Thunb. Prodr. 79. Andr. Repof. t. 347. *S. orboides*; Berg. Cap. 142.)—Stamens deciduous; woolly at the base. Germen downy. Keel acute. Leaflets lanceolate, downy beneath. Legume silky.—Native of the Cape of Good Hope. The late Thomas Cornwall, esq. an assiduous cultivator of exotic plants, is said by Mr. Aiton to have first introduced this species in 1767. The seeds have often been imported since the plant, being frequent near Cape Town. It flowers with us in July and August, being sheltered in winter in the greenhouse. This is a tall shrub, or small tree, having alternate pinnate leaves, with an odd leaflet, like the whole genus. The leaflets are very numerous, uniform, about an inch long, acute; shining, and nearly smooth, on the upper side. Flowers in stalked, axillary, downy clusters, shorter than the leaves, each half the size of a common Sweet-pea, white, with a pink, lunate spot on the standard. Legume downy, two inches long.

2. *V. aurea*. Great-flowered *Virgilia*. Poir in Lam. n. 2. Lam. fig. 1. Ait. n. 1. (*Podalyria aurea*; Willd. Sp. Pl. v. 2. 502. *Robinia subdecandra*; L'Herit. Stirp. Nov. 157. t. 75.)—Stamens permanent. Germen downy. Leaflets elliptical, obtuse, pointless. Legume smooth.—Native of Abyssinia. Sent to Kew in 1777, by M. Thouin. A greenhouse shrub, flowering in July. The leaflets are full as numerous as in the foregoing, and longer, more elliptical and obtuse, smooth on both sides; paler, and a little glaucous, at the back. Flowers yellow, according to L'Heritier; Poir says white; the size of the former, in axillary clusters as long as the leaves. Legume two or three inches long, quite smooth.

3. *V. intrusa*. Small-flowered *Virgilia*. Br. in Ait. n. 2.—Stamens permanent. Germen smooth. Calyx concave externally at the base. Leaflets oval, obtuse, with a small point.—Native of the Cape of Good Hope, from whence it was sent to Kew garden, by Mr. Masson, about the year 1790. A greenhouse shrub, flowering most part of the summer. Aiton.

4. *V. secundiflora*. Unilateral-flowered *Virgilia*. Cavan. Ic. v. 5. 1. t. 401. Poir in Lam. n. 3. ("Broussonetia secundiflora; Ortega Dec. 5. 61. t. 7.")—Germen and legume downy. Calyx tapering at the base. Leaflets oval, obtuse, pointless.—Native of New Spain. It flowered at Madrid in April. We have a specimen from Cavanilles, but the plant has not yet found its way into the English greenhouses. The stem is shrubby, three feet or more in height, with stout, round, finely downy branches. Leaflets rather fewer than in any of the rest, coriaceous, veiny, smooth or very slightly silky, an inch long, sessile, mostly alternate, on a channelled common stalk. Cluster terminal, dense, of numerous flowers all turned one way, scarcely fo

large as in the first or second species. *Calyx* finely silky, with shallow divisions. *Petals* blue; the *standard* much paler than the rest. *Stamens* smooth. *Germen* very silky.

5. *V. lutea*. Yellow American *Virgilia*. Pursh n. 1.—“Leaflets alternate, ovate, short-pointed, smooth. Clusters elongated, pendulous. Legumes stalked, flat.”—On mountains between Georgia and Tennessee. A handsome tree, much like our *Laburnum*, flowering in June. The bark gives a beautiful yellow dye. *Pursh*.

VIRGILIAN HUSBANDRY. See HUSBANDRY.

VIRGILIANÆ SORTES. See SORTES.

VIRGIN, VIRGO, a female who has had no carnal commerce with a man; or, more properly, who has still the *flor virginis*, or maidenhood.

By the Mosaic law, the priests are enjoined to take none to wife but those that are virgins; the widow, the divorced, and the harlot, are to be refrained from.

In the Roman breviary there is a particular office for virgins departed, answering to those of saints, martyrs, and confessors.

VIRGIN is also applied, by way of eminence, to Mary the mother of our Saviour.

Many of the fathers, with the modern churches, hold, that the Virgin not only conceived, but brought forth, or was delivered without breach of her virginity; otherwise, faith St. Augustine, it would be false which is said in the creed, that he was born of a virgin. It is even alleged that she still remained a virgin to the end of her life; whence the Greeks always called her *αι παρθενος*, ever *Virgin Mary*; and after them the Latins, *semper virgo*. Though, as this is not recorded in Holy Writ, many have denied it, and held that she had afterwards to do with Joseph, and bore other children; and this as early as the time of Origen. Tertullian himself is produced as one that denied the perpetual virginity; and the like may be said of Apollinaris and Eusebius, with their followers. See AN-TIDICOMARIANITES and HELVIDIANS.

VIRGIN, *Charity of the Holy*. See CHARITY.

VIRGIN, *Nativity of the*. See NATIVITY.

VIRGIN, *Presentation of the*. See PRESENTATION.

VIRGINS of Love. See MISSION.

VIRGIN is also applied, figuratively, to several things that retain their absolute purity, and have never been made use of. Thus,

VIRGIN *Copper*. See COPPER.

VIRGIN *Gold*. See GOLD.

VIRGIN *Oil*. See VIRGIN OIL.

VIRGIN *Parchment*. See PARCHMENT.

VIRGIN *Quicksilver*, is that found perfectly formed, and fluid in the veins of mines; or at least such as is got from the mineral earth, by mere lotion, without fire.

VIRGIN *Sulphur*. See SULPHUR.

VIRGIN *Wax*. See VIRGIN WAX.

VIRGIN's *Bower*, in Botany. See CLEMATIS.

The leaves and flowers of the upright virgin's bower, or *clematis creta* of Linnæus, called also *flammula Jovis*, and distinguished by its pinnated oval leaves and erect stalk, are extremely acrid; the former, when fresh, raising blisters on the part to which they are applied.

This is one of the new medicines introduced by Dr. Stoerck. He has published several cases of its efficacy in cancerous, venereal, and other malignant ulcers, oblitinate pains of the head and bones, inveterate itch, and other diseases proceeding from peculiar acrimony. It was used internally, in infusion of the flowers or leaves, and extract of the plants; and the powder was sprinkled on the ulcers externally, where it was found to act as a most excellent escharotic and detergent.

The medicine is said to have proved diuretic to some patients, and sudorific to others, but rarely to have moved the belly. Small doses, of only half a grain of the extract, and half a drachm of the dried leaves in infusion, were at first exhibited, which were gradually increased. Lewis.

VIRGIN's *Milk*, in the *Materia Medica*, is a name given to a solution of benzoïn in spirits, mixed with twenty times its quantity, or more, of water, which renders it milky.

It is said to be of great service in disorders of the breast, for resolving obstructions of the pulmonary vessels, and promoting expectoration. It is also used as a cosmetic.

VIRGIN's *Milk*. See VIRGIN's MILK.

VIRGIN's *Thread*, a sort of meteor that flies in the air, like small untwisted silk, and which falling upon the ground, or open plants, changes itself into a substance like a spider's web.

In these northern climates it is most frequent in summer; the days being then temperately warm, the earth not exceeding dry, nor yet overcharged with moisture.

This has formerly passed for a sort of dew of an earthy slimy nature; but naturalists are now agreed, that the virgin's threads are no other than so many spiders' webs.

VIRGIN, *Cape*, in Geography, a cape on the S. E. coast of South America, at the entrance into the Straits of Magellan. It was so called by Magellan, because he discovered it on the feast of St. Ursula. S. lat. 52° 24'. W. long. 67° 52'.

VIRGIN *Islands*, a group of islands in the West Indies, E. of Porto Rico, extending 60 miles in length and upwards of 36 in breadth; dangerous to navigators, though in the middle of them there is a basin, 18 or 20 miles long, and 9 or 12 broad, in which ships may anchor and be sheltered from all winds, called the “Bay of Sir Francis Drake,” from his having passed through them to St. Domingo. Some have erroneously supposed that the name was bestowed upon them, in 1580, by Sir Francis Drake, in honour of queen Elizabeth; but the fact is, that these islands were named “Las Virgines” by Columbus himself, who discovered them in 1493, and gave them this appellation, in allusion to the well-known legend in the Romish church of the 11,000 virgins. After having been long neglected by the Spaniards, they were visited in 1596 by the earl of Cumberland, in his way to Porto Rico; and the historian of that voyage describes them as “a haunt of little islands, wholly uninhabited, sandy, barren, and craggy.” The whole group comprehends about 40 islands, islets, and keys, and they are at present divided between the English, the Spaniards, and Danes. The English hold Tortola, and Virgin-Gorda, called Penmiston, and corruptly Spanish-Town, in which are two very good harbours; Jofan Dykes, Guana isle, Beef and Thatch islands, Anegada, Nickier, Prickly Pear, Camane's, Ginger, Cooper's, Salt island, Peter's island, and several others of little value. The Danes possess Santa Cruz, or *Sta. Croix* (which see), St. Thomas, with about twelve smaller dependent islands, and St. John, having the best harbour of any island to the leeward of Antigua; and the Spaniards claim Crab island, the Green or Serpent island, the Tropic Keys, and Great and Little Passage. Those islands which now belong to the British government were first possessed by a party of Dutch Buccaneers, who fixed themselves at *Tortola* (which see), and the English title has remained. The colony struggled with difficulties until the year 1773; when a petition was presented to his majesty, requesting that the governor and council might be permitted to frame proper laws for their government and welfare; pledging themselves, in such case, to grant to his majesty, his heirs and successors, an impost of 4½ per cent., in specie, upon all commodities the growth of these islands, similar to that which

was paid in the other Leeward islands. This application succeeded; and an assembly was convened Feb. 1. 1774, which honourably complied with their engagement to the crown. They afterwards passed a grant of 400*l.* currency *per annum*, as their proportion towards the salary of the governor-general. Such was the price at which the Virgin islands purchased the establishment of a constitutional legislature. The chief and almost the only staple productions of these islands are sugar and cotton. These islands lie in about N. lat. 18° 20'; and the passage through them is safe, at W. by N. and W.N.W. as far as to the W. end of the fourth island. Edwards's Hist. of the West Indies, vol. i.

VIRGIN Rocks, rocks in the Atlantic, 60 miles S.E. of Cape Race, on the coast of Newfoundland. N. lat. 46° 20'. W. long. 50°.

VIRGINAL, is a keyed musical instrument of one string, jack, and quill to each note, like a spinet; but in shape resembling the present small piano-forte. It has been imagined to have been invented in England during the reign of queen Elizabeth, and to have been thus denominated in honour of that virgin princess; but we have here not only a proof of its use in this kingdom before she was queen, but a drawing and description of it appeared in Lucinius's *Mufurgia*, before she was born. Dr. Johnson imagines that this instrument had its name from being chiefly cultivated by young ladies.

VIRGINAL-Book of Queen Elizabeth. See **QUEEN Elizabeth**, and **BIRD**.

VIRGINAL-Book of Lady Nevil. See **BIRD**.

For the first music that was printed for the virginal, see **PARTHENA**.

VIRGINALE CLAUSTRUM, in *Anatomy*, the same as hymen.

VIRGINES, LAS, Bay of, in *Geography*, a bay on the coast of New Albion, between Cape Colne and Point Zuniga.

VIRGINEUS MORBUS, the *Virgin's disease*; the green-sickness, or chlorosis.

VIRGIN-GORDA, in *Geography*. See **SPANISH-Town**.

VIRGINIA, one of the United States of America, situated between 36° 30' and 40° 43' N. lat., and 1° 40' E. and 6° 20' W. long. from Washington; and bounded on the N. by Maryland, Pennsylvania, and Ohio; on the S. by North Carolina and Tennessee; on the E. by Maryland and the Atlantic ocean; and on the W. by Kentucky and Ohio. Its extent from N. to S. is 220 miles, and from E. to W. 370 miles; and its area about 64,000 square miles, or 40,960,000 acres. The number of inhabitants, deduced from the census of 1810, and stated by Mr. Melish, is 974,622, as in the following.

Topographical Table.

Counties.	No. of Inhabitants.	Chief Towns.
Accomack	- 15,743	Drummond.
Albemarle	- 18,268	Charlottesville.
Amelia	- 10,594	
Amherst	- 10,548	New Glasgow.
Augusta	- 14,308	Staunton.
Bath	- 4,837	Warm Springs.

* Laid out since last census.

The aspect of the country is different in various parts of it. On the eastern shore it is level, interspersed with swamps and meadows. In the middle it is mountainous, with many rich valleys, and on the west side hilly. With regard to the *mountains*, it is observed, that they are not solitary, and scattered confusedly over the face of the country; but they commence at about 150 miles from the sea-coast, and are disposed in the ridges one behind another, running nearly parallel to the sea-coast, but rather approaching as they advance towards the N.E. To the S.W. the mountains converge into a single ridge, which as it approaches the gulf of Mexico subsides into plain country, and gives rise to some of the waters of that gulf, and particularly to a river called Apalachicola. Hence the mountains were denominated the Apalachian mountains, being in reality the termination only of the great ridges passing through the continent. The name, however, has been extended by European geographers; some giving it, after their separation into different ridges, to the Blue Ridge, others to the North mountains, others to the Alleghany, and others to the Laurel Ridge. The veins of lime-stone, coal, and other minerals, lie generally in the same direction. But the courses of the great rivers are at right angles with these. James and Potomac penetrate through all the ridges of mountains E. of the *Alleghany* (which see), which is broken by no water-course, but is in reality the spine of the country, between the Atlantic on one side, and the Mississippi and St. Laurence on the other. The passage of the Potomac through the Blue Ridge exhibits one of the most stupendous scenes in nature. The only remarkable cascade in this country, is that of the Falling Spring in the county of Augusta, formed by a water of James river, here called Jackson's river; but it bears no comparison with that of Niagara. In the lime-stone country, there are several extensive *caverns*; the most noted of which is called Madison's cave, on the N. side of the Blue Ridge. It extends into the earth about 300 feet, and branches into subordinate caverns. There are also some others, such as that near the North mountain, in the county of Frederick, and the Blowing cave, in the ridge which divides the waters of the Cow and Calf pasture; besides another of the same kind with this last in Cumberland mountain. But of all nature's works, the most sublime is the Natural Bridge; lying on the ascent of a hill which seems to have been cloven through its whole length by some great convulsion.

The fissure just at the bridge is reckoned to be 270 feet deep, about 45 wide at the bottom, and 90 at the top, which is of course the length of the bridge, and its height above the water. Its breadth in the middle is about 60 feet, and the thickness of the mass at the summit of the arch about 40 feet. This bridge is in the county of Rockbridge. The stream passing under it is called Cedar creek, which is a water of James river.

The *minerals* of this state are iron, coal, lime-stone, and some copper, black-lead, and gold. The ore from which gold was extracted was found on the N. side of Rappahannock, about four miles below the Falls. On the Great Kanaway, in the county of Montgomery, are mines of lead; the ore containing a small portion of silver not worth the pains of separation. A valuable lead-mine is also said to have been discovered in Cumberland, below the mouth of Red river. A mine of copper was once opened in the county of Amherst, but the discovery was not prosecuted. There are several mines of iron, particularly two in the valley between the Blue Ridge and the North mountain. Considerable quantities of black-lead are taken occasionally for use from Winterham, in the county of Amelia. Mineral coal of a very excellent quality is abundantly supplied by the country on James river, from fifteen to twenty miles above Richmond, and for several miles northward and southward; also by the western country in no many places, that the whole tract between the Laurel mountain, Mississippi, and the Ohio, has been supposed to yield coal. On James river, at the mouth of Rockfish, there is great abundance of good marble. There is known only one vein of lime-stone below the Blue Ridge; from the Blue Ridge westwardly, the whole country seems to be founded on a rock of lime-stone, which is cut into beds, and range, like the mountains and sea-coast, from S.W. to N.E., the lamina of each bed declining from the horizon towards a parallelism with the axis of the earth. Near the western foot of the North mountain are immense bodies of schist, which contain impressions of shells in a variety of forms.

Mineral springs are numerous; but the most efficacious of these are two in Augusta, near the first sources of James river, where it is called Jackson's river. One is called the Warm spring, the other the Hot spring. The sweet springs are in the county of Botetourt, at the eastern foot of the Alleghany, about forty-two miles from the warm springs. On Potomac river, in Berkeley county, above the North mountain, are medicinal springs that are much more frequented than those of Augusta. At Richmond there is a weak chalybeate; and it is said that there are sulphur springs, one on Howard's creek of Greenbriar, and another at Boonsborough, on Kentucky. There is also in the low grounds of the Great Kanaway, seven miles above the mouth of Elk river, and sixty-seven above that of the Kanaway itself, a hole in the earth, capable of holding thirty or forty gallons, from which issues a gas or bituminous vapour in so strong a current, as to cause the sand about its orifice to exhibit the motion which it has in a boiling spring; and on presenting a candle or lighted torch to it, it flames up in a column of eighteen inches in diameter, and four or five feet in height, and burns for several days: there is another similar to it on Sandy river, with a column of flame twelve inches in diameter, and three feet high. In this country there are also several syphon fountains.

The *rivers* of Virginia are the Potomac or Potowmack, Shenandoah, Rappahannock, Mattaponi, Pamunky, York, James, Rivanah, Appomattox, Elizabeth, Nottaway, Meherrin, Staunton, Ohio, Sandy, Great Kanaway, Little Kanaway, Monongahela, and Cheat. Several of these

VIRGINIA.

these are navigable for vessels of various sizes, and of considerable distances. The principal of them are separately noticed under their respective names.

The *soil* in the low part of the state is sandy, but rich on the banks of rivers: between the head of tide-waters and the mountains it is pretty good. The mountains are poor, and in various places incapable of culture, but they are interspersed with many fertile valleys. West of the mountains the soil is generally good.

Of the *produce* of this state, wheat and tobacco are the staples; corn, rye, barley, buckwheat, hemp, flax, roots, grafs, fruit, indigo, and some silk, are also cultivated.

As to the *climate*, in the low country, the summers are hot, and winters mild; in the upper country, and among the mountains, the air is pure, and the weather pleasant: towards the west, temperate.

With respect to the state of *literature* in Virginia, the college of William and Mary is the only public seminary of learning. (See COLLEGE.) Besides this, it has a number of flourishing academies; one in Prince Edward county, one at Alexandria, one at Norfolk, one at Hanover, and others at other places. Since the declaration of independence, the laws have been revised, and one object in this revision was the diffusion of knowledge more generally through the mass of the people. The bill for this purpose proposed to lay off every county into small districts of five or six miles square, called hundreds, and in each of them to establish a school for instruction in reading, writing, and arithmetic.

As to the *religion* of Virginia, we may observe, that the first settlers were emigrants from England, belonging to the English church; and though they were flying from persecution, they manifested a considerable degree of intolerance: which was also the case with their Presbyterian brethren, who had emigrated to the northern government; and the Quakers, who were seeking an asylum from persecution, experienced the effects of this intolerance. At the commencement of the late revolution, two-thirds of the people are said to have become dissenters of one description or another. The present denominations of Christians in Virginia are, Presbyterians, who are the most numerous, and inhabit the western parts of the state; Episcopalians, or, as Mr. Jefferson calls them, "Anglicans," who are the most ancient settlers, and occupy the eastern and first settled parts of the state; and intermingled with these, Baptists and Methodists in great numbers.

With regard to the *character* of the Virginians, it is observed, that as a political and military body, they rank among the first in the page of history; some of them having been most active in effecting the revolutions in America, and influencing the great mass of the people, who would otherwise have indulged their indolence and indifference. Valuing themselves on their inheriting the ancient dominion, they have thought themselves entitled to the first rank in the union, and without doubt they have reason to boast of their "Washington." But Virginia, though claiming priority of the northern states in point of age, is far from being equal to some of them as to literary, mechanical, nautical, agricultural, and manufactural improvements. Allowing for some few instances, the Virginians have made very little progress in the arts and sciences. Before the revolution they were represented by travellers who passed through their country as indolent and inactive, fond of society, addicted to convivial pleasures, and of course indisposed for any enterprise that exposed them to fatigue and danger. The authority which they exercised over their slaves rendered them vain and imperious, and strangers to that elegance of sentiment which is

peculiarly characteristic of refined and polished nations. Hence they were led to extravagance, ostentation, a disregard of economy, and inattention to business: they were haughty and jealous of their liberties, impatient of restraint, and averse from being controuled by any superior power. They are, however, liberal and generous; and are ready to furnish necessary supplies for the support of government, as well as for the purposes of hospitality. Their women are, upon the whole, handsome, though in this respect inferior to those of England: having few advantages, their accomplishments are inconsiderable, and their temper reserved. The only amusement to which they are much addicted is dancing, and it is almost the only one of which they participate. The Virginians, says a discerning traveller cited by Morfe, are rich, and in general sensible, polite, and hospitable, and of an independent spirit; the poor are ignorant and abject: but all are of an inquisitive turn, and in many other respects very much resemble the people in the eastern states. They differ from them, however, in their morals: the former being much addicted to gaming, drinking, swearing, horse-racing, cock-fighting, and most kinds of dissipation. There is a much greater difference between the rich and poor in Virginia than in any of the northern states.

As to the *constitution*, and *judiciary administration* of Virginia, we observe, that the executive powers are lodged in the hands of a governor, annually chosen, and incapable of acting more than three years in seven. He is assisted by a council of eight members. The judiciary powers are divided among several courts. Legislation is exercised by two houses of assembly; the one called the house of delegates, composed of two members from each county, chosen annually by the citizens possessing an estate for life in 100 acres of uninhabited land, or 25 acres with a house upon it, or in a house or lot in some town: the other called the senate, consisting of twenty-four members, chosen quadrennially by the same electors, who for this purpose are distributed into twenty-four districts. The concurrence of both houses is necessary for passing a law. There are three superior courts, to which appeals lie from the courts below; viz. the high court of chancery, the general court, and the court of admiralty. There is one supreme court, called the court of appeals, composed of the judges of the three superior courts, assembling twice a year, at stated times, at Richmond. It receives appeals in all civil cases from each of the superior courts, and finally determines them; but has no original jurisdiction. In 1785, the assembly enacted that no man should be compelled to support any religious worship, place, or minister whatsoever, nor be enforced, restrained, molested, or burdened in his body or goods, nor otherwise suffer on account of his religious opinions or belief; but that all men should be free to profess, and by argument to maintain, their opinions in matters of religion; and that the same should in no wise diminish, enlarge, or affect their civil capacities. In October 1786, an act was passed by the assembly, prohibiting the importation of slaves into the commonwealth, upon penalty of the forfeiture of the sum of 1000*l.* for every slave. And every slave imported contrary to the true intent and meaning of this act, becomes free.

History of Virginia.—In the year 1584, two patents were granted by queen Elizabeth, one to Adrian Gilbert (Feb. 6), the other to sir Walter Raleigh (March 25), for lands not possessed by any Christian prince. Under the direction of sir Walter, two ships were sent out, and in July, 1585, arrived on the coast, anchoring in a harbour seven leagues W. of the Roanoke. On the 15th of July they took formal possession of the country, and in honour of their virgin queen Elizabeth, called it Virginia. Before this event the country was

known

known by the general name of Florida; afterwards Virginia became the common name for the whole of North America. In 1586, a colony of more than one hundred people was stationed at Roanoke, under the direction of captain Ralph Lane; which colony endured extreme hardships, and mult have perished, if sir Francis Drake had not fortunately returned to Virginia, and carried them to England. In 1587, sir Walter sent another company to Virginia, under governor White, with a charter and twelve assistants; and in July this colony arrived at Roanoke, where 115 people were left at the old settlement. In 1590, governor White came over again to Virginia, with supplies and recruits for his colony; but not a man was to be found, all having perished either by famine, or massacred by the Indians. Some further unsuccessful attempts were made for settling this province. At length, in 1606, James I., by patent, divided Virginia into two colonies. The first, under the name of South Virginia, was granted to the London company; the northern, called the second colony, and known by the general name of North Virginia, was granted to the Plymouth company; and each of these colonies had a council of thirteen men to govern them. The Plymouth colony broke up, after enduring many hardships, in 1608. In 1610, the South Virginia or London company sealed a patent to lord De la War, or Delaware, constituting him governor and captain-general of South Virginia, and he soon after embarked for America with 150 men, in three ships. From this time we may date the effectual settlement of Virginia. By a marriage in April, 1613, of Mr. John Rolfe, a worthy young gentleman, with Pocahontas, the daughter of Powhatan, a famous Indian chief, the connection, equally agreeable to the English and the Indians, laid the foundation of a friendly and advantageous commerce between them. The descendants of Pocahontas became the heads of some of the most respectable families in Virginia. Her brother-in-law, Tomocono, accompanied her to England, and on his return, being asked by Powhatan how many people there were in England, replied, "count the stars in the sky, the leaves on the trees, and the sands on the sea-shore; for such is the number of the people in England." The government of Virginia was settled in consequence of a charter obtained in 1609, on the 24th of July, 1621; but dissensions afterwards occurred between the company to which the charter was granted and the king: inasmuch that, partly by law, and partly by force, the company was ousted of all its rights, without retribution, after having expended 100,000*l.* in establishing the colony. King James suspended their powers by proclamation, July 15, 1624, and Charles I. took the government into his own hands. But this state of things did not continue for any long time; for the northern parts of the country were granted away from the original proprietors to the lords Baltimore and Fairfax, the first of these obtaining the rights of separate jurisdiction and government. In 1650, the parliament, conceiving itself as occupying the place and powers of the deposed king, began to assume and exercise a right over the colonies, by passing an act for prohibiting their trade with foreign nations. This colony, having maintained its opposition to Cromwell and the parliament, was induced, in 1651, to lay down its arms, on condition of previously securing their most essential rights by a solemn convention. This convention, as the colony imagined, ensured the ancient limits of the country, its free trade, its exemption from taxation, except by its own assembly, and exclusion of military forces. But this convention was violated in every particular by subsequent kings and parliaments, until at last resistance on the part of this and of the other colonies terminated in an appeal to arms; and this appeal being

crowned with success, they issued a declaration of their independence, in July 1776, and the subsequent establishment of their "federal constitution," to which Virginia acceded after considerable opposition. See AMERICA and UNITED STATES.

VIRGINIA, a post-town of the county of Cavan, Ireland, situated on Lough Ramor; 40½ miles N.W. from Dublin.

VIRGINIAN ACACIA, in Botany. See ROBINIA.

VIRGINIAN Creeper. See CLEMATIS.

VIRGINIAN Guelder-Rose. See SPIRÆA *Opulifolia*.

VIRGINIAN Poke. See PHYTOLACCA *Decandra*.

VIRGINIAN Silk. See PERIFLOCA.

VIRGINIANA BOLUS, is a pure earth, of a compact texture, hard and heavy, of a pale red or rose colour, variegated with veins of deep red, and often with large spots and veins of bright yellow: it is of a glossy surface, does not colour the hands, adheres firmly to the tongue, melts with difficulty in the mouth, is of a rough alstringent taste, leaves no grittiness in the teeth, and is diffusible with difficulty in water. It burns in the fire to an almost stony hardness, without any change of colour. It is the product of Pennsylvania, and most parts of America. This kind of bole has not yet been used in medicine.

VIRGINIS, SPICA. See SPICA.

VIRGINITY, VIRGINITAS, the test or criterion of a virgin; or that which entitles her to the denomination.

In the first ages of the Christian church, virginity grew into great honour and esteem, inasmuch that the women were admitted to make solemn vows of it in public. Yet was it held infamous among the Jews for a woman to die a maid.

The vestals among the ancients, and the nuns or religious among the moderns, found guilty of a breach of the vow of virginity, are allotted a severe punishment; the first to be buried alive, the latter to be immured.

The physicians, both ancient and modern, are exceedingly divided upon the subject of virginity, some holding that there are no certain marks or testimonies of it; and others that there are. Solomon says expressly, there are four things too wonderful for him to know: "the way of an eagle in the air; of a serpent on the rock; of a ship in the middle of the sea; and the way of a man in a maid;" which our translators have rendered, less justly, *the way of a man with a maid*.

Yet Moses established a test, which was to be conclusive among the Jews. The nuptial sheets, it seems, were to be viewed by the relations on both sides: and the maid's parents were to preferre them as a token of her virginity, to be produced, in case her husband should ever reproach her on that score.

In case the token of virginity was not found on them, she was to be stoned to death at her father's door.

This test of virginity has occasioned abundance of speculation about the parts concerned; but the nicest enquiries cannot settle any thing certain about them. Dr. Drake says expressly, that, whatever might be expected among the Jews, there is not the same reason to expect those tokens of virginity in these countries; for, besides that the Hebrews married extremely young, as is the custom in all the Eastern countries, there are several circumstances which may here frustrate such expectations, even in virgins not vitiated either by any male contact, or any wantonness of their own.

In effect, in these northern climates, the inclemency of the air exposes the sex to such checks of perspiration, as gives a great turn to the course of the humours, and drives so much humidity through the parts, as may extraordinarily supple

supple and relax those membranes from which the resistance is expected; and from which, in hotter countries, it might more reasonably be depended on.

What most commonly passes among us for the test of virginity is the *hymen* (which see); and yet the most curious among the anatomists are greatly divided, not only about the figure, substance, place, and perforations of this famous membrane, but even about the existence of it, some positively affirming, and others as flatly denying it. See GENERATION.

As nice a point as that of virginity is among anatomists, the midwives and matrons treat it with less diffidence. In the statutes of the sworn matrons, or midwives of Paris, containing likewise divers formulas of reports and depositions made in court, upon their being called to visit girls that made their complaint of being deflowered, they laid down fourteen marks on which to form a judgment.

Laur. Joubart, a famous physician of Montpellier, has transcribed three of these reports; one made to the provost of Paris, another in Languedoc, and a third in Berne. These reports are very consistent with each other, and contain fourteen marks of virginity, expressed in their proper terms, such as were received among the women in that profession, and authorized in court.

M. Joubart does not explain those terms, nor do we find any explanation of them any where, but in another report, of the 23d of October, 1672, inserted in the Picture of Love of Venette, a physician of Rochel.

In Peru, and several other provinces in South America, we are assured by Pedro de Cieca, in the history of the Incas, &c. that the men never marry but on condition that the next relation or friend of the maid shall undertake to enjoy her before him, and take away her virginity. And our countryman, Lawson, relates the like of some of the Indian nations of Carolina. So little is the *stos virginis* valued in some places.

VIRGINIUS RUFUS, L., in *Biography*, a distinguished Roman citizen and commander, whose merit raised him to the consulate in the reign of Nero, A.D. 63. When the Gauls revolted under Vindex, A.D. 68, he marched to Besançon, in order to resist his designs. On this occasion the legions proclaimed him emperor, but he refused the title, alleging that the disposal of the empire belonged not to them, but to the senate and people. After the death of Nero, and the succession of Galba, he was again solicited by the army to become a candidate for the empire, and he was threatened with death by one of the tribunes if he did not comply with the wishes of the soldiers. But he resolutely resisted, and prevailed with them to acknowledge the new emperor. When Otho acquired temporary dominion, he endeavoured to engage the attachment of the German legion, by conferring a second consulate, A.D. 69, on Virgilius, their old commander; and after his death, he was a third time urged by the soldiery to accept the empire, but he persisted in refusing the offer. Upon Vitellius's entrance into Rome, Virgilius was very unjustly suspected of a design to assassinate him; and though Vitellius had no doubt of his innocence, it was not without great difficulty that he preserved his life. From this time till the reign of Nerva he lived in retirement, calling the place of his retreat near Alaium "the rest of his old age." To Pliny the younger he was guardian, and was always regarded by him with filial veneration; and at Rome he was respected as one of the most excellent of its citizens. "He read," according to the account given of him by Pliny, "verses and histories of which he was the subject, and lived, as it were, with his own posterity;" and Pliny relates the following instance of

his love of historical fidelity. Cluvius Rufus, an eminent historian, said to him, "You are sensible, Virgilius, of the fidelity required in a writer of history; if, therefore, you meet with any thing in my work which is displeasing to you, I request that you will pardon it." He replied, "Are you ignorant, Cluvius, that my purpose, in doing what I have done, was that you writers might freely say what you should think fit." In his eighty-third year Nerva honoured him by advancing him to a third consulate, as his own colleague in that office. On this occasion he intended to deliver a discourse, and whilst he was preparing at home for the recitation of it, a large book fell from his hand upon the floor; and, in stooping for it, his foot slipped, and in the fall he broke his thigh. The fracture occasioned his death, A.D. 97. His remains were honoured with a public funeral, and his eulogy was pronounced by Cornelius Tacitus. The epitaph which he had written for himself was compressed in two lines, and merely recorded one of the principal actions of his life, with its motive:

"Hic situs est Rufus, pulso qui Vindice quondam
Imperium asseruit, non sibi, sed patriæ."

"Here Rufus lies, who, by the repulse of Vindex, secured the empire, not for himself, but for his country." Crevier. Plin. *Épist.* Gen. *Biog.*

VIRGO, in *Astronomy*, one of the signs or constellations of the zodiac, into which the sun enters in the middle of August. See CONSTELLATION.

The stars in the constellation Virgo, in Ptolemy's catalogue, are 32; in Tycho's, 33; in Hevelius's, 50; and in the *Britannicæ*, 110.

VIRGULA, in *Grammar*, a term which Latin, French, and some other authors use for a point in writing, usually called by us, *comma*.

Virgulas, F. Simon observes, are an invention of the modern grammarians, to give the greater clearness to discourse. The use of them was unknown to the ancient Greeks and Romans, who wrote all without taking off the pen, so that their books lie all together, without any distinction of points and virgulas.

VIRGULA, or *Virgola*, in *Music*, the tail or stem to a note. The first notes in the old time-table had no tails till the minim was invented, which had a tail to distinguish it from the semibreve, as the crotchet had a black head to distinguish it from the minim, of which the head is white, and the quaver a hook to the tail, to distinguish it from the crotchet, of which the tail was straight, &c.

VIRGULA Divina, or *Baculus divinatorius*, a forked branch in form of a Y, cut off a hazle-tree, by means of which people have pretended to discover mines, springs, &c. under ground.

The method of using it is this: the person who bears it walking very slowly over the places where he suspects mines or springs may be, the effluvia exhaling from the metals, or vapour from the water, impregnating the wood, makes it dip or incline, which is a sign of a discovery.

We find no mention made of this virgula in any author before the 11th century; but from that time it has been in frequent use. Divers fine names have been invented for it, some calling it *caduceus*, others *Aaron's rod*, &c.

Some dispute the matter of fact, and deny it to be possible; others, convinced by the great number of experiments alleged in its behalf, look out for the natural causes of them. The corpuscles, say these authors, rising from the springs, or minerals, entering the rod, determine it to bow down, in order to render it parallel to the vertical lines which the effluvia describe in their rise.

In effect, the mineral or watery particles are supposed to be emitted by means of the subterraneous heat, or of the fermentations in the entrails of the earth: and the virgula, being of a light porous wood, gives an easy passage to those particles, which are also very fine and subtle; the effluvia then driven forwards by those that follow them, and oppressed, at the same time, by the atmosphere incumbent on them, are forced to enter the little interstices at the fibres of the wood; and, by that effort, they oblige it to incline or dip down perpendicularly, to become parallel with the little columns which those vapours form in their rise.

A late writer has recited no less than six hundred experiments, made with all possible attention and circumspection, and several of which are very curious and extraordinary, in order to ascertain the facts attributed to the divining rod; and he has also undertaken to unfold their resemblance to the admirable and uniform phenomena of electricity and magnetism. See M. Thouvenel's *Memoire Physique et Medicinale* Montrant des Reports evidens entre les Phenomenes de la Baguette divinatoire, &c. 12mo. Paris, 1781.

Mr. Pryce has collected several observations on the nature and use of the virgula divinatoria, in his *Mineralog. Cornub.* lib. iii. cap. 1.

VIRCULARIA, in *Botany*, so called from *virga*, in allusion to its slender wand-like branches, by the authors of the *Flora Peruviana*.—Poiret in *Lamarck Dict.* v. 8. 679.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Scrophulariæ*, Juss.

Gen. Ch. Cal. Perianth inferior, bell-shaped, permanent, somewhat two-lipped, with ten angles, and five sharp spreading teeth; the two lowermost a little distant. Cor. of one petal, bell-shaped, irregular; tube a little recurved; mouth inflated, gibbous; limb in five roundish, concave segments; the two uppermost shortest, ascending; three lowermost spreading, the middle one narrowest. Stam. Filaments four, thread-shaped, compressed, hairy at their base, inserted into the tube, two of them shorter than the rest; anthers inclining, arrow-shaped, of two cells. Pist. Germen superior, obovate; style awl-shaped, recurved, as long as the corolla; stigma oblong, compressed, of two lobes, the uppermost channelled, half sheathing the lower. Peric. Capsule invested with the calyx, oval, obtuse with a point, with two furrows, two cloven valves, and two cells, the partition contrary. Seeds numerous, very small, inserted into a convex central receptacle, attached to each side of the partition.

Eff. Ch. Calyx five-toothed, with ten angles. Corolla somewhat bell-shaped, irregular, recurved. Stigma with one lobe sheathing the other. Capsule of two cells, two valves, and a transverse partition. Seeds numerous.

This genus appears to come near *Buddlea*. It is said to consist of only two known species, natives of Peru, of a shrubby habit, with numerous slender twigs. Neither of the species has as yet been described.

VIRGULTUM, in our ancient *Law-Books*, is used for anholt, or plantation of twigs, or others.

Sometimes, also, for a coppice of young wood. "Et præterea concedo virgultum meum, et totam communiam domini mei." Mon. Angl.

In another place of the same work, *virgultum*, or rather *virgulta*, may be taken for *virgata*; viz. "Dedit prædictæ ecclesiæ unam virgultum terræ in manerio de Crumptonne." See *YARD-Land*.

VIRBALLUM, in *Ancient Geography*, a promontory on the western side of the isle of Corsica, between the gulf Casulus and the mouth of the river Cicidius: supposed to be Punta di Adiazza.

VOL. XXXVII.

VIRICONIUM. See **URICONIUM**.

VIRIDARIO ELIGENDO, in *Law*, a writ that lies for the choice of a verdor in the forest. See **VERDEROR**.

VIRIDE ÆRIS, the same as *æругo*, or *verdigrise*, which see.

VIRIDELLUS, a word used by some medical writers to express the epilepsy, and, by some of the chemical ones, as a name for the common green vitriol.

VIRIEU, in *Geography*, a town of France, in the department of the Ière; 6 miles S.S.E. of La Tour du Pin.

VIRIEU le Grand, a town of France, in the department of the Ain; 6 miles N. of Belley.

VIRILE, something that belongs, or is peculiar to man, or the male sex.

Thus, virile member, *membrum virile*, is frequently used for the penis.

VIRILE AGE, *Ætas virilis*, is the strength and vigour of a man's age, viz. from thirty to forty-five years, which is an age in which we are equally removed from the extremes of youth and old age. See **AGE**.

The civil lawyers only make one age of youth and virility, and yet their different temperatures seem to require a distinction, for which reason some compare youth to summer, and virility to autumn.

At Rome, the youth quitted the prætexta at fourteen or fifteen years of age, and took the virile gown, *toga virilis*, to shew, it seems, that they then entered on a serious age.

M. Dacier will have it, that children do not take the prætexta till thirteen years of age, nor quit it for the toga virilis till seventeen.

VIRILIA, a man's genitals, or privy members, including the penis and testes. See **GENERATION**.

The cutting off the virilia, according to Bracton, was felony by common law; and that whether the party were consenting or not.

"Henricus Hall et A. uxor ejus capti et detenti in prisona de Evilchetter, eo quod reſtati fuerunt, quod ipsi abſciderunt virilia Johannis Monachi, quem idem Henricus deprehendit cum predicta A. uxore ejus." Rot. Claus. 13 Hen. III.

VIRILIS Testis Musculus, in *Anatomy*, a name given by Vesalius and others, to the muscle generally known by the name of the cremaster.

VIRIMGAM, in *Geography*, a town of Hindoostan, in Guzerat; 55 miles W. of Amedabad.

VIRITES, a name by which the writers of the middle ages have called the pyrites.

VIRIVILLE, in *Geography*, a town of France, in the department of the Ière; 12 miles N.N.W. of St. Marcellin.

VIRNENBURG, a town of France, in the department of the Rhine and Moselle, late capital of a county, to which it gave name; 20 miles W. of Coblenz. N. lat. 50° 27'. E. long. 6° 58'.

VIROLA, in *Botany*, the vernacular name in Guiana of a sort of bastard Nutmeg-tree; Aubl. Guian. 904. t. 345. Juss. 81. (See **MYRISTICA**.) Aublet calls it *V. sebifera*, and describes it as a tree from thirty to sixty feet high, and above two feet in diameter, with numerous spreading branches. Leaves alternate, stalked, oblong, acute, entire, wavy, eight inches long; downy beneath. Flowers dioecious, in compound, dense, axillary panicles. Anthers but three. Capsule globose, pointed, coriaceous, of two valves, containing a seed like a nutmeg, enveloped in a many-cleft tunic, like mace, and yielding a copious oily acid substance, used for making candles.—This tree is common in Cayenne and Guiana. Swartz in his Fl. Ind. Occ. 1129, and

Willd. in Sp. Pl. v. 4. 872, have referred it to *Myrsifera*, by the specific name of *sebisera*, where, notwithstanding our learned friend Mr. Brown's doubts, we should think it ought to remain.

VIROSIDUM, in *Ancient Geography*, a town of Great Britain, thought by Camden to be Warwick, in Cumberland.

VIROVESA, a town of Hispania Citerior, S.E. of Julio-Brigduna, one of the ten cities of the Autrigones, according to Pliny. In the Itin. Anton. it is marked on the route from the Gauls to the place named Ad Legionem Geminum, between Segafamundum and Segefamona. Ptolemy calls it *Vireusta*, and it is now named *Briviesca*.

VIROVIACUM, a place marked in the Itin. Anton. between Castellum and Turnacum, or Cassel and Tournai, at the same distance from both places.

VIROUR, in *Geography*, a town of Hindoostan, in Tinevelly; 57 miles N.N.E. of Neermul.

VIROPINACH, a town of Istria; 9 miles E.N.E. of Pedena.

VIRREIES, three small islands among the Philippines. N. lat. 13° 18'. E. long. 121° 48'.

VIRSBO, a town of Sweden, in Westmanland; 24 miles N. of Stroemholm.

VIRTON, a town of France, in the department of the Forests; 10 miles S.W. of Arlon.

VIRTUNGIANUS DUCTUS, or *Ductus Virfungii*, so called from the inventor, Virfungius, a professor at Padua, in *Anatomy*, a canal, more usually called *ductus pancreaticus*. See PANCREAS and PANCREATIC Juice.

VIRTU, Ital. force, talents.

VIRTUAL, **POTENTIAL**, something that has a power, or virtue, of acting, or doing.

The term is chiefly understood of something that acts by a secret invisible cause, in opposition to *actual* and *sensible*.

VIRTUAL Focus, in *Optics*. See FOCUS.

VIRTUALITY, **VIRTUALITAS**, in the *Schools*, denotes some mode or analogy in an object, which, in reality, is the same with some other mode, but, out of regard to contradictory predicates, is considered as if distinct from it.

And hence arise what we call *virtual distinctions*, by which one virtuality is distinguished from another, not one thing from another.

Thus it is, the divine nature is distinguished from the divine person; and the divine understanding from the divine will.

VIRTUALLY, **VIRTUALITER**, is applied to a mode of existence. A thing is said to be virtually any where, when it is deemed to be there by some virtue, influence, or other effect, produced by it. Thus the sun is virtually on earth, *i. e.* by his light, heat, &c.

A thing is also said to be virtually present, when the virtues, or properties, belonging to it, and issuing from it, remain. In which sense, the forms of the elements are held to be virtually in mixed bodies.

A thing is also said to be a cause virtually, or a virtual cause, and that two ways: the first, when there is no real distinction between it and the effect attributed to it; and yet it is conceived by us as if it were really the cause of it. Thus, immutability in God is the cause of eternity.

Secondly, when any effect is not of the same kind with the cause, and yet the cause has the power or virtue of producing the effect; thus the sun is not formally, but virtually hot; and fire is not contained formally, but virtually, in heat.

VIRTUE, **VIRTUS**, a term used in various significations. In the general, it denotes *power*, or *perfection*, of

any thing, whether natural or supernatural, animate or inanimate, essential or accessory. Hence the virtues, that is, the powers of God, angels, men, plants, elements, &c.

VIRTUE, in its more proper and restrained sense, is used by some writers to signify an habit, which improves and perfects the possessor and his actions. Accordingly, in this sense of the term, virtue is a principle of acting or doing well and readily; and as there are two faculties or powers in man from which all his actions proceed, *viz.* the understanding and the will, so the virtue (as these authors say), by which he is perfected, or by which he is disposed to do all things rightly, and to live happily, must be two-fold; the one of the understanding, the other of the will. That which improves the understanding, is called *intellectual*, or *dianoetic*; and that, the will, *moral*, or *ethical*. For, since there are two things required in order to live aright, *viz.* to know what should be done, and, when known, readily to perform it; and since man is apt to err various ways in each respect, unless regulated by discipline, &c. he alone can deport himself rightly in his whole course of life, whose understanding and will have attained their utmost perfection.

VIRTUE, *Intellectual*, then, according to Aristotle, is an habit of the reasonable soul, by which it conceives or speaks the truth, either in affirming or denying.

The virtues which come under this class are divided into *speculative*, which are those conversant about necessary things, that can only be known or contemplated; and *practical*, which are conversant about contingent things, that may likewise be practised.

Aristotle has another division of intellectual virtue, derived from the subject; as some of them are seated in the *speculative*, or *contemplative part*; *viz.* those conversant about necessary things, as *science*, *wisdom*, *intelligence*; and others in the *practical part*, such as those conversant about contingent things, as *prudence*, *art*, &c.

VIRTUE, *Moral*, is defined by Aristotle to be an elective habit, placed in a mediocrity, determined by reason, and as a prudent man would determine. See the sequel of this article.

We shall here subjoin as concise an account as possible of the principal systems of morality or ethics that have been proposed by different writers, both ancient and modern, who have treated of this subject; from which the reader will be able to discover the opinions that have chiefly prevailed with regard to the nature, foundation, and obligation of virtue, referring for a more extended and elaborate account of the subject to the article *MORAL PHILOSOPHY*.

It may be proper to premise, that virtue has been distinguished into *abstract* or *absolute*, and *relative* or *practical* virtue. *Abstract* virtue is, most properly, a quality of the external action or event; and denotes what an action is, considered independently of the sense of the agent; or what, in itself and absolutely, it is right such an agent, in such circumstances, should do, and what, if he judged truly, he would judge he ought to do: *Practical* virtue, on the contrary, has a necessary relation to, and dependence upon, the sense and opinion of the agent concerning his actions; or it signifies what he ought to do, upon supposition of his having such and such sentiments of things. Agreeably to this distinction, good actions have been by some divided into such as are *materially* good, and such as are *formally* so. The enquiry concerning the foundation of virtue refers to absolute virtue: and if it be asked what the foundation of virtue is, we may mean either, what is the true account or reason that such and such actions are right, or apprehended as such by us; or, what are the primary principles and heads

VIRTUE.

heads of virtue, *i. e.* the considerations inferring obligation in particular cases, and rendering particular actions right and fit to be done; or, moreover, what are the motives, causes, and reasons, which engage or attach us to it, and support the practice of it in the world. In this last sense the term must be used by those who represent the will of God, self-interest, the reasons of things, and the moral sense, as all distinct and coincident foundations of virtue.

An ingenious writer, in forming his arrangement of the different systems of moral philosophy, of which we shall here avail ourselves, observes, that in treating of the principles of morals, there are two questions to be considered: first, wherein does virtue consist, or what, in temper and conduct, constitutes the excellent and laudable character? and secondly, by what power of the mind is this character, whatever it be, recommended to us? The first question is examined when we consider whether virtue consists in benevolence, as Dr. Hutcheson imagines; or in acting suitably to the different relations of persons and things, as Dr. Clarke supposes; or in a conformity to the will of God; or in the prudent pursuit of our own true happiness, as others have maintained. In reference to the second question we consider, whether the virtuous character, whatever it consists in, be recommended to us by self-love, which makes us perceive that this character, both in ourselves and others, tends most to promote our own private interest; or by reason, which points out to us the difference between one character and another, in the same manner as it does that between truth and falsehood; or by a peculiar power of perception, called a moral sense, which this virtuous character gratifies and pleases, as the contrary disgusts and displeases it; or lastly, by some other principle in human nature, such as the modification of sympathy, or the like.

The different accounts which have been given of the nature of virtue, may be reduced to three different classes. According to some, virtue, or the virtuous temper of mind, does not consist in any one species of affections, but in the proper government and direction of all our affections, which may be either virtuous or vicious, according to the objects which they pursue, the principles and motives that direct the pursuit of them, and the degree of vehemence with which they pursue them. According to these authors, therefore, virtue consists in propriety.

According to others, virtue consists in the judicious pursuit of our own private interest and happiness, or in the proper government and direction of those selfish affections which aim solely at this end. In the opinion of these authors, virtue consists in prudence.

Others again make virtue consist in those affections only which aim at the happiness of others, not in those which aim at our own. According to them, therefore, disinterested benevolence is the only motive which can stamp upon any action the character of virtue.

According to Plato, Aristotle, and Zeno, virtue consists in propriety of conduct, or in the suitability of the affection from which we act to the object which excites it. In the system of Plato, reason is the judging and ruling faculty; and virtue, according to him, consists in that state of mind in which every faculty confines itself within its proper sphere, without encroaching on that of any other, and performs its proper office with that precise degree of vigour which belongs to it: or, in other words, virtue consists in propriety of conduct.

Virtue, according to Aristotle, (as we have already stated,) consists in the habit of mediocrity, according to right reason; every particular virtue lying in a kind of medium between two opposite vices; and thus, by making

virtue to consist in practical habits, he probably had in view to oppose the doctrine of Plato, who seems to have thought that just sentiments concerning what was fit to be done or avoided were of themselves sufficient to constitute the most perfect virtue. Aristotle, on the contrary, was of opinion, that no conviction of the understanding was capable of getting the better of inveterate habits, and that good morals arose not from knowledge but from action.

Others disallow the Peripatetic notion of virtue, as placed in a habit: for a habit, or habituality, say they, includes two things; a custom, and facility; the first as a cause, and the second as an effect: so that a habit is nothing but a facility acquired by custom. They, therefore, who make virtue a habit of doing well, must, of necessity, ascribe it to a frequent exercise of good actions. But this cannot be; for the virtue must be before the good actions; and the habit, after them. Indeed, whence should the actions proceed, but from virtue? Virtue, therefore, is before the good actions, and, certainly, before a habit, resulting from a frequency of good actions. Hence, they define virtue to be a firm purpose, or resolution, of doing whatever right reason demands to be done. For, though a custom of doing well be required to make a person esteemed good among men; yet it does not follow that that custom, or habit, is the formal cause of that denomination, or the goodness itself.

Besides, from the definition of Aristotle, none can know what virtue is; for what mediocrity is, or what an extreme, in which he supposes vice to consist, can never be determined, till we know what is agreeable to the nature of things; and, moreover, the definition is faulty, because there are some branches of virtue which cannot be carried to an extreme.

In this connection we may observe, that as on various occasions mankind act more from habit than reflection, and that they are in a great degree passive under their habits, the exercise of virtue, the guilt of vice, or the use of moral and religious knowledge, consist in forming and contracting these habits. Hence it appears, that it is in many cases a very important and useful principle of nature (see *HABIT*); and we shall thus be able to explain the nature of *habitual* virtue. Whatever definition of virtue we may adopt, a man may, in fact, perform many acts that justly merit the denomination of virtuous, without thinking at the time of the principle from which he acts; whether it be rectitude, benevolence, a regard to the will of God, or a view to his own happiness.

According to Zeno and the Stoics, virtue consisted in choosing and rejecting all different objects and circumstances according as they were by nature rendered more or less the objects of choice or rejection; in selecting those which were most to be chosen, when all could not be obtained; and in selecting those which were least to be avoided, when all could not be avoided. This constituted the essence of virtue, and was what the Stoics called to live consistently, to live according to nature, and to obey those laws which nature, or the Author of nature, prescribed for our conduct: and in this course, they required the most perfect apathy, and considered every emotion which might in the smallest degree disturb the tranquillity of the mind, as the effect of levity and folly.

Besides these ancient there are some modern systems, according to which virtue consists in propriety; or in the suitability of the affection from which we act, to the cause or object which excites it. The system of Dr. Clarke, Mr. Balguy, and other writers, which places virtue in acting according to the relations of persons and

things, in regulating our conduct according to the fitness or incongruity which there may be in the application of certain actions to certain things, or to certain relations: that of Mr. Grove and others, who explain virtue by saying, that it is the conformity of our actions to reason or wisdom; that of many others, who represent it as originating in a regard to the will of God; that of Mr. Wollaston, which places it in acting according to the truth of things, actions as well as words having a language, so that when this action is agreeable to the nature of things, the action is virtuous, and when it implies a false assertion, vicious: that of lord Shaftesbury, which places it in maintaining a proper balance of the affections, and allowing no passion to go beyond its proper sphere, or in a certain just disposition of a rational creature towards the moral objects of right and wrong: are all of them reducible to the same fundamental idea of propriety, as it has been explained.

The most ancient of those systems, which make virtue consist in prudence, is that of Epicurus, who maintained that bodily pleasure and pain were the sole ultimate objects of natural desire and aversion, and were the sources of those of the mind; and who placed the most perfect happiness which man was capable of enjoying in ease of body, and in tranquillity of mind. According to him, virtue did not deserve to be pursued for its own sake, nor was itself one of the ultimate objects of natural appetite, but was eligible on account of its tendency to prevent pain, and to procure ease and pleasure. Among our modern writers on the subject of morality, there have been some who have placed all virtue in a wise regard to our own interest: this seems to have been the opinion of Dr. Waterland, Dr. Rutherford, &c.

The system which makes virtue consist in benevolence, seems to have been the doctrine of most of those philosophers who, about and after the age of Augustus, called themselves Eclectics, who pretended to follow chiefly the opinions of Plato and Pythagoras, and who are commonly known by the name of the later Platonists. In the divine nature, according to them, benevolence was the sole principle of action, and directed the exertion of all the other attributes. The wisdom of the Deity was employed in finding out the means for bringing about those ends which his goodness suggested, as his infinite power was exerted to execute them. Benevolence, however, was a supreme and governing attribute, to which the others were subservient, and from which the whole excellency of the divine operations was ultimately derived. The whole perfection and virtue of the human mind consisted in some resemblance and participation of the divine perfections, and, consequently, in being filled with the same principle of benevolence, which influenced all the actions of the Deity. This system, as it was much esteemed by many of the ancient fathers of the church, was, after the Reformation, adopted by several divines of the most eminent piety and learning, and of the most amiable manners; particularly by Dr. Ralph Cudworth, Dr. Henry More, and Mr. John Smith, of Cambridge. Mr. Bayes has also more lately considered benevolence as the spring of the divine actions; whilst Mr. Balguy referred them all to rectitude, and Mr. Grove to wisdom. The subject was ably canvassed by these writers, and several excellent pamphlets published on the occasion. But of all the patrons of the system of benevolence, the late Dr. Hutcheson pursued it to the greatest extent, and with distinguished acuteness and accuracy. Accordingly, he defines moral goodness to be a quality apprehended in some actions, which produces approbation and love towards the actor, from those who receive no benefit from the action; and he observes, that the mix-

ture of any selfish motive diminishes or altogether destroys the merit which would otherwise have belonged to any action, and, therefore, that virtue must consist in pure and disinterested benevolence alone. Others, and particularly Dr. Cumberland, in his Law of Nature, have placed the whole of virtue in the love of God and our fellow-creatures: to this purpose he observes (De Legat. Nat. cap. i. sect. 4.), the foundation of all natural law is this, that the greatest benevolence of every rational agent towards all forms the happiest state of every and of all the benevolent, as far as is in their power, and is necessarily requisite to the happiest state which they can attain; and, therefore, the common good is the supreme law. Archdeacon Paley, deservedly esteemed as one of our most popular modern writers, defines virtue to be "the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness." According to this definition, in our judgment partly just and partly erroneous (see *Moral Philosophy*), but comprehending the sentiments of those who refer virtue to benevolence, to the will of God, and to a regard to their own happiness, the good of mankind is the subject, the will of God the rule, and everlasting happiness the motive of human virtue.

The three systems above recited comprehend the principal accounts which have been given of the nature of virtue. To one or other of these, all the other definitions or descriptions of virtue, how different soever they may appear, are easily reducible. That system which places virtue in obedience to the will of the Deity, may be counted among those which makes it consist in prudence, or among those which make it consist in propriety. When it is asked, why we ought to obey the will of the Deity, the question can admit but of two different answers. It must either be said, that we ought to obey the will of the Deity because he is a being of infinite power, who will recompense or punish: or it must be said, that, independent of any regard to our own happiness, or to rewards and punishments of any kind, there is a congruity and fitness that a creature should obey its Creator, and a limited imperfect being submit to one of infinite perfection. In the first case, virtue consists in prudence, or in the proper pursuit of our own final and supreme interest; since it is upon this account that we are obliged to obey the will of the Deity: and in the latter case, virtue must consist in propriety; since the ground of our obligation to obedience is the suitability or congruity of the sentiments of humility and submission to the superiority of the object which excites them. That system which places virtue in utility, coincides too with that which makes it consist in propriety.

All the systems above recited suppose, that there is a real and essential distinction between virtue and vice, whatever these qualities may consist in. There is a real and essential difference between the propriety and impropriety of any affection; between benevolence and any other principle of action; between real prudence and short-sighted folly or precipitate rashness. And the general tendency of all these systems is to encourage the best and most laudable dispositions and habits.

There are, however, some other systems, which seem altogether to annihilate the distinction between vice and virtue, and the tendency of which is, therefore, wholly pernicious: such are the systems of Rochefoucault, and Mandeville, who ascribes actions commonly accounted virtuous to the frivolous motive of vanity: treating every thing as vanity that has any reference to what are, or ought to be the sentiments of others; and by means of such sophistry he establishes his favourite conclusion, that private vices are public benefits.

After the enquiry concerning the nature of virtue, the

next question of importance in moral philosophy concerns the principle of *approbation* (which see), or that faculty of the mind which renders certain characters agreeable or disagreeable to us, makes us prefer one tenor of conduct to another, denominate the one right and the other wrong, and consider the one as the object of approbation, honour, and reverence, and the other as that of blame, censure, and punishment. Three different accounts have been given of this principle of approbation. According to some, we approve and disapprove both of our own actions and of those of others, from self-love only, or from some view of their tendency to our own happiness or disadvantage. (See *UTILITY*.) According to others, reason, the same faculty by which we distinguish between truth and falsehood, enables us to distinguish between what is fit and unfit both in actions and affections; according to others, this distinction is altogether the effect of immediate sentiment and feeling, and arises from the satisfaction or disgust with which the view of certain actions or affection inspires us.

Those who account for the principle of approbation from self-love, differ in their representation of its influence. According to Mr. Hobbes, and many of his followers, man is driven to take refuge in society, not by any natural love which he bears to his own kind, but because without the assistance of others, he is incapable of subsisting with ease or safety: virtue being the great support, and vice the great disturber of human society, whence the former necessarily pleases, and the latter is as naturally offensive. Moreover, a state of nature, according to Mr. Hobbes, being a state of war, so that antecedent to the constitution of civil government, there could be no safe and peaceable society among men; to preserve society was to support civil government, and the support of civil government depends upon the obedience that is paid to the supreme magistrate; hence it was inferred, that the laws of the civil magistrate ought to be regarded as the sole ultimate standard of what was just and unjust, right and wrong. See *HOBBSISM*.

In order to confute so odious a doctrine, it was necessary to prove, that antecedent to all law or positive institution, the mind was naturally endowed with a faculty, by which it distinguished in certain actions and affections the qualities of right, laudable, and virtuous, and in others, those of wrong, blameable, and vicious. This faculty was reason, which pointed out the difference between right and wrong, in the same manner in which it did between truth and falsehood. Right and wrong, it is argued, denote simple ideas, and are, therefore, to be ascribed to some immediate power of perception in the human mind, which power is the understanding. Besides, all actions have a nature; some character belongs to them, and there is something that may be affirmed of them, *i. e.* some are right and others wrong. But if our actions are, in themselves, either right or wrong, or any thing of a moral and obligatory nature, which can be an object to the understanding, it must follow that in themselves they are all indifferent. From such reasoning it follows, that morality is eternal and immutable: because right and wrong denote what actions are; and whatever any thing is, that it is not by will, or decree, or power, but by nature and necessity. No will can render any thing good and obligatory, which was not so antecedently and from eternity; or any action right, that is not so in itself. In this view of it, morality appears not to be, in any sense, factitious, or the arbitrary production of any power, human or divine; but equally everlasting and necessary with all truth and reason. Some have supposed, however, that, in men, the rational principle, or the intellectual discernment of right and wrong, should be aided by somewhat instinctive. Of this number is Dr. Price,

who, in his reasoning concerning the original of our ideas of the *beauty* and *deformity* of actions, observes, that in contemplating the actions and affections of moral agents, we have both a perception of the understanding, and a feeling of the heart; and that the latter, or the effects in us accompanying our moral perceptions, are deducible from two springs; they partly depend on the positive constitution of our natures, but the most steady and universal ground of them is the essential congruity or incongruity between the object and faculty; in other words, *placet sicut natura—virtus: Sen. or, Etiam si à nullo laudetur, natura est laudabile.* Tully. See *COMMON SENSE*.

This leads us to mention those systems which make sentiment the principle of approbation; these may be distributed into two different classes.

According to some, the principle of approbation is founded upon a sentiment of a peculiar nature, upon a particular power of perception exerted by the mind at the view of certain actions and affections; some of which affecting this faculty in an agreeable, and others in a disagreeable manner, the former are stamped with the characters of right, laudable, and virtuous; the latter with those of wrong, blameable, and vicious.

This sentiment being of a peculiar nature, distinct from every other, and the effect of a particular power of perception, they give it a particular name, and call it a moral sense.

Dr. Hutcheson, having taken great pains to prove that the principle of approbation was not founded on self-love, and that it could not arise from any operation of reason, supposed it to be a faculty of a peculiar kind, with which nature had endowed the human mind, in order to produce this particular and important effect. This power, which he called a moral sense, he supposed to be somewhat analogous to the external senses.

According to his system, the various senses or powers of perception, from which the human mind derives all its simple ideas, were of two different kinds, of which one were called the direct or antecedent, the other the reflex or consequent senses. The direct senses were those faculties from which the mind derived the perception of such species of things, *e. gr.* sounds and colours, as did not pre-suppose the antecedent perception of any other quality or object. The reflex or consequent senses, were those faculties from which the mind derived the perception of such species of things as pre-supposed the antecedent perception of some other; such as harmony and beauty.

The moral sense was considered as a faculty of this kind. That faculty, which Mr. Locke calls reflection, and from which he derived the simple ideas of the different passions and emotions of the human mind, was according to Dr. Hutcheson a direct internal sense. That faculty again, by which we perceived the beauty or deformity, the virtue or vice of those different passions and emotions, was a reflex internal sense.

Dr. Hutcheson endeavoured still farther to support this doctrine, by shewing that it was agreeable to the analogy of nature, and that the mind was endowed with a variety of other reflex senses exactly similar to the moral sense; such as a sense of beauty and deformity in external objects; a public sense, by which we sympathize with the happiness or misery of our fellow-creatures; a sense of shame and honesty, and a sense of ridicule.

To this system it has been objected, that it makes virtue an arbitrary thing, depending on the positive constitution of our minds; that right and wrong are only qualities of our minds and sensations, depending on the particular frame and structure

structure of our natures, which have no other measure or standard besides every one's private structure of mind and sensations; that it implies, that a creature with intelligence, reason, and liberty, could not have performed one good action, without that instinctive affection to which Dr. Hutcheson ascribes every good action; that it makes brutes capable of virtue, because they are capable of affections; that it estimates the excellency of characters by the strength of passions, by no means in our power; and that, upon the whole, it gives us a much less honourable idea of virtue than other systems, which make it to consist in the agreement of the actions of an intelligent being, with the nature, circumstances, and relations of things, and of which reason is the judge.

We shall only add, that the opinion of those who maintain our ideas of morality to be derived from sense, is far from being entirely modern. There were, among the ancients, philosophers, particularly Protagoras and his followers, who entertained a like opinion, but extended it much farther, that is, to all science, denying all absolute and immutable truth, and ascribing every thing to be relative to perception.

According to others, who ascribe the principle of approbation to sentiment, there is no occasion for supposing any new power of perception; nature acting in this, as in all other cases, with the strictest economy, and producing a multitude of effects from one and the same cause; and therefore, sympathy, they say, a power which has always been taken notice of, and with which the mind is manifestly endowed, is sufficient to account for all the effects ascribed to this peculiar faculty. Of this number is Dr. Adam Smith. (See SYMPATHY.) See also Smith's Theory of Moral Sentiments, passim; and particularly part i. sect. 1, 2, 3.

The term *obligation of virtue*, or moral obligation, frequently occurs among moral writers; and it is very differently defined and explained. Mr. Balguy defines obligation to be a state of the mind into which it is brought by perceiving a reason for action; but an excellent writer observes, that this is the effect of obligation perceived, rather than obligation itself.

Other writers, with Dr. Cumberland, have defined obligation the necessity of doing a thing in order to be happy: but if this be the only sense of obligation, what is meant when we say, a man is obliged to study his own happiness? In this case we can only mean, that it is right to study our own happiness, and wrong to neglect it.

Dr. Warburton maintains, that moral obligation always denotes some object of will or law, or implies some obliger; and accordingly, the word obligation signifies only the particular fitness of obeying the divine will, and cannot properly be applied to any other fitness, which is restraining the sense of the word in a manner unwarranted by the common use of it.

Moral obligation, says Dr. Paley, is like all other obligations; and all obligation is nothing more than an *inducement* of sufficient strength, and resulting, in some way, from the command of another. As the will of God is our rule, to inquire what is our duty, or what we are obliged to do, in any instance, is, in effect, to inquire, what is the will of God in that instance? This is to be determined either by his express declarations, which must be sought for in scripture, or by the light of nature, *i. e.* what we can discover of his designs and disposition from his works; and therefore it is absurd to separate natural and revealed religion from one another.

Mr. Hume, in his fourth Appendix to his Principles of Morals, has been pleased to complain of the modern scheme of uniting ethics with the Christian theology. They who

find themselves disposed to join in this complaint will do well to observe what Mr. Hume himself has been able to make of morality without this union. And for that purpose, let them read the second part of the ninth section of the above essay; which part contains the practical application of the whole treatise,—a treatise, which Mr. Hume declares to be “incomparably the best he ever wrote.” When they have read it over, let them consider, whether any motives there proposed are likely to be found sufficient to withhold men from the gratification of lust, revenge, envy, ambition, avarice, or to prevent the existence of these passions. Unless they rise up from this celebrated essay, says archdeacon Paley, with stronger impressions upon their minds, than it ever left upon mine, they will acknowledge the necessity of additional sanctions. But the necessity of these sanctions is not now the question. If they be *in fact established*, if the rewards and punishments held forth in the gospel will actually come to pass, they *must* be considered. Such as reject the Christian religion are to make the best shift they can to build up a system, and lay the foundations of morality without it. But it appears to be a great inconsistency in those who receive Christianity, and expect something to come of it, to endeavour to keep all such expectations out of sight in their reasonings concerning human duty.

Dr. Hutcheson says, a person is obliged to an action, when every spectator, or he himself, upon reflection, must approve his action, and disapprove omitting it. Obligation to act, however, and reflex approbation or disapprobation, do, in one sense, always accompany and imply one another; yet they seem as different as an act and an object of the mind, or as perception and the truth perceived. After all it may be observed, that however variously and loosely this word may be used, its primary and original signification coincides with rectitude: right implies duty in its idea, so that to perceive an action to be right, is to see a reason for the doing it in the action itself, abstracted from all other considerations whatever; and this perception, this acknowledged rectitude in the action, is the very essence of this obligation, or that which commands the approbation and choice, or binds the conscience of every rational being. See Price's Review of the Principal Questions, &c. in Morals, chap. vi.; Adams's Sermon on the Nature and Obligation of Virtue; and Paley's Principles of Moral and Political Philosophy, vol. i.

Moralists usually distinguish four principal, or, as they are vulgarly called, *cardinal virtues*; *viz.* *prudence, justice, fortitude, and temperance*: the reason of which division is founded in this: that, for a man to live virtuously and honestly, it is necessary he know what is fit to be done; which is the business of *prudence*. That he have a constant and firm will to do what he judges best; which will perfect the man, either as it refrains too violent perturbations, the office of *temperance*: or as it spurs and urges on those that are too slow and languid, which is the business of *fortitude*: or, lastly, comparatively, and with regard to human society; which is the object of *justice*.

To these four all the other virtues are referred, either as parts, or as concomitants.

Some ethical writers divide virtue into *benevolence, prudence, fortitude, and temperance*; by others it is distinguished into two branches only, *prudence and benevolence*; the former attentive to our own interest, and the latter to that of our fellow-creatures, both directed to the increase of happiness, and taking equal concern in the future as in the present: but the division that is now most common, is into duties towards *God*, as piety, reverence, resignation, gratitude, &c.; towards *other men* (relative duties), as justice, charity, fidelity, loyalty,

loyalty, &c.; towards *ourselves*, as chastity, sobriety, temperance, preservation of life, of health, &c.

VIRTUES, in the *Celestial Hierarchy*, the third rank, or choir, of angels, being that in order between *dominations* and *powers*.

To these is attributed the power of working miracles, and of strengthening and reinforcing the inferior angels in the exercise of their functions.

VIRTUES of *Plants*, in the history of *Botany*, are generally understood to be certain qualities, appropriated to every plant, and inherent in its constitution, by which it is rendered effectual in the cure of particular diseases. The discovery of such qualities was, doubtless, at first, in every country, casual, or empirical; and the history or knowledge of them traditional. Such knowledge, acquired to any considerable extent, rendered its possessor an important personage in human society; and when combined with skill in the discrimination of diseases themselves, completed the character of a physician. Such was the science of Hippocrates and Dioscorides; the former having been best versed in the knowledge of diseases; the latter in a practical acquaintance with their reputed remedies. This kind of practical knowledge makes up the whole history of ancient medicine. How soon hypothetical enquiries, or opinions, may have arisen, it is scarcely possible to learn, or even to conjecture. Among these, the supposed influence of the heavenly bodies upon the properties of plants, particularly with respect to the time when they ought to be gathered in order to be the most effectual, seems one of the most ancient hypotheses. When the imagination was once let loose, and theory took place of experience, mankind were disposed to run headlong into this, like every other superstition or folly. The complete history of such, is buried in the darkness of antiquity; but its traces are abundantly visible in the medical records of every ancient nation, especially of China, Hindoostan, Arabia, and Greece, nor are they quite effaced among the most enlightened people. Into these it is by no means our present purpose to enter.

At that memorable era in the history of mankind, emphatically termed the revival of learning, the first object of learned physicians was to inform themselves of the opinions of the ancients, on every subject connected with their science, and above all, on the Medical Virtues of Plants. No one presumed to have an opinion which was not authorized by a Greek or Latin, or perhaps an Arabian, writer. So that here the science of medicine, philosophically considered, made a complete stand, and became once more traditional and empirical.

We have, under the article ODONTITES, spoken of one method, which was systematically used, to investigate the qualities of plants; a comparison of their outward form with certain parts of the human body, on which they were supposed specifically to act. Some traces of this notion may be found in Dioscorides; in his account of the *Orchis*, for instance; which plant is indeed so remarkable for the figure of its root, that one cannot wonder at any fancies it may have excited, nor that supposed qualities, founded thereon, should have been handed down to our times. The celebrated restorative properties of Salep rest, we believe, on no firmer foundation, whatever may be the effect of the wine, sugar, or aromatics added to make that mucilaginous substance palatable, or whatever nutriment it may, as a mucilage, contain. If however there be, in this instance, some casual coincidence between the shape and the specific virtue of the plant, the same will scarcely be believed to exist between heart-shaped leaves, or roots, and the human heart; or between herbs with capillary stalks, like ferns or mosses,

and the hair of our heads. A person raging with the tooth-ache would not twice recur for a cure, to the various kinds of Toothwort, because of their notched roots, though one of them, *Laitrea Squamaria*, be ever so good an imitation of the fore teeth. Yet these, and many other vain imaginations, are found in the elaborate book of Baptista Porta. So far we might take him for an honest enthusiast. But when he purposely delineates the roots of *Doronicum* or *Arnica*, with the precise shape of a scorpion, to prove the plants a cure for its sting; we can scarcely believe he intended to deceive himself, and therefore he must have had some other aim, not worth inquiring into. Few persons will be led by this author, to believe in any connection between the hooked prickles of a Bramble, and the teeth of a Viper, or the scales of a Lily-root, and those of a Fish. We shall detain the reader no longer on this part of our subject.

Chemical analysis has proved absolutely useless to detect the properties of plants. The world is obliged to Geoffroy, Chomel, and their pupils, who with this aim have analysed nearly two thousand different species; because their labours, having led to no discovery whatever, except of their own futility, no man in future will have any inducement to waste his time in this pursuit.

Linnaeus was, if we mistake not, the first person who suggested an enquiry into the qualities of plants, on the principle of botanical affinity, or technical characters. That vegetables of one great obvious natural class, such as Grasses, Leguminous or Umbelliferous plants, should have a general agreement with each other, is probable at first sight. Each class may be expected to be throughout salutary or dangerous, and they generally prove so, with certain limitations. The Darnel is almost a solitary instance of any thing pernicious among Grasses; Umbellate plants in a dry soil are aromatic and wholesome; in a wet one, acrid and highly dangerous. The *Convulvulus* genus affords several eminently purgative roots, nor would any rational botanist venture to use them without caution; though the operations of cookery render one of this genus, *C. Batatas*, wholesome and delicious. The acrid qualities of one species of *Euphorbia*, as being a most decidedly marked, and very peculiar, genus, are found in more or less activity, in all. Agreement in the parts of fructification is therefore, with great reason, set forth by the learned author of the sexual system, as the index to a similarity of properties. Thus the *Stellate* are diuretic, the *Asperifoliae* emollient, the *Luride* narcotic and dangerous, the *Bicornes* astringent, the *Verticillate* fragrant and harmless, the *Compositae* greatly meliorated by culture and cookery. All these, though named from various characters, are distinguished by their fructification. The different insertion of parts sometimes indicates a difference of quality, of which the class *Icosandra* is a memorable and often repeated example. The insertion of its *stamens* into the *calyx*, is attended with a wholesome fruit, and the same insertion in other classes, may be safely trusted in that respect. Plants which have a *necessary* distinct from the *petals*, are always to be mistrusted. So are milky plants in general, yet not without exception. A dry soil usually renders plants aromatic and wholesome, and abounds most with such; moisture, or much wet, nourishes viscid, acrid, poisonous tribes, of various descriptions. Sweet-smelling and agreeably-flavoured vegetables are, for the most part, wholesome, for it were a sort of treachery in Nature to have made them otherwise. Fetid bitters and nauseous fruits are revolting to our senses, and warn us of danger. Linnaeus observes that a pale colour indicates insipidity, at least in the herbage; yellow is a sign of biternels or acrimony;

mony; red, of acidity or astringency; black, of a noxious quality. Even this last however is overruled by the insertion of the flames into the calyx; witness *Prunus* and *Ribes*.

Such are a few of the hints given by Linnæus. They are well worthy of consideration, and may be extended or modified by practical observation. Exceptions, of course, will prefer themselves, but scarcely more than occur in any other department of natural science.

It is hardly necessary to say that the above rules relate exclusively to the human constitution. Some animals feed on what are fatal poisons to others. The Goat and Deer browse on the *Clematis*, which would blister our throat, or even our skin; and delight in the nauseous virulent seed of the Horse Chestnut. Insects thrive on the most bitter or burning milky herbs or shrubs, which no quadruped could taste with impunity. Nature teaches every animal what is salutary to itself, and what is dangerous; but man is capable of reason and science, to make experiments and observations, and to enlarge the sphere of his knowledge by drawing general conclusions.

VIRTUOSO, A man possessed of talents in any of the fine arts is called a virtuoso, but particularly in music, where it usually implies a professor of talents.

Among us, the term seems appropriated to those who apply themselves to some curious and quaint, rather than immediately useful art or study; as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRTZ, in *Geography*, a lake of Russia, in the government of Riga, about forty miles in circumference; 96 miles N.N.E. of Riga.

VIRUCINATES, in *Ancient Geography*, a people of Vindelicia, denominated Rucinates by Hardouin, who is justified in this reading by Ptolemy.

VIRUELA, in *Geography*, a town of Spain, in Aragon; 6 miles from Tarracona.

VIRVESCA. See **BIRVESCA**.

VIRULENT, a term applied to any thing that yields a virus, that is, a contagious or malignant pus.

The gonorrhœa virulenta is what we popularly call a clap.

VIRUNI, in *Ancient Geography*, a people of Germany, placed by Ptolemy with the Teutonari, between the country of the Saxons and that of the Suevi.

VIRUNUM, a town situated in the northern part of Germany, probably belonging to the Viruni, and supposed by Cluvier to be the present Waren, in Mecklenburg.—Also, a town of Norica, or ille of Norica, in the middle of the Danube, upon the route from Aquileia to Lauriacum, between Santicum and Candalica, according to Anton. Itin. In the table of Peutinger it is named Varenum. It is thought that the emperor Claudius established a colony in this place. Cellarius supposes that this is the present Volckmarck, in Carinthia.

VIRUPAKSHA, in *Mythology*, a name of the Hindoo deity *Siva*; which see. It is said to mean *with three eyes*, similar to *Trilokan*; which see. The epithet *Sri*, or divine, is commonly prefixed to this name. See **SRI** and **SRI-VIRUPAKSHA**.

VIS, or **VISAY**, in *Commerce*, a weight in the East Indies, which is the eighth part of the maund. See **MAUND**.

VIS, in *Physiology*, a term employed to denote the vital powers; thus, *vis insita* is the contractile power of a muscle, so named because it is inherent in the organization of the part, and not dependent on any other influence: it is equivalent to *vis irritabilis*. *Vis nervosa* is that power of contraction which depends on the nerves. *Vis vite* is a general expression for the vital power altogether. See **LIFE**, **MUSCLE**, and **NERVOUS System**.

VIS, a Latin word, signifying force or power; adopted by physical writers, to express divers kinds of natural powers or faculties. See **FORCE**.

This is active and passive; the *vis activa* is the power of producing motion; the *vis passiva*, that of receiving or losing it. The *vis activa* is again subdivided into *vis viva* and *vis mortua*.

Vis Absoluta, or *absolute force*, is that kind of centripetal force which is measured by the motion that would be generated by it in a given body, at a given distance, and depends on the efficacy of the cause producing it.

Vis Acceleratrix, or *accelerating force*, is that centripetal force which produces an accelerated motion, and is proportional to the velocity which it generates in a given time.

This is different at different distances from the same central body; and depends not on the quantity of matter that gravitates, being equal in all sorts of bodies at equal distances from the centre. See **ACCELERATION**.

Vis Impressa is defined by sir Isaac Newton to be the action exercised on any body to change its state, either of rest or moving uniformly in a right line.

This force consists altogether in the action; and has no place in the body after the action has ceased. For the body perseveres in every new state by the *vis inertia* alone.

The *vis impressa* may arise from divers causes; as from percussion, pressure, and centripetal force.

Vis Inertia, *power of inactivity*, is defined by sir Isaac Newton to be a power implanted in all matter, by which it resists any change endeavoured to be made in its state, *i. e.* whereby it becomes difficult to alter its state, either of rest or motion.

This power, then, coincides with the *vis resistendi*, power of resisting, by which every body endeavours, as much as it can, to persevere in its own state, whether of rest or uniform rectilinear motion; which power is still proportional to the body, and only differs from the *vis inertia* of the mass, in the manner of conceiving it.

Bodies only exert this power in changes brought on their state by some *vis impressa*, force impressed on them. And the exercise of this power is, in different respects, both resistance and impetus; resistance, as the body opposes a force impressed on it to change its state; and impetus, as the same body endeavours to change the state of the resisting obstacle. Phil. Nat. Princ. Math. lib. i.

The *vis inertia*, the same great author elsewhere observes, is a passive principle, by which bodies persevere in their motion, or rest, receive motion, in proportion to the force impressing it, and resist as much as they are resisted.

For the effect of the *vis inertia*, in resisting and retarding the motion of bodies, &c. see **RESISTANCE**.

Vis Insita, or *innate force* of matter, is a power of resisting, by which every body, as much as in it lies, endeavours to persevere in its present state, whether of rest or of moving uniformly forward in a right line.

This force is ever proportional to that body whose force it is, and differs nothing from the *vis inertia* but in our manner of conceiving it.

Vis Centripeta. See **CENTRIPETAL Force**.

Vis Centrifuga. See **CENTRIFUGAL Force**.

Vis Motrix, or *moving force*, of a centripetal body, is the tendency of the whole body towards the centre, resulting from the tendency of all the parts, and is proportional to the motion which it generates in a given time, so that the *vis motrix* is to the *vis acceleratrix*, as the motion to the celerity; and as the quantity of motion in a body is estimated by the product of the celerity into the quantity of matter, the

the *vis motrix* arises from the *vis acceleratrix*, multiplied by the quantity of matter.

The followers of Leibnitz use the term *vis motrix* for the force of a body in motion, in the same sense as the Newtonians use the term *vis inertia*; this latter they allow to be inherent in a body at rest; but the former, or *vis motrix*, is a force inherent in the same body whilst in motion, which actually carries it from place to place, by acting upon it always with the same intensity in every physical part of the line which it describes. See FORCE and MOTION.

Vis Viva, in *Mechanics*, a term used by Leibnitz and his disciples for *force*, (which see,) which they distinguish into two kinds, *vis mortua*, and *vis viva*; understanding by the former any kind of pressure, or an endeavour to move, insufficient to produce actual motion, unless its action on a body be continued for some time, and by the latter, that force or power of acting which resides in a body in motion.

VISAKNA, or SALZBURG, in *Geography*, a town of Transylvania, famous for its salt-works; 4 miles N. of Hermanstadt.

VISANDONE, a town of Italy, in Friuli; 5 miles S.W. of Udina.

VISBECK, or FISCHBECK, a town of Westphalia, in the county of Schauenburg, with an imperial free Lutheran abbey for ladies, on the Wefer; 8 miles E. of Rinteln.

VISBURGII, in *Ancient Geography*, a people of Germany, N. of the Hercynian forest. Ptol. According to Cluvier, they are the same people with those placed by Ptolemy in Sarmatia, and named Burgiones. He thinks they inhabited the mountains of Sarmatia and the Vistula, and that from the name of this river they were called Thi-Wisselburges, which the Latins corrupted into Visburgi, and others into Burgiones.

VISCAGO, in *Botany*, from *viscum*, bird-lime, and *ago*, to produce or bear, a name borrowed by Dillenius, in Hort. Elth. 416, from Cæsalpinus and Camerarius, and applied to such species of the old genus *Lychnis*, as have several cells in the capsule. These come chiefly under SILENE; see that article. The above name alludes to the viscosity of these plants, and is synonymous with their English appellation, Catchfly.

VISCAGO is also used by some pharmaceutic writers to express a mucilage.

VISCARDO, in *Geography*, a sea-port town on the N. coast of Cephalonia, opposite to the island of Teaki, which gives name to a narrow strait that separates the two islands.

VISCARIA, in *Botany*, a word of the same import as VISCAGO; see that article. It was originally applied by Tabernæmontanus to the common Lobel's Catchfly, *Silene Armeria*; and has been retained by Linnæus, as the specific name of the German Catchfly, *Lychnis Viscaria*. He always wrote it with a capital letter, as if it had previously been used for a generic or proper name, which not being the case, it had better have been considered as an adjective, and made *viscata*.

VISCERA, in *Anatomy*, a term originally applied to the bowels or intestines, but now used indiscriminately for the organs contained in any cavity of the body. Thus, the heart, lungs, &c. are called the thoracic viscera; the liver, spleen, pancreas, stomach, and intestines, the abdominal viscera, &c.

The term is formed of *vesci*, to feed; by reason eatables, called in Latin *vesca*, undergo divers preparations in the viscera.

The word is also frequently used singularly, *viscus*, to express some particular part of the entrails, because the word *entrails* has no singular.

VOL. XXXVII.

The different internal organs, comprised under the general designation of viscera, are described under their respective heads: see HEART, LUNGS, THYMUS, STOMACH, INTESTINES, LIVER, SPLEEN, PANCREAS, EPIPLOON, and GENERATION.

We have only to add, in the present article, an explanation of the references in the plates representing the anatomy of the viscera.

ANATOMY (*Viscera*). Plate I.

Fig. 1. is a front view of the chest and abdomen in a newly born child; the sternum and neighbouring part of the ribs, with the corresponding pleuræ, the front of the abdominal parietes and diaphragm, having been cut through and removed.

1. Os hyoides.
2. 2. Portion of the sterno-hyoideus and omo-hyoideus muscles.
3. 3. Portion of the sterno-thyroideus turned back.
4. Thyroid cartilage.
5. 5. Hyo-thyroideus.
6. 6. Thyroid gland.
7. Trachea.
8. 8. Portion of the sterno-cleido-mastoideus.
9. 9. Clavicle.
10. 10. First rib.
11. 11. Ninth rib.
12. Thymus.
- 13-15. Right lung: 13. Its superior lobe; 14. Middle lobe; 15. Inferior lobe.
16. 17. Left lung: 16. The superior lobe; 17. The inferior lobe.
18. Pericardium.
19. 19. Diaphragm.
20. 21. Liver: 20. The right lobe; 21. The left lobe.
22. Suspensory ligament of the liver.
23. The umbilical vein turned back.
24. The spleen.
25. 26. Great omentum: 25. Its portion lying on the mesocolon; 26. Loose portion.
27. 27. Arch of the colon.
28. Left portion of the colon.
29. The right portion.
30. 30. The jejunum, filled partly with meconium, partly with air.
31. 31. The ileum.
32. Urinary bladder, with its fundus turned forwards.
33. 33. Umbilical artery.
34. Utraculus.
35. Internal surface of the peritoneum.
36. 36. Internal jugular vein.
37. 37. Thyroid vein.
38. 38. Subclavian vein.
39. 39. Common carotid artery.
40. 40. Subclavian artery.
41. Œsophagus.

Fig. 2. exhibits the same view as the last, except that the thymus and pericardium have been removed, and the liver turned up towards the right, so as to expose the stomach.

- 1-4. The heart: 1. Appendix of the right auricle; 2. Pulmonary ventricle; 3. Appendix of the left auricle; 4. Aortic ventricle. (The outline of the heart is marked by a dotted line on the surface of the liver.)
5. Pulmonary artery.

K k

6. Aorta.

VISCERA.

6. Aorta.
7. Left subclavian artery.
8. Left carotid.
9. Arteria innominata.
10. Right carotid.
11. Right subclavian artery.
12. Superior vena cava.
13. 14. Right internal jugular vein: 13. Portion in the chest; 14. Portion in the neck.
15. Right subclavian vein.
16. 17. Left internal jugular vein: 16. Thoracic portion; 17. Cervical portion.
18. Left subclavian vein.
- 19-22. Concave or under surface of the liver: 19. Right lobe; 20. Square portion; 21. Left lobe; 22. Lobulus Spigelii, seen through the small omentum.
23. Part of the superior or convex surface.
24. 24. Thin edge.
25. 25. Thick edge.
26. Umbilical vein cut through and turned back.
27. The pons covering the notch of the umbilical vein.
28. Gall-bladder.
29. Part of the diaphragm.
30. Spleen.
31. Œsophagus entering the stomach.
32. Œsophagus in the neck.
33. Stomach.
34. Pylorus.
35. Duodenum.
36. 36. Transverse portion of the colon.
37. Right portion of the colon. The other parts are the same as in the preceding figure.

ANATOMY (*Viscera*). Plate II.

Two views from a subject of the same age, as that from which the figures of *Plate I.* are taken, to shew the more deeply seated parts.

Fig. 1. The heart and large vessels only are seen in the chest, the other parts having been removed. The small intestine is removed from the abdomen, and the arch of the colon is turned upwards.

1. Right or pulmonary ventricle of the heart.
2. Aortic or left ventricle.
3. Appendix of the right auricle.
4. Appendix of the left auricle.
5. Pulmonary artery.
6. Aorta.
7. Arteria innominata.
8. Right carotid.
9. Right subclavian.
10. Left carotid.
11. Left subclavian.
12. Inferior vena cava covered by the pericardium.
13. Superior vena cava.
14. Right internal jugular vein.
15. Left internal jugular vein.
16. Trachea.
17. 17. Thyroid gland.
18. Thyroid cartilage.
19. 19. Thyro-hyoideus.
20. 20. Sterno-thyroideus detached and turned back. (The sterno-hyoideus is removed.)
21. 21. Part of the sterno-cleido-mastoideus.
22. 22. Clavicle.
23. 23. First rib.
24. 24. Second rib.

25. 25. Cut edge of the diaphragm.
26. Arch of the colon.
27. Right portion of the colon.
28. Part of the left colon.
29. Transverse mesocolon.
30. Stomach seen obscurely through the mesocolon.
31. Left or great extremity of the stomach.
32. Spleen.
33. Right kidney.
34. Right portion of the colon.
35. Cæcum and appendix vermiformis.
36. End of the ileum.
37. Commencement of the jejunum.
38. Mesentery.
39. 39. Sigmoid flexure of the colon.
40. Its mesocolon.
41. Rectum.
42. Urinary bladder turned forwards and downwards.
43. 43. Umbilical arteries.
44. Urachus.

Fig. 2. All the thoracic viscera are removed; also the diaphragm, and the small intestine, excepting the duodenum. The peritoneum is cleared from the kidney and larger vessels.

1. 1. Thyroid gland.
2. 2. Portion of the sterno-cleido-mastoideus.
3. 3. Sterno-thyroideus detached and turned back. (The sterno-hyoideus is removed.)
4. 4. Thyro-hyoideus.
5. Thyroid cartilage.
6. 6. Clavicle.
7. Trachea.
8. 8. Œsophagus; its longitudinal muscular fibres are exposed.
- 9-11. Stomach moderately distended.
9. The cardia.
10. The blind pouch.
11. Pylorus.
- 12-14. Duodenum: 12. The first curvature; 13. The second; 14. The third.
15. Pancreas.
16. Spleen.
17. Right kidney.
18. Left kidney.
19. Right renal capsule.
20. Portion of diaphragm.
21. Arch of the aorta with its three great branches.
See *fig. 1.* N^o 7. 10. 11.
22. Canalis arteriosus.
23. Descending thoracic aorta.
24. Descending abdominal aorta.
25. Right iliac artery.
26. Left iliac artery.
30. 30. Spermatic artery and vein.
31. 31. Ureter.
32. The cut orifice of the rectum.
33. Urinary bladder turned down.
34. 34. Umbilical artery.
35. Urachus.
36. 36. First rib.

ANATOMY (*Viscera*). Plate III.

Views of the thoracic and abdominal viscera from behind.

Fig. 1. The muscles of the neck and back, the back of

VISCERA.

of the ribs, and the spinous processes of the vertebrae, are removed.

1. 1. First rib.
2. 2. Eleventh rib.
3. 3. The fifth rib, with the diaphragm and abdominal muscles still attached. The ribs are gently drawn aside, to expose the lungs.
4. 4. Sixth cervical vertebra.
5. 5. Sacrum.
6. 6. Gluteus maximus.
7. 7. Gluteus medius.
8. 8. The vertebral theca of the dura mater.
9. The same, covering the cauda equina.
10. 10. The scapulae a little drawn aside.
11. 12. The left lung: 11. Superior lobe; 12. Inferior lobe.
- 13—15. Right lung: 13. Superior lobe; 14. Middle lobe; 15. Inferior lobe.
- 16—18. Diaphragm: 16. Covering the left lobe of the liver, stomach, and spleen; 17. Covering the right lobe; 18. 18. Attached to the twelfth rib.
19. Right renal capsule.
20. Left kidney.
21. Right kidney.
22. Inferior surface of the right lobe of the liver.
23. Left part of the colon.
24. Sigmoid flexure of the colon.
25. Portion of the ileum.

Fig. 2. The vertebral column, together with part of the os innominatum, is removed.

1. 1. First rib.
2. 2. Eleventh rib.
3. 3. Scapula drawn aside.
4. 4. Internal jugular vein.
5. 5. Common carotid artery.
6. 6. Subclavian artery.
7. 7. Inferior thyroid artery.
8. Part of the aortic arch.
9. 10. Descending aorta: 9. Thoracic; 10. Abdominal.
11. Division of the aorta into the common iliacs.
12. Middle sacral artery. The intercostal, renal, and lumbar arteries are not numbered.
13. Vena azygos cut off.
14. Inferior vena cava.
15. Left renal vein.
16. Right renal vein, double in this subject.
17. Union of the iliac veins to form the inferior cava.
18. Par vagum.
19. 19. Thyroid gland; the blood-vessels are drawn aside by a hook on the left side.
20. Lower part of the pharynx.
21. 21. Thyroid cartilage.
22. Oesophagus.
23. Oesophagus entering the stomach.
24. Part of the stomach.
26. 27. Superior and inferior lobes of the left lung.
28. 29. 30. Superior, middle, and inferior lobes of the right lung.
31. 31. 31. Diaphragm.
32. 32. Abdominal muscles.
33. Spleen.
34. Part of the pancreas.

12. 13. 14. Orifices of its three great superior branches.

VISCERA, *Wounds of the*. See WOUNDS.

VISCERALIA, a term used by physicians to denote such medicines as impart strength and firmness to the sanguineous viscera, such as the liver, spleen, &c.

VISCERATIONES, among the Romans, a feast consisting of the entrails of animals, given to the people at the burial of great men in Rome.

VISCHAR, in *Geography*, a town of Persia, in the province of Irak; 20 miles S.S.E. of Hamadan.

VISCHER'S ISLAND, a small island in the Pacific ocean, near the E. coast of Morty. N. lat. 2° 21'. E. long. 128° 39'.

VISCHERA, a river of Russia, which runs into the Kama, 16 miles N. of Solikamsk, in the government of Perm.—Also, a river of Russia, which runs into the Vitcheгда, 20 miles E. of Nebdankoi, in the province of Utiug.

VISCHMA, a town of Russia, in the government of Tobolsk; 268 miles S.W. of Tobolsk. N. lat. 62° 36'. E. long. 60° 14'.

VISCHNEIVOLOGOK, a town of Russia, in the government of Tver, on a canal, which forms a communication between the Msta and the Tvertza; 60 miles N.W. of Tver. This place is remarkable for the extensive canals on which the great inland navigation of Russia is carried on. The communication just mentioned is by a navigable canal of at least 500 versts, uniting the Caspian with the Baltic. N. lat. 57° 8'. E. long. 34° 54'.

VISCIDITY, or VISCOSITY, the quality of something that is *viscid*, or *viscous*, i. e. glutinous and sticky, like bird-lime; which the Latins call by the name *viscus*.

Viscid bodies are those which consist of parts so implicated within each other, that they resist, a long time, a complete separation, and rather give way to the violence done them by stretching, or extending each way.

The too great viscosity of foods has very ill effects; thus meals, or farinae not fermented, jellies, &c. of animals, tough cheese, or curd too much pressed, produce a weight, or oppression in the stomach; wind, yawnings, crudities, obstructions of the minuter vessels in the intestines, &c. Hence an inactivity of the intestines themselves, a swelling of the abdomen; and hence a viscosity of the blood, from the reunion of the viscid particles; obstructions of the glands, palenets, coldness, tremors, &c.

VISCO, in *Geography*, a village of Italy, in Friuli; 2 miles E. of Palma Nuova.

VISCONTI, CATERINA, of Milan, in *Biography*, an opera singer of great reputation in her day, arrived here in 1742, at the beginning of lord Middlesex's regency, and performed with Monticelli in the operas of Galuppi and Lampugnani, &c. till the year 1745, when the breaking out of the rebellion occasioned an interdict against the whole opera band, vocal and instrumental.

The Visconti had a shrill flexible voice, and could run divisions faster than the violins of those times could follow her. And *bravura* or execution was then so new, that she pleased more in rapid songs than she could have done in those that required high colouring and pathos, if she had been possessed

of either. She was so fat, that her age being the subject of conversation in a company where lord Chichesterfield was present; when a gentleman, who supposed her to be much younger than the rest, said she was but two-and-twenty; his lordship, interrupting him, said, "you mean *stone*, sir, not years." She was engaged a second time in the Haymarket for the season of 1753 and 1754; but having been heard in her better day, her talents were pronounced on the decline, which occasioned a declension in the public favour. And at the end of a heavy season she gave way to Mingotti, who, in the autumn of 1754, revived the favour of our lyric theatre, and for two or three seasons gave it a considerable degree of splendour.

VISCOUNT. See VICOUNT.

VISCUM, in *Botany*, so called by Pliny, and by some Latin writers *Viscus*, derives its name from the Greek *ἴσος*, altered by the Æolians into *βισκος*. The transition is easy enough to the Latin, though scarcely to the English appellation of this plant, Milletoe, so famous in the history of our superstitious and barbarous ancestors. We have hinted, under the biographical article *SITHORON*, that this learned traveller and botanist, though he reckoned our *V. album*, still called *ἴσος*, to be the *ἴσος* of Dioscorides, nevertheless suspected latterly that the *Loranthus europæus* might have been considered by the ancients as a more genuine or perfect kind. The latter grows in Arcadia on the Oak; our *Viscum album* on the Silver Fir only. Hence perhaps the Druids, not knowing the *Loranthus*, or true Milletoe of the Oak, attached such importance to the particular plants of the *Viscum* found on this tree; in which over-curious persons, who see with the eyes of tradition and prejudice, rather than with their own natural organs, still affect to perceive something peculiar. We submit this point to the consideration of the learned, not being aware of its having ever been suggested by any one before.—Linn. Gen. 517. Schreb. 68c. Willd. Sp. Pl. v. 4. 737. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1074. Prodr. Fl. Græc. Sibth. v. 2. 256. Ait. Hort. Kew. v. 5. 371. Swartz Ind. Occ. 266. Pursh 114. Juss. 212. Tourn. t. 380. Lamarck Dict. v. 3. 55. Illustr. t. 807. Gærtn. t. 27.—Clafs and order, *Dioecia Tetrandria*. Nat. Ord. *Aggregateæ*, Linn. *Caprifolia*, Juss.

Gen. Ch. Male, *Cal.* none. *Cor.* Petals four, calyx-like, ovate, equal, dilated and connected at the base. *Stam.* Filaments none; anthers four, oblong, pointed, dotted, each attached to the disk of one of the petals.

Female, *Cal.* a slight four-cleft border. *Cor.* Petals four, superior, small, ovate, sessile, calyx-like, deciduous. *Pist.* Germen inferior, oblong, three-sided, crowned with the obsolete calyx; style none; stigma obtuse, scarcely notched. *Peric.* Berry globose, smooth, of one cell. *Seed* solitary, heart-shaped, compressed, obtuse, fleshy, lodged in viscid pulp.

Ess. Ch. Male, Calyx none. Petals four, calyx-like, dilated and cohering at their base. Anthers sessile upon the petals.

Female, Calyx a slight border. Petals four, calyx-like, dilated at the base. Style none. Berry inferior, with one seed.

Obf. The analogy, or natural affinity, of this genus has always induced us to follow Jusseu, rather than Linnaeus, in denominating the principal, or only, integument of its flowers a *corolla*, rather than a *calyx*. All the known species are parasitical, and though probably to be cultivated, if sown on the branches or stems of particular trees, like our only English one, provided we could have their berries fresh, none of them has yet been introduced into any garden, except that species. Their habit is rigid and coriaceous;

leaves,

leaves, if present, simple, undivided, entire, on short stalks, opposite as well as the branches. *Flowers* in axillary heads or spikes, sessile or stalked, generally greenish and inconspicuous. The species are by no means well understood. We follow Willdenow, who has given the best account of them.

1. *V. album*. Common Mistletoe. Linn. Sp. Pl. 1451. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1470. Mill. Illustr. t. 87. Woodv. Suppl. t. 270. (Vifcum; Matth. Valgr. v. 2. 161. Camer. Epit. 555. Ger. Em. 1350).—Leaves lanceolate, obtuse, ribbles. Stem forked. Flowers five together, in terminal, sessile heads.—Found throughout Europe, on the branches of old apple-trees, hawthorns, lime-trees, oaks, Scotch fir, or the silver fir, as above mentioned, flowering in the spring, and ripening its large white *berries* late in autumn. The plant forms large, smooth, perennial, bushy tufts, of a pale green, becoming yellowish, and therefore most conspicuous, in winter. The *stems* are round, repeatedly forked. *Leaves* about an inch, or inch and half, long, thick and leathery, smooth, tapering down into short thick *footstalks*. *Flowers* crowded, yellowish. *Antlers* singularly and beautifully dotted, almost as large as the *petals* on which they lie. The sweetish viscid pulp of the pearly *berries* makes an indifferent sort of bird-lime. This Mistletoe, the golden bough of Virgil, which was Æneas's passport to the infernal regions, and the sacred plant of the Druids, still retains some respect in our churches and kitchens at Christmas, intermixed with Holly, which last, if we mistake not, is Virgil's *Acanthus*.

2. *V. macrostachyon*. Long-spiked Mistletoe. Jacq. Coll. v. 2. 109. t. 5. f. 3. Willd. n. 2.—Leaves linear-lanceolate, obtuse, ribbles. Spikes axillary, slender, many times longer than the leaves. Flowers remote.—Gathered by Jacquin on trees in Martinico. *Branches* and *leaves* smooth, not unlike the foregoing, but the long, slender, articulated *spikes* abundantly distinguish this species. The *flowers* are either opposite, or solitary, having but three *petals*, at least the female ones, according to Jacquin.

3. *V. orientale*. East Indian Mistletoe. Willd. n. 3.—Leaves elliptic-oblong, obtuse, three-ribbed; tapering at the base. Stalks axillary, aggregate, about three-flowered.—Native of the East Indies. We have specimens from the author, as well as from the Rev. Dr. Rottler. The *branches* are angular when dry. *Leaves* an inch or more in length, and full half as broad, on short stalks. *Flowers* either solitary or three together, on very short stalks, as well as crowded into a sort of axillary whorls. *Berries* red. Willdenow.

4. *V. pauciflorum*. Hoary Cape Mistletoe. Linn. Suppl. 426. Thunb. Prodr. 31. Willd. n. 4.—Leaves oblong, obtuse, three-ribbed, hoary, smooth; tapering at the base. *Flowers* axillary, solitary.—Gathered by Thunberg, at the Cape of Good Hope. The plant is described as hoary, though not downy. The ribs do not extend beyond the middle of the *leaf*, and escaped the observation of the younger Linnæus. We have seen no specimen.

5. *V. rubrum*. Red Mistletoe. Linn. Sp. Pl. 1451. Willd. n. 5. ("V. foliis longioribus, baccis rubris; Catef. Car. v. 2. t. 81.")—Leaves obovato-lanceolate, obtuse. Spikes axillary, whorled.—Found upon trees in Carolina. *Catef* alone appears to have seen this species.

6. *V. purpureum*. Purple Mistletoe. Linn. Sp. Pl. 1451. Willd. n. 6. ("V. foliis latioribus, baccis purpureis, pediculis infidentibus; Catef. Car. v. 2. t. 95.")—Leaves obovate, obtuse, obscurely three-ribbed. Spikes axillary, shorter than the leaves. *Flowers* opposite.—Native of Carolina. *Berries* purple.

7. *V. buxifolium*. Box-leaved White Mistletoe. Willd. n. 7. (V. purpureum β ; Linn. Sp. Pl. 1451. V. baccis niveis racemosis, foliis buxi luteis; Plum. Ic. 256. t. 258. f. 3.)—Leaves obovate, obtuse, single-ribbed. Spikes axillary, nearly the length of the leaves. *Flowers* opposite.—Native of trees in the West Indies. *Berries* white. We suspect this may be the first *Vifcum* in Browne's Jamaica, p. 356, which he mistook for the *verticillatum* of Linnæus, a widely different plant. But Browne's specimen has occasionally traces of three ribs in the *leaves*, and he has confounded with it the *flavens* of Swartz.

8. *V. myrtilloides*. Bilberry Mistletoe. Willd. n. 8.—Leaves obovate, obtuse, five-ribbed. Spikes solitary, axillary. *Flowers* whorled.—Native of trees in Martinico. *Leaves* an inch long, coriaceous, with five ribs, the lateral ones least conspicuous. *Spikes* opposite, rather longer than the *footstalks*. Willdenow. We have West Indian specimens answering to these characters, except that the *leaves* are three inches long, and rather elliptic-lanceolate than obovate.

9. *V. rotundifolium*. Round-leaved Cape Mistletoe. Linn. Suppl. 426. Thunb. Prodr. 31. Willd. n. 9.—Leaves nearly orbicular, acute, ribbles. *Flowers* somewhat whorled.—Found by Thunberg on trees at the Cape of Good Hope. Willdenow says the *flowers* are either solitary, or simple, aggregate, axillary stalks; or many together, on solitary stalks.

10. *V. antarcticum*. Antarctic Mistletoe. Forst. Prodr. 70. Willd. n. 10.—Leaves oblong, tapering at each end, obtuse, ribbles. Clusters terminal, of about five flowers.—Native of trees in New Zealand.

11. *V. capense*. Naked Cape Mistletoe. Linn. Suppl. 426, excluding the synonym. Willd. n. 11. Thunb. Prodr. 31.—Stem leafless, obscurely quadrangular, roughish, rugose. *Flowers* whorled, sessile.—Gathered at the Cape of Good Hope by Dr. Sparrmann. The *stem* is much branched, jointed, roughish to the touch, each joint crowned with two scales, like a *Salicornia*. *Leaves* none. *Antlers* two or four, dotted with minute excavations. *Berries* opposite, sometimes three together, sessile, crowned with a small, angular, hardly four-cleft, *calyx*.

12. *V. vaginatum*. Sheathed Mistletoe. Willd. n. 12.—Stem leafless, quadrangular. *Branches* compressed, semi-cylindrical. *Joints* sheathing.—Gathered by Humboldt and Bonpland, on trees on the mountains of Mexico. *Stem* round below, angular upwards. *Joints* each crowned with a tubular permanent sheath. *Leaves* none. *Berries* in the bottom of the sheaths, opposite, solitary. Willdenow.

13. *V. opuntioides*. Wedge-jointed Mistletoe. Linn. Sp. Pl. 1452. Willd. n. 13; excluding Plumier's synonym. (V. opuntioides, ramulis compressis; Sloane Jam. v. 2. 93. t. 201. f. 1.)—Stem profliferous, much branched, leafless. *Joints* wedge-shaped, furrowed, compressed.—Native of trees in Jamaica, and the Isle of Bourbon. The flat *joints* at once distinguish this species. Each *joint* is an inch or inch and half long, of a yellowish-green. *Flowers* small, terminating each joint, in pairs. *Berries* white, resembling our English Mistletoe.—Sloane. Plumier's t. 258. f. 1, must surely be *Cañus pendulus*, Ait. Hort. Kew. v. 3. 178, which is *Cafsyba baccifera* of Solander, in Mill. Illustr. t. 29.

14. *V. obscurum*. Elliptical Cape Mistletoe. Thunb. Prodr. 31. Willd. n. 14.—Leaves elliptical, smooth. *Stem* shrubby.—Gathered at the Cape of Good Hope, on trees, by Thunberg. Nobody else appears to have seen it.

15. *V. flavens*. Yellowish Mistletoe. Swartz Ind. Occ. 266. Willd. n. 15. Pursh n. 1? (V. aliud racemosum, foliis

foliis latifimis; Plum. Ic. 256. t. 258. f. 4. V. racemosum; Aubl. Guian. v. 2. 895.—Leaves ovate, five-ribbed, veiny. Spikes axillary, from one to four at each side. Flowers whorled.—Found on trees in the West Indies, especially near the sea. Two feet high, with round, livid, roughish branches. Leaves two inches or more in length, bluish, of a livid hue. Spikes stalked, sometimes solitary.

16. *V. latifolium*. Broad-leaved Mistletoe. Swartz Ind. Occ. 268. Willd. n. 16.—Leaves roundish-ovate, acute, flat, obscurely veined. Spikes axillary, stalked, solitary or in pairs.—On trees in Jamaica. Two feet high, smooth. Leaves contracted at each end, brownish-green, on very short stalks. Flowers minute. Berries oblong.

17. *V. verticillatum*. Whorled Mistletoe. Linn. Sp. Pl. 1452. Willd. n. 17; excluding the synonyms of Browne and Plumier. (V. ramulis et foliis longis, densissimis, striatis et radiatis; Sloane Jam. v. 2. 93. t. 201. f. 2.)—Ultimate branches aggregate, imperfectly whorled, toothed at the end.—Native of Jamaica, where it hangs from the branches of trees. The main stem is divided, angular, striated, smooth, beset here and there with whorls of simple spreading branches, an inch and half or two inches long, destitute of leaves, tipped with a few scales. Nothing is known of the fructification, so the genus is very doubtful. It may turn out a *Castus*, or at least of the same genus as *C. pendulus* above-mentioned under n. 13. What we here describe is, however, the plant intended by Linnæus, though he has confounded with it one altogether different, and has thence perverted the specific character.

18. *V. capitellatum*. Capitate Mistletoe.—Leaves wedge-shaped, concave, obtuse. Berries capitate, on axillary stalks.—Gathered in Ceylon by Koenig, who sent specimens to Linnæus, but the plant has remained hitherto undescribed, though certainly very distinct. The stems are three inches high, branched, roughish to the touch. Leaves an inch long at most, smooth, fleshy. Flower-stalks rather shorter, crowned with two thick bractæe under the little head of four or five flowers. Berries oval, crowned with a blunt calyx.

Willdenow rightly observes that *V. terrestre*, Linn. Sp. Pl. 1452, is no other than *Lysimachia stricta*, Willd. Sp. Pl. 818. Ait. Hort. Kew. v. 1. 314. (L. bulbifera; Curt. Mag. t. 104.)—Kalm gathered it in Philadelphia, and whether the mistake were his own, or his great preceptor's, it is one of the most reprehensible that ever was made.

Several species of *Viscum* probably are still undescribed among the botanical treasures of the West, and perhaps East, Indies.

Viscum, in Gardening, furnishes a plant of the under-shrub, evergreen, curious, parasitic kind, of which the first made use of is, the white-berried or common mistletoe (*V. album*).

It has a woody branchy growth and yellowish-green appearance, producing white transparent berries of a considerable size, which ripen themselves in the winter.

It is a remarkable plant, as not growing in the earth or soil, but upon the trunks or branches of other plants, mostly on those of the soft-wooded tree sorts, being often found in woods and orchards, on the ash, the hazel, the maple, the crab, and the apple-tree.

Method of Culture.—It is for the most part increased by the seeds which are accidentally dispersed and deposited upon some parts of the trees by means of birds, commonly taking root and fixing themselves on the under sides of the boughs or branches, to which parts they have been washed by the rains or in other ways, being kept in such situations until they strike root, or plant their radical fibres in the bark between it and the wood, by their soft glutinous quality;

the young plants growing downwards in a pendulous manner. The plants may also be propagated in garden or orchard plantations, by procuring some fully ripened berries or seeds in the winter, and sticking or rubbing them on the smooth parts of the under sides of the branches of some of the above kinds of trees, where they will grow as already noticed. The outer bark, in some cases, is cut or rubbed off in the part before this is done, in order to make it more certain.

The want of success, in particular instances, is to be ascribed to the defective fecundation of the plants from which the berries or seeds were taken which are employed. They should of course always be gathered from plants where different sorts grow together.

They are chiefly grown for curiosity; but sometimes for medicinal purposes.

Viscum is also used for bird-lime. This was esteemed a poison among the ancient Greeks, and is seldom omitted under the class of deleterious things enumerated in their writings.

It is called by these authors *ixias*; but this word has occasioned great errors in late writers, the word *ixias* having been applied to the white chamæleon thistle, not because of any poisonous quality it had, for they all declare it to be innocent, but because of its yielding a viscous or clammy juice. The black chamæleon thistle was always esteemed poisonous among them; and hence some have supposed the word *ixias* to be applied to that, and the poison *ixias*, mentioned by the Greeks, to be the root of that plant. Paulus Ægineta, indeed, seems to have understood it so, the poison *ixias* being by him placed among the roots; but Galen, who calls it a slow poison, and says that it kills by stopping up and gluing together the intestines, plainly enough means bird-lime, not the root of any plant.

Viscum Caryophylloides, a name given by sir Hans Sloane, and many other authors, to a genus of plants of a very peculiar kind.

They are called *viscum*, from their growing upon other trees, in the manner that the mistletoe does with us; and *caryophylloides*, from their leaves, in some degree, resembling those of our pinks or carnations; but the plant itself, in all its species, is wholly different, both from the mistletoe and pink, in all the several respects.

The several species of these plants differ greatly also from one another; the most fragrant species in Jamaica is a very large one, called by the common people the wild pine. See the description of it in Phil. Transf. N^o 252. p. 114.

VISCUS, and VISCOSITY. See VISCERA and VISCIDITY. **VISEGLIA**, in Geography. See BISEGLIA.

VISENTIUM, or VISENTUM, in Ancient Geography, a town of Italy, in Etruria, upon the western bank of the lake Trasiménè. Pliny suggests that this town belonged to the Visentini who inhabited the vicinity of the Vulcanian lake: it is the present Bisentio.

VISET, in Geography, a town of France, in the department of the Ourthe, situated on the E. side of the Meuse. It was surrounded with walls in the year 1338, by Adolphus de la Mark, bishop of Liege. John de Heinsberg, the fifty-second bishop, granted it many privileges, in the year 1429; among others, the liberty of choosing their own magistrates; 6 miles S. of Maëricht.

VISEU, a town of Portugal; in the province of Beira. This town was founded by the Romans, and by them called "Visontium." It is the see of a bishop, contains three parish churches, an hospital, and three convents. In 1027, Alphonso V. king of Leon, was killed by an arrow before

this

this town, as he attempted to take it from the Moors; 27 miles S. of Lamego. N. lat. 40° 45'. W. long. 7° 46'.

VISHIANARY, a town of Hindoostan, in Tinevelly; 18 miles S.S.E. of Palamcottah.

VISHNU, in *Mythology*, is one of the chief deities of the Hindoo trimurti or triad. He is reckoned the second person of this mysterious unity, being a personification of the *preserving* power of the deity. On the whole, Vishnu may be called the chief of the Hindoo gods; as either in himself, or through his consort, or active energy, Lakshmi, or in his various incarnations, he is, perhaps, the god most extensively worshipped: if the numerous facts that indirectly adore him be included, he certainly is. Like the gods and goddesses of other polytheistic people, all the deities of the Hindoo Pantheon are resolvable ultimately into one; that one is the sun, and he, the Hindoo theologians affirm, is merely a symbol of that "infinitely greater light which alone can irradiate our intellects." This eoteric doctrine is of course unknown to the multitude who address and adore Vishnu, as well as the other deities, in the grossness of idolatrous superstition.

Under the article SIVA it is shewn that Vishnu, in a strictly mythological view, is the *preserving* attribute: he represents also the *wisdom* of the deity, as Brahm does his *power*, and Siva his *justice*. Extending our view, we find that Vishnu metaphysically is a personification of *space*; *matter* and *time* being assignable to his coeternal associates in the Hindoo triad. In physics, Vishnu is *water*, or the humid principle generally: thus he is the *air*; and in a degree of relationship less intimate, he is the *earth*. He is also *time*; and, as before said, the *sun*. See LAKSHMI, the name of the fakti, or consort of Vishnu; SARASWATI, the consort of the creative Brahma; and PARVATI, the active energy of the *destroying* Siva, for farther particulars of this *preserving* attribute of the inseparable Hindoo triad. These female divinities, which we indiscriminately call the active energy, or power, or consort of their respective lords, are generally termed their *Sakti*; which see. See also MATRI.

As well as wives, or active helpmates, the Hindoo gods have severally *vehicles* assigned them. These are termed *Vahan*; which see. Vishnu, the Jove of India, has his eagle, like his brother of Greece and Rome. The Hindoo bird is named Garuda and Superna. Under the latter word an account of him will be found.

The whole race of Hindoos may be theologically comprehended under the two denominations of *Saivas* and *Vaishnavas*, or worshippers of Siva and Vishnu; either directly of the god himself, or of his fakti; or indirectly of a symbol, or through the intervention of an incarnation. This, however, opens a door to diversity and schism. Under the article SECTS of Hindoos, we have endeavoured to class them in a triple arrangement, of *theological*, *civil*, and *philosophical* sectarists. To that article, to SAIVA, VAISHNAVA, and PHILOSOPHY of the Hindoos, with others therein referred to, connected with and farther explaining them, we beg to refer the reader inquisitive on points relating to this branch of the mythology of the Hindoos. See also the Hindoo Pantheon.

Representations of Vishnu are very common in all parts of India; in metallic casts, in carvings in wood, stone, or ivory, and in pictures. See the plates of the work just named. When in his own person, he is depicted young and handsome; sometimes two, but commonly four-handed. In his hands are usually seen a club or mace, called gada, a shell or shank, a lotos or padma, and a discus or quoit, called chakra or vajra.

The chakra is a discus or quoit, with a hole in its centre, which Vishnu is fabled to turn it round his fore-finger so

vehemently, that irresistible fire flames from its periphery. It is said to be a missile still used; but whatever mythological mischief may have ensued from its effects, it does not seem capable of producing much sent from a mortal finger. With the Hindoos now, as with the Egyptians of old, this is a very mysterious symbol; the word in Sanscrit means a *wheel*, or something rotatory; and has a like meaning in several spoken dialects of India. *Chakra-varti*, or the Chakra-whirler, is a name of Vishnu, and is sometimes given to other deities and mythological heroes.

The notion of incarnations of their deities is very common among the Hindoos. This terrestrial manifestation they call *avatara*, meaning a *descent*. The avatars of Vishnu have been very numerous; but ten of them are of great celebrity; and the histories of them form the principal subject of several of the sacred poems called *Purana* (which see), and of a great many books in all the languages of the East. We subjoin the names of these ten descents, or *dasa-avatara*, as they are called in Sanscrit; with some incidental remarks in addition to what we have offered under several of their names. 1. Matsyavatara. This, as the name implies, was a descent in the form of a *fish*; and is represented by a figure of Vishnu, half man half fish; reminding us strongly of the pisciform god of the Assyrians; "sea-monster, Dagon named, upwards man and downwards fish," as well described by Milton. This incarnation and the next are supposed to have allusion to the flood, and representations of half man half fish to Noah. 2. Kurmavatara, or the descent in the form of a *tortoise*. 3. Varahavatara, in the form of a *boar*. 4. Narasingha, or *man-lion*. 5. Vamana, or the *dwarf*. 6. Parasu Rama, a hero so named. 7. Rama, surnamed Chandra. 8. Krishna. 9. Booth or Budha, or Saka. 10. Kalki is the last, and is yet to come, when Vishnu will appear mounted on a white horse; and, as mentioned under the article KALKI, end the present iron or kali age, and renovate the creation with an era of purity, called Satya or Sati. See KALI and SUTTEE.

These are the chief of the descents of Vishnu, called pre-eminently *dasa-avatara*. The reader will see them very ingeniously discussed in Maurice's Indian Antiquities and Ancient History of India.

Besides these grand incarnations, Vishnu has descended in various places and times, usually accompanied by his fakti or consort Lakshmi, also incarnated for that purpose; sometimes retaining her own name and sometimes taking another.

In the spirit of Grecian mythology, these avatars, as the Hindoos more decorously describe them, would appear as the *sons* of Jove. But we have not convenience to pursue, in this place, these analogies of eastern and western fable.

Vishnu, like Siva, and others of the Hindoo deities, has many names. He is said to have a thousand; but this may mean merely a great many. They are strung together in a sort of metrical arrangement, and are mentally recited in some species of worship; the votary sometimes holding in his hand a rosary, and dropping a bead as each name and the excited idea occur: to aid abstraction, the hand and rosary are put into a bag. This silent adoration is called *jap*; which see. Among the names of Vishnu are the following: *Janardana*, said to mean the devourer or absorber of souls. Vishnu being the sun, this may have some solar allusion; otherwise we do not see its applicability to the *preserving* energy. *Heri*, a name also of Krishna, who is, indeed, by sectaries, identified with Vishnu. *Heriprya*, meaning beloved of Heri, is a name of Lakshmi. In other avatars, a *portion* only of his essence is said to have been incarnated; but in that of Krishna the whole deity, in all his plenitude of potentiality. *Bhagavan*, alluding to the lord of nature:

Bhaga

Bhaga and Bharga are names of Siva, of like allusion. *Padmanabha*, meaning lord of Padma; the latter being a name of Lakshmi, and of the lotos, the appropriate symbol of a deity who is a personification of the humid principle. Lakshmi is the queen of beauty, and the lotos is the proverbial type of female loveliness. (See *LOTOS* and *PADMA*.) *Prabhu*: this name may allude to Vishnu's solar godhead; for a word of the same root, *Prabha*, implies *brilliance*, *splendour*, *effulgence*; and is a name of the consort of the sun. See *PRAHA* and *SURYA*, in which last article, being the name of the Hindoo Phœbus, are many particulars explanatory of the solar Vishnu. *Narayana*, meaning moving on or abiding in the waters, is a name applied to Vishnu by his sectaries, and to other deities by theirs. (See *SECTS OF Hindoos*.) Although Vishnu hath this *aqueous* name and character, he does not agree with the Neptune of the West so intimately as Siva. (See *SIVA*, *TRISULA*, and *VARUNA*.) *Sri* is a name or epithet meaning holy or divine, given to gods, goddesses, and men; among them to Vishnu; but it is not indiscriminate. *Kesava* is a name of Krishna and Vishnu, said to allude to the fineness of the hair of the incarnated deity. *Madhava* is derived from a giant named Madhu, destroyed by Vishnu: it is a name also of Krishna, as is *Murari* of both. *Trivikera*, or *Trivikrama*, alluding to *three steps*, taken by Vishnu in the Vamanavatara, is a designation by which he is not unfrequently called. *Pitamba*, or *Pitamber*, descriptive of a yellow coloured garment worn by Krishna, is sometimes given as a name to him and to Vishnu. See *PRITHU*, for some account of that name and form of the deity now under our consideration, and *WITTOBA* for another. *Shyamula*, meaning *black-faced*, is a name applied to Parvati as well as to Vishnu, in his form of Krishna, who is usually black or blue-faced. *Syama* has the like derivation. *Vinkateihin*, *Vinkatrama*, *Viratarupa*, and *Yadava*, are other names of Vishnu. *Yama*, the judge of departed souls, is sometimes called an emanation of him. The name Vishnu is said to come from the root *vis*, which means to *penetrate* or *pervade*; and may allude to him more particularly in his form of Surya, or the sun. (See *SURYA*.) All these names of Vishnu, and a great many others, are discussed, as to their derivation and mystical properties, in a Sanscrit poem called "Sahakra Nama."

The name of this important mythological personage is variously pronounced in different parts of India, and variously written by Europeans: *Bishen*, *Vishu*, *Vishnoo*, &c.

These may suffice of the names of Vishnu. Like other Hindoo gods, he has a particular abode assigned him: his is called *Vaikontha*; which see.

VISHWARUPA, is the father of the two wives of Ganesh, the god of prudence and policy; called also *Pollair*, which see. The names of these wives were *Sidi* and *Budhi*. (See *SIDI*.) *Vishwarupa*, or *Vishvarupa*, is said to be the son of *Tvashta*, or *Vishwakarma*. See those articles.

VISIAPOUR, in *Geography*. See *BEJAPOUR*.

VISIAPOUR, *Vijapur*, or *Bejapur*, a country, and at a former period a considerable kingdom, of Hindoostan, bounded on the N. by Dowlatabad, on the E. by Golconda, on the S. by Mysore, and on the W. by the Gauts, or mountains which separate it from Concan: formerly governed by kings of the Patan race; afterwards conquered by Aurungzebe, and now in possession of the Mahrattas.

VISIBLE, *VISIBLE*, something that is an object of sight, or vision; or something by which the eye is affected, so as to produce a sensation. See *SIGHT* and *VISION*.

The school philosophers make two kinds of visibles, or visible objects; the one *proper*, or *adequate*, which are such

as are no other way perceivable but by sight alone; the other *common*, which are subject to divers senses, as the sight, hearing, feeling, &c.

Again, the first, or *proper object of vision*, is of two kinds, *viz. light and colour*; for these two are only sensible by sight. The first, and primary, *viz. light*, they make the formal, and *colour*, the material object.

The Cartesians think they philosophize better, when they say that light alone is the proper object of vision; whether it flow from a luminous body through a transparent medium, and retains its first name, *light*, or whether it be reflected from opaque bodies, under a certain new modification, or habitude, and exhibit their images; or, lastly, whether in being reflected, it is likewise refracted, after this or that manner, and affects the eye with the appearance of *colour*.

But, agreeable to fir Isaac Newton's sentiments, *colour* alone is the proper object of sight; *colour* being that property of light by which the light itself is visible, and by which the images of opaque bodies are painted on the retina.

Aristotle (*De Anima*, lib. ii.) enumerates five kinds of common visibles, which are usually received for such in the schools, *viz. motion, rest, number, figure, and magnitude*.

Others maintain nine, as in the verities:

"Sunt objecta novem visus communia: quantum, Indefigura, locus, sequitur distantia, situs, Continuumque et discretum, motusque, quiesque."

Authors reason very variously as to these common objects of vision; there are two principal opinions among the schoolmen.

The adherents to the first hold, that the common visibles produce proper representations of themselves, by some peculiar species, or image, by which they are formally perceived, independently of the proper visibles.

But the second opinion prevails most, which imports, that the common visibles have not any such formal peculiar species to become visible by; but that the proper objects are sufficient to throw themselves in this or that place or situation, and in this or that distance, figure, magnitude, &c. by the circumstances of their conveyance to the sensory.

In effect, since these common visibles cannot be represented alone (for whoever saw place, distance, figure, situation, &c. of itself?), but are always conveyed along with the images of light and colour to the organ; what necessity is there to conceive any such proper images by which the common visibles should be formally perceived by the soul? It is much more probable, that from the peculiar manner in which the sensitive faculty perceives a proper object, it is apprized of its being in this or that situation or place; in this or that figure, magnitude, &c. How this is effected may be conceived from what follows:

I. The situation and place of visible objects are perceived without any intentional species of them, merely by the impulse being made from a certain place and situation, either above or below, on the right or left, before or behind, by which the rays of the proper visibles are thrown upon the retina, and their impression is conveyed to the sensory.

For, since an object is seen by those rays which carry its image to the retina, and in that place to which the visible power is directed by the rays it receives, as it perceives the impulse of the rays to come from any place, &c. it is abundantly admonished of the objects being in that place and situation. See *APPARENT PLACE*.

Philosophers, in general, had formerly taken for granted, that the place to which the eye refers any visible object, seen by reflection or refraction, is that in which the visual ray meets a perpendicular from the object upon the reflecting or

the

the refracting plane. That this is the case with respect to plane mirrors is universally acknowledged; and some experiments with mirrors of other forms seem to favour the same conclusion, and thereby afford reason for extending the analogy to all cases of vision. If a right line be held perpendicularly over a convex or concave mirror, its image seems to make one line with it. The same is the case with a right line held perpendicularly within water; for the part which is within the water seems to be a continuation of that which is without, at least when it is viewed with no more than common attention, and in some positions. But Dr. Barrow called in question this method of judging of the place of an object, and thereby opened a new field of enquiry and debate in this branch of science. This, with other optical investigations, he published in his *Optical Lectures*, first printed in 1674. Having, as he imagined, refuted the common hypothesis concerning the place of visible objects, he substitutes another rule, by which, he says, our judgments are actually directed in this case. According to him, we refer every point of an object to the place from which the pencils of light, that give us the image of it, issue, or from which they would have issued, if no reflecting or refracting substance intervened. Pursuing this principle, Dr. Barrow proceeded to investigate the place, in which the rays, issuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that if the refracting surface was plane, and the refraction was made from a denser medium into a rarer, those rays would always meet in a place between the eye and a perpendicular to the point of incidence.

If a convex mirror be used, the case will be the same; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be concave. He also determined, according to these principles, what form the image of a right line will take when it is presented in different manners to a spherical mirror, or when it is seen through a refracting medium.

Dr. Barrow, however, mentions an objection against the maxim which he endeavoured to establish, concerning the supposed place of visible objects, and candidly owns that he was not able to give a satisfactory solution of it. The objection is this; let an object be placed beyond the focus of a convex lens, and if the eye be close to the lens, it will appear confused, but very near to its true place. If the eye be a little withdrawn, the confusion will increase, and the object will seem to come nearer; and when the eye is very near the focus, the confusion will be exceedingly great, and the object will seem to be close to the eye. But in this experiment the eye receives no rays but those that are converging; and the point from which they issue is so far from being nearer than the object, that it is beyond it; notwithstanding which, the object is conceived to be much nearer than it is, though no very distinct idea can be formed of its precise distance.

The first person who took much notice of Dr. Barrow's hypothesis, and the difficulty attending it, was Dr. Berkeley, who, in his *Essay on a New Theory of Vision*, p. 30, observes, that the circle formed upon the retina by the rays which do not come to a focus, produces the same confusion in the eye, whether they cross one another before they reach the retina, or tend to it afterwards; and therefore, that the judgment concerning distances will be the same in both the cases, without any regard to the place from which the rays originally issued; so that in this case, as, by receding from the lens, the confusion, which always accompanies the nearness of an object, increases, the mind will judge that the object comes nearer. See *Apparent Distance*.

M. Bouguer, an ingenious writer on *Optics*, in his *Traite d'Optique*, p. 104, adopts the general maxim of Dr. Barrow, in supposing that we refer objects to the place from which the pencils of rays seemingly converge at their entrance into the pupil. But when rays issue from below the surface of a vessel of water, or any other refracting medium, he finds that there are always two different places of this seeming convergence: one of them of the rays that issue from it in the same vertical circle, and, therefore, fall with different degrees of obliquity upon the surface of the refracting medium, and another of those that fall upon the surface with the same degree of obliquity, entering the eye laterally with respect to one another. Sometimes, he says, one of these images is attended to by the mind, and sometimes the other; and different images may be observed by different persons. An object, plunged into water, affords an example, he says, of this duplicity of images.

G. W. Kraft has ably supported the opinion of Dr. Barrow, that the place of any point seen by reflection from the surface of any medium, is that in which rays issuing from it, infinitely near to one another, would meet; and considering the case of a distant object, viewed in a concave mirror by an eye very near to it, when the image, according to Euclid and other writers, would be between the eye and the object, and the rule of Dr. Barrow cannot be applied; he says, that in this case, the speculum may be considered as a plane, the effect being the same, only that the image is more obscure. *Com. Petropol.* vol. xii. p. 252. 256. See *Priestley's Hist. of Light*, &c. p. 89. 688, &c.

From the principle above illustrated, several remarkable phenomena of vision are accounted for: as,

1. That if the distance between two visible objects be an angle that is insensible, the distant bodies will appear as if contiguous; whence a continuous body being the result of several contiguous ones; if the distances between several visibles subtend insensible angles, they will appear one continuous body; which gives a pretty illustration of the notion of a continuum.

Hence parallel lines, and long vistas, consisting of parallel rows of trees, seem to converge more and more, the farther they are extended from the eye; because the apparent magnitudes of their perpendicular intervals are perpetually diminishing, while, at the same time, we mistake their distance. When two parallel rows of trees stand upon an ascent, the more remote parts appear farther off than they really are, because the line that measures the length of the vistas now appears under a greater angle than when it was horizontal; the trees, in such a case, seeming to converge less, and sometimes, instead of converging, seeming to diverge. See *PARALLELISM of Rows of Trees*.

The proper method of drawing the appearance of two rows of trees that shall appear parallel to the eye, is a problem that has exercised the ingenuity of several philosophers and mathematicians. That the apparent magnitude of objects decreases with the angle under which they are seen, has always been acknowledged; and it is also acknowledged, that we learn to form a judgment both of magnitudes and distances only by custom and experience; but in the application of these maxims to the above mentioned problem, all persons, before M. Bouguer, made use of the real distance instead of the apparent one, by which only the mind can form its judgment. And it is manifest, that if any circumstances contribute to make the distance appear otherwise than it is in reality, the apparent magnitude of the object will be affected by it, for the same reason, that if the magnitude be misapprehended, the idea of the distance will vary. For want of attending to this distinction,

tion, Tacquet pretended to demonstrate, that nothing can give the idea of two parallel lines to an eye situated at one of their extremities, but two hyperbolical curves, turned the contrary way; and M. Varignon maintained, that, in order to make π vista appear of the same width, it must be made narrower, instead of wider, as it recedes from the eye. M. Bouguer observes, that very great distances, and those that are considerably less, make nearly the same impression upon the eye. We, therefore, imagine great distances to be less than they are, and on this account the ground plan of a vista always appears to rise. The visual rays come in a determinate direction, but as we imagine they terminate sooner than they do, we necessarily conceive that the place from which they issued is elevated.

Every large plane, therefore, as A B (*Plate XX. Optics, fig. 5.*) viewed by an eye at O, will seem to lie in such direction as A b; and consequently lines, in order to appear truly parallel, on the plane A B, must be drawn so as that they would appear parallel on the plane A b, and be from thence projected to the plane A B. To determine the inclination of the apparent ground plane A b to the true ground plane A B, M. Bouguer directs us to draw upon a piece of level ground two straight lines of a sufficient length, making an angle of three or four degrees with one another. Then a person placing himself within the angle, with his back towards the angular point, must walk backwards and forwards till he can fancy the lines to be parallel. In this situation, a line, drawn from the point of the angle through the place of his eye, will contain the same angle with the true ground plane which this does with the apparent one.

M. Bouguer also shews other more geometrical methods of determining this inclination, and says, that by these means, he has often found it to be four or five degrees, though sometimes only two, or two and a half degrees; the determination of this angle being variable, and depending upon the manner in which the ground is illuminated, and the intensity of the light, the colour of the soil, the conformation of the eye, and the part of the eye on which the object is painted.

In looking towards a rising ground, the difference between the apparent ground plane and the true one, he says, will be much more considerable, so that they will sometimes make an angle of 25 or 30 degrees. *Ac. Par. 1755. M. 156.*

2. If the eye be placed above an horizontal plane, objects, the more remote they are, the higher will they appear, till the last be seen in a level with the eye. Whence it is that the sea, to persons standing ashore, seems to rise higher and higher the farther they look.

3. If any number of objects be placed below the eye, the most remote will appear the highest; if they be above the eye, the most remote will appear the lowest.

Thus the remoter parts of a horizontal walk, or long floor, will appear to ascend gradually; whereas, the ceiling of a long gallery appears to descend.

M. Bouguer observes, that when a man stands upon a level plane, it does not seem to rise sensibly, but at some distance from him: the apparent plane, therefore, has a curvature in it, the form of which is not very easy to determine; so that a man standing upon a level plane of infinite extent, will imagine that he stands in the centre of a basin. The case is the same with a person standing upon the level of the sea.

4. The upper parts of high objects appear to stoop, or incline forwards; as the front of churches, towers, &c. And statues at the tops of buildings, to appear upright,

must incline, or bend backwards. See farther under the articles of REFRACTION and HORIZON.

II. The mind perceives the distance of visible objects, from the different configurations of the eye, and the manner in which the rays strike the eye, and in which the image is impressed on it. For the eye disposes itself differently, according to the different distances it is to see; viz. for remote objects the pupil is dilated, and the crystalline brought nearer the retina, and the whole eye is made more globular; on the contrary, for near objects, the pupil is contracted, the crystalline thrust forwards, and the eye lengthened.

Philosophers are agreed, that we have a power of altering the form of our eyes, so as to make the rays of any pencil to converge at different distances from the pupil: and hence we are capable of viewing objects with almost equal distinctness, though they are placed at considerably different distances; but with regard to the alteration that takes place in the eye, and the mechanism by which it is produced, different accounts have been given.

It was the opinion of Kepler, that the contraction of the processus ciliaris changes the form of the eye, and by the elongation of it, places the crystalline at a greater distance from the retina; whereas Des Cartes imagined, that the curvature of the crystalline itself suffers an alteration by the contraction of those ligaments.

M. de la Hire maintained that, in order to view objects at different distances, there is no alteration but in the size of the pupil, or the aperture of the eye; and he made a curious experiment, which, he thought, proved his assertion.

M. Le Roi, a member of the Royal Academy at Montpellier, has lately attempted to defend the opinion of M. de la Hire, which had long been exploded by all philosophers; and he says, that the accommodation of the eye to the view of objects, placed at different distances, by the contraction or dilatation of the pupil only, does not consist in the change of the place of the crystalline, by means of the ligamenta ciliaria, the strength of which is inadequate to the purpose. Besides, he observes, that they are not attached to the edge of the capsula, as has been supposed, but that they extend a considerable way along the interior surface of it, without any close adherence to it. He is also of opinion that these fibres are not muscular, but are only ramified vessels, which, according to all appearance, he says, answer no other purpose than that of secreting an aqueous humour, to lubricate the surface of the crystalline.

That nothing is requisite but the contraction of the pupil in order to view the nearest objects with distinctness, is evident, he says, from experiment. For when an object is placed so near, that the eye cannot bear as great a degree of contraction as is necessary for viewing it distinctly, the same end is obtained by an artificial pupil. For if a small hole be made in a card, the nearest object may be viewed through it with the greatest ease and distinctness.

That the variation of the pupil is sufficient for the purpose of viewing objects at all distances, he also thought he could demonstrate by experiment with an artificial eye; for when, with a large aperture, the images of near objects were confused, and ill defined upon the retina of this instrument, they became very distinct, and well defined, by contracting the aperture. *Ac. Paris, 1755. M. p. 920.*

But the most satisfactory discussion of this subject we owe to Dr. Porterfield, who proved, by a series of experiments,

ments, in which an object was viewed through small slits in a thin plate of iron, at a less distance than the diameter of the pupil (which, therefore, was of no use in this case), that we are possessed of a power of changing the conformation of our eyes, and of adapting them to various distances; and that this change always follows a similar motion in the axes of vision, with which it has been connected by use and custom. Porterfield on the Eye, vol. i. p. 411. 415. 421.

However, among those who suppose a conformation of the eye for this purpose, independent of a variation in the aperture, it is by no means agreed in what it consists. Some have said, that the crystalline becomes more or less convex for this purpose, by the action of certain muscular fibres which enter into its composition. But Dr. Porterfield (ubi supra, p. 442.) observes that, though the crystalline, when dry, appears to consist of many thin concentric laminae, or scales, their disposition is but ill qualified for changing the figure of the crystalline; or if they were so, it is not easy, he says, to prove that these fibres are muscular, and capable of contraction.

His own opinion is, that the crystalline has a motion by means of the ligamentum ciliare, by which the distance between it and the retina is increased or diminished, according to the different distances of objects. The structure and disposition of the ligamentum ciliare, he says, excellently qualify it for changing the situation of the crystalline, and removing it to a greater distance from the retina, when objects are too near for us; because, when it contracts, it will not only draw the crystalline forward, but also compress the vitreous humour lying behind it, so that it must press upon the crystalline, and push it towards the retina.

He adds, that the crystalline, being moved forwards, must, at the same time, press the aqueous humour against the cornea; by which means that membrane, which is flexible, will be rendered more convex, and enable us still better to see near objects distinctly.

That the situation of the crystalline is made use of in conforming the eye to the distinct view of objects placed at different distances, Dr. Porterfield thinks, is very evident from what is observed concerning persons who have cataracts couched; for the same lens is not useful to them for seeing all objects distinctly, but they are obliged to make use of glasses of different degrees of convexity, in proportion to the nearness of the object.

To the objection of M. de la Hire, and others, among whom are the celebrated anatomists Haller and Zinn, that the ciliary ligament is not muscular, and consequently has no power of contraction, he observes, that they have been led into this mistake by apprehending that the colour of muscles is always red; whereas this is not the case universally, for the muscular fibres of the intestines and stomach have hardly any redness in their colour. It is also certain, he says, that the pupil contracts and dilates itself according as objects are more or less luminous, and yet none of the fibres which perform that action are in the least red. Ubi supra, vol. ii. p. 434. 447. 450.

Dr. Jurin (Ess. on distinct, &c. Vision, p. 143.) supposes, that when the eye is to be suited to greater distances than fifteen or sixteen inches, the ligamentum ciliare contracts, so as to draw part of the anterior surface of the capsula of the crystalline, into which the fibres of it are inserted, a little forwards and outwards, on which the water within the capsula must flow from under the middle towards the elevated part of it; and the aqueous humour must flow from above the elevated part of the capsula to the middle.

In consequence of this, the whole anterior surface, within the insertion of the ciliary ligament, will be reduced to a less convexity. When this contraction ceases, the capsula will return to its former situation, by its own elasticity. To this hypothesis it has been objected, that unless the water within the capsula has a greater refractive power than the aqueous humour, the retiring of it from one place to another to make room for that humour, will have no effect upon the pencils of rays.

Dr. Jurin, however, not attending to this circumstance, and seeming to consider the water within the capsula as having the same refractive power with the crystalline itself, attempts to shew by calculation, that this change in the convexity of it is quite sufficient to extend the natural distance of distinct vision from fifteen inches to fourteen feet five inches, without the least motion of the crystalline itself, and a very small one of the anterior surface of the capsula.

M. Muschenbroeck, or rather Albinus (whose Anatomical Observations on the Eye he has published in his *Introd. ad Phil. Nat.* vol. ii. p. 759.) supposes, that the change of conformation in the eye is performed by means of the zona ciliaris, in the following manner. In viewing a very near object, in consequence of which the pencils of rays tend to a focus beyond the retina, the zona ciliaris, and the anterior membrane of the capsula, as also the vitreous humour, being driven forward by the compression of the coats of the eye, push the crystalline, and make it recede from the retina. At the same time the crystalline, pushing the aqueous humour into the cornea, makes it more prominent. Perhaps, also, he says, the crystalline may be made rounder, so that, on these accounts, the pencils will come to their foci sooner than otherwise. On the other hand, when the object is too remote for distinct vision, so that the pencils come to their foci too soon, the zona ciliaris becomes tense, and, with the anterior membrane of the capsula, pushes the crystalline farther within the vitreous humour. By this pressure the crystalline becomes flatter, so that, on these several accounts, the foci of the pencils are carried farther. The zona ciliaris, and the anterior membrane of the capsula, can only push the crystalline into the vitreous humour one half of its own thickness, which he shews is not sufficient to make vision distinct at a competent distance, and therefore concludes, that some change must take place in the form of the crystalline, as, he says, Dr. Pemberton has well demonstrated. He supposes, that the provision for suiting the eye to different distances is the same in all animals, and does not depend on the change of the sclerotica in any of them, which is hard, and incapable of being compressed. Priestley's *Hist. of Light*, &c. p. 638—652. See *Apparent Distance*. See also *EYE*.

It seems to be now pretty generally allowed, that the change, by which the eye accommodates itself to different distances, is produced by an increase of the convexity of the crystalline lens, arising from an internal cause. The arguments in favour of this conclusion are of two kinds; some of them are negative, derived from the impossibility of imagining any other mode of performing the accommodation, without exceeding the limits of the actual dimensions of the eye, and from the examination of the eye in its different states by several tests, capable of detecting any other changes if they had existed: for example, by the application of water to the cornea, which completely removes the effect of its convexity, without impairing the power of altering the focus, and by holding the whole eye, when turned inwards, in such a manner as to render any material alteration of its length utterly impossible. Other arguments

gements are deduced from positive evidence of the change of form of the crystalline, furnished by the particular effects of refraction and aberration which are observable in the different states of the eye; effects which furnish a direct proof that the figure of the lens must vary; its surfaces, which are nearly spherical in the quiescent form of the lens, assuming a different determinable curvature when it is called into exertion. The objections which have been made to this conclusion are founded only on the appearance of a slight alteration of focal length in an eye from which the crystalline had been extracted; but the fact is neither sufficiently ascertained, nor was the apparent change at all considerable; and even if it were proved that an eye without the lens is capable of a certain small alteration, it would by no means follow that it could undergo a change five times or ten times as great.

The motion of the optical axes serves likewise, as we have already observed, to assist us in judging of the distance of objects. These axes, or the directions of the rays falling on the points of most perfect vision, naturally meet at a great distance; that is, they are nearly parallel to each other; and in looking at a nearer object, we make them converge towards it, wherever it may be situated, by means of the external muscles of the eye; while in perfect eyes the refractive powers are altered, at the same time, by an involuntary sympathy, so as to form a distinct image of an object at a given distance. This correspondence of the situation of the axes with the focal length is in most cases unalterable; but some have perhaps a power of deranging it in a slight degree, and in others the adjustment is imperfect: but the eyes seem to be in most persons inseparably connected together with respect to the changes that their refractive powers undergo, although it sometimes happens that those powers are originally very different in the opposite eyes.

These motions enable us to judge pretty accurately, within certain limits, of the distance of an object; and beyond these limits, the degree of distinctness or confusion of the image still continues to assist the judgment. We estimate distances much less accurately with one eye than with both, since we are deprived of the assistance usually afforded by the relative situation of the optical axes; thus we seldom succeed at once in attempting to pass a finger or a hooked rod sideways through a ring, with one eye shut. Our idea of distance is usually regulated by a knowledge of the real magnitude of an object, while we observe its angular magnitude; and on the other hand, a knowledge of the real or imaginary distance of the object often directs our judgment of its actual magnitude. The quantity of light intercepted by the air interposed, and the intensity of the blue tint which it occasions, are also elements of our involuntary calculation; hence, in a mist, the obscurity increases the apparent distance, and consequently the supposed magnitude of an unknown object. We naturally observe, in estimating a distance, the number and extent of the intervening objects; so that a distant church in a woody and hilly country appears more remote than if it were situated in a plain; and for a similar reason, the apparent distance of an object seen at sea, is smaller than its true distance. Young's Course of Lectures on Natural Philosophy, &c. vol. i.

Accordingly, in judging of the distance of a visible object, we must take into our account the angle which the object makes, with the distinct or confused representation of the object; and the briskness or feebleness, or the rarity or spiffitude of the rays.

To this it is owing, 1. That objects which appear obscure, or confused, are judged to be more remote; a principle which the painters use to make some of their figures

appear farther distant than others on the same plane. Thus, supposing the eye to be accommodated to a given distance, objects at all other distances may be represented with a certain indistinctness of outline, which would accompany the images of the objects themselves on the retina: and this indistinctness is so generally necessary, that its absence has the disagreeable effect called hardness. The apparent magnitude of the subjects of our design, and the relative situations of the intervening objects, may be so imitated by the rules of geometrical perspective as to agree perfectly with nature, and we may still further improve the representation of distance by attending to the art of aerial perspective, which consists in a due observation of the loss of light, and the blueish tinge, occasioned by the interposition of a greater or less depth of air between us and the different parts of the scenery.

We cannot indeed so arrange the picture, that either the focal length of the eye, or the position of the optical axes, may be such as would be required by the actual objects: but we may place the picture at such a distance, that neither of these criterions can have much power in detecting the fallacy; or, by the interposition of a large lens, we may produce nearly the same effects in the rays of light, as if they proceeded from a picture at any required distance. In the panorama, which has lately been exhibited in many parts of Europe, the effects of natural scenery are very closely imitated: the deception is favoured by the absence of all other visible objects, and by the faintness of the light, which assists in concealing the defects of the representation, and for which the eye is usually prepared, by being long detained in the dark winding passages which lead to the place of exhibition. Young, *ubi supra*. See *Apparent MAGNITUDE*.

2. To this it is likewise owing, that rooms, whose walls are whitened, appear the smaller; that fields covered with snow, or white flowers, shew less than when clothed with grass; that mountains covered with snow, in the night-time, appear the nearer; and that opaque bodies appear the more remote in the twilight.

III. The magnitude or quantity of visible objects is known chiefly by the angle comprehended between two rays drawn from the two extremes of the object to the centre of the eye. An object appears to be as large as the angle it subtends; or bodies seen under a greater angle appear greater; and those under a less, less, &c. Hence the same thing appears now bigger, and now less, as it is less or more distant from the eye. This we call the *Apparent MAGNITUDE*; which see.

Now, to judge of the real magnitude of an object, we consider the distance; for, since a near and remote object may appear under equal angles, the distance must necessarily be estimated; that if it be great, and the optic angle small, the remote object may be judged great; and *vice versa*.

The magnitude of visible objects is brought under certain laws, demonstrated by the mathematicians; as,

1. That the apparent magnitudes of a remote object are as the distances reciprocally; or rather, in a somewhat less ratio.

2. That the co-tangents of half the apparent magnitudes of the same objects, are as the distances; hence the apparent magnitude and distance being given, we have a method of determining the true magnitude; the canon is this. As the whole sine is to the tangent of half the apparent magnitude, so is the given distance to half the real magnitude. The same canon, inverted, will, from the distance and magnitude given, determine the apparent one.

3. Objects seen under the same angle, have their magnitudes proportional to their distances.

4. The

VISIBLE.

4. The subtense A B (*Plate XX. Optics, fig. 6.*) of any arc of a circle appears of equal magnitude in all the points D C E G, though one point be vastly nearer than another; and the diameter D G appears of the same magnitude in all the points of the periphery of the circle. Hence some have derived a hint for the most commodious form of theatres.

5. If the eye be fixed in A (*fig. 7.*), and the right line B C be moved in such manner, as that the extremes of it always fall on the periphery, it will always appear of the same magnitude. Hence the eye, being placed in any angle of a regular polygon, the sides will appear equal.

6. If the magnitude of an object directly opposite to the eye be equal to its distance from the eye, the whole object will be taken in by the eye, but nothing more. Whence the nearer you approach an object, the less part you see of it.

IV. The figure of visible objects is estimated, chiefly, from our opinion of the situation of the several parts of it.

This opinion of the situation, &c. enables the mind to apprehend an external object under this or that figure, more justly than any similitude of the images in the retina, with the object, can; the images being frequently elliptical, oblong, &c. when the objects they exhibit to the mind are circles, squares, &c.

The laws of vision, with regard to the figures of visible objects, are:

1. That if the centre of the pupil be exactly against, or in the direction of a right line, the line will appear as one point.

2. If the eye be placed in a direction of a surface, so that only one line of the perimeter can radiate on it, it will appear as a line.

3. If a body be opposed directly towards the eye, so as only one plane of the surface can radiate on it, it will appear as a surface.

4. A remote arc, viewed by an eye in the same plane, will appear as a right line.

5. A sphere, viewed at a distance, appears a circle.

6. Angular figures, at a distance, appear round.

7. If the eye look obliquely on the centre of a regular figure, or a circle, the true figure will not be seen; but the circle will appear oval, &c. See *Apparent Figure*.

V. The number of visible objects is perceived, not only by one or more images formed in the fund of the eye; but also by such a position of those parts of the brain whence the optic nerves spring, as the mind has been used to, in attending to a certain place; and that either single or manifold.

Accordingly, when either of the eyes, with the contiguous part of the brain, are forced out of their just parallelism, with the other, *v. gr.* by pressing it with the finger, &c. all things appear double; but when they are in the requisite parallelism, though there be two images in the fund of the two eyes, yet the object will appear single. Again, one thing may appear double, or even manifold, not only with both eyes, but even with only one of them open; by reason the common concourse of the cones of rays reflected from the object to the eye, either falls short of the retina, or goes much beyond it.

VI. Motion and rest are seen when the images of objects represented in the eye, and propagated to the brain, are either moved, or at rest; and the mind perceives these images either moving or at rest, by comparing the moved image to another, with respect to which it changes place; or by the situation of the eye to the object being continually changed. So that motion is only perceived, by perceiving the images

to be in different places and situations; nor are these changes perceived unless effected in time. So that to perceive motion, a sensible time is required. But rest is perceived by the visual faculty, from the reception of the image in the same place of the retina, and the same situation for some sensible time.

Hence the reason, why bodies moving exceedingly fast appear at rest; thus, a live coal, swung briskly round, appears a continual circle of fire; the motion not being commensurate with visible time, but much swifter than the same; so that, in the time the soul requires to judge of any change of situation of the image on the retina, or that it is moved from this place to that, the thing itself performs its whole circuit, and is in its own place again.

Laws of vision, with regard to the motion of visibles, are:

1. That if two objects unequally distant from the eye move from it with equal velocity, the more remote one will appear the slower; or, if their celerities are proportionable to their distances, they will appear to move equally swift.

2. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal one of their distances from the eye.

3. A visible object, moving with any velocity, appears to be at rest, if the space described in the interval of one second be imperceptible at the distance of the eye. Hence it is, that a near object, moving very slowly, as the index of a clock; or a remote one very swiftly, as a planet; seem at rest.

4. An object moving with any degree of velocity, will appear to rest, if the space it runs over in a second of time be to its distance from the eye, as 1 to 1400: nay, in fact, if it be as 1 to 1300.

5. The eye proceeding straight from one place to another, a lateral object, not too far off, either on the right or left, will seem to move the contrary way: the eye, in this case, being sensible of its motion, distant objects will seem to move the same way, and with the same velocity.

6. If the eye and the object move both the same way, only the eye much swifter than the object, that last will appear to go backwards.

7. If two or more objects move with the same velocity, and a third remain at rest, the moveables will appear fixed, and the quiescent in motion the contrary way. Thus, clouds moving very swiftly, their parts seem to preserve their situation, and the moon to move the contrary way.

8. If the eye be moved with a great velocity, lateral objects at rest appear to move the contrary way. Thus, to a person sitting in a coach, riding briskly through a wood, the trees seem to retire the contrary way; and to people in a ship, &c. the shores seem to recede.

9. An object moving very swiftly is not seen, unless it be very luminous. Thus, a cannon-ball is not seen, if it is viewed transversely; but if it be viewed according to the line it describes, it may be seen, because its picture continues long on the same place of the retina, which, therefore, receives a more sensible impression from the object.

10. A live coal swung briskly round in a circle, appears a continued circle of fire, because the impressions made on the retina of light being of a vibratory, and consequently of a lasting nature, do not presently perish, but continue till the coal performs its whole circuit, and returns again to its former place.

11. If a person turns swiftly round, without changing his place, all objects about him will seem to move round in a circle the contrary way; and this deception continues not

only

only while the person himself moves round, but, which is more surprising, it also continues for some time after he ceases to move, when the eye, as well as the object, is at absolute rest.

The reason why objects appear to move round the contrary way, when the eye turns round, is not so difficult to explain; for though, properly speaking, motion is not seen, as not being itself the immediate object of sight, yet by the sight we easily know when the image changes its place on the retina, and thence conclude that either the object, or the eye, or both, are moved. But by the sight alone we can never determine how far this motion belongs to the object, how far to the eye, or how far to both.

If we imagine the eye at rest, we ascribe the whole motion to the object, though it be truly at rest. If we imagine the object at rest, we ascribe the whole motion to the eye, though it belongs entirely to the object: and when the eye is in motion, though we are sensible of its motion, yet if we do not imagine that it moves so swiftly as it really does, we ascribe only a part of the motion to the eye, and the rest of it we ascribe to the object, though it be truly at rest.

This last, says Dr. Porterfield, is what happens in the present case, when the eye turns round; for though we are sensible of the motion of the eye, yet we do not apprehend that it moves so fast as it really does; and, therefore, the bodies about appear to move the contrary way, as is agreeable to experience.

But the great difficulty still remains, *viz.* why, after the eye ceases to move, objects should, for some time, still appear to continue in motion, though their pictures on the retina be truly at rest, and do not at all change their place.

This, Dr. Porterfield imagined, proceeds from a mistake with respect to the eye, which, though it be absolutely at rest, we nevertheless conceive it as moving the contrary way to that in which it moved before; from which mistake, with respect to the motion of the eye, the objects at rest will appear to move the same way which the eye is imagined to move; and consequently will seem to continue their motion for some time after the eye is at rest. Porterfield on the Eye, vol. ii. p. 422. 424.

VISIBLE Horizon, Place, and Species. See the substantives.

VISIER, VIZIER, or Visir, an officer or dignitary in the Ottoman empire, of which there are two kinds; the first called by the Turks *visir azem*, that is, *grand visir*, first created in 1370, by Amurath I., in order to ease himself of the chief and weightier affairs of the government.

The *grand, or prime visir*, is the prime minister of state of the whole empire, and presides at the divan, or great council. Being the lieutenant of the sultan, in whose name he governs, and from whom he holds the seal, invested with the greatest authority, and entrusted with all the power of execution, the visir may strike off the heads of persons receiving salaries who oppose the progress of the government, who throw obstacles in the way of its administration, who do not obey its orders, or do not execute them according to its pleasure; he commands the armies in person; he disposes of the finances; he names, or causes persons to be named, to all the administrative and military employments. Nothing, in a word, is foreign to his powers, but the interpretation of the law entrusted to the ulemas.

But the greater the power of the grand visir, the greater is his responsibility. He is accountable, both to the sovereign and to the people, for the acts of injustice which he commits, for the unfortunate result of his administration, for the extortions which he does not repress; he is accountable, above all, for the unexpected dearth of provisions, for

too frequent fires, and for the defeats of the armies: all the misfortunes of the state are attributed to him. The sword, always suspended over his head, strikes him equally whether he displease the people, or disoblige the sultan.

In the frequent excursions which he makes inland, in the city, for the purpose of having an eye to good order, of informing himself of the state of the articles of food, examining the weights and measures, and inspecting the conduct of agents appointed for the distribution of provisions, the visir, accompanied by a public executioner, and some officers disguised like himself, orders delinquents to be apprehended and punished on the spot: he calls out, if necessary, the guard of the quarter; he directs the bastinado to be given to the shop-keepers who vend aliments of bad quality; he causes him who is found with false weights to be nailed by the ear against the door of the shop; he even punishes with death rapscals or malversations of too ferocious a nature. During fires, he orders to be struck off the head of the thief caught in the very fact; but, in those cases, the law has pronounced before-hand the penalty of death. Charged to listen to the complaints of individuals, to cause justice to be done to all, the visir cannot, under any pretext, dispose legally of the life and fortune of citizens. It is not that he does not too frequently abuse his authority; it is not that he does not sometimes yield to perfidious advice, that he does not suffer himself to be led away by motives of hatred and revenge, that the thirst of gold does not impel him to arbitrary acts; but woe be to him if his injustice be too revolting! When he too frequently puts himself above the laws, the people, in their turn, trample him under foot, unless the sultan be expeditious in administering justice. Thus circumstanced, it is extremely rare for a visir to grow old in the post which he occupies.

The title of visir is given to all the pachas with three tails. Six of these ordinary visirs, whose reputation for wisdom and intelligence was universally allowed, formerly composed the divan or council of the grand visir. The visir asked their opinion when he thought it necessary. Soon after the accession of Selim to the throne, he composed this council of twelve persons the most distinguished by their office. The visir and the musti are presidents of it; the one in his quality of lieutenant-general of the empire for temporal affairs; the other as vicar of the sultan for the interpretation and depository of the laws. The other ten members are the kiaya-bey, the reis-effendi, the tefterdar-effendi, the tchélibé-effendi, the terfana-émini, the tchiaoux-bachi, two ex-reis-effendi, and two ex-tefterdars-effendi. See BASHAW, BEY, KIAYA-BEY, &c.

The first of those above enumerated is the lieutenant of the visir; the second is secretary of state, or high chancellor of the empire; the third is the minister of the finances; the fourth is the receiver-general of the tax on wine, etables, and most articles of merchandize, and the administrator of these funds, &c.; the fifth is the minister of marine; the sixth secretary of state.

Renegade Christians have been sometimes raised to the visirate; such were Khairerdain, surnamed Barbarossa; Ulug Ali, Cuproli, &c.

VISIGAPATAM, in *Geography*, a town of Hindoostan, in the circar of Cicacole, on the coast. Near the town is a pagoda, dedicated to monkeys, which abound in the neighbourhood; they are fed by the priests, and regularly assemble at certain hours; 50 miles S.W. of Cicacole. N. lat. 17° 40'. E. long. 83° 30'.

VISIGNANO, a town of Ithria; 11 miles N. of Rovigno.

VISINA, a town of Ithria; 42 miles S.E. of Umago.

VISION,

VISION.

VISION, *Visio*, the act of seeing, or perceiving external objects by the organ of sight.

Vision is well defined to be a sensation, by which, from a certain motion of the optic nerve, made in the bottom of the eye by the rays of light emitted or reflected from objects, and hence conveyed to the common sensory in the brain, the mind perceives the luminous object, its quantity, quality, figure, &c.

The phenomena of vision, the causes of it, and the manner in which it is effected, make one of the greatest and most important articles in the whole system of natural knowledge. Indeed, a great part of the physical, mathematical, and anatomical discoveries and improvements of the moderns, terminate here, and only tend to set the business of vision in a clearer light.

Hitherto refer what Sir Isaac Newton and others have discovered of the nature of light and colours; the laws of inflection, reflection, and refraction of the rays, the structure of the eye, particularly the retina and optic nerves, &c.

It is not necessary we should here give a minute detail of the process of vision from its first principles; the greatest part is already delivered under the respective articles. The eye, the organ of vision, we have described under the article **EYE**; and its several parts, tunics, humours, &c. under their proper heads, **CORNEA**, **CRYSTALLINE**, &c.

The immediate and principal organ of vision, *viz.* the retina, according to some, and the choroides, according to others, are also distinctly considered; as also the structure of the optic nerve, which conveys the impression to the brain; and the texture and disposition of the brain itself, which receives them, and represents them to the soul. See **RETINA**, **CHOROIDES**, **OPTIC NERVES**, **BRAIN**, **SENSORY**, &c.

By means of this arrangement of the various refracting substances, many peculiar advantages are procured. The surface of the cornea only, if it had been more convex, could not have collected the lateral rays of a direct pencil to a perfect focus, without a different curvature near its edges; and then the oblique pencils would have been subjected to greater aberration, nor could they have been made to converge to any focus on the retina. A second refraction performs both these offices much more completely, and has also the advantage of admitting a greater quantity of light. If also the surfaces of the crystalline lens, thus interposed, had been abrupt, there would have been a reflection at each, and an apparent haziness would have interfered with the distinct view of every luminous object; but this inconvenience is avoided by the gradual increase of density in approaching the centre, which also makes the crystalline equivalent to a much more refractive substance of equal magnitude; while, at the same time, the smaller density of the lateral parts prevents the usual aberration of spherical surfaces, occasioned by the too great refraction of the lateral rays of direct pencils, and causes also the focus of each oblique pencil to fall either accurately, or very nearly, on the concave surface of the retina, throughout its extent.

Again, the nature of light, which is the medium or vehicle by which objects are carried to the eye, is laid down at large under the articles **LIGHT** and **COLOURS**; and the chief properties thereof concerned in vision, under **REFLECTION**, **REFRACTION**, &c.; and also many of its circumstances under **RAY**, **MEDIUM**, &c. What remains for this article, therefore, is only to give a general idea of the whole process, in which all the several parts are concerned.

Vision, *different Opinions or Systems of*. The Platonists and Stoics held vision to be effected by the emission of rays out of the eyes; conceiving that there was a sort of light thus darted out; which, with the light of the external air,

taking, as it were, hold of the objects, rendered them visible; and thus returning back again to the eye, altered and new modified by the contact of the object, made an impression on the pupil, which gave the sensation of the object.

The reasons by which they maintain their opinions are derived, 1. From the brightness and lustre of the eye. 2. From our seeing a remote cloud, without seeing one with which we are encompassed (the rays being supposed too brisk and penetrating to be stopped by the near cloud, but growing languid at a greater distance, are returned to the eye). 3. From our not seeing an object laid on the pupil. 4. From the eye's being weary with seeing; *i. e.* by emitting great quantities of rays. And lastly, from animals which see in the night, as cats, lions, moles, owls, and some men.

Our own countryman, Roger Bacon, distinguished as he was in a variety of respects, does not hesitate to assent to the opinion that visual rays proceed from the eye; giving this reason for it, that every thing in nature is qualified to discharge its proper functions by its own powers, in the same manner as the sun, and other celestial bodies. *Opus Majus*, p. 289.

The Epicureans held vision to be performed by the emanation of corporeal species, or images from objects; or a sort of atomical effluvia continually flying off from the intimate parts of objects to the eye.

Their chief reasons are, 1. That the objects must necessarily be united to the visive faculty; and since it is not united by itself, it must be so by some species that represents it, and that is continually flowing from bodies. 2. That it frequently happens, that old men see remote objects better than near ones; the distance making the species thinner, and more commensurate to the debility of their organ.

The Peripatetics hold, with Epicurus, that vision is performed by the reception of species; but they differ from him in the circumstances; for they will have the species (which they call *intentionales*) to be incorporeal.

It is true, Aristotle's doctrine of vision, delivered in his chapter "De Aspectu," amounts to no more than this; that objects must move some intermediate body, that by this they may move the organ of sight. To which he adds, in another place, that when we perceive bodies, it is their species, not their matter, that we perceive; as a seal makes an impression on wax, without the wax's retaining any thing of the seal.

But this vague and obscure account the Peripatetics have thought fit to improve. Accordingly, what their master called *species*, the disciples understanding of real proper species, assert, that every visible object expresses a perfect image of itself, in the air contiguous to it; and this image another, somewhat less in the next air; and the third, another, &c. till the last image arrives at the crystalline, which they hold for the chief organ of sight, or that which immediately moves the soul. These images they call *intentional species*.

The modern philosophers, as the Cartesians and Newtonians, give a better account of vision. They all agree, that it is performed by rays of light reflected from the several points of objects received in at the pupil, refracted and collected in their passage, through the coats and humours, to the retina; and thus striking, or making an impression, on so many points thereof; which impression is conveyed, by the correspondent capillaments of the optic nerve, to the brain, &c.

Baptista Porta's experiments with the camera obscura, about the middle of the 16th century, convinced him, that
vision

VISION.

vision is performed by the intermission of something into the eye, and not by visual rays, proceeding from the eye, as had been the general opinion before his time; and he was the first who fully satisfied himself and others upon this subject, though several philosophers still adhered to the old opinion.

As for the Peripatetic series or chain of images, it is a mere chimæra; and Aristotle's meaning is better understood without than with them. In effect, setting these aside, the Aristotelian, Cartesian, and Newtonian doctrines of vision are very consistent; for Sir Isaac Newton imagines, that vision is performed chiefly by the vibrations of a fine medium, which penetrates all bodies excited in the bottom of the eye by the rays of light, and propagated through the capillaments of the optic nerves, to the sensorium. And Descartes maintains, that the sun pressing the materia subtilis, with which the world is filled every way, the vibrations and pulses of this matter reflected from objects are communicated to the eye, and thence to the sensorium; so that the action or vibration of a medium is equally supposed in all.

VISION, *Modern Theory of.* In order to vision, we are certain, it is required, that the rays of light be thrown from the visible objects to the eye. What befalls them in the eye will be conceived from what follows.

Suppose, *e. gr.* Z the eye, and ABC the object (*Plate XX. Optics, fig. 8.*); now, though every point of an object be a radiant point, that is, though there be rays reflected from every point of the object to every point of the circumambient space, each carrying with it its respective colour, (which we falsely imagine to be those of the object,) yet, as only those rays which pass through the pupil of the eye affect the sense, we shall here consider none else but these.

And again, though there be a great number of rays passing from one radiant point, as B, through the pupil; yet we shall only consider the action of a few of them, as BD, BE, BF.

Now, then, the ray BD, falling perpendicularly on the surface EDF, will pass out of the air into the aqueous humour, without any refraction, and proceed right to H, where, falling perpendicularly on the surface of the crystalline humour, it will go on, without any refraction, to M; where, again falling perpendicularly on the surface of the vitreous humour, it will proceed straight to the point O, in the fund or bottom of the eye.

Again, the ray BE, passing obliquely out of the air upon the surface of the watery humour EDF, will be refracted, and approach towards the perpendicular EP; and thus, proceeding to the point G, in the surface of the crystalline, it will be there refracted still nearer to the perpendicular. So also EG, falling obliquely out of air into a harder body, will be refracted towards the perpendicular GR, and, falling on the point L of the surface of the vitreous humour, it will still be brought nearer to M.

Lastly, GL, falling obliquely out of a denser, upon the surface of a rarer body LMN, will be refracted, and recede from the perpendicular LT; in receding from which, it is evident, it approaches towards the ray BDO, and may be so refracted, as to meet the other in O. In like manner, the ray BF, being refracted in B, will turn to I, and thence to N, and thence to the others in O. But the rays between BE and BF, being somewhat less refracted, will not meet precisely in the same point O.

Thus will the radiant point B affect the fund of the eye, in the same manner as if the pupil had no breadth, or as if the radiant itself had only emitted one single ray, such as were equal in power to all those between BE and BF.

In like manner, the rays proceeding from the point A, will be so refracted in passing through the humours of the eye, as to meet near the point X; and the rays from any intermediate point between A and B, will nearly meet in some other point in the fund of the eye between X and O.

Upon the whole, it may be asserted universally, that every point of an object affects one point in the fund of the eye; and, on the contrary, that every point in the fund of the eye only receives rays from one point of the object. Though this is not to be understood with the utmost rigour.

Now, if the object recede from the eye, in such manner as that the radiant point B does not decline from the line BD; the rays which would proceed from B, not enough divaricated, would be so refracted in passing the three surfaces, as that they would meet before they reached the point O; on the contrary, if the object should be brought nearer the eye, the rays passing from the point to the pupil, being too much divaricated, would be refracted so, as not to meet till beyond the point O: nay, the object may be so near, that the rays proceeding from any point may be so divaricated, as that they shall never meet at all. In all which cases, there would be no point of the object but would move a pretty large portion of the fund of the eye; and thus the action of each point would be confounded with that of the contiguous one.

And this would commonly be the case, but that nature has provided against it; either by contriving the eye so that its bulk may be lengthened, or shortened, as objects may be more or less distant; or, as others will have it, so as that the crystalline may be made more convex, or more flat; or, according to others, so as that the distance between the crystalline and the retina may be lengthened or shortened.

The first expedient has been thought by some to be the most probable; on the footing of which, when we direct our eyes to an object so remote, as that it cannot be distinctly viewed by the eye in its accustomed figure, the eye is drawn back into a flatter figure, by the contraction of four muscles; by which means the retina, becoming nearer the crystalline humour, receives the rays sooner; and, on the other hand, when we view an object too near, the eye, being compressed by the two oblique muscles, is rendered more globular; by which means the retina, being set farther off from the crystalline, does not receive the rays of any point before they meet. See VISIBLE.

Those who maintain the opinion now stated farther allege, that this access and recede of the crystalline is so necessary to vision, that whereas, in some birds, the coats of the eye are of such a bony consistence, that muscles would not have been able to contract and dilate them; nature has taken other means, by binding the crystalline down to the retina, with a kind of blackish threads not found in the eyes of other animals. Nor must it be omitted, that of the three refractions above-mentioned, the first is wanting in fishes; and that, to remedy this, their crystalline is not lenticular, as in other animals, but globular. Lastly, since the eyes of old people are generally worn flatter than those of young ones, so that the rays from any point fall on the retina before they become collected into one, they must exhibit the object somewhat confusedly; nor can such eyes see any but remote objects distinctly. In others, whose eyes are too globular, the case is just the reverse. See PRESBYTA and MYOPS.

From what has been shewn, that every point of an object moves only one point of the bottom of the eye; and, on the contrary, that every point in the fund of the eye only receives rays from one point of the object, it is easy to conceive, that the whole object moves a certain part of the

retina;

retina; that in this part there is a distinct and vivid collection of all the rays received in at the pupil; and that as each ray carries its proper colour along with it, there are as many points painted in the fund of the eye as there were points visible in the object. Thus is there a species, or picture, on the retina, exactly like the object: all the difference between them is, that a body is here represented by a surface, a surface frequently by a line, and a line by a point; that the image is inverted, the right-hand answering to the left of the object, &c. and that it is exceedingly small; and still the more so, as the object is more remote.

What we have shewn, under other articles, of the nature of light and colours, readily accounts for this painting of the object on the retina. The matter of fact is proved by an easy experiment, long since tried by Des Cartes, thus: the windows of a chamber being shut, and light only admitted at one little aperture; to that aperture apply the eye of some animal newly killed, having first dexterously pulled off the membranes that cover the bottom of the vitreous humour, viz. the hind part of the sclerotic, choroides, and even part of the retina; then will the images of all the objects, without doors, be seen distinctly painted on any white body, as on an egg-shell, that the eye is laid upon. And the same thing is better shewn by an artificial eye, or a camera obscura.

The images of objects, then, are represented on the retina; which is only an expansion of the fine capillaments of the optic nerve, and from which the optic nerve is continued into the brain. Now, any motion or vibration, impressed on one extreme of the nerve, will be propagated to the other: hence the impulse of the several rays, sent from the several points of the object, will be propagated as they are on the retina, (i. e. in their proper colours, &c. or in particular vibrations, or manners of pressure, corresponding thereto,) to the place where those capillaments are interwoven into the substance of the brain. And thus is vision brought to the common case of sensation.

For such, we know, is the law of the union between the soul and body, that certain perceptions of the first do necessarily follow certain motions of the last; but the different parts of the object do separately move different parts of the fund of the eye; and those motions are propagated to the sensory: it follows, therefore, that there must arise so many distinct sensations at the same time. See SENSATION.

Hence, 1. We easily conceive, that the perception, or image, in the mind, must be the clearer, and more vivid, the more rays the eye receives from the object; and consequently, the largeness of the pupil will have some share in the clearness of vision.

2. Considering only one radiant point of an object, we may say, that that point would move the sense more weakly, or be seen more obscurely, as it is more remote; because the rays coming from any point, like all qualities propagated in orbem, are always diverging; and therefore the more remote, the fewer of them will be received in at the pupil. But the pupil dilating itself more, as the object is more remote, takes in more rays than it would otherwise do.

3. The distinctness of vision is somewhat concerned in the size of the image exhibited in the fund of the eye. For there should be, at least, as many extremes of capillaments, or fibres of the optic nerve, in the space that image possesses, as there are particles in the object that send rays into the pupil; otherwise every particle will not move its separate capillament; and if the rays from two points fall on the same capillament, it will be the same as if only one point had fallen there; since the same capillament cannot be differently

moved at the same time. And hence it is, that the images of very remote objects being very small, they appear confused, several points of the image affecting each capillament; and hence, also, if the object be of different colours, several particles affecting the same capillament at the same time, only the brightest and most lucid will be perceived. Thus, a field, furnished with a good number of white flowers, among a much greater quantity of green grass, &c. at a distance, appears all white. See *Distincta Vision*, infra.

Our seeing of objects *single*, though with two eyes, in each of which is a separate image, or picture; and our seeing of them *erect*, whereas the picture is really inverted, are two great phenomena in vision; which we have considered under the article SEEING.

For the manner of seeing and judging of the distance and magnitude of objects, see VISIBLE, MAGNITUDE, &c.

VISION, in *Optics*. The laws of vision, brought under mathematical demonstrations, make the subject of *Optics*, (which see,) taken in the greatest latitude of that word: for, among the writers of mathematics, optics is generally taken, in a more restrained signification, for the doctrine of *direct* vision; catoptrics, for the doctrine of *reflected* vision; and dioptrics, for that of *refracted* vision.

VISION, *Direct* or *Simple*, is that performed by means of direct rays; that is, of rays passing directly, or in right lines, from the radiant point of the eye. Such is that explained in the preceding article, VISION.

VISION, *Reflected*, is that performed by rays reflected from specula, or mirrors. The laws of this kind of vision, see under REFLECTION, and MIRROR.

VISION, *Refracted*, is that performed by means of rays refracted, or turned out of their way, by passing through mediums of different density; as air and water, and chiefly through glasses and lenses. The laws of this, see under the article REFRACTION.

VISION, *Arch* of. See ARCH.

VISION, *Distincta*, denotes that by which an object is seen distinctly. An object is said to be seen distinctly, when its outlines appear clear and well defined, and the several parts of it, if not too small, are plainly distinguishable, so that we can easily compare them one with another, in respect to their figure, size, and colour.

In order to such distinct vision, it has hitherto been commonly thought, that all the rays of a pencil, flowing from a physical point of an object, must be exactly united in a physical, or, at least, in a sensible point of the retina. But it seems certain, from the experiments mentioned by Dr. Jurin, that such an exact union of rays is not always necessary to distinct vision.

Hence the doctor divides distinct vision into two species, viz. into vision *perfectly distincta*, or *perfect* vision, and vision *imperfectly distincta*; which he calls simply by the name of *distincta* vision. The former is that in which the rays of each pencil are collected into a single physical, or sensible point of the retina; the other species is that in which those rays occupy some larger space upon the retina, yet so as the object is distinctly perceived.

Perfect vision in a given eye, and a given disposition of that eye, depends only upon the dilance of the object; it has no dependence upon the magnitude of the object; but *distincta* vision, in a given eye, and a given disposition of the eye, depends upon the dilance and magnitude of the object jointly. There appearing, therefore, a real difference between *perfect* vision, and what we call *distincta* vision, the learned doctor has enquired very particularly into the reason why an object may be seen distinctly without perfect vision.

He shews that objects may be seen with sufficient distinctness, though the pencils of rays issuing from the points of them do not unite precisely in the same point on the retina; but that since, in this case, pencils from every point, either meet before they reach the retina, or tend to meet beyond it, the light that comes from them must cover a circular spot upon it, and will, therefore, paint the image larger than perfect vision would represent it. Whence it follows, that every object, placed either too near, or too remote for perfect vision, will appear larger than it is by a penumbra of light, caused by the circular spaces, which are illuminated by pencils of rays proceeding from the extremities of the object. All the varieties occasioned by this circumstance he traces with great accuracy, and he applies his observations upon it to the explanation of many phenomena in vision. See *Circle of DISSIPATION*.

Dr. Jurin observes, that when objects are large, they will appear tolerably distinct at a much less distance than small objects, because the penumbra will not interfere so much; and on this account, a large print may be read much nearer to the eye than a small one. In this case the former will appear only ill defined, but sufficiently distinct, when the latter is quite indistinct, the penumbra of one letter interfering with that of another, and thereby making marks altogether unlike any that are in the book. The dispersed light of these penumbrae, he says, is of different densities; and Mr. Robins, in his Remarks on Dr. Jurin, p. 279, observes, that the whole circle made by the confused image of any print, will be proportioned to the diameter of the pupil of the eye, which limits the whole pencil.

The smallest distance of perfect vision, or that in which the rays of a single pencil are collected into a physical point on the retina in the generality of eyes, Dr. Jurin, from a number of observations, states at five, six, or seven inches. The greatest distance of distinct and perfect vision he found to be more difficult to determine; but by considering the proportion of all the parts of the eye, and the refractive power of each, together with the interval that may be discerned between two stars, the distance of which is known, he fixes it, in some cases, at fourteen feet five inches, though Dr. Porterfield had confined it to twenty-seven inches only, with respect to his own eye.

When vision is indistinct, Dr. Jurin thinks that there are two methods of rendering it distinct. One is for the eye to apply the same power, by which it conforms itself to the view of objects placed at different distances, so as to obtain perfect vision; and the other is the contraction of the pupil by the lesser muscular ring of the uvea, which is chiefly made use of in a strong light, and which will sometimes render the other means altogether unnecessary. In a weak light, he says, the pupil is so far from contracting, that there is rather a necessity for dilating it, to take in more light. But upon this Dr. Whytt (*Ess. on vital and involuntary Motions*, p. 133.) observes, that in the same, or a less degree of light, the pupil will be contracted, in order to view a nearer or a smaller object. For other observations on this subject, see Jurin's *Ess. on distinct and indistinct Vision*, at the end of Dr. Smith's *Optics*; and Robins's Remarks on Dr. Jurin, in his *Math. Tracts*, vol. ii. p. 278, &c.

VISION, Field of. See *FIELD*.

VISION, among Divines, is used for an appearance, which God occasionally sent to his prophets and saints; either by way of dream, or in reality.

Such were the visions of Ezekiel, Amos, &c.; the vision of St. Paul, lifted up to the third heaven, &c.; of Joseph, by which he was assured of the purity of the Virgin, &c.

Some have represented our blessed Lord's temptation in the wilderness, Matt. v. 1, &c. as a vision. Mr. Farmer, in particular, considers it as a divine vision, representing the trials he was to endure, and designed to prepare him for encountering and vanquishing them. See *TEMPTATION*.

Many among the Romish saints have pretended to visions: as St. Theresa, St. Bridget, St. Catharine de Sienna, &c.

Hence the word has come into disrepute, and become a common name for all chimeras, or spectres, which either our folly or fear possesses us with: and hence, a person that frames to himself wild romantic notions, is called a *visionary*. Quevedo's *Visions* are descriptions of what passed in the imagination of that author.

VISION, Beatific, denotes the act by which the angels and blessed spirits see God in Paradise.

VISIR, VISIER, or Visier. See *VISIER*.

VISITATION, VISITATIO, an act of jurisdiction, by which a superior or proper officer visits some corporation, college, church, or other public or private house, to see that their respective laws and regulations be duly observed.

Among us, the bishop of each diocese is obliged to hold a visitation every third year, and the archdeacon the other two years; to see that the discipline be well observed, the people well instructed, and to take care that neither the church, nor the pastors of it, receive any detriment. For the first 600 years after Christ, the bishops in their own persons visited all the parishes within their respective dioceses every year; but since the law and practice of triennial visitations have been established, the bishop is not only not obliged by law to visit annually, but he is restrained from it.

The business of parochial visitation, in order to inspect and take account of the fabrics and mansions, ornaments and utensils, vestments and books of the church, peculiarly belongs to the archdeacon. In all visitations of parochial churches made by bishops and archdeacons, the law hath provided, that the charge of them shall be defrayed by the procurations then due, and payable by the inferior clergy; in which custom, as to the quantum, shall prevail. These procurations are due to the person visiting of common right; and although originally due by reason of visitation only, yet the same may be due without actual visitation. They are suable only in the spiritual court, and are merely an ecclesiastical duty; and they may be levied by sequestration, or other ecclesiastical process. Free chapels and donatives (unless such donative hath received the augmentation of queen Anne's bounty) are exempt from the visitation of the ordinary, and of course pay no procurations; the first being visitable only by commission from the king, and the second by commission from the donor. And there are also other churches and chapels exempted, which belonged to the monasteries; which by 25 Hen. VIII. c. 21. were made visitable by the king, or by commission under the great seal.

Anciently the regarder's office was expressed to be the *visitation of manners*. See *REGARDER*.

The lawyers hold it a branch of the king's prerogative, to visit the universities; to enquire into the statutes, and the observation of them; to expel delinquents, &c. But some of the colleges disallow this privilege, and plead themselves, by royal charters, exempt from all civil and royal visitations.

With regard to all ecclesiastical corporations, the ordinary is their visitor, so constituted by the canon law, and thence derived to us. The pope formerly, and now the king, as supreme ordinary, is the visitor of the archbishop or metropolitan: the metropolitan has the charge and coercion of all

his suffragan bishops; and the bishops in their several dioceses are in ecclesiastical matters the visitors of all deans and chapters, of all parsons and vicars, and of all other spiritual corporations. With respect to all lay corporations, the founder, his heirs or assigns, are the visitors, whether the foundation be civil or eleemosynary; for in a lay corporation the ordinary neither can nor ought to visit. In general, the king being the sole founder of all civil corporations, and the endower the persicent founder of all eleemosynary ones, the right of visitation of the former results to the king, and of the latter to the patron or endower. The king being constituted by law the visitor of all civil corporations, the law has also appointed the place in which he shall exercise this jurisdiction; which is the court of king's bench, where, and where only, all misbehaviours of this kind of corporations are enquired into and redressed, and all their controversies decided. Accordingly this is the meaning of lawyers, when they say that these civil corporations are liable to no visitation; *viz.* that the law having by immemorial usage appointed them to be visited and inspected by the king their founder, in his majesty's court of king's bench; according to the rules of common law they ought not to be visited elsewhere, or by any other authority.

As to eleemosynary corporations, by the dotation the founder and his heirs are of common right the legal visitors, to see that property is rightly employed, which might otherwise have defecended to the visitor himself: but if the founder has appointed and assigned any other person to be visitor, then his assignee so appointed is invested with all the founder's power, in exclusion of his heir. Eleemosynary corporations are chiefly hospitals, or colleges in the university. With regard to hospitals, it has long been held, that if the hospital be spiritual, the bishop shall visit; but if lay, the patron. This right of lay patrons was indeed abridged by 2 Hen. V. cap. 1. which ordained, that the ordinary should visit all hospitals founded by subjects: though the king's right was reserved, to visit by his commissioners such as were of royal foundation. But the subject's right was in part restored by stat. 14 Eliz. cap. 5. which directs the bishop to visit such hospitals only, when no visitor is appointed by the founders of them; and all the hospitals founded by virtue of the stat. 39 Eliz. c. 5. are to be visited by such persons as shall be nominated by the respective founders. But still, if the founder appoints nobody, the bishop of the diocese must visit. Colleges in the universities were formerly considered by the popish clergy, under whose direction they were, as ecclesiastical, or at least as clerical, corporations; and therefore the right of visitation was claimed by the ordinary of the diocese. In some of our colleges, where no special visitor is appointed, the bishop of that diocese, in which Oxford was formerly comprised, has immemorially exercised visitatorial authority; which can be ascribed to nothing else but his supposed title as ordinary to visit this, among other ecclesiastical foundations. And it is not impossible, that the number of colleges in Cambridge which are visited by the bishop of Ely, may in part be derived from the same original. But whatever might be formerly the opinion of the clergy, it is now held as established common law, that colleges are lay corporations, though sometimes totally composed of ecclesiastical persons; and that the right of visitation does not arise from any principles of the canon law, but of necessity was created by the common law. In a disputed case it was held by lord chief justice Holt, that by the common law the office of the visitor is to judge according to the statutes of the college, and to expel and deprive upon just occasions, and to hear all appeals of course; and that from him, and him only, the party grieved ought to have redress; the

founder having reposed in him so entire a confidence, that he will administer justice impartially, that his determinations are fixed, and examinable in no other court whatsoever.

To this leading case all subsequent determinations have been conformable. But where the visitor is under a temporary disability, then the court of king's bench will interpose, to prevent a defect of justice. Also it is said, that if a founder of an eleemosynary foundation appoints a visitor, and limits his jurisdiction by rules and statutes, if the visitor in his sentence exceeds those rules, an action lies against him; but otherwise, where he mistakes in a thing within his power. Blackst. Comm. book i.

Among the Romanists, the general of each religious order is obliged to visit the several monasteries of his order.

In abbeys, that are chiefs of their orders, there are particular officers, called visitors; who are dispatched into all the houses and congregations depending on them, to see that the regular discipline is observed.

In Spain there is a visitor, and inquisitor-general. The visitation of the cloister belongs to the ordinary.

VISITATION, in a moral and religious sense, is also applied to the afflictions that befall mankind; as coming from the hand of God, to try or prove them. In which sense, the plague, among us, is frequently called the visitation.

VISITATION OF THE *Virgin Mary*, is a feast instituted in memory of the visit paid by the Virgin to Elizabeth, first established by Bonaventure, general of the order of St. Francis, by a decree of the general chapter, comprehending the churches of his own order, held at Pisa in 1263; and afterwards extended to the whole church, by pope Urban IV. in the year 1379, and ordained to be kept on the 2d of July.

VISITATION is likewise an order of monks founded by Francis de Sales and his mother Chantal.

VISITORS. See VISITATION, supra.

VISITORS OF THE *Inquisition*. See INQUISITION.

VITITZ, in *Geography*, a town of Austria; 4 miles S.E. of Bavarian Waidhoven.

VISIVE, VISIVUS, in the *School Philosophy*, a term applied to the power of seeing.

Authors are exceedingly divided about the place where the visive faculty resides: some will have it in the retina; others, in the choroides; others, in the optic nerve; others, as sir Isaac Newton, in the place where the optic nerves meet, before they come to the brain; and others, in the brain itself.

VISKAIA, in *Geography*, a fort of Russia, in the government of Upha; 64 miles W.S.W. of Tchelibinsk.

VISKAIA, *Usl*, a fort of Russia, in the government of Upha, near the Tobol; 88 miles S.E. of Tchelibinsk.

VISMEA, in *Botany*, received its name from the younger Linnaeus, who erroneously called it *Vifnea*, in honour of Mr. De Vifme, a merchant at Lisbon. Willdenow retains the latter orthography; Schreber, better instructed, uses the former. This name, though not rumbling with consonants, like some with which our science is encumbered, is nevertheless most irreconcilable to Latin pronunciation; nor ought such to be admitted, but when supported by the highest possible pretensions, which in this case are not conspicuous. The worthy Masson, personally informed on the subject, used vehemently to exclaim against the above name, and the French botanists have preferred its barbarous synonym *Mocanera*, by which the shrub in question is known in the Canary islands. Mr. De Vifme, it seems, was a plant amateur; but as he endeavoured to diffuse a taste for plants among the Portuguese, who were previously little disposed to any such elegancies, or to any thing useful or praiseworthy

in their stead, we cannot but think him full as deserving of commemoration as many of our own horticulturists, who do but follow a fashion, and therefore are not entitled to literary honours, in a science which they perhaps "ignorantly worship." If they study its principles, they rank as botanists, and render eminent services to those who have not the means of promoting the game pursuit in the same way.—Linn. Suppl. 36. Schreb. Gen. 327. Willd. Sp. Pl. v. 2. 926. Mart. Mill. Dict. v. 4. Lamarck Dict. v. 4. 208. (Mocanera; Juss. 318.)—Class and order, *Dodecandria Trigynia*. Nat. Ord. *Calycanthemis*, Linn. *Onagra*, Juss.

Gen. Ch. Cal. Perianth half superior, of five lanceolate, recurved, permanent leaves, the three outermost hairy. Cor. Petals five, equal, elliptical, undivided, spreading, longer than the calyx. Stam. Filaments twelve, inserted into the receptacle of the flower, erect, thread-shaped, shorter than the petals; anthers erect, quadrangular, each tipped with a bristle. Pist. Germen half inferior, hairy, taper-pointed; styles three, thread-shaped, smooth; stigmas simple. Peric. Nut ovate, pointed, smooth, of two or three cells, half inferior, coated, or covered, above half way up, with what might be called the tube of a monophyllous calyx, and surrounded with its converging segments. Seeds solitary.

Eff. Ch. Calyx half inferior, of five leaves. Petals five. Stigmas simple. Nut of two or three cells, coated below. Seeds solitary.

1. *V. Mocanera*. Linn. Suppl. 251. Willd. n. 1.—Gathered by Mr. Masson, in the mountainous woods of the Canary islands. A small shrub, with a round, rugged, or somewhat warty, stem. Leaves alternate, erect, on short stalks, coriaceous, elliptical, veiny, ferrated, very smooth. Flower-stalks axillary, solitary, drooping, scarcely longer than the footstalks, naked, each bearing one small yellow flower. After impregnation the stalks become erect, the calyx closes and thickens, its three outer segments turning brown and hairy. This, the only known species, is a stranger to our gardens.

VISNAGA, Matth. Valgr. v. 1. 477. t. 479. Rivin. Pentap. Irr. t. 84, an herbaceous plant of the south of Europe, is the *Daucus Visnaga* of Linn. Sp. Pl. 348. Gærtner, t. 21, establishes it as a genus by itself. Desfontaines, and the author of this article, in Prodr. Fl. Græc. Sibth. v. 1. 186, have referred the plant to *Anmi*. There is some reason to believe it the *γυγυδιον* of Dioscorides. See GIN-
GIDIUM.

VISNAVITRA, in *Biography*. See VISWAMITRA.

VISNE, VISNETUM, in *Lavæ*, a neighbouring place, or a place near at hand. See VENUE.

VISNEA, in *Botany*, Linn. Suppl. 36. See VISMEA.

VISNIZA, in *Geography*, a town of European Turkey, in Moldavia; 30 miles N. of Suzcava.

VISO, EL, a town of Spain, in New Castile; 25 miles S.S.E. of Ciudad Real.

Viso, a mountain of France, in the department of the Stura, supposed to be one of the highest parts of the Alps.

Viso *Marso*, a town of Naples, in Calabria Citra; 13 miles W.N.W. of Scalea.

VISOKICH, a town of Russia, in the government of Irkutsk, on the Lena; 8 miles N.N.W. of Orlenga.

VISON, a town of France, in the department of the Tanaro; 3 miles E.S.E. of Acqui.

VISONTIUM, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Pclendones. Ptol.—Also, a town of Higher Pannonia, of the number of those which were remote from the Danube.

VISP, in *Geography*, a town of the Vallais, and chief place of a dixin, or tytlung; 22 miles E. of Sion.

VISPE, or USPE, in *Ancient Geography*, a town belonging to the Saracens, in the vicinity of the Bosphorus of Thrace; and not far from the river Pania. Tacitus says that it was strongly fortified. The Romans besieged it and were repulsed. When they afterwards attacked the place by escalade, the inhabitants sent a deputation to petition for the life of free persons, with an offer of 10,000 slaves. The besiegers rejected these conditions, and revolting at the cruelty of massacring persons who voluntarily surrendered themselves, and imprisoning to great a number of persons, they recurred to the right of war, which exhibits a horrible example of the ferocity of the Romans. They gave the signal for escalade, but afterwards entered into treaty. In consequence of this event, which was attended with the destruction of Vispe, no record of it remains.

VISPELLIONES, among the Romans, were slaves who could not be manumitted.

VISRAVA, in *Mythology*, a name of the Hindoo Plutus, who is more commonly called *Kuvera*; which see. See also VAISRAVA, another mode of pronouncing this name, which is likewise given to the father of Kuvera and of his half-brother Ravena. (See RAVENA.) These two last named half-brothers are also called Paulastya, or Pulastya. Visrava, or Vaivrava, is sometimes named Visvavra and Visravana.

VISRUTI, one of the three daughters of Swayambhuva, a personage of importance in their fabulous legends. Some notice of him occurs under his name in this work.

VISSE, in *Geography*, a town of the Popedom, in the marquisate of Ancona; 15 miles S. of Camerino.

VISSEGRAD, a town of Bosnia; 40 miles S.E. of Bofnaferai.

VISSEGRAD. See VICEGRAD.

VISSEHOVEDE, a town of Germany, in the county of Verden; 10 miles E. of Verden.

UIST, NORTH, one of the islands of the Hebrides, in the shire of Inverness, Scotland, is of a very irregular shape, and extends in length about twenty miles, and from twelve to eighteen in breadth. The word *Uist* is said to be taken from the Scandinavian word *uisl*, which signifies *west*, and was given by the Danes, when in possession of these countries, on account of its westerly situation. The western part of the coast, which is washed by the Atlantic, is inaccessible to vessels, or even to fishing-boats, except in the calmest weather, on account of rocks and shoals. On the eastern coast are several inlets of the sea, which form safe and commodious harbours. Of these, the best is loch Maddie, which affords good anchorage for vessels of any burden. Along the coast round these harbours the ground is barren, hilly, and almost uninhabited. The western and northern parts of the island, almost the only cultivated parts, are low and level for about a mile and a half from the sea, when the surface becomes moory, with hills of small height covered with black heath. It has mostly a sandy soil, which, as it approaches the moorlands, is a thin black loam, on a gravelly, or on a free-stone bottom. In favourable summers, the cultivated parts yield luxuriant crops of oats and barley; but as there are no trees to afford shelter during the inclemency of winter, the appearance is then greatly changed, and verdure is scarcely to be seen; so that the cattle, in these seasons, are fed partly on straw, and partly on sea-weed thrown up by storms. The number of cows kept on the island is about 2000, of which 300 are annually exported; the number of horses is about 1600. Agriculture is in a low state; and the implements of husbandry, with a few exceptions, are the same kind that were used a century past. Here are numerous fresh-water lakes, abounding with excellent trout, and frequented by innumerable

able flocks of aquatic fowls. Kelp is manufactured to a considerable extent, the annual produce being about 1200 tons; of which the greater part belongs to lord Macdonald, the sole proprietor of the island, from which he derives a yearly rent of 2100*l.* sterling, besides the profits of the kelp. A parochial school is established here, from which one scholar is annually sent to the university. The parish of North Uist comprehends several adjacent isles. In the year 1811, the population was estimated at 3773. Here are the remains of several Danish forts: and also of some Druidical temples, which are described by Dr. Smith, in his History of the Druids.—*Beauties of Scotland*, vol. v. Invernesshire, 1808. *Gazetteer of Scotland*, 1806. *Carlisle's Topographical Dictionary of Scotland*, 1813.

Uist, *South*, another of the Hebrides islands, also included in the shire of Inverness, is in length about thirty miles, and the greatest breadth may be estimated from seven to nine miles; affording an area of about 40,000 acres, capable of cultivation. Towards the west and north-west, where it is bounded by the ocean, the soil is light and sandy, and most part rendered useless by the severity of the storms: further inland is a series of lakes, which abound with a variety of fish; and to the east are high and rugged mountains, covered with heath and a partial degree of verdure, which afford pasturage in the summer and autumn months for black cattle, horses, sheep, and goats; but the grain produced on the island does not serve the inhabitants more than nine months in the year. About 7000 sheep are generally kept here, and about 3000 cows; but the greatest source of emolument (as well as in North Uist) is the manufacture of kelp, to the amount of 1100 tons annually: its first introduction into these islands was in the year 1750, by a Mr. Macleod, who brought it from Ireland, where it had been carried on for several years. The parish of South Uist, which includes some small contiguous isles, contained, in the year 1811, a population of 4825; being more than doubled since the year 1755, notwithstanding numerous emigrations.—*Beauties of Scotland*, vol. v. Invernesshire, 1808. *Carlisle's Topographical Dictionary of Scotland*, 1813. *Gazetteer of Scotland*, 1806.

VISTAMENTE, in the *Italian Music*, is used to give notice to play or sing quick, briskly, &c.

VISTE, in *Botany*, a name given by some authors to the common white mountain coralloides: it is the Lapland name for the same plant; the rein-deer and many other creatures feeding on it, when all other vegetables are destroyed.

VISTER, in *Geography*, a town of European Turkey, in Bulgaria; 44 miles S.W. of Ismail.

VISTNOU, VISTNUM, or *Vishnu*, in the *Modern History of Mythology*, a name given in the theology of the Brahmins, to one of the three great gods of the first class, which are the objects of worship to the inhabitants of Hindoostan: the other two are *Brahma* and *Ruddiren*.

According to the *Vedam*, these three gods were created by the Supreme Being, to be his ministers in nature. *Brahma* is represented as the creator, *Vistnou* as the preserver, and *Ruddiren* as the destroyer of beings. However, there are some sects which maintain, that *Vistnou* is superior to *Brahma*, and that he gave him existence. *Vistnou*, it is said, distributed mankind into three classes, the rich, the poor, and those of middle state; and created many worlds, inhabited by spirits destined for the preservation of other beings. *Vistnou* is most respected in the kingdom of Carnata, *Brahma* in the Mogul empire, and *Ruddiren* in Malabar. *Un. Hist.* vol. vi. 8vo. See *VISHNU*.

VISTRITZA, in *Geography*, a river of European

Turkey, which runs into the Vittriza, 16 miles E.S.E. of Edeffa, in Macedonia.

VISTRIZA, a river of European Turkey, in Macedonia, which runs into the Varder, 25 miles N.W. of Saloniki.

VISTULA, a river which rises in the south-east part of Silesia, on the borders of Poland, passes by Cracow, Sandomirz, Zawichost, Warfaw, Wladislaw, Thorn, Culm, &c. and runs into the Baltic, at Dantzic.

VISUAL, something belonging to the sight, or seeing.

VISUAL Angle. See ANGLE.

VISUAL Line. See LINE.

VISUAL Point, in *Perspective*, is a point, in the horizontal line, in which all the ocular rays unite. See POINT.

Thus, a person standing in a straight long gallery, and looking forwards; the sides, floor, and ceiling, seem to meet, and touch one another in a point, or common centre.

VISUAL Rays, are lines of light, imagined to come from the object to the eye. See RAY.

All the observations of astronomers and geometers are performed by means of the visual rays, received in at the sights, or pinnule, or alidades.

VISUM. See *HABERE facias visum*.

VISURGIS, the *Weser*, in *Ancient Geography*, a very considerable river of Germany; it made a separation between the Romans and Cherusci, according to Pliny, and became celebrated by the defeat of the Roman army on its banks, according to Velleius Paterculus.

VISWADEVA, a sacrifice or oblation offered by pious Hindoos to all their gods collectively. The word means all the gods. "One oblation to the assembled gods, thence named *Viswadeva*, is ordained both for evening and morning." *Init. of Menu*, iii. 121. (See *MENU*.) Of other sacrifices of the Hindoos, see *SRADHA*.

VISWAJENNI, in *Mythology*, a name of the Hindoo goddess *Parvati*; which see. It means *all-prolific*, and is applied to her in her character of *Prakriti*, or nature. See *PRAKRITI*.

VISWAKARMA, is a personage of considerable importance, and his name frequently occurs in Hindoo books. Sir W. Jones (*As. Ref. vol. i.*) thinks *Viswakarma* to be the Vulcan of the Greeks and Romans; being, like Vulcan, the forger of arms for the gods; and inventor of the *Agniakra*, or fiery shaft, used in the wars between them and the *Daityas*, or Titans. He is deemed the architect of the universe, and chief engineer of the gods. He revealed the fourth *Upaveda* in various treatises on sixty-four mechanical arts, for the improvement of such as exercise them; and he is the inspector of all manual labours and mechanical arts. See *VEDA*.

It is fabled that *Viswakarma* was employed by Krishna to build for him the city of Dwarka, in Guzerat; and it is not unusual for any very magnificent or stupendous work of antiquity to be attributed to him: the excavations at Ellora, for instance. (See *ELLORA*.) Between *Viswakarma* and the Pandus, the labour and honour of the excavations at Ellora, *Elephanta*, *Karly*, &c. are shared. See *ELEPHANTA*, *KARLY*, and *PANDU*.

Viswakarma is the reputed son of *Bhuvana*, and a daughter of his is sometimes mentioned, named *Barhilmati*; but their names seldom occur. A son of the divine artist is named *Vishwawarupa* (which see), father of the wives of *Ganesa*, or *Pollax*. Under our article *TARA* is a ridiculous, but characteristic legend of *Viswakarma* having, like most of the other Hindoo deities, begotten an ape! *Twashta* is another

another name of this divine architect, and also of the sun. See TWASHTA.

VISWAMITRA, in *Biography*, is the name of a very celebrated and fancified personage in the theological legends of the Hindoos. His age is anterior to authentic research, since his name occurs frequently in the Veda, the Hindoo scriptures, which is professed to have been written thousands of years ago. (See VEDA.) He was the Rishi, (see RISHI,) or faint, to and by whom was revealed the hymn in which is contained the holiest verse of the Veda, called the adorable, the ineffable, Gayatri. (Of this see under O'M.) His grandson, named Yajnyawalkya, is the reputed author of a code or institutes of law that is still in use. It is arranged in three chapters, containing 1023 couplets. The commentaries on it are very voluminous. The name of Viswamitra, which means universal friend, or friend to all, occurs very frequently in Sanscrit writings; and indeed not unfrequently in this dictionary. His self-inflicted austerities, and persevering devotions, are the theme of frequent praise. Under the article MENAKA, the Upsara, "of fascinating symmetry of form," as she is described in the Ramayana, it is noticed how the rigid mortifications of the ascetic were interrupted; and their reward averted by the wiles of that damsel employed by Indra. Under RAMAYANA and UPSARA will be found some account of the work, and of the semi-divine, faint-seducing beauties, severally so called. See also INDRA and RHEMBA, the name of the Venus Marina of the Hindoos, and queen of beauty and of beauties. Viswamitra, though not of Brahma, was the guru, or spiritual preceptor of the great Rama; and is the author of much of the moral precept scattered through that curious work the Ramayana; which details the exploits, among much other matter, of its divine hero. (See RAMA.) In the Ramayana, Viswamitra is often called "son of Kashika;" and occasionally a person named Gadhri, is called his father. The interesting Sakountala, introduced to the English reader by Sir W. Jones's translation of the Hindoo drama of that title, is spoken of as his daughter. Though not a Brahman by birth, he is said to have become one through his devotion.

Under our article SURABHI an anecdote is given of Viswamitra, which, with that alluded to above, tends to shew that he was tainted with the vice of avarice as well as lust. In our article TAREKA he appears as the tutor of his obedient pupil Rama.

VISWASWARA, a name of the Hindoo god Siva; which see. It means lord of all; and is probably given to him by the sects who exclusively, or especially worship him, of whom see under SECTS of Hindoos. The name does not often occur. In one of the Puranas is this verse. "The Vedas and Sastras all testify that Viswaswara is the first of Devas (or gods), Kashi (Benares) the first of cities, Ganga (the Ganges) the first of rivers, and Charity the first of virtues."

VITA, LIFE. See LIFE.

VITA, Cui in. See CUI.

VITE, Aqua. See AQUA.

VITE Arbor, in *Anatomy*, the appearance produced by a particular section of the cerebellum. See BRAIN.

VITE, Arbor. See TREE of Life.

VITE, Lignum. See GUAIAACUM.

VITA Longa, a name given by some botanical authors to the piper *Ethiopicum*, or Ethiopian pepper.

VITACA, in *Ancient Geography*, a town of Africa, in Mauritania Cesariensis. Ptol.

VITAL, VITALIS, in *Anatomy*, something that ministr

ters principally to the constituting or maintaining of life in the bodies of animals.

Thus, the heart, lungs, and brain, are called vital parts. See VIS.

VITAL Air, in *Agriculture, Vegetable Economy*, &c. pure air or oxygen, which is one of the constituent parts of atmospheric air, and of great use in the germination of grain and seeds, and the vegetation and growth of plants, as well as the respiration of animals. But though it is necessary to these and some other functions of vegetables, it is remarked by the writer of a late work on agricultural chemistry, that its great importance in nature is in its relation to the last, or the economy of animals.

It is stated that atmospheric air taken into the lungs of animals, or passed in solution in water through the gills of fishes, loses vital air or oxygen; and that for the vital air or oxygen that is lost, about an equal volume of carbonic acid appears. That the action of the atmosphere on plants differs at different periods of their growth, and varies with the various stages of the development and decay of their organs, as is evident in the progress of their vegetation and decline. As if a healthy seed be moistened and exposed to the air at a temperature not below 45°, it soon germinates or sprouts; and shoots or sends forth a plume which rises upwards, and a radicle that descends. If the air be confined, it is found that in this process the vital air or oxygen of it, or a part of it, is absorbed. As to the other parts, the azote remains unaltered, and no carbonic acid is taken away from it; on the contrary, some is added. Grain and seeds are incapable of germinating or sprouting, except when vital air or oxygen is present. In the exhausted receiver of the air-pump, in pure azote, and in pure carbonic acid, when moistened they swell, but do not vegetate; and if kept in these gases, lose their living powers, and undergo putrefaction. If a grain or seed be examined before germination, it will be found more or less insipid, or at least not sweet; but after germination, or the act of sprouting, it is always sweet. Its coagulated mucilage, or starch, is converted into sugar in that process; a substance difficult of solution is thus changed into one easily soluble; and the sugar carried through the cells or vessels of the cotyledons of the grain or seeds, is the nourishment of the infant plant.

It is noticed that the absorption of vital air or oxygen by the grain or seed in germination, or the operation of sprouting, has been compared to its absorption in producing the evolution of foetal life in the egg; but that this analogy is only remote. All animals, from the most complete to the least perfect classes, require, it is said, a supply of vital air or oxygen for their production and evolution. From the moment the heart begins to pulsate until it ceases to beat, the aeration of the blood, or the supply of this sort of air, is constant, and the function of respiration invariable; carbonic acid is given off in the process, but the chemical change produced in the blood is unknown; nor is there any reason to suppose the formation of any substance similar to sugar. In the production of a plant from a grain or seed, some reservoir of nourishment is needed before the root can supply sap for it; and this reservoir is the cotyledon, in which it is stored up in an insoluble form, and protected if necessary during the winter, and rendered soluble by agents which are constantly present on the surface. The change of starch into sugar, connected with the absorption of vital air or oxygen, may rather, it is supposed, be compared to a process of fermentation than to that of respiration; it is a change effected upon an organized matter, and can be artificially

Artificially initiated; and in most of the chemical changes that take place when vegetable compounds are exposed to air, oxygen or vital air is absorbed, and carbonic acid formed or evolved. Much advantage may be taken of this in the sowing of different kinds of grain and seeds, and in the tillage cultivation of different sorts of land, as well as in different other practices and processes; the former not being done too deeply in any case, nor the latter too lightly in stiff tenacious soils. See *TILLAGE*.

When the roots and leaves of the infant plant are formed, the cells and tubes throughout its structure become, it is said, filled with fluid, which is usually supplied from the soil of the land, and the function of nourishment is performed by the action of its organs upon the external elements. The constituent parts of the air are subservient to this process; but, as might be expected, they act differently under different circumstances, it is thought. When a growing plant, the roots of which are supplied with a proper nourishment, is exposed in the presence of solar light to a given quantity of atmospheric air, containing its due proportion of carbonic acid, the carbonic acid after a certain time is destroyed, and a certain quantity of vital air or oxygen is found in its place. If new quantities of carbonic acid gas be supplied, the same result occurs; so that carbon is added to plants from the air by the process of vegetation in sun-shine; and vital air or oxygen is added to the atmosphere, as proved by the experiments of Priestley, Ingenhousz, and many others more lately. The absorption of carbonic acid gas, and the production of vital air or oxygen, are performed by the leaf; and leaves recently separated from the tree or plant effect the change, when confined in portions of air containing carbonic acid; and absorb the same acid, and produce vital air or oxygen, even when immersed in water holding carbonic acid in solution. It is supposed that this acid is probably absorbed by the fluids in the cells of the green or parenchymatous part of the leaf; and that it is from this part that vital air or oxygen gas is produced during the presence of light. M. Senneber, it is said, found that the leaf, from which the epidermis was stripped off, continued to produce vital air or oxygen when placed in water containing carbonic acid gas, and that the globules of air rose from the denuded parenchyma; and it is shewn, by the experiments of the same writer as well as those of Woodhouse, that the leaves most abundant in parenchymatous parts produced most vital air or oxygen in water impregnated with carbonic acid. Some few plants, it is said, will vegetate in an artificial atmosphere, consisting principally of carbonic acid; and many will grow for some time in air containing from one-half to one-third; but they are not so healthy as when supplied with smaller quantities of this elastic substance. Plants exposed to light have been found to produce vital air or oxygen gas in an elastic medium, and in water containing no carbonic acid gas; but in quantities much smaller than when that acid gas was present. In the dark, no vital air or oxygen gas is produced by plants, whatever be the elastic medium to which they are exposed; and no carbonic acid absorbed. In most cases, on the contrary, vital air or oxygen gas, if it be present, is absorbed, and carbonic acid gas is produced. In the changes that take place in the composition of the organized parts, it is supposed probable that saccharine compounds are principally formed during the absence of light; gum, woody fibre, oils, and resins during its presence; and that the evolution of carbonic acid gas, or its formation during the night, may be necessary to give greater solubility to certain compounds in the plant. It was once suspected that all the carbonic

acid gas produced by plants in the night, or in shade, might be owing to the decay of some part of the leaf, or epidermis; but the late experiments of Mr. D. Ellis are opposed to this notion; and it was found that a perfectly healthy plant of celery, placed in a given portion of air for a few hours only, occasioned a production of carbonic acid gas, and an absorption of vital air or oxygen.

It has been supposed by some, it is said, that plants exposed in the free atmosphere to the vicissitudes of sun-shine and shade, light and darkness, consume more vital air or oxygen than they produce, and that their permanent agency upon air is similar to that of animals; and this opinion is countenanced by the inquiries on vegetation of the writer just noticed. But the whole of the experiments brought forward in favour of this notion, and particularly those of this writer, have, it is said, been made under unfavourable circumstances to the accuracy of result. The plants have been confined and supplied with food in an unnatural manner; and the influence of light upon them has been very much diminished by the nature of the media through which it passed. Plants confined in limited portions of atmospheric air soon become diseased; their leaves decay, and by their decomposition they rapidly destroy the vital air or oxygen of the air. In some of the early experiments of Priestley, before he was acquainted with the agency of light upon leaves, air, it is said, that had supported combustion and respiration, was found purified by the growth of plants when they were exposed in it for successive days and nights; and his trials are the more unexceptionable, it is thought, as the plants, in many of them, grew in their natural states; and shoots, or branches from them, only were introduced through water into the confined atmosphere. And some further researches on this subject made by the able writer of the work on agricultural chemistry noticed above, furnish facts which confirm the popular opinion, that when the leaves of vegetables perform their healthy functions, they tend to purify the atmosphere in the common variations of weather, and changes from light to darkness.

In germination, and at the time of the decay of the leaf, vital air or oxygen must, it is said, be absorbed; but when it is considered how large a part of the surface of the earth is clothed with perennial grasses, and that half of the globe is always exposed to the solar light, it appears by far the most probable opinion, that more vital air or oxygen is produced than consumed during the process of vegetation; and that it is this circumstance which is the principal cause of the uniformity of the constitution of the atmosphere. Animals produce no vital air or oxygen gas during the exercise of any of their functions, and they are constantly consuming it; but the extent of the animal, compared to that of the vegetable kingdom, is, it is said, very small; and the quantity of carbonic acid gas produced in respiration, and in various processes of combustion and fermentation, bears a proportion extremely minute to the whole volume of the atmosphere: if every plant during the progress of its life makes a very small addition of vital air or oxygen to the common air, and occasions a very small consumption of carbonic acid, the effect may, it is supposed, be conceived adequate to the wants of nature.

It is supposed that it may occur as an objection to these views, that if the leaves of plants purify the atmosphere, towards the end of autumn, and through the winter and early spring, the air in our climates must become impure, the vital air or oxygen in it diminish, and the carbonic acid gas increase, which is not the case: but there is a very satisfactory answer, it is said, to this objection; the different parts of the atmosphere are constantly mixed together by

winds,

winds, which, when they are strong, move at the rate of from sixty to a hundred miles in an hour. In our winter, the south-west gales convey air, which has been purified by the vast forests and savannas of South America, and which, passing over the ocean, arrives in an uncontaminated state. The storms and tempests which often occur at the beginning and towards the middle of our winter, and which generally blow from the same quarter of the globe, have a salutary influence. By constant agitation and motion, the equilibrium of the constituent parts of the atmosphere is preserved; it is fitted for the purposes of life: and those events, which the superstitious formerly referred to the wrath of heaven, or the agency of evil spirits, and in which they saw only disorder and confusion, are, it is said, demonstrated by science, to be ministrations of divine intelligence, and connected with the order and harmony of our system.

The close analogy which some have supposed to exist between the absorption of vital air or oxygen, and the formation of carbonic acid gas in germination, and in the respiration of the fœtus, has been already contended against; and similar arguments will, it is said, apply against the pursuit of this analogy, between the functions of the leaves of the adult plant, and those of the lungs of the adult animal; several of which are ingeniously stated: and it is concluded, that the functions of the leaf must vary according to the composition of the sap passing through it; and according to the nature of the products which are formed from it. When sugar is to be produced, as in early spring at the time of the development of the buds and flowers, it is probable that less vital air or oxygen will be given off, than at the time of the ripening of the seed, when starch, or gums, or oils, are formed; and the process of ripening the seed usually takes place when the agency of the solar light is most intense. When the acid juices of fruits become faccharine in the natural process of vegetation, more vital air or oxygen, there is every reason to believe, it is said, must be given off, or newly combined, than at other times; for all the vegetable acids contain more vital air or oxygen than sugar. It appears probable, it is said, that in some cases, in which oily and resinous bodies are formed in vegetation, water may be decomposed, its vital air or oxygen set free, and its hydrogen absorbed. When the leaves of some plants, and particularly such as produce volatile oils, are exposed in water saturated with vital air or oxygen gas, this air or oxygen is given off in the solar light; but the quantity is very small, and always limited; and the writer has not been able to ascertain with certainty, whether the vegetative powers of the leaf were concerned in the operation, though it seems probable. In all cases in which buds are formed, or shoots thrown forth from roots, vital air or oxygen appears to be uniformly absorbed, as in the germination or sprouting of grain and feeds. This was satisfactorily shewn by trial with the potatoe, which, when placed in proper circumstances, soon threw forth a shoot, which, when half an inch long, had nearly absorbed a cubical inch of vital air or oxygen, and formed about three-fourths of a cubical inch of carbonic acid. There was a sweet taste in the juices of the shoot, when separated from the root; and the absorption of vital air or oxygen, and the production of carbonic acid, were probably, it is thought, connected with the conversion of a portion of starch into sugar. As frozen roots of this kind become sweet when thawed, vital air or oxygen may probably, it is supposed, be absorbed in this operation, and if so, the change may be prevented by thawing them out of the contact of air; as under water lately in the boiling state. See AIR, &c.

These and different other statements that may be seen in

the work noticed above, shew the great importance of vital air or oxygen in the ways that have been mentioned in the beginning of this article, as well as in the economy of vegetables, and for other purposes.

VITAL Functions, or Actions, are those operations of the vital parts by which life is affected; so as that it cannot subsist without them.

Such are the musculous action of the heart, the secretory action in the cerebellum, the respiratory action of the lungs; and the circulation of the blood and spirits through the arteries, veins, and nerves. See FUNCTION and ACTION.

VITAL Principle, or Substance, denotes a kind of agent or instrument, supposed by Dr. Grew to be employed under the direction and in subordination to the will of the Creator, in the production of plants, animals, &c.

This principle corresponds to the plastic nature of Dr. Cudworth. The supposed existence of these principles produced a dispute between M. Bayle and M. Le Clerc, which the former conceived to favour atheism, though he allows that neither Dr. Cudworth nor Dr. Grew were aware of the consequence; but the latter maintains, that the plastic or vital natures, admitted by these writers, cannot in the least favour the atheists, because they are only instruments in the hand of God, and have no efficacy but what they receive from him, who directs and rules all their actions. Of this dispute Dr. Warburton observes, that Cudworth's plastic life of nature is fully overthrown by Bayle, whose superiority in the controversy with Le Clerc is clear and indubitable. See Grew's *Cosmologia Sacra*, fol. 1701. p. 31, &c.; and Cudworth's *Life*, prefixed to Birch's edition of the *Intellectual System*, vol. i. p. 15, &c.

VITAL Spirits are the finest and most volatile parts of the blood. See SPIRITS.

VITALBA, in *Botany*, a name given by some authors to the viorna, or traveller's joy. See VIORNA.

VITALIA, a name given by some authors to the cardiac medicines.

VITALIANUS, in *Biography*, pope, was born at Segna, in Campania, and elevated to the pontificate A.D. 657, on the death of Eugenius. When, according to custom, he sent legates to Constantinople, with his confession of faith, to be presented to the emperor Constant and his son Constantine, the Monothelite doctrine was fashionable at the imperial court, and, therefore, the pope was very guarded in his communication. In 663 Constant entered Italy, and advanced towards Rome; and though he was treated with great respect by Vitalian and his clergy, he was not thus prevented from robbing the churches of all the treasure to which he could have access. In 667, Wighard, archbishop-elect of Canterbury, was sent to Rome to receive ordination from the pope; but as Wighard died of the plague in that capital, the pope, notwithstanding the compliment that was paid him by the British kings, took this opportunity of extending the prerogative of the papacy, and of nominating one Theodore, a monk, to supply the place of the deceased prelate. Vitalian, in some other instances, manifested his zeal for the interest and influence of the Romish church, and the authority of its visible head; but after a pontificate of 14½ years, he died in 672. His zeal procured for him a place among the canonized pontiffs. Some letters written by him on ecclesiastical affairs are still extant. Dupin. Bower.

VITALIS, in *Botany*, a name given by some authors to the common telephium, called the English orpine, and live-long, from its quality of living and flourishing a long time after it is taken from the root.

VITCHEGDA, in *Geography*, a river of Russia, which rises

rises in the province of Ustiug, and runs into the Dwina, near Sol Vithegodsk.

VITE, TIMOTEO DELLA, DA URBINO, in *Biography*, was born at Urbino in 1470. After having some time studied the art of painting at Bologna, under Francesco Francia, he returned, when about 26 years old, to his native country; and thence went to Rome, to his countryman and relation Raffaele. He there engaged himself to assist that renowned artist, and prepared for him the Sibyls in the church of La Pace, and was permitted by his master to retain the cartoons. He did not remain long at Rome, but returned to Urbino; and there, in conjunction with Girolamo Genga, executed several large works for the cathedral, and other public places.

He brought to Rome a style which was dry and laboured, as of the preceding century, as may be seen in his Madonnas at the palace Bonaventura, in the Capitol at Urbino, and at Pesaro in the Discovery of the Cross. Under Raffaele he improved his style, and acquired much of his grace, attitudes, and colour; though he always remained a timid inventor, and had a certain weakness of pencil, and was more exact than grand. The Conception at the Osservanti in Urbino, and the Noli me Tangere in the church of S. Angelo at Cagli, are perhaps the best remains of Timoteo. He died in 1524, aged 54.

VITEGRA, in *Geography*, a river of Russia, which runs into lake Onezkoï, near the town of Vitegra.—Also, a town of Russia, in the government of Olonetz, at the fourth end of lake Onezkoï; 88 miles E. of Olonetz. N. lat. 60° 55'. E. long. 35° 44'.

VITELLIA, in *Antiquity*, a town of Italy, in Latium, in the country of the Æqui; it took its name from the family of Vitellius.

VITELLIA Via, one of the roads of Italy, which led from the Janiculum to the sea.

VITELLIANI, in *Antiquity*, a kind of tablet or pocket-book, in which people anciently used to write down their ingenious, humorous, and even wanton fancies and impertinences; the same with what, in English, we may call a *trifle-book*. See Martial, lib. xiv. epig. 8.

Some will have them to take their name from *vitellus*, a yolk of an egg; because the leaves were rubbed with it. Others derive the name from one Vitellius, their inventor.

VITELLIO, or VITELLO, in *Biography*, a Polish mathematician, flourished about the end of the 13th century, as we may infer from the dedication of his work on Optics to the pope's penitentiary, William de Morbeta, who lived about the year 1296. His work, though now of little value, was probably in estimation at the early period in which it was written, as it contained a collection of materials furnished by Euclid, Archimedes, Ptolemy, and Alhazen. It was published together with that of Alhazen under the following title: "Opticæ Thefaurus, Alhazeni Arabis Libri VII. nunc primum editi. Item Vitellonis, Thuringo-poloni, Libri X. omnes inaurati, Figuris illustrati et aucti, adjectis etiam in Alhazenum Commentariis, A. Frederico Risnero," Basilizæ, 1572. fol. Montucla Hist. Math.

VITELLIUS, AULUS, Roman emperor, was born A.D. 16, and resided in his youth at Capræ, the infamous abode of Tiberius. To Caligula he recommended himself by his skill as a charioteer; and by his passion for play, to Claudius, who made him consul A.D. 48. He likewise presided at the games, in which Nero exposed himself as a musician. At this time Vitellius disgraced himself by his ferocity and meanness; but in the post of governor of Africa, he obtained some credit. At length, however, he was

reduced to indigence by his licentiousness, and was thus led to practise fraud, with regard to the offerings and ornaments of the temples, by substituting base metal for real silver and gold. On the accession of Galba to the empire, A.D. 68, Vitellius was appointed to the command of the legions in Lower Germany; Galba assigning as a reason for this preference, that a man addicted to gluttony was not to be feared. The German legions were much disaffected to Galba; but Vitellius had contrived to recommend himself to favour. When the day (*viz.* January 1st) arrived, on which the troops were required to renew their oath of fidelity to their emperors, those commanded by Vitellius performed the ceremony reluctantly, and with ill will; but in the army of Upper Germany, two legions openly renounced allegiance to Galba. When this event was communicated to the Lower army, Valens, one of the general officers, came to Cologne, and saluted Vitellius as emperor, who was also recognized under this appellation in other provinces of the empire. At Rome, however, Otho was invested with the imperial dignity, on the murder of Galba; and the two competitors began with negotiation, and proceeded to attempts against each other's life. When Otho put an end to his own life, after the defeat of his troops, Vitellius was recognized without opposition at Rome, in April, A.D. 69. One of the first acts, after receiving the news of his accession, was that of conferring knighthood on a vile freedman, named Asiaticus. Although he treated the general officers of Otho's party with a clemency that did him honour, he incurred reproach by the execution of several of the inferior officers, and by ordering the death of Dolabella, on a false accusation. However, stupid insensibility was his predominant foible, rather than a revengeful spirit; and this was the effect of his insatiable and shameful gluttony. His extravagance in indulging his appetite for costly dishes, covered with all the varieties which he could procure, had no bounds. He is said to have consecrated a silver dish, which on account of its size he called the buckler of Minerva, and to have filled it solely with the livers of a small and delicate fish, the brains of peacocks and pheasants, and the tongues of flamingoes, and the roes of lampreys. The expences of his table, during eight months of his reign, have been estimated at five millions sterling; but Tacitus states this sum as the cost of all his profusions.

On his way to Rome, he visited the field of battle on which Otho had been defeated; and when he saw it strewn with dead and mangled bodies, he did not manifest the least emotion; and when some of his attendants complained of the stench arising from the uninterred carcases, he had the fool-hardiness to utter this observation, "A dead enemy smells well, especially a dead citizen." He entered Rome with great pomp, at the head of troops that massacred a number of the populace who went out to meet him, and pronounced a panegyric on himself, which was applauded by the fervile crowd. He afterwards affected popularity, but his character was so devoid of every virtue, that no act he performed could be thought of any value. "Every evil which Rome had suffered under the worst emperors seemed to be its destiny in the reign of Vitellius." But a deliverance was preparing for the seemingly devoted city. The Eastern army was approaching, and Vespasian was proclaimed emperor. Vitellius was roused from his lethargy, but it was too late; and after the defection of some of his troops, and the defeat of others, he again sunk into his stupefying luxury. Despairing of redress, he determined to abdicate; and with this view negotiated with Flavius Sabinus, brother of Vespasian, who was prefect of Rome. The populace, however, whose compassion was

excited by the mournful habit and distressing circumstances in which he left the palace, obliged him to return. Upon this the city-guards attacked Sabinus, who had sought refuge for himself and his adherents in the Capitol. The partisans of Vitellius, yielding to the impulse that had been excited, stormed this sacred place, and in the tumult the temple of Jupiter Capitolinus was consumed by fire. Sabinus was seized, and carried before Vitellius, who wanted to save him; but he was massacred in the most ignominious manner. These outrages were in a little while dreadfully revenged. The victorious army approached the city; and the Vitellian soldiers, well apprized that no mercy awaited them, made a desperate resistance; so that Rome, in the midst of the licentious festivities of the Saturnalia celebrated at this time, was a scene of slaughter and blood. Vitellius took no part in this business, but withdrew to the house of his wife on mount Aventine; from hence he removed again to the palace, and was at length found in the porter's lodge, intreating in the most abject manner that his life might be spared. But all his intreaties were ineffectual. With his hands tied behind him, and a cord about his neck, he was dragged like a common criminal in the midst of insults of every kind. Having escaped the murderous aim of a German soldier, he was at length taken to the Gemonian stairs, down which the body of Sabinus had been thrown, and being dispatched in a barbarous manner, his head was cut off, and stuck upon a spear, to be carried through the city, and his trunk was thrown into the Tiber. Thus he closed a short and ignominious reign in the 57th year of his age, A.D. 69. Suetonius. Tacitus. Crevier. Gen. Biog.

VITEPSK, in *Geography*, a town of Russia, in the government of Polotsk, on the Duna, taken from Poland in the year 1654; 56 miles E.S.E. of Polotsk. N. lat. 55° 15'. E. long. 30° 50'.

VITERBO, a town of the Popedom, and capital of the Patrimonio, given by the empress Matilda to the pope; in memory of which donation, an inscription, on stone, is put up on the town-house. This city lies in a beautiful and fertile valley, is large, the streets, for the greater part, broad and well paved, the houses good, but thinly peopled, the number of the inhabitants being scarcely 15,000, though that of the churches, convents, and hospitals, is not less than 69. The bishop is immediately under the pope. Four popes lie interred in the cathedral. Not far from the city is a warm mineral spring; 34 miles N.N.W. of Rome. N. lat. 42° 25'. E. long. 12° 6'.

VITES, in *Botany*, the seventy-second natural order in Jussieu's system, the twelfth of his thirteenth class, is so called from *Vitis*, one of its genera. For the characters of this class, see GERANIA. The order, which consists of *Cifus* and *Vitis* only, is thus defined.

Calyx of one leaf, (superior,) short, nearly entire. *Petals* definite, four, five, or six, broad at the base. *Stamens* equal in number to the petals, and opposite thereto, with distinct filaments, inserted into the disk, or receptacle of the flower. *Germen* simple; style one, or none; *stigma* simple. *Berry* of one or many cells, with one seed, or several, in a determinate number, whose surface is unequal, and which are inserted into the bottom of the cells. *Corculum* descending, its lobes straight, destitute of albumen. *Stem* shrubby, or rarely arborescent, trailing, knotty. *Leaves* alternate, with stipular. The tendrils, or flower-stalks, are opposite to the leaves. These plants are akin to *Aquilegia* (*Leca*) and *Melia* in the broad base of their petals, sometimes in their leaves and inflorescence. On the other hand, some of the shrubby *Gerania* (*Pelargonium*) betray an affinity in habit to the *Vites*,

and like them are occasionally acid in the taste of their herbage.

VITESSA, or VITTESSA, in *Mythology*, a name of the Hindoo Kuvera, regent of wealth. See KUIVERA.

VITETZ, in *Geography*, a town of Bosnia; 14 miles S. of Serajo.

VITEX, in *Botany*, an old Latin name, of whose origin Linnæus professed ignorance, but which evidently comes from *vicio*, to bind, and alludes to the flexible nature of the twigs of the original species of this genus, the *vitis*; of the Greeks.—Linn. Gen. 326. Schreb. 427. Willd. Sp. Pl. v. 3. 390. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 66. Sm. Prodr. Fl. Græc. Sibth. v. 1. 441. Brown Prodr. Nov. Holl. v. 1. 511. Juss. 107. Tourn. t. 373. Lamarck Dict. v. 2. 611. Illustr. t. 541. Gartn. t. 56.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Vitices*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cylindrical, short, with five broad shallow teeth. *Cor.* of one petal, ringent; tube cylindrical, slender, curved; limb flat, two-lipped; the upper lip in two segments; lower in three, the middle one largest. *Stam.* Filaments four, capillary, rather longer than the tube, two of them shorter than the rest; anthers versatile. *Pist.* Germen roundish, in the bottom of the calyx; style thread-shaped, the length of the stamens; stigmas two, awl-shaped, spreading. *Perc.* Drupa globose. *Seed.* Nut solitary, bony, of four cells, with a solitary kernel in each.

Ess. Ch. *Calyx* with five teeth. Limb of the corolla two-lipped; middle segment of the lower lip largest. Drupa with a nut of four cells.

Obf. Linnæus, and even Jussieu, misled perhaps by Tournefort's figure, describe the corolla as having six segments. We have never seen more than five in any species, though, if Tournefort be correct, six or seven may accidentally occur.—The species are shrubby or arborescent, with opposite, stalked, almost always digitate, leaves, without stipular. *Flowers* aggregate, numerous, panicled, sometimes whorled, mostly bluish. Jussieu, with great reason, doubts the genus of *V. pinnata*, because of its alternate pinnate leaves.

1. *V. ovata*. Ovate-leaved Chaste-tree. Thunb. Jap. 257. Willd. n. 1. Ait. n. 1. (*V. rotundifolia*; Linn. Suppl. 294.)—Leaves simple, ovate.—Native of Japan, near the sea-shore. *Stem* shrubby, trailing, with quadrangular branches, round when young. *Leaves* on short stalks, elliptical, or roundish, entire, with one rib, and several transverse veins; green and smooth above; white and finely downy beneath. *Panicle* terminal, oblong, silvery, with three-forked branches. *Calyx* hoary. *Corolla* purplish; downy and white on the outside. *Fruit* globular, the size of a pepper-corn, greenish, half covered by the permanent calyx.

2. *V. triflora*. Three-flowered Chaste-tree. Vahl Elog. fasc. 2. 49.—Leaves ternate, entire, smooth on both sides. Stalks axillary and terminal, three-flowered.—Gathered by Von Rohr, in Cayenne. *Branches* purplish; downy and rusty when young. *Leaflets* elliptic-lanceolate, or obovate, quite entire, from two to five inches long; their common stalks an inch and half. *Calyx* near an inch in length; *Corolla* twice as much, clothed externally with tawny pubescence. *Vahl*.

3. *V. divaricata*. Spreading Chaste-tree. Swartz Ind. Occ. 1078. Willd. n. 3. Vahl Symb. v. 2. 76.—Leaves ternate, entire, smooth on both sides; the middle one very large. *Panicle* forked, divaricated.—Native of the West Indies. Gathered by Masson in St. Lucia; by Ryan in Martinico

Martiano and Santa Cruz. A tree, with square, smooth branches, ash-coloured when young, most leafy at the extremity. *Leaflets* ovato-lanceolate; the lateral ones an inch long; the odd one three or four times as much. *Flowers* whitish, five-cleft. *Drupa* half an inch long.

4. *V. pubescens*. Downy Chaste-tree. Vahl Symb. v. 3. 85. Willd. n. 4. (Pistacio-vitex; Linn. Zeylon. 195, according to Vahl, from the inspection of Hermann's Herbarium.)—Leaves ternate, downy. Panicles three-forked. Bractæas as long as the calyx.—Native of the East Indies. *Leaflets* near two inches long, ovate, thin, entire; nearly smooth above; ribbed, veiny, and downy, not hoary, beneath. Panicles large, terminal, their lowermost branches axillary. Bractæas oblong, obtuse, hoary. *Flowers* fix or seven on the ultimate branches of the panicle, sessile, alternate, externally downy. *Fruit* the size of pepper.

5. *V. altissima*. Tall Ceylon Chaste-tree. Linn. Suppl. 294. Willd. n. 5. Ait. n. 2. (Mail-Elou; Rheede Hort. Malab. v. 5. t. 1.)—Leaves ternate, pointed, nearly entire; downy beneath. Panicle with racemose whorled branches.—Found in the extensive forests of Ceylon by Koenig, who in his MSS. has indicated the indubitable synonym of Rheede, which the younger Linnæus neglected to quote, and which is likewise omitted in Hort. Kew. and Willdenow. Rheede speaks of this as a tree fifty feet high, found in many parts of Malabar, with a heavy reddish wood, fit for many uses. The *footstalks* are downy, sometimes winged, from one to three inches long. *Leaflets* elliptical, contracted at each end, from two to four inches in length; nearly smooth above; very downy and soft, not hoary, beneath; their margin usually entire; sometimes serrated. *Flowers* small, sweet-scented, bluish, numerous. The lower branches of the panicle are some of them four together. Each branch bears numerous, dense, partly stalked, many-flowered whorls, with downy lanceolate bractæas. Linnæus, after Koenig, describes but three seeds in each drupa, but Rheede says there are three or four.

6. *V. latifolia*. Broad-leaved Chaste-tree. Lamarck n. 5. (Katou-Mail Elou; Rheede Hort. Malab. v. 5. t. 2.)—Leaves ternate, ovate, pointed, entire, minutely downy on both sides. Panicle much branched, forked, downy. Bractæas ovate.—Sent by Dr. Roxburgh from Calcutta. The *leaflets* are from two and a half to five inches long, and two or two and a half broad, finely veined; the younger ones soft to the touch. Panicle terminal, with large, opposite, stalked bractæas, downy on both sides. *Calyx*, and unexpanded corolla, very downy.

7. *V. Agnus-castus*. Common Chaste-tree. Linn. Sp. Pl. 890. Willd. n. 6. Ait. n. 3. Woodv. Med. Bot. t. 222. Sm. Fl. Græc. Sibth. t. 609, unpublished. (Vitex; Camer. Epit. 105. Matth. Valgr. v. 1. 177. Ger. Em. 1387. f. 1, 2.)—Leaves digitate, with five or seven lanceolate nearly entire leaflets; hoary beneath. Clusters paniced. *Flowers* whorled.—Native of low marshy places, about the banks of rivers, in Italy, Sicily and the Levant. Very common throughout Greece, in such situations, flowering in autumn. A low spreading shrub, with long, trailing, tough and pliant branches. *Leaflets* long and narrow, tapering at each end, with partial footstalks, usually quite entire, but sometimes broader and serrated, as in Gerarde's fig. 2. Their upper side is of a greyish-green, with a peculiarly fine velvet-like softness; the under white, and densely downy. *Common footstalks* downy, about half the length of the leaflets. Clusters terminal, long and cylindrical, divided into many dense whorls of numerous, light blue, or

white, flowers. Bractæas lanceolate, solitary under each flower, the length of the calyx. The seeds have been celebrated for a marvellous power of promoting chastity. The seed of the recent plant is, to us, peculiarly unpleasant, causing a degree of nausea or faintness, which may perhaps account for its reputed virtues. The priestesses of Ceres are reported to have made their beds of the boughs of this tree, but whether this arose from the name in Greek being synonymous with chastity, or whether the name was given in allusion to the quality of the plant, no author has recorded, though Dioscorides seems to imply the latter.

8. *V. incisa*. Cut-leaved Chaste-tree. Lamarck n. 2. Willd. n. 7. Ait. n. 4. (V. Negundo; Curt. Mag. t. 364. V. Mill. Ic. 183. t. 175. f. 1, 2.)—Leaves digitate, with three or five pinnatifid leaflets; hoary beneath. Clusters paniced. *Flowers* whorled.—Native of China. Long known in our gardens, as a greenhouse shrub, by the name of *V. Negundo*. Lamarck, who speaks of this plant as nearly hardy in the open ground at Paris, first distinguished it as a species. It is smaller in every part than the preceding, and differs in having fewer, shorter, broader, deeply cut or pinnatifid leaflets. The flowers are purplish, with rounder segments; the lower one concave and somewhat heart-shaped.

9. *V. Negundo*. Indian Chaste-tree. Linn. Sp. Pl. ed. 1. 638. ed. 2. 890. Willd. n. 12. (Negundo arbor mas; Bauh. Hist. v. 2. 189. Bem-nofi; Rheede Hort. Malab. v. 2. 15. t. 12.)—Leaves digitate, with three or five elliptic-lanceolate, somewhat serrated, leaflets; hoary beneath. Clusters paniced. *Flowers* loosely whorled.—Native of the East Indies. This appears to be a shrub nearly related to the two last, but rather larger than either, with more decidedly quadrangular branches. The leaflets, more generally three than five, are broader than the last, yet not pinnatifid, but only bluntly, and rather sparingly, serrated. Partial flower-stalks more lax and corymbose. Yet this plant certainly differs from the serrated variety of *V. Agnus-castus*, having fewer, as well as broader, leaflets, and looser whorls. The flowers seem to be smaller than in that species. The synonym of Rumphius, cited by Linnæus, evidently belongs to *V. Leucosylon*. Willdenow and Curtis copy without examination Linnæus's citation of Bauhin, which ought to be v. 2, not v. 1. The inflorescence in Bauhin's figure is very badly represented, nor are the leaves at all correct; yet there is enough to shew that it may be taken from our plant, though certainly nothing capable of giving a just idea of the species.

10. *V. trifolia*. White-leaved Paniced Chaste-tree. Linn. Sp. Pl. 890. Willd. n. 9. (Cara-nofi; Rheede Hort. Malab. v. 2. 13. t. 11. Lagodium vulgare; Rumph. Amboin. v. 4. 48. t. 18.)—Leaves ternate, sometimes quinate; leaflets ovate, acute, entire; hoary beneath. Cluster compound, with forked, elongated, zigzag branches.—Native of the East Indies. The perfectly entire leaflets, and their ovate or elliptical form, clearly mark this species, which is still more certainly distinguished by the long, spreading, doubly forked branches of its cluster, which assumes the aspect of a panicle, whose common stalk is straight. The calyx is angular. As to the other synonyms quoted by Linnæus, Plukenet's t. 206. f. 5. may be any thing; and Burm. Zeyl. t. 109. is a *Rbus*, with a prodigious confusion of synonyms not worth unravelling.

11. *V. Leucosylon*. Green-leaved Corymbose Chaste-tree. Linn. Suppl. 293. Willd. n. 8. Ait. n. 5. (V. paniculata; Lamarck n. 3, excluding Plukenet's synonym. Lagodium littorum; Rumph. Amboin. v. 4. 50. t. 19.)

—Leaves ternate or quinate; leaflets elliptical, entire; slightly downy beneath. Panicles repeatedly forked, corymbose.—Native of the forests of Ceylon. *Koenig*. Sent to Kew, by Dr. Roxburgh, in 1793, through the hands of Sir Joseph Banks. The leaves somewhat resemble those of *V. trifolia* in shape and size, but they are not at all hoary, though paler, at the back, with much longer partial stalks to the leaflets. The panicles are totally different, being cymose, or level-topped, downy, but not hoary. As to the “berry,” as Koenig and Linnaeus term it, “with a single seed,” there is no reason to think it different from the rest of the genus.

12. *V. umbrosa*. Umbrageous Chaste-tree. Swartz Ind. Occ. 1076. Willd. n. 10.—Leaves quinate; leaflets elliptical, pointed, entire, nearly smooth on both sides. Clusters compound, axillary.—Native of mountainous situations in Jamaica. A large and spreading tree, with nearly cylindrical branches, leafy at the summit. Common foot-stalks two or three inches long, flattened, two-edged. Leaflets coriaceous, from three to five inches long and two broad, veiny; paler beneath, but not hoary; neither are they, as Dr. Swartz says, perfectly smooth; but rather roughish to the touch, from very minute hairs scattered over both their surfaces. Clusters from the bosoms of two or three of the uppermost leaves, and about the same length, rather downy, oblong, with simply forked branches. Flowers small. *Drupa* yellow, the size of a cherry, depressed at the summit.

13. *V. capitata*. Capitate Chaste-tree. Vahl Eclog. fasc. 2. 50. t. 18. Willd. n. 11.—Leaves quinate; leaflets lanceolate, entire, smooth. Flowers in capitate umbels, on axillary stalks.—Native of the island of Trinidad. *Ryan*. A tree of a moderate size, with roundish branches, somewhat angular when young. Leaflets four inches long, on partial stalks, the outer pair sessile, and smaller, as in the other species. Flower-stalks axillary, solitary, the length of the footstalks, smooth and slender, each bearing from six to twelve flowers, at first sessile, but subsequently elevated on short partial stalks, forming a kind of umbel. *Drupa* twice the size of a pea. *Vahl*.

14. *V. pinnata*. Pinnate Chaste-tree. Linn. Sp. Pl. 890. Willd. n. 13. Burm. Ind. 138. t. 43. f. 2.—Leaves pinnate, entire. Panicles triply forked.—Native of Ceylon. A very doubtful species. The Linnæan specimen is certainly only *V. trifolia*; but in Sir Joseph Banks's herbarium is one supposed to be the true *pinnata*. Whether Vahl's *pulestensis*, n. 4, be specifically distinct from this last, we are not informed.

14. *V. acuminata*. Pointed Chaste-tree. Brown n. 3.—Leaves ternate or quinate; leaflets ovate-oblong, pointed, smooth, entire. Cluster with forked branches. Calyx nearly without teeth. Stamens shorter than the corolla. Found by Mr. Brown, in the tropical part of New Holland.

15. *V. glabrata*. Smooth Chaste-tree. Brown n. 4.—Leaves ternate or quinate; leaflets ovate, smooth, entire. Flower-stalks axillary and terminal, forked. Calyx without teeth.—Gathered by Mr. Brown in the tropical part of New Holland, but the flowers were over. *Corolla* in Sir Joseph Banks's plate four-cleft, above an inch long.

16. *V. macrophylla*. Great Simple-leaved Chaste-tree. Brown n. 5.—Leaves simple, ovate-oblong, entire, smooth, with transverse ribs; and two glands at the base. Stem arborescent.—Gathered in the tropical part of New Holland, by Sir Joseph Banks, who sent a plate of this, and the preceding, to Linnaeus. The leaves are six or eight inches

long, and four broad. *Panicle* terminal, large, with zig-zag, racemose, stout, many-flowered branches. *Calyx* somewhat two-lipped. *Corolla* five-cleft, an inch long, apparently white, with a dark purple lip.

VITEX, in *Gardening*, contains plants of the hardy and under-shrubby kinds; among which the species cultivated are, the official chaste-tree (*V. agnus-castus*); the cut-leaved chaste-tree (*V. incisa*); the three-leaved chaste-tree (*V. trifolia*); and the five-leaved chaste-tree (*V. negundo*.)

The first is a high shrubby plant of the late flowering kind, of which there are varieties with narrow leaves, with broad leaves, with blue flowers, and with white flowers.

The second sort is a low shrubby plant, with bright red flowers.

The third is of a shrubby growth, with violet flowers.

And the last has a small tree-like stem, with purplish flowers.

Method of Culture.—The first sort may be increased by cuttings and layers: the cuttings should be planted in the early spring, in a fresh light soil, being often refreshed with water till they have taken root; afterwards the plants must be kept clear from weeds, and be protected during the following winter with mulch or mats; and about the middle of the following March, when the season is fine, be removed into the places where they are to grow, or into the nursery for two or three years, to become strong; being pruned up to form regular stems.

The layers of the branches may be laid down in the spring, being careful not to split them, watering them in dry weather; when in about a year they may be taken off, and planted out in the same manner as the cuttings.

The second sort may likewise be increased by cuttings, which should be planted in pots, plunged in a moderate hot-bed, covering them with glasses: when well rooted, they may be taken up, and be planted in separate small pots, filled with light earth, putting them in the shade till fresh rooted; afterwards placing them in a sheltered situation, with other greenhouse plants, until the autumn, when they must have protection from frost, and have very little water. They are late in putting out leaves in the spring, so as almost to appear dead.

The third sort is raised from cuttings, which should be planted in pots in the early spring, as April, plunging them in a moderate hot-bed, covering them with hand-glasses, being slightly watered: when they have taken root, they should have free air admitted in a gradual manner; then they may be taken up, and planted out in separate pots filled with light earth, replunging them in the bed, and giving due shade. They should afterwards have plenty of free air, when the weather is suitable; being treated as tender plants. It must be constantly kept in the stove, having free air in the summer season. It retains its leaves all the year. This may also be raised from layers.

The fourth sort may also be raised from cuttings, in the same manner as the second.

The first two sorts may be introduced in the shrubberies, clumps, &c. succeeding well in any common soil and situation; and the latter kinds afford variety in stove and greenhouse collections, among other similar sorts.

VITI CHOREA, in *Medicine*. See *CHOREA*.

VITIA, in *Ancient Geography*, a country of Asia, in the vicinity of Armenia and of the Caspian sea. Strabo.—Also, a country of Asia, in the environs of Media, founded by the Ænians of Thessaly, according to Strabo, and named *Æneiana*; which was also the name of the principal city.

VITICES,

VITICES, in *Botany*, one of Juffieu's natural orders, named from *Vitex*, which belongs to it. This order is the thirty-eighth in his system, the fifth of his eighth class, standing between the **JASMINEE** and **LABIATE**. (See those articles, under the last of which the character of this eighth class is indicated.) This same order is now, it seems, called *Verbenaceae* by its author, in *Ann. du Muséum*, v. 7. 63, which name is adopted in Brown's *Prodr. Nov. Holl. v. 1.* 510. The genera which compose it are chiefly found in the latter part of the **PERSONATE** of Linnæus. (See that article.) Mr. Brown's definition, as follows, is the latest and best, respecting this order.

Calyx tubular, permanent. *Corolla* inferior, of one petal, tubular, deciduous; the limb mostly irregular. *Stamens* generally four, two long and two short; rarely all of equal length; sometimes only two. *Germen* of two or four cells, the rudiments of seeds erect, solitary or in pairs. *Style* one, either cloven or undivided. *Pericarp* a drupa, or a berry. *Albumen* none, or very small. *Embryo* erect.

The plants of this order are trees or shrubs, rarely herbaceous. *Leaves* without stipulas, usually opposite; either simple or compound. *Flowers* either oppositely corymbose, or alternately spiked; sometimes crowded into a sort of head; rarely axillary and solitary.

Juffieu notes that the *stamens* are sometimes six, of which we find no instance, except casually in *Teñona*, whose stamens are properly five, all nearly equal. The *stigmata* are sometimes unequal. This author makes three sections.

SECT. 1. *Flowers oppositely corymbose.*

Clerodendrum, *Volkameria*, *Ægiphila*, *Vitex*, *Callicarpa*, all Linnæan genera; *Manabea* of Aublet, allied to *Ægiphila*; *Præmia* of Linnæus; *Petitia* of Jacquin; *Cornulia*, *Gmelina*, *Teñona* (called *Theka* by Juffieu), and *Avicennia* of all authors. To these are to be added *Pityrodia* of Brown; and also his *Chloanthus*, notwithstanding its solitary flowers.

SECT. 2. *Flowers spiked; alternate.*

Petræa, *Citibaresyllum*, *Duranta*, *Lippia*, *Lantana*, of Linnæus; *Spielmannia* of Medicus and Juffieu; *Taligala*, of Aublet, which is *Amasonia* of Linnæus; *Tamonea* of Aublet, of which *Verbená lappulacea* is an example. See **VERBENA** n. 13; and *Perama* of Aublet, Schreber's *Mutuschkeæ*.

SECT. 3. *Genera akin to Vitices (or Verbenaceæ).*

Eranthemum, *Selago*, and *Hebenstretia* of Linnæus. The first of these Mr. Brown has indicated, in his *Prodr. v. 1.* 477, to be very confused in its history, the original type of the genus being next akin to *Justicia*, only having a nearly regular, and falver-shaped, *corolla*, with two of the *stamens* imperfect. What Juffieu intends under the name of *Eranthemum* are probably certain Cape species of *Selago*, with only two *stamens*, erroneously referred hither by Linnæus.

The order in question certainly forms a very natural link between the *Josmineæ* and the *Labiatae*, being most akin to the former in habit, scent of the flowers, and other qualities, as well as in the nature of the *pericarp*; while its *stamens*, *seeds*, and quadrangular *branches*, more obscurely connect it with the latter; to some genera of which, as *Ballota*, its often faint herbage, not to mention colour, pubescence, and inflorescence, betray an unexpected relationship.

VITIFERA, in *Ornithology*, a name by which many have called the common emmethe, a bird well known in England by the name of the wheat-eat.

VITIGUDINO, in *Geography*, a town of Spain, in the province of Leon; 31 miles W.S.W. of Salamanca.

VITILIGO, a disease frequent among the Arabians: it is the same with what is otherwise called alphas.

VITILIGO, in *Botany, so named from its leprous or scurfy appearance. See **SPILOMA**.*

VITIMSKOI, in *Geography*, a town of Ruffia, in the government of Irkutsk, on the Lena. N. lat. 59° 5'. E. long. 112° 34'.

VITIS, or **UTENS**, in *Ancient Geography*, a river of Italy, in Cispadana, in the neighbourhood of Ravenna, between Sapis and Anemo.

VITIS, in *Botany*, usually derived from *vico*, in allusion to the flexibility of its branches, is traced by De Theis to the Celtic *Gwidi*, a tree, or shrub, as being the chief, or best, of trees. This would hardly satisfy us, were not *Gwin* the name of wine in the same language, from whence comes evidently enough, the Greek *ovos*, Latin *vinum*, Anglo-Saxon and French *vin*, English *wine*, &c.—Linn. Gen. 112. Schreb. 156. Willd. Sp. Pl. v. 1. 1180. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 51. Sm. Prodr. Fl. Græc. Sibth. v. 1. 161. Pursh 169. Juss. 267. Tourn. t. 384. Lamarck Illustr. t. 145. Dict. by Poirét, v. 8. 594. Gært. t. 106.—Class and order, *Pentandra Monogynia*. Nat. Ord. *Hederaceæ*, or perhaps *Cucurbitaceæ*, Linn. *Vites*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, minute, five-toothed. *Cor.* Petals five, small, rude, cohering by their summits, deciduous before they fade. *Stam.* Filaments five, awl-shaped, spreading, a little ascending, deciduous; anthers simple, incumbent. *Pistl.* Germen superior, ovate; style very short; stigma capitate, obtuse. *Peric.* Berry large, roundish, of one cell. *Seeds* five, erect, obovate, bony, contracted at the base, deeply furrowed on one side.

Eff. Ch. Petals cohering at the summit, unfading. Berry superior, with five erect obovate seeds.

Obs. The seeds are naturally five, though two or three are generally abortive in our northern climates, which has puzzled some writers. They are described by Linnæus as half bilocular, because the lateral furrows are so deep, as to encroach half way on the cavity of their stelly covering. The North American species are said to be all dioecious, which however is not the case with *V. quinquefolia*, nor *V. arborea*, both improperly removed to *Cissus* by Perfoon and Pursh, and referred by Michaux to his new genus *Ampelopsis*, whose characters are not sufficient to separate it from *Cissus* or *Vitis*. *Cissus* is properly distinguished from *Vitis*, not so much by having four-cleft tetrandrous flowers, which circumstance is variable or inconstant, but by the reflexed petals, and the presence of a cup-like nectary, surrounding the germen.

1. *V. vinifera*. Common Vine. Linn. Sp. Pl. 293. Willd. n. 1. Ait. n. 1. Schmidl. Ic. 32. t. 7. Jacq. Ic. Rar. t. 50. Sm. Fl. Græc. Sibth. t. 242, unpublished. Inf. of Georgia, v. 1. 87. t. 44? Matth. Valgr. v. 2. 655. Camer. Epit. 1003. Ger. Em. 875.—Leaves heart-shaped, five-lobed, sinuated, naked.—Found, naturalized at least, in most parts of the more temperate climates of the globe; yet it is not supposed to be a native of America. Mr. Hawkins judged it to be truly wild on the banks of rivers in Greece. The cultivated Vine, sporting in endless varieties of the shape, colour, and flavour of its fruit, and differing much with respect to hardness of constitution, is well known as an important and interesting object of horticulture. (See **VINE** and **WINE**.) Our business here is with the same plant in its native state, as found in Greece, flowering in May or June. The stem is woody, tough, sending out long, trailing, subdivided, furrowed, leafy branches, which climb by means of tendrils to a great extent, and when young are clothed with loose shaggy down. *Leaves* alter-

nate, on longish stalks, simple, roundish-heart-shaped, notched, coarsely serrated, veiny, divided about half way into five, more or less distinct, lobes; when young they are downy like the branches, especially beneath; but otherwise naked and smooth; deciduous. *Tendrils* opposite to each foot-stalk, solitary, spiral, divided, about the length of the leaves. *Clusters* here and there in the place of a tendril, drooping, paniced, much branched, the ultimate stalks somewhat umbellate, or corymbose. Flowers very numerous, small, green, fragrant like Mignonette. *Petals* forced from their base by the flaments, which elevate them in the form of an umbrella, downy at the top. *Berry* small, black. Every part of the plant is acid, with some astringency.—One variety only is particularly noticed by Linnæus, the *V. corinthiaca*, sive *apyrena*, Bauh. Hist. v. 2. 72, of which a specimen from Madeira is preserved in the Linnæan herbarium. The fruit is said to be very small, without seeds. The late Dr. Sibthorp brought a living plant, supposed to be of this kind, from the ruins of Corinth, with no small trouble and care; but his ignorant gardener threw it away. Whether the Zante Currant be precisely the same is doubtful. This is cultivated at Kew, and in some other curious gardens.

2. *V. palmata*. Palmate Vine. Vahl Symb. v. 3. 42. Willd. n. 2. Pursh n. 6.—“Leaves palmate, smooth; their segments deeply serrated. Umbels racemose.”—Said to be a native of Virginia, but Mr. Pursh met with nothing in North America answering to this description. Vahl had his specimen from the Paris garden. The branches are purplish, smooth. *Leaves* as broad as long, smooth; heart-shaped at the base; their segments lanceolate, tapering; the lateral ones having lanceolate teeth at their outer margins; the central one deeply serrated at each side. *Stipules* lanceolate. *Clusters* an inch long, composed of small crowded umbels. Vahl. We presume this to be a mere variety of *V. vinifera*, as well as the two following, which therefore we here place near it.

3. *V. laciniosa*. Parsley Vine. Linn. Sp. Pl. 293. Willd. n. 8. Ait. n. 5. (V. folio apii; Bauh. Hist. v. 2. 73.)

β. *V. laciniatis foliis*; Cornut. Canad. 182. t. 183. Schmidel. Ic. 34. t. 8.

Leaves of five many-cleft leaflets, or deep pinnatifid lobes.—Long known in gardens, but no botanist has discovered its native country. The leaves are quite smooth. We know no difference between this and *V. vinifera*, except, which indeed is very remarkable, the leaves being either composed of five deeply cut, partial-stalked leaflets, as in the Linnæan original specimen, and Bauhin's figure; or only very deeply five-lobed and jagged, like the plates of Cornuti and Schmidel. We readily allow them to constitute one and the same species with the Common Vine, and probably the following.

4. *V. pinnata*. Pinnate Vine. Vahl Symb. v. 3. 43. Willd. n. 11.—“Leaves pinnate, smooth, with tooth-like serratures.”—Given to professor Vahl by Mr. Schumacher. Its native country is unknown. The branches are purplish, smooth and round. *Leaflets* five; the middle ones nearly sessile; the rest stalked; the two lowermost often furnished with an accessory lobe at the outer margin, ovate, pointed, with three or four large serratures at each side; pale green beneath, two inches long. *Flower-stalks* opposite to the leaves, twice compound; partial ones umbellate. *Flowers* small. This seems an intermediate variety between the α and β of *V. laciniosa*, probably obtained from some garden.

5. *V. indica*. Indian Vine. Linn. Sp. Pl. 293. Willd. n. 3. Ait. n. 2. Swartz Obf. 95. (V. fructu minore

rubro acerbo, folio subrotundo, minus laciniato, subtus albâ lanugine tecto; Sloane Hort. v. 2. 104. t. 210. f. 4. Schembra-valli; Rheede Hort. Malab. v. 7. 11. t. 6.)—Leaves heart-shaped, toothed; downy beneath. *Tendrils* bearing the clusters.—Native of the East and West Indies. Swartz says the twigs, when cut, distil a cool refreshing watery juice, highly grateful to the natives of the torrid zone. The leaves are sharply toothed, not lobed; very white at the back, according to Sloane; but this is wanting in the Linnæan East Indian specimen, which we suspect rather to belong to *Cifus*. This however is not an original specimen. The fruit is red, or deep purple, the size of currants, and agreeably acid as well as astringent. Sloane.

6. *V. flexuosa*. Zigzag Japan Vine. Thunb. Tr. of Linn. Soc. v. 2. 332. Willd. n. 4. (V. indica; Thunb. Jap. 103.)—Leaves heart-shaped, toothed; villous beneath. Stem zigzag. Panicles elongated.—Native of Japan, where it is called *Itadori*. The leaves are chiefly villous at the ribs underneath. *Footstalks* slender, as long as the nail. *Panicles* unattended by tendrils. Thunb.

7. *V. Labrusca*. Downy-leaved Vine, or Fox-grape. Linn. Sp. Pl. 293. Willd. n. 5. Ait. n. 3. Pursh n. 1. “Jacq. Hort. Schoenbr. t. 426.” Sm. Inf. of Georgia, v. 1. 55. t. 28.)—Leaves broadly-heart-shaped, angular or slightly lobed, toothed; white and cottony beneath. *Berries* few, somewhat depressed.—Native of shady woods, from Canada to Florida, flowering in June and July. *Berries* black, large, of a disagreeable foxy smell, whence they are commonly called Fox-grapes. A variety with white berries is called Bland's Grape. Pursh. The leaves appear to be sometimes but slightly toothed. Each bunch consists of about six grapes, three-fourths of an inch in diameter, red before they are ripe. We have not seen the fourth volume of Jacquin's Hortus Schoenbrunensis, and are therefore obliged to take our references from Pursh, under this and a few other species.

8. *V. asifivalis*. Summer Grape. Michaux Boreal-Amer. v. 2. 230. Pursh n. 2. “Jacq. Hort. Schoenbr. t. 425,” according to Mr. Pursh. (V. Labrusca; Walt. Carol. 242.)—Leaves broadly-heart-shaped, with three or five lobes, finely toothed; downy and rusty when young. Clusters of fruit oblong.—In fields and woods, from Virginia to Carolina, flowering in May and June. *Berries* small, dark blue, very agreeable to eat, and frequently converted into very good home-made wine. It is known by the name of Summer Grape. Pursh. This author mentions, by the name of *sinuata*, a variety which he thinks may be a distinct species, and which is thus defined: “Leaves sinuato-palmate, coarsely toothed; each sinus rhomboid.” Can this be the plant figured in Sm. Inf. of Georgia, t. 44. as *V. vinifera*? (See the first species.) We have from the late Rev. Dr. Muhlenberg a specimen answering exactly to the above specific character of Michaux and Pursh, but without any information annexed. Whether it be *labruscoides*, Muhlenb. Cat. 27, as we should guess by that name, or *intermedia* of that work, as indicated by the synonymy, there is no possibility of knowing. The leaves in our specimen are glaucous beneath, and clothed with loose, partly rusty, cobweb pubescence, not with dense white cottony down like *V. Labrusca*. The veins terminate in small, acute, marginal teeth. *Clusters* downy and rusty, as well as the *footstalks*.

9. *V. vulpina*. Winter Grape, or Chicken Grape. Linn. Sp. Pl. 293. Willd. n. 6. Ait. n. 4. (V. cordifolia; Michaux Boreal-Amer. v. 2. 231. Pursh n. 3. “V. incisa; Jacq. Hort. Schoenbr. t. 427.”)—Leaves heart-shaped, pointed, sharply serrated, smooth on both sides,

sides, with axillary glandular tufts to the veins beneath. Clusters lax, nearly smooth.—On the margins of rivers, and in woods, from Canada to Florida, flowering in June and July. *Berries* green or amber-coloured, small, ripening extremely late, of a very tart taste. *Pursh*. This is certainly the *vulpina* of Linnæus, and consequently of Willdenow, though Pursh cites the latter author under the foregoing species. The *leaves* of the present have but a slight indication of a lobe at each side, and are more oblong and pointed than either of the two last; being moreover quite smooth, from the earliest period, except the little axillary tufts of hair on the under side. The *footstalks* and *branches* are smooth.

10. *V. riparia*. Sweet-scented Vine. Michaux Boreal-Amer. v. 2. 231. Pursh n. 4. (*V. odoratissima*; Donn Cant. ed. 5. 53.)—"Leaves unequally and deeply toothed, slightly three-lobed; their margins, ribs, and footstalks, downy."—On the gravelly shores and islands of the rivers, from Pennsylvania to Carolina, flowering from May to July. Female plants are very seldom found north of the Potowmac river, though the male extend very far beyond it. The *flowers* have an exquisitely fine smell, somewhat resembling *Roseda odorata*. *Pursh*. We have seen the male plant in blossom in some gardens, though not noticed by Mr. Aiton. The scent is not superior to that of the common *V. vinifera*, which likewise exactly resembles Mignonette.

11. *V. rotundifolia*. Bull or Bullet Grape; sometimes called Muscadine Grape. Michaux Boreal-Amer. v. 2. 231. Pursh n. 5. (*V. vulpina*; Sm. Inf. of Georg. v. 1. 81. t. 41.)—"Leaves kidney-heart-shaped, smooth and shining, nearly equally toothed. Flowers in numerous little heads."—On river sides, and islands, from Virginia to Florida, flowering in June and July. *Berries* very large, dark blue, agreeable, commonly called Bull or Bullet-grapes. *Pursh*. We have seen no specimen. Mr. Abbot, in his drawing for the Insects of Georgia, represents the *fruit* full three-quarters of an inch in diameter, dark purple, dotted, few in each cluster. *Leaves* smaller, shorter, more strongly toothed than in the last; apparently quite smooth.

12. *V. heterophylla*. Various-leaved Vine. Thunb. Jap. 103. Willd. n. 7.—"Leaves simple, naked, with three or five deep serrated lobes."—Found near Nagasaki, and on Papenberg, in Japan, flowering in July and August. It is there called *Inu Ganebu*, or Wild Vine. The *stem* is climbing, smooth, branched and knotty. *Lower leaves* five-lobed; uppermost undivided; all pale beneath, with rough veins. *Panicles* forked. By the description of an annular *nectary*, this seems to be a *Cissus*.

13. *V. hederaea*. Five-leaved Vine, or Virginian Creeper. Ehrh. Beitr. v. 6. 85. Willd. n. 9. Ait. n. 6. (*V. quinquefolia*; Sm. Inf. of Georg. v. 1. 59. t. 30, reversed. *Hedera quinquefolia*; Linn. Sp. Pl. 292. *Edera quinquefolia canadensis*; Cornut. Canad. 99. t. 100. *Ampelopsis quinquefolia*; Michaux Boreal-Amer. v. 1. 160. *Cissus hederaea*; Pursh 170.)—Leaflets five, ovate, pointed, serrated, smooth. Clusters zigzag, corymbose.—On the Alleghany mountains; from Pennsylvania to Virginia, flowering in June and July. Well known in England, where it has long been cultivated, as an ornamental climber, for covering lofty buildings. It flourishes even in the close courts, and pestiferous cemeteries, of the city of London. In autumn, the leaves, before they fall, assume splendid tints of red and orange. The *tendrils* attach themselves to the surface of the smoothest flint. The *leaves* are bright green, smooth and shining, of five stalked *leaflets*, about two inches long. Common *footstalks* three inches in length. *Panicles* lateral and terminal, many-flowered, divaricated, smooth. *Flowers*

umbellate, green, destitute of a *nectary*; their *petals* concave, cohering at the summit, and separating from the base, exactly as in a true *Vitis*, so that we cannot but wonder at the confusion of recent authors respecting the genus of this plant, even more than at Linnæus for referring it to *Hedera*. The *berries* are bluish-black, less than a common pea. Pursh mentions a variety named *hirsuta*, whose *leaves* are downy on both sides, which he thinks may be specifically distinct. But he had never seen the *flowers*, nor are we further informed on the subject.

14. *V. arborea*. Pepper Vine. Linn. Sp. Pl. 294. Willd. n. 12. Ait. n. 7. ("V. caroliniana, foliis apii, uvâ corymbose purpuraceâ; Comment. Bonon. v. 2. part 2. 365. t. 3." *Ampelopsis bipinnata*; Michaux Boreal-Amer. v. 1. 160. *Cissus vitans*; Pursh n. 3. *Frutex scandens, petrefolius virginianus*; Pluk. Mant. 85. t. 412. f. 2.)—Leaves twice or thrice compound; leaflets ovate, partly wedge-shaped, cut.—In shady woods, by river sides, in Virginia and Carolina, flowering in June and July. *Stem* upright. *Pursh*. The *leaflets* are about an inch long, more or less acute, stalked, somewhat hairy, especially the veins, which are furnished with axillary glands beneath. *Tendrils* branched. *Clusters* lateral, corymbose, somewhat forked. Plukenet says this was first raised from seed in England, by Mr. Samuel Reynardson, an eminent merchant of London, at his villa at Hillingdon, before the year 1700. His house and garden still remain, and we have there often admired the largest Cedar of Lebanon in England, blown down about the year 1794.

V. heptaphylla, Linn. Mant. 212, proves by the specimen to be very nearly, if not quite, the same as *Aralia Sciadophyllum*, Willd. Sp. Pl. v. 1. 1519, nor is there any appearance of its being an East Indian plant.

The late Mr. Donn has a *V. lucida*, Hort. Cant. ed. 5. 53, a New Holland shrub, introduced in 1790, of which we find no other mention.

Vitis, in *Gardening*, contains plants of the deciduous climbing kind; among which the species cultivated are, the common vine, or grape vine (*V. vinifera*); the Indian vine (*V. indica*); the parley-leaved vine (*V. laciniata*); and the tree or pepper vine (*V. arborea*).

The first sort has a weak brown-coloured stem, and is a native of most of the temperate parts of the world. In very cold regions it refuses to grow; and within 25° or even 30° of the equinoctial line, it seldom flourishes so as to produce good fruit. In the northern hemisphere, the proper wine country is from 25° to 51° of latitude; and, according to Forsyth, the following are the varieties which are in most esteem in this climate for the hot-house, vinery, and the natural wall.

Sorts proper for the Hot-house.

The white muscat of Alexandria, or Alexandrian Frontinac, in which the berries are oval, and the bunches long. It has a rich vinous juice, and is esteemed an exceeding good grape for the hot-house.

The red muscat of Alexandria, which resembles the former, only the berries are of a red colour.

The black muscat, which has large oval berries of a black colour and pleasant juice.

The red muscadell, which has large red berries of an oval shape, and ripens late. The bunches are very large.

The black Damascus, which has large, round, black-coloured berries; the flesh is rich and well-flavoured. It is an excellent late grape.

The black grape from Tripoli, which has large black berries, and is an excellent grape.

The white Hamburg, which has large oval-shaped berries, and is a pretty good bearer.

The red grape from Syracuse, which is a very fine large grape.

Le cœur grape, or Morocco grape, which has berries of a tawny colour, and is highly esteemed.

The golden Galician grape, which has large oval berries of a yellow colour, and tolerable flavour.

The black raisin grape, which has large black berries of an oval form; the skin is thick, and the flesh firm.

The white raisin grape, which resembles the preceding, only that the berries are white.

The Malvoise, sometimes called the blue Tokay, which has small brownish berries, powdered with a blue bloom; the juice is vinous.

The Syrian grape, which has large, white, oval berries, with a thick skin and hard flesh, and is a good bearer.

The damson grape, which has very large berries of a purple colour.

The Cornichon grape, which has berries of a remarkable shape, long and narrow, of a white colour, with a firm sweet flesh.

The red chaffelas, which is very like the chaffelas blanc in size and shape, but is of a dark-red colour. It is a very good grape, but ripens later than the white.

Sorts proper for the Vinery.

The red Frontinac, or muscat rouge, which is a very fine grape, and greatly esteemed. It has large brick-coloured berries, and the juice is of a highly vinous flavour.

The large black cluster, which is larger than the former, and has a very rough harsh taste. Mr. Speechley says, that he had this grape from Lisbon, and was assured that it is the grape of which they make red Port wine. He has had the same grape eight or ten years.

The white grape from Alcobaca, which bears large bunches of white juicy berries.

The white parsley-leaved grape, or ciotat, which has round berries, white, juicy, and sweet. There is a sort of the parsley-leaved grape with red fruit.

The white Corinth grape, which has a small round berry, with a fine juicy flesh of an agreeable flavour.

The St. Peter's grape, which has a large oval berry, of a deep black colour when ripe; the bunches are large, and the flesh juicy. It ripens late.

Sort proper for the Wall.

The white or common muscadine, by some called the chaffelas, which resembles the royal muscadine, but the berries are smaller; and although it is not so sweet as the royal, it is the best grape that we have for a common wall, and a great bearer.

Sorts proper for the Hot-house and Vinery.

The black muscadine, which is a good bearer, and the berries are beautifully powdered with a bluish bloom.

The royal muscadine, d'Arboyce, or chaffelas blanc, which is an excellent grape; the bunches are large, and composed of round amber-coloured berries of a rich vinous taste. In a fine season it ripens in September.

The white muscat from Lunel, which has large oval berries of an amber-colour, and full of a vinous juice. It is a plentiful bearer, and highly esteemed.

The black Spanish, or Alicante grape, which has black berries of a pleasant flavour.

The black grape from Lisbon, which has large, round,

juicy berries, and the bunches resemble the black Hamburg. It is a good grape.

The black Frontinac, or muscat noir, which has pretty large round berries, black when ripe, and covered with a mealy powder.

The grisly Frontinac, which has round berries, of a colour composed of brown, red, and yellow. It has an excellent flavour.

The black Hamburg, which has the bunches large, composed of large oval black berries, of a pleasant sweet juice and vinous flavour. It ripens in November.

The red Hamburg, which has thin-skinned berries of a dark red. They have a rich vinous flavour, and ripen about the same time with the former.

The white morillon, which has an oval-shaped juicy berry, and the leaves are downy on the under side.

The Aleppo grape, which has middle-sized berries, with a juicy flesh of a very fine flavour. It is a curious grape, frequently striped black and white.

The genuine Tokay, which is a white grape, with a thin skin, delicate flesh, and agreeable juice.

The Lombardy grape, which has fine, large, flame-coloured berries, full of a fine juice; and the bunches grow to a great size, frequently weighing more than six pounds.

The Smyrna grape, which has a large red berry, of a very fine flavour, and is esteemed a very good grape.

The brick grape, so called from its colour, has small berries, but the juice is sweet.

The claret grape, which has small black berries, with a blood-red juice; but the grape is very harsh, if not perfectly ripe.

The cat's grape, which has small berries of a pale-green colour; the flesh is soft and juicy, but of a very disagreeable taste, unless quite ripe.

The Greek grape, in which the berries are of a blueish-white colour; and it is esteemed a fine grape.

The black Corinth, or currant grape, which has a small roundish berry, generally without a stone, of a deep black colour. It has a sweet juice, and ripens in October.

The new muscat of Jerusalem, which has large round berries of a red colour; some of which, in fine seasons, are as large as a gooseberry; but as it does not ripen well on the natural wall in this country, it might be worth while to try it in a hot-house or vinery.

The black Prince, which has fine large berries, and the bunches grow to a large size. Mr. Forsyth has had them, in a favourable season, on the natural wall, weighing a pound and a half: it ripens on the natural wall in October. It deserves a place in the hot-house and vinery.

Sorts proper for the Vinery and Wall.

The July grape, or morillon noir hatif, is a small round black berry of a fugary juice, and is principally esteemed for being early ripe, which is in September.

The Malmsey muscadine somewhat resembles the preceding; the juice is very sweet, and of a high flavour. This is a good bearer, and a very fine grape.

The black sweet-water has a small roundish berry, of a sweet taste; but being apt to crack, is not in much repute. The birds are very fond of this grape, which ripens in September.

The small black cluster has small oval berries; the leaves are covered with a hoary down. This is a very pleasant fruit.

The early white grape from Teneriffe; the berries are of a middling size, and the flesh remarkably sweet and juicy.

The Auverna, or true Burgundy grape, sometimes called
the

the black morillon, is an indifferent fruit for the table, but is esteemed one of the best for making of wine.

Sorts proper for the Hot-house, Vinery, and Wall.

The white sweet-water, which has a large berry of a white colour, and very agreeable juice; it is esteemed an excellent grape, and ripens in September.

The white Frontinac, or muscat blanc, which has large bunches composed of round berries: the juice of this grape, when fully ripe, is exquisite.

To this list are added the following sorts, without any descriptions.

The black Frankindale, the black Gibraltar, the black muscat of Alexandria, the Miller grape, the new white sweet-water, the passe musk, the pearl muscadine, the red Constantia, the red raisin, the fir Abraham Pitcher's fine black, the West's St. Peter, the white Constantia.

And the following are the sorts recommended for a small garden, by the same author.

The white muscadine, white sweet-water, black sweet-water, large black cluster, small black cluster, the Miller grape: the St. Peter's and the black Hamburgh answer well in favourable seasons.

The writer of the Scotch Forcing Gardener remarks, that amongst the numerous varieties of grapes, he does not know above eighteen or twenty kinds worth a place in the vinery, and even that number cannot have places in an ordinary-sized house; but where there are two or three houses, a variety to the extent of twenty-four kinds may be encouraged, without transgressing the bounds of moderation. The following is the list which he advises.

White sweet-water, white muscadine, royal ditto, black ditto, black Frontinac, white ditto, red ditto, Grilly ditto, black Hamburgh, white ditto, white raisin, red ditto, Syrian, white Tokay, flame-coloured ditto, white passe musque, Grecian, white muscat of Alexandria, black ditto, large black cluster, black Constantia, white ditto, St. Peter's grape, Lombardy.

Out of which, it is thought, the proprietors of grape-houses may choose so as to stock any grape-house.

To the above sorts may probably be added the verdello, which is pronounced *verdello*, as it is said to be the most prevailing grape in the vineyards, and the most famous for producing the best wine of the Madeira kind; though the celebrated white wine obtained from that island is mostly understood to be the production of a mixture of different grapes.

Cuttings of this vine, procured from the above place, are said not only to grow remarkably well and with great vigour in the vinery here, but to be greatly productive of fruit, frequently giving three bunches on a shoot. As it does not, however, form a large bunch, it will probably not be thought worthy of culture here, except by those who are curious in the flavour of their grapes. The berry is small, of an oval shape, and many very small berries without seeds are usually interspersed: these being cut out with scissors, will, it is asserted, much improve the appearance of the bunch. The fruit is said to be very acid until it arrives at the last stage of maturity, when the berries become of a fine amber colour, and of a very rich saccharine flavour. It is supposed that this vine will succeed in favourable situations on the open wall, especially where the soil is light, dry, and shallow; but that in a deep highly manured soil, it will run too much into wood and foliage.

The leaf is very thick, of a dark green colour, and resists the autumnal frosts somewhat longer than the chasselas, and some other kinds; and will therefore, it is supposed, in the

ordinary course of the seasons here, afford protection to the fruit till towards the end of the month of October.

The second species or sort has a woody branching stem, affording small round watery berries of a brownish-green appearance. But it is said to produce a great quantity of black grapes in the lower hills of Jamaica, which are of a rough taste, and would doubtless make an excellent wine, if properly managed. It seems to thrive best on the Red-hills, and is there known by the name of water-witbe.

The third species or sort has the stalks and branches like those of the common grape, but has only a few plants, occasionally preserved for the sake of variety.

The last species or sort has the stem woody with slender branches, but does not afford fruit in this climate.

Method of Culture.—The vine may be increased in different ways: as by seeds, cuttings, layers, as well as by grafting and inoculation; but the cutting and layer methods are the most commonly employed.

In raising vines from seeds, they should be sown in the early spring, as about the beginning of March, in small pots filled with mould of the light fresh kind, to the number of three or four seeds in each, plunging the pots in a moderate hot-bed, the mould being gently sprinkled over with water, from a fine-roled watering-pot, every day when the weather is hot and dry, which should be performed in the latter part of the day as the sun disappears from the frame. But when the season is such as to keep the mould in the pots properly moist, the waterings may be omitted. As soon as the waterings have been performed, the frames should be shut down, and be kept in that state during the night, when the heat is not too great.

When the heat of the bed begins to decline, a lining of horse-dung and fresh leaves should be added; or the heat be renewed by stirring the old beds up and making slight additions to them. This should be continued till the plants have acquired sufficient strength to support themselves without bottom heat.

It will be necessary about the end of August, Mr. Forryth suggests, to take the lights off, that the plants may be hardened before winter, taking care to shelter them in frames covered with mats, which will prevent the frost in the latter end of October and beginning of November from injuring the tender shoots. And when the plants are about six inches high, they should, it is thought, be transplanted singly into deep pots, forty-eights, filled with the same sort of vegetable mould that is directed to be used for vines; taking great care not to hurt the roots, nor to break the leaders; then plunging them again into the hot-beds: but if the heat of the old bed be too much decayed, it will be necessary to have a new one prepared before-hand, to receive the pots as soon as the plants are transplanted. When they grow vigorously, it will also be necessary to shift them into thirty-twos. When the plants are above six inches high, they should be carefully tied to small rods, leaving only one stem for the first year. The rods should be as high as the frame will permit. And when the leaves begin to drop, they should be carefully picked off the pots, to prevent the plants from getting mouldy, which would very much injure their growth.

It is likewise advised, that they should be kept under frames, or put into the greenhouse in hard winters, to shelter them from severe frosts. In the spring, about March or the beginning of April, if from seed ripened in this country, they may be planted out against the walls where they are to remain; but if from seed imported from vine countries, it is advised not to plant above one or two against the wall, or in the hot-house, before a specimen of the fruit has been obtained.

tained, and proof afforded that the vines are worth cultivation. It is likewise recommended, that after they are planted, they should be cut at the third eye, if strong; but at the second, if weakly; at the same time rubbing off the lower bud with the finger and thumb, as directed below.

But where the method by cuttings is made use of, these should be chosen from the shoots that are best ripened, and have the shortest joints; always having one or two joints of the last year's wood, cutting it perfectly smooth and a little rounding at the lower end, and as near to a joint of the old wood as possible. The upper end should also be cut smooth and sloping towards the wall; but if they are planted in beds or borders, the cut should always face towards the north. When cuttings are planted against piers or walls, it should be at about a foot distance from each other, according to the vacant space, and so deep as to have the second eye level with the ground, constantly rubbing off the lower eye; as by this means, where no accident happens to the top bud, there will be a shoot produced from each eye, with a little under, which should always be rubbed off as soon as it begins to swell; as if suffered to grow to any considerable size, there will be danger of injuring the large one in rubbing the small one off. All the runners and side-shoots should likewise be picked off as directed above, leaving only two shoots, which should be trained at their full length. About the beginning of February they may be pruned, leaving one or two eyes on each, according to the strength of the shoot, which should be managed as explained below.

It is remarked by the above writer, that for the first year, especially if the summer be dry, and proper attention be not paid to the watering of them, they will make but little progress; but in the second year it may be plainly discerned which is the strongest plant, which only should be left to fill up the vacant space on the wall; the rest should be taken up and planted in other situations where they are wanted for fruit.

However, a method is made use of by Mr. Speechley and others, of propagating the vine from one eye, and a few inches of the preceding year's wood, which they prefer to those raised by cuttings in the common way, on these accounts: they have more abundant roots, grow shorter jointed, are more prolific, and will, if permitted, come into bearing the second year.

In regard to the mode of management, it is advised that choice should be made of cuttings after a warm dry season, when the wood ripens well; each cutting having two inches of the old wood, with one eye of the new. When the vines are pruned there is great choice; they should therefore be then selected of a middling size, the wood round and perfectly ripened.

After this, pots are to be filled with rich light mould, that has been well mellowed and prepared some time before. The cuttings being then prepared for planting, by the bottom part being cut perfectly smooth; if any of the old dead snags remain, they should be cut off close to the quick wood, and the top cut sloping towards the back of the hot-house or frame, when placed in them. Mr. Forfyth recommends planting only one cutting in each pot, which as to the size should be a deep forty-eight; by that means he thinks the plants will grow much stronger and quicker than when many are crowded together, and the sun and air will have a freer admission to ripen the wood; for, when many are planted in one pot, they shade one another, and in a considerable degree prevent the sun and air from passing freely among them. When the plants begin to get strong, and the pots full of roots, it will be necessary to shift them from the forty-eights to thirty-tuos. This method is, he contends,

best adapted for private gardens; but for nurferymen, &c. who raise plants for sale, and cannot conveniently spare so much room, it may be necessary to plant three or more cuttings in each pot.

And in these cases, the same rules for watering, transplanting, shifting, &c. are to be attended to as was directed for the seedling plants.

The same writer remarks, that it is a method very frequently practised by nurferymen and gardeners, when they wish to have their plants fit for sale the same year, to plant them in pots, and place them in the hot-house among the tan, on the flues, or round the curbs of the pit. And he has seen it employed with great success. In this way they may, it is asserted, be raised either by planting them singly in small pots, or several in a pot, according to its size, planting them out separately when they have taken root, having a hot-bed ready to plunge the pots in as soon as they are transplanted. In this manner they become much forwarded in their growth, and are before the autumn in a state fit for sale.

In raising vines in the layer manner, the method usually made use of is by floots, in the open quarters of the garden, in the same manner as nurferymen propagate fore-trees and shrubs; but the best way, according to Forfyth, is to take layers from these on walls or palings, training the shoots at full length during the summer; when about the month of February some of the finest and strongest shoots should be chosen, laying them across the foot-path into pots (twenty-fours or sixteens) filled with fresh mould, and plunging them in the ground about two inches below the surface; at the same time making an incision or two in the old wood, or giving it a twist just below a joint; and though they will generally take without notching or twisting, it is nevertheless advised, as the surest way, to have that done. The layers should then be cut, leaving two or three strong eyes upon each. And when the shoots begin to run, they should be tied to long stakes, to prevent their being broken by the wind; all the runners and side-shoots being picked off, leaving only two or three fine strong floots on each plant, which should be trained at full length during the summer season.

As soon as the shoots are laid down, it will be necessary to mulch them with good rotten dung, or rotten leaves, which will keep the mould moist: and in very dry summers, a good watering should be given once or twice a week; this will wash in the dung or leaves about the roots, and induce the layers to shoot with more vigour. The above writer thinks that in this method of laying, two or three rows of layers may be had from one wall: taking care to lay the branches alternately, and to keep the pots plunged about two inches below the level of the ground.

The same writer advises in choosing vines from the nurfery, to select those which have the strongest and longest floots. And he observes, that where the above directions are properly attended to, the plants will be well rooted in the pots before autumn, and fit for planting in vineries, hot-houses, or other situations. And when they are to be planted out, they should, he thinks, be carefully cut off from the mother vine, and carried in the pots to where they are intended to be planted; taking care to preserve the balls as much as possible when they are turned out of them.

It is also added, that if the season be warm and fine, the grapes of the early kinds ripen very well on these layers before they are taken up; and, if properly managed, they will bear some fruit the first year after planting. One of the strongest floots must be left nearly at full length, cutting it as high as the uppermost full bud, leaving nothing but
round

round well-ripened wood. If there are three shoots, the remaining two should be cut so as to leave only two full eyes upon each, which should be trained at length, as before directed, to produce fine wood for the next year. The shoot which was trained the preceding year should then be cut down, leaving only two strong eyes to produce wood for the following year; and so on every year, cutting the branches alternately: by this means the walls always may be kept covered with fine healthy bearing wood, and a great deal of time be saved in furnishing hot-houses, vineries, and other places. It is remarked, that this method of laying is practised with great success by many nurserymen in the neighbourhood of London.

In producing of vines by grafting, choice should be made of cuttings for grafts, or scyons, from the best-bearing branches of the sorts intended to be propagated at the season of pruning. In general, the bottom part of the last year's shoot is to be preferred; and in well-ripened vigorous wood, any part of the shoot will answer, provided it be not too long jointed. These cuttings should be preserved in pots filled with light sandy earth till the time of grafting.

The periods for performing the operation are different according to the vines; for those in the pine stove, the beginning of January may be proper, but the middle of March for those growing in the open air. In general, they should be grafted about three weeks before they begin to break into bud. And upon small stocks not more than an inch in diameter, cleft-grafting is the most proper; but upon larger stocks, whip-grafting is to be preferred. In both methods, care should be taken in fitting the stock and scyon together, and the operation should be performed with great exactness; fastening them together with bass matting, and covering them with clay in the usual way. After the operation, the scyon will sometimes begin to push in a few weeks, but it frequently remains dormant two or three months; during this period the stock must be stripped of all its shoots as soon as they appear; and to preserve the scyon in a vegetative state, the clay must be kept moderately moist by wrapping wet moss round it, and by keeping the moss constantly sprinkled with water. And when it has made shoots five or six inches long, the clay and bandage must be carefully taken off.

The method of grafting by approach is advised by some, however, as the best mode of raising vines. In this case, it is necessary to have the plant intended to be propagated in a pot. Strong plants that have been two or three years in pots are to be preferred; but plants from the nursery may be potted, and grafted in the same season, if brought into a hot-house or vinery. It is suggested that fine grapes and good wood may be obtained even the first season by any of these methods, but particularly by the last; in which it is evident the graft has a double support, as from the stock and the plant in the pot.

In this sort of grafting, the clay and bandage should remain two or three months after the graft has formed an union; for if it be taken off sooner, the graft will be very liable to spring from the stock. The pot should be plentifully supplied with water till the month of August, when the graft should be separated from the plant in the pot. Two or three inches of wood below the bottom of the graft may be left, but should be taken clean off at the next pruning in winter.

The Syrian vine is recommended as the most proper for stocks, and plants of this sort raised from seeds are greatly preferable for this purpose to plants either raised from layers or cuttings. See GRAFTING.

The principal advantages of the grafting mode of raising vines are; that if a wall should have been planted with bad kinds, instead of stubbing them up, and making a new border, by which several years must elapse before the wall can again be completely filled; in this way their nature may be changed immediately, as good grapes may be obtained from the same year's graft; and in a hot-house the grafts, if permitted, will frequently shoot thirty or forty feet the first summer; that in small vineries or frames, where great variety could not be had in the common way, it may be procured by this means on the same plant; and that of the improvement of the various kinds, particularly the small ones, which generally make weak wood. The method by inoculation may likewise have advantages in some cases of a similar kind.

When any of the vines that have been raised from seed do not prove of a good flavour, they are proper for grafting or inarching the finer sorts of vines on; for, as the coarser sorts grow more vigorously than the finer, they are on that account more fit for grafting or inarching.
