WITTOBA, in *Hindoo Mythology*, is a name of the god Vishnu in one of his numerous *descents*, or *avataras*, as they are called. Some account of these avataras is given under our article VISHNU. This, now under consideration, was one of inferior importance; and not, it is said, of very ancient occurrence, and therefore not described in the Puranas, unless it be in the one supposed to be more modern than the rest, which is entitled Maha Bhagavat. (See PURANA, and SRI BHAGAVATA.) A splendid temple is dedicated to the worship of Wittoba, or Vishnu, at Panderpoor, a town of great respectability on the river Beemah, about 100 miles to the south-eastward of Poona. The manifestation is said to have taken place there. He is there represented sculptured in stone, of the size of a man, standing with his feet parallel to each other; his hands upon his hips, the fingers pointing forward, his thumbs backward. Two of the wives of Vishnu in his avatara of Krishna accompanied him in this; these were Rukmeni and Satyavama, and they have smaller temples at Panderpoor, besides their lord's. (See KRISHNA, RUKMENI, and SATYAVAMA.) Images of Wittoba are common in the Mahratta country, generally of clumsy manufacture. Several representations of Wittoba and his wives are given in the Hindoo Pantheon, from casts and pictures. That work contains also a history of the avatara, and many particulars respecting it.

WITTORF, in *Geography*, a town of Germany, in the county of Verden; 10 miles S.S.E. of Rotenburg.

WITTOW, a town on a peninsula at the northern extremity of the island of Usedom, near Artona, an ancient fortress destroyed by the Swedes. N. lat. 54° 44′. E. long. 13° 27′.

WITTSTOCK, a town of Brandenburg, in the Mark of Pregnitz; 47 miles N.N.W. of Berlin. N. lat. 53° 10′. E. long. 12° 39′.—Also, a town of Brandenburg, in the New Mark; 12 miles N. of Custrin. N. lat. 52° 49′. E. long. 14° 50′.

WITWALL, in *Ornithology*, a common Englifh name for the great fpotted wood-pecker, the *picus varius major* of authors.

WITZELRODE, in *Geography*, a town of Germany, in the county of Henneberg; 3 miles E.N.E. of Salzungen.

WITZELSTORFF, a town of Auftria; 4 miles S.E. of Hoffmarckt.

WITZENBURG, a town of Weftphalia, in the bifhopric of Hildefheim; 6 miles S.E. of Alfeld.

WITZENHAUSEN, a town of Germany, in the principality of Heffe Rhinfels; 13 miles E. of Caffel. N. lat. 51° 10'. E. long. 9° 48'.

WIVELISCOMBE, a large market-town in the hundred of Weft Kingfbury, and county of Somerfet, England, is fituated in a valley, at the diftance of 11 miles W. from Taunton, 25 miles W. from Somerton, and 156 miles W. by S. from London. It appears to have been of fome note under the Romans, though not diftinguifhed in their annals as a ftation or military poft. In the earlier part of their tranfactions in this ifland, they had a large caftrum, or encampment, on a hill about a mile eaftward from the town, which ftill is called the caftle. Its fummit contains about twelve acres; and though moftly covered with coppice-wood and bufhes, the veftiges of fortifications, and the foundations of buildings, are yet difcernible on its furface. Part of the foffe, which is very deep, and extended round the hill, has been deftroyed by the working of a quarry. Near the centre of the area, a great number of Roman coins of various emperors were difcovered in the beginning of the laft century. The Danes, during their incurfions into this county, availed themfelves of this caftle, and after their departure, the Saxons, recovering their tranquillity, tranfplanted themfelves to the adjacent vale, and gave their new habitations the name of Wivelifcombe. From this time it progreffively became of importance, conftituted the head of a large lordfhip, and was always held by the Saxon kings, till Edward the Confeffor granted all the lands to the church of Wells. The bifhops of that fee had a ftately palace here for nearly three centuries: it is now in ruins; a workhoufe, erected in 1735, occupies a part of the ancient feite. The town now confifts of feven irregular ftreets: it is governed by a bailiff and portreeve, who are annually chofen in May. Here were formerly two markets, one on Tuefdays, the other on Saturdays; the latter only is now retained, with three annual fairs. A confiderable woollen manufacture has been carried on for more than two hundred years, and ftill flourifhes; the chief articles made are, blanketings, knap-coatings, kerfies and other coarfe cloths, fhrouds, ermine, and baize. Many of thefe are fent to London, Briftol, and Exeter, for home confumption, and for exportation to Spain and Guernfey. The church is a plain ftructure, and confifts of a nave and two aifles, with a tower and fpire at the weft end. The parifh befides the town includes four fmall hamlets, and according to the population return of the year 1811 contains 567 houfes, and 2550 inhabitants.—Collinfon's Hiftory, &c. of Somerfetfhire, vol. ii. 1791.

WIVENHOE, a village of England, in the county of Effex, fituated on the river Coln; it is the harbour of Colchefter, and here is a cuftom-houfe. The oyfters, called Colchefter oyfters, are barrelled in this place. In 1811, the population was 1046.

WIZE, a river of England, in the county of Cumberland, which runs into the Wever.

WIZNA, a town of the duchy of Warfaw; 88 miles N.E. of Warfaw.

WIZUNY, a town of Lithuania; 20 miles N.N.E. of Wilkomiers.

WIZZARD, in *Agriculture*, a term applied in Norfolk to any particular fort of cart for farm-work.

WIZZENED, a term provincially applied to fignify withered or fhrivelled, as hay.

WLADISLAW, in *Geography*, a town of Moravia, in the circle of Iglau; 12 miles S. of Meferitfch.

Wladislaw, or *Inowroflaw*, a town of the duchy of Warfaw, and capital of a palatinate of the fame name, on the Viftula: the fee of the bifhop of Cujavia, removed from Krufwica in 1173; 108 miles N.W. of Warfaw. N. lat. 52° 35'. E. long. 18° 35'.

WLODOWA, a town of Auftrian Poland; 18 miles N.E. of Chelm.

WLODZIMIERZ, a town of Poland, in Volhynia, on the Bog; the fee of a Greek bifhop, united to the church of Rome; 48 miles W. of Luckow.

WOAD, in *Agriculture*, a plant cultivated in the field for the ufe of the dyers. It is a plant which has a ftrong thickifh fibrous root, which penetrates deep into the foil, and which is principally raifed for the ufe of the leaves, which, after being properly manufactured, are made ufe of in the art of dyeing to produce a blue colour, as well as the bafis of black, and fome others.

Soil.—It is evident from the nature of its root that it requires a foil which has much depth or ftaple, and which is perfectly frefh, fuch as thofe of the rich, mellow, loamy, and deep vegetable kind. Where this fort of culture is carried to a confiderable degree of perfection, as in Lincolnfhire, the deep, rich, putrid, alluvial foils on the flat tracts extending upon the borders of the different large rivers are chiefly employed for the growth of this fort of crop; and it has been fhewn by repeated trials that it anfwers moft perfectly when they are broken up from a ftate of fward immediately for it. In fome places, it is the practice to take lands of this defcription at high prices, for the purpofe of breaking them up and growing it upon them for two or three years; on the more low rich foils, for four years, but on thofe of lefs fertility only for three; and in fome, which are more elevated and expofed, two are confidered fufficient. For this fort of culture, people are employed, who move from place to place, and form a fort of colony. Mr. Cartwright, in the above county, has however found, that it is capable of being confined to one fpot with equal or greater fuccefs, by having a fufficient extent of ground for changing the place of its growth as may be neceffary, and for appropriating an adequate proportion annually to the raifing of the plant, by which the houfes and expenfive machinery that are neceffary for its preparation may be kept conftantly and regularly employed in the bufinefs.

Preparation.—In order to prepare the land for this crop, it is advifed by fome to plough it up with a good deep furrow, immediately before the winter commences, laying it in high narrow ridges, to have the full effect of the frofts; and early in the fpring to give another ploughing in the contrary direction, leaving the ground in the fame kind of ridge as before. When it has remained in this ftate fome length of time, and weeds appear, it fhould be well harrowed down with a heavy harrow, repeating the operation fo as to render it perfectly fine and clean. About the beginning of June a third ploughing fhould be given to the full depth with a narrow furrow, and the land be afterwards well harrowed down as before; the fourth or final ploughing being given towards the beginning of July, in a light manner, leaving the furface as even as poffible for the feed. But fome take much lefs trouble in the bufinefs of preparation.

tion. In cafes where the foils are fufficiently dry, only breaking them up early in the month of February; and where the contrary is the cafe, deferring it to a later period, taking care to plough the land in a perfect manner to the depth of five inches, or more: and that the furrow-flices may be well turned, laid flat, and nicely jointed, a perfon is employed with a fpade for the purpofe of adjufting them. This prevents the graffy matters from rifing in the feams. When this has been done, the furface is repeatedly harrowed over, to raife a fufficient depth of good mould for the drill to work in; and before the feed is put in a roller is paffed over the land.

It is probable, however, that this method is inferior to the former, as the land is not brought nearly to fo fine a ftate of mould, or the graffy material fo effectually covered and deftroyed, from which injury may be done to the woad plants in their early growth.

But a method which is equally effectual with the firft, more expeditious, and which has a fuperiority over it, in more completely deftroying grubs, infects, and other vermin, which are apt to feed on the plants in their early growth, is that of paring and burning. This is, however, chiefly practifed where the fward is rough, and abounds with rufhes, fedge, and other plants of the coarfe kind, but might be had recourfe to on others, with vaft benefit.

Where the latter modes are made ufe of as foon as the feed has been put in, the land fhould be carefully drained by forming grips in fuitable directions, as wherever water ftagnates, the woad plants are liable to be injured or deftroyed.

Seed.—In refpect to the feed, it fhould be collected from ground that has been left covered with the beft plants from the preceding feafon, as they only run up to ftem and form feeds in the fecond year; and in order to have good feed, the leaves fhould not be cropped at all or but once, the ftems being fuffered to remain till the feeds in the hufks become perfectly ripened; which is fhewn by their attaining a brownifh-yellow colour, and the pods having a dark blackifh appearance. It fhould then be gathered as foon as poffible, by reaping the ftems in the manner of grain, and then fpreading them in rows thinly upon the ground if the weather be fine, when in the courfe of a few days they will be in a ftate to be threfhed out from the hufks or pods. When they are fuffered to remain too long, the pods are liable to open, and fhed the feed. Although the pod in which the feeds are contained is of a large fize, the feeds are lefs than thofe of the turnip. New feed, where it can be procured, fhould always be fown in preference to fuch as has been kept for fome time; but when of the latter kind, it fhould be fteeped for fome time before it is put into the ground.

In regard to the quantity of feed which is neceffary, it muft be regulated by the foil, and the manner in which it is fown. Where the drill is employed, lefs will be required than in the broad-caft method. It has been found that a rood of land, where the crop is good, will in general afford feed fufficient for eight or ten acres; and in fome cafes, in the broad-caft method, five or fix bufhels are made ufe of to the acre. In Kent they ufe ten or twelve pounds to the acre.

Sowing.—The time of fowing crops of this nature muft be regulated, in fome degree, by the mode of preparation that has been employed. Where the firft of the above methods has been followed, it will be much later than in the other cafes. But early fowing is in general to be preferred, as there will be lefs danger of the plants being injured by the attacks of the fly or grub. Where the weather is fuitable, and the land in a proper ftate of preparation, the feed may be fown in the latter end of February or March, continuing the fowings, in different portions of land, till about the middle of May, at fuitable intervals of time to vary the times of cropping the leaves of the plants. The late fowings are commonly executed about the latter end of July, or early in the following month at the fartheft.

With refpect to the manner in which the feed is fown, it differs according to the nature and ftate of preparation of the land. Where it is in a fine ftate of mould, the drill or row method is the method moftly practifed, which is by much the beft, as by it the plants may be kept more eafily clean and free from weeds, becoming more ftrong and vigorous, from the earth being more ftirred about the plants: but where the contrary is the cafe, the broad-caft mode is generally followed; but which does not by any means admit of the plants being kept fo free from weeds, or the mould fo well ftirred about the roots of them.

Where the firft method is had recourfe to, the feed is fown by a drilling-machine, fuch as is ufed for turnips, in equidiftant rows, eight or nine inches apart, covering it in, either by means of a harrow attached to the implement, or by paffing a light common harrow over the ground afterwards, once in a place, raking off any clods that may be prefent to the fides, or into the furrows: but in the latter mode, it muft be difperfed by the hand in as equal a manner as poffible, over the whole of the land, being then harrowed in by a light harrow, fo as to leave the land in as even and level a ftate as poffible. The ground is frequently rolled afterwards, that the furface may be left as even as poffible.

In favourable feafons with good feed, the plants moftly appear in the courfe of a fortnight, when much attention fhould be paid to fee that they are not deftroyed by the turnip-fly, or the frofts in thofe of the more early fowings; as, where that is the cafe, the land fhould be immediately refown; as in fome cafes it is not uncommon to fow the greateft part of the crop two or three times over. In the very late fowings, where the crops rife thin on the ground, it is fometimes a practice to give a better plant by forming holes with a hoe in the vacant fpots, and directing feeds to be dropped into them by the hand by women or children. This is the cafe with the late fpring-fowings till the beginning of June, or a later period.

Culture while growing.—From much of the goodnefs of the woad plants depending on the luxuriance of their growth, and the thicknefs of their leaves, it is neceffary to beftow great attention in the culture of the crop while growing. It is advifed that the fpring-fown crops, as well as thofe that are fown in the latter part of the fummer, fhould have the firft hoeings given them as foon as the plants are fully diftinguifhable above the ground, as by this means the weeds will not only be prevented from retarding the vegetation of the plants, but thefe by being thinned out to greater diftances be more at liberty to advance and become vigorous in their firft or early growth, which is a matter of much confequence to the fuccefs of the crop; and fecond hoeings fhould be given in the courfe of four or five weeks afterwards, when the plants fhould be thinned out to the full diftances at which they are to ftand, which may be fix or feven inches, or more, according to the goodnefs of the foil, conftantly leaving fufficient room to prevent the plants from being in any way crowded. The work is fometimes executed in much the fame manner as for turnips, by hand-hoes; but in others by fmall fhort fpuds, ufed with one hand, while the other is employed in clearing away the weeds; the labourers, moftly women and children, kneeling while they perform the work. When this work has been done, nothing further is neceffary till the firft cropping of the

the leaves has been performed, when the plants ſhould be again immediately well weeded; and after each cropping the ſame operation be had recourſe to; the extent of crop cleared in the day being, in moſt caſes, weeded before night.

With the late-ſown crops, after the ſecond weeding in October, nothing further will be requiſite till the ſpring, about the middle of April, when the work ſhould be again well executed, the mould being completely ſtirred about the roots of the plants, that they may derive the fulleſt benefit from the operation. This will be ſufficient to keep them clean till the taking of the firſt crop; after which they muſt be again weeded, and the ſame operation be had recourſe to after each cropping of the leaves, as in the above caſe.

In reſpect to the buſineſs of gathering the crops with the ſpring-ſown ones, the leaves will generally be ready to be gathered towards the latter end of June, or beginning of July, according to the nature of the ſoil, ſeaſon, and climate; but for thoſe put in at a later period in the ſummer, they are often fit to be gathered earlier. This buſineſs ſhould, however, conſtantly be executed as ſoon as the leaves are fully grown, while they retain their perfect green colour, and are highly ſucculent; as when they are let remain till they begin to turn pale, much of their goodneſs is ſaid to be expended, and they become leſs in quantity, and of an inferior quality for the purpoſes of the dyer. In favourable ſeaſons, where the ſoils are rich, the plants will often riſe to the height of eight or ten inches; but in other circumſtances they ſeldom attain more than four or five: and where the lands are well managed in the culture of the plants, they will often afford two or three gatherings, but the beſt cultivators ſeldom take more than two, which are ſometimes mixed together in the manufacturing of them. It is neceſſary that the after-croppings, when they are taken, are conſtantly kept ſeparate from the others, as they would injure the whole if blended together, and conſiderably diminiſh the value of the produce. It is ſaid that the beſt method, where a third cropping is either wholly or partially made, is to keep it ſeparate, forming it into an inferior kind of woad.

Upon an acre of land, when well managed, in favourable ſeaſons, the produce is moſtly from about a ton to a ton and a half. The price varies conſiderably; but for woad of the prime quality, it is often from twenty-five to thirty pounds the ton, and for that of an inferior quality ſix or ſeven, and ſometimes much more.

Seeding-Crops.—With ſuch parts of the crops as are reſerved for ſeed, it is a practice with ſome to crop the leaves two or three times the firſt year, and then leave the plants to run up to ſeed in the following one; but it is a better practice to only remove the ſide-leaves, as in this way the plants are leſs weakened, and the produce of the ſeed much increaſed. The plants are likewiſe ſometimes fed down by ſheep during the winter ſeaſon; but this, from its tendency to weaken them, is equally improper and prejudicial.

Preparation of for the Dyer.—The woad, after it has been gathered, undergoes ſeveral proceſſes to prepare it for the dyer; but in the improved method it is conveyed in one-horſe carts, ſo contrived as to be lifted from the axis, and, by folding doors in the bottoms, to diſcharge their contents upon the floor above the mill, on being hoiſted up to their proper ſituation: round this floor holes are formed for putting the plants down through, in order that they may drop under the grinding-wheels. The mills for this purpoſe have ſeveral wheels for grinding the plants, which have leſs diameters on one ſide than the other, and are about three feet in width, being conſtructed with iron bars for cruſhing the woad. They are wrought by horſes, or any other power, as may be the moſt convenient. The materials are preſerved under the grinding-wheels by proper contrivances, which, as ſoon as they are ſufficiently reduced, force it out of the tracks upon the ſtone floors on the ſides; thus making way for new parcels without the mill being ſtopped. The bruiſed woad is then thrown into rooms on the ſides of the mill, deſtined for its reception, by means of ſhovels. In theſe it remains till the juice is ſo much drained off as to leave it in a proper condition for being formed into balls; which is done by labourers, with apparatus for the purpoſe, and then laid upon trays to be conveyed to the drying ranges, in which they are placed upon grating-ſhelves that ſlide on ſledges in the drying-houſes. Theſe are placed on the ſides of galleries, for the convenience of being eaſily depoſited upon them and removed again. It is kept in theſe till it is ſufficiently dried to be laid up in other rooms, until the whole of the crop has undergone the ſame operations, and the workmen are ready to manufacture it.

It is ſtated in the Corrected Lincolnſhire Report on Agriculture, that to prepare it for uſe in the art of dyeing, it is neceſſary for it to take on a proper ſtate of fermentation, which is accompliſhed in the courſe of ſeven or eight weeks, and, in the technical language of the art, is termed *couching*. It is effected by regrinding the balls, in the ſame mill as before, to a fine powder, and then ſpreading it upon the floors of the rooms in which the balls were formed, to the thickneſs of about three feet; where it is then moiſtened with water, ſo as to keep it in a proper ſlow ſtate of fermentation; and ſo managed by turning that it may pervade the whole in an equal manner. In this buſineſs, the direction of an experienced workman is neceſſary. In the turning, it is of much importance that the parts of the materials be perfectly divided, which can only be effected by a nice management of the ſhovel: and it is added that much advantage has been found in the goodneſs of the woad, from the drying and ſtoring of it being performed in a careful manner. When this attention is neglected, the woad will not, on being broken between the finger and thumb, draw out into fine hair-like filaments, or, in the technical language of the manufacturer, *beaver* well; as the uſe of this ſubſtance in the blue vat of the dyer, is not merely to afford the colour of the plant, but, by bringing on a very gentle fermentation, excite the indigo in the ſame vat to yield its colouring principle more perfectly. This is even neceſſary for its own colouring-matter being fully imparted. The ſubſtance ſhould, therefore, be ſo prepared in the different operations as to produce this effect in the moſt certain and perfect manner. When the heat in the proceſs of couching has gone too far, the ſubſtance will be what is termed *foxy*; and when it has not proceeded to a ſufficient degree, it will be what is called *heavy*. If the material be good, it does not ſoil the fingers on being rubbed between them; but ſuch as is heavy does. In the concluſion of the proceſs, the cooling is effected in ſo gradual a manner, as to render it not fit for taking on the ſame proceſs; and of courſe proper for being preſerved in caſks, or in any other way. It is then ready for uſe.

The preparation of woad for dyeing, as practiſed in France, is minutely deſcribed by Aſtruc, in his Memoirs for a Natural Hiſtory of Languedoc. The plant puts forth at firſt five or ſix upright leaves, about a foot long, and ſix inches broad: when theſe hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much reſembling the oil or tan-mills, and ground into a ſmooth paſte. If this proceſs was deferred for ſome time, they

they would putrefy, and fend forth an infupportable ftench. The pafte is laid in heaps, preffed clofe and fmooth, and the blackifh cruft, which forms on the outfide, re-united if it happens to crack : if this was neglected, little worms would be produced in the cracks, and the woad would lofe a part of its ftrength. After lying for fifteen days, the heaps are opened, the cruft rubbed and mixed with the infide, and the matter formed into oval balls, which are preffed clofe and folid in wooden moulds. Thefe are dried upon hurdles : in the fun, they turn black on the outfide ; in a clofe place, yellowifh, efpecially if the weather be rainy : the dealers in this commodity prefer the firft, though it is faid the workmen find no inconfiderable difference betwixt the two. The good balls are diftinguifhed by their being weighty, of an agreeable fmell, and when rubbed of a violet colour within. For the ufe of the dyer, thefe balls require a farther preparation : they are beat with wooden mallets, on a brick or ftone floor, into a grofs powder ; which is heaped up in the middle of the room to the height of four feet, a fpace being left for paffing round the fides. The powder, moiftened with water, ferments, grows hot, and throws out a thick fetid fume. It is fhovelled backwards and forwards, and moiftened every day for twelve days ; after which it is ftirred lefs frequently, without watering, and at length made into a heap for the dyer.

The powder thus prepared gives only brownifh tinctures, of different fhades, to water, to rectified fpirit of wine, to volatile alkaline fpirits, and to fixed alkaline lixivia : rubbed on paper, it communicates a green ftain. On diluting the powder with boiling water, and after ftanding fome hours in a clofe veffel, adding about one-twentieth part of its weight of lime newly flacked, digefting in a gentle warmth, and ftirring the whole together every three or four hours, a new fermentation begins, a blue froth arifes to the furface, and the liquor, though it appears itfelf of a reddifh colour, dyes woollen of a green, which, like the green from indigo, changes in the air to a blue. This is one of the niceft proceffes in the art of dyeing, and does not well fucceed in the way of a fmall experiment.

Aftruc propofes the manufacturing of frefh woad leaves in Europe, after the fame manner as the indigo plant is manufactured in America ; and thus preparing from it a blue fecula fimilar to indigo, which from his own experiments he has found to be practicable. Such a management would doubtlefs be accompanied with fome advantages, though poffibly woad fo prepared might lofe thofe qualities which now render it, in a large bufinefs, preferable on fome accounts to indigo, as occafioning greater difpatch when once the vat is ready, and giving out its colour lefs haftily, fo as to be better fitted for dyeing very light fhades. Neumann's Chem. by Lewis, p. 437, &c.

The ancient Gauls and Britons ufed to dye or ftain their bodies with this plant, and were probably led from this application of it to ufe it for dyeing cloth.

Some hold that it was from this plant glafs took its denomination ; though others derive both *glafs* and *glaftum* from the Britifh *glafs*, which to this day denotes a blue colour. See GLASS.

A woad blue is a very deep blue, almoft black ; and is the bafe of fo many forts of colours, that the dyers have a fcale, by which they compofe the divers cafts or degrees of woad, from the brighteft to the deepeft.

WOAD, in *Botany*. (See ISATIS.) There are four fpecies.

The broad-leaved woad is cultivated in feveral parts of England for the purpofes of dyeing, being ufed as a foundation for many of the dark colours.

Some feed down the leaves of woad in winter with fheep ; a practice which Mr. Miller condemns.

Woad grows wild in fome parts of France, and on the coafts of the Baltic fea : the wild woad, and that which is cultivated for the ufe of dyers, appear to be of the fame fpecies.

Befide the plant properly fignified by the name woad, which dyes a blue colour, we have two others known in our Englifh herbals under that name, as alfo that of *wold* or *weld*. Thefe are both called by the common people *dyer's weed*, and are the *luteola* and the *genifta tinctoria*.

The ancients confounded all thefe three plants alfo under the fame names. Paulus Ægineta feems to make them all the fame plant ; and Neophytus, fpeaking of the *ifatis*, or our woad, properly fo called, fays, that it was called by the Latins *lutum*. This *lutum* has been by fome underftood to mean the *luteola*, and by others the *genifta tinctoria* ; but the latter opinion only is right, for it is defcribed to us by the ancients as having leaves like the *linum*, or flax, and flowers like the broom.

WOAD-*Mill* and *Houfe*, that fort of mill and houfe which is neceffary and proper for preparing and fitting this kind of fubftance for the ufe of the dyer. The reprefentation of a mill and excellent apparatus for effecting the preparation of the woad plant, which is made ufe of by Mr. Cartwright, with much fuccefs and advantage, in Lincolnfhire, may be feen in the fecond volume of the "General Dictionary of Agriculture and Hufbandry."

WOAHOO, or OAHOO, in *Geography*, one of the Sandwich iflands ; as far as could be judged from the appearance of the north-eaft and north-weft parts, it is much the fineft ifland of the whole group. Nothing can exceed the verdure of the hills, the variety of wood and lawn, and rich cultivated valleys, which the whole face of the country difplayed. The road is formed by the north and weft extremities. Should the ground-tackling of a fhip be weak, and the wind blow ftrong from the north, to which quarter the road is entirely open, this circumftance might be attended with fome danger ; but with good cables there would be little rifk, as the ground from the anchoring-place, which is oppofite to the valley through which the river runs to the north point, is a fine fand. This ifland is fuppofed to contain 60,000 inhabitants. N. lat. 21° 43′. E. long. of the anchoring-place 202° 9′. See SANDWICH *Iflands*.

WOALDS, in *Agriculture*, a term not unfrequently applied by writers on hufbandry to crops of the woad kind. See WOAD.

WOAPO, in *Geography*, one of the Ingraham iflands in the Pacific ocean. Captain Ingraham called it Adams. It was afterwards vifited by captain Roberts, who named it Jefferfon. S. lat. 9° 27′.

WOBBEL, a town of Weftphalia, in the county of Lippe ; 6 miles E.N.E. of Horn.

WOBURN, or WOOBURN *Weft*, or *Bifhop's Wooburn*, a village in the hundred of Defborough, Buckinghamfhire, England, is fituated in a narrow valley, at the diftance of 3 miles W.S.W. from Beaconsfield, and 26 miles W. by N. from London. The manor of Bifhop's Wooburn had from time immemorial belonged to the fee of Lincoln, till the year 1547, when bifhop Holbeach gave it to the crown in exchange. It was granted in 1549 to John, earl of Bedford. In the 17th century it came by marriage to Philip, lord Wharton, whofe fon and grandfon, the celebrated marquis and duke of Wharton, fucceffively held it. After the death of the latter, it was fold to the Berties ; from whom it was purchafed, in 1784, by Mrs. Dupré, mother

mother of James Dupré, esq. of Wilton-park, who is the present proprietor. The old manor-house was a palace of the bishops of Lincoln, several of whom died here. The marquis and the duke of Wharton are said to have expended incredible sums of money on the house and gardens: of the latter, which in a former age were highly celebrated, scarcely a vestige now remains. The mansion was pulled down in 1750; when one of the wings was fitted up as a dwelling-house, which has since been enlarged and improved, and is now occupied by the countess of Orkney. The parish-church is a spacious and ancient structure, with a nave, two aisles, and a tower. The latter was built about the year 1480, as appears by the epitaph of John Goodwin and Pernell his wife, who are called its founders. In the chancel are several monuments of the families of Bertie and Wharton, among which is one of grey marble to the memory of Philip, lord Wharton, who died in 1695. The font is a curious piece of ancient sculpture. This parish contains 2596 acres, chiefly disposed in arable and wood land. In the population return of the year 1811, the inhabitants were estimated at 1604; the number of houses at 318. An annual fair is held, for which lord Wharton obtained a charter in 1686. A fair was also granted by king Henry VI., but is now discontinued.—Beauties of England and Wales, vol. 1. Buckinghamshire. By J. Britton and E. W. Brayley, 1802. Lysons' Magna Britannia, vol. 1. Buckinghamshire, 1806.

Woburn, or *Old Woburn*, a market-town in the hundred of Manshead, and county of Bedford, England, is situated near the western confines of the county, at the distance of 14 miles S.W. by S. from the county-town, and 42 miles N.W. by N. from London. Great part of the town was consumed by fire in 1724, which, though distressing to individuals, proved ultimately beneficial, as the houses were rebuilt in a more convenient and regular manner, with the addition of several good inns, and a market-house. The whole expence of the new buildings was defrayed by the duke of Bedford. The market-house was finished in 1737, but has been materially improved by the late duke Francis. It consists of two floors; the lower fitted up for butchers' shambles, over which is a spacious room for a corn-market. In the population return of the year 1811, the inhabitants of the parish are stated to be 1506, occupying 299 houses. A weekly market is held on Fridays, which was granted in 1242 to the abbot of Woburn, and four fairs annually. The church was erected by Robert Hobbs, the last abbot of Woburn. This structure furnishes a peculiar instance of capricious taste; the body being completely detached from the tower, which stands at about six yards distance. The tower is a small square building, with large buttresses at the corners, and four pinnacles; the church consists of three aisles and a chancel; the whole has recently undergone a thorough repair. Adjoining to the church-yard is a free-school, founded by Francis, earl of Bedford. Here are also alms-houses for twelve poor persons, founded by the Bedford family, and endowed with 50*l. per annum*, which was confirmed by act of parliament in 1761.

About a mile east of the town is Woburn abbey, the seat of the duke of Bedford. This magnificent mansion is situated in the midst of an extensive park, and occupies the four sides of a quadrangle of more than 200 feet. It was erected about the middle of the last century by Flitcroft, for John, the fourth duke of Bedford, of the Russel family, on the scite of an old abbey. The original building was founded in the year 1145, by Hugh de Bolebec, for monks of the Cistercian order. In 1234 the monastery was so reduced, that the establishment was for a time broken up, and the monks dispersed into different convents till their debts were paid. But by various benefactions their revenues were so much improved, that at the general dissolution they were estimated at 391*l.* 18*s.* 2*d.* clear yearly value. The last abbot was hanged for denying the king's supremacy. The scite of the abbey was granted in 1547 to John, lord Russel, afterwards earl of Bedford, and has ever since been the principal seat of that noble family. There are no remains of the conventual buildings. The present mansion, originally fitted up in a very costly style, has received many considerable improvements, particularly during the time it was in the possession of the late duke. Mr. Holland, the architect of Drury-lane theatre, has displayed much taste and ability in the additional buildings which have been executed under his direction. The west front is built of the Ionic order, with a rusticated basement. The principal floor, or suite of rooms on this side, consist of a saloon, state bed-rooms, drawing and dining-rooms; the south side contains the library, breakfast, Etruscan, and duke's rooms; the east, the vestibule, servants' offices, &c.; and the north, the French bed-rooms, and various other chambers. Most of the apartments are embellished with fine paintings: the gallery, in particular, exhibits a large and valuable collection of portraits by the old masters. The late duke's favourite pursuits are well known to have been experimental agriculture and breeding of cattle. For this purpose he kept several farms in his own hands. The principal of these, distinguished by the name of the Park-farm, is situated in the park, about half a mile from the house. All ingenious contrivances to shorten labour, and facilitate useful operations, are here concentrated. The farm-yard is replete with conveniences. It contains barns, stables, fatting-houses, &c.; a very complete mill, furnished with a curious machine which threshes and dresses at the same time; a maltern; two pair of stones for grinding wheat and barley; and every requisite for dressing flour, making oatmeal, &c. In another part is a small water-wheel, which gives motion to some very ingenious machinery for bruising malt, and cutting chaff. This farm originated with the late duke, through whose patronage and exertions many improvements have been made in the different branches of husbandry. The present duke follows the steps of his brother in patronising agricultural improvements, and keeps up all the establishments which he formed with a view to that purpose.—Beauties of England and Wales, vol. 1. Bedfordshire. By J. Britton and E. W. Brayley, 1801. Lysons' Magna Britannia, vol. 1. Bedfordshire, 1806.

Woburn, a town of the state of Massachusetts, in the county of Middlesex, containing 1277 inhabitants; 15 miles N.W. of Boston.

WOCANELLY, a town of Hindoostan, in Golconda; 40 miles N.W. of Adoni.

WODEN, in *Mythology*. See Odin.

WODERCUM, in *Geography*. See Worcum.

WODNANY, or Wodnian, a town of Bohemia, in the circle of Prachatitz; 12 miles N.E. of Prachatitz. N. lat. 49° 10′. E. long. 14° 2′.

WODWALLA, a town of Sweden, anciently a sea-port, but now much reduced, and its privileges removed to Gotheburg, at eight miles distance.

WOEL, a town of France, in the department of the Meuse; 12 miles N.E. of St. Mihel.

WOELFLIES, a town of Saxony, in the principality of Gotha; 21 miles S.E. of Gotha.

WOERAMATTA, a small island in the East Indian sea. S. lat. 7° 2′. E. long. 131° 36′.

WOERDEN, or Worden, a town of Holland, built by by Godfrey de Rhenen, the twenty-eighth bishop of Utrecht, on the river Rhine, about the year 1160, to keep the citizens of Utrecht in subjection, and maintain his authority. It had a castle, which was formerly supposed to be impregnable; but when the French took the city in 1672, they entirely demolished it, before that time falling to decay. This city had its own particular lords till the year 1296, when Herman de Woerden fortified it, having been convicted of being a party in the murder of Florent V. comte of Holland, who was assassinated by a gentleman named Gerard de Velsen, whose wife he had ravished. It was afterwards sold by Philip II. king of Spain, to Eric, duke of Brunswick; from whom it came, in 1581, under the dominion of the States-General. In 1672, the French having made themselves masters of this place, the Dutch came to besiege it, under the prince of Orange and the comte de Zuylestein. The comte de Marck, who commanded in the city, began to be much pressed, when the duke of Luxemburg arrived with 9000 men. He passed the morass by a way which was supposed to be inaccessible, forced the intrenchments, and put the enemy to flight. The Dutch lost 2000 men, killed and wounded, among the former of whom was the comte of Zuylestein; and the French about 1000; 8 miles W. of Utrecht.

WOGGORA, a small high province of Abyssinia, on the E. of Gondar, which is sown with wheat. This province and Dembea are the granaries of the country.

WOGGT, a river of Austria, which runs into the Ager, near Voglabruck.

WOGLYDURGAM, a town of Hindoostan, in Mysore; 15 miles S. of Oussoor.

WOGOW, a town of Prussia; 18 miles S. of Königsberg.

WOGSHAID, a town of Austria; 7 miles S.W. of Aigen.

WOHLAU, a town of Silesia, and capital of a principality, on all sides surrounded with marshes, which are a kind of natural defence. It has two suburbs, a Roman Catholic and a Lutheran church. In the year 1640, it was taken by the Swedes; in 1642, surprised by the Imperialists, but soon after retaken by the Swedes; and in 1644, recovered by the Imperialists; 20 miles N.W. of Breslau. N. lat. 51° 20′. E. long. 16° 35′.

Wohlau, or *Wolau*, a principality of Silesia, bounded on the north by the principality of Glogau, on the east by Poland and the principality of Oels, on the south by the principalities of Breslaw and Lignitz, and on the west by the principalities of Lignitz and Glogau; situated on both sides of the Oder. The soil is in some parts dry, in others marshy, or overrun with woods and bushes, though several tracts also yield good corn.

WOHRA, a river of Germany, which runs into the Werra, 2 miles N.W. of Echwegen, in the principality of Hesse.

WOHRD, a town of Bavaria, in the territory of Nuremberg, near Nuremberg.

WOINITSCH, a town of Austrian Poland; 36 miles E. of Cracow.

WOITSBACH, a town of Bohemia, in the circle of Boleslaw; 8 miles E. of Krottau.

WOITSBERG. See Voitsberg.

WOKING, a town of England, in the county of Surrey; 8 miles N. of Guildford.

WOKINGHAM, or Oakingham, a market-town and parish in the hundred of Sonning, and county of Berks, England, is situated in Windsor forest $7\frac{1}{2}$ miles E.S.E. from Reading, and $32\frac{1}{4}$ W.S.W. from London. The population in 1811 was 2085 persons, inhabiting 435 houses. The market is held on Tuesday, and the fairs on the 23d of April, 11th of June, 10th of October, and 2d of November. The town, incorporated by James I., is governed by an alderman, high steward, recorder, burgesses, and a town-clerk; and at this place are held all the courts for Windsor forest. Although within the bounds of Berkshire, the church stands in an insulated part of Wiltshire: it is a large and handsome edifice. The inhabitants are chiefly employed in agriculture, throwing silk, sorting wool, and making shoes: the gauze manufacture was some years ago introduced. At Luckelygreen, near this town, is an hospital, founded in 1665 by Henry Lucas, esq. for sixteen poor men and a master: the trustees of the charity are the Drapers' company of London. About four miles S.E. from Wokingham, is a large and irregular fortification, with a double ditch, commonly called Cæsar's camp, situated on the summit of a hill. Half a mile to the southward of this camp is the Devil's ditch, a raised road nearly ninety feet wide, running east and west, with a trench on each side. In 1661 George Staverton gave the rent of a house in this place for the purpose of buying a bull, to be baited and killed at Christmas, for the benefit of the poor of Wokingham; but this being thought insufficient, the inhabitants are in the habit of purchasing another beast for the same purpose. Archbishop Laud gave a portion of certain fee-farm rents, which produces about 40*l. per annum*, to the parish. Every third year it is divided, pursuant to the donor's intention, between three poor maidens of the age of eighteen, natives of the town, and members of the church of England, who have served the same master or mistress for three years together: the other years it is appropriated to the apprenticing of poor boys. Dr. Thomas Godwin, bishop of Bath and Wells, was a native of this town, where he was born in 1517.

About four miles S. from Wokingham is Billingbear, one of the seats of lord Braybrooke. The house is a large irregular building, seated in a fine park. A particular history and description of this place is given, with a view, in Havell's Views of Seats, folio, 1816.—Beauties of England and Wales, Berkshire; by J. Britton and E. W. Brayley, London, 8vo. 1802. Magna Britannia, by S. and the Rev. D. Lysons, vol. 1. 4to. 1806.

WOKSCHITZ, a town of Bohemia, in the circle of Konigingratz; 2 miles W. of Gitschin.

WOLBECK, or Waldbeck, a town of Germany, in the bishopric of Munster; 7 miles S.S.E. of Munster. N. lat. 51° 53′. E. long. 7° 52′.

WOLBORZ, a town of the duchy of Warsaw; 41 miles S. of Siradia.

WOLCHRADITZ, a town of Moravia, in the circle of Brunn; 18 miles S.S.E. of Brunn.

WOLCKENSTEIN, a town of the duchy of Stiria; 6 miles W.N.W. of Rottenmann.

WOLCKERSDORF, a town of Germany, in the margravate of Anspach; 2 miles N. of Schwabach.—Also, a town of Austria, on the Rusbach; 8 miles E.N.E. of Korn Neuburg.

WOLCKERSHAUSEN, a town of the duchy of Wurzburg; 6 miles N. of Schweinfurt.—Also, a town of the county of Henneberg; 3 miles N. of Menungen.

WOLCOTT. See Woolcott.

Wolcott, a town of Connecticut, in the county of New Haven, near Fairfield, with 952 inhabitants.

WOLD, signifies a plain, down, or open champaign ground, hilly, and void of wood.

Hence the names Stow in the Wold, and Cotswold, in Gloucester-

Gloucestershire; whence also that part of Leicestershire, which lies northward beyond the Wrekin, is called the Wold of Leicestershire.

Wold, or *Weld*, among *Dyers*. See Weld.

WOLDEGGE, or Woldeck, in *Geography*, a town of the duchy of Mecklenburg; 13 miles S.E. of New Brandenburg.

WOLDENBERG, a town of the New Mark of Brandenburg; 9 miles N.E. of Friedburg. N. lat. 53°. E. long. 15° 45'.

WOLEIN. See Mirzin.

WOLESCHITZ, a town of Bohemia, in the circle of Kaurzim; 4 miles W.S.W. of Kaurzim.

WOLF, Christian, in *Biography*, an eminent mathematician and philosopher, was born at Breslau in 1679, and well educated under able masters in different branches of literature and science. At the age of 21, he was entered at the university of Jena, which was then in high reputation; and quitting Jena in 1702, he prosecuted his studies at Leipsic, where, in the following year, he took his degree of master of arts, publishing on the occasion a dissertation, intitled "Philosophia practica Universalis Mathematico modo conscripta." In 1704 he published another dissertation, on the differential and infinitesimal calculus. Having studied theology as well as philosophy at Leipsic, he officiated as a preacher; and being invited to undertake the office of pastor in a country village, he was advised by Leibnitz to decline it, and to pursue the study of philosophy. As he commenced his literary career with great reputation, he was proposed to be an associate in the periodical work, intitled "Acta Eruditorum;" and in this connection he continued for many years, employing his leisure hours in teaching mathematics, logic, and natural philosophy. When the Swedes made an incursion into Saxony in the year 1706, he quitted Leipsic, and removed to Berlin; where a recommendatory letter of Leibnitz procured for him from Frederic I. the office of professor of mathematics at Halle. In 1709 he published, in Latin, his treatise on "Aerometry;" and in the following year his "Elements of Mathematics," in 4 vols. which have passed through several editions. Having composed a very ingenious essay on the intense cold of the ensuing winter, he was elected a member of the Royal Society of London, and soon after a member of the Academy of Sciences at Berlin. In 1711 he published his tables of sines and tangents, and in the next year his treatise on logic, in German, highly commended by Formey, and translated into Latin, French, and other languages. The first two volumes of his large work on the mathematics appeared in 1713, and these were afterwards followed by three more. By the advice of his friend Leibnitz, he refused an invitation from Peter the Great to remove from Halle to Petersburgh. On the death of Leibnitz in 1726, Wolf drew up his life, which supplied Fontenelle with materials for his eloge. In 1718 he published "Meditations on God, the World, and the Human Soul," which were reprinted in the following year. About this time the reputation of Wolf and the jealousy of his rivals occasioned a literary contest, which lasted for a considerable time, and which was not very honourable to either party. Wolf having delivered a dissertation on his quitting the pro-rectorate of Halle university in 1721, on which he took occasion to compare his own principles with those of Confucius and the Chinese, and having announced the opinion which he entertained on the doctrine of necessity, an outcry was raised against him, and he was represented by his enemies as a man whose principles tended to atheism, and to corrupt the morals of the people. Notwithstanding this malignant attack, he employed himself in publishing three volumes of experimental philosophy, and a volume of dogmatical philosophy, which he dedicated to the emperor of Russia, and which the emperor caused to be translated into the Russian language, repeating to him the offers which had before been made, in order to induce him to remove to Petersburgh. The contest that had been excited against him still continued; and though he attempted to justify himself in a treatise on the subject of fatality, the king was at length persuaded that his principles were dangerous, and ordered him, in November 1723, to quit his territories in two days, under pain of death. Wolf immediately proceeded to Cassel, where he met with the king of Sweden, who appointed him professor of mathematics at Marpurg, an office which he had refused sixteen years before. The clergy of Halle pursued him with their enmity and opposition to Marpurg; but Wolf was suffered to remain in the quiet enjoyment of his office during his residence at that place. Several students who attended him at Halle followed him hither, and his lectures, which he commenced in 1724, were attended by pupils from all parts of Europe. His mind being now undisturbed, he resumed his literary labours, and published his "Remarks on Metaphysics," in which he answered the principal objections against his doctrine, and gained a decided victory over his enemies. The grounds of the censure that had been passed on Wolf had been every where canvassed; and almost every German university was inflamed with disputes on the subject of liberty and necessity, so that the names of Wolfian and anti-Wolfian were every where heard. Wolf, having thus vindicated his philosophy from reproach, received new invitations from Petersburgh and Leipsic; but gratitude to his protector induced him to remain in his situation at Marpurg, which he found to be very agreeable, and to afford him leisure for pursuing his speculations. After an interval of nine years, the current of public opinion turned in favour of Wolf, and he now received numerous tokens of respect from men of rank and learning; and in 1733 he was invited to fill, in the Academy of Sciences, one of the eight places allotted to foreigners distinguished in the highest branches of science. On this occasion, Reaumur and he commenced an intimate friendship, which lasted till the time of his death. The king of Prussia was convinced of Wolf's innocence, reversed his sentence of exile, and wished to repair the injury which he had sustained. He made tempting offers, both of title and money, to induce him to return to Halle; but he declined the acceptance of them; as he also refused an invitation from George I. of England to accept a place in the new academy which he had founded at Gottingen. The clergy of Halle made some other attempts to reproach and ruin him, but they recoiled on his adversaries. In the year 1740, he prefixed to the first volume of his "Droit Naturel, or Treatise on the Law of Nature," a dedication to the hereditary prince of Prussia, afterwards Frederick the Great, which was acknowledged by a very flattering letter.

Frederick the Great, as soon as he ascended the throne, recalled Wolf to Halle; and with the permission of the king of Sweden, he consented to accept the office of professor of the law of nature and nations, and also of mathematics, with a salary of 2000 crowns, and liberty to teach whatever he thought proper. He obtained also the rank of privy-counsellor, and was made first vice-chancellor, and afterwards chancellor of the university. In 1745 he was created a baron by the elector of Bavaria. Wolf was now at the height of his prosperity. At more than 60 years of age he resumed his labours, and completed his work on the law of nature and nations, which was written in Latin, and extended to eight volumes 4to. He alfo wrote prefaces to the works of others, and particularly one to Suffmilch's work on population. Notwithftanding his great celebrity, perhaps on this account, he had many and powerful enemies. Leibnitz, Maupertuis, and Voltaire, were of this number: and with refpect to the latter, we may obferve, that both in his writings and in his converfation with the king, he contributed in no fmall degree to leffen the veneration which Frederick II. entertained for him. In 1752 he was made a member of the Inftitute at Bologna; but he did not long furvive this honour, as he died in the month of April 1754, in the 76th year of his age. He left one fon, who inherited a confiderable eftate which he had purchafed.

The adverfaries of Wolf attacked not only the principles of his philofophy, but his method and his ftyle. His Latin, it muft be acknowledged, was not elegant; but his German has been commended and imitated; and he is faid to have improved his native tongue both in precifion and energy. With regard to his general difpofition and demeanour, he is faid to have united a great degree of complaifance and affability, with irreproachable morals and exceffive vanity, which he was not able to conceal. He did not hefitate to extol himfelf and his own merits publicly and without referve, and even to exhibit them in emblematical devices on the titles of his books. Brucker fums up the character of Wolf as a writer in the following concife manner: — "He poffeffed a clear and methodical underftanding, which by long exercife in mathematical inveftigations was particularly fitted for the employment of digefting the feveral branches of knowledge into regular fyftems; and his fertile powers of invention enabled him to enrich almoft every field of fcience in which he laboured, with fome new addition. The lucid order which appears in all his writings enables his reader to follow his conceptions with eafe and certainty through the longeft train of reafoning. But the clofe connection of the feveral parts of his works, together with the vaft variety and extent of the fubjects on which he treats, renders it impracticable to give a fummary of his doctrines." Brucker's Philofophy by Enfield, vol. ii. Preface to M. de Vattel's Law of Nations. See Leibnitzian *Philofophy*.

Wolf, Jerome, a German philofopher, was born in the county of Oettingen, in the year 1516, and inftructed in the elementary parts of education at a college eftablifhed by the fenate of Nuremberg. But his ftudies were interrupted by an appointment in the fervice of Julius, the chancellor of count Von Oettingen. This interruption, however, contributed to allay the feverity of his countenance and manner, and to meliorate the morofenefs of his temper; whilft thefe unamiable qualities were amply counterbalanced by probity, diligence, and modefty, which engaged the confidence and efteem of his employer. His habitual difpofition again returned, and he refumed the ftudy of poetry, and of the ancient Greek writers, againft the remonftrances of the chancellor, who recommended attention to jurifprudence and public bufinefs, as the moft effectual means of acquiring both honour and competence. Remonftrances were ineffectual, and he perfifted in purfuing a courfe which cherifhed his morbid melancholy and difquieting irritability. Still devoted to his literary purfuits, he was fortunate in gaining the patronage of John James Fugger; and in being afterwards advanced to the poft of the director of the college of Augfburg, and that of librarian to this inftitution. In this fituation he remained till his death, which happened in the month of October 1580. Wolf was particularly diftinguifhed as a laborious tranflator, in which literary department he gained the commendation of Huet; though Henry Stephen cenfures his performances. When the edition of the Annals of Zonaras, publifhed by Wolf at Bafle in 1557, became rare, a new one, with notes by Du Cange, was printed at the Louvre in Paris in 1687. Wolf's tranflation of Demofthenes was firft printed at Bafle by Oporinus; and being much approved, it paffed through two other editions. After being revifed by the tranflator, Epifcopius printed it at Bafle in 1572, with the orations of Æfchines, the commentaries of Ulpius, and the notes of Wolfius. His other works, which were numerous, almoft wholly related to Greek and Latin authors. Eloges par Formey et Teiffier.

Wolf, John Christopher, a German Lutheran divine and eminent fcholar, was born in 1613, at Wernigeroda, and removing in 1695 to Hamburgh, was educated under the protection of the celebrated Fabricius, by whom he was employed, under the age of 20 years, in making a catalogue of all the writers quoted in Euftathius's Commentary on Homer, afterwards inferted by Fabricius in his "Bibliotheca Græca." Having profecuted his ftudies at Wittenberg, and graduated mafter of arts, he became, in 1706, adjunct of the philofophical faculty. Upon his return to Hamburgh, he undertook a tour in 1708 through Holland to England, and for fome time refided at Oxford for the ufe of the Bodleian library. His next migration to Denmark led, in 1710, to the appointment of extraordinary profeffor of philofophy at Wittenberg, where his lectures collected a great number of pupils. Although he was here advanced to the chair of theology, he removed in 1712 to Hamburgh, and was appointed profeffor of the oriental languages in the Gymnafium, and in 1715 promoted to be rector of that inftitution. He was likewife a preacher-extraordinary at the cathedral, and became paftor of the church of St. Catharine; and foon after a member of the Academy of Sciences at Berlin. He commenced his literary contributions to the "Acta Eruditorum" in 1708; and he collected from various repofitories an aftonifhing number of rabbinical and oriental books and MSS.; which library he bequeathed to the library at Hamburgh, where he died in June 1739. Of his numerous works, we fhall here enumerate his "Bibliotheca Hebræa," in 4 vols. fol.; "Hiftoria Lexicorum Hebraicorum;" "Primitiæ Flemburgenfes, five Oratio de Præcocibus eruditis, et Orationes binæ de Neceffitate et Utilitate declamandi;" "Hiftoria Bomogilorum;" "Differtatio de Atheifmi falfo fufpectis;" "Curæ philologicæ et criticæ in Novum Teftamentum," 4 vols. 4to. He was alfo the editor of feveral learned works. Gen. Biog.

Wolf. There are biographical articles for five German muficians of that name in Gerber's Continuation of Walther's Mufical Lexicon.

Firft, *Michael Chriftian Wolf*, organift and mufic director in St. Mary's church at Stettin, born 1709, and who died in 1789, after publifhing the following works: "Six Duets for two German Flutes at Berlin;" "Six Harpfichord Sonatas," Stettin, 1776; "Songs with a Harpfichord or Harp Accompaniment," Ebend, 1777; "Exercifes for the Organ in Choral Mufic;" and having in MS. a Pfalm for Four Voices, with an Accompaniment for the Organ, and many other pieces for the church and chamber.

II. *Ernft Friederic Wolf*, brother to the preceding mafter, ftate organift at Cologne, who died in 1772. He had been two years under the chapel-mafter Stölzd, for compofition; and under the concert-mafter Hühn, at Gotha, for the violin. But at nine years old he had previoufly ftudied the fcores of great mafters, and the Gradus ad Parnaffum

 of

of Fouche, fo that early in life he became a great extempore player on the organ.

Of thefe two brothers we have never heard or feen the productions; but of

Ernft William Wolf, born at a village near Gotha, in 1735, chapel-mafter at Weimer, we have feen and admired many of the works.

Wolf, in *Aftronomy*. See Lupus.

Wolf, *Lupus*, in *Zoology*, the *canis lupus* of Linnæus, a beaft of prey of the dog kind, with the tail bending inwards, rather long and bufhy, and the largeft and fierceft of that race of animals. It is extremely like the domeftic dog in fhape, and if the head, which is long, with a pointed nofe, did not differ a little in figure, the upper part of the face being broader, one would be apt to declare it the very fame animal. It is diftinguifhed alfo by fuperior fize, ftronger limbs, and more mufcular body. It has a very fierce look about the face; its eyes are more obliquely placed than thofe of the dog, and are more glaring and favage; its jaws are much ftronger; and its teeth, which are large and fharp, and the opening of its mouth, which is fhorter in proportion than that of the dog, fierce and frightful. The ancients had an opinion, that the neck of the wolf was all of one folid bone; but, on the contrary, this creature is able to turn and twift it about better than the dog kind.

The wolf, as well as all the other beafts of prey, can endure hunger a long time, though very voracious when it meets with food. The wolf differs from the dog in his note, for inftead of the barking of the dog this creature only howls; his ears, which ftand erect, and his tail, make him alfo greatly refemble the fox.

The hair of the wolf is long; the legs are long; the head and neck cinereous: and the body generally pale grey, tinged with yellow; fometimes found white; in Canada fometimes black; and taller than a large grey-hound.

The wolf inhabits the continents of Europe, Afia, Africa, and America.

How numerous thefe animals were formerly in Britain we may infer from the laws of king Edgar, who attempted to extirpate them by commuting the punifhments for certain crimes into the acceptance of a number of wolves' tongues from each criminal; in Wales by converting the tax of gold and filver into an annual tribute of three hundred wolves' heads. In fucceeding times their deftruction was promoted by certain rewards; and fome lands were held on condition of deftroying the wolves which infefted thofe parts of the kingdom.

In 1281, thefe animals infefted feveral of the Englifh counties; but after that period, our records make no mention of them. The laft wolf known in Scotland was killed in 1680, and in Ireland one was killed in 1710.

The wolves of North America are the fmalleft; and it is faid, that from thofe proceeded the dogs which were found there by the Europeans on their firft arrival: when reclaimed, they are the dogs of the natives. In the lefs inhabited parts of the country, they gather in large droves, and hunt the deer and other animals like hounds with hideous howlings, and it is affirmed that they will attack even the buffalo. In the inhabited parts, they are become rare. In fome parts of Europe their number has fomewhat increafed; *e. g.* in Sweden they were rare till about the year 1720. The Swedes deftroy them by ftuffing the carcafe of a fheep or other animal with a fpecies of lichen or tree-mofs, (lichen vulpinus,) which is confidered as a certain poifon to the wolf, and alfo, as the name imports, to the fox. This is faid to be mixed with pounded glafs, which is probably more deftructive than the lichen. The wolves of Senegal are the largeft and fierceft; and they prey in company with the lion. Thofe of the Cape are grey ftriped black; others are black.

Wolves are cruel, but cowardly animals; they fly from man, except when impelled by hunger; in which cafe, they prowl by night in great droves through villages, and deftroy any perfons they meet; and having once got the tafte of human blood, give it the preference. In hard weather wolves affemble in large troops, and join in dreadful howlings. They have a fine fcent, and hunt by the nofe: between them and the dogs a mutual enmity fubfifts. This animal has a very ftrong carnivorous appetite; and yet crafty, ftrong, and nimble as he is, and in every refpect capable of feizing his prey, he often dies of hunger. Being driven into the foreft, he finds only a few fpecies of wild animals, who fave themfelves by flight, fo that he perifhes with want. Although he is naturally timid and daftardly, he braves danger, when preffed with famine, and attacks thofe animals that are under the protection of man, and carries away lambs, fmall dogs, and kids, returning often to the charge, until being wounded by his purfuers, he retires to his den in the day, but iffues forth in the night to his ferocious and deftructive ravages. When his hunger is extreme, he attacks women and children, and fometimes darts with favage violence upon men, till at length he falls a facrifice to his own rage. We have occafional accounts of the terror which this animal has excited, and of the deftruction which he has committed among women and children in France. To fuch a degree did his ravages excite terror in 1764, that prayers are faid to have been offered for his deftruction.

Wolves, in the northern parts of the world, fometimes get on the ice of the fea, in order to prey on young feals, which they feize when afleep; but fometimes the ice detached from the fhore carries them to a great diftance from the land, and large diftricts have thus been cleared of thofe pernicious animals, which have been heard howling in a dreadful manner far in the fea.

The wolf is fometimes affected with madnefs, accompanied with fymptoms fimilar to that of dogs; and this difeafe happens to them in the depth of winter, and therefore, as Mr. Pennant obferves, cannot be attributed to the rage of the dog-days. The time of geftation in the wolf is, according to Buffon, about three months and a half; and the young whelps are found from the end of April to the beginning of July; and this difference in the time of geftation, being in the wolf about one hundred days, and in the dog only fixty, he confiders as a proof of the real difference between the two fpecies.

Although the wolf feems to be naturally favage, he is capable, when taken young, of being tamed, and of being wholly divefted of the ferocious character of his fpecies. Ray. Pennant. Shaw.

Wolf, *Golden*. See Jackall and Aureus.

Wolf, *Marine*. See Hyæna.

Wolf, *Mexican*, *Canis Mexicanus*, with deflected tail and afh-coloured body, variegated with dufky bands and fulvous fpots, a fpecies that inhabits the hot parts of Mexico, agreeing in its manners with the European wolf. Its head, jaws, and teeth, are large; in the upper lips are ftrong briftles bent backwards, of a grey and white colour; the ears are large, erect, and cinereous, and the fpace between them marked with broad tawny fpots; the head afh-coloured, croffed with dufky ftripes; the neck fat and thick, and marked with a tawny ftroke; on the breaft is another of the fame kind; the body is afh-coloured fpotted with black, and the fides ftriped with the fame colour; the belly

belly cinereous, the tail long, of the ſame colour, tinged in the middle with tawny; the legs and feet ſtriped with black and aſh-colour. This wolf is ſometimes found white. Pennant.

Wolf, *Black*, *Canis Lycaon*, with ſtraight tail, is conſidered by Buffon and others as a variety of the common wolf, and confounded by Schreber and Gmelin with the black fox; but regarded as a diſtinct ſpecies. It is found both in Europe and America, and in ſome parts of Aſia. In America it is chiefly found in Canada, and in Europe in the more northern regions. Shaw.

Wolf, in the *Hiſtory of Inſects*, the name of a ſmall white worm or maggot, which infeſts granaries, and does very great damage there.

It is in this ſtate of the worm that it does the miſchief; but this is not its perfect form, for it is afterwards tranſformed into a ſmall moth, with white wings ſpotted with black.

This little maggot has ſix legs, and as it creeps along, there iſſues from its mouth an extremely fine thread or web, by which it faſtens itſelf to every thing it touches, ſo that it cannot fall. Its mouth is furniſhed with a pair of reddiſh forceps, or biting inſtruments, by means of which it gnaws its way not only into wheat and other grain, but perforates even beams of wood, boxes, books, and every thing it meets with.

Towards the end of ſummer theſe pernicious inſects may be ſeen crawling up the walls of corn-chambers, infeſted with them in great numbers; they are then ſearching a proper place where they may abide in ſafety during their aurelia ſtate; for when the time of their undergoing this change approaches, they forſake their food, and the little cells they had formed of hollowed grains of corn clotted together, by means of the web coming from their mouths. They now wander about till they find ſome wood, or other ſubſtance into which they gnaw holes with their fangs, capable of concealing them; and there enveloping themſelves in a covering of their own ſpinning, they ſoon become a dark-coloured ſort of aurelia. They remain in this ſtate all the winter; but in April or May they come forth in their moth-ſhape, and are then ſeen in vaſt numbers, taking ſhort flights, and creeping up the walls. In this ſtate they eat nothing; but they ſoon copulate and lay eggs, which are in the ſhape of a hen's egg, but no larger than a grain of ſand. Each female lays ſixty or ſeventy eggs, which ſhe depoſits in the little wrinkles of the grains of corn, where in about ſixteen days they hatch, and the minute maggots immediately perforate the grain, and eat out all its ſubſtance, and with the threads which come from their mouths cement other grains to it, which they, in the ſame manner, ſcoop out and deſtroy.

The watchful obſerver has two opportunities of deſtroying theſe devourers from among his corn. One is, when they forſake their food, and aſcend the walls, which they will ſometimes almoſt cover. The other, when they appear in the moth-ſtate. At both theſe times they may be cruſhed to death againſt the walls in great numbers, by clapping ſacks upon them; but they may be exterminated more effectually by cloſing up all the windows and doors, and burning brimſtone on a pan of charcoal, letting the room be full of the fumes of it for twenty-four hours. This certainly deſtroys the animals, and does no ſort of injury to the grain, not communicating the ſlighteſt ſcent to it. Baker's Microſ. p. 222.

Wolf's *Bane*, in *Botany*. See Aconitum.

Wolf's *Bane*, *Winter's*, a ſpecies of *hellebore*; which ſee.

Wolf-*Fiſh*. See Lupus *Marinus*.

Wolf's *Grapes*. See Lycostaphylæ.

Wolf-*Net*, a term uſed by the ſportſmen for a kind of net uſed in fiſhing, which takes great numbers, and has its name from the deſtruction it cauſes.

It is uſed both in rivers and ponds, and is of the nature of the rattle, excepting only the wanting of the four wings. The trunk or coffer conſiſts of ſeven feet, beſides the two gullets. It is ſupported by hoops, and is to be placed in ſome part where there is an abundance of ſedges, ruſhes, and water-graſs. There is to be a place made for the net here, by the uſe of a paring-knife, cutting away all the weeds and other matter, for the ſpace that will contain it; and when the net is placed, there are to be two alleys cut or cleared in the ſame manner, one on each ſide of the net, that the fiſh may be invited into them, and by them into the net. There muſt be ſome ſtones or leaden weights uſed to ſink the net, and a long pole faſtened to the upper part of the mouth of it, by means of which, when it is well filled with fiſh, it may be lifted up and taken to the ſhore.

Wolf's *Peach*. See Lycopersicon.

Wolf, *War*, an ancient military machine, differently deſcribed by different writers. Procopius makes it a kind of portcullis, or rather a harrow for defending a gate. Matthew of Weſtminſter, and Camden, deſcribe it as a machine for throwing ſtones. "At the gates," ſays Procopius, (Hiſt. of the Gothic Wars, book i.) "they ſet up wolves in the following manner:—They erected two beams from the ground reaching to the battlements, and laid chequerwiſe pieces of wrought timber, ſome upright and ſome croſs; they jointed them ſo that the mortiſing holes met one another; and before each joint ſtuck out a pointed piece of wood, like a thick ſpar, and faſtening the croſs timbers to another beam, which from the top reached half-way down: they laid the beams flat along upon the gates, and when an enemy approached, men above laid hold of the higher ends of the beams, and thruſt them down, which falling ſuddenly among the aſſailants, with the wooden points ſticking out, killed all upon whom they deſcended." Probably there was a chain or cord to draw back the machine after it had produced its effect.

The war-wolf, for throwing ſtones, is deſcribed by Matthew of Weſtminſter, ann. 1304; by Camden, in his Remains, to which we refer; and alſo to Groſe's Mil. Antiq. vol. i. p. 383.

Wolf *Iſland*, in *Geography*, an iſland in the North Atlantic ocean, near the eaſt coaſt of Labrador. N. lat. 53° 55′. W. long. 55° 40′.—Alſo, an iſland at the north-eaſt end of lake Ontario. N. lat. 44°. W. long. 76° 50′.—Alſo, an iſland in the gulf of St. Lawrence, near the ſouth coaſt of Labrador. N. lat. 50° 2′. W. long. 60° 55′.—Alſo, a ſmall iſland in the Atlantic, near the coaſt of Georgia. N. lat. 31° 19′. W. long. 81° 30′.

Wolf *River*, or *Chickſaw Bluff*, a river of Georgia, which runs into the Miſſiſſippi, N. lat. 34° 45′. W. long. 90° 42′.

Wolf *Rock*, a very low, flat, rocky iſlet, in the North Pacific ocean, ſurrounded by rocks and breakers, which extend ſome diſtance from it; 10 miles from the ſouthern coaſt of the Prince of Wales's Archipelago. N. lat. 55° 1′. E. long. 226° 42′.—Alſo, a rock near the eaſt coaſt of Labrador, and not far from the iſland called Wolf iſland.—Alſo, a rock at the entrance of the Engliſh channel; 10 miles S. of Land's-End. N. lat. 49° 58′. W. long. 5° 45′.

WOLFBOROUGH, a townſhip of New Hampſhire,

ſhire, in the county of Strafford, on the Winnipiſcogee lake, containing 1376 inhabitants; 35 miles N.N.W. of Durham.

WOLFDORF, a town of Bohemia, in the circle of Leitmeritz; 7 miles N. of Kamnitz.

WOLFENBUTTEL, a principality which lately conſtituted a part of the duchy of Brunſwick, divided into two parts by the principality of Halberſtadt, and the dioceſe of Hildeſheim. The north part is ſurrounded on the north by the principality of Luneburg and the marquiſate of Brandenburg, on the eaſt by the duchy of Magdeburg, on the ſouth by the principality of Halberſtadt, and on the weſt by the dioceſe of Hildeſheim. The ſouth part is bounded on the north by the biſhopric of Hildeſheim and the principality of Calenberg, on the eaſt by the dioceſe of Hildeſheim and the Harz foreſt, on the ſouth by the principality of Grubenhagen and Calenberg, and on the weſt by the territories of the abbey of Corvey and Calenberg. The eaſtern half contains under it a part of the Harz foreſt, the mines and ſalt-works which the prince held in common with the elector of Brunſwick Luneburg. In the weſtern half of this ſouthern part is a part of the foreſt of Sollinger, conſiſting of oak and beech, with a chain of mountains covered with woods. Thus the ſouthern part of the principality conſiſts chiefly of hills and woods, with little arable land; but, on the other hand, has a great plenty of timber, iron, and glaſs-houſes, the manufactures of which are greatly admired, particularly thoſe of looking-glaſſes, with a fine porcelain manufacture, and the very rich mines and ſalt-works in the Harz foreſt. The north part of the principality is more level, and produces abundance of grain, flax, and hemp, together with various kinds of pulſe and fruit. Their graziery here turns to very good account, beſides which it has a ſalt-work. The culture of ſilk is now followed, and premiums are aſſigned by the prince for the encouragement of it. The Weſer, the Leine, the Inner See, and the Ocker, are the principal rivers. In this principality are 18 towns, 386 villages, and 17 fees and convents. The eſtabliſhed religion here is Lutheraniſm. The country of Brunſwick was anciently under lords of its own, who poſſeſſed it as their abſolute and hereditary property, and derived their lineage from Ludolphus, duke of Saxony; and, conſequently, by his grandmother Haſala, or Giſela, from duke Witikind, whoſe daughter ſhe was. From king Henry I., grandſon to Ludolphus, was deſcended his ſon Henry, duke of Bavaria, among whoſe iſſue was count Bruno, on whom the emperor Otho conferred a tract of land in Saxony, near Brunſwick, namely, Melverode and Hohenwart. Count Bruno, his ſon, enlarged Brunſwick; and his ſon, count Ludolphus, on the demiſe of the emperor Henry II., was the firſt that obtained the full ſovereignty over Brunſwick and Tanwarderode, and died in 1038. His ſon Egbert I. became margrave of Thuringia and Miſnia; and his ſon Egbert II. likewiſe attained to thoſe dignities. This laſt prince being killed in battle, in 1091, his ſiſter Gertrude ſucceeded to the country of Brunſwick, which country ſhe brought to her ſecond huſband, Henry the Fat, count of Nordheim; and by their daughter Ricienza it came to her huſband Lothario, count of Supplinburg, afterwards emperor. By his daughter Gertrude it deſcended to her huſband, Henry the Magnanimous, duke of Bavaria and Saxony, and thus to the houſe of Welpho. The principality of Wolfenbuttel was poſſeſſed of a vote among the princes, both in the college of the princes of the empire, and likewiſe in the diet of Lower Saxony; in each of which, by virtue of an agreement concluded in 1706, when the ſeniority lies in the houſe of Brunſwick Wolfenbuttel, it precedes thoſe of the elector of Brunſwick and Luneburg, for Zelle, Grubenhagen, and Calenberg, but otherwiſe comes after them; farther, the houſe of Wolfenbuttel, when ſenior, obtained the joint direction of the circle of Lower Saxony. In 1807, this principality was annexed to Weſtphalia.

WOLFENBUTTEL, a city of Weſtphalia, and capital of a principality of the ſame name, ſituated in a low marſhy ſoil, on the Ocker: it is well built and fortified. In it is a château, a long time the reſidence of the dukes, in which is a noble library containing 120,000 volumes of printed books and manuſcripts. The principal church contains the ſepulchral monument of the dukes. Wolfenbuttel very probably owes its name to the firſt builder of the palace, called Wolf, or Wolfer, or Wolfhard; 24 miles E. of Hildeſheim. N. lat. 52° 10′. E. long. 10° 40′.

WOLFERSDORF, a town of Saxony, in the circle of Neuſtadt; 4 miles S.W. of Weyda.—Alſo, a town of Saxony, in the circle of Neuſtadt; 6 miles E.N.E. of Weyda.

WOLFERSDYCK, a ſmall iſland of Zealand, between North and South Beveland.

WOLFERSHEIM, a town of Germany, in the principality of Solms Braunfels; 12 miles S.S.E. of Wetzlar.

WOLFERSTORFF, a town of Auſtria; 2 miles S.E. of Laab.

WOLFERZHAUSEN, a town of Bavaria; 12 miles N.E. of Weilhaim.

WOLFESHEAD, or WULVERSHEAD, Saxon, *wulferheafod*, compounded of *wulf*, *wolf*, and *heafod*, *head*, *caput lupinum*, denoted the condition of thoſe outlawed for criminal matters in the Saxon time, and not yielding themſelves to juſtice. For if they could have been taken alive, they muſt have been brought to the king; and if they, for fear of being apprehended, did defend themſelves, they might be ſlain, and their heads brought to the king; for their head was no more to be accounted of than a wolf's head. LL. Edw. in Lamb. fol. 127. and Bract. lib. iii. tract. 2. c. 11. See CAPUT *Lupinum*, and OUTLAWRY.

WOLFESTAAL, in *Geography*, a town of Auſtria; 2 miles E. of Hainburg.

WOLFFACH, a town of Germany, in the lordſhip of Furſtenberg; 4 miles S.S.E. of Hazlach. N. lat. 48° 13′. E. long. 8° 16′.

WOLFFEG, a town of Auſtria; 5 miles N.W. of Schwanaſtadt.

WOLFFEGG, or WOLFECK, a château and village of Germany, which gives the title of count to a noble family, divided into ſeveral branches, *viz.* Wolffegg Zeil, Wolffegg Zeil Wurzach, Wolffegg Wolffegg, and Wolffegg Waldſee; 10 miles W. of Leutkirch.

WOLFFEN, a town of Saxony; 3 miles N.W. of Bitterfeld.

WOLFFPASSING, a town of Auſtria; 9 miles S. of Ips.

WOLFFSHAGEN, a town of Brandenburg, in the Mark of Pregnitz; 6 miles W. of Pritzwalk.

WOLFGANG, a town of Germany, in the county of Henneberg, on an iſland in a lake; 7 miles S.W. of Meinungen.

WOLFGANG, *St.* a town of Auſtria; 3 miles S.S.W. of Aigen.—Alſo, a town of Auſtria; 1 mile N. of Kirſchſchlag.—Alſo, a town of Auſtria, on a lake, called the Abernſea, and St. Wolfgang's lake; 54 miles S.S.W. of Lintz.

Lintz. — Alfo, a town of Switzerland, in the canton of Zug; 4 miles W. of Zug.

WOLFGAST, or WOLGAST, a town of Anterior Pomerania, on the Pena, about three miles from the Baltic, with about 3500 inhabitants. It was anciently a confiderable fortrefs, and refidence of the dukes; 30 miles S.E. of Stralfund. N. lat. 54° 2'. E. long. 13° 45'.

WOLFIA, in *Botany*, a genus of Schreber's, feems by its orthography intended to commemorate Dr. de Wolf, of Dantzic, of whofe whimfical attempt in the NOMENCLATURE of plants, we have given a fufficient account at the conclufion of that article. This writer, to whom the praife of labour and originality cannot be denied, and whofe index, entitled *Concordantia Botanica*, is truly valuable, died in 1784, aged 60. There have been feveral German naturalifts and phyficians of the name of Wolf, but none eminent in botanical ftudies.—Schreb. Gen. 801.—Clafs and order, *Octandria Monogynia*. Nat. Ord. *Trihilatæ*, Linn. *Sapindi*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coloured: tube very fhort, fomewhat dilated at the bafe, permanent: limb in five deep, linear, obtufe, moderately fpreading fegments. *Cor.* none. Nectary of eight linear, obtufe, villous, upright fcales, one-third the length of the calyx, and inferted into it at the bafe of the limb. *Stam.* Filaments eight, awl-fhaped, erect, the length of the calyx, into which they are inferted alternately with the fcales of the nectary, in the fame row; anthers ovate, attached by the back, erect, directed inwards. *Pift.* Germen fuperior, oblong, ending in a cylindrical upright ftyle, the height of the ftamens; ftigma oblong, downy, unilateral. *Peric.* Berry? ovate, of one cell, fomewhat fix-fided, with three keels furrounding its fummit. *Seeds* three, nearly ovate, oblique, externally gibbous, contracted below the middle, abrupt at the bafe, enclofed in a tunic.

Obf. There appear to be feveral feeds, fome of which prove abortive.

We have tried in vain to guefs any thing more refpecting this genus than its natural order, of which there can be fcarcely a doubt. No author has adopted *Wolfia*. There are, in its characters, fome indications of *Jambolifera*, Willd. Sp. Pl. v. 2. 326. *Cyminofma*, Gærtn. t. 58, (which ought to have found a place in our 18th volume; fee CALYPTRANTHES alfo); and a botanift who compares Schreber's defcription, literally tranflated above, with *Jambolifera pedunculata*, will find feveral coincidences, which, allowing for one or two eafy mifconceptions, might almoft perfuade us he had defcribed that plant; but ftill there are infuperable difficulties. Schreber's index directs us, at the word *Pitumba*, to the fame number as his *Wolfia*, 1749. But no fuch fynonym occurs there, nor, as far as we can find, elfewhere in his book. *Pee tumba*, Rheede Hort. Mal. v. 9. t. 46, is a *Jufticia*, and can have no connection with the prefent plant. See other obfcure genera, thus circumftanced, at the articles MEYERA, WHELERA, SPARTINA, and XYSTRIS.

WOLF-MONETH, a name given by our Saxon anceftors to the month of January, on account of the ravages committed by the wolves in that month through the feverity of the cold.

WOLFRAM, in *Mineralogy*, an ore of tungften. (See TUNGSTEN.) The colour of Wolfram is generally a brownifh or greyifh-black; it gives a reddifh-brown ftreak when cut with the point of a knife, to which it yields readily, a property characteriftic of this mineral. It occurs both maffive and cryftallized, and in concentric lamellar concretions. The form of the cryftal is a flat rectangular prifm; the lateral planes are generally ftreaked longitudinally. The ftructure is lamellar, with a very diftinct cleavage in one direction, and an indiftinct cleavage at right angles to the former. The luftre of the principal cleavage is fplendent or fhining, and is metallic; that of the indiftinct cleavage is gliftening. The crofs fracture is coarfe-grained and uneven. It is brittle and frangible. The fpecific gravity of Wolfram is from 7.1 to 7.3. Before the blow-pipe it decrepitates, and melts with difficulty into a black flag.

The conftituent parts of Wolfram, as given by Vauquelin, are,

Tungften acid	67
Oxyd of iron	18
Oxyd of manganefe	6
Silex	1.50

Wolfram moft frequently occurs in veins with tin-ftone, but may be diftinguifhed from it by its greater degree of foftnefs, and the reddifh ftreak which it yields to the knife. It is common in many of the mines of Cornwall, and in thofe of Saxony, and of Zinnweld and Schlackenwald, in Bohemia. This mineral has not hitherto been applied to any ufeful purpofe in the arts. It was originally miftaken for antimony, which by the alchymifts was called the wolf, becaufe it appeared to deftroy the bafer metals in the procefs of refining gold.

WOLFRAMITZ, in *Geography*, a town of Moravia, in the circle of Znaym; 20 miles N.E. of Znaym.

WOLFRAMITZKIRCHEN, a town of Moravia, in the circle of Znaym; 7 miles N.W. of Znaym.

WOLFSBACH, a river of Silefia, which runs into the Bober, near Loewenberg.

WOLFSBERG, a town of the duchy of Carinthia, on the river Levant, with a citadel; 10 miles N.N.W. of Lavamunt.

WOLFSDORF, a town of Pruffia, in the province of Ermeland; 18 miles W.S.W. of Heilfberg.—Alfo, a town of Saxony, in the circle of Neuftadt; 5 miles S.W. of Weyda.

WOLFSHAGEN, a town of the principality of Heffe Caffel, on the Erpe; 15 miles W. of Caffel. N. lat. 51° 18'. E. long. 9° 10'.

WOLFSON, a fmall ifland in the gulf of Finland. N. lat. 59° 22'. E. long. 24° 44'.

WOLFSPACH, a town of Auftria; 8 miles E. of Steyr.

WOLFSTEIN, a town of France, in the department of Mont Tonnerre; 43 miles W.N.W. of Manheim.

WOLHAUSEN IM MARKT, a town of Switzerland, in the canton of Lucerne; 7 miles W.S.W. of Lucerne.

WOLIN, or WOLYNIE, a town of Bohemia, in the circle of Prachatitz; 8 miles N.N.W. of Prachatitz. N. lat. 49° 10'. E. long. 13° 45'.

WOLIN, a town of Brandenburg, in the Middle Mark; 10 miles S.S.W. of Brandenburg.

WOLKART, a mountain of Carinthia; 8 miles N.E. of Milftatt.

WOLKENMARCK. See VOLKENMARK.

WOLKENSTEIN, a town of Saxony, in the circle of Erzgebirg, with a citadel, fituated on a rock, near the Zfchopa. About half a league from the town are fome warm medicinal baths; 13 miles S.S.E. of Chemnitz. N. lat. 50° 36'. E. long. 12° 59'.—Alfo, a town of the county of Tyrol; 3 miles W. of Lientz.

WOLKOMYSK, a town of Lithuania, in the palatinate of Novogrodek; 40 miles W.S.W. of Novogrodek.

WOLLACOMB BAY, a bay of England, on the weſt coaſt of Devonſhire, ſituated to the north of Barnſtaple bay.

WOLLAPALLAM, a town of Hindooſtan; 10 miles E. of Coimbetore.

WOLLASTON, WILLIAM, in *Biography*, an ethical writer, was born in 1659 at Cotton Clanford, in Staffordſhire, and finiſhed his education as a penſioner of Sidney college, Cambridge. In 1681 he commenced M.A. and entered into deacon's orders. His firſt ſettlement was as an aſſiſtant in the free ſchool at Birmingham, to which a ſmall lectureſhip was annexed; and about four years afterwards he was advanced from this laborious ſituation to the office of ſecond maſter in the ſame ſchool. In 1688 a relation died, whoſe deceaſe put him in poſſeſſion of a conſiderable landed eſtate, upon which he removed to London, and marrying a lady of conſiderable fortune, he reſided in Charterhouſe-ſquare. Diſmiſſing all thoughts of church preferment, he devoted himſelf to the retirement of private life and to a courſe of ſtudy, comprehending the learned languages, together with Hebrew and Arabic. The firſt publication which iſſued from the preſs was a poem on Eccleſiaſtes, which he would afterwards have ſuppreſſed, from a conviction that his talents were not adapted to poetry. In the progreſs of his life and literary purſuits, he was ſo much amuſed by compoſition, that he wrote many treatiſes on various ſubjects, both in Latin and Engliſh, which he committed to the flames. Of the well-known work which has perpetuated his name, and which is intitled "The Religion of Nature delineated," he printed a few copies to be diſtributed among his friends in 1722, but his declining health prevented his completing his original deſign. However, in 1723 he was prevailed upon to reviſe what he had printed for publication, and it accordingly appeared in 1724, in which year he died, at the age of 65, leaving a large family, and having loſt his wife, to whom he was affectionately attached, about four years before. In his private character he is ſaid to have exemplified the virtues which his work inculcated. The ſyſtem which he developed, and which founded morality upon "truth," excited much attention, and his book, though not written in a popular manner, paſſed through ſeven editions to the year 1750. The laſt of theſe editions includes an appendix, conſiſting of a tranſlation of the Latin notes by Dr. J. Clarke, dean of Saliſbury, undertaken at the particular requeſt of queen Caroline, who was a great admirer of the work. Dr. Warburton, in his ſtrictures on Wollaſton's theory in his Divine Legation, honours the author by ranking him as "one of our moſt celebrated writers," and compliments him with having "demonſtrated with greater clearneſs than any before him the natural eſſential difference of things;" and though modern ſyſtems have in a conſiderable degree antiquated that of Mr. Wollaſton, the author muſt always be regarded as a man of extenſive learning and ſtrong reaſoning powers. Biog. Brit.

WOLLERSDORF, in *Geography*, a town of Germany, in the margravate of Anſpach; 10 miles E. of Anſpach.

WOLLERSTORFF, a town of Auſtria; 5 miles W.N.W. of Neuſtatt.

WOLLIEN, a town of Brandenburg, in the Ucker Mark; 10 miles E.S.E. of Prenzlow.

WOLLIN, a town of Anterior Pomerania, on the eaſt coaſt of the iſland ſo called, ſeparated from the continent of Pomerania by the river Dirnow, over which is a bridge, at which all travellers pay a toll. In this town are a ſeat and prefecturate. It ſtands on the ſcite of the ancient city of Julin, which was formerly ſo famous for its commerce, though its origin is very obſcure. The firſt mention of this city in hiſtory occurs immediately after the time of Charlemagne; and in the 11th century its proſperity was ſuch, that Adam Von Bremen ſpeaks of it as the largeſt city at that time in Europe. So early as the records of the 12th century, it is called Wolin. In the year 1127, it was ſet on fire by lightning, and being built of wood, was entirely conſumed. The Pomeranian biſhopric, which had been erected there but two years before, was tranſlated upon that to Uſedom, but on the rebuilding of the city, was reſtored to it. In the year 1170, being taken by Woldemar I. king of Denmark, and Jaromar I. prince of Rugen, it was ſacked and burned; and after retrieving this calamity was, in the year 1175, again ſet on fire, and utterly deſtroyed, inſomuch that in the very ſame year the duke of Pomerania removed the biſhopric to Cammin. It was indeed rebuilt again, but never recovered its former greatneſs; 25 miles N. of Old Stettin. N. lat. 53° 48′. E. long. 14° 35′.

WOLLIN, an iſland formed at the mouth of the Oder, between the Baltic and the Friſche Haff; the form of an irregular triangle, about thirty miles in circumference. This iſland is frequently in danger of being overflowed, and the ſea-winds hurt it conſiderably, by throwing up drifts of ſand. It produces excellent cattle, with plenty of game and fiſh; and one part of it, called the Pritter, is remarkable for the great quantity of eels taken there. Beſides the town of Wollin, it contains ſeveral villages.

WOLLO, a town of Africa, on the Ivory Coaſt.

WOLLY. See WOOLLI.

WOLMIRSTADT, a town of Weſtphalia, in the duchy of Magdeburg. In the year 1642, this town was ſet on fire by the Imperial troops; 10 miles N. of Magdeburg. N. lat. 52° 18′. E. long. 11° 45′.

WOLMSDORF, or WONSDORF, a town of Pruſſia, in the province of Smaland; 24 miles S.E. of Königſberg.

WOLNITZ, a town of Saxony, in the principality of Eiſenach; 2 miles S. of Jena.

WOLNZACH, a town of Bavaria; 6 miles N.E. of Pfaffenhofen.

WOLPA, a town of Lithuania, in the palatinate of Novogrodek; 54 miles W. of Novogrodek.

WOLPAFFING, a town of Auſtria; 4 miles S.S.E. of Weikerſdorf.

WOLSDORFF, a town of the duchy of Bremen; 5 miles S. of Carlſtadt.

WOLSEY, or WULCEY, THOMAS, cardinal, in *Biography*, was the ſon of a butcher at Ipſwich, Suffolk, and born there in 1471. He finiſhed his education at Magdalen college, Oxford, and was graduated B.A. at the age of 15. He was afterwards fellow of his college, and having taken the degree of M.A. became maſter of the ſchool dependent upon that college, where he had under his tuition three ſons of the marquis of Dorſet, by whom he was preſented to the rectory of Lymington in Somerſetſhire, into which he was inducted in 1500. His advancement was rapid, firſt as domeſtic chaplain to the archbiſhop of Canterbury, and afterwards as chaplain to the houſehold of Henry VII. His manners were inſinuating, and he became the confidante of the king, who communicated to him his projected marriage with the daughter of the emperor Maximilian. Wolſey met the emperor at Bruges, and executed his commiſſion ſo much to the king's ſatisfaction, that he nominated him to the deanery of Lincoln. After the death of Henry VII. he was recommended by Fox, biſhop of Wincheſter, to Henry VIII., whoſe favour

favour and confidence he conciliated by his blending amusement with business, insomuch that he supplanted the ministers of the late king, and became himself uncontrouled minister. His preferments, civil and ecclesiastical, very speedily succeeded one another, and even profusely accumulated. He was introduced into the privy-council in 1510, made reporter of the star-chamber, registrar, and afterwards chancellor of the garter; and advanced to the sees of Tournay and Lincoln in 1513, to that of York in 1514, and to the dignity of cardinal in 1515. Thus promoted, his pride and love of pomp kept pace with his elevation of rank. In his train of servants, 800 in number, were many knights and gentlemen; and the sons of noblemen acted occasionally as his domestic menials. His equipage and furniture were of the most costly kind; but it is needless to multiply particulars. The most pardonable, not to say laudable, display of his magnificence was exhibited in his patronage of literary men and promotion of literature, both by the exercise of private bounty and the establishment of public institutions. The pope nominated him legate *à latere*, by which office he acquired legal pre-eminence over the archbishop of Canterbury; and in December 1515, he was elevated to the office of high-chancellor. By the equity of his decisions in the exercise of this office he gained great credit, but his conduct as legate *à latere* was so arbitrary and oppressive, as to produce complaints against him to the king. Charles V. and Frederic I. purchased his interest with Henry VIII. by pensions, and he was also retained in the same way by the pope. Charles flattered him with hopes of the papal crown, and settled upon him the revenues of two bishoprics in Spain. Still insatiable in the pursuit of ecclesiastical preferments, he obtained the administration of the see of Bath and Wells, and the temporalities of the abbey of St. Alban's, to which were afterwards added successively the rich bishoprics of Durham and Winchester. His revenues, thus amounting nearly to that of the crown, were expended partly in the ostentation of pomp, and partly in laudable munificence. He founded several lectures at Oxford for liberal and useful studies, and at length erected in that university the celebrated college of Christchurch. He also established a collegiate school in his native town of Ipswich. The palace which he built at Hampton Court he presented, in 1528, to the king, and he further ingratiated himself with Henry by an arbitrary loan for the supply of his wants; but by these measures he became more and more odious to the nation. But his fall was approaching; and the first step to it was the divorce of queen Catharine. This was followed by the marriage of Henry with Ann Boleyn, whose influence was employed in effecting his downfall. At length the king, not without hesitation and reluctance, employed the dukes of Norfolk and Suffolk, in 1529, to require him to surrender the great seal, and to quit York-place, a palace which he had built in London, and which afterwards became a royal residence under the name of Whitehall. His furniture and plate were seized for the king's use, and he was ordered to retire to Esher, a palace which belonged to him as bishop of Winchester. These measures overwhelmed the favourite, destitute of any inward resources of magnanimity; and when he received a slight token of the king's favour in this state of mental depression, he was transported with joy, dismounted on meeting the messenger, and fell upon his knees in the dirt to receive the expression of his master's kindness. Henry, however, was capricious and inconstant; a cloud overspread this gleam, and Wolsey was ordered to be indicted in the star-chamber, and abandoned by his sovereign to the rigour of parliament. An accusation, consisting of 44 articles, was exhibited against him by the house of lords; and in the commons, he was so ably defended by Thomas Cromwell, who had been raised by the cardinal from a low condition to a high station, that his enemies were defeated. They thus changed their plan, and indicted him upon the statute of provisors, which prohibited his procuring bulls from Rome, and which he had violated by obtaining the legantine power; and this was made the ground of a sentence, putting him out of the king's protection, forfeiting all his lands and goods, and declaring him liable to imprisonment. When these measures had induced him to resign to the king York-place with all its furniture, he obtained a full pardon for all his past offences, and the restoration of the revenues of his archbishopric, with part of his goods. But fresh tokens of royal displeasure awaited him. The earl of Northumberland was ordered to arrest him for high treason, and to conduct him to London for trial. In his way from York to London, he was seized with a disorder which obliged him to stop at Leicester, where he was hospitably received in the abbey. His disorder in a few days terminated his life, in the 60th year of his age. Shortly before he expired he closed a conversation with the constable of the Tower, which related to the king, with this exclamation, "Had but I served God as diligently as I have served the king, he would not have given me over in my grey hairs!" Thus he sunk to the grave as a victim to tyranny, but to a tyranny which he had himself formed; exhibiting an instructive example to all future ministers of the insecure possession of power and wealth acquired by extortion and oppression, and of the folly of placing confidence in princes embracing arbitrary and despotic measures, and governed by caprice and personal ambition. Biog. Brit.

The magnificence of the cardinal's chapel-establishment, as described by Cavendish, his contemporary and domestic, seems far to have surpassed that of the Roman pontiff himself.

"First, he had there a deane, a great divine, and a man of excellent learning; a sub-dean, a repeatour of the quire, a gospeller and epistollor; of singing priests, ten, a master of the children. The seculars of the chapell, being singing-men, twelve; singing-children, ten, with one servant to waite upon them. In the vestry, a yeoman and two grooms; over and besides other retainers that came thither at principal feasts. And for the furniture of his chapell, it passeth my weak capacity to declare the number of the costly ornaments and rich jewels that were occupied in the same. For I have seen in procession about the hall forty-four rich copes, besides the rich candlesticks, and other necessary ornaments to the furniture of the same."

The earl of Northumberland, whose passion for Ann Boleyn is supposed to have occasioned his disgrace at court, seems to have been treated with great insolence and indignity by the cardinal, who, by an extraordinary extension of power, demanded his choral books for the use of his own chapel. Letters concerning this requisition are still preserved in the family, in which the earl says, "I do perceayff my lorde cardinall's pleasour ys to have such boks as was in the chapell of my lat lorde and ffayther (wos soll Jhu pardon.) To the accomplychment of which, at your desyer, I am confformable, notwithstandinge I trust to be able ons to set up a chapell off myne owne.—I shall with all sped send up the boks unto my lord's grace, as to say iiij *Antiffonars* (Antiphoners), such as I think wher not seen a gret wyll—v *Gralls* (Graduals)—an *Ordeorly* (Ordinal)—a *Manuall*—viij *Proffessioners* (Processionals)." Northumberland Household Book.

WOLSINGHAM, in *Geography*, an irregular town in the

WOLKOMYSK, a town of Lithuania, in the palatinate of Novogrodek; 40 miles W.S.W. of Novogrodek.

WOLLACOMB BAY, a bay of England, on the weft coaft of Devonfhire, fituated to the north of Barnftaple bay.

WOLLAPALLAM, a town of Hindooftan; 10 miles E. of Coimbetore.

WOLLASTON, WILLIAM, in *Biography*, an ethical writer, was born in 1659 at Cotton Clanford, in Staffordfhire, and finifhed his education as a penfioner of Sidney college, Cambridge. In 1681 he commenced M.A. and entered into deacon's orders. His firft fettlement was as an affiftant in the free fchool at Birmingham, to which a fmall lecturefhip was annexed; and about four years afterwards he was advanced from this laborious fituation to the office of fecond mafter in the fame fchool. In 1688 a relation died, whofe deceafe put him in poffeffion of a confiderable landed eftate, upon which he removed to London, and marrying a lady of confiderable fortune, he refided in Charterhoufe-fquare. Difmiffing all thoughts of church preferment, he devoted himfelf to the retirement of private life and to a courfe of ftudy, comprehending the learned languages, together with Hebrew and Arabic. The firft publication which iffued from the prefs was a poem on Ecclefiaftes, which he would afterwards have fuppreffed, from a conviction that his talents were not adapted to poetry. In the progrefs of his life and literary purfuits, he was fo much amufed by compofition, that he wrote many treatifes on various fubjects, both in Latin and Englifh, which he committed to the flames. Of the well-known work which has perpetuated his name, and which is intitled "The Religion of Nature delineated," he printed a few copies to be diftributed among his friends in 1722, but his declining health prevented his completing his original defign. However, in 1723 he was prevailed upon to revife what he had printed for publication, and it accordingly appeared in 1724, in which year he died, at the age of 65, leaving a large family, and having loft his wife, to whom he was affectionately attached, about four years before. In his private character he is faid to have exemplified the virtues which his work inculcated. The fyftem which he developed, and which founded morality upon "truth," excited much attention, and his book, though not written in a popular manner, paffed through feven editions to the year 1750. The laft of thefe editions includes an appendix, confifting of a tranflation of the Latin notes by Dr. J. Clarke, dean of Salifbury, undertaken at the particular requeft of queen Caroline, who was a great admirer of the work. Dr. Warburton, in his strictures on Wollafton's theory in his Divine Legation, honours the author by ranking him as "one of our moft celebrated writers," and compliments him with having "demonftrated with greater clearnefs than any before him the natural effential difference of things;" and though modern fyftems have in a confiderable degree antiquated that of Mr. Wollafton, the author muft always be regarded as a man of extenfive learning and ftrong reafoning powers. Northumberland Household Book.

WOLSINGHAM, in *Geography*, an irregular town in the

the county of Durham, England, is pleafantly fituated in the vale of the Wear, on a point of land formed by the confluence of that river and the Wefcrow. The church is fituated at the north fide of the town on rifing ground, but poffeffes nothing worthy of remark. Near it are fome remains of a confiderable building, inclofed with a deep moat, fuppofed by fome writers to have been part of a monaftery, which was founded by Henry de Pudfey; but Hutchinfon, in his Hiftory of Durham, refers them to the ancient manor-houfe of the bifhop's, which is mentioned in Hatfield's Survey. The inhabitants of this parifh, according to the returns of 1811, are 1983, the houfes 399. The views down the Wear from the hill above Wolfingham include a very extenfive and beautifully diverfified country. Between this town and Stanhope, the commencement of the lead diftrict is every where intimated by large parcels of lead lying near the fides of the road, and from the blue unwholefome vapours arifing from the fmelting mills in Bollihope. On Bollihope common, in 1749, was found a Roman altar with an infcription. This town is 6 miles S.E. by S. from Stanhope, and 259 N.N.W. from London. Here is a market held on Tuefday, and a fair on the 18th of May. The petty feffions are holden here. The parifh, which is large, confifts of Bradley, Hilton-park, Thornley, Wolfingham town quarter, Eaft fide quarter, Park quarter, and South fide quarter.—Beauties of England, Durham, vol. iv.; by J. Britton and E. W. Brayley.

WOLTERSDORF, a town of Saxony; 2 miles S.W. of Zahna.

WOLTIN, a town of Hinder Pomerania; 12 miles S.W. of Stargard.

WOLTZTORFF, a town of Auftria; 2 miles N.N.W. of Weikerftorf.

WOLVERENE. See GLUTTON.

WOLVERHAMPTON, formerly HAMPTON, in *Geography*, an important market-town in the hundred of N. Seifdon, and county of Stafford, England, is particularly noted for its extenfive manufactures of locks, keys, and other articles of ironmongery. It is fituated on a rifing ground 16 miles S. from Stafford, 14 S.W. from Lichfield, 13 N.W. from Birmingham, and 130 in the fame direction from London. Wolverhampton is of ancient date, for as early as 996 a monaftery was founded there by Wulfruna, from whom the town received the firft member of its name. The inftitution, confifting of a dean and fecular canons, was about the year 1200 transferred by the dean, Peter of Blois, to the archbifhop of Canterbury, to convert it into an abbey for Ciftercian monks; but this defign feems not to have been executed, for the feculars appear to have been not long after in poffeffion of the eftablifhment. The church, which was confidered as one of the king's free chapels, was by Edward IV. annexed to the deanery of Windfor; but in the feventh year of Edward VI. a grant of the college of Wolverhampton and feven prebends was made to John, duke of Northumberland. Coming again to the crown by his attainder, queen Mary reinftated the dean and prebendaries, and endowed them with all the lands, &c. which formerly belonged to the inftitution, then valued at the yearly rent of 113*l.* 13*s.* On a queftion arifing concerning thofe poffeffions, the grants of Mary were confirmed by James I., who appointed the celebrated Marc-Antonio de Dominis, who had been archbifhop of Spalatro in Dalmatia, to be dean of Windfor, and dean and firft prebendary of Wolverhampton: thofe deaneries continue to be united, but the colleges are feparate.

Wolverhampton is well built, and confidered as falubrious, notwithftanding it is in the vicinity of many coal-mines. The parifh is of great extent, being nearly 30 miles in circuit, and comprehends, befides the town, feventeen confiderable townfhips, or villages, among which are, Bilfton, Featherftone, Hatherton, Hilton, and Kinvafton. According to the returns to parliament in 1811, the houfes in the whole parifh were 2936, and the inhabitants 14,836. A market is held on Wednefday, and a fair on the 10th of July. The fkill and ingenuity of the lock-fmiths of the town and the environs, (for many of the farmers themfelves are concerned in the bufinefs,) and the trade carried on in thefe and fimilar articles of iron manufacture, are unparalleled in England: the trade is particularly promoted by the Staffordfhire and Worcefterfhire grand trunk, and the Birmingham canals, which unite about a mile to the N. of the town. The town is governed by two conftables, and in it are held the petty feffions for the N. and S. divifions of Seifdon hundred.

The collegiate church of St. Peter ftands on an elevation on the E. fide of the town, and confifts of a lofty nave, with fide-aifles and a chancel. From the centre of the building, which is of ftone, rifes a tower. The nave is feparated from the aifles by five pointed arches, fupported by octagonal pillars. Againft one of the S. pillars is erected a very curious ftone pulpit. The font, which is octagonal, and covered with fculptured figures, &c. appears to be very ancient. In the great chancel is a full-length ftatue, in brafs, of the celebrated admiral fir Richard Levefon, who had a command againft the Spanifh armada, under fir Francis Drake. In the church-yard ftands a round column twenty feet high, profufely but rudely carved in divifions, and the whole furmounted by a plain capital. It is evidently ancient, and may have fupported a crofs, or the figure of the patron-faint. The fituation of Wulfruna's monaftery is unknown; but in the S.W. corner of the burying-ground is a large room fupported by groins, the walls of which are three yards in thicknefs. Befides St. Peter's, Wolverhampton poffeffes another church, dedicated to St. John, which was erected by fubfcription, and confecrated in 1761. Diffenters of various denominations abound in the parifh of Wolverhampton, and comprehend more than one half of the inhabitants: chapels for their accommodation are confequently numerous. A free-fchool was founded here by fir Stephen Jennings of Wolverhampton, who was lord-mayor of London in 1668; befides which, charity-fchools are maintained for children of both fexes. Bilfton, a large and populous village two miles S.E. from the town, is within the parifh of Wolverhampton; but as to all parochial concerns it is a feparate townfhip. In 1811 Bilfton contained 1862 houfes, and the inhabitants amounted to 9646. Here is a parochial chapel, which is a neat modern ftructure: the living is a perpetual curacy within the exempt jurifdiction of the dean of Wolverhampton; but the nomination and prefentation of the incumbent are vefted in the inhabitants at large. Bilfton contains likewife two diffenting meetings, and an excellent charity-fchool. The bufinefs of Bilfton confifts chiefly of japanned and enamelled goods. The vicinity abounds in coal, iron-ftone, with numerous fmelting-furnaces and forges, &c. in which the operations are performed by fteam-engines. Bilfton furnifhes alfo a peculiar kind of fand of great ufe in cafting metals. At Bradley, near Bilfton, the fubterraneous coal has been burning for feveral years paft, and every attempt to extinguifh it has hitherto proved fruitlefs, by which feveral

ral acres of land have been rendered unproductive. The fire proceeds from a burning stratum of coal about four feet thick, and eight or ten yards deep, to which the air has free access; as the main bed of coal has been dug out from under it. In collecting the calcined substances for repairing the roads, sulphur and alum are frequently found. Tatenhill, a small village on a steep eminence two miles N. from Wolverhampton, was the scene of a severe battle between Edward the Elder and the Danes, in the beginning of the 10th century. In this place was founded, before the Norman Conquest, a college with a dean and five prebends, which subsisted till the general dissolution by Henry VIII. The present church, or chapel, is apparently a part of that establishment. At Wrottesley, a village in the parish of Wolverhampton, extensive ancient remains have been discovered, supposed, by Dr. Plott, in his History of Staffordshire, to be vestiges of the old Theotenhall of the Danes: but later antiquaries imagine these remains to belong to the Uriconium of Roman Britain. The parish of Wolverhampton, although varied with eminences, is in general level, and ornamented with a number of agreeable hamlets and country-seats.—History and Antiquities of Staffordshire, by the Rev. Stebbing Shaw, fol. Lond. 1798. Beauties of England and Wales, Staffordshire, 8vo. Lond. 1814.

WOLVES-TEETH, of a horse, are overgrown grinders, the points of which, being higher than the rest, prick the creature's tongue and gums in feeding, so as to hinder chewing of the meat.

They are seldom met with but in young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

There are usually two of these wolves-teeth, which are small, and grow in the upper-jaw, next to the great grinding-teeth: these are so tender and painful, that the horse cannot chew his meat, but is forced to let a great part of it fall out of his mouth, or swallow it half chewed.

The remedy, in this case, is to tie up the horse's head to some part of the rafter, and open his mouth with a cord; then with an instrument like a carpenter's gauge, and a mallet, the teeth that are thus troublesome are to be knocked out, and the holes filled up with salt.

If the upper-jaw teeth hang over those of the under-jaw, and by that means cut the mouth, the same instrument is to be used, and the teeth are to be pared shorter by little and little. When they are sufficiently pared down, they must be filed smooth, and the mouth washed with vinegar and salt, and the whole complaint will be thus removed.

WOLVES, *Rout of*. See ROUT.

WOLVES *Islands*, in *Geography*, a cluster of small islands near the E. coast of Maine. N. lat. 45° 4′. W. long. 66° 50′.

WOLVEY, a village of England, in the county of Warwick. It was at this place that Edward IV. was surprised and taken prisoner by Richard Nevil, earl of Warwick; 10 miles N.E. of Coventry.

WOLZ. See WELS.

WOMAN, FŒMINA, *Mulier*, the female of man.

A woman, in England, as soon as she is married, with all her moveables, is wholly *in potestate viri*, or at the will and disposal of her husband.

There are divers considerable things relating to women in the laws of England, which see under WIFE.

St. Augustine calls women the *devout sex;* at least, this is the common opinion; though others rather think, that in the prayer usually attributed to that father, and still rehearsed in the Romish church to the Holy Virgin, the words "intercede pro devoto fœmineo sexu," are to be understood of women devoted or consecrated to God in religious houses; which had been sufficiently expressed by the words, "ora pro populo, interveni pro clero."

It is a popular tradition among the Mahometans, which obtains to this day, that women shall not enter paradise.

An anonymous author, about the close of the sixteenth century, published a little Latin dissertation, to prove that women are not men; that is, are not reasonable creatures: "Dissertatio perjucunda, qua anonymus probare nititur mulieres homines non esse." He also endeavours to prove, what naturally follows from this principle, *viz.* that women shall not be saved, that there is no future life or happiness for them. His proofs are all taken from Scripture, or founded on Scripture. Though, after all, his aim is not so much to degrade women to the condition of brutes, as to ridicule the principle or method of many Protestants, who, in points of controversy, admit of no proofs or considerations but what are taken from Scripture alone. This appears from the conclusion of the work. "Probavi, opinor, invictissimis SS. literarum testimoniis, mulierem non esse hominem, nec eam salvari: quod si non effeci, ostendi tamen universo mundo, quomodo hujus temporis hæretici, et præsertim Anabaptistæ, sacram soleant explicare Scripturam, et quo utantur methodo ad stabilienda sua execranda dogmata."

Yet Simon Gediccus, a Lutheran divine, wrote a serious confutation of this piece in 1595, wherein the women are restored to the expectation of heaven, on their good behaviour.

The ancient Marcionites allowed their women to baptize; as we are assured by St. Epiphanius, Hær. 42. cap. 4. the Montanists admitted women to the priesthood, and even the episcopate, Epiph. Hær. 49. cap. 2. The modern Quakers also permit their women to preach and prophesy, on an equal footing with the men.

It is a point much controverted, how far learning and study become the sex? Erasmus handles the question at large in one of his letters to Budæus. Lud. Vives, in his Institutio Fœminæ Christianæ, has a chapter expressly on the same subject. Madam Schurman, a German lady, has gone beyond them both, in a treatise on this problem, "Num fœminæ Christianæ conveniat studium literarum?"

Several of the women remarkable for learning have been also distinguished for their want of conduct. The reason, no doubt, lay in this; that their first studies lying in books of gallantry and intrigue, the imagination was early turned that way, and the memory filled with a sort of ideas, which a favourable disposition, and age, adopted too easily, and improved too fast. It is not that study in itself has any natural tendency to produce such effects; rather the contrary: the close abstracted researches of metaphysics, logics, mathematics, physics, criticism, &c. no doubt would be the surest means to secure and establish the virtue of continency in a woman.

For an account of women hired to weep at funerals by the Romans, see PRÆFICÆ.

Women were allowed to sing, in 1772, in the collegiate church of St. Gudula, at Brussels. It was in the performance of high mass on a Sunday, when a considerable number of voices and instruments were assembled in the choir; and we were glad to find among the former two or three women, who though they were not fine singers, yet their being employed, proved that female voices might have admission in the church, without giving offence or scandal to piety, or even bigotry. If the practice were to become general, of admitting women to sing the soprano part in the cathedrals,

 is

it would, in Italy, be a ſervice to mankind, and in the reſt of Europe render church muſic infinitely more pleaſing and perfect; in general, the want of treble voices, at leaſt of ſuch as have had ſufficient time to be poliſhed, and rendered ſteady, deſtroys the effects of the beſt compoſitions, in which, if the principal melody be feeble, nothing but the ſubordinate parts, meant only as attendants, and to enrich the harmony of the whole, can be heard.

Women, *Appeals of*. See Appeal.

Women, *Jury of*. See *Jury of* Matrons.

Women, *Stealing*, or *Seduction of*, is puniſhable by the ſtatute 4 & 5 Ph. & Mar. cap. 8. which enacts, that if any perſon above the age of fourteen unlawfully ſhall convey or take away any woman child unmarried, (which is held to extend to baſtards as well as to legitimate children,) within the age of ſixteen years, from the poſſeſſion and againſt the will of the father, mother, guardians, or governors, he ſhall be impriſoned two years, or fined at the diſcretion of the juſtices: and if he deflowers ſuch maid or woman child, or, without the conſent of parents, contracts matrimony with her, he ſhall be impriſoned five years, or fined at the diſcretion of the juſtices, and ſhe ſhall forfeit her lands to her next of kin, during the life of her ſaid huſband. But this latter part of the act is now rendered almoſt uſeleſs, by proviſions of a very different kind, which make the marriage totally void, in the ſtatute 26 Geo. II. cap. 33. See Marriage. See alſo Forcible *Abduction*, Rape, and Raviſhment.

WOMB, Matrix, or *Uterus*, in *Anatomy*, that part of the female of any kind, wherein the fœtus is conceived and nouriſhed till the time of its delivery.

The ancient Greeks called the *matrix*, μητρη, from μητηρ, *mother:* whence diſorders of the womb are ſtill frequently called *fits of the mother*. They alſo call it υστερα, as being the laſt of the entrails, by its ſituation. Sometimes they alſo call it φυσις, or *natura;* and *vulva*, from *volvo, to fold*, or *envelope*, or from *valvæ, doors*. See Uterus.

Womb, *Dropſy of the*. See Dropsy.

Womb, *Falling down of the*. See Procidentia *Uteri*.

Womb, *Inflammation of the*. See Inflammation.

Womb, *Suffocation of the*. See Suffocation.

Womb, *Ulcers of the*. See Ulcers.

Womb, in *Geography*, a town of Sweden, in the province of Skonen; 12 miles E. of Lund.

WOMBACH, a town of Germany, in the county of Rieneck; 3 miles S. of Lohr.

WOMBAT, in *Zoology*, an animal of which Mr. E. Home has given an anatomical deſcription in the 2d part of the 98th volume of the Philoſophical Tranſactions. It was brought from the iſlands in Baſſa's ſtraits, and lived with him in a domeſticated ſtate for two years. Whenever it had an opportunity, it burrowed in the ground, and covered itſelf in the earth with ſurpriſing quickneſs. It was quiet in the day, but in conſtant motion during the night; very ſenſible of cold; ate all kinds of vegetables; was particularly fond of new hay, which it ate ſtalk by ſtalk. It appeared attached to thoſe to whom it was accuſtomed, and who were kind to it. It allowed children to pull and carry it about, and when it bit them it was not in anger or with violence. It appeared to have arrived at its full growth, weighed about twenty pounds, and was about two feet two inches long. Another animal called the 'Koala,' is a ſpecies of the wombat, partaking of its peculiarities. It inhabits the foreſts of New Holland, about fifty or ſixty miles S.W. of Port Jackſon, whither it was brought in Auguſt 1803, and is called by the natives the 'koala wombat.' It is commonly about two feet long and one high; in the girth about a foot and a half: it is covered with fine ſoft fur, lead-coloured on the back and white on the belly: the ears are ſhort, erect, and pointed; the eyes generally ruminating, ſometimes fiery and menacing: it bears no ſmall reſemblance to the bear in the fore-part of its body: it has no tail; and its cuſtomary poſture is ſitting. The New Hollanders eat the fleſh of this animal; and are very dextrous in the purſuit of it, climbing with wonderful rapidity the loftieſt gum-trees in ſearch of it. The koala feeds upon the tender ſhoots of theſe trees; and during the day reſts on the tops of them, either feeding at eaſe, or ſleeping. In the night it deſcends, prowls about in ſearch of ſome particular roots, creeping rather than walking; and when incenſed or hungry, it utters a long ſhrill yell, and aſſumes a fierce and menacing look. Theſe animals are found in pairs, and the young is carried by the mother on its ſhoulders. It ſoon forms an attachment to the perſon who feeds it.

The external form of the wombat has been deſcribed by M. Geoffroy, in the 2d volume of the "Annales du Muſeum National de France;" and ſeveral parts of its internal ſtructure have been taken notice of by M. Cuvier, in his "Leçons d'Anatomie Comparé." The mechaniſm of the bones and muſcles of the hind legs differs in many reſpects from that of all other animals, except the koala. This has been minutely examined and deſcribed by Mr. Brodie, at the deſire of Mr. Home; and it appears that there is nothing ſimilar to it in the hind legs of the mole, or other burrowing animals. The internal ſtructure of the wombat reſembles that of the beaver; but it is ſo different from that of the kangaroo, and all the other animals of the opoſſum tribe, that it forms a very extraordinary peculiarity. The male and female organs of generation have been deſcribed; the former by M. Cuvier, and the latter by Mr. Bell in New South Wales. The male and female organs of the wombat and koala are ſimilar to thoſe of the opoſſum; and hence it is concluded, that theſe animals form the intermediate link between the opoſſum and kangaroo. See Didelphis.

WOMBINELLORE, in *Geography*, a town of Hindooſtan, in Baramaul. It was taken by the Britiſh, under general Meadows; 100 miles S.E. of Seringapatam. N. lat. 11° 43′. E. long. 78° 15′.

WOMBORN, a townſhip of England, in Staffordſhire; 3 miles S.W. of Wolverhampton.

WOMELSDORF, a town of Pennſylvania; 15 miles W. of Reading.

WONDA, a town of Africa, in Manding; 30 miles N.E. of Kamalia. See Manding.

Wonda, a river of Manding, which, at Fonilla, a ſmall walled village on its banks, is called Ba Woolima (red river); and towards its ſource it has the name of Ba Qui (white river); the middle part of its courſe being called Wonda.

WONDER. See Miracle.

The ſeven wonders of the world, as they are popularly called, were, the Egyptian pyramids; the mauſoleum erected by Artemiſia; the temple of Diana at Epheſus; the walls and hanging gardens of the city of Babylon; the coloſſus, or brazen image of the ſun, at Rhodes; the ſtatue of Jupiter Olympius; and the pharos, or watch-tower, of Ptolemy Philadelphus: inſtead of the latter, ſome reckon the royal palace of Cyrus, built by Menon, the ſtones of which were cemented with gold. See Pyramid.

WONDERFUL Water. See Water.

WONDRA, or Wondreb, in *Geography*, a river which riſes in Bavaria, and runs into the Egra, near Königſberg, in Bohemia.

WONDRZEGOW, a town of Bohemia, in the circle of Kaurzim; 10 miles W.S.W. of Kaurzim.

WONSDORF, a town of Pruſſia, in Natangen; 25 miles S.E. of Königſberg.

WONSIEDEL. See WUNSIEDEL.

WONTAMITTA, a town of Hindooſtan, in Myſore; 45 miles E. of Chinna Balabarum.

WOO-CHIN, a town of China, in the province of Kiang-ſi, near the lake Poyang, which is a place of conſiderable importance, as the great mart for exchanging commodities between the north and ſouth of China. The warehouſes are ſpacious and well filled, dwelling-houſes large and ſubſtantial, temples richly decorated, and the ſhops filled with articles of all kinds, including no inconſiderable proportion of European goods. Here are ſeveral ſmall bronze veſſels of ancient and modern workmanſhip, not unlike the Grecian and Etruſcan. Near it is a temple dedicated to Wang-ſhin-choo, the god of longevity, ſurpaſſing moſt others in riches of carved-work and gilding.

WOOD, WILLIAM, F.L.S., in *Biography*, a Proteſtant diſſenting miniſter of diſtinguiſhed reputation for general literature and ſcience, character, and uſefulneſs, was born at Collingtree, a village near Northampton, on May 29, O.S. 1745. His father, though occupying a humble ſtation, was a perſon of approved integrity and piety, in connection with the Chriſtian ſociety at Northampton, under the perſonal care of the juſtly-celebrated Dr. Doddridge, and paid particular attention to the religious inſtruction and moral conduct of his children. Mr. Wood, at an early age, manifeſted promiſing talents, and having finiſhed his ſchool-education under the late Dr. Addington of Market-Harborough, was introduced, at the age of 16, with a view to the miniſtry, among Proteſtant diſſenters, which was the object of his choice, to a diſſenting academy in London, conducted at the time of his admiſſion by Dr. David Jennings and Mr. (afterwards Dr.) Morton Savage, and before the cloſe of his ſtudies by Mr. Savage, Mr. A. Kippis, and Mr. A. Rees. The writer of this ſketch can bear perſonal teſtimony to his exemplary conduct during the period of his continuance at the academy, and to the diligence and ſucceſs with which he proſecuted the various branches of literature and ſcience to which his attention was directed. Few perſons ever left a public ſeminary with ſuperior qualifications for the exerciſe of the profeſſion to which he was devoted, and performed the duties of it, in the progreſs of a long and honourable life, more acceptably and more uſefully. It was then the cuſtom, admitting of few exceptions, to ordain miniſters when they were elected by particular congregations, and introduced into the full diſcharge of the paſtoral office; and ſome, we underſtand, of the wiſeſt and beſt of the Non-conformiſt miniſters have lamented the too general diſcontinuance of this decorous practice, againſt which it is thought by many that no ſufficient objection has been alleged. Ordination among Proteſtant diſſenters is a public ſervice, uſually conducted at the place where the miniſter, who is ordained or ſet apart, is about to be ſettled; and conſiſts of a ſermon addreſſed to the people, a charge delivered to the perſon ordained, and prayers for a divine bleſſing on his future labours, and for the edification and proſperity of the Chriſtian ſociety with which he is connected. It has been ſometimes accompanied with a confeſſion of faith on the part of the perſon who is thus ſet apart; but this part of the ſervice, having been miſunderſtood, is frequently omitted, though in caſes which allow of unreſtricted liberty, and in which the confeſſion neither deſcends into a variety of minute particulars, nor contains any pledges that embarraſs or reſtrain future free inquiry, it is thought to be unexceptionable. Ordination, however, among the perſons to whom we now refer, is not conceived to impart any new qualifications or powers which the perſon ordained did not poſſeſs previouſly to this ſervice, or to conſtitute him either a miniſter in general, or the paſtor of any particular church. But to return from this digreſſion: Mr. Wood was publicly ordained, and the occaſion afforded an opportunity for many miniſters of acknowledged reputation among diſſenters to bear their united teſtimony to his talents and character. He commenced his public ſervices at Debenham in Suffolk, on the 6th of July 1766, with a ſermon peculiarly appropriate to the occaſion, from Luke, ix. 26., and he ſpent the remaining part of this year, and a great part of the year 1767, in the vicinity of London, where he occaſionally officiated to the ſatisfaction of thoſe who attended, and gained the friendſhip of ſome of the moſt eminent of the diſſenting miniſters of that period. In September 1767, he ſettled at Stamford, in Lincolnſhire; and removed from thence to Ipſwich in November 1770, where he remained till the cloſe of the year 1772. In 1773, having nearly completed his 27th year, he was unanimouſly choſen to ſucceed Dr. Prieſtley at Mill-hill chapel, Leeds, and in that connection he continued till his death. About two years after his ſettlement with this congregation, he publiſhed a ſmall volume conſiſting of twelve ſermons on ſocial life, which entitled the author, in the judgment of a contemporary critic, to the character of a uſeful and elegant preacher. In 1780 he formed a matrimonial connection with a daughter of Mr. George Oates, of Low-hall, near Leeds, which laſted twenty-ſix years, and contributed in a high degree to his domeſtic felicity. By this lady he had four children, of whom three ſurvived their parents.

Ardently devoted to the ſtudies that were more immediately or more remotely connected with his profeſſion, and attached by affectionate gratitude as well as intereſt to the congregation in the ſervice of which he was engaged, and which claimed his moſt aſſiduous and reſpectful attention, he commenced for the benefit of the young a courſe of lectures, in the year 1785. Theſe were comprehenſive and improving; and though they were delivered once a fortnight, they laſted ſeveral years. Our limits will not allow us to avail ourſelves of the detail, furniſhed by his excellent biographer, of the ſubjects which were diſcuſſed in this extenſive courſe of uſeful inſtruction. It will be ſufficient to obſerve, that they contributed no leſs to the information of thoſe who attended them than to the reputation of the lecturer, as well as to the mutual reſpect and eſteem which were thus cemented between Mr. Wood and his congregation. The public would probably have derived inſtruction from the peruſal of them, if ſome circumſtances had not occurred which rendered it neceſſary for Mr. Wood to devote a conſiderable part of his time and attention to ſubjects of a very different nature. Without abandoning the ſtudies connected with his profeſſion, he was led by the ſtate of his health, and by ſome other conſiderations, to the purſuit of natural hiſtory, and particularly of Engliſh botany; but whilſt he was thus occupied, he rendered his inveſtigations ſubſervient to the great object of his life and miniſtry, the promotion of religion and virtue, as well as the perſonal ſatisfaction and future happineſs of thoſe with whom he was connected. His new purſuits were the means of introducing him to acquaintance and friendſhip with many eminent perſons; and more eſpecially with Dr. (now ſir James) Smith, the juſtly celebrated preſident of the Linnæan Society. To Mr. Wood the good opinion and friendly regard of *one*, who commands the reſpect and eſteem of all who know him, by mental accompliſhments and moral qualities of the moſt excellent and engaging kind, muſt have afforded a ſatisfaction which, as we can teſtify from perſonal know-

 ledge,

ledge, he very highly appreciated. The good opinion of ſuch a judge of merit, in the department of natural hiſtory, which now engaged his attention, muſt have encouraged his aſſiduity and perſeverance. He was thus qualified for contributing ſeveral valuable articles to this Cyclopædia, in the reputation and ſucceſs of which the editor is happy to ſay he felt and expreſſed a peculiar intereſt. His contributions comprehended the botanical articles that occur, with ſome few exceptions, from the beginning of the letter B to the end of C; and the editor, who moſt ſincerely lamented his death as a pupil and a friend, as well as a coadjutor in this work, would have found it difficult to ſupply the loſs, if the kindneſs and condeſcenſion of the Linnæus of our time, for ſo, it is hoped, we may be allowed to denominate him without offending his delicacy, had not relieved his anxiety, and amply compenſated the injury which the botanical department of the Cyclopædia muſt have ſuſtained.

Mr. Wood had attained, by his talents and cultivation of them, to ſo high a rank among his brethren in that part of the country where his lot was caſt, that few public ſervices occurred in which he was not expected to be active and conſpicuous. Attached to liberty, civil and religious, from his youth, he had in his maturer years thoroughly acquainted himſelf with the genuine principles of the Britiſh conſtitution; and accordingly he took occaſion on the centenary of the Revolution, in 1788, to expreſs his conviction and feelings in two ſermons, which were afterwards publiſhed. In the three following years he took an active part in the application of the diſſenters to parliament for the repeal of the teſt and corporation acts. In 1794 he preached a funeral ſermon, on occaſion of the death of the Rev. W. Turner, of Wakefield; and in the following year be performed the ſame ſervice in conſequence of the deceaſe of the Rev. Mr. Ralph, of Halifax: the ſermons which he delivered in both caſes were publiſhed. The ſhort account of Leeds which was this year communicated to Dr. Aikin for his Hiſtory of Mancheſter deſerves to be noticed, as he took great pains in exactly aſcertaining the number of its inhabitants. About this time he commenced a courſe of education, addreſſed to young females, with a view partly to his own emolument, but principally for the benefit of thoſe who were diſpoſed to avail themſelves of his inſtruction; and indeed few perſons could be found capable of conducting ſuch a courſe with greater ſatisfaction and advantage to thoſe who attended it. His lectures occupied three years, and comprehended hiſtory, geography, natural philoſophy, grammar, the belles lettres, natural hiſtory, mental and moral philoſophy, and the evidences of natural and revealed religion. His next publication was his ſermon occaſioned by the death of the Rev. Newcome Cappe, which contained a very appropriate and juſtly-merited eulogy of his late revered friend. It was dedicated to Mrs. Cappe, who claimed from her talents and character, as well as relation to the deceaſed, a tribute of reſpect; and annexed to it ſome brief memoirs of Mr. Cappe's life. In the year 1801, Mr. Wood publiſhed a liturgy, conſiſting of five forms, for the uſe of his congregation at Mill-hill chapel, and compoſed, for the moſt part, from the ſervice of the eſtabliſhed church, the Liverpool, Shrewſbury, and other liturgies before publiſhed by the diſſenters, as well as from a ſimilar ſervice compoſed by the Rev. T. Simpſon. Of this performance it will be ſufficient to ſtate, that it was executed with judgment and taſte. On the reſtoration of peace in the year 1802, he publiſhed an animated diſcourſe, which he delivered, in the courſe of his public ſervices, on that occaſion. About this time he exerted himſelf in eſtabliſhing at York the academical inſtitution, which had for ſome years ſubſiſted at Mancheſter, and which was likely to be diſcontinued in conſequence of the reſignation of the late Rev. G. Walker, the theological tutor.

Intending, as he advanced in life, and when he had finiſhed the education of his daughter, to relinquiſh the anxiety and labour of tuition, he propoſed to engage in ſome literary undertakings. Accordingly he was a contributor, in the department of natural hiſtory, to the Annual Review; but the work which occupied his chief attention, and which afforded him the greateſt pleaſure, was the Cyclopædia already mentioned.

As a preacher, the laſt of his publications was a ſermon delivered at Birmingham, June 9, 1805, for the benefit of the Proteſtant diſſenting charity-ſchool, ſupported by the joint contributions of the two ſocieties of the old and new meeting-houſes. After his return from an excurſion in the months of July and Auguſt 1806, he was attacked by a ſevere paroxyſm of the gout, to which he had been long ſubject; and in a few days his diſorder was ſo alarming, that his recovery was not expected. As an aggravation of his diſtreſs, the affectionate partner of his life was ſeized with a diſorder, which terminated in her death. For ſome time his ſtate was ſuch, that it was prudent to conceal from him both the progreſs and termination of her diſorder. The mournful event which he had apprehended was gradually diſcloſed to him; and he received the afflictive intelligence with a degree of compoſure and reſignation, which evinced the efficacy of his religious principles, and the conſolation derived in ſuch circumſtances from Chriſtian hope. During a long illneſs, which interrupted bis public labours, and which was attended with a conſiderable expence, the ſociety with which he was connected had an opportunity of teſtifying, by ſubſtantial acts of kindneſs, the high ſenſe they entertained of his meritorious ſervices. Providence at length reſtored his health to ſuch a degree, that he was able to reſume his public labours; but they were of no long continuance. On Sunday the 27th of March 1808, he performed the uſual ſervices with an uncommon degree of animation. On the following day, however, having previouſly experienced ſymptoms of a flying gout, he was ſuddenly ſeized at dinner with a violent ſickneſs, which continued for many hours. This was ſucceeded by an inflammation of the bowels, which ſoon terminated in a mortification. The conſequence was a delirium; and on Friday, the 1ſt of April, he expired ſo quietly, that the friends who attended his bed were not apprized of the moment of his departure. Thoſe who wiſh for further information concerning the natural talents and acquired endowments, the private character and public ſervices of Mr. Wood, will be amply gratified by the peruſal of the "Memoirs of his Life and Writings," and of the "Addreſs and Sermon" delivered on occaſion of his death, by his friend and neighbour the Rev. Charles Wellbeloved of York.

Wood, Anthony, the *Oxford Antiquary*, was born at Oxford in 1632, and entered of Merton college in 1647. Having commenced M.A. and acquired a taſte for ſtudies pertaining to antiquity, he purſued with indefatigable diligence both at Oxford and in London reſearches, which furniſhed him with materials for his "Hiſtory and Antiquities of the Univerſity of Oxford," a copy of which he ſold to the univerſity in 1669 for 100*l*. It was written in Engliſh, but afterwards tranſlated into Latin, under the inſpection of Dr. Fell; and the verſion was publiſhed from the Oxford preſs in 1674, under the title of "Hiſtoria et Antiquitates Univerſitatis Oxonienſis, duobus Voluminibus comprehenſa," fol. The firſt part of this work includes the annals of the univerſity, from its earlieſt period to the year 1648; and the ſecond contains an account of all its particular foundations, endowments, officers, &c. The tranſlation is badly executed, and Wood, the original author, was deftitute of thofe qualifications that would have rendered him a fit hiftorian of a learned univerfity. Another of Wood's works was his "Athenæ Oxonienfes; or, an Account, in Englifh, of almoft all the Writers educated at Oxford, and many of thofe at the Sifter Univerfity, from the year 1500." It was firft publifhed in 1691, 2 vols. fol., and foon after fubjected him to a profecution in the vice-chancellor's court for his account of lord Clarendon, and to various other attacks, occafioned by his partialities, and more efpecially by his ftrong bias in favour of popery. His ftyle is vulgar, and his fentiments illiberal and unphilofophical; but his veracity entitles him to confidence. He died in 1695, and bequeathed his books and papers to the univerfity of Oxford. A fecond edition of this work, corrected and enlarged from the author's MS., was publifhed in 1721. Biog. Brit.

This curious and diligent antiquary, whofe whole life was fpent in the fervice of the dead, and whofe labours, fince his deceafe, have fo much facilitated the inquiries, and gratified the curiofity of the living, tells us, in the Memoirs of his Life, written by himfelf, with monaftic fimplicity, that in 1651, "he began to exercife his natural and infatiable genie to mufick. He exercifed his hand on the violin, and having a good eare to take any tune at firft hearing, he could quickly draw it out from the violin, but not with the fame tuning of ftrings that others ufed. He wanted underftanding, friends, and money, to pick him out a good mafter, otherwife he might have equalled in that inftrument, and in finging, any perfon then in the univerfity. He had fome companions that were mufical, but they wanted inftruction as well as he."

The next year, being obliged to go into the country to try to get rid of an obftinate ague, by exercife and change of air, he tells, that "while he continued there he followed the plow on well-dayes, and fometimes plowed. He learned there to ring on the fix bells, then newly put up: and having had from his moft tender yeares an extraordinary ravifhing delight in mufick, he practifed there, without the help of an inftructor, to play on the violin. It was then that he tuned his ftrings in 4ths, and not in 5ths, according to the manner; and having a good eare, and being ready to fing any tune upon hearing it once or twice, he could play it alfo in a fhort time with the faid way of tuning, which was never knowne before."

"After he had fpent the fummer in a lonifh and retired condition, he returned to Oxon. And being advifed by fome perfons, he entertained a mafter of mufick to teach him the ufual way of playing on the violin; that is, by having every ftring tuned five notes lower than the other going before. The mafter was Charles Griffith, one of the mufitians belonging to the city of Oxon., whom he then thought to be a moft excellent artift. But when Anthony Wood improved himfelf in that inftrument, he found he was not fo. He gave him 2*s.* 6*d.* entrance, and fo quarterly. This perfon, after he had extreamly wondered how he could play fo many tunes as he did by 4ths, without a director or guide, tuned his violin by 5ths, and gave him inftructions how to proceed, leaving then a leffon with him to practice againft his next coming."

In 1653, he found that "heraldry, mufick, and painting, did fo much crowd upon him, that he could not avoid them; and could never give a reafon why he fhould delight in thofe ftudies, more than in others, fo prevalent was nature, mixed with a generofity of mind, and a hatred of all that was fervile, fneaking, or advantageous for lucre fake."

"Having by 1654 obtained a proficiency in mufick, he and his companions were not without filly frolicks, not now to be maintained."—What fhould thefe frolics be, but to difguife themfelves in poor habits, and like country-fiddlers fcrape for their livings. After ftrolling about to Farringdon fair, and other places, and gaining money, victuals, and drink for their trouble, in returning home they were overtaken by certain foldiers, who forced them to play in the open field, and then left them without giving them a penny. "Moft of his companions would afterwards glory in this, but he was afhamed, and could never endure to hear of it."

By 1656, his record informs us, that "he had a genuine fkill in mufick, and frequented the weekly meetings of mufitians in the houfe of William Ellis, organift of St. John's college, fituated on that place whereon the theatre was built." Here he gives a lift of the ufual company that met and performed their parts on lutes and viols; among thefe eight were gentlemen. "The mufick-mafters were, William Ellis, bachelor of mufick, and owner of the houfe, who always played his part either on the organ or virginal. Dr. John Wilfon, the public profeffor, the beft at the lute in all England: he fometimes played on the lute, but moftly prefided (directed) the confort. —— Curteys, a lutenift, lately ejected from fome choire or cathedral church. Thomas Jackfon, a bafe-violift. Edward Low, then organift of Chrift church: he played only on the organ, fo when he played on that inftrument, Mr. Ellis would take up the counter-tenor viol, if any perfon were wanting to performe that part. Gervace Littleton *alias* Weftcot, or Weftcot *alias* Littleton, a violift. He was afterwards a finging-man of St. John's college. William Glexney, who had belonged to a choire before the war: he played well upon the bafe-viol, and fometimes fung his part. —— Proctor, a young man, and a new comer. John Packer, one of the univerfitie mufitians; but Mr. Low, a proud man, could not endure any common mufitian to come to the meeting, much lefs to play among them. Of this kind I muft rank John Hafelwood, an apothecary, a ftarched formal clifterpipe, who ufually played on the bafe-viol, and fometimes on the counter-tenor. He was very conceited of his fkill (though he had but little of it), and therefore would be ever and anon ready to take up a viol before his betters; which being obferved by all, they ufually called him Handlewood. The reft were but beginners. Proctor died foon after this time. He had been bred up by Mr. John Jenkins, the mirrour and wonder of his age for mufick, was excellent for the lyra-viol and divifion-viol, good at the treble-viol and violin, and all comprehended in a man of three or four-and-twenty yeares of age. He was much admired at the meetings, and exceedingly pitied by all the faculty for his lofs."

At this time Anthony Wood tells us, that "what by mufick, and rare books that he found in the public library, his life was a perfect *Elyfium*."

"Anthony Wood was now advifed to entertain one William James, a dancing-mafter, to inftruct him on the violin, who by fome was accounted excellent on that inftrument, and the rather becaufe, it was faid, that he had obtained his knowledge in dancing and mufick in France. He fpent in all half a yeare with him, and gained fome improvement; yet at length he found him not a compleat mafter of his facultie, as Griffith and Parker were not: and, to fay the truth, there was no compleat mafter in Oxon. for that inftrument, becaufe it had not been hitherto ufed in confort among gentlemen, only by common mufitians, who played but two parts. The gentlemen in private meetings, which Anthony Wood frequented, played three, four, and five parts with viols, as treble-viol, tenor, counter-tenor, and

bafe,

bafs, with an organ, virginal, or harpficon, joyned with them; and they efteemed a violin to be an inftrument only belonging to a common fidler, and could not endure that it fhould come among them, for feare of making their meetings to be vaine and fidling. But before the reftoration of king Charles II., and efpecially after, viols began to be out of fafhion, and only violins ufed, as treble violin, tenor, and bafe violin; and the king, according to the French mode, would have twenty-four violins playing before him, while he was at meales, as being more airie and brifk than viols."

"In the latter end of the yeare 1657, Davis Mell, the moft eminent violinift of London, and clock-maker, being in Oxon., Peter Pitt, William Bull, Kenelm Digby, and others of All Soules, as alfo Anthony Wood, did give a very handfome entertainment in the taverne called the 'Salutation.' The company did look on Mr. Mell to have a prodigious hand on the violin, and they thought that no perfon, as all in London did, could goe beyond him."

By connecting the fcattered fragments of this zealous Diletante's life, which concern mufic, we fhall be able to form an idea of the ftate of the art, not only at Oxford, but in every other part of the kingdom where it was more fecretly practifed during the latter part of the Ufurpation.

Under the year 1658, Anthony Wood tells us, that "he entertained two eminent mufitians of London, named John Gamble and Thomas Pratt, after they had entertained him with moft excellent mufick at the meeting-houfe of William Ellis. Gamble had obtained a great name among the people of Oxon. for his book of 'Ayres and Dialoges to be fung to the Theorbo, or Bafe-viol.' The other for feveral compofitions, which they played in their conforts."

He then gives an account of the arrival of Baltzar, a wonderful performer on the violin, from Lubec, arriving at Oxford, and deftroying, by his great fuperiority of hand, all the little vanities, not only of the beft fiddle-players of the univerfity, but of others from London, who had long enjoyed the reputation of great performers. See BALTZAR.

Anthony Wood purfues his mufical records, and tells us, that "all the time he could fpare from his beloved ftudies of Englifh hiftory, antiquities, heraldry, and genealogies, he fpent in the moft delightful facultie of mufick, inftrumental or vocal; and if he had miffed the weekly meetings in the houfe of William Ellis, he could not well enjoy himfelf all the week after. Of all or moft of the company, when he frequented that meeting, the names are fet downe under the year 1656. As for thofe that came in after, and were now performers, and with whom Anthony Wood frequently played, were thefe: Charles Perot, M.A. fellow of Oriel college, a well-bred gentleman, and a perfon of a fweet nature; Chriftopher Harrifon, M.A. fellow of Queen's college, a maggot-headed perfon, and humourous; Kenelm Digby, fellow of All Soule's college, he was afterwards Dr. of L., he was a violinift, and the two former violifts; William Bull, M.A. for the viol and violin; John Vincent, M.A. a violift; Sylvanus Taylor, fellow of All Soule's college, violift and fongfter, his elder brother, captain Silas Taylor, was a compofer of mufick, played and fung his parts; Henry Langley, M.A. a violift and fongfter; Samuel Woodford, M.A. a violift; Francis Parry, M.A. a violift and fongfter; Chriftopher Coward, and Henry Bridgman, both mafters of arts; Nathan Crew, M.A. a violinift and violift, but alwaies played out of tune, as having no good eare, he was afterwards bifhop of Durham; Matthew Hutton, M.A. an excellent violift; Thomas Ken of New college, afterwards bifhop of Bath and Wells, he would be fometimes among them and fing his part; Chriftopher Jefferyes, a junior ftudent of Chrift church, excellent at the organ and virginals, or harpficon, having been trained up to thofe inftruments by his father George Jefferyes, organift to king Charles I. at Oxon.; Richard Rhodes, another junior ftudent of Chrift church, a confident Weftmonafterian, a violinift to hold between his knees."

"Thefe did frequent the weekly meetings, and by the help of publick mafters of mufick, who were mixed with them, they were much improved. Narciffus Marfh would come fometimes among them, but feldom played, becaufe he had a weekly meeting in his chamber, where mafters of mufick would come, and fome of the company before-mentioned. When he became principal of St. Alban's hall, he tranflated the meeting thither, and there it continued, when that meeting at Mr. Ellis's houfe was given over, and fo it continued till he went over to Ireland, where he became afterwards archbifhop of Tuam.

"After his majefty's reftoration, when the mafters of mufick were reftored to their feveral places that they before had loft, or gotten other preferment, the weekly meetings at Mr. Ellis's houfe began to decay, becaufe they were only held up by fcholars who wanted directors and inftructors. So that thefe meetings were not continued above two or three yeares, and I think they did not go beyond 1662."

Our Oxford annalift terminates his account of the mufical tranfactions of that univerfity, during the interregnum, by the following anecdote.

"In October 1659, James Quin, M.A. and one of the fenior ftudents of Chrift church, a Middlefex man borne, but fon of Walter Quin, of Dublin, died in a crazed condition. Anthony Wood had fome acquaintance with him, and hath feveral times heard him fing with great admiration. His voice was a bafs, and he had a great command of it. 'Twas very ftrong and exceeding trouling, but he wanted fkill, and could fcarce fing in confort. He had been turned out of his ftudent's place by the vifitors; but being well acquainted with fome great men of thofe times, that loved mufick, they introduced him into the company of Oliver Cromwell, the protector, who loved a good voice and inftrumental mufick well. He heard him fing with very great delight, liquored him with fack, and in conclufion faid, 'Mr. Quin, you have done very well, what fhall I do for you?' To which Quin made anfwer with great compliments, of which he had command with a great grace, that 'your highnefs would be pleafed to reftore him to his ftudent's place;' which he did accordingly, and fo kept it to his dying day."

If this minute and indifcriminate antiquary and biographer is fometimes thought to want tafte and felection fufficient to give his records due weight, it muft be afcribed to the conftant habit he was in of journalizing, collecting anecdotes, and making memorandums of every perfon, tranfaction, and circumftance, that arrived at his knowledge, in the uncouth and antiquated language of his early youth. For this dialect being inelegant and vulgar, even when he learned it, renders his writings frequently ridiculous, though they contain fuch information as can be nowhere elfe obtained. But the few opportunities he had of knowing the gradual changes in our colloquial dialect, by converfing with men of the world, or even the language of elegant books by his favourite courfe of reading, degrade him to a level with writers infinitely his inferiors both in ufe and entertainment. An excellent apology has been made for his imperfections by the editor of his life, written by himfelf, and publifhed in 1772; which is fo interefting, that he muft be an incurious inquirer, indeed, who, having dipped into it, is not fufficiently fafcinated by the original fimplicity of the ftyle and importance

of

of many of the anecdotes, to give it an entire perufal before he lays it down. Anthony Wood was credulous, and perhaps too much an enthufiaft in mufic to fpeak of its effects with critical and philofophical precifion ; however, without his affiftance, the ftate of the art at Oxford, and the academical honours beftowed on its profeffors, as well as memorials of their lives and works, would have been difficult to find. Upon his decifions in matters of tafte, we are not always perhaps implicitly to rely. The high character he has given Dr. Wilfon's productions and abilities may have proceeded from want of experience, knowledge, and penetration into the finer parts of the art ; and as to Dr. Rogers, his judgment of him feems to have been manifeftly warped by friendfhip. Yet, upon the whole, it muft be allowed that it is only from fuch minute records as thofe of Anthony Wood that any true and fatisfactory knowledge can be acquired of the characters, manners, and domeftic occurrences of our anceftors. The great features of hiftory, and the events which occafion the ruin or profperity of a ftate, muft be nearly the fame in every age and country ; but comforts, conveniences, and the diftreffes of private life, furnifh the mind with reflections far more varied and interefting to the generality of mankind, than the rife of ftates or downfall of kings and heroes.

Wood, ——, a performer on the violin, who led the band many years at the theatre in Covent Garden, and father of —— Wood, his fucceffor in that orcheftra, organift of St. Giles's, and of Chelfea college. They were both active profeffors ; but though performers only of the fecond clafs, they conftantly ranked themfelves of the firft. Burney.

Wood, in *Vegetable Anatomy*, is that more or lefs hard and compact fubftance, which makes up the bulk of the trunk and branches of a tree or fhrub, and is concealed from view by the bark. When cut tranfverfely, the wood is found to confift of numerous concentric layers, very diftinct in the fir, and the trees of cold or temperate countries in general ; lefs fo in thofe appropriated to a tropical climate. The external part of each circular layer being much the moft hard and compact, often with fomewhat of a horny appearance, diftinguifhes the limits of each. Scarcely any two layers of the fame tree are precifely alike, in the proportion which this compact part bears to the reft ; nor does any one layer exhibit a precife uniformity of diameter in its whole circle. On the contrary, each layer is broader on that fide of a tree where the expofure has been moft favourable to its growth, where, confequently, there have been more branches and leaves, fo as to yield a greater depofit of woody matter. Hence the layers being all, for the moft part, broadeft on one fide of a tree, their aggregate difproportion throws the common centre, or pith, very much out of the actual centre of the trunk. It having been remarked in felling trees, that the greateft breadth of the concentric circles is very often on their fouth fide, a rule has been propofed for travellers to afcertain thereby the direction of the compafs. But travellers muft be ftrangely at a lofs, if they could find no eafier method of judging. Nor is the mode in queftion infallible. It would indeed fhew on which fide the growth of each particular tree had been moft favourable, whether from its expofure, or the nature of the foil which its roots had met with ; but this may not always be towards the fouth. We muft ftay to fell great part of a foreft, to form a precife opinion ; and the procefs would be, as it were,

"—— to tell what hour o' the day,
The clock did ftrike—by algebra."

The number of thefe concentric layers, in any tree, if it be found to the heart, very correctly demonftrates the number of years the trunk has been growing. This is a general opinion, and undoubtedly correct, provided the layers are well marked. The obferver muft be aware that each annual layer is compofed of a great number of thinner and fcarcely diftinguifhable ones, which occafionally affume a more confpicuous appearance than ufual, in confequence of fluctuating feafons, or any accidental checks in the growth of a tree, as hard winters render the outfide, or horny part, of each circle, more decided ; while favourable fummers make the circle itfelf altogether broader. But there is always a fufficient diftinction between fummer and winter, beyond the tropics, to eftablifh the above rule. Ever-greens, for the moft part, and trees of hot countries, exhibit flighter traces of thefe concentric layers ; but they may be difcerned in every mahogany table. Monocotyledonous plants have been faid to be entirely without any fuch annular ftructure. But there is no reafon why they fhould neceffarily be fo. Mr. Salifbury once demonftrated this ftructure to us in a *Dracæna ;* and its abfence in palms and ferns is to be attributed to a peculiar mode of depofiting wood in thefe plants, rather than to their being monocotyledonous. What has been faid already under the articles Circulation *of Sap*, and Cortex, will fufficiently explain this. As the inner furface of the bark depofits the matter of the wood, it muft lie in concentric circles ; and in proportion as this operation goes on more conftantly and uniformly, thefe layers muft be the more homogeneous and uninterrupted. Perennial roots of herbaceous plants often exhibit concentric circles, of annular formation, even in hot climates, as may be feen in Jalap. Each circle, no doubt, marks the increafe which has taken place in each fucceffive feafon ; and while the herb is not growing, nothing is added to the root.

The theory of vegetation, as explained in the articles juft cited, fhews the reafon of the fpiral-coated veffels being found in the young wood only, and not in the bark. Thofe veffels, formerly fuppofed to contain air alone, are the real arteries of the plant, and convey its fap, or blood, through the wood, to be returned through the bark, where it depofits particular fecretions. This theory alfo explains why the *alburnum*, as being the layer of unhardened wood for the prefent year, is tender, and even a mere jelly, at one period. But the bark is in the fpring of the year, before the depofit of wood begins, moft readily ftripped from the tree ; though it alfo readily, and without harm to the tree, comes off in winter, while vegetation is at a ftand.

We fcarcely need here detail the experiments of Du Hamel, to determine whether the wood forms the bark, or the reverfe. Thin metallic plates introduced between thefe two parts, and carefully bound up, fhewed, after a few feafons, when the branch thus treated was cut acrofs, that the bark had depofited layers of wood on the outfide of thefe foreign fubftances, with little or no prejudice to the growth of the plant. But Dr. Hope's experiment (fee Cortex) is ftill more ftrikingly decifive. The Linnæan hypothefis, that the pith added a layer every year to the wood internally, is thus entirely fet afide. Indeed nothing but a preconceived theory, of the great importance of the pith, and its analogy to the medullary or nervous fyftem of animals, (for the fupport of which opinion arguments are not wanting,) could have led to fo erroneous a conclufion. It is fufficient to remark, what indeed could not efcape the intelligent author of this hypothefis, that trees grow vigoroufly, though their heart is is become rotten by age, when the pith, with numerous adjoining layers of wood, have long ſince been obliterated.

A tranſverſe ſection of the wood of a tree diſplays various veſſels, and other parts, which microſcopic authors take delight in exhibiting; but, without a ſcientific explanation, little is to be learned from their plates, however beautiful to the eye. Siliceous petrifactions, of oak-wood eſpecially, fine ſpecimens of which are brought from Hungary, ſhew its vaſcular ſtructure in the greateſt perfection. In the ſections to which we have juſt alluded, the pith, with its highly cellular texture, makes a conſpicuous appearance in the centre. In the body of the wood, the ſap-veſſels are generally the largeſt and moſt numerous. Theſe, when young and tender, eaſily diſplay their ſpiral coats, if pulled aſunder longitudinally; but are not found at all in the bark. Among them, in the reſinous trees like the fir, or any that abound with ſecreted fluids, as the fig, much larger veſſels are interſperſed through the wood and bark, in which the peculiar ſecretions are lodged. But beſides the determinate and continued concentric layers of wood above-deſcribed, numerous thin plates are interſperſed, known to workmen, eſpecially in oak-wood, by the name of the SILVER GRAIN. (See that article.) Mr. Knight, who is there quoted, further remarks, that if a board of Engliſh oak be cut for a floor, in ſuch a direction, that the *laminæ* of the ſilver grain lie parallel with the ſurface of the board, it is rarely or never ſeen, when properly laid, to deviate from its true horizontal poſition. But a board ſawed, on the contrary, acroſs the ſilver grain, "will, during many years, be incapable of bearing changes of temperature, and of moiſture, without being warped; nor will the ſtrength of numerous nails be ſufficient entirely to prevent the inconvenience thence ariſing. That ſurface of a board of this kind which grew neareſt the centre of the tree, will always ſhew a tendency to become convex, and the oppoſite one concave, if placed in a ſituation where both ſides are equally expoſed to heat and moiſture." *Knight*, *Phil. Tranſ. for* 1801, 345. This writer adds, that the ſmall clefts in the ſurface of an oak-tree, ſtripped of its bark, and expoſed to the ſun and air, are cauſed by the plates of the ſilver grain having parted from each other. They will long continue to open and cloſe again with the changes of the weather. In the middle of a dry day they are open, but much leſs ſo during the night. After long expoſure to the air and light, wood loſes this property. *Knight* as above.

A different degree of hardneſs, and in ſome trees a remarkable difference of colour, exiſts between a number of the external concentric layers of the wood, and about as many or more of thoſe next the centre. Theſe latter are called the heart of the timber; the former the ſap or *alburnum;* but theſe are vulgar appellations, and the latter eſpecially are improper. The true *alburnum* is the layer of new unhardened wood of the preſent year, which alſo workmen often term the ſap. The SAP, properly ſo called, is the fluid from which all their ſecretions, and even the wood itſelf, are formed. (See that article.) Thoſe who uſe wood for mechanical purpoſes are well aware of the above difference between its different parts, however incorrect the names by which they are diſtinguiſhed. The ſofter external layers have little durability in compariſon with the heart. They retain more of the vital principle, and more of the peculiar juices of the plant in a fluctuating condition, liable to be acted upon by external or internal cauſes, and not yet united, in a fixed ſtate, to the ſolid body of the old wood. This change, however, is not limited in any particular kind of tree to a determinate period in the age of each layer of its wood, nor even to any determinate ſeries of the concentric circles of any individual tree. It often extends to a greater number of rings on one ſide than on another. The more vigour there is in a tree, or in any ſide or portion of its trunk, the ſooner is the *alburnum*, to uſe its popular denomination, made perfect wood, or heart.

The term wood, philoſophically ſpeaking, is not confined to the ſubſtance of a tree. The central part of a root, diſtinguiſhed from its bark, is the wood, and in many perennial roots conſiſts, as we have already mentioned, of ſeveral diſtinct layers. In a carrot, the yellow part is the wood, encompaſſed by a thick reddiſh bark. In a turnip, the woody part is of ample dimenſions, while the bark is thin.

A moſt remarkable difference exiſts between the ſolidity of the wood in ſome trees and in others. Some wood is ſo heavy as to ſink in water; ſome is as light as cork, or even lighter. In general, wood of different trees, of the ſame natural order, poſſeſſes ſimilar properties and the ſame degree of value. But there is often, in the ſame genus, a moſt remarkable difference between the fitneſs of the wood of different ſpecies, for particular purpoſes. The oaks (ſee QUERCUS) abundantly exemplify this fact. The very hard and ponderous timber of *Q. Ilex*, the live oak, however laſting in a dry ſituation, is ſo prone to deſtruction when expoſed to wet, as to be among the moſt worthleſs in the world; its hardineſs and heavineſs only rendering it the leſs fit for uſe, where it would be likely to endure. On the other hand, many of this genus afford timber more or leſs uſeful in every circumſtance and ſituation, among which our Engliſh *Q. Robur* ſtands pre-eminent. See TIMBER.

All kinds of wood are to be preſerved from the worm, and from many other occaſions of decay, by oily ſubſtances, particularly the eſſential oils of vegetables. Oil of ſpike is excellent, and oil of juniper, turpentine, or any other of this kind, will ſerve the purpoſe; theſe will preſerve tables, inſtruments, &c. from being eaten to pieces by theſe vermin, and linſeed-oil will ſerve in many caſes to the ſame purpoſe; probably nut-oil will do alſo, and this is a ſweeter oil, and a better varniſh for wood.

The ingenious Dr. Hales, whoſe attention was uniformly directed to ſchemes of domeſtic or national benefit, was induced by the great damage done to ſhipping by worms to propoſe various methods for preventing it. Oily, unctuous materials, he apprehends, are not likely to penetrate deep into oak, which has a watery ſap; but oil is known to penetrate far into fir, and to give it a very conſiderable degree of toughneſs. He therefore propoſes to mix with oil applied to the fir-boards with which ſhips are ſheathed ſome ingredient that is diſagreeable to the worms; and he apprehends that a ſmall proportion of verdigriſe uſed in the operation of paying would be of great ſervice: or if copper-filings were mixed with the paying, ſea-water would turn them into verdigriſe. It might be uſeful to ſoak planks in water ſtrongly impregnated with verdigriſe.

Mr. Reid recommends the trial of the acid juice of tar, prepared either with copperas or ochre, for preſerving ſhips either from rotting or worms.

In the Eaſt Indies, it is ſaid, they have an effectual way of preventing worms from deſtroying their ſhips, by paying them firſt with a mixture of muſtard, oil, and lime of ſhells, and hog's blood: they then ſheath the ſhip, and renew it after ſome years.

The following receipt has been recommended by a perſon who never knew it fail of ſucceſs. Take 100 lbs. of the fineſt

fineſt pitch ; melt it over a ſlow fire of coal, and add to it, when melted, 30 lbs. of rolled brimſtone groſsly bruiſed, and boil the whole till 30 lbs. are waſted. The matter thus prepared muſt be kept in caſks in a dry place ; and when it is to be uſed, melt 100 lbs. of it, and add gradually 35 lbs. of brick-duſt or marble-duſt, ſifted and well heated. The compoſition, when uſed, muſt be very hot, and the boards dry.

An ingenious ſhip-builder obſerves, that turpentine and brimſtone form the beſt compoſition he has met with, and comes home from a voyage with leaſt damage.

Eaſt India ſhips are firſt ſheathed, and that ſheathing is filled with ſmall broad-headed nails, which is a ſafe and effectual defence from the worms, and ſoon becomes a continued cake of ruſt, and not liable to be damaged by cables, or common accidents. See Pay and Ships.

The following, ſays Dr. Hales, is an approved method of preſerving the boards and timber of out-door work : *viz.* melt 6 lbs. of pitch, and add, by ſifting, 1 lb. of dried brown Spaniſh, or whiting, and a quart of linſeed oil. Hales's Ventilators, part i. p. 164. part ii. p. 289, &c.

Dr. Lewis obſerves, that though tar has been uſed for preſerving wood, and alſo for coating common tiles, in imitation of the black glazed tiles, which are ſold at a much higher price, both tar and pitch are of themſelves too ſoft for theſe intentions, being liable to be melted off by the ſummer heat : and, therefore, different powdery ſubſtances, as aſhes, ochres, and other mineral pigments, have been mixed with them.

In the Swediſh Tranſactions for 1740 and 1742, two compoſitions are recommended, which are ſaid to be firm, durable, and gloſſy. One is prepared by melting the tar over a gentle fire, ſo as to make it fluid, but not to boil, and ſtirring in as much coal-duſt or powdered charcoal as will render it thick : the other is prepared by mixing the melted tar with a ſufficient quantity of lamp-black. Coatings formed of theſe mixtures are, however, liable to be conſiderably ſoftened by the heat of the ſun. The mixture of powdered pit-coal and melted tar, made of ſuch a conſiſtence as to be freely ſpread while warm with a bruſh, is leſs liable to ſoften than either of the other two. The tar obtained from coal, in the method lately diſcovered by the earl of Dundonald, appears from various teſtimonies of thoſe who have tried it to be much better calculated to preſerve wood and iron, as well on land as in water, than vegetable tar. It has alſo this peculiar advantage, that it will not admit or harbour thoſe worms that are ſo injurious to the bottoms of ſhips at ſea. See an Account of the Qualities and Uſes of Coal and Coal-varniſh, &c. by the Earl of Dundonald, 8vo. 1785.

Mr. Parkes recommends, for the preſervation of wood, the tar which is obtained from the pyroligneous acid. See Tar.

Dr. Lewis obſerves, that the coating or painting of wood does not in all caſes contribute to its preſervation : unleſs the wood be very thoroughly dry, eſpecially thoſe kinds of wood whoſe juices are not oily or reſinous, the painting, by confining the watery ſap, haſtens the corruption. Com. Phil. Techn. p. 363, &c. On this ſubject, ſee Timber.

Some of the Weſt India trees afford a ſort of timber which, if it would anſwer in point of ſize, would have great advantages over any of the European wood, in ſhip-building for the merchant-ſervice, no worm ever touching this timber. The acajou, or tree which produces the caſhew-nut, is of this kind ; and there is a tree of Jamaica, known by the name of the *white-wood*, which has exactly the ſame property, and ſo have many other of their trees. Phil. Tranſ. N° 36.

To ſeaſon wood expeditiouſly for ſea-ſervice, it has been uſual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a deſideratum in the art of carving. He ſays he had been credibly informed of its having been practiſed at the Hague ; and ſuſpects that it might have been performed by ſome menſtruum that ſoftens the wood, and afterwards allows it to harden again, in the manner that tortoiſe-ſhell is moulded. Or, perhaps, by reducing the wood into a powder, and then uniting it into a maſs with ſtrong but thin glue. And he adds, that having mixed ſaw-duſt with a fine glue made of iſinglaſs, ſlightly ſtraining out what was ſuperfluous through a piece of linen, the remainder, formed into a ball and dried, became ſo hard as to rebound when thrown againſt the floor. Works abr. vol. i. p. 130. See Glue.

The people who work much in wood, and that about ſmall works, find a very ſurpriſing difference in it, according to the different ſeaſons at which the tree was cut down, and that not regularly the ſame in regard to all ſpecies, but different in regard to each. The button-mould makers find that the wood of the pear-tree, cut in ſummer, works tougheſt ; holly, on the contrary, works tougheſt when cut in winter ; box is melloweſt when it has been cut in ſummer, but hardeſt when cut about Eaſter ; hawthorn works mellow when cut about October, and the ſervice is always tough if cut in ſummer. Merret's Notes on Neri, p. 263.

It is a very well-known quality of metals to be longer and larger when hot, and ſhorter and ſmaller when cold ; a thouſand experiments prove this, and the books of experimental philoſophy have ſufficiently expatiated upon it ; on the contrary, it is found to be the property of wood, that it is longeſt in cold weather and ſhorteſt in hot ; this change is owing to the remains of the ſap yet in the wood, which being condenſed by cold, is enlarged in its ſurface, as all liquors are, when frozen into ice ; and ſhrinks into a leſs ſpace or bulk again, when liquated by heat.

It follows from this that all wood muſt change its ſurface more or leſs, according as it contains more or leſs ſap, and this may be made a teſt of great uſe for the determining what kinds of wood have moſt, and what leaſt ſap. This would be a very valuable piece of knowledge, ſince there are many uſes for which that ſort of wood muſt always ſerve beſt, which has the ſmalleſt quantity of ſap remaining in it. See Hygroscope.

Thus, in the great article of preſerving flour, no barrels are at preſent uſed but thoſe of ſeaſoned dry oak ; the whole advantage of this wood is, that it contains leſs ſap than others ; for the ſap in the wood makes the flour damp, and it then becomes rancid, and breeds worms. (See Meal.) So that if any other wood can by this means be found out to contain leſs ſap, when dried in the common way, than oak does, it will be ſo much the better for this purpoſe ; or, if a cheaper wood ſhould be found only to contain as little ſap as the oak, it would do as well, and the price of oak would be ſaved in theſe veſſels.

A proper way of trying when the ſap was ſufficiently exhaled out of trees, might alſo be found by this experiment, and much benefit would accrue from it ; for our ſhips, when made of timber not ſufficiently dried, prove injurious to the health of people on board ; and it has been remarked, both by the French and ourſelves, that many more men in general die in the firſt voyage of a new ſhip than in the ſame time in an old one ; and indeed the firſt ſix months are uſually obſerved

ſerved in this caſe to be moſt fatal. The exhalation of the ſap from the wood of the veſſel is certainly the occaſion of this, and if it could be contrived to have this ſap properly exhaled before the timber was uſed, it would not only prevent this mortality among the men, but the veſſel itſelf would be the ſounder and the better for it. Deſlandes, Trait. de Phyſ.

Woods are diſtinguiſhed into divers kinds, with regard to their natures, properties, virtues, and uſes. Of wood, conſidered according to its qualities, whether uſeful, curious, medicinal, &c. the principal is that called timber, uſed in building houſes, laying floors, roofs, machines, &c. See TIMBER.

Woods valued on account of their curioſity are, *cedar*, *ebony*, *mahogany*, *walnut-tree*, *box*, *calambo*, &c. which, by reaſon of their extraordinary hardneſs, agreeable ſmell, or beautiful poliſh or grain, are made into cabinets, tables, combs, beads, &c.

The *medicinal woods* are, *guaiac*, which the Spaniards call *ligno ſancto*; *aloes*, or *agallochum*; *ſaſſafras*, *nephriticum*, *ſantal*, *logwood*, *aſpalathum*, *eagle-wood*, or *pao d'aquilo*, &c.

Woods uſed in dyeing are, the *Indian wood*, *Braſil*, *Campeche*, &c.

In extracting the colouring-matter of dye-woods, and in making ſome other colours for the uſe of calico-printers, Mr. Parkes obſerves (Chem. Eſſ. vol. ii.), that it is of great conſequence to heat the veſſels by ſteam; for by this method of preparing decoctions, the workmen are prevented from ever giving the materials a greater heat than that of 212°; and the injury which was formerly done by the burning of the groſſer matters at the bottom and ſides of the copper is avoided. Several manufacturers, ſays this ingenious chemiſt, have now adopted this method. This leads us to take notice of a beneficial application of charcoal, as a ſlow conductor of caloric, for preſerving an equable temperature. Ground charcoal, it is ſaid, will conduct heat more ſlowly than even dry ſand, in the proportion, according to Guyton, of three to two. Accordingly, all thoſe veſſels which are heated by ſteam, if they were made double, and the ſpace between the inner and outer veſſel filled with ground charcoal, the heat would be ſo prevented from eſcaping, that any given temperature might be maintained for a long time, and thus there would be a material ſaving in the article of fuel. Moreover, when churches or other large buildings are to be warmed by ſteam, thoſe parts of the conducting-pipes which are not within the buildings ſhould be always ſurrounded in this manner, and then no heat could eſcape until it had been conveyed to the ſpace which it was intended to warm by it. Thus alſo in the manufactories of ſtarch, paper, gunpowder, blue, and a variety of other articles, every part of the apparatus for drying theſe by ſteam, and which is not actually within the drying-rooms, ought to be ſecured in the ſame way. The common ſteam-working apparatus, and other culinary utenſils, would be much improved by being fitted with double covers, and by filling up the intermediate ſpaces with carbonaceous matter. Moreover, by ſecuring the conducting-pipes in this manner, buildings might be effectually warmed, and proceſſes conducted at any diſtance from the boiler, as ſteam is the moſt faithful carrier of heat that can poſſibly be; for it cannot depoſit it on any bodies that have already acquired the temperature of 212°. It is alſo this non-conducting property of charcoal that renders it ſo common, ſays Fourcroy, cited by Parkes, in France as a material for coating furnaces, and for confining the heat, to which uſe its incombuſtible nature adapts it in a peculiar manner, as it is the moſt refractory body that is known, provided it be excluded from oxygen. Charcoal is applicable to other purpoſes in domeſtic economy; ſuch as the preſerving of animal food from taint, by covering it with a few pieces of freſh-burnt charcoal, and the recovery of it by boiling it for ſome minutes in water with a few ounces of ſuch charcoal. By the ſame means, molaſſes or treacle may be deprived of its diſagreeable taſte, ſo that it might be uſed inſtead of ſugar. A patent has likewiſe been taken out for refining ſugar by means of charcoal by M. Cronſtat, who required for it, of the joint body of ſugar-bakers in London, a remuneration of 50,000*l.*; and Mr. Parkes apprehends, that in a ſmall concern of this kind eſtabliſhed in the metropolis, which manufactures double loaves of a finer quality than thoſe of any other houſe, the purpoſe is effected by the ſame means. The empyreumatic flavour acquired by ſome brandies in diſtillation may be removed, ſays the ingenious writer now cited, by digeſting them in charcoal; and common malt-vinegar, boiled on charcoal, becomes colourleſs, without loſing its ſtrength. Water, which in long voyages acquires a diſagreeable taſte and ſmell from long ſtanding in the wooden caſks, may be purified by filtration through ground charcoal; or it may be kept ſweet in caſks that have been charred withinſide.

For the above-mentioned purpoſes, the charcoal ſhould be freſh made, or heated red-hot under a cover of ſand, immediately before it is uſed; and the requiſite quantity ſhould be previouſly aſcertained by experiment. In ſome caſes, it ſhould be uſed in the form of powder, having been pounded immediately from the fire, before it has been expoſed to the air, and the reſidue ſhould be preſerved for future uſe in bottles cloſely ſtopped. For other uſes to which charcoal is applied, ſee CHARCOAL and CARBON.

Wood uſed for fuel is required of various kinds, in regard to the various works to be performed by it.

Neri every where commends oak for the wood to be burnt in the glaſs-houſes, as the propereſt wood for making a ſtrong and durable fire with a good flame.

Imperato, on the contrary, commends aſh on the ſame occaſion; becauſe, as he ſays, it gives a ſubſtantial rather than a great flame: and Camerarius deſervedly commends juniper wood, as affording a laſting, ſtrong, and ſweet fire, could plenty of it be had. Among the ancients, Pliny commends light dry wood; and Plutarch, the tamariſk in particular, for making the glaſs-houſe fires; but glaſs-making requires ſo great a fire, as cannot be eaſily made from ſuch wood. Nor can aſh be proper, becauſe, though it gives a good fire, it ſoon decays. Merret's Notes on Neri, p. 275.

If wood be burnt in the open air, the greateſt part of it will be diſſipated in gas. Common oak, properly charred, will loſe only from $\frac{2}{3}$ds to $\frac{7}{10}$ths of its weight; whereas, if the ſame kind of wood be burnt in an open fire-place, the reſiduum of the combuſtion will not be more than about $\frac{1}{50}$th, or $\frac{1}{75}$th of the original weight of the wood employed. Dr. Watſon ſays, that he obtained 22 grains of charcoal from 96 of dry oak: others have given different reſults. From Neumann (Chem. vol. ii.) we learn, that for the reduction of the metallic oxyds, the charcoal of the heavier woods, *e. g.* that of the oak and beech, is preferable; and that, for common fuel, ſuch charcoal gives the greateſt heat, and requires the moſt plentiful ſupply of air to keep it burning, while thoſe of the lighter woods preſerve a glowing heat with a much leſs draught of air; and that for purpoſes which require a ſteady and ſtill fire, charcoal made from wood previouſly diveſted of its bark ſhould be employed, as it is the cortical part which crackles and flies off

off in ſparks during combuſtion, which the coal of the wood itſelf ſeldom does. The charcoal of wood is ſaid to be eſſential to the perfection of bar-iron; but when wood became ſcarce, and government reſtricted its uſe, cinders and coke were ſubſtituted for it; and thus the quality of Engliſh iron was ſo much debaſed, that Ruſſian and Swediſh iron, which is prepared by means of the coal of wood, are employed by thoſe who work in this metal. The ſuperiority of the iron made with charcoal is attributed by M. Haſſenfratz to its combination with potaſſium. It was by 1 Eliz. c. 15. that it was enacted, that no oak, beech, or aſh-timber, one foot ſquare at the ſtub, ſhould be converted into charcoal for making iron in any part of England or Wales, except in the county of Suſſex, the weald of Kent, and certain pariſhes in the county of Surrey. This reſtriction led to the practice of making bar-iron with the coke of pit-coal, the method of preparing which was kept a ſecret from the generality of the trade. When Mr. Henry Horne publiſhed his "Eſſays on Iron and Steel," in the year 1773, he gave directions for a better method than they had before known of charring pit-coal, ſo as to make it a proper ſuccedaneum for wood-charcoal in the manufacture of iron. Since that time the coke of pit-coal has come into very general uſe, ſo that the conſumption of this ſubſtance is now very conſiderable. (See Coke.) Crayons of charcoal are beſt made of the willow; whereas the coals of the hard woods, ſuch as box and guaiacum, are much harder than others, whilſt the charcoal of the kernels of fruits is quite ſoft and friable. As a pigment, the coal of ivory, or that which is procured by burning real ivory in cloſed veſſels, is the moſt intenſely black, and the moſt beautiful. The beſt charcoal for uſe as a powder for cleaning the teeth is made from the ſhell of the cocoa-nut. The difference between the charcoals of animal and vegetable ſubſtances may be determined by the following teſt. A vegetable coal will burn on a red-hot iron into white aſhes, which will be readily diſſolved by ſulphuric acid into a bitteriſh liquor; whilſt the aſhes of animal ſubſtances are little affected by that acid, and form with it a compound with a very different taſte. (See Ashes, Carbon, Charcoal, and Gun-*Powder*.) For the method of charring wood, ſee Timber and Charring *of Poſts*. This appears to have been a very ancient practice. The piles that formed the foundations of the Temple of Diana at Epheſus, not long ſince taken up, appeared to have been charred; and about fifty years ago ſome oak-ſtakes were found in the bed of the Thames in the very ſpot where Tacitus ſays that the Britons fixed a number of ſuch ſtakes, to prevent the paſſage of Cæſar's army; and theſe ſtakes, which were charred to a conſiderable depth, had completely retained their form, and were firm at the heart. About ſixty years ago one of the timbers that ſupported Trajan's bridge over the Danube, near Belgrade, was taken up, and the outer part, to the depth of half an inch, was found to be converted into an agate, the inner parts being ſlightly petrified, and the central being ſtill perfect wood, though this timber had been in the water 1700 years. (See Kirwan's Geological Eſſays, cited by Parkes in his Eſſays, vol. ii.) Many other inſtances occur of wood petrified and converted, more or leſs, into agates of various colours. Writers on this ſubject have recommended the practice of charring every piece of wood before it is placed in the ground. Dr. Watſon, (late biſhop of Landaff,) in his "Chemical Eſſays," vol. iii. ſuggeſts the propriety of charring all the wood that is uſed in mines and ſubterraneous drains, and particularly that which covers troughs, through which a current of water paſſes, and which rot in a few years by the alternate change of wet and dry. In this connection we may add, on the authority of Chaptal, in his "Chemiſtry applied to the Arts," that when old cheſnut and other trees are rotted within the trunk, and threatened with ſpeedy deſtruction by the progreſs of the carious trunk, it may be ſtopped by applying fire to the decayed part, ſo as to char the whole of the neighbouring ſurfaces.

Wood, in *Gardening*, is a term uſed to ſignify the ſhoots or branches left in fruit-trees. See Pruning, &c.

Wood, an epithet applied to various ſorts of weeds. See Weed.

Wood *and Bark of Trees*, *Canker or Eroſion of*, in *Agriculture* and *Gardening*, a diſeaſed ſtate in theſe parts of them. It has been ſtated by a late philoſophical writer, that the cauſe ſeems to be an exceſs of alkaline and earthy matter in the deſcending ſap, as he often found carbonate of lime on the edges of the canker in apple-trees; and that ulmin, which contains fixed alkali, is abundant in the canker of the elm. The old age of a tree, in this reſpect, is, it is thought, faintly analogous to the old age of animals, in which the ſecretions of ſolid bony matter are always in exceſs, and the tendency to oſſification great.

It is ſuggeſted, that perhaps the application of a weak acid to the diſeaſed part might be of uſe; or that where the tree is of great value, it might be watered occaſionally. See Canker.

Wood, *Lignin?* in *Chemiſtry*, the ſubſtance which conſtitutes the baſis of wood uſually ſo called.

To obtain this ſubſtance in a ſtate of purity, it is neceſſary to digeſt wood in a ſufficient quantity of water and afterwards of alcohol, by which means all foreign ſubſtances ſoluble in theſe fluids will be removed; the ſimple *woody fibre* will thus remain, which poſſeſſes the following properties.

It is compoſed, in general, of longitudinal fibres eaſily ſeparable from one another. Theſe fibres, when very much ſubdivided, become ſomewhat tranſparent. They have no ſmell nor taſte, and are not altered by expoſure to the atmoſphere.

The woody fibre is inſoluble in water and alcohol. It is ſoluble in a weak alkaline ſolution without being decompoſed, and may be again ſeparated by an acid. Concentrated alkaline ſolutions render it brown, and decompoſe it, eſpecially when aſſiſted by heat.

When heated it becomes black without melting, exhales ſtrong acrid fumes, and leaves a charcoal, retaining exactly the form of the original maſs. When diſtilled in cloſe veſſels it yields an acid liquor, of a peculiar taſte and ſmell, called the *pyroligneous acid*, and which was properly conſidered as a diſtinct acid. Fourcroy and Vauquelin, however, long ago demonſtrated, that it conſiſts of nothing but the acetic acid combined with an empyreumatic oil. (See Acetous and Pyroligneous *Acid*.) Pure acetic acid is now prepared from wood both in this country and France.

The fibre of different woods has been analyſed by Gay Luſſac and Thenard by means of the oxymuriate of potaſh. The following are the reſults:

	Oak.	Beech.	Mean.
Oxygen	41.78	42.73	42.25
Carbon -	52.53	51.45	52.00
Hydrogen	5.69	5.82	5.75
	100.00	100.00	100.00

Wood when burnt with a ſmothered flame leaves, as is well

well known, a quantity of charcoal behind. The following is the proportion yielded by one hundred parts of different woods, according to the experiments of Prouſt:

Black aſh - - -	25
Guaiacum - - -	24
Pine - - - -	20
Green oak - - -	20
Heart of oak - - -	19
Wild aſh - - -	17
White aſh - - -	17

Count Rumford, by continuing a very moderate fire for ninety-ſix hours, procured much larger proportions of charcoal from different woods than were obtained in the above experiments of Prouſt. According to this chemiſt, one hundred parts of different wood yielded,

Poplar - - -	43.57
Lime - - -	43.59
Fir - - - -	44.18
Maple - - -	42.23
Elm - - -	43.27
Oak - - -	43.00

The woody fibre, when completely burnt, always leaves a certain proportion of earthy and ſaline matters, which conſtitute the *aſhes* of wood. Different woods yield very different proportions of aſhes. See Ashes and Charcoal, where other experiments by Mr. Muſhet on this ſubject are related.

The following Table exhibits the quantity of aſhes left by different woods, according to Sauſſure junior. Sauſſure has extended the inveſtigation to herbaceous and other plants; but we have omitted theſe, from their not being immediately connected with the preſent ſubject. See Carbon.

Table of Incinerations.				Conſtituents of 100 Parts of Aſhes.					
Names of Plants.	Aſhes from 1000 Parts of the Plant.		Water from 1000 Parts of the Plant. Green.	Soluble Salts.	Earthy Phoſphates	Earthy Carbonates	Silica.	Metallic Oxyds.	Loſs.

See Dr. Thomſon's Syſtem of Chemiſtry, vol. iv. 5th edit.

Wood, *On making Bread from*. Profeſſor Autenrieth, of Tubingen, has lately attempted to make bread from wood, and his experiments ſeem to have been attended with conſiderable ſucceſs. He had been led to form the opinion that the woody fibre was only rendered unfit for food from the foreign ſubſtances uſually attached to it, and from its compact aggregation. The firſt of theſe difficulties he attempted to obviate, by ſelecting thoſe woods which have little taſte and ſmell, and which conſequently contain leſs foreign matters; ſuch, for example, are the birch and beech, eſpecially the birch, which was the wood he chiefly employed in his experiments.

To render wood alimentary, it is neceſſary to reduce it to a ſtate of extremely minute diviſion, or abſolute powder. It alſo requires the repeated action of the heat of an oven, by which means it is not only better fitted for being ground, but probably alſo undergoes ſome internal change which renders it more digeſtible, as is evidently the caſe in regard to coffee. Wood prepared in this way acquires the ſmell and taſte of corn-flour. It is, however, never white, but always yellowiſh. It alſo agrees with corn-flour in requiring the addition of ſome leaven, to enable it to undergo the fermentative proceſs, and the ſour leaven of corn-flour is found to anſwer the beſt. With this it makes a perfectly uniform and ſpongy bread, like common brown bread; and when it is thoroughly baked, and has much cruſt, it has a much better taſte of bread than what in times of ſcarcity is prepared of bran and huſks of corn.

To make wood-flour in perfection, the wood, after being thoroughly ſtripped of its bark, is to be ſawed tranſverſely into diſks of about an inch in diameter. The ſaw-duſt is to be preſerved, and the diſks to be beaten to fibres in a pounding-mill. The fibres and ſaw-duſt mixed together are next to be deprived of every thing harſh and bitter, and which is ſoluble in water, by boiling them in a large quantity of water when fuel is abundant, or by ſubjecting them for a longer time to the action of cold water, as by placing them in a rivulet, for example, encloſed in a ſack. The whole is then to be completely dried, either by the ſun or fire, and repeatedly ground in a flour-mill till it paſs through the boulting-cloth.

The ground wood is next to be baked into ſmall flat cakes, with water rendered ſlightly mucilaginous by the addition of ſome decoction of linſeed, or any other ſimilar ſubſtance. Profeſſor Autenrieth prefers marſh-mallow roots, of of which one ounce renders eighteen quarts of water fufficiently mucilaginous, and thefe ferve to form four pounds and a half of wood-flour into cakes. Thefe cakes are to be baked in an oven until they are quite dry, and become of a brownifh-yellow colour on the furface. After this they are to be broken to pieces, and again ground repeatedly, until the flour pafs through a fine boulting-cloth, and upon the finenefs of the flour does its fitnefs to make bread depend. The flour of a foft wood, fuch as birch, will be fufficiently prepared by the procefs as defcribed; but the flour of a hard wood will require the fteps of baking and grinding to be repeated.

That the wood thus prepared is altered in its nature and rendered foluble, is proved by the quantity of real ftarch that is obtained from it by the fame procefs, by which it is feparated from wheat-flour. If wood-flour tied up in fine linen be long kneaded in a veffel of water, the water is rendered milky, and depofits flowly a quantity of ftarch, which with boiling water forms a thick, tough, trembling, tenacious jelly, like that of wheat-ftarch, and it is only neceffary to fee this ftarch to be convinced that the wood-flour is foluble and nutritious. This ftarch cannot be afcribed to the mucilaginous matter added to the ground wood before it is baked, as the added mucilage does not amount to more than the one-hundred and forty-fifth part of the wood, whereas the wood-flour lofes about half its weight by the feparation of the ftarch. The refiduum left in the linen feems to be the woody fibres unchanged, which have not been ground fufficiently fine.

Wood-flour does not ferment fo readily as wheaten-flour; but profeffor Autenrieth found fifteen pounds of birch-wood flour, with three pounds of four wheat leaven, and two pounds of wheat-flour, mixed up with eight meafures of new-milk, yielded thirty-fix pounds of very good bread. The beft mode of preparing it was to mix up the five pounds of wheat leaven and flour with a portion of the wood-flour and milk to a preparatory dough; let it ftand for fome hours in a moderately warm place to rife, and then to knead in thoroughly the reft of the wood-flour and milk. This dough is rolled out into thin cakes, allowed to ftand in a warm place to rife for a longer time than wheat-flour requires, and laftly to be put into the oven and baked thoroughly.

Profeffor Autenrieth made many experiments upon animals, as well as upon himfelf and family, in order to afcertain the nutritious properties of wood-flour, in the various forms of foup, dumplings, cakes, &c.; and he found that it was not only very palatable in all thefe forms (efpecially when combined with milk or fome fatty fubftances), but alfo fufficiently nutritious, and that it did not diforder the digeftive organs, or apparently produce any other ill effects.

From thefe experiments, it is obvious, fays the writer from whom we have made thefe extracts, that in cafes of neceffity wood may be made to furnifh a confiderable quantity of nourifhment; but it is no lefs obvious, that the procefs is fo troublefome and expenfive, that it never can become an article of food, except where there is an abfolute fcarcity of provifions. On fuch occafions the labour is of very fecondary importance, and at any rate cannot be fo profitably applied as in procuring the means of fubfiftence.

In fome diftricts of Norway and Lapland, the bark of the fir is manufactured into a fpecies of bread, apparently much inferior in quality to the bread of wood-flour, and this with dried fifh and a little rein-deer tallow conftitute the chief articles of food among the lower claffes, during the protracted and rigorous winter of thefe inhofpitable climates. See Von Buch's Travels in Norway and Lapland.

Wood, *Diftillation of.* See Charcoal, Colour, Gun-*Powder*, Pyroligneous *Acid*, and Wood *fupra.*

Wood, *Tenacity and Strength of.* See Cohesion and Strength *of Materials.*

Wood *and Wood*, a term in fhip-building, implying that when a tree-nail, &c. is driven through, its point is directly even with the infide furface, whether plank or timber.

Wood, *Cord*, denotes wood for the fire, generally the branches or loppings of trees, piled up in order. See Cord.

Wood, *Foffil, Subterraneous.* There are divers places where wood is found under ground: fuppofed to have been overturned, and buried there from the time of the Deluge, or at fome other period.

Whole trees, or parts of them, are very frequently found buried in the earth, and that in different ftrata; fometimes in ftone, but more ufually in earth; and fometimes in fmall pieces loofe among gravel. Thefe, according to the time they have lain in the earth, or the matter they have lain among and in the way of, are found differently altered from their original ftate; fome of them having fuffered very little change, and others being fo highly impregnated with cryftalline, fparry, pyritical, or other extraneous matter, as to appear mere maffes of ftone or lumps of the common matter of the pyrites, &c. of the dimenfions, and more or lefs of the internal figure of the vegetable bodies, into the pores of which they have made their way.

The foffil wood, which we find at this day, may, according to thefe differences, be ranged into three kinds: 1. The lefs altered. 2. The pyritical. And, 3. The petrified.

Of the trees or parts of them lefs altered from their original ftate, the greateft ftore is found in digging to fmall depths in bogs, and among what is called peat or turf-earth, a fubftance ufed in many parts of the kingdom for fuel. In fome places there are whole trees fcarcely altered except in colour; the oaks in particular being ufually turned to a jetty black: the pines and firs remain as inflammable as ever, and often contain between the bark and wood a plain refin. Parts of trees have been alfo found unaltered in the ftrata of clay and loam, among gravel, and fometimes even in folid ftone. See *Foffil* Plants, and *Bog* Wood.

It is idle to imagine, that thefe have been thus buried either at the Creation, or, as many are fond of believing, at the univerfal Deluge: at the firft of thefe times the ftrata muft have been formed before trees were yet in being, and the peat wood is fo far from being of antediluvian date, that much of it is well known to have been growing within thefe three hundred years, in the very places where it is now found buried. See Morass.

The fubftances that are more altered are the larger and longer branches of trees found bedded in the ftrata of ftone, and partly affuming its nature; and the fhorter and fmaller branches found in pits of blue clay, which externally bear the refemblance of what they once were, but, having their pores filled with the matter of the common vitriolic pyrites, internally appear to be maffes of that matter.

The irregular maffes or fragments of wood are principally of oak, and moft ufually found among gravel, but varioufly altered by the infinuation of cryftalline and ftrong particles. Thefe make a beautiful figure when cut and polifhed, as they commonly keep the regular grain of the wood, and fhew the feveral circles which mark the different years growth. Thefe, according to the different matter which has filled their pores, affume various colours, and the appearance of the various foffils that have impregnated them. Of thefe fome pieces have been found with every pore filled

with

with pure pellucid cryſtal, and others in large maſſes, part of which is wholly petrified, and ſome mere ſtone, while the reſt is crumbly and unaltered wood.

All theſe pieces of petrified wood are uſually capable of a high and elegant poliſh. Hill.

Wood has been found in ſalt-mines, incloſed in a maſs of hard ſalt, and its pores filled with the matter of the ſalt in which it lay. Wood has likewiſe been found converted as it were into iron, or thoroughly impregnated with the particles of this metal. Act. Erud. ann. 1710.

Wood, *Petrified*. The opinions of the judicious part of the world have been very different in regard to the bodies preſerved in the cabinets of the curious, under the name of petrified wood; ſome affirming theſe bodies to have been only pebbles, or flints accidentally formed in this ſhape, and with veins reſembling thoſe of the wood; and others affirming with equal warmth, that they have been really wood, into which ſtony matter has been brought by water.

Many ſubſtances, it is certain, have been preſerved in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibroſe and fiſtular texture of the ſtriæ, and the veſtiges of the utriculi and tracheæ or air-veſſels are yet remaining, and the ſeveral circles yet viſible, which denoted the ſeveral years growth of the tree, none can deny ſuch ſubſtances to be real foſſil wood.

Many good arguments have been produced on both ſides the queſtion, but M. De la Hire has attempted to bring the diſpute to a certain concluſion, by means of ſome peculiarly happy ſpecimens, which were of the palm-tree petrified, found in the deſarts of Africa: theſe on comparing them with pieces of the palm-tree cut out of the recent wood, appeared to have every where the beautiful and regular veins of that wood, and left no room to doubt but that they certainly had been once the vegetating wood of that tree, though now converted into hard ſtone; the petrified pieces were perfect ſtone, in all its qualities; they had its hardneſs, its ſound when ſtruck upon, and were, as many other ſtones are, opake in ſome places, and tranſparent in others; they were found on weighing them to be often of the ſpecific gravity of recent pieces of the palm wood of the ſame dimenſions.

Father Duchat alſo, an author of unqueſtioned credit, affirms, from his own perſonal knowledge, that in the kingdom of Ava there is a river whoſe waters petrify recent wood into flint; and that he has often ſeen trees ſtanding in it, whoſe bottom part, ſo far as covered with the water, has been true flint, while all above was mere dry wood, and fit for firing. Mem. Acad. Par. 1692.

Wood, *Shining*. There are a great many things in which a piece of rotten wood that ſhines in the dark agrees with a burning coal; and there are alſo many things in which they differ. They agree in theſe particulars: 1. They have light reſiding in them, and are not like bodies which are only luminous according to the quantity of light which falls upon them from other bodies, and which they reflect. 2. Both ſhining wood and burning coals require the preſence of the air to keep them ſhining, and both require alſo an air of a conſiderable denſity; and both having been deprived of their ſhining quality by the pumping out of the air, will recover it again on the admitting of freſh air to them. 3. Both of them will eaſily be quenched by putting them into water, and many other liquors. And, 4. As a live coal will not be extinguiſhed by any coldneſs of the air, neither will the ſhining wood be deprived of its light on any additional coldneſs in that element.

However, they differ in the following particulars: 1. A burning coal is eaſily put out by compreſſion, the treading on it and ſqueezing it together readily diveſting it of its light; on the other hand, compreſſion or cruſhing of any kind ſeems not to have any effect upon the ſhining wood; its bruiſed parts ſhining as brightly as its entire ones. If a piece of this ſhining wood be ſqueezed between two glaſſes, this experiment will be moſt fairly tried; and in this caſe, though the contexture of the whole be evidently broken, and the parts ſeparated, the light is as ſtrong in them as while the piece was entire. 2. A burning coal extinguiſhed by the drawing out of the air will, after a few minutes, be irrecoverable, on the admiſſion of air in any manner; but, on the contrary, the ſhining wood, when thus extinguiſhed and kept extinct for half an hour, will be immediately re-kindled on admitting the air to it. 3. A live coal, included in a ſmall glaſs, will continue ſhining but a few minutes; but a piece of ſhining wood, in the ſame circumſtances, will continue bright for ſeveral days. 4. The coal, while it burns, ſends forth ſmoke and other exhalations; the rotten wood ſends out none, and conſequently a coal all the while that it is ſhining waſtes itſelf at a great rate; but the rotten wood does not waſte itſelf at all. And finally, the burning coal is actually and vehemently hot; the rotten wood, though it ſhines, is not ſo much as warm. Phil. Tranſ. N° 32.

The light of ſhining fleſh and fiſh, when putrefied, is wholly of the ſame nature with that of rotten wood, as to its dependence on the air for its ſplendour; and in the ſame manner loſes its light in the exhauſted receiver, and regains it on the admiſſion of the air into it again, in the ſame ſudden manner. Phil. Tranſ. N° 31. See Light, and Putrefaction.

Wood, *Bog*, or *Subterraneous*, a name given by the inhabitants of many parts of this kingdom to ſuch wood as is found buried in the earth in boggy places, and which is found hard and ſtrong at this time. See *Foſſil* Wood *ſupra*.

We have in the Philoſophical Tranſactions (N° 275. p. 983, &c.) an account of vaſt quantities of this ſort of wood found under ground in Hatfield Chace. Many of the roots and bodies of trees are found there; which are of all growths, and are moſtly ſuch trees as are the growth of our own ſoil, ſuch as oaks, firs, birch, beech, yew, holly, willow, aſh, and the like. The roots of all theſe trees ſtand in their natural poſitions as when growing, and ſtand as thick together as they could grow in a foreſt. The bodies are uſually broken off, and laid all along juſt by them.

The large trees are uſually found fallen in a north-eaſt direction, and the ſmaller ones lying all ways; the fir-tree or pitch-tree is more common than any other kind, and is found ſometimes of twenty, thirty, and thirty-five yards long, and ſo ſound and firm that many of them have been ſold to make maſts for ſhips. Oaks have been found of the ſame length, though wanting ſome yards of their natural tops; theſe have been ſold at ten or fifteen pounds a piece, and are as black as ebony, and very ſound and laſting in whatever ſervice they are put to. The aſh-trees do not preſerve their firmneſs in this manner, many of them are ſo ſoft that the workman's ſpade cuts through them; and when expoſed to the air, they uſually fall to pieces; but the willows, though a much ſofter wood than the aſh, preſerve their texture, and are found very ſtrong and firm. In ſome of the fir-trees it is very obſervable, that they have ſhot

out-

outſide branches after they were fallen, which have grown into large trees. Many of theſe foſſil-trees appear plainly to have been burnt; the fir-trees are particularly very common in this ſtate: and of theſe ſome are burnt quite through, others only on one ſide. Some of theſe alſo have been found with the plain marks of human work upon them; many with their branches chopt off, and their trunks cut into two or three pieces. Some ſquared and others in part cleft, and the wooden wedges uſed in cleaving them are ſtill found remaining in the cracks. Stones are found in ſome of them in the place of wooden wedges, but in none iron ones. The heads of axes are alſo ſometimes found; they are of a ſtrange form, and ſomewhat repreſent the ſacrificing axes of the ancients. Theſe are found at ſuch depths, that it is impoſſible they ſhould have ever been lodged there ſince the time of this place's being a foreſt; nor ever could have been found, but by means of the ground's being drained by a late invention. The general opinion as to theſe trees is, that they were buried in this manner at the time of the univerſal Deluge; but they are plainly of later origin as foſſils, the coins of ſome of the Roman emperors having been found buried under them.

The earth of bogs is not the only ſoil that preſerves theſe trees; for in the low parts of Lincolnſhire, between the towns of Burningham and Brumley, there are ſeveral large hills compoſed only of looſe ſand, and as this blows away there are continually diſcovered whole trees, or parts of trees, and particularly the roots and ſtumps of firs, and ſome other kinds, all with the marks of the axe upon them, and looking as freſh as if done but yeſterday. Under theſe hills, and in the bogs before-mentioned, not only the wood of the fir-tree, but its cones are found in immenſe number; many buſhels being often laid in a heap together. In cutting a drain for a river of a conſiderable depth, there were found at the very bottom ſeveral parcels of cut wood, in poles, beams, and the like; the head of an axe was alſo found ſomewhat reſembling the ancient battle-axe, and a coin of the Roman emperor Veſpaſian; but what was yet more remarkable was, that what they were now ſunk to ſeemed to be the original ſurface, the ground not being looſe, like all above it, but ſound and firm, and lying in ridges and furrows, with the evident marks of having formerly been ploughed. So that all the bog-earth above ſeems plainly to have been added ſince; and that the foſſil wood, ſuppoſed of antediluvian origin, is but of the time of the ancient Romans, or leſs than that.

All the bogs in this kingdom afford in like manner foſſil-trees; and not only thoſe, but other places, have at all times accidentally diſcovered them. Giraldus Cambrenſis tells us, that ſo long ſince as in king Henry the Second's time, the ſands on the ſhores of Pembrokeſhire were driven off by peculiar ſtorms and tempeſts, and that deep under thoſe ſands there were then diſcovered great numbers of the roots and bodies of trees in their natural poſtures; and many of theſe had the ſtrokes of the axe upon them, the marks at that time remaining as plain as when firſt made. Some of theſe reſembled ebony; and many other ſuch trees were diſcovered at Neugall in the ſame county, in the year 1590. Camden tells us of ſuch wood found in the bogs in Somerſetſhire, Cheſhire, Lancaſhire, Weſtmoreland, Yorkſhire, Staffordſhire, and Lincolnſhire; and ſince his time many other counties have been found to be as fruitful in it. Dr. Plot mentions them in many parts of his Hiſtory of Staffordſhire, and by their ſtanding in their natural poſtures, as to the roots at leaſt, properly concludes, that they certainly once grew there, and were not brought from elſewhere.

Dr. Leigh, in his Hiſtory of Lancaſhire, gives an account of the ſame ſort of trees found in the draining of the boggy lands at Martin-Meer; and determines them not to have been of the ancient date many pretend, in referring them to the Deluge.

He obſerves, that they are plainly of no older date than the time of the ſavage inhabitants of England, about the time of the Roman conqueſts; for in this place, beſide the roots and bodies of trees and their fruit, there were found eight canoes, or ſmall boats, ſuch as the wild inhabitants uſed at that time. And in another moor in the ſame county, a braſs kettle, with a ſmall mill-ſtone, and ſome beads of wrought amber. In the ſame place were alſo found ſeveral human bodies whole and entire, at leaſt to outward appearance, and the whole head of an hippopotamus, or river-horſe. This is perhaps the hardeſt thing to be accounted for of the whole ſet, as to its coming there. The boggy places in Angleſea, and the Iſle of Man, are all full of buried trees of the ſame kind; and the bogs of Ireland abound no leſs with them. England, and its adjacent iſlands, are not the only places where this buried wood is found; for Verſtegan tells us, that the moors in the Netherlands abound with them; they all lie north-eaſt, as our's do. Helmont alſo mentions the Peel there, a moraſs of eight or nine miles broad, which is full of them. The French naturaliſts tell us of foſſil-trees alſo in their country; and in Switzerland and Savoy; but all in the low grounds.

Ramazzini tells us, that in the territories of Modena, which are now a dry and fruitful country, yet in the time of the Cæſars were only a great lake, there are found at the depth of thirty, forty, and even fifty feet, the ſoil of a low marſhy country, with ſedges, water-graſs, and other marſh-weeds; and under this there lie the trunks of trees, and their roots ſtand near them in as natural a poſture as when growing. Many old coins of the Roman emperors are alſo found there; as alſo ſeveral buſts, wrought marble, and ſquared ſtones, evidently ſhewing the work of ſuch tools as the Romans have been known to uſe. Some of the trees in theſe places ſtand upright. See more on this ſubject under the article MORASS.

WOOD, *Cutting of.* See CUTTING.

WOOD, *Meaſure of.* See MEASURE.

WOOD, *Stack of.* See STACK.

WOOD, *Staining of.* See DYEING *of Wood*, &c.

Wood may be ſtained yellow, by bruſhing it over ſeveral times with the tincture of turmeric root, made by putting an ounce of the powdered root to a pint of ſpirit, and after it has ſtood ſome days, ſtraining off the tincture. A redder caſt may be given to the colour by adding a little dragon's blood. A cheaper, and leſs bright and ſtrong yellow may be given to wood by rubbing it over ſeveral times with the tincture of French berries, made boiling hot; and when the wood is dry, bruſhing it over with a weak alum-water uſed cold.

In order to render theſe ſtains more beautiful and durable, the wood ſhould be bruſhed after it is coloured, and then varniſhed with the ſeed-lac varniſh, or with three or four coats of ſhell-lac varniſh.

For a bright red ſtain for wood, make a ſtrong infuſion of Braſil in ſtale urine, or water impregnated with pearl-aſhes in the proportion of an ounce to a gallon; to a gallon of either of which add a pound of the Braſil wood. With this infuſion, after it has ſtood, with frequent ſtirring, two or three days, ſtrained and made boiling hot, bruſh the wood over till it appears ſtrongly coloured; and while it is wet, bruſh it over with alum-

 water

water made in the proportion of two ounces of alum to a quart of water.

For a lefs bright red, brufh over the wood with a tincture made by diffolving an ounce of dragon's blood in a pint of fpirit of wine.

For a pink or rofe red, add to a gallon of the above infufion of Brafil wood two ounces of pearl-afhes, and ufe it as before: obferving to brufh the wood over often with the alum-water. Thefe reds may be varnifhed as the yellows.

Wood may be ftained blue by means either of copper or indigo. The brighter blue may be obtained by brufhing a folution of copper (fee VERDITER), while hot, feveral times over the wood: and then brufhing a folution of pearl-afhes in the proportion of two ounces to a pint of water hot over the wood. It is ftained blue with indigo, by brufhing it with the indigo prepared with foap-lees as when ufed by the dyers, boiling hot; and then with a folution of white tartar or cream of tartar, made by boiling three ounces of either in a quart of water, brufhing over the wood plentifully before the tincture of indigo be quite dry. Thefe blues may be brufhed and varnifhed as the reds, if neceffary.

Wood may be ftained green by diffolving verdigrife in vinegar, or the cryftals of verdigrife in water, and with the hot folution brufhing over the wood till it be duly ftained.

A light red-brown mahogany colour may be given to wood by means of a decoction of madder and fuftic wood, ground in water, in the proportion of half a pound of madder and a quarter of a pound of fuftic to a gallon, or, inftead of the fuftic, an ounce of the yellow berries may be ufed. Brufh over the wood with this folution, while boiling hot, till the due colour be obtained. The fame effect may to a confiderable degree be produced by the tincture of dragon's blood and turmeric root, in fpirit of wine.

For the dark mahogany, take the infufion of madder as above, and fubftitute for the fuftic two ounces of logwood: and when the wood has been brufhed over feveral times, and is dry, brufh it over flightly with water in which pearl-afhes have been diffolved, in the proportion of about a quarter of an ounce to a quart. The wood, in the better kind of work, fhould be afterwards varnifhed with three or four coats of feed-lac varnifh; but for coarfe work, with the varnifh of refin and feed-lac, or they may be well rubbed over with drying oil.

Wood may be ftained purple by brufhing it over feveral times with a ftrong decoction of logwood and Brafil, made in the proportion of one pound of the logwood and a quarter of a pound of the Brafil, to a gallon of water, and boiled for one hour or more. Let the wood, well coloured, dry, and be then flightly paffed over by a folution of one drachm of pearl-afhes in a quart of water. A folution of gold in fpirit of falt or aqua regia will give a durable purple ftain to wood.

For a deep black the wood is brufhed over four or five times with a warm decoction of logwood, made as above without the Brafil, and afterwards as often with a decoction of galls, made by putting a quarter of a pound of powdered galls to two quarts of water, allowing it to dry thoroughly between the feveral applications of the liquors: thus prepared, it receives a fine deep black colour, from being wafhed over with a folution of vitriol in the proportion of two ounces to a quart: in the room of which fome ufe a folution of iron in vinegar, keeping the vinegar for this purpofe upon a quantity of the filings of the metal, and pouring off a little as it is wanted. A pretty good black is alfo obtained, more expeditioufly, by brufhing over the wood, firft with the logwood liquor, and afterwards with common ink.

A very fine black may be produced by brufhing the wood feveral times over with a folution of copper in aqua fortis, and afterwards with the decoction of logwood, repeated till the colour be of fufficient force, and the greennefs produced by the copper overcome. The blacks may be varnifhed as the other colours.

Where the ftains are defired to be very ftrong, as in the cafe of wood ufed for fineering, it is generally neceffary it fhould be foaked, and not brufhed; for which purpofe the wood may be cut into pieces of a proper thicknefs for inlaying. Lewis's Phil. Com. Techn. p. 97. 434. Handmaid to the Arts, vol. i. p. 508, &c.

WOOD, *Stealing of*. See LARCENY.

WOOD, *Engraving on*. See WOOD-ENGRAVING, *infra*.

WOOD, *Painting on*. See PAINTING.

WOOD, *Sculpture in*. See SCULPTURE.

WOOD, *Sylva*, in *Geography*, a multitude of trees, extended over a large continued tract of land, and propagated by nature, or without culture.

Many great woods only confift of trees of one kind. At Cape Verd, in Africa, are woods of orange and lemon trees; in Ceylon, are woods of cinnamon-trees; in the Molucca iflands, woods of clove-trees; in the iflands of Nero, Lontour, Lofgain, &c. woods of nutmeg-trees; in Brafil, woods of Brafil-trees, &c.; in Numidia, woods of date-trees; in Madagafcar, woods of tamarind-trees, &c.

WOOD-*Afhes*, in *Agriculture*, the afhes which are formed by burning wood.

The afhes of fome forts of wood, too, are found to be more powerful as a manure than thofe of others, as thofe from the afh and fome other fuch trees.

It is faid by fome that they are an excellent dreffing for improving cold wet pafture land; and that poor hungry paftures have been very profitably benefited by them, to near double their former value; that nothing equals them on low fpongy pafture land. Others, however, have tried them on grafs-lands with little or no effect.

The difference in the burning and forming of them may probably caufe this difference in the effects which they have on land.

WOOD-*Bound*, a term ufed to fignify fuch land as is encumbered with tall woody hedge-rows, fo as to prevent the free circulation of air and admiffion of the fun, by which the natural fertility and ftrength of it cannot be fully exerted or brought into action. See WOOD-*Land*.

WOOD-*Coppices*. In the firft raifing of coppices, two things are to be confidered; firft, the nature of the foil, that fuch trees may be planted in it as will thrive well there; and fecondly, the ufes that the wood is intended to be fold for, that fuch kinds may be planted as will be moft proper for thofe ufes.

If the principal vent for wood be for the fire, the beft trees for fire-wood muft be planted, fuch as the oak, beech, hornbeam, or other hard wood. Thefe are the moft profitable for felling as fire-wood, and one or more of thefe grow in any foil.

If there be a demand in the country where the coppice is to be planted for hoops and hop-poles, then the afh, the chefnut, the oak, alder, and hazel, are to be planted.

According

According to the profits of the underwood, the thicknefs of the ftandard-trees is to be regulated; for as they ftand more or lefs thick, they more or lefs injure the underwood. It is alfo to be confidered at what growth the underwood is to be fold. The taller and larger the underwood of a coppice in general is, the more profitable will it be for firing, and all other ufes, and the ftandards will be the better for its being left to grow to a proper height, for their bodies will be always, unlefs very great accidents occur, carried up ftraight as far as they are fhaded by the coppice-wood.

A deep foil makes the fhrubs as well as trees grow more vigoroufly than any other, and they will be fooner fit for cutting in fuch places. The perfon who owns thefe woods muft contrive to cut down only a certain quantity of them every year, and regulate this fo that he may have a conftant fucceffion of a like quantity; that part of the wood which was at firft felled, may be grown up to its fize for felling again by the time the laft is cut. This is, in different places, to be calculated to all the various numbers between eight years and twenty or thirty.

The cutting of wood feldom yields the more and the better timber; but the cutting of it oftener has greater advantages, in that it makes it grow thicker, and gives the feedlings time to come up. If many timber-trees grow in the coppice, and are to be cut down, they and the underwood fhould be felled together, cutting off the ftumps as clofe to the ground as may be, in the trees, and in the fhrubs and underwood the ftumps fhould be left about half a foot high, and cut flanting and very fmooth.

Sawing is the beft method of felling timber-trees; but it fometimes kills the root; and if this is obferved to be the cafe in the coppice, no new fhoots arifing from the root, then it is proper to ftub up the root, that it may not unneceffarily encumber the ground, and that the other young plants may have the benefit of it.

In the firft raifing of coppices from feed, the ground muft be prepared by good tillage, as much as if it were intended for corn. The feeds of the feveral trees are to be fown in February, and if the foil be fhallow, the ground fhould be ploughed into great ridges: this will make the foil lie the thicker upon the top of each ridge, by which means the roots will have more depth to run to for nourifhment, and in a few years the furrow will be filled up to the level of the reft with the dead leaves; and thefe, as they rot at the bottom, will make a kind of foil, through which the young fhoots will fpread, and be conducted from one ridge to another, and fo the whole ground will be occupied by them. If the coppice be to be raifed on the fide of a hill, plough the ridges crofs-way of the defcent of the hill, that the water may be detained among them, and not fuffered to run off, as it otherwife would by the furrows; but if it happen that the ground be over-wet, which is more rarely the cafe, then the contrary method is to be obferved, and the furrows ploughed deep and ftraight downwards, that all water may be carried off by them, as by fo many trenches or drains.

Some fow a crop of corn along with the feeds of the underwood, for the advantage of the firft year; but as the feafon of fowing the feeds of the trees is too late for the fowing of the corn, it feldom turns to much advantage. It is better to fow the trees alone, and keep them well weeded the two firft years; after which they are ftrong enough to take care of themfelves againft fuch enemies.

In very barren ground, where the young trees can hardly ftand the heat in fummer, it is proper, after fowing them, to fcatter a quantity of furze-feed over the land; the furze will grow quick, and over-top the trees at firft, but it will ferve as a guard to them at this time, defending them from injuries, and keeping the ground moift about their roots. In a few years the trees will grow up beyond thefe bufhes, and they will then foon deftroy them by their dropping.

In the raifing of coppices, the neareft diftance for the plantations ought to be five feet for the underwood, but as to what number, and fcantlings of timber are to be left on each acre, the ftatutes in this cafe direct; but it is an ordinary coppice, which will not afford three or four firfts, fourteen feconds, twelve thirds, and eight wavers, according to which proportion the fizes of young trees in coppices are to fucceed one another. In coppice or underwood felled at twenty-four years growth, there are to be left twelve ftore-oaks upon every acre, or, in defect of them, the fame number of elms, beech, or afh: thefe are to be ftraight-bodied trees, and are to be left till they are ten inches in diameter, at a yard from the ground; but it is better for the owner to have a much greater number of timber-trees, efpecially in places where underwood is cheap; and as to the felling, it is always neceffary to begin regularly with one fide, that the carriages, neceffary to the taking off the wood, may come on without injury to the reft: and in large woods, a cart-way fhould always be left in the middle, quite through the wood. The timber of the underwood may be cut from the month of October to February; but the laft month is much the beft, in places where there is but a fmall quantity to be felled, and it can all be got down before the fpring is too much advanced. All the wood fhould be carried out by Midfummer, and made up by April at the lateft; for when the rows and brufh lie longer than this unmade up, and unbound, many of the fhoots and feedlings are fpoiled by them. It is always worth the owner's while to inclofe the coppice well the winter before felling, to keep out the cattle, which would elfe greatly damage the fupply from the feedlings and young fhoots.

New-weaned calves are the leaft prejudicial to newly cut woods of any creatures, and may be put in where there is much grafs; the next in harmleffnefs to thefe are young colts, which, at about a year old, may be put in to feed in the fame manner; but about May they muft all be put out.

If the woods happen to be cropped by cattle, it is beft to cut them up, and they will make new fhoots; for that which has been bitten by the cattle will not grow for feveral years in any degree.

If the coppice-woods are too thin, this is to be remedied by laying down the longeft and fmalleft fhoots of thofe fhrubs or trees which are the moft advantageous, in the place, or of fuch as are neareft the bare place; thefe will each fend forth a great number of fuckers, and the whole wood will be thickened as much as defired in a very little time. Mortimer's Hufbandry, vol. ii. p. 64. See Coppice.

Wood, *Almiggim*. See Almiggim.

Wood *Anemone*. See Anemone.

Wood-*Bine*, or *Wood-bind*, in *Botany*, a fpecies of *lonicera;* which fee.

Wood-*Bind*, *Spanifh*, a fpecies of *ipomoea;* which fee.

Wood-*Chat*, in *Ornithology*, *lanius minor primus* of Aldrovandus, a fpecies of butcher-bird, wth a horn-coloured bill; the feathers at the bafe are whitifh; above is a black

black line drawn acrofs the eyes, and then downwards on each fide the neck; the head and hind part of the neck are of a bright bay; the upper part of the back dufky; the coverts of the tail grey; the fcapulars white; the coverts of the wings dufky; the quill-feathers black, having a white fpot at the bottom; the throat, breaft, and belly of a yellowifh-white; the legs black. In the female, the upper part of the head, neck, and body, are reddifh, ftriated tranfverfely with brown; the lower parts of the body are of a dirty white, rayed with brown; the tail of a reddifh-brown, marked near the end with dufky, and tipt with red. Pennant.

Wood-*Cock*, *Scolopax ruflicola* of Linnæus, called by other writers *la becaffe*, a well-known bird diftinguifhed by its fize, which is fomewhat fmaller than that of the partridge, and by its colour, which is on the back a variegation of black, grey, and a reddifh-brown; on the forehead the black predominates; the quill-feathers are dufky, indented with red marks; and on the belly a pale grey, variegated with tranfverfe ftreaks of brown. Its beak is three inches long, dufky toward the end, and reddifh at the bafe, and the upper chap a little longer than the under: the tongue flender, long, fharp, and hard at the point; the eyes large, and placed near the top of the head, that they may not be injured when the bird thrufts its bill into the ground: from the bill to the eyes is a black line; the forehead is a reddifh afh-colour; the chin is of a pale yellow; the tail confifts of twelve feathers, dufky or black on the one web, and marked with red on the other; the tips above are afh-coloured, below white: the legs and toes are livid, the latter divided almoft to their origin, baving only a very fmall web between the middle and interior toes.

Thefe birds, during fummer, are inhabitants of the Alps, Norway, Sweden, Polifh Pruffia, the Mark of Brandenburg, and the northern parts of Europe; whence they emigrate at the approach of winter into milder climates, where the ground is open and adapted to their manner of feeding. The time of their appearance and difappearance in Sweden coincides exactly with that of their retreat from and arrival in Great Britain. They live on worms and infects, which they fearch for with their long bills in foft ground and moift woods. They generally arrive here in flocks, taking advantage of the night or a mift; they foon feparate: but before they return to their native haunts, pair. They feed and fly by night; beginning their flight in the evening, and returning the fame way to their day-retreat.

They leave England the latter end of February, or beginning of March; though they have been known to continue here accidentally. In Cafewood, near Tunbridge, a few breed almoft annually. During incubation they are very tame. They come over to the coaft of Suffolk fparingly in the firft week of October, the greater number not arriving till the months of November and December, and always after fun-fet. They are determined in their flight by the wind, and arrive feparate and difperfed. When the red-wing appears on the coaft in autumn, the wood-cocks are at hand; and when the Royfton crow is arrived, they are come. Between the 12th and 25th of March they flock towards the coaft to be ready for their departure, having the red-wings for their harbingers in fpring, as in autumn. If the wind be favourable, they immediately depart; but otherwife, they are detained in the neighbouring woods, or among the ling and furze on the coaft: as foon as a fair wind fprings up, they are fuddenly gone.

In the fame manner they are known to quit France, Germany, and Italy; making the northern and cold fituations their general fummer rendezvous. In the winter they are found as far fouth as Smyrna and Aleppo, and alfo in Barbary; and fome have appeared as far fouth as Egypt, which feems to be the limit of their migration in that way. In Japan they are found very common. Thofe that refort into the countries of the Levant probably come from the defarts of Siberia or Tartary, or the cold mountains of Armenia.

Our fpecies of wood-cock is unknown in North America; but they have a fort of wood-cock refembling ours in its general appearance; about half its fize, and wanting the bars on the breaft and belly. Pennant.

They hate flying high, and they are afraid to fly among trees, becaufe, like the hare, they fee but very badly ftraight before them; and it is owing to this imperfection in their fight, that they are fo eafily taken in nets fpread in their places of refort.

The draw-net, in countries which are very woody, is extremely profitable in this fport, it being no uncommon thing to take ten or a dozen wood-cocks at a time in it.

There is another method of taking thefe birds in high woods, with thofe nets called *hays*, of the nature of the rabbit-hays, only with fmaller mefhes. The wood-cocks are to be driven into thefe, and there fhould always be at leaft two or three of them planted together. When the fportfman has provided himfelf with nets, he is to take five or fix perfons into the wood with him. The proper woods for this purpofe are thofe of feven or eight years' growth; and the people are to go into fome part of them near the middle. The nets or hays are to be placed in the fame manner as they are for taking of rabbits, but two or three joining together at the end, and hanging over flopewife that way which the wood-cocks are intended to be driven.

The nets being thus fixed, let the company go to the end of the wood, placing themfelves at about ten rods diftance from one another; they muft all have fticks in their hands, and they are to move forward flowly towards the nets, making a noife by ftriking the fticks againft the trees and branches, and by hallooing with their voices: in this manner they are to move up to the net; and the wood-cocks in that part of the wood will all be terrified before them, but will not take wing, but run along upon the ground, and thus be driven along like a drove of beafts, fo that when the company come up, they will find almoft all of them in the net. When that part of the wood is thus driven, the nets are to be turned the other way, and placed flopewife in the contrary direction, and the company retiring to the other end of the wood, are to drive the wood-cocks that are in that part with the fame noife, till they have fent them into the nets in the fame manner.

Thus all the wood-cocks in the wood may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is by means of noozes or fpringes.

The wood-cock and the fnipe are both eafily taken with bird-lime, when their places of refort are known, but they are not fo eafily found as many other birds.

The cuftom of the wood-cock is ufually to be upon the banks under hedges, and by the fides of ditches toward the fun; and they will fuffer the fportfmen to come nearer them in the day-time after a moon-fhiny night, than after a dark one. The reafon of which is, that having fed well by moon-light, they are only fit for reft the day following;

but

but when the night has been dark, they are feeking food all day long.

The fnipes naturally lie by the fides of rivers, when the plafhes and ponds are frozen, and they always lie with their heads up or down the ftream, never tranfverfely.

In order to take either of thefe birds by bird-lime, the fportfman muft be provided with a large number of fmall and fmooth twigs, neatly and evenly covered with good bird-lime. Thefe muft be placed floping, fome one way, fome another, and the whole place about where they refort muft be covered with them. The fportfman then muft conceal himfelf very carefully, that the fight of him may not frighten away the game. See Cock-*Road*.

Wood-*Cock Apple*, in *Rural Economy*, a fine cyder fruit. See Apple-*Tree*.

Wood-*Cock Shell*, a name given by the Englifh naturalifts to a peculiar kind of the purpura. It is called in French, *becaffe*, from the length of its beak. There are two fpecies of this, a prickly and a fmooth one.

The prickly kind is an extremely beautiful and elegant fhell. It is of a yellowifh colour; and its tail or beak (for the hinder extremity of the fhell, which runs out into an immoderate length, is fometimes called by the one, fometimes by the other of thefe names) is furnifhed with four rows of large and very long fpines: between the rows of thefe, there are alfo rows of fmall and fhort fpines. The body of the fhell is furrowed very deep, with a number of tranfverfe circular lines; and both this and the clavicle are befet with feveral rows of long fpines.

The fmooth becaffe, or wood-cock fhell, is a very elegant fpecies, but much lefs fo than the other. It is of a yellowifh colour, radiated with black and grey lines. It is all over deeply furrowed, and the ridges are befet with tubercles, the clavicle is elevated, and the tail extremely long, and hollowed into a fort of tube. The mouth of this, as well as of the other, is fmall and roundifh, and in this fpecies is of a light flefh-colour.

Wood-*Cock Soil*, in *Agriculture*, a term applied to fuch land as has the mould of a dapple-brownifh colour, and which is faid not to be of a good quality for many purpofes. See Soil.

Wood-*Corn* is a certain quantity of oats, or other grain, anciently given by cuftomary tenants to their lord, for the liberty to pick up dead or broken wood.

Wood-*Evil*, or *Cramp in the Legs*, a difeafe among fheep, which is fo named in confequence of its being fuppofed in general to arife from the drippings of trees in cold and wet weather. It fhews itfelf by feizing the legs of the fheep, and making them totally incapable of walking; and will fometimes all at once fpread through the whole flock.

In regard to the means of cure, a tea-fpoonful of the flour of muftard has been advifed to be given every night and morning. The affected parts fhould alfo be well rubbed with warm flannel, and the fheep be kept dry, which are very effectual aids. The ufe of a little oil of turpentine externally may often alfo be advantageous, where the other mode of rubbing does not fucceed: and in bad cafes the ufe of mild mercurials with opium may be had recourfe to with much benefit.

Wood-*Fuel, Saw for cutting of*, in *Rural Economy*, a tool ufed for this purpofe. On the continent they employ an improved inftrument of this kind, the iron part of which confifts of a faw, three inches in breadth, and fixteen inches in length, double toothed, in the manner of the gardener's pocket faw, and fixed in a frame of tough afh-wood, as below. The edge part of the faw is made broader than the back, in order that it may work more freely and with greater eafe.

The frame of the faw at the top part has a ftrong cord tied round each fide of it, fo as to tighten the faw and keep it from bending, being capable of being twifted tighter by a fmall thin piece of wood put between the double cord, and which may be kept from untwifting by being refted againft the crofs-bar in the upper part, which is mortifed and firmly faftened into the two fide pieces, being the only means that keeps the frame together in a fafe manner. The fide pieces are each twelve inches in length; and the additional length of the handle part of one of them five inches. It is evident that this faw will, on the principle of leffening friction, and of keeping the cutting part from bending, work with much greater facility and expedition than the common carpenter's faw.

With this wood-faw twice as much work may be done in a day as with the common hand-faw that is in general ufe in this country.

Wood-*Geld*, *Woodgeldum*, in our ancient cuftoms, the gathering or cutting of wood within the foreft. Or it may denote the money paid for the fame to the forefters. Sometimes it alfo feems to fignify an immunity from this payment, by the king's grant. Crompton fays exprefsly, it fignifies to be free from the payment of money for taking of wood in a foreft. See Geld.

Wood-*Hay*, an ancient cuftom at Exeter; by which a log out of every feam of wood brought over Ex-bridge is taken towards the reparation of that bridge. Antiq. of Exeter.

Wood-*Land*, in *Agriculture*, a term ufed by the farmers of many counties of England for a fort of foil, from its conftant humidity and dark colour, refembling the foil in woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and fun, together with the fall of leaves, deftroyed and wafhed to pieces by the wet.

This foil in the open countries has a confiderable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it fticks firmly to the ploughfhare, and in dry is very apt to crack. In uncultivated places it ufually produces rufhes and rufh-grafs. A moift and dripping year is extremely detrimental to this fort of land.

As to the clearing of wood-land in order to bring it into a ftate of cultivation and improvement, the firft ftep is that of properly digging out the roots of whatever forts they may be, after the wood has been cut off, to prepare the ground for the operation of the plough, without mixing the under ftratum of the land with the fertile furface mouldy layer of earth. The hollows and pits are then to be filled and levelled.

In fome inftances it may be beneficial to encourage and promote the fward and herbage by fowing over the furface fuitable grafs-feeds, after it has been broken and fpread over with the collected and decayed or burnt woody and leafy matters, ftocking the land hard with fheep, and mowing off occafionally the wood-fhoots that may arife; thus keeping the whole in a ftate of clofe pafturage, until the fmaller root parts that may have been left in the land become fufficiently decayed, to render them obedient to the plough, when the land may be broken up for corn. The ufe of lime and calcareous fubftances in mixture with thefe matters, or fpread alone over the land, would alfo ferve to encourage the finer forts of herbage, the delight of fheep; and, of courfe, induce them to eat the grafs more clofe,

and

and bring the land fooner into the ftate of a thick fet fward, the productive matrix of corn-crops.

Wood-*Lark*, in *Ornithology*. See *Wood*-Lark.

Wood-*Layer*, in *Agriculture*, a term ufed to fignify the young oak or other timber plants which are laid down into hedges, among the white thorn or other plants ufed in fences. See Hedge.

Wood *of Life*, in *Botany*. See Guaiacum.

Wood-*Lock*, in *Ship-Building*, a piece of elm, clofely fitted and fheathed with copper, in the throating or fcore of the pintle, near the load-water-line; fo that when the rudder is hung, and the wood-lock nailed in its place, it cannot rife, becaufe the latter butts againft the underfide of the brace and butt of the fcore.

Wood-*Loufe*. See Millepedes.

Wood-*Meil*, a coarfe, hairy kind of ftuff, made of Iceland wool, with which the fhip-carpenters, in fome of his majefty's yards, line the ports of fhips of war.

Wood-*Mite*, in *Natural Hiftory*, the name of a little animal frequently made the fubject of microfcopical obfervations, and by fome called the *wood-loufe;* though that lefs properly, as there is another larger animal generally known by that name.

The wood-mite is in fhape and colour very like a loufe, and is frequently found running very nimbly, but always by ftarts and jumps, on old books and rotten wood. The eyes of this creature are of a fine gold colour, and can be thruft out or drawn in at pleafure; and when examined by the microfcope the periftaltic motion of the guts is feen very diftinctly, and beautifully; and what is more wonderful, there is obferved a very diftinct and regular motion in the brain.

This probably is the fame animal with the pediculus pulfatorius, defcribed by Dr. Derham, as one of the death watches. Baker's Microfcope, p. 185.

Wood-*Men*, certain foreft-officers appointed to take care of the king's woods.

Wood-*Mote*, the ancient name of that foreft-court, now called the court of attachment.

Wood-*Pecker*, in *Ornithology*, the Englifh name of fome fpecies of picus.

The green wood-pecker, *picus viridis* of Linnæus, called alfo the rain-fowl and pluvialis avis, weighs about fix ounces and a half, is thirteen inches long, and twenty and a half broad; the bill is dufky, triangular, and near two inches long; the crown of the head is crimfon, fpotted with black; the eyes are furrounded with black, beneath which the males have a crimfon mark; the back, neck, and leffer coverts of the wings, are green; the rump of a pale yellow; the greater quill-feathers are dufky, fpotted on each fide with white; the tail confifts of ten ftiff feathers with black tips, and barred alternately with dufky and deep green; the whole hinder part of the body is of a very pale green; the thigh and vent are marked with dufky lines; the legs and feet all of a cinereous green.

The greater-fpotted wood-pecker, *picus major* of Linnæus, called alfo *witwall*, weighs two ounces three-fourths, is nine inches long, and fixteen broad; the bill is one inch and a quarter long, of a black horn colour; the irides are red; the forehead is of a pale buff colour; the crown of the head of a gloffy black; the hind part marked with a rich deep crimfon fpot; the cheeks white, bounded beneath by a black bar paffing from the corner of the mouth, and furrounding the hind part of the head; the neck is encircled with a black colour; the throat and breaft are of a yellowifh-white; the vent-feathers of a light crimfon; the back, rump, and coverts of the tail, and leffer coverts of the wings, are black; the fcapular feathers and coverts, adjoining to them, are white; the quill-feathers black, elegantly marked on each web with round white fpots: the four middle feathers of the tail are black; the next tipt with yellow; the bottom of the two outmoft black, the upper parts a dirty white; the exterior feather marked on each fide with two black fpots; the next with two on the inner web, and one on the other; the legs are of a lead colour. The female wants the crimfon fpot on the head. This fpecies is much more uncommon than the preceding; and keeps altogether in the woods.

The middle wood-pecker, or *picus medius* of Linnæus, agrees with the preceding in fize and colours, except that the crown of the head in this is of a rich crimfon; the crown of the head in the male of the former being black, and the crimfon in form of a bar on the hind part.

The leffer-fpotted wood-pecker, *picus minor* of Linnæus, is alfo called *hickwall*, and has all the characters and actions of the greater kind, but is more rare. Pennant.

Wood-*Pigeon*. See *Ring*-Dove.

Wood-*Plea Court*, is a court held twice a year in the foreft of Clun, in Shropfhire, for determining all matters relating to wood, and the feeding of cattle there. Perhaps it was originally the fame with wood-mote court.

Wood-*Pucerons*, in *Natural Hiftory*, a name given by M. Reaumur to a fmall fpecies of infect of the puceron kind, of a greyifh colour, and diftinguifhed by its two hollow horns on the hinder part of its body.

Thefe animals very much refemble, both in fhape and fize, the pucerons of the alder; but as thofe live always on the furface of the ftalk, thefe make their way deep into the wood of a tree.

M. Reaumur found large quantities of thefe lodged at a confiderable depth in the wood of fome elms, after they were cut down; the paffages, by which they had made their way in, were not to be found; but they were lodged in large and long holes, of the diameter of a goofe-quill, and running many inches along the tree in a longitudinal direction.

All the pucerons found in thofe places appear to be females, and none have wings; they all have vaft numbers of young ones of different degrees of maturity within them, and thefe may be forced out with preffing their bodies. Reaum. Hift. Infect. vol. vi.

Wood-*Roof*, or *Wood-ruffe*, in *Botany*. See Asperula.

The leaves and roots dried have been efteemed aperient and diuretic; and recommended in obftructions of the liver, and thence fuppofed efficacious in the jaundice: but they are now difufed.

Wood-*Sage*. See Sage.

Wood-*Soot*, in *Agriculture*, a fubftance of the foot kind, which has been found highly beneficial as a manure in cafes of cold clayey or ftiff loamy foils or lands, when in either the ftate of pafture or in that of tillage for grain, or other arable crops.

It is ftated to be ufed in thefe proportions on different forts of land. On light loams, when for pafture, from twenty-two to twenty-four bufhels on the acre; when for barley, from thirty-three to thirty-four; for turnips, from thirty-three to thirty-fix.

On chalky loams, when for pafture, from twenty-three to twenty-fix bufhels on the acre; when for turnips, from thirty-three to thirty-eight; for barley, from thirty-five to forty.

On ftrong loams, when for pafture, from twenty-two to twenty-

twenty-six bushels on the acre; when for artificial grasses, or green crops, from twenty-eight to thirty-four. See Soot and *Wood*-Soot.

Wood-*Sorrel*, in *Botany*. See *Wood*-Sorrel.

Wood-*Spite*, in *Ornithology*, an English name given by many to the common green wood-pecker.

Wood-*Wash*, in *Agriculture*, a name sometimes applied to dyer's-broom by farmers.

Wood, *Waxen*, in *Gardening*. See Genista.

Wood, in *Geography*, a county of Virginia, with 3036 inhabitants.

Wood *Creek*. See Preston's *Creek*.

Wood *Creek*, a river of New York, which runs into the Hudson, near Fort Edward.—Also, a river of New York, connected with the Mohawk by the canal at Rome, through which the navigation is extended into Oneida lake.—Also, a river of New York, which rises in Kingsbury, and runs N. by Port Anne village, into lake Champlain, at Whitehall landing, formerly Skenesborough.

Wood *Island*, a small island near the coast of Maine; 15 miles N.E. of Cape Porpoise. N. lat. 43° 26′. W. long. 70° 24′.

Wood *River*, a river of North America, which runs into the Mississippi, N. lat. 44°. W. long. 92° 25′.—Also, a river of North America, which runs into the Mississippi, N. lat. 38° 25′. W. long. 90° 58′.

WOODBERRY, a township of Pennsylvania, in the county of Huntingdon, with 1107 inhabitants.

WOODBRIDGE, a large and populous market-town in the hundred of Loes, and county of Suffolk, England, is situated on the banks of the river Deben, at the distance of 8 miles E.N.E. from Ipswich, and 77 miles N.E. by E. from London. It is said to have taken its name from a wooden bridge built over a hollow way to make a communication between two parks, separated by the road which leads towards Ipswich; and near the spot where this bridge is supposed to have stood is a house, which to this day retains the name of the Dry Bridge. But when it is considered that in ancient times this town was written Oddebruge, or, as in Domesday-book, Udebruge, it may with greater probability be supposed thence to have derived its present appellation. The principal streets in Woodbridge, one of which is nearly a mile in length, contain many good houses, and are well paved. The market-place is well-built, and in the centre of it is an ancient shire-hall, where the quarter sessions for the liberty of St. Ethelred are held; under which is the place for the corn-market. A weekly market, granted in the reign of Henry III., is held on Wednesdays, and here are two annual fairs. The only manufactures are those of sack-cloth and salt: but the commerce is of great importance. The Deben, which towards its mouth is called Woodbridge-haven, is navigable up to the town, which thereby carries on a very considerable traffic in corn, flour, malt, and various other articles, with London, Hull, Newcastle, and the continent: here are several docks for building vessels, with commodious wharfs and quays. In the population return of the year 1811, Woodbridge is stated to contain 702 houses, occupied by 4332 persons. The church, a spacious structure, is considered to have been built in the reign of Edward III. by John, lord Seagrave. It consists of a nave, chancel, and two side aisles, the roofs of which are supported by fourteen beautiful slender pillars. The exterior walls are of black flints, as is also a large quadrangular tower, 108 feet in height; near the top, the flint and stone are curiously intermixed in various devices. On the south side of the church formerly stood a priory for black canons of the Augustine order. At the dissolution the scite was granted by Henry VIII. to John Wingfield. After passing through several families, the estate was divided and sold, when the capital mansion, called the abbey or priory, was purchased by Francis Brooke, esq. of Ufford. The town contains meeting-houses for Independents, Quakers, and Methodists; also a free grammar-school for ten boys, sons of the poorer inhabitants of the town, who are to be instructed in Latin and Greek, and fitted for the university. Here is likewise an alms-house, worthy of particular notice, which was founded and endowed in 1587, under a patent of queen Elizabeth, by Thomas Seckford, esq. for thirteen men and three women. The endowment was an estate in Clerkenwell, London, then let for 112*l.* 13*s.* 4*d.*; but leased in 1767 for sixty years at 563*l. per annum*, clear of all charges. And as vast sums have been recently expended upon the estate, it may reasonably be supposed that a considerable advance will take place at the expiration of the lease. The governors are the master of the rolls and the chief justice of the common pleas, who are empowered to make such regulations as from time to time shall be necessary. By the last ordinances, the annual allowance to the residents in the alms-house was increased to 27*l.* for the principal or nominal governor, and 20*l.* to each of the other twelve poor men, besides wearing apparel, and a chaldron and half of coals. The three women are appointed as nurses and attendants on the men, and receive 12*l. per annum*, and clothing. The men wear a silver badge, with the Seckford arms, and are required to attend divine service at the parish-church on Sundays, Wednesdays, and Fridays, and all holidays.—Kirby's Suffolk Traveller, 8vo. 1764. Beauties of England and Wales, vol. xiv. Suffolk, by F. Shoberl.

Woodbridge, a town of New Jersey; 4 miles N. of Amboy.

Woodbridge, a township of Connecticut, in the county of New Haven, with 2030 inhabitants; 7 miles N.W. of New Haven.

WOODBURY, a town of the state of Connecticut, in the county of Lichfield, with 1963 inhabitants; 30 miles S.W. of Hartford.—Also, a town of the state of New Jersey, on the E. side of the Delaware; 9 miles S. of Philadelphia. N. lat. 39° 51′. W. long. 75° 15′.—Also, a town of Vermont, in the county of Caledonia, with 254 inhabitants; 20 miles N. of New Haven.—Also, a township of Pennsylvania, in the county of Bedford, with 1658 inhabitants.

WOODCHESTER, a parochial village in the hundred of Longtree, and county of Gloucester, England, is situated $2\frac{1}{2}$ miles S.W. from Stroud, $12\frac{1}{2}$ S. from Gloucester, and 104 W. by N. from London. In 1811 the number of houses in the parish was 162, and the inhabitants 845. By its name Woodchester indicates its having been originally a Roman station, and many Roman antiquities have been frequently discovered there, of which the most remarkable is a mosaic pavement, partially laid open by digging graves in the church-yard under which it lies. It appeared to have formed a square of 48 feet 10 inches; and for size and richness of ornament is certainly superior to any similar tessellated pavement hitherto discovered in Britain. The tesera were imbedded in a cement about 8 inches thick: and under all were flues crossing each other at right angles. Besides this curious work, others have been occasionally discovered at Woodchester: particularly in 1795 and 1796, the ground-plot of a very extensive Roman building was laid open, of which the remains in the church-yard formed the N. extremity, and the other parts extended under an adjoining orchard and field. The plan of this building comprised two

courts,

courts, which, with the great room, containing the principal pavement, ran through the middle, having numerous apartments of different dimenfions branching out from them. In three large rooms on the N. fide of the great or firft court were found fragments of columns, ftatues, and marbles. The fecond or inner court had galleries on three fides. The great mofaic pavement feemed to have belonged to the *cavaedium*, an interior court or hall, which communicated with feveral fuites of rooms. Various parts of the building appear to have belonged to the apartments allotted for baths, exercife, &c. That thefe remains were portions of a fplendid Roman villa is fcarcely to be doubted; and from their character the villa may have been the refidence of the proprætor, while Britain was fubject to Rome. Fragments of ftatues, pottery, ftags'-horns, glafs, and coins, have been found among the ruins. Of the coins, the oldeft was one of Hadrian, and the lateft of Valens. A dagger of iron, much corroded, two fpurs of the fame metal, a fmall brafs hatchet, a fibula, a key apparently of hardened clay, &c. were alfo difcovered. The manor of Woodchefter belongs to lord Ducie, who has a feat at Spring-park, in the parifh, now deferted. It is romantically fituated amidft fine woods. A full account of the Roman villa, with plates, has been publifhed by S. Lyfons, in imperial folio.

WOODCOCK, ——, in *Biography*, one of the Hereford waits, with a ftrong hand on the violin, fo famous in our youth for playing Vivaldi's Cuckoo concerto, that he was fent for far and near to perform it at country concerts. See VIVALDI.

WOODCUTTER's CREEK, in *Geography*, a river of Eaft Florida, which runs into the Atlantic, N. lat. 29° 57'. W. long. 81° 40'.

WOODEN, a town of Poland, in the palatinate of Lublin; 52 miles N. of Lublin.

WOODEN *Ball*, a fmall American ifland, near the coaft of Maine. N. lat. 43° 50'. W. long. 68° 40'.

WOODEN *Frames, for preferving and retarding the Bloffoms of Fruit-trees*, in *Gardening*, fuch as are contrived for the purpofe of protecting the bloffoms of them from the deftructive effects of fpring-frofts, &c. In this intention nets of different kinds, and fcreens of canvas rolled up in the day-time and let down at night, or in the time of heavy rains, have been moftly employed while the trees are in flower; but thefe frames are found to be fuperior, efpecially in expofed northern fituations. By means of thus retarding and defending the bloffoming of thefe forts of tender trees, until the frofts be chiefly over, much advantage is faid to be gained in the fetting of the fruit.

Thefe frames are conftructed in a fimple cheap manner; the revolving parts of which are covered with the branches of the filver fir, or thofe of fome other fuch tree, which are found to anfwer the purpofe very effectually; and when they are properly formed, they will open and fhut with the greateft eafe and expedition. They are in ufe from about the middle of February until towards the end of April, or later in fome cafes; being only opened as there may be a neceffity in the ftate of the bloffoms.

They have been employed with great fuccefs for peaches and apricots, and may be ufed for many other forts of tender fruit-trees.

In forming them, the upright pofts are made of wood, two inches fquare, and fourteen feet fix inches long, into which crofs-bars are mortifed; the poles ftanding fix feet afunder. The upper leaves, which open outward on their pivots, are made of inch-deal, by an inch and a quarter in breadth. There are fmall pieces of wood nailed on the infides of the upper and middle bars, to prevent the leaves of the frames from falling inward on the wall. The lower leaves of the frames, which open out above, in order to admit the rays of the fun to the lower parts of the wall, revolve on pivots. The bottom or low end of the frames ftand out two feet from the wall, and every other pole in them is fixed at the top, with an iron holdfaft immediately under the coping of it. The leaves of the frames are covered with branches of the filver fir, fo as to wholly occupy the vacant fpaces at the end, middle, and fides of them. The crofs-bars are made of inch and quarter wood, and of a breadth to correfpond with the upright poles into which they are mortifed. There are fmall wooden pins in the ends of the crofs-bars, to hold the frames tight when they are up. The fpace between the wall and the frames fhould have a fort of partition at every twelve feet, formed by the filver fir-branches, tied to the trees and every fecond pole, which will prevent a too free circulation of air along the wall, and preferve a degree of ferenity very effential to the fetting of the fruit.

Thefe frames may be found very beneficial in many open and expofed afpects of garden-grounds. See a paper on the fubject in the firft volume of the "Memoirs of the Caledonian Horticultural Society."

WOODEN *Saddle*. See PACK-*Saddle*.

WOODEN's *Ifland*, in *Geography*, a rocky iflet in the North Pacific ocean, on the S. coaft of King George III.'s Archipelago: fo called by captain Vancouver, from Ifaac Wooden, one of his crew, who fell overboard near it, and was drowned, a little to the eaft of Cape Ommaney.

WOOD-ENGRAVING, or *Xylography*, is the art of making fuch incifions and hollows, imitative of natural or ideal objects, at the will of the defigner, on a block or tablet of wood, as may afterward yield impreffions on paper, its furface being fupplied with printers'-ink in the manner of letter-types.

The wood of the apple or pear-tree, either of them occafionally, but more frequently the pear-tree, was ufed by thofe engravers of the European continent, who flourifhed during the 14th, 15th, and 16th centuries, and is believed to have been ufed for the fame purpofe, from a much earlier period, in China. The reafon of this preference is the fuperior compactnefs of the texture of thofe woods: but the wood of the box-tree has latterly—for the fame reafon, namely, becaufe it is yet more compact than the pear-tree in its grain, and harder in its fubftance—fuperfeded it; at leaft for the fmaller purpofes of fuch book-blocks as are intended to be combined in the letter-prefs, and printed at the fame operation with alphabetic types.

The inftruments ufed in this art are few and fimple; and are probably the fame now, with a few improvements of no great importance, that have been in ufe from the very commencement of the art: namely, *gravers*, more or lefs fquare or lozenge in their proportions, according to the breadth and depth of the lines required to be cut; *fcrapers*, of various fizes, both flat and round, but chiefly the latter; *knife-tools* and *fpit-fickers*, for the finer lines, pecks, or ftipplings; and *gouges*, for the broader and deeper hollows, which are intended to be left untouched by the ink and paper in the procefs of printing.

The defigns which formed the fubjects of the more ancient engravers in wood, confifted either of pure outlines, or very little more than outlines; the engraved blocks or tablets

tablets furnifhing merely the lineaments of the figures, &c. reprefented, and the colourift, or illuminift, (as he has fometimes been termed,) fupplying the reft. By degrees a few light hatchings were introduced, thinly fcattered upon the folds of the draperies, fhadows of the flefh, and other parts of the defign; and occafionally, when the opening of a door or a window, or the mouth of a cavern, was to be expreffed, the block was left untouched, that it might print black in fuch places, and thereby diminifh the tafk of the colourift. It was foon difcovered, that with little additional labour of the wood-engraver, much more might be accomplifhed. It was eafy to reprefent the bugbear figure of Lucifer with its appropriate blacknefs, and at the fame time to exprefs the internal markings of his body and limbs, by means of thin lines cut in the block, and which would be rendered white in the impreffion.

The ornamental borders which, in fome inftances, furrounded the devotional cuts of thofe times, were rendered more attractive to the eye, by the oppofition of broadifh white and black lines; and fometimes intermediate fpaces of greater extent were enlivened by large white dots cut out, or perhaps punched at equal diftances, on the block; or decorated with fprigs of foliage, or fmall flowers, relieved by a fimilar procefs, upon a black ground. Gradations of fhadow next began to be attempted in the figures and other parts of wood-engravings, by means of white dots, differing from each other in their magnitude and proximity according to the degree of fhade or darknefs required.

This mode of finifhing engravings in wood appears to have been practifed at Mentz, among other places, at an early period of the invention of typography, and was afterwards occafionally reforted to by the wood-engravers of other countries; efpecially thofe of Paris, where, at the clofe of the 15th and commencement of the 16th centuries, numerous fmall books of devotion were printed by Antoine Verrard, Simon Voftre, and others, in which the borders furrounding the pages were decorated by figures very delicately engraved, and relieved upon a black ground, fpecked over, with extreme nicety of workmanfhip, with minute white dots, fuch as have been defcribed.

Thefe innovations or improvements in the art of wood-engraving, were fuch as involved but little additional labour or difficulty in the execution; at the fame time, they were calculated to give to the decorations of books a fhewy effect: but the artifts of Germany, finding or fancying them to be incompatible with the purpofe of imitating by wood-cuts the appearance of their original defigns, the former and more fimple method was again reforted to.

It appears to have been at the earlier period of the art the practice of thofe mafters, who furnifhed defigns for the wood-engravers to work from, carefully to avoid all crofs-hatchings, which it is probable were by many perfons confidered as beyond the power of the xylographift to reprefent. Wolgemuth perceived that though it was difficult to effect crofs-hatchings, it was not impoffible; and in the cuts of the Nuremberg Chronicle,—the execution of which he doubtlefs fuperintended, befide furnifhing the defigns,—a fuccefsful attempt was firft made to imitate the bold hatchings of a pen-drawing, croffing each other, as occafion prompted the defigner, in various directions. To Wolgemuth belongs the praife of having been the firft who duly appreciated the powers of this art; and it is more than probable that he proved with his own hand, to the artifts who were employed under him, the practicability of the ftyle of workmanfhip that he required.

Engraving on wood now offered inducements to its practice, which had not before been contemplated. Albert Durer early applied himfelf to the ftudy and further advancement of an art which at once promifed to reward his labours with fame and fortune; and fo well had Nature qualified him for the tafk, that before the termination of the 15th century, he produced his feries of wood-cuts of the Apocalypfe; a work which it cannot be doubted was received throughout Europe with wonder and univerfal applaufe.

Mr. Bartfch ftrongly infifts that neither Durer, Schauflein, Burgmair, nor the other great defigners of the German fchool, who were contemporaneous, or nearly fo, ever engraved in wood themfelves; but that all they did was to furnifh the defigns, leaving the tafk of cutting them upon the tablets to the ordinary engravers in wood. Mr. Ottley is, however, perfuaded that this opinion is in a great meafure erroneous, notwithftanding the infcriptions which Bartfch refers to, written anciently upon the backs of fo many of the engraved tablets of the celebrated triumph of Maximilian, and other works defigned by Hans Burgmair, and recording the names of the individual wood-engravers who were employed to execute particular pieces of thofe extenfive undertakings.

One hundred and thirty-five of the folio tablets of Maximilian's triumph are ftill preferved in the imperial library at Vienna, where an edition of them was ftruck off in the year 1796. According to Bartfch, they were engraved from the defign (for the whole forms but one long proceffion) not of Albert Durer, as had formerly been fuppofed, but of Hans Burgmair, in 1516 and the three following years. The names of the different wood-engravers employed are written, fays Mr. Bartfch, upon the backs of feveral of the blocks, in the following manner. Upon N° 18. of the edition juft mentioned, "Der kert an die Ellend. hat Wilhalm gefchitten;" *i. e.* this block joins to that which reprefents the elks. It was engraved by William: and fo of the reft.

The names or initials of engravers found upon the backs of thefe extraordinary tablets are feventeen in number, and are as follow: 1. Jerome André, furnamed Refch, or Röfch (one of the moft eminent engravers of Nuremberg.) 2. Jan de Bonn. 3. Cornelius, (perhaps Cornelius de Bonn.) 4. Hans Frank. 5. Saint German. 6. Wilhelm. 7. Corneille Liefrink. 8. Wilhelm Liefrink. 9. Alexis Lindt. 10. Joffe de Negker. 11. Vincent Pfarkecher. 12. Jaques Rupp. 13. Hans Schaufelien. 14. Jan Taberith. 15. F. P. 16. A monogram, compofed of H. F. 17. W. R.

The imperial library likewife poffeffes an hundred and twenty-two blocks, engraved from the defigns of Burgmair, reprefenting the faints, male and female, of the family of Maximilian. One hundred and nineteen of thefe were republifhed in the year 1799; and upon the backs of the blocks were found the names of the eight following engravers on wood; *viz.* 1. Hans Frank. 2. Corneille Liefrink. 3. Alexis Lindt. 4. Joffe de Negker. 5. Wolfgang Refch. 6. Hans Taberith. 7. Wilhelm Taberith. And, 8. Nicholas Seeman. Probably no writer who has entered upon a critical examination of thefe early works has been fo well qualified to judge of them as Mr. Ottley: and that gentleman, while he admits that thefe infcriptions of names fufficiently prove that the great bulk of the numerous wood-cuts bearing the initials of Burgmair, were not cut upon the wooden blocks by his own hand; and that by parity of reafoning it might be fair to conclude the fame of a large proportion of thofe bearing the monograms or initials of Durer, and other eminent defigners; yet he can by no means perfuade himfelf that the abilities of the ordinary wood-engravers, who abounded in Germany at the

 clofe

close of the 15th century, could have been such as to render them in any material degree instrumental in bringing about that sudden and considerable improvement which took place in their art at that period. They had been accustomed to manufacture the barbarous wood-cuts used by the illuminists and venders of playing-cards, and were probably incapable of comprehending or appreciating those delicate, but free and masterly touches, which characterize the designs of a great and finished artist like Durer; and if so, wholly unqualified to represent them with any tolerable degree of fidelity. We may, therefore, readily believe that the numerous and flourishing school of wood-engravers, which we find spreading over Germany, and from thence to Italy, in the early part of the 16th century, owes its excellence to the great designers of that time; and especially to Albert Durer, who during his youth assiduously applied himself to the practice and improvement of the art, and afterward taught it to numerous pupils, who, already grounded in the principles of design, and working continually under the eye of their master, by degrees became qualified to assist him greatly in his numerous works of this kind. The intelligence, the delicacy, and the feeling, which we observe in the execution of most of the wood-cuts of Albert Durer, can only, Mr. Ottley thinks, be accounted for in this way; and the reader will probably admit that his opinion on the subject is not a little strengthened by the circumstance of Durer having been himself the publisher of all his chief works of this kind, more especially when added to the fact, that of the years 1509, 1510, and 1511, during which so large a proportion of his wood-engravings were executed, we have scarcely any thing by his hand engraved in copper.

The sudden and considerable improvement of which we have spoken, consisted of a superior style of execution, as well as of design. The meagre and miserable forms derived from the legends of superstition, and the Greek painters of the dark ages, began to give way to a clearer view of nature; and the few and scanty single-lined hatchings, which rather indicated than expressed shadow, were superseded by those bold courses of lines, as if hatched with a pen, and crossed with second and in some instances with third courses of lines, which Wolgemuth introduced, and Durer improved.

This mode of execution appeared to many persons so very difficult, and requiring so much more of pains and patient labour than they were warranted by other parts of these engravings in believing to have been bestowed on them, as to have excited considerable doubts whether the prints which contain these dark crossings were really impressed from wooden blocks. They were by some persons rather supposed to have been printed from casts, for which the engraved blocks served perhaps as matrixes; and a controversy hinging on this doubt has been for some time carried on by antiquarian inquirers, with sufficient boldness on both sides. The truth, however, could only remain with one party, and the subsequent production by Mr. Ottley, of some of the engraved blocks of wood themselves, either from the hands of Albert Durer, or those of his disciples, has proved that the dark crossings were actually delivered from wood, and settled the controversy, as far as respects that artist and his contemporaries, if not his successors.

The readers of our account of the German school of engraving, may have observed that ourselves were among the number of sceptics. As the truth was our object, we willingly confess our earlier mistake now that the fact is ascertained; and have too much respect for truth and the public to feel the least backwardness in recording it. Whether we flatter ourselves that we can afford this record out of the stock of our reputation, is for our private feelings. If from our expression of doubt, research in the right direction, and satisfactory ascertainment, have resulted, our scepticism has not been in vain; nor have we been in vain anxious to tell what we believed, as well as what we knew. Respecting the dark cross-hatchings which so frequently occur in the works of Albert Durer, Mr. Ottley's argument is conclusive: yet there are two things in his book on engraving, for which we cannot award to him the same approbation; and these are, his discontinuing his history precisely at the same epoch where Mr. Landseer had been obliged to break off a course of (published) lectures that are confessedly imperfect; and his mis-stating both the words and meaning of that writer, in the only place where he professes to have quoted him.

We shall next proceed to describe the modes of workmanship, or execution, which have prevailed among the more modern practitioners of the art; beginning with that which is in use for the more common or ordinary purposes, and following with those refinements of the art which are practised only by its superior professors. Our account will be followed by some anecdotes and remarks relative to the earlier history of the art, which we hope will prove in no small degree worthy of the notice of the connoisseur and print-collector.

Before the artist begins his engraving, the surface of the block or tablet which is to receive it, must, by means of an instrument termed a *scraper*, succeeding to a fine watch-spring saw, be made level, and sufficiently smooth for the reception of the design which is intended to be represented. Should this design be very simple in its nature, such as a small geometrical diagram, for example, being previously drawn on paper either with a black-lead pencil, or Indian ink, it is sometimes laid on an engraver's sand-bag, or other such hard cushion, and the block being carefully placed over it, a smart blow struck on the back of the block with a broad-faced hammer, will transfer the lines from the paper to the wood, in a manner sufficiently plain and accurate for such purposes, when by means of the gravers, gouges, scrapers, &c. which have been before mentioned, the engraver begins his work of incisions and hollows, scooping away the whole surface of the block, except the diagram, or other simple design required.

In other cases, the design to be engraven is either traced by passing a blunted steel-point over the outlines, the back of the drawing being rubbed with powdered red-chalk, or is sketched out with a black-lead pencil, and the different shades washed in with Indian ink, in the same manner as a chiaro-scuro drawing on paper. This method is used in making drawings for cuts to be introduced in common and cheap publications, in which a bold shewy effect is chiefly required. In engraving such drawings made on the wood, the artist renders the several forms and tints by incisions cut in the block; and the principle on which he proceeds may be readily conceived by recollecting (what we have alluded to in an earlier part of this article), that were the block to be printed before the engraver commenced his operations, it would yield merely a black spot: every incision therefore made in the block will produce the impression of a white line or hatching, and thus afford the means of introducing any portion of light that may be required. By the multiplication of these white lines or hatchings, the engraver lightens the tint at his pleasure; and by the various widths, thicknesses, crossings, and intertextures of the incisions thus made in the wood, not only the forms and various gradations of shadow from light to darkness, but also the textures or external

external characters of the various objects which may enter into the compoſition, may be very well repreſented.

Another mode of proceeding is occaſionally reſorted to in caſes where engravings of a ſuperior and more elaborate character are required, and which we have reaſon to believe was firſt practiſed in England by our countryman, Mr. John Thurſton. In theſe caſes, all the light and curious part of the deſign are hatched in, line by line, by the draftſman or deſigner himſelf, on the block, and which is performed either with a pen and Indian ink, after the manner of thoſe ancient artiſts of the German ſchool of whom we have treated, or elſe with the more modern and elegant inſtrument, a black-lead pencil. In ſome inſtances we have known the whole compoſition in all its details, both of light and obſcurity, thus finiſhed upon the wood in the moſt elaborate manner, before the engraver began his work of inciſion and ſcooping; but in moſt inſtances, the ſhadows and parts requiring leſs definition, and where the engraver may with more ſafety be left to the guidance of his own judgment, are merely waſhed in with a camel's-hair pencil and Indian ink, as in the foregoing method. Or elſe the deſigner uſes a black-lead pencil, with which he rubs or ſcumbles in the leſs important tints. And the drawing on the wood being thus prepared, the engraver proceeds with the manual and linear portion of it, by cutting away the interſtices between the pencilled or penned lines, as in the ancient manner, and the waſhed portion is treated in the modern method which we have deſcribed above.

Conſiderable ſkill on the part of the engraver is ſometimes requiſite in finiſhing the work, in order to unite and harmonize the whole, in which the deſigner's aid is not unfrequently required, who on a proof impreſſion taken for the purpoſe hatches and works, with a fine camel's-hair pencil and white paint, over the diſſonant parts, regulating at the ſame time the general effect, the drawing of the parts, and the ſtyle of execution. This touched-proof, viewed in the reverſing glaſs, is carefully copied by the engraver on his block, which concludes the proceſs.

There is, however, in the nature of things, no reaſon whatever why theſe two characters of engraver and deſigner may not exiſt united in the ſame individual; nor are the inſtances of ſuch union unfrequent in fact. Mr. Bewick, of Newcaſtle,—whoſe highly-enriched volumes of engravings of birds and quadrupeds, adorned with delightful vignettes, are maſter-pieces of the art, and have merited and found a place in almoſt every library,—poſſeſſes, with his xylographic powers, a fund of exquiſite humour, an originality of thought, and an accuracy of obſervation of the details of nature; together with an adequate talent of expreſſing thoſe obſervations, which are really as ſurpriſing as they are diverting and inſtructive.

We believe that this artiſt, or his deceaſed brother, was the firſt who adopted an expedient which the preſent writer has been informed was originally ſuggeſted by Mr. Bulmer, proprietor of the Shakſpeare printing-office,—that of lowering a little the ſurface of his engraving, by means of a very broad flat ſcraper, in thoſe parts where tenderneſs and delicacy of impreſſion were more peculiarly deſirable; a thing trivial in itſelf, yet of ſufficient importance in works that have pretenſions to be regarded as highly finiſhed, to have been ſubſequently imitated by moſt of the other engravers in wood. Among thoſe who in modern times have united in themſelves the characters of deſigners and wood-engravers, ſhould alſo be mentioned Mr. Clennell, who has executed ſome of his own energetic compoſitions in a vigorous and maſterly ſtyle, which few have been able to ſurpaſs.

Mr. Thurſton,—more verſed in all the technic varieties of linear practicability, and more accompliſhed in his academic powers of delineating the human form through all its gradations of action, character, and expreſſion, than any of his predeceſſors in the xylographic art,—in his habits of thought and ſtyle of deſign, is poetical, didactic, profound, allegoric, recondite, ideal. Of the profeſſors of imitative art, who have wiſely employed their talent to a moral purpoſe, few have improved and delighted us ſo much, or cauſed us to reflect ſo variouſly or ſo deeply. But though Mr. Thurſton has engraved very ſucceſsfully on copper, we believe that he has always entruſted his deſigns on wood to be executed by others, (ſome of them latterly by a ſon of promiſing talents,) and from the black-lead drawings of this artiſt, performed on the blocks themſelves, have been produced the beſt engravings of the London and Liverpool ſchools. We ſubjoin the names and monograms of the principal of thoſe artiſts who have been engaged in their execution:—T. Clennell, C. Neſbit, R. Branſton, J. Thompſon, H. F. P. Hole, W. Hughes.

By the two latter of theſe we have ſeen landſcape ſubjects of recent execution, which have excited in us no ſmall degree of admiration of their profeſſional powers. In a park-ſcene after Cuitt, engraved by Mr. Hughes, (who profeſſes to have ſtudied under Mr. Hole,) the trees more eſpecially,—which have been generally and juſtly regarded as objects more difficult to expreſs in this mode of art, than almoſt any other ſpecies of objects whatever,—are treated with a degree of looſeneſs, freedom, and local knowledge of the characters of their various foliage, and modes of branching and ramification, that we believe is quite unprecedented, and much more reſembling an etching on copper from the needle of Waterloo or Middiman, than any former production of the wood-engravers' art. And there has alſo very lately appeared a book, entitled "The Club," after the deſigns of Thurſton, which is not leſs excellent in its way. It conſiſts of twenty-four characteriſtic head-pieces of the ſeveral members of the club, a title-page repreſenting the club collectively, beſide various tail-piece vignettes, and impreſſes us with a depth of philoſophical penetration into the human character in all its varieties both natural and aſſumed; for here the nicer phyſiognomical traits which mark the leſſer diſcriminations between wit, humour, and ridicule, in their various modifications, are faithfully rendered: indeed with a degree of delicacy and fidelity which until now we had not conceived to lie within this province of art.

In wood-engravings, like the beſt of theſe modern productions which we have mentioned, there is more original feeling, more of the truth of nature, and the blandiſhments of art, than in all the dry, monkiſh, legendary rubbiſh put together, toward which the dealers in and writers on ſuch rarities (who are frequently the ſame perſons) are ſo very anxious to attract and retain the public attention, and which are ſo ardently ſought after by the wooden and would-be connoiſſeurs of the day.

Some few connoiſſeurs there are, neverthleſs, that with great ſenſibility to the beauties of meritorious works of this kind, collect alſo the early rarities of the art as curioſities, and as intereſting ſteps in tracing the march of European xylography, from its rude outſet towards its preſent attainments: but the idle occupation which ſo many expenſive books have ridiculouſly promoted, the affected exquiſiteneſs of regard for what is merely ſcarce, and which, if it were plentiful, would be juſtly eſteemed as mere rubbiſh, can ſcarcely be too ſeverely reprehended, when we obſerve that

by

by giving an erroneous direction to the public tafte, it operates as the very bane of modern merit, and of all principled encouragement of the art.

A man who collects thefe early rarities, and thefe only, may be pretty certainly pronounced to be a perfon of no intrinfic relifh for the productions of art, and by no remote analogy may be eafily perceived to be in the predicament of Rochefoucault's man of gravity, who affumes a myfterious carriage of the body to cover the defects of the mind.

Between the territories of Error and Truth, there is no neutral ground; neither can be made to recede without the other's advancing. Among the caufes that, concurrently with the above, have retarded the progrefs of the art of wood-engraving, indifferent and bad printing ought firft and chiefly to be mentioned; for this evil is feverely felt by all modern defigners and engravers on wood, (and, like moft other evils, by far the moft heavily by the beft,) the delicate parts of whofe moft elaborate performances are fo frequently marred by this operation.

The bad printing of wood-cuts generally proceeds from one or more of the following miftakes, to ufe the mildeft term that occurs to us: Printers being unable of themfelves to judge of the effect required in an impreffion; their being generally too much reftricted in price by the publifhing-bookfellers to afford the neceffary attention, even were they better informed; the falfe refpect exacted by opulence, which renders them too ignorantly proud to fubmit to the direction of artifts, who are generally poorer men than themfelves; with which caufe, prejudice in favour of old methods of practice is always ready to unite itfelf; the practice of over-damping Englifh, French, and even India paper. To which may be added the ufe of blanketing, and the neglecting to have the engravings properly made ready under the direction of the artift: all of which lead to the general corollary, or inference, that the engraver fhould always fuperintend the printing of his own works.

Wood-Engraving, *Origin and Ancient Hiftory of.* Father Du Halde adduces very fatisfactory reafons for our believing that the art of engraving on wood exifted and was practifed in China for feveral centuries before its appearance in Europe. Whether it is of Chinefe tranfplantation, or fpontaneous European growth; whether it was introduced by the Venetian traders and travellers to India, or was re-invented, as the baron Heinnekin fuppofes, in Germany, by the Briefmalers and Formfchnieders, who fabricated playing-cards, and the miferable legends of monkifh fuperftition; or whether it was not difcovered, as Papillon has afferted, at Ravenna, as early as the year 1285; have been examined with great critical attention, and at leaft as much perfeverance as the public will fympathize with, by the abbé Zani, Mr. Ottley, and others. To the works refpectively of the Italian abbé, and the Englifh hiftorian and connoiffeur, we refer thofe who may be defirous of obtaining more local and detailed information concerning the early curiofities of the art than belongs to the plan of our Cyclopædia. The ftory of the two Cunio, which they have repeated at great length from Papillon, and illuftrated by their own more profound knowledge of the fubject, is romantic in the extreme: fo much fo, that the antiquarian intereft which the reader may feel with us on the fcore of the curious wooden blocks from "the life of the great and magnanimous Macedonian king," merges in the chivalry and fine art, the poetic and pictoral fervour, and the tragic fate, of the twin brother and fifter, the ancient pride of Ravenna, and of the illuftrious houfe of Cunio.

Papillon relates, that when he was a young man, he "difcovered an epoch of engraving prints and characters on wood, certainly much more ancient than any hitherto known in Europe;" and the ftory of his difcovery is, that being employed about a century ago in papering a clofet for a Swifs captain of the name of De Greder, in the village of Bagneux, near Mont-Rouge, the captain, finding he poffeffed a tafte for fuch matters, fhewed him two or three very ancient volumes, and they converfed together concerning the prints contained in them, and the antiquity of engraving on wood. Papillon proceeds to give the defcription of the principal, *i. e.* the moft ancient, of thefe volumes, as follows:—Upon a cartouch, or frontifpiece, decorated with fanciful ornaments, and meafuring about nine inches in width by fix in height, with, at the top of it, the armorial bearings no doubt of the family of Cunio, are rudely engraven the following words, in bad Latin, or ancient Gothic Italian, with many abbreviations, which were rendered and explained to him by M. de Greder.

"*The heroic actions reprefented in figures, of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, prefented, and humbly offered to the moft holy father pope Honorius* IV., *the glory and fupport of the Church, and to our illuftrious and generous father and mother, by us, Aleffandro Alberico Cunio, cavaliere, and Ifabella Cunio, twin brother and fifter: firft reduced, imagined, and attempted to be executed in relief, with a fmall knife, on blocks of wood, made even and polifhed by this learned and dear fifter, continued and finifhed by us together, at Ravenna, from the eight pictures of our invention, painted fix times larger than here reprefented; engraved, explained by verfes, and thus marked upon the paper to perpetuate the number of them, and to enable us to prefent them to our relations and friends, in teftimony of gratitude, friendfhip, and affection. All this was done and finifhed by us when only fixteen years of age.*"

The cartouch mentioned above is enclofed in a fquare formed by a fimple black line, one-twelfth of an inch in thicknefs; a few light hatchings, irregularly placed, and executed without precifion, indicate the fhadows of the ornaments. "Immediately following this frontifpiece (fays Papillon) are the eight pictures, engraved in wood, of the fame dimenfions, and furrounded by a fimilar fillet: they have alfo a few faint hatchings, to indicate the fhadows. At the bottom of each of thefe prints, between the broad line or fillet which bounds the fubject, and another parallel line diftant from it about the breadth of a finger, are four Latin verfes engraved upon the block, which poetically explain the fubject; and above each is its title. The impreffions of all of them are of a grey tint, and fpotty; as if the paper had not been damped or wetted before it was laid upon the engraved blocks. The figures, which are paffable in refpect to their outlines, although of a femi-gothic tafte, are fufficiently well characterized and draped; one may perceive by them that in Italy the arts of defign were then beginning by degrees to experience melioration. The names of the principal perfonages reprefented are engraved under their figures, as Alexander, Philip, Darius, Campafpe, and others."

Papillon next defcribes the eight engravings feverally, which bear the names refpectively of the twins Alexander and Ifabel Cunio, and it would appear from his defcriptions that Ifabel was the fuperior artift of the two.

Upon the blank leaf which follows the laft print, badly written in old Swifs characters, and with ink fo pale as to be fcarcely legible, is the following memorandum.

"This precious book was given to my grandfather, Jan. Jacq. Turine, a native of Berne, by the illuftrious count di Cunio, magiftrate (podefta) of Imola, who honoured

noured him with his liberal friendſhip. Of all the books I poſſeſs, I eſteem it the moſt, on account of the quarter from whence it came into our family; and on account of the ſcience, the valour, the beauty of the amiable twins Cunio, and their noble and generous intention of thus gratifying their relatives and friends. Behold their ſingular and curious hiſtory in the manner in which it was ſeveral times related to me by my venerable father, and according to which I have cauſed it to be written more legibly than I myſelf could have done it." What follows is written in a better hand, and with blacker ink.

"The young and amiable Cunio, twin brother and ſiſter, were the firſt children of the ſon of the count di Cunio, which he had by a noble and beautiful Veroneſe lady, allied to the family of pope Honorius IV., when he was only a cardinal. This young nobleman had eſpouſed this young lady clandeſtinely, without the knowledge of the relations of either of them; who, when they diſcovered the affair by her pregnancy, cauſed the marriage to be annulled, and the prieſt who had married the two lovers to be baniſhed. The noble lady, fearing equally the anger of her father and that of the count di Cunio, took refuge in the houſe of one of her aunts, where ſhe was delivered of theſe twins. Nevertheleſs the count di Cunio, out of regard to his ſon, whom he obliged to eſpouſe another noble lady, permitted him to bring up theſe children in his houſe, which was done with every inſtruction and tenderneſs poſſible, as well on the part of the count as on that of his ſon's wife, who conceived ſuch an affection for Iſabella Cunio, that ſhe loved and cheriſhed her as if ſhe had been her own daughter; loving equally Aleſſandro Alberico Cunio her brother, who, like his ſiſter, was full of talent, and of a moſt amiable diſpoſition. Both of them made rapid advances in various ſciences, profiting by the inſtruction of their maſters; but eſpecially Iſabella, who, at thirteen years of age, was already conſidered as a prodigy; for ſhe perfectly underſtood and wrote Latin, compoſed verſes, had acquired a knowledge of geometry, was ſkilful in muſic, and played upon ſeveral inſtruments; moreover, ſhe was practiſed in drawing, and painted with taſte and delicacy. Her brother, urged on by emulation, endeavoured to equal her; often, however, acknowledging that he felt he could never attain to ſo high a degree of perfection. He himſelf was, nevertheleſs, one of the fineſt young men of Italy; he equalled his ſiſter in beauty of perſon, and poſſeſſed great courage, elevation of ſoul, and an uncommon degree of facility in acquiring and perfecting himſelf in whatever he applied to. Both of them conſtituted the delight of their parents, and they loved each other ſo perfectly, that the pleaſure or chagrin of the one or the other was divided between them. At fourteen years of age, this young gentleman could manage a horſe, was practiſed in the uſe of arms, and in all exerciſes proper for a young man of quality; he alſo underſtood Latin, and had conſiderable ſkill in painting.

"His father having, in conſequence of the troubles of Italy, taken up arms, was induced, by his repeated ſolicitations, to take him with him the ſame year, (*viz.* at the age of 14,) that under the eyes of his father he might make his firſt campaign. He was entruſted with the command of a ſquadron of twenty-five horſe; with which, for his firſt eſſay, he attacked, routed, and put to flight, after a vigorous reſiſtance, almoſt two hundred of the enemy; but his courage having carried him too far, he unexpectedly found himſelf ſurrounded by many of the fugitives; from whom, nevertheleſs, with a valour not to be equalled, he ſucceeded in diſengaging himſelf, without ſuſtaining any other injury than that of a wound in his left arm. His father, who had flown to his ſuccour, found him returning with one of the ſtandards of the enemy, with which he had bound up his wound: he embraced him, full of delight at his glorious achievement, and at the ſame time, as his ſon's wound was not conſiderable, and as he was deſirous to reward ſuch great bravery upon the ſpot, he ſolemnly made him a knight, (*i. e.* a knight-banneret,) although he was already one by his birth; dubbing him in the ſame place where he had given ſuch proofs of his extraordinary valour. The young man was ſo tranſported with joy at this honour conferred on him in the preſence of the troops commanded by his father, (who, in conſequence of the death of *his* father, which had recently happened, was now become the count di Cunio,) that, wounded as he was, he inſtantly demanded permiſſion to go and ſee his mother, that he might inform her of the glory and of the honour which he had juſt acquired; which was granted by the count the more readily, as he was glad to have this opportunity of teſtifying to that noble and afflicted lady (who had always remained with her aunt a few miles from Ravenna) the love and eſteem which he ever continued to entertain for her; of which he certainly would have given more ſolid proofs, by re-eſtabliſhing their marriage, and publicly eſpouſing her, had he not felt it his duty to cheriſh the wife his father had obliged him to marry, by whom he had ſeveral children.

"The young knight, therefore, immediately ſet out, eſcorted by the remains of his troop, out of which he had eight or ten men killed or wounded. With this equipage, and theſe attendants, who bore teſtimony to his valour wherever he paſſed, he arrived at the reſidence of his mother, with whom he ſtaid two days; after which he repaired to Ravenna, to ſhew a ſimilar mark of reſpect to the wife of his father, who was ſo charmed by his noble actions, as well as by his attentions towards her, that ſhe herſelf led him by the hand to the apartment of the amiable Iſabella, who, ſeeing him with his arm bound up, was at firſt alarmed. He remained a few days in that city; but impatient to return to his father, that he might have an opportunity of diſtinguiſhing himſelf by new exploits, he ſet off before his wound was yet healed. The count reprimanded him for not having ſent back his troop, and for not remaining at Ravenna till he was cured, and would not permit him to ſerve again during the reſt of the campaign: ſhortly after, when his arm was perfectly healed, he ſent him home, ſaying to him pleaſantly, that he did not chooſe to be outdone by him all the remaining time the troops would continue in action that year. It was ſoon after this that Iſabella and he began to compoſe and execute the pictures of the actions of Alexander. He made a ſecond campaign with his father, after which he again worked upon theſe pictures, conjointly with Iſabella, who applied herſelf to reduce them, and to engrave them on blocks of wood. After they had finiſhed and printed theſe pieces, and preſented them to pope Honorius, and to their other relations and friends, the cavalier joined the army for the fourth time, accompanied by a young nobleman, one of his friends, called Pandulfio; who, enamoured of the lovely Iſabella, was deſirous to ſignalize himſelf, that he might become more worthy of her hand before he eſpouſed her. But this laſt campaign was fatal to the cavalier Cunio: he fell, covered with wounds, by the ſide of his friend, who, whilſt attempting to defend him, was alſo dangerouſly wounded. Iſabella was ſo much affected by the death of her brother, which happened when he was not yet nineteen, that ſhe determined never to marry: ſhe languiſhed and died, when ſhe had ſcarcely completed her twentieth year. The death of this beautiful and learned young lady was followed by that of her lover, who had always hoped that his attentions and affections towards her would be rewarded by her conſent at length to become his,

and

and alfo by that of her mother, who could not furvive the lofs of her beloved children. The count di Cunio, who had been deeply afflicted by the death of his fon, could fcarcely fupport that of his daughter. Even the countefs di Cunio, who loved Ifabella with great tendernefs, fell ill of grief for her lofs; and would have funk under it, had fhe not been fupported by the manly fortitude of the count. Happily the health of the countefs was, by degrees, re-eftablifhed. Some years afterwards, the generous count di Cunio gave this copy of the actions of Alexander, bound, as it now is, to my grandfather; and I have caufed the leaves of paper to be inferted, upon which, by my orders, this hiftory was written."

From the name of pope Honorius IV. being engraved on the frontifpiece of thefe ancient prints, it is certain that this precious monument of the art of engraving on wood was executed between the years 1284 and 1286; becaufe that pope governed the church only for the fpace of two years, ending in April 1287. The epoch, therefore, of this ancient fpecimen of engraving, is anterior to all the books printed in Europe that have been hitherto known. Papillon adds, that it is very probable that the copy of the work, which is recorded to have been prefented to pope Honorius, may very poffibly be preferved in the library of the Vatican.

The baron Heinnekin and our countryman Strutt diftruft the truth of this ftory of the twins and their ancient work; but the latter has let efcape that he read the original French with hafty inattention, and the former, after offering his objections, is compelled to add, "ftill there muft be fomething true in Papillon's account; for, from my knowledge of his character, and his manner when I converfed with him, I am firmly perfuaded that he did not invent that which he told me."

On the other hand, Zani confeffes his entire belief of the account of Papillon, finding in it, as he ftates, "every mark of truth:" and Mr. Ottley conclufively adds, that "Papillon from his infancy had begun to collect materials for illuftrating the hiftory of his favourite art, of which, as is well known, he became a profeffor of fome eminence, having been inftructed in it by his father, who was alfo an engraver on wood. This practical experience combined with refearch could not but give him great advantages, and render him the lefs liable to be deceived in his decifions.

"His remarks, indeed, are thofe of a man well accuftomed to examine ancient prints. The blocks, he fays, appear to have been printed by means of the preffure or friction of the hand, with a light tint of Indigo in diftemper; he defcribes the impreffions to be granulous in fome places, as if the paper had been applied to the engraved block without being firft damped. Now, it is well known that many of the very early wood-prints were printed without any mixture of oil in the colours ufed for the purpofe; and there is good reafon alfo to believe that the paper was often applied in its dry ftate. The obfervations of Papillon are, therefore, not only evidence that he examined thefe prints with great attention, but that his eye was habituated to very nice difcrimination, touching all thofe particulars which, perhaps, more than any others that could be named, are guides to enable us to judge of the antiquity of wood-engravings. And the probity of Papillon's character feems to preclude the idea that he had any intention to deceive."

The general corollaries refulting from thefe elaborate inquiries, which have been purfued to much greater length than we have chofen to follow, are, that the *origin* of *European* wood-engraving is unknown, (that is to fay, that no perfon is acquainted with the precife facts of *who* firft engraved on wood in this part of the world, or *when* it was done); and the reluctant acknowledgment that it cannot be fhewn to be an European difcovery at all.

Notwithftanding the detailed prolixity with which the chevalier Cunio's own account of his graphic enterprize is written, and though he ftates that himfelf and his fifter invented the eight defigns or pictures from which their tablets were engraven, he fays nothing of the far more important fact, had it been fo, of their having invented an art of multiplying thofe defigns, fo much more likely to have been announced by an ardent youth of fixteen, had there been the leaft foundation for fuch an announcement. No. He was too fincere: and he probably knew alfo that pope Honorius, and his noble relatives, were too well acquainted with fimilar proceffes employed by the Italian carvers, fealers, bookbinders, and other artifans of Venice and Ravenna, (for the bindings of books were even then ornamented by means of heated iron ftamps,) to have believed him, had he been lefs attentive to truth. He evidently regarded, and expected that his readers would regard, what he terms in one place engraving, and in another execution in relief with a fmall knife, as an expedient which might have been adopted by any other perfon in the exifting ftate of that kind of knowledge, and which himfelf and fifter practifed—in all probability from the imperfect report of fome inexperienced reporter, who might be their inftructor in drawing.

At the period of which we are treating, Venice, as is well known, was the fplendid emporium of exotic luxuries; and the reader will not hefitate to believe, that, with the facilities of Italian intercourfe which then fubfifted, much of the imported knowledge would travel at leaft to Ravenna, along with thofe foreign commodities and that commercial enterprize which were then fpreading through Europe. The father and the uncle of Marco Polo, who had penetrated to Tartary and to China, returned from their nineteen years of travel in the Eaft, in the fame year in which the Cunio were born. Nothing, therefore, is more likely, under all the attendant circumftances, than that thefe travellers brought home the information neceffary to the rude practice of the wood-engravers' art from *China*, which we are inclined to deem the parent country of wood-engraving, paper, and printing; and that it thus became known, though through what particular medium cannot now be traced, to the illuftrious and romantic twins of Ravenna.

Should it be objected here, that Marco Polo has not noticed this art, in the account which he has left us of the marvels which he had witneffed in China; the anfwer is obvious. Marco did not himfelf travel thither until after the firft return of his father and uncle, nor did his book appear until ten years after that of "the heroic actions of the great and magnanimous Macedonian king," when wood-engraving would feem to have been no marvel. Marco very wifely preferred inftructing the public in matters with which they were not hitherto acquainted.

In corroboration of this account may be mentioned, that the manner in which the work of the Cunio is defcribed to have been performed, is precifely that in which the Chinefe have from time immemorial engraven on wood, and in which they ftill continue to practife that art, as may be feen by any perfon who may pleafe to indulge himfelf in the curiofity of infpecting thofe engraved or carved tablets of wood which are preferved in the mufeum of the Honourable Eaft India Company, in Leadenhall-ftreet.

We have purfued this mixture of fact and probability thus far, becaufe it appeared to us to contain the beft evidence on the fubject that is now obtainable; and becaufe even this feems to render the ufelefsly-protracted and never-ending difputes, which have been fo long kept up by certain interefted

refted

refted print-dealers and their prey, and their literary jackalls, about the fuperior pretenfions of Italy or Germany to the difcovery of this art; a mere recreation of idle credulity; a wafting of controverfial ink and ftrength in ftrenuous idlenefs; an affair of fpurious importance between "tweedle dum and tweedle dee."

If ridicule might find any other place in our Cyclopædia than under the letter R, we fhould here have recommended thefe rakers together of early German and Italian rubbifh; thefe difciples of their rival pretenfions; thefe admirers of the miferable virgins, and meagre faints and faviours of thofe dark ages of art, which preceded the refurrection of the antique fculpture; thefe complimenting and catalogue-making worfhippers of the pagods of tafteleffnefs, who affect fuch an exquifite feeling for their wooden prodigies, to be confiftent, and ufe their utmoft diligence in feeking after the chips of the twins of Ravenna, or the ftill earlier chips of the wood-engravers of China, and to tell the taftelefs and doting world of bibliographical cognofcenti, that thefe antique excifions are "graceful," or even more "elegant," than thofe which Cupid in fhaving from his bow, in the celebrated picture by Corregio, in the collection of the moft noble the marquis of Stafford.

In order to confer as much of factitious importance as might be found practicable on thofe relics of early European engraving and printing, for which thefe writers affect fo great veneration; and to keep up the delufive idea that xylography and block-printing were *invented* here rather than *feen* elfewhere, the difference between change of form and change of colour in rendering impreffions has been dwelt on with fome emphafis: but nothing in the procefs of impreffing ftamps is of more frequent and ordinary occurrence, than for fufficient dirt to accumulate in an intaglio ftamp that has lain by for any length of time, to produce a change of colour in the firft impreffion yielded after fuch lapfe of time. It muft even have been a common, becaufe obvious and efficient, mode of cleaning out the engraver's work. How frequently muft this have occurred in fealing, for example. How frequently does it occur now: and here, without genius or meditation, is the link fupplied at once in the chain of petty caufes and effects, that has been fo much magnified by the ftupidity and tafteleffnefs of modern dealers and collectors.

Of the impreffion of eight copies, mentioned by Papillon, of the life of Alexander, from the hands of the Cunio, it is not known that any remain; nor will this excite furprife, when we reflect that entire editions of fome works that have been fubfequently printed, have been fwept from the face of day. The wood-engravings which fucceeded thefe by the interefting twins of Ravenna, or were produced about the fame period, appear to have been honeftly thought of at the time; that is to fay, thought of very little, becaufe unworthy of being thought of much. From their non-importance, they have either all difappeared, or, from the fame caufe, not having been dated, the age of fuch of them as do remain, if any remain, is not known. The former of thefe is probably the chief reafon of their difappearance; for who would think of feeking for the tops of ballads, or the dying fpeeches of criminals, or dirty playing-cards, which were printed even fifty years ago, or of preferving fuch things if accidentally found? and the early European wood-engravings of which we are treating, until Michael Wolgemuth arofe, and introduced his better works of this kind into the Nuremberg Chronicle, were fcarcely of more confequence than thefe loweft objects of the notice of the vulgar.

But though the prints have difappeared, a decree of the fenate of Venice remains to atteft their former exiftence, and that "the art and myftery of making cards and printed figures had," *in the year* 1441, "*fallen to total decay*, and this in confequence of the *great quantity* of playing-cards and coloured figures printed, which are made out of Venice." The decree proceeds: "to which evil it is neceffary to apply fome remedy, in order that the faid artifts, who are a great many in family, may find encouragement rather than foreigners; let it be ordered and eftablifhed," &c. &c.

This edict, as Mr. Ottley has well obferved, fpeaks of "the art of making cards and printed figures in terms which would have been every way appropriate, had the edict had for its object the eftablifhment of the oldeft manufacture of Venice; and when coupled with other circumftances, efpecially the account of the two Cunio, furnifhes a ftrong ground for the conjecture that engraving in wood had from a very early period been practifed by the Venetians, who may eafily be fuppofed to have learnt it in the courfe of their commerce with the Chinefe."

The "printed figures," which are fpoken of along with the playing-cards in the Venetian edict, were of the fuperftitious or devotional character to which we have already alluded, and which are defcribed by Heinnekin as being foon afterward common in Germany and the Low Countries, when they were, — both the legendary wonders and the playing-cards,—defignated by the fame general term, and manufactured by the fame hands; that is to fay, cut in wood by the *Formfchnieders*, and coloured afterward by the *Briefmalers*. And to this teftimony of the German writer, the profeffor Fufeli adds, that "in the vulgar tongue of Zurich, and ftill more in that of the Roman Catholic cantons of Switzerland, *Helgen*, which is a corruption of *Heiligen*, meaning holy faints, is ufed to denote any hiftorical print." The reafon he gives for which is, "the firft prints reprefented the figures of faints, or other devotional fubjects, and were, on that account, termed *Helgen;* the term, in procefs of time, became generic, as others do, and is now ufed to denote prints of any kind, even thofe of profane fubjects."

Of thefe fuperftitious excitements of the vulgar, the baron ftates, that he faw feveral which he believes to be of ancient date in the library of Wolfenbuttel. "Thefe pieces," fays he, "are of the fame dimenfions as our playing-cards: they meafure three inches and a quarter in height, by two inches and a half in width." There are alfo in the fame library, at the end of the book entitled "*Ars Moriendi*," five prints, in which are engraved divers figures of angels, devils, dying perfons, faints, &c. fimilar to playing-cards, and of the fame fize, each figure being marked with a letter of the alphabet.

An engraved outline of a figure of this kind, of St. Bridget writing, with the Virgin and Child above, furrounded by a fort of cloud of Gothic fcroll-work, and behind her a pilgrim's hat, wallet, and ftaff, Mr. Ottley has brought forward from the collection of earl Spencer. Perfpective is grofsly violated here, and it is of more than twice the dimenfions of an ordinary playing-card; but this print, with another mentioned by M. Thierry as being in the library of the public Academy at Lyons, and which is faid to be dated 1384, Mr. Ottley thinks may help to fill up the chafm between the work of the Cunio; and the larger print of St. Chriftopher croffing the water with the facred Infant, which is dated 1423, is alfo in the collection of the fame noble earl, and will be found mentioned in a more particular manner in the commencement of our account of the German *School of Engraving*.

WOODFORD, in *Geography*, a county of Kentucky, bordering on the Ohio, with 9171 inhabitants, of whom 3179 are flaves. Verfailles is the chief town, containing 488 inhabitants, of whom 235 are flaves.—Alfo, a town of Vermont, eaft of Bennington, in the county of Bennington, with 254 inhabitants.

WOODGURRY, a town of Hindooftan, in Bednore; 35 miles N.E. of Simogu.

WOODIOUR, a town of Hindooftan, in Coimbetore; 10 miles N. of Daraporum.

WOODRIFF, a town of Tunis; 7 miles N.W. of Gabs.

WOODRUFF, Sweet, in *Agriculture*, a perennial plant, which is eat by different forts of live-ftock; and the aromatic flowers of which, when infufed in water, excel in flavour, it is faid, the fineft teas.

WOODS, *Lake of the*, in *Geography*, a lake of North America, fo called from the multiplicity of wood growing on its banks, fuch as oaks, pines, firs, &c. Its greateft length is about 70 miles, and greateft breadth forty. It contains but few iflands, and thofe fmall. N. lat. 49°. W. long. 90°.

Woods, a town of South Carolina; 32 miles W.N.W. of Georgetown.

Woods's *Bay*, a bay on the ftraits of Magellan; 15 miles W. of Cape Froward. S. lat. 53° 58′. W. long. 72° 55′.

Woods's *Ifland*, a fmall ifland near the north coaft of Jamaica. N. lat. 18° 12′. W. long. 76° 8′.

WOODSAMADRUM, a town of Hindooftan, in Golconda; 12 miles S. of Damapetta.

WOODSBOROUGH, a poft-town of Maryland; 75 miles N. of Wafhington.

WOODSIA, in *Botany*, owes its name to Mr. R. Brown, who dedicates this genus to the commemoration of Mr. Jofeph Woods, F.L.S., an excellent Britifh botanift. A valuable paper on the Rofes of this country, about to appear in the Tranfactions of the Linnæan Society, will abundantly prove Mr. Woods' claims to fuch a diftinction, even were it far lefs indifcriminately beftowed than ufual.—Brown Tr. of Linn. Soc. v. 11. 170. Sm. Compend. Fl. Brit. ed. 2. 152. Purfh 660.—Clafs and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorfales*.

Gen. Ch. *Fructification* in roundifh *groups*, on the back of the leaf. *Involucrum* cup-like, open, fmall, nearly flat, jagged, fringed with awl-fhaped, incurved, jointed hairs. *Capfules* feveral, obovate, on fhort ftalks, crowded, in the centre of the involucrum, each bound by a vertical, jointed, elaftic ring, and burfting irregularly at one fide. *Seeds* numerous, kidney-fhaped, granulated, extremely minute.

Eff. Ch. Groups of capfules fcattered, roundifh, each feated on a capillary-fringed involucrum.

Obf. We gladly here adopt the term *group*, as technically fynonymous with Sorus, (fee that article,) inftead of dot, fpot, or line, which are liable to much exception.

1. W. *ilvenfis*. Long-leaved Woodfia. Br. n. 1. Purfh n. 2. (Acroftichum ilvenfe; Linn. Sp. 1528. Fl. Dan. t. 391. Polypodium ilvenfe; Swartz Syn. Fil. 39. Willd. Sp. Pl. v. 5. 198. "Schkuhr Crypt. 16. t. 19." Nephrodium lanofum; Michaux Boreal.-Amer. v. 2. 270. Lonchitis afpera ilvenfis; Dalech. Hift. 1221. f. 3.)—Frond pinnate; leaflets lanceolate, deeply pinnatifid, with numerous, nearly uniform, oblong lobes. This appears to have been firft difcovered in the Mediterranean ifle of Ilva, whence the fpecific name, which is very exceptionable, the fame fpecies being found on rocks in the north of Europe, as well as in North America, from Canada to Virginia. We have American fpecimens from Mr. Francis Boott, agreeing exactly with Siberian ones in the Linnæan herbarium. We know not of this fpecies having been detected in Britain. The *fronds*, five or fix inches high, grow erect, in denfe tufts. Their *ftalks*, not quite half that height, are brown, bearing, like the mid-rib of each principal *leaflet*, many ftrap-fhaped, taper-pointed, membranous fcales. The *frond* itfelf is oblong, or lanceolate, compofed of twelve or more pairs of oblong lanceolate *leaflets*, or *pinnæ*, oppofite or alternate, each about an inch long, numeroufly pinnatifid; their lower fegments wavy, nearly equal and uniform; upper confluent: their upper furface is even, nearly fmooth, of a fine green; lower covered with pale brown fcales, and crowded hairy *groups* of *capfules*.

2. W. *hyperborea*. Round-leaved Woodfia. Brown n. 2. t. 11. Purfh n. 1. Sm. Compend. 158. (Acroftichum hyperboreum; Liljeblad in Stockh. Tranf. for 1793. 201. t. 8. A. alpinum; Bolt. Fil. Brit. 76. t. 42. Polypodium hyperboreum; Swartz Syn. Fil. 39. Willd. Sp. Pl. v. 5. 195. Sm. Engl. Bot. t. 2023. P. arvonicum; Fl. Brit. 1115. P. ilvenfe; With. 774. Filicula pumila, Lonchitidis Marautæ fpecies Cambrobritannica; Pluk. Phyt. t. 89. f. 5.)—Frond pinnate; leaflets heart-fhaped, rounded, pinnatifid, lobes rounded, waved, unequal.—Native of alpine rocks, chiefly in the northern parts of Europe. It occurs, though rarely, on the higheft fummits of the Welfh and Scottifh mountains. A fmaller plant than the preceding, often not above an inch high, though generally about three inches. The *leaflets* are fhorter, and more rounded, as well as their lobes; of a thinner texture; much lefs deeply pinnatifid, except at their bafe, where the bottom pair of lobes are often fo deeply feparated, as to form two little *leaflets*, wavy, or obfcurely lobed, and fometimes of unequal fize. The *main ftalk* is fcaly; *leaflets* hairy on both fides.

We readily agree with Mr. Brown, that fome intermediate varieties of each fpecies render the fpecific characters of both confiderably difficult. Yet there feems no reafon to doubt their being diftinct plants. Mr. Bauer's delineation of this fern, in the Linnæan Tranfactions, excellently engraved by Warner, is one of the fineft illuftrations of a natural production that can any where be feen.

WOODSTOCK, (New,) in *Geography*, a borough and market-town in the hundred of Wootton, and county of Oxford, England, is fituated 8 miles N.N.W. from Oxford, and 62½ W.N.W. from London. It has a market on Tuefday, and fairs on the 5th of April, Tuefday in Whitfun-week, 2d of Auguft, 2d of October, Tuefday after the 1ft of November, and 17th of December. The town fends two reprefentatives to parliament, the mayor being the returning officer. The corporation confifts of a mayor, a high-fteward, a recorder, town-clerk, four aldermen, and fixteen common-council men. In 1811, the houfes in Woodftock were 235, and the inhabitants 1540. The fouth part of the prefent church is a fragment of an ancient chapel; but the northern face and the tower were erected in 1785. Adjoining to the church is a grammar-fchool, founded in 1585 by Mr. Cornwell, a native of the place; and near the fouthern entrance of the town is a range of alms-houfes, erected in 1793 by the duchefs of Marlborough, for fix poor widows. The town-hall, a ftone building, has under it the market-place, and was erected in 1766, from a defign of fir William Chambers, at the expence of the late duke of Marlborough. The principal manufactures of the town are thofe of gloves and of polifhed fteel. Various articles of this fteel have been executed with great delicacy, and fold at high prices. This manufacture was introduced into Woodftock at the beginning of the laft century; but it it has much declined, on account of the cheapnefs of the cutlery goods furnifhed by Birmingham and Sheffield. The glove-manufacture is of later date; but has increafed in the prefent day fo much, that from 300 to 400 pairs of gloves are made weekly in the town and the neighbouring villages, and thus afford employment for about 1400 women and girls, and 70 men. Old Woodftock, of which only one manfion and a few irregular houfes remain, ftood in a fheltered fituation on the little river Glyme, which fupplies the magnificent piece of water in Blenheim-park. The manor-houfe, or royal palace, on the N. bank of the deep valley of the Glyme, within the bounds of the park, was the refidence of Fair Rofamond, whofe romantic adventures are deeply interwoven with the hiftory of Henry II.; but the building has long difappeared. In this palace, that king, in 1164, received the homage of Malcolm, king of Scotland, and Rice, prince of Wales. In 1275 Edward I. held a parliament at Woodftock, and there was born his fecond fon, Edmund, as was alfo the renowned Black Prince. Woodftock was inhabited occafionally by Richard II., and there Henry III. narrowly efcaped affaffination by a fanatic prieft: an attempt was there alfo made by Morifco on the life of Henry VIII. The old palace was afterwards employed as a prifon for Elizabeth, his daughter. In the time of the civil wars it fuffered feverely from the parliament's party; and about a century ago the gate-houfe, the laft fragment of the edifice, was pulled down. But Woodftock is moft worthy of note for having produced Chaucer, who was born there about 1328. The houfe in which he afterwards refided, while the court was in the palace, ftood at the W. end of the town, near the ufual entrance into Blenheim-park. Some relics of this building are ftill pointed out.

The great object of attraction at Woodftock is the magnificent palace of Blenheim, with the furrounding grounds, water, and park. The honour and eftates of Woodftock, long belonging to the crown, were in 1705 conveyed by queen Anne, on the addrefs of the houfe of commons, to the illuftrious John, duke of Marlborough, to preferve the memory of his eminent fervices as a warrior and a ftatesman; particularly for the fignal victory obtained by him, and prince Eugene of Savoy, at Blenheim, in Germany, over the French and Bavarians, on the 2d of Auguft 1704. The houfe was erected by fir John Vanbrugh, at a convenient diftance from the S. brink of a deep dell, in which ran the Glyme. The general diftribution of this fuperb ftructure confifts of a central mafs of building, inclofing two fmall courts, and connected by colonnaded wings to two fpacious quadrangles, forming the grand court of entrance. The centre is ornamented with a Corinthian portico, furmounted by a pediment and military emblems. The wings are crowned with towers ferving at once to contain the chimneys, and to contribute to the picturefque grandeur of the edifice. The garden-front, extending from E. to W. 348 feet, is grand and magnificent. The interior of the manfion contains many noble apartments, adorned with paintings of eminent mafters; particularly with a feries of mythological pictures from the admirable pencil of Titian, prefented to the firft duke of Marlborough by the king of Sardinia, and with portraits of many eminent characters by the beft artifts. The library, occupying the whole of the W. front, 183 feet long and nearly 32 wide, is a magnificent room, originally deftined to be a picture-gallery, but afterwards furnifhed with the grand Sunderland collection of books, containing upwards of 17,000 volumes. At one end is a marble ftatue of queen Anne by Ryfbrack. In the W. wing is the chapel appropriately fitted up, and containing a monument, by the fame fculptor, of the firft duke, his duchefs, and their two fons, who died young. In the E. quadrangle of offices is the theatre, originally a green-houfe, calculated to accommodate 200 fpectators. Near the E. angle of the manfion an obfervatory was erected by the late duke of Marlborough, and provided with a complete apparatus for aftronomical obfervations by Ramfden; a grand telefcope by Herfchel was prefented to the duke by his majefty, after his vifit to Blenheim in 1786. The ftate-approach to the palace is by a ftraight avenue from the N. extremity of the park, over the river, by a bridge of one fpacious and two fmaller arches. Flowing in a deep dell, the fmall ftream is made to affume the appearance of a naturally-winding river, expanding below the bridge into a broad irregular lake; thus, with the bridge, according with the grandeur of the palace and the noble extent of the park. A lofty column is erected in the midft of the great avenue, furmounted by a ftatue of the great duke, and charged on the pedeftal with infcriptions ftating his fervices and rewards. In the N.W. part of the park of Blenheim, veftiges may be traced of the ancient road, Akeman-ftreet. Nearly two miles W. from the park is the village of Stonesfield, at which place was difcovered, in 1711, a teffellated pavement 35 feet by 20, reprefenting, among other figures, a Bacchus, with his thyrfus and cup, mounted on a tyger. In addition to this curious antique, in 1779 were difcovered, near the fame fpot, the areas of a number of other apartments paved in the fame manner; and adjoining were the remains of a bath with its hypocauft: Roman coins from Vefpafian downwards were found on the fame fpot. A plan and fome account of thefe remains have been publifhed by Henry Hakewill, efq. architect.—Beauties of England and Wales, Oxfordfhire, by J. N. Brewer, 8vo. 1811. The Blenheim Guide, by Dr. Mafon, 12mo. 1817. Havell's Views of Seats include two fine Engravings of Blenheim Palace, and a critical Account of the Houfe, Scenery, &c. folio, 1818.

Woodstock, a town of the ftate of Connecticut, in the county of Windham, with 2654 inhabitants; 57 miles S.W. of Bofton.—Alfo, a town of North Carolina, on the left bank of Pamlico river; 22 miles N.N.E. of Newbern. —Alfo, a poft-town of Virginia; 112 miles W. of Wafhington.—Alfo, a poft-town of Vermont, in the county of Windfor, with 2672 inhabitants; 5 miles N.W. of Windfor. —Alfo, a townfhip of New York; 46 miles S. of Albany. —Alfo, a poft-town of New Jerfey; 26 miles S.S.W. of Philadelphia.

WOODVILLE, William, M.D. in *Biography*, was born at Cockermouth, in the year 1752. Having received a good claffical education in his native town, he was placed with a refpectable apothecary, to whom he ferved a fhort apprenticefhip. He afterwards proceeded to Edinburgh, where, after the ufual refidence, he obtained, in 1775, the degree of M.D., having written and defended a very ingenious thefis "De irritibilitate fibrarum motricium." After paffing fome time on the continent, he returned and fettled near his native place, where he practifed his profeffion five or fix years. Dr. Woodville then came to London, and was foon appointed one of the phyficians to the Middlefex Difpenfary, the duties of which office he difcharged in an exemplary manner. In 1790 he publifhed the firft part, which was afterwards completed in four quarto volumes, of a highly valuable work, intitled "Medical Botany." In 1791 he was elected phyfician to the Small-pox Hofpital, in the room of the late Dr. Archer; and it may truly be faid, that no man ever devoted, more confcientioufly or zealoufly, time and great talents, to the promotion of an object, than did Dr. Woodville to improvement in the medical treatment of the patients, as well as in the general government of the eftablifhment. To the officers of the hofpital, and thofe governors who took moft intereft in its welfare, his merits were well known; and fome of the fruits of his genius and induftry are before the public in a volume which was publifhed in 1796, intitled "The Hiftory of the Small-pox in Great Britain, &c." This work, which it was the author's defign to occupy two volumes in 8vo., was well conceived, including a brief hiftory of the difeafe, and a review of all the publications on the fubject of inoculation, with an experimental inquiry into the relative advantages of the various meafures that had been recommended. Only the firft volume of this work, which is well written, and contains much valuable information, was publifhed, the happy difcovery of the efficacy of vaccination having, in the author's opinion, fuperfeded the neceffity of the fecond appearing. Dr. Jenner's grand difcovery made a due impreffion on the mind of Woodville; and as no other man had equal opportunities of witneffing and lamenting the ravages of the fmall-pox, fo no perfon could be more fincerely anxious and active in the adoption of thofe means that were found adequate to guard mankind againft that peftilence. It is very true, that on the fubject of vaccination he was, like every body elfe, at firft fceptical; but he fuffered no opportunity to be loft of afcertaining its efficacy, and then of proclaiming his belief in it. Unhappily, in fome of his early experiments an error was committed; he was not aware of the influence of the variolous atmofphere of the hofpital. The refult was, that in certain inftances, either pure fmall-pox matter, or a deteriorated vaccine lymph, had been inferted into the arms of fome patients. The effects were faithfully detailed; but being fo different from thofe that had been defcribed by Dr. Jenner, that excellent man and benefactor to the human race vifited Dr. Woodville, with whom he argued and remonftrated on the fubject. It is to be regretted that fome afperities of remark took place between them, although both were equally and honourably engaged in the developement of truth. The difcuffion, however, as is always the cafe, proved very ufeful in the diffemination of the new practice; and if Dr. Jenner had reafon to find fault with the refult of Dr. Woodville's early proceedings, he muft have been abundantly gratified by his fubfequent experiments and publications. The ample field in which Woodville was placed enabled him to vaccinate great multitudes, fome thoufands of whom he afterwards tefted by variolous inoculation, and thus gave that publicity to vaccination, and that confidence in it, which it could not otherwife have attained in the courfe of many years. He was alfo ardently engaged in the inquiry into the nature and origin of the vaccine lymph; and, at his requeft, the writer of this fhort article three times inoculated him with frefh greafe from the heel of a difeafed horfe. If in the heat and bitternefs of contention men feek an apology for unguarded expreffions and affertions, this cannot be granted to thofe who calumniate the dead; and therefore the ftatement in a late hiftory of vaccination of Dr. Woodville having fallen a victim to the drinking of ardent fpirits, is deferving of reprobation. Dr. Woodville cultivated the fociety of his profeffional brethren, by whom, on account of his talents and companionable qualities, he was held in high eftimation; and one of thofe who enjoyed the intimacy of his friendfhip, from the period of his fettling in London until the day of his death, contradicts the above unfounded calumny. His difeafe, which terminated in dropfy, had made fuch gradual advances during the laft year of his life, that he frequently talked of his death, which no man ever contemplated with greater equanimity, as likely to take place about a certain affigned period.

He died at the hofpital on the 26th of March 1805; and on the 3d of April, a warm and juft eulogium was pronounced over the body in the faloon by his friend Mr. Highmore. His parents having been Quakers, he by his own defire was interred in the Friends' burial-ground in Bunhill-fields, after a very appropriate addrefs at the grave by Mrs. Pryor.

The editor is indebted for the preceding article to his much-efteemed friend J. Norris, efq., no lefs diftinguifhed by his mental and moral qualities than by judgment and extent of reputation in his profeffion.

Woodville, in *Geography*, a poft-town of Virginia; 94 miles W. of Wafhington.

WOODWARD, John, in *Biography*, was born in Derbyfhire in 1664, and, being intended for trade, was apprenticed in London; but in a little while abandoned the fhop for the fake of fcientific purfuits. In 1687 Dr. Barwick took him into his family, and for the fpace of four years gave him inftruction in medicine and anatomy. He then recommended him to the medical profefforfhip in Grefham college, to which he was elected in 1692. Having directed his particular attention to foffils, with a view to which he had travelled through many diftricts of England, he publifhed in 1695 "An Effay towards a Natural Hiftory of the Earth and terreftrial Bodies, efpecially Minerals; as alfo of the Sea, Rivers, and Springs; with an Account of the Univerfal Deluge, and of the Effects that it had upon the Earth," 8vo. His preparatory knowledge for a work of this kind was very flight, and therefore the execution of it was attacked by Dr. Martin Lifter, and others. However, in the imperfect ftate of geology at that time, his performance engaged notice, and he was chofen in 1693 a fellow of the Royal Society. At this time he was in poffeffion of an ancient iron fhield, in the concavity of which was a fculpture reprefenting the ftory of Camillus and the Gauls at Rome; and as it was a great curiofity among the learned, Dodwell gave an account of it in a Latin treatife, entitled "De Parma equeftri Woodwardiana Differtatio." By this circumftance Woodward was led to increafe his acquaintance with a certain clafs of literati, though he did not efcape the ridicule of the wits. In 1695 he was created M.D. by archbifhop Tenifon, and in 1696 he obtained the fame degree from Cambridge; and thus honoured, he was prepared for an admiffion into the College of Phyficians as a fellow in 1702. But purfuing his inquiries into natural hiftory and antiquities, he publifhed fome pieces in thefe departments: *viz.* "Some Thoughts and Experiments concerning Vegetation," communicated to the Royal Society, and printed in the Philofophical Tranfactions for 1669; "Naturalis Hiftoria Telluris illuftrata et aucta: accedit Methodica Foffilium in Claffes Diftributio," 1714, intended as a grand reply to thofe who objected to his Natural Hiftory of the Earth, which had been tranflated into Latin by Scheuchzer at Zurich; and "An Account of fome Roman Urns, and other Antiquities, lately digged up near Bifhopfgate; with brief Reflections upon the ancient and prefent State of London: in a Letter to Sir Chriftopher Wren." In his medical capacity, he publifhed in 1718 "The State of Phyfic and of Difeafes, &c." 8vo., in which he advanced the notion, that the bile and its falts, re-abforbed into the blood, were the true caufe of life and animal motions, and that the fame fermenting in the ftomach were the caufe of difeafes; whence he was led to conclude that emetics to evacuate the morbid bile, and oily and unguinous medicines to correct it, were univerfal remedies. This publication produced a controverfy with Dr. Freind, in which Woodward was anfwered both ludicroufly and ferioufly, fo that he gained little credit by his medical theory or practice. His chagrin, however, was diverted by the ftudy of foffils, and the augmentation of his cabinet of fpecimens.

ſpecimens. He ſoon after fell into a decline, which terminated his life in his apartments at Greſham college in 1727, at the age of 63. He bequeathed his perſonal property to the univerſity of Cambridge, for the endowment of an annual lectureſhip, on a ſubject taken from his own writings in natural hiſtory or phyſic. Soon after his death were publiſhed an Engliſh edition of his "Method of Foſſils," with various additions; and "A Catalogue of Foſſils in the Collection of J. Woodward, M.D.," in 2 tomes, 8vo., a work of permanent eſtimation among geologiſts. In 1737 Dr. Templeman publiſhed Woodward's "Select Caſes and Conſultations in Phyſic," in which ſome valuable obſervations are interſperſed. One of his hypotheſes was, that the life reſides in the blood, and in the ſeparate parts of the body, not in the nerves; in confirmation of which he made many experiments, eſtabliſhing the vis inſita of muſcles. Biog. Brit. Haller. Gen. Biog.

Woodward, an officer of the foreſt, whoſe function is to look after the *woods*, and obſerve any offences either in vert, or veniſon, committed within his charge; and to preſent the ſame; and in caſe any deer are found killed, or hurt, to inform the verderor thereof, and preſent the delinquents at the next court of the foreſt.

Woodwards may not walk with bows and ſhafts, but with foreſt-bills. *Arcum et calamos geſtare in foreſta non licet, ſed* (*ut reſcripti utar verbo*) *hachetum tantummodo*. Term. Hil. an. 13 Ed. III.

WOODWARDIA, in *Botany*, a very fine and well-marked genus of ferns, dedicated by the writer of this article to the honour of his long and highly-valued friend, and botanical companion, Thomas Jenkinſon Woodward, eſq., LL.B., F.L.S., one of the beſt Engliſh botaniſts, whoſe ſkill and accuracy are only equalled by his liberality and zeal in the ſervice of ſcience. Mr. Woodward's name is well known as the important aſſiſtant of Dr. Withering in his national *Flora* (ſee Witheringia), as well as by his communications to the Linnæan Society; amongſt which, an eſſay on the *Britiſh Fuci*, written in conjunction with the preſent learned biſhop of Carliſle, and printed in the third volume of that Society's Tranſactions, ſtands conſpicuous.—Sm. Mem. de l'Acad. de Turin, v. 5. 411. t. 9. f. 3. Tracts 238. t. 1. f. 3. Willd. Sp. Pl. v. 5. 416. Swartz Syn. Fil. 116. Sprengel Crypt. Engl. ed. 131. t. 4. f. 29. Ait. Hort. Kew. v. 5. 523. Purſh 669.—Claſs and order, *Cryptogamia Filices*; ſect. annulatæ. Nat. Ord. *Filices dorſiferæ*.

Eſſ. Ch. Groups of capſules oblong, diſtinct, ſtraight, ranged in a ſimple row, in bordered cavities, parallel to each ſide of the rib. Involucrum ſuperficial, vaulted, ſeparating towards the rib.

Obſ. Mr. Brown has ſeparated from this genus, by the name of *Doodia*, Prodr. Nov. Holl. v. 1. 151, ſuch ſpecies as have a flat *involucrum*, unconnected at its inner margin, and originating from an interbranching, or connecting, vein, at its oppoſite ſide. In theſe the *capſules* are not ſunk into any bordered cavity, nor are the *groups*, with their *involucrums*, ſo turgid, or prominent. *Woodwardia caudata*, Cavan. Leccion. 264. Swartz Syn. Fil. n. 2. Willd. n. 2, belongs to this genus of *Doodia*; and Mr. Brown defines two others, *aſpera* and *media*, as likewiſe natives of New Holland, in which country, it ſeems, no true *Woodwardia* has been found.

1. W. *anguſtifolia*. Narrow-leaved Woodwardia. Sm. n. 1. Swartz n. 1. ("W. floridana; Schkuhr Crypt. 103. t. 111." W. onocleoides; Willd. n. 1. Purſh n. 1. Onoclea nodulosa; Michaux Boreal.-Amer. v. 2. 272. Swartz Syn. Fil. 111. Acroſtichum areolatum; Linn. Sp. 1526. A. n. 12; Linn. Am. Acad. 274. Oſmunda caroliniana; Walt. Carol. 257. Lonchitis major virginiana, folio vario, alis Polypodii in modum conjunctis; Moriſ. ſect. 14. t. 2. f. 24. Filix floridana, prælongis et anguſtis pinnulis, &c.; Pluk. Amalth. t. 399. f. 1.)—Fronds pinnate; leaflets linear, acute, entire; the barren ones finely ſerrated.—In cedar and cypreſs ſwamps, from New Jerſey to Florida, fructifying in Auguſt. Perennial, about a foot high. *Purſh*. The *root* is creeping, ſcaly and ſhaggy, bearing ſeveral ſtalked, upright, ſmooth *fronds*, of a lanceolate figure, with a long taper point: the barren ones conſiſting entirely of lanceolate, acute, finely ſerrated *leaflets*, decurrent at their baſe, and ſomewhat confluent: the fertile of rather fewer, more diſtant, longer and narrower ones, likewiſe ſlightly decurrent and confluent at their baſe, each *leaflet* being nearly covered at the back, on each ſide of the rib, with a cloſe ſeries of turgid, nearly cylindrical, *groups*, a quarter of an inch long, of numerous *capſules*, every *group* cloſely covered by its own convex *involucrum*. Each *group* is encompaſſed with a conſiderably elevated uninterrupted line, bordering the hollow in which it lies. Willdenow has moſt unadviſedly changed the eſtabliſhed ſpecific name, without any right or pretence, ſurely for the worſe rather than the better.

2. W. *japonica*. Blunt-lobed Japan Woodwardia. Sm. n. 2. Swartz n. 3. Willd. n. 3. Sprengel as above, f. 29. (Blechnum japonicum; Thunb. Jap. 333. t. 35. Linn. Suppl. 445.)—Frond pinnate; leaflets ſeſſile, half pinnatifid, with cloſe, obtuſe, ſerrated lobes. Rows of fructification extremely cloſe and crowded.—Gathered by Thunberg near Nagaſaki, and in other parts of Japan, fructifying in June. *Frond* two feet, or more, in height. *Stalk* roughiſh, and ſomewhat ſcaly, not ſmooth. *Leaflets* five or ſix inches long, pointed, quite ſeſſile, ſcaly at the baſe, each divided about half way to its rib into twelve pair, or more, of broad, bluntiſh, rounded, ſerrated lobes, above an inch long, and half an inch broad, quite cloſe and parallel at the ſides; paler beneath. *Groups* oblong, three or four in a continued line, cloſe to the rib on each ſide. The *involucrum* reflexed to one ſide, after the *capſules* are fallen, leaves the cavity expoſed, and like a box with its lid. The *capſules* appear all to be inſerted into that margin of the cavity to which the *involucrum*, or lid, is attached.

3. W. *orientalis*. Sharp-lobed Japan Woodwardia. Swartz n. 4. alſo p. 315. Willd. n. 4. ("Blechnum radicans; Houtt. N. Hiſt. v. 2. t. 97. f. 1.")—Frond pinnate; leaflets ſtalked, deeply pinnatifid, with ſpreading, acute, ſerrated lobes. Rows of fructification cloſe. Involucrum ſomewhat creſcent-ſhaped.—Gathered by Thunberg in Japan. Very diſtinct from the laſt, as well as from *W. radicans*. The *frond* is more coriaceous than either, and ſeems to be rather glaucous. *Stalk* ſmooth and naked, at leaſt in its upper part. *Leaflets* the ſize of the laſt, but tapering at their baſe into a ſhort ſtalk; their ſegments conſiderably diſtant from each other, except at the very baſe, and ſomewhat revolute; ſharply ſerrated, particularly at the point. *Groups* ſlightly lunate outwards, eſpecially the upper and ſhorter ones, about ſeven in each row, crowded, and cloſe to the rib. Perhaps it was from a ſpecimen of this, confounded with the preceding, that Profeſſor Thunberg deſcribed the main *ſtalk* as altogether ſmooth, and zigzag.

4. W. *virginica*. Virginian Woodwardia. Sm. n. 3. Swartz n. 7. Willd. n. 6. Ait. n. 2. Purſh n. 2. (W. Baniſteriana; Michaux Boreal.-Amer. v. 2. 263. Swartz n. 8. Blechnum virginicum; Linn. Mant. 307. Filix mas, vulgari ſimilis, pinnulis amplioribus planis, nec

 crenatis,

crenatis, virginiana; Pluk. Almag. 151. Phyt. t. 179. f. 2.)—Frond pinnate; leaflets feffile, deeply pinnatifid, with fpreading, obtufe, flightly crenate lobes. Rows of fructification accompanying their mid-rib as well as the ribs of the lobes.—In the fwamps and fhady woods of Virginia and Carolina. *Purfh.* We received it from Kew garden in 1785. The fructification is perfected in July and Auguft. The *frond* is eighteen inches, or more, in height, with a pale fmooth *ftalk. Leaflets* alternate, above a finger's length, and about an inch, or more, in width, bright green, fmooth; their numerous fegments fpreading moderately from each other, forming an acute angle at the bafe; their margin is fomewhat revolute, and very obfcurely crenate. *Fructification* moft abundant on the leaflets of the upper half of the frond, forming lines all along their principal rib, at each fide, as well as along the rib of each fegment; the *groups* finally confluent. The depreffions in which the groups are feated are very flight, though not imperceptible, and the *involucrum* of each is narrower, lefs vaulted, and fooner turned afide, than in any other fpecies with which we are acquainted, fo that the prefent plant is in fome meafure intermediate between *Woodwardia* and *Doodia*. Perhaps it may prove thefe two genera not to be diftinct, but while they remain fo, we concur with Mr. Brown in keeping this fpecies where it is. Plukenet's figure was drawn by Mr. Banifter, the original difcoverer of this fern.

5. W. *thelypterioides.* Small Woodwardia. Purfh n. 3. —"Frond pinnate; leaflets feffile, linear-lanceolate, pinnatifid; villous at the bafe: fegments of the barren ones oblong and bluntifh; of the fertile ones fhortened, triangular, and acute; all entire. Stalk downy, angular."—In fandy fwamps of South Carolina, near Charleftown, fructifying in July. Refembles the preceding, but is not half the fize. *Purfh.*

6. W. *fimbriata.* Fringed Woodwardia.—Frond pinnate; leaflets feffile, deeply pinnatifid, with fpreading, rather acute, lobes, fringed with fharp teeth.—Gathered by Mr. Menzies, on the weft coaft of North America. This is larger in every part than *W. virginica*, and diftinguifhed from that fpecies by its more acute fegments, whofe margin is very confpicuoufly and copioufly fringed with prickly teeth, directed towards the point. *Groups* of capfules large and turgid, ranged, a little obliquely, along the ribs of the fegments, from three to five pair on each fegment, none at the mid-rib of the leaflet itfelf. *Involucrum* ftrongly and permanently vaulted. The bottom lobe of each *leaflet*, at the lower fide, is fhortened, dilated, and half heart-fhaped, as is more rarely the cafe in *W. virginica*. Several of the upper *leaflets* are decurrent and confluent; the top ones undivided, and barren.

7. W. *radicans.* Rooting-ftalked Woodwardia. Sm. n. 4. Swartz n. 5. Willd. n. 5. Ait. n. 1. "Schkuhr Crypt. 104. t. 112." (Blechnum radicans; Linn. Mant. 307, excluding the reference to Plukenet, fee *W. virginica*. Filix italica non ramofa maxima glabra, polypodii folio, gallas ferens, D. Micheli; Till. Pif. 62. t. 24.)

β. W. *ftans.* Swartz n. 6. "Schkuhr Crypt. 104. t. 113." *Willd.*—Frond pinnate; leaflets nearly feffile, deeply pinnatifid, with parallel, taper-pointed, fharply ferrated lobes.—Native of deep clayey fiffures of rocks in Madeira, according to Koenig. Found alfo in Italy and Portugal. A hardy greenhoufe plant in England, and one of the moft handfome of its tribe. The *fronds* are two or three feet high, and a foot and a half or near two feet in breadth, of a fine green, fmooth, beautifully reticulated with veins, each main ftalk producing at the back, near the top, a round fcaly bud, or bulb, the origin of a young plant. *Leaflets* generally alternate, often a fpan long, fomewhat pectinate, with a long very flender point; their numerous fegments more or lefs crowded, flightly curved, lanceolate, minutely and fharply ferrated, each tapering to a fharp elongated point. *Groups* of capfules about feven pair on each fegment, (none at the mid-rib of the *leaflet*,) clofe, direct, fcarcely ever at all divaricated, turgid, pale brown, the cavities in which they lie very neatly and confpicuoufly bordered: uppermoft leaflets fimple and confluent, as in the foregoing fpecies. We know not how the *W. ftans*, which Cavanilles feems, by Swartz's work, to have firft noticed, is fuppofed to differ from the *radicans*; but Willdenow afferts, on a comparifon of numerous fpecimens, from different countries, that there is no fpecific diftinction between them.

8. W. *difpar.* Various-leaved Woodwardia. Willd. n. 7. (Filix latifolia, pinnulis ferè acuminatis, dentata; Plum. Fil. 13. t. 16.)—Fronds pinnate; leaflets feffile, lanceolate, pointed, pinnatifid, with elliptic-lanceolate, entire lobes. Fructification crowded on the much fmaller lobes, of a feparate narrower frond.—Found by Plumier in Martinico. Willdenow appears to have adopted this fpecies entirely from Plumier, a hazardous meafure, as its genus can only be gueffed from analogy. The barren *fronds* approach the laft fpecies in fize, but their fegments are fhorter, entire, rather obtufe, and by no means taper-pointed. Thofe *fronds* which bear fruit have *leaflets* fimilar in fhape and lobes to the others, but about one-third as large, at moft, bearing a fimple crowded row of *fructification* clofe to the rib of each fegment. The *groups* of capfules are fomewhat elliptical, and there is nothing adverfe to the generic character of a *Woodwardia*; but, on the other hand, there is no particular indication of that character.

The *root* is defcribed above an inch thick, and fix inches in length; externally black, with feveral vermicular branching fibres, clothed with tawny or golden pubefcence. *Stalk* of each *frond* near eighteen inches high, pale brown and fmooth, leafy from its middle part to the fummit, where it terminates in a large erect *leaflet*, conftructed exactly like the reft, being equal in fize to the larger lateral ones, and confiderably exceeding thofe immediately below it. Such is the habit of *W. anguftifolia*, but not of the other fpecies in general.

WOODY *Fibrous Matter*, in *Agriculture*, that which is produced from fmall particles of different forts of woody fubftances.

When merely formed of thefe parts, it is fuppofed to be the only vegetable matter that requires the aid of fermentation to render it nutritive to plants. The ufed bark of the tanner is a fubftance of this fort, which is very abforbent and retentive of moifture, but not penetrable by the roots of plants. See TANNERS' *Bark*.

Woody fibrous matter may likewife be prepared fo as to become a manure, by the action of lime upon it.

It is obferved in the "Elements of Agricultural Chemiftry," that as woody fibre confifts principally of the elements of water and carbon, the latter being in larger quantities than in the other vegetable compounds, any procefs that tends to abftract carbonaceous matter from it, muft bring it nearer in compofition to the foluble principles; and that this is done in fermentation, by the abforption of oxygen and production of carbonic acid; and that a fimilar effect is produced by lime. See LIME.

WOODY *Nightfhade*. See NIGHTSHADE.

WOODY *Head*, in *Geography*, a high cape on the coaft of New Zealand, in the South Pacific ocean. S. lat. 37° 42′.

WOODY *Iſland*, an iſland in the Eaſt Indian ſea. N. lat. 1° 46′. E. long. 106° 5′. See VICTOIRE.

WOODY *Point*, a cape on the weſt coaſt of North America. N. lat. 50°. W. long. 128° 5′.

WOODYCUTTY, a town of Hindooſtan, in Canara; 8 miles E. of Onore.

WOOF, among *Manufacturers*, the threads which the weavers ſhoot acroſs, with an inſtrument called the *ſhuttle*, between the threads of the warp, to form the web.

The woof is of different matter, according to the piece to be wrought. In taffety, both woof and warp are ſilk. In mohairs, the woof is uſually flax, and the warp ſilk. In ſattins, the warp is frequently wool, and the woof ſilk.

WOOFE, a name given in ſome parts of England to the ſea-wolf, or *lupus marinus;* which ſee.

WOOGINOOS, in *Botany*. See BRUCEA *Antidyſenterica*.

WOO-HOO-SHIEN, in *Geography*, a town of China, in the province of Kiang-nan, near the river Yang-tſe-kiang, a narrow cut leading from the river to the city, and flowing through the ſuburbs. This is a place of conſiderable trade; in the ſuburb there are ſeveral good dwelling-houſes, apparently belonging to perſons of diſtinction; and in the city itſelf there are many ſhops, which, it is ſaid, would not diſgrace the Strand or Oxford-ſtreet in London. Theſe ſhops are ſpacious, conſiſting of an inner and outward compartment, and well ſupplied with articles of all kinds, both of raw and manufactured produce. The porcelain ſhops are particularly large, and contain great varieties of the manufacture. The main ſtreet leading directly through the city is not leſs than a mile in length. Several ſtreets branch off from this, which are all paved, and contain good houſes. The number of ſhops that are filled with lanterns of all deſcriptions, both horn and paper, indicate manufactories of thoſe articles. The principal wall of the city extends on the north face; and the other is ſo overtopped with houſes, that it almoſt eſcapes notice in paſſing down the main ſtreet, which it croſſes. On the declivity of a hill to the northward are the temple and ancient tower. The temple, to which there is an aſcent by a very ſteep ſtone ſtair-caſe, reſembles that at Nankin, the god Fo being repreſented by the ſame attributes, and the principal hall being ſurrounded by ſimilar figures of ſages, in the ſame ſtyle. In another temple in the ſuburb there was a greater reſemblance to that of Nankin. Woo-hoo-ſhien does not ſeem to be populous in proportion to the number of ſhops, and the quantity of accumulated produce expoſed for ſale. The ſuburb near the city contains ſeveral good ſhops, which were crowded with people. Ellis's Journal of the late Embaſſy to China, vol. ii. Lond. 1818.

WOOJEDA, a town of Algiers, in the province of Tremecen, anciently called Guagida; 20 miles W.S.W. of Tremecen.

WOOL, in *Natural Hiſtory* and *Manufactures*, Latin *lana*, *lanicium*, Fr. *laine*, ſignifies ſoft hair or down, more particularly that of ſheep, but is applied to the ſoft hair of other animals, as of the vicunna, commonly called Vigonia wool, that of the yak of Tartary, &c.; and alſo to fine vegetable fibres, as cotton. The Romans applied the term extenſively to the ſoft hair or down of all quadrupeds, and even to that of birds, as lana anſerina, the wool or down of the gooſe; lana caprina, goat's-wool.

They alſo applied the term to vegetable ſubſtances:

——" Nemora Æthiopium molli canentia lana."
Virg. Georg. ii. 120.

" The trees of Ethiopia, white with ſoft wool, or cotton."

The diſtinction between wool and hair is rather arbitrary than natural, conſiſting in the greater or leſſer degrees of fineneſs, ſoftneſs, and pliability of the fibres. When they poſſeſs theſe properties ſo far as to admit of their being ſpun and woven into a texture ſufficiently pliable to be uſed as an article of dreſs, they are called wool. The gradations between wool and hair on the ſkins of ſome animals are often too minute to admit of accurate diſtinction. The fleeces of many ſheep contain fibres ſo hard and coarſe, that they may moſt properly be called hair; and ſome hairy animals produce on part of their ſkins fibres poſſeſſing all the properties of wool; even in fleeces from the ſheep, we may ſometimes obſerve the very ſame fibre to be a coarſe hair at one end, and at the other end a comparatively ſoft wool. The power of words, when inaccurately applied in retarding the progreſs of improvement, may frequently be traced in the moſt common occurrences of life, and we are perſuaded it has had no inconſiderable effect in this inſtance, in preventing the cultivation of wool, in Europe, on the ſkins of other animals beſides ſheep. No one will deny that it is impoſſible to produce wool on the backs of the ox or the aſs, if we reſtrict the term wool to the fleece of the ſheep; but if by wool we mean a ſoft fine hair, poſſeſſing all the properties which render it ſuitable to be ſpun, woven, and fulled, to make cloth, the oxen of Thibet and the aſſes of Chili do produce and have for centuries produced ſuch wool. Many of the aſſes and oxen even in this kingdom have ſoft woolly tufts of hair on ſome parts of their ſkins, and if ſuch cattle were ſelected, and the breed cultivated, it is probable we might obtain from them a valuable addition to the materials on which national induſtry might be profitably employed.

Sheep's-wool appears to be the product of cultivation; we know of no wild animal which reſembles the wool-bearing ſheep. The argali, from which all the varieties of ſheep are ſuppoſed to be derived, is covered with ſhort hair, at the bottom of which, cloſe to the ſkin, there is a ſofter hair, or down. (See ARGALI and SHEEP.) This is not peculiar to the argali; almoſt all quadrupeds inhabiting cold climates are covered in the ſame manner with a ſoft hair or down, which is protected by a coat of longer and coarſer hair. By removal to a temperate climate, or when placed under the foſtering care of man, and protected from the inclemencies of the weather, and ſupplied regularly with food, the coarſe long hair falls off, and the animal retains only the ſofter and ſhorter hair, or wool. It is alſo obſerved that European ſheep, removed to tropical climates and much expoſed, ſoon become languid and ſickly, and loſe their fleece, which is ſucceeded by a covering of ſhort coarſe hair. Sheep in expoſed ſituations in Europe often produce ſhort coarſe white hairs called kemps, intermixed with the finer wool; on removal to a warmer ſituation, and to a richer paſture, the coarſe hairs fall off, and do not grow again. Theſe facts are ſufficient to prove the effect of cultivation on the fleece; and it muſt be obſerved that ſheep's-wool of a good quality is never found but in thoſe countries which have been the ſeats of the arts, and where a conſiderable degree of luxury or refinement exiſts, or has once prevailed. This is a ſtrong preſumptive proof that ſuch wool has been originally obtained by a careful and long-continued attention to the ſelection of thoſe ſheep which produced the fineſt and moſt valued fleeces.

Angora, the ancient Ancyra, the former ſeat of arts and manufactures, ſtill retains its breed of fine-woolled animals, among which the goat at the preſent time produces a fleece nearly equal to ſilk in luſtre and fineneſs; and the cat and the rabbit of that diſtrict yet produce fine long wool. Damaſcus, and the other ancient cities of Aſia Minor, preſerve in in their vicinity the traces of the former cultivation of fine-woolled animals. The Tarentine fine-woolled fheep, fo much valued by the Greeks and Romans, were obtained from Afia Minor, and were on that account fometimes called Afianæ. It is highly probable that thefe fheep came originally from the more eaftern feats of luxury, where the foft fleeces are now grown, of which the fhawls and cloths of India are fabricated.

In countries where manufactures have once flourifhed, their effects continue for a long time vifible in the race of fheep which ftill remain there. Even in the prefent condition of the fleeces from Barbary and the adjoining ftates, the experienced eye may perceive the veftiges of a fine-woolled race of fheep, degenerated by utter neglect, in a climate naturally unfavourable to the production of fine wool. In Sicily and the fouthern parts of Italy, the remains of the ancient Tarentine breed preferve to the prefent day a race of fine-woolled fheep, but greatly degenerated by neglect. In Portugal the fine-woolled fheep retain more of their original purity, but are ftill much neglected. In Spain attention to the growth of fine wool appears never to have been entirely loft fight of, and it is here that the race of fine-woolled fheep exift in the higheft degree of perfection, though, as we fhall afterwards ftate, probably inferior in fome important qualities to the original Tarentine race. Some writers have afferted that fine wool is the refult of climate and food; but this is not the fact, though we admit that both have fome influence on the quality of wool. It is the breed alone that primarily determines the finenefs of the fleece; this has been ably demonftrated by the experiments of lord Sommerville, Dr. Parry of Bath, and others in this country, and by experiments on a larger fcale in Sweden, Denmark, Saxony, and France.

It has been afcertained by Mr. Bakewell of Difhley, in Leicefterfhire, that the form of animals might be changed by felecting fuch as had any remarkable peculiarities, and continuing to breed from them for a few generations, when a new race is eftablifhed, in which thefe peculiarities continue permanent. It has been afcertained by careful obfervations, both of cattle-breeders and phyfiologifts, that in producing a new breed from two varieties of the fame fpecies, the female has more influence over the form of the progeny than the male; but with refpect to wool the cafe is reverfed, the quality of the fleece depending more on the fire than the dam. Beginning to breed from a coarfe-woolled ewe and a pure fine-woolled ram, the produce of the firft crofs will have a fleece approaching one-half to the finenefs of that of the ram; and continuing to crofs this progeny with a fine-woolled ram, equal to the firft in quality, the fleece of the fcore and crofs will approach three-fourths to the finenefs of the firft, and in a few croffes more will be brought to an equal quality. If we ftate it numerically, and fuppofe the wool of the ewe to be twice as coarfe as that of the ram, or as 320 to 160, the firft crofs will have the fibre reduced to 240, the fecond to 200, the third to 180, the fourth to 170, the fifth to 165, the fixth to $162\frac{1}{2}$, which to all practical purpofes may be regarded as equal to the firft number. This ratio of approximation may be ftated as correct on a large fcale of experiment. If we breed with a fine-woolled ewe and a coarfe-woolled ram, the feries would be reverfed, and in a few generations all veftiges of the fine-woolled race would be nearly, if not entirely, extinct. The ancient Romans, in the time of Columella, feem to have been fully aware of the effects of breed on the finenefs of the wool, and as much as 200*l.* fterling was paid for a fine-woolled ram.

When a flock of fine-woolled fheep are once formed, they can only be kept pure by felecting and preferving the fineft-woolled rams, and moft carefully avoiding all intermixture with fheep from coarfer-woolled flocks that may exift in the country. Where this is neglected, the quality of the wool will foon be debafed.

But fuppofing all the flocks in a country were of the fine-woolled race, accidental varieties of coarfe-woolled fheep will occur among them, or of fheep having fleeces intermixed with coarfe hair. If thefe be not carefully examined and removed, the wool will deteriorate, and more fo where the climate is variable, and the fheep are expofed to great and fudden viciffitudes of temperature.

What has been ftated may fuffice to explain the circumftance of fine-woolled breeds of fheep being only found in the vicinity of prefent or ancient manufactures, or where they have been tranfported from fuch diftricts. Wherever fine-woolled fheep are neglected by man, the wool becomes either coarfe, or intermixed with coarfe hairs; the latter is the cafe in the Shetland ifles, and in all countries where the arts and manufactures have been entirely deftroyed, and ignorant barbarians have fucceeded as the poffeffors of the foil.

Moft ancient writers on wool, and even many moderns, feem not to be aware of any difference in wools, except the finenefs or coarfenefs of the fibre; but the length of the fibre conftitutes a far more important diftinctive character. Long wool, or what is called combing-wool, differs more from fhort or clothing wool, in the ufes to which it is applied, and the mode of manufacture, than flax from cotton.

Sheep's-wool may, therefore, be divided into two kinds. Short wool, or clothing-wool, and long or combing wool: each of thefe kinds may be fubdivided into a variety of forts, according to their degrees of finenefs. This procefs is the proper labour of the wool-forter.

Short wool, or clothing-wool, may vary in length from one to three or four inches; if it be longer it requires to be cut or broken, to prepare it for the further proceffes of the cloth manufacture. Short or clothing wool is always carded or broken upon an inftrument with fine fhort teeth, by which the fibres are opened and fpread in every direction, and the fabrics made from it are fubjected to the procefs of felting, which we fhall afterwards defcribe. By this procefs, the fibres become matted together, and the texture rendered more compact.

Long or combing wool may vary in length from three to eight or ten inches: it is prepared on a comb or inftrument, with rows of long fteel teeth, which open the fibres, and arrange them longitudinally: in the thread fpun from combed wool, the fibres or filaments of the wool are arranged in the fame manner, or fimilar to thofe of flax, and the pieces when woven are not fubjected to the procefs of felting.

The fhorter combing-wools are principally ufed for hofe, and are fpun fofter than the longer combing-wools, the former being made into what is called hard worfted yarn, and the latter into foft worfted yarn.

Short Clothing-Wool.—The principal qualities deferving attention in clothing-wools are the regular finenefs of the hair or pile, its foftnefs and tendency to felt, the length and foundnefs of the ftaple, and the colour. The wool-buyer alfo regards as important the clean ftate of the fleece, and to the grower its weight is particularly deferving attention; for in fleeces equally fine, from fheep of the fame fize, fome may be much heavier than others, the fibres of wool being grown clofer to each other on the fkin.

The finenefs of the hair or fibre can only be eftimated to any ufeful purpofe, in the woollen manufacture, by the wool-forter or wool dealer, accuftomed by long habit to difcern

difcern a minute difference, which is quite imperceptible to common obfervers, and fcarcely appreciable by the moft powerful microfcopes. Of the various attempts that have been made to reduce the finenefs of wool to a certain ftandard, by admeafurement with a micrometer, we fhall afterwards fpeak. From fome experiments we have made, as well as from thofe made by Mr. Luccock, Dr. Parry, and others, we may eftimate the thicknefs of the hair of the fineft Spanifh and Saxony wool to be not more than the fifteen-hundredth part of an inch, and that of the fineft native Englifh to be from twelve to thirteen-hundredth parts, whilft the inferior forts gradually increafe to the fix-hundreth part of an inch and more. A difference in the fize of thefe fibres, too minute to be noticed by the common obferver, may occafion a difference of 40 *per cent.* or more in the value of the wool. The finenefs of the hair has been ever confidered as an important quality fince the clothing manufacture emerged from its rudeft ftate. Fine wool was formerly valued becaufe a finer thread could be fpun from it, and a thinner fabric made, than from the coarfer wools; but fince recent mechanical improvements have been introduced into the woollen manufacture, it has been found practicable to fpin coarfe wools to the fame length as the finer wools were formerly fpun to. It is well known, however, to cloth-manufacturers, that whatever be the finenefs of the yarn, unlefs the wool be fine, it is impoffible to make a fine, compact, and even cloth, in which the thread fhall be covered with a thick foft pile; nor would a thin cloth made from coarfe wool have the fame durability or appearance as one from fine wool of equal weight *per* yard. Fine wool will, therefore, always preferve a fuperior value to the coarfe; indeed it was long confidered as the principal and almoft the only quality deferving the attention of the wool-grower, the wool-ftapler, and the clothier.

The regular finenefs of the fibre is alfo an object of confiderable importance; the lower end of the ftaple, or that part of the fleece neareft the fkin, will fometimes be very fine, and the upper part coarfe. In fome fine fleeces there will frequently be an intermixture of long, filvery, coarfe hairs, and in other fine fleeces an intermixture of fhort, thick, opaque hairs, called kemps. When the wool is thus irregularly fine or intermixed, it is technically called not being *true grown.* The fine fleeces of Spain and Portugal, particularly of the latter country, are many of them injured by the intermixture of the long filvery hairs before-mentioned: whether this be owing to the original Tarentine breed having been croffed with the coarfe-woolled native fheep of Spain, (fee the article SHEEP,) and ftill preferving a tendency to revert to their firft condition, or whether it be the effect of heat on the fkin, is uncertain. The Saxony fleeces, from the fame breed, removed to colder climates, are generally free from this defect. The coarfe fhort hairs, or kemps, are not uncommon in fome of the fine-woolled flocks of England and Wales, particularly thofe which are more expofed to the inclemencies of the weather, and have a fcanty or irregular fupply of food. It has been obferved, in the firft part of the article SHEEP, that in fome flocks the proportion of fine wool in each fleece is much greater than in others, for in few or none is the wool grown uniformly fine over the whole body.

On the Merino fheep the fleece is more regular, whatever be the degree of finenefs, than on any of our native Englifh fine-woolled breeds. The Merino fleece admits of a divifion into four forts, the *refina*, the *fina*, and the *tercera*, with a very minute portion of coarfe from the fhanks and head, which is not fent to market. The three forts are diftinguifhed in commerce by the marks R, F, and T. On the average, there will be in each fleece nearly three-fourths of the beft or R wool. The fecond and third forts, or the F and T, will alfo contain a confiderable portion as fine as the beft; but being fhorter and difcoloured, or intermixed with coarfe hairs, which require their locks to be feparated from the beft fort, or the refina.

In the native Englifh fleeces, however fine fome part may be, the proportion of the beft fort rarely exceeds one-third part, and is frequently not more than one-fixth part of the whole fleece.

The value of the beft part of a Spanifh fleece, or the R wool, varies greatly in different flocks. When this fort, from the moft efteemed flocks, may be worth fix fhillings and fixpence *per* pound in the Englifh market, the R wool from another flock may not be worth more than three fhillings and fixpence. The F and T wools are from 25 to 50 *per cent.* lower than the firft fort: thus, the inferior forts from the fineft piles may be of greater value than the beft fort or R wool of other piles; but they are never intermixed by the dealers, as they are applicable to different fabrics. In the Englifh mode of wool-forting, there will frequently be eight or ten forts in a fingle fleece; and if the beft wool of one fleece be not equal to the fineft fort, it is thrown to a fecond, third, or fourth, or a ftill lower fort, which is of an equal degree of finenefs with it. The beft Englifh fhort native fleeces, fuch as the fine Norfolk and South Down, are generally divided by the wool-forter into the following forts, varying in degree of finenefs from each other, which are called,

Prime,
Choice,
Super,
Head,
Downrights,
Seconds,
Fine abb,
Coarfe abb,
Livery,
Short coarfe or breech wool.

Befides thefe forts of white clothing wool, two and generally three forts of grey wool are made, confifting of locks which may be black, or intermixed with grey hairs. Some wool-forters alfo throw out any remarkably fine locks in the prime, and make a fmall quantity of a fuperior fort, which they call picklock. The origin of fome of the above names is obfcure, but the names of the finer forts appear to indicate either a progreffive improvement in the quality of the wool, or in the art of wool-forting. The relative value of each fort varies confiderably, according to the greater demand for coarfe, fine, or middle cloths; and the variation during and fince the late war in the Spanifh peninfula has been much increafed by temporary caufes. Before that period, when the R wool of good Spanifh piles fold at from five fhillings and fixpence to fix fhillings *per* pound, the prime from Herefordfhire fleeces was fold at about three fhillings and fixpence, and that from the Norfolk and South Down from three fhillings to three fhillings and twopence *per* pound. The higher price of the Herefordfhire was in part owing to its being in a cleaner ftate. The Spanifh wool is alfo cleaner than any of the Englifh wools, being fcoured after it is fhorn; but the latter is only imperfectly wafhed on the fheep, previoufly to its being fhorn. A pack of Englifh clothing wool of 240 pounds weight, in its marketable ftate, will wafte about 70 pounds in the procefs of the manufacture: the fame quantity of Spanifh wool, as fent to market, will not wafte more than 48 pounds on on the average. This contributes to enhance the difference between the prices of each, as well as the ſuperior fineneſs of the latter.

Different wool-ſorters make a conſiderable variation in their modes of ſorting the ſame kind of fleeces: ſome divide them into more ſorts than others; but the following table will ſhew what may be taken as the average relative value of each ſort, when the prime is worth about three ſhillings and two-pence *per* pound, and may ſerve to ſhew the ſkill required to eſtimate the value of fine Engliſh wool in the fleece.

	s.	*d.*		*s.*	*d.*
Prime - -	3	0	to	3	4
Choice - -	2	4	to	2	8
Super - -	2	0	to	2	2
Head - -	1	8	to	1	10
Downrights -	1	5	to	1	6
Seconds - -	1	3	to	1	4
Fine abb -	1	0	to	1	1
Coarſe ditto -	0	9	to	0	10
Livery - -	0	8	to	0	10
Short coarſe -	0	7	to	0	8

The demand for coarſe woollen goods having greatly increaſed of late, the prices of the lower ſorts are conſiderably advanced from the above-ſtated prices, and are at preſent as under:

	s.	*d.*

Head - -	1	10	
Super - -	2	0	
Choice - -	2	2	
Prime - -	2	6	
Picklock -	3	0	

The Softneſs of fine clothing Wool is next in importance to the fineneſs of the fibre, though it has been too little attended to in the culture of Engliſh wool. This quality is not dependent on the fineneſs of the fibre; it conſiſts in the peculiar feel which approaches to that of ſilk or down, but in which the wool of all European ſheep is inferior to that of Eaſtern Aſia, or to the wool of the vicunna, or lama of Peru and Chili. In foreign European wools there are different degrees of this property, where the fibre is equally fine. In our native Engliſh wools, the like difference exiſts between the ſoftneſs of wool poſſeſſing the ſame degree of fineneſs, but grown in different diſtricts. In the harder wool, the fibre is elaſtic and hard to the touch, and cloth made from it has the ſame harſh feel; it is alſo more looſe in its texture, and the ſurface of the thread is generally more bare. The difference in the value of cloth from two kinds of wool, equally fine, but one diſtinguiſhed for its ſoftneſs, and the other for the contrary quality, is ſuch, that with the ſame proceſs and expence of manufacture, the one will make a cloth more valuable than the other from twenty to twenty-five *per cent.*

Though the Engliſh woollen manufactures had been carried on for ſo long a period, the cauſe of this difference in cloths made from wool equally fine was but very imperfectly known till the preſent century. Mr. Robert Bakewell, then of Wakefield in Yorkſhire, firſt directed the attention of wool-growers and manufacturers to this ſubject, in a work, entitled "Obſervations on the Influence of Soil and Climate on Wool." The reaſon why the manufacturers remained ſo long ignorant reſpecting it aroſe, he obſerved, from the manner in which the woollen-trade had been carried on in Yorkſhire, the great ſeat of the manufacture of Engliſh clothing-wool, the diviſion of employment there not permitting the wool-dealer, or even the clothier, to witneſs the final reſult of the proceſs. The wool-buyer in the diſtant counties, and the wool-ſorter, who divided the fleece, were equally unacquainted with the cloth manufacture. The Yorkſhire clothier ſold his goods in an undreſſed, and often in an undyed ſtate; they were bought and finiſhed by the cloth merchant, who was formerly unacquainted with the previous proceſſes of the manufacture, or the qualities of wool. In a promiſcuous lot of undreſſed cloth bought at the ſame price, and apparently of the ſame quality in the rough ſtate, if ſome pieces were finiſhed much better and ſofter than others, it was attributed to lucky chance, the patron divinity of the ignorant. Mr. Bakewell proved that the hardneſs of Engliſh wools does not depend on the nature of the food, or even entirely on the breed; it is the effect of the ſoil acting on the ſurface of the fleece. The wools from chalk diſtricts, or light dry calcareous ſoils, have the natural yolk or moiſture abſorbed by the particles of calcareous earth that penetrate the fleece, and the wool is thereby rendered hard. The ſame effect is produced on a ſkin where lime is uſed; it may alſo be produced by keeping wool for a longer or ſhorter time in a dry hot temperature; and when wool has been ſo dried, no proceſs will reſtore to it its priſtine ſoftneſs. On the contrary, wools grown on rich loamy argillaceous ſoils are always diſtinguiſhed for their ſoftneſs. The quantity of greaſe or yolk in the fleece has a conſiderable degree of influence on the ſoftneſs of Merino wool, the pile being ſo cloſe as in a conſiderable degree to prevent the earthy particles from penetrating the fleece; but in all Engliſh fleeces the wool is grown thinner on the ſkin, and admits the more eaſy acceſs of the abſorbent particles. Expoſure to the direct rays of a ſummer ſun has alſo a tendency to injure the ſoft quality of the wool. We ſhall have occaſion to refer to the methods recommended by Mr. Bakewell to improve the ſoftneſs of wool on ſoils naturally unfavourable to its growth.

Of fine European wools, the Saxony generally poſſeſſes a greater degree of ſoftneſs than the Spaniſh, which we believe to be owing to the ſheep being leſs expoſed to the action of light and heat. The native fine Italian wool, before the introduction of the Merino race, poſſeſſed a conſiderable degree of ſoftneſs, judging from wools which we have ſeen from thence, but they were deficient in ſoundneſs, and not *true grown.* The wools on the chalk ſoils in the ſouthern and eaſtern ſide of England are generally hard, except, as in Kent, where the chalk is covered by thick argillaceous beds. Nottingham foreſt, Chamwood foreſt in Leiceſterſhire, and ſome parts of Shropſhire, produced not the fineſt, but ſome of the ſofteſt wools in England before the late incloſures. The Cheviot hills in Cumberland are not paſtured by the fineſt-woolled Engliſh ſheep, but their fleeces poſſeſs a degree of ſoftneſs exceeding any from the other diſtricts of England, and they are rendered ſoft by artificial means, which we ſhall deſcribe. It is ſtill ſomewhat uncertain, whether there are two diſtinct breeds of ſheep, from which the fine ſhawl wool of India are grown; or whether one ſpecies of the animal which yields it is not to be claſſed with the goat. The fleeces from India, which we have ſeen, are grown on a very ſmall ſheep; cloſe to the ſkin, there is a wool as ſoft as the ſofteſt fur; this is covered by long coarſe hairs growing through it. When the wool is once ſhorn, the ſeparation of theſe hairs from the ſoft wool

wool is a work of extreme difficulty; but on the back of the sheep we believe the separation can be made with great ease. The softness of the Indian wool is not even distantly approached in the very softest Merino fleeces from Saxony and Spain; this may be proved by comparing the finest cassimere cloth from Saxony wool, with the shawls or shawl-cloth of India. The ancient Tarentine sheep, called by way of excellence 'molles oves,' were treated with peculiar care by the Romans, and clothed in skins, which we believe was intended to preserve the softness of the wool, as it is still practised in some parts of Asia for that purpose. In Europe no experiments have been made directly to improve the softness of wool, though wool approaching in softness to that of India would be a most valuable acquisition to our manufactures. To be convinced of this, it need only be stated, that the yarn from Indian wool has been sold here at three guineas *per* pound, not on account of the superior fineness of the spinning, but for the softness of the wool. For coarse goods, indeed, such as blankets, carpets, and cloths called duffields, raised with a hairy pile, a considerable degree of hardness or elasticity of the fibre is an advantage; but in all the finer articles of the woollen or worsted manufacture, the opposite quality is of great value.

The felting property of wool is intimately connected with its softness, the softest wools having the greatest tendency to felt, and the hard wools are all defective in this respect. The felting property appears to depend on a peculiar structure of the surface of the fibres, by which they are disposed to move in one direction more easily than another. This is perceptible in drawing a hair through the fingers, first from the end to the point, and again from the point to the end; in one direction the hair feels perfectly smooth, in the other direction a peculiar roughness is felt. The cause of this is supposed to be owing to the surface of the fibres having laminæ, like the scales of fishes, with the edges laid over each other. Indeed in the furs of some animals we have observed with a powerful microscope, that the surface is composed of laminæ laid over each other, resembling the arrangement of the leaves of the artichoke. On this property the process of hat-making depends; the short fibres of the fur being repeatedly compressed, move and interlock with each other, so as to form a compact substance; this motion is further aided by heat and moisture. A similar process takes place to a certain degree in cloth subjected to the strokes of a fulling-mill; the fibres cohere, and the piece contracts in length and breadth, and its texture is rendered more compact and uniform. This process is essential to the beauty and strength of woollen cloth; and it is observed, that the softer wools felt in much less time than the harder, and form a closer pile on the surface of the cloth, on which account it is a common practice to mix a certain quantity of soft wool with the hard, to enable the former to felt with more facility.

The length and soundness of the staple of clothing wool is the quality next to be considered. By the staple of wool is meant the separate locks into which the fleece naturally divides in the skin, each lock consisting of a certain number of fibres, which collectively are called the staple.

The best length of staple for fine clothing-wool, if found, is from two to three inches. If it be longer it requires breaking down to prepare it for the process of carding. Saxony wool, being generally more tender than the Spanish, and more easily broken down, is sometimes four or five inches long; but as it works down easily, it is preferred, on account of the length of its staple, for such goods which require fine spinning, as cassimeres, pelisse cloth, and shawls. Much of the English clothing-wool of a middle quality is grown longer than is desirable for the purpose of the clothier, and when found is thrown out for the hosiery trade, if the demand for the latter be great. As the grower could not shorten the length of the staple without diminishing the weight of the fleece, he has no motive to induce him to grow shorter wool; but the object might be obtained with much benefit to himself by shearing twice in the year, once the latter end of April, and again the latter end of August; the wool would then be grown of a suitable length for the card, and from experiments that have been made we believe the weight would exceed what can be obtained from one clip: the increase would not be less than fifteen *per cent.*, and the condition of the sheep thereby improved.

The soundness of the staple in clothing-wools is not so important as in combing-wools; but for some kinds of colours which injure the wool, it is particularly desirable that the fibre should be sound and strong; this is judged of by drawing out the staple and pulling it by both ends. The soundness and strength of the staple depend primarily on the healthy state of the animal, and on a sufficient supply of food. The staple on some parts of the fleece will always be more tender than on other parts, but by mixture they tend to form a dense pile on the surface of the cloth.

The colour of the fleece should always approach as much as possible to the purest white, because such wool is not only necessary for cloths dressed white, but for all cloths to be dyed bright colours, for which a clear white ground is required, to give a due degree of richness and lustre. It is probable that all sheep's-wool was first of a black or reddish colour: the latter is often referred to by the ancients. Before the invention of dyeing, coloured wool must have had a preference to white; but after the act of communicating beautiful colours to the fleece, white wool would be in the greatest demand, and those sheep which had white fleeces would be selected to breed from. The most ancient flocks of sheep which we have any record of are those of Laban and Jacob, described in the book of Genesis. The fleeces appear to have been principally brown, or spotted and striped, which was in all probability the general colour of the flocks throughout that part of Asia. We learn that in the course of twenty years a great change was effected in the colour of a large portion of the sheep of Laban: though Jacob appears to have concealed from his father-in-law the method by which this change was effected, we are expressly told in the sequel that it was by crossing with rams which had fleeces of the colours required.

Dark-brown or black woolled sheep are not uncommon in many parts of the European flocks, but such wool being of less value than the white, these sheep ought always to be expelled. Some of the English fine-woolled sheep, as the Norfolk and South-Down, have black or grey faces and legs. In all such sheep there is a tendency to grow grey wool on some part of the body, or to produce some grey fibres intermixed with the fleece, which renders the wool unfit for many kinds of white goods; for though the black hairs may be too few or minute to be detected by the wool-sorter, yet when the cloth is stoved they will become visible, forming reddish spots, by which its appearance is much injured. The Herefordshire sheep, which have white faces, are entirely free from this defect, and yield a fleece without any admixture of grey hairs. We have no doubt that by carefully rejecting those sheep from the South-Down flocks, in which the grey is most apparent, this defect might be gradually removed. It is particularly desirable with respect to to thefe fheep, as the wool grown on chalk foils, though lefs foft than on other foils, is generally whiter, and better fuited to fuch goods which require the procefs of bleaching or ftoving, and do not require to be fo much fulled as many other cloths.

The ancients were fo well aware of the neceffity of expelling dark-coloured wool from their flocks, that in felecting the fheep to breed from, they did not truft to the colour of the fleece alone, but carefully examined the mouth and tongue of the ram, and if the leaft blacknefs or fwarthinefs appeared he was immediately rejected; and though fome moderns have doubted the ufe of this precaution, we believe it was well founded.

> "Illum autem, quamvis aries fit candidus ipfe,
> Nigra fubeft udo tantum cui lingua palato,
> Rejice, ne maculis infufcet vellera pullis
> Nafcentem." Vir. Georg. iii.

Pliny alfo ftates, that particular attention was on this account had to the colour of the mouth. "Arietum maxime fpectantur ora." We are informed that this kind of infpection takes place in the Spanifh flocks at prefent, a practice in all probability derived from the Roman fhepherds, as we believe the flock to have been from thofe of Italy, or the Tarentine breed. The colour of the foil on which fheep graze, if very dark or red, communicates to the wool a tint more or lefs ftrong, which is indelible, and renders fuch wool lefs proper for cloths or hofiery goods that are to be finifhed white; for though the colour may be improved by ftoving, yet on wafhing the cloths, they foon return to a brownifh or yellowifh tint. The tint from the foil is, however, rarely of fufficient ftrength to be regarded for dyed goods, excepting for exceedingly light colours.

The cleannefs of wool is principally regarded by the purchafer, as it affects the weight. To the grower thofe fleeces are generally the moft profitable that are well filled with the greafe, or yolk as it is called, becaufe it keeps the wool in a found ftate, and improves its foftnefs. It ought, however, to be wafhed out as much as poffible before it is expofed to fale. The fleeces of the Merino fheep are more plentifully fupplied with yolk than thofe of any of our native fine-woolled breeds; indeed it is fo abundant, that the Englifh mode of wafhing on the back of the fheep will fcarcely produce any effect upon the fleece. The yolk or greafe in the fleece appears, from the experiments made upon it by M. Vauquelin, to be a native foap, confifting principally of animal oil combined with potafh. It is moft copioufly produced in thofe breeds which grow the fineft and fofteft wool, and is always moft abundant on thofe parts of the animal which yield the fineft parts of the fleece. To this fubject we fhall again refer in treating of the improvement of wool. This yolk, though fo beneficial to the wool in a growing ftate, becomes injurious to it when fhorn; for if the fleeces remain piled in an unwafhed ftate, a fermentation takes place, the yolk becomes hard, and the fibre is rendered hard and brittle. This effect takes place more rapidly in hot weather. The Spaniards remove this yolk in a great meafure by wafhing the wool after it is fhorn and forted. In Saxony fine-woolled fheep of the fame race are wafhed in tubs with warm water, foap-lees, and urine, and afterwards in clean water.

In England the wool is wafhed on the back of the fheep by immerging the animal in water, and fqueezing the fleece with the hand. From thefe different modes of wafhing, the wool is left more or lefs pure. Mr. Bakewell, in his Obfervations on the Influence of Soil and Climate on Wool, has given the following table, containing a ftatement of the quantity of neat wool in every hundred pounds, taken on an average of each fort, and fuppofing each to be free from lumps of pitch employed in marking the wool, and cleared from what are called the *dog-locks*. The firft column reprefents the average weight after the wool has been fcoured perfectly clean with foap and water, and dried; the fecond the amount of wafte.

	Pure Wool.	Wafte.
100 lbs. of Englifh wool wafhed on the fheep's back - - - -	75	25
Ditto Saxony fleece-wool - -	80	20
Ditto Spanifh R, or refine - -	88	12
Ditto Spanifh and Portugal unwafhed -	75	55
Ditto Englifh fleeces unwafhed - -	60	40
Ditto lightly greafed wools of Northumberland wafhed on the fheep's back	65	35

Hence it is obvious, that the ftate of the fleece with refpect to cleannefs is an object of great importance to the wool-buyer. The Englifh Merino fheep, from the difficulty of wafhing the wool on the fheep's back, have generally been fhorn in an unwafhed ftate, and the wool offered for fale in this ftate. The purchafers were frequently unacquainted with the great amount of the lofs it would fuffer by wafhing, and were much difappointed at the refult. This circumftance, we conceive, more than any other, tended to prejudice the manufacturer againft the Anglo-Merino wool. The wool is alfo injured by remaining in the greafe, as we have before ftated, and though this has been contradicted, we have no hefitation in afferting the fact from our own experience. Indeed the French manufacturers of fine cloth affert, that the beft wools from Spain, though cleared in a great meafure from the yolk, yet ftill retain fufficient to injure the wool if it be fuffered to grow old when it is packed, the yolk becoming rancid and hard, and communicating the latter property to the wool. We have frequently obferved this effect in the wools from Portugal, that retain a greater portion of the yolk than thofe from Spain.

After wool has been wafhed in the ufual manner practifed in England, and piled or packed, a certain procefs takes place in eight or nine weeks, called *fweating*. This is well known to wool-dealers and manufacturers, but has not been before noticed by any writer that we are acquainted with. It is evidently an incipient fermentation of the remaining yolk; and the inner part of the pack or pile becomes fenfibly warm. This procefs produces a certain change in the wool, whereby it becomes in a better condition for manufacturing, being what is called in the north of England lefs *fuzzy*. This effect refults from a diminution of the natural elafticity of the fibre.

When this fermentation takes place in unwafhed wool, it proceeds farther, and injures the colour and foundnefs of the ftaple or fibre. A fimilar effect is produced in wool or cloth which has been oiled, and remains fome time in an unfcoured ftate. Inftances of fpontaneous combuftion from heaps of refufe wool remaining in a greafy ftate have been known to occur, and occafion the moft ferious accidents in woollen factories.

The weight of the fleece is an object of great importance to the grower. It is generally fuppofed by the Englifh wool-dealers, that an increafe of weight implied an increafe of coarfenefs; indeed the words coarfe and heavy are confidered by them as fynonymous, but this is not abfolutely

 the

the cafe ; a fleece grown upon the fame animal may be increafed in weight either by the fibres becoming coarfer, or by their being grown longer, or by a greater number of fibres being grown in the fame fkin. To the wool-grower it can never anfwer to increafe the weight of the fleece on fmall fine-woolled fheep, by growing the wool coarfer ; if this be his object, the long-woolled breeds of fheep are to be preferred. He may produce wool fomewhat longer by increafing the quantity of food ; but it generally lofes fomething of its finenefs, and is lefs fuitable for the cloth trade. He may, however, increafe the weight confiderably by felecting fuch breeds as grow the wool clofe upon the fkin, and are thickly covered with wool over every part of the body. In this refpect, the Merino fheep have greatly the advantage over any of the native breeds of Englifh fheep ; many of them yielding from three to four pounds of pure wool, whilft the fineft Englifh fleeces rarely exceed two pounds, and would lofe one-fourth of this weight when brought to a pure ftate by fcouring. It has been doubted whether all fheep's-wool, when clean, poffeffes the fame fpecific gravity ; but admitting there may be fome variation in the wool from different piles, we conceive that it is too minute to deferve the attention of the wool-grower or manufacturer.

The filaments of fine wool being fo minute, it requires an eye habituated by long experience to appreciate the relative finenefs of two piles, which may differ in value as much as twenty-five *per cent.* Even thofe who have been long practifed in fuch examinations find it difficult to form immediately a correct opinion of the finenefs, if they are removed for a few weeks from all opportunity of viewing wool. It is not furprifing then that the wool-grower, who only directs his attention to the fubject during one part of the year, fhould often be unable to judge whether his wool has improved or not fince the preceding fummer. On this account it would be highly defirable that fome eafy and correct method of admeafurement by the micrometer could be invented, which might enable the obferver to decide this with certainty. Mr. Daubenton employed a graduated fcale, adapting it to the eye-piece of a compound microfcope ; but his method does not admit of accuracy. Mr. Luccock made ufe of a more fimple inftrument, which we have feen ; it confifted of a lens about half an inch in focal length, adjufted to a graduated fcale. On this fcale a number of fibres were ftretched and compreffed by a flider and fcrew into a given fpace ; the filaments covering this fpace were then counted by the aid of the lens, and a number of admeafurements being taken of the fame fort, the mean of the whole was fuppofed to give the correct diameter of the filament. In this method, however, fome of the filaments muft unavoidably overlap part of the others, on which account a greater number will be feen in a given fpace than there would be were the whole diameter of each fibre vifible. The error refulting from this may be ftated at one-fifth. Thus Mr. Luccock makes the beft Englifh wool to meafure the fourteen-hundredth part of an inch, which is finer than the beft Spanifh, as meafured by Dr. Parry, by a more accurate but more laborious method. According to Mr. Luccock, a fample of moderately fine Spanifh wool reached to the fixteen-hundredth part of an inch ; according to Dr. Parry, the very beft Spanifh is not fmaller than the fourteen-hundredth part of an inch.

With the above deduction of one-fifth, which we believe to be a near approximation to correctnefs, the diameter of the fibres of the beft Englifh wool, as forted in the ufual method, will be nearly as follows :

	Parts of an Inch.
Prime - - -	$\frac{1}{1120}$
Choice - - -	$\frac{1}{1024}$
Super - - -	$\frac{1}{928}$
Head - - -	$\frac{1}{800}$
Downrights - -	$\frac{1}{710}$
Seconds - - -	$\frac{1}{640}$
Abb - - - -	$\frac{1}{580}$
Fine livery (variable) -	$\frac{1}{480}$

The method of meafurement adopted by Mr. Luccock might be fufficiently correct with the deduction of one-fifth, were the inftrument always ufed by the fame perfon, and a fimilar degree of preffure given in each experiment ; but as this is required, it becomes uncertain in its refults, and inadequate to practical purpofes.

Dr. Parry's method of meafurement is effected with an inftrument fimilar in principle to the lamp micrometer of Dr. Herfchel, of which an account is publifhed in the Philofophical Tranfactions for 1782. (See MICROMETER.) An object of a known diameter being placed in the focus of a compound microfcope, and ftrongly illuminated, a piece of white paper is placed horizontally at fome diftance beneath it ; then looking through the microfcope with one eye, and keeping the other fteadily open, you will fee the object apparently projected on the paper, which is to be meafured, whilft viewing it, with a pair of compaffes. Divide the length of the image fo meafured with the known diameter of the object, which will give the magnifying power of the microfcope. This being found, place the object you wifh to meafure in the focus, and projecting its image on the paper as before, meafure it with the compaffes, and divide the refult by the magnifying power, which will be the real magnitude of the object required.

The light of a lamp is to be preferred to day-light, and the fibres to be meafured are to be *ftretched* on a glafs, and waxed down at both ends. The under fide of the glafs fhould be blackened with Indian ink, except in three parts, the middle, and near the two ends. The unblackened fpaces being placed in the focus of the microfcope, ten or more filaments may be examined and meafured fucceffively, both in the middle part of the glafs, and near the ends, which will give the diameter of the filament at the upper and lower end of the ftaple, and in the middle. Each lock of ten filaments being thus examined in three different parts, the mean of the three meafurements muft be taken for the mean diameter of each filament, and the mean diameter of the ten filaments may be taken for the finenefs of the whole lock.

In place of the blackened glafs, we would recommend a thin flide of ivory or brafs, about five inches in length, and half an inch in breadth, with three tranfverfe flits or openings, one in the middle, and the two others about three-fourths of an inch from each end. On this flide the filaments may be ftretched, it will not be liable to break, and the edges of the filaments will be more correctly defined than when a plate of glafs is placed under them.

The farther the paper is removed from the eye, the larger will be the apparent fpace covered by the image of the object, but it muft not be too far for the hand to meafure it with compaffes. But if in place of the compaffes we have a fheet of pafteboard graduated into minute divifions from a black line upwards, and a fliding index be adjufted, the pafteboard may be placed at a much greater diftance, the obferver adjufting the flide, until the edge of it and the black line coincide with both edges of the filament. An

 horizontal

horizontal pofition for the microfcope will be the moft convenient, illuminating the object with a lamp and lens. In this way, the apparent diameter may be greatly increafed, and we think the obfervations might be made with greater eafe and accuracy.

By the above method the diameter of very minute filaments may be afcertained, and minute differences detected, which the unaffifted eye is unable to detect. We are aware, however, that it requires fome addrefs and time to enable the obferver to manage the inftrument, on which account it cannot, we fear, be made generally ufeful.

The following admeafurements of different fine wools were taken with Dr. Parry's inftrument; the firft column reprefents the outward end of the filament, the fecond the middle, and the third the bottom, in fractional parts of an inch; the latter column the mean of ten filaments of the fame wool.

TABLE of comparative Diameters of the Filaments of various Clothing Wools, by Dr. Parry.

Long Wool, or *Combing Wool*, being prepared for fpinning by a procefs entirely different from that of fhort or clothing wool, and the pieces made from it being finifhed in a very different manner, the qualities moft required in this kind of wool are length and foundnefs of the ftaple, without which the fleece is unfuited for the comb. The finenefs of the hair is a fecondary quality, required only in certain kinds of goods. The wool-comb is an inftrument of fimple conftruction, confifting of a wooden handle, with a tranfverfe piece or head, in which are inferted three rows of long fteel teeth. The wool, which is to be combed after being clean fcoured, dried, and oiled, is firft drawn upon thefe teeth with the hand, until the comb is fufficiently loaded. It is then placed on the knee of the comber, and another comb of a fimilar kind is drawn through it, and the operation is repeated till all the hairs or fibres are combed fmooth in one direction. This operation requires confiderable ftrength, but the comb being previoufly heated, and the wool thoroughly oiled, facilitates the procefs. When completed the combed wool is drawn off with the fingers, forming what is called a *fliver*; the fhorter part of the wool fticks in the teeth of the comb, and is called the *noyl:* this is fold to the clothiers.

From the above defcription, it is evident that if the ftaple of the wool be not found, the greater part of it will be broken by the procefs of combing, and form noyls. The ftaple muft alfo have a fufficient degree of length for the combs to operate upon it. Length and foundnefs of the ftaple are therefore the moft effential and characteriftic qualities of combing-wools.

Long wools may be claffed into two kinds: firft, thofe fuited for the manufacture of hard yarn for worfted pieces; and fecond, thofe fuited for the manufacture of foft yarn ufed for hofiery. The former require a greater length of ftaple than the latter. The firft may therefore be called long combing-wool, and the latter fhort combing-wool; between thefe there are gradations of wool, which may be applied to either purpofe.

Long combing-wool fhould have the ftaple from fix inches to eight, ten, or even twelve, in length. Before the recent improvements in fpinning by machinery, a very great length of ftaple was confidered as an excellence in long combing-wools; and on this account the hog-wool, or the firft fleeces from fheep which had not been fhorn when lambs, was more valuable than the wether wool from the fame flock, and bore a higher price than the former, by at leaft fifteen *per cent.* Since that time the wether wool has rifen in relative value on account of the evennefs of the ftaple, each lock being nearly equally thick at both ends; but the ftaple of hog-wool is pointed, or what is technically called *fpirey*. Eight inches, if the wool be found, may be regarded as a very proper length for heavy combing-wools. The longer ftapled wool was formerly worked by itfelf, and ufed for the finer fpun yarn, or mixed in fmall quantities with the wether wool, to improve the fpinning. It is found that an equal length of ftaple contributes to the evennefs of the thread when fpun by machinery, and a very great length of ftaple is rather injurious than otherwife in the procefs of machine fpinning. To the wool-grower, however, it muft always be defirable to increafe the length of his heavy combing fleeces, as he thereby materially increafes the weight; and we have not yet learned that the price has ever been reduced on this account, for if the wool be too long for fome branches of the worfted manufacture, there are others in which it may be worked with advantage.

The length of the ftaple may be increafed by a plentiful fupply of nutritious food. The fame effect may alfo be produced by letting the wool remain a longer time on the fheep before it is fhorn. We have feen a ftaple of Lincolnfhire wool which was twenty inches in length: it had grown two years without fhearing. This, however, would be unattended with any advantage to the grower. The more frequently fheep are fhorn, provided the wool is fufficiently long, the greater will be the weight grown in a given time on the fame animal; for, from obfervations which we have made, we are fatisfied that wool is grown more rapidly immediately after the fheep are fhorn than at any other time. Length of ftaple in wool depends primarily on the breed, but may be more affected by culture than many other qualities of the fleece. The foundnefs of the ftaple may be eafily judged of by pulling both ends of it with the fingers with confiderable force. In weak or unfound wool the ftaple eafily breaks in one or more parts, and on obferving it, it will be feen that the fibres are much thinner in the part which breaks. This is occafioned either by a deficient fupply

ply of food, by difeafe, or by inclement feafons, which caufe a ftoppage in the growth of the fleece. This goes on to a greater or lefs degree. In fome inftances, the ftoppage has been fo entire that the upper part of the ftaple is nearly feparated from the lower, and is only connected with it by a few filaments: in fuch cafes, the ftoppage has continued for a confiderable time, and the bottom part of the ftaple may be confidered as a new fleece, protruding the old one from the fkin. Connected with the foundnefs of wool, there is another property required; this is, that the ftaple be free and open, or that the fibres fhall not be matted or felted together; an effect which takes place frequently when the wool is unfound. It is in fact a natural felting of the wool on the back of the animal, when by any caufe it has ceafed to grow. Sometimes the lower part of the fleece next the fkin will be fo completely matted as to form a fubftance nearly as hard as a hat, and will hold to the fkin by a few hairs only. Thefe are called cotted fleeces; all approach to this ftate is peculiarly injurious to combing-wools. The wool-buyers generally throw out the cotted and unfound fleeces when they pack the wool from the grower, and buy them at a very reduced price. The foftnefs of combing-wool, though of lefs importance than in clothing-wool, yet enhances its value, as it is found that fuch wool makes a clofer and fofter thread, and in every procefs of the manufacture finifhes more *kindly*. Combing-wools grown on light calcareous foils are deficient in this refpect; fuch are the combing-wools of Oxfordfhire and the Cotfwold hills, which are formed of that fpecies of lime-ftone called oolite, or roe-ftone. A copious fupply of the yolk is neceffary to the healthy condition of the fleece, and as this in many flocks is nearly equal in weight to the wool, the fleeces contain from fix to eight pounds or more of it before they are wafhed, for in the unwafhed ftate they often weigh eighteen pounds in many of the long-woolled flocks in England.

The whitenefs of the fleece is lefs important in the long combing than in clothing wool, provided it be free from grey hairs. The latter circumftance does not frequently occur in combing-wools. There is, however, a peculiar colour communicated by the foil, which is fometimes fo deep as to injure the wool for particular ufes, and what is of more importance, there is a dingy-brown colour given to the fleece by impoverifhed keeping or difeafe, which is called a *winter ftain*; it is a fure indication that the wool is not in a thoroughly found ftate, and fuch fleeces are carefully thrown out by the wool-forter, being only fuited for thofe goods which are to be dyed dark colours.

The finenefs of heavy combing-wool is of lefs importance than the other qualities. In every fleece of this kind there will be a certain fmall portion of fhort clothing-wool on the fhanks, the belly, the throat, and the buttocks. The clothing-wool from fuch fleeces is not often divided into more than two or three low forts, and the combing-wool is feldom thrown into more than four forts, that is, two forts of the hog-wool, and two forts of the wether-wool, of which three-fourths, if the fleece be good, will form the beft fort in each.

There is, however, a fine long combing-wool which is required for bombazines and the finer kinds of worfted goods; this is moft frequently felected from the longer parts of clothing fleeces, and admits a divifion into four or five forts, the fineft being equal in hair to that of the head or fuper in clothing-wool; whereas the beft fort of the common heavy combing-wools feldom ranges higher in point of finenefs than the coarfeft fort of clothing-wool above the breech locks; *viz.* the low abb and the livery.

Short combing or hofiery wool requires a different length of ftaple, according to its finenefs: for the better forts, the ftaple fhould not be fhorter than four or five inches; the lower forts may range as high as eight inches. A greater length than this is not defirable for any kind of foft worfted. What has been faid of the foundnefs and finenefs of ftaple required for long combing-wool, applies equally to the hofiery wool, but in this the finenefs of the hair and foftnefs are of more importance. Moft of the fleeces which yield fine combing-wool produce nearly an equal quantity of fhort wool, which is thrown in the fame manner as the regular clothing forts. The combing forts for the hofiery are generally called,

Super matching,
Fine matching,
Fine drawing,
Altered drawing,
Brown drawing,
Saycaft.

The names of thefe forts derive their origin from ancient proceffes of the manufacture, with which we are unacquainted at prefent. The lower fort, or faycaft, was probably at firft the long coarfe combing-wool, thrown out for the manufacture of fays, of which we have frequent mention in the earlieft hiftory of the woollen trade in England. The relative value of thefe forts, compared with each other, varies according to the demand for the finer or coarfer kinds of hofiery, and is alfo affected by the clothing trade. When any clothing fort which ranges in finenefs with one of the combing forts is in great demand, the wool-forter will break down the fhorter combing-wool of this fort, and throw it to the clothing-wool, which enhances the price of the former by making it fcarce. The finenefs of thefe forts out of the beft combing-wools, ftated numerically, as compared with clothing forts, will be nearly as under, in the fractional parts of an inch.

Moft of the beft forters throw out the hog combing-wool from the beft forts, making a fuperfine hog for the bombazine trade, hog-wool being lefs fuitable for the hofiery, which does not require yarn fo finely fpun as for hard yarn.

As all the different forts of fhort combing-wool, together with feveral forts of clothing-wool, will frequently occur in one Englifh fleece, it is obvioufly the intereft of the grower that his fleece fhould produce as great a proportion of the beft forts as can be done without materially diminifhing the weight.

Skin Wool, or *Pelt Wool*, is the wool feparated from the fkins of flaughtered fheep by the fellmonger. The quantity of this wool, in a country like England, where fo much animal food is confumed, is very confiderable, and has been eftimated at near 50,000 packs of 240lbs. *per annum*, for England and Wales. Soon after fhearing, the fkin-wool is too fhort to be worked by itfelf, and is generally kept and mixed in with the longer wools. The procefs by which wool is feparated from the fkins has a tendency to make it hard, and deftroy or injure its felting or milling property, on which account fhort-fkin wools are feldom ufed for the manufacture of cloth, but more generally for flannels, ferges, and thofe kinds of goods which require little or no milling;

 the

the fineſt kinds are much uſed for ſtockings made of yarn from carded wool. In the ſpring, when the wool on the ſkins has acquired a conſiderable length, it is thrown into combing ſorts; the finer kinds are uſed for knitting hoſiery yarn, and the coarſer for hard yarn for the warps of ſerges and other goods, having a warp of combed and a weft of carded wool. The value of ſkin-wool is ſeldom equal to that of fleece-wool of the ſame degree of length and fineneſs, owing to the felting property being injured, which renders it more unfit for the manufacture of woollen cloth.

Lamb's Wool.—The wool of the lamb is, with certain exceptions, ſofter than that of ſheep's-wool, from the ſame flocks. It poſſeſſes the property of felting in a remarkable degree, and on this account is principally manufactured into hats, except ſkin lamb's-wool, which loſing its felting property in a great degree, is employed in the manufacture of flannels and woollen yarn for lamb's-wool hoſiery. In the northern parts of Europe, the lambs of ſome of the breeds of ſheep poſſeſs a fleece ſo delicately ſoft, that it conſtitutes a moſt valuable fur, being dreſſed on the ſkin, and uſed as a coſtly article of attire. According to Pallas, the inhabitants of the Ukrain and Podoli, as ſoon as the lamb is dropped, (which comes into the world with a pretty wavy ſkin, even without the aſſiſtance of art,) to augment its beauty, and make it bring a higher price, ſew it up in a ſort of coarſe linen ſhirt, ſo as to keep up a conſtant gentle preſſure on the wool, pouring warm water over it every day to make it ſoft and ſleek; only letting out the bandage a little from time to time as the animal increaſes in ſize, but ſtill keeping it tight enough to effect their purpoſe, which is to lay the *wool* in beautiful gloſſy ringlets, and thereby produce a delicate ſpecies of fur in great requeſt for lining clothes and morning-gowns. By this treatment, the ſtaple of the fine ſoft wool which riſes in the infancy of the lamb takes a handſome arrangement; and the animal is killed younger or older according to the ſpecies of fur intended to be produced; from a ſhort gloſſy nap, like ſatin, only fit from its thinneſs for the purpoſe mentioned above, to a warm thick fur for a winter great-coat. The firſt of theſe furs in eſtimation and price is a fine black, that looks like ſilk damaſk; an inferior black fur comes next, much thicker, uſed for *peliſſes*, or *ſhubes*, as the upper winter garb worn out of doors is called; and the leaſt in eſtimation is the whiteſt, except it be of a very pure colour and ſilky appearance, where it is a rival to the firſt; eſpecially for night-gowns, a very common dreſs both morning and evening amongſt the Ruſſians; particularly in the interior parts of the empire.

The Boucharian ſheep, as deſcribed by Pallas, grows a compact, ſoft, and elaſtic wool, which is elegantly formed into frizzled ringlets. In the lamb, the wool is formed into delicate little circular waves, as if preſſed cloſe to the ſkin by art; but when taken from the mother, or killed immediately after birth, they are ſtill more beautiful, and often elegantly marbled with feathered waves, like ſilk damaſk. Theſe three furs are the fineſt and moſt precious of the kind known to Europe and the Eaſt; they are brought to us by the Boucharian Tartars and Perſians, who ſell them dear. The moſt prized are, the *blue*, the black, and the ſilver grey; but of the *unborn lamb-ſkins*, as the fine gloſſy thin furs are called, which ſo much reſemble ſilk damaſk, the fine black is deareſt and moſt eſteemed. To obtain theſe valuable furs, the Boucharian Tartars purchaſe whole flocks of male lambs juſt dropped from their mothers: as to kill a female till paſt the age of breeding is held as a kind of crime by all Tartar hordes; ſuch is their reverence for an animal which conſtitutes their greateſt riches, and the propagation and care of which are the great buſineſs of their lives; ſo that all the fur we ſee of this ſpecies ſold by the Tartars are from young rams. The Boucharians are of opinion, that art is neceſſary to preſerve theſe furs in their greateſt beauty; and under that idea, keep the lambs under ſhades, &c. during the meridian ardour of the ſun; but Dr. Pallas has reaſon to think, that theſe precautions are uſeleſs, as he obſerved that the ſame variety of ſheep produced the ſame fine hues equal in every reſpect, without any ſort of care, in the hands of the Kirguite Tartars.

It is very remarkable that the lamb's-wool, in many of the Merino flocks, is coarſer than the ſheep's-wool. In ſome of the flocks, the lambs are at firſt covered with coarſe hair, which falls off afterwards, and they produce the fineſt wool.

Wool from other animals beſides the ſheep is employed in manufactures, and ſpun and woven into fabrics of different kinds, either unmixed or mixed with ſheep's-wool. The goats of Thibet, which grow the fine ſhawl wool, produce it as a fine down at the bottom of the long coarſe hair, with which the animals are covered. Many of the common goats in Europe grow a ſimilar down, which, by cultivation, might become a valuable article of commerce. It is not, however, yet clearly aſcertained, whether the ſhawls and ſhawl cloth of India are all manufactured from goat's-wool; part of it appears to be made from ſheep's-wool peculiarly ſoft and fine. The Angora goat grows a hair extremely fine and ſilky, which is much uſed in ſome of the French worſted goods mixed with ſilk. This goat is properly a long-woolled animal. Dr. Anderſon ſays, that the Angora goat will proſper and preſerve its peculiarities in France and Sweden. The wool of the vicunna, called Vigonia wool, is generally of a reddiſh-fawn colour; it is peculiarly ſoft and ſilky, but intermixed with long coarſe hairs, which are very difficult to ſeparate. (See VICUNNA.) From the lama and pacos of Peru a ſtronger and longer ſtapled wool is obtained, which is ſometimes white. Under a liberal government which protected and encouraged commerce, we have no doubt the fleeces of theſe animals might be greatly improved, and would become an article of great value. The wool from the yak of Tartary, and the muſk ox of Hudſon's bay, has yet received little attention. We have ſeen ſtockings made of the latter, and which are worn in that country; the wool was ſoft but not fine, and much intermixed with long coarſe hairs.

The quantity of ſheep's-wool annually grown in England and Wales was eſtimated, by perſons in the wool trade examined before the houſe of commons in the year 1800, at ſix hundred thouſand packs. Mr. Luccock, in his Treatiſe on Wool, ſeems to conſider this eſtimate as greatly exceeding the real amount, and has given an eſtimate founded on the ſuppoſed extent of ſurface paſtured by ſheep, and the quantity of ſheep *per* acre in each county. This table we ſubjoin, as the only attempt that we know of to determine the queſtion on certain data; though we conſider it only as an approximation to truth, and are inclined to believe that the quantity is under the real amount. Such is alſo the opinion of the moſt intelligent perſons in the wool trade, whom we have had an opportunity of conſulting.

From this table, it will appear that the total amount, including ſkin-wool and lamb's-wool, is ſomewhat ſhort of four hundred thouſand packs, which is probably one-fourth below the true quantity, could it be aſcertained. Mr. Luccock is inclined to believe that the flocks of ſheep in England and Wales are not ſo numerous as formerly, but he ſays thoſe of Ireland and Scotland are rapidly increaſing. Even in England and Wales, he ſays, we have more than three millions of acres capable of being improved, and carrying a more numerous ſtock. We have two millions of ſheep whoſe fleeces are ſcarcely wool, and which might be brought to contribute their ſhare to ſupport the woollen manufacture, and to increaſe the wealth of the country.

It may be proper to remark, that the quantity of wool grown annually in England is more variable than is generally ſuppoſed, owing to the variable temperature of our climate. In long-continued and ſevere winters, the ſheep not obtaining the ſame quantity of food, and being alſo rendered leſs vigorous by the cold, do not grow ſo much wool as in milder ſeaſons. The difference between the weight of the fleeces grown in ſevere and in very mild ſeaſons, may be ſtated at one-fifth of the whole annual clip: indeed we believe it exceeds that proportion. About the year 1700, the annual value of Engliſh wool was eſtimated at two millions ſterling. If we ſuppoſe the average price at that time to have been eight-pence *per* pound, or eight pounds *per* pack, this will make the total weight of wool two hundred and fifty thouſand packs. Indeed when we conſider the improved ſtate of our agriculture, the great increaſe of our population, and of our woollen exports, we may fairly ſtate the preſent weight of wool grown to be double the amount of what it was at the period referred to. In a ſubſequent part of this article, it will be ſeen that the cloth manufactures of Yorkſhire, principally from Engliſh wools, have increaſed eight-fold in the laſt eighty years; and though the woollen manufactures have removed from ſome other ſituations, yet the great increaſe on the whole in England cannot be doubted. Since the date of Mr. Luccock's table in 1805, in conſequence of the high price of long combing-wool, the growers have paid more attention to the weight of their fleeces; and many who had rendered their fleeces lighter by exchanging the Lincolnſhire for the Leiceſter breeds of ſheep, have ſince been reverting to the former breed, or rather to a mixed breed, endeavouring to combine the improved form of the Leiceſter ſheep with the heavy fleece of the Lincoln. The quantity of long combing-wool grown annually is greater than it was even ten years ſince; the high and increaſing price and demand operating naturally as a premium for its cultivation.

The wool of Scotland may, perhaps, be estimated at 70,000 packs, of which the greater part, particularly that grown in the Highlands, is of the very coarsest kind. Of the quantity of wool grown in Ireland, we can form no correct estimate, but it cannot be great. From the returns at the Custom-house, it appears that the quantity of wool imported from Ireland and the Isle of Man in 1816 amounted to about 2600 packs; whilst the value of woollens imported from England was upwards of 500,000*l.* sterling. The woollen and worsted manufactures in Ireland are no where on an extensive scale; perhaps 60,000 packs are the full amount of the wool annually shorn in Ireland: this was the amount stated about a century since.

The quantity of wool imported into England may be seen from the following return at the Custom-house for the year 1817, amounting to about thirty thousand packs. The qualities we have annexed in the last column.

An Account of the Quantity of Sheep and Lamb's Wool imported into Great Britain, in the Year ending 5th January 1817; distinguishing the Countries from whence imported.

Countries from whence imported.	Year ending 5th Jan. 1817.	Quality.

The whole of the imported wool, with scarcely an exception, is worked on the card, none of it being suited for the comb. The coarser kinds are principally employed for carpets, &c.; and the fine from Spain, Germany, Portugal, and France, supply our manufactures of superfine broad cloths, cassimeres, &c. So large a portion being of the finer kinds, the total value cannot be less than one million and a half pounds sterling.

Wool of New Holland.—The annual value and amount of the fine wool imported into England for our own manufactures being so great, we must surely applaud the meritorious exertions of those who attempt to supply the demand with the produce of our own country, or of our dependent colonies, and more particularly if they can raise this supply from parts where no wool was before grown. In this view, it cannot fail to be highly interesting to learn, that the exertions of one enlightened agriculturist have been eminently successful in spreading over an immense region dependent on England the very finest-woolled sheep, where the soil had never before yielded any produce serviceable to civilized man.

John Macarthur, esq. descended from an ancient family in Argyleshire, captain in a regiment then commanded by general Grose, went to New Holland in 1789. Fortunately for the future prosperity of the colony, his active spirit of inquiry and enterprise led him to direct his attention to the natural advantages which the soil and climate presented to the agriculturist, and having by purchase and grants obtained a considerable tract of country, he quitted the service in 1793, and commenced his farming operations. His stock at first consisted only of a few oxen and thirty Bengal ewes, growing a coarse kind of wool or hair. About the year 1795, he obtained from captain Kent, of the Royal Navy, one Merino ram and two ewes, purchased from the Dutch governor of the Cape of Good Hope. With these he began to cross his coarse-haired sheep, and to select the finest-woolled progeny to breed from. Having occasion to return to England in 1802, be brought over specimens of his wool, which were shewn to a body of the clothiers from the west of England, then in London on public business, who were so sensible of the advantages which might result from encouraging the growth of fine wool in the colony, that they presented a petition to the privy council, by whom Mr. Macarthur was examined. His plans being approved, the privy council recommended the secretary of state for the colonies to give him an additional grant of land, in a tract of country, from its fertility, called the cow-pastures, forming part of Camden county. On his return he took with him three Merino rams and two ewes, purchased from his majesty's flocks; and thus encouraged, he proceeded with rapid steps in the increase and improvement of his flocks, the climate being every way suited to secure the healthy condition of the sheep, and preserve the fineness of the wool.

The numbers increase four-fold every five years, so that his flocks already amounted to about four thousand sheep and lambs, including the fine and mixed breeds, when the unfortunate disputes with governor Blight, and the subsequent arrest of the latter, obliged Mr. Macarthur once more to return to England, and in some degree interrupted the progress of improvement. In 1817 his flocks had increased to about seven thousand, and the wool which has been sent to this country at different times, is become an important source of profit, the better sort being equal to the best Merino piles from Spain or Saxony. What we have seen more nearly resembles the latter, and were they both in the same state of cleanness, the most experienced eye could not discern any difference between them in fineness of the hair, length of staple, soundness, colour, or other properties.

The

The wool has been hitherto washed on the sheep's back in the English method, by which it is not rendered so clean as by the Spanish or German mode; but making allowance for the additional waste, its value is equal to that of the very best Merino wool imported from any part of Europe.

The quantity imported this year is about eighteen thousand pounds weight, and a farther arrival is expected. The laudable example of Mr. Macarthur has been followed by other persons in the colony, and the total amount of wool sent from thence this year is about fifty thousand pounds weight; and such is the spirit of agricultural improvement, that at the annual sales of sheep established by Mr. Macarthur, rams and ewes have been sold at from ten to thirty guineas each. Though the absence of Mr. Macarthur impeded the progress of improvement, yet this will be more than compensated by the valuable information he has obtained with respect to the management and improvement of his flocks, from observations made on the continent; and he has further benefited the colony by taking back with him a selection of olive-trees, vines, and oranges. The dryness and mildness of the climate of New Holland, and the almost total absence of briars and underwood, are extremely favourable to sheep. His stock is divided into flocks of about four hundred, with shepherds and Spanish dogs to each. Under these propitious circumstances, and as the flocks double in number every thirty months, we may anticipate, that in the course of twenty or twenty-five years, the importation of fine wool from this colony will be fully equal to the total amount at present imported into England from all the different countries of Europe. It might repay the exertions of this enlightened agriculturist, and of the British government, could they procure from India the animals, whether sheep or goats, which yield the peculiarly soft wool for shawls. This would be a most valuable article, and is much wanted by our manufacturers.

There can scarcely be a doubt, that under the favourable climate of the British settlements in New Holland, all the Asiatic wool-bearing animals, particularly those of Cashmere and Thibet, might be introduced with every prospect of success. The coarse wool grown in the colony is chiefly manufactured in the country for domestic use. It is estimated that there are at present sixty thousand sheep in the colony, and a little perseverance and attention would suffice to change the coarse-woolled breeds into finer ones; a change which is at present rapidly taking place, and deserves the greatest encouragement, as wool is the only article of produce which the colonists have at present to export in exchange for British manufactured goods.

The Improvement of Wool depends primarily on attention to the breed of sheep, but there are various circumstances of soil, climate, and food, which are important to be regarded. The experiments that have been made in various parts of Europe within the last half century, have sufficiently removed the prejudice that long prevailed, respecting the impossibility of growing the finest clothing-wool in almost every part of the globe where sheep will subsist and thrive. It is different with the long combing-wools, to grow which in perfection, luxuriant pastures seem absolutely requisite, and these cannot be obtained under a parching sun, nor could the animal subsist in tropical climates, covered with such a load of wool as is grown on our sheep in Lincolnshire. Under such circumstances, an entire change seems to take place in the animal system; the long-woolled sheep become diseased and feverish, and only recover by casting the fleece, which is replaced by a coat of short hair. The rich pasture in England, and the opposite coasts of Flanders, seem more favourable to the growth of heavy combing fleeces, than any other country in the known world; and the Leicestershire and Lincolnshire sheep seem every way well suited to these pastures, and the prices of the wool obtained at present are sufficient to secure attention to its cultivation. At one period, indeed, during the American revolution, the price of long combing-wool not being more than about three-pence *per* pound, the growers turned their attention principally to the improvement of the carcase, and neglected the weight of the fleece. At present the price is about eighteen-pence, and the average weight being about eight pounds, the wool forms an important object, and the growers are endeavouring to increase the weight of their fleeces. For the common purposes of the worsted manufactures, this wool is so well suited as to leave nothing further to be desired; and it is this kind which foreign manufacturers are so desirous to obtain from us. In many situations, however, where heavy long-woolled sheep are introduced, and where the soil is not sufficiently rich to grow it in perfection, it would be possible to grow a fleece weighing five or six pounds of very fine combing-wool, by crossing the long-woolled ewes with the Anglo-Merino rams. The increasing demand for finer goods, and the great improvement made in the spinning of combing-wool by machinery, make such a change desirable where the pastures are not sufficiently rich to bear the heavy long-woolled breeds of Leicester and Lincoln.

In many cold and exposed situations it would be desirable to provide better shelter for the flocks; and the practice of *greasing*, hereafter described, might be introduced with great advantage, and would tend to preserve the sheep and improve the quality of the wool.

The experiments made on the fine-woolled sheep on a large scale in different parts of Europe, prove that the peculiarities of food and climate have comparatively small influence on the quality of clothing-wool, and that it may be grown equally fine in situations where the sheep are confined and kept on dry meat a great part of the year, as in Saxony, Sweden, and Denmark. It may also be grown in the richest pastures, provided the pastures be over-stocked, to keep the herbage bare. There cannot, however, be a doubt, that a dry light soil, particularly in the moist climate of England, is most favourable to the health of the sheep, and to the quality of the wool.

The experiments that have been made in England on the Merino sheep have not been so successful as in other countries, principally arising from two causes.

In the first place, the demand for meat in England will always make the wool but a secondary object with the grazier, and no cross of the Merino sheep with the English has yet produced a race that equal in symmetry of form the South Down sheep, or that will produce the same quantity of meat to the butcher in the same space of time, and with the same food. In the second place, the mode of washing the Merino and Anglo-Merino wool in England will, so long as it is practised, prevent the wool from obtaining its proper value in the market. From the great quantity of natural yolk or grease in the Merino fleece, it is impossible to wash the wool on the sheep's back by mere immersion in water. In Spain no attempts are made to wash the wool upon the sheep's back, but all the fleeces of a pile are regularly sorted, and the different sorts scoured and dried before the wool is packed. But where the quantity of wool which any one grower possesses is small, as in England, it would not answer to send for wool-sorters from a distance; and to wash the wool before it is sorted, would so intermingle the fine with the coarse locks, as to render the regular sorting extremely difficult and expensive. In

Saxony

Saxony and Sweden the wool is washed on the sheep's backs. The following account of the process is thus described by baron Schulz. The sheep are first washed with one part clear ley, and two parts lukewarm water, and then in another tub with less ley in the water; after which the sheep are washed, laying them always on their backs, with their heads up, in a tub with clean water; and lastly, there is poured on the sheep, when standing on the ground, a sufficient quantity of water, which is as much as possible squeezed out of the wool. The sheep are afterwards driven into an unpastured meadow adjoining, and remain there, to prevent their soiling themselves in the sheep-house. They remain there a day and a night, or longer, till the wool be dry, which in fine weather will be in three days. Some persons wash their sheep twice, but the wool becomes harder in consequence of it, and has a greyer appearance.

The great quantity of grease which the finest Spanish wool contains at the first washing mixes with the ley-water, and makes it quite soapy; but this grease is wanting in the second washing, so that the water is not in the least softened. Some mode of washing like the above must be introduced in England, before the manufacturer will encourage the Anglo-Merino wool; for after his purchase, when he thinks he has obtained sufficient allowance in the price to cover the waste, he is generally much disappointed in finding the loss in the manufacture so greatly to exceed his expectation, and he is deterred from making a second trial.

In the northern counties of England, and in Scotland, a practice has long prevailed of greasing the sheep with a mixture of tar and butter, to preserve the animal from the effects of moisture, and the inclemency of the weather in hilly and exposed situations. This practice seems at present peculiar to Britain, but the ancients evidently made use of mixtures of the dregs of olive wax, tar, wine, and other ingredients, to protect the skin of sheep after shearing, and to soften and improve the wool. Such was the practice of the Italian shepherds, as described by Virgil:

> " Aut tonsum tristi contingunt corpus amurca,
> Et spumas miscent argenti vivaque sulfura,
> Idæasque pices et pingues unguine ceras
> Scyllamque helleborosque graves nigrumque bitumen."
> Georg. lib. iii.

That this practice was extremely beneficial in warm climates, by protecting the skin of the sheep from insects after shearing, and by keeping the wool in a soft state, cannot be doubted.

The practice of greasing the sheep in Scotland, and the northern counties of England, with a mixture of tar and butter, seems to have been introduced merely to preserve the sheep, and was generally supposed to be injurious to the wool. Indeed the great proportion of tar, too frequently employed, gave some ground for entertaining this opinion; and the breed of sheep, on which this mixture was most generally applied, is naturally the worst which exists in Britain for the production of wool, the fleeces more nearly resembling coarse hair than wool; but Mr. Bakewell, in his Treatise on Wool, observes, that "in Northumberland, where the fine-woolled sheep have received the benefit of greasing with a mixture in which the proportion of tar was merely sufficient to give it due tenacity, the wool is greatly improved by the process, but the ignorance or selfishness of the wool-buyers for a long time prevented the acknowledgment of the fact." Many were afraid to purchase the wool on account of its dirty appearance, but its value is now better understood in the Yorkshire markets, and it is purchased by the manufacturers of coloured cloth in preference to the ungreased wool of the same degree of fineness. The same preference is also given to the cloths in the halls, where they are sold in an undressed state. When these cloths are finished, their superiority is more apparent, possessing a degree of softness far beyond the ungreased wool. These wools appear to improve in every process of the manufacture, and yield a cloth of greater value by twenty or thirty *per cent.* than the ungreased hard wools, though the latter may be equally fine.

But even in Northumberland, where the wool is so greatly improved by the practice, its good effects in this respect are not sufficiently known, and the operation is delayed till the approach of winter. By this delay, the upper part of the staple which is first grown, is deprived of the advantage of being kept in a moist soft state during the summer heat. When the operation has taken place, a perceptible improvement may be observed in the wool which is afterwards grown. The line of distinction is clearly marked by the stain which the unguent leaves in the staple, the bottom part of which, where it is applied, is finer and softer than the upper part which was grown before its application. This difference is so great, that a careful examination of the fine-greased wools of Northumberland might alone be sufficient to demonstrate the advantage of the practice, and the inconvenience of delaying the operation to the end of the year. To derive the most advantage from the ointment both to the wool and the sheep, it should be applied immediately after shearing, and again at the approach of winter. By the first greasing, the wool will be kept soft and moist during the sultry heats of July and August, and the top of the staple would not become harsh and discoloured, which is frequently the case with English wool. One acknowledged advantage of greasing immediately after shearing should not be overlooked; it destroys the sheep-tick, and has a tendency to prevent cutaneous distempers, and to protect the skin from the bite of the fly. The manner of preparing the ointment in Northumberland is as follows:—From sixteen to twenty pounds of butter are placed over a gentle fire, and melted; a gallon of tar is then added, and the mixture stirred with a stick until the tar and butter are well combined, and form a soft tenacious ointment. Some skill is required in its application, the want of which has prevented the practice from prevailing more generally. If the ointment be rubbed on the wool, it collects on the top of the staple, where it detains the loose soil, and becomes hard, and is injurious to the wool. The proper method is to divide the staples or locks with one hand, and apply the ointment with the finger immediately upon the skin; it is thus kept constantly soft by the warmth of the animal, and is equally diffused through the fleece. Attention to this circumstance is of the greatest importance to the success of the practice. The quantity laid on each animal varies in different districts. In the lighter mode of greasing, one gallon of tar and twenty pounds of butter will be sufficient for fifty sheep. In Scotland, where greasing is applied merely to preserve the animal against the inclemency of the climate, a much larger portion of tar is used: this would be very injurious to the wool, were it of any other than the very coarsest kind.

Could a cheap substitute for tar be found, which would possess equal tenacity, the ointment might be applied with great advantage to all our native breeds of English sheep, both for the preservation of the animal and the improvement of the wool. Mr. Bakewell states, that long combing-wools, which have been greased in this manner, produce a softer and superior yarn to any ever made from wool of the native English breeds which have not undergone the process.

cefs. On all chalk and light calcareous foils, the wool is always much harfher than wools of the fame degree of finenefs grown on argillaceous or filiceous foils; and this arifes from the calcareous earth penetrating the fleece, and abforbing the natural greafe, and thus rendering the fibres hard and elaftic. Thefe foils cover a large portion of the fouth-eaftern counties of England, and of fome of the midland counties; and it is well known to cloth manufacturers that the wool from thefe diftricts do not work fo well, nor make fo foft a cloth, as wool on filiceous or argillaceous foils. Nor will this wool felt in the fulling-mill like the fofter wools. The practice of greafing would be of undoubted advantage in calcareous diftricts, applying the ointment more fparingly than in the northern counties. Perhaps twenty-five pounds of butter, and one of tar, or two of bees'-wax, might be fufficient for one hundred South-Down fheep; and if the mixture were applied once after fhearing, and again in October, the expence would be abundantly compenfated by the improved condition both of the fheep and wool. The foftnefs of wool appears to be effentially connected with the property of felting, and depends partly on the ftructure of the furface of the fibre, and partly on its poffeffing but a moderate degree of elafticity. The procefs of felting is beft illuftrated in the hat manufacture, where the fibres of wool or fur are brought into contact by preffure and warmth, and form a compact fubftance without the aid of fpinning and weaving. In fome parts of Tartary, coarfe cloth for tents is manufactured by fpreading the wool on the ground, and preffing it in warm water with the feet; this was probably the firft mode of making cloth. All good woollen cloth is ftill woven comparatively loofe, and is made firm and clofe in the fulling-mill. The fibres of wool or fur have a tendency to move more eafily in one direction when preffed, than in the oppofite direction. This motion has been compared to that of an ear of barley placed under the coat-fleeve, with the points of the beards downwards; by the action of the arm the ear is moved in a retrograde direction, until it has advanced from the wrift to the fhoulder. When we draw a hair of wool or fur through the fingers in a direction from the points to the root, we can feel a fenfible degree of roughnefs, which is not felt if the hair be drawn from the root to the point. Hence we may fuppofe, that the furface is covered with a number of points or rings, which are too minute to be obferved by the microfcope, except in fome kinds of fur, as in that from the South-fea feal, in which, with a powerful microfcope, we have feen the furface covered with diftinct leaves or points, fhaped like thofe of the artichoke. We have a ftriking illuftration of this tendency of the fibre to move in one direction in that particular procefs of hat-making, where it is intended to cover the felt or fubftance of the hat with fur of a fuperior kind. The felt on which this fur is to be laid being finifhed, the hair of the beaver is uniformly fpread upon the furface, and being covered with a cloth, it is preffed and agitated by the hand for a certain time. The fibres of beaver-hair introduce themfelves by their roots into the felt, and proceed to a certain depth, and become firmly fixed in it. If the preffure were continued for a longer time, the hairs would pafs entirely through the felt, going out at the under furface, as each hair follows the direction it acquired at the beginning of the procefs.

As the felting property, therefore, feems to depend on the minute ftructure of the furface of the fibre, it is eafy to conceive how this may be injured by a dry calcareous foil, and how this property is beft preferved in thofe furs which are grown under a covering of coarfe hair, and protected from external injury. The procefs of greafing is in fome refpects a fubftitute for fuch a covering, and not only defends the furface, but prevents the fibre from becoming dry, harfh, and elaftic. The ancient Greeks and Romans were in the practice of covering their foft-woolled fheep, called *molles oves*, with fkins: this has been fuppofed to have been intended merely as a protection from briars and underwood; but we have no doubt that wool fo covered would be much fofter than wool expofed to the action of light, and of the foil. That the rays of the fummer fun have a tendency to make wool both coarfer and harfher, may be feen in the effect produced on fheep that are expofed to it without fhelter immediately after fhearing. The top point of the ftaple which was grown at that time is almoft always coarfer and harder than the bottom of the ftaple which has been grown under the cover of the upper part of the fleece, and confequently more protected from light. An analogous effect is produced on the fkins of horfes kept in coal-mines, which become fleek and foft. Thefe facts may fuggeft to wool-growers defirous of improving their wool, the advantage of providing fhade for their flocks during the fultry heats of fummer. The natural inftincts of fheep might teach them the impropriety, not to fpeak of the cruelty, of keeping their fheep in fummer inclofed in pens, and unfheltered, upon a dry foil, where the animals are almoft roafted alive; a practice not lefs injurious to the health of fheep than to all the beft qualities of the wool. Next to a regular fupply of food, protection from the effects of heat and wet are objects of the firft importance in the management of fheep; and it may be ftated as an undoubted truth, that whatever contributes to the comfort of the animal, will enable it to fatten with a fmaller quantity of food, will tend to preferve it in a healthy ftate, and will alfo increafe the quantity and improve the quality of the wool.

WOOL, *Chemical Examination of.* The chemical properties of wool are very fimilar to thofe of hair, and as we omitted to fpeak of thefe in their proper place, we fhall introduce them here.

From the experiments of Achard and Hatchett, it appears that hair contains gelatine, to which it owes its fupplenefs and toughnefs. When hair is boiled in water, this principle is feparated, and the hair becomes much more brittle than before. Indeed, if the procefs be continued long enough, the hair crumbles to pieces between the fingers. The portion infoluble in water poffeffes, according to Mr. Hatchett, the properties of coagulated albumen.

Mr. Hatchett has concluded, from his experiments, that the hair which lofes its curl in moift weather, and which is fofteft and moft flexible, is that which yields its gelatine moft readily; whereas ftrong and elaftic hair yields it with the greateft difficulty, and in the fmalleft proportion. This conclufion has been confirmed by a very confiderable hair merchant in London, who affured him that the firft kind of hair was much more injured by boiling than the fecond.

Vauquelin has publifhed a curious fet of experiments on human hair of different colours. He found it completely foluble in a Papin's digefter. During this procefs, fulphuretted hydrogen was evolved. The folution thus obtained contains a kind of bituminous oil, which is depofited very flowly. This oil was black when the hair was black, but yellowifh-red when red hair was the fubject of experiment. When this oil was removed, nut-galls and chlorine produced copious precipitates. Silver was blackened, and acetate of lead precipitated brown. When concentrated by evaporation, it did not concrete into a jelly.

Water

Water containing only four *per cent.* of potaſh diſſolves hair, while hydro-ſulphuret of ammonia is evolved. If the hair be black, a thick dark-coloured oil, with ſome ſulphur and iron, remain undiſſolved. If the hair be red, this oil is yellowiſh. Acids throw down from this ſolution a precipitate, ſoluble in exceſs of acid.

Sulphuric and muriatic acids become red when firſt poured on hair, and gradually diſſolve it. Nitric acid turns hair yellow, and diſſolves it, while an oil ſeparates, varying in colour, as before-mentioned, according to the colour of the hair employed. The ſolution contains a great deal of oxalic acid, beſides bitter principle, iron, and ſulphuric acid. Chlorine reduces it to a ſubſtance of the conſiſtence of turpentine, partly ſoluble in alcohol.

Alcohol, digeſted on black hair, extracts from it two kinds of oil. The firſt, which is white, ſubſides in white ſhining ſcales as the liquor cools; the ſecond is obtained by evaporating the alcohol. It has a greyiſh-green colour, and at laſt becomes ſolid. From red hair alcohol alſo extracts two oils, one white, as above, the other red as blood. After this latter has been extracted, the hair becomes cheſnut. Hence its red colour appears to depend upon this oil.

Hair on incineration yields iron and mangane ſe, ſulphate and carbonate of lime, muriate of ſoda, and a conſiderable proportion of ſilica. The aſhes of red hair contain leſs iron and manganeſe. Thoſe of white hair ſtill leſs; but in thoſe we find magneſia, which is wanting in the aſhes of other hair. The aſhes of hair do not exceed .015 of the hair.

Hence, according to this analyſis, hair conſiſts of

1. Animal matters conſtituting the greateſt part.
2. A white ſolid oil, ſmall in quantity.
3. A greyiſh-green oil, more abundant.
4. Iron, ſtate unknown.
5. Oxyd of manganeſe.
6. Phoſphate of lime.
7. Carbonate of lime, very ſcanty.
8. Silica.
9. Sulphur.

Vauquelin infers from theſe experiments, that hair depends for its colour upon a kind of oil, which varies according to the colour of the hair in which it is found. He alſo ſuppoſes, that ſulphuret of iron contributes to the colour of black hair. The ſudden change of colour in hair from grief, he thinks, is owing to the evolution of an acid. Bichat, however, attributes this change, perhaps with greater probability, to the abſorption of the colouring principle. To whatever cauſe it be owing, the fact appears undoubted; and it ſhews a cloſer connection between the living powers and the hair, than many phyſiologiſts are inclined to admit.

Wool appears, according to the experiments of Berthollet, to coincide almoſt exactly in its chemical properties with thoſe of hair above-mentioned. When growing on the back of the animal, it is enveloped in a greaſy matter, called the *yolk*, and which appears to be a kind of ſoap; or, more properly ſpeaking, according to the experiments of Vauquelin, who has examined it, of

1. A ſoap of potaſh.
2. Carbonate of potaſh.
3. A little acetate of potaſh.
4. Lime.
5. A little muriate of potaſh.
6. An animal matter.

This ſubſtance appears to have the property of protecting the animal from inſects to a certain degree, and of preſerving the ſoftneſs of the wool, which are perhaps its chief uſes. It is removed from the wool before it is manufactured, by the proceſs termed *ſcouring*. The affinity of the animal matter of wool for all colouring principles is very great, and in general far exceeds that of the different vegetable fibres, as cotton, flax, &c. for ſuch principles. There is one kind of coarſe wool, however, which, according to Dr. Bancroft, does not poſſeſs this property, and receives colours with great difficulty. See DYEING, and the preceding article.

WOOL, *Laws relating to.* The jealouſy entertained on the ſubject of our wools, may be learnt from the legal reſtriction which has been made in relation thereto; as alſo with the view that as much employment as is poſſible may be found for the labouring claſſes. This is effected by the prohibition of the exportation of wool in an unmanufactured ſtate, as will be ſeen below. It muſt be obvious, however, that it would be to little purpoſe to be thus ſtrict reſpecting the article itſelf, if that which produced it was not equally guarded; therefore as early as 13 & 14 Ch. II. c. 18. it was made felony to export ſheep from England or Ireland, or even to Scotland: now however the penalty is forfeiture of every ram, ſheep, or lamb, and the veſſel in which ſuch is ſhipped with intent to exportation from Great Britain and the iſlands belonging thereto; and offenders are to forfeit 3*l.* for every ſheep, &c. ſo ſhipped, and to ſuffer three months ſolitary impriſonment, and till the forfeiture be paid, but not to exceed twelve months; and for any ſecond offence 5*l.* for each ram, &c. and ſix months impriſonment, and till the fine is paid, but not to exceed two years. 28 Geo. III. c. 38. § 2.

By the 9th and 37th ſections, no wool, woolfells, mortlings, yarn, or worſted made of wool, woolflocks, coverings, cruels, waddings, or other manufactures, or pretended manufactures ſlightly wrought up ſo that it may be reduced to wool again, or mattreſſes, or beds ſtuffed with wool combed or fit for combing or carding, may be ſhipped or exported, or carried or moved for that purpoſe, from Great Britain, or Guernſey, Jerſey, Alderney, Sark, or Man, to any foreign place, on forfeiture of the wool, with the carriage, ſhip, or cattle on which it is laden or removed; but 300 ſheep may be ſent annually from Liverpool or Whitehaven to the Iſle of Man (51 Geo. III. c. 50.); and the perſon offending to forfeit 3*s.* for every pound weight, or 50*l.* in the whole, and to be impriſoned three months, and till the penalty is paid, but not to exceed ſix months; but for a ſecond offence he is to forfeit the like ſums, and to be impriſoned for ſix months, and till ſuch fine be paid, not exceeding two years; but this is not to extend to lambſkins dreſſed for furs and linings.

And perſons qualified by the governors of the following iſlands may export the reſpective qualities ſet againſt them from Southampton to thoſe places in every year:

	Tods.
To Jerſey - -	4000
To Guernſey -	2000
To Alderney -	400
To Sark - -	200

28 Geo. III. c. 38. § 16, 17. And 20,000 pounds weight of worſted and woollen yarn may be exported annually from London to Lower Canada, by permiſſion of his majeſty in council. 47 Geo III. c. 9. 52 Geo. III. c. 55.

By the 48 Geo. III. c. 44. wool may be ſhipped in England for exportation to Ireland, on being duly entered and bond given for its true exportation there; and upon obtaining a licence under the hands of the commiſſioners of the cuſtoms to allow it.

No

No wool ſhipped to be ſent coaſtwiſe from one part of Great Britain to another, until due notice be given and bond entered into, and a licence obtained under the hand of three commiſſioners of the cuſtoms. Penalty, forfeiture. 28 Geo. III. c. 38. § 34. And wool muſt alſo be ſhipped coaſtwiſe in Britiſh ſhip, Britiſh owned and manned, the owner of which does not reſide out of Great Britain. § 19. and 12 Car. II. c. 18. Formerly there were penalties and forfeitures for keeping or removing wool in Kent and Suſſex within certain diſtances of the ſea (ten and fifteen miles), without entry and bond, and procuring certificates or permits, and alſo for removing wool within five miles of the ſea-coaſt of Great Britain before ſun-riſing and after ſun-ſet; but by the 54 Geo. III. c. 78. all the regulations formerly required *antecedent to the removal* of wool on land throughout England are repealed.

Wool to be packed in packs, or truſſes of leather, or canvas, called 'Pack-cloths,' or in linen or woollen, and to be marked '*Wool*,' in letters three inches long, on forfeiture of the wool, and 1*s. per* pound. 28 Geo. III. c. 38. § 28.

Perſons packing wool, &c. into boxes, barrels, caſks, or cheſts, and other than as above, or preſſing or ſteaning the ſame, to forfeit the goods, and 3*s. per* pound. Ibid. § 30, 31.

Inſurances for the conveyance of wool contrary to this act void, and the parties may be puniſhed. § 45, 46, 47, 48.

King's ſhips empowered and required to ſearch ſhips for wool ſhipped without licence. § 49, 50, 51.

No perſon can ſeize wool unlawfully removing but officers of cuſtoms, exciſe, and ſalt-duties, or perſons accompanied by a conſtable (§ 52.); and perſons neglecting their duty to forfeit 20*l.*, and making colluſive ſeizures or agreements to be ſubject to like penalties as exporters. (§ 53. 55.) Hindering, obſtructing, or beating officers, ſubjects offenders to tranſportation; and bribery of them, whether accepted or not, to the penalty of 300*l.* § 56, 57.

If any queſtion ariſes upon the growth of the wool, the *onus probandi* is to lie upon the owners. § 60.

Informations may be laid in any court of record, and penalties, &c. under 200*l.* may be determined before two juſtices of the peace; and juſtices at quarter-ſeſſions may direct ſhips, goods, wool, &c. to be ſold. § 62, 63.

Proſecutions to be commenced within three years. § 77.

Wool the growth of Ireland may be exported to England, and no where elſe. 1 W. & M. c. 32. 7 & 8 W. III. c. 28. 10 & 11 W. III. c. 10. 26 Geo. III. c. 11.

And the Admiralty is to appoint three ſhips of the ſixth rate, and eight or more armed ſloops, to prevent the exportation of wool from Ireland to foreign ports. 5 Geo. II. c. 21.

Wool the produce of any of the colonies, &c. in America, or countries on the continent of America, ſubject to any foreign European ſtates, imported into certain Britiſh Weſt India iſlands, may be imported into Great Britain under the regulations of the 12 Car. II. c. 18.

Thoſe places are, Jamaica, Granada, Dominica, Antigua, Trinidad, Tobago, New Providence, Crooked iſland, St. Vincent, Bermuda, Caicos, Tortola, Curacoa, and the Bahamas. 27 Geo. III. c. 27. 45 Geo. III. c. 57. 47 Geo. III. ſeſſ. 2. c. 34.

Britiſh hare or coney wool may not be exported, (except to Ireland, 39 & 40 Geo. III. c. 67.) on penalty of forfeiture. The owner or ſhipper to pay 100*l.*, and the maſter of the ſhip 40*l.* 24 Geo. III. c. 21.

Wool, *Cheeſe made under*, in *Rural Economy*, a term applied to that ſort of high-taſted ewe cheeſe which is made before the ſheep are ſhorn. See Cheese.

Wool, *Pack of*, a quantity of wool packed up cloſely together in a large bag of the ſack-cloth kind, which in London is conſtituted of two hundred and forty pounds. See Wool.

Wool, *Pocket of*. See Pocket.

Wool, *Sarplar of*. See Sarplar.

Wool-*Stapler*, a perſon who ſtaples and deals in wool. See Wool.

Wool-*Stapling*. See Stapling *of Wool*.

Wool-*Balls*, in *Natural Hiſtory*, maſſes of wool compacted into firm and hard balls, and found in the ſtomachs of ſheep, as the hair-balls are in oxen and other animals.

Theſe are doubtleſs formed in the ſame manner as thoſe hair-balls of the outer covering of the animal; but they are much more uncommon; they are found in numbers, three, four, or five, in the ſtomach of the ſame animal. Their outſide has commonly much the ſame appearance of a puff-ball, and is uſually either in part or wholly covered with a very thin and ſoft blackiſh ſmooth ſkin; the inner ſubſtance is entirely wool, but that wrought together as cloſely as the hatter does his furs in the making of them into hats.

They are uſually ſoft, ſmooth, and ſomewhat elaſtic, of a pale buff-colour, very light, and of irregular figures rather cubic than globular, and ſeldom of any great ſize, an inch in diameter being their common ſtandard. Moreton's Northampt. p. 451. See Balls.

WOOLASSEY, in *Geography*, a town of Bengal; 42 miles N.E. of Calcutta.

WOOLDALE, a townſhip of England, in the Weſt Riding of Yorkſhire, near Wakefield.

WOOLDAW, a town of Bengal; 40 miles W. of Nagore.

WOOLDERS, *Single and Double-Handed*, in *Ship-Building*, are ſticks about three feet long, and four inches in circumference, with ſtraps of rope-yarn made faſt, to fix on the rope in making, and aſſiſt the men at the hooks in cloſing the rope.

WOOLDING, is winding ſeveral cloſe turns of rope in a tight manner round the maſts and yards, that are made of ſeveral united pieces, to ſtrengthen and confine the ſame together. In making new maſts and yards, this method is diſcontinued, and iron hoops uſed in lieu.

Woolding is alſo the rope employed in this ſervice.

WOOL-DRIVERS, are thoſe who buy wool of the ſheep-owners in the country, and carry it on horſeback to the clothiers, or market-towns, to ſell it again.

WOOLER, anciently Willove, in *Geography*, a market-town, and pariſh in the ward of Coquet-dale, and county of Northumberland, England. The former is ſituated near the Cheviot-hills, 17 miles S. from Berwick-upon-Tweed, 46 N. by W. from Newcaſtle, and 320 in the ſame direction from London. In 1811 the houſes in the pariſh were 284, inhabited by 1704 perſons. A market is held on Thurſday, and fairs on the 4th of May and 17th of October. Wooler was a barony, and conſiſted of ſeveral manors in the time of Henry I., who conferred it on Robert de Muſcamp, whoſe ſucceſſor Robert, in the reign of Henry III., was the moſt powerful baron in the north of England: it now belongs to the earl of Tankerville. The church was rebuilt in 1765, and the town contains ſome meeting-houſes for diſſenters. Situated near the confines between the kingdoms

doms of England and Scotland, the environs of Wooler prefent many intrenchments, cairns, and other memorials of the fanguinary conflicts which in former times occurred between the rival nations on the borders. About ten miles N. from the town, on the road to Scotland, is the celebrated Flodden-field, where the Scotch, in 1513, received a fignal defeat, and James IV. was flain.—Beauties of England, Northumberland, by the Rev. J. Hodgfon, 8vo. 1812.

WOOLHASA, a town of Algiers; 6 miles N.W. of Tackumbreet.

WOOLLEN MANUFACTURE, *Progrefs of the.* The origin of the woollen manufacture, like that of many other ufeful arts, is not precifely known. At a very early period, domeftic fheep were extenfively fpread over Weftern Afia. The introduction of fheep into Europe is not recorded by ancient writers, unlefs we fuppofe the expedition of the Argonauts to Colchis refers to this event. Sheep were probably firft domefticated for their milk, and afterwards for their fkins, which muft have been the firft drefs of paftoral nations. Sheep and goats, in the early ages of fociety, were nearly of equal value. The Greeks, who oftentatioufly refer all ufeful difcoveries to their own country, and rank their inventors among the gods, have afcribed to Minerva the invention of fpinning and weaving. Thefe arts appear, however, to have been firft practifed, at a very early period, in Egypt, and applied to the fpinning and weaving of flax. At what time they were firft applied to wool is unknown. Though Pliny informs us, that Nicias of Megara difcovered the art of fulling cloth, the property which wool poffeffed of felting was known in the Eaft at a much earlier period, and probably gave rife to the firft manufacture of woollen goods which were not woven, but felted like the fubftance of hats.

On this fubject, Mr. Luccock, in his Treatife on Wool, judicioufly remarks, "whilft the fkins of fheep dreffed with their wool on ferved as clothing, it is obvious that only one ufeful fleece could be obtained from one animal, and as the fleece is generally caft, or falls off once a year, this produce muft have been wafted. In a very early period, however, the property which wool poffeffes of felting was difcovered, or, in other words, it was found that by preffure and moifture the fibres of wool might be made to adhere together, and produce a compact pliable fubftance, quite as durable and more convenient than the fkins formerly ufed. This appears to have been the firft effort to produce a woollen manufacture." It is probable the felting property was difcovered by accident, as fome fleeces will felt upon the fheep's backs; among farmers, thefe are called cotted fleeces. When the application of this difcovery was firft made, the knowledge of the art was foon widely fpread. The tents of the Arabs and Tartars are, at the prefent day, all made of felt from the wool of fheep, mingled with the hair of goats, camels, and other quadrupeds, and may be confidered as remains of the original art of cloth-making.

The art of fpinning and weaving threads made from wool was, in all probability, derived from the Eaft; they are alluded to by Mofes as exifting nearly fifteen hundred years before the Chriftian era, and it appears that the early patriarchs had numerous flocks of fheep.

The greater part of thefe fheep, we are informed, were, at firft, either dark-coloured or fpotted; hence we may infer that the art of dyeing wool was then unknown. When the felection and cultivation of white wool gave to woollen cloth the property of receiving the tints of the dyer, the value and ufe of wool muft have greatly increafed, owing to the great eftimation in which richly-coloured garments are held by people advancing to a ftate of civilization.

Thus, in addition to the fuperior pliability and comfort of woollen cloth, compared with fkins or felts, the tafte for it muft have been widely fpread by the art of dyeing. It had alfo the great recommendation to its general adoption, that it could be fabricated with eafe in every family. The machinery required for the purpofe was extremely fimple. The diftaff and the loom, fays Mr. Luccock, were little more in the hands of the firft manufacturers, than the fpade in thofe of the hufbandman. Spinning and weaving, as we have already obferved, were in ufe at leaft fifteen hundred years before the Chriftian era; but the manner in which they were performed is not related until about three centuries afterwards. Then the loom confifted of a frame of wood, in fome refpect different from the modern one, but well adapted to the fame purpofes.

The alterations which have been made in it confift, perhaps, more in the pofition of the beam, and the mode of opening the web for the paffage of the fhuttle, than in any other circumftance. Nor was the earlieft mode of fpinning lefs perfect, than that which was practifed in the moft celebrated manufacturing countries for many ages afterwards. It was performed by means of a rod or ftaff, about which the wool to be fpun was carefully wrapt, and held in the left-hand, while a rough kind of fpindle, quickly twirled betwixt the right-hand and the thigh, was fuffered to continue its motion when fufpended by the thread which the artift gradually lengthened with his fingers. This leaft complex of fpinning-machines is not entirely laid afide even now. A few years fince it was not uncommon in the county of Norfolk, and its continuance in ufe through fo many ages is the beft proof of its excellence.

The preparing of wool for fpinning was probably firft effected by the fingers, and afterwards by the fuller's teazle or thiftle, the dipfacus fullorum, which with its rough and hooked points was well adapted to the purpofe, and has continued in ufe to the prefent day. The card afterwards ufed was probably a fubftitute for the carduus, or teazle. The application of the wheel to a fpindle, or the fpinning-wheel, is, we believe, unnoticed in hiftory. Whenever thefe inventions took place, it is probable their firft introduction contributed more to increafe the quantity, than improve the quality of the yarn and cloth. For a confiderable period after the commencement of the woollen manufacture, the improvements made in fpinning or weaving of wool were effected by the improved addrefs and fkill of the manufacturer, rather than by any alteration in his machinery, as we now fee the manufacturing nations of the Eaft execute very elaborate works with inftruments of the moft fimple conftruction. In proportion as luxury and refinement increafed, the demand for fuperior fabrics would induce the growers of wool to pay great attention to the fleece, and to felect and preferve for breeding thofe fheep which produced the fofteft and fineft wool; with the ancients thefe terms were fynonymous. The produce of fine white wool from fheep is entirely the refult of cultivation; it has never been grown except in countries were the woollen manufactures have flourifhed. The race of fine-woolled fheep has, however, been partly preferved in thofe countries after the deftruction of their trade. The grower would alfo foon learn to pay particular attention to the whitenefs of his fleeces, as a clear white ground is neceffary for receiving the moft brilliant dyes. Blue, purple, and fcarlet, were the tints moft admired; and though the ingredients, by means of which they were produced, are in fome meafure unknown, yet we have the moft indubitable teftimonies to their excellency, and the eftimation in which they were held. To produce them in their richeft luftre,

luftre, a felection of the wool moft adapted to receive them muft be made, and this would operate with great precifion upon the wool-forter's attention.

While the manufacture of wool was confined to the houfes of the grower, and the bufinefs of it tranfacted by his domeftics in a fecluded ftate, there was lefs room for the ftimulation and exercife of invention than in after-ages, when it became the appropriate calling of one particular part of the community, and their fuccefs depended upon the opinion which others formed of the fabric. Yet in the fimpleft days of Greece, it was not deemed an employment unfuitable to palaces, nor did a princefs degrade her dignity by fuperintending the labours of the loom, the diftaff, and the dyeing vat.

We have little information refpecting the woollen manufactures of the Greeks and Romans, as diftinct from their domeftic manufactures; but large eftablifhments were neceffary for the clothing of diftant armies, and for foreign commerce. That the Romans had carried the manufacture of fine woollen cloth to a high degree of perfection, is proved by a variety of circumftances, and particularly by the great attention paid to the cultivation of fine-woolled fheep, and by the high prices at which the wool and fheep were fold, as appears from the writings of Pliny, Varro, and Columella. Pliny defcribes two kinds of fheep: the one which grew coarfe long wool, and was on this account called *hirtum* or *hirfutum*, and from its hardinefs and ruder treatment *colonicum* or ruftic; the other breed was called *molle*, from the foftnefs of the wool, and *generofum* or noble, from its excellence; alfo *pellitum*, from its being clothed with fkins to protect the wool. The race is fometimes alfo called Tarentinum, Apulum, Calabrum Atticum, and Græcum, from the neighbourhood or diftrict in which it chiefly lived; but what is of more importance, as fhewing the origin of the fine-woolled fheep of Italy, the race is called Afianum; and, according to Pliny, a fimilar race exifted in his time at Laodicea in Syria. The defcription given of thefe fheep by Pliny agrees with the prefent race of Merino fheep. There is not, fays Dr. Parry, throughout Europe, any breed of fhort-woolled fheep now exifting befides the Merino, of which the males are horned and the females not.

That the Romans imported their Tarentine fheep into their weftern colonies, with the art of manufacturing fine cloth, we learn from Strabo and Pliny. The former writer, who flourifhed in the reign of Auguftus, fays, that in Turdetania in Portugal, then a part of Spain, "they formerly imported many garments, but now their wool was better than that of the Coraxi, and fo beautiful, that a ram for the purpofe of breeding was fold for a talent, and that fabrics of extraordinary thinnefs were made of this wool by the Saltratæ." Probably this was fimilar to the fhawl cloth of India, and woven in the fame manner, as Pliny calls it fcutulatus, a term which he applies alfo to the fpider's-web. The little attic talent of filver is eftimated to equal in value 216*l.* of Englifh money, which fhews the high eftimation in which the beft wool was held even in the colonies of Rome.

All ranks of people of both fexes among the Romans chiefly wore woollen garments. In the reign of Aurelian, 270 years after Chrift, a pound of filk, according to Vopifcus, was equal to a pound of gold. A people fo pre-eminent in wealth, and in all the refinements of art, would naturally be folicitous to attain the higheft degree of excellence in the manufacture of thofe fabrics, which were calculated to gratify their paffion for adorning their perfons, and it was equally as neceffary to confult their eafe as their vanity. The fummer-heat of Italy was fo great, that the affluent could fcarcely have fupported a woollen drefs, had it not been made of the lighteft and thinneft cloth. We find alfo, that during the Auguftan age, and for a confiderable time afterwards, it was the fafhion to wear cloths which, as at prefent, were furnifhed with a raifed nap or pile. Such cloths were called *pexæ*, in contradiftinction to tritæ or thread-bare. Thus Horace:

> " ——— Si forte fubucula pexæ
> Trita fub eft tunicæ —— rides."

> " You laugh if you efpy a thread-bare veft
> Under a well-dreffed tunic."

And alfo Martial:

> " Pexatus pulchre, rides mea, Zoile trita."

The term pexatus, applied to cloth, leads us to fuppofe that the nap or pile was raifed with a comb, having very fine teeth. Pliny informs us, that in his time the price of wool had never exceeded 100 feftertii the libra, or pound; now the Roman feftertius being about 8*d.* of our money, and the libra about 5245 grains, it follows that an avoirdupois pound, or 7008 grains, would have coft about 1*l.* 2*s.* of our money. From the intercourfe with Perfia and the Eaft, the Romans would become acquainted with the fhawl-cloths of India, and would naturally wifh to imitate fo beautiful and delicate a fabric. Thefe are made from very foft fine fhort wool, and not from combed wool, as has been generally fuppofed in this country. The exiftence of that manufacture in Hindooftan for many ages, is a proof of the high degree of perfection to which the fabrication of woollen cloth had been carried in former times. For fhawl-cloth is only woollen cloth, woven with a twill, and unmilled, but it is fpun to a great degree of finenefs, and from wool fo peculiarly foft, that it has never been rivalled by any European nations. The perfection of the colours, and the fkill difplayed in the weaving, we have no reafon to believe are greater now than in the time of Alexander the Great; and if thefe manufactures were fuccefsfully imitated by the Greeks or Romans, or even diftantly approached in the manufacture of their fine cloths, we may form fome idea of the perfection to which they had arrived. When in the decline of the Roman empire, their colonies were overrun by favage barbarians, all their public eftablifhments and manufactures were deftroyed, but the art of producing from the fleece a warm and fubftantial clothing was never entirely loft, even during the darkeft days of ignorance. It began to revive, and became the feparate occupation of one clafs of the community about the middle of the tenth century in the Low Countries, where it remained the glory of the people, and the fource of their opulence, through more than four hundred years. The wool which it confumed for the firft few years was the produce of their own paftures, which had but lately been reclaimed from the foreft; but as the manufacture extended itfelf, the demands became larger, and were fupplied from a greater diftance. The wealth which it diftributed was foon vifible, and people crowded into the country, engaged in its commerce, and pufhed their fpeculations with increafing vigour through a hundred and fifty years, when an inundation of the fea threatened to involve the art, the artift, and the country, in one general deftruction. The difperfion of the people who fled from the calamity which appeared to overwhelm their hopes, inftead of deftroying the infant manufacture, gave it additional vigour, and was the means of eftablifhing a connection be-

tween

tween the Netherlands and foreign countries, which proved of the higheft importance to commerce. It contributed to a much more fpeedy recovery of the arts connected with the woollen manufacture, from the ruin which feemed to threaten them, and gave a ftriking inftance of their partiality for the feats where they have once flourifhed, under the patronage of a government liberal enough to encourage, and fufficiently powerful to protect them, even in fituations attended with natural difadvantages. The influence of thefe manufactures upon the fleeces of the Low Countries muft have been very confiderable; for before the year 960 we have no reafon to fuppofe that their quality was fuperior to that which we find in the neighbouring diftricts; yet it was not very long ere Flanders and Brabant became famous for the manufacture of fine cloths, even at a period when they imported but little foreign wool. Perhaps the fabrics might not be equal to thofe which we now produce from the fleeces of Spain, or even from the improved ones of our own fheep, but they were preferable to thofe of England and the nations of the continent, Italy and Spain excepted. It was about the year 1200 that the merchants began to import the wools of other countries, to extend their connections much more widely, and to grow by this means ftill more rich and powerful. The manufactures required a larger quantity of the raw material than ufual, and the population of the country had reached that extent which does not admit of a great number of fheep being kept, even though the employment of the people depend upon the fleeces, and their fubfiftence upon the food which they furnifh. We fhall obferve inftances of a fimilar kind when we treat more particularly of England. The operation of thefe two caufes was evidently fufficient to induce the manufacturer to go farther from home, and to feek the moft convenient methods of fupplying his looms. It might have been expected that he would have turned his attention to France and to Germany; but independent of the hoftile difpofitions of fome of the neighbouring fovereigns, the raw material was too bulky to be conveyed at an eafy expence through the bad roads of a half cultivated country; and the fhips of Spain and of Britain, who found an intereft in fupplying the wants of the Netherlands, unladed their cargoes almoft at his very door, and folicited in payment but little elfe than the goods which he had manufactured.

Spain was the firft country on the weftern fide of Europe, where the Tarentine breed of fine-woolled fheep were cultivated with fuccefs by the Romans. See SHEEP.

This breed, intermixed with the native flocks, gave rife to the prefent fine-woolled fheep of Spain; and it does not appear that this valuable race was ever greatly neglected in that country. That it abounded in fheep in what is called the middle age cannot be doubted. At the period when the Saracens extended themfelves in Spain, about the eighth century, to ufe the quaint words of Roderic, archbifhop of Toledo, "it was fruitful in corn, pleafant in fruits, delicious in fifhes, favoury in milk, clamorous in hunting, and gluttonous in herds and flocks,"—*gulofa armentis et gregibus*. He wrote in A.D. 1243. In England at that time fheep were fo fcarce, that a fleece was eftimated at two-thirds the value of the ewe which produced it, together with the lamb.

Into Spain the invaders either carried the arts of luxury, or, what is more probable, improved them by their fuperior induftry. The revenue of one of their fovereigns in the tenth century amounted to fix millions fterling; a fum, fays Gibbon, which at that time probably furpaffed the united revenues of the Chriftian monarchs. When, feveral centuries afterwards, the Saracens were gradually expelled by their Chriftian neighbours, Spain faw nothing but the change of religion to compenfate the lofs of population, of agricultural and mechanical fcience, of induftry, and wealth. On the recovery of the Seville from the Moors in 1248, not lefs than 16,000 looms are faid to have been found in that city. Of thefe, the greater number was probably employed in the fabric of woollen cloths. According to Uftarix, "Theory and Practice of Commerce," the manufactures of Segovia flourifhed moft, both in point of number and quality, and were in high efteem, being the beft and fineft that were known in ancient times. The temperature of the climate, and the luxurious propenfities of the inhabitants, would naturally determine thefe fabrics to be of the lighteft and fofteft kinds. Hence in the midft of the boafted ancient manufactures of England, we read only of two or three inftances of the importation of Englifh cloth into Spain. The Spaniards had certainly at that time their own native fleeces beft adapted to their own tafte and climate.

We are told by Dillon, in his "Hiftory of Peter the Cruel," that the woollen cloths of Barcelona were in high efteem in Seville in the reign of that prince, and in the preceding century. So far back as 1243, the woollen cloth of Lerida is fpoken of in terms of great eftimation. A few years after, Baurlas, Valis, Gerena, Perpignan, and Tortofa, were remarkable as manufacturing towns, and for the finenefs of their cloths, fuftians, and ferges. So great was their exportation, that in 1353 there were 935 bales of cloth taken on board a fhip from Barcelona to Alexandria by a Genoefe privateer; and 1000 bales of cloth were taken on board three Catalonian fhips in 1412, by Antonio Dorco, in the port of Callus. We are told by the fame author, that, according to records ftill extant in Barcelona, confiderable orders for wool were fent to England in 1446, in order to be manufactured there and returned to England in the form of cloth, the Spaniards themfelves difdaining to wear it.

According to Lucius Marineus Siculus, who wrote in the time of the emperor Charles V., Spain was then full of herds and flocks, more efpecially it contained innumerable fheep; fo that many fhepherds, whom he knew, had flocks of 30,000 each; on which account Spain not only fupplied its own people moft abundantly, but alfo foreign nations, with the very fofteft wool.

This account is confirmed by what is related by Sandoval, who ftates, that in an infurrection in Spain in 1519, the army of infurgents, among whom were many cloth-workers, ftipulated, among other points, that the cloths imported into Spain fhould be of the fame fize and goodnefs as thofe wrought there; and that the merchants and clothiers might have leave to feize, in order to work up, half the wools fold for exportation, paying the owners the price at which they had been bought. Hence we learn the fuperiority of Spanifh cloth, and the great fale of Spanifh wool to foreign countries at that time.

Damianus a Goes, who was page to Emanuel, king of Portugal, in 1516, has written a fhort account of the memorable things of Spain, which he dates at Louvain in the year 1541. In this work he fays, that there are annually exported from Spain to Bruges 40,000 facks of wool, each felling at the loweft for twenty gold ducats.

Now from an authentic acquittance, preferved in the Fœdera, from queen Elizabeth to Cofmo de Medici, for a fum borrowed by him of Henry VIII., we find that the gold ducat or florin was in 1545 equal to five fhillings of our money. In this year, the 36th of Henry VIII., the bafe coinages began; but as queen Elizabeth feems to have continued receiving the inftalments of the Florentine debt for

for ſeveral years at the ſame rate, when the ſhilling was of ſomething more than the preſent value, we think it probable that the rate was fixed at the beginning of the year 1545, when the ſhilling was at 1*s.* $1\frac{3}{4}$*d.* of our preſent coin. This wool was, therefore, worth at leaſt 5*l.* 14*s.* 7*d.* the ſack of $181\frac{1}{2}$ lbs., and 11*l.* 9*s.* 2*d.* the ſack of 364 lbs.

In 1560, in the time of Guicciardini, Spaniſh wool in the Netherlands was at a ſomewhat lower price. He tells us, "that they uſed formerly to ſend annually from Spain to Bruges more than 40,000 ſacks, but that in this year the Spaniards, having made more cloth at home, had ſent only 25,000 ſacks, at 25 crowns each." The crown being 4*s.* and the ſhilling 1*s.* $0\frac{1}{4}$*d.* of our money, this would be 10*l.* 1*s.* 1*d.* the ſack of 364 pounds. The depreciation ſeems in truth to have ariſen from a diminiſhed demand for this wool in the Netherlands. The wools imported into the Netherlands from Spain were the lower or coarſer kinds.

The ſuperfine wools of Spain ſeem to have been firſt introduced among the Italian ſtates. Thus Damianus a Goes in 1541, after having ſpecified the 40,000 ſacks to Bruges, as before-mentioned, adds, "and alſo to Italy, and other cities of the Netherlands, are annually ſent about 20,000 ſacks, of which thoſe uſed in Italy, being of the choiceſt wool, are ſold at from forty to fifty gold ducats each."

From this account, we have a fair opportunity of drawing two important inferences: the firſt is, that the Spaniſh wool which went to the Netherlands was, as we have before obſerved, of the coarſeſt kind, being of only half the price of that which was exported to Italy; ſecondly, we can compare the value of the latter with that of our Engliſh wool, the beſt of which, according to the act of parliament in 1534, already quoted, did not in England exceed 5*s.* the ſtone of 14 pounds, of 6*l.* 10*s.* the ſack of 364 pounds. The ſhilling, however, being then equal to 1*s.* $4\frac{1}{2}$*d.* of our coin, increaſes the price of the ſack 8*l.* 18*s.* 9*d.*; to which add cuſtom and ſubſidy, 3*l.* 13*s.* 4*d.* or 5*l.* 0*s.* 10*d.*, and the reſult will be 13*l.* 19*s.* 7*d.* The additional charges of freight and merchant's profit would ſcarcely bring the whole amount to 16*l.* 16*s.* On the other hand, according to the teſtimony of Damianus a Goes, the Spaniſh ſack of $181\frac{1}{2}$ pounds was in 1541 worth 14*l.* 6*s.* $5\frac{1}{2}$*d.*, and the ſack of 364 pounds 28*l.* 14*s.* 6*d.* of our preſent money. If the author ſpeaks only of the value of this wool in Spain itſelf, then a farther addition muſt be made of freight, merchant's profit, and probable duty to the crown. On the whole, this calculation is ſufficient to ſhew in the ſtrongeſt light the ſuperior price of ſuperfine Spaniſh wool, to that of the very beſt at that time produced in Britain.

Next in order of time to the Italians, the manufacture of ſuperfine wool ſeems to have been adopted by the French, who, according to Guicciardini, in 1560 ſent by land to Antwerp ſome very fine cloths of Paris and Rouen, which were highly prized.

It is probable, however, that theſe cloths were made only of mixed wool.

A ſtrong confirmation of the early uſe of the beſt Spaniſh wool, unmixed with coarſer by the Italian ſtates, is furniſhed by Richelieu's Political Teſtament, printed in 1635, in which, ſpeaking of the fine woollen manufactures of France, the author ſays, "the Turks prefer the draps de ſceau de Rouen to all others, next to thoſe of Venice, which are made of Spaniſh wool."

And the author of "England's Safety in Trade's Increaſe," written in 1641, tells us, that "the greateſt part of their (the Venetians) wools from Spain, and the reſt from Conſtantinople, is commonly brought in Engliſh ſhipping."

In 1646, Nicholas Cadeau and other Frenchmen had letters patent for twenty years, for making at Sedan black and coloured cloths, like thoſe of Holland, of the fineſt Spaniſh wool.

The inhabitants of the north of Europe, as before-mentioned, were not at firſt able to manufacture fine Spaniſh wool, without the aſſiſtance of that which was longer and coarſer. But what in the beginning was a matter of neceſſity, became afterwards an object of choice; and the more ſkilful clothiers, whether in Holland or elſewhere, either carding the finer and dearer Spaniſh with the coarſer and cheaper Engliſh, or forming a warp of the latter, which they covered with a woof of the former, contrived to make a cheap and ſerviceable cloth, which pleaſed the eye equally well with the more coſtly fabrics of entire Spaniſh wool. This though generally concealed with great care at the time, yet is afterwards candidly acknowledged by writers actually engaged in the commerce of wool, and ſufficiently refutes the prejudices which had here prevailed from the middle of the 16th to the middle of the 17th century. Hence it appears that our wool, when placed in connection with Spaniſh, was chiefly valuable from being well calculated not to improve but to adulterate it.

A treaty between France and Spain in 1659, enabled the former freely to obtain the wool of the latter, and thus to gain great advantage over us in the Levant trade. From the proximity of France to the woollen manufactures in the north of Spain, it might have been expected that the French would have earlier engaged in this manufacture; but owing to their frequent northern wars, and their attention being directed to the manufacture of ſilk, the French do not appear to have commenced the fabrication of woollens for exportation extenſively before the 16th century. About this time, France made great progreſs in her manufactures of wool, and in ſecuring the export trade, particularly that to Tartary, for which ſhe was better ſituated than Holland or England.

The nature of her trade to warm climates directed her attention to the fabrication of finer and lighter cloths, than thoſe made by her northern neighbours; in conſequence of which ſhe preſerved the greater part of the Turkey trade to the period of the French revolution, and in general fine French cloths had attained a celebrity for their ſuperiority, both in texture and dye, over thoſe of any other country in Europe. The native breeds of ſheep in France were greatly improved by intermixture with ſheep imported from Spain. With theſe advantages, France might have nearly ſecured a monopoly of the finer branches of the woollen manufacture, had not the abſurd policy of her rulers, in the revocation of the edict of Nantz, driven the manufacturing Proteſtants to other countries, where they contributed, by their exertion, their ſkill, connections, and capital, to form eſtabliſhments which rivalled thoſe of the country from which they were expelled.

Notwithſtanding this, as France ſupplied the greater part of her own population of twenty millions with cloth, beſides her foreign exports, we conceive that the woollens manufactured in that country, before the late revolution, equalled in quantity the cloth made in England at the time, and greatly exceeded it in value. Under the emperor Napoleon, the beſt Merino flocks were imported in multitudes from Spain, which have ſpread over the country, and are equal to ſupply extenſively her manufactures of woollens, when they ſhall be again fully eſtabliſhed. Conſiderable quantities of fine wool have been imported from France into England ſince the peace of 1815.

The

The confufion attendant on a great revolution, continued for twenty years, gave fo fevere a blow to the manufacturing eftablifhments of France, that a confiderable time muft elapfe before they are completely eftablifhed. Prior to this revolution, the fuperfine cloths of France were fuperior to thofe of England, in texture, colours, and foftnefs. In the finer articles of worfted goods, and in the mixed worfted goods made partly with long combing-wool, and partly with filk or goat's-wool from the Levant, they furpaffed the manufactures of this country; but the manufacturers of the commoner kinds of worfted goods, as tammies and fhalloons, could not rival us in foreign markets for want of a proper fupply of wool fuited to the purpofe. The following were the principal feats of the fuperfine and fine woollen manufactures in France, arranged according to the different qualities of the goods made at each, beginning with the fineft:

1. The manufactures of Gobelins.
2. Of Sedan.
3. Of Abbeville.
4. Of Louviers.
5. Of Elbœuf.
6. Of Rouen and Darnetal.

Befides feveral detached manufacturing eftablifhments of fuperfine cloth in Languedoc, Champagne, and other parts of France.

At the Gobelins, fuperfine cloths of the very firft quality were manufactured; but the manufactures there were confined folely to the broadeft white cloth intended to be dyed fcarlet or purple, and the brighteft colours from cochineal.

Sedan followed next to Gobelins for the beauty of its fuperfine cloths, where they were alfo made of various breadths and colours.

Abbeville may be placed next after Sedan: fome have even fuppofed that it equalled Sedan in the finenefs of its cloths; but this arofe from the cloths of the latter place being of various forts: the lower kinds were certainly inferior to thofe of Abbeville; but the quality of the greater part of the cloths of Sedan were of a better kind than the average quality of the cloths of Abbeville. In the manufactures of Sedan, each manufacturer confined himfelf to a particular kind of cloth, for which he became diftinguifhed, fome being celebrated for fine, and others for fuperfine cloths exclufively; whereas in Abbeville, Louviers, and the other diftricts enumerated, there were manufacturers who made various forts, and the proportion of the fine to the fuperfine was greater than at Sedan.

Elbœuf was one of the moft ancient feats of the woollen manufacture in France, but the quality of the cloths made there had greatly degenerated from the years 1760 to 1770; but afterwards the manufacturers returned to the former quality of their cloths, which were partly made of the fine wools from Berry, and partly from fine Spanifh wool, or from a mixture of Spanifh with the beft wools of Berry.

Rouen and Darnetal may be placed in the fixth clafs of manufacturing diftricts of fine cloth, in which the fineft wools of France were principally ufed, mixed with thofe of Spain.

The eftablifhments for the manufacture of common cloth and coarfe woollens were much more widely fpread over France. The goods appear to have been principally confumed in that country to fupply the demand of a population of twenty millions, and the numerous military eftablifhments, befides what might be fent to the French colonies.

As the French never exported any confiderable quantity of common or coarfe woollen cloths, the manufactures of thefe articles never equalled in extent thofe of England. The circumftance of the coarfe cloth manufacture being fo widely fpread over the country, tended alfo to prevent that degree of rivalry which promotes the fpirit of improvement where manufactures are more concentrated; add to this, the French had not that abundant fupply of the coarfer clothing-wools which could enable them to rival us in the export of heavy woollen goods.

The worfted manufactures of France, including ferges and thofe goods made with a warp of worfted, were principally carried on in four of the provinces of France, but more extenfively in Picardy than elfewhere. The long combing-wools which fupplied this manufacture, were partly the produce of France, and partly imported from Holland, England, Flanders, and Germany. M. Rolland, in the French Encyclopædia, defcribing the French manufactures in the year 1783, foon after the American war, fays, that during that war the Englifh adminiftration tacitly encouraged the exportation of wool to promote the interefts of agriculture. He defcribes the French combing-wool as being coarfer and more harfh than the wool of Holland, as wafting much more in the manufacture, and making goods of a very inferior quality. The combing-wools of England, though generally lefs found and fine, and of a lefs pure white, than thofe of Holland, were particularly well fuited to fome parts of the worfted manufacture.

The combing-wools from Germany were coarfe and harfh, and only ufed in default of other fupplies. Very fine worfted yarn was alfo obtained from Saxony and the environs of Gottingen; but this yarn was tender, and required to be mixed with worfted yarn from Englifh or Dutch wool. The yarn of Turcoign was fuppofed to be Dutch, but was principally from Flanders and Artois. The goat's-wool came from the Levant, by way of Marfeilles, in bales of from 200 to 300 lbs. It fold from four livres to twelve livres *per* French pound; the price of that moft generally ufed was about 4 livres 10 fous *per* pound. The filks ufed in filk camelots, &c. were obtained from Paris and Lyons.

The following table gives the quantity and value of wool yarns and worfted pieces in Picardy; but he fuppofes the quantity to be under the real amount, the manufacturers concealing the extent of their trade to avoid arbitrary taxation.

Wool confumed in the Worfted Manufactures of Picardy.

		fous.	livres.
French wool	3200000	at 22	3520000
Dutch ditto	180000	at 40	360000
Englifh ditto	200000	at 32	320000
German ditto	100000	at 22	110000
	3680000		4310000

Yarn imported.

Yarn of Turcoign	60000	at 8 10	510000
German yarn -	100000	at 7 0	700000
Levant yarn, or mohair -	220000	at 5 10	1210000
Silk ufed in fine worfted goods	20000	at 35 0	700000
Total value of wool and yarn - -			7430000

Brought

Brought forward - -	7430000
Combing and fpinning 3680000 lbs. of wool	4310000
Winding, warping, and weaving - -	4770000
Dyeing of yarn and pieces - - -	190000
Profit of the wool-dealers, manufacturers	1300000
Total value of 150000 pieces coming from the manufacturer - - -	18000000
Value of dyeing-wares - - -	500000
To which carriage and profit of the merchant and draper - - -	2000000
Total value of worfted goods in Picardy	20500000

One million and fifty thoufand pounds weight of wool were alfo confumed in hofiery in the fame province, of which the greateft part was native; and the remainder about two hundred and fifty thoufand pounds weight from Holland. The number of working manufacturers in Picardy is thus ftated:

50000 men who gain	140 livres *per annum*		7000000
50000 women	70	- -	3500000
150000 children	40	- -	6000000

The greater part of the manufacturers refided in the country, and were employed part of the time in agriculture; this was alfo the cafe with the manufacturers in the towns, fo that not more than eight months in the year were devoted to manufactures. This change of employment, fo conducive to the health and comfort of the labouring claffes, may be regarded as prefenting the happieft form under which manufactures can be carried on. This was alfo in a confiderable degree the fituation of the woollen and worfted manufacturers in Yorkfhire, before the late introduction of machinery had driven the population into large factories; a change which may be regarded as one of the greateft evils that ever afflicted civilized fociety, tending directly to degrade and enfeeble the human race, and to render man a wretched machine, a prifoner from the cradle to the workhoufe or the grave, devoid of moral feeling and phyfical energy.

What was the extent of the worfted manufacture in the other provinces of France where it was carried on, we have no correct means of afcertaining. In the middle of the laft century, the export of cloths and worfted goods from Languedoc alone amounted annually to about 60,000 pieces, fent to the Levant and to Barbary. At that time alfo, Spain, and all the countries bordering the Mediterranean, received worfted goods from France. In the variety of worfted articles, in the ingenuity of the patterns, and the fuperiority of the workmanfhip, as well as of the dyes, France may be regarded as having furpaffed any other nation in Europe, prior to the year 1780, or about the clofe of the American revolution. Since that period, the manufactures of England have aftonifhingly increafed, and have obtained a decided preference in foreign markets.

The woollen manufactures of Saxony and Germany have been long eftablifhed; the fugitives from the edict of Nantz contributed much to improve and extend them. During the late war, all the manufactures in Germany and every part of the European continent fuffered greatly, but are at prefent rapidly reviving, and will abridge the amount of our exports in Europe.

In Ruffia, Sweden, and Denmark, the woollen manufacture, as a diftinct occupation, is comparatively new; yet it has exifted long enough to produce great alteration in their flocks. And as this change was attempted in a more enlightened period, and conducted by fcientific men, the beft means were adapted to promote the improvement, and new breeds of fheep have been introduced into both countries. The fame remark applies to Saxony and other circles of the German ftates, and even Hungarian flocks are not without evident indication of a change for the better.

Of the worfted manufacture as diftinct from the woollen, we have little information refpecting its origin. It comprifes all thofe goods made of combed wool in diftinction from carded wool. We are unacquainted with the period when the wool-comb was invented, or when worfted goods were firft manufactured. It is probable, that worfted goods were originally woven in the Eaft, and that the knowledge of them was brought into Europe either by the Armenian merchants, or thofe who returned from the extravagant expeditions which were undertaken for the recovery of the Holy Land from the dominion of the infidels. The garments which are now worn by the Turks, fome of which feem to have been produced by means of the comb, the incidental mention of that inftrument in an account which we have of Angora, and the demand for worfted goods through the Levant, confirm the conjecture, and lead us to fuppofe, that there exift very confiderable manufactures of this kind in the Turkifh empire, although we know little more of its domeftic and rural condition, than can be obtained from the moft vague accounts and uncertain deductions. After the art of fpinning worfted yarn was known in the weft of Europe, the looms of the Netherlands became active in converting it into thofe peculiar kinds of goods to which it was adapted, and it feems as though the diftinction between thefe and woollen articles was not generally noticed until fome years afterwards. It might have been expected from the nature of the article, that the manufacture of worfted goods fhould in many fouthern countries have preceded that of cloth. Long-ftapled wool fuited to the comb feems more fpontaneoufly the produce of uncultivated fheep, than fhort wool, which is to be manufactured by carding, and its mode of manufacture more nearly refembles that of flax; hence it is not improbable, that worfted goods were made in Egypt and the Eaft before the manufacture of woollen cloth. This is, however, uncertain.

In the manufacture of long wool, the fibres are arranged parallel to each other, like thofe of flax; but before they are fpun, they require to be laid even by fome kind of inftrument, which fhall feparate the fibres, that they may draw out eafily in fpinning. A comb of a very fimple conftruction, with a few wires for the teeth, was probably firft made ufe of. It was afterwards found, that the application of heat to the comb contributed more effectually to the regular arrangement of the fibres; and thus the invention of the common wool-comb arofe, but at what period is unknown. Vulgar tradition afcribes the invention to bifhop Blaize, who firft ufed it in Alderney; but there does not appear any authority in fupport of this opinion. The bifhop lived in Armenia, and was raifed to the epifcopal dignity about the time of Dioclefian, and fuffered martyrdom under that tyrant. Before he was beheaded, he was tortured with iron combs, with which his flefh was torn; and hence when an inftrument of that kind was brought into common ufe, the workmen chofe him for their patron faint. The traditions of the origin and progrefs of the worfted manufacture are thus extremely imperfect; we fhall have occafion to fpeak of its introduction and progrefs in this country in the following fection.

Rife

Rife and Progrefs of the Woollen Manufactures in England. — The Romans, as we have ftated on the authority of Camden, had a cloth manufacture at Winchefter. The firft account of any diftinct body of manufacturers afterwards occurs in the reign of Henry I., but either the people of this country were wholly clothed in fkins or leather in the intervening fpace, or, what is more probable, coarfe cloths were manufactured in a rude manner in moft of the towns and villages in England. A great part, however, of the drefs of the labouring claffes in the country was made of leather, particularly the breeches and waiftcoats, even till the prefent reign. George Fox, the founder of the Quakers, in the reign of Charles I., travelled on his miffions through the country, buttoned up in a leathern doublet, or waiftcoat with fleeves, which fupplied the place of a coat. This was not, as his adverfaries afterwards affirmed, from any fuperftitious prejudice refpecting that coftume; it was the common drefs of the labouring mechanics at that time, to which clafs he belonged.

The firft account of any foreign weavers fettled in England is recorded by William of Malmfbury and Giraldus Cambrenfis, who relate that a number of Flemings were driven out of their own country, by an extraordinary encroachment of the fea in the time of William the Conqueror. They were well received, and firft placed in the neighbourhood of Carlifle, and on the northern frontier; but not agreeing with the inhabitants, they were tranfplanted by Henry I. into Pembrokefhire. They are faid to have been fkilful in the woollen manufacture, and are fuppofed to have firft introduced it into England as a feparate trade. Cloth-weavers are mentioned in the exchequer accounts as exifting in various parts of England in the reign of Henry I., particularly at London and Oxford. The weavers of Lincoln and Huntingdon are reprefented as paying fines for their guild in the 5th of Stephen; and in the reign of Henry II. (1189), there were weavers in Oxford, York, Nottingham, Huntingdon, Lincoln, and Winchefter, who all paid fines to the king for the privilege of carrying on their trade. (Chronicon Pretiofum, p. 64.) There were alfo cloth dealers in various parts of Yorkfhire, Norwich, Huntingdon, Gloucefter, Northampton, Nottingham, and Newcaftle-upon-Tyne; alfo feveral towns in Lincolnfhire, and at St. Alban's, Baldock, Berkhamftead, and Chefterfield, who paid fines to the king that they might freely buy and fell dyed cloths. Thefe are fuppofed to have been cloths imported from the Flemings. The red, fcarlet, and green cloths, enumerated among the articles in the wardrobe of Henry II., were moft probably foreign, as the Englifh had attained little fkill at that time in the art of dyeing. Madox's Hiftory of the Exchequer.

In the 31ft of Henry II. the weavers of London received a confirmation of their guild, with all the privileges they enjoyed in the reign of Henry I.; and in the patent he directed, that if any weaver mixed Spanifh wool with Englifh in making cloth, the chief magiftrate fhould feize and burn it. (Stowe's Survey of London.) This abfurd edict was iffued under the pretext of the inferiority of the Spanifh wool, but was doubtlefs intended to encourage the growth of Englifh wool, an article from which our kings derived a confiderable revenue. The circumftance rather proves the fuperior excellence of Spanifh wool at that time, and the jealoufy which its importation had excited among the Englifh wool-growers.

In the reign of Henry III. an act was paffed limiting the breadth of broad-cloths, ruffets, &c. to two yards within the lifts. In the year 1284, foreign merchants were firft permitted to rent houfes in London, and buy and fell their own commodities, without any interruption from the citizens. Previous to this date they hired lodgings, and their landlords were the brokers, who fold all their goods, and received a commiffion upon them. It was foon after pretended that the foreign merchants ufed falfe weights, and a clamour being raifed againft them, twenty of them were arrefted and fent to the Tower. Amidft the numerous abfurd reftrictions to which commerce and manufactures were fubjected, we need not be furprifed at the little progrefs which they made.

The materials which hiftory affords refpecting the woollen manufacture before the reign of Edward III. are but fcanty; it appears that the office of aulnager, or cloth infpector, was very ancient. In the reign of Edward I. we are informed by Madox, that Peroult le Tayleur, who held the office of aulnager of cloth in the feveral fairs of the realm, having forfeited it, the king, by writ of privy feal, commanded the treafurer to let Pieres de Edmonton have it, if he were fit for it, and a writ was made out accordingly, and he took the oaths of that office before the treafurer and barons. The facts above-ftated prove the exiftence of the cloth manufacture in England before the time of Edward III., who is generally fuppofed to have firft introduced the art into the kingdom. There is no doubt, that a new impulfe was given to it during this reign by the liberal protection granted to foreign manufactures here: in all probability, they firft introduced the manufacture of ftuffs from combed wool or worfteds; an art requiring more fkill, and more complicated proceffes, than are employed in the making of cloth.

In the year 1331, John Kemp, a mafter manufacturer from Flanders, received a protection to eftablifh himfelf here with a number of dyers and fullers to carry on his trade, and in the following year feveral manufacturers came over from Brabant and Zealand. It is faid, that the king's marriage with the daughter of the earl of Hainault enabled him to fend over emiffaries without fufpicion, to invite the manufacturers to this kingdom. Thefe manufacturers were diftributed over the country, at the following places:—The manufacturers of fuftians (woollens) were eftablifhed at Norwich, of baize at Sudbury in Suffolk, of fayes and ferges at Colchefter in Effex, of broad-cloths in Kent, of kerfies in Devonfhire, of cloth in Worcefterfhire and Gloucefterfhire, of Welfh friezes in Wales, of cloth at Kendal in Weftmoreland, of coarfe cloths, afterwards called Halifax cloths, in Yorkfhire, of cloth in Hampfhire, Berkfhire, and Suffex, and of ferges at Taunton in Devonfhire. (Rymer's Fœdera, vol. i. p. 195.) Frefh fupplies of foreigners contributed to advance the woollen trade of thefe diftricts.

Kendal, in Weftmoreland, claims the honour of firft receiving John Kemp, where his defcendants ftill remain, and the woollen trade is at prefent carried on. In the following reign, we find the manufacturers of Kendal petitioning to be relieved from the regulations impofed on broad-cloths. Kendal green is mentioned by Shakfpeare as an article of drefs in the time of Henry IV., and there is reafon to believe, that in the reign of Elizabeth, the woollen manufactures of that town were as extenfive as at prefent.

In the year 1336, two woollen manufacturers from Brabant fettled at York, under the king's protection: they are ftiled in the letters of protection, "Willielmus de Brabant & Hanckeinus de Brabant, Textores." Thefe perfons probably laid the foundation of the woollen and worfted manufactures, which have fince fo extenfively flourifhed in the weftern part of that county. It is not very improbable, that the manufacturer Hancks, called Hanckeinus, gave

gave the name to the ſkein of worſted, which is to this day called a hank.

The references which we have ſoon afterwards to the woollen manufacture, as exiſting in the diſtricts before-named, tend to confirm the belief, that the diſtribution of the foreign manufacturers we have given is correct. About this time, we learn that Thomas Blanket, and other inhabitants of Briſtol, ſet up looms in their own houſes, but were ſo haraſſed by the impoſitions of the mayor and bailiffs of the place, that they were obliged to obtain letters from the king to permit the free uſe of their trade, without impediment, calumny, or exaction. The letter to the mayor and bailiffs accuſes them in the following terms: "vos diverſas pecuniæ ſummas ab eiſdem Thomas et aliis exigitis et ea occaſione multipliciter inquietatis et gravatis, ut aſſerunt." Dr. Parry has conjectured, that blanket, which at firſt meant a coarſe white undreſſed cloth, derived its name from the ſame Thomas Blanket of Briſtol. The encouragement given to the woollen manufacturers during this reign, and the conſequent conſumption of wool at home, diminiſhed the export of it ſo much, that a duty was laid on cloth exported to ſupply the place. Blackwell-hall was appointed by the mayor and common council of London for the market, where cloth manufacturers might ſend their goods for ſale, in the year 1357.

In the courſe of the reign we find ſeveral other acts relating to the meaſurement and fulling of cloth, and the fees to be paid to the aulnager.

In order to form a more diſtinct idea of the relative value of wool, cloth, and other articles, after and before the reign, it may be proper to refer to the ſtate of the ſilver coinage.

Summary of the impulſage of the out-carried above the in-brought commodities, amounteth to - - - -	255,214	3	11

Admitting the correctneſs of this ſtatement, which we have no reaſon to doubt, we muſt obſerve, that the cloth imported was of a higher value *per* yard than the cloth exported. Hence it may be inferred, that for ſeveral years after the arrival of the Flemiſh weavers, we were partly dependent on foreigners for our fine cloths; the coarſer kinds then, as at the preſent day, forming the larger quantity of our exports. It is obvious alſo, that worſted goods had become an article of manufacture, nearly equal in importance with the woollen; and hence it is not improbable, that the greater part of the Flemiſh manufacturers were makers of ſtuffs and worſted goods, which was probably an entirely new trade in England.

The ſtatutes in the following reigns, relating to the woollen manufacture, prove the narrow and ſelfiſh policy by which the manufacturers were influenced: theſe ſtatutes refer either to reſtrictions which they wanted to impoſe, in order to confine the trade to themſelves, or are made to prevent them from fraudulently packing or weaving their goods. In conſequence of theſe fraudulent practices, the 13th ſtatute of Richard II. makes the following regulations, which are curious, as marking the ſpirit of the manufacturers, and alſo as proving the early eſtabliſhment of the woollen trade in the weſtern counties, where it now flouriſhes. It runs thus: "Foraſmuch as divers plain cloths, wrought in the counties of Somerſet, Dorſet, Briſtol, and Glouceſter, be tacked and folded together for ſale; of which cloths a greater part be broken, bruiſed, and not agreeing in the colour, neither according to the breadth, nor in no manner to the part of the ſame cloths ſhewed outwards, but falſely wrought with divers wools, to the great loſs and damage

damage of the people, infomuch that the merchants that buy the fame, and carry them out of the realm to fell to ftrangers, be many times in danger to be flain, and fometimes imprifoned and put to fine and ranfom. Therefore it is ordained, that no plain cloth tacked and folded fhall be fet to fale within the fame counties." The fame act permits certain cloths of coarfe wool to be made of the breadth of three quarters, and appoints one weight and meafure through the kingdom, except in the county of Lancafter. Another ftatute, in the fame reign, allows every perfon to make cloth of what length and breadth he will, provided the aulnage and other duties are paid, and it be meafured and fealed by the king's aulnager, and contain no deceit. The kinds of worfted goods which might or might not be exported, were alfo fpecified in this ftatute. During this reign it appears, notwithftanding the increafe of our trade, that we annually exported about one hundred and thirty thoufand packs of wool, paying a duty of one hundred and fixty thoufand pounds.

In the 4th of Henry IV. the cloths made in London and the fuburbs were ordered to have a feal of lead attached, and in a fubfequent ftatute no cloths were to be folded before the aulnager had fet his feal to them. In the following reign, the narrow cloths, called the dozens of Devonfhire and Cornwall, are ordered to pay cocket cuftoms, after the rate of broad-cloths.

In the reign of Henry VI. the exportation of woollen yarn is prohibited, and this prohibition feems to have been in full force when wool was allowed to be freely exported. The only reafon affigned for this is, that the yarn paid no duty. During this reign two cloth-fearchers were appointed for every hundred throughout the realm, who were to infpect and feal all cloth, taking one penny for each. This proves that the manufacture of woollens had fpread over a great part of the kingdom. It is probable that this infpection extended to all cloths made in private families, which were fent to the fulling-mills.

The worfted trade was alfo increafing rapidly at this time: four wardens of worfted-weavers were appointed for the city of Norwich and two for the county of Norfolk, who were to make due fearch of worfteds, and of what length and breadth they were made. In the fame reign it was ordained, that "if our woollens were not received in Brabant, Holland, and Zealand, then the merchandize growing or wrought within the dominions of the duke of Burgoine fhall be prohibited in England, under pain of forfeiture." Hence we learn, that we very foon began to fupply thefe fame countries with woollens and worfteds, from which we had received workmen a century before.

In the third year of Edward IV. the woollen trade had increafed fo much, that the importation of woollen cloth, caps, &c. was prohibited. Woollen caps or bonnets were then univerfally worn; they were either knitted or made of cloth, and a large quantity of wool muft have been confumed in their fabrication. About the year 1482, hats made from felts were introduced; but the manufacturers of caps, called the cappers, continued a powerful body a century afterwards. In the fame reign, the wardens of worfteds at Norwich were doubled, or increafed to eight.

The manufacture of fine broad-cloth muft have been confiderably improved about this time; for in the fourth of Henry VII. it was thought prudent to fix a maximum on the price of fine cloth, by which every retailer of cloth who fhould fell a yard of the fineft fcarlet grained cloth above fixteen fhillings, or a yard of any other coloured cloth above eleven fhillings, was to forfeit forty fhillings *per* yard for the fame.

In the year 1493, in confequence of a quarrel between Henry VII. and the archduke Philip, all intercourfe between the Englifh and Flemifh ceafed, and the mart for Englifh goods was transferred from Antwerp to Calais. This interruption to the regular courfe of trade was feverely felt by the woollen manufacturers. Lord Bacon, mentioning the renewal of the trade with Flanders, which took place again in 1496, fays, "By this time the interruption of trade between the Englifh and Flemifh began to pinch the merchants of both nations very fore. The king, who loved wealth, though very fenfible of this, kept his dignity fo far as firft to be fought unto. Wherein the merchant adventurers likewife did hold out bravely; taking off the commodities of the kingdom, though they lay dead upon their hands for want of vent." The merchant adventurers he defcribes as "being a ftrong company, and underfet with rich men." It is not, however, very probable, that this company would continue to purchafe goods without a profpect of gain. Thefe merchant adventurers were divided into two bodies; thofe of London, which were the moft powerful; and the merchant adventurers of England, who paid a fine to the former on all goods fold at the foreign marts.

In the reign of Henry VIII. the woollen trade, and particularly all kinds of worfted manufactures, appear to have been in a very flourifhing ftate, though trade fuffered feveral fevere checks from the wars in which we were engaged. In the year 1527, Henry having entered into a league with France againft the emperor Charles V., all trade with Spain and the Low Countries ceafed. The goods fent to Blackwell-hall found no purchafers, the merchants having their warehoufes filled with cloths; the poor manufacturers being thus deprived of employment, an infurrection took place in the county of Suffolk, where four thoufand of them affembled, but were appeafed by the duke of Norfolk. The merchants were fummoned to appear before cardinal Wolfey, who in the name of the king reprimanded them in an angry tone for not purchafing the goods brought to market, and threatened them that his majefty would open a new mart at Whitehall, and buy of the clothiers to fell again to foreign merchants; to which menace one of them pertinently replied, "My lord, the king may buy them as well at Blackwell-hall, if it pleafes him, and the ftrangers will gladlier receive them there than at Weftminfter."—"You fhall not order that matter," faid the cardinal; "and I fhall fend into London to know what cloths you have on your hands, and by that done, the king and his council fhall appoint who fhall buy the cloths, I warrant you." With this anfwer the Londoners departed. Grafton's Chronicle, vol. ii. p. 1167-8.

The interference of the cardinal raifed the fpirits of the manufacturers for a time, but originating in ignorance of the nature of trade, it could only have a temporary effect, and goods fell again till a truce between England and Flanders was made for the benefit of trade. This fact fhews the dependance of England, even at that time, on the export of manufactured woollens. In this reign we find Lancafhire and Chefhire firft named as feats of the manufacture of coarfe woollens; they are mentioned, together with Cornwall and Wales, as diftricts where friezes were made. It appears from various references, that Norfolk and Suffolk were then flourifhing feats of the worfted manufacture, and of all goods made with a worfted warp. Wardens were allowed to the towns of Yarmouth and Lynn, but with a felfifh reftriction, that the pieces were to be dyed, fpun, or callendered in the city of Norwich. In the laft year of this reign, an act was paffed to prevent any perſons beſides woollen manufacturers, who bought wool for their own uſe, and merchants of the ſtaple, who bought for exportation, to purchaſe wool with the intent to ſell again. This act extended to twenty-eight counties, and ſecured a monopoly of the wool to the merchants of the ſtaple, and to the rich clothiers. In the firſt year of the following reign, Edward VI., it was repealed, ſo far as to allow every perſon dwelling in Norwich and Norfolk, to buy wool the growth of that county, by themſelves or agents, and retail it out in open market. The reaſon aſſigned is this: That almoſt the whole number of poor inhabitants of the county of Norfolk and city of Norwich had been uſed to get their living by ſpinning of Norfolk wool, which they uſed to purchaſe by eight pennyworth or twelve pennyworth at a time, ſelling the ſame again in yarn; and becauſe the grower choſe not to parcel it in ſuch ſmall quantities, therefore for the benefit of the poor, the wool of Norfolk was allowed to be purchaſed by wool-dealers. By this act, the 33d of Henry VIII., for prohibiting the exportation of yarn is made perpetual. The manufacture of woollens in the counties adjoining London appear to have been extenſive, particularly in the county of Berkſhire; for in the beginning of the reign of Henry VIII., John Winchcombe, of that county, commonly called Jack of Newbury, was celebrated as the greateſt clothier in England. He kept one hundred looms in his own houſe, and in the expedition againſt the Scotch, he ſent to Flodden-field one hundred men, fully equipped, at his own expence. Even ſo early as the 13th century, one Thomas Cole was diſtinguiſhed by the name of the rich clothier of Reading, in Berkſhire.

York, then the ſecond city in the kingdom, and from its connection with the port of Hull well ſituated for the export trade, was probably an early ſeat of the woollen manufacture. We have already mentioned the ſettlement of two clothiers from Brabant in the time of Edward III. We do not learn preciſely in our early hiſtorians, when the manufactures emanated from that city into the weſtern parts of the county; but from an act in the 34th of Henry VIII. we are informed, that the chief manufacture of that city was the making of coverlets; the act recites, "that the poor of that city were daily employed in ſpinning, carding, dyeing, weaving, &c. for the making of coverlets, and that the ſame have not been made elſewhere in the ſaid county till of late; that this manufacture had ſpread itſelf into other parts of the county, and was thereby debaſed and diſcredited, and therefore it is enacted, that none ſhall make coverlets in Yorkſhire but the people of York." Thus we ſee, under the flimſy pretext of public benefit, the manufacturers were willing to diſguiſe that ſelfiſh ſpirit of monopoly, which diſgraces almoſt every page of our commercial hiſtory. The municipal regulations of the city of York, which were, and ſtill continue to be, hoſtile to a free trade, probably obliged many manufacturers, who were not ſharers in the monopolies of the guild, to eſtabliſh themſelves in the weſtern villages of the county, where proviſions were cheaper, and where they could carry on their trade without reſtriction. In the reign of Philip and Mary, ſoon after this period, we have the following intereſting account of Halifax, in conſequence of an act paſſed in the 37th of Henry VIII. to prevent any other perſons than merchants of the ſtaple and woollen manufacturers from buying wool in the county of Kent and twenty-ſeven ſhires. The poorer manufacturers, who were unable to lay in their ſtock of wool at one time, being hereby deprived of their trade, made application for redreſs, which was granted. The act recites as follows: "Whereas the town of Halifax being planted in the great waſte and moors, where the fertility of the ground is not apt to bring forth any corn nor good graſs, but in rare places, and by exceeding and great induſtry of the inhabitants; and the ſame inhabitants altogether do live by cloth-making, and the greater part of them neither getteth corn, nor is able to keep a horſe to carry wools, nor yet to buy much wool at once, but hath ever uſed to repair to the town of Halifax, and there to buy ſome two or three ſtone, according to their ability, and to carry the ſame to their houſes, three, four, or five miles off, upon their heads and backs, and ſo to make and convert the ſame either into yarn or cloth, and to ſell the ſame, and ſo to buy more wool of the wool-driver; by means of which induſtry, the barren grounds in thoſe parts be now much inhabited, and above five hundred houſeholds there newly increaſed within theſe forty years paſt, which now are like to be undone and driven to beggary by reaſon of the late ſtatute (37th of Henry VIII.) that taketh away the wool-driver, ſo that they cannot now have their wool by ſuch ſmall portions as they were wont to have, and that alſo they are not able to keep any horſes whereupon to ride or fetch their wools further from them in other places, unleſs ſome remedy may be provided. It was therefore enacted, that it ſhould be lawful, to any perſon or perſons inhabiting within the pariſh of Halifax, to buy any wool or wools at ſuch time, as the clothiers may buy the ſame, otherwiſe than by engroſſing and foreſtalling, ſo that the perſons buying the ſame do carry the ſaid wools to the town of Halifax, and there to ſell the ſame to ſuch poor folks of that and other pariſhes adjoining, as ſhall work the ſame in cloth of yarn, to their knowledge, and not to the rich and wealthy clothier, or any other to ſell again. Offending againſt this act to forfeit double the value of the wool ſo ſold."

From this we learn that many woollen manufacturers had been either driven from York at an early period, by the oppreſſion of the municipal regulations, or had retired where proviſions were cheaper, and where they had better ſtreams for the erection of fulling-mills, and for other proceſſes of the manufacture, ſuch as dyeing and ſcouring.

The woollen manufactures alſo gradually retired from the vicinity of the metropolis, owing to the increaſed price of proviſions and labour, and probably alſo to the difficulty of obtaining commodious ſtreams for the ſcouring and fulling of cloth, when the country round London became more populous. In the latter part of the reign of Henry VIII. we are informed, that the king demiſed to William Webbe the ſubſidy and aulnage of all cloth made in the county of Monmouth, and in the twelve ſhires of Wales. A former act of this reign, ſpeaking of the manufacturers of North Wales, ſays, they had been uſed to ſell their cloths ſo craftly and hard rolled together, that the buyer could not perceive the untrue making thereof. Theſe acts prove the extenſion of the woollen manufactures weſtward.

In the ſame reign, an act mentions the woollen manufactures as being eſtabliſhed in Worceſterſhire, but prohibits any one from making cloth in the county, except within the city of Worceſter, and in the towns of Eveſham, Droitwich, Kidderminſter, and Bromſgrove; and forbids the owners of houſes in thoſe places from letting them at advanced prices to the cloth-manufacturers. The woollen manufacture has continued to the preſent day at the two laſt of theſe towns. In the reign of Edward VI. Coventry and Mancheſter are mentioned as manufacturing places. The manufacturers in the old eſtabliſhed ſeats of the woollen trade appear to have been greatly alarmed at the extenſion of the cloth manufacture, and to have exerted all their influence to reſtrain it. Near the concluſion of the reign of Philip

Philip and Mary, an act in 53 sections was passed, relating to the making of woollen cloths. It enacts, that no person shall make woollen cloth but only in a market-town, where cloth hath commonly been used to be made for the space of ten years last past, or in a city, borough, or town corporate. From this restricting act, however, the following exceptions are made: to all persons who dwell in North Wales or South Wales, Cheshire, Lancashire, Westmoreland, Cumberland, Northumberland, the bishopric of Durham, Cornwall, Suffolk, Kent, the town of Godalmin in Surrey, or in Yorkshire, being not within twelve miles of the city of York, or any towns or villages near the river Stroud in Gloucestershire. This act, so absurd and oppressive, was obliged to be modified in the first year of the following reign, by an act entitled "An Act for the continuing and making of Woollen Cloths in divers Towns in the County of Essex." Bocking, Watherfold, Cockshill, and Dodham, are the towns specified.

In consequence of the increase of our manufactures, the export of wool had nearly ceased before the reign of Elizabeth; and a considerable advance appears to have taken place in the price of food, clothing, and rents. The export trade of England was carried on very extensively by three companies of merchants, the merchants of the Still-yard, who were foreigners, the merchants of the Staple, and the merchant adventurers, who were English. See STILLYARD, STAPLE, and ADVENTURERS.

The merchants of the Stillyard were of ancient standing, and were originally from the Hanse towns: they had great privileges granted them, and particularly they were allowed to export and import all wares and merchandize, on payment of the small duty of one and a quarter *per cent.* This gave them a decided advantage over the other companies; and it is alleged that they lent their name to cover the import and export of goods belonging to private merchants, and thereby evaded the regular duties on such goods. This company had engrossed a considerable part of the cloth trade. In the year 1551 they exported 44,000 cloths; soon after which this company was dissolved. The merchant adventurers succeeded to that branch of their trade: according to the account of John Wheeler, secretary to the company, there were annually shipped by them 60,000 white cloths, worth 600,000*l.*, and 40,000 cloths of all sorts, baizes and kersies, worth 400,000*l.*, besides wool and woolfels. We are told by Camden, that, in this reign, the commerce between England and the Netherlands rose to above twelve millions yearly, and the woollen trade alone amounted to five millions. The Latin terms which Camden employs, *milliones aureorum*, leaves the amount intended uncertain: if we suppose it to be ducats, the quantity is much greater than England exported at that time; probably florins were intended, which makes the amount about 750,000*l.*

Besides the exports to Antwerp, English cloth was at this time sent to Amsterdam, Hamburgh, Sweden, Russia, and other countries. The woollen trade of England had now advanced to a higher state of prosperity than at any former period; and from this time it appears to have declined until after the revolution of 1668. In this reign, the price of wool, which we believe to mean long or combing wool, had advanced from 13*s.* 4*d.* to 22*s.* *per* tod; and the shilling containing the same weight of silver as our late coinage, *viz.* 86 grains, the relative value of a tod of long wool was considerably more than it has ever been during the present reign.

The declension of our manufactures in the succeeding reigns of the Stuarts, as we have reason to believe, extended much more to woollen cloths than to worsted pieces. Long wool, or combing-wool, was more the peculiar produce of England than clothing-wools. The latter were grown in abundance, and of a superior quality, in Spain, Portugal, and France; but the combing-wools of England, on account of the superior soundness of the staple or fibre, and the quantity supplied, gave a decided advantage to our manufacturers of stuffs or worsted pieces.

The persecution of the Protestants by the duke of Alva in the Netherlands drove multitudes of the manufacturers into England, where they were graciously received by Elizabeth, who gave them liberty to settle at Norwich, Colchester, Sandwich, Maidstone, and Southampton. These refugees contributed to extend our manufactures of worsted goods and light woollens, called bays and says; they also introduced the manufacture of linens and silks, and it is supposed that they first taught the art of weaving on the stocking-frame.

In the latter part of the reign of Elizabeth an act was passed to relieve the counties of Somerset, Gloucester, and Wiltshire, from those absurd and oppressive statutes which confined the making of cloth to corporate towns. This act, which gave to all persons residing in these counties the privileges of free trade, could not fail to extend and establish the woollen manufactures in these parts, and they have remained to the present time the principal seats of the superfine cloth trade, whilst many manufacturing corporate towns, which were then flourishing, have sunk to decay. Various acts, regulating the length, breadth, and tentering of woollen goods of different kinds, were also passed in this reign, referring to the counties of Oxfordshire, Devon, and the counties north of Trent, particularly Yorkshire and Lancashire. The importation of foreign wool-cards was also prohibited. The act recites, that many thousands of woollen card-makers and card-wire drawers, living in London, Bristol, Gloucester, Norwich, Coventry, and elsewhere, had heretofore subsisted themselves and families upon that business, which was now greatly impaired by the importation of wool-cards. No laws prohibiting the export of wool were thought necessary in this period of our history, and it continued to be exported during the whole of this reign, as appears by the account of the merchant adventurers, who exported it together with cloth; but though wool was freely exported, an act was passed to prevent the carrying of live sheep, lambs, or rams out of England; but the reasons for this act are not recited, though it states it was for divers good causes and considerations. The internal tranquillity that the country enjoyed during this long reign, the influx of foreign makers of new kinds of worsteds, and other articles not known before, the opening of a new trade to Turkey and the Barbary states, by treaty in the year 1579 and in 1585, all greatly contributed to the extension of the woollen trade and manufactures. There were indeed other circumstances which must have operated against our manufacturers in part of this reign. The interruption of commerce between England and the Netherlands in 1564, which lasted some time, the wars with Spain, the sacking of Antwerp, in which the English merchants suffered severely, gave a considerable check to the foreign trade; yet we have seen that the merchant adventurers alone exported woollens to the amount of one million sterling towards the latter end of this reign. The demand at home for woollens must also have greatly increased during the long period of domestic tranquillity which the nation at that time enjoyed, and particularly from the prevailing taste for costly dresses which has spread from the court through the country.

A great part of our woollen exports hitherto consisted of white undressed cloth; but in the following reign of James I. it was represented as bad policy to permit the exportation of cloth in this state, and thereby lose the profit on the dyeing and finifhing. A letter exifts addreffed to king James on this fubject, afcribed to fir Walter Raleigh, but without fufficient evidence, as "the moft ancient manufcripts of this letter in the libraries of the nobility afcribe it to John Keymer." (Oldy's Life of Sir W. Raleigh.) In this letter it is ftated, "that there have been eighty thoufand undreffed and undyed cloths exported yearly, by which the kingdom has been deprived of four hundred thoufand pounds for the laft fifty-five years, which is nearly twenty millions that would have been gained by the labour of the workmen in that time, with the merchants' gains for bringing in dyeing-wares, and return of cloths dreffed and dyed, with other benefits to the realm." The writer proceeds, in another part, to ftate, that there had alfo been exported in that time annually, of baizes and northern and Devonfhire kerfies, in the white, fifty thoufand cloths, counting three kerfies to a cloth, whereby had been loft about five millions to the nation in labour, profit, &c. The author informs us, that the baizes fo exported were dreffed and dyed at Amfterdam, and fhipped to Spain, Portugal, and other kingdoms, under the name of Flemifh baize, fetting their own feal upon them; "fo that we lofe the very name of our home-bred commodities, and other countries get the reputation and profit thereof." The author concludes with afferting, that the nation lofes a million a year by the export of white cloths, which might be dreffed and dyed as well at home. This letter has been often quoted as containing unanfwerable reafons for confining the whole procefs of the cloth manufacture to our own country; but, like other monopolifts, the writer feems to forget that there are two parties in all mercantile tranfactions, and that manufactured goods muft be fent in that ftate in which the purchafer is willing to receive them, unlefs it be proved that he cannot procure them elfewhere. Let us mark the refult. Alderman Cockayne, and other London merchants, had fufficient influence with the government to obtain the prohibition of the export of white cloths, and to fecure a patent for dreffing and dyeing of cloths. In confequence of which, the Dutch and Germans immediately prohibited the importation of dyed cloths from England, which gave fo great a check to our export trade, that in the year 1616, the whole amount of cloths exported of every kind amounted only to fixty thoufand, fo that the export trade in woollens had fallen to lefs than one-third of its former amount; and in the year 1622,

	l.	*s.*	*d.*
All our exports of every kind amounted only to	2,320,436	12	10
Whilft our imports were	2,619,315	0	0
Leaving a balance againft us of	298,878	7	2

It being from experience proved, that the policy of dreffing and dyeing all our goods at home had produced the greateft injury to the woollen trade, the reftrictions were taken off, and the export for white cloth left free. In the former reign, cloths about four pounds value were, by ftatute, to be fent out dyed, by all perfons except the company of merchant adventurers, who obtained a licence to export all forts of white cloths; and though this was itfelf a monopoly, yet, as it gave foreigners an opportunity of receiving our finer cloths in the ftate which they moft wanted, it was the means of increafing our trade: indeed it is faid by Miffelden, that "within a few years after granting this licence, the vent for cloth in foreign parts increafed to twice as much as it had been during the ftrict obfervance of the ftatute." With this fact before their eyes, it is fcarcely poffible that our ftatefmen at that time could have proceeded to the prohibition of white cloth exports, unlefs they had been (as was afferted) influenced by prefents from alderman Cockayne and the rich merchants, who expected to receive the benefit arifing from the prohibition, and the exclufive right of dyeing and dreffing. The wool-growers equally felt the ill effects of this prohibition. Wool is faid to have fallen from thirty-three fhillings *per* tod to twenty fhillings; if by this is meant the long combing-wools, the former price, confidering the value of money at that time, is much higher than it has been in the laft or the prefent century.

During the reigns of the Stuarts, the infamous policy they adopted ftruck not only at the liberty, but at the commercial profperity of the country. Archbifhop Laud, imbued with the malignant zeal of a bigot, commenced his attacks on the defcendants of the French Proteftants, eftablifhed as manufacturers of woollens in Norfolk and Suffolk, from which counties his perfecuting fury drove fome thoufand families. Many of them fettled in New England; but others went into Holland, where they were encouraged by the Dutch, who allowed them an exemption from taxes and rents for feven years. In return for this, the ftates were amply repaid by the introduction of manufacturers, with which they were before unacquainted. In the year 1622, king James iffued a proclamation to prohibit the exportation of wool, fuller's-earth, &c. In 1640 wool was again admitted to be exported on the payment of certain duties; and we are told, that in the fame year fir John Brownlowe, of Belton in Lincolnfhire, fold three years' wool at twenty-four fhillings *per* tod to a baize-maker of Colchefter. As it is reafonable to fuppofe that this was the long combing-wool of that county, it fhews the high relative price of the article at that time. In 1647, owing to the high price of wool, its exportation was again prohibited.

During the civil wars, the manufactures and export trade of England declined, and the Dutch availed themfelves of this to extend their own manufacture and export of woollens, particularly to Spain, from whence they brought fine Spanifh wool. At this time it appears, that the woollen manufactures in Poland and Silefia were rapidly increafing; and the Englifh government received information that two hundred and twenty thoufand cloths were made there annually, befides confiderable quantities made at Dantzic, and in the vicinity.

The duke of Brandenburg, it was alfo ftated to our government, had ordered one hundred thoufand ells of Silefia cloth at Köningfberg for his troops, which had been heretofore fupplied with Englifh cloth. The eftimation in which our cloth had been held is faid to have been loft by negligence in the manufacture, particularly in the fpinning and weaving. The Dutch and Poles had a little before this time received a great number of Proteftant manufacturers, who fled from the perfecution of the duke of Alva in Brabant and Flanders.

Here it may be proper to remark, that the Englifh as a nation had little intercourfe with other parts of the world, except through a few large trading companies: hence they were extremely ignorant refpecting the ftate of foreign countries, and fuppofed that the cloth trade had been confined to their own country for three hundred years; and they confidered the eftablifhment of other manufacturers as a novelty and infringement of their juft rights. With thefe views, it was propofed to obtain a complete monopoly of all the clothing-wools in Spain, in order to prevent the Dutch and other nations from rivalling our manufactures. This is the more extraordinary, as the Englifh had not then learned, like the Dutch, to manufacture Spanifh wool, without mixing it with that of their own country. It is needlefs to fay, that the negociation of fir William Godolphin for this felfifh monopoly of wool was not fuccefsful. During the whole reign of Elizabeth, when our woollen manufactures were in the higheft ftate of profperity, wool and woolfels were permitted to be exported. In the reign of James I. and Charles I., when the trade was declining, proclamations were iffued to prevent the exportation of wool, and alfo that of fuller's-earth. During the commonwealth, an ordinance of parliament was iffued to prohibit the exportation of wool and fuller's-earth, on pain of forfeiture of the wool, and a penalty of 3*s. per* pound on every pound of fuller's-earth. The firft act of parliament which abfolutely prohibited the exportation of wool by making it felony, and which could not be fet afide by a royal licence, is the 12th of Charles II., which was paffed foon after the Reftoration.

The grounds of this meafure are ftated in the preamble of the act: "For the better preventing the loffes and inconveniences which have happened by and through the fecret and fubtile exportation of wool out of the kingdom; and for the better fetting to work the poor people and inhabitants of the kingdom, to the intent that the full and beft ufe and benefit of the principal native commodities of the kingdom may redound to and be unto and amongft the fubjects and inhabitants of the kingdom, and not unto any foreign ftates." Previous to this time, the proclamations and ordinances iffued to prevent the exportation of wool, for the moft part, fignified nothing more than the impofition of a duty or a compofition for exporting by licence from the government, what on other terms was forbidden, under penalties of confifcation, fine, or imprifonment. We have feen that, from the death of Elizabeth to the Revolution in 1688, the woollen trade was generally in a languifhing ftate. In the year 1665, Thomas Telham of Warwickfhire, with two thoufand manufacturers, left the kingdom, and eftablifhed themfelves in the Palatinate, and commenced a woollen manufacture there, and were greatly encouraged by the elector. The eftablifhment was foon afterwards joined by a number of manufacturers from Hertfordfhire.

During the period from Elizabeth to the year 1668, the Englifh appear to have made no improvement whatever in their modes of manufacture of woollen cloth, whilft the neighbouring nations had been making a gradual progreffion, both in the ftyle of their manufacture, and the amount annually produced. It was efpecially in the manufacture of fine cloths that their fuperiority was manifeft. The Dutch, in particular, were far more expert than the Englifh in the dreffing and dyeing of cloth. This will appear from the following remarkable fact ftated by Coke, vol. ii. p. 169. In the year 1668, one Brewer, with about fifty Walloons, who wrought and dyed fine woollen cloths, came into England, and received the royal protection and encouragement. By him the Englifh were firft inftructed how to manufacture cloth of the beft Spanifh wool, without any admixture with inferior wool; and alfo to manufacture and dye fine cloths cheaper by 40 *per cent.* than they had done before. Ten years before this time, it had been publifhed and admitted in England, that "Spanifh wool alone could not be wrought into cloth." It may feem truly extraordinary that the Englifh, who had fo long carried on the manufacture of woollen cloth, had not availed themfelves of the revolution in Flanders, which drove away the beft mafter manufacturers, to encourage their fettlement in this country. M. Huet explains the fact in a way which is not very creditable to the liberality of the Englifh manufacturers, or to the wifdom of our inftitutions. "It was owing to the municipal laws of England, and its ufages towards ftrangers; who, befides being doubly rated at the cuftom-houfe, were excluded from all companies or fraternities of trade; and were not allowed to carry on manufactures as mafters or partners, unlefs fuch as the natives were unacquainted with; fo that none of the Flemifh mafter manufacturers of fine cloth went thither (to England), their's being a myftery not accounted new, though very much fuperior to the cloth working then known in England. It was only thofe who wrought in new kinds of worfteds, ferges, damafks, or ftockings, who went thither. The fame policy was alfo adopted by the Hanfe towns: hence the greater part of the vaft and profitable trade, which was loft to Antwerp, centered neceffarily in Holland, where the manufacturers from Brabant were cordially received." This appears a fatisfactory explanation why the Englifh, in 1668, were fo much inferior to the Dutch in the manufacture of fine cloth.

In the year 1660, however, our manufacturers began to be aware of the fuperiority of Spanifh wool, and to mix it with the beft Englifh, probably in what were called medleys or mixture-cloths, or elfe employing the Englifh wool for warp, and covering it with weft of Spanifh wool. The beft Spanifh wool was then 4*s.* and the fecond fort 3*s. per* pound, and the beft Englifh 1*s.* 6*d. per* pound.

It is deferving of notice, that, in the latter period of the Commonwealth, our trade is faid to have greatly revived, but to have fuffered a miferable depreffion almoft immediately after the reftoration of Charles II. In a letter of M. Downing of the Hague to the prefident of the council in London, 1660, printed in Thurloe's State Papers, vol. vii. p. 848. it is ftated, that great quantities of wool were brought fecretly from England to Holland; and he adds, that the Dutch had at that time got in a great meafure the manufacture of fine cloth, and would probably, with Silefia, engrofs alfo the manufacture of coarfe cloth, and leave England nothing but its native wool to export.

In the year 1662, great complaints were made againft the merchant adventurers for their neglect of the cloth trade; in reply to which they faid, that the demand for Englifh cloths failed in the foreign markets, the white clothing trade having abated from 100,000 cloths annually to 11,000. In the year 1663 our whole exports were only about two millions, and our imports four, leaving a balance of two millions againft this country. It is, however, deferving notice, that the number of wardens for the infpection of ftuffs at Norwich being too few, they were at this time increafed from five to eight. A letter on the ftate of trade, publifhed in 1667, fays, clothing-wools were fo much fallen at that time, that the beft Spanifh was fold at 2*s.* 2*d. per* pound, and Englifh at 8*d. per* pound. The writer afcribes the fall in the price of Englifh wool to our wearing fo much Spanifh cloth, a great part not manufactured by ourfelves, as Dutch blacks; but it is obvious, from the price of Spanifh wool, that the low price of clothing-wools at that time depended on a more general caufe, affecting all manufacturing countries. To relieve the cloth trade from the great depreffion under which it laboured between the years 1660 and 1678, various fchemes were devifed. Among others, the mayor and common council of London paffed an act "for the regulation of Blackwell-hall, Leaden-hall, and Welfh-hall, (the three public markets for cloth in London,) and for preventing foreigners buying and felling!" By foreigners are underftood all perfons not free of the city of London. This act, a moft fingular monument of the ignorance or felfifhnefs of its authors, prohibits the fale of all woollen cloths fent to London, except at the above halls, where certain duties were to be paid upon them, and from whence they could not be removed for three weeks, unlefs they were fold in the meantime to fome draper, or other freeman of the city. The hall-keepers were to attend ftrictly at the halls, and

 turn

turn out all foreigners and aliens coming to purchafe cloth; and every freeman of the city who fhould introduce a purchafer into the halls not free of the city fhould forfeit, for the firft offence, five pounds,—for the fecond, ten,—and for the third, fifteen pounds! Thus, in thofe days, turning purchafers out of the public markets, and fecuring the fale to a certain clafs of buyers, was confidered an act for the benefit of the public.

The Irifh had, a little before this time, commenced the manufacture of woollens and worfteds, which appears greatly to have alarmed the Englifh manufacturers. The wools of Ireland had increafed in quantity, in confequence of a tyrannical act paffed a little before this period, to prevent the Irifh from fending cattle to England, which obliged them to convert their grounds into fheep-paftures. They were, however, prohibited from exporting their wool to foreigners, it being made felony; and the exportation to England, in any other than a raw ftate, expofed it to confifcation. About the year 1640 fome clothiers from the weft of England eftablifhed a woollen manufacture at Dublin, where it flourifhed a confiderable time. About the fame period, fixty families of manufacturers from Holland fettled at Limerick: thefe were ruined by the wars which enfued. Other Englifh clothiers fettled at Cork and Kinfale; a few French manufacturers of druggets fettled at Waterford; and a more confiderable eftablifhment of the cloth manufacture was formed at Clonmel, fupported by the capital of fome London merchants, who had agents there. Thefe eftablifhments, though obvioufly inadequate to the fupply of one-fourth part of the population of Ireland, excited great jealoufy in the Englifh manufacturers; and during the great depreffion of the woollen trade between the years 1660 and 1668, a part of this diftrefs was afcribed to the rivalry of the Irifh clothiers. The Englifh farmers, at the fame time, afcribed the low price of wools to the great importations of wools from Ireland; and the merchants afcribed the failure of the foreign demand for cloth to the clandeltine exportation of Englifh and Irifh wools.

Sir William Petty, in the year 1672, eftimates the fheep in Ireland at four millions, and the weight of each fleece at two pounds. The latter, however, is obvioufly not more than half the true average weight of the fleece, and the number is fuppofed by fome to be below what it was a few years afterwards. If the number of fheep be correct, and taking the fleece of each at four pounds, this would make the total amount of Irifh wools only 66,000 packs, of which three-fourths were confumed in Ireland.

The alarm and jealoufly excited in England by the Irifh woollen manufactures produced meafures that almoft compelled the Irifh to export their wools clandeftinely to the continent. An act was paffed in the year 1699 prohibiting the exportation of woollen manufactures from Ireland, except to a few parts in England and Wales, where the duties impofed amounted to a total prohibition. Various addreffes have been prefented to the king and both houfes of parliament, "befeeching his majefty to take effectual meafures to prevent the growth of the woollen manufactures in Ireland." The Irifh parliament was influenced to impofe a duty in the fame year of four fhillings in the pound on their own manufactures when exported. Thefe unjuft proceedings were intended to annihilate the export trade for Irifh woollens; and, in confequence, their wool and worfted yarn that was not confumed at home were fent to England, or to the continent clandeftinely. The firft four years after the deftruction of their manufactures, thefe exports to England were as follow:

	Stone of Wool, 18lbs. *per* Stone.	Stone of Yarn, 18lbs.	Total of Wool and Yarn.
1700	336,292	26,617	362,909
1701	300,812	23,390	326,202
1702	315,473	43,648	359,121
1703	360,862	36,873	397,735

The average annual amount of wool and yarn, as above, may be ftated at thirty thoufand packs. But after this period the exports to England declined, owing no doubt to the clandeftine exportation of wool to the continent, for which the numerous creeks and harbours offered fuch facility.

In 1711, and the three following years, the quantity exported to England was as under:

	Wool.	Yarn.	Total.
1711	310,136	52,273	365,409
1712	263,946	60,108	324,054
1713	171,871	68,548	240,409
1714	147,153	58,147	205,800

A few years after this, the decline was ftill more confiderable in the amount of wool exported, but that of yarn continued to increafe a little:

1726	51,371	87,261	138,632
1727	58,182	72,047	130,229
1728	49,784	80,428	130,212
1729	38,667	91,854	130,521

A further encouragement to clandeftine importation was given by an impolitic duty of 2*s*. 4*d*. *per* ftone on wool fent to England, which, as the average price did not exceed 6*s*. 6*d*., was full thirty *per cent*. on the firft coft. It will be feen fubfequently, that the woollen manufactures of England were all this time progreffively increafing, fo that the decline in the imports of wool from Ireland were not occafioned by a declenfion of trade; the Irifh had found other markets for their wool.

From a work entitled "A New Difcourfe of Trade," by fir Jofhua Child, fuppofed to have been publifhed about the year 1667, we learn feveral important particulars refpecting the woollen trade. "Though our vent for fine cloths and ftuffs to Turkey, Italy, Spain, and Portugal, were, he fays, declined, yet we retained a confiderable part, principally becaufe the wool of which our middling coarfe cloths are made is our own, and confequently cheaper to us than the Dutch can fteal it from us." In another part he judicioufly obferves, that the acts for regulating manufactures, refolve themfelves at laft into a tax on the commodity, without refpect to the goodnefs of it, as moft notorioufly appears in the bufinefs of aulnager, which doubtlefs our predeceffors intended for a fcrutiny into the goodnefs of the cloth; and to that purpofe a feal was invented as a fignal, that the commodity was made according to the ftatute; which feal, it is faid, may now be bought by thoufands, and put upon what the buyers pleafe. Sir Jofhua Child admits that wool was eminently the foundation of Englifh riches, and that all poffible means fhould be ufed to keep it within the realm; but the only efficacious meafures to effect it are not penal ftatutes, but encouragement to trade. The impediments at that time he ftates to be, 1ft, The high rate of intereft; 2d, Want of hands, which an act of naturalization would cure; 3d, Compulfion (perfecution) in matters of religion. For he adds, "while our neighbours the Dutch have money at lower intereft and more hands, by reafon of general liberty of confcience, with other free privileges, both to natives and foreigners, there is no queftion but they will be able to give a better price for our wool than we can afford ourfelves, and they that can give the beft price for a commodity fhall never fail to have it by one means or another, notwithftanding the

 oppofition

oppofition of any laws by fea or land; of fuch, force, fubtilty, and violence, is the general courfe of trade."

The fame enlightened writer appears to have been the firft Englifhman who faw the injuftice, abfurdity, and impolicy of the numerous reftrictions by which the manufacturers were obliged to make cloths of certain weights and lengths, to keep only a certain quantity of looms, or to prohibit dyers, fullers, &c. from carrying on other branches of the trade. "It would be (he juftly obferved) for the advantage of the trade of England, to leave all men at liberty to make what cloth and ftuffs they pleafe, how they will, when and where they will, and of any lengths or fizes."

One of the principal caufes of the decay of our woollen manufactures fir Jofhua Child might not think it prudent to ftate. This was the encouragement given to the confumption of French cloths and woollens in England, together with the total prohibition of Englifh goods imported into France, or the impofition of duties which amounted to a prohibition. The French, under the adminiftration of Colbert, had been extending and improving every branch of the woollen manufacture, and were become our great rivals in foreign markets, as well as at home. In the year 1678, acts were paffed, the 29th and 30th of Charles II., prohibiting the importation of French commodities for three years. From this time trade began gradually to revive, and would have greatly increafed, had not political caufes operated as a check to our profperity.

The improvements introduced in the manufacture of fine cloths by Brewer in 1668, and the more extenfive confumption of Spanifh wool, enabled us to oppofe, with fome fuccefs, the rivalry of the French.

After the acceffion of William, our manufacturers, who were warmly attached to the caufe of religious liberty, being the greater part Proteftant diffenters, were animated to uncommon exertions in the reftoration of their trade. This is evident from the ftate of our exports in the following year after the revolution in 1689, when they amounted to near feven millions, of which the woollens were nearly three millions. This is the largeft amount till the year 1715. A fhort time after the revolution, about the clofe of the century, our writers on Political Arithmetic, Mr. King and Dr. Davenant, give the following eftimate of our national wealth, including wool, &c.:

	£
The annual income of England, of which the people fubfift - - - - - -	43,000,000
Yearly rent of land - - - - - -	10,000,000
Value of wool yearly fhorn - - -	2,000,000
Woollen manufacture of England - -	8,000,000
Woollen manufactures exported - -	2,000,000

From this period, the woollen trade of England kept progeffively increafing, though fubject to fome fluctuations. In the following years the amount exported were as under:

		£
1718	value of woollens exported	2,673,696
1719	- - - - - -	2,730,297
1720	- - - - - -	3,059,049
1721	- - - - - -	2,903,310
1722	- - - - - -	3,384,842

About the year 1722, the plague at Marfeilles, by preventing the exportation of French woollens, increafed the demand for Englifh manufactures confiderably. In the year 1737, the woollen exports amounted to 4,158,643*l.*; and it is remarkable, that at that period the price of wool was uncommonly low.

	£
The yearly medium value of woollen exports, from 1739 to 1748, or to the peace of Aix-la-Chapelle, was - - - - - -	3,327,057
Yearly medium of woollen exports, from 1749 to 1753, was - - - - - -	4,189,195

From this time to the period of the American war in 1775, the woollen manufactures, and particularly the worfted, ftill continued to increafe, with occafional checks. The quantity of long combing-wools grown in England had given to the manufacturers of worfted goods a decided advantage over thofe of France, though the ingenuity of the latter in the manufacture of les petites draperies, as the worfted goods are called, was greatly fuperior to what our own workmen had ever fhewn. The demand for worfted goods at home, for tammies and ftuffs, which were the general drefs of females before the year 1775, was very great; befides which, we fupplied with worfted goods many of the fouthern parts of Europe, and particularly Spain and Portugal, for the ufe of their South American colonies, and for the dreffes of the clergy, monks, and nuns, which form no inconfiderable part of the population in thofe countries. About the year 1775, the introduction of Arkwright's inventions for fpinning, carding, &c. into the cotton trade, produced a great change in the article of female drefs in England, ftuffs and tammies being fupplanted by cotton goods, which were become extremely cheap. The failure of the foreign trade alfo greatly affected our manufacturers, both woollens and worfteds. The price of Englifh wool at the latter end of the American war was lower than it had been in any period of our hiftory, when money was of much higher relative value. A tod of 28lbs. of the beft Lincolnfhire wool for combing was not worth more than nine fhillings, and the inferior kinds fix fhillings, or about threepence and four-pence *per* pound. From the time of Elizabeth to the middle of the laft century, fcarcely any alteration or improvements had taken place in the proceffes of manufacture, either in woollen or worfted, beyond the variation of colours or patterns, to fuit the fafhion of the day. The ingenious mechanical inventions of Arkwright, applied to the fpinning and carding of cotton, were foon after modified, and applied to the woollen and worfted trade, and produced an entire revolution in fome of the feats of their manufacture. Before that period, the manufacture of heavy woollens and coarfe worfted goods had been gradually concentrating into Yorkfhire and Lancafhire, where the cheapnefs of living, the active induftry of the inhabitants, and, above all, the cheapnefs and abundance of coal, gave the manufacturers a decided advantage over thofe in the midland and weftern counties. The following table, fhewing the amount of broad and narrow cloths made in the Weft Riding of Yorkfhire, will prove the fact moft decifively. It may be proper to remark, that eighty years fince, about 1738, when our woollen exports exceeded four millions fterling, the total number of pieces of broad and narrow cloth made in Yorkfhire was only fifty-fix thoufand nine hundred. At prefent our woollen exports are only about double what they then were; but the number of cloths manufactured in Yorkfhire is not lefs than four hundred and ninety thoufand pieces, or eight times more than the quantity made at the period above referred to. It muft be remarked alfo, that this account does not include the cloth manufactured in Lancafhire, and the borders of Chefhire adjoining Yorkfhire, nor the blankets, ferges, baizes, flannels, caffimeres, toilinets, carpets, rugs, worfted goods, or any other defcription of woollens or worfteds, except plain and narrow broad-cloths. The total amount of thefe different woollen articles exceed, we believe, in weight, if not in value, that of the woollen cloths.

An Account of the Number of Broad Cloths, milled at the feveral Fulling Mills in the Weft Riding of the County of York, from the 24th of June, 1725, (the Commencement of the Act,) to the 12th of March, 1726, and thence annually, diftinguifhing each Year; and of the Narrow Cloths, from the 1ft of Auguft, 1737, (the Commencement of the Act) to the 20th of January, 1738, and thence annually, diftinguifhing each Year; likewife the Number of Yards in Length, made each Year, from Eafter Seffions, 1768.

In

In the table that will be afterwards given, it will be feen that the quantity of yards of different woollen articles exported, which are not included with cloths, greatly exceeds that of broad and narrow cloths. Taking this as a ftandard, it would appear that the cloth returned at the fulling-mills in the Weft Riding of Yorkfhire is not more than one-third of the total quantity of woollens and worfteds of every defcription made in the Weft Riding of Yorkfhire, and the borders of Chefhire and Lancafhire. Now to make the quantity of broad and narrow cloth given in the returns of the Weft Riding, would require about one hundred and ten thoufand packs: we may therefore ftate the annual confumption of wool in thefe diftricts to be from two hundred and fifty to three hundred thoufand packs of 240 pounds each; and we may further ftate the amount confumed in thefe diftricts to exceed that of all the other parts of England and Wales collectively by one-third, including hofiery and all other articles made of wool. This will make the total amount of wool manufactured in England to be nearly what we have before eftimated, or five hundred thoufand packs.

The number of perfons immediately employed in the various branches of the woollen manufacture in England was ftated, in the year 1800, to be 1,500,000, and that the trade directly and collaterally employed double the above number. This was afferted in the fpeech of Mr. Law, now lord Ellenborough, in the houfe of lords, as council for the petitioners againft the export of wool to Ireland. But we apprehend that the ftatement greatly exceeds the actual number employed in this trade, including their families.

The amount of the population of the Weft Riding of Yorkfhire is nearly afcertained, and perhaps two-thirds of the whole may be engaged in the woollen manufacture, including the families of the perfons employed. If we ftate thefe to be 340,000, exclufive of the woollen manufacturers in Chefhire and Lancafhire, we fhall certainly not under-rate them. A large part of the Weft Riding being agricultural folely, and in the manufacturing diftricts cutlery, as at Sheffield, and cottons in the more weftern parts, employ no inconfiderable portion of the people. If then we take 340,000 as the amount of perfons, with their families, engaged in the woollen trade in the Weft Riding, exclufive of Lancafhire and Chefhire, and if we fuppofe that they are one-third of the total number of perfons employed in the fame manufacture in England, it will make the whole rather exceed 1,000,000 of manufacturers, including their families, which we apprehend is not far from the true eftimate. We fhall, however, give the precife words of Mr. Law's fpeech in the houfe of lords on the above occafion, the object of which, it muft be recollected, was to enhance the importance of the woollen manufacture. "In order to give your lordfhips fome idea of its magnitude, I may venture to ftate, that there are no lefs than 1,500,000 perfons who are immediately concerned in the operative branches of this vaft manufacture; and if what Dr. Campbell ftates in his 'Political Survey of the Kingdom' be true, that from the wool-grower to the confumer a piece of broad-cloth paffes through 100 different hands, and that there are nearly the fame number of hands dependent on the woollen manufacture, though not actually concerned in it, I may affume that the trade directly and collaterally employs double the above number of hands, or 3,000,000. If we eftimate the magnitude of this queftion (the export of wool) according to the number of perfons interefted in it, it goes to nearly one-third of the entire population of this kingdom, eftimating that population at what is generally reckoned, namely between 9 and 10,000,000." Though the woollen manufactures of England have confiderably increafed within the laft fifty years, we do not apprehend the number of hands employed is greater than before the introduction of mechanical inventions for carding, fpinning, and combing. The working up of one pack of wool, particularly of combing-wool, formerly employed a great number of hands, and was divided into fmall portions, to be fpun in the houfes of cottagers in remote diftricts. This afforded employment to the wives and families of labourers who were engaged in agriculture; but fo much time was occupied in taking out and collecting in the work, that at the period we refer to, few, if any, of the mafter manufacturers in Yorkfhire confumed more than one pack of wool *per* week in their trade. At prefent there are numerous manufacturers in Yorkfhire and Lancafhire, who confume from twenty to fifty packs of wool *per* week.

The cotton manufacture, which may be regarded as of recent date, has employed the population that would otherwife have been thrown out of work in the woollen trade fince the introduction of machinery, and has prevented any inconvenience of this kind from being felt at prefent in Yorkfhire. We may, however, obferve, that many branches of the woollen and worfted trade have been gradually retiring from the fouth of England, and concentrating in the Weft Riding of Yorkfhire and in Lancafhire. Thefe diftricts were the firft to introduce mechanical improvements into the woollen manufacture, and thus gained a decided advantage over the more ancient feats of the woollen trade. For feveral years afterwards the effects were felt in the manufacturing diftricts in the weft of England, and great diftrefs from want of due employment for the labouring claffes was the confequence.

At prefent all kinds of machinery that have hitherto been applied to wool are extenfively employed in the weft of England, and the manufacture of fuperfine cloth is in a flourifhing ftate in the counties of Gloucefterfhire, Somerfetfhire, and Wiltfhire, all ancient feats of the clothing trade. The manufacture of broad-cloth in other parts of the fouth and weft of England is not carried on to any great extent. The manufacture of flannels, ferges, baizes, &c. though branches of the woollen manufacture, are diftinct from the cloth trade, and feldom carried on in the fame diftrict.

The export of woollen goods of all kinds from England, in the year 1815, amounted in declared value to ten millions one hundred and ninety-eight thoufand pounds. This was rather an extraordinary quantity; and in the following year the exports fell under nine millions, which may be taken as the regular annual amount of woollen exports at prefent.

The following table gives the amount of different kinds of woollens exported, with their value, and the places to which they were fent in the year 1816; a year in which our foreign trade was confidered as in a declining ftate. It may be worthy of remark, that though our woollen exports fcarcely reached eight millions and a half, the amount taken by the United States of America in that year exceeded three millions; a fact which proves the vaft importance of the American market to our manufacturers.

If we ſtate the amount of woollen goods exported to be about one-third of our own conſumption, or from one-third to one-fourth, which is probably more correct, this would make the total value of manufactured woollens to exceed thirty millions annually. Of the woollen goods exported, the quantity conſumed on the European continent ſcarcely exceeds three millions ſterling in value, and a great part of that amount given in the preceding account was for army cloth. Hence it appears, that a very ſmall proportion of the general population of Europe is indebted to this country for its woollens, including under the term both woollen and worſted goods. The increaſed demand for woollens of every deſcription in England ariſes partly from the increaſe of population, but more from the increaſing demand for articles of luxury or convenience. In the middle of the laſt century, carpets were ſcarcely to be ſeen in the country, except in the houſes of the nobility; at preſent almoſt every houſe in England, except thoſe of cottagers and the labouring claſſes, has carpets ſpread in ſome of the rooms. The conſumption of worſted yarn in articles of furniture, and in the linings of carriages, and what is called horſe millinery, is very great; add to which the people of England are better dreſſed than they were formerly. We may from all theſe cauſes ſtate, that the home conſumption of woollens, in proportion to our population, is double that of any other nation in Europe. To prove that we do not over-rate the proportion of woollens conſumed at home, it may be ſufficient to ſtate, that the Weſt Riding of Yorkſhire alone manufactured, in the year 1817, nearly twice as many pieces of cloth as were exported in that year; but few woollen broad-cloths are made for exportation in the weſt of England, the manufactures there being principally fine and ſuperfine cloth for home conſumption, the value of which *per* yard on the average is much greater than that of the Yorkſhire cloth. In the preſent ſtate of Europe, we think it an encouraging circumſtance to our woollen manufacturers, that ſo large a proportion of their goods are conſumed at home, where the demand will remain certain; and again, that the United States of America take ſo conſiderable a part of our exports, as from the increaſing population of theſe ſtates, we may expect that the demand will be increaſing for many centuries, and will ſoon exceed what it will be in the power of this country to ſupply.

In the year 1800, the woollen manufacturers of England were greatly alarmed at the liberty which was intended to be granted, of exporting wool to Ireland, and petitioned parliament againſt the meaſure. The grounds on which their alarms reſted, were partly the preference given to the Iriſh, and partly the ſuppoſed facility that would be afforded to ſmuggling wool to the continent. Several manufacturers and wool-dealers from different parts of the kingdom were examined before the two houſes of parliament; but neither in their evidence, nor in the ſpeeches of the learned council, who were heard in ſupport of the petitioners, can we trace any comprehenſive or enlightened views of the ſubject. The objections urged againſt the export of wool were grounded principally on the practice of former reigns, particularly thoſe of Edward III. and queen Elizabeth: but the facts we conceive were in oppoſition to the ſtatements; for during the whole of the latter reign, in which our woollen manufactures were in a highly flouriſhing condition, the export of wool was freely admitted, on the payment of certain duties; and during the reign of Edward III., the prohibition to export wool under heavy penalties was confined to denizens and foreigners, in order to ſecure a larger amount of duties to the king, the former paying leſs duty on exports than natives; nor was it till the reign of Charles II. that the export of wool was ſtrictly prohibited. All the former prohibitions were evadable by licences, which were readily granted for money. It is from this reign, therefore, we muſt date the prohibition to export wool, as forming an eſtabliſhed law of the land; and it is not unworthy of remark, that immediately after this period, and to the time of the revolution in 1688, our woollen manufactures were in a very declining ſtate, which proves that they had not derived much benefit from the meaſure. The policy of admitting the export of wool has been again recently agitated in parliament, and has renewed the alarm of the manufacturers. It is not by precedents drawn from former ages, but ſolely by the wiſdom and juſtice of the meaſure, as applicable to one preſent condition, that a queſtion of this kind ſhould be determined. With reſpect to ſhort or clothing wool, we believe that a permiſſion to export it would not produce the leaſt effect, as we already import theſe wools from almoſt every nation in Europe; it is not, therefore, probable, that foreigners would give a better price for them than our own manufacturers can afford. With long combing-wools, the caſe is ſomewhat different, as by the acknowledgment of the French themſelves, theſe wools are wanted to mix with and improve their own. We apprehend, however, that as much is exported at preſent clandeſtinely in the form of worſted yarn, as the market may require, the free export of cotton yarn giving great facility for evading the penalty, by packing them together. The permiſſion to export wool to Ireland, which was granted in 1800, has not been attended with any one of the fatal effects which our manufacturers anticipated; nor do we apprehend, that permitting the free export of wool under certain duties would be found to injure our own woollen trade.

In taking this view of the ſubject, which we truſt is an impartial one, we readily admit that the permiſſion to export wool, were it granted, would not be attended with any permanent benefit to the landed intereſt. A ſmall pamphlet on the ſubject, recently publiſhed by John Maitland, eſq., contains the following judicious obſervations:—"The manufacturer of our native wool claims from government the preſervation of it for his uſe; for *by the ſtatute law of the land, he is confined to its ſoil for the expreſs purpoſe of working up the wool which grows upon it.* This wool cannot, therefore, upon any juſt or moral principle, be permitted to go out of the country in an unmanufactured ſtate, without allowing the manufacturer to follow it, or without obliging the grower and exporter of it to maintain him and his children." This is ſo obviouſly juſt, that whenever the export of wool is admitted, we cannot any longer, as at preſent, prohibit the woollen manufacturers from emigrating and carrying their induſtry to the beſt market. "The wool," as Mr. Maitland elſewhere obſerves, "does not on an average compoſe more than one-ſixth part of the value of the animal on which it grows; and the manufacturer, by obtaining this ſixth part, at ſuch a moderate rate as may enable him to ſell his goods, when manufactured at a reaſonable profit, inſures to the owner of land a moral certainty of obtaining the full value for the remaining five-ſixths, and receiving an ample price alſo for all the other productions of his ground." The truth of this obſervation we know to be fully proved in the Yorkſhire markets. Whenever there is any conſiderable depreſſion of the woollen trade, it is always attended with a decreaſed conſumption of animal food, ſupplied principally from Lincolnſhire, and the counties which produce the largeſt quantity of wool. Should the permiſſion to export wool be attended with any effect in diminiſhing our own manufactures, the reſult would be highly injurious to the land-owner, who would then have to find new cuſtomers for his

his general produce, and new aſſociates to ſhare with him the burden of taxation.

The prices of heavy combing-wool in Lincolnſhire, Nottinghamſhire, or Leiceſterſhire, may be taken as the average price of this kind of wool over the whole kingdom, there being little variation in the value of this wool from different diſtricts. The following table will ſhew what have been the prices for a great part of the laſt century:

Price *per* Tod of Lincolnſhire Fleeces, the Tod weighing 28 lbs.

From the year 1744 to the year 1777, the prices, though occaſionally fluctuating, continued much the ſame as in the preceding years, but we have not the means of aſcertaining preciſely what they were in each year. The following table will ſhew the prices of Nottinghamſhire and Leiceſterſhire heavy combing-wool, taken from the moſt authentic ſource. We conſider the value of this wool to have been fully equal to that of Lincolnſhire on each year.

Price *per* Tod of 28 lbs. of Nottinghamſhire and Leiceſterſhire heavy Combing-Wools.

The above were the average prices of the beſt lots; the inferior ones might range from one to two ſhillings *per* tod under the prices here given. It may be obſerved, that the price of this kind of wool was lower towards the cloſe of the American war, or about the year 1781 and 1782, than in any former or ſubſequent period of our hiſtory, if we take into conſideration the relative value of money. At that time, the quantity of wool unſold in the hands of the farmer was nearly equal to three years annual growth; a quantity too large to have been conſumed by our manufacturers, had not the introduction of machinery enabled them to work it up with much greater facility than formerly. The average weight of theſe fleeces may be ſtated at four or ſeven pounds each fleece to the tod of 28 pounds. Since the commencement of the preſent century, the price of this kind of wool, it will be ſeen from the above table, has been amply ſufficient to remunerate the wool-growers; and we confeſs we are utterly at a loſs to diſcover on what grounds of ſound policy or intereſt they would wiſh to make any change in the laws reſpecting the export of wool. With reſpect to ſhort or clothing wools, any change in the exiſting laws would make no alteration whatever in the price; for it is the extreme of prejudice to aſſert, that our native clothing fleeces are neceſſary to the foreign manufacturer, either to ſupply his demand or improve the quality of his own wool. We might with equal juſtneſs revive the abſurd opinion, ſo confidently maintained a few years ſince, that the beſt Spaniſh wool would not make cloth without an admixture with that of England.

Woollen *Manufacture, Process of.* In an early part of this work, under the article Cloth, we have given a general view of the process of cloth-making, furnished by a principal manufacturer in the west of England. In the present article, we shall confine our account chiefly to those improvements in the processes which have since been introduced, and shall add a description of the machines which were only slightly noticed in the article Cloth, and give references to the plates. The processes of the woollen manufacture may be classed under two heads; those by which wool is prepared for the weaver, and those by which the cloth is finished after it is taken out of the loom. The sorting of wool has already been referred to under the article Wool. English wool is supposed to be sufficiently cleaned from pitch marks or other extraneous substances by the wool-sorter, and left by him in a proper state to commence the process of cloth-making. Spanish wool in the bale has generally some part of the pitch employed to mark the sheep still adhering to it, which must be carefully cut off. It was till recently the practice to beat the wool with rods, in order to shake out the dust and open the staples; but this is now principally done by an opening machine with long coarse teeth, called a devil, or wool-mill. Spanish wool is frequently so hardly pressed together in the bag, that it requires to be opened out by beating, to prepare it for the further processes.

In the west of England, wool is generally scoured before it is dyed or carded; but in Yorkshire this is seldom practised on wool intended for white cloths, and among the smaller manufacturers who dye their own wool, it is frequently put into the dyeing-vat unscoured; a practice which injures the brightness of the colours, but which enables the manufacturer to make a greater weight of cloth with the same quantity of wool. There is also some saving of labour and expence; but this is more than counter-balanced by the increased quantity of oil *per* pack required for unscoured wool, which is at least one-third more than would be necessary if the wool were scoured. In the west of England, where the wool is scoured previously to its manufacture, the process is carried on with a degree of neatness and cleanliness, which form a perfect contrast with the horrid stench and disgusting filthiness of the woollen factories in Yorkshire. For fine cloths, olive-oil, called Gallipoli, from the part where it was supposed to be sent, is principally used; and for the coarser cloths rape-oil. Where attention to colour is not required in very coarse goods, fish-oil is sometimes employed; but if the latter remain in the wool or cloth, it turns it brown, undergoing a degree of fermentation injurious to the cloth, and which sometimes occasions spontaneous combustion. To lessen the expence of oil for coarse cloths, some manufacturers in Yorkshire make use of a mixture of soap and water with oil, which answers very well in moist weather, if the wool be immediately carded and spun; but if it remain some time unwashed, or the weather be very hot, the mixture evaporates. It has been attempted to work wool without any oil whatever, but without success. The use of oil is to cover the surface of the fibres, and enable them to slide easily over each other in carding or spinning. What we have before said of the structure of the surface of wool or hair, under the article Wool, will suffice to shew the advantage that must result from oiling. The wool is sprinkled with oil as evenly as possible. In Yorkshire the proportion on fine wool is about six gallons *per* pack, and this is more equally distributed over it by the wool-mill, through which it passes previous to the process called scribbling. This process is a kind of coarse carding, and is performed on a machine similar to that used for scribbling cotton, but larger, and with coarser cards, the principle being similar to that of the carding-machine, hereafter to be described. By this engine the longer fibres are broken down, and they are all laid straight and nearly parallel to each other. The wool leaves the roller of the scribbling-mill in one thin undivided sheet, and the more clear, even, and transparent it appears when held between the eye and the light, the more perfectly has the operation been performed. On the carding-engine, the operation is repeated on finer cards; but instead of leaving the machine in one continued sheet, it is finally divided into separate portions, which by a fluted roller are formed into separate round pieces about one inch in diameter, and two feet three inches in length. The fibres are now arranged so as more easily to slide over and twist round each other in the next process, which is a kind of coarse spinning called slubbing, performed with the slubbing-machine, which will be described. On this machine each of the rolls from the carding-machine are joined together, and drawn out into a loosely-twisted thread, and wound round a spindle, forming what is technically called a *slubbing*. These slubbings being taken to the spinning jenny, which will also be described, are twisted in an opposite direction, and drawn out into threads of yarn of the requisite length. For very fine yarn used in shawls, a machine called the mule is sometimes employed, nearly similar to the cotton mule (see *Manufacture of* Cotton), the slubbing passing through rollers which assist in drawing out the thread smaller and more regular. The yarn is now prepared for winding, sizing, warping, and weaving. (See Cloth.) Since the article Cloth was written, broad-cloth is almost universally woven by one person only in a loom, making use of the fly-shuttle. (See Weaving.) The next process is scouring and burling, already described under the articles Cloth and Fulling. The cloth is then sent to the fulling-mill; the finer kinds are prepared for fulling by a mixture of soap and water; in coarse kinds, fuller's-earth supplies the place of soap. (See Fulling-*Mill*, and a farther description at the end of the article.) The principle on which the felting depends has been described under the article Wool. By the process of fulling, the cloth becomes shortened in length and breadth, and the fibres are incorporated and intimately united with each other. In the best manufactured cloths, this incorporation is so complete, that the separate threads can scarcely be distinguished, the bottom of the cloth appearing to form one even continuous substance. An improvement in this respect has recently been made at Leeds, by spinning the wool much softer and thicker than has usually been the practice, and uniting the threads in the fulling-mill, and then working the substance of the cloth down to a requisite degree of thinness by the gig-mill, hereafter to be described. At the end of the process, the face or surface of the cloth is much softer, and greatly superior in appearance to cloth manufactured in the common process. A pack of wool of 240 lbs. will make when milled about one hundred and twenty yards of mixed or coloured cloth from fifty to sixty inches in breadth, according to the quality and fineness of the wool. The process of raising, shearing, and pressing, have been mentioned under the article Cloth, and will be more fully described when an account is given of the gig-mill and shearing-machine. The object of these processes is to cover the thread with a soft pile, consisting of the fibres of the wool, cut down to an even surface over the whole piece.

There are various kinds of woollen goods worked on the same principle as cloth, and made with both the warp and the weft

weft of carded wool, but which being unmilled, or finiſhed in a different manner, receive different names. Blankets are manufactured on the card, but from wool that poſſeſſes a greater length of ſtaple, and which therefore admits of a deeper pile, being raiſed on the ſurface. The yarn is ſpun thicker, and left as ſoft as poſſible, in order that it may form a full cover or pile. Fine blankets are made much ſtouter and heavier than coarſe ones; they are both ſcoured in the mill, but are ſcarcely ſuffered to undergo the fulling proceſs. Thick cloths with a long pile, called duffields, fearnoughts, and bear-ſkins, are manufactured on the ſame principle as blankets, but they are milled much thicker and dyed, and alſo raiſed to a deeper pile. Flannels and very light cloths, ſuch as Bath coatings, are uſually ſpun ſmall, in proportion to the quality of the wool. In weaving plain cloths, the chain or warp is equally divided by the gears, one half of the threads being above and the other half below, and they croſs each other every time the thread of the weft is thrown through by the ſhuttle. In weaving kerſeymeres or caſſimeres, on the contrary, the warp is unequally divided, to produce what is called the twill, or tweel, (ſee Weaving,) one-third being always above and two-thirds below the ſhuttle as it paſſes. It is owing to this arrangement of the warp, that it forms a ſlanting or diagonal rib acroſs the body of the cloth, which is the diſtinguiſhing character of this kind of woollens. See Draught *of Looms*.

Caſſimeres are uſually ſet in the loom from thirty-four to thirty-ſix inches wide, and milled to twenty-ſeven inches. Forty pounds of wool from the bag will make rather more than ſixty yards of common milled fine caſſimeres; the double milled ones make leſs in proportion to the degree of milling they receive.

Swandowns and toilinets are made with a cotton warp; the weft is woollen or worſted yarn of various colours, according to the patterns required. Woollen cords have alſo the warp of cotton and the weft of woollen; they are woven and cut preciſely in the ſame manner as cotton cords. See Fustian.

Serges are made with the warp of worſted and the weft of coarſe woollen yarn, and are twilled. Theſe goods have been for a very long time manufactured extenſively in Devonſhire, and are principally purchaſed by the Eaſt India company for the China trade.

Carpets have worſted warps and woollen wefts. See Carpet and Weaving.

From the moſt remote period of the woollen manufacture until the latter end of the laſt century, or about the year 1780, very few, if any, mechanical improvements had been introduced into it. During the whole time the various proceſſes were carried on nearly in the ſame manner, but with greater or leſs ſkill, and were employed upon materials more or leſs valuable. The carding and ſpinning of wool, and the weaving and finiſhing of cloth, in the early part of the reign of George III., were effected by the ſame machines as in the time of Edward III., which probably were ſimilar to thoſe of the ancient Romans, but more rude in their conſtruction. In an art which had ſeen ſo many centuries roll on without any change, it did not appear poſſible to the manufacturer that any improvement could be effected; and had not the genius of Hargreaves and Arkwright changed entirely the modes of carding and ſpinning cotton, the woollen manufacture would probably have remained at this day what it was in the earlieſt ages of civilized ſociety. That it would have been better for general ſociety if it had ſo remained we readily admit; but after the improved modes of working cotton were diſcovered, this was impoſſible. The ſpinning jenny, which was the ſame as that employed in the cotton manufacture, but ſomewhat larger, was introduced into Yorkſhire from Lancaſhire about the year 1780, but did not become general till about three years afterwards. In the firſt jennies, not more than eighteen or twenty threads could be ſpun, and the mode of winding the thread upon the ſpindle was very imperfect. The carding was ſtill effected by the hand, and the ſlubbing or roving was prepared on the common ſpinning-wheel. For ſome time conſiderable difficulty was experienced in carding by machinery, particularly in clearing the wool from the card; and a ſlight change in the conſtruction of the machine was found neceſſary to prepare the wool for the ſlubbing-billy, of which an account will be given in the deſcription of the carding-machine. Soon after this, the carding and ſpinning of wool and yarn by machinery became general through the manufacturing diſtricts of the Weſt Riding of Yorkſhire, and large mills were erected, in which the carding and ſcribbling machines were turned by a water-wheel, and the roving or ſlubbing performed on the billy. The wool carded at theſe mills was ſent to the ſmaller manufacturers in the ſtate of ſlubbing, and the farther proceſs of ſpinning was effected on jennies in their own premiſes. Before the year 1787, the old proceſſes of carding by the hand, and ſpinning on the wheel, were entirely diſcontinued in Yorkſhire; but it was ſome years after before the new proceſſes were generally introduced in the weſt of England, and thus, as we have before ſtated, the woollen trade became more concentrated in Yorkſhire, where cloths could be manufactured at leſs expence. About this time, machinery began to be applied to the combing and ſpinning of long combing-wool, to make worſted yarn. See Worsted *Spinning*.

In conſequence of the great increaſe of trade in Yorkſhire, it was found difficult to obtain ſituations for mills to be turned by water, and the application of the ſteam-engine to woollen machinery became very general. The abundance of fuel was highly advantageous to the Yorkſhire manufacturer; and it was found to be equally cheap to work the machines by ſteam as by water, where any conſiderable rent was paid for the water. The motion of the improved ſteam-engine was alſo rendered as regular as a water-wheel, and the great inconvenience and loſs from the interruption of the works by froſts or continued droughts were thereby avoided.

The ſmaller manufacturers in Yorkſhire were at firſt benefited by the introduction of machinery, but in a little time large capitaliſts began to engage in the woollen trade, and performing all the proceſſes with their own machinery, they were enabled to work cheaper and underſell the ſmaller makers. The facility alſo with which wool could now be worked up kept the markets always well ſtocked with goods, and prevented the manufacturers from taking the advantage of a temporary ſcarcity or a briſk demand, which they had formerly done, an overſtocked market always reducing the profits.

Soon after the year 1800, the number of ſmall manufacturers began rapidly to decreaſe many of them, being ruined by the change which had taken place, and compelled to become workmen in the factories of the large capitaliſts.

The gig-mill and the ſhearing-machine were not introduced into Yorkſhire until they had been ſeveral years employed in the weſt of England, owing to the reſiſtance made to them by the working cloth-dreſſers or croppers in the north.

The manufacture of worſted is properly a branch of the woollen manufacture, and noticed as ſuch in our hiſtory of its progreſs in England; yet the mode of manufacture, both in preparing the worſted yarn and finiſhing the goods, being entirely

entirely different from woollens made of carded wool, and part of it being applied to hofiery, we refer, for a further account of it, to the articles WORSTED *Manufacture*, and WORSTED *Spinning*.

Defcription of the Machines employed in the Woollen Manufacture.—The *wool-mill*, or *willy*, is the firft machine which is employed on the raw wool to open and difentangle the clofe matting, in which the wool comes from the wool-ftapler. It is alfo ufed for clearing the dyed wool from the dye ftuff, and again for mixing different parcels of wool together; alfo for incorporating the oil with the wool.

The wool-mill ufed in Yorkfhire confifts of a cylindrical drum, about three feet long and two feet and a half diameter, which is made to revolve near three hundred times *per* minute. Its circumference is furnifhed with teeth or fpikes, and immediately above it five fmall rollers are placed, which are alfo furnifhed with fimilar teeth. The teeth of the rollers and thofe of the drum interfect each other when they all turn round; and the teeth of the five fmall rollers alfo interfect each other. The cylinder and rollers are inclofed in a box or cafe, which is clofed on all fides, except a door in front, which turns down, the hinges being at the lower fide. When this door is fhut up it ftands in a perpendicular plane, very near to the teeth of the drum; when the door is opened, or turned down into the horizontal pofition, the wool is laid upon it, about one pound weight at once, and the door being clofed the wool is brought within reach of the teeth of the cylinder, which take the wool and carry it upwards, fo as to work it between the teeth of the cylinder and thofe of the five rollers placed over it. This effects the opening of the wool, and breaks the fibres if the ftaple is too long: it alfo feparates the matted fibres. In about three feconds, the pound of wool is generally fufficiently worked, during which time the cylinder has made about fifteen turns. The lower part of the cafe in which the cylinder revolves is a grating of wooden rods, through which the dirt and duft efcape. The cylinder is fitted very clofe to this grating, fo that the wool cannot efcape from the cylinder, but is carried round in it, and is thus repeatedly fubmitted to the action between the teeth of the cylinder and thofe of the rollers. When it is judged that the wool is fufficiently worked, the door is opened again, and the centrifugal force throws out the wool in an inftant; a frefh charge is then laid upon the door, and fhut up in the machine. A preferable mode is to have two doors on oppofite fides of the cafe; one to put in the raw wool, and the other for the finifhed wool to come out at.

The wool for coarfe goods is paffed feveral times through the wool-mill; firft, to break the mats of the raw wool and render it light; then a fecond time after it is dyed; a third time to mix the different forts together; and laftly, after the wool is oiled, it is paffed a fourth time through the wool-mill, with a view to incorporate the oil well with the fibres of the wool.

Scribbling-Machine.—This is the firft ftage of carding. The operation tends to difentangle the fibres which were before clofely entangled, and draw them out feparately, fo as to render the wool light and flaky. The fcribbling-machine is very fimilar to the carding-machine, having a large cylinder or drum, which is covered on the furface with fheets of leather ftuck full of projecting wire-teeth, called card-wires. The teeth are fo clofe together as to cover the whole furface of the cylinder, like the briftles of a brufh. This cylinder is turned rapidly round by the machinery, and the wool is regularly and flowly fupplied by feeding machinery to its teeth, which take it up, and the cylinder, as it were, clothes itfelf with wool. This wool is carded or worked by the teeth of feveral other fmaller cylinders, called workers and clearers, which are fixed around the great cylinder in pairs. The teeth of the workers take the wool from the great cylinder, and give it to the clearers, which return it again to the great cylinder. It is then transferred to another worker, and by its clearer is given back to the great cylinder, and fo on. It is by the repeated transferring of the wool from one cylinder to another, that the chief action of fcribbling or carding is performed. The teeth of the different cylinders do not actually touch each other, but they work fo near together, that the fibres of the wool which the teeth of one card contains are caught by the teeth of the other card, and drawn out a very few at a time. This action tends to feparate the fibres, and renders the wool light and open, and alfo diftributes the wool with great evennefs over the furfaces of the cylinders. After the wool has paffed between three or four pairs of workers and clearers, it is taken up by a cylinder, called the doffer, which is fmaller than the great cylinder, and turns round very flowly. The wool is ftripped off from this doffer by a fteel comb, which is fituated parallel to the axis of the doffer, and is moved rapidly up and down by a crank through a fmall fpace. In afcending, the comb does not touch the doffer; but when the comb makes its down ftroke, it comes in contact with the teeth of the cards, and combs out almoft all the wool they contain. As the doffer turns round very flowly, and the comb acts at fmall intervals, the fucceffive portions of wool which it combs or ftrips off, hang together in a continued fleece or web of a very thin texture, which hangs down from the doffer, and is received in a bafket.

The wool in this ftate is faid to be fcribbled, but the fibres are not yet fufficiently combed out or feparated; for on examination of the fcribbled wool, many fmall knots and films of wool are found, which are ftill clofely entangled. The fcribbling is therefore repeated twice or three times, and then the wool undergoes another operation, which is called carding, but which is very nearly the fame as the fcribbling, only the wool is formed into fmall cylindrical rolls, which are the firft rudiments of a thread.

We have thought it needlefs to give a drawing of a fcribbling-machine, as it may be readily conceived from the following defcription of the carding machine.

Carding-Machine. (See *Plate* IV. *Woollen Manufacture.*)—A is the wood frame of the machine, but the beft machines have caft-iron frames; C C is the outfide of the large cylinder, which is about thirty inches diameter, and twenty-fix inches wide: its axis is fupported on bearings at each fide of the frame, and it is put in motion by an endlefs ftrap applied upon a pulley at one end of its axis, which pulley cannot be feen in the figure. The cylinder revolves about 100 times *per* minute. B is an arch of wood to receive fcrews, which fupport the fix fmall cylinders marked 2 *a* and 2; thefe are the workers and clearers. The workers 2 *a* are larger, and turn flower than the clearers 2; each worker is acted upon by its clearer, and both worker and clearer act againft the cards of the great cylinder.

The raw wool is fpread evenly upon the feeding-cloth 5, at one end of the machine: it is an endlefs fheet ftretched over two rollers, one of which has a cog-wheel G upon the end of its axis, and receives motion from a pinion fituated behind the pulley F. This pulley is turned by an endlefs cord paffing round a pulley *n*, fixed upon the cog-wheel E, which is turned by a pinion 8 on the end of the axis of the great cylinder. The wool which is fpread on the cloth 5 is taken off, between a pair of feeding-rollers, which are clothed with cards laid on in fpiral fillets. Thefe rollers cannot be feen, being within the frame; they are about $2\frac{1}{2}$ inches

inches diameter, and are turned round by toothed pinions on the axis of the cloth-roller, fo as to move rather quicker than the feeding-cloth. The feeding-rollers give the wool to a cylinder 4 *a*, called the carrier, which is about nine inches diameter. The carrier works againft the cylinder C; but as its furface moves more flowly than the furface of the cylinder, the wool contained in the teeth of the carrier is taken up by the cylinder. The carding-machine reprefented in our plate is fhewn with a cylinder 3, beneath the carrier; this is not ufed in the prefent machines, but the feeding-rollers give the wool at once to the carrier 4 *a*.

That part of the cylinder which is adjacent to the carrier moves upwards, fo as to carry up the wool it has taken from the carrier, and give it to the workers 2 *a* and clearers 2. The furfaces of the workers 2 *a* move in the fame direction as the furface of the great cylinder, but they turn flowly, being put in motion by the chain 9, which paffes over wheels at the ends of all the three workers. Thefe wheels have cogs or teeth to enter into the links of the chain, and prevent it from flipping; the chain paffes beneath a wheel fixed on the axis of the cog-wheel E, but withinfide the frame. The wheel E is turned by a pinion 8, fixed on the extremity of the axis of the great cylinder; and the proportions are fuch, that the workers 2 *a* revolve once to about four turns of the great cylinder, and the workers being about $6\frac{1}{2}$ inches diameter, whilft the cylinder is 30 inches diameter, the furface of the cylinder moves about $18\frac{1}{2}$ times as faft as the furfaces of the workers.

The fmall rollers 2, called clearers, are placed fo as to card the wool on the workers, and on the great cylinder alfo. The clearers are turned round very quickly, and take the wool from the workers, but their furfaces do not move fo faft as the furface of the cylinder. Thus the ftrap 13 paffes over a wheel of about $8\frac{1}{2}$ inches diameter, fixed on the extremity of the axis of each clearer; this ftrap is put in motion by a wheel of about 22 inches diameter, fixed on the axis of the great cylinder; therefore, the clearers turn about $2\frac{1}{2}$ times to one of the great cylinder; but as they are only $3\frac{1}{4}$ inches diameter, and the great cylinder is 30 inches diameter, the furface of the cylinder moves near $3\frac{1}{2}$ times as faft as that of the clearer. The carrier 4 *a* is turned by the fame ftrap 13; but being larger than the clearers, its furface moves much quicker, fo that the cylinder's furface moves only about once and a half as faft as the carrier's furface.

The ftrap 13 alfo turns a cylinder 2, at the right-hand end of the machine, called the fly: its furface moves the fame way as the furface of the cylinder, but moves nearly once and a half as faft; the pulley at the end of the fly being only $4\frac{1}{4}$ inches diameter, and the fly itfelf nine inches. The fly is not placed fo clofe to the cylinder as to take the wool away therefrom, but is intended to raife and loofen it in the cards of the cylinder, fo that the cylinder 4 beneath it, called the doffer, can take off the wool more readily. This doffer is 14 inches diameter, and is covered with feparate fheets of card-wire, each about 4 inches wide, leaving vacant fpaces between them parallel to the axis of the cylinder. The doffer moves round very flowly, its furface moving only $\frac{1}{31}$ of the velocity of the furface of the cylinder: it is turned by a band from a pulley on the axis of the roller D, which we fhall next defcribe.

The comb which works againft the furface of the doffer, and ftrips off the wool from it, cannot be feen in the drawing. The comb is fupported by two upright rods, fcrewed to it one at each end; the upper ends of thefe rods are guided by two horizontal levers, and the lower ends are jointed to two fmall cranks formed on an horizontal axis, which is fituated at the lower part of the frame near the ground, and put in rapid motion by a ftrap, from a pulley at the bottom of the frame beneath the great cylinder. This pulley has a fmaller one fixed on the extreme end of its axis, and receives its motion from the fame ftrap 13, which turns the clearers. Every revolution of the cranks caufes the comb to rife and fall about two inches; and when the comb defcends, the teeth on its edge act againft the cards, on the furface of the doffer 4, fo as to take out the wool from them. This wool is feparated in a continued fheet or film, becaufe the ftrokes of the comb fucceed each other very quickly, and the doffer turns round flowly; but owing to the vacant fpaces between the cards on the doffer, this film only continues for a width of about four inches, and is then difcontinued until the vacant fpace on the doffer has paffed by the comb, which then acts again to ftrip off the wool, and fo on: hence the wool is drawn off from the machine in a carded ftate, in fmall and very delicate films or webs of about 4 inches wide, and 27 or 28 inches long, which is the length of the doffer.

Thefe detached portions of wool are next rolled up fo as to form fmall cylindrical rolls, which is done by what is called the roller-bowl D: it is a cylinder of wood, with fhallow flutes upon its furface, parallel to its axis; it is turned round flowly by a pulley H on the end of its axis, and an endlefs band, 14, which paffes round a pulley I, fixed on the wheel E. The lower part of the roller-bowl, D, is inclofed within a hollow cylinder of wood, called the fhell; it encompaffes the lower half, being fixed beneath the revolving cylinder; the fhell is fluted within fide, but does not touch the bowl, leaving a fmall interval between the two. The portions of wool, as they are ftripped or combed off from the doffer, fall down over the edge of the fhell, which for that purpofe is fituated clofe to the doffer, at that part of its circumference where the comb works: by this means, the wool which is ftripped off falls down into the fpace between the fhell and the roller-bowl; and when the portion of wool is completely detached and drops off, the motion of the bowl within its fhell rolls the wool between them with a rolling motion, which forms the wool into a very round and ftraight cylindrical roll, called a carding, when thefe cardings drop out from between the roller-bowl and its fhell; they fall upon a flat table, *a a*, as fhewn at 7 7 7. This table is covered with an endlefs cloth, which is ftretched over two horizontal rollers; one of thefe rollers has a crofs, marked 16, 16, fixed on the end of its axis; the arms of the crofs are feized by a cranked lever, 15, which is fixed to the axis of the roller-bowl, and at every revolution the crofs 16 is turned round one-fourth: this moves the endlefs cloth forwards, and carries the cardings away in the manner fhewn at 7 7 7, as faft as they drop out from the fhell, and from this table they are carried away to the flubbing-machine, or billy.

In moft modern machines the latter movement is altered, the endlefs cloth being kept in a continual and flow motion by an endlefs band paffing round a fmall pulley fixed to the pulley H, and a larger pulley fixed in place of the crofs 16.

In fome old carding-engines many of the motions were performed by toothed wheels and pinions; but of late years all the parts are moved by bands or ftraps, which produce a much more equable and fteady movement. The large cylinders are generally made by placing two or more wheels of caft iron on one axle, the circumference of the wheels being cafed with wood, which is attached to them by fcrews or rivets. The fmaller rollers are formed in a fimilar manner on wooden difks, but all are made hollow, to avoid warping, which would render the action of the cards irregular and uncertain.

We

We muſt now return to the ſcribbling-machine: it is the ſame as the carding-machine, except that the breadth of the cylinder is greater, and the teeth are coarſer; there is no roller-bowl D, and the doffer 4 is completely covered with cards, without any breaks or intervals; hence the film of wool which is taken off is continuous, and is ſuffered to fall down into a baſket.

Double Scribblers.—In Yorkſhire it is common to employ double ſcribblers; that is, two of the machines combined together, and placed in one frame; there are two large cylinders, each ſurrounded with its workers and clearers, and doffer, as we have deſcribed, making in all ſeventeen ſmall cylinders. The firſt great cylinder has a feeding-cloth and carrier, to ſupply the wool to the cylinder; but the ſecond large cylinder is ſupplied with wool from the doffer of the firſt cylinder, which doffer ſerves in place of a carrier to the ſecond; it therefore has no comb. The doffer of the ſecond cylinder has a comb to take off the wool, which then falls into a baſket.

This machine is ſaid to ſave trouble of attendance, and does more work than two ſingle machines. The uſual practice is to paſs the wool once through the double machine, and then once through a ſingle machine. A double machine will ſcribble about a hundred weight of wool *per* day.

After the wool is ſcribbled it is weighed, and when it is taken to the carding-machine, a certain weight is ſpread over a certain length of the feeding-cloth, ſo as to ſupply the wool to the machine with perfect regularity. The proper weight which ſhould be allowed is aſcertained experimentally, according to the fineneſs of the thread which is required to be ſpun. The cardings are weighed from time to time, to aſcertain if each one contains the proper quantity of wool.

The cardings produced by the united operations of ſcribbling and carding are compoſed of fibres of wool laid very lightly together with the leaſt poſſible entanglement; they are very regular and even in ſize, and upon this circumſtance the perfection of the ſpinning chiefly depends.

Slubbing-Machine, or Billy.—This performs the firſt proceſs of ſpinning. It reduces the cardings, and draws them out in length; joins them together, and gives them a ſlight twiſt, in order to form a coarſe and looſe thread, called a ſlubbing or roving, which muſt be ſpun over again in the jenny, to make a thread fine enough for the loom.

This operation was formerly performed by hand on the common hand ſpinning-wheel, which is ſimilar to that uſed for ſpinning wool, but of a ſmaller ſize. Machines were then contrived by which a number of ſlubbings could be drawn out together; but the aid of the hands was required for joining the rolls or cardings of wool together in ſucceſſion, and for other purpoſes, which were found to take ſo much time, that very little, if any, ſaving of labour was effected by the uſe of ſuch machines.

A perſpective view of the ſlubbing-machine, now univerſally employed, is given in *Plate* I. *Woollen Manufacture.* A A is the wood frame of the machine; within this frame is a moveable carriage, D D, which runs upon the lower ſide-rails at *a a*, with wheels 1, 2, to make it move eaſily; and it is capable of running backwards and forwards in the frame from one end to the other. The carriage contains a number of perpendicular ſpindles, marked 3, 3, which are put in rapid motion by a long cylinder F, and a ſeparate band from each ſpindle, which paſſes round a ſmall pulley on the ſpindle. The cylinder F extends horizontally acroſs the whole breadth of the carriage; it is made of tin plate, hollow like a tube, and covered with paper on the outſide.

The ſpindles are placed in a frame, ſo as to ſtand nearly perpendicular, at about four inches from each other; their lower extremities are ſharp-pointed, and turn in ſockets, and they are retained in their perpendicular poſition by a ſmall collar of braſs for each, which ſurrounds the ſpindle at about the middle of its length. The upper half of each ſpindle projects above the frame, and on the lower part the ſmall pulley or whirl is fixed, to receive the band from the horizontal cylinder, which is about ſix inches in diameter, and a little longer than the row of ſpindles; it is placed before them with its centre at a lower poſition than the row of whirls. The cylinder receives motion by a pulley at one end, with an endleſs band from a wheel E, made like the large wheel uſed in ſpinning wool by hand, and of the ſame dimenſions. The wheel is ſituated at the outſide of the great frame of the machine, and its axis is ſupported by upright ſtandards erected from the carriage D; the wheel is turned by the left-hand of the ſpinner, applied to a winch, which is plainly ſeen in the drawing, and gives motion to the cylinder F, which again turns all the ſpindles at once with a great velocity.

Each ſpindle receives a thread, or ſlubbing, which threads iſſue from beneath a roller, C C, at one end of the frame, and proceed to the row of ſpindles placed in the carriage, ſo that the ſlubbings are extended nearly in an horizontal direction. The ſpindles, by the motion of the carriage, are capable of advancing or retreating from the roller C, ſo as to extend any required length of ſlubbing.

The cardings of wool, which are to be ſpun into ſlubbings, are extended ſide by ſide upon an endleſs cloth, which is ſtrained in an inclined poſition between two horizontal rollers, one marked B B, and the other cannot be ſeen. There is one carding for each ſpindle, and the number is uſually from 50 to 80. C is a light wooden roller to bear upon the cardings which lie upon the cloth, and preſs ſlightly upon them by its weight. Immediately before this roller is a wooden rail G, and another beneath it, which is fixed horizontally acroſs the frame: the cardings are conducted between theſe two rails, the upper of which is capable of riſing; but when it falls by its weight, it holds the cardings faſt between the two, and hence theſe rails are called the claſp; the upper moveable rail G of the claſp is guided between ſliders, and a wire 7 deſcends from it to a lever 6. When the carriage D is wheeled cloſe home to the end of the machine, a wheel 5 lifts up the end 6 of the lever; and this, by the wire 7, raiſes the upper rail G ſo as to open the claſp, and releaſe all the cardings: in this ſtate, if the carriage is wheeled or withdrawn back from the claſp, it will draw the cardings forward. There is a ſmall catch which receives the upper rail G of the claſp, and bears it up from falling until the carriage has retreated a certain diſtance, and drawn out about eight inches length of the cardings; a ſtop on the carriage then comes againſt the catch and withdraws it; the upper rail of the claſp G then falls and holds the cardings faſt, whilſt the carriage continues to recede, and draw out or ſtretch that portion of each carding which is between the claſp and the ſpindle. All this time the wheel is turned to keep the ſpindles in motion, and give twiſt to the cardings in proportion as they are drawn out, by which means it is prevented from breaking; becauſe as the carding diminiſhes in ſize, and increaſes in length, the increaſing twiſt combines the fibres of the wool, ſo as to give ſtrength to the coarſe thread or ſlubbing which is thus produced.

The ſlubbing is lapped round the ſpindle, but the claſp being higher than the upper ends of the ſpindles, the direction of the ſlubbing is not quite at right angles to the ſpindle; hence the ſpindle, when it is turned round, will give twiſt to the ſlubbing, without winding or gathering it up up upon the ſpindle, becauſe the ſlubbing always ſlips over the top-end of the ſpindle; but when a portion of each ſlubbing is finiſhed, and it is required to wind it up round the ſpindle in a ball, the ſlubbing muſt be preſſed down by a wire 8, ſo as to bear it from the point of the ſpindle, and place it oppoſite to the middle part of the cop or ball upon the ſpindle, and then the motion of the ſpindle will cauſe it to wind up upon the ſpindle, and form a ball.

The wire 8 is made to operate upon the whole row of ſlubbings at once, and for this purpoſe a horizontal rail 4 is placed in the front of the row of ſpindles, being provided with pivots at its extreme ends, on which it is ſupported in ſtandards riſing from the carriage D. It has a ſmall arm or lever projecting from it at each end, and the wire 8 is ſtretched between theſe arms. By turning the rail 4 round upon its pivots, the wire is capable of being raiſed up, as in the figure, or lowered down at pleaſure: when the wire is lowered, it deſcends below the level of the top of the ſpindles, ſo as to bear down the threads which, when the wire is raiſed up, as ſhewn in the figure, proceed from the points of the ſpindles.

The ſpinner holds the rail 4 in his right-hand, and it is by this that he draws the carriage either in or out, according as it may require; and by turning the rail 4 round, he can elevate or depreſs the wire 8, ſo as to make it bear down the ſlubbings to any degree at pleaſure; by this means, he diſtributes the ſlubbings upon the ſpindles in a proper manner, to form a regular ball or cop, as ſhewn in the figure.

As the cardings are very ſlight and tender, they would be liable to break if they were dragged forwards on the inclined cloth, or even if the cloth were to be moved round its roller by the force applied to the cardings. To avoid this, a cord is applied round a groove in the middle part of the upper roller, and after paſſing over proper pulleys, as ſhewn in the drawing, it has a weight ſuſpended to one end, and a ſmaller weight to the other; the ſmall weight is only to keep the rope tight, but the large weight tends to turn the rollers and endleſs cloth round in a direction to deliver out the cardings, ſo that there will be no ſtrain on them. Every time that the carriage is wheeled home, the large weight is wound up by means of a piece of wood projecting from the carriage, which ſeizes a knot in the cord at the part which lies horizontally; this puſhes the cord back a certain diſtance, ſo as to draw up the great weight; but the endleſs cloth cannot turn backwards, becauſe there is a ratchet and click at one end of the roller which prevents it; the rope, therefore, ſlips round upon the roller. When the carriage retires, the great weight turns the roller and endleſs cloth round, ſo as to deliver out the cardings at the ſame rate as the carriage retreats and takes them up; but when the proper quantity is given out, the knot in the rope arrives at a fixed ſtop, which does not permit it to move any farther; and at the ſame inſtant the roller 5 quits the lever 6, and allows the upper rail G of the claſp to fall, and hold the carding faſt from being drawn out any farther; the wheel E is then put in motion to turn the ſpindles round, and the carriage is drawn back, which extends the ſlubbings, and twiſts them at the ſame time, as before mentioned.

When the carriage is drawn out to its full extent, and the neceſſary twiſt is given, the wire 8 is put down to bear down the ſlubbing from the point of the ſpindle, and the motion of the wheel being continued, the ſlubbings are wound up upon the middle part of the cop or ball which is formed upon the ſpindle; but as faſt as the ſlubbings are wound up, the ſpinner muſt puſh back the carriage towards the claſp; and he muſt turn the wheel round at ſuch a rate that the ſpindles will not wind up any faſter than the carriage returns, otherwiſe the ſlubbings would be broken or unequally ſtretched; he muſt alſo raiſe and lower the wire 8 continually, by turning the rail 4 round in his hand, in order to diſtribute the ſlubbing on the cop in a regular manner, ſo as to make a firm ball or cop.

A child attends the machine to bring the cardings from the carding-machine, and place them upon the inclined cloth; and when they are exhauſted, freſh ones are joined on, ſo as to keep the machine conſtantly ſupplied.

The degree of twiſt which is given to the ſlubbing is regulated by the diſcretion of the ſpinner in turning the wheel at a proper rate, correſponding to the quickneſs with which he draws out the carriage. Slubbings which are intended to be ſpun into yarn for the warp of the cloth require to be more twiſted than the ſlubbings intended for the weft; but the proper quantity of twiſt depends on the fineneſs of the wool, and the length of its fibres. In general it may be ſtated, that no more twiſt is given to the ſlubbings than is neceſſary to make them draw out to the required extent without breaking. This twiſt is of no uſe to the yarn, becauſe the ſlubbing will be twiſted in the contrary direction, when it is ſpun the ſecond time in the jenny.

An improved ſlubbing-machine has been introduced, which is put in motion by the mill, and the carriage is made to draw out by the power of the machine. The ſpinner has only to puſh the carriage in, and turn the handle, in order to wind up the ſlubbings; by this means, a greater degree of regularity is attained in the quantity of twiſt which is given to the ſlubbings when they are drawn out. The movements to effect this are taken from the mule uſed in cotton-ſpinning. See *Manufacture of* COTTON.

Spinning Jenny.—In this machine, the ſlubbings are ſpun over again, and reduced to the requiſite fineneſs for weaving. The jenny has nearly the ſame parts as the billy, but differently arranged. The ſpindles are placed at one end of the frame, and the claſp which holds the ſlubbings is placed on the carriage, ſo that it can be moved backwards and forwards, to and from the ſpindles by the ſpinner, in order to draw out and extend the yarn at the ſame time it is twiſted.

A perſpective view of the jenny is given in *Plate* II. *Woollen Manufacture.*

The ſpindles 3, 3, 3, are placed perpendicularly at about four inches aſunder at one end of the frame A A of the machine. The lower extremities of the ſpindles are pointed, and turn in ſmall cups or ſockets in a croſs-rail of the frame; they are ſupported near the middle of their length by paſſing through braſs-collars in a horizontal rail. Near the lower end of each ſpindle a ſmall pulley is fixed, to receive an endleſs band, which paſſes round the horizontal cylinder or roller 2, about ſix inches diameter. The cylinder is ſupported on pivots at its ends in the ſides of the frame, and lying in a direction parallel to the row of ſpindles, it turns them all round by a ſmall band for each. This cylinder is uſually made of tin-plate, that it may not alter its figure by the weather, as wood would do; and its ſurface is covered with coarſe brown paper, to prevent the bands from ſlipping upon it. The cylinder 2 is put in motion by a ſtrap or band 1, 1, which paſſes round a pulley at the end of it, and alſo round the great wheel B B, which is ſupported in a framing ſuſpended over the machine from the ceiling, but which is not ſhewn in the drawing. The wheel B is turned by applying the right-hand to the winch B. In front of the row of ſpindles, and about a foot higher than their points, a long croſs-rail 16 is ſituated horizontally: it is ſupported at each extremity by being mortiſed into blocks of wood *c c*, which are furniſhed with

with ſmall wheels or caſtors, forming a ſort of carriage, to run horizontally upon the ſide-beams of the main-frame in grooves, which guide them, ſo that the rail 16 can be moved backwards and forwards through a ſpace of about ſix or ſeven feet, in a horizontal poſition, without varying from its parallelism with the row of ſpindles. The underſide of the rail 16 is formed into a number of narrow notches for the ſlubbings to paſs through; and theſe notches are partly filled up by projecting pieces, riſing up from a ſecond croſs-rail 5, 5, ſo as to form the claſp which confines or pinches the ſlubbings in the notches when the lower rail is raiſed up; but the ſlubbings can draw freely through the notches when the lower rail is let down. This lower rail is guided and limited to move up and down only a ſmall ſpace by ſtaples, which project downwards from the rail 16, and receive the ends of the lower rail 5 of the claſp. The riſing and falling of the lower rail is effected by ſmall cords faſtened to it at about every yard of its length; theſe cords are conducted over ſmall pulleys (concealed in the ſubſtance of the upper rail 16), and are all attached to a handle, ſituated over the middle of the upper rail at 16, and beneath an arched bar, which is fixed on the top of the claſp. The ſpinner holds this handle in the left-hand, whilſt the right is employed in turning the wheel; and by the fingers of the left-hand ſhe can raiſe up the lower rail 5 of the claſp, and draw it cloſe to the upper one. It will then be retained in that poſition by a ſmall ſpring-catch, and will claſp the ſlubbings faſt in the notches, through which they paſs; but when the ſpring-catch is puſhed back, ſo as to relieve the handle, the lower rail will fall down by its own weight, and releaſe the ſlubbings, to allow them to ſlide through the notches.

The cops of ſlubbings which are to be ſpun are ſupported in an inclined frame 4, 4, faſtened within the main frame of the machine. The cops are mounted upon iron wires; they are placed in two rows, one above the other, as ſhewn in the drawing; but each row ſhould only contain half as many cops as there are ſpindles.

Each ſlubbing is conducted through a notch in the claſp, and thence it proceeds nearly in an horizontal poſition to the ſpindles 3, 3.

When the yarns have been drawn out and twiſted they are wound up on the ſpindles in balls, in a ſimilar manner to the billy. The wire which is uſed for bearing down the thread from the points of the ſpindles is marked 12; it is attached to a horizontal rail, which is ſupported on pivots at its ends, cloſe to the row of ſpindles. There is a ſmall pulley 11, fixed at one end of the rail, and a ſhort lever at the other, which lever is hidden in the drawing by a part of the framing. Between the pulley 11 and the lever, the wire 12 is extended, and by turning the rail round upon its pivots, the wire will have a motion up or down.

The ſpinner can communicate motion to the pulley 11 by means of a cord 7, 7, which paſſes round it, and extends the whole length of the frame, the end being made faſt to a pin at A; this cord lies over the ſurface of one of the blocks *c*, which contains the wheels of the carriage, and paſſes between three ſmall pulleys 9, 6, and 8. The centre pins of the pulleys 9 and 8 are fixed to the block; but the centre pin of the pulley 6 is fixed to a ſmall ſlider, and can be drawn in the direction of the rail 16, by applying the finger to a ſmall trigger near the handle 16. This action removes the pulley 6 out of the line of the other two pulleys, ſo as to ſhorten the cord 7, and turn round the pulley 11; this brings down the wire 12, and bears down the threads upon the ſpindles. A ſmall counterweight is ſuſpended from the wheel 11, to return the wire to its former poſition when the preſſure of the finger on the trigger is removed. By this movement, the ſpinner has full command of the wire 12, to raiſe or lower it in any degree ſhe thinks proper; and this is done independently of the motion of the carriage, becauſe the pulleys 9, 6, and 8, run freely along the cord 7, and their motion has no tendency to move the wheel 11 either way.

The jenny is worked by one perſon, who ſtands within the frame, and turns the wheel B with the right-hand, whilſt he holds the claſp in the left, ſo as to run it backwards and forwards along the frame at pleaſure. The ſlubbings are drawn between the moveable rails 16 and 5, in the notches of the claſp, and each ſlubbing is faſtened on to its correſponding ſpindle. The claſp being left open is drawn backwards from the ſpindles, and the ſlubbings run freely through the notches of the claſp; the ſlubbings are drawn off the balls at 4, when the claſp retires from the ſpindles, until a certain length of each ſlubbing is drawn out and extended nearly in an horizontal poſition between the ſpindles and the claſp: this length is regulated by a mark made on the frame of the machine, to indicate when the claſp has arrived at its proper poſition. The bars of the claſp are then brought together by raiſing up the handle under the catch, as before deſcribed, and it faſtens all the ſlubbings in the notches. This being done, the ſpindles are put in rapid motion by turning round the large wheel B B; they twiſt thoſe parts of the ſlubbings which are extended, and the motion being in a contrary direction to the twiſt of the ſlubbing, the firſt tendency is to untwiſt the ſlubbing, at the ſame time that the carriage and claſp are gently drawn back, or from the ſpindles. By this means, the ſlubbings are ſtretched or drawn out in length at the ſame time that they get a new twiſt in the oppoſite direction; this keeps them from breaking, and when they are drawn to their intended extent by the carriage being moved back to the ſtops at the extremity of the main frame, the great wheel is turned round as many turns as is neceſſary to give them all the twiſt which thoſe portions of thread are intended to have.

The threads extended between the claſp and the ſpindles are now finiſhed, and it only remains to wind them up upon the ſpindles, previouſly to drawing out a freſh portion of each ſlubbing, in order to ſpin it in the ſame manner. To wind up the threads, they are puſhed down upon their reſpective ſpindles, by preſſing the trigger which moves the wire 12; and the motion of the great wheel B is continued, in order to wind up the ſlubbings in balls upon the ſpindles, at the ſame time that the carriage and claſp are puſhed back towards the ſpindles. When the carriage is got home, the thread is finiſhed and wound up, and a freſh portion of ſlubbing is extended. To do this, the lower rail of the claſp is dropped down, and it releaſes the ſlubbings; the carriage is then drawn back to the mark upon the frame, as before deſcribed, which ſhews that a proper length of each ſlubbing is drawn off from the balls, and extended between the ſpindles and the claſp. The claſp is then cloſed, and the wheel B put in motion to twiſt the threads whilſt the carriage is drawn out; thus the ſpinning operation is repeated as before, and prepares another length of each of the threads. When finiſhed, they are puſhed down from the points of the ſpindles, in order to make them wind up thereon in the balls, as before.

There is ſome diſcretion required in ſpinning with the jenny, to draw out the carriage with a movement correſpondent to the rapidity with which the ſpindles give the twiſt, or rather untwiſt, to the ſlubbing; for the principal extenſion of the thread is effected whilſt the ſlubbing is untwiſting, and whilſt the firſt portion of twiſt is given to the threads. Theſe motions muſt be properly proportioned by the

the ſpinner, who muſt alſo be careful to give an equal degree of twiſt to each ſucceſſive portion of thread which is ſpun, otherwiſe the thread will conſiſt of hard and ſoft places.

When the yarn is intended for the warp of the cloth, the ſpindles are turned for a given time after the thread is extended to its full length, as we have before mentioned; but for the yarn which is to be uſed as weft, it is different: the whole of the twiſt is given during the extenſion of the thread, and none afterwards; this difference is to render the weft ſofter than the warp, becauſe in the cloth the weft appears more on the ſurfaces than the warp, and it is principally the felting and interlacing of the fibres of the weft that will form the ſurface of the cloth when finiſhed.

The yarns are uſually extended in the jenny two and a half or three times the length of the ſlubbings from which they are ſpun; and that degree of twiſt given to them which is ſuitable to the purpoſe for which the yarn is to be employed.

The *Mule for ſpinning of Yarn* is very nearly the ſame machine as the mule for ſpinning cotton; this is uſed for ſpinning ſome kinds of woollen yarn inſtead of the jenny. When the mule is employed for ſpinning yarn for weft, it is uſed in the ſame manner as deſcribed in our article Cotton *Manufacture*; but for ſpinning warp, the ſpindles are made to revolve, and twiſt the thread ſome time after the carriage is run completely out, and the ſtretching of the yarn is finiſhed. There is a movement in the machine that ſhifts the endleſs ſtrap which turns the mule upon a larger pulley, as ſoon as the carriage is run fully out, ſo as to give a more rapid motion to the ſpindles after the ſtretching, or drawing out, is finiſhed, than they had during the drawing back of the carriage. By this means ſome time is ſaved, becauſe the ſpindles may be allowed to run very quick when it is only required to twiſt the threads; but whilſt the extenſion is going on, the twiſting motion muſt be moderate, or the threads would be broken. A very ſimilar movement is uſed in the mule for ſpinning cotton, and is called the double-ſpeed; but the deſcription of this mechaniſm is omitted in the article Manufacture.

The mule has not, till lately, been in much repute for ſpinning woollen yarn, and the jenny is ſtill thought to ſpin better yarn: but we have no doubt that when certain modifications are made, it will become a much more perfect method than the jenny, being much leſs dependent on the diſcretion and dexterity of the ſpinner; for if the machine is once conſtructed ſo as to ſpin properly, it will always continue to do ſo.

To keep the yarn to the ſize which is intended, a few of the coppins are reeled off, in order to meaſure out a certain length of the yarn, which is weighed; and if it does not prove of the weight expected, the quantity of wool which is ſpread over a given ſurface of the feeding-cloth of the carding-machine muſt be increaſed or diminiſhed accordingly; and when the right quantity is formed, the lead weights which are uſed for weighing the given quantity of wool are altered to ſuit it. The draft of the jenny may alſo be altered to effect the ſame thing.

The ſpinning proceſſes are now finiſhed, and it remains to weave the yarns into cloth. From the deſcription we have given, it will appear that woollen yarn is ſpun in a very different manner from cotton. The opening proceſſes and the ſcribbling and carding are very ſimilar, except that the carded wool, inſtead of being drawn into a continued ſliver like cotton, with the fibres ſtretched the lengthways of the ſliver, is formed into ſeparate rolls, with the fibres diſpoſed croſſwiſe or ſpirally round the roll.

By the ſlubbing-machine theſe are joined together, drawn out in length, and ſlightly twiſted, by operations ſimilar to that of roving in cotton-ſpinning; but the operation of drawing, which is ſo frequently repeated for cotton, would be uſeleſs, and to a certain extent even prejudicial for wool. The object of that proceſs is to elongate and ſtretch the fibres of the cotton ſtraight, and lay them parallel to each other; but it does not reduce the ſliver to a ſmaller ſize, becauſe as many times as the ſliver is extended in length, ſo many ſlivers are put together into the drawing-frame at once, leaving the ſliver which has been drawn the ſame ſize as it was before, but elongated to three or four times the length, and all its fibres fully extended.

As woollen cloth is intended for felting, it is not deſirable to ſtraighten the fibres, but only to diſentangle all knots, and unfold any fibres which may be doubled, alſo to lay the fibres in the direction of the length of the thread. There is a natural curl in the fibres of wool which ſhould be preſerved, and will contribute to the firmneſs with which the fibres will entangle in the felting.

The operation of ſpinning by the jenny and billy are very ſimilar, but both differ from the manner in which the extenſion is made in the cotton ſpinning-machines by rollers. In the jenny, the extenſion is made upon a conſiderable length of the carding or ſlubbing at once; but in the rollers, the length of cotton which is ſubmitted to the action of drawing out is very ſhort, indeed very little longer than the length of the fibres of the cotton. In mule ſpinning both modes of extenſion are practiſed; firſt, drawing the roving by rollers, and then a certain length is ſtretched out to a greater extent.

Warping.—The coppins of yarn are mounted on wires in a frame, and the yarns are drawn off from them, in order to combine a ſufficient number of them together, to form the warp for the web of cloth which it is intended to weave. For inſtance, for making the cloth called double drab, which we ſhall take as an example, 2960 threads, each 65 yards long, are laid parallel to each other; but a ſeparation is preſerved at every 40 threads, dividing the whole into 74 parcels, for the convenience of the weaver.

The warping is performed by the warping-mill, which is a large reel, with its axis horizontal; the ends of the threads are made faſt to the reel, which is turned round, and it draws the threads off the coppins, ſo as to wind them upon its circumference; and to prevent the different turns of the threads from lying one over another, the threads are guided through an eye or ring affixed to a ſlider, which is moved along a wooden rail, in a direction parallel to the axis of the reel, by a cord that winds round one end of the axis of the reel.

A warping-mill for ſilks is deſcribed in our article Silk, and will give a clear idea of the preſent, which only differs in the horizontal poſition of the axis, and in the greatneſs of its dimenſions. The threads for the warp being thus aſſembled together, are taken off the reel, and rolled up into a bundle.

The warp is then ſcoured in urine, to remove the greaſineſs of the wool, and is next ſized; to do this, it is dipped into the cauldron of ſize, about ten yards in length at a time, and well worked in by the hands. After ſizing, the yarns are ſtretched out at length in a field, till they are dry, and the warp is then ready for the loom.

The yarn for the weft is wound off from the cops of the jenny to the quills or ſmall bobbins, which are to be put into the ſhuttle.

The loom for weaving broad-cloth has the ſame parts as the ſimple loom deſcribed in our article Weaving; but it is made very ſtrong, to enable it to reſiſt the ſtrain of weaving fuch broad and heavy cloth. The fly-fhuttle, invented by John Kay in 1737, is now in general ufe; it enables one weaver to do the work, which formerly employed two men at oppofite fides of the piece, to throw the fhuttle from one to the other, the width being greater than a man can reach. The warp is wound on the yarn-beam, which is placed in the loom, and the threads being drawn through the heddles and the reed, and faftened to the cloth-beam, the loom is ready for working, in the ufual manner of weaving plain cloth. At each edge of the warp a few threads of ftrong and coarfe yarn are placed; thefe form what are called the lifts when the cloth is woven, and ferve to give ftrength to the cloth, and receive the hooks by which the piece is ftretched in the tenters after milling.

The width of the cloth is meafured between the lifts and the number of yarns, which we have fpecified will make 100 inches in width for the double drab-cloth, or for common cloth 3000 threads will make a piece $103\frac{1}{2}$ inches wide. The quantity of weft ufed for thefe cloths is upon an average one pound weight to a yard in length. The length of the warp contracts a little in the weaving, fo that the fixty-five yards of yarns will make only fixty-two yards of cloth.

Scouring.—The piece of cloth muft be cleanfed from the greafinefs of the oil before it can be felted; for this purpofe, it is firft foaked three hours in a mixture of urine and pig's dung, it is then fcoured in the mill for two hours, and laftly, for half an hour with fair water. The fcouring is performed at the fulling-mill by a pair of ftocks. (See FULLING-*Mill.*) The pair of ftocks are two large wooden hammers, fufpended with the helves or handles in an inclined pofition, and the heads are lifted in fucceffion by cogs or tappets, fixed on the axis of a water-wheel. When the cogs quit the hammers, they fall by their own weight, and ftrike the piece of cloth, which is contained in a wooden ciftern or trough, in which the hammers work. The action of the hammers is to beat and comprefs the folds of cloth, and to turn the piece continually round in the trough or ciftern in which it is placed. The form of the trough is fuch, that the weight of the piece of cloth caufes it to occupy the lower part of the trough, and each hammer when it defcends drives the cloth out from this loweft part, and forces it up a curved fweep. When the hammer is lifted up, the cloth falls again into the fpace which it before occupied, and at the fubfequent defcent of the hammer it is again driven out; the heap of cloth is of a confiderable bulk, and this action of the hammers is chiefly on the lower part of the heap; the beaks of the hammers ftrike nearly horizontally under it, as it were to undermine the heap, fo that the top part falls over when the hammers retreat. This action caufes a continual circulation or turning round of the piece of cloth within the trough, and effects the fcouring, by continually bending and folding the cloth in a frefh direction; and as the ftrokes act upon a great number of folds at once, the different furfaces of the cloth are caufed to rub againft each other, with a very fimilar action to wafhing cloth by hand.

When the fcouring is finifhed, the piece of cloth is taken out, and extended in a vertical plane, in a frame called the tenter, where it remains till dry.

The *tenter* confifts of a number of vertical pofts fixed in the ground with a continued horizontal rail, which is fixed on the top of them, and is as long as the piece of cloth; there is alfo another line of horizontal rails, which are fitted between the upright pofts, fo as to flide freely up and down; and they can be fixed at any diftance beneath the upper rails by means of pins in the pofts, according to the width of the piece of cloth. Both the upper and lower horizontal rails are driven full of tenter-hooks, which are fmall iron rails fharpened at both ends, and bent at right angles, like an L; on thefe hooks the lifts of the cloth are faftened, and the lower or moveable rails are fixed at the proper diftance beneath the upper rails, in order to extend the cloth to its full width.

Burling.—The cloth being dried is burled, that is, examined minutely in every part, and all knots and uneven threads or ftraws, or extraneous matters, removed; any rents or defects which can be found are repaired, by introducing frefh threads. This being done before the milling or felting, the fibres of the new threads will become fo entangled as to render fuch defects nearly imperceptible in the finifhed cloth.

Fulling-Mill for felting the Cloth.—There is another kind of ftocks in a fulling-mill; but the fhape of the trough in which the ftocks or hammers work on the cloth is different from that defcribed in the article FULLING-*Mill*, which is only proper for fcouring. In order to fubject the cloth to the blows of the hammers, the trough for milling is formed in fuch a manner that the cloth cannot efcape from them, becaufe that part of the trough which is oppofed to the beaks of the hammers is nearly a flat furface, and perpendicular to the direction in which the hammers ftrike, fo that the cloth is actually beaten between the beaks of the hammers and the flat bottom or rather fide of the trough.

The hammers are made to ftrike very heavy blows; but they do not bruife or injure the cloth, becaufe there is always a great number of folds of cloth on which they ftrike. The helves or handles of the hammers are placed in a different pofition from the fcouring-ftocks, in order to make the hammer-heads fall in a more perpendicular direction when they make their ftroke, and hence they ftrike with more force. On this account they are called falling-ftocks, whilft thofe ufed for fcouring are called hanging-ftocks, in which the helves of the hammers being nearer to the perpendicular, the heads move in a more horizontal direction, in the manner of a pendulum, and exert lefs force on the cloth; the other difference is, that the hammers of the fcouring-ftocks only drive the heap of cloth round in the trough, there being no part directly oppofed to the beaks of the hammers but a fair curve, which is fo much inclined to the direction in which the hammers move, that the cloth mounts up the inclined curve when the hammer ftrikes, and evades the direct force of the blow.

There is another kind of fulling-ftocks, in which the trough and hammer are conftructed with a view to mill or felt the cloth; but the hammers are put in motion in a different manner: thus the helves are fufpended in a vertical pofition, like pendulums, and the force of the cogs on the horizontal fhaft, which is turned by the water-wheel, is applied to drive the hammers forwards againft the cloth, and produce the felting. To return or draw back the hammers, a chain is attached to each, and thefe chains are linked to the oppofite ends of an horizontal lever, like a fcale-beam, which is fixed in front of the ftocks. This lever and chains draw back one hammer when the other is pufhed forwards; and as the hammers are actuated alternately by the cogs, a conftant action is kept up.

The moft fimple fulling-mill by a water-wheel has no other wheels, but the tappets or cogs which lift the hammers are fixed immediately into the axis of the water-wheel, and it ufually gives motion to two pair, one at each fide of the wheel. It rarely happens that this conftruction of a mill allows the water to be ufed to the greateft advantage, becaufe the circumference of a water-wheel fhould not move with a greater velocity than between 180 and 240 feet *per* minute;

minute; and the hammers of a fulling-mill ſhould be ſo timed, that each one will make from about 30 to 36 blows *per* minute. This requires that the cogs for the hammers ſhould be numerous, and fixed in the circumference of a large wheel fixed on the axis of the water-wheel, otherwiſe the water-wheel muſt be made to turn ſo quickly as to loſe a great part of its force. A better way is to apply a cog-wheel on the axis of the water-wheel to turn a pinion on the horizontal ſhaft, which carries the cogs for the hammers, and this horizontal ſhaft may have a fly-wheel upon it, to regulate the motion and render it uniform.

Mr. Smeaton's proportions for a fulling-mill for two pair of ſtocks were as follows:—The water-wheel, 14 feet diameter, 7 feet broad; it was a breaſt-wheel, and the fall of the water was five feet from the ſurface of the mill-pond to the tail-water below. The ſpur-wheel on the axis of the water-wheel 72 cogs, and 9½ feet diameter; the lantern turned by it 23 rounds. Upon the ſame ſhaft as this lantern was a fly-wheel of eight feet diameter, with a rim of caſt-iron ſeven inches ſquare, and alſo the two cogs or tappets for each of the four hammers forming two pair of ſtocks. The ſame mill was adapted to be turned by the power of horſes in dry ſeaſons; for this purpoſe, another lantern of 13 teeth was applied on the other end of the ſame horizontal axis, which could be occaſionally turned by a horizontal cog-wheel of 90 teeth and 12 feet diameter, fixed on the vertical ſhaft, which the horſes turned. The levers by which the horſes drew were 15 feet long, ſo that the horſes' track was 30 feet diameter.

It required four horſes to work one pair of ſtocks in this mill, and when Mr. Smeaton tried the expenditure of water at this mill, and alſo at another mill with an overſhot-wheel, he found it required from 1200 to 1400 cubic feet of water *per* minute, falling one foot, to work a pair of ſtocks. Taking the force of a horſe at 352 cubic feet *per* minute raiſed one foot, this is very nearly equal to four horſes. Theſe ſtocks were uſed for fulling of bays, and we apprehend the power for working the fulling-mills for broad-cloth is greater.

Proceſs of Milling.—A piece of cloth of ſixty-two yards long has ſix pounds of ſoap allowed for it, which is diſſolved in water, and a handful ſpread upon every yard in length; the piece is then put into the trough of the mill, and worked for three hours; during this time the cloth is frequently moved in the trough, to expoſe freſh ſurfaces to the action of the hammers. The blows upon the cloth cauſe a motion of the fibres of the wool amongſt one another, and the ſoap facilitates this motion; the fibres of the wool have the ſingular property of moving always forwards in the direction of the roots of the hairs, when a number of hairs are rubbed or worked together, but they will not retreat in the oppoſite direction; this produces the matting or entangling of all the fibres together. After three hours milling, the piece of cloth is taken out of the trough, and ſoaped again, then returned and milled again for three hours. This is repeated four times, making twelve hours milling in the whole, and then a ſtream of fair water is admitted into the trough, to waſh away the ſoap. The piece of cloth, when taken out of the mill the laſt time, is generally found reduced to about 60 inches broad, and 40 yards in length; before the operation, it was 100 inches broad, and 62 yards in length.

The operation of felting is ſo well explained by M. Monge, in the Annales de Chimie, that we think proper to give an extract from his memoir, in addition to what is ſtated in our articles Felting, Fulling, and Wool.

If we examine a human hair, a fibre of wool, or the hair of a rabbit, hare, beaver, &c. in a microſcope of the greateſt magnifying power, the ſurface of each hair appears ſmooth and even; or at leaſt if any inequalities are perceptible, they ſeem rather to ariſe from ſome difference in the colour and tranſparency of particular parts of the fibres than from the irregularity of their ſurfaces; for their images, when viewed by a ſolar microſcope, are terminated by even lines, without any roughneſs. Neverthcleſs it is probable the ſurfaces of theſe objects are formed either of *laminæ*, which cover each other from the root to the point, much in the ſame manner as the ſcales of a fiſh cover the animal from the head to the tail; or ſtill more probably of zones placed one over the other, like what is obſerved in the ſtructure of horns; to this conformation it is, that ſuch ſubſtances owe their diſpoſition to what is called felting.

If with one hand we take hold of a hair by the roots, and draw it between two fingers of the other from the root towards the point, we are hardly ſenſible of any friction or reſiſtance, nor can we diſtinguiſh any ſound; but if, on the contrary, we draw it between the fingers from the point towards the root, we are ſenſible of a reſiſtance which did not exiſt in the former caſe. A ſort of tremulous motion is alſo produced, which is not only perceptible to the touch, but may alſo be diſtinguiſhed by the ear.

It is evident, therefore, that the texture of the ſurface of a hair is not the ſame from the root towards the point, as from the point towards the root. As this texture is the principal object of the preſent memoir, it is neceſſary to demonſtrate it by ſome other obſervations.

If a hair is held between the fore-finger and thumb, and rubbed by them backwards and forwards alternately in the direction of its length, a progreſſive motion of the hair will take place; but this motion is always with the root forwards, although the rubbing of the finger and thumb is alternately in both directions. This effect does not at all depend on the nature of the ſkin of the fingers, or its texture; for if the hair be turned, ſo that the point is placed where the root was, the movement then becomes contrary, *viz.* its motion is always directed towards the root.

What is obſerved in the above inſtance is entirely analogous to what happens when country children, by way of ſport, introduce an ear of rye between the wriſt and the ſhirt-ſleeve; the points of the beards of the ear are directed outwards, and by the various motions of the arm, this ear, ſometimes catching againſt the ſhirt, ſometimes againſt the ſkin, takes a progreſſive motion backwards, but the beards always reſiſt its return, ſo that it ſoon gets up to the arm-pit. It is very clear, that this effect is produced by the aſperities upon theſe beards, which being all directed towards the point, do not permit the ear to move in any other direction than towards that part which was united to the ſtalk. There can be no doubt that it is the ſame with reſpect to hair, and that its ſurface is beſet with aſperities, which being laid one upon the other and turned towards the point reſiſt all motion, except towards the root.

Theſe obſervations, which it would be uſeleſs to multiply, relate to long hair, which have been taken as examples; but they apply with equal propriety to wool, furs, and in general to every kind of animal hair. The ſurface of all theſe is, therefore, to be conſidered as compoſed of hard *lamellæ* placed one upon another, like tiles, from the root to the point; which *lamellæ* allow the progreſſive motion of the hair towards the root, but prevent a ſimilar motion towards the point.

From what has been ſaid, it will be eaſy to explain why the contact of woollen ſtuffs is rough to the ſkin, while that of cotton or linen cloths is ſmooth: the reaſon is, that notwithſtanding the flexibility of each particular fibre, the aſperities

perities upon the furface of the fibres of the wool, by fixing themfelves in the fkin, produce a difagreeable fenfation, at leaft till we are accuftomed to it; whereas the furface of the fibres of hemp or flax, of which linen is made, being perfectly fmooth, do not caufe any fuch fenfation. It is alfo probable, that the injury arifing to wounds or fores from the application of wool does not proceed fo much from any chemical properties, but is occafioned folely by the form of the furface of the fibres, the afperities of which attach themfelves to the raw and expofed flefh, which they ftimulate and irritate to fuch a degree as to produce inflammation.

The afperities with which the furface of wool is every where furrounded, and the difpofition which it has to affume a progreffive motion towards the root, renders the fpinning of wool and making it into cloth difficult operations. In order to fpin wool and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling up the cavities, renders the afperities lefs fenfible; in the fame way as oil, when rubbed upon the furface of a very fine file, renders it ftill lefs rough.

When a piece of cloth is finifhed it muft be cleanfed from this oil, which, befides giving it a difagreeable fmell, would caufe it to foil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil it is fcoured at the fulling-mill, by working it with hammers in a trough full of water or urine, in which fuller's-earth is fometimes mixed. This earth combines with the oil which it feparates from the cloth, and both together are wafhed away by the frefh water, which is afterwards brought to it in the machine. Thus after a certain time the oil is entirely wafhed out of the cloth.

The fulling, which fucceeds the fcouring of the cloth, is aided by the application of the foap. The alternate preffure given by the hammers to the piece of cloth, efpecially when the milling is pretty far advanced, occafions an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compofe one of the threads, whether of the warp or the weft, affume a progreffive movement with their roots forwards, and introduce themfelves among the fibres of the threads neareft to them, then into thofe which follow; and thus by degrees all the threads, both of the warp and the woof, become felted together. The cloth, having by the above means become fhortened in all its dimenfions, and thickened in its fubftance, partakes both of the nature of cloth and of that of felt; for at the fame time that the threads give it confiderable ftrength, it may be cut without being fubject to ravel, and on that account we are not obliged to hem the edges of the pieces of which wearing apparel is made. Laftly, as the threads of the warp and thofe of the weft are no longer fo diftinct and feparated from each other as to leave interftices between them, the cloth forms a warmer clothing, independently of its having acquired a greater degree of thicknefs. Knit worfted is alfo rendered lefs apt to run, in cafe a ftitch fhould drop, by the operation of fulling.

Tentering.—When the milling is finifhed, the cloth is ftretched again on the tenter. It is ufual to extend the piece to forty-two yards in length, but not at all in breadth; indeed only one inch of extenfion in each yard is allowed by law. The cloth remains in the open air until it is perfectly dry and ready for the fucceeding operations of finifhing, which are only intended to give it a beautiful furface, for it already poffeffes all the ufeful qualities of cloth.

Dreffing the Cloth with Teafels.—This operation is to raife up the nap or loofe fibres on the furface of the cloth, by fcratching it over with a fpecies of thiftles called teafels, in order to form a wool on the furface, which can be removed by fhearing. The teafels are the balls or ears which contain the feed of the plant called *dipfacus fullonum;* the fcales which form the ball project on all fides, and are terminated with fharp points, which turn downwards, like hooks, and are very elaftic. See TEASEL.

A number of teafels are put into a fmall frame, which is compofed of a handle eight or ten inches long, having a fmall ftick paffed through it at one end about eight inches long, which is fplit into two at each end nearly all its length. There is alfo another fimilar ftick, which is paffed through the handle near the middle of its length; the two fplit fticks are perpendicular to the ftem or handle, and parallel to each other. The fpace between them is filled with teafels, which are jambed in very faft between them, and alfo in the clefts of the fplit fticks, where they are fecured by ftrings extended between the ends of the fplit fticks, and twifted, until they draw the fticks forcibly together, and bind the teafels very faft. This frame filled with teafels forms a tool, which very much refembles the curry-comb ufed to clean horfes, and is ufed in a fimilar manner, to fcratch over the whole furface of the cloth, and draw out all loofe ends of the fibres of the wool, which are not firmly confined by the entanglement of the felting.

The dreffing is performed by two men, who hold the teafel-frame by its handle, and work the cloth, when it is hung up in a vertical pofition over two rails fixed to the ceiling; when they have worked over as much furface as they can reach, they draw down a frefh portion, which they work in turn, and thus proceed until they have finifhed the whole piece. The firft time the cloth is dreffed it is wetted with water; it is worked three times over in the wet ftate, by ftrokes in the direction of the length of the piece, and then it is worked again three times in the other direction; by this means all the fibres are raifed, and the cloth is prepared for fhearing.

In the moft improved manufactories, the dreffing is performed by the gig or gig-mill. This is a cylinder covered on its furface with teafels, and turned rapidly round whilft the cloth is drawn over it.

The *Gig-mill* is reprefented in perfpective in *Plate* V. *Woollen Manufacture.* M is the wood frame of the machine; F F is the cylinder or drum, which is compofed of 12 rails or troughs, filled with teafels F F, 3, 4, &c. Thefe are faftened on the circumference of two or three wheels fixed upon a wooden axis 7; the drum is put in motion by a pulley E D at one end of its axis, which receives an endlefs ftrap, 2, from the drum C, fituated above the machine. There are two pulleys, E and D, one fixed faft on the axis, and the other fitted on loofely, with liberty to turn round freely upon it; the ftrap can be fhifted to either pulley, and accordingly the machine will be put in motion, or will ftand ftill.

The drum C is fixed on one end of an iron fhaft 1, which is put in motion by a bevelled wheel B, from the larger wheel A, fixed on the great horizontal fhaft, which proceeds the whole length of the mill. The drum, F F, covered with teafels, is mounted on bearings fupported by the frame, and the piece of cloth G is conducted over it, to receive the action of the teafels; one end of the piece of cloth is wound round a roller J, and the other end of the piece is wound on the roller L; both thefe rollers are put in motion from a bevelled wheel 6, fixed on the extremity of the axis of the drum; this turns a wheel H upon an inclined axis, which has a pinion at each end; one of thefe pinions, 9, turns a bevelled wheel, K, on the end of the axle of the upper roller

roller L; and the other, 8, turns the wheel I belonging to the lower roller J. By means of this wheel-work both rollers are turned round in the proper direction, to make the upper roller L wind up or draw the cloth, whilft the lower roller unwinds and gives out the cloth. N is a pipe, which conveys water to the machine; it is pierced with a number of holes to throw jets of water on the cloth, and wet it.

As faft as the cloth is taken up by the roller L, it is given out by the other roller J, and is then drawn over the furface of the cylinder, as at G, the teafels of which, as it revolves, act very effectually on the cloth to raife the nap. When the whole piece has paffed, and is gathered up on the roller L, the machine is ftopped, by fhifting the ftrap 2 to the loofe pulley D, then the two rollers L and J are exchanged, and the operation is repeated as before, and fo on till the nap is fufficiently raifed.

The mode of repeating the action on the cloth by exchanging the rollers is troublefome, and a better mode is to provide the means of difengaging either of the wheels K or I from its refpective pinion, making the machine fo that only one wheel and pinion can be engaged at once; alfo to make the motions in fuch direction that the roller which is engaged fhall always wind up the cloth upon itfelf. Each roller muft have a fmall wheel upon one end of it, as fhewn at 10, with a lever and weight 11, to prefs upon the circumference of the wheel with fuch force as to occafion a friction, and make the cloth draw tight when it is drawn off the roller. In this way, the cloth can be made to work either backwards or forwards; becaufe that roller which is engaged with the wheel-work will wind up the cloth, and draw it off from the other roller acrofs the drum; but when all the cloth is wound off, that roller which has taken the cloth muft be difengaged, and the other put in action, which will make the cloth work back again.

The moft improved gig-mills ufed in Yorkfhire have a ftill better method of moving the cloth. This is by means of a pair of rollers in the place of the upper roller L: they are turned round by a large fpur-wheel on the end of the roller, which works in a fmaller wheel on the end of the drum; one roller is mounted over the other, like the two rollers of a flatting-mill, and preffed together by fcrews with fufficient force to draw the cloth between them. The piece of cloth, when brought to the machine, is laid down on a board on the ground before the machine, and one end is paffed under the roller J, which is merely to guide it; then it is carried over the drum, as at G, and introduced between the pair of rollers at L, which draw it flowly forwards; from thefe the cloth turns upwards, and is extended horizontally over two rollers which are fufpended from the ceiling. After quitting thefe rollers, it defcends perpendicularly, and is gathered on the ground in folds on a board or bench, clofe to the place where the piece of cloth was laid before the dreffing was begun. In order to make the piece of cloth pafs a fecond time through the machine, or as many times as is required, the two ends of it are fewed together, fo that it circulates continually over the drum without any interruption or trouble: it is ufually done three or four times.

It is an advantage of this method, that the cloth, in defcending from the ceiling, hangs perpendicularly, and with that fide which has been dreffed oppofite to the light, fo that the workman who gathers it in folds can examine the progrefs of the work; and when he judges that the cloth is fufficiently dreffed, he cuts the fewing which unites the two ends together, and then the end of the piece comes out of the machine, and the cloth is carried away to give place to another piece.

The drum or cylinder of the gig-mill is compofed of a number of fhallow troughs, fixed on the circumference of the wheels of the drum, and parallel to its axis: into thefe troughs, frames filled with teafels, like thofe we have before defcribed, are faftened in a very fimple manner; and the frames are placed fo clofe together, that the trough is wholly filled, and forms a continuous furface of teafels to act upon the cloth when the cylinder revolves. When the hooks of the teafels become filled with flocks or fibres of wool, which they have drawn out from the cloth, they are removed from the cylinder, in order to be cleaned by children, who pick out the flocks with a fmall fteel comb.

The teafels are cultivated very largely in the clothing countries; but it fometimes happens, in particular feafons, that the crops fail, and they are then very dear. This has produced many trials of metallic teeth as fubftitutes for teafels. Mr. Price of Stroud, in Gloucefterfhire, has two patents, dated 1807 and 1817, for this object; Mr. Laffalle of Briftol took a patent in 1816, Mr. Williams of Furfley in 1817, and Meffrs. Lewis of Brinfcomb in 1817. We are not informed if any of thefe inventions are yet brought into real ufe in the manufacturing diftrict.

Shearing or Cropping the Cloth.—By the operation of the teafels, the wool is become raifed all over the furface of the cloth in a loofe fur, which muft be removed by fhearing before the cloth will be fit for wearing, becaufe the fur would gather dirt and duft, and would wear very unequally.

The fhears ufed for cropping by hand are the fame as thofe ufed in the common fhearing-machine, and are reprefented at E, E, in *Plate* III. *Woollen Manufacture.* The clothier's fhears confift of two very large flat blades of fteel, united together by a ftem of fteel, which is bent into a circular bow, and is fufficiently flexible to allow one of the blades to be moved upon the other, in order to make them cut. Both blades are ground to fharp and ftraight edges, which apply one to the other, but the blades are not in parallel planes like fciffars, for one of the blades is laid quite flat upon the cloth, and the plane of the other blade will then be inclined to the cloth at about an angle of 45 degrees, as is fhewn in *Plate* III. The cutting-edge of this inclined blade bears upon the furface of the flat blade, and the fpring of the bow is fo fet, as to prefs the two edges always in contact. The lines of the edges of the two blades are not parallel to each other, but inclined, fo that the edge of the upper blade croffes the edge of the lower blade, and bears upon the flat furface of that blade, at the end neareft to the bow, whilft the other end of the edge of the upper blade is removed over the edge of the lower blade, thus leaving an interval between the two edges, when the fhears are open, as is plainly fhewn in the figure. In this ftate, the fhears being open, if the lower blade is laid flat upon the furface of the cloth, the nap or wool, which is to be removed by the cropping, will ftand up above the edge of the lower blade, in the interval between the two edges; then if the blades be forced together, the edge of the upper blade will pafs or crofs over that of the lower, and cut away all the wool which projects above the edge of the lower blade. The contact of the cutting-edges begins at the end neareft to the bow, and proceeds regularly to the other, becaufe, as before mentioned, the edges are not parallel to each other. The blades open or return to their former pofition by the elafticity of the bow, but in order to make the cut they are clofed by means of a handle or lever 10, which is fitted or lodged on a round part of the ftem of the bow, fo as to play thereupon as upon a centre of motion. A double cord is made faft to the lever or handle near to this centre, and the

the other end of the cord is faftened to a block of wood, which is fcrewed to the flat of the lower blade, and rifes up to a proper height. By depreffing this handle, the fhears are clofed, and make their cut with the greateft facility, the elafticity of the bow returning the handle.

The manner of cropping with thefe fhears is as follows: — The piece of cloth is laid down in folds upon a plank or low bench placed on the ground, and the end is drawn acrofs a table or bench, which is covered with cloth, and ftuffed with horfe-hair, like a cufhion. The cloth is ftretched out flat upon the furface of the table, and is retained by hooks and weights. Two workmen are employed to fhear a piece of cloth; they place the lower blades of their fhears flat on the furface of the cloth, with the line of the edge in the direction of the length of the piece; one of the fhears is laid on the edge or lift of the cloth, and the other exactly in the middle of the breadth of the cloth. The bows and ftems of the fhears project over the edge of the table, and the workmen place themfelves at that edge. Each man guides the fhears with his left-hand, and makes the cut with his right. To hold the fhears by, a fhort ftaff is lafhed to the bow of the fhears, and fecured by a ftay to the lower blade; its direction is nearly parallel to the back edge of the upper blade. The workman puts his arm through the bow as far as the elbow-joint, then lays the fore-arm flat againft the ftaff, which he grafps with the hand; and in this way he has a great command of the fhears, leaving the right-hand at liberty to work the handle which clofes the fhears. This handle is moved backwards and forwards with great rapidity, to make cuts or clips on the cloth, and between every cut the lower blade is moved a fmall fpace on the cloth, to cut in a frefh part.

The art of fhearing confifts in moving the fhears with great regularity and parallelifm, fo that every part of the furface fhall be equally cropped. The clofenefs with which the fhears cut is regulated by weights laid upon the flat of the lower blade; thefe prefs the blade down into the foft cufhion on which the cloth is fpread, fo that the fur will ftand up more above the edge of the blade.

As the two fhearers advance in their work, their fhears proceed acrofs the breadth of the piece of cloth, and when the man who began in the middle has worked to the lift of the cloth, the other who began at the lift will have worked to the middle, where the firft began; the whole breadth is now fhorn, and they remove the fhears, and draw the piece of cloth forwards acrofs the table, to obtain a frefh furface to work upon.

For fhearing common cloth, it is cut wet the firft time, then it is dreffed again with teafels, dried on the tenter, and cut again in a dry ftate three times over.

Shearing-Frame. — The moft common machine ufed in Yorkfhire is only applied to give motion to the fame kind of fhears as are ufed for cropping by hand, and is ufually called the fhearing-frame. At the fide of the table or cufhion on which the cloth is fpread, a long ftool is placed, having grooves at the edges to guide the wheels of a carriage, to which the fhears are affixed by their bows. There is a carriage for each pair of fhears, and they are flowly and gradually moved along the ftool, by a cord which winds upon a roller turned by wheel-work; and at the fame time, the handles of the fhears are continually pulled by a cord connected with a fmall crank, which turns round very rapidly. The direction of the cuts is the lengthways of the piece of cloth, and the two pair of fhears advance acrofs the breadth of the piece until a whole breadth is cut; the machine is then ftopped, the fhears removed, and the piece of cloth fhifted upon the table. Thefe fhearing-frames operate very well, but require great care and attention to make the different cuttings join, in order to cut equally over the whole furface.

The machine invented by Mr. Harmar of Sheffield was of this defcription; his firft patent was in 1787, and another in 1794. At one period his machines were in general ufe, but the prefent fhearing-frames, although of the fame kind, are very much fimplified, and work equally well.

A perpetual Shearing-Machine is reprefented in *Plate* III. *Woollen Manufacture*; it is ufed in the weft of England, and is beft adapted for narrow cloths. The fhears lay croffwife over the piece, which is drawn regularly beneath the fhears in the direction of its length without any interruptions; hence it is called a perpetual fhearing-machine.

The fhears, E E, are the fame as what we have already defcribed. Each pair is faftened acrofs the frame by means of a piece of wood, to which the lower blade of the fhears are fcrewed; immediately beneath this blade is the cufhion to bear the cloth, which paffes between the blade and the cufhion. The piece of cloth is wound round the roller C, upon the end of which is a wheel N, and a lever M, which bears up againft the lower part of this wheel with fo much friction as to make the cloth ftrain tight in drawing off from the roller. The cloth firft paffes over a rail B, from which it proceeds in an horizontal direction beneath the two pair of fhears E E, then turns over another rail at the other end of the frame, and defcends to a roller D, which is turned flowly round by the machinery, in order to wind up the cloth.

The machine is put in motion by the endlefs ftrap round the drum F upon a fhaft, which proceeds all the length of the mill. The ftrap turns the pulley G upon the end of the fmall horizontal fpindle H: in this fpindle two cranks are formed at *a* and *b*, which are connected, by wires 7 and 8, with the handles 9 and 10 of the fhears E, fo as to give them a continual motion, and make a cut of each pair of fhears every time the fpindle H makes a turn. The motion of the machine can be ftopped by releafing the lever P, on which the bearing of the fpindle is fcrewed: when the lever P is depreffed, and kept down by the catch, as reprefented in the drawing, the endlefs ftrap is drawn tight, fo as to turn the fpindle; but if the catch is removed, and the lever raifed up, the ftrap becomes loofe, and flips round upon the pulley without turning it. A fmall pulley is fixed upon the fpindle at I, to receive an endlefs ftrap which paffes round a larger wheel J. Upon the fame axis with this are three other pulleys of different diameters, which receive a ftrap 2, and give motion to three fimilar pulleys fixed upon a fpindle 3: the latter fpindle has a pinion on the end of it, which works a bevelled wheel fixed on the end of the roller D, and thus it is turned flowly round. The three pulleys on the fpindles 3 and J are placed reverfed to each other, that is, the fmalleft pulley on one is oppofite to the largeft on the other; by this means, the fame ftrap 2 may be fhifted, and will work on any of the three pair of pulleys, but each one will communicate a different degree of movement to the roller D, and confequently to the cloth, fo as to draw it quicker or flower, and make the fucceffive cuts of the fhears at a greater or lefs diftance afunder at pleafure.

The cufhions which bear up the cloth againft the fhears are moveable on centres of motion, and are capable of being raifed or lowered. When they are lowered down, the cloth can be readily introduced beneath the lower blades of the fhears; and when raifed up, they prefs the cloth up to the fhears, and the force of this preffure can be regulated by turning a fmall handle. In many machines this motion is

applied

applied to the ſhears themſelves, inſtead of to the cuſhion or bed, and is much more convenient.

The perpetual machines anſwer very well for ſhearing narrow cloth, when the ſhears can cut at once acroſs the whole breadth; and then as the two ſhears E work in ſucceſſion over the ſame ſurface, they crop the cloth twice over in paſſing once through the machine. It has been attempted to ſhear wide cloths in this machine, by making one pair of ſhears take one half the breadth, and the other pair the other half; but it is very difficult to draw a wide piece of cloth ſo evenly over the cuſhions, as to keep it ſtretched to the full breadth without any wrinkles in the lengthways of the piece; and if there are any ſuch wrinkles, the cloth will be cut very irregularly. In this particular, the firſt machines have the advantage, becauſe the cloth is ſtretched over the cuſhion by the workman with diſcretion, and he makes it tight before the cropping is begun.

There have been many patents for the improvements of ſhearing-machines. Mr. Buffington's, in 1804, is for a method of ſtretching or extending the cloth breadthways whilſt it is in the ſhearing-frame. His plan is to attach a narrow web of ſtrong cloth to the liſts of the cloth, by ſewing or lacing; the outer edge of this web is alſo ſewed to a cord or ſmall rope, ſo that the cloth becomes edged or bordered with ropes. Theſe ropes are conducted through holes or openings in the frame, which will ſuffer the cloth and ropes to be moved in the direction of their length; but as the ropes cannot draw ſideways out of theſe openings, the cloth may be continually ſtretched in its breadth. The openings ſhould have rollers to facilitate the motion of the ropes.

Mr. Joſeph Fryer's patent ſhearing-machine, dated 1802, acts with three ſhearing-blades, one long one, which extends acroſs the breadth of the piece to form the lower or fixed blade, and two other moveable blades of half the length, which are jointed to the long blade at the two ends, and are moveable thereon, ſo as to cut in the manner of ſciſſar-blades. The moveable blades are preſſed into contact with the edge of the fixed blade by ſprings, and are put in motion by means of two cranks upon an horizontal ſpindle, ſo that the blades make their ſtrokes or cuts alternately. The edge of the lower blade is a ſtraight line, but the edges of the moveable blades are convex on the cutting ſide, ſo as to cauſe them to interſect the edge of the lower blade always at the ſame angle when they are wide open, as when they are nearly cloſed.

The piece of cloth is conducted over proper rollers, and wound up by one, which is turned round by the machine, ſo as to draw the piece of cloth from one end to the other with a ſlow and progreſſive motion. The cloth, when it is immediately beneath the edge of the long blade, is bent ſuddenly over a narrow ridge of metal, which is parallel with the edge of the lower blade, but ſo far diſtant as to permit the cloth to paſs between them. This ridge of metal is capable of adjuſtment by means of ſcrews, and can be placed ſo that the nap of the cloth will be ſhorn longer or ſhorter, as it is required.

In ſome caſes, eſpecially in finiſhing broad-cloths, inſtead of drawing the piece from end to end, it may be more convenient to cauſe it, or part of it, to move under the ſhearing-blades from liſt to liſt, or from one ſide to the other. This will require a machine conſiderably larger, though the ſame blades will ſuffice; or it is found equally convenient to cauſe the blades, at the time they are cutting, to move over the cloth in any direction, but more eſpecially from liſt to liſt.

Mr. Fryer alſo contemplated the finiſhing of the cloth by the ſame machine which performed the ſhearing. Thus after the cloth has undergone the operation of ſhearing or cropping, in its paſſage down to the cylinder on which it is wound up, it is expoſed to a current of ſteam thrown out from a horizontal tube at a number of ſmall apertures, ſo as to give ſoftneſs and pliability to the cloth; a bruſhing cylinder is next made to move againſt it, by which the remaining wool or fur is laid in one direction. It then paſſes between two poliſhed metal cylinders, which are made hollow, and kept hot by the admiſſion of ſteam or otherwiſe. Theſe occaſion a great preſſure on the cloth, and diſſipate all the water imbibed from the ſteam.

Rotatory Shearing-Machine.—A very complete machine for cropping cloth of any breadth was invented by Mr. Price, of Stroud, in Glouceſterſhire, and for which he obtained a patent in 1815. This machine ſhears or crops the cloth acroſs the breadth, beginning at one end of the piece, and continuing regularly to the other. For this purpoſe, the cloth is conducted through the machine by the motion of rollers, and is drawn over a bed or ſupport which lies beneath the ſtationary or fixed blade of the ſhears or croppers, (which anſwers to what is called the ledger-blade in the common ſhears,) ſo that the cloth paſſes between the bed and the ſtationary blade.

The moving blades of the ſhears are fixed on the circumference of a cylinder ſituated above the fixed blade, with its axis exactly parallel thereto, and capable of revolving by the power of machinery, ſo that the edges of the moving blades will be carried againſt and paſſed over the edge of the fixed blade, in order to cut away all the wool of the cloth which riſes above the edge of the fixed blade. Several ſuch moving blades are fixed upon the ſame cylinder, to act in ſucceſſion againſt the fixed blade; and theſe moving blades are placed obliquely to the axis of the cylinder, or in ſuch a manner as to form portions of ſpirals; but as all parts of the cutting edges are equidiſtant from the axis of the cylinder, it is manifeſt, that in the revolution of the cylinder, every part of each ſpiral edge is brought in ſucceſſion into contact with the fixed blade, ſo that in its revolution it crops off all the wool, which by the progreſſive motion of the cloth over its bed is raiſed up againſt the fixed edge. The edges of the moving blades are placed at ſuch a degree of obliquity to the axis of the cylinder, that at the ſame inſtant the end of one ceaſes to cut againſt the edge of the fixed blade, the following revolving blade will begin its action at the other end of the cylinder; therefore, by the time that any one of the revolving edges has paſſed over and made its cut againſt the whole length of the fixed blade, and is ready to quit it, the ſucceeding revolving edge is brought into action, and when this has paſſed, the next in ſucceſſion begins, ſo as to keep up a continued action.

The cloth is ſtretched in width by a contrivance which he calls ſtretching-bands, to prevent it getting into folds or wrinkles, which would be injured by the ſhears, or make irregularities in the ſhearing. Theſe ſtretching-bands are endleſs ſtraps or bands, each of which is extended over two wheels. The bands have ſharp pins projecting from them to prick into the liſts at the edges of the cloth, and the bands being ſo ſituated that one of them lies exactly beneath each liſt, they will be cauſed to circulate round their reſpective wheels by the motion of the cloth. The ſtretching of the cloth is effected by the poſition of the wheels on which the bands circulate, the direction of the bands being ſlightly oblique to the lengthways of the cloth. The endleſs ſtraps are ſo fitted into grooves or troughs, that they are firmly retained to move ſtraight forwards in their oblique direction; and the direction of the obliquity is ſuch, that the bands are neareſt together at that end where their pins take hold of the liſts of the cloth; but as the bands move forwards with the cloth, they recede from each other, and extend the cloth in breadth in conſequence of their obliquity, which may be increaſed or diminiſhed as is found neceſſary. The actual width between the two bands can alſo be regulated according to the width of the piece of cloth.

It is not uſual to crop the liſts of the cloth, and indeed as the liſts are uſually of thicker ſubſtance than the other parts of the cloth, they would bear up the fixed blade too high from the cloth to cut the nap quite cloſe.

For this reaſon, the bed or ſupport on which the cloth is cut is ſo conſtructed, that it can be adapted in length to the breadth of the piece of cloth between the liſts, in order that the cloth only may be ſupported or borne up to the edge of the fixed blade; whilſt the liſts, being depreſſed or borne down below the level of the bed, (by thin ſlips of metal called guards,) will eſcape the action of cropping, and thereby remain with the long wool upon their ſurfaces. The bed by which the cloth is borne whilſt it is cut is only a narrow ridge of metal, over which it paſſes, ſo as to be bent with a ſudden curvature, and in this way, the nap can be cut more cloſe and even than upon a flat bed or ſoft cuſhion. The operation of cutting is facilitated by a row of pieces of metal ſcrewed to a ſtrong bar, to form a ſtraight edge, very ſimilar to the cutting edge of the fixed blade, but thin and elaſtic; this edge is placed cloſe to the elevated ridge of the bed, and preſſes the cloth gently down upon the bed immediately before it comes to the edge of the fixed blade, againſt which the nap is to be cut off; this elaſtic edge being placed on one ſide of the ridge, and the cutting edge of the lower blade on the other ſide, the cloth is only expoſed for a very narrow ſpace juſt where it comes to the cutting edge. By this means, the cloth can with ſafety be brought nearer to a level with the upper ſurface of the fixed blade, ſo as to ſhear it cloſer than could otherwiſe be done without endangering the cloth.

The ends of the ridge part of the bed are compoſed of a number of narrow plates of metal, accurately fitted together, and placed ſide by ſide in a mortiſe made in the end of the ſolid bed; their upper ends project out of the mortiſe ſo as to line with the elevated ridge, and form a continuation thereof; but there is a ſliding piece in the bottom of the mortiſe on which they all bear, and the point of it is of a wedge form. By removing this wedge, any number of the moveable pieces may be let down, ſo as to diminiſh the length of the elevated part of the bed at pleaſure, according to the breadth of the cloth. The whole of this machine is very well contrived to effect the deſired object; it will be found fully deſcribed with drawings in the Repertory of Arts, vol. xxix. p. 65.

Frizing is an operation ſometimes uſed in the finiſhing of woollen cloth: it conſiſts in rolling up and entangling the fibres, which form the nap on the ſurface of the cloth into ſmall knots or burs, which cover near the whole ſurface, ſo that the cloth appears covered with ſmall grains, which almoſt touch each other.

This operation is of no utility to the cloth, and it is difficult to ſay for what reaſon it was ever practiſed at all. The French firſt introduced it, and it was ſo much the faſhion many years ago, that no other cloth was thought comparable in beauty. At preſent it is but little uſed, except for foreign markets, where our cloth meets the French cloth, which is ſtill prepared in this manner, but generally on the back-ſide of the cloth only.

The frizing is done by a ſimple machine, in which the cloth is drawn acroſs a narrow table by means of rollers, to give it a very ſlow progreſſive motion. The table is covered with a coarſe ſtrong cloth, and over the table is placed a heavy plank of wood, of the ſame ſize as the table. The lower ſide of this plank, which bears upon the cloth, is covered with an artificial ſtone, compoſed of coarſe ſand, which is ſtuck together into a ſolid maſs by glue or other cement, and a ſmall but rapid reciprocating motion is given to the plank by means of two cranks of very ſmall radius. Theſe cranks are formed at the tops of two vertical ſpindles, the upper ends of which are fitted in ſockets at the ends of the fixed table, and the ends which project up a few inches above the ſurface of the table are received into ſockets formed in each end of the moveable plank. The projecting parts of the ſpindles are not in ſtraight lines with thoſe parts which are fitted in the fixed collars at the ends of the table, but are ſlightly cranked; hence, if the ſpindles are turned round, they muſt communicate motion to the plank, and ſlide it over the cloth backwards and forwards; or rather they move it with a circular motion, cauſing every point and grain of ſand cemented to the plank to deſcribe a ſmall circle upon the cloth. It is this action which gathers together the fibres of the nap, and entangles them into knots or grains, as before mentioned.

To put the two ſpindles in motion, each one has a trundle or lantern fixed on the middle part of it, and the lower end is received in a ſtationary ſocket. Theſe lanterns are turned round by the teeth of two face-wheels, fixed upon an horizontal axis, which lies beneath the machine. By this means, both the ſpindles and cranks are turned round at the ſame time, and with a very rapid motion. The rollers which draw the cloth forwards are turned round ſlowly by a communication of wheel-work, and draw the piece of cloth through the machine, that is, acroſs the frizing-table, ſo that every part is in turn ſubjected to the action of the ſand cemented to the plank. The nap muſt be left long for that cloth which is intended to be frized, and the operation is repeated twice or three times. See ſome further particulars in our article FRIZING, vol. xv.

Bruſhing.—After being ſhorn for the laſt time, the cloth is bruſhed all over, to remove the looſe cuttings. This operation is now commonly performed by a machine which has two horizontal drums, or cylinders, covered with hair-bruſhes on the circumference. The piece of cloth is conducted over a ſyſtem of rollers to extend it and draw it ſlowly forwards: it is conducted over one of the bruſhing-cylinders, and under the other; and as they are kept in rapid motion by the machine, they bruſh over both ſides of the cloth at the ſame time, and lay all the fibres one way.

Preſſing.—This is the laſt finiſh to the cloth, and gives it a ſmooth and even ſurface. The piece of cloth is folded backwards and forwards at every yard, ſo as to form a pack on the board of a ſcrew-preſs; and between every fold ſheets of glazed paper are placed, ſo that no part of the ſurfaces of the cloth can come in contact; alſo at every twenty yards three hot iron plates are put in between the folds, the plates being laid ſide by ſide, ſo that they occupy the whole ſurface of the folds; and thin iron plates, which are not heated, are alſo put above and below the hot plates to moderate the heat. When the pack of cloth is properly folded, and the preſs contains a proper quantity, the ſcrew is forced down to give a very ſevere preſſure to the pack. The cloth remains in the preſs until the plates are quite cold; it is then taken out and folded again, ſo that the creaſes of the former folds will come oppoſite to the ſurfaces of the paper, in order to be preſſed with other hot plates.

The heat tends to ſoften the fibres of the wool, and the preſſure

preſſure againſt the glazed paper, whilſt they are ſo ſoftened, lays all the fibres flat and ſmooth, ſo that the cloth has a very gloſſy appearance, and feels ſmooth, like ſatin; but this high finiſh to the cloth is very objectionable, becauſe the ſlighteſt ſhower of rain will take it away, and when the drops of rain only wet it in parts, the cloth will become ſpotted and disfigured. For this reaſon, in preſſing ſuperfine cloth, the plates are very ſlightly warmed, and the cloth has but little gloſs given to it. The glazed paper is a thick kind of cartridge, which is prepared by glazing or rubbing it very forcibly with a flint, as it lies upon a hard metal table. This operation is done by a water-mill.

For coarſer cloths, ſome manufacturers gloſs them with a large hot iron: it is a hollow box, into which a red-hot heater is introduced. The cloth is ſpread out upon a large flat table, and extended by hooks. The iron box is ſuſpended by a tackle from the ceiling, ſo that it can be hoiſted over to the middle of the table, and then two men work it backwards and forwards over the whole ſurface of the cloth, by means of two long poles or handles, which are jointed to it at one end.

The cloth is now finiſhed, and is packed up in bales of twenty or twenty-five pieces, in order to be tranſported. The bale is firſt incloſed in paper, and then in canvas, and cloſely compreſſed by the ſcrew-preſs. Some manufacturers uſe the hydroſtatic preſſes for this purpoſe.

In conſidering the proceſſes of the woollen manufacture, as they were practiſed forty or fifty years ago, and comparing them with the preſent practices, we find great changes and improvements, but they are by no means carried to ſo great an extent as in the cotton manufacture. This is owing in a great degree to the circumſtance that the manufacture of woollen cloth was rendered very perfect, as far as the goodneſs and beauty of the cloth was concerned, long before the improved ſyſtem was begun; and there were great numbers of experienced and able workmen trained up for each proceſs, who by habit and dexterity performed their work as well as it could be done by machinery. The reduction of labour, or the ſubſtitution of ordinary hands for experienced workmen, was in this caſe all that machinery of the moſt perfect kind could effect; both theſe were advantages to the public and the manufacturer, but were ſo directly oppoſite to the inclination and intereſt of the able workmen, that we find they have made greater and more effectual oppoſition to the introduction of improvements in the woollen than in any other of our great manufactures.

At various periods attempts have been made by the workmen to ſuppreſs machinery, and many mills have been deſtroyed. In July 1802, conſiderable riots took place in Wiltſhire and Somerſetſhire, in conſequence of an attempt to ſet up the machines called gig-mills. It was contended that this was the ſame machine which was prohibited by an ancient ſtatute of Edward VI. The diſputes ran ſo high, that the attention of parliament was called to the ſubject of the laws then exiſting for the regulation of the woollen manufacture, and a committee was appointed to inveſtigate the policy of encouraging or regulating machinery. In conſequence, all the prohibitions of machinery were ſuſpended. The report of this committee contains the following remarks, ſome of which are applicable to other manufactures as well as the woollen.

The introduction of the gig-mill and other machines was oppoſed from an idea that it would throw a conſiderable number of hands out of work; and it was contended, that it was highly injurious to the quality and texture of the cloth. With reſpect to the actual effects of the gig-mill and ſhearing-frame on the cloth, the committee report that deciſive evidence has been adduced before them by merchants and manufacturers of the greateſt credit and experience, to prove that theſe machines, eſpecially the gig-mill, when carefully employed, finiſh the cloth in the moſt perfect manner, and that manufacturers reſiding in parts of the country where the gig-mill is not uſed, frequently ſend their cloths to a diſtance to be dreſſed by it.

It alſo appeared in evidence, that alarms ſimilar to the preſent had exiſted among workmen at the introduction of ſeveral of the machines which are now in general uſe. Such alarms have gradually ſubſided as prejudice died away; and the machines are now fully eſtabliſhed, without, as it appears, impairing the comforts or leſſening the numbers of workmen. The committee remark with much ſatisfaction, that in many inſtances in which it was apprehended that the introduction of particular machines would throw ſuch a number of people out of employment as to occaſion great diſtreſs, the reſult has been very different; for beſides the occupations which the attendance on ſuch machines has given riſe to, a freſh demand for labour to an immenſe extent has ariſen out of the increaſed ſale of the article, in conſequence of the cheapneſs and ſuperior quality of the manufacture.

They approve the ſyſtem of patents, by which the inventor of any new machine ſecures to himſelf the excluſive benefits of his diſcovery for fourteen years; and only, at the end of that term, they are thrown open to the public; this provides in moſt caſes againſt the too ſudden and general eſtabliſhment of any invention, by which a number of workmen might at once be thrown out of employment.

They next obſerve, that if the principles on which the uſe of theſe particular machines is objected to were once admitted, it would be impoſſible to define the limits or to foreſee the extent of their applications. If the parliament had acted on ſuch principles fifty years ago, the woollen manufacture could never have attained to near its preſent extent. The rapid and prodigious increaſe of late years in all the manufactures and commerce of this country is univerſally known, as well as the effects of that increaſe on our revenue and national ſtrength. In conſidering the immediate cauſes of that augmentation, it appears to the committee, that it is principally to be aſcribed, under the favour of Providence, to the general ſpirit of enterprize and induſtry among a free and enlightened people, left to the unreſtrained exerciſe of their talents in the employment of a vaſt capital, puſhing to the utmoſt the principle of the diviſion of labour, calling in all the reſources of ſcientific reſearch and mechanical ingenuity, and, finally, availing themſelves of all the benefits to be derived from viſiting foreign countries, not only for forming new and confirming old commercial connections, but for obtaining a perſonal knowledge of the wants, the taſte, the habits, the diſcoveries and improvements, the productions and fabrics, of other civilized nations. Thus bringing home facts and ſuggeſtions, perfecting our exiſting manufactures, and adding new ones to our domeſtic ſtock; opening, at the ſame time, new markets for the product of our manufacturing and commercial induſtry, and qualifying ourſelves for ſupplying them.

The committee declare it to be their opinion, that by theſe means alone, and above all by the effect of machinery in improving the quality and cheapening the fabrication of our various articles of export, notwithſtanding a continually accumulating weight of taxes, and with all the neceſſaries and comforts of life gradually increaſing in price, (the effects of which on the wages of labour could not but be very conſiderable,) our commerce and manufactures have alſo been increaſing in ſuch a degree as to ſurpaſs the moſt ſanguine calculations of the ableſt political writers who have ſpeculated

lated on the improvements of a future age. The exports of woollen goods at the time of this report, (1807,) amounted to fix millions of pounds official, or nine millions of real value.

It appeared alfo to be an important confideration, of which we fhould never lofe fight, that we are at this day furrounded by powerful and civilized nations, who are intent on cultivating their manufactures and pufhing their commerce; and who are more eager to become our competitors in trade, from having witneffed the aftonifhing effect of our commercial profperity. The attempts which have been made to carry our machines and implements over to foreign countries, and to tempt our artifans to fettle in thofe countries, evince the importance of machinery, under the directions of men of approved fkill, in conftructing and ufing them. It is needlefs to remark how much thefe attempts would be favoured by our throwing any obftructions in the way of enterprize and ingenuity, and the free application of capital in this country; for any machines which fhould be prohibited here would infallibly find their way into foreign nations in a very fhort time.

Among the attempts to improve the woollen manufacture, we muft not omit to notice the invention of Mr. Jofeph Booth, for fabricating woollen cloth without fpinning or weaving. This was effected by felting wool into a web by the aid of machinery, which operated mechanically upon a tiffue of carded wool, to entangle and interlace the fabrics together. The inventor took a patent for this in 1793 or 1794, but before the time for the enrolment of the fpecification of his procefs, he obtained an act of parliament, the preamble of which ftates, that on account of the great importance of the art, and the danger of its being carried abroad to the injury of the ftaple manufacture of the kingdom, parliament had determined to keep the fpecification fealed; hence we are not able to give the details of this machinery.

We find thefe expectations have not been realized; for, although the procefs has been repeatedly tried on a large fcale and in the moft complete manner, it has been abandoned. Three large mills were eftablifhed at Taunton and near Salifbury, by experienced woollen manufacturers of the weft of England; another mill was converted to the purpofe at Lewifham, in Kent; and the laft mill was erected at Merton, in Surrey, the property of James Perry, efq. We learn from this gentleman, that he was able to manufacture cloth of a fine furface, and of a very even and regular fubftance, but it was rather deficient in ftrength, for want of the threads which form the fubftance of common cloth; and in refpect to wear it was lefs durable than common cloth, as it did not long withftand brufhing; otherwife the expence of the procefs, which was not one-fourth of the common procefs, would have brought it into general wear.

There has been a great number of other projects and patents for the improvement of different branches of the woollen manufacture; but as we have already noticed moft of thofe which have come into ufe, we fhall not enumerate any more of the unfuccefsful attempts.

The machinery for manufacturing long combing-wool is defcribed in the article WORSTED.

WOOLLEN *Nets*, in *Gardening*, a kind of nets employed as a protection in the fetting of the fruit of different forts of tender trees. See WOODEN *Frames*, &c.

WOOLLEN *Rags*, in *Agriculture*. See *Woollen* RAGS.

WOOLLENS, *Bleaching of*. See BLEACHING.

WOOLLEY-WOOLLEY, in *Geography*, a town of Africa, in the kingdom of Yani.

WOOLLI, a kingdom of Africa, bounded by Walli on the W., by the Gambia on the S., by the fmall river Walli on the N.W., by Bondou on the N.E., and on the E. by the Simbani wildernefs. The country every where rifes into gentle acclivities, which are generally covered with extenfive woods, and the towns are fituated in the intermediate valleys. Each town is furrounded by a tract of cultivated land, the produce of which is thought to be fufficient for fupplying the wants of the inhabitants; the foil appeared to Mr. Park to be every where fertile, except near the tops of the ridges, where the red iron-ftone and ftunted fhrubs fufficiently marked the boundaries between fertility and barrennefs. The chief productions are, cotton, tobacco, and efculent vegetables; all which are raifed in the valleys, the rifing grounds being appropriated to different forts of corn. The capital is Madina, or Medina, fignifying in the Arabic *city*. (See MEDINA.) The inhabitants are Mandingoes, (fee MANDING,) who, like moft of the Mandingo nations, are divided into two great fects, the Mahometans, who are called Bufhreens, and the Pagans, who are denominated indifcriminately Kafirs, *i. e.* unbelievers, and Sonakies, *i. e.* men who drink ftrong liquors. The latter are the moft numerous, and the government of the country is vefted in them; for though the Bufhreens are confulted in all matters of importance, they are not allowed to take any fhare in the executive government, which refts folely in the Manfa, or fovereign, and great officers of the ftate. Of thefe, the firft in point of rank is the prefumptive heir of the crown, called the Farbonna; and next to him are the Alkaids, or provincial governors, who are more frequently ftyled Keamos. Then follow the two grand divifions of freemen and flaves, the Slatees being confidered as the principal of the former; but in all claffes great refpect is paid to the authority of aged men. Park's Travels, vol. i.

WOOLLIMA, BA, a river of Africa, called alfo *Wonda*; which fee.

WOOLLY-PASTINUM, in *Natural Hiftory*, a name given by the Eaft Indians to a fpecies of native red arfenic, or orpiment, found in that part of the world.

It is of a paler colour than the red orpiment of Germany.

WOOLMAN, JOHN, in *Biography*, a minifter of the fociety of Friends in North America, chiefly remarkable as an early and faithful advocate of the rights of the enflaved Africans, was born at Northampton, in Burlington county, Weft New-Jerfey, in the year 1720. From fome memoirs of his life left by himfelf, it appears that he had ftrong impreffions of religion in childhood, which being feconded by the care and admonition of pious parents, he arrived at manhood, after a ftruggle of fome years with youthful levities, with a decidedly religious character. An incident which befel him when a child, and which he records as a proof of the early influence of divine grace on the mind, may be mentioned here, as connected alfo with his future character, and with the firft developement of thofe tender fympathies of the heart which, under the guidance of Chriftian principle, fitted him fo eminently to efpoufe the caufe of the oppreffed negroes. Going on an errand to a neighbour's, he obferved that a robin quitted her neft at his approach, and flew about in alarm for her young ones. He ftood and threw ftones at her, till being ftruck, fhe fell down dead. "At firft," he fays, "I was pleafed with the exploit, but after a few minutes was feized with horror. I beheld her lying dead, and thought thofe young ones, for which fhe had been fo careful, muft now perifh for want of their dam to nourifh them: and after fome painful confiderations on the fubject, I climbed up the tree, took all the young birds, and killed them, fuppofing that better than to leave them to pine away,

away, and perish miserably. I then went on my errand, but for some hours could think of little else but the cruelties I had committed, and was much troubled. Thus He, whose tender mercies are over all his works, hath placed a principle in the human mind, which incites to exercise goodness towards every living creature: and this being singly attended to, people become tender-hearted and sympathising, but being frequently and totally rejected, the mind becomes shut up in a contrary disposition." Of his opinions at one-and-twenty he writes thus: "I was early convinced in mind that true religion consisted in an inward life, wherein the heart doth love and reverence God the Creator, and learns to exercise true justice and goodness, not only toward all men, but also toward the brute creatures. I found no narrowness respecting sects and opinions, but believed that sincere, upright-hearted people in every society, who truly loved God, were accepted of him."

The right of every individual, of whatever colour, who has not offended against society, to liberty and the common gifts of providence, was consequently at this time an article of John Woolman's *religious creed:* and we shall see that he soon brought himself to act in consistency with his faith. The first occasion of trial occurred while he was yet in servitude; for he had engaged himself as clerk and assistant to a shop-keeper at a place called Mount-Holly. His employer parted with a negress, and desired Woolman to write out a bill of sale for her. "The thing," says he, "was sudden, and although the thought of writing an instrument of slavery for one of my fellow-creatures felt uneasy, yet I remembered that I was hired by the year, that it was my master who directed me to do it, and that it was an elderly man, a member of our society, who bought her. So through weakness I gave way and wrote; but at the execution of it I was so afflicted in my mind, that I said before my master and the friend, that I believed slave-keeping to be a practice 'inconsistent with the Christian religion.' This in some degree abated my uneasiness; yet as often as I reflected seriously upon it, I thought I should have been clearer if I had desired to be excused from it, 'as a thing against my conscience:' for such it was." Accordingly, on the next occasion he took this second step. "A young man of our society," he proceeds, "spoke to me to write a conveyance of a slave to him, he having lately taken a negro into his house. I told him I was not easy to write it: for though many of our meeting and in other places kept slaves, I still believed the practice was not right." Other cases followed, in which being employed (as it appears for an adequate fee) to write the will of a neighbour or a friend, he uniformly refused to be accessary to their bequeathing as property the persons of his fellow-men. "Deep-rooted customs," he observes, "though wrong, are not easily altered; but it is the duty of all to be 'firm in that' which they certainly know is 'right for them.' A charitable benevolent man, well acquainted with a negro, may, I believe, under some circumstances, keep him in his family as a servant for no other motive than the negro's good. But man, as man, knows not what shall be after him, nor hath assurance that his children will attain to that perfection in wisdom and goodness necessary rightly to exercise such power," *viz.* as that of the owner over his slave. As the first-fruits of this firmness, and which no doubt were highly grateful, he relates instances in which his refusal, and the reasons he gave for it, procured the freedom in lieu of the transmission of the slaves in question.

Having been acknowledged by his friends in the capacity of a minister of the gospel, he made some journies in the exercise of his gift, which served to give him a further insight into the condition of the negroes on that continent, and further excited his attention to the then practice of the society of friends, in common with others, of holding them in bondage, and even of buying them. In the year 1746 he passed through Virginia, Maryland, and Carolina, of which he writes as follows: "Two things were remarkable to me in this journey: first, in regard to my entertainment, when I ate, drank, and lodged at free-cost with people who lived in ease on the hard labour of their slaves, I felt uneasy; and as my mind was inward to the Lord, I found, from place to place, this uneasiness return upon me at times through the whole visit. Where the masters bore a good share of the burthen, and lived frugally, so that their servants were well provided for, and their labour moderate, I felt more easy; but where they lived in a costly way, and laid heavy burthens on their slaves, my exercise (trouble of mind) was often great, and I frequently had conversation with them in private concerning it. Secondly, this trade of importing slaves from their native country being much encouraged among them, and the white people and their children so generally living without much labour, was frequently the subject of my serious thoughts. And I saw in these southern provinces so many vices and corruptions, increased by this trade and this way of life, that it appeared to me 'as a gloom over the land;' and though now many willingly run into it, yet in future the consequence will be grievous to posterity. I express it as it hath appeared to me, not once nor twice, but as a matter fixed on my mind."

It is probable that the inhabitants of the southern provinces of North America now see pretty clearly that their negro population, without consummate prudence, as well as great kindness in the management of them, are likely one day to justify these anticipations.

On his return from the above-mentioned journey, he committed to paper his sentiments on slave-keeping, and after the MS. had lain long by him, it was published, with the approbation and at the expence of his friends, who began (in Pennsylvania and the Jerseys at least) to be more generally influenced by the humane and Christian views of Woolman, Benezet, and others on this subject. It was entitled "Some Considerations on the keeping of Negroes;" and in 1762 was followed by a "Second Part," the expence of which he preferred to take upon himself, for a reason which evinces his strict regard to justice. He considered that many, who did not yet see the evil of the practice, nor approve of his writings against it, were contributors to the general fund of the society, out of which the cause was proposed to be defrayed.

Some other reflections, written in 1757, while he was on a journey among slave-holders, and recorded in his "Memoir," are forcibly descriptive of his views and feelings.

The necessary brevity of this article will permit only a general account of John Woolman's labours in the cause of humanity. From private conferences with the holders of slaves, he proceeded to public addresses to the society in their meetings for discipline: and when at length the principle of the unlawfulness to Christians of this degrading practice had been generally recognized among them, he united other members with himself in paying visits to such of the society, within his sphere of action, as required the stimulus of remonstrances to induce them to comply with the sense of their brethren on this subject. These proceedings were prosecuted through several journies; in which at one time the religious welfare in a more general sense, at another the right conduct in this particular of his fellow-members, engaged his attention. He did not live to see the completion of his wish, as it related to the society; for it was not

till

till the year 1787 that the laft flave difappeared from among them. But the near approach of this confummation was witneffed by his coadjutor, Anthony Benezet, who died in 1784, whofe fame has fpread wider than Woolman's, becaufe his opportunities were more extenfive, who lived for the caufe throughout Europe, and carried its fuccefsful plea from the narrow limits of the fociety of Friends into the world at large. Of this excellent man, whofe biography efcaped the early part of this work, it may not be too late here to record in brief,—that he was born at St. Quintin, in Picardy, of a refpectable family, in 1713; that he was carried by his father, who fled from the perfecutions which fell upon the Huguenots, to London, and there formed for mercantile purfuits; that upon removing to Philadelphia with his family in 1731, having now entered into the fociety of Friends, he devoted his life, upon principle, firft to the education of youth in ufeful knowledge and the Chriftian faith, and ultimately to the nobleft toils of humanity. But to return to our prefent fubject: in the year 1772, John Woolman, believing it his duty to pay a religious vifit to the friends in England, embarked for that purpofe at Chefter, on the Delaware, and arrived at London in time to attend their yearly meeting. After it he travelled, exercifing his miniftry among his friends, through feveral counties, as far as York. Here, at a large quarterly meeting, he once more pleaded for the negroes, endeavouring, and probably with effect, to engage the fupport of thofe prefent to the caufe of humanity: foon after which he was feized with the fmall-pox. During a fevere ftruggle with this difeafe, he manifefted great patience and humility, with a firm faith in the Redeemer: and nature finking in the conflict, he expired in peace in his fifty-fecond year.

As a preacher, we hear not of his eloquence nor of his learning, except, fays one of the refpectable friends who has favoured us with the documents of this article, "in heart-knowledge, and in the fchool of Chrift;" but in life, he was a bright example of the integrity, meeknefs, charity, and beneficence which in that fchool alone are to be acquired; and his memory for his works' fake is bleffed. Memoir of John Woolman, chiefly extracted from a Journal of his Life and Writings, London, 1815.

WOOLPER'S CREEK, in *Geography*, a river of Kentucky, which runs into the Ohio, N. lat. 38° 53'. W. long. 85° 7'.

WOOLPIT, a village of England, in the county of Suffolk; 8 miles E. of Bury St. Edmunds.

WOOLSTANTON, a village of England, in Staffordfhire; 2 miles N. of Newcaftle-under-Line.

WOOL-STAPLE, denotes a city or town where wool ufed to be fold. See STAPLE.

WOOLSTED. See WORSTED.

WOOLSTON, THOMAS, in *Biography*, an Englifh divine, was born in 1669 at Northampton, and admitted in 1685 of Sidney college, Cambridge, where he was diftinguifhed by his diligence and regularity. He was elected fellow of his college, took orders, preached with approbation, and was efteemed for his learning and piety. In his exercifes for the degree of B.D. he maintained "the exact fitnefs of the time in which Chrift was manifefted in the flefh," in a difcourfe which was well received. But his temper being naturally enthufiaftic, and perufing the works of Origen, he indulged a great fondnefs for allegorical interpretations of fcripture, which afterwards led him into a variety of fingular and extravagant opinions. He began in 1705 with "The old Apology for the Truth of the Chriftian Religion againft the Jews and Gentiles revived," maintaining that all the actions of Mofes were typical of Chrift, and of his church; and the book was iffued from the univerfity prefs. Woolfton remained in college till the year 1720, when he went to London, and publifhed a Latin differtation concerning the fuppofed epiftle of Pontius Pilate to Tiberius, relative to Jefus Chrift. In the fame year he alfo publifhed two Latin epiftles, addreffed to Whitby, Waterland, Whifton, and others: "Circa Fidem vere Orthodoxam et Scripturarum Interpretationem," defending Origen's allegorical interpretation of fcripture. His deviation from the eftablifhed faith was more apparent in his inquiry, "Whether the people called Quakers do not the neareft of any other fect in religion refemble the primitive Chriftians in principles and practice?" Blending farcafm with argument, he now feemed to indulge a fpirit of animofity againft the clergy. Declining at the fame time to refide at college, he was deprived of his fellowfhip in 1721. In his "Four Free Gifts to the Clergy," he denominated them "hireling priefts," and "minifters of the letter." Although he might be fufpected, he was not yet chargeable with hiftorical incredulity; for in 1726 he publifhed "A Defence of the Miracle of the Thundering Legion againft Mr. Moyle." At length he engaged in the controverfy between Anthony Collins and his opponents, and publifhed "The Moderator between an Infidel and an Apoftate," and "Two Supplements," in which he not only contended for myftical interpretations of the miracles of Chrift, but maintained that they were never actually wrought. Confidered as an avowed enemy to the Chriftian religion, a profecution was inftituted againft him by the attorney-general, but ftayed by the interpofition of Whifton, and fome other advocates of toleration. Notwithftanding this lenity, he proceeded in publifhing "Six Difcourfes on the Miracles," and two "Defences of the Difcourfes," in which, blending ridicule and buffoonery with argument, he maintained his offenfive opinions. This pertinacity and rudenefs prejudiced believers in the divine miffion of Chrift againft him; replies iffued from the prefs; but as he again became amenable to the law, he was tried at Guildhall before lord chief juftice Raymond, when, after many arguments for and againft him, he was found guilty, and fentenced to a year's imprifonment, and a fine of 100*l*. Unable to pay his fine, he refided within the rules of the King's Bench, and fubfifted by an annual allowance granted to him by his brother, and the contributions of fome learned and liberal friends, who vindicated his intentions, whilft they difapproved his enthufiafm and fanaticifm. Among thefe were fome, and particularly Dr. S. Clarke, who condemned every fpecies or femblance of religious perfecution, and who endeavoured to procure his releafe; but they could not prevail upon him to ftipulate that he would not perfevere in publifhing his peculiar opinions. But death gave him that releafe, which his friends could not obtain for him; as he was carried off by an epidemic difeafe, within four days after his feizure, in January 1732–3. Not long before he expired, he faid, "This is a ftruggle which all men muft go through, and which I bear, not only patiently, but willingly." His moral character is faid to have been unimpeachable, and his head was thought to have been more difordered than his heart. Biog. Brit.

WOOLWICH, in *Geography*, a market-town and parifh in the hundred of Blackheath, lathe of Sutton-at-Hone, and county of Kent, England, is fituated on the S. bank of the Thames, 8 miles E. from London. The etymology of Woolwich, a name very varioufly written at different periods, is uncertain: according to Hafted, in his "Hiftory of Kent," one of the ancient names, Hulviz, fignified the "dwelling on the creek." The parifh comprehends about

about 700 acres, of which above one-half, however, lie on the oppofite bank of the Thames, in the county of Effex, and confifts of marfh-land, on which ftood formerly a few houfes, and a chapel of eafe. The manor of Woolwich is fubordinate to the royal manor of Eltham. The town confifts chiefly of one narrow irregular ftreet, confined between the rifing land and the river; but feveral other ftreets, rows, and lanes, are connected with it. The church, a fpacious brick building, confifts of a nave, chancel, and aifles. It is fituated on an eminence overlooking the town and the dock-yard, and was completed in 1740. Befides this building, Woolwich contains feveral different diffenting meeting-houfes. The principal charitable eftablifhments are an alms-houfe and two fchools. Woolwich was originally but a fmall place, inhabited by fifhermen, and is indebted for its importance to the eftablifhment of a royal dock there in the reign of Henry VIII. Since that time, it has gradually arrived at its prefent augmented ftate; but particularly fince the eftablifhment there of the head-quarters of the artillery and the royal arfenal; by which means the population within the laft hundred years has increafed fix-fold. The precife period of the eftablifhment of the dock-yard is uncertain: it appears, however, that the Harry Grace de Dieu, of 1000 tons, was built there in 1512. This celebrated fhip is ftated to have been in length 128 feet, and in breadth 48 feet: fhe had three flufh decks, a forecaftle, half-deck, quarter-deck, and round-houfe, and carried 176 pieces of ordnance: fhe had eleven anchors, the largeft of which weighed 4400lbs. In its prefent enlarged ftate, the yard extends about five furlongs along the river by one furlong in breadth. It comprehends two dry docks, feveral flips, three maft-ponds, a fmith's-fhop and forges for making anchors, a model-loft, ftore-houfes, fheds, dwellings for various officers, and all other requifite buildings. The whole is under the immediate infpection of the navy board, but conducted by feveral refident officers. The number of artificers and labourers employed during peace is about 1500; but in war-time it rifes towards 4000. Between the dock-yard and the royal arfenal, formerly called the Warren, is the rope-walk, 400 yards in length. The military and civil branches of the office of ordnance have been eftablifhed at Woolwich fince the acceffion of George I. In the time of peace, this arfenal is the great repofitory of naval ordnance, where the guns of moft of the fhips of war are laid up there in order. The repofitory contains alfo an extenfive collection of military machines and models. The arfenal, comprehending about fixty acres of ground, contains, with other buildings, the foundery, and the late military academy, which was erected by fir John Vanbrugh. The foundery is provided with feveral furnaces, the largeft of which will melt about feventeen tons of metal at once. It contains alfo machinery for boring brafs cannon, as they are improperly called, for they are compofed of copper and tin inftead of zinc. In the adjoining laboratory, bombs, carcafes, cartridges, &c. for the navy and army, are prepared. The number of perfons employed in the arfenal during war is about 300, exclufive of the convicts belonging to the hulks or prifon-fhips lying in the river. The military academy, although founded in 1719, was not finally arranged till 1741, and has been fortunate in poffeffing, in the mathematical chairs, the eminent profeffors Derham, Simpfon, and Hutton. Befides the mathematical profeffors, here are mafters in chemiftry, fortification, arithmetic, French, drawing, fencing, &c. The number of pupils or cadets, deftined for the two corps of artillery and royal engineers, has been lately about 300. To provide neceffary accommodation, with offices, &c. a new edifice was conftructed and opened in 1806, about a mile S. from the town, on the upper part of the common. It is built in the caftellated form, from defigns by Mr. James Wyatt. The principal front facing the N. extends above 200 yards. The expence of the ftructure is eftimated at not lefs than 150,000*l.* The eftablifhment is appropriated to the fenior clafs of the cadets, the junior being for the prefent fixed at Black-Water in Hampfhire. Between this new academy and the town are extenfive ranges of barracks, &c. for the royal artillery, horfe and foot, which has increafed during the late war beyond all former example.

The population of Woolwich, in the return of 1800, was ftated at 9826, exclufive of the military, inhabiting 1362 houfes; but the number was probably under-rated; for in the return of 1811, the inhabitants are ftated to be 17,054, and the houfes 2487. Woolwich-common unites with the extenfive plain of Blackheath on the S., which gives name to the hundred. At its eaftern extremity rifes Shooter's-hill, which commands extenfive and interefting profpects in all directions. The view from it of London, the Thames, and the fhipping, is peculiarly impreffive. Over this hill paffed the great Roman road from the E. coaft of Kent, through *Durovernum*, now Canterbury, and *Durobriva*, Rochefter, to London. Its courfe is nearly purfued by the prefent road from Shooter's-hill, for eight miles, to a place beyond Dartford.—Beauties of England, Kent, by E. W. Brayley, 8vo. 1806.

Woolwich, a townfhip of New Jerfey, in the county of Gloucefter, with 3063 inhabitants; 10 miles S.E. of Philadelphia.—Alfo, a townfhip of the province of Maine, containing 1050 inhabitants, on the E. fide of the Kennebeck; 16 miles N.E. of Brunfwick.

WOOL-WINDERS are perfons employed in winding up fleeces or wool into bundles to be packed, and fold by weight. Perfons winding and felling deceitful wool, fhall forfeit for every fleece 6*d.* Thefe are fworn to do it truly between the owner and the merchant. 8 Hen. VI. cap. 22. 23 Hen. VIII. cap. 17.

WOORLA, in *Geography*, a town of Hindooftan, in Vifiapour; 16 miles N. of Merritch.

WOOTAMALLY, a town of Hindooftan, in Madura; 15 miles S.W. of Coilpetta.

WOOTTON, John, in *Biography*, an eminent, though not very able, painter of landfcape and animals, who flourifhed in England about 1720. He was a pupil of John Wyck, and was much employed in the portraits of horfes and dogs, and in painting the fports of the field, particularly fox-hunting; upon which fubject there are feven pictures of his engraved by Canot. Once at leaft he attempted (but he did not frequently repeat the attempt) to pourtray a battle, and his fubject was that of Culloden at the time of the rout of the rebel army. It has been engraved by Baron, though it is but an indifferent performance. He died in 1765. He had been fuccefsful in the purfuit of his art, for he was enabled by its proceeds to build a houfe in Cavendifh-fquare, where he lived, and had painted it with tafte, according to Walpole, who praifes his works ridiculoufly. His pieces, he fays, were high, forty guineas for a fingle horfe the fize of life, and twenty if fmaller.

WOOTTON-BASSET, in *Geography*, a borough and market-town of Wiltfhire, England, is fituated near the northern extremity of the county, at the diftance of 36 miles N. by W. from Salifbury, and 89 miles W. from London. It confifts chiefly of one principal ftreet, about half a mile in length. The houfes are moftly conftructed of brick with thatched roofs. Two reprefentatives have been regularly deputed from this town to ferve in parliament

ment fince the 25th of the reign of Henry VI. They are elected by the inhabitant houfeholders legally fettled there, and paying fcot and lot. The corporation is compofed of a mayor, two aldermen, and twelve burgeffes. The market-day is Tuefday, weekly; and there are alfo fix fairs annually. In the centre of the town are a market-houfe and fhambles; and near this is the town-hall, in which a machine, called a "cucking or ducking-ftool," formerly ufed for the punifhment of female fcolds, was lately preferved. The church is an old building dedicated to St. Bartholomew, but it is not remarkable for beauty of architecture, nor does it contain any monument or infcription worthy of notice.

According to the population returns of 1811, the borough and parifh contained 321 houfes, and 1390 inhabitants, who formerly carried on a confiderable trade in broad-cloths; but there is now no ftaple manufactory of any fort, though fome attempts have been lately made to introduce the bufinefs of rope-making and fack-making. In this parifh are two free-fchools and a Sunday fchool. The former were founded and endowed by the earl of Clarendon, one of them for twelve boys, and the other for twelve girls.

At the time of the Conqueft, this place was called fimply 'Wodeton.' It was then the property of Milo Crifpin; but in lefs than a century afterwards it was poffeffed by the Baffets of Wycomb, a branch of the noble family of the Baffets of Drayton. The prefent proprietor is the earl of Clarendon. The ancient manor-houfe, which ftands on the fummit of a confiderable eminence, is now converted into a farm-houfe, whence the eye furveys a very extenfive profpect into Somerfetfhire, Gloucefterfhire, &c. A variety of curious conical ftones, refembling fmall fir-apples, have been dug up in different fpots around the town, imbedded in a fort of blue marly ftone.

Liddiard-Tregooze, or Lydiard-Tregofe, is a village and parifh, fituated at the diftance of three miles north-eaft from Wootton-Baffet. According to the population returns of 1811, the parifh contains 95 houfes, and 613 inhabitants.

The church, an ancient ftructure, is divided into a nave, two fide aifles, and a chancel, with a fquare tower at the weft end, furmounted by an open baluftrade and angular pinnacles. The church contains feveral interefting monuments of the St. John family; alfo a very curious genealogical table with arms, &c.

Adjoining to the church is Liddiard-park, the feat of lord Bolingbroke. The attached grounds are extenfive, and contain many large clumps of trees, among which are a great number of old oaks.—Beauties of England and Wales, Wiltfhire, by J. Britton, 1815.

WOOTZ, in *Metallurgy*, a metal extracted from an ore of iron in the Eaft Indies, the nature of which is not known at prefent in Europe. Wootz is highly efteemed by the natives of India, and applied to various purpofes in the arts.

Dr. Scott gave the following account of its properties, in a letter to the prefident of Bombay:—"Wootz admits of a harder temper than any thing known in that part of India. It is employed for covering that part of gun-locks againft which the flint ftrikes. It is ufed for cutting iron on a lathe, for cutting ftones, and for chifels; alfo for making files and faws, and for every purpofe where exceffive hardnefs is neceffary: it cannot, however, bear any thing beyond a flight red heat, which makes it work very tedioufly in the hands of the fmith. It has a ftill greater inconvenience or defect, that of not being welded with iron or fteel, to which, therefore, it is only joined by fcrews and other contrivances." Dr. Scott obferves farther, that when wootz is heated above a light red heat, part of the mafs feems to run, and the whole is loft, as if it confifted of metals of different degrees of fufibility. The working with wootz is fo difficult, that it is a feparate art from that of forging iron. The magnetical power can only be imperfectly communicated to it. Specimens of wootz fent from India were examined by Dr. George Pearfon, who ftates in the Phil. Tranf. vol. xcv., that they were in the form of round cakes, about five inches in diameter and one thick, each of which weighed more than two pounds. The cake had almoft been cut through, fo as to divide it into two nearly equal parts. It was externally of a dull black colour, the furface was fmooth, the cut part was alfo fmooth, and, excepting a few fmall holes, the texture appeared to be uniform. No indentation could be made in it by blows with a heavy hammer, nor was it broken by blows that might have broken a like piece of fteel. Fire was elicited on collifion with flint. It poffeffed the hardnefs of fome kinds of crude iron, but did not effectually refift the file, like highly tempered fteel, and many kinds of crude iron. It admitted a polifh equal to the beft fteel. The wootz-filings were attracted by the magnet like common iron-filings. When broken, it exhibited the fracture and colour of a rather open-grained fteel. It was taftelefs and inodorous. Its fpecific gravity in different ftates, as given by Dr. Pearfon, ranges from 7.2 to about 7.7, which is nearly the fame as fteel. From the properties of this fubftance, Dr. Pearfon concludes, that wootz approaches nearer to the ftate of fteel than raw iron, although it poffeffes fome of the properties of this laft fubftance. It is not to be referred to that kind of fteel in which there is either an excefs or deficiency of carbon, but it contains fomething befides carbon and iron, otherwife it would be common fteel. The folution in nitrous and dilute fulphuric acid contained only oxyd of iron, and the refidue of carbonaceous matter, as in common fteel. Hence, fays Dr. Pearfon, it is obvious to fufpect, that wootz contains oxygen, either equally united with every part of the mafs, or united with a portion of iron to compofe oxyd, which is diffufed through the mafs. To this circumftance, Dr. Pearfon feems inclined to attribute the fmaller quantity of hydrogen gas given out during folution, than is afforded by common fteel, and to account for its partial fufibility and difficult malleability, and may be the reafon of its taking a fine edge or polifh. The oxyd is not perhaps equally diffufed; hence the wootz is not quite uniform in its texture and hardnefs until it has been remelted. The proportion of oxygen in wootz, fays Dr. Pearfon, muft, however, be very fmall, otherwife it would not poffefs fo much ftrength, and break with fo much difficulty. The oozing out of matter when fufed is analogous to what appears on refining raw iron. Although no account is given by Dr. Scott of the procefs for making wootz, we may without much rifk conclude, that it is made directly from the ore, and confequently that it has never been in the ftate of wrought iron, for the cake is evidently a mafs which has been fufed, and appears to have been cut almoft quite through while white hot at the place where wootz is manufactured. The particular ufes to which wootz may be applied are to be inferred from the preceding account of its properties and compofition; and may be proved by an extenfive trial of it in all the arts which require iron. See Phil. Tranf. vol. xcv.

WOPANKEN, in *Geography*, a town of Pruffia, in the province of Bartenland; 2 miles E. of Bartenftein.

WOPELBACH, a river of Ofnabruck, which runs into the Dalcke, 2 miles N. of Weidenbruck.

WORADA, a country of Africa, of an oval form, about 90 miles in circumference, S. of Konkadoo.

WORANY, a town of Lithuania; 28 miles S. of Troki.

WORBIS, or STADT WORBIS, a town of Weftphalia, in the territory of Eichsfeld, on the Wipper; 8 miles S.S.E. of Duderftadt.

WORBIS, *Breiten*, a town of Weftphalia, in the territory of Eichsfeld; 9 miles S.E. of Duderftadt.

WORBIS, *Kirch*, a town of Weftphalia, in the territory of Eichsfeld; 8 miles S.S.E. of Duderftadt.

WORBITZ, a town of Bohemia, in the circle of Czaflau; 10 miles S. of Czaflau.

WORBITZ *See*, a lake of the Ucker Mark of Brandenburg, near Joachimfthal; 28 miles N.N.E. of Berlin.

WORBSTADT, a town of France, in the department of Mont Tonnerre; 10 miles S.S.W. of Mentz.

WORCESTER, the capital city of a county of its own name, in the W. of England, fituated in N. lat. 52° 10′, and W. long. 2° 00′; diftant 26 miles N. from Gloucefter, 27 S.W. from Birmingham, 30 E. by N. from Hereford, and 111 W.N.W. from London. The inhabitants in 1811 were, according to the returns made to parliament, 5953 males, and 7861 females, in all 13,814, and the houfes 2527.

Hiftorical Events.—Worcefter is a place of high antiquity, as implied by the latter part of the name, indicating that the original town occupied the pofition of a Roman ftation: its proper name under thofe people, however, has not yet been afcertained. Camden indeed conceives it to be the *Branonium* of Antoninus' Itinerary, the fame with the *Branogenium* of Ptolemy; but that town is placed by Horfley at Ludlow, more to the N.W., on the S. border of Shropfhire. Nennius, who wrote in the beginning of the 7th century, points out Worcefter by the Britifh names *Caer-Guorangon* and *Caer-Guorcon*. By the Saxons it was called *Weogare-ceafter*, or *Wegeorna-ceafter*, from which came *Wigornia*, the Latin name ftill in ufe. In the Domefday-book it is called *Wireceftre*. The diocefe of Worcefter was founded by Ethelred, king of Mercia, about 680, the firft bifhop nominated being Tatfrith; but dying before confecration, the firft who filled the epifcopal chair was Bofel, a learned man from the celebrated monaftery of St. Hilda, at Whitby in Yorkfhire. St. Egwin, the third bifhop, who was appointed in 693, was the founder of the abbey at Evefham. Milred was nominated in 744. The 17th prelate was the famous St. Dunftan, who was appointed in 957. St. Wulftan II., appointed in 1062, was the founder of the prefent cathedral. Adam de Orleton, bifhop in 1327, is fuppofed to have prompted the murder of Edward II. by the equivocal anfwer he gave when confulted on the project: "*Edwardum occidere nolite timere bonum eft.*" The 69th bifhop, nominated to Worcefter in 1521, was the celebrated Julius de Medicis, a cardinal, and afterwards pope Clement VII. His fucceffor, Jerome de Ghinucci, alfo an Italian, was deprived at the Reformation, and, in 1535, was fucceeded by Hugh Latimer, who fuffered for his Proteftant profeffion, under queen Mary, in 1555. John Prideaux, the 84th prelate, appointed in 1641, was difmiffed during the interregnum, his bifhopric fequeftered, and himfelf allowed four fhillings and fixpence *per* week for his maintenance. The eminent fcholar Stillingfleet filled the fee from 1689 to 1699. In 1717, the fee was filled by John Hough. (See his biographical article.) The learned bifhop Hurd, appointed in 1781, was fucceeded in 1799 by the prefent prelate, bifhop Cornwall. The revenues of the fee were, in 1699, fixed at 1302*l.* 15*s.* 4½*d.*; but now fuppofed to exceed 3000*l.* The fee has poffeffed one pope, four faints, feven high-treafurers of England, eleven archbifhops, befides chancellors of the kingdom, and other great officers of the ftate. Few places, perhaps, have fuffered more than Worcefter by the inteftine broils of the country, and by cafual difafters. Ruined by the Danes about the year 894, it was rebuilt by Ethelred and Ethelfleda; but the inhabitants refufing to pay the tax called danegelt, the city was again laid wafte by Hardicanute. Again reftored, it fuffered feverely during the conteft between king Stephen and the emprefs Maud, as well as by a fire, from which the walls of the cathedral alone were preferved. Taking the part of Lewis, the dauphin of France, againft king John, the king's troops exercifed every tyrannical feverity on the inhabitants; the church was plundered, and a heavy fum exacted from the clergy. John was neverthelefs interred in the cathedral in 1216. It was in Worcefter that, previoufly to the battle of Evefham, young Edward raifed the ftandard of loyalty for his father, Henry III. After the acceffion of Henry VII. feveral citizens were beheaded, and a fine of 500 marks was levied on the city. In 1642 Worcefter witneffed the fanguinary conteft which terminated fo fatally for the affairs of Charles I. (See CHARLES.) In 1646, the city furrendered by capitulation to the parliament's army, having been the firft city in England to declare for the crown, and the laft which held out in its defence. In 1651 happened the fecond battle of Worcefter under Charles II.; a battle which decided the deftructive and vindictive controverfy between the royalifts and the parliamentary party, by which the latter obtained a complete afcendancy; and the king himfelf efcaped with difficulty out of the country. To preferve the memory of this fuccefs, "the lord-general Cromwell, on the 18th of September 1651," fays Leach, in his Diurnal, "with many officers of the army, was at Woollidge, at the launching of a gallant new frigot of the ftates, carrying three-fcore peeces of ordnance, and called her name Worcefter."

Prefent State.—Worcefter is diftinguifhed among the provincial towns of England for its refemblance, in various refpects, to the metropolis. It is defcribed to be well built, well paved, and well lighted. It confifts principally of one great ftreet running from N. to S., and terminating at the cathedral; alfo thirteen other collateral ftreets, befides lanes of inferior dimenfions. The circuit of the city exceeds three miles and a half. The Severn, bathing the weftern fide, and carrying veffels of confiderable burthen, is of great utility in facilitating the commerce to and from, as well as the requifite fupplies of the city. On it, paffage-boats fail up as far as Shrewfbury, and down to Gloucefter and Briftol. The buildings now extend beyond the ancient limits, which may, however, ftill be traced; the old wall, according to a plan made before the civil wars, was in extent 11,650 paces; but this wall, after the laft battle of Worcefter, was almoft wholly deftroyed. The caftle was erected by Urfo of Abitoth about 1088. The area, now called the College-green, was, in the Norman times, the outer ward of that caftle, behind which to the S. was the inner ward, or fortrefs itfelf. A gaol for the retention of the prifoners of the county is all that now remains of the caftle, on the fpot where the kings of England formerly kept their court. A fteep artificial mount, on which probably ftood the keep of the fortrefs, is a prominent object; the furrounding ditch and rampart may alfo be eafily traced.

Cathedral.—The original cathedral of Worcefter was founded in 680; but in 969 its revenues were transferred to to the monaſtery of St. Mary, an eſtabliſhment of the beginning of the eighth century. The church of this monaſtery being unſuitable to its novel application, another cathedral was erected and conſecrated by St. Oſwald, the biſhop, in 983. Being ruined by Hardicanute in 1041, the foundation of a new cathedral was laid in 1084, by biſhop Wulſtan II.; and in 1089 he finiſhed it, together with the monaſtery, and called the ſame *Monaſterium St. Mariæ in Cryptis*. The original plan of this church ſeems to have been a ſimple croſs, the entrance being at the weſt end of the preſent choir, which occupies the place of the ancient nave. This ancient ſtructure had probably a central or principal tower; as it is recorded that the *new* tower fell down in 1175, and two ſmaller ones were deſtroyed by a ſtorm in 1222. The antiquity of this part of the edifice is particularly apparent from the crypt or undercroft, which extends under the choir and its aiſles. This is a curious and intereſting part of the fabric. Twice ſeverely injured by fire, in 1113 and in 1202, the cathedral was re-conſecrated in 1218, by biſhop Silveſter, in the preſence of Henry III. and his court. Six years afterwards the foundation of an additional work, the preſent nave, was laid by biſhop William de Bloys, in which is diſplayed the ſkill of the architect, in adapting the new parts to the former ſtructure. The ſtone-vaulting of the edifice was begun by biſhop Cobham in 1327, and the whole was finiſhed in 1357. The beautiful central tower was conſtructed in 1374. Worceſter cathedral is in the exterior extremely plain, and its attractions conſiſt principally in the height, ſpace, and the lightneſs of its architecture, to which the lofty pinnacles, riſing from every termination of the building, as well as from the tower, not a little contribute. The external length, including buttreſſes, is 426 feet; the internal, 394: that of the nave, from the front to the weſt tranſept, 180; of the choir, including the organ-loft, 120; of the Lady-chapel, 60; of the weſt croſs or tranſept, 128; and of the eaſt tranſept, 120 feet. The nave is ſeparated from the aiſles by ten cluſtered columns on each ſide, ſupporting three ranges of pointed arches; an arrangement alſo carried on through the choir. A ſtone pulpit, originally placed near the weſt end of the nave, is now fixed at the north ſide of the choir. It is of an octagonal form, ornamented with emblematic ſculpture, and ſurmounted by a canopy.

Worceſter cathedral has, like many other edifices of the ſame nature, been a great ſufferer by the lapſe of time, and by the various modes of repair adopted at different periods. It now ſcarcely contains one arris or moulding, as originally conſtructed. Roman cornices now occupy the place of battlements; buttreſſes are pannelled in various heterogeneous ways; pinnacles have been reſtored after the Grecian ſchool; windows formed without ramifications or cuſps, and filled with modern ſtained glaſs, deſtitute of ſubject or deſign; Roman arches reſting on entablatures, to ſupport or ſtrengthen the tranſepts; Roman ſquares with leaves, inſtead of proper baſes to regular cluſtered pillars. Indeed this edifice affords a curious, but not a very pleaſing, diſplay of heterogeneous parts and ſtyles.

Of the numerous monuments contained in the cathedral, a few only can be noticed in this work. Between the pulpit and the communion-table, in the midſt of the choir, is placed the altar-tomb of king John, who died in 1216. On it is extended his effigy. The inſcription, "Johannes Rex Angliæ," is now almoſt illegible. The figure, as large as life, has in the right-hand a ſceptre, and in the left a ſword, with its point in the mouth of a lion couchant at the feet. On each ſide, on a level with the pavement, are ſmall figures of biſhops Oſwald and Wulſtan. It had long been imagined that this monument was merely an honorary cenotaph, while the body of John really lay in the Lady-chapel; but by an inveſtigation in 1797, the contrary was aſcertained. Removing the effigy and ſtone on which it reſted, the interior of the monument was laid open. Between two brick walls, and under ſome elm boards, lay a ſtone coffin containing the royal corpſe. The body had evidently been deranged at ſome former period; but many of the parts were very perfect. Inſtead of the crown, however, as ſhewn in the effigy, the head had been inveſted with the hood of a monk's cowl. The body had been enveloped in an embroidered robe, ſeemingly of crimſon damaſk. The coffin reſted on the pavement of the choir, and the original cover was the ſtone on which the effigy is ſculptured. On the right-hand of the communion-table, occupying one of the arcades between the choir and the ſouth aiſle, ſtands the celebrated monumental chapel or chantry of Arthur, eldeſt ſon of Henry VII., and elder brother of Henry VIII. This chapel, of an oblong form, is richly ornamented on the north, weſt, and ſouth ſides, by open ſcreen-work; the pillars adorned with a number of ſmall ſtatues, with ſhields, roſes, and other figures emblematic of the houſes of York and Lancaſter, whoſe contending claims to the Engliſh throne were united in that young prince, who died in 1502, in the 17th year of his age. Againſt the eaſt end was placed an altar, behind which was a wall ornamented with five figures; in the centre the Saviour, on the right-hand two kings in their robes, and on the left another ſimilar king, and a warrior in armour. Over the ſtatues are richly-wrought canopies. To preſerve thoſe figures from deſtruction, they had been covered over with plaſter, probably in the reign of Elizabeth, and remained thus unknown until November 1788, when the plaſter being removed, they were once more laid open to view. The tomb of prince Arthur is of marble, with the arms of England and France quartered, painted on the ſides; round the edge of the cover is an inſcription in Engliſh.

Worceſter cathedral contains alſo the monument of the celebrated judge Littleton, the father of Engliſh law, a juſtice of the common pleas under Edward IV., who died in 1481. Of more modern ſepulchral monuments it will be ſufficient to mention thoſe of biſhops Hough, Maddox, and Johnſon, not only for the eminent names they commemorate, but as diſtinguiſhed examples of modern ſculpture. Attached to the ſouth ſide of the nave of the church is the ancient cloiſter, a ſquare of about 120 feet, on the eaſt ſide of which is the chapter-houſe, a decagon of 58 feet in diameter, and 45 in height, the roof of which is ſupported by a central column: it now ſerves as a library, as well as a council-room, and contains a valuable collection of books, and of manuſcripts, chiefly relating to the canon law. Adjoining to the ſouth ſide of the cloiſter is the ancient refectory of the monaſtery attached to the cathedral, called the college-hall, a lofty and ſpacious room, 120 feet long by 38 broad, now kept as the king's ſchool. Here are alſo held the triennial muſical meetings of the three choirs of Worceſter, Hereford, and Glouceſter, for the benefit of the widows and orphans of the clergy of their reſpective counties. This ſchool was founded by Henry VIII. for forty ſcholars, who are prepared for the univerſity, and inſtructed in various branches of modern education. A little to the eaſtward of the chapter-houſe ſtands the audit-hall, anciently called the Gueſten-hall, built in 1320, for the entertainment of ſtrangers reſorting to the monaſtery and cathedral. It is ſtill the ſcene of hoſpitality during the annual audits of the chapter of the cathedral. At the back of the feventh prebendal houfe, which formerly belonged to the kitchener or cook of the monaftery, are the remains of the great kitchen, a fpacious octagonal apartment, 34 feet in diameter.

Other places of worfhip belonging to the eftablifhment in Worcefter are, the churches of St. Peter the Great, St. Michael, St. Alban, St. Helen, St. Andrew, St. Clement, St. John Baptift, All Saints, St. Swithun, St. Martin, St. Nicholas, and Claines. Of thefe buildings, fome preferve their ancient appearance. St. Andrew's church is diftinguifhed by a fquare tower, 90 feet high, fupporting an octagonal fpire, in height 155 feet 6 inches; the whole height being 245 feet 6 inches. The church and tower are fuppofed to have been erected in the eleventh century, but the fpire was not added till 1751. Among the various monaftic inftitutions of Worcefter was that remarkable one, now called the *Commandery*, eftablifhed for the maintenance of two chaplains, five poor men, and two poor women, founded by St. Wulftan, who died in 1097: it became, after the diffolution, a part of the endowment of Chrift-church in Oxford. Commanderies were, among the knights-hofpitallers of Jerufalem, the fame with the preceptories among the knights-templars; being focieties placed on the country eftates of the order, under the controul of a commander, but accountable to the grand prior or mafter in London. Part of the ancient buildings ftill exift; but the whole, now in the poffeffion of a private individual, has of late years undergone great alteration.

Though containing fo many parifh-churches in proportion to the population, Worcefter is not deficient in the number of chapels for various claffes of diffenters. Among thefe, are reckoned Anabaptifts, Independents, Methodifts, Prefbyterians, Quakers, and Roman Catholics.

On the fouth fide of the cathedral and cloifter is an open fpace, called the College-green, on the eaft fide of which is a gate, known by the name of Edgar's tower, having on the outer front the ftatues of that king and his two queens, Elfleda and Elfrida. Antiquarian curiofity has been much excited by characters once exifting on this tower, fuppofed to indicate a date much older than the received introduction of our prefent numerical figures into this part of the world. But the characters were probably mifunderftood; nor is the tower itfelf believed to be of the age of Edgar, who died in 975.

Northward from the cathedral, on the rifing bank of the Severn, is the bifhop's palace, originally furrounded with embattled walls in 1270, but brought into its prefent ftate by bifhop Stillingfleet and fucceeding prelates. The weft fide ftill retains much of the antique architecture.

Public Buildings.—The chief of thefe is the guildhall, fituated on the weft fide of the High-ftreet, near the market-place. It is a handfome edifice of two fpacious ftories, finifhed in 1723: the lower part is in one room, 110 feet 6 inches long, by 25 feet 6 inches broad, and 21 feet high, in which are held the feveral courts of juftice for the city and the county. The council-chamber is 109 feet long, by 26 broad, and 15 feet 8 inches high. The bridge over the Severn, in length between the abutments 270 feet, and in breadth 25, is an elegant ftone ftructure of 5 femicircular arches, opened in 1781. The centre arch is in fpan 41 feet, but the other arches gradually diminifh in width. Connected with the bridge a new ftreet has been opened, leading into the middle of the city, and the new roads from the weftward, the embankments, and quays along both fides of the river, are at once ornamental and ufeful.

Charitable Inftitutions.—The chief of thefe is the houfe of induftry, completed in 1794, a handfome building on the eaft fide of the city, advantageoufly fituated on an eminence, and calculated to accommodate 150 perfons belonging to the different parifhes of the city. The infirmary, fituated in an airy pofition, overlooking the race-ground, the river, and the north-weft parts of the county, was commenced in 1767: it receives about 58 patients on an average annually. A number of hofpitals and alms-houfes, fome of ancient foundation, provide fupport for age, and education for youth. A free-fchool on the Lancafterian plan was eftablifhed fome years ago. The old county-gaol is fituated in the caftle-yard; but a new one has been lately erected in the neighbourhood of the infirmary, on the Howardian plan. The city-gaol is an ancient building in a crowded fituation, having been originally a Francifcan convent, founded in the 13th century, but granted to the city at the diffolution.

Public Amufements.—Worcefter has long maintained its claim to be one of the moft fafhionable cities in the weftern parts of the kingdom: it is confequently the winter-refidence of a number of confiderable families from the furrounding counties of England and Wales. The theatre, affemblies, concerts, races, the various public walks, clubs, the public library, &c. render Worcefter a bufy, gay, and much-frequented city.

Municipal Government.—The city was incorporated by Henry I., but the firft charter was granted in the 45th year of Henry III. In 1621, the 19th year of James I., a mayor was eftablifhed. The corporation now confifts of a mayor, fix aldermen, 24 common-council-men, and 48 affiftants, by which laft two bodies the magiftrates are chofen. But the right of electing the members for parliament extends to upwards of 2000 citizens, the fheriff being the returning officer. Worcefter fent two reprefentatives to parliament in the 23d year of Edward I. Florence of Worcefter, the author of the Chronicon, a general hiftory of the world down to 1118, when he died, was a monk of the cathedral of this city. William of Worcefter was educated in Oxford in 1434, and drew up his "Polyandria Oxonienfis," a hiftory of the learned men bred in that univerfity. His Annals, at the end of the "Black Book" of the exchequer, contain notes on the affairs of his own times. The famous empyric and myftic philofopher, Edward Kelly, was born in Worcefter towards the middle of the 16th century. The relation of the impoftures of this perfon and his affociate Dr. Dee, furnifhed by Lilly, prefent a humiliating picture of the human mind and underftanding in thofe days, on the continent as well as in England. Worcefter produced, in 1650, the eminent lawyer lord Somers, who, by his knowledge and eloquence, defended the caufe of liberty and juftice in the latter part of the reign of Charles II., when but few warm and able advocates were found on their fide in Weftminfter-hall. See SOMERS, *Lord*.

Worcefter has long been rendered very interefting, from the circumftance of the *Royal Porcelain Works* being eftablifhed within its walls. It is, on our part, a moft pleafing duty, not only to trace its rife and progrefs, but to hold up its elegant and highly-finifhed productions to the attention of the liberal and fcientific. A very material difference exifts between this eftablifhment, and others of a fimilar kind on the continent; as the improvements made by expenfive experiments are *here* effected at the fole charge of the proprietors, while the *moft famed* manufactories on the continent are fupported and carried on at the coft of the government of the countries to which they belong. The Worcefter porcelain works were founded in the year 1751, by Dr. Wall and a company of proprietors, compofed of many gentlemen of fortune and confideration in the city and county; who continued to carry on the concern under thofe adverfe circumto the monaftery of St. Mary, an eftablifhment of the beginning of the eighth century. The church of this monaftery being unfuitable to its novel application, another cathedral was erected and confecrated by St. Ofwald, the bifhop, in 983. Being ruined by Hardicanute in 1041, the foundation of a new cathedral was laid in 1084, by bifhop Wulftan II.; and in 1089 he finifhed it, together with the monaftery, and called the fame *Monafterium St. Mariæ in Cryptis*. The original plan of this church feems to have been a fimple crofs, the entrance being at the weft end of the prefent choir, which occupies the place of the ancient nave. This ancient ftructure had probably a central or principal tower; as it is recorded that the *new* tower fell down in 1175, and two fmaller ones were deftroyed by a ftorm in 1222. The antiquity of this part of the edifice is particularly apparent from the crypt or undercroft, which extends under the choir and its aifles. This is a curious and interefting part of the fabric. Twice feverely injured by fire, in 1113 and in 1202, the cathedral was re-confecrated in 1218, by bifhop Silvefter, in the prefence of Henry III. and his court. Six years afterwards the foundation of an additional work, the prefent nave, was laid by bifhop William de Bloys, in which is difplayed the fkill of the architect, in adapting the new parts to the former ftructure. The ftone-vaulting of the edifice was begun by bifhop Cobham in 1327, and the whole was finifhed in 1357. The beautiful central tower was conftructed in 1374. Worcefter cathedral is in the exterior extremely plain, and its attractions confift principally in the height, fpace, and the lightnefs of its architecture, to which the lofty pinnacles, rifing from every termination of the building, as well as from the tower, not a little contribute. The external length, including buttreffes, is 426 feet; the internal, 394: that of the nave, from the front to the weft tranfept, 180; of the choir, including the organ-loft, 120; of the Lady-chapel, 60; of the weft crofs or tranfept, 128; and of the eaft tranfept, 120 feet. The nave is feparated from the aifles by ten cluftered columns on each fide, fupporting three ranges of pointed arches; an arrangement alfo carried on through the choir. A ftone pulpit, originally placed near the weft end of the nave, is now fixed at the north fide of the choir. It is of an octagonal form, ornamented with emblematic fculpture, and furmounted by a canopy.

Worcefter cathedral has, like many other edifices of the fame nature, been a great fufferer by the lapfe of time, and by the various modes of repair adopted at different periods. It now fcarcely contains one arris or moulding, as originally conftructed. Roman cornices now occupy the place of battlements; buttreffes are pannelled in various heterogeneous ways; pinnacles have been reftored after the Grecian fchool; windows formed without ramifications or cufps, and filled with modern ftained glafs, deftitute of fubject or defign: Roman arches refting on entablatures, to fupport or ftrengthen the tranfepts; Roman fquares with leaves, inftead of proper bafes to regular cluftered pillars. Indeed this edifice affords a curious, but not a very pleafing, difplay of heterogeneous parts and ftyles.

Of the numerous monuments contained in the cathedral, a few only can be noticed in this work. Between the pulpit and the communion-table, in the midft of the choir, is placed the altar-tomb of king John, who died in 1216. On it is extended his effigy. The infcription, "Johannes Rex Angliæ," is now almoft illegible. The figure, as large as life, has in the right-hand a fceptre, and in the left a fword, with its point in the mouth of a lion couchant at the feet. On each fide, on a level with the pavement, are fmall figures of bifhops Ofwald and Wulftan. It had long been imagined that this monument was merely an honorary cenotaph, while the body of John really lay in the Lady-chapel; but by an inveftigation in 1797, the contrary was afcertained. Removing the effigy and ftone on which it refted, the interior of the monument was laid open. Between two brick walls, and under fome elm boards, lay a ftone coffin containing the royal corpfe. The body had evidently been deranged at fome former period; but many of the parts were very perfect. Inftead of the crown, however, as fhewn in the effigy, the head had been invefted with the hood of a monk's cowl. The body had been enveloped in an embroidered robe, feemingly of crimfon damafk. The coffin refted on the pavement of the choir, and the original cover was the ftone on which the effigy is fculptured. On the right-hand of the communion-table, occupying one of the arcades between the choir and the fouth aifle, ftands the celebrated monumental chapel or chantry of Arthur, eldeft fon of Henry VII., and elder brother of Henry VIII. This chapel, of an oblong form, is richly ornamented on the north, weft, and fouth fides, by open fcreen-work; the pillars adorned with a number of fmall ftatues, with fhields, rofes, and other figures emblematic of the houfes of York and Lancafter, whofe contending claims to the Englifh throne were united in that young prince, who died in 1502, in the 17th year of his age. Againft the eaft end was placed an altar, behind which was a wall ornamented with five figures; in the centre the Saviour, on the right-hand two kings in their robes, and on the left another fimilar king, and a warrior in armour. Over the ftatues are richly-wrought canopies. To preferve thofe figures from deftruction, they had been covered over with plafter, probably in the reign of Elizabeth, and remained thus unknown until November 1788, when the plafter being removed, they were once more laid open to view. The tomb of prince Arthur is of marble, with the arms of England and France quartered, painted on the fides; round the edge of the cover is an infcription in Englifh.

Worcefter cathedral contains alfo the monument of the celebrated judge Littleton, the father of Englifh law, a juftice of the common pleas under Edward IV., who died in 1481. Of more modern fepulchral monuments it will be fufficient to mention thofe of bifhops Hough, Maddox, and Johnfon, not only for the eminent names they commemorate, but as diftinguifhed examples of modern fculpture. Attached to the fouth fide of the nave of the church is the ancient cloifter, a fquare of about 120 feet, on the eaft fide of which is the chapter-houfe, a decagon of 58 feet in diameter, and 45 in height, the roof of which is fupported by a central column: it now ferves as a library, as well as a council-room, and contains a valuable collection of books, and of manufcripts, chiefly relating to the canon law. Adjoining to the fouth fide of the cloifter is the ancient refectory of the monaftery attached to the cathedral, called the college-hall, a lofty and fpacious room, 120 feet long by 38 broad, now kept as the king's fchool. Here are alfo held the triennial mufical meetings of the three choirs of Worcefter, Hereford, and Gloucefter, for the benefit of the widows and orphans of the clergy of their refpective counties. This fchool was founded by Henry VIII. for forty fcholars, who are prepared for the univerfity, and inftructed in various branches of modern education. A little to the eaftward of the chapter-houfe ftands the audit-hall, anciently called the Gueften-hall, built in 1320, for the entertainment of ftrangers reforting to the monaftery and cathedral. It is ftill the fcene of hofpitality during the annual audits of the chapter of the cathedral. At the back

of

of the feventh prebendal houfe, which formerly belonged to the kitchener or cook of the monaftery, are the remains of the great kitchen, a fpacious octagonal apartment, 34 feet in diameter.

Other places of worfhip belonging to the eftablifhment in Worcefter are, the churches of St. Peter the Great, St. Michael, St. Alban, St. Helen, St. Andrew, St. Clement, St. John Baptift, All Saints, St. Swithun, St. Martin, St. Nicholas, and Claines. Of thefe buildings, fome preferve their ancient appearance. St. Andrew's church is diftinguifhed by a fquare tower, 90 feet high, fupporting an octagonal fpire, in height 155 feet 6 inches; the whole height being 245 feet 6 inches. The church and tower are fuppofed to have been erected in the eleventh century, but the fpire was not added till 1751. Among the various monaftic inftitutions of Worcefter was that remarkable one, now called the *Commandery*, eftablifhed for the maintenance of two chaplains, five poor men, and two poor women, founded by St. Wulftan, who died in 1097: it became, after the diffolution, a part of the endowment of Chriftchurch in Oxford. Commanderies were, among the knights-hofpitallers of Jerufalem, the fame with the preceptories among the knights-templars; being focieties placed on the country eftates of the order, under the controul of a commander, but accountable to the grand prior or mafter in London. Part of the ancient buildings ftill exift; but the whole, now in the poffeffion of a private individual, has of late years undergone great alteration.

Though containing fo many parifh-churches in proportion to the population, Worcefter is not deficient in the number of chapels for various claffes of diffenters. Among thefe, are reckoned Anabaptifts, Independents, Methodifts, Prefbyterians, Quakers, and Roman Catholics.

On the fouth fide of the cathedral and cloifter is an open fpace, called the College-green, on the eaft fide of which is a gate, known by the name of Edgar's tower, having on the outer front the ftatues of that king and his two queens, Elfleda and Elfrida. Antiquarian curiofity has been much excited by characters once exifting on this tower, fuppofed to indicate a date much older than the received introduction of our prefent numerical figures into this part of the world. But the characters were probably mifunderftood; nor is the tower itfelf believed to be of the age of Edgar, who died in 975.

Northward from the cathedral, on the rifing bank of the Severn, is the bifhop's palace, originally furrounded with embattled walls in 1270, but brought into its prefent ftate by bifhop Stillingfleet and fucceeding prelates. The weft fide ftill retains much of the antique architecture.

Public Buildings.—The chief of thefe is the guildhall, fituated on the weft fide of the High-ftreet, near the market-place. It is a handfome edifice of two fpacious ftories, finifhed in 1723: the lower part is in one room, 110 feet 6 inches long, by 25 feet 6 inches broad, and 21 feet high, in which are held the feveral courts of juftice for the city and the county. The council-chamber is 109 feet long, by 26 broad, and 15 feet 8 inches high. The bridge over the Severn, in length between the abutments 270 feet, and in breadth 25, is an elegant ftone ftructure of 5 femicircular arches, opened in 1781. The centre arch is in fpan 41 feet, but the other arches gradually diminifh in width. Connected with the bridge a new ftreet has been opened, leading into the middle of the city, and the new roads from the weftward, the embankments, and quays along both fides of the river, are at once ornamental and ufeful.

Charitable Inftitutions.—The chief of thefe is the houfe of induftry, completed in 1794, a handfome building on the eaft fide of the city, advantageoufly fituated on an eminence, and calculated to accommodate 150 perfons belonging to the different parifhes of the city. The infirmary, fituated in an airy pofition, overlooking the race-ground, the river, and the north-weft parts of the county, was commenced in 1767: it receives about 58 patients on an average annually. A number of hofpitals and alms-houfes, fome of ancient foundation, provide fupport for age, and education for youth. A free-fchool on the Lancafterian plan was eftablifhed fome years ago. The old county-gaol is fituated in the caftle-yard; but a new one has been lately erected in the neighbourhood of the infirmary, on the Howardian plan. The city-gaol is an ancient building in a crowded fituation, having been originally a Francifcan convent, founded in the 13th century, but granted to the city at the diffolution.

Public Amufements.—Worcefter has long maintained its claim to be one of the moft fafhionable cities in the weftern parts of the kingdom: it is confequently the winter-refidence of a number of confiderable families from the furrounding counties of England and Wales. The theatre, affemblies, concerts, races, the various public walks, clubs, the public library, &c. render Worcefter a bufy, gay, and much-frequented city.

Municipal Government.—The city was incorporated by Henry I., but the firft charter was granted in the 45th year of Henry III. In 1621, the 19th year of James I., a mayor was eftablifhed. The corporation now confifts of a mayor, fix aldermen, 24 common-council-men, and 48 affiftants, by which laft two bodies the magiftrates are chofen. But the right of electing the members for parliament extends to upwards of 2000 citizens, the fheriff being the returning officer. Worcefter fent two reprefentatives to parliament in the 23d year of Edward I. Florence of Worcefter, the author of the Chronicon, a general hiftory of the world down to 1118, when he died, was a monk of the cathedral of this city. William of Worcefter was educated in Oxford in 1434, and drew up his "Polyandria Oxonienfis," a hiftory of the learned men bred in that univerfity. His Annals, at the end of the "Black Book" of the exchequer, contain notes on the affairs of his own times. The famous empyric and myftic philofopher, Edward Kelly, was born in Worcefter towards the middle of the 16th century. The relation of the impoftures of this perfon and his affociate Dr. Dee, furnifhed by Lilly, prefent a humiliating picture of the human mind and underftanding in thofe days, on the continent as well as in England. Worcefter produced, in 1650, the eminent lawyer lord Somers, who, by his knowledge and eloquence, defended the caufe of liberty and juftice in the latter part of the reign of Charles II., when but few warm and able advocates were found on their fide in Weftminfter-hall. See Somers, *Lord.*

Worcefter has long been rendered very interefting, from the circumftance of the *Royal Porcelain Works* being eftablifhed within its walls. It is, on our part, a moft pleafing duty, not only to trace its rife and progrefs, but to hold up its elegant and highly-finifhed productions to the attention of the liberal and fcientific. A very material difference exifts between this eftablifhment, and others of a fimilar kind on the continent; as the improvements made by expenfive experiments are *here* effected at the fole charge of the proprietors, while the *moft famed* manufactories on the continent are fupported and carried on at the coft of the government of the countries to which they belong. The Worcefter porcelain works were founded in the year 1751, by Dr. Wall and a company of proprietors, compofed of many gentlemen of fortune and confideration in the city and county; who continued to carry on the concern under thofe adverfe circum-

 ftances

ftances generally attending the introduction of *a new fpecies* of manufacture: for at that time little was known of porcelain in England, except by the imports from foreign nations. The Worcefter porcelain company had the merit of difcovering the method of transferring impreffions from *engraved copper-plates* to the furface of the porcelain. The invention, after a lapfe of feveral years, was conveyed into Staffordfhire, and now forms a grand branch of the extenfive foreign and home trade carried on in the potteries, giving employment to many thoufands. The *founders* of this manufactory, befides the printing, produced neat enamelled defigns, but not very fuperior either in defign or execution. Thefe extenfive premifes, fituate on the banks of the Severn, were fubfequently purchafed by Meffrs. Jofeph Flight and Martin Barr, and by a liberal policy, and great exertion and expence in a long feries of experiments, the productions of thefe works have rifen rapidly in the public eftimation. His prefent majefty, the queen, and princeffes, in the year 1788, honoured the manufactory by minutely infpecting its various proceffes; and at this time the king gracioufly granted his patent, when thefe works were ftyled 'Royal,' being the firft that enjoyed this diftinction. His majefty condefcended to fuggeft the eftablifhment of a warehoufe in London, and one was immediately opened in Coventry-ftreet. The proprietors have fince had the honour of receiving a patent and every encouragement from his royal highhefs the prince regent, the enlightened patron of the arts; and from the late princefs Charlotte, as well as from other members of the royal family, and even from foreign courts; but our limits forbid our entering into detail. On the demife of Martin Barr, efq. in the year 1813, he was fucceeded by his fons; and the works are now carried on under the firm of Flight, Barr, and Barr. It is not a little remarkable, that a confiderable part of the export trade of the Worcefter porcelain works is to our fettlements in the Eaft Indies, and even to Canton. We cannot but obferve the fingular change in our commercial relations *in this manufacture;* for the Chinefe, who feventy years fince furnifhed this country and nearly all Europe with porcelain, are now excluded from our markets, and thrown into the back-ground, and their extenfive manufactories nearly ruined. What Wedgwood did in his coarfer clays, in his beautiful imitations of the Etrufcan vafes, and in antique defigns on jafper, will long live in the recollection of his country. The fame fpirit feems to actuate the proprietors of the Royal Worcefter Porcelain Works, as they have fpared no expence *in their finer materials*, and highly-finifhed models and paintings, to excel the manufactories on the continent. In thefe works, the utmoft attention is paid to the ftudy of hiftorical compofitions, landfcapes, flowers, &c.; and the fuccefs which has attended the new method is moft evident, as the productions now fairly rival the beft foreign fpecimens. It is with peculiar pleafure we can at length announce, that we have feen a *fabric*, recently made by the prefent proprietors of thefe works, which in its colour, fracture, and tranfparency, is equal to the porcelain made at Sevre or Drefden. This fabric is compofed *entirely of Britifh materials*, and the fact muft be the ground of triumph, after all that has been faid of the impoffibility of finding in this country proper materials *for a true porcelain*. The *procefs* is moft curious and elaborate, of which we can but give a flight defcription, as its details are fo numerous. It may be viewed by tickets, granted by order of the proprietors to any refpectable individuals leaving their names. The materials, feveral of which are procured from the county of Cornwall, are firft felected with great care, and fome undergo a fevere calcination previous to their being compofed in proper proportions; they are then weighed and mixed, and burnt in a kiln to a very intenfe degree of heat, and form what is termed a 'frit.' This is ground under a maffive iron roller previous to an admixture of a certain proportion of the pureft argil, or working clay, which is ground with the frit in a mill, the bottom of which is laid with ftone, over which large ftones of about fifteen hundred or a ton weight are driven by upright 'drivers,' fixed in wooden arms attached to the centre fhafts; thefe, with water, reduce the fubftance to a thick white liquid, which is afterwards paffed through an extremely fine lawn fieve, and is run from cifterns into large brick pans, warmed by flues underneath; the heat being fufficient to drive off, by evaporation, the water that cannot be collected on the furface, fo that the refiduum is a moift clay, which is afterwards tempered in ftone vaults, and rendered fit for the ufe of the potter. The man who firft brings the rude mafs of clay into form, on a circular block, moved horizontally by a boy, who drives a vertical wheel, is called a 'thrower.' The dexterity and rapidity with which the clay appears to fpring into the fhape required feems like magic, as it is performed filently, and almoft unperceived, by the preffure of the fingers and thumb. This mode of 'throwing' differs from the Chinefe method, and that practifed on the continent, where the thrower moves his block by the action of his feet: in the one he has the advantage of an undivided attention, and the clay is literally obedient to his touch; while in the foreign method, the thrower is diftracted with two diftinct operations, and at the beft it can be but a clumfy exhibition. By this mode all *round* veffels derive their firft formation; any article of an oval, fquare, or other fhape, muft be made off a mould formed of alabafter, prepared in a powder, and with water brought into a liquid form, when it is run on the model, and fets quite hard, prefenting a cafe the precife reverfe of the model, on which layers of clay, cut to a proper thicknefs, are preffed with a fponge and the hand, and the artift from this is termed 'a preffer.' Great care is requifite in drying the different articles in a ftove after they come from the thrower, to render them fufficiently firm to hang on a lathe, where they are reduced to a proper thicknefs, and a more accurate form, by a turner, who works his wheel on the fame principle as one for wood or ivory. It is again committed to the ftove, where it is rendered quite dry and crifp; and the furface is afterwards fponged, and then rubbed with paper perfectly fmooth. In pieces which have any particular marks or decorations in the clay, they are preffed from moulds, and the handles are attached to the veffel fimply by the clay reduced to a liquid form. When burnt, the union is fo complete, that it appears to have been made altogether, and is perfectly as firm. We cannot trace the operations in this ftage any farther, but are furprifed to fee how many hands the moft fimple article paffes through, while the rifk and labour in thefe and more elaborate fpecimens are very great in this tender ftate of the clay. From the potter's-ftove the ware is carried to what is termed the bifcuit-kiln, and placed in cafes of fire-clay, called feggars, in which each piece requires particular fupports to prevent its yielding to the fire, and lofing its proper fhape. Here the porcelain is burnt to an intenfe degree of heat, and is rendered quite white and tranfparent, but has a flight roughnefs on its furface. From hence it is carried to the warehoufe, examined, freed from duft and other imperfections, and then dipped in a liquid termed the glaze, dried in a ftove, and afterwards every piece is carefully examined and 'trimmed;' which confifts in rendering the furface quite even, and fcraping the glaze from the feet, which, if not removed, would *melt* and adhere to the cafes in which they are burnt.

 From

From the glazing-room the articles are carried to the fecond kiln, and here they undergo another fevere fire, which fluxes the glaze, and gives to the porcelain a beautiful gloffy furface. In this kiln the loffes are great, as the porcelain can have no fupport. It is again warehoufed, examined, and delivered to the painters, who decorate it with gold, reduced by a chemical procefs, fo that it may be worked in a liquid form. In paintings of various defigns, the outline is made with a black-lead pencil, on the glazed furface, corrected with Indian ink; and the colours, all of which are prepared from mineral fubftances, worked in oil and fpirits of turpentine, are laid on with fine camel's-hair pencils. The colours in this ftate are difficult for ftrangers to underftand, as their tints are fo furprifingly changed by the action of the fire; while their opaque and obfcure appearance is increafed at every ftage of drying at a common fire, previous to their being burnt in the kiln. The finer kinds of paintings in figures, landfcapes, flowers, &c. require repeated burnings, in order to give them fufficient depth and richnefs by working one tint over another. The enamelling kiln, in which they are fired, is rendered fufficiently hot to fufe the glaze, without occafioning it to run; while the colours, by the aid of their fluxes, are melted into the glaze, fo as to render their union perfect, and give them their rich tranfparent effect.

The *durability* of thefe colours, which cannot be acted on by any atmofphere, renders good painting in this ftyle very defirable. It has long been a defideratum with the greateft mafters to procure colours for painting on canvas, on which *time* can have no injurious effect; but in this they have hitherto unfortunately not fucceeded, and it was the regret of an eminent artift, that his paintings had not *the permanency of porcelain colours*. A method of printing, entirely different from the original mode invented by the founders of the works, is now carried on here. (For a defcription, fee PRINTING *on Porcelain*, in the *Addenda*.) The laft operation is the burnifhing of the gold, which is executed with a ftone, black in its external appearance, and remarkable for its hardnefs and the high polifh it takes. This work is performed by women, who render the gold extremely brilliant by rubbing its furface with great care and fkill. The emboffed gold, for which this manufactory is celebrated, is burnifhed with a fine agate, which is alfo ufed in chafing and in finifhing the handles of vafes, &c. We have now fketched the procefs, but we fhould not omit to mention that in *every ftage* the porcelain is very liable to accident and imperfections; and if not totally fpoiled, it may require a repetition of firings, which much increafes the rifk and expence. The moft coftly articles are expofed in the fire from 150 to 200 hours, in their different ftages collectively. An important colour ufed in porcelain manufactories is the rich dark blue, generally called 'royal.' It is prepared from cobalt, and the oxyd of this ore is fo powerful as to require the heat of the glaze-kiln to bring out its beautiful tint. It is not, like other colours, worked on a glazed furface, but laid on the porcelain after the firft burning, when in the rough or 'bifcuit' ftate, then fired, and afterwards dipped in the glaze, and paffed through the glaze-kiln, frequently requiring two or three fuch ordeals of heat to perfect its colour. We were formerly fupplied with this mineral from the mines of Saxony, but have now the pleafure to learn that the proprietors of thefe works made fome fuccefsful experiments for a company of gentlemen, who difcovered cobalt-ore in Cornwall; which by a particular preparation produces *as fine a blue as the Saxon cobalt*, and it is now ufed in preference to the foreign, which can only be imported in the adulterated form of a zaffer. The reflection, that by fcience and labour the rude materials of the earth are raifed and converted into elegant and ufeful forms, and embellifhed with claffical and tafteful defigns, is highly pleafing; while it affords the means of maintenance to fo many induftrious workmen and ingenious artifts. All the perfons employed in thefe interefting works are *Britifh*, and this manufacture ftands as one proof of the increafed civilization of England. —The Hiftory and Antiquities of Worcefter, by Valentine Green, 2 vols. 4to. 1796. Beauties of England and Wales, Worcefterfhire; by F. C. Laird, 8vo. 1813. Graphic and Hiftorical Defcription of the Cathedrals of Great Britain, Worcefter, 8vo. 1815. Hiftory, &c. of Worcefter, by J. Chambers, 8vo. 1818.

WORCESTER, the fouth-eafterly county of the ftate of Maryland, with 16,971 inhabitants, including 4427 flaves. Snowhill is the chief town.—Alfo, a county of Maffachufetts, large and populous, with 50 townfhips, 53 congregational churches, and 64,910 inhabitants; 50 miles long from N. to S. and 40 broad.—Alfo, a town of the ftate of Maffachufetts, containing 2577 inhabitants. This is the chief town of a county of the fame name, and one of the largeft inland towns in the ftate. It contains two churches, a town-houfe, and a gaol; 34 miles W. of Bofton. N. lat. 42° 10′. W. long. 71° 46′.—Alfo, a townfhip of Vermont, in the county of Chittenden, with 41 inhabitants; 30 miles N. of New Haven.—Alfo, a townfhip of Pennfylvania, in the county of Montgomery, with 868 inhabitants; 18 miles N.W. of Philadelphia.—Alfo, a town of Ohio, in the county of Wafhington, with 385 inhabitants.

WORCESTERSHIRE, an inland county in the weftern part of England, bounded by Herefordfhire, which feparates it from Wales, on the S.W., by Shropfhire on the N.W., by Staffordfhire on the N., by Warwickfhire on the E., and by Gloucefterfhire on the S. The form of the county is very irregular, having on every fide detached parts furrounded by other counties, and comprehending within its bounds parts belonging to the neighbouring fhires. The mean length may be eftimated at about 30 miles, and the mean breadth at 25 miles, giving a furface of 750 fquare miles, or 480,000 acres; but according to the official report laid before parliament, the contents are reduced to 431,360 acres: about two-thirds of the county lie on the E. and one-third on the W. fide of the river Severn. Worcefterfhire comprehends one city, eleven market-towns, three of them parliamentary boroughs, and in all 152 parifhes; the whole is diftributed into five hundreds. The inhabitants amounted, in 1811, to 160,546, of whom 78,033 were males, and 82,513 females, and the inhabited houfes were 30,206.

Hiftorical Events.—Worcefterfhire is fuppofed to have formed a part of the territory of the *Cornavii*, who alfo inhabited the contiguous diftricts of Warwickfhire, Staffordfhire, Shropfhire, and Chefhire. That numerous tribe appear from the *Notitia Imperii* to have furnifhed bodies of troops to the Roman armies; but no trace of their name is now to be difcovered in the tracts they are believed to have occupied. The county was called by the Saxons *Wireceafter-fcire*, and in Domefday-book *Wirecefre-fcire*, and the inhabitants in Bede's time were named *Wicci*; a term which, in the opinion of Camden, may have been derived from *Wich*, fignifying, in the old Englifh language, a falt-pit, in allufion to the mines of that fubftance found in the county. Of the Roman hiftory of Worcefterfhire but little is known. Ptolemy feems to take no notice of it; nor does it appear to be traverfed by any of the roads traced out in the Itineraries of Antoninus. It is highly probable, however, that Worcefterfhire muft have been the theatre of parts

parts of the exploits of Oſtorius, when proprætor in Britain; becauſe he was certainly poſted on the *Sabrina*, now the Severn. The other river mentioned by the hiſtorians of his operations, the *Antona*, has been by ſome writers conjectured to be the Avon, which falls into the Severn in the S. part of the county, while others ſuppoſe it to ſignify the Nen of Northamptonſhire. The Roman roads, of which veſtiges are diſcovered in different parts of Worceſterſhire, although not known to be laid down in the Itineraries, ſufficiently prove the county to have profited by the arts and the policy of the conquerors, in the opening of communications; one of the earlieſt and moſt effectual means of promoting civilization, as well as of eſtabliſhing dominion, among a rude and vanquiſhed people. One of theſe ancient or Roman roads is the Runed-way, or Ridgeway, on the E. ſide of the county, running between Worceſter and Alceſter, in Warwickſhire: another is a paved way from Kencheſter, in Herefordſhire, pointing N.E. towards Worceſter. The great Ikening-ſtreet enters the county from Staffordſhire, and paſſes near Bromſgrove: another great road, ſuppoſed by Naſh to be the ancient Portway, but now called the King's head-land, paſſes over Hagley common. According to Dr. Stukeley, a Roman road extended from Worceſter down the bank of the Severn to Upton, and thence to Tewkeſbury on the N. border of Glouceſterſhire, where it joined Ricning-ſtreetway. Worceſterſhire formed a part of the Saxon kingdom of Myrcnaric, or Mearc-lond, in Latin changed into Merkia. This, by much the largeſt kingdom of that people in England, was founded by Crida about the year 586, and enlarged by Penda, under whom the Chriſtian religion was introduced among the Merkians. During the ſtruggles between the native Britons and their invaders, this part of the country muſt have ſuffered ſeverely; but at laſt the Britons, driven from the plains, retired behind the Severn into the mountainous tracts of Wales. The ravages of the Danes in the 9th and 10th centuries were not unknown in Worceſterſhire; and to that people tradition aſcribes various ſepulchral and military antiquities diſcovered in it.

During the heptarchy, the greater part of Worceſterſhire, Glouceſterſhire on the E. of the Severn, and a portion of Warwickſhire, were inhabited by the *Wiccii*, and under the juriſdiction of the biſhop of Worceſter: but on the acceſſion of William of Normandy, the epiſcopal government was ſuperſeded, and the civil power entruſted to the ſheriffs of Worceſter. The firſt of theſe was Urſo of Abitoth, as he is ſtyled in Domeſday-book, ſon of the lord of that place, in Normandy, and brother of Robert Le Deſpenſer, anceſtor of the preſent families of that name in England. Urſo is alſo ſtyled *Vice-comes*, having received from the king the hereditary ſhrievalty, with the conſtableſhip of the caſtle of Worceſter. He ſat in the great councils held in London in the 15th, and in Weſtminſter in the 18th years of William I. During the conſpiracy of Roger, earl of Hereford, and Ralph, earl of Norfolk, he prevented the former from paſſing over the Severn to form a junction with the inſurgents: His daughter and heireſs, Emmeline, married Walter, the progenitor of Beauchamp, whoſe family afterwards became earls of Warwick. The firſt earl of Worceſter was Walleran de Mellent, a relation of the royal family. He held alſo the paternal honours in Normandy; but ſiding with the barons againſt Henry I., his eſtates were laid waſte, himſelf long held a priſoner, and even when enlarged not entruſted with the keeping of any of his own caſtles. Taking part with Stephen againſt the empreſs Maud, his city of Worceſter was carried by aſſault, and reduced to aſhes. Dying a priſoner in Normandy, his ſon inherited the Norman but not the Engliſh honours. All this happened in the 12th century; and the title of earl of Worceſter ſeems to have lain dormant until 1397, when it was conferred on Thomas Percy, ſon of Henry, lord Percy, by his firſt wife Mary, daughter of Henry Plantagenet, earl of Lancaſter, and brother of Henry I. earl of Northumberland. This gallant earl of Worceſter, accompanying the Black Prince to France, &c. diſtinguiſhed himſelf under the command of John of Gaunt, duke of Lancaſter. The title in 1420 was beſtowed on Richard Beauchamp, of the houſe of Warwick, deſcended from the firſt Norman ſheriff or earl. He ſerved with great reputation in France; but dying in 1449 without male iſſue, the title was granted to John Tibetot or Tiptoft, baron of Powis. Under Henry VI. he was charged with the guard of the narrow ſeas, and appointed lord-deputy of Ireland; and by Edward IV. juſtice of North Wales, conſtable of the Tower of London, and treaſurer of the exchequer. Soon after he became chancellor of the kingdom, ſtill, however, retaining his command at ſea. It was not in military and ſtate affairs alone that this nobleman diſtinguiſhed himſelf. Educated at Oxford in all the learning of thoſe days, he afterwards viſited Jeruſalem for devotion; alſo Padua, Venice, and Rome, to conſult the libraries and the learned ſocieties of thoſe places; and was the author of ſeveral works. On the temporary reſtoration of Henry VI. by Neville, earl of Warwick, the earl of Worceſter was apprehended and beheaded at London in 1471. His ſon was afterwards replaced in the family honours and eſtates by Edward IV.; but dying without iſſue in 1485, the title was, by Henry VIII., conferred on Charles, natural ſon of Henry, duke of Somerſet. His grandſon, Henry, was created marquis of Worceſter by Charles I.; and his grandſon, Henry, was, in 1682, by Charles II. created duke of Beaufort, the title of marquis of Worceſter being by courteſy attached to the eldeſt ſon of that family to the preſent time.

State of Property.—Prior to the Norman Conqueſt, great part of the lands of Worceſterſhire belonged to the church; but on that event much was beſtowed on the favourites and followers of the Conqueror. Very little is now poſſeſſed by the deſcendants of the ancient proprietors; for in the various revolutions of the kingdom, the adherents of the loſing ſovereign were in general deprived of their property. William Beauchamp, baron of Elmſley, poſſeſſed great eſtates by deſcent from the firſt earl of Worceſter; but loſt them by adhering to the empreſs Maud againſt Stephen. They were reſtored however by Henry II. In the conteſts between king John and the barons, the grandſon of William Beauchamp was a material ſufferer; for having taken the ſide of the nobles, the church of Worceſter, on the re-eſtabliſhment of John's power, laid hold of the opportunity to enlarge their precincts, abridging the accommodations of the caſtle, ſo that it was no longer fit for the habitation of the ſheriff and his retinue; and from that time it began to fall into decay. The whole county was then the property of, or poſſeſſed by eccleſiaſtics, and by a few barons; nor was it until a much later period that a more general diviſion of lands, from various cauſes, took place. In the reign of Richard II., the Beauchamps, earls of Warwick, were again deprived of their lands: under Henry VII. other large poſſeſſors of land, who had borne arms in Boſworth-field, were ſtripped of their property. But the greateſt forfeiture of lands in Worceſterſhire took place in conſequence of the attainder and execution of Edward, earl of Warwick, who had taken the part of Perkin Warbeck againſt Henry VII. Conſiderable changes were alſo occaſioned by the transfer under Henry VIII. of the

the lands of the diffolved religious eftablifhments, to his favourites and the nobles who co-operated in his fchemes. In the unhappy reign and life of Charles I., Worcefterfhire was often the theatre of warfare; many eftates were dilapidated or ruined, and but few really acquired; for the prices fet on the church-lands by the parliamentary furveyors were fo enormous, that though fold at nominally a few years value, the purchafers generally loft by the acquifition. In later times, the changes of property in this county have been numerous and frequent; but the caufes of thofe changes depending on private motives and not on public interefts, as in former days, they do not come within the fcope of this article. It is, however, worthy of remark, that out of the great number of families who recorded their armorial bearings, on the firft vifitation of the county by the Clarencieux, king at arms, in 1533, only fix or feven now remain, and of thefe only two refide on the ancient family eftates. Of thofe named in the laft vifitation (1683) but few defcendants now exift. By thefe changes, however, it has happened in Worcefterfhire, as in other diftricts where manufactures and commercial enterprize prevail, that the landed property is now diftributed amongft a much greater number of proprietors, and that the country is incomparably better peopled and cultivated than in former times.

General Afpect, Soil, and Climate.—When viewed from any of the numerous furrounding eminences, Worcefterfhire affumes the afpect of a plain, the gentle flopes and rifings on the eaft and weft of the capital being then fcarcely defcernible. From thofe eminences alfo the cultivation of the plains is viewed to great advantage, as there are no tracts of confiderable extent fo barren or fo neglected as not to prefent an agreeable as well as profitable verdure. On a nearer view, from a hill in the centre of the county, to the eaftward of the capital, a moft beautiful landfcape prefents itfelf; the whole back-ground, diftant from eight to twelve miles, appears to be the continuation of one range of hills, enclofing rich and beautiful plains, in which the flourifhing hop-grounds and plentiful orchards conftitute very interefting and gratifying objects.

The foil of the county is various; but it chiefly confifts of rich loamy fand, mixed with a fmall proportion of gravel, in the central parts on the north of Worcefter. Towards the eaft the foil is a very light fand, containing a few fpots of clay, and fome peat-earth; but the eaftern diftrict of the county is, in general, a ftrong clay, the wafte lands being principally a deep black peat-earth. Between Worcefter and the vale of Evefham, in the fouth-eaft part of the county, the foil is partly red marle, and partly ftrong clay, whilft the fubfoil in fome places is compofed of lime-ftone. In the celebrated vale of Evefham, watered by the river Avon, the foil is particularly deep, of a darkifh earth, refting on clay, and in parts on gravel. Farther fouth limeftone prevails, in the upper lands, on the fkirts of the Cotfwold hills, and a rich loam in the lower lands. In the fouth-weft divifion of the county, between the Severn and the Malvern hills, the foil is in general clay, mixed with fand or gravel; but farther to the northward the gravel increafes, until it terminates in the light fands of the northern border of the county. In all of thefe diftricts, however, fome rocky and ftony foil is found; but according to Mr. Pomeroy, in his Agricultural Survey, no traces of chalk or flint any where occur; nor have any been found, it is faid, in the lime-quarries. The vale of Severn is defcribed by Mr. Pitt, in his fubfequent furvey of the county, to contain probably ten thoufand acres of a deep rich fediment, depofited in the courfe of ages by the river and its tributary ftreams. In fome parts, this fediment confifts of a pure water-clay, fit for brick-making, but generally of a rich mud, fertile and favourable to vegetation. The county has been lately diftributed in the following manner:

	Acres.
Common fields of arable land eftimated at	20,000
Inclofed ditto - - - - - -	340,000
Permanent grafs-land - - - -	100,000
Kitchen-gardens, &c. - - -	5,000
Woods, waftes, rivers, roads, &c. -	35,000
Whole county about - -	500,000

Refpecting the corn-produce of the county, it is thus eftimated in Pitt's furvey: In 360,000 acres of arable land, 43,500 are fuppofed to be laid down in wheat, yielding from 20 to 32 bufhels *per* acre, or 1,200,000 bufhels on an average. From this quantity deducting 108,750 bufhels, at $2\frac{1}{2}$ *per* acre, the remaining neat produce is 1,091,250 bufhels.

The climate of Worcefterfhire, particularly in the middle, fouthern, and weftern parts, is ftated to be remarkably mild, foft, and healthy. The vale of the Severn rifes but little above the fea, and the valleys of the Avon and Teme are nearly on the fame level; and the adjoining uplands, feldom rifing at the moft 150 feet higher, poffefs a warmth and foftnefs which ripen the grain and bring to perfection the fruits of the earth, from a fortnight to a month earlier than in more elevated counties, even enjoying a fimilar foil and furface. The principal bleak and inclement parts are the Bredon and Broadway hills on the fouth border of the county, and the Lickey range on the north: for the Malvern hills on the weft, although only fheep-pafture, poffefs a moft falubrious climate.

Hills.—The higheft hills are certain points of the Lickey range, which, rifing to the north-eaft of Bromfgrove, runs north towards Hagley, and diverges to the eaftward. Some of thofe points are eftimated to be elevated 800 or 900 feet above the general level of the country. On this range is a fmall fpring producing two ftreams, one of which flows northward to the Rea, which falls into the Trent, and with it is difcharged into the German ocean on the eaft fide of the ifland; the other, falling into the Stour, is carried by the Severn into the Briftol Channel on the weft. Bredon-hill, in the fouth-eaft corner of the county, is of about equal elevation. The higheft point of the Malvern range of hills, called the Herefordfhire beacon, rifes, according to the great ordnance furvey of England, 1444 feet above the level of the fea: the Worcefterfhire beacon, barometrically meafured, rifes 1298 feet; and North-hill 1211 feet above the Severn.

Rivers.—Thefe are, the Severn, the Avon, the Teme, and the Stour; the fmaller ftreams are, the Salwarp, Arrowe, Ledden, Rea, &c. The Severn, called by the Romans *Sabrina*, is fuppofed to be fo named from the Britifh terms *fabr*, fand, or *fabrin*, fandy, becaufe it is often turbid, efpecially when heavy rains fall on the Welfh mountains. See SEVERN.

The river Avon is faid to have been originally fo named by the Britons, on account of the gentlenefs of its courfe. It is commonly diftinguifhed from a number of other rivers in Britain of the fame name, as the Warwickfhire-Avon, and will be ever memorable while the name of Shakfpeare remains. Entering Warwickfhire towards the fouth-eaft corner, the Avon, by a winding courfe, waters the vale of Evefham, paffes by Perfhore, and unites with the Severn in the neighbourhood of Tewkefbury. It is navigable for barges

barges through the whole extent of the county, by means of locks in different places. See Avon.

The Teme, rifing in Radnorfhire, enters Worcefterfhire a little above Tenbury, and thence purfuing a winding but rapid courfe, through a fucceffion of beautiful and romantic fcenery, along the woods and dales of Stanford, the feat of fir Edward Winnington, bart., it is loft in the Severn below Worcefter. From the declivity of its bed, and confequent rapidity, it is navigable for barges only up to Powick bridge, a mile and a half from the Severn. But although on this account the Teme be of little commercial ufe, it is peculiarly ornamental to the county, no part of which furpaffes the banks of this ftream in variety of ground, wood, and open lawn. A ramble along its various windings, extending upwards of twenty miles, through a fucceffion of orchards, hop-grounds, corn and pafture land, is, in autumn, peculiarly agreeable. The Stour, an inconfiderable ftream, has rifen into notice fince the opening along its courfe of the important canal by Kidderminfter, uniting the Severn and the Merfey. The Salwarp purfues its fhort courfe to the Severn by Bromfgrove and Droitwich, where it formerly received the overflowings of the falt-fprings, but thefe are now turned into the new canal from that town to the Severn. The other little ftreams of Worcefterfhire merit no particular notice.

Canals.—Connected with the natural rivers are the artificial canals opened throughout the county. Thefe are, the Trent-and-Severn, or the Staffordfhire and Worcefterfhire canal, more commonly called the Stourport canal, from the place where it falls into the Severn, eleven miles north from Worcefter; the Droitwich canal, for the conveyance of the produce of the falt-fprings to the Severn; the Worcefter and Birmingham canal; the Dudley extenfion canal; and the Leominfter canal, near Tenbury. See Canals.

Woods and Forefts.—About the time of the Norman Conqueft, Worcefterfhire was confidered to poffefs five forefts; namely, thofe of Feckenham, Omberfley, Horewell, Malvern, and Wyre; but of the laft only a fmall portion lies within the county. Feckenham foreft, once very extenfive, has now almoft difappeared, owing to the continual demand for fuel to the falt-works at Droitwich, until of late years a fufficient fupply of pit-coal has been obtained. Omberfley foreft, on the north of Worcefter, and Horewell foreft on the fouth, have long been difafforefted. Malvern foreft or chafe extended between the Severn and the fummit of the hills of the fame name, where may ftill be traced the trench which divided the foreft and the county from Herefordfhire on the weft. Wyre foreft, on the north border of the county, now more properly belongs to Shropfhire and Staffordfhire. Befides the veftiges of thefe forefts, the county contains feveral tracts of woodland, of oak, elm, and beech: but from the demand for young trees to make hop-poles, and for trees to be converted into charcoal for the iron-works in the neighbouring counties, much timber of fuperior fize cannot now well be expected in Worcefterfhire.

Mineralogy.—The minerals of this county are neither numerous nor peculiarly valuable. Clay and lime-ftone are abundant; but coal, to render the latter ufeful in agriculture as well as building, is not eafily procured where the ftone is found. Some coal is indeed raifed in the northweft diftrict, about Mamble, where is a rail-way leading to the Leominfter canal. Coal is alfo found at Penfax, and the Whitley-hills, in the fame quarter, and is much ufed for coke for the hop-kilns and lime-pits; but the vein is too thin to promife much advantage to the county at large, which is principally fupplied from the Staffordfhire mines, by means of the Severn. In the vale of Evefham, and many other parts of the county, fuel is particularly fcarce and dear. The lime-ftone quarries about Dudley are very extenfive, and extremely curious excavations: but although the town ftands in a detached part of the county, inclofed by Staffordfhire, thofe quarries actually belong to the latter county. Building-ftone of different forts is alfo found in feveral parts. But the principal mineral riches of Worcefterfhire arife from the falt-mines of Droitwich, a parliamentary borough, fituated fix miles north-eaft from Worcefter, on the road to Birmingham. Thefe falt-works are of great antiquity, having been granted by Kenulph, king of Mercia, to the church of Worcefter, in 816; and it appears from Domefday-book, that fhares in them were annexed to many eftates at even a confiderable diftance, on account probably of the wood they yielded for the manufacture of the falt. The principal brine-pits, however, belonged to the crown, but were granted by king John to the burgeffes of Droitwich. The general fubftratum of the environs of the town is fuppofed to be a falt-rock, lying ufually from 150 to 200 feet below the furface. On boring in any part, the falt-fprings are met with about 110 feet below the furface: the boring-machine then paffes through about 130 feet of gypfum to the brine-river, in depth about 22 inches, beyond which is a bed of falt-rock hitherto unexplored. In fearching for this brine-river fome years ago, the miners paffed through four feet of mould, 32 of marle, 40 of gypfum, a brine-river of 22 inches, and 75 feet of another ftratum of gypfum, below which they came to the falt-rock. (See Droitwich and Salt.) For an account of the mineral waters of *Malvern*, fee that article; and more particularly the paper of Mr. Horner, in the firft volume of the Geological Society of London. Befides thefe, Worcefterfhire has fome chalybeate fprings at Sandbourne and the Round-hill, in the parifh of Kidderminfter.

Manufactures and Commerce.—The commerce of Worcefterfhire is confiderable, from its own productions, and from the depofit and tranfit of thofe of the neighbouring mining and manufacturing diftricts. Of its own products may be noticed the hops, fruit, cyder, and perry, which render the capital the principal mart for thofe articles in the weftern part of the kingdom. The county alfo exports a confiderable furplus of its own manufactures, confifting of Kidderminfter ftuffs and carpets; of Worcefter gloves, china and glafs-ware, and of nails, bar and fheet iron. Great quantities of falt are annually fent from Droitwich; Evefham furnifhes oil and oil-cake; timber, grafs-feeds, corn, flour, malt, falmon, cattle and fheep, and other agricultural productions are furnifhed by the county in general.

Civil and Ecclefiaftical Divifions.—Worcefterfhire is divided into five hundreds; *viz.* Ofwaldeflow, Halffhire, Doddington, Perfhore, and Blackenhurft: the firft containing the capital and the centre of the county, with feveral detached portions in other quarters; the fecond occupying the northweft parts; the third, the north-eaft; the fourth, the fouth; and the fifth, the fouth-eaft quarter, around Evefham. In ecclefiaftical matters, the county is under the government of the bifhop of Worcefter, and contains 152 parifhes. The diocefe was formerly of great extent; but in 1541 the fee of Gloucefter, and in 1542 that of Briftol, being erected, a confiderable part of the epifcopal jurifdiction of Worcefter was withdrawn. At prefent the bifhopric comprehends all the county, with the exception of 15 parifhes and 8 chapelries belonging to Hereford; about one-third part of Warwickfhire, together with the parifhes of Brome and Clent in Staffordfhire, and Hales-Owen in Shropfhire. The diocefe thus contains 116 rectories, 79 vicarages, 26 curacies, and 41 chapelries, all diftributed into 9 deaneries.

Parliamentary

Parliamentary History.—Worcestershire has been represented in parliament ever since the third year of Edward III., and at and ever since the revolution has maintained a respectable character for independence in the choice of its representatives. In the early part of the last century, sir John Pakynton accused the bishop of interfering in the election, of forbidding the clergy to vote for sir John, of threatening the tenantry of the see not to renew their leases if they voted for him, and even of desiring the baronet to withdraw his pretensions. The charges were established; and after a long contest between the two houses of parliament, on an address to queen Anne, the bishop was dismissed from his office of almoner. Worcestershire, which is included in the Oxford circuit, sends nine members to parliament; *viz.* two for the county, two for the city of Worcester, two for each of the boroughs of Droitwich and Evesham, and one for the borough of Bewdley.

Mansions and Country-seats.—Of these, Worcestershire contains a very considerable number, some of which are highly deserving of notice. Hagley-park, the "British Tempe" of Thomson, the favourite seat of the ingenious and amiable lord Lyttelton, the historian of Henry II., is situated toward the northern frontier of the county. The grounds have long been celebrated for variety and beauty of scenery. Croome-court, the handsome seat of the earl of Coventry, eight miles to the south of Worcester, is more indebted to modern art and skill for its beauties than to the natural features of the ground. The agricultural improvements, chiefly carried on by the late earl, are both extensive and important. Six miles north from Worcester is Omberfley, the residence of the marchioness of Downshire, in the midst of spacious grounds. The house has been lately modernized. Grafton-hall, about a mile west from Bromsgrove, the property of the earl of Shrewsbury, was in ancient times a capital mansion; but being burned down in 1710, the porch and a part of the hall alone remain as specimens of its original magnificence. The latter has been converted into a chapel for a modern building annexed. Madresfield, six miles south-west from Worcester, the residence of viscount Beauchamp, is an ancient baronial castle, greatly altered in the modern style. Whitley-court, the seat of lord Foley, eight miles north-west from Worcester, is a highly improved and spacious mansion, in the midst of an extensive park. The parish-church, closely adjoining to the house, is one of the most elegant in the kingdom. Annexed to the see of Worcester is the ancient castle of Hartlebury, the residence of the bishops from the time of Henry III., situated between nine and ten miles north from Worcester. The principal part of the buildings, as they now stand, is the work of bishop Hough. Much of the improvements, however, are due to the late bishop Hurd, who furnished the palace with a valuable library, for the use of his successors in the see, in which are the principal books from the libraries of Mr. Pope and bishop Warburton.—Collections for the History of Worcestershire, by the Rev. Tredway Nash, D.D. 2 vols. fol. Lond. 1781–2. Supplement to ditto, ditto, 1799. General View of the Agriculture of the County of Worcester, by William Thomas Pomeroy, 4to. Lond. 1794. General View of the Agriculture of the County of Worcester, by W. Pitt, 8vo. Lond. 1813. Beauties of England and Wales, Worcestershire, by F. C. Laird, 8vo. Lond. 1816.

WORCUM, or Woudrichem, or *Wodercum*, a town of Holland, situated on the south side of the Wahal, first surrounded with walls in 1460, and defended with four bastions; 13 miles E.N.E. of Dort.

Worcum, a sea-port town of Frieseland, situated in a fertile country, but subject to inundations of the sea, especially when the wind blows from the east. The harbour is blocked up with sand, but it carries on a considerable trade by means of its canals; 18 miles S.W. of Lewarden. N. lat. 53°. E. long. 5° 35′.

WORD, in *Language*, is an articulate sound, designed to represent some idea.

Word, in *Writing*, is an assemblage of several letters, forming one or more syllables, and signifying some thing.

The Port-royalists define words to be distinct articulate sounds, agreed on by mankind for conveying their thoughts and sentiments.

The proper character of a word, according to the ingenious Mr. Harris, is that of its being a sound significant, of which no part is of itself significant; and hence he infers, that words are the smallest parts of speech.

The first and most obvious distinction of words is into such as are significant absolutely or by themselves, and such as are significant by relation: the former may be called principals, and the latter accessories. Moreover, all words whatever, significant as principals, are either *substantives* or *attributives;* and those, which are significant as accessories, acquire a signification either from being associated to *one word*, in which case they only define and determine, and may justly be called *definitives*, or to *many words at once*, in which case they serve to no other purpose than to connect, whence they are called *connectives*. Accordingly, Mr. Harris refers all words to these four species. Hermes, p. 20, &c. See Speech.

Grammarians divide words into eight classes, called *parts of speech;* which are, the *noun*, *pronoun*, *verb*, *participle*, *adverb*, *conjunction*, *preposition*, and *interjection;* to one or other of which, all the words and terms in all languages, which have been, or may be invented to express our ideas, are reducible. See each.

Words, again, are divided into *primitives* and *derivatives*, *negative* and *positive*, *simple* and *complex*, *common* and *proper*, *abstract* and *concrete*, *synonymous* and *equivocal*.

With regard to their syllables, words are farther divided into *monosyllables* and *polysyllables*.

The grammatical figures of words, which occasion changes in the form, &c. thereof, are, *syncope*, *apocope*, *apostrophe*, *diæresis*, *aphæresis*, *prosthesis*, *epenthesis*, *paragoge*, *metathesis*, &c. See Syncope, Apocope, &c. See also Figure.

The use of words, we have observed, is to serve as sensible signs of our ideas; and the ideas they stand for in the mind of the person that speaks, are their proper significations.

Simple and *primitive* words have no natural connection with the words they signify; whence there is no rationale to be given of them: it is by a mere arbitrary institution and agreement of men, that they come to signify any thing. Certain words have no natural propriety or aptitude to express certain thoughts, more than others: were that the case, there could have been but one language.

But in derivative and compound words the case is somewhat different. In the forming of these, we see a regard is to be had to agreement, relation, and analogy: thus most words that have the same ending, have one common and general way of denoting or signifying things; and those compounded with the same prepositions, have a similar manner of expressing and signifying similar ideas in all the learned languages where they occur.

For the perfection of language, it is not enough, Mr. Locke observes, that sounds can be made signs of ideas; unless these can be made use of, so as to comprehend several particular

particular things; for the multiplication of words would have perplexed their ufe, had every particular thing needed a diftinct name to be fignified by.

To remedy this inconvenience, language had a farther improvement in the ufe of general terms, by which one word was made to mark a multitude of particular exiftences; which advantageous ufe of founds was obtained only by the difference of the ideas they were made figns of: thofe names becoming general, which are made to ftand for general ideas; and thofe remaining particular, where the ideas they are ufed for are particular.

Some of our philofophers have complained much of the great ufe, or rather abufe, of vague and general terms, which have no precife definite fignification. To diftinguifh thefe, F. Malebranche obferves, that every thing that is, and confequently every thing that is intelligible, is either a being, or a mode and manner of being. Hence it is evident, that every term which does not fignify either of thefe, fignifies nothing, and is an obfcure and confufed term. In metaphyfics, the ufe of fuch terms, he fays, is fometimes neceffary and allowable, as in fpeaking of the divine perfections, &c. But in phyfics it is always mifchievous, however common.

It is obfervable, that the words which ftand for actions, and notions quite removed from fenfe, are borrowed from fenfible ideas; as, to imagine, apprehend, comprehend, underftand, adhere, conceive, inftil, difguft, difturbance, tranquillity, &c. which are all taken from the operations of things fenfible, and applied to modes of thinking. *Spirit*, in its primary fignification, is no more than breath; *angel*, a meffenger. By which we may guefs what kind of notions thofe were, and whence derived, which filled the minds of the firft beginners of languages; and how nature, even in the naming of things, unawares, fuggefted to men the originals of all their knowledge: whilft, to give names that might make known to others any operations they felt in themfelves, or any other ideas that came not under their fenfes, they were forced to borrow words from the ordinary and known ideas of fenfation.

The ends of language, in our difcourfe with others, are chiefly three: firft, to make our thoughts or ideas known one to another. This we fail in, 1. When we ufe names without clear and diftinct ideas in our minds. 2. When we apply received names to ideas, to which the common ufe of that language doth not apply them. 3. When we apply them unfteadily, making them ftand now for one, and anon for another idea.

Secondly, to make known our thoughts with as much eafe and quicknefs as is poffible. This men fail in, when they have complex ideas, without having diftinct names for them; which may happen either through the defect of a language, which has none; or the fault of the man, who has not yet learned them.

Thirdly, to convey the knowledge of things. This cannot be done, but when our ideas agree to the reality of things. He that has names without ideas wants meaning in his words, and fpeaks only empty founds. He that has complex ideas without names for them, wants difpatch in his expreffion. He that ufes his words loofely and unfteadily, will either not be minded, or not underftood. He that applies names to his ideas, different from the common ufe, wants propriety in his language, and fpeaks gibberifh; and he that has ideas of fubftances, difagreeing with the real exiftence of things, fo far wants the materials of true knowledge.

Words, *Divifion of*. See Division.

Words, *General*. See General.

Words *of Command*. See Exercise.

Word, *Watch-Word*, in an *Army* or *Garrifon*, is fome peculiar word or fentence, by which the foldiers are to know and diftinguifh one another in the night, &c. and by which fpies and defigning perfons are difcovered.

It is ufed alfo to prevent furprizes. The word is given out in an army every night by the general, to the lieutenant, or major-general of the day, who gives it to the major of the brigades, and they to the adjutants; who give it firft to the field-officers, and afterwards to a ferjeant of each company, who carry it to the fubalterns.

In garrifons it is given, after the gate is fhut, to the town-major, who gives it to the adjutants, and they to the ferjeants.

Word, in *Heraldry*, &c. See Motto.

Words, *Defamatory*, *Treafonable*, &c., in *Law*. See Defamation, Scandal, and Treason.

WORDEN, in *Geography*, a town of the duchy of Holftein, on the right fide of the Elbe; 10 miles N.W. of Gluckftadt.

Worden, *Groffen*, a town of the duchy of Bremen; 10 miles N.N.W. of Stade.

WORDERNBERG, a mountain of the duchy of Stiria; 6 miles S.S.E. of Eifenhartz.

WORDINGBERG, a fea-port of Denmark, fituated on the fouth coaft of the ifland of Zealand, oppofite the ifland of Falfter. In the year 1066, Waldemar I. built a ftrong caftle here, which is now gone to decay. Waldemar III., who was exceedingly fond of this place, refided here for the moft part; and in derifion of the Hanfe towns, built the well-known tower, which, from a golden goofe erected on the top of it, he called *Gans*, that is, *The Goofe*. In this tower, he purpofed to confine the prifoners of the Hanfe towns that fhould fall into his hands in the war he intended to carry on againft them. As the old caftle gradually fell to decay, prince George, who was brother to Chriftian V., and married to Anne, queen of England, built here an entire new caftle, which Frederick IV. afterwards enlarged; but that edifice has been pulled down. The ufual paffage to the iflands Falfter and Laaland is from this place. In 1240, at a famous diet held here, the Old Juftifche Low-buck, or Codex Legum Juricarum, was compiled and promulged: this body of laws is ftill in force in South Jutland. In 1256 another diet was held here; and in 1658, preliminaries for a peace between Denmark and Sweden were treated of in this town; 43 miles S.W. of Copenhagen. N. lat. 55° 3′. E. long. 11° 58′.

WORE. See Wyre.

WORENZUTTE, a town of Pruffia, in Ermeland; 8 miles S. of Heilfberg.

WORGAN, Dr. John, in *Biography*, a mufical graduate of Oxford, organift of St. Mary-Axe, Bedford chapel, and many years a diftinguifhed performer on the organ at Vauxhall, and Dr. Arne's fucceffor there in the compofition of cantatas, fongs, and ballads.

He learned the rudiments of mufic of his elder brother, who had likewife an organift's place in the city, and played the violoncello in the Vauxhall band. Their fcholars on the harpfichord were very numerous, particularly within Temple-bar; and John, as an organift and opener of new organs, rivalled Stanley. He was a very ftudious man, and dipt very early into the old ecclefiaftical compofers of Italy. He fucceeded Gladwin in playing the organ at Vauxhall. His firft ftudy in compofition and organ-playing was directed by Rofeingrave, who pointed his attention to the pure harmony and modulation of Paleftrina, and organ-fugues of Handel. His conftant ufe of the organ at Vauxhall, during the fummer, ſummer, ranked him with Stanley and Keeble; and his enthuſiaſm for Scarlatti's leſſons, with which he was impreſſed by Roſeingrave, rendered him equal to Kelway in their execution.

With an extempore prelude, *alla Paleſtrina*, and one of Handel's organ-fugues, he uſed to preface his concerto every night.

At length he got acquainted with Geminiani, ſwore by no other divinity, and on conſulting him on the ſubject of compoſition, he was told that he would never be acquainted with all the arcana of the ſcience, without reading "El Porque della Muſica," a book written in Spaniſh per Andres Lorente, en Alcala, 1672. But where was this book to be had? Geminiani told him, and told him truly, that the tract was very ſcarce. He had, indeed, a copy of it himſelf; but he would not part with it under twenty guineas. Worgan, on fire to be in poſſeſſion of this oracular author, immediately purchaſed the book at the price mentioned; not underſtanding a word of Spaniſh, he went to work in learning it as eagerly as Rowe the poet, when lord Oxford had expreſſed a wiſh that he underſtood that language, which Rowe thought would qualify him for a good place under government. But after hard drudgery, when he haſtened to acquaint the miniſter of ſtate that he thought himſelf a tolerable maſter of the Spaniſh tongue, "I give you joy (ſays lord Oxford); you are now able to read Don Quixote in the original."

The knowledge of Spaniſh and ſtudy of Lorente ſeem to have had no other effect on Worgan's compoſitions, than to ſpoil his Vauxhall ſongs; which though ſung into popularity by dint of repetition, had no attractive grace, or pleaſing caſt of melody.

He compoſed ſeveral oratorios, in which the choruſſes are learned, and the accompaniments to his ſongs ingenious. The *cantilena* was original, it is true, but it was original awkwardneſs, and attempts at novelty without nature for his guide.

His organ-playing, though more in the ſtyle of Handel than of any other ſchool, is indeed learned and maſterly, in a way quite his own. In his youth, he was impreſſed with a reverence for Domenico Scarlatti by old Roſeingrave's account of his wonderful performance on the harpſichord, as well as by his leſſons; and afterwards he became a great collector of his pieces, ſome of which he had been honoured with from Madrid by the author himſelf. He was the editor of twelve at one time, and ſix at another, that are admirable, though few have now perſeverance ſufficient to vanquiſh their peculiar difficulties of execution. He is ſtill in poſſeſſion of many more, which he has always locked up as Sybil's leaves.

He had the misfortune to labour under two dreadful calamities; a bad wife, and the ſtone. He got rid of the former, after great mortifications and expence, by divorce; but in too early wiſhing to abridge his ſufferings from the latter, he loſt his life in the torture of an operation, Auguſt 20, 1790.

WORGAUM, in *Geography*, a town of Hindooſtan, in the country of the Mahrattas; 20 miles W. of Poonah.

WORK, in the *Manege*. To work a horſe, is to exerciſe him at pace, trot, or gallop, and ride him at the manege.

To work a horſe upon volts, or head and haunches in or between two heels, is to paſſage him, or make him go ſideways upon parallel lines.

To Work, in *Sea Language*, is to direct the movements of a ſhip, by adapting the ſails to the force and direction of the wind. A ſhip is alſo ſaid to work when ſhe ſtrains and labours heavily in a tempeſtuous ſea, ſo as to looſen her joints or timbers. See Rolling.

Work, *Carpenter's*, *Clock*, *Crown*, *Field*, *Fire*, *Fret*, *Groteſque*, *Horn*, *Moſaic*, *Out*, *Regimen of the*, *Ruſtic*, *Scratch*, *Stream*, *Vermicular*, and *Wax*. See the ſeveral articles.

Work, *Diſcharge*, in *Calico-Printing*, &c. a peculiar kind of proceſs, in which the cloth is firſt dyed of ſome uniform colour, by means of a mixture of iron-liquor and ſome one or more of the common vegetable dyeing ſubſtances; and calicoes thus prepared are ſaid to be dyed of ſelf-colours. They are then waſhed and dried, and when properly preſſed or calendered, they are fit for receiving any pattern, according to the views of the artiſt. This operation is generally effected by means of the mineral acids, previouſly fitted for the purpoſe by diſſolving in them a portion of one or more of the metals, according to the nature of the dye which is intended to be *diſcharged*, or of the colour to be produced. In doing this, the diſcharging liquor ſhould be ſo made as to be capable of diſſolving the iron which is contained in the dye, and which is always uſed in quantity ſufficient for covering, or at leaſt diſguiſing in a great meaſure, the other colour or colours which had been employed with it, and at the ſame time for acting as a mordant in beautifying and fixing thoſe colours. Thus a piece treated with a decoction of Braſil-wood, and dyed black by being *padded* with iron-liquor, if when dried it be printed with a peculiar ſolution of tin, the ferruginous portion of the dye will be diſſolved, and the printed part will be inſtantly converted from a deep black to a brilliant crimſon. The term *padding* denotes the operation of paſſing the pieces from a roller through a trough containing a ſolution of iron, or any other mordant, and is ſynonymous with *blotching*. In the ſame way, an olive-coloured calico, dyed in a ſolution of iron and a decoction of weld, will be as ſpeedily changed to a bright pale yellow; and the various drabs and ſlates of every ſhade which have been in their compoſition, will undergo as ſudden a change by the ſame treatment; though the colour of the figures produced upon them will depend on the materials with which the cloths were originally dyed. Even the deepeſt gold colours, or ſtrongeſt buffs, if produced by iron only, may, by a peculiar preparation of tin, be diſcharged; and thoſe parts of the cloth which have been treated with this metallic ſolution, will be reſtored to their former whiteneſs. Calicoes alſo, dyed of a light blue in the indigo-vat, then paſſed through ſumach and copperas, and finiſhed in a bath of quercitron bark and alum, may have figures of a bright green imparted to them. In this caſe, the green is originally formed by means of the indigo-vat and the bark, though it is enveloped by the iron of the copperas, which overcomes the other colours, till the ſolution of the tin is applied, which removes the iron from thoſe particular parts, and gives a brilliancy to the remaining colour, which they would not otherwiſe have poſſeſſed; the tin being a powerful mordant for the bark, by which the yellow of the green is procured. A good ſelf-colour may likewiſe be given to calicoes, merely by dyeing them in ſumach and copperas, and then running them through an alkaline ſolution of annotto; and here the figures produced by the application of a colourleſs ſolution of tin will be of a bright orange.

In the inſtances above cited from Mr. Parkes's Eſſays, vol. ii., he refers only to that branch of diſcharge-work in which all the purpoſes are attained by diſſolving the iron that makes a part of the colour intended to be diſcharged; whereas the finer and more expenſive work is done by a different proceſs. The particular kind of chemical diſcharge-work above-defcribed is fubject to the imperfection of not being perfectly faft; that is, the goods thus produced will not bear frequent wafhing like thofe which are done by the bath of madder or bark. In this connection with permanent colours, Mr. Parkes is led to mention a very valuable *green*, not long ago invented by a Mr. Iflet of London, fecured to him by patent, which was produced by printing ground indigo, mixed with a peculiar kind of folution of tin, and then faftening the indigo within the fibres of the calico, by means of that procefs denominated *china-blue dipping*. (See DIPPING.) After this, the goods are to be dyed in a copper of bark or weld, which converts the blue into a green, and the whites are to be cleanfed by croft-bleaching, &c.

In another kind of difcharge-work, the agent that is employed is the citric acid, in various degrees of concentration, according to the purpofe to which it is to be applied, or the ftrength of the ground intended to be difcharged. This is employed chiefly for the production of white figures upon felf-coloured grounds produced by madder and fundry other dyes. The acid for this purpofe is mixed with either gum or pafte to a proper confiftency for the black, the plate, or the cylinder, and from thence it is transferred to the piece; and wherever it attacks, the mordant, whether iron or alumine, is difcharged, and a delicate white appears in its ftead. In ufing citric acid for this purpofe, a portion of one of the mineral acids is fometimes mixed with it. There is another fpecies of difcharge, on which the agent employed by the printers is the nitrous, and fometimes the nitro-muriatic acid. See DISCHARGING *of Colour* and COLOUR.

WORKALLEN, in *Geography*, a town of Pruffia, in Oberland; 4 miles S.W. of Liebftadt.

WORK-HOUSE, a place where indigent, vagrant, and idle people are fet to work, and maintained with clothing, diet, &c. See HOUSE *of Correction*.

Such are the Bridewells, and feveral other places about the city of London, or fuburbs; fuch alfo was the foundation of that in Bifhopfgate-ftreet, for employing the poor children of the city and liberties, who have no fettlement; and that for the parifh of St. Margaret's, Weftminfter, called the Grey-coat hofpital.

By 43 Eliz. cap. 2. the church-wardens and overfeers, with the confent of two juftices, are empowered to fet to work the children of the poor and other deftitute perfons, and to provide for the relief of the lame, old, blind, and fuch as are poor, but not able to work; and they may erect, with the leave of the lord of the manor, on any wafte or common, of which the parifh is parcel, convenient houfes of dwelling for the poor. (See POOR.) By 3 Car. IV. they may fet up and ufe any trade, merely for the employment and relief of the poor. By 9 Geo. cap. 7. they may contract for the maintenance and employment of the poor in houfes purchafed or hired; and poor perfons refufing to be lodged and maintained in fuch houfes, fhall be put out of the parifh-books, and not entitled to receive relief from the church-wardens and overfeers; and two or more parifhes are allowed to unite in lodging their refpective poor in one houfe; and the officers of one parifh are allowed to contract with thofe of another for the maintenance, &c. of their poor. Moreover, by 8 & 9 Will. cap. 30. parifh poor that are relieved are required to wear on the fhoulder of the right fleeve of the uppermoft garment, in red or blue cloth, a large Roman P, together with the firft letter of the name of the parifh or place to which they belong. By 24 Geo. II. cap. 43. no fpirituous liquor fhall be fold or ufed in any work-houfe, or houfe of entertainment for parifh poor. The ftatute 22 Geo. III. cap. 83. eftablifhes many new regulations with regard to the maintenance of the poor; but leaves it optional in any parifh or place whether they will adopt thefe, or retain the prefent mode. At Amfterdam they have a famous work-houfe, or houfe of correction, called the *Rafphuyfe*, (which fee,) which, by a privilege granted in 1602, has alone the right of fhaving and cutting the dyer's woods, as brafil, fantal, campechy, faffafras, &c. Each perfon, tolerably ftrong, kept in the houfe, is obliged to furnifh two hundred and fifty pounds of rafped wood *per* day; and the weaker, a certain proportionable quantity of chips.

WORKING *to Windward*, in *Sea Language*, denotes the operation by which a fhip endeavours to make a progrefs againft the wind. See BEATING, PLYING, TACKING, and TURNING.

WORKING *Furnace*. See FURNACE.

WORKING *of Glafs*. See GLASS.

WORKINGTON, in *Geography*, a confiderable market and fea-port town in the ward of Allerdale-above-Derwent, county of Cumberland, England, is fituated on the borders of the river Derwent, at the diftance of 34 miles S.W. by W. from Carlifle, and 310 miles N.W. by N. from London. The manor was anciently poffeffed by the Culwens, now Curwens, a family of great confequence in the county, of whom eight out of ten, in fucceffive defcent, were knights of the fhire. The prefent importance of the town has originated from the working of the collieries fince the reign of queen Elizabeth, at which period the entire maritime ftrength of the county confifted of only twelve veffels, though the number now belonging to this port alone is more than 160, and many of them are from one to three hundred tons burthen. Thefe are principally engaged in the exportation of coals to Ireland, and fome few to the Baltic. The river is navigable to the town for fhips of four hundred tons; and on each bank, near the mouth, are piers. The harbour is one of the fafeft on the coaft; and many improvements have been recently made in the fituation and conftruction of the quays. The appearance of the town is diverfified: feveral of the ancient ftreets are narrow and irregular; thofe of modern erection are better formed; the public buildings are all of late date. The houfes are principally difpofed in two clufters: in that called the Upper Town a new fquare has been erected, in the area of which is the corn-market; at a little diftance are the butchers' fhambles. The church, a neat edifice, contains the monument of fir Patrick Curwen, baronet, who died in 1661. In the town are meeting-houfes for Prefbyterians and Methodifts, and a Catholic chapel; alfo a theatre and an affembly-room. Two large weekly markets are held on Wednefdays and Saturdays for meat and other provifions. Corn is fold only on the Wednefdays, which is the principal market-day. Here are alfo two annual fairs for cattle, but of no great note. The principal manufactures are thofe of fail-cloth and cordage, and every thing connected with fhipping. Veffels of from four to five hundred tons, copper-bottomed, are built here, and fold to the merchants of Liverpool, Cork, &c. In the population return of the year 1811, the town of Workington is ftated to contain 1059 houfes, and 5807 inhabitants. The parifh includes the townfhips of Great Clifton, Little Clifton, Stainburn, and Winfcales, making an addition of 726 to the population, and of 161 to the number of houfes.

On an eminence, near the eaft end of the town, overlooking the river Derwent, is Workington-hall, the feat of John Chriftian Curwen, efq., who has nearly rebuilt it, from the defigns of Mr. Carr of York, and greatly extended and improved the park and pleafure-grounds. The old manfion, manſion, of which there are ſcarcely any remains, was caſtellated, purſuant to a licence granted by Richard II. to ſir Gilbert de Culwen in 1379. Mr. Gough obſerves, that the walls were ſo remarkably thick, that in making ſome recent improvements; a paſſage was excavated through one of them lengthways, leaving ſufficient thickneſs on each ſide to anſwer every purpoſe of ſtrength. In this manſion, Mary, queen of Scots, when ſhe landed in England in 1568, was hoſpitably entertained by ſir Henry Curwen, till he was required by queen Elizabeth to reſign his royal gueſt, who was removed to Cockermouth caſtle, and afterwards to that of Carliſle.—Beauties of England and Wales, vol. ii. Cumberland, by J. Britton and E. W. Brayley, 1802. Lyſons's Magna Britannia, vol. iv. 4to. Cumberland, 1816.

WORKS, Opera, in *Fortification*, the ſeveral lines, trenches, ditches, &c. made round a place, an army, or the like, to fortify and defend it. See Line, Parallel, and Trench.

Works, *Covenant of*, in *Theology*. See Covenant.

WORKSBORN, in *Geography*, a river of Northumberland, which runs into the North Tine.

WORKSOP, a market-town in the hundred of Baſſetlaw, and county of Nottingham, England, is ſituated 22 miles N. from Nottingham, the ſame diſtance N.W. from Newark, and 146 N. by W. from London. The town is ſmall, but neat and pleaſantly ſeated in a valley, near the ſource of the river Ryton. According to the population returns of 1811, the houſes were then 759, and the inhabitants 3702. A market, noted for malt, is held on Wedneſday, and fairs on the 20th of March, 20th of May, 21ſt of June, and 3d of October. Workſop, anciently Wirkenſop, was, before the Norman Conqueſt, the property of a Saxon nobleman. Long afterwards it belonged ſucceſſively to the families of Furnival, Nevill, and Talbot, earls of Shrewſbury. The Talbot eſtates deſcending to co-heireſſes, a part was conveyed to the Howards, earls of Arundel, afterwards dukes of Norfolk, by whom the lands of Workſop are ſtill poſſeſſed, and who, on this account, enjoy the privileges of furniſhing a glove for the king's right-hand at his coronation, and of ſupporting that hand while he holds the ſceptre. Workſop was in former times defended by a caſtle, long ago deſtroyed : but its ſcite is ſtill pointed out on a circular hill, encompaſſed with a trench, at the W. ſide of the town.

Workſop was formerly noted for its monaſtery, founded by William de Lovetot, in the reign of Henry I., for canons regular of the order of St. Auguſtine. The inſtitution was ſubſequently enriched by the gifts of various proprietors of the town ; but at the general diſſolution its poſſeſſions were ſeized by Henry VIII. Few veſtiges of the monaſtery now remain ; but the church ſtill partly ſubſiſts, and is a noble ſpecimen of ancient architecture. What now remains is but the W. end of the original church, with two lofty towers. The W. entrance conſiſts of an arch with zigzag ornaments, whilſt the towers have the windows in a gradation of different ſtyles of architecture. The interior of the church, in length about 135 feet, conſiſts of a nave and two aiſles ; the roof is ſupported by eight pillars, alternately octangular and cylindrical : the ancient pulpit is ſtill preſerved. On the N. ſide of the church are fragments of walls ; and foundations are diſcovered in the adjoining meadows : but the moſt curious veſtige of the ancient buildings is a ruinous chapel, at the S.E. corner of the church, now uſed as a place of burial, of which the windows, ſtill well preſerved, furniſh examples of the lancet form. The gate of the monaſtery is nearly entire, and retains a few of the ſtatues with which it was formerly furniſhed. The church and church-yard contain ſome monuments for eminent perſons of former times : one is the tomb of John, brother of Ralph Nevill, the firſt earl of Weſtmoreland, and treaſurer of England. The trade of Workſop, and its appendage Radford, has been much promoted by the Cheſterfield canal, which paſſes cloſe by the N. end of the town. The ſale of liquorice, formerly conſiderable, has been for ſome years at an end, none being now raiſed in the neighbourhood. On the S.W. of the town ſtands the noble manſion of the duke of Norfolk, ſtyled *Workſop-manor*, in the midſt of a park, eight miles in circuit, containing a great variety of ground, and much ancient timber of a fine growth, having once been a part of the great foreſt of Sherwood. The original manſion was erected by the renowned Talbot, the firſt earl of Shrewſbury, on a ſcale of extent and magnificence ſuited to his character and fortune : but in 1761 the whole was unfortunately burnt down ; by which accident, the loſs ſuſtained was very great, not only in the furniture, but in the library, the paintings, and the antique ſtatues, part of the celebrated Arundelian collection. Soon after this misfortune, the duke of Norfolk commenced a new manſion, on a plan of great magnificence, compriſing a quadrangle incloſing two courts ; but the execution of the ſcheme was interrupted by the unexpected death of the heir of the family. One ſide, however, which is the front, has been finiſhed, and is 318 feet in length, of great elegance and grandeur. In the centre is a portico of ſix Corinthian columns, on a ruſtic baſement. In the tympanum of the pediment is an emblematic repreſentation of the high alliances of the houſe of Norfolk ; and on the points are placed three ſtatues. The body of the building is crowned with an open baluſtrade. The interior contains many valuable paintings and portraits of anceſtors and connections of the family. The chapel is adapted to the Roman Catholic ſervice, to which the dukes of Norfolk have always, with the exception of the late duke, been ſteadily attached : it ſerves as a place of worſhip for a number of perſons of the ſame perſuaſion reſiding in the neighbourhood.

At no great diſtance to the S. of Workſop-manor is Welbeck abbey, the ſeat of the duke of Portland. This place belonged to Sweyn the Dane before the Conqueſt. A monaſtery is ſuppoſed to have been founded in the reign of Stephen, by Thomas de Cukeney, for Premonſtratenſian canons, who were removed from Newhouſe in Leiceſterſhire. In the reign of Edward III., the manor of Cukeney was purchaſed by the biſhop of Ely, and beſtowed on the monaſtery. At the diſſolution it was purchaſed by a perſon named Whalley, from whom it came to ſir Charles Cavendiſh, youngeſt ſon of ſir William, who married the celebrated counteſs of Shrewſbury. The ſon of ſir Charles, afterwards duke of Newcaſtle, was the author of a well-known treatiſe on horſemanſhip. His grand-daughter, marrying John Hollis, duke of Newcaſtle, left an only daughter and child, who by marriage conveyed the eſtates to the earl of Oxford ; and their only child and daughter by marriage transferred Welbeck to the anceſtor of the preſent proprietor. The manſion is a large irregular ſtructure, erected at different periods, containing, particularly within, portions of the ancient monaſtic buildings. The greater part of what is now ſeen was conſtructed about 1604. The interior contains many ſpacious and elegant apartments, which are decorated with a number of portraits of perſons important in Engliſh hiſtory.

The

The grand riding-houfe and ftables were erected by the noted duke in 1623 and 1625: having been long neglected they have been of late years reftored, and are now among the moft remarkable in the kingdom. Welbeck-park is about eight miles in circuit, and contains noble woods of venerable oaks, fome of very great age and extraordinary fize. One in particular, noticed in Evelyn's Silva, was in his time thirty-three feet round at the bottom, and is conceived to be 700 years old: it is now much decayed. But the moft remarkable tree is "the duke's walking-ftick," in height about 112 feet; the folid contents are eftimated at 440 feet. Near the gate leading to Workfop is a group of trees, called the "feven fifters," there having been formerly feven ftems fpringing from one root, but one has lately been broken off. The late duke formed an extenfive piece of water in the park, and raifed a bridge of three fpacious arches over it, but which fell down juft as it was completed.

About two miles to the eaftward of the parks of Workfop and Welbeck is that of Clumber, a feat of the duke of Newcaftle. The manfion is a magnificent ftone ftructure of three fronts, one of which is ornamented with a light Ionic colonnade. The apartments are fpacious, particularly the ftate dining-room, fixty feet in length, thirty-four in breadth, and thirty in height, which is fitted up with great magnificence. In the various rooms are feveral very valuable paintings. The arrangements for the domeftic accommodation of the family are well worthy of notice. The park, now eleven miles in compafs, was not long ago a wide tract of foreft-land. It is in a manner wholly the creation of the late duke of Newcaftle. It now contains about 4000 acres; but half a century ago the ground was little better than a black heath, interfperfed with bogs and marfhes, through which ran a fmall ftream. The park comprehends, however, two woods of ancient oaks, from one of which the manfion takes its name.

Adjoining to Clumber-park, on the fouth, is that of Thorefby, the feat of earl Manvers. The old houfe was deftroyed by fire in 1745, after which it was rebuilt by the proprietor, the laft duke of Kingfton, grandfather of the prefent poffeffor. The manfion, which is rather a comfortable refidence than a magnificent feat, confifts of brick, on a ruftic ftone bafement, with an Ionic portico of four columns in the principal front. The great ftair-cafe, fingle at the bottom, but divided into two at the firft landing, opens into a dome fupported by columns, on which refts a gallery, which communicates with the upper chambers. The apartments contain fome valuable portraits and paintings. The park is about thirteen miles in circumference, and contains feveral pieces of water, of which one, near the houfe, affumes the appearance of an extenfive river.—Thoroton's Hiftory of Nottinghamfhire, by Throfby, 3 vols. 4to. London, 1790. Beauties of England and Wales, Nottinghamfhire, by F. C. Laird, 8vo. London, 1812.

WORLD, Mundus, the affemblage of parts which compofe the univerfe.

The *duration* of the world is a fubject which has been greatly difputed. Plato, after Ocellus Lucanus, held it to be eternal, and to have flowed from God, as rays flow from the fun. Ariftotle was much of the fame mind: he afferts, that the world was not generated, fo as to begin to be a world, which before was none; and, in effect, his whole eighth book of Phyf. and firft book de Cœlo, are fpent in proving the eternity of the world.

He lays down a pre-exifting and eternal matter, as a principle; and thence argues the world eternal. His argument amounts to this; that it is impoffible an eternal agent, having an eternal paffive fubject, fhould continue long without action.

His opinion was long generally followed; as feeming to be the fitteft to end the difpute among fo many fects about the firft caufe.

Epicurus, however, though he makes matter eternal, yet fhews the world to be but a new thing, and fays it was formed out of a fortuitous concourfe of atoms. See Lucretius, lib. v.

Some of the modern philofophers refute the imaginary eternity of the world, by this argument: that, if it be *ab æterno*, there muft have been a generation of individuals, in a continual fucceffion from all eternity; fince no caufe can be affigned why they fhould not be generated, *viz.* one from another. Therefore, to confider the origin of things, and the feries of caufes, we muft go back in infinitum, *i. e.* there muft have been an infinite number of men, and other individuals, already generated; which fubverts the very notion of number. And if the caufe which now generates have been produced by an infinite feries of caufes, how fhall an infinite feries be finite, to give room for new generations? See God.

Dr. Halley fuggefts a new method of finding the age of the world, from the degree of faltnefs of the *ocean*; which fee.

It is another popular topic of controverfy, whether the world be finite, or infinite? See the arguments on both fides, under Universe.

It is likewife difputed, whether the plurality of worlds be poffible? See Plurality.

Some hold the affirmative, from an opinion of the infinite power of the Deity; it being a fetting bounds to omnipotence to fay, that he created fo many bodies at firft, and that he could not create more.

The Cartefians maintain the negative, upon thefe principles: that it is a contradiction to fay, there are feveral worlds exifting at the fame time, fince this implies feveral univerfes of created beings, the world being the το παν. That if there were feveral worlds, they muft either be at a diftance from one another, or contiguous; but neither can be faid: for were they contiguous, they would only conftitute one; and were they diftant, there muft be fomething between. But what can be between? If it be extended, it is corporeal; and, inftead of feparating the feveral worlds, it will connect them all into one.

The *exiftence* of an external world has been much controverted. The arguments on either fide, fee under Abstraction, Body, and Existence.

The world is fometimes divided into *upper* and *lower*: the *lower*, or *fublunary*, is the globe of our *earth* (which fee); and the *upper* includes the heavens, and heavenly bodies.

WORLITZ, in *Geography*, a town of Saxony, in the principality of Anhalt; 5 miles E. of Deffau.

WORM, a river of Norway, which flows from the lake Miofs into the Glom, or Glomen.

WORMDIT. See Warmstadt.

WORMHOUT, a town of France, in the department of the North; 5 miles S. of Bergues.

WORMIA, in *Botany*, a genus of plants firft eftablifhed by Rottböll, was named by him in memory of the famous Danifh phyfician and naturalift, Olaus Wormius, fucceffor of of Caſpar Bartholin in the profeſſorſhip of medicine at Copenhagen. He died rector of that univerſity in 1654. His Latin writings, on the hiſtory and antiquities of Denmark and Norway, are valued for their accuracy. His ſon William publiſhed, in 1655, the *Muſæum Wormianum*, a handſome work in folio, the ſecond book of which, according to Haller, conſiſts entirely of botanical ſubjects. Olaus Wormius herein deſcribes and figures ſeveral rare plants, or monſtrous varieties, with a detail of their anatomy. His letters, not publiſhed till 1751, are ſaid to contain many things relating to Botany. — " Rottb. Nov. Act. Hafn. for 1783. v. 2. 522. t. 3." Saliſb. Parad. at p. 73. De Cand. Syſt. v. 1. 433. — Claſs and order, *Polyandria Pentagynia*. Nat. Ord. *Magnoliæ*, Juſſ. *Dilleniaceæ*, De Candolle.

Gen. Ch. *Cal.* Perianth inferior, of five roundiſh, concave, very obtuſe, coriaceous, permanent leaves. *Cor.* Petals five, roundiſh, concave, larger than the calyx, tapering at the baſe, deciduous. *Stam.* Filaments very numerous, crowded, ſhort, equal; anthers terminal, linear, longer than the filaments, ſhorter than the petals, recurved, burſting by a double orifice at the ſummit. *Piſt.* Germens five, or more, ſuperior, diſtinct, ovate, compreſſed, crowded; ſtyles terminal, tapering, recurved, longer than the germens; ſtigmas notched. *Peric.* Capſules as many as the germens, and of the ſame form, each of one cell and one valve, burſting at the inner edge, crowned with one of the permanent ſtyles. *Seeds* ſeveral, from 8 to 12, roundiſh, "each with a pulpy tunic at the baſe." *Saliſb.*

Eſſ. Ch. Calyx inferior, of five coriaceous, permanent leaves. Petals five. Anthers with two terminal pores. Capſules five, compreſſed, diſtinct, many-ſeeded. Styles thread-ſhaped. Stigmas notched. A genus of trees or ſhrubs, with rather twining *ſtems*, and round ſmooth *branches*. *Leaves* alternate, ſtalked, ſimple, oval, coriaceous, with a ſingle mid-rib, and many tranſverſe parallel partial ribs. *Stipulas* large, oblong, pointed, deciduous; the young ones convoluted, forming a terminal point, as in the *Magnolia* tribe. *Flower-ſtalks* about the ends of the branches, oppoſite to the leaves, angular, either racemoſe or panicled; often unilateral. *Flowers* white or yellow. *Calyx* remaining coriaceous and dry, not becoming pulpy, in which, as well as the ſeparate *ſtigmas*, and elongated *ſtyles*, this genus differs abundantly from *Dillenia*. (See that article.) M. De Candolle notices the two terminal pores of the *anthers* in *W. alata*, which he thought might afford a character for dividing the genus, if the ſame were not found in all the ſpecies. We find this character in *W. dentata*, as well as in our new *W. ſericea*, and therefore venture to make it a part of the generic diſtinction.

1. W. *madagaſcarienſis*. Madagaſcar Wormia. De Cand. n. 1.—" Leaves oval, bluntly ſinuated. Cluſters panicled."—Gathered by Commerſon in Madagaſcar. An elegant tree, with thick round *branches*. *Stipulas* ſolitary, large, long, leafy, externally villous, deciduous, each leaving an annular ſcar on the branch. *Leaves* oval or orbicular, ſmooth, with broad, obtuſe, ſhallow, marginal notches. *Footſtalks* long, channelled above, and marked with tranſverſe wrinkles. *Flower-ſtalks* nearly oppoſite to the leaves, erect. *Partial-ſtalks* ſingle-flowered, without *bracteas*. *Petals* undulated, thrice as long as the calyx. *Seeds* roundiſh. *De Candolle.*

2. W. *dentata*. Toothed Wormia. De Cand. n. 2. (Dillenia dentata; Thunb. Tr. of Linn. Soc. v. 1. 201. t. 20. Willd. Sp. Pl. v. 2. 1253, excluding Rottböll's ſynonym. Poiret in Lam. Dict. v. 7. 151.)—Leaves ovate, abrupt, coarſely and rather ſharply toothed. Footſtalks ſimple, triangular, ſmooth. Flower-ſtalks triangular, from three to ſix-flowered.—Gathered by Thunberg in Ceylon. We received a ſpecimen, preciſely anſwering to the above plate, in 1786, from profeſſor David Van Royen, marked *Dillenia indica*; *Reaumuria* of Koenig, by whom it was gathered; and *Ghodaparra* of the Cinghaleſe. This is a *tree*, with round branches. *Leaves* four inches long, of a broad, elliptic-ovate figure, very abrupt, coriaceous; paler beneath; entire at the baſe; wavy at the ſides; moſt toothed at the end; tranſverſe ribs very ſtraight. Convoluted *ſtipula*, at the end of the branch, acute, two-edged, ſmooth. *Footſtalks* linear, narrow, near two inches long, acutely triangular, not bordered, ſmooth. *Cluſter* ſimple, on a long, ſmooth, angular ſtalk, not quite oppoſite to the uppermoſt leaf, in our ſpecimen conſiſting of ſix *flowers*, whoſe partial ſtalks are about an inch long. Thunberg repreſents three *flowers* only, whoſe *petals* are obovate, about an inch in length.

3. W. *triquetra*. Triangular Wormia. " Rottb. Nov. Act. Hafn. v. 2. 532. t. 3." De Cand. n. 3.—Leaves ovate, bluntiſh, bluntly and ſlightly ſinuated. Footſtalks ſimple, triangular. Flower-ſtalks triangular, racemoſe.—Native of Ceylon. *Van Royen.* Deſcribed by De Candolle from a dried ſpecimen. "*Branches* round, brown, ſmooth, with an elevated ring round the origin of each leaf. *Footſtalks* ſtraight, two inches long. *Leaves* oval, or oblong; rather tapering at the baſe; obtuſe, or ſomewhat pointed, at the end; either entire, or very bluntly and ſlightly waved; the ribs pinnate, (as in the reſt,) having about eight or ten lateral ribs at each ſide. *Flower-ſtalks* ſimple, nearly oppoſite to the leaves. Two outer *calyx-leaves* rather the largeſt. *Petals* concave. *Stamens* very ſhort. *Germens* triangular, crowded. *Styles* reflexed." Such is De Candolle's deſcription, but he doubts whether this be a diſtinct ſpecies from the laſt. We have ſeen neither ſpecimen nor figure, but the plant having been received from profeſſor Van Royen, like our ſpecimen of the preceding, rather confirms the doubt than removes it.

4. W. *alata*. Wing-ſtalked Wormia. De Cand. n. 4. (Dillenia alata; Banks Ic. unpubliſhed, communicated with ſpecimens, in flower and fruit, to Linnæus.)—Leaves oval, entire. Footſtalks ſmooth, winged.—Gathered by ſir Joſeph Banks, in New Holland, near Endeavour river. The *branches* are round, ſmooth, except the annular ſcars left by the *ſtipulas*. *Leaves* three or four inches long, and above half as broad, ſmooth, obtuſe, with diſtant tranſverſe ribs, and copious reticulated veins; their under ſurface ruſty-coloured, but poliſhed. *Footſtalks* an inch or an inch and a half long, winged at each ſide with an entire leafy border, contracted at the apex, and quite ſmooth. *Flower-ſtalk* oppoſite to the upper leaf of the branch, ſolitary, racemoſe, triangular, ſmooth, ſhorter than the leaves, bearing two or three yellow *flowers*, larger than thoſe of *W. dentata*. *Petals* undulated. *Anthers* long, linear, with two pores at the end, like *W. dentata*. *Styles* ſometimes nine or ten, recurved. *Capſules* coriaceous, gaping, apparently real *follicles*, with a number of round *ſeeds*, inſerted into the margins, deſtitute, as far as we can ſee, of any pulpy tunic.

5. W. *ſericea*. Silky-ſtalked Wormia.—Leaves oval, bluntly ſerrated. Footſtalks depreſſed, ſilky, as well as the flower-ſtalks and calyx.—Native of the Eaſt Indies. A ſpecimen in the herbarium of the younger Linnæus, which he ſuppoſed to be *Dillenia indica*, is marked "*Mallei Mangatſokeri*, a tree with ſnow-white *flowers*." We cannot refer this to any thing in profeſſor De Candolle's work. It undoubtedly belongs to the genus before us. The *branches*

branches are round, ſtrongly ſcarred; when young, finely downy. *Leaves* crowded about the extremity of each branch, apparently deciduous, being found on young ſhoots only, ſhaped like the laſt, and nearly as large, but ſomewhat ſerrated, and, in a young ſtate at leaſt, finely downy; their tranſverſe ribs much more copious, ſtraight, and parallel, than in that. *Footſtalks* half an inch long, ſtout, broad, and depreſſed, blunt-edged, not bordered, denſely clothed with fine, white, ſilky, permanent down. *Stalks* ſimple, ſingle-flowered, ſilky, about the length of the footſtalks, each oppoſite to a leaf. *Calyx-leaves* obovate, concave, an inch long; ſmooth within; ſilky at the back. The *petals* we have not ſeen. *Filaments* ſhort. *Anthers* long, compreſſed, two-edged, each opening by two terminal orifices. *Germens* crowded together. *Styles* five, recurved at the extremity. *Stigmas* ſmall, abrupt.

We have at the end of the article DILLENIA, hazarded an opinion, that the *D. elliptica*, *integra*, and *retuſa* of Thunberg, as well as his *dentata*, above-deſcribed, belong to this genus of *Wormia*, to which profeſſor De Candolle ſeems, by a remark under *D. integra*, in his Syſt. v. 1. 437, diſpoſed to agree. Probably he thought it beſt, having examined no ſpecimens, to leave theſe plants where he found them, but we cannot omit the following, on the authority of Thunberg's figure.

6. W. *retuſa*. Abrupt Wormia. (Dillenia retuſa; Thunb. Tr. of Linn. Soc. v. 1. 200. t. 19. De Cand. Syſt. v. 1. 437. Willd. Sp. Pl. v. 2. 1253.)—Leaves obovate, abrupt, diſtantly toothed, ſmooth. Footſtalks hairy at the baſe. Stalks ſingle-flowered, ſmooth.—Native of woods in Ceylon. *Thunberg*. A *tree*, apparently nearly related to *W. dentata*, but the flowers are ſolitary, and rather ſmaller, each on a ſimple ſtalk, oppoſite to the uppermoſt leaf. *Styles* five, evidently thoſe of a *Wormia*, not a *Dillenia*.

WORMING, in *Ship-Building*, windling a rope cloſe along the cuntlines of larger ropes to ſtrengthen them, and make a fair ſurface for the ſervice. See *Plate* I. *fig*. 46. *Rigging*.

WORMING, in *Animals*, an operation which is ſometimes performed on the young of the dog and ſome other kinds. Young puppies are thus cut, in ſome caſes, under an ignorant ſuppoſition that it prevents their going mad; but in reality to cure them, as it generally does, of the diſpoſition to gnaw every thing in their way. It conſiſts in the removal of a ſmall worm-like ligament, ſituated beneath the tongue; and the part being afterwards ſore for ſome days, the animal is thus weaned of his miſchievous habits. See *Diſeaſes of* DOGS.

WORMIUS, OLAUS, in *Biography*, a Daniſh phyſician, deſcended from a family which fled from Arnheim, in Guelderland, to Denmark, from the perſecution of the duke of Alva, was born at Aarhuus, in Jutland, in 1588, and finiſhed his education at the univerſity of Marpurg; afterwards availing himſelf of the lectures which he attended in the principal German academies, and in his tour through France, Italy, Switzerland, and Holland. He then returned to Denmark in 1610, and having in the following year taken the degree of doctor in medicine at Baſle, he paſſed through the Netherlands to England, and in 1613 returned to his native country, where by ſucceſſive preferments he became profeſſor of medicine in 1624, in conſequence of the reſignation of Caſpar Bartholin. Although he obtained in 1636 a canonicate in the chapter of Lund, he continued his profeſſional practice, and was often conſulted by Chriſtian IV. and Chriſtian V. His knowledge of antiquities, medicine, and anatomy, was profound; and in 1628 he diſcovered bones in the human ſkull, called after his name "ſex officula Wormiana in futura cranii lamdoidea." His collection of curioſities was, after his death, lodged in the royal muſeum. He was thrice married, and had 18 children. He died in 1654. His writings were very numerous; and the principal of them are enumerated in the General Biography, to which we refer.

WORMS, in the *Linnæan Syſtem of Nature*. See VERMES.

WORMS, in *Huſbandry*, are very prejudicial to corn-fields, eating up the roots of the young corn, and deſtroying great quantities of the crop.

Sea-ſalt is the beſt of all things for deſtroying them. Sea-water is proper to ſprinkle on the land where it can be had; where the ſalt-ſprings are, their water does as well; and where neither are at hand, a little common or bay ſalt melted in water does as well.

Soot will deſtroy them in ſome lands, but it is not to be depended upon, for it does not always ſucceed. Some farmers ſtrew on their land a mixture of chalk and lime; and others truſt wholly to their winter-fallowing to do it; if this is done in a wet ſeaſon, when they come up to the ſurface of the ground, and ſome nails with ſharp heads be driven into the bottom of the plough.

If they are troubleſome in gardens, the refuſe brine of ſalted meat will ſerve the purpoſe, or ſome walnut leaves, ſteeped in a ciſtern of water for a fortnight or three weeks, will give it ſuch a bitterneſs that it will be certain poiſon to them.

A decoction of wood-aſhes, ſprinkled on the ground, will anſwer the ſame purpoſe; and any particular plant may be ſecured both from worms and ſnails by ſtrewing a mixture of lime and aſhes about its roots. It is a general caution among the farmers to ſow their corn as ſhallow as they can, where the field is very ſubject to worms. Mortimer's Huſbandry, p. 328.

In the roots of ſome ſorts of garden crops, ſuch as the carrot, onion, ſhallot, cauliflower, broccoli, and ſome others, worms and maggots are not unfrequently very injurious and hurtful, unleſs they be deſtroyed in ſufficient time to prevent ſuch effects. In the firſt, much advantage is ſuppoſed to have been gained by the full uſe of pigeon dung in preventing the worm.

And in this and the other ſorts of garden crops it is found, that much benefit in removing ſuch evils may be produced by a proper ſucceſſion of cropping, as that of following ſtrawberries which have been four or five years planted with onions, and artichokes that have ſtood the ſame length of time with carrots; as theſe ſorts of vermin do not attack either the ſtrawberry or the artichoke. In ſome caſes, it is ſuppoſed that it may be ſafe to crop two or three times with onions or carrots on the ſame ſpot, but not oftener, as ſome appearances of the worm and maggot are generally diſplayed in the ſecond or third year; but that from the ground being four or five years under ſtrawberries or artichokes, plants on which thoſe vermin cannot ſubſiſt, they ſoon periſh, and the land where the rows ſtood has all the advantage of a new ſoil.

Soot when applied as a manure is ſaid to be a good preventive of the maggot in onion crops; and that ſhallots, as requiring only a ſmall ſpot, may be much improved in growth, and entirely preſerved from the maggot, by the application of old hot-bed dung as manure, in the bottoms of the drills, well-mixed with ſoot; planting the ſhallots on this mixed manure, and covering them in to a proper depth. The ſoot in this caſe prevents the appearance of the maggot, and at the ſame time greatly improves the ſtrength of of the ſhallot plants: it is a method which has never been found to fail in preventing worms and maggots in ſuch crops.

Cauliflowers, broccoli, and the roots of other ſuch plants, may be preſerved from the effects of worms, by watering the drills of them well with ſoap-ſuds before planting them out, and afterwards occaſionally: this not only, it is ſaid, prevents the worm, but encourages the growth of the plants, and in ſome meaſure prepares the ground for other vegetables that are liable to the ſame ſort of attacks.

The maggot is conſidered by ſome as peculiar to the onion and ſhallot, and that whenever the former becomes diſeaſed, it is moſt liable to its attacks; and that as it could never be detected in the ſoil, it is highly probable that the ova or eggs of it are depoſited in the root, and may be hatched in the greateſt numbers when the plants are in a ſickly ſtate. It is not ſuppoſed, that the maggot ever paſſes from one onion to another; but that any remedy which is ſufficiently powerful to deſtroy the inſect muſt inevitably deſtroy the onion itſelf; that all that can be done is, therefore, to ſelect proper ſoils and ſituations for the onion crops.

It is remarked, however, that the maggot which attacks the carrot is unqueſtionably to be found in the ſoil, and that it viſibly enters from without.

It is concluded on the whole, that worms and inſects of theſe kinds in general are driven from their retreats under ground, by pouring bitter or acrid water upon it, as ſuch in which green walnuts have been ſteeped, or of which a ley has been made by diſſolving potaſh. See ſeveral papers in the firſt volume of the "Memoirs of the Caledonian Horticultural Society."

Worms, in *Medicine*. Three ſpecies of worms infeſt the human body; namely, the Ascaris, Lumbricus, and the *Tænia* or Tape-*Worm*; which ſee reſpectively.

Worms were formerly ſuppoſed to be a common cauſe of a ſeries of morbid ſymptoms, eſpecially in children; but it is now well underſtood, that the diſeaſe aſcribed to their influence is a maraſmus depending upon other morbid conditions of the alimentary canal. The ſymptoms of this diſeaſe have been already detailed, under the head of *Diſeaſes of* Infants, to which we refer.

Tin is often recommended as a good remedy againſt worms, particularly of the flat kind. Dr. Alſton, in the Med. Eſſ. Edinb. vol. v. art. 7. directs an ounce and a half of the powder of pewter-metal to be mixed in half a Scotch mutchkin, or about half a pint Engliſh meaſure of treacle, for children; but to grown perſons, he gives two ounces of the powder of pure tin, paſſed through the fineſt hair-ſieve, and mixed with eight ounces of treacle. As to the adminiſtration of this medicine, the original receipt directs half of it to be taken the Friday before the change of the moon; the day after, half the remainder, and the reſt on Sunday. On the Monday, a purge is to be taken. The doctor thinks there is probably nothing in the particularities of the day; but ſays, the medicine ſucceeds well in ſeveral ſpecies of worms.

The efficacy of fern-root againſt worms was known in the time of Dioſcorides; and towards the beginning of this century, Meſſieurs Andry and Marchant publiſhed accounts of ſucceſsful modes of exhibiting it in theſe caſes. But it has been principally celebrated of late as a ſpecific in the cure of the tænia, or tape-worm.

Dr. Prieſtley, conſidering how fatal nitrous air is to inſects, and likewiſe its great antiſeptic power, conceived that conſiderable uſe might be made of it in medicine, in the form of clyſters; and he apprehends, that if nitrous air was diluted with common air, or fixed air, the bowels might bear it better, and that it might ſtill be deſtructive to worms of all kinds, and be of uſe to check or correct putrefaction in the inteſtinal canal, or other parts of the ſyſtem. Prieſtley's Obſ. on Air, vol. i. p. 227.

Worms, in *Animals*, a troubleſome ſort of vermin often found in the inteſtines of the horſe, and ſome other animals, cauſing diſeaſe. See Botts, Earth-*Worms*, Ascarides, Tænia, and Teretes.

With reſpect to the cauſe of worms in horſes, it is imagined, that, as in the human ſubject, ſome conſtitutions are more inclinable to breed worms than others. Gibſon ſays, the moſt uſual cauſe of worms is foul or high feeding, which occaſion crudities and ſlimy indigeſted matter in the ſtomach and bowels, (eſpecially in horſes that have been pampered for ſale,) forming a proper nidus for worms. This indeed may be the caſe, but the primary cauſe of worms is that which occaſions theſe crudities, to wit, a want of energy in the functions of the ſtomach and bowels, as worms are never found in animals perfectly healthy in theſe reſpects.

According to Gibſon, the ſigns of worms in horſes are various, according to their different kinds. The botts that many horſes are troubled with in the beginning of ſummer are always found ſticking to the rectum, and are often thruſt out with the dung, along with a yellowiſh-coloured matter, like melted ſulphur. They are no way dangerous there, but they are apt to make a horſe reſtleſs and uneaſy, and rub his breech againſt the poſts. The ſeaſon of their coming is uſually in the months of May and June, after which they are ſeldom to be ſeen, and rarely continue in any one horſe above a fortnight or three weeks. Thoſe that take poſſeſſion of the membranous portion of the ſtomach are extremely dangerous in cauſing convulſions, and are ſeldom diſcovered by any previous ſigns before they bring a horſe into violent agonies. See Botts.

But the teretes or earth-worms give little diſturbance to a horſe, and would hardly be diſcovered, unleſs they were ſeen now and then to come away with the dung. Frequently horſes void one or two, and no more; and ſometimes they will void pretty large quantities of the young brood, not much larger than the aſcarides, only of a red colour, and not white, as the latter generally are. They are moſt uſual in autumn, or the beginning of winter, though a horſe may now and then void one or two of theſe at other times of the year.

However, the aſcarides, or ſmall needle-like worms, are very troubleſome to horſes, breed at all times of the year, and often when one brood is deſtroyed another ſucceeds. Theſe are not at all dangerous, yet when a horſe is peſtered in this ſort of way, though he will go through his buſineſs tolerably well, and ſometimes feed heartily, yet he always looks lean and jaded; his hair ſtares as if he was ſickly, and nothing that he eats makes him thrive. That he feels pain, too, is plain, for he often ſtrikes his hind foot againſt his belly, which ſhews where his grievance lies, and is ſometimes griped, but yet without the very violent ſymptoms that attend a colic or ſtrangury. He never rolls or tumbles, but only ſhews uneaſineſs, and generally lays himſelf down quietly on his belly for a little while, and then gets up, and begins to feed; but the ſureſt ſign is, when a horſe voids theſe worms with his dung.

In regard to the cure, if a horſe be troubled with botts, Gibſon ſays, he may be relieved without much expence or trouble, only by giving him a ſpoonful of ſavin, cut very ſmall, once or twice every day, in oats or bran moiſtened; and if three or four cloves of chopped garlic be mixed with

with the favin, it will do better, for garlic is of great fervice in thefe complaints. Horfes that are troubled with botts ought to be purged with calomel and aloetic purges before the weather grows too hot; and if they be kept to a clean diet after this, it will be a great chance if ever they are troubled with them any more. As the botts generally happen about the grafs feafon, thofe horfes that are turned out to grafs often get rid of them there, by the firft fortnight's purging; and, therefore, thofe that have the convenience of a good pafture for their horfes need not be very folicitous about giving them medicines.

And the earth-worms, which fome writers call teretes, rotundi, or lumbrici, are alfo beft conquered by calomel and occafional aloetic purges, for worms often come away in purging, when, till then, it has not been known that the horfe was troubled with them; and it has been obferved, after thefe have been voided, that the animal has thriven better, grown more lively, and fhewn more alertnefs at his bufinefs. There can fcarcely be a better plan of treatment than is fupplied in the following *formulæ*, recommended by Mr. Denny in his ufeful work: — Take of calomel, one drachm; anifeeds, in powder, half an ounce; treacle, enough to make a ball. This is directed to be given in the evening; and the next morning the following:—Take of fuccotrine aloes, in powder, one ounce; ginger, in powder, two drachms; treacle, enough to make a ball: and the above bolus and purgative ball muft be repeated, with an interval of nine days, until the horfe has taken three dofes. Then it is advifed to give the following alterative powder, daily for about a month; this procefs does not require any change of diet, or involve any hazard from the effects of cold:—Take of Ethiops mineral, crude antimony, prepared, and anifeeds in powder, each half an ounce; mix them. The management of the horfe during this courfe of worm medicines is that in common cafes of phyfic; but fome prefer giving Barbadoes aloes for the removal of worms, thinking it the more efficacious, becaufe its operation is very rough: and Gibfon thinks it may be given to hackneys, and other horfes of fmall value; but he never found it more efficacious than the fuccotrine, at the fame time that it expofes a horfe more to gripes and other dangerous diforders, unlefs it be properly managed. The following he gives as a cheap well-corrected purge of this kind:—Take of Barbadoes aloes, one ounce; falt of tartar, two drachms; ginger, grated, a drachm and a half; oil of amber, a middling fpoonful; fyrup of buckthorn, fufficient to make a ball. The only objection to this is the quantity of aloes, which would be too confiderable even if of a milder fort for fome horfes.

It may be obferved, that the fort of worms called afcarides fometimes come away from a horfe in great numbers, with the help of a purge, and fome get quite clear of them with purges only; but this does not very often happen, for the horfes that breed afcarides, above all others, are fubject to flime and foulnefs in their inteftines. In the human body, afcarides are thought to be bred in the rectum, near to the fundament; but in horfes no other kind than botts ufually adhere to that gut. On the contrary, thefe worms in them feem to be lodged about the beginning of the fmall inteftines near the ftomach, where they feed on the alimentary parts of the chyle. The botts in a horfe are often feen fticking near the fphincter ani, and are continually dropping away with the dung; but the afcarides are feldom feen there, except when the animal has had a purge given him, or when he falls into a natural purging, which often happens from the irritation of the bowels, and then they come away in very great numbers, accompanied with much flime and mucus. Botts feldom alter a horfe's looks, but thefe not only make a horfe grow lean, and look emaciated, but on opening his mouth one may perceive a more than ordinary languid whitenefs, and a fickly fmell, inftead of that livelinefs of colour that is always perceivable in the mouth of a found and vigorous horfe; fo that, whatever be the primary caufe, thefe worms feem in a great meafure to proceed from a vitiated appetite and a weak digeftion, which renders them the more difficult to be removed; for which purpofe recourfe muft be firft had to the foregoing remedies, and after them, fuch medicines as are proper to ftrengthen the ftomach, promote digeftion, and give tone to the folids.

The treatment advifed by Gibfon for thefe worms is chiefly the following: — Take of calomel, prepared, two drachms; diapente, half an ounce; make thefe into a ball, with a fufficient quantity of conferve of rofes, and give it in the morning, keeping the horfe from meat an hour or two before and after the dofe; and the next morning adminifter a moderate aloetic purge, taking great care to keep the horfe from wet, or from any thing that may expofe him to take cold. The above calomel ball and the purge may be repeated in fix or eight days, and again in fix or eight days more. Or the following mercurial purge may be given, which will be lefs troublefome, though not lefs efficacious:—Take of crude quickfilver, two drachms; Venice turpentine, half an ounce. Rub the quickfilver with the turpentine in a mortar till no particle of the former appear; then add, oil of favin, thirty or forty drops; fuccotrine aloes, in powder, half an ounce; ginger, grated, one drachm; fyrup of buckthorn, enough to make it up into a ball.

One of thefe mercurial purges may be given in the foregoing manner, *viz.* one in fix or eight days, with all the fame precautions: it will work mildly, and with little or no griping or ficknefs. And another mercurial purge, which is proper to deftroy worms and to cleanfe the firft paffages, is this:—Take of diagridium, calx of antimony, and calomel, of each two drachms; fuccotrine aloes, fix drachms; ginger, grated, one drachm; oil of favin, cloves, or anifeeds, thirty or forty drops; fyrup of buckthorn, enough to form the ball. To be given as the preceding.

When a horfe has gone through a courfe of thefe mercurial purges, fome advife the following drink to be given two or three times a-week, or till the horfe begins to thrive and look healthy:—Take of rue, camomile flowers, horehound, of each a handful; galangals, bruifed in a mortar, three drachms; liquorice-root, fliced, an ounce. Boil thefe in a quart or three pints of forge-water fifteen or fixteen minutes in a covered veffel, and keep it covered till cold; then ftrain it through a piece of coarfe canvas, and give it in the morning upon an empty ftomach.

Powdered tin has likewife been advifed with the intention of deftroying worms; and alfo moft of the preparations of antimony: fulphur is alfo good in all fuch cafes; and even crude antimony in fine powder, given with equal parts of fulphur, often fucceeds in the proportion of an ounce in the morning and another at night.

The worms which infeft the bodies of other animals of different domeftic kinds may be deftroyed, expelled, or got rid of, by the fame remedies and modes of treatment, only proportioning their quantities to the nature and ftrength of the animals to which they may be given, and regulating the manner of exhibiting and continuing them, to that of the ftates in which they may be at the time, from the effects of the worms and other caufes.

There is alfo a kind of worms which are frequently fatal to the gallinaceous birds, of which a curious account has been given by Mr. Weinſenthal, in the Medical and Phyſical Journal. The inconvenience produced by theſe creatures is at firſt but ſlight: however, it gradually becomes more and more oppreſſive, until it ultimately deſtroys the birds. Very few indeed recover; they languiſh, grow diſpirited, droop, and die. It is found, on diſſection, that theſe ſymptoms are occaſioned by worms in the trachea. The writer has ſeen the whole of it completely filled with theſe worms, and has been aſtoniſhed at the animal's being capable of reſpiration at all under ſuch circumſtances.

They are of a reddiſh colour, and at firſt view reſemble the human lumbricus; but when examined are materially different. When expoſed to the microſcope, they are found to have an orifice or mouth at one end, formed for ſuction; the other end, as far as it can be aſcertained, is imperforated. The inteſtinal tube is much convoluted, like that of the lumbricus.

It does not appear that any effectual remedy has been yet diſcovered for removing theſe moſt deſtructive animals. They have been drawn out of the trachea by means of a feather, ſtripped from near its end, which is paſſed into the larynx and twiſted round, till it engages one or two of the worms, which are extracted, but without any relief to the animal, after the operation has been performed.

Worm, in *Timber*, a diſeaſe in growing fir, and perhaps other timber-trees, produced by a worm. For which it is ſuppoſed by Mr. Nicol, in his "Practical Planter," that there can be no remedy except in the draining and improvement of the ſoil. Indeed, this diſeaſe is not known on ſoils congenial to the nature of the plant; nor does it ever appear until the tree becomes ſickly, by its roots having touched a cankering bottom.

It has been ſuppoſed this worm is the ſame with that which is found in deal, and ſome other ſorts of wood.

Worms, *Aquatic*. See *Water*-Worms *infra*.

Worm, *Aſcaris*, in the *Linnæan Syſtem*, a genus of the order of *inteſtina*, and claſs of *vermes;* the characters of which are, that the body is round and filiform, and attenuated towards both ends. There are two ſpecies. See Ascarides.

Worm, *Bee*. See *Generation of* Bees.

Worm, *Butterfly*. See Aurelia, and Caterpillar.

Worm, *Canker*. See Scarabæus.

Worm, *Chur*. See Gryllus.

Worm, *Cochineal*. See Coccus.

Worm, *Connough*, or *Connaught*, in *Natural Hiſtory*, a name given by the common people of Ireland to a kind of caterpillar found in many parts of that kingdom; and, from its ugly aſpect, reputed to be poiſonous.

It is ſaid to be the only poiſonous creature of that kingdom, and many miſchievous effects are attributed to its ſting, and to its poiſonous quality, when eaten by cattle. As to the firſt of theſe opinions, it is evidently erroneous; the creature having no power to ſting at all. The other is not ſo eaſily proved falſe, but is much to be ſuſpected. The reaſons on which it is founded are theſe: the cattle in Ireland are ſubject to a very terrible diſeaſe, which is moſt frequent in autumn; about the time when theſe animals are in the greateſt plenty.

It is moſt frequent alſo among thoſe cattle which feed in low and marſhy grounds, where this creature lives and feeds; cows and hogs, which feed in theſe places, are the only creatures ſubject to the diſtemper, and this is imputed to the cow's eating by large mouthfuls, becauſe ſhe chews the cud a ſecond time; and the hogs feeding ſo foul and greedily, as to eat things which other creatures refuſe. Finally, the great cauſe of aſſigning this diſeaſe to this creature is, that the worm only appears in great numbers about once in ſeven years; and in theſe, and theſe years only it is, that the diſtemper among the cattle is common.

The ſymptoms by which this diſeaſe is diſtinguiſhed from all others are, great ſwelling of the head, and a falling down of the anus; the gut often hanging out to the length of ſix or ſeven inches. The common cure among the more intelligent people is a ſtrong decoction of the plant called bear's-foot, or great black hellebore, with ſome rue and garlic given with butter and beer; this is found to have great ſucceſs with the cows. The hogs are cured only by mixing reddle, or the common red ochre powdered, with butter-milk, and making them eat a large quantity of it.

The Iriſh peaſants have recourſe to many idle remedies; but theſe are found often of real ſervice. The caterpillar, ſuppoſed to occaſion this diſeaſe, feeds on the common ragwort, and is larger than moſt other creatures of this kind, being of the length and thickneſs of a man's finger; it is marked with two large ſpots behind the head, which are ſuppoſed by the vulgar to be the eyes, but are only round variegations, of the nature of thoſe common on other caterpillars; and what they take to be a ſting in the tail, is no other than a horn in that part, which is not peculiar to this caterpillar, but found on many others. That the common people are deceived in regard to the external parts of this creature is evident; but experiments are required yet to prove whether or not they are ſo, in regard to its poiſonous quality.

One trial is remarked by Mr. Molyneux to have been made on a dog, who eating the ſkin of only one of the creatures was found dead about three days after; another dog, which drank the juices expreſſed from that ſkin, received no hurt. The inſect is deſcribed in Liſter's edition, under the name of the elephant caterpillar. Phil. Tranſ. N° 168. p. 880.

Worm, *Earth*, *lumbricus*, a genus of the order of *inteſtina*, including two ſpecies. See Earth-*Worm* and Lumbricus.

Worm, *Flower-root*. See Flower.

Worm, *Fly*, in *Natural Hiſtory*, the worm or maggot produced of the egg of a fly, and afterwards to be tranſformed into one.

Theſe worms are to the fly, what the caterpillar is to the butterfly it produces. The cuſtom of the world has appropriated the term caterpillar to that one ſpecies of the flying inſects' firſt ſtate; but we have unfortunately no term of diſtinction yet eſtabliſhed for any of the firſt ſtate of any of the other flying inſects, the creature produced by the egg of the fly ſcarce being indeterminately called worm. Till more expreſſive names ſhall be invented for theſe, it may not be improper to diſtinguiſh thoſe of the different claſſes by the additional name of the inſect they are to be changed into, and to call that which is to become a beetle, the *ſcarab-worm;* that which is to be hereafter a fly, the *fly-worm;* and ſo of the reſt.

Thoſe which are to be hereafter winged creatures of the fly-claſs are extremely different one from another in form and figure, and may very properly be arranged into ſeveral claſſes.

The moſt remarkable and ſtriking differences between the claſſes of thoſe creatures, are thoſe of the form and ſhape of their heads. Many of them have heads which it is not eaſy to diſtinguiſh to be ſuch, as they carry no one mark of the head of an animal viſibly about them. There are many whoſe heads are variable at the pleaſure of the creature, and which at times are ſeen to be more or leſs long, more or leſs thick, more or leſs flat, more or leſs ſhortened at pleaſure

by

by the animal, and eafily bent and turned about in any direction. The heads of thefe creatures are compofed of a very foft and flexible flefh.

There are others whofe heads are hard, and which always retain the fame regular figure. The firft general arrangement of thefe worms may be into thofe which have a variable, and thofe which have an invariable head. The fubordinate diftinctions may be deduced from the number, difpofition, ftructure, and form of the other parts. Some worms of this kind have no legs; thofe of others are membranous or fcaly; and others have them both membranous and fcaly. Some worms have the power of altering the figures of their bodies at pleafure, both as to length and bulk: the bodies of others are rigid, and incapable of thefe changes. Some, again, have a thin membranous coat; whereas that of others is firm and fcaly, or cruftaceous. Moreover, confiderable differences are obfervable with regard to the pofition, number, and figure, of their organs of refpiration.

Among the fly-worms of variable heads, the difpofition of the ftigmata, or air-holes, at which the tracheæ of thefe animals terminate, will afford feveral diftinctions of genera: *e. gr.* the worms of the common flefh-fly has in its ftigmata fix apertures, three in each, refembling button-holes; but the worms of many other flies have only one fmall eminence in each: others have them cylindric and hollow, and projecting like horns, of which fome have two, and others three, differently fituated and difpofed. The number and figure of the hooks, which ferve thefe creatures for teeth, may alfo ferve for matter of diftinction. The common worm of the flefh-fly has two hooks, with a dart between them; others have hooks without a dart; fome have one hook, and others none. The figure of the body, and the differences of fize and colour, may furnifh farther diftinctions with regard to the genera of the firft clafs.

Thofe of the fecond clafs, which have variable heads, and differ from the former in having legs like thofe of the caterpillar clafs, have often a fort of hooks faftened to them: they have alfo a long flefhy tail, capable of being lengthened or contracted at pleafure, and refembling the tail of a rat; whence thefe are called *rat-tailed worms*. In thefe worms, the tail is the principal organ of refpiration; its end being always open, and fupplying the office of the ftigmata of the other genera.

The fly-worms of the third clafs, which have invariable heads, and have nothing analogous to the organization of moveable jaws, have pointed heads, or fuch as feem truncated, and no fcaly legs: thefe form a very numerous family both in the terreftrial and aquatic kingdom, and all of them furnifh two-winged flies. Under this clafs Reaumur enumerates and defcribes eight genera. This ingenious writer mentions worms of another clafs, which ufually produce four-winged flies, having heads of an invariable figure, and two teeth or moveable jaws near the aperture of the mouth, without fcaly legs, and with the ftigmata placed on the fides of their bodies. The flies produced from thefe are, the bees, wafps, ichneumons, gall-flies, &c. There is another clafs of the hexapode, or fix-legged worms, which are transformed into fome fpecies of the libellæ; which have no mouth, but two openings at the top of their antennæ, through which their aliment may pafs. The formica leo, and the puceron eaters, belong to this clafs. There is another clafs, which have bodies like thofe of the caterpillar clafs, and fix legs, befides two other fhorter legs or hooks near their hinder part, which ferve for motion and for fixing themfelves. The water-worms, which make for themfelves cafes of different materials, and are transformed into papilionaceous flies, are of this clafs. There is alfo a clafs of worms, called falfe or baftard caterpillars. See Fausse *Chenille*. See the more particular defcription of thefe claffes, and their fubordinate genera, in Reaumur's Hift. Inf. tom. iv. p. 161, &c.

Worm, *Gourd*, the name of a fpecies of *tænia*, or tapeworm; the body of which is of an oblong form, flat on the belly, and rounded on the back; its fkin is foft, and its mouth large, horizontal, and emarginated, or dented in the middle. It refembles the common gourd in figure, and from thence has got this name of *vermis cucurbitinus*, or the gourd-worm. It is frequently found in the inteftines of animals.

Worm, *Golden*. See Aphrodita.

Worm, *Guinea*, or *Hair*-Worm. See Chætia, Amphisbæna, and Dracunculi.

Worm, *Gally*, *Glow*, *Gnat*, *Goofeberry*, *Hay*, *Horfe*, *Lyfimachia*, *Mufhroom*, *Oyfter*, *Pile*, *Sheep-nofe*, *Silk*, *Solitary*, and *Truffle*. See the refpective articles.

Worms, *Meal*. There are two very different infects found in our meal or flour; the one is fo fmall, that it is only to be feen by the microfcope; all that the naked eye can difcover of it is, that fomething is alive in the place, from the whole fubftance of the flour being in motion. See Flour.

The other meal-worm is larger, and more frequently offers itfelf to our obfervation: it confifts of eleven rings, and has three pair of legs. The mouth of this worm is made into a kind of forceps, and from this arife, on each fide, a great number of fmall fpinulæ; thefe ferve inftead of teeth, and the animal feeds by means of them. They are found fometimes very foft and tender, fometimes hard and firm; at fome feafons they are very brifk and lively, at others they have fcarce any life in them.

The moft remarkable thing in regard to thefe worms is, that they are always exactly of the colour of the flour which they live among. Ray has obferved, that the white flour breeds white ones; the coarfer flour breeds larger and greyer ones; and that flour which has the bran among it, breeds brown ones of the fame colour with that of itfelf. This is a provifion of nature for the fafety of the animal, fince were it of a colour different from that of the flour, it muft be eafily difcovered among it, and would be picked out and thrown away. The caterpillar tribe are thus preferved, by being of the colour of the leaves they feed on; their green ufually fuiting itfelf exactly to that of the tree or plant. Deflandes, Trait. Phyf.

Worms *of the Sea*. The fea-worms are of the number of thofe animals which, with the oyfter and feveral other fhell-fifh, furnifh us an inftance of animals which remain all their lives fixed in the manner of plants to one fpot, whence there is no probability of their moving themfelves.

Thefe worms are included in a fort of cafes or pipes, and may be divided into two claffes, according to the nature of thofe cafes. In the one fpecies thefe only are made of grains of fand, fragments of fhells, and the like, faftened together by a vifcous humour; and in the other they are compofed of a true fhelly matter.

Thofe worms which have fhelly cafes are fixed fometimes to the fand at the bottom of the fea, fometimes to ftones, or fea fubftances, and fometimes to the fhells of other fifhes; their fhells are rounded, and, in fome degree, conic, as they always gradually grow wider from their point or apex to the mouth; as to the reft, their fhape is different in almoft every individual, forming divers irregular curves, and often refembling the fhapes into which a common earth-worm curls and twifts itfelf in its various motions.

 When

When we confider the effects of the glutinous juice iffuing from the body of this animal, in faftening together any loofe fubftances it meets with, fo as to form a cafe for it, it may be eafily fuppofed that the adhefion of the balani-marini, and other the like fhells, which remain all their lives fixed to fome one fpot, is performed in the fame manner. Mem. Acad. Par. 1711. See VERMICULUS.

WORMS, *Water*. Of thefe there are fome which transform themfelves by a fingular procefs, without any vifible change in its exterior form, into flies, and belong to the third clafs of fly-worms. They are particularly defcribed by M. Reaumur, Hift. Inf. tom. iv. p. 310, &c.

There is a fingular fpecies of thefe creatures, which is found to be capable of reproduction or multiplication from cuttings, in the manner of the polype.

The difcovery Mr. Trembley made of this ftrange property in the polype, gave occafion to the trying of the experiment in regard to fome other infects. Worms were the moft natural objects of thefe experiments; and though they failed in many fpecies, they yet fucceeded in fome, and proved, that nature has not given that amazing property of reproduction of its moft effential parts, to only one fpecies of animals.

Mr. Bonet tried the experiment on a very nimble kind of water-worm, by cutting it into two in the middle, and the fuccefs perfectly anfwered the expectation; for the two pieces continued alive and vigorous, and in a little time became two complete worms. The ftructure of thefe worms, though it appear fimple to the naked eye, is very worthy the examination of the microfcope, and when viewed with this affiftance, there are difcovered in it parts extremely deferving our attention. Phil. Tranf. N° 469. p. 470.

Dr. Hales, in his Vegetable Statics, relates a curious experiment, by which it is proved that the bones of animals, when they are offified to a certain degree, do not grow any longer, except at their extremities; and the cafe is the fame in regard to thefe worms; for the old piece, which is the middle of the animal, never lengthens itfelf, but the addition of new rings to each end makes the increafe of length in the worm.

In all thefe pieces the liquor, which ferves as blood to the animal, is found circulating from the tail-part towards the head, in the ufual way; and by this motion of the blood it is always eafy to know, even in the fmalleft pieces, which is the head and which the tail-end, and the new head and tail are always feen to come regularly from the proper ends. Phil. Tranf. N° 469. p. 470, &c. See REPRODUCTION.

WORM, in *Chemiftry*, denotes a long, winding pewter-pipe, which diftillers and apothecaries place in a tub of water, to cool and condenfe the vapour in the diftillation of fpirits.

This the chemifts alfo call a *ferpentine*. Formerly, this worm, or fomething like it, was placed above the head of the ftill, with a refrigeratory at the upper end of it, which is ufeful enough in the diftilling of fpirit of wine.

WORM, in *Gunnery*, is a fingle or double-wired iron fcrew, mounted on a wooden handle by means of a focket, or fixed on the end of a rammer, to pull out the wad of a cannon, firelock, carabine, or piftol; it is the fame with the *wad-hook*, only the one is more proper for fmall fire-arms, and the other for cannon.

This inftrument ferves to draw out the wadding, or pieces of cartridges, which remain in the gun after frequent firing, and which would otherwife accumulate fo much, that other cartridges could not be rammed home enough to reach the priming, whereby the gun would mifs fire.

To WORM *a Cable* or *Hawfer*, in *Sea Language*, fignifies to ftrengthen it, by winding a fmall line, or rope, all along between the ftrands.

WORM-*Powders*. See POWDER.

WORM-*Seed*, *Semen Contra*, *Semen Sanctum*, or *Semen Santonicum*, is a hot, bitter, drying kind of feed, proper to deftroy worms generated in a human body, and particularly in children.

This feed is light, fmall, oval, compofed of a number of thin membranous coats, of a yellowifh-green or brownifh colour, eafily friable on being rubbed between the fingers into a fine chaffy kind of fubftance, a bitter tafte, and a ftrong fmell. It muft be chofen new, greenifh, of a fharp, bitter, aromatic tafte, not a little difagreeable.

The place where it is produced is Perfia, about the frontiers of Mufcovy. It is brought to us from Aleppo, &c. Naturalifts have not been agreed about the plant that produces it.

J. Bauhine has a large differtation on the fubject. Some will have it the fpecies of abfinthium, or wormwood, called *fantonicum*, or *marinum abfinthium;* others will have it the *tanacetum;* others the *abrotanum;* but it is now fuppofed to be the produce of a fpecies of *artemifia*, refembling in its general appearance our fine-leaved mugwort, called by Linnæus *artemifia fantonica*, and the *artemifia auftriaca* of Jacquin.

M. Tournefort gives us the following account of this notable drug, in the fecond volume of his Travels. The fementine, or worm-powder, is not gathered like our feeds. The plant grows in the meadows, and muft be let ripen; and the mifchief is, that as it grows near to maturity, the wind fcatters a good part of it among the grafs, where it is loft; and this makes it fo dear.

As they dare not touch it with the hand, for fear of making it fpoil the fooner, when they would gather what is left in the ear, they have recourfe to this expedient. They take two hand-bafkets, and, walking along the meadows, fweep the bafkets, the one from right to left, the other from left to right, as if they were mowing; by this means the feed is fhaken out into the bafkets.

Thefe feeds have been chiefly recommended as anthelmintics, and commonly taken, in this intention, either along with molaffes, or candied with fugar. For other purpofes they appear to be a ftrong bitter. They give out their virtue both to water and fpirit. The extract made by rectified fpirits, appears to be the moft eligible preparation of the fantonicum for the purpofes of an anthelmintic; and the watery extract, or a tincture drawn from it, for the more general intentions of bitter medicines.

Some have afcribed their quality of deftroying worms folely to their bitternefs; but it appears from Baglini, that worms (lumbrici) immerfed in a ftrong infufion of thefe feeds were killed in five, and according to Redi feven or eight hours; while in the infufion of wormwood, and in that of agaric, the worms continued to live more than thirty hours; and hence it has been inferred, that their vermifuge effects would not wholly depend upon the bitternefs of this feed. To adults, the dofe in fubftance is from one to two drachms in a day. (Woodville's Med. Bot.) The worm-feeds of former pharmacopœias are now properly rejected, as their place is fupplied by anthelmintics of more certain efficacy.

WORM-*Tincture*, in *Chemiftry*, a name given by many to a medicine prepared by Hoffmann from earth-worms; and in many parts of Germany efteemed one of the moft noted medicines in the world, though lefs known in other places.

The preparation is this: the worms are to be collected in the spring or summer months, and the larger sort are the best. They are to be carefully dried, and reduced to a fine powder; this powder is to be mixed up into the consistence of a poultice, with oil of tartar *per deliquium*, and this is to stand twenty-four hours; then spirit of wine is to be poured on it, so as to reach three fingers-breadth above it, and a drachm of saffron, and half a drachm of castor, are to be added, and the whole is to stand three days in infusion, and after this be filtered off for use. Some add a small quantity of opium to the tincture, but as it is often wanted in cases where opium is not proper, it is better to keep it separate thus made; and when there is occasion to have it opiated, to add as many drops of laudanum as is judged necessary.

The oil of tartar in this case penetrates the very innermost structure of the worms, and is a means of extracting such a tincture from them, as no art could otherwise contrive to make; and the medicine becomes, according to Hoffmann, much more than an anodyne, from the admixture of the salt of tartar in the tincture.

When it is intended to be made with opium, it is always proper to add also some of the hound's-tongue root, which is found as an anodyne to emulate the virtues of opium.

This tincture, whichever way prepared, is excellent in abating the pains of diseases that do not admit a cure. The fits of the gout are rendered easier by every dose of it; and even in cancers, the pain is quieted in a wonderful manner by it, and life rendered much more supportable. Hoffmann's Act. Laborator. Chym.

Worms, in *Geography*, late a bishopric of Germany, in the circle of the Upper Rhine, surrounded by the Lower Palatinate, the county of Katzenelnbogen, and the electorate of Mentz; about ten miles in length along the borders of the Rhine. In ancient times, the Vangiones inhabited this district. In the middle ages it was called "Wormbsveld," "Wormatzfeld," or "Wormsergau;" and one of the bishops, named Victor, is said to have assisted at a council at Cologn, in the year 347. Of the ancient bishops here, however, we have little certainty. The series of the prelates of Worms, which may be most depended on, begins with Erembert, who was appointed bishop thereof about the year 770. The bishop of Worms was subject to the archbishopric of Mentz. In the circle of the Upper Rhine, he was the summoning prince and director. In the council of the princes of the empire, he exchanged place on the spiritual bench with the elector of Wurzburg. The whole of the bishopric situated on the left side of the Rhine is annexed to France, and included in the department of Mont Tonnerre.

Worms, a town of France, in the department of Mont Tonnerre, late an imperial city of Germany, in the circle of the Upper Rhine, and capital of a bishopric of the same name, anciently the capital of the Vangiones. It was situated nearly in the centre of the diocese to which it gave name, not far from the Rhine, and near the place where the Eisbach and Giessenbach fall into it. This city was accounted one of the free Lutheran imperial cities, with toleration and freedom of worship to the Catholics. The Calvinists had also a church here. To the Catholics belonged not only the cathedral, but likewise four collegiate and the like number of parish churches in or near the city, a college, a gymnasium, three convents, and three nunneries. The bishop's palace here was built quite new, in 1719, at the expence of bishop Francis Louis. The kings of the Francs appointed counts and dukes over it. From time immemorial it has been termed a free imperial city, and is so styled in some records of the emperor Charles IV., bearing date in 1355 and 1356, and in the register of the cities of 1386, and was also acknowledged such in 1479, in the diet at Nuremberg; and by the emperor Maximilian I., in formal instruments of 1507 and 1508. In 1495, 1521, 1545, and 1578, diets were held here, and this was the place in which the reformation began in 1525. In 1743, a treaty was concluded here betwixt his Britannic majesty, the queen of Hungary, and the king of Sardinia. In the beginning of the revolution, Worms surrendered to a detachment of the French republican army, and was laid under a heavy contribution by Custine, but evacuated after the loss of Mentz. It was again taken in 1794; 25 miles S. of Mentz. N. lat. 49° 36′. E. long. 8° 22′.

Worms. See Bormio.

Worms's *Head*, or *Penrhyn Gwyr*, a rock on the south coast of Wales, in the county of Glamorgan. N. lat. 51° 36′. W. long. 4° 17′.

WORMSDORF, a town of Saxony, in the circle of Leipsic; 20 miles E. of Leipsic. N. lat. 51° 16′. E. long. 12° 53′.

WORMSER Joch, a mountain of the Tyrolese, between the sources of the Adige and the Adda; 8 miles S. of Glurentz.

WORMVILLE, a town of United America, in the Mississippi territory.

WORMWOOD, Absinthium, in *Botany*. See Artemisia *Absinthium*.

The common wormwood, *artemisia absinthium* of Linnæus, grows wild about dunghills, and on dry waste grounds, flowers in June or July, and may be propagated by slips in March or October, or raised from seeds sown soon after they are ripe. The leaves have a strong offensive smell, and a very bitter nauseous taste; the flowers are equally bitter, but less nauseous; the roots are warm and aromatic, without the bitterness and offensiveness of the other parts: the leaves lose part of their ill smell by being dried and kept for some time. The active parts of this plant seem to be extractive, essential oil, and a small portion of resin.

Wormwood leaves give out nearly the whole of their smell and taste both to aqueous and spirituous menstrua; the former, prepared without heat, being the least ungrateful. Rectified spirit elevates little from this plant in distillation; water brings over nearly the whole of its smell and flavour Along with the aqueous fluid there arises an essential oil, which smells strongly, and tastes nauseously of the wormwood, though not bitter. The oil drawn from the fresh herb is commonly of a dark green; from the dry, of a deep yellowish-brown colour. The quantity of oil varies according to the season and soil in which the wormwood is produced: in some years, ten pounds have afforded upwards of two ounces; in others, twenty pounds have yielded little more than one ounce. Geoffroy observes (Mem. Acad. Par. 1721), that in rainy seasons and moist soils, it yields the most oil; that in dry years the oil is accompanied with a resinous matter, and proves of a fine green colour; and that in wet seasons it is less resinous, and not green. A decoction of wormwood in water, long boiled, and inspissated to the consistence of an extract, loses the smell and flavour of the plant, but retains its bitterness. An extract, made with rectified spirit, contains, along with the bitter, nearly the whole of the nauseous part; the watery extract gives out its simple bitterness, not only to water again, but to rectified spirit.

Wormwood is a moderately warm stomachic and corroborant: for these intentions it was formerly in common use, but it has now given place to bitters of a less ungrateful kind. An infusion of the leaves, with the addition of fixed alkaline

alkaline falt, is a powerful diuretic in dropfical cafes. The effential oil is fometimes given, in dofes of a drop or two, properly diluted by folution in fpirit of wine, as a mild antifpafmodic. Its more frequent ufe is a vermifuge; for which purpofe it is both applied to the belly, and taken in pills made with crumb of bread. Dr. Lewis, however, fays, that the fpirituous extract promifes to be, in this intention, preferable to the pure oil; as it contains, along with the oil, all the bitter matter of the wormwood. This plant very powerfully refifts putrefaction, and is made a principal ingredient in antifeptic fomentations. Boerhaave commends, in tertian agues, a medicated liquor, prepared by grinding about feven grains of the oil with a drachm of fugar, and two drachms of the alkaline falt extracted from the afhes of wormwood, and afterwards diffolving the compound in fix ounces of the diftilled water of the plant. Two hours before the fit is expected, the patient is to bathe his feet and legs in warm water, and then drink half an ounce of the liquor every quarter of an hour, till the two hours are expired: by this means, he fays, cafes of this kind are generally cured with eafe and fafety, provided there is no fcirrhofity or fuppuration.

Dr. Lewis obferves, that this medicine is a very ferviceable aperient, where obftructions of the vifcera prohibit the immediate ufe of the bark, and in fuch obftructions as the imprudent ufe of the bark may have occafioned. Its virtues, he fays, might be improved by an addition of the bitter watery extract; though the compound, thus laborioufly prepared, would not be at all fuperior to a fimple infufion of the plant in pure water, impregnated with a due proportion of fixed alkaline falt.

The roots of wormwood, fays Dr. Lewis, promife to be applicable to fome ufeful purpofes: their virtue refides chiefly in the cortical part; and rectified fpirit extracts their flavour more perfectly than watery liquors. The Edinburgh college directs a tincture of the dried flowering tops of wormwood, in the proportion of fix ounces to a quart of rectified fpirit, under the title of *tinctura abfinthii.* This, in the opinion of Dr. Cullen, is a light and agreeable bitter, and at the fame time a ftrong impregnation of the wormwood. Dr. Cullen concurs with Bergius and Gladitfch in afcribing to the odour of wormwood a quality of occafioning fome confufion of the head; and formerly, he fays, when it was the fafhion with fome people in the country to drink purl, that is, ale in which wormwood is infufed, it was commonly alleged to be more intoxicating than other ales. This effect he inclines to attribute to its narcotic power; and he is of opinion, that there is in every bitter, when largely employed, a power of deftroying the fenfibility and irritability of the nervous power. The dofe in fubftance may be ℈j to ℈ij, and of the infufion, made by macerating ʒvj of the plant in f℥xij of water, f℥j to fʒxij three or four times a day. Lewis's Mat. Med. Woodville's Med. Bot.

The afhes of wormwood afford a more pure alkaline falt than moft other vegetables, excepting bean-ftalks, broom, and the larger trees. In the Amœn. Acad. vol. ii. p. 160. Linnæus mentions two cafes, in which an effence, prepared from this plant, and taken for a confiderable time, prevented the formation of ftones in the kidneys or bladder; the patients forbearing the ufe of wine and acids.

Many naufeous infects are deftroyed or driven away by the fmell of this plant; and it is no uncommon practice among the good women in the country, to preferve their clothes from moths, by laying bundles of dried wormwood among them.

Some of our brewers have a method of ufing wormwood inftead of the hops, to give the bitter tafte to their malt-liquors, and to preferve them. It is found to anfwer the latter purpofe very well; but the tafte is fo difagreeable, that it is much complained of. The reafon of this is, that the people who ufe it do not underftand the time of gathering it.

All plants are fulleft of juice while in the fhoot, but fulleft of virtue when they have their feeds on them. This is the cafe with wormwood, as well as a thoufand others; and though, in the feeding-time, it produces much more flavour than when younger, yet it is without that naufeous bitter of the crude juice, which gives us the diftafte to the plant.

Some people have found the proper way of managing wormwood, and have given a flavour with it to their malt-liquors, even preferable, in the opinion of all palates, to that given in the common way by hops.

The method is this: the plant is to be gathered when fully ripe, and the feeds upon it, and in this ftate hung up in fmall bunches to dry. When thoroughly dried, a certain quantity of good ftrong malt-liquor is to be impregnated with it, to the utmoft ftrength that it can poffibly give it. This is to be fet by for ufe, to add to all the reft.

When the hops fhould in the common way be added to the beer, this liquor is to be added in a proper quantity, making the tafte the judge when there is enough of it.

By this means juft what degree of bitter is required may be given to the liquor, and the bitter of this common plant, thus managed, is as perfectly agreeable as that of any vegetable in the world.

The wormwood, for this purpofe, fhould have its feeds carefully preferved in the drying, and it is beft if not ufed till the year after it was gathered. Phil. Tranf. N° 124.

The effential falt of wormwood is afforded in great quantity, and poffeffes in many refpects the virtues of the plant. It does not differ from other vegetable fixed alkalies, provided they be equally pure.

Wormwood fhares with all other bitters the virtues of an abfterfive deobftruent, and is in fome degree purgative, as all bitters are. Wormwood is one of thofe plants which the chemifts have generally chofen for their proceffes of the refufcitation of plants from their afhes; and though the pretended principles of this art are falfe, yet there have been fome of the artifts fo cunning as to form reprefentations of this plant, that have deceived and puzzled the greateft unbelievers, though they have not convinced them. Phil. Tranf. N° 74.

Wormwood, *Sea*, *artemifia maritima* of Linnæus, falfely called in our markets *Roman wormwood*, and fubftituted for it: it is a native of Britain, and grows plentifully about our falt-marfhes, and in feveral parts on the fea-coaft, flowering in Auguft and September. In tafte and fmell it is lefs unpleafant than the common wormwood; and hence is preferred by the college as an ingredient in fome of the diftilled waters; the effential oil is lefs ungrateful, and the watery extract lefs bitter than thofe of the common fort. The virtues are the fame, differing only in degree. It is lefs effectual as an antifeptic and anthelmintic, but more eligible as a ftomachic. A conferve of the tops, made by beating them with thrice their weight of fine fugar, is kept in the fhops; but it is now fcarcely ever ufed.

Wormwood, *Roman*, *artemifia pontica* of Linnæus, has more numerous, more finely divided, and darker coloured leaves than the former, and is hoary only underneath, whereas that is hoary all over. This is a foreign fpecies, but as hardy and as eafily raifed as the others. It is confiderably

fiderably lefs ungrateful than either of the former fpecies; its fmell is weaker, and its bitternefs is mixed with a kind of aromatic flavour. This appears to be the moft eligible of the three, as a ftomachic and corroborant; in which intention a conferve of the tops has been greatly recommended.

WORMWOOD, *Mountain*, *artemifia glacialis* of Linnæus, is fine-leaved, and covered with a gloffy filk-like down. The mountain wormwood of Valais, or *abfinthium feriphium montanum candidum* C. B. is covered with a cotton-like down, and the leaves are curled about the edges. Haller informs us, that the firft of thefe plants is frequent in ftony grounds on the Alps; and the fecond by the fides of fandy roads in the territory of Valais, in Switzerland; that the former is bitterifh and aromatic, of great eftimation among the inhabitants of the Alps, and the common remedy againft the intermittent fevers which often rage there, and for exciting the menftrual difcharges, checked by the cold; and that the latter has an acrid aromatic fmell and tafte, without bitternefs, and promifes, from its fenfible qualities, to be a plant of great virtues. They have not yet been introduced into practice in this country. Lewis. See ARTEMISIA.

WORMWOOD-*Tree*, in *Gardening*. See ARTEMISIA.

WORMWOOD-*Fly*, in *Natural Hiftory*, a very fmall black fly, found on the ftalks of the common wormwood in June and July.

WORMWOOD-*Wine*, *Vinum Abfinthites*. See VINUM, and ABSINTHITES.

WOROFIDOW, in *Geography*, a town of Poland, in the palatinate of Braclaw; 26 miles N.E. of Braclaw.

WORONETZ, a town of Ruffia, in the government of Orlof, fituated upon a river of the fame name, near the fpot where it falls into the Don, and thus poffeffing an eafy intercourfe with the Black fea. It is qualified for becoming a great capital, being placed fo as to enjoy the advantages of both warm and cold climates, and holding an intercourfe with all parts of the empire. The ftreets are wide, but not paved. Tallow is a great article of trade here, and alfo iron. Here is alfo the moft confiderable cloth manufactory in Ruffia, firft eftablifhed by Peter the Great: the gypfy tribe is very prevalent here.

WORPE, a river of Germany, which runs into the Wumme, 7 miles N.E. of Bremen.

WORRAL, in *Zoology*, an animal of the lizard kind, of about four feet long, and eight inches broad, with a forked tongue, which it puts out like a ferpent, but without teeth.

It is a harmlefs animal, and feeds only on large flies, and the fmaller fpecies of lizards. It is found in Egypt only during the hotteft months, and principally frequents the grottos and caverns in the mountains on the weft of the Nile, where it fleeps during the winter feafon.

It is faid to be greatly affected by mufic; but experiment fhews this to be an erroneous opinion. Pococke's Egypt, vol. i. p. 208.

WORSBOROUGH, in *Geography*, a village of England, in the county of York, with a medicinal fpring; 3 miles S. of Barnefley.

WORSE, a river of England, which runs into the Severn, near Bridgenorth.

WORSHIP *of God*, *Cultus Dei*, amounts to the fame with what we otherwife call *religion*.

This worfhip confifts in paying a due refpect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal refpect, &c. is to be fhewn and teftified by external acts; as prayers, facrifices, thankfgivings, &c.

The Quietifts, and fome other myftic divines, fet afide not only all ufe of external worfhip, but even the confideration of rewards and punifhments. Yet, even the heathens had a notion, that God did not require us to ferve him for nought: "Dii quamobrem colendi fint," fays Cicero, "non intelligo, nullo nec accepto ab illis nec fperato bono."

The fchool divines divide worfhip into divers kinds, *viz.* *latria*, that rendered to God; and *idolatria*, that rendered to idols, or images. To which the Romanifts add, *dulia*, that rendered to faints; and *hyperdulia*, that to the Virgin.

Some theological writers have obferved, that the Greek word προσκυνειν, *to worfhip*, is not defcriptive only of the honour which is appropriated to God, but is indifferently ufed to fignify the honour and refpect which are paid to fuperiors of all kinds, in heaven or on earth. Accordingly, they have diftinguifhed between *civil* and *religious* worfhip.

The general principles upon which the worfhip of God is confidered as an exercife or act of religion, to which its meaning is commonly appropriated, have been already ftated under the articles PRAYER and SUNDAY; and it has been illuftrated in three different views of it, as private, domeftic, and public. To this article we have referred the more particular confideration of public worfhip, as a duty of indifpenfable obligation, and of indifputable importance and utility. If the worfhip of God, fays archdeacon Paley, be a duty of religion, public worfhip is a neceffary inftitution; becaufe without it, the greater part of mankind would exercife no religious worfhip at all. Befides, affemblies appointed for this purpofe afford regularly recurring opportunities for moral and religious inftruction to thofe who would otherwife receive no fuch inftruction. If we advert to fact, it will be found that the general diffufion of religious knowledge among all orders of Chriftians, in all Proteftant, and in moft Chriftian countries, compared with the intellectual condition of barbarous nations, can be afcribed to no other caufe than the regular eftablifhment of affemblies for divine worfhip; in which portions of Scripture are recited and explained, or the principles of Chriftian erudition are fo conftantly taught in fermons, incorporated with liturgies, or expreffed in extempore prayer, as to imprint, by the very repetition, fome knowledge and memory of thefe fubjects upon the moft unqualified and carelefs hearer. If this practice were not obferved even by thofe members of the community who do not fo much need the affiftance that is indifpenfable with regard to others, and fanctioned by their prefence and example, we may eafily forefee how foon religious affemblies would fink into contempt and difufe. This argument meets the only ferious apology that can be made for abfence from public worfhip. But even this is a very infufficient apology in another point of view, becaufe public worfhip is a duty, independently of the effect of example, of univerfal obligation. Man is a focial being; and as fuch enjoys many bleffings which demand public acknowledgment, and is chargeable with many errors and tranfgreffions which he ought publicly to unite with others in confeffing, and is expofed to many evils which he fhould deprecate in common with others who are in the fame fallible or mutable ftate with himfelf.

"Surely, fome will fay," as Paley ftates another objection againft public worfhip, "I may be excufed from going to church fo long as I pray at home, and have no reafon to doubt but that my prayers are as acceptable and efficacious in my closet as in a cathedral; still less can I think myself obliged to sit out a tedious sermon, in order to hear what is known already, what is better learnt from books, or suggested by meditation." They, whose qualifications and habits best supply to themselves all the effect of public ordinances, will be the last to prefer this excuse, when they advert to the general consequence of setting up such an exemption, as well as when they consider the turn which is sure to be given in the neighbourhood to their absence from public worship. You stay from church, to employ the sabbath at home in exercises and studies suited to its proper business: your next neighbour stays from church, to spend the seventh day less religiously than he passed any of the six, in a sleepy, stupid rest, or at some rendezvous of drunkenness and debauchery, and yet thinks that he is only imitating you, because you both agree in not going to church. The same consideration should over-rule many small scruples concerning the rigorous propriety of some things, which may be contained in the forms, or admitted into the administration of the public worship of our communion; for it seems impossible, that even "two or three should be gathered together" in any act of social worship, if each one require from the rest an implicit submission to his objections; and if no man will attend upon a religious service, which in any point contradicts his opinion of truth, or falls short of his ideas of perfection.

We may add, that there are other valuable advantages resulting from religious assemblies, that are not immediately designed in the institution, or contemplated by the individuals who compose them; *e.g.* 1. Joining in prayer and praises to their common Creator and governor has a sensible tendency to unite mankind together, and to cherish and enlarge the generous affections. 2. Assemblies for the purpose of divine worship, placing men under impressions, by which they are taught to consider their relation to the Deity, and to contemplate those around them with a view to that relation, force upon their thoughts the natural equality of the human species, and thereby promote humility and condescension in the highest orders of the community, and inspire the lowest with a sense of their rights. Thus, things are made to appear little, by being placed beside what is great. In which manner, superiorities, that occupy the whole field of the imagination, will vanish, or shrink to their proper diminutiveness, when compared with the distance by which even the highest of men are removed from the Supreme Being: and this comparison is naturally introduced by all acts of joint worship. If ever the poor man holds up his head, it is at church: if ever the rich man views him with respect, it is there; and both will be the better, and the public profited, the oftener they meet in a situation in which the consciousness of dignity in the one is tempered and mitigated, and the spirit of the other erected and confirmed. Moreover, the public worship of Christians is a duty of divine appointment. (Matt. xviii. 20. Heb. x. 25.) Independently of these passages of Scripture, a disciple of Christianity will hardly think himself at liberty to dispute a practice set on foot by the inspired preachers of his religion, coeval with its institution, and retained by every sect into which it has been since divided. Paley's Philos. vol. ii.

As to the manner in which public worship should be conducted, if we advert to the history of the primitive church, we shall find, that when the congregation was assembled, the first act of divine service which they performed was the reading of the Holy Scriptures. (See Tertullian de Anima, c. 3. Justin Martyr, Apolog. ii.) When the reading of the Scriptures was ended, then followed the singing of psalms. (See Tertullian, *ubi supra*. Pliny Epist. ad Trajan. Clemens Alex. Stromat. l. 6. Origen, De Orat. § 6.) The psalms or hymns which were sung by the primitive Christians were either taken out of the Holy Scriptures, and particularly out of the book of Psalms, or such as were of their own private composition. (Tertullian, Apolog. c. 39.) As to their manner of singing, it was, says Origen, (De Orat. § 6.) in good tune and concert, all the people bearing a part in it. With respect to church-music, organs, and the like, they were not known in the primitive ages to which we now refer; for it cannot be rationally conceived that in those days of continual persecution or violence they could either use or preserve them. The singing of psalms was followed by the preaching of the word. (See Tertullian de Anima, c. 3.) The subject of the sermon was usually a commentary or explication of the lessons that had been just before read. (See Just. Martyr, Apolog. ii. Origen contra Celsum, lib. iii.) As for the length of the sermon, it usually lasted an hour. It began with an exordium, and then explained verse after verse, and sentence after sentence, shewing the natural and literal signification of the words, and then the spiritualized or mystical meaning of them, and concluded with a suitable application of all, either by way of exhortation to piety and virtue, or by way of dehortation from vice and impiety; always accommodating the discourse to the capacities of the hearers. (Origen contra Celsum, lib. iii.) The preacher was usually the bishop of the parish. (Just. Martyr, Apolog. ii.) Or, the bishop decreed a presbyter, or some other fit person, to preach in his room. When the sermon was finished, the congregation rose up to present their common and public prayers unto Almighty God (Just. Martyr, Apolog. ii.); standing being the usual posture of praying, at least the constant one on Sundays, on which days they esteemed it a sin to kneel; and the preacher frequently concluded his sermon with an exhortation to his auditors to stand up and pray to God, which is found to be the case in Origen's sermons. When the congregation stood up, all turned their faces towards the east, which was their usual custom (Tertullian, Apolog. c. 16.); for which practice they alleged the following reasons: 1. Respect and reverence to their lord and master Jesus Christ; this being the title given to him in the Old Testament, according to an erroneous translation of the word *branch* in the Septuagint. So that the east was called by Tertullian a type of Christ. 2. The similitude (Zach. vi. 12.) of the arising of the sun to our spiritual arising out of the darkness of sin and corruption, as Clem. Alex. expresses it. (Stromat. lib. vii.) 3. The advice of Origen to pray towards the eastern climate, as denoting our diligence in the service of God, in being more forward to arise and set about it than the sun is to run its daily course, for which he produces the authority of an Apocryphal text, Wisdom, xvi. 28. (Orig. de Orat. § 20.) 4. The opinion they entertained of the excellence of this quarter above others. (Orig. De Orat. § 21.) The congregation being thus turned towards the east, they put themselves into a posture of prayer, stretching out their hands, and lifting up their eyes towards heaven. (Clem. Alex. Stromat. lib. vii. Tertull. Apolog. c. 30.) The minister then began to pray, his usual garb being a pallium, or, as we call it, a cloak; which was deemed a more simple and plain garment than the toga, which was used through the whole Roman empire. But it does not appear from any authority of ancient writers, that they put a surplice or any other kind of linen garment over their cloaks. The prayer was pronounced, as Cyprian says (De Orat. Domin. § 2.), with a modest and bashful voice, that being most proper for those who came to acknowledge the multitude and heinousness of their sins, and to beg God's pardon and grace, which is the end and design of prayer. The people did not vocally join with the minister in the prayers, but satisfied themselves with testifying their assent to what he expressed, by saying Amen, or so be it. Indeed it was impossible for the people to respond, since they had no fixed public form of prayer, except the Lord's prayer, which they frequently, though not always, repeated; and as to their other prayers, every bishop or minister of a parish was left to his own liberty or ability therein. The constant repetition of the Lord's prayer with other prayers was not thought to be necessary, but it was frequently omitted. Accordingly they regarded the Lord's prayer as given by Christ for a pattern of all other prayers, so that Cyprian (De Unit. Ecclef. § 11.) calls it the law or rule of praying. But though the repetition of the Lord's prayer was not necessary, yet it was usual. Although they used that, they had also other prayers. Their usual method, according to Tertullian (De Orat.), seems to have been, first to begin with the Lord's prayer, as the ground and foundation of all others, and then, according to their circumstances and conditions, as he expresses it, to offer up their own prayers and requests. These other prayers, however, were not restricted or imposed forms; but the words and expressions of them were left to the prudence, choice, and judgment of every particular bishop or minister. In other words, the primitive Christians had no stinted liturgies, or imposed forms of prayer. As to prescribed forms, there is not the least mention of them in any of the primitive writings, nor the least word or syllable tending to it, according to lord King, which, as he says, is an unaccountable silence if there ever were such, but rather some expressions intimating the contrary; such as the minister's praying ὅση δύναμις, according to his ability. (Just. Mart. Apolog. ii. Origen, Comment. in Matth. et in Johann.) The noble author now cited has shewn from parallel passages, that the minister's praying ὅση δύναμις, or according to the utmost of his ability, imports the exercise of his gifts and parts in suitable matter and apt expressions; and that the primitive prayers were such appears farther from a passage in Origen, which explains the verse in Matth. vi. "When ye pray, use not mere repetitions, &c." It is very unlikely, continues his lordship, that they were obliged to prescribed forms, because they never read a syllable of their prayers out of any book whatever; which is evident from their posture of prayer, that was two-fold, either with their hands and eyes lifted up to heaven, or with their eyes shut. (Tertull. de Orat. Origen in Matth. vi. 5. De Orat. § 9. Contra Celsum, lib. vii.) If they had used prescribed and imposed forms, they must necessarily have remembered them, which would have been an intolerable load to the strongest memory; especially to have repeated, word after word, the prayers of their fast-days, which must have been several hours long, since some of their fasts were prolonged from the morning of one day to the beginning of another. Whether their prayers were divided into several collects, our author has not been able positively to determine; but he thinks it probable, that on their fast-days they made several distinct prayers, and that at their ordinary meetings, their prayer after sermon was but one entire piece. According to Just. Martyr (Apolog. ii.), the prayer that preceded the confirmation of the eucharistical elements "was one long prayer, to which the people said, Amen." Lord King's Enquiry into the Constitution, Discipline, Unity, and Worship of the Primitive Church, part ii. See LITURGY.

WORSLEY, in *Geography*, a populous township in the parish of Eccles, and county of Lancaster, England, 6 miles W.N.W. from the town of Manchester. In the year 1811, this place contained 6151 inhabitants, who occupied 1012 houses; and nearly the whole of whom were engaged in manufactures and the coal-mines. At this place is the famous tunnel for the Bridgewater canal, (see CANAL,) and a large brick mansion, called Worsley-hall, which belonged to, and was inhabited by, the late duke of Bridgewater. See Lancashire Gazetteer, 1808.

WORSTED, or WORSTEDE, a market-town in the hundred of Tunstead, and county of Norfolk, England, is situated 4 miles S.S.E. from North Walsham, and 120 miles N.E. by N. from London. It was formerly a place of much celebrity, and of considerable trade; but is now greatly on the decline, and is chiefly remarkable for the invention, or first twisting, of that sort of woollen yarn or thread, which hence obtained the name of worsted. This manufacture is mentioned in the second year of Edward III. when the weavers and workers of worsted stuffs were required by parliament to work them in a better manner than they had previously done. These stuffs, and knit and wove hose, constitute the chief manufacture of the town. A weekly market is held on Saturdays, and here is an annual fair. The church consists of a nave, two aisles, a chancel, and a square tower. The population of the parish, according to the return of the year 1811, amounted to 619, occupying 112 houses.

Contiguous to the town is Worsted-hall, the seat of sir George Berney Brograve, bart., a commodious mansion, situated in a pleasant park.—Beauties of England and Wales, vol. xi. Norfolk; by J. Britton, F.S.A. 1809. Blomefield's History of Norfolk, vol. xi. 1810.

WORSTED, and WORSTED *Manufacture*. The term worsted is applied to yarn, and manufactured goods made of combed wool. Worsted is properly a branch of the *Woollen Manufacture*, to which article we refer our readers; but the latter term, strictly speaking, is applied only to yarn, or pieces made entirely or in part of carded wool. The characteristic distinction between combing-wool and short or clothing-wool has been already stated under the article WOOL. (See WOOL and WOOLLEN *Manufacture*.) Worsted goods were made in England as early as the time of Edward II. In the account of exports in the following reign, already given in the article WOOLLEN *Manufacture*, the number of pieces of worsted goods exported is nearly double that of woollen cloths. According to Camden, the name is derived from Worsted, a town in Norfolk, where worsted stuffs were first made. According to Dr. Parry, in his "Essay on the Merino Breed of Sheep," worsteds were called by the Flemings '*Ostades*,' and as the manufacture was in their hands long before it was introduced into England, it is probable that our appellation is a corruption of their's. Ostade was long ago a common surname in Flanders, and was perhaps that of some person famous for this particular branch of the woollen trade, which afterwards was appropriated to an establishment of similar manufacturers in Norfolk.

Worsted yarn is made of long or combing-wool, in which the fibres are all laid even parallel with each other by the wool-comb. It may be classed into two great divisions, the soft and the hard worsted yarn. The soft yarn is made of the shorter kinds of combing-wool, the sorting of which has been already described under the article WOOL. The short and long combing-wools are both prepared for spinning by the comb in the same manner, except that for some kinds of fine hard yarn made from the latter, the wool is combed, and afterwards spun nearly without oil. This is the case with the yarn for bombazines. The soft yarn for hosiery receives but little twist in the spinning, and two, three, or more threads are afterwards twined together on what is called a doubling-mill, to make a thread of requisite strength and thickness to be woven on the stocking-frame. See STOCKING-*Frame*.

Knitting-

Knitting-yarn is twined much harder than yarn for the frame. For mixed coloured ftockings, part of the wool is dyed and mixed with the white in the procefs of combing. The principal feats of the worfted hofiery manufacture in England were Nottingham and Leicefter ; but of late years the worfted hofiery has declined at the former place, the trade there being principally confined to filk and cotton articles. Formerly hofiery comprifed a variety of worfted articles, particularly caps, which were generally worn in England before the introduction of hats.

At Aberdeen, in Scotland, there is a confiderable manufacture of hofiery, the wool being principally fupplied from London. Worfted ftockings, and lamb's-wool hofiery, to the amount of from fifty to feventy thoufand pounds, are faid to have been annually exported from Aberdeen to Holland. Of the number of hands employed in worfted hofiery in England, or the annual value of the goods made, we have no correct account. Perhaps fome eftimate may be formed from the amount of exports of woollen hofiery given under the head *Woollen Manufacture*, in the table of exports, in which it will be feen, that in the year 1816 the worfted hofiery exported amounted to one hundred and fifty-one thoufand and fixty pounds. This, we believe, includes the hofiery made of woollen yarn, or what is generally called lamb's-wool yarn, an article which, fince the beginning of the prefent century, has been greatly increafing in demand. Soft worfted yarn for hofiery, during the laft twenty years, has been principally fpun and doubled by machines in large worfted-mills. Previoufly to that time, worfted-making by hand-fpinning was a diftinct trade from hofiery. The worfted-maker bought his different forts of combing-wool from the wool-ftapler, combed and fpun it, and fold the yarn to the hofier. Since then, the hofiers have been principally fupplied with worfted yarn from large mills eftablifhed in Leicefterfhire, Nottinghamfhire, and Warwickfhire. Of late, however, many of the hofiers are manufacturing their own yarn on machines or mules turned by the hand, or in fmall mills turned by horfes or water.

The combing-wools of Kent are better fuited for hofiery worfted yarn than any other in England, particularly for machine-fpinning. This excellence is derived partly from the foftnefs as well as foundnefs of the wool; but particularly from the ftaple being nearly of one uniform thicknefs from the bottom to the top. See Wool.

Picardy and Normandy were the principal feats of the worfted hofiery in France. Under the article Woollen *Manufacture*, it will be feen that 1,250,000 pounds weight of wool were confumed annually in the manufacture of hofiery in Picardy before the French revolution.

The ftocking-frame was invented by William Lee, M.A. of Cambridge, in 1589, and was afterwards introduced into France. This invention took place in England only 28 years after the knitting of hofiery yarn on needles had been introduced from Spain. See Stocking-*Frame*.

Hard worfted yarn for worfted ftuffs or pieces is fpun much fmaller, and twifted much harder, than the foft worfted yarn for hofiery. In all the ftouter kinds of worfted goods, the long or heavy combing-wool is ufed. (See Wool.) Under the article Woollen *Manufacture* we have noticed the introduction of the worfted trade into England, and various places where it was firft eftablifhed. Norwich and fome of the towns in Norfolk and Suffolk appear to have been the firft where any confiderable quantity of worfted pieces or ftuffs were made. The names which the different kinds of worfted pieces have received are very numerous, being often derived from the manufacturer who introduced a flight change either in the mode of weaving or finifhing the goods. Thefe names foon became obfolete, being fupplanted by other kinds of worfted goods, fo that we do not know at prefent to what particular kind of pieces fome of them were formerly applied ; the effential difference confifting in their being woven plain, twilled, or figured, or made with a warp of fingle or doubled yarn, and woven ftouter or more flightly, or of greater or lefs width, and whether they were glazed or not in the finifhing.

The moft important diftinction between worfted pieces and woollen cloth confifts in the former not being milled or raifed, fo as to cover the furface with a pile, but the thread is left bare. To take off the loofe hairs which rife from the furface, the worfted pieces are paffed over a red-hot cylinder, in the fame manner as many kinds of cotton (fee Cotton *Manufacture*): this procefs is called *finging*. For fome particular purpofes, a flight degree of milling has recently been attempted to be given to worfted pieces in the fulling-mill. The glazing communicated to fome kinds of worfted goods is given by preffing them between fheets of ftiff glazed prefs-paper and heated iron plates, which are compreffed in a ftrong preffing-frame. For the weaving of figured pieces, fee Weaving, and Draught *of Looms*.

Some kinds of very fine worfted goods are made with a warp of mohair or filk, as filk camlets and bombazines. The latter goods, with a filk warp and wefted with hard worfted yarn of the fineft kind, are manufactured at Norwich. The term bombazine appears to be derived from bombycina, a kind of filk drefs ufed by the Romans, and faid to come from Affyria. It is generally underftood to have been made from the threads of an infect called the bombyx. Bombycina is fometimes confounded by commentators with byffinum and fericum. Byffinum appears to have been a very fine kind of linen or lace; fericum unqueftionably means filken ftuff, fo called from the Seres, the nation whence it was procured. Probably bombycina was a coarfer kind of filk. In the middle ages, the word bombycina was applied to cotton. Macpherfon's Annals of Commerce. See Byssus.

Bombazines are woven with a twill, and have, as before ftated, a warp of filk and a weft of fine worfted yarn. The Dutch refugees, who fled from the perfecution of the duke of Alva, introduced the manufacture of this article into Norwich in the year 1675, when the Dutch elders, according to Blomefield, prefented bombazines in court at Norwich. (Blomefield's Hift. of Norfolk, vol. ii. p. 205.) Worfted goods were made in Norwich as early as the reign of Edward II. This appears from a patent granted to John Peacock, for the meafuring every piece of worfted made in the city of Norwich or county of Norfolk. Norwich has continued from that time one of the principal feats of the worfted and ftuff trade. The fale of ftuffs made in Norwich only, in the reign of Henry VIII., amounted to 100,000*l.* annually, befides worfted ftockings, which were computed at 60,000*l.*

Norwich is at this day the only part of England where any confiderable number of the very fineft ftuffs and bombazines are made. The manufacture of the coarfer kinds of worfteds, except camlets, has been transferred in a great meafure into Yorkfhire. The period preceding the American revolution, from the year 1743 to 1763, may perhaps be regarded as the moft flourifhing era of the worfted manufactures of Norwich. According to the account of Arthur Young in 1771, the manufactures of this place had increafed four-fold in the preceding 70 years. The number of looms was then eftimated at 12,000, and each loom was fuppofed to employ fix perfons in preparing and finifhing

 the

the material; and the total annual value of the goods was eftimated at above 1,200,000*l*. Of thefe goods the eftimate then was,

		£
The export to Rotterdam	- -	480,000
——— to London	- -	550,000
——— to various places	- -	200,000
Total value	-	1,230,000

The number of perfons employed being from feventy to eighty thoufand.

Since the time to which Arthur Young refers, the manufacturers of Norwich have engaged extenfively in the trade of filk fhawls and other articles, in which no worfted whatever is ufed. Still, however, the worfted manufactures of Norwich may be confidered as in a flourifhing ftate. The number of looms employed in worfted at the prefent time (1818) may be eftimated at 10,000; half of which weave camlets, calimancoes, and other ftuffs; and the other half bombazines, narrow and broad. The former are chiefly for home confumption, the latter for the Spanifh market. The Eaft India company take a confiderable quantity of the fine camlets manufactured at Norwich.

By far the greateft part of the worfted yarn employed at Norwich is fupplied by machine-fpinning, from the worfted-mills in Yorkfhire, Lancafhire, and Durham. But fome yarn ftill continues to be fpun in the old manner, by the running-wheel, in Suffolk, Effex, Hertfordfhire, and Cambridgefhire. In Norfolk alone, the ufe of the diftaff ftill remains. This inftrument is the moft ancient of which we have any notice, either in facred hiftory, or the fabulous traditions of Grecian mythology handed down to us by Homer and Hefiod. It is at prefent vulgarly called the rock. In ufing it, the thread is drawn out from the end of the fliver of combed wool. The motion is communicated to a rough kind of fpindle, by twirling it between the right-hand and the thigh, which is fuffered to continue revolving when fufpended by the thread, which the fpinftrefs gradually lengthens with her fingers.

In wheel-fpinning, a fmall portion of the combed wool or fliver is laid acrofs the finger, from the centre of which, called the twitch, the thread is drawn out. About thirty years fince, the counties of Norfolk, Suffolk, Hertfordfhire, and Effex, not only fupplied all the yarn that was wanting for the manufactures of thofe diftricts, but fent large quantities of worfted yarn to Halifax and Manchefter. At prefent the trade is completely turned, and, as we have before ftated, the greater part of the yarn ufed at Norwich is fent there from the northern counties of England. This change has occafioned great diftrefs in the villages where the yarn was formerly fpun, by depriving the wives and children of the cottagers of their common employment.

Until the middle of the laft century, worfted goods were manufactured in confiderable quantities in Warwickfhire, Oxfordfhire, and Northamptonfhire; but about that time the extenfion of the worfted trade in the Weft Riding of Yorkfhire, particularly at Halifax, Bradford, and Wakefield, gradually drew this trade in a great meafure away from thofe counties. The manufacturers in Yorkfhire, or rather the merchants who bought the worfted pieces from the manufacturers, were, however, long unacquainted with the beft modes of dyeing and dreffing them; they were therefore fent to London or Coventry to be finifhed, but afterwards they were finifhed in Yorkfhire. The demand to Spain, Portugal, Italy, and the Levant, took off the greater part of the worfted goods manufactured at Halifax; thofe manufactured round Wakefield and Bradford, confifting chiefly of tammies and fhalloons, were confumed principally by England and her colonies. The Piece-hall at Halifax was firft opened about the year 1780; and the intervening time, from thence to the year 1792, or the breaking out of the French war, may be regarded as the moft flourifhing era of the worfted trade in Yorkfhire. Though the cheapnefs of calicoes, as an article of female drefs, fince the improvements in the cotton manufacture, materially abridged the fale for fome kinds of worfted goods in England, this was more than compenfated by the increafed demand for carpets with worfted warps, and other articles of luxury, in which worfted yarn was employed.

The demand in foreign markets, from the year 1782 to 1792, for Englifh worfted goods, greatly exceeded that of any former period; but after the breaking out of the French war, the worfted trade at Halifax began to decline. The greater part of the foreign markets being clofed againft us, moft of the mercantile houfes engaged in the export of worfted pieces were in confequence ruined or declined; the trade altogether, and many of the fmall manufacturers, engaging in the cotton trade. The introduction of Englifh calicoes into Turkey and other parts tended alfo to leffen the regular demand for fhalloons and other worfted goods, as articles of female drefs, in thofe countries. Soon after the breaking out of the French war in 1792, the fpinning of worfted by machinery was eftablifhed at Bradford and the vicinity; and continuing to increafe, drew round that place the manufacturers of worfted goods on the decline of the Halifax trade. Bradford is now become the principal feat of the worfted manufacture in Yorkfhire; and fome of the proprietors of the worfted mills, befides fupplying the fmaller manufacturers with yarn, employ a very great number of looms themfelves, and carry on this branch of trade on a fcale of extent never before known in the worfted manufacture. Within the laft two years, the worfted trade has alfo greatly revived at Halifax.

The following are the kinds of worfted pieces at prefent principally made in Yorkfhire.

Bombazets are woven both plain and twilled, with the warp of fingle thread; they were preffed, and finifhed without glazing: the width 22 inches, length 29 yards.

Tammies, or *durants*, with fingle warps twilled, and generally coarfer than twilled bombazets: width from 32 to 36 inches, length 29 yards.

Shalloons are woven with a twill, and have a warp of fingle thread. We believe the name was derived from Châlons in France. The pieces are from 32 to 36 inches wide, and 29 yards long.

Cubicas are very fine fhalloons fo called.

Sayes, or *anafcottes*, are twilled and made with fingle warps; they are of two kinds, one running 27 inches wide and 30 yards in length, the other 42 inches in width and 44 yards in length.

Moreens are woven plain and watered or emboffed, and are made very ftout, being principally ufed for furniture: their width is 28 inches, length 24 yards.

Calimancoes are woven plain and ftriped: width 17 inches, length 29 yards.

Camlets are both plain and twilled: width 18 inches, length 29 yards. They are fhorter than bombazets, but not many are made in Yorkfhire with doubled warps.

Laftings have doubled warps, fometimes of two and fometimes of three threads, and are made with great variety of patterns, either plain, twilled, or flowered, and are diftinguifhed by different names, according to their figures and quality;

quality; as prunelle, amens, (probably from Amiens in France, where they were manufactured,) and drawboys: the width 18 inches, length 30 yards.

Worfted fhag, or velvet woven like corduroi and cut, is made principally at Banbury, in Oxfordfhire, and at Coventry; but has been manufactured alfo in Yorkfhire.

In the worfted manufactures of France, there were greater varieties of pieces than in England. One kind of camlet, made with a fine warp from the wool of the Angora goat and a weft of fine worfted, was remarkably beautiful; but we believe it has not been manufactured in Yorkfhire or at Norwich.

For fome account of the worfted manufactures of France, fee Woollen *Manufacture;* under which article we have given the hiftory of the worfted manufacture as connected with the woollen, and where may be feen the number and value of the worfted pieces exported from England in the year ending January 1817. See alfo *long combing-wool,* under the article Wool.

Worsted *Spinning*. In the article Wool we have given an account of the different kinds of long wool which are proper for fpinning into worfted, alfo the manner of forting and fcouring them. This wool muft be prepared for fpinning by repeated combings, with a comb or heckle that is provided with a great number of long fteel pins which are fharp-pointed. Thefe points being few in number compared with the teeth of cards, they can be fafely introduced between and drawn through the long fibres of the wool, in order to feparate and ftraighten them, without materially breaking them. Another object of the combing is, to feparate the fhort fibres which are intermixed with the long ones; for in fpinning any kind of thread, it is defirable that the fibres fhould be all as nearly as poffible of a length.

Wool-combing.—In the ordinary procefs of wool-combing by hand, the implements ufed are, 1. Two combs for each workman. 2. A poft, to which either of the combs can be fixed, to fupport them during the operation. 3. A comb-pot, which is a fmall ftove to heat the teeth of the combs, which is found to facilitate the combing. The combs are fhewn at *fig.* 1. *Plate* I. *Woollen Manufacture:* each comb is compofed of two rows of pointed fteel teeth, *a* and *b*, difpofed in two parallel planes. One of the rows contains longer teeth than the other. They are fixed into a wooden ftock or head *c*, which is covered with horn, and has a handle *d* fixed into it, perpendicular to the planes of the rows of teeth. The rows of teeth are about feven inches long, and each row contains about twenty-four teeth. The length of the longeft teeth is near twelve inches, and the fhorter ones about eight inches. The teeth are made of fteel, of a round figure, and regularly tapering from the bafe, where they are fixed into the ftock, to the point, which is quite fharp. The teeth are about one-fixth of an inch in diameter at the bafe; and the interval between the two adjacent teeth at the bafe is rather lefs than their diameter, or one-eighth of an inch. The fpace between the two planes in which the teeth are difpofed is about one-third of an inch at the bafes of the teeth. The teeth fhould be ftraight and well-tempered, and polifhed. If they become crooked in working, the workman muft ftraighten them, and fet them all in a true line. The combs ufed for the laft combing of the wool have three rows of teeth.

In the wool-comber's fhop a poft is fixed, as fhewn by *fig.* 2, in order to fupport the combs occafionally during the working. An iron ftem *g* is fixed faft into the poft, and projects horizontally from it; the extreme end of it turns upwards with a point, which is inferted into a hole through the middle of the handle of the comb. Alfo at the other end of the ftem *g*, clofe to the poft, there is a fmall hook *h* rivetted, which terminates with a pointed pin, fituated in an horizontal direction. This point is inferted into a hole made in the end of the handle of the comb, in the direction of its length. The end of the comb-handle being firft placed on the point of the hook *h*, it is let down upon the other point *g*, which, by paffing through the handle, fixes the comb quite faft to the poft, as fhewn at *fig.* 2.

In the operation of combing wool, it is neceffary to heat the teeth of the combs, in order to foften and relax the fibres of the wool, and render them more eafy to work. The heat alfo tends to diftribute the oil with which the wool is lubricated. The combs are heated in a comb-pot or ftove, *fig.* 3, which is a fmall furnace built in brick, to inclofe a fire-place, of which A is the door, B the afh-pit, and C the flue. Above the fire a circular caft-iron plate *a a* is placed. This is made flat, except in the central part, where there is a concavity, to obtain a better action of the fire. Immediately over the plate *a*, another plate, *b b*, is placed parallel to the former, but with a fufficient fpace between them to admit the teeth of the combs: feveral pieces of iron are placed between the two plates, to keep them at a proper diftance afunder, and to divide the fpace into fmall cells proper for the combs.

In ufing this ftove, the workman muft be careful not to heat it too much, and a damper in the flue is very ufeful to regulate the draught; if the heat is too great, it fpoils the temper of the comb-teeth, and injures the wool alfo. The moft improved ftove is heated by fteam, which will give a fufficient warmth, but cannot overheat the combs.

In order to comb the wool, it is feparated into handfuls, each containing near four ounces of wool, which is about a proper quantity to be combed at once. Thefe handfuls are fprinkled with oil, and the wool is rolled in the hands to diftribute it equally. The quantity of oil varies from $\frac{1}{10}$th to $\frac{1}{12}$th of the quantity of wool by weight. The comb is firft heated by introducing the teeth into the ftove, in one of the cells between the two iron plates; when it has acquired fufficient heat it is withdrawn, and another comb is put in its place. The heated comb is then faftened to the poft, with its teeth pointing upwards, in order to be filled with wool; the comber takes one-half of the handful of wool in his hand, and catches it upon the teeth of the comb by throwing the wool over the points, fo that they penetrate it; then by drawing the wool towards him, and at the fame time downwards to the bottom of the teeth, a portion of the wool will remain in the teeth. The lock of wool is again caft upon the teeth, and drawn through them, and every time fome wool remains; this is repeated as often as is neceffary, until all the wool is gathered upon the teeth. The comb thus filled is placed with its points in the ftove, and the wool which is upon it remains outfide of the ftove, but will become flightly warmed. The other comb, which was heating whilft the firft was filling, is now filled in turn, in the fame manner as the firft, and is then put to heat with the wool upon it, and whilft this is going on, the workman occupies himfelf in making a handful ready for the next combing.

When both combs are properly warmed, the comber holds one of them with his left-hand over his knee, as he is feated on a low ftool, and with the other comb held in his right-hand he combs the wool upon the firft, by introducing the points of the teeth of one comb into the wool contained in the other, and drawing them through it; this is repeated for 14 or 15 ftrokes, until the fibres of the wool are feparated, difentangled, and laid parallel. In combing, he di- rects reƈts the combs ſometimes with the teeth of one parallel to the teeth of the other, and ſometimes with the teeth of the two combs at right angles, or in a croſs direction; but in all caſes he muſt take care to begin gradually, by introducing the points of the teeth, firſt into the extremity of the wool which is contained in the teeth of the comb, and then penetrating deeper into the wool at every ſucceeding ſtroke, till at laſt he works the combs as near as he poſſibly can without actually bringing their teeth in contact: without this precaution, he could not draw the comb through the wool without breaking the fibres, and tearing the wool out of the teeth of the comb; but if he proceeds cautiouſly, the wool will be diſentangled, ſeparated, and ſtraightened.

During the working, he frequently changes the combs, ſo as to work the wool upon both combs; but as the wool will gradually accumulate upon that comb which is moſt worked, he manages them ſo that at the end of about 35 or 40 ſtrokes nearly all the wool will be gathered upon one of the combs, and will hang from its teeth in a fair lock of ſtraight and regular wool. This comb he puts to heat for a moment, then fixes it to the poſt, and proceeds to draw off the wool from the comb in a ſliver. To do this, he takes hold of the wool which projects from the teeth with the fingers and thumbs of both hands, and draws it away from the teeth of the comb in a direction perpendicular to their length, without ſliding it off their points: as the wool comes away, he takes freſh hold, always ſeizing the wool at a given diſtance from the teeth. A portion of the wool which conſiſts of ſhort fibres will not come off, becauſe it does not reach to the place where the comber graſps the wool; it therefore remains in the teeth of the comb, and is drawn off afterwards. This ſhort wool, which is called noil, is unfit for worſted ſpinning; it is compoſed in part of the ſhort fibres which are naturally intermixed in the long ones, and alſo of the fragments of long fibres which are broken in the proceſs of combing. The quantity of the noil depends upon the kind of wool, and alſo on the care with which the comber has conducted his proceſs; but it will ſeldom exceed $\frac{1}{6}$th or $\frac{1}{8}$th of the quantity of the raw wool by weight.

The wool which is drawn off from the comb forms a continued ſliver or band, the fibres of which are ſtraight and parallel, but not ſufficiently ſo for ſpinning; it is therefore combed over again, and frequently it is repeated a third time. The firſt combing is called hacking, and the ſlivers produced by it are extended five together upon a table; then holding them down with one hand, they are broken again into handfuls by drawing them with the other. Theſe are combed again in the manner before deſcribed, but the heat given to the combs is much leſs. The ultimate ſliver, which is drawn off from the comb the laſt time, ſhould be very even, and compoſed of long and parallel fibres. On examining it againſt the light, every part ſhould appear equally denſe, without any entanglements of the fibres, for on theſe particulars the perfection of the ſpinning will in a great meaſure depend.

The combed wool produced from ſixteen pounds of wool uſually weighs eleven or eleven and a half pounds, for about two pounds are loſt in waſhing, and the reſt in noil and waſte in the combing. When the combing is finiſhed, the ſlivers are formed into ſix parcels, each containing ten or eleven ſlivers, which are rolled up together into a ball, and ticketed with their weight and quality, the wool-comber's mark, and wool-ſtapler's mark. In this ſtate, combed wool is called tops or Jerſey, and is ſold to the ſpinners in the country, and in cottages, who ſpin it into worſted-thread by the ſimple hand ſpinning-wheel; but the manufacturers who ſpin by machinery have wool-combers at their mills, and they uſually employ combing-machines in addition.

Combing-Machines.—The firſt combing-machine was invented by the Rev. Edmund Cartwright. His firſt two patents were in 1790, and he had another in 1792; but the machine was not rendered perfect, or brought into extenſive uſe, till a later period: and in 1802 he obtained an act of parliament to renew or extend the term of his patent. The ſpecification which he enrolled in conſequence contains drawings and deſcriptions of machines nearly of the ſame kind as thoſe which are now in uſe at many of the great worſted-mills, and which we ſhall deſcribe. Mr. Cartwright propoſed to form the raw wool into continued ſlivers, by joining the pieces of wool together, and ſlightly twiſting them, and in this ſtate they could be preſented to the combing-machine; but as this plan was not found to ſucceed, it was found neceſſary to comb the wool firſt by hand, in order to reduce it to ſlivers. This is ſtill the common practice, and takes away great part of the advantage of the machine; but we have ſeen a preparing-machine for this purpoſe, which operated very well upon the raw wool. The inventor's name we have not learned; but the rudiments of it are to be found in Mr. Cartwright's ſpecification of 1790.

Preparing-Machine.—The raw wool is ſpread upon a horizontal feeding-cloth, which is extended over two rollers, and circulates upon them: by its motion, the wool is carried forwards, and preſented to a pair of fluted rollers, which draw it in. This feeding-cloth is ſituated at the top of the machine, at the height of about five feet from the floor, ſo as to allow room for the reſt of the machinery beneath it. A principal part of the machinery is carried by a horizontal wheel of five feet diameter, which is mounted upon a vertical axis, and is turned rapidly round by the mill. This wheel carries four porcupines, which are ſmall cylindrical rollers, armed with ſpikes or teeth rather hooked. The rollers are ſituated horizontally in the plane of the wheel, with their length nearly in the direction of radii. They are about ſeven inches in diameter, and fourteen inches long, and are fixed upon horizontal ſpindles, which proceed from the circumference of the great wheel nearly to its centre, one extremity of each ſpindle being ſuſtained by the rim of the wheel, and the other in a ſupport fixed to the perpendicular axis. The porcupines are fixed on the ends of the ſpindles, near the circumference of the wheel; and on the oppoſite end of each ſpindle is a ſmall cog-wheel, to work in a worm or endleſs ſcrew, which is fixed concentric with the axis, being cut on the outſide of a hollow tube, through which the vertical axis paſſes.

By this means, the four porcupines which the wheel contains have a two-fold motion, *viz.* they are all carried round in a circle by the motion of the wheel, and at the ſame time each one has a ſlow rotative motion on its own axis, in conſequence of the cog-wheels, which work in the threads of the fixed worm.

The feeding-cloth is ſo ſituated, that the four porcupines in the great wheel will paſs in ſucceſſion exactly beneath the fluted rollers, which take the wool from the feeding-cloth; and the teeth of the four porcupines being ſharp-pointed, and rather bent forwards at the points, they penetrate and catch the wool as it comes through theſe fluted rollers, and hangs down from them. A portion of wool is thus carried away by each porcupine every time it paſſes beneath the fluted rollers; but by the ſlow revolving motion of the porcupines on their own axes, each one preſents a different row of teeth every time, and thus by degrees they become clothed with the wool which they take up.

This wool they deliver to a larger porcupine, which is placed beneath the revolving-wheel, or on the oppofite fide to the feeding-cloth. This porcupine is a cylinder nineteen inches diameter, and fourteen inches long: its axis is placed horizontally, and directed nearly to the centre of the vertical axis; fo that the fmall porcupines will be parallel to the large one when they pafs over it. The great porcupine is furnifhed with rows of teeth exactly fimilar to thofe of the fmall ones, which teeth are not very numerous, but large and fharp-pointed, and rather hooked, with the points forwards. When the fmall porcupines pafs over the large one, there is fo little clear fpace between their teeth, that the wool which is contained in the teeth of the fmall ones will be taken off by the large one, and remain in its teeth. The reafon of this is, that the teeth of the large porcupine prefent themfelves to the teeth of the fmall ones with the points forwards, and the fmall porcupines at the fame time move with the points of their teeth backwards. It was before ftated, that the porcupines move with the points forwards when they take the wool from the feeding-rollers, but this wool is applied on the upper fide of the porcupines, and the great porcupine is at the lower fide; hence the direction of the teeth is reverfe in the two cafes, and occafions the wool to be given to the great porcupine, a fmall quantity at a time, from each of the fmall porcupines, as they pafs over it. The great porcupine being turned flowly round upon its axis clothes itfelf with the wool in a continued fleece, and this is drawn off from its teeth by a pair of fluted rollers, between which it paffes in a continued fliver or band; this band is alfo conducted through a fhort tube, which revolves round its axis, and rolls up the fliver, to make it adhere better together in a round and compact form.

The action of this machine is not to comb the wool, but to divide the mafs of raw wool, which is fpread on the feeding-cloth, into a great number of fmall and equal portions by the fucceffive ftrokes of the fmall porcupines; thefe portions are again mixed together in one film of wool upon the great porcupine, from which the wool is drawn off in a continued fliver, and as much twift is given to it as is requifite to make the fliver fufficiently compact to fubmit it to the combing-machine.

Cartwright's Combing-Machine, or *Combing-Table;* called alfo amongft the workmen *Big Ben.*—In *Plate* II. *fig.* 1. *Worfted Spinning*, is a horizontal plan of the machine, which exhibits nearly all its parts; we have alfo given a perfpective view in *fig.* 2. of the operative parts, as they would appear if detached from the framing which fuftains them. A A is a circular ring of wood, which is fixed down on the framing; B B is a fimilar ring, which is fitted into the fixed ring, with liberty to turn round within it. The interior of this ring is furnifhed with a row of comb-teeth, with the points directed to the centre, and there are two other rows of fhorter teeth beneath, fo as to make three circular rows of teeth. This forms a large circular comb, called the combing-table, about five feet diameter; it is moved flowly round in the direction of the arrow by means of a pinion, which works into a ring of cogs, fixed in fegments withinfide of the circular comb beneath the row of teeth, as is fhewn in the fection, *fig.* 3.

The wool is filled upon the teeth of the circular comb by means of two machines F and G, called crank-lafhers. Thefe fupply the wool by lafhing or throwing the lock of wool upon the teeth of the comb, and then drawing up the wool from the comb, with a motion very fimilar to that of the hand of the workman in filling the combs, as we have before defcribed. The crank-lafhers repeat their ftrokes with great rapidity; but as the comb-table is kept in continual motion, the wool which is lafhed upon the teeth by the firft crank-lafher F is carried away, and in its courfe comes beneath the other crank-lafher G, by which more wool is filled upon the teeth, and they receive the intended portion. This wool, by the rotation of the comb-table, is then carried beneath a fmall comb K, which works by a crank movement, but with its teeth always horizontal; they penetrate through the wool, and then rife up fo as to comb it. After this operation, the wool is taken off from the teeth of the comb-table between a double pair of fluted rollers N, fituated immediately over the comb-teeth; thefe draw off the combed wool in a continued fliver, which is conducted through another pair of plain rollers R, and falls into a tin can placed there to receive it.

This machine was not found capable of combing the raw wool, chiefly becaufe the comb-teeth are not heated, and alfo becaufe the actions of lafhing on the wool, and afterwards combing it, begin to act upon wool, at firft with their full force, and break the fibres if they are entangled together; hence it is found beft to comb the wool by hand once over, or for fine goods twice. The wool is thus formed into flivers, which are joined together, by laying them on a table, with the ends lapped over each other; and rolling them together, they will join into one long fliver. Three of thefe flivers are put into tin cans *i i*, which are placed upon a circular table I, and carried upwards to the crank-lafher F or G, which are both of fimilar conftruction. The table I is mounted on an axis, fo as to be capable of turning flowly round horizontally, in order to twift the three flivers together into one; but in the machines which we have feen in ufe, this movement is commonly neglected, for if the flivers are prepared by hand-combing, as we have before defcribed, they will hang together without twifting.

The flivers, which are carried up from the cans to the crank-lafher (fee *fig.* 3.), firft pafs over a roller at *e*; the axle of this roller is alfo the fixed centre of motion of a trough H, which forms one part of the crank-lafher. The fliver of wool is conducted along the trough H, and then turns over a fecond roller at *f*; the centre-pin of this roller is the joint, which unites the end of the trough H with a moveable frame *d d*, which has a tube *g* fixed in front for the fliver of wool to pafs through. A little below the middle of this frame *d d* are holes through its fides, to receive the pin of a crank *b b*, of which the central axis is fupported in bearings fcrewed to the frame of the machine, and it is turned round by the power of the mill. By means of a pair of bevelled wheels D and E, *fig.* 1. the cranks of the two crank-lafhers are connected together, and have a common motion, but in a direction at right angles to each other. At the lower end of each of the moving frames *d d*, a pair of fluted rollers *i* are fixed, which draw the fliver between them. The rollers are put in motion by means of a cog-wheel *k*, fixed on the extremity of the axis of the lower roller; this is turned by a fmall pinion, fixed at the end of an axis, which paffes through the frame *d d*, and which at the oppofite end has a wheel *h*, that receives motion from a pinion fixed faft to the pin of the crank. The upper of the two fluted rollers is preffed down againft the lower one by fprings, which bear on its pivots with fufficient force to hold the wool firmly between them, and draw the fliver forwards when they turn round.

The motions of the crank-lafher are not eafy to be underftood from a verbal defcription. It muft be recollected, that the upper end of the frame *d d* which carries the rollers, being jointed to the end of the trough H, it muft always move in the arch of a circle, as fhewn by the dotted lines, *fig.* 3; the centre of this arch is *e*: alfo that the middle part of the frame *d*, where the crank-pin paffes through it, it, muſt deſcribe a circle when the crank revolves: in conſequence, the rollers *i*, which are at the lower end of the frame, will move in a curve, as ſhewn by the dotted lines. It is an oval or diſtorted ellipſis, with the longeſt diameter horizontal.

At the ſame time the fluted rollers circulate in this orbit, they are in continual motion on their own axis, by the communication of wheel-work before deſcribed, and they draw the ſliver of wool down the tube *g*; the end of the ſliver, which projects from below the rollers, hangs down from them in a lock, and by the motion of the crank-laſher this is thrown againſt the points of the teeth in the comb-table. At the period when the wool is thus thrown on the teeth, the rollers are moving nearly in an horizontal direction, ſo as to draw the wool in the direction of the length of the teeth, and they penetrate the wool; but as the rollers proceed in their elliptic orbit, they begin to riſe and draw the wool upwards away from the teeth in an inclined direction, as is evident by tracing the dotted courſe marked out for the rollers. By thus drawing up the wool between the teeth, a portion of the wool will be left in them; the rollers then riſe up rapidly in their oval courſe, and the wool is raiſed quite above the teeth; the rollers then move forwards to make another ſtroke, and during ſuch advance, the rollers, being in continual motion, draw forwards the ſliver of wool, and the end hangs down ready to be laſhed on the teeth of the comb next time.

The motions of the ſmall comb K muſt be next deſcribed. The whole machine receives its motion by means of a wheel or pulley *c*, *fig.* 1, upon the axis of the crank for the laſher G; D and E are the bevelled wheels by which the other crank is turned; at the extreme end of the axis C is a pinion, which turns a bevelled wheel L, and on the axis of this is a wheel turning two others M M of equal ſize; on the extremities of the axes of the wheels M M are two cranks *l l* of equal radii, which are both jointed to an iron bar *m m*, and both turning round together in the ſame direction, they cauſe the bar to move in a direction parallel to itſelf, and every part of the bar deſcribes a circle equal to the radius of the cranks. The ſmall comb K is fixed to this bar, and partakes of its motion, whereby the points of its teeth are carried horizontally into the wool contained in the teeth of the great comb, then riſe upwards and draw through the fibres, in order to comb them.

In order to remove the little comb when it becomes filled with wool, it is attached to the bar *m* by means of a comb-holder or ſocket L, which has a groove at each end to receive the little comb, and it can be mounted or withdrawn at pleaſure. This ſocket L is moveable upon a horizontal pin fixed at the end of the bar *m*, ſo that it can be turned with either end upwards; and as the little comb can be fixed at either end of the ſocket, a ſpare comb is placed in the upper groove of the ſocket, whilſt the lower groove holds the comb which is in uſe; but when this becomes filled with wool, which it has gathered from the comb-table, the ſocket L is inverted by turning it half round upon its centre-pin, and by this means the freſh comb is brought down into uſe, and the other can be taken away to clear off the wool from it. There is a ſmall bolt fixed to the pin on which the ſocket L turns, which can be ſhot into a notch when the ſocket is in a perpendicular poſition, and will then hold the ſocket faſt from turning, and keep the comb in a proper poſition for its work. In this way, the little comb can be taken away and replaced by a freſh one as often as is neceſſary, without ſtopping the machine, for the ſmall comb does not move very quick. The ſame boy who attends to change the combs, when neceſſary, alſo ſets up the wool in the great comb-teeth with a ſmall ſcraper, ſo that the ſmall comb will penetrate through it with more certainty and effect. The plane of the rows of teeth in the ſmall comb is not horizontal, or parallel to the teeth of the combing-table, but inclined thereto, ſo that thoſe teeth of the ſmall comb which firſt come into action upon the wool do not penetrate deeply into it; but as the comb-table turns round, the wool advances beneath the ſmall comb, and is operated upon thoſe teeth which go deeper, and the laſt teeth of the comb go as deep as they can, not to touch the teeth of the comb-table.

The wool is now combed, and only remains to be drawn off in a continued ſliver; this is done by the drawing-off rollers N, which are fluted iron rollers, placed horizontally over the comb-teeth, and nearly in the direction of a radius of the comb-table: they are ſupported in an iron frame, and are turned round by a pair of bevelled wheels from a vertical axis P. This axis extends the whole height of the machine, and is put in motion by means of a pair of bevelled wheels, and an oblique axis Q, which is turned by a bevelled wheel and pinion on the extreme end of the axis of the firſt crank-laſher.

The great comb receives its motion from the perpendicular axis P, which turns a large wheel T by a pinion on the lower end of it: on the upper end of the axis of this wheel is the pinion which works in the ring of teeth withinſide of the comb-table: in this way, a very ſlow motion is given to the comb-table. There are two pair of drawing-off rollers N, ſituated cloſe together, and parallel to each other; the firſt pair are put in motion as we have deſcribed, and the back pair are turned by means of equal cog-wheels, ſo that they move with the ſame velocity.

The wool upon the comb-table is gathered in the hand, to form a ſliver, and the end is introduced between the rollers, which continually draw off the wool as the comb-table turns round. After paſſing through both pairs of rollers, the ſliver is conducted through a forked iron, then through a round wooden tube, and is at laſt delivered by two plain wooden rollers R into a tin can placed beneath to receive it. Theſe rollers are alſo turned by bevelled wheels on the perpendicular axis P. The drawing-off rollers only take away the long wool, the fibres of which are long enough to reach to the rollers. The two rollers compoſing the front pair of drawing-off rollers are not placed immediately over each other, but the upper roller overhangs the lower one, ſo that the plane in which the axes of the upper and lower rollers are both ſituated is inclined at about an angle of 45 degrees to the plane of the comb-table: by this means, the wool is drawn off from the comb, at an angle of 45 degrees, to paſs between the rollers.

The noils, *i. e.* the ſhort wool and broken fibres, which will not reach the drawing-off rollers, remain in the teeth of the comb-table, and alſo as much of the long wool as is on the lower ſide of the comb, and theſe are called backings: both are taken off by a boy, who is ſeated for that purpoſe within the circle of the comb-table; he firſt draws off the backings from beneath the comb, and then, with one hand above the teeth, and the other below, he draws off the noils.

Theſe two ſorts of wool are handed to a boy on the outſide of the machine, who puts them into ſeparate boxes. The backings are filled on the ſmall combs before they are put into the machine, and become ſomewhat combed by the action of the ſmall comb: when the ſmall combs are removed from the machine, the wool upon them is further combed by hand, and then drawn off from them in a continued ſliver, by means of an additional piece of machinery, which is at the ſide of the machine.

This

This combing-machine is found to break the fibre of the wool, and it increafes the quantity of noil very much, unlefs the wool is previoufly combed once or twice by hand; and as it then becomes only a fubftitute for the fecond or third combing, it faves little or no expence. The advantage of the machine is found, in the great regularity and equality of the fliver which is produced by it, a circumftance of particular importance for fine fpinning. In combing by hand when the fliver is drawn off, thofe fibres which the comber firft takes hold of are longer than the others; then as the fliver continues to be drawn, fhorter fibres are found in it, and the fhorteft are laft of all. Thefe are called the long and fhort ends of the fliver; the fhort end is always marked by twifting or rolling it up, in order that when the flivers are joined together into one for fpinning, the long and fhort ends may be equally intermixed and difperfed throughout the whole length. In drawing off the wool from the combing-machine, the long and fhort fibres are intermixed and taken up together, fo that the fliver is of very equal texture.

There have been feveral other attempts to make combing-machines which deferve notice, though they have not come into ufe.

Meffrs. Wright and Hawkfley had a patent in 1793 for a combing-machine; and Mr. Toplis of Cuckney had alfo a patent of the fame date, which contains fome good ideas. Mr. Hawkfley, in 1797, had a patent for improvements on Cartwright's: the principal one was, to make the combing-table by the combination of a number of fmall combs, which could readily be applied to the table, or detached at pleafure. If this would allow the combs to be heated, as the inventor propofed, they would work much better.

Mr. Amatt had a patent in 1795, and Mr. Pearce in 1798: after this time, Mr. Cartwright's machines had received fome improvements from Mr. Hawkfley, and came into ufe; and we find lefs fpeculation on the fubject.

Gilpin's Combing-Machine.—In 1811, Mr. George Gilpin of Sheffield perfected a very ingenious machine, which combed the raw wool in a moft complete manner. We do not hear that this machine is yet come into ufe, although we have no doubt of its anfwering the purpofe, having frequently examined it while at work: its only fault was a complication of parts, which might be eafily removed.

The outline of this machine is taken from that of Mr. Toplis in 1793, but is very much improved and perfected. *Fig.* 4. of *Plate* I. *Worfted*, is a fketch of the principal parts. The machine works with eight combs at once, which are of rather larger fize than the ordinary hand-combs, the rows of teeth being twenty inches long. Thefe combs are fixed upon two reels or frames A, B, which revolve upon their axles by the power of the mill; four combs, D and E, are fixed upon each reel, and in fuch pofition that both ends of the comb-teeth, *viz.* the points and roots, are equally diftant from the centre of the reel to which they are fixed; and the reels, with the combs fixed upon them, form two revolving wheels or frames. The combs D and E are fo made, that they can be detached from the reels, or replaced and fixed faft in a moment, by the attendants; and they can, therefore, be heated in a ftove, in the fame manner as the hand-combs. The wool is alfo filled upon the combs by hand, and the combs and wool are heated in the ufual manner before they are put into the machine, in order to comb the wool.

One of thefe reels A is fimply turned upon its axis, but the other reel B has a curious compound motion given to it by the machinery: thus it revolves on its own axis; but the axis alfo advances to, and recedes from, the other reel with a motion parallel to itfelf, which is repeated four times in every revolution. Whilft B advances towards A, it moves with only one-third of the velocity with which it returns from A. The advancing movement is of a limited and conftant extent; but at the fame time, there is a third movement which regulates this extent, fo that at every fucceeding ftroke which the machine makes, the two reels will approach nearer together.

Suppofe all the combs filled with wool, and mounted in their places upon the reels, the machine is then put in motion, and the two reels A and B turning round in oppofite directions, their combs D and E meet each other; and by the compound movement of B, (*viz.* advancing flowly towards A, and turning round at the fame time,) the combs D and E approach in fuch a manner, that the points of each comb penetrate the wool which is in the other comb, and this is reciprocal of both combs. When the teeth are thus entered into the wool, the moveable reel B retreats quickly from the other, and the teeth, by drawing through the wool, comb and feparate its fibres.

The circular motion of both reels is not regular and equable, but is communicated by means of elliptical cog-wheels, which occafion the reels to move round very flowly, at the moment when the comb of the reel B is drawing out or combing the wool; but this motion being finifhed, the reels begin to turn round more rapidly, and at the fame time the reel B approaches towards A with a flow movement, in order to prefent another pair of combs to each other, which meet; and each one penetrates the wool which is upon the other, and then the reel B draws out to comb it, in the manner before defcribed.

In this way they continue to make fucceffive ftrokes, until the wool is fufficiently combed: the machine is then ftopped, and the combs taken off one by one, to be replaced by others, which are filled with frefh wool, and properly heated.

There is likewife another movement of the reel A, which we have not yet mentioned: the axis of that reel has a flow motion backwards and forwards, endways in the direction of its length, for a fhort diftance. The intention of this is, that the fame parts of the combs fhall never come oppofite to each other at two fucceffive ftrokes.

It fhould be obferved, that when the machine is firft fet to work, the combs at their point of meeting do not come within three or four inches of each other, and the points only penetrate amongft the longeft fibres of the wool upon the combs; but at every ftroke which is made, the combs advance nearer together, and take deeper into the wool, until, after a certain number of ftrokes are made, the combs approach as near as they can without touching. They continue to work in this manner for fome time, and when the intended number of ftrokes is made, a bell rings as an indication that the machine fhould be ftopped. This is done by drawing a lever, and in confequence the machine will ftop itfelf in the exact pofition for changing one of the combs on each reel. Thefe are removed, and others ready filled with wool and heated are put on in their places, which being done on both reels at the fame time by two perfons, is only the work of a moment. The machine is then put in motion again, but by the machinery it will ftop itfelf again at the required pofition for changing the next pair of combs; it is then put forwards, and fo on, until all the eight combs are changed.

The combs which are removed from the machine are put into the ftove to heat for a few moments, and then the wool is drawn off from them by a feparate machine. The head of the comb is here placed in a perp dicular groove, fo that its teeth ftand horizontal; and a piece of of metal, which is fixed to the head of the comb, and projects therefrom like a tooth, enters into the fpiral groove of a fcrew, which ftands in a perpendicular pofition, and is continually turned round by the machinery. By this means, the comb is regularly and flowly let down in the groove, from top to bottom. A pair of fluted rollers is placed horizontally, and parallel to the teeth of the comb, in fuch a pofition that the comb, in defcending, will pafs with its teeth at a proper diftance from them, to draw off the wool in a fliver. After paffing through thefe fluted rollers, the fliver is conducted through a perpendicular revolving tube, which gives a roundnefs to it, the fame as it would acquire by being rolled between the hands, and then it is conducted between a pair of plain rollers, which deliver it into a tin can placed before the machine.

A wooden roller is placed above the fluted rollers, with eight pieces of board projecting from it in the direction of radii. When the roller turns round, thefe boards act to ftroke the wool upon the comb, and raife it into a proper fituation to be drawn off by the fluted rollers.

The combs are prepared for drawing off the wool, by heating them as before mentioned, and by fliding the wool from the roots of the teeth half way towards their points. In this ftate, the combs are carried one by one to the drawing-off machine, and the head of one comb is put into the top of the perpendicular groove: it will be prevented from falling down in the groove by the projecting tooth, which enters the fpiral groove of the perpendicular fcrew. The wool is gathered up and introduced between the fluted rollers; the machine is then put in motion, and by means of the fcrew the comb is gradually lowered down, and the wool is drawn off from it in a fliver, which is rolled up into a compact form by the revolving tube, through which it paffes, and is delivered into the can by the plain rollers.

The attendant holds another comb ready to follow the firft, and when the firft has defcended to a certain point, he flips the next comb into the perpendicular groove, fo that it refts upon the former, and the wool upon the two combs joins as it were in one. The ftroker, when they pafs before it, lays the fibres all one way, and the wool is drawn off by the rollers in a continued fliver, which does not prefent the flighteft appearance of joinings. Another comb is then put in, and the wool joins to the former, and fo on. The backings, or wool at the back of the comb, are drawn off by the boy ftationed behind the machine; and the combs, as they come through below, are received by boys, who afterwards take away the noil or fhort wool which remains in the teeth, and then put the combs back into the ftove to heat them, ready to be filled again, in order to proceed with another combing. When the wool of all the eight combs is drawn off, the motion of the drawing-off machine is ftopped at the moment when the eighth or laft comb has defcended half way through its courfe. In this ftate, the machine waits till another combing is finifhed, and then the fucceeding comb being placed on the top of that one which continues in the machine, the continuity of the fliver will be preferved.

The inventor of this machine ftates in his fpecification, that for common work the wool only requires to be operated upon once by the combing-machine; and in that cafe, the machine muft be adapted to make twenty-four ftrokes of each pair of combs before the bell rings. For medium work, fuch as would require to be combed twice over, in the ufual manner of hand-combing, it muft be combed twice over by the machine: thus, after having been combed once in the manner before defcribed, the fliver of wool is broken up into handfuls, and filled on the combs again by hand as before, and combed over again in a fimilar manner; but the combs are lefs heated for the fecond time of combing. By changing a wheel, the machine fhould be adapted to make only fourteen or fixteen ftrokes before it ftops, when it is intended to comb twice over. The wool intended for the fineft fpinning fhould be combed three times over, and the machine fhould be fet to make fourteen or fixteen ftrokes of each pair of combs.

The machine has alfo two different movements for the drawing out of the moveable comb-reel: in one, the motion is over a fpace of ten inches, and is adapted to comb fuch wool as is fix or eight inches length of ftaple, and is called wether wool; but by a flight alteration, the excurfion of the moveable reel can be increafed to thirteen inches, and is then adapted to comb hey wool, or wool which is from eight to eleven inches length of ftaple.

Mr. Gilpin's machine has the advantages of heating the combs and of filling them by hand, both of which are effential to any machine which is propofed to comb the raw wool. The filling is an operation which requires difcretion, if it is expected that the long fibres fhall be preferved without breaking. The perfon who fills the wool on the teeth takes a greater or lefs lock of wool in his hand, according to the condition of it, and the degree of entanglement: alfo in drawing it between the comb-teeth, the force is proportioned to what the wool will bear. Mr. Gilpin's fpecification ftates, that under certain circumftances, when the wool will not wafh well, but remains taggy, it is advifeable to fill it upon the combs, and flip it off; then fill it again, preparatory for the machine. As the object of this firft filling is chiefly to warm the wool, the end may be in part attained by laying the wool upon the top of the ftove for a few minutes before it is filled.

Planking.—Let us fuppofe that the wool is combed either by the hand, or by the machine, and we will proceed to explain the means of preparing it into a thread. The combing-machines reduce the wool into a continued fliver, which is ready for the drawing-frame; but the fhort flivers produced by the hand-combing muft be firft joined together by what is called planking. Thefe flivers are rolled up by the combers, ten or twelve together, in balls called tops, each of which weighs half a pound: at the fpinning-mill thefe are unrolled, and the flivers are laid on a long plank or trough, with the ends lapping over, in order to fplice the long end of one fliver into the fhort end of another. The diftinction of the two ends of the fliver has been before explained; the long end being that which was firft drawn off from the comb, and contains the longeft fibres of the wool; the fhort end is that which came laft from the comb, and contains the fhort fibres. The wool-comber lays all the flivers of each ball the fame way, and marks the long end of each by twifting up the end of the fliver. It is a curious circumftance, that when a top or ball of flivers is unrolled and ftretched out ftraight, they will not feparate from each other without tearing and breaking, if the feparation is begun at the fhort ends, but if they are firft parted at the long ends they will readily feparate.

Breaking-Frame.—Here the flivers are planked or fpliced together, the long end of one to the fhort end of another; they are immediately drawn out and extended by the rollers of the breaking-frame. A fketch of this machine is given in *Plate* II. *fig.* 5; it confifts of four pairs of rollers, A, B, C, D. The firft pair A receives the wool from the inclined trough E, which is the planking-table. The flivers are unrolled, parted, and hung loofely over a pin, in reach of the attendant, who takes a fliver and lays it flat in the trough, and the end is prefented to the rollers A, which being in motion

motion will draw the wool in; the fliver is then conducted through the other rollers, as shewn in the figure: when the fliver has paffed half througb, the end of another fliver is placed upon the middle of the firft, and they pafs through together; when this fecond is paffed half through, the end of a third is applied upon the middle of it, and in this way the fhort flivers produced by the combing are joined into one regular and even fliver.

The lower roller C receives its motion from the mill, by means of a pulley upon the end of its axis, and an endlefs ftrap. The roller which is immediately over it is borne down by a heavy weight *e*, fufpended from hooks, which pafs over the pivots of the upper roller. The fourth pair of rollers D moves with the fame velocity as C, being turned by means of a fmall wheel upon the end of the axis of the roller C, which turns a wheel of the fame fize upon the axis of the roller D, by means of an intermediate wheel *d*, which makes both rollers turn the fame way round. The firft and fecond pairs of rollers, A and B, move only one-third as quick as C and D, in order to draw out the fliver between B and C to three times the length it was when put on the planking-table. The flow motion of the rollers A is given by a large wheel *a*, fixed upon the axis of the roller A, and turned by the intermediate cog-wheels *b*, *c*, and *d*; the latter communicates between the rollers C and D. The pinions on the rollers C and D being only one-third the fize of the wheel *a*, C and D turn three times as faft as A, for *b*, *c*, and *d*, are only intermediate wheels. The rollers B turn at the fame rate as A. The upper roller *c* is loaded with a heavy weight, fimilar to the rollers A; but the other rollers, B and D, are no farther loaded than the weight of the rollers.

The two pairs of rollers A B and C D are mounted in feparate frames, and that frame which contains the third and fourth pairs, C D, flides upon the caft-iron frame F, which fupports the machine, in order to increafe or diminifh the diftance between the rollers B and C. There is a fcrew *f*, by which the frame of the rollers is moved, fo as to adjuft the machine according to the length of the fibre of the wool. The fpace between B and C fhould be rather more than the length of the fibres of the wool. The intermediate wheels *b* and *c* are fupported upon pieces of iron, which are moveable on centres: the centre for the piece which fupports the wheel *b* is concentric with the axis of the roller A; and the fupporting piece for the wheel *c* is fitted on the centre of the wheel *d*. By moving thefe pieces, the intermediate wheels *b* and *c* can be always kept in contact, although the diftance between the rollers is varied at times. By means of this breaking-frame, the perpetual fliver which is made up by planking the flivers together is equalized, and drawn out three times in length, and delivered into the can G.

Drawing-Frame.—Three of thefe cans are removed to the drawing-frame, which is fimilar to the breaking-frame, except that there is no planking-table E. There are five fets of rollers, all fixed upon one common frame F, the breaking-frame which we have defcribed being the firft. As faft as the fliver comes through one fet of rollers, it is received into a can, and then three of thefe cans are put together, and paffed again through another fet of rollers. In the whole, the wool muft pafs through the breaker and four drawing-frames before the roving is begun. The draught being ufually four times at each operation of drawing, and three times in the breaking, the whole will be $3 \times 4 \times 4 \times 4 \times 4 = 768$; but to fuit different forts of wool, the three laft drawing-frames are capable of making a greater draught, even to five times, by changing the pinions; accordingly the draught will be $3 \times 4 \times 5 \times 5 \times 5 = 1500$ times.

The fize of the fliver is diminifhed by thefe repeated drawings, becaufe only three flivers are put together, and they are drawn out four times; fo that in the whole, the fliver is reduced to a fourth or a ninth of its original bulk.

The breaking-frame and drawing-frame, which are ufed when the flivers are prepared by the combing-machines, are differently conftructed; they have no planking-table, but receive three of the perpetual flivers of the combing-machine from as many tin cans, and draws them out from ten to twelve times. In this cafe, all the four rollers contribute to the operation of drawing: thus the fecond rollers B move $2\frac{1}{3}$ times as faft as the rollers A; the third rollers C move 8 times as faft as A; and the fourth rollers E move $10\frac{1}{2}$ times as faft as A. In this cafe, the motion is given to the different rollers by means of bevelled wheels, and a horizontal axis, which extends acrofs the ends of all the four rollers, to communicate motion from one pair of rollers to another.

There are three of thefe fyftems of rollers, which are all mounted on the fame frame; and the firft one, through which the wool paffes, is called the breaking-frame, but it does not differ from the others, which are called drawing-frames. The flivers which have paffed through one fyftem of rollers are collected four or five together, and put through the drawing-rollers. In all, the flivers pafs through three drawings, and the whole extenfion is feldom lefs than 1000 times, and for fome kinds of wool much greater.

After the drawing of the flivers is finifhed, a pound weight is taken, and is meafured by means of a cylinder, in order to afcertain if the drawing has been properly conducted; if the fliver does not prove of the length propofed, according to the fize of worfted which is intended to be fpun, the pinions of fome of the drawing-frames are changed, to make the draught more or lefs, until it is found by experiment that one pound of the fliver meafures the required length.

Roving-Frame.—This is provided with rollers the fame as the drawing-frames: it takes in one or two flivers together, and draws them out four times. By this extenfion, the fliver becomes fo fmall, that it would break with the flighteft force, and it is therefore neceffary to give fome twift; this is done by a fpindle and flyer. (See *fig.* 6.) A B are the two pairs of rollers, between which the fliver is paffed; the firft rollers A turn round flowly, but the others B revolve four times as quick, to draw the fliver to four times its original length; and as faft as it iffues from the roller, it is twifted by the motion of the fpindle C, and wound up upon the bobbin *a*. The fpindle C is put in motion by a whip-cord band, which paffes round the pulley *c*, and alfo round the wheel D. This wheel is fixed on a vertical axis *e*, which has a pinion on the upper end, to give motion to the lower roller B, by means of a bevelled wheel upon the end of its axis. The oppofite end of the axis has alfo a bevelled pinion upon it, to give motion to a bevelled wheel fixed upon an horizontal axis, which carries another bevelled pinion, to give motion to a bevelled wheel fixed upon the end of the axis of the back rollers A. The fizes of thefe wheels and pinions are fo proportioned, that the back rollers A turn only once to every four turns of the front rollers B, as before mentioned.

The back rollers are capable of being fet at a greater or lefs diftance from the front rollers, according to the length of the fibres of the wool, and in all cafes the diftance fhould be rather more than the length of the fibres, but not a great deal.

The

The fpindle is fupported on its point, and fuftained by a collar at the middle of its length. Upon the top of the fpindle, the flyer *e* is fcrewed; it has two branches, which turn downward, and one of them has an eye at the lower end, through which the roving is conducted, in order to lay it upon the bobbin *a*. This bobbin is fitted loofely upon the upper part of the fpindle, and refts with its weight upon a piece of wood projecting from the bobbin-rail *f*. The rail is made to rife and fall continually with a flow motion, fo as to prefent every part of the bobbin in fucceffion to the eye of the flyer, and thereby wind the roving upon every part of the length of the bobbin. The bobbin is not fixed upon the fpindle, but is fitted loofely thereupon; and by refting upon the piece of wood which is fixed to the bobbin-rail, there is fo much friction and refiftance to the motion of the bobbin, that it gathers up the roving by winding it round itfelf as faft as the rollers give it out. The twift given to the roving is juft enough to make it hang together, and one turn in each inch is ufually enough. Some roving-frames are made with four pairs of rollers, and draw ten or twelve times; and in this way, it is not neceffary for the fliver to pafs fo frequently through the drawing-frame.

Spinning-Frame.—This is fo much like the roving-frame, that a fhort defcription will be fufficient. The fpindles are more delicate, and there are three pairs of rollers inftead of two; the bobbins which are taken off from the fpindles of the roving-frame, when they are quite full, are fluck upon wires at L (*fig.* 7.), and the roving which proceeds from them is conducted between the rollers. The back pair A turns round flowly; the middle pair turns about twice for once of the back rollers; and the front pair B makes from twelve to feventeen turns for one turn of the back rollers B, according to the pinions which are employed, and thefe can be changed according to the degree of extenfion which is required.

The fpindles muft revolve very quickly in the fpinning-frame, in order to give the requifite degree of twift to the worfted. The hardeft twifted worfted is called tammy-warp, and when the fize of this worfted is fuch as to be twenty or twenty-four hanks to the pound weight, the twift is about ten turns in each inch of length. The leaft twift is given to the worfted for fine hofiery, which is from eighteen to twenty-four hanks to the pound. The twift is from five to fix turns *per* inch. The degree of twift is regulated by the fize of the whirls or pulleys upon the fpindle, and by the wheel-work, which communicates the motion to the front rollers from the band-wheel, which turns the fpindles.

It is needlefs to enter more minutely into the defcription of the fpinning machinery for worfted, becaufe the conftruction is very fimilar to the water-frame for fpinning cotton, invented by fir Richard Arkwright, and which is fully defcribed in our article *Manufacture of* COTTON. The differences between the two are chiefly in the diftance between the rollers, which in the worfted-frame is capable of being increafed or diminifhed at pleafure, according to the length of the fibres of the wool, and the draught or extenfion of the roving is far greater than in the cotton.

Reeling.—The bobbins of the fpinning-frame are placed in a row upon wires before a long horizontal reel, and the threads from 20 bobbins are wound off together. The reel is exactly a yard in circumference, and when it has wound off 80 turns, it rings a bell; the motion of the reel is then ftopped, and a thread is paffed round the 80 turns or folds which each thread has made: the reeling is then continued till another 80 yards is wound off, which is alfo feparated by interweaving the fame thread; each of thefe feparate parcels is called a ley, and when feven fuch leys are reeled, it is called a hank, which contains 560 yards. When this quantity is reeled off, the ends of the binding thread are tied together, to bind each hank faft, and one of the rails of the reel is ftruck to loofen the hanks, and they are drawn off at the end of the reel. Thefe hanks are next hung upon a hook, and twifted up hard by a ftick, then doubled, and the two parts twifted together, to make a firm bundle. In this ftate, the hanks are weighed by a fmall index-machine, which denotes what number of the hanks will weigh a pound, and they are forted accordingly into different parcels. It is by this means that the number of the worfted is afcertained as the denomination for its finenefs: thus No. 24. means that 24 hanks, each containing 560 yards, will weigh a pound, and fo on.

This denomination is different from that ufed for cotton, becaufe the hank of cotton contains 840 yards inftead of 560; but in fome places, the worfted hank is made of the fame length as the cotton.

To pack up the worfted for market, the proper number of hanks are collected to make a pound, according to the number which has been afcertained; thefe are weighed as a proof of the correctnefs of the forting, then tied up in bundles of one pound each, and four of thefe bundles are again tied together. Then 60 fuch bundles are packed up in a fheet, making a bale of 240 pounds, ready for market.

From this account of the proceffes of worfted fpinning, it will be feen that they are very fimilar to thofe of cotton-fpinning, after the firft preparation of the wool by combing inftead of carding.

WORSTED-*Cord*, in *Sheep-Farming*, is a fort of cord which is fometimes ufed for tying round the necks of fheep affected with the fcab, after it has been well fmeared over with the common mercurial ointment of the fhops, in order to cure them of that difeafe. See SCAB.

WORT, in the *Materia Medica*, is the fweet infufion of malt; firft propofed by Dr. Macbride as a dietetic article to fcorbutic perfons, from an apprehenfion that it would ferment in their bowels, and give out its fixed air, by the antifeptic powers of which the ftrong tendency to putrefaction in this difeafe might be corrected. It was fome time before a fair trial of this propofed remedy could be obtained, and different reports were made concerning it. In 1762, the lords of the admiralty gave orders to have the wort tried in the naval hofpitals at Portfmouth and Plymouth; but the murmurs of the patients, on account of reftrictions that were neceffary for determining its efficacy, put a ftop to the farther exhibition of it; and indeed Dr. Huxham, in 1764, informed the ingenious and benevolent propofer of this remedy, that it had been tried with very bad effects. But Dr. Macbride affures us, on the teftimony of a gentleman who made ufe of the wort, that it may be taken for a length of time, to the quantity of a quart in the day, without producing any ill effect whatever; and he refers to Van Swieten's Commentary, vol. iv. p. 673. where we learn, that the baron's lady, when a nurfe, ufed regularly to drink a pint of it every night going to bed, in order to increafe her milk.

After the failure of fuccefs in the naval hofpitals, orders were iffued to have the wort adminiftered on fhip-board, where no temptations of frefh vegetables would offer to make the men uneafy. But a confiderable time elapfed, before any reports were made either of its good or bad effects. Dr. Macbride, however, perfifted in recommend-

ing

ſing it, and lived to publiſh ſeveral caſes, in a poſtſcript to the ſecond edition of his work, in 1767, from which it appears, that ſcorbutic complaints of the moſt dangerous kind have actually been cured at ſea by the uſe of wort. Its general effects were, to keep the patients open, and to prove highly nutritious and ſtrengthening; it ſometimes purged too much; but this effect was eaſily obviated by the tinctura thebaica. Other unqueſtionable caſes of its ſucceſs in this diſeaſe are to be ſeen in the London Med. Obſ. and Inq. vol. v. p. 61. See alſo SCURVY.

The uſe of wort has hence been adopted in other caſes, where a ſtrong putrid diſpoſition in the fluids appeared to prevail, as in cancerous and phagædenic ulcers; and inſtances are publiſhed of its remarkable good effects in theſe caſes. See London Med. Obſ. and Inq. vol. iv. p. 367, &c. Prieſtley on Air, vol. 3. Appendix.

As the efficacy of the malt infuſion depends upon its producing changes in the whole maſs of fluids, it is obvious that it muſt be taken in large quantities for a conſiderable length of time, and rather as an article of diet than medicine. The quantity of one to four pints has generally been directed. See SCURVY.

WORT, *Improved Machine for ſtirring Malt in making of*, in *Rural Economy*, a contrivance for this purpoſe in brewing and diſtilling, ſuited to vats of this ſort, which are employed in forming the wort or waſh. There are many modes of ſtirring malt in the vats or tubs for maſhing in, employed in different places and inſtances; but they are in moſt caſes either expenſive, or inadequate to the purpoſes as well as the powers which are made uſe of in the work. Among the former may be ranked the admirably well-contrived machine that is in uſe by Jellet and Co. at Dollhill, in Somerſetſhire, which is on a planatory ſyſtem, and anſwers the intention very effectually; but its great coſt renders it liable to objection in many caſes. The well-known contrivance of a male ſcrew ſtanding upright in the centre of the vat, on which a bar works by means of a female ſcrew operating on the male ſtandard one, and thus cauſing the ſpikes with which the different wings of the bar are armed to ſtir the malt as the ſpiral motion proceeds, is certainly ſimple, neat, and cheap; but as it requires two men, one at each end, and makes but little change of locality among the malt-grain, much cannot be urged in favour of its efficiency for this uſe. The inſtrument known by the name of the hedge-hog, which is in uſe in ſome breweries, is a dreadful-looking machine, that would ſeem intended to divide ſome very tough or viſcous ſubſtance rather than to ſtir malt in this intention. It conſiſts of a roller about two feet in diameter, and ſix or ſeven in length, made of iron ſkeleton work; the longitudinal bars are bound with rings or hoops, furniſhed with ſpiky rims, to keep in due bounds a ſort of chain-work, armed alſo with ſpikes, which chains revolve upon the rings as the frame rolls round, urged by the power of horſes, and thus not only tears a paſſage through the contents of the maſhing-vat, but keeps raking them up, carrying a conſiderable portion with the ſpiky chain quite over the wheel, and expoſing the malt perpetually to the influence and action of the air; a practice invariably diſapproved of by all good brewers. In this caſe, there are expence, labour, friction, &c. all crowded into one form, without any material advantage.

A plan has, however, been lately ſuggeſted for ſtirring malt while in the maſhing-vat by a machine or contrivance wrought by the power of horſes, or in other ways, which is nearly without friction, and diveſted of the intervention of any ſecondary action that may be troubleſome or expenſive. It is very ſimple; and one vat of this ſort may be ſtirred by a very trifling power; but as in large breweries and diſtilleries from malt a number of maſhing-vats are moſtly requiſite, which generally require to be ſtirred in ſucceſſion, an arrangement is given for facilitating and bringing the operations of five vats, one in the middle and four around it, into a narrow or ſmall compaſs, and under the action of one power; which not only affords much convenience, but occaſions the expence and the labour to be greatly leſſened; conſequently it may be uſeful in large as well as ſmall eſtabliſhments of this nature.

In this plan, the centrical circular vat for this purpoſe is raiſed ſufficiently to admit the neceſſary gear and other matters for a horſe-walk underneath it. The upright axle paſſes through the floor, and through the centre of the vat, proceeding up to a beam in which it moves in a metal buſh, as it does alſo below, where it reſts on a ſtep. It does not, however, touch either the floor or the vat; but at the diſtance of a few inches it is ſurrounded by a cylinder, forming part of the vat, which prevents its contents from paſſing through the aperture in the floor. This cylinder correſponds in height with the exterior edge of the vat, and is firmly cloſed at the bottom, where, as well as at the outer part, it is rounded off, ſo as to be the more eaſily drained and cleaned.

As it is requiſite at times to move the malt in the other vats, while the central one is at reſt, there ariſes a neceſſity for conſtructing the wings of the ſtirring-frame in the latter in ſuch a manner as may liberate them, leaving them inactive, while the axle proceeds in its ordinary revolutions.

The ſtirring-frame is made of iron; it has four wings ſtanding at right angles, and they all join to an iron collar which ſurrounds the axle at ſome diſtance, that is, leaving about an inch intermediately all around. When the ſtirring-frame is to move with the axle, it is faſtened to it by two iron pins, with long handles, ſo as to enable the workmen to affix them in their proper ſockets, without going into the vat. Theſe pins paſs through the collar into the axle, thereby cauſing the ſtirring-frame to move round in the vat, as the axle is moved round by the horſe, or other power.

As the ſtirring-frame in the centre vat cannot be connected all the way down its depth with the axle, on account of the cylinder, and as it would be liable to ſwag, if depending entirely on its junction with the collar, oblique ſtays are indiſpenſable; they are carried out about two-thirds of the length of the frame, where they are rivetted: their upper ends are ſecured to another collar, ſurrounding the axle above.

Each wing of the frame conſiſts of two iron bars, one at the top, and one at the bottom; between the bars are three fixed upright valves made of thin ſheet-iron, and ſtanding at angles of forty-five degrees; and they are faſtened above and below into the horizontal iron bars, ſo as to be perfectly ſtrong and ſteady in their poſitions. The valves do not, however, all ſtand the ſame way: the internal ones all point inwards, the outward ones all point outwards, and the middle ones alternately inwards and outwards.

Thus far wholly relates to the centrical vat, which may be ſurrounded by four others of leſs capacity, in which there will be found the differences noticed below: 1. That the bottoms not being perforated no cylinders are required. 2. That the axles for their reſpective frames reſt on ſteps at their bottoms, in which iron gudgeons move in iron buſhes. 3. That the frames all connect with the axles for the whole of their depth. And 4. That no ſtays or collars are wanted in them.

On

On the main axle are four drums of about one-fourth the diameter of the centre vat; they are each about one foot in thicknefs, and deeply grooved all around, like the fheave of a pulley, for the purpofe of receiving a band. An interval of about fix inches is left between them, in the intention of receiving the band refpectively, fo that the correfponding drums on the axles in the other vats may be left at reft whenever thofe vats are not at work. Thus the four drums which are firmly fixed to the main axle, and revolve with it, turn the four drums fixed to the axles in the four vats refpectively. But as the four drums on the main axle are all of different heights from the furface of the vat, the feveral drums on the axles in the other vats muft be refpectively of correfponding heights with thofe that act upon them on the main axle. An idea of the manner in which the bands extend to the four vats may be formed by obferving that in order to produce greater conftriction, and confequently greater power, they all form a figure of 8 in their progrefs; thereby occafioning the four furrounding vats to be ftirred by a counter motion; that is, the frames will revolve the oppofite way to that in the centrical vat. The drum on each of the leffer vats fhould, however, be of the fame fize as that on the central axis from which it receives its motion, whereby the whole will move at the fame rate, and the malt be equally ftirred.

The intervals between the different vats will allow ample accefs to the works, and admit befides of ftandards, &c. for the fupport of the flooring above, there being no part of the machinery that in the leaft interferes with thofe fpaces; and the bands being completely out of the paffage of all work, they can be eafily fhifted off and on to the central drum by means of a pole with an iron at its end, formed fo as to embrace and direct them into the grooves.

On the whole it is fuppofed, that the plan here laid down may be fafely afferted to be cheap, fimple, and effectual; and that it would not probably be eafy to find any machinery for this ufe lefs complex, and in which the power is fo immediately applicable to the object. For though it might be objectionable in work requiring perfect regularity, and an unvaried equable motion, without which the operations would be ill performed, and the machinery itfelf be liable to great injury, and to be perpetually out of order, yet in the bufinefs of merely ftirring the malt in a mafhing-vat in the making of wort or wafh, inequality of motion can never produce any bad effect.

The driving power in thefe cafes fhould move rather flowly, and when of the animal kind, it may be increafed without the addition of more ftrength, merely by extending the length of the lever, and caufing the animal by fuch means to defcribe a larger circle; but which may not, however, be always convenient for want of perpendicular fupport for the flooring above. On moft occafions, the mafhing-vats in making wort or wafh may, however, be computed not to exceed twelve feet in diameter, in which cafes the horfe-walks need not be more than twenty feet over, equal to about twenty yards in circumference; and in this cafe, fuppofing the horfe to move at the rate of two miles in the hour, he would go round eighty-eight times in the courfe of that time, and caufe the malt to be ftirred nearly three times in the fpace of every two minutes; but if the lever were longer, the motion within the vats would be flower in proportion.

WORTH, in *Geography*, a town of Bavaria; 12 miles E. of Ratifbon.—Alfo, a town of the principality of Heffe Darmftadt; 20 miles E.S.E. of Darmftadt.

WORTH *Barrow Bay*, a bay of the Englifh Channel, on the fouth coaft of the county of Dorfet; 11 miles E. of Weymouth.

WORTHIEST *of Blood*, in *Law*, an expreffion denoting the preference given in defcents to fons before daughters.

WORTHING, in *Geography*, a fafhionable and much-frequented watering-place in the parifh of Broadwater, and county of Suffex, England, is fituated on the fea-coaft, 11 miles W. from Brighthelmftone, 9½ E.S.E. from Arundel, and 58 S. by W. from London. Formerly an obfcure fifhing-village, Worthing is much indebted for its prefent improvement to its fituation on a very extenfive ftretch of fine level fandy beach, peculiarly convenient for bathing, and to the range of chalk-hills behind it called the South Downs, affording at once fhelter to the town and fands, and fpace for exercife to the invalid. The town extends northward from the fhore, but fome new buildings are fituated near the beach, and are adapted to the reception of families of the firft rank. The Steyne, a range of handfome houfes, and the parallel row called Warwick-buildings, form the E. and W. fides of a fquare, open to the fea on the S. and to the Downs on the N. A quarter of a mile from the beach is a neat chapel, erected by fubfcription in 1812. Worthing has a theatre, libraries, bathing-machines, and warm baths, and is thus amply provided for the ufe and amufement of vifitors. Warwick-houfe is not only the moft diftinguifhed manfion in Worthing, but for its extent and appearance entitled to a high rank among the noble manfions of the kingdom. It was erected by the earl of Warwick, while proprietor of the manor of Broadwater; but no longer belonging to that family, it is ufually occupied by fome perfons of diftinction in the bathing-feafon. Broadwater village is half a mile from Worthing; it was the chief place of the barony of Camois, in the time of Edward I. The parifh alfo comprehends Offington, the ancient but now much-altered feat of the lords de la Warr. The church of Broadwater is conftructed on the cathedral plan, with a mixture of the circular and early-pointed ftyles of architecture. The population of Worthing fluctuates according to the feafon of the year; but that of the whole parifh of Broadwater, in 1811, was 2692 perfons, and the houfes were 629.—Beauties of England and Wales, Suffex; By F. Shoberl, 8vo. London, 1813.

WORTHINGTON, a poft-town of Maffachufetts, in the county of Hampfhire, containing 1391 inhabitants; 19 miles N.W. of Northampton.

WORTLEY, a townfhip in the parifh of Tankerfley, and county of York, England. According to the population report of 1811, it contained 173 houfes, and 925 inhabitants, moft of whom were employed in agriculture.

WORTON CREEK, a river of Maryland, which runs into the Chefapeak, N. lat. 39° 20′. W. long. 76° 16′.

WORTOWA, a town of Bohemia, in the circle of Chrudim; 14 miles S. of Chrudim.

WORUMBANG, a town of Africa, in Mandingo. N. lat. 12° 40′. W. long. 6° 55′.

WOSCHNICK, or WOZNICKI, a town of Silefia, in the principality of Oppeln; 14 miles N.N.E. of Beuthen.

WOSITZ, a town of Pomerelia; 10 miles S.E. of Dantzic.

WOSSBERK. See WEISENBERG.

WOSTERZEDECK, a town of Bohemia, in the circle of Kaurzim; 12 miles S.W. of Kaurzim.

WOSTOCK, a town of Brandenburg, in the Middle Mark; 11 miles S.S.E. of Berlin.

WOSTROW, a town of Bohemia, in the circle of Czaflau; 12 miles S.W. of Czaflau.

WOTCHAT,

WOTCHAT, in *Agriculture* and *Rural Economy*, a term provincially applied in ſome diſtricts to an orchard.

WOTRALLY, in *Geography*, a town of Hindooſtan, in Myſore; 8 miles N. of Allumbaddy.

WOTROW. See OSTRITZ.

WOTTON, *Sir* HENRY, in *Biography*, was born at Boughton-hall, in Kent, in 1568, and in 1584 entered of New college, Oxford, from which he removed to Queen's college. During his reſidence in the univerſity, he applied with diligence to the ſtudy of logic and philoſophy, of polite literature and civil law, and at this time compoſed a tragedy, which gained the applauſe of his fellow-collegians. Upon the death of his father in 1589, he availed himſelf of the ſmall patrimony that was left to him in travelling through France, Italy, Germany, and the Low Countries, in order to improve his acquaintance with men and manners in theſe ſeveral countries. On his return in 1596, he was appointed ſecretary to the earl of Eſſex; and when this nobleman was apprehended on a charge of high treaſon, he conſulted his own ſafety by quitting the kingdom. As he fixed his reſidence chiefly at Florence, he employed himſelf in compoſing a treatiſe, which was publiſhed after his death in 1657, under the title of "The State of Chriſtendom; or, a moſt exact and curious Diſcovery of many ſecret Paſſages and hidden Myſteries of the Times." When a plot was detected by the grand-duke of Tuſcany for taking away the life of James, king of Scotland, Wotton was engaged to communicate intelligence of it to the king. Having fulfilled this miſſion, he returned to Florence; and when James came to the crown, he recompenſed his ſervice by conferring upon him the honour of knighthood. In 1604 he was appointed ambaſſador in ordinary to Venice, where he acquired ſuch reputation that ſeveral young gentlemen of rank attended him for improvement. In his way through Augſburg, he drew up the following humorous definition of an ambaſſador:—"Legatus eſt vir bonus peregre miſſus ad mentiendum reipublicæ cauſa;" *i. e.* an ambaſſador is a good man, ſent abroad to lie for the ſervice of his country. This ſentence was afterwards alleged as a maxim avowed by the religion profeſſed by the king of England; and it ſo far excited the diſpleaſure of James, that Wotton, after his return, remained for five years unemployed. An apology, however, regained the royal favour, and he was ſent on an embaſſy firſt to the United Provinces, and afterwards in 1615 to Venice. After three years' reſidence he returned with the hope of ſucceeding to the office of ſecretary Winwood, but he was otherwiſe employed in various foreign embaſſies, from the laſt of which to Venice he did not return till after the death of James, when he was appointed, as a recompence for his ſervices, to the provoſtſhip of Eton college in 1624. Soon after his ſettlement in this ſituation, he publiſhed his "Elements of Architecture." But as the ſtatutes of the college required his aſſuming the clerical character, he took deacon's orders, without undertaking what he conſidered as too ſerious a charge, the cure of ſouls. In his domeſtic entertainments he maintained the reputation of hoſpitality, and in his connection with the ſeminary over which he preſided, he was a liberal encourager of genius and application. For the amuſement of advanced life he had contemplated a life of Luther, with the hiſtory of the Reformation; but Charles I. perſuaded him to undertake a hiſtory of England, in which, however, he made little progreſs. Having large demands on government for money advanced in foreign ſervices, his circumſtances were embarraſſed, and he frequently ſolicited his majeſty to grant him new preferment. But death was the only termination of his wants and wiſhes; and this happened in December 1639, in the 72d year of his age. His remains were interred in the chapel of Eton college, and the following epitaph was inſcribed on the ſtone that covered them by his own order: "Hic jacet hujus ſententiæ primus author, *Diſputandi Pruritus Eccleſiarum Scabies.* Nomen alias quære." His accompliſhments and literary acquiſitions were very diſtinguiſhed; and they are hyperbolically ſtated in Cowley's elegy, when he ſpeaks of him as one

"Who had ſo many languages in ſtore,
That only fame ſhall ſpeak of him in more."

Buſineſs occupied ſo much of his time, that he had little leiſure for writing. After his death were publiſhed his "Reliquiæ Wottonianæ;" and they have often been reprinted. Of his poems, there is one entitled "A Hymn to my God in a Night of my late Sickneſs," which has been highly extolled. Biog. Brit.

WOTTON, WILLIAM, a learned clergyman, was born in 1666, and under the tuition of his father, who was alſo a clergyman, he became a perfect phenomenon as to the knowledge of languages; for at the age of five years he could read the Latin, Greek, and Hebrew languages almoſt as well as Engliſh. Accordingly he was entered of Catharine-hall, Cambridge, ſome months before he was ten years of age: at twelve years and five months he took the degree of B.A., ſome time before which he had been celebrated in a copy of verſes by Dr. Duport, not only for his acquaintance with the learned languages, including Arabic, Syriac, and Chaldee, but his knowledge of geography, logic, philoſophy, mathematics, and chronology. He commenced B.D. in 1691, and being chaplain to the earl of Nottingham, this nobleman preſented him in 1693 to the rectory of Middleton-Keynes, in Buckinghamſhire. His firſt work appeared in 1694, and was entitled "Reflections upon Ancient and Modern Learning." A ſecond edition was publiſhed in 1697, and to this was annexed Dr. Bentley's Diſſertation upon Phalaris, which involved Wotton in controverſy, and ſubjected him to the ſarcaſm of Swift's Battle of Books. Wotton defended his own book againſt the objections of ſir W. Temple and others, and ſome obſervations in the Tale of a Tub, in the third edition in 1705. In 1701 he publiſhed "The Hiſtory of Rome, from the Death of Antoninus Pius to the Death of Severus Alexander," 8vo. undertaken at the requeſt of biſhop Burnet, for the uſe of his pupil the duke of Glouceſter; and recommended by Leibnitz to George II. when electoral prince. In 1706 he attacked "Tindal's Rights of the Chriſtian Church," and in 1707 archbiſhop Teniſon conferred upon him the degree of D.D. Notwithſtanding his talents and learning, his life was irregular, and of courſe his circumſtances embarraſſed, ſo that in 1714 he was obliged to retire into South Wales, where he employed himſelf in writing. He alſo acquired the Welſh language, and was able to preach in it. Dr. Wotton, ſays one of his biographers, was one of thoſe ſcholars, whoſe early proficiency, being chiefly the reſult of an extraordinary memory, was not followed by mature products correſponding to the expectations they excited. He died at the age of 60, in the year 1726. Nichols's Lit. Anecd. Gen. Biog.

WOTTON-*under-Edge*, in *Geography*, a large and populous market-town in the upper diviſion of the hundred of Berkeley, Glouceſterſhire, England, is ſituated at the baſe of a ridge of woody hills (whence its name is evidently derived), at the diſtance of 19 miles S.S.W. from Glouceſter, and 108 miles W. by S. from London. It is a borough by preſcription, though it ſends no members to parliament. In the

the reign of king John it was nearly deftroyed by fire, and a place called the Brands is fuppofed to mark its ancient fcite. The prefent town confifts of feveral ftreets, and ftands on nearly fixty acres of ground; the buildings in general are good, and fome, belonging to families of property, are modern and elegant. The government of the town is vefted in a mayor and twelve aldermen. In the year 1252, Maurice, lord Berkeley, an anceftor of the prefent earl of Berkeley, who now holds the manor, obtained a grant of a weekly market on Fridays, and an annual fair, both of which are ftill held. The church is a fpacious, handfome fabric, and contains numerous monuments and fepulchral memorials. Here is a free-fchool, erected in 1385, by Catherine, relict of Thomas, lord Berkeley: alfo an alms-houfe for fix poor men and fix women, built and endowed in 1632, by Hugh Perry, alderman of London, at the charge of 1000*l.*: a like fum was given by fir Jonathan Dawes, fheriff of London, for the relief of the poor. In the population return of the year 1811, the houfes in this town were enumerated as 217, the inhabitants as 1527; the latter are chiefly employed in the clothing manufacture, which is carried on to a confiderable extent in the town and its vicinity: one factory only, called New Mill, employs under its roof about 200 men, women, and children. Spanifh wool alone is manufactured at this place, and is employed for the weaving of broad-cloth and kerfeymere.—Rudge's Hiftory of Gloucefterfhire, 2 vols. 8vo. 1803. Beauties of England and Wales, vol. v. Gloucefterfhire, by J. Britton and E. W. Brayley, 1804.

WOTYECHOW, a town of Poland, in the palatinate of Lublin; 12 miles W.S.W. of Lublin.

WOTZLERSDORF, a town of Auftria; 10 miles W. of Zifterfdorf.

WOUDRICHEM. See WORCUM.

WOVEN STOCKINGS. See STOCKING.

WOUGHS, in *Mines*, are the walls or fides fometimes of hard ftones, and fometimes foft; when foft, the miners fay they are rotten: thefe are the bounds of an entry. Betwixt them all forts of earth, ftones, and ore lie; or, as philofophers fay, grow.

WOULD, or WELD, among *Dyers*. See WELD, and DYER's *Weed*.

WOULD, in *Agriculture*, a term applied in fome cafes to fignify an open uninclofed tract of country.

WOULD *Land*, that which remains in the ftate and condition of would. There is much of this fort of land in many counties and diftricts of this country which might be ftill greatly improved and converted to far better purpofes than at prefent, by fimply inclofing them and turning them into a ftate of proper and fuitable cultivation. This has been already done with large tracts in Yorkfhire and Gloucefterfhire to very great benefit, and the fame may be the cafe with many others in different places. See WASTE *Land*.

WOULDS, a term applied by fome writers on hufbandry to crops of the woad kind. See WOAD.

WOULDING. See WOOLDING.

WOULMARA, in *Geography*, a town of Bengal; 28 miles S. of Midnapour.

WOUNDS, in *Surgery*, conftitute the moft ancient and important branch of it, accidental injuries of this kind having in all probability preceded the exiftence of many of the difeafes to which mankind are now liable. The turbulent and enterprifing fpirit of the earlieft generations foon produced wars, and the effufion of human blood; and even the natural habits of every people, in a ftate of inferior civilization, would conduce to the receipt of wounds, fince the chace, by which food was fo commonly procured, would itfelf caufe many accidental hurts. Surgeons ufually define a wound to be a folution of continuity, or a divifion of the foft parts, more or lefs recently produced, commonly attended with a greater or leffer degree of hemorrhage, and almoft always occafioned by an external mechanical caufe.

There are fome chirurgical writers who make objections to defining a wound to be a *recent* and *bleeding* divifion of the foft parts, and M. Richerand is one of this number. He difapproves of thefe terms, becaufe a wound, when long in healing, and accompanied with fuppuration, cannot admit of fuch a definition. And he obferves, that writers who have defined a wound in this way, have been obliged to call every fuppurating wound, if only of three days' ftanding, an ulcer, which he conceives to be altogether abfurd. The epithet *bleeding*, he contends, is not applicable in a general definition of wounds, fince gun-fhot wounds are not ordinarily followed by an effufion of blood from the divided parts. Nofographie Chir. tom. i. p. 2. edit. 4.

It muft be acknowledged, that there is confiderable difficulty in fixing the precife period when a wound fhould ceafe to be fo denominated, and take the appellation of an ulcer. The wound, after feveral important furgical operations, is fometimes a month or two before it is entirely healed; yet, generally fpeaking, as long as there is a profpect of a cure within a reafonable length of time, and the cicatrization does proceed, though flowly, furgeons moftly ftill call the fuppurating breach of continuity a wound, and not an ulcer. When, however, a wound is very long kept from healing by injudicious applications, conftitutional caufes, attacks of hofpital gangrene, debility, &c. the cafe, we think, is moft commonly regarded rather as a fore, or ulcer, than as a wound. An ulcer, ftrictly fo called, does indeed feem to imply a breach of continuity arifing from the procefs termed *ulceration*, or *ulcerative abforption*, in which a chafm, or lofs of fubftance, is actually produced in the part by the action of the abforbent veffels. (See ULCERATION, and ULCER.) This procefs is alfo concerned in the production of every fore which is the confequence of a burn; for though parts may be at once killed, and converted into efchars by the fire itfelf, yet the feparation of fuch deadened parts, or floughs, fo as to leave an ulcer behind, is the refult of a procefs, in which the abforbents of the adjoining living furface remove the particles of matter, which form the connection between thofe parts which are killed and thofe which are alive.

In the perufal of Richerand's fentiments, who has betrayed fo much delicacy and fo many fcruples about the admiffion of definitions, and who is at the fame time the author of a modern fyftem of phyfiology, we confefs that we were rather furprifed to find him infifting upon burns, and the apertures by which abfceffes fpontaneoufly burft, being wounds, and not ulcers. In fact, he feems to regard the formation of a breach of continuity, in thefe cafes, as entirely the refult of phyfical and mechanical caufes, and not as the confequence of a vital procefs, in which the action of the abforbent veffels has a very confiderable fhare.

With refpect to the propriety of the epithet *bleeding*, in the definition of a wound, there cannot be any real objection to it in a general fenfe; for although a wound does not bleed when in a fuppurating ftate, yet it has almoft always done fo on the firft occurrence of the injury. Even the generality of gun-fhot wounds, though it may not be their ufual nature to bleed much, commonly pour out fome blood.

We have ftated, that wounds are produced by external mechanical caufes. There are, however, exceptions to this remark;

remark; for it ſometimes happens that breaches of continuity, both in the ſoft and hard parts, are cauſed by the violent action of the muſcles. Thus, the patella and os brachii are occaſionally fractured by the powerful contraction of the muſcles; and the muſcles either tear themſelves aſunder, or rupture the tendons with which they are connected. Sometimes, alſo, the ſharp point of a broken bone wounds the ſuperincumbent integuments, and changes the caſe into a compound fracture. Here we ſee the cauſe is mechanical, but yet not of an external kind, as in ordinary examples.

Wounds are divided by the writers on ſurgery into ſeveral kinds, the diſtinctions being founded either upon the ſort of weapon with which the injury was inflicted; or upon the circumſtance of a venomous matter having been inſerted into the part; or, laſtly, upon the particular ſituation of the wound, and the nature of the wounded parts themſelves. Hence we have *cuts*, *inciſions*, or *inciſed wounds*, which are ſuch as are produced by ſharp-edged inſtruments, and are generally free from all contuſion and laceration. The fibres and texture of the wounded part have ſuffered no other injury but their mere diviſion; and there is conſequently leſs tendency to inflammation, ſuppuration, gangrene, and other bad conſequences, than in the generality of other ſpecies of wounds. Inciſed wounds alſo may uſually be healed with greater quickneſs and facility than other wounds, which are accompanied with more or leſs contuſion and laceration: the ſurgeon has only to prevent the ſolution of continuity from gaping, or, in other words, he has ſimply to bring the oppoſite ſides of the wound into contact with each other, and keep them in this ſtate a few hours, and they will unite and grow together.

Another claſs of wounds are *ſtabs*, or *punctured wounds*, made by the thruſt of pointed weapons, like bayonets, lances, ſwords, daggers, &c. and alſo by the accidental and forcible introduction of conſiderable thorns, large nails, &c. into the fleſh. Theſe wounds frequently penetrate to a great depth, ſo as to injure large blood-veſſels, viſcera, and other organs of importance; and as they are generally inflicted with much force and violence, the parts ſuffer more injury than what would reſult from their ſimple diviſion. It alſo deſerves notice, that a great number of the weapons, or inſtruments, by which punctured wounds are occaſioned, increaſe materially in diameter from the point towards their other extremity; and hence, when they penetrate far, they muſt force the fibres aſunder like a wedge, and cauſe a ſerious degree of ſtretching and contuſion. It is on this account that bayonet wounds of the ordinary ſoft parts are very often followed by violent inflammation, an alarming degree of tumefaction, large abſceſſes, fever, delirium, and other very unfavourable ſymptoms. The opening which the point of ſuch a weapon makes is quite inadequate for the paſſage of the thicker part of it, which can only enter by forcibly dilating, ſtretching, and otherwiſe injuring the fibres of the wounded fleſh.

A third deſcription of wounds are the *contuſed* and *lacerated*, which ſtrictly comprehend, together with a variety of caſes produced by the violent application of hard, blunt, obtuſe bodies to the ſoft parts, all thoſe intereſting and common injuries denominated *gun-ſhot wounds*. Many bites rank alſo as contuſed and lacerated wounds. In ſhort, every ſolution of continuity, which is ſuddenly produced in the ſoft parts by a blunt inſtrument, or weapon which has neither a ſharp point nor edge, muſt be a contuſed, lacerated wound.

Poiſoned wounds are thoſe which are complicated with the introduction of a venomous matter, or fluid, into the part. Thus the ſtings and bites of a variety of inſects afford us examples of poiſoned wounds; but a more ſerious and dangerous inſtance, which we meet with in this climate, is ſeen in the cuts accidentally received in the diſſection of putrid bodies, or in handling inſtruments infected with any irritating venomous matter; as ſometimes happens to the ſurgeon in the performance of operations on gangrenous limbs, and in the application of dreſſings to venereal and other infectious ulcers. The moſt dangerous, however, of all the poiſoned wounds, which ever occur in this kingdom, are thoſe reſulting from the bite of the viper, and from the bites of rabid animals, particularly the dog and cat. See HYDROPHOBIA.

Wounds are farther divided by ſurgical writers into *wounds of the head*, *wounds of the face*, *wounds of the throat*, *wounds of the cheſt or thorax*, *wounds of the belly or abdomen*, *wounds of the limbs or extremities*, *wounds of the arteries*, *wounds of the veins*, &c. &c.

Wounds may likewiſe be univerſally referred to two other general claſſes, *viz. ſimple* and *complicated*. A wound is called *ſimple*, when it occurs in a healthy ſubject; has been produced by a clean, ſharp-edged inſtrument; is unattended with any ſerious ſymptoms; and the only indication is to re-unite the freſh-cut ſurfaces. A wound, on the contrary, is ſaid to be *complicated*, whenever the ſtate of the whole ſyſtem, or of the wounded part, or wound itſelf, is ſuch as to make it neceſſary for the ſurgeon to deviate from the plan of treatment requiſite for a common ſimple wound. The differences of complicated wounds muſt, therefore, be very numerous, as they depend upon many incidental circumſtances, the principal of which, however, are, hemorrhage, nervous ſymptoms, contuſion, the unfavourable ſhape of the injury, the diſcharge or extravaſation of certain fluids indicating the injury of particular bowels or veſſels, the preſence of foreign bodies or of a virus in the part, loſs of ſubſtance, the attack of hoſpital gangrene, &c. See ULCER.

All large or deep wounds are attended with more or leſs ſymptomatic fever. It uſually comes on, as Dr. Thomſon obſerves, at a period varying from ſixteen to thirty-ſix hours after the infliction of the injury. Its occurrence is indicated by an increaſed warmth of the ſkin; by increaſe in the frequency, and generally alſo in the ſtrength of the action of the heart and arteries; by anxiety, thirſt, and by the ſuppreſſion of the powers of digeſtion. The ſymptomatic fever from wounds is generally of the inflammatory character; and it even ſometimes happens that a very high degree of ſymptomatic fever occurs in debilitated conſtitutions, and in perſons who have loſt a conſiderable quantity of blood. In theſe caſes, the frequency of the pulſe, however, is more remarkable than its ſtrength, and the fever which occurs ſeems to reſemble more an aſthenic fever than it does one that is truly inflammatory. It is of great conſequence to attend to the type of this fever in the treatment; for the loſs of blood, which may be required and ſuſtained with impunity in the one ſpecies of fever, may prove moſt injurious, if not fatal, in the other. Thomſon's Lectures, &c. p. 292.

We ſhall now proceed to offer a general deſcription of the ſeveral kinds of wounds, and the manner of treating them; and then notice the wounds of particular parts, and the ſurgical meaſures which ſeem beſt calculated to promote their cure. As, however, *wounds of the head*, comprehending its external coverings, and the cranium and brain, form the ſubjects of articles already publiſhed, theſe caſes will not fall under conſideration in the ſubſequent columns, the reader being referred for information concerning them to

Compression, Concussion, Extravasation, Head, *Injuries of*, and Trepanning.

Of Cuts or incifed Wounds.—Sharp-edged inftruments may produce a divifion of the parts upon which they act, altogether on the principle of direct preffure; in which cafe, they may be regarded as operating in the manner of a wedge. In other inftances, they both prefs and faw at the fame time, and then the folution of continuity is made with more facility, and carried to a greater depth, becaufe the fibres are elongated in the direction in which the inftrument faws, as well as in that in which it preffes.

In whatever way a cutting inftrument operates, feveral confequences refult from the divifion of the parts. 1ft, An effufion of blood from the divided veffels. 2dly, Pain, arifing from the divifion of nerves. 3dly, A gaping of the wound, or feparation of its edges from each other.

Anatomy teaches us, that almoft every part of the body is furnifhed with a confiderable number of blood-veffels, which indeed exift in fuch myriads, that it is impoffible to prick the fkin with the point of the moft minute needle, without opening one or more ramifications of veffels containing blood. But this effect always happens in a ftill greater and more remarkable degree, when the divifion, caufed by a fharp-edged inftrument, is at all extenfive.

If the wounded veffels are of fmall fize, the blood iffues from them only in moderate quantity; but when they are large, the hemorrhage is more copious, and it may be fo rapid as to prove almoft inftantly fatal. Many of the phenomena of hemorrhage have been already confidered in another place (fee Hemorrhage); and, on this account, we fhall not have occafion now to travel over the whole of that interefting topic again. There are, however, certain parts of the fubject which muft fall under confideration in the courfe of this article; and in mentioning them, we fhall take the opportunity of noticing a few ingenious fuggeftions, which have been made fince the period when the above-mentioned article was written, and which, when further inveftigated, may lead to very important improvements in the treatment of wounds.

It has been ftated, that hemorrhage is one of the circumftances which render wounds complicated; yet it is to be underftood, that when the bleeding is not fo confiderable as to hinder the union of the parts, and a further effufion of blood can be prevented by the very fame preffure which is neceffary to promote this union, the cafe is always regarded as a fimple wound. Such is that which is produced by the operation for the harelip, &c.

The fame experiment which demonftrates the prefence of blood-veffels in every fituation, namely, pricking any part of the body with a needle, proves alfo that filaments of the nerves are found every where, and at every point; for the flighteft prick of the fkin occafions pain, and pain cannot happen except where there are nerves. But wounds are obferved to be attended with a pain, which is more or lefs acute, according to the kind of cutting inftrument with which they are inflicted, the extent of the divifion, and efpecially according as the wounded perfon happens or not to be in expectation of the receipt of the injury. A patient, on whom an operation is to be performed, turns his whole attention to the effect which the ufe of the knife will produce upon his feelings, and he fuffers a great deal; but if an incifion be made when not expected, or a foldier be wounded in the heat of battle, the injury is fometimes not perceived till the bleeding attracts notice.

Immediately a part is divided with a cutting inftrument, the edges of the wound feparate more or lefs diftantly from each other, and the injury prefents a gaping appearance. This is an occurrence which is owing to feveral caufes, neceffary to be underftood by every furgeon who is defirous of knowing the beft mode of obviating it.

The firft caufe of the feparation of the lips of a wound from each other is, no doubt, the thicknefs of the inftrument with which the folution of continuity is made. A cutting inftrument, acting like a wedge, muft unavoidably feparate the parts between which it enters; but if this were the only caufe, the gaping of a wound would be very inconfiderable, fince the blades of moft cutting weapons are extremely thin. We find, however, that the oppofite furfaces of many wounds are drawn away from each other feveral inches, and the caufes to which the phenomenon is to be afcribed are the elafticity and contractile nature of the divided parts; fometimes one of thefe properties operating fingly, fometimes both of them together in the fame wound.

Elafticity is a quality which belongs to all animal fubftances, and it is inherent in them even after they have been deprived of life; but it does not prevail in an equal degree in every texture. Thus, the gaping of a wound depending upon this caufe varies very confiderably, according to the nature of the divided parts. The edges of an incifion made in the fkin become widely drawn afunder, becaufe the integuments are endued with great elafticity. The cellular membrane, when cut, gapes very little, becaufe it is lefs elaftic. The mufcles alfo are not remarkably elaftic; yet wounds of them, efpecially tranfverfe wounds, always have their oppofite fides feparated a vaft diftance from each other: but this is a circumftance which is owing not altogether to the elafticity of the parts, but partly to their contractile powers.

The feparation of the edges of a wound is not always in proportion to the elafticity of the wounded part; it is likewife proportioned to the tenfion of this part at the very moment of the injury. An exceedingly fimple experiment proves the truth of this obfervation: if the fkin which covers the knee be divided tranfverfely in the dead fubject, while the leg is bent upon the thigh, and another fimilar incifion be made in the other knee, while the leg is extended, the feparation which happens between the edges of the divifion will be found to be much greater in the firft than in the fecond example.

The contractile power, or irritability, which is a peculiar property of mufcular fibres, and by virtue of which they tend continually to fhorten themfelves, is the moft powerful caufe of the feparation which occurs between the oppofite fides of a tranfverfe wound of any mufcle. The feparation thus produced is the greater in proportion as the cut mufcular fibres are longer, inafmuch as the contraction of which the mufcles are capable, by reafon of their contractile power, is itfelf in a ratio to the length of the mufcular fibres. Thus, as Boyer obferves, if two mufcles be divided tranfverfely, the fibres of one of which are three times as long as thofe of the other, the feparation which takes place between the edges of the wound of the former will be three times as great as what follows, between the fides of the divifion made in the latter.

The force with which the feparation is produced by the contractile power of the mufcles, is not in proportion to the length of the mufcular fibres, but to their quantity. Each mufcular fibre being regarded as a feparate diftinct power, it is obvious, that the more thefe powers are multiplied, the greater muft be the effect refulting from their action.

It appears alfo, that in addition to the firft contraction of a divided mufcle, a fecondary and increafed contraction of the part may be excited, when it is expofed and irritated.

From

From what has been ftated, it feems then that in wounds of parts deftitute of contractile properties, as the fkin, cellular membrane, ligaments, fafciæ, &c. their elafticity is the only caufe of fuch wounds gaping, or of the feparation which happens between the oppofite furfaces of the injury; but that in mufcular wounds the feparation is the effect both of the contractile and elaftic powers of the part. Hence, as we have already obferved, the feparation is greater the more tenfe the mufcle is at the inftant when the wound is inflicted.

"The edges of every incifed wound (fays profeffor Thomfon) are more or lefs retracted, or drawn from each other, and this generally in proportion to the fize of the wound, and the nature of the parts upon which it is inflicted. The different foft textures of which the human body is compofed are more or lefs elaftic, and are in the healthy condition of the body kept in a certain degree of tenfion. When the fibres, therefore, of any of thefe textures are divided, they recede from each other; thofe of fkin farther than thofe of cellular membrane, and thofe of mufcle farther than thofe of fkin. The fibres of mufcle contract moft of all. The extremities of a divided artery recede confiderably from each other; the veins lefs than the arteries, and the nerves probably lefs than the veins. To oppofe this contraction of divided parts by fuitable means, is one of the main objects which the furgeon propofes to himfelf in the cure of wounds; for the retraction of the edges of wounds from each other always prevents re-union by the firft intention, and very often retards it for a long time by the fecond." See Thomfon's Lectures on Inflammation, p. 280; alfo Union *by the Firft Intention*.

The prognofis of wounds made with a cutting inftrument varies according to the extent and depth of the divifion, the nature of the injured parts, and the circumftances which attend the accident. Deep large wounds are more dangerous and more difficult to cure than thofe which only intereft the fkin. Wounds, accompanied with injury of confiderable veffels or nerves, are more or lefs dangerous, according to the magnitude or number of thofe veffels or nerves. Simple wounds, in which the only indication is to bring the divided parts together, fo that they may re-unite, are the moft favourable cafes of all. On the other hand, complicated wounds are more or lefs hazardous, according to the particular nature of the complication. In the prognofis of wounds alfo, we muft not forget to take into confideration the patient's age, his kind of conftitution, and the difeafes under which he may labour. Generally fpeaking, the moft dangerous examples of incifed wounds are thofe which are made about the throat by perfons who attempt to deftroy themfelves. Here there are fo many large blood-veffels, nerves, and other parts of great importance, that deep incifed wounds too often prove fatal, either immediately, or in the courfe of a few days. Sometimes the patient opens the carotid artery, and perifhes of hemorrhage on the fpot, before any affiftance can be rendered. In other inftances, he divides fome of the principal branches of the external carotid, and after lofing a great deal of blood he faints, and the hemorrhage fpontaneoufly ceafes for a time. The fainting indeed is often the very thing which faves his life, by checking the effufion of blood until a furgeon arrives, who ties the veffels as foon as they begin to bleed again. Cut wounds of the extremities, when fuch arteries as the femoral and brachial are injured, may alfo fuddenly deftroy the patient, by the great quantity of blood which is fometimes loft before the arrival of furgical affiftance.

A furgeon, called to a recent cut or incifed wound, has three objects which he fhould endeavour to accomplifh without the leaft delay.

The firft, and that which requires his immediate interference, is the bleeding, which muft be checked, or the patient may lofe his life in a few minutes.

The fecond is the removal of all extraneous matter, foreign bodies, &c. from the cavity of the wound.

The third is to bring the oppofite furfaces of the wound into even contact, and to adopt proper meafures for keeping them in this pofition, until they have grown together again.

1. *Hemorrhage.*—For an explanation of the means which nature employs in the fuppreffion of bleeding from divided arteries, as well as for an account of the beft chirurgical meafures for promoting this object, and a detail of numerous obfervations on the principles by which the conduct of the furgeon fhould be regulated in the ufe of the ligature, we beg to refer to the articles Hemorrhage and Ligature.

In the prefent place we fhall briefly notice how the furgeon ought to act in cafes of incifed wounds, accompanied with hemorrhage, without paffing over, however, a few things which have been fuggefted fince the above-mentioned articles were written.

It has been ftated, that in every wound the bleeding is the thing which demands the earlieft attention; becaufe if lofs of blood be not prevented without delay, the patient will frequently die in the courfe of a few feconds, or minutes. Every other confideration may be deferred; but when large veffels are injured, they muft be immediately fecured, or elfe the fudden death of the patient will leave the furgeon no opportunity of exhibiting his fkill and ufefulnefs in other matters connected with the treatment.

It is not, however, every bleeding which is thus ferious and alarming; for the flighteft and moft fuperficial cuts are always attended with fome effufion of blood. When the divided veffels are of inferior fize, the bleeding foon fpontaneoufly ceafes, and no furgical meafures need be taken on this particular account. When the wounded veffels are even fomewhat larger, and their fituation is favourable for compreffion with a bandage, it is often advifeable to clofe the wound, and apply a comprefs and roller, inftead of having recourfe to ligatures, which always produce irritation, fuppuration, and an obftacle to the union of that part of the wound in which they lie. Yet, let the furgeon, before he determines to truft to preffure, be well affured, that the bleeding can be thus perfectly and fafely commanded without the employment of ligatures; for by the failure of compreffion, hemorrhage has often been renewed from time to time, and many a life been loft. We therefore wifh it to be diftinctly underftood, that in almoft all cafes of confiderable bleeding, the patient will not be fafe unlefs the veffels be tied, and that the only exceptions are a few inftances in which the bleeding arteries can be effectually compreffed againft a fubjacent bone, and are not of very large fize. In all other examples, tying the bleeding veffels is the only fafe mode of proceeding. When the artery is of large diameter, and its mouth can be readily feen, the moft proper inftrument for taking hold of it is a pair of arterial forceps. With this inftrument, the end of the veffel is to be drawn out a little way from the furrounding flefh, in order that a ligature may be put round it without the inclufion of any other parts, which would be unneceffary, painful, and on feveral accounts difadvantageous. In applying the ligature, the furgeon muft take care to pull its two ends in fuch a manner that the noofe will not rife above the mouth of the veffel; and, for the purpofe of altering the direction of the force employed in drawing the ligature, the ends of the thumbs are found moft convenient. When the bleeding arteries are not very large and diftinct, they are generally taken up with a tenaculum; and of late years a double tenaculum, the points of which fhut together, like the blades of a pair of forceps, has been occafionally ufed, and we have heard fome well-informed furgeons fpeak highly of the invention, which we believe was originally made by profeffor Afalini, an ingenious furgeon at Milan, in Italy.

The ligatures having been applied, one end of each is to be cut off clofe to the knot, in order to diminifh the quantity of extraneous matter in the wound.

When a large artery, like the brachial or femoral, is opened, but not cut through, it often happens that the furgeon cannot get at it without making a dilatation of the wound, and bringing the wounded part of the veffel more fairly into view. In cafes of this defcription, the firft duty of the practitioner is to comprefs the artery above the wound, and apply a tourniquet. Thus he will put an immediate ftop to the bleeding; but if he omit this effential ftep, the veffel will continue to bleed fo profufely and rapidly, that in the inevitable obfcurity and confufion thence refulting, the patient may actually lofe his life before the veffel is fecured. When, however, a tourniquet has been applied, the furgeon can examine the wound, and fearch for the artery with much greater fuccefs, as now the ftate of things is no longer concealed under a continual ftream of blood.

As foon as the wounded portion of the artery is difcovered, it ought not to be extenfively diffected and feparated from its furrounding connections in order to let the furgeon pafs his finger under it. This mode of proceeding is now acknowledged by fome of the beft furgeons to be unneceffary and injurious; and it will be quite fufficient to feparate the artery fufficiently to pafs an eye-probe or aneurifmal needle under it, with which a double ligature is to be drawn beneath it. The probe or needle having been cut off, one ligature is then to be tied above the aperture in the artery, and the other below it. Were only a fingle ligature applied above the wound in the artery, the bleeding would ftill be kept up, becaufe the blood paffes into the lower continuation of the veffel through numerous large anaftomofes, in a quantity that is truly furprifing.

The principles which fhould guide the furgeon in the ufe of the ligature, were not known until the late Dr. Jones publifhed his valuable treatife on hemorrhage. As an able furgeon has obferved, "he has banifhed the ufe of thick and broad threads, of tapes, of referve ligatures, of cylinders of cork and wood, linen compreffes, and all the contrivances, which, employed as a fecurity againft bleeding, only ferved to multiply the chances of its occurrence." Lawrence in Medico-Chir. Tranf. vol. vi. p. 162.

In the article SURGERY, we have noticed the method of cutting off both ends of the ligature clofe to the knot on the face of the ftump, with a view of leffening the quantity of extraneous matter in the wound, and promoting a complete union of the divided parts, without any fuppuration. The period of the firft invention of this method appears uncertain. Mr. Hennen, who feems to have been the firft who adopted the method in the army, had it fuggefted to him in 1813 by a Mr. Hume, as the practice of fome American naval furgeon; and he has fince found that it had been done in Scotland 16 years before the above year. Dr. Ferguffon alfo faw the practice adopted in Sweden as early as the peace of Amiens. Mr. Hennen mentions 34 amputations, in which this treatment was followed by fuccefs. His accounts are highly in favour of the method. See Hennen's Military Surgery, p. 189, &c.

This plan has been tried by Mr. Lawrence: "The method I have adopted (fays this gentleman) confifts in tying the veffels *with fine filk ligatures*, and cutting off the ends as clofe to the knot as is confiftent with its fecurity. Thus the foreign matter is reduced to the infignificant quantity, which forms the noofe actually furrounding the veffel, and the knot by which that noofe is faftened. Of the filk which I commonly employ, a portion fufficient to tie a large artery, when the ends are cut off, weighs between $\frac{1}{50}$th and $\frac{1}{80}$th of a grain: a fimilar portion of the thickeft kind I have tried weighs $\frac{1}{30}$th of a grain, and of the flendereft $\frac{1}{120}$th."

Mr. Lawrence ftates, that the kind of filk twift which is commonly known in the fhops by the name of dentift's filk, and which is ufed in making fifhing-lines, is the ftrongeft material, in proportion to its fize, and therefore the beft calculated for our purpofe, which requires confiderable force in drawing the thread tight enough to divide the fibrous and internal coats of the arteries. This twift is rendered very hard and ftiff by means of gum, which may be removed by boiling it in foap and water; but the twift then lofes a part of its ftrength. The ftouteft twift which Mr. Lawrence has ufed, is a very fmall thread compared with ligatures made of inkle. The quantity of fuch a thread neceffary for the noofe and knot on the iliac artery weighs $\frac{1}{70}$th of a grain; or, if the gum has been removed, about $\frac{1}{76}$th. But the fineft twift kept in the filk fhops is ftrong enough in its hard ftate for any furgical purpofe; and the noofe and knot, according to Mr. Lawrence's ftatement, would not weigh $\frac{1}{30}$th of a grain.

It farther appears from the report of this gentleman on the fubject, that there is no danger of thefe ligatures cutting completely through the veffel, as fome furgeons have apprehended; and that although he has not yet afcertained what becomes of the pieces of ligature after the wound is united, he has never feen abfcefs nor any other bad fymptom occafioned by them. At the time when Mr. Lawrence wrote, he had employed this method of fecuring the arteries in ten or eleven amputations, in fix operations on the breaft, and in the removal of two tefticles. The cafes all did well, excepting a man who loft his thigh, and who died of an affection of the lungs. See Lawrence on a New Method of tying the Arteries in Aneurifm, Amputation, &c. in Medico-Chir. Tranf. vol. vi. p. 156, &c.

It merits notice, however, that the propofal of cutting off the ends of the ligatures clofe to the artery has not received the univerfal approbation of furgeons; and, in particular, Mr. Guthrie, of London, and Mr. Crofs, of Norwich, have urged objections againft the practice. The former gentleman, at the fame time, does not entirely condemn the method, but merely argues that it is liable to inconveniences, when adopted in wounds which are to be healed by the firft intention. See Obf. on Gun-fhot Wounds of the Extremities, p. 93.

Profeffor Scarpa alfo, whofe experiments lead him to prefer large ligatures and intervening fubftances between them and the veffel, muft be numbered amongft thofe who difapprove of the new plan. Like all his writings, the memoir which he has recently publifhed refpecting the ligature of arteries is highly interefting, and drawn up with the greateft candour.

Mr. Crofs, of Norwich, is more decidedly adverfe to this new practice; and he founds his objections chiefly upon fome

fome experiments which were made upon animals, and which, he conceives, juftify the following conclufions:

Firft, If the wounds do not unite by the firft intention, the ligatures may efcape with the difcharge, without any inconvenience.

Secondly, If common ligatures of twine are cut fhort, the wound may unite over them, and they may be found in abfceffes after an interval of many weeks.

Thirdly, If the fineft dentift's filk be employed in the fame way, the wound uniting over it, the ligature may be detached from the veffel, and remain buried in an abfcefs, where it will be found at different periods, from one to feven months; and this may happen whether the veffel be firmly compreffed with a fingle ligature, or divided between two ligatures, fo as to imitate the circumftances under which veffels are tied after operations.

Fourthly, If Indian filk, fine as hair, be put round a veffel, fo as to diminifh its diameter, or to effect its obliteration, by juft compreffing its fides together, it may remain in this fituation without exciting abfcefs, or producing any inconvenience. The ligature may be thus applied to comprefs an artery for the cure of aneurifm; but not to fecure veffels divided in operations. If a thin ligature be drawn fufficiently tight upon a veffel on the face of a ftump to be fecure, Mr. Crofs is perfuaded, that the extremity of the veffel, which becomes infulated as it were, muft die. (See London Med. Repofitory, vol. vii. p. 363.) In one cafe of amputation alfo, in which the practice was tried, the ftump was long in healing, and feveral fmall abfceffes repeatedly formed.

On the other hand, we muft take into confideration, that M. Delpech, of Montpellier, has practifed it to a confiderable extent for feveral years paft, without any inconvenience. M. Roux has alfo tried the plan in three operations on the breaft; the cafes did well, and no ill confequences arofe from the prefence of the bits of thread under the cicatrix. See Relation d'un Voyage fait à Londres en 1814, ou Parallele de la Chirurgie Angloife avec la Chirurgie Françoife; Paris, 1815, p. 134—136.

Mr. Hennen, in anfwer to Mr. Guthrie, alfo obferves, that in the cafes where it was tried at Bilboa, "neither pain, heat, nor tumour, febrile exacerbation, nor formation of pus, could be fairly traced to the fhort cut ligatures, which would not in all human probability as readily have fucceeded to the ligatures ufually employed; while, on the contrary, the progrefs of healing has been fenfibly more rapid where they have been ufed." Obf. on Military Surgery, p. 193.

Since Mr. Lawrence communicated to the Medical and Chirurgical Society of London the defcription of a "New Method of tying the Arteries in Aneurifm, Amputation, and other Surgical Operations," he has conftantly employed the method therein propofed, both in St. Bartholomew's hofpital and in private practice; and, as he informs us, he has now tried it in many operations of almoft every defcription. "The general refult of my experience is (fays he), that this plan, by diminifhing irritation and inflammation, and fimplifying the procefs of dreffing, very materially promotes the comfort of the patient, and the convenience of the furgeon, *while it has not produced ill confequences or any unpleafant effect in the cafes which have come under my own obfervation.*

"I have found in my own practice, what has been confirmed by others, who have communicated to me the refult of their experience, that the fmall knots of filk generally feparate early, and come away with the difcharge; that where the integuments have united by the firft intention, the ligatures often come out rather later, with very trifling fuppuration, and no painful inflammation; and that, in fome inftances, they remain quietly in the part.

"In two or three inftances, I have been told that the ligatures feemed to have caufed irritation and pain. Thefe were amputations; and we are accuftomed to fee effects, quite as confiderable as were alluded to here, produced by the ftate of the bone and other caufes, where the ordinary method of fecuring the arteries is practifed; fo that I could not, on clofe inquiry, find any reafon to afcribe what was complained of to the ufe of the filk ligatures, and the practice of cutting off their ends clofe to the knots." Medico-Chir. Tranf. vol. viii. p. 490.

Mr. Lawrence contends, that under fome circumftances the method will be attended with peculiar advantages, as in crowded military hofpitals, where the deftructive hofpital gangrene either exifts, or may make its appearance. Every meafure tending to accelerate the union of wounds, whether after operations or under other circumftances, is of great importance in averting the probability of this calamitous occurrence.

This mode of cutting off both ends of the ligature clofe to the knot has now been fuccefsfully applied to operations for aneurifm. Mr. Lawrence has himfelf found it anfwer his expectations; and we learn, that Mr. Carwardine, of Thaxted, tied the femoral artery with a fmall filk ligature, in a cafe of popliteal aneurifm, and cut off the ends clofe to the knot. The wound united entirely by the firft intention, not a particle of pus having been formed at any time; and it continued perfectly found at the diftance of fome months from the operation. Op. cit. p. 492.

If this practice prove generally beneficial in operations for aneurifm, there can be no doubt it will alfo be advantageous in other cafes, in which the furgeon is called upon to cut down to and take up punctured or partially divided arteries in accidental wounds.

Although doubts are yet entertained by fome practitioners, whether this new method of applying ligatures is entitled to praife and imitation, all furgeons are unanimous about the propriety of leffening as much as poffible the quantity of extraneous bodies in wounds: hence, even they who difapprove of cutting off both ends of the ligature clofe to the knot, fanction and adopt the practice of cutting off one-half of each ligature clofe to the veffel, as the other portion will fuffice for the removal of the knot and noofe as foon as they are detached from the tied artery. When the wound is brought together, the ligatures are to lie in the neareft interfpaces left between the plafters.

2. *Of the Removal of Clots of Blood, extraneous Subftances, foreign Bodies, &c. from the Wound.*—This forms the fecond indication to which the attention of the furgeon is particularly required, when he is firft called to an incifed wound. It is, indeed, an object of very material importance, becaufe if it be not attended to, the wound may be brought together as nicely, as accurately, and as fkilfully as poffible, and every thing look well in the beginning; yet that defirable event, union by the firft intention, will not follow, but inftead of it a fevere degree of pain, confiderable fwelling of the circumference of the injury, extenfive rednefs, and fuppuration and abfceffes. All thefe fevere and untoward confequences arife from the irritation produced by the prefence of foreign bodies in wounds; and as an incifed wound can generally be examined with the utmoft facility, and made properly clean, without putting the patient to much pain, the neglect on the part of the furgeon becomes the more blameable. In other deep, narrow, lacerated wounds, and in many gun-fhot injuries, it is often difficult at firft to afcertain

tain whether there are extraneous ſubſtances in the fleſh or not; but in open inciſed wounds no ſuch difficulty and obſcurity prevail, and the practitioner who cloſes them, without having aſſured himſelf that they are perfectly free from all extraneous matter, betrays either the moſt ſupine negligence, or an utter ignorance of his profeſſional duty. It is true an inciſed wound made with a clean, ſharp inſtrument, which has not broken, can obviouſly have no foreign bodies in it. But very conſiderable and dangerous cuts are often produced by glaſs, china, &c. which are apt to break at the moment, and leave ſome of their fragments in the part. Sometimes alſo the weapon with which the wound is made is unclean, and occaſionally dirt, gravel, &c. get into the wound, in conſequence of the patient falling upon the ground at the time when he receives the injury. We ſhall merely repeat, that as extraneous bodies operate as an irritation to all kinds of wounds, the ſurgeon ought to take care to remove them immediately the bleeding veſſels have been ſecured.

Mr. John Hunter believed, that blood retaining the living principle was rather an uſeful ſubſtance in the union of wounds than otherwiſe; and he only conſidered blood, which had been deprived of this principle by long expoſure, the effect of ſtyptics, &c. as hurtful, when left on the ſurface of the wound. Yet this is a doctrine which is by no means ſanctioned by the approbation of the beſt modern practitioners, all of whom are decidedly of opinion, that leaving any blood upon the ſurface of a recent wound, when the oppoſite ſurfaces of ſuch wound are to be brought into contact, is diſadvantageous, retarding the cure, and rendering union by the firſt intention leſs certain. The preſence of blood in the cavity of the wound, indeed, muſt have the effect of producing a greater or leſſer ſeparation of thoſe ſurfaces, which ought ſtrictly to touch each other; and we decidedly believe, that the practiceof freeing wounds as much as poſſible from clots of blood may be ſucceſsfully defended both upon theoretical and practical principles.

3. *Union of the Wound, Dreſſings, &c.*—We have ſaid, that when the ſurgeon has ſtopped the bleeding, removed extraneous ſubſtances, and properly cleaned the wound, the next indication is to bring the oppoſite ſides of the injury into contact with each other, and keep them quietly and ſteadily in this poſition until they have grown together again. Wounds are healed by two proceſſes; *viz.* by one, in which pus is produced, and granulations and new ſkin are formed; and by another, in which, if it perfectly and univerſally ſucceed, no ſuppuration whatſoever takes place. The latter, when it can be practiſed, is always the moſt deſirable, becauſe it is not only the quickeſt means of cure, but alſo the moſt perfect; the part being covered by the old original ſkin, which is always ſtronger and leſs diſpoſed to ulceration than what is new formed. Surgeons have termed this way of healing wounds *Union by the Firſt Intention*, (ſee theſe laſt words,) or *Adheſion;* and Mr. Hunter named the proceſs by which it, together with many other analogous effects, was accompliſhed in the animal body, the *Adheſive Inflammation.* See Inflammation.

The great recommendations of union by the firſt intention are, celerity of cure, the diminution of the pain and inflammation ariſing from the expoſure of raw ſurfaces, freedom from the inconveniences of ſuppuration, the prevention of the deformity, which would otherwiſe reſult from a large cicatrix, and the greater permanency and ſoundneſs of the cure, for the reaſons above ſtated.

The ſtrong tendency which divided parts of the animal body have to grow together, when kept a certain time in contact with each other, is an important fact, of which the moderns have taken much more advantage than the ancients. There are even caſes and experiments on record in ſupport of the opinion, that it is not entirely impoſſible for parts entirely detached from the reſt of the body to become united again, if quickly replaced. In the article Union *by the Firſt Intention*, we have noticed the intereſting experiments made by Duhamel and Mr. Hunter. The reſearches of the latter celebrated philoſopher brought to light ſeveral very curious and inſtructive facts. He proved that the teſticles of a cock, when removed and introduced into the abdomen of a hen, contracted a vaſcular connection with the ſurface of the viſcera, and lived. He aſcertained, that a ſound tooth might be tranſplanted from its ſocket, and acquire an union to the alveolary proceſs of another perſon. He alſo cut off the ſpurs of a young cock, and found that they might be made to unite to its comb, or that of another cock, and grow in ſuch ſituation. The poſſibility of this ſpecies of union ſhews how ſtrong the diſpoſition of the freſh ſurfaces of an inciſed wound muſt be to grow together; particularly when it is conſidered, that in the foregoing and in ſome of the following inſtances, there can be on one ſide no aſſiſtance given to the union, as the part entirely ſeparated from the reſt of the body is hardly able to do more than preſerve its own living principle, and (as Mr. Hunter expreſſes himſelf) accept of union.

The following obſervations on this ſubject are taken from profeſſor J. Thomſon's excellent book on inflammation: "Beſides thoſe examples that are ſeen in the tranſplantation of the teeth, it muſt be confeſſed, that inſtances of re-union among parts which had been entirely ſeparated are very rare in the human body; ſo rare, indeed, that moſt practitioners ſtill treat with diſbelief and ridicule the few inſtances which have been put upon record. But the different facts which have been learned reſpecting the tranſplantation of the teeth, together with the experiments of Duhamel and Mr. Hunter, prove indiſputably the poſſibility of parts being re-united which have been completely ſeparated from the animal ſyſtem to which they belonged, and in which the circulation of the blood muſt neceſſarily have ceaſed for a time. There is nothing therefore in the nature of the fact recorded, that can juſtify us, I conceive, (ſays Dr. Thomſon,) in doubting the veracity of thoſe, by whom ſimilar inſtances of re-union between other parts of the body have been related.

"That practitioners have generally failed in effecting this re-union, is frankly acknowledged by thoſe who have related caſes ſo very extraordinary. I ſhall mention to you (continues this author) a few of thoſe rare caſes, and leave it to your own judgment to deduce from them the concluſions, which the characters of the authors by whom they are related, and the nature of the facts themſelves which they relate, may ſeem to you to warrant.

"The firſt example of this kind which I find diſtinctly recorded is by Phiorovant, in the 54th page of his ſecond book of the Secrets of Surgery: 'In that time, when I was in Africa, there happened a ſtrange affair: a certain gentleman, a Spaniard, that was called Il Signior Andreas Gutiero, of the age of twenty-nine years, upon a time walked in the field, and fell at words with a ſoldier, and began to draw. The ſoldier ſeeing that, ſtruck him with the left-hand, and cut off his noſe, and there it fell down in the ſand. I then happened to ſtand by, and took it up, and piſſed thereon to waſh away the ſand, and dreſſed it with our balſamo artificiato, and bound it up, and ſo left it to remain eight or ten days, thinking that it would have come to matter; nevertheleſs when I did unbind it, I found it faſt conglutinated, and then I dreſſed it only once more, and he was perfectly whole, ſo that all Naples did wonder thereat, as is well

known;

known; for the ſaid Signior Andreas doth live, and can teſtify the ſame.'

"Blegny, in his Zodiacus Medico-Gallicus, for the month of March, 1680, mentions a caſe, in which a noſe that had been cut off with a ſabre was replaced by a military ſurgeon of the name of Winſault, and in which a perfect re-union was obtained, he affirms, by the uſe of ſtitches, and of agglutinating plaſters.

"A third caſe of the ſame kind is related by Garengeot, at the 55th page of the third volume of his Operations of Surgery. 'In the month of September, 1724, a ſoldier of the regiment of Conti, coming out of L'Epée Royale from an inn, at the corner of the ſtreet Deux-Ecus, was attacked by one of his comrades, and in the ſtruggle had his noſe bitten off, ſo as to remove almoſt all the cartilaginous part. His adverſary perceiving that he had a bit of fleſh in his mouth, ſpat it into the gutter, and endeavoured to cruſh it by trampling upon it. The ſoldier, who on his part was not leſs ſpirited, took up the end of his noſe, and threw it into the ſhop of M. Galin, a brother-practitioner of mine, till he ſhould run after his adverſary. During this time, M. Galin examined the noſe that had been thrown into his ſhop, and as it was covered with dirt, he waſhed it at the well. The ſoldier returning to be dreſſed, M. Galin waſhed his wound and face, which was covered with blood, with a little warm wine, and then put the extremity of the noſe into this liquor to heat it a little. Having in this manner cleanſed the wound, M. Galin now put the noſe into its natural ſituation, and retained it there by means of an agglutinating plaſter and bandage. Next day the re-union appeared to be taking place; and on the fourth day, I myſelf dreſſed him with M. Galin, and ſaw that the extremity of the noſe was perfectly re-united and cicatrized.'

"Theſe (ſays profeſſor Thomſon) are the only caſes which I have been able to find diſtinctly ſtated of the re-union of a noſe which had been completely cut off. This event, from analogy, we have reaſon to believe is poſſible, and nothing ſhort of a contrary teſtimony in the inſtances I have related could juſtify us, I conceive, in denying the truth of the fact."

Dr. Thomſon then details a caſe, extracted from vol. xxxiii. of the Journal de Médécine, where the point of a finger which had been cut off was re-united by M. Boſſu, ſurgeon at Arras. Dr. Thomſon alſo mentions, that he has been informed by different perſons entitled to credit of a conſiderable number of caſes ſimilar to the preceding, in which the points of fingers and toes completely ſeparated were afterwards re-united.

Although it muſt be acknowledged that the foregoing caſes of the union of parts completely ſevered from the body are uncommon, the ſame obſervation does not apply to inſtances in which the detached part ſtill retains a partial and ſlight connection with the reſt of the body, by means perhaps of only a few fibres or little bit of ſkin. "Many caſes," ſays Dr. Thomſon, "are upon record, and many more have been obſerved, in which parts have re-united, which were divided all to a very ſmall portion of cutis,—a portion ſo ſmall that it is not eaſy to conceive that any effectual circulation could be carried on through it; and in theſe caſes it deſerves to be remarked, that it was generally the noſe, or the extremities of the fingers and toes, which re-united, after having been ſeparated and replaced. I have ſeen two examples of the re-union of the noſe, where it was almoſt entirely ſeparated. In one of them it adhered only by the ſkin of one of the alæ, and in the other chiefly by the ſeptum. Arcæus mentions a caſe in which the noſe, with moſt of the upper jaw, was ſo ſeparated as to hang down upon the chin, and yet a re-union was effected. A caſe is mentioned by Lombard, in which the noſe, nearly cut off and unreplaced for ſome hours in winter, was made to re-adhere by ſtitching and proper dreſſings. Another caſe of the ſame kind occurred to Loubet." (Lectures on Inflammation, p. 243.) In the Dictionary of Practical Surgery, an inſtance is mentioned, in which an ear that had been completely ſeparated from the head, with the exception of a ſmall bit of ſkin, was united again with the aid of a ſuture; and Dr. Thomſon has himſelf ſeen portions of the little toe and little finger, after being nearly cut off, ſucceſsfully re-united.

The knowledge of all theſe facts cannot but prove uſeful in the practice of ſurgery, inaſmuch as it teaches the practitioner to attempt the union of parts, under circumſtances which would otherwiſe appear entirely hopeleſs and diſcouraging.

In promoting union by the firſt intention, ſurgery is merely to officiate as the handmaid of nature. There are only two indications to be fulfilled: the firſt is to bring the edges of the wound into reciprocal contact, and keep them ſo; the other is to avert the acceſs of immoderate inflammation, by which the agglutination of the wound would certainly be prevented. The firſt object is accompliſhed by a proper poſition of the wounded part, by bandages, by adheſive plaſter, and by ſutures. The ſecond is fulfilled by a ſtrict obſervance of the antiphlogiſtic regimen, and particularly by avoiding every kind of motion and diſturbance of the wound. The reſt is the work of nature.

The poſition of the part is to be regulated on the principle of relaxing the wounded integuments and muſcles. If the extenſor muſcles are injured, the joints which they move ought to be placed in an extended poſture; if the flexor muſcles are wounded, the limb is to be bent. When the integuments alone are cut, the ſame poſture which relaxes the muſcles ſituated immediately beneath the wound alſo ſerves in general to relax the ſkin. In tranſverſe wounds of muſcular fibres, it is aſtoniſhing what immenſe effect the obſervance of a proper poſture produces. This is never to be neglected, whatever may be the other means adopted.

Bandages may frequently be made to contribute very eſſentially to keeping the ſides of wounds duly in contact with each other. This is ſtrikingly illuſtrated in caſes of harelip, where we ſee that the oppoſite edges of the fiſſure may be brought forward ſo as to touch, and be maintained in this poſition by the ſimple uſe of compreſſes and a bandage. Such was the mode of treatment preferred by M. Louis after the operation for the harelip, and were it not for the greater convenience and certainty of the twiſted ſuture, it is the plan to which ſurgeons would yet have recourſe. (See HARELIP.) The *uniting*, or, as it was formerly named, the *incarnative bandage*, is one which operates in keeping the oppoſite ſurfaces of wounds accurately applied to each other, ſo that the opportunity may be afforded for them to unite and grow together again. The common uniting bandage can only be uſed in wounds which take a direction correſponding to the length of the body or limbs, and which are ſituated where a bandage can be employed with convenience and effect. It conſiſts of a double-headed roller, having a ſlit between the two heads. The ſlit muſt be ſufficiently large to allow one head of the roller to paſs through it with facility. The wound having had the requiſite dreſſings put on it, the ſurgeon is to take one head of the roller in each hand, and apply the bandage to that part of the limb which is oppoſite the wound. One head of the roller is then to be brought round, ſo as to bring the ſlit over the breach of continuity. The other head is then to be brought round in the oppofite direction, and paffed through the flit. The bandage is now to be drawn moderately tight, and its two heads being carried round the limb again, the fame artifice is to be repeated. A fufficient number of turns of the roller muft be made to cover the whole length of the limb.

When the wound is deep, it is recommended to place fmall longitudinal compreffes beneath the roller, at a little diftance from the edges of the wound.

As the uniting bandage can only be made ufe of for longitudinal wounds, which never have a confiderable tendency to gape, nothing can be more abfurd than the application of it with immoderate tightnefs. By fuch cruel and injudicious practice, many a limb and life have been loft; for, if the bandage be very tight on its firft application, what a dangerous conftriction of the limb or part muft follow, when the fwelling, neceffarily arifing from the wound, has had time to come on. It is thus that infufferable pain, gangrene, and fphacelus, have frequently been brought on, when, if the part had been fimply dreffed and left uneonfined, every thing would have gone on moft favourably. It is right to ftate, however, that modern furgeons are not partial to the uniting bandage, and we freely declare our conviction, that it is a means which may very well be difpenfed with in practice.

If it has any advantages, they confift in its having more power than the adhefive plafter alone to maintain the oppofite fides of deep wounds in contact, and in its acting without the irritation frequently arifing from the application of refinous fubftances to the fkin. It is not, however, exempt from ferious inconveniences. Its total concealment of the wound, its lying in irregular folds, fo as to create an uneven cicatrix, and the preffure and conftriction attending its ufe, &c. might be mentioned. (See Firft Lines of Surgery, p. 68. edit. 3.) So little is the uniting bandage now employed, that although we have feen fome thoufands of wounds, we have not noticed its ufe in a fingle inftance during the laft twelve or fifteen years. When preffure can be made to affift the other dreffings, furgeons almoft always refort to compreffes and a fimple roller. In a few particular cafes, in which the limb would be too much difturbed by the application and removal of a common roller, the eighteen-tailed bandage is to be preferred. See BANDAGE, and FRACTURE *of the Thigh*.

Adhefive plafter may be faid to be the moft common means employed in the practice of furgery for bringing the edges of wounds together. When ufed for this purpofe, it was fometimes technically called by the old furgeons the *dry future*, in oppofition to futures ftrictly fo named, which are ufually made with a needle, and are invariably attended with a degree of bleeding. It was at one time fuppofed, that adhefive plafter could be of no material ufe, except in fuperficial wounds of the fkin. It is true, that adhefive plafter has no direct effect in bringing together the fides of a deep mufcular wound; yet we ought to recollect, that by drawing the integuments over the deeper part of the injury, it at once prevents the continuance of the expofed ftate of the cut furfaces, under which fuppuration would unavoidably follow. Nor does the ufe of adhefive plafter hinder recourfe to other meafures more calculated to bring the oppofite furfaces of the deeper part of the wound into contact, fuch as the obfervance of a proper pofition, and the ufe of compreffes and a bandage. It is alfo an error to fuppofe that adhefive plafter cannot be ufed in fituations where hair grows, or where it will foon become wet. If the part be well fhaved, and perfectly dried at firft, the application will not become loofe fo foon as to prove ineffectual. In fuch inftances, the plafter fhould be very frefh, and its quality may be made rather more adhefive than in ordinary cafes.

Adhefive plafter is generally applied in ftrips, between every two of which an interfpace is recommended to be left, for the purpofe of allowing any difcharge to efcape. To bring the edges of the wound effectually together, and at the fame time to leave a little room for the exit of the difcharge, are the objects to which we ought particularly to attend in the employment of adhefive plafter: hence, when the ftrips are broad, it is not unfrequent to cut out an oval piece of each ftrip juft where it croffes the line of the wound. Equal parts of the emplaftrum plumbi, and of the emplaftrum refinæ, form the compofition generally ufed in this country for adhefive plafter. They are melted over a flow fire and well mixed together, after which they are fpread upon linen with a warm fpatula.

Sutures, or *Stitches*, are of feveral kinds, but the only one which is now ufually employed in the cure of wounds is the *interrupted future*. The *quilled future* is rarely ufed at prefent, though it was formerly much in favour, and is not yet paffed over by fyftematic writers. As a defcription of thefe futures has been given in a feparate article (fee SUTURE), we fhall not repeat the particulars of the manner of making them. The *twifted future* is not unfrequently preferred for holding together the edges of cuts in the face, where the parts are liable to be in almoft conftant motion, and where the avoidance of the disfigurement of a large fcar is peculiarly defirable. This is the future which is always employed in the cure of the *Harelip*, in which article a defcription of it will be found. Thefe, and a future called *gaftroraphe*, which will be noticed in fpeaking of *wounds of the abdomen*, are all the kinds of futures which are ever employed by modern practitioners. The *glover's future*, or *continued ftitch*, is now nearly rejected from practice, and confined to the fewing up of dead bodies; a purpofe for which it is better adapted than for the union of any wound in a living fubject.

On the fubject of the propriety and advantage of ufing futures, as a means of keeping the fides of wounds in contact, much diverfity of fentiment has prevailed. Some furgeons, efpecially M. Pibrac and M. Louis, have urgently recommended their entire difcontinuance; and their obfervations are accompanied by facts which muft have confiderable weight. Their opinions and arguments, we acknowledge, have conftantly influenced us in practice; and if we do not join in the fentiment, that futures ought to be entirely abandoned, we at leaft believe that they are ftill a great deal too much ufed. M. Pibrac and M. Louis, however, are entitled to great praife for having leffened the employment of needles in furgery; and though there are few inftances in which the utility of futures appears to be confirmed by experience, there are many others in which the practice is altogether unneceffary and injudicious. "The practice of ftitching," fays Dr. Thomfon, "is undoubtedly much lefs followed at prefent than in any former period of the furgical art; and unlefs in fuperficial wounds, where we wifh to heal by the firft intention, or in wounds where (as in thofe of the abdomen) it is neceffary that the edges fhould not be allowed to feparate from each other, the ufe of ftitches may be, in moft inftances, advantageoufly fuperfeded by adhefive plafters and proper bandaging. It is by limiting the ufe of futures, not by profcribing them altogether, that the furgeon is likely to derive advantage from the employment of means fo powerful." (See Lectures on Inflammation, p. 287.) There are certainly hardly any two furgeons who think exactly alike about the cafes in which futures

futures are truly beneficial or not. Thus we do not admit that they ought to be ufed as frequently as the remarks of the above diftinguifhed profeffor would warrant; and the majority of fuperficial wounds, in which union by the firft intention is indicated, certainly, fo far from being benefited by futures, would be injured. Further obfervations, however, on this fubject will be found in the article SUTURE.

When futures are judged neceffary, their operation is always affifted by the application of fuitable compreffes and a bandage, the good effects to be derived from pofition of the part being alfo not neglected. The ftitches ought in general to be removed between the third and feventh day; for if they are allowed to remain longer, or even in fome cafes fo long, they excite inflammation, and fometimes ulceration.

Such then are the means which furgeons adopt for keeping the oppofite furfaces of wounds in contact, until an union has taken place. When the parts grow together again without any fuppuration, the mode of cure, as we have already explained, is well known to furgeons by the term *union by the firft intention.* Of the nature of this procefs, and of the way in which a connection is eftablifhed again between the parts which have been divided, we have endeavoured to give fome account in a preceding volume; we fhall not, therefore, expatiate on the fubject. See UNION *by the Firft Intention.*

The firft plafters and dreffings applied with a view of bringing about this defirable method of cure, fhould be allowed to continue at leaft three or four days, unlefs any untoward fymptoms, fuch as exceffive pain, the renewal of hemorrhage, &c. indicate the contrary. The feverity of the pain is fometimes owing to the future, fometimes to the immoderate tightnefs of the roller, and occafionally to there being extraneous fubftances yet lodged in the wound.

When too much inflammation is apprehended, the bandage fhould never be tight; and wetting it with cold water may be of ufe by keeping the parts cool. Perfect quietude, and the ufual antiphlogiftic remedies, are alfo not to be omitted. The old plan of covering the dreffings with thick woollen rollers, caps, and large maffes of tow, has now gone very much out of fafhion, as being inconfiftent with thofe principles which are recognized by every fcientific furgeon as beft calculated to avert and leffen inflammation.

When the firft dreffings are removed, the furgeon often finds union by the firft intention only accomplifhed at certain parts of the injury; and the connection, even there, ftill requires further fupport. However, when the wound is dreffed again, it is generally unneceffary to apply as many ftrips of adhefive plafter as were employed in the firft inftance. Their number may be gradually leffened at each future dreffing. The futures, if there be any, fhould alfo be now withdrawn, as they will do no more good, and their continued prefence may excite irritation and do harm. Suffice it to add, that throughout the fubfequent treatment the reft of the dreffings fhould be light, fimple, and unirritating.

Of the Cure of Wounds by Granulations, &c.—We remarked, that wounds are healed by two proceffes, one of which was not attended with the formation of pus, was the quickeft and moft perfect in its effects, and was called *union by the firft intention*, or *adhefion.* The other procefs now requires defcription. "When, in the treatment of a wound," fays profeffor Thomfon, "the re-union by adhefion, or by the firft intention, has either not been attempted at all, or, if attempted, has failed, nature brings about a cure by that flower and more complicated operation, which we now denominate the *procefs of granulation;* a procefs termed (as we have already remarked) by Galen *re-union by the fecond intention.* By many of the older furgeons, this mode of healing wounds is defcribed by the appellation of *fyfarcofis*, or *concarnation*, terms perhaps lefs liable to objection than that of granulation, which, in ftrict propriety, is a term expreffive of only one of the ftages of this mode of re-union, and which, of courfe, in order to avoid all ambiguity in the language we employ, ought not to have been ufed as a general term for the whole. In re-union by the fecond intention, the edges of the wound fwell and inflame more than in the procefs by adhefion; but, as in that procefs, fo in this, a layer of coagulable or organizable lymph is thrown out upon the divided furfaces. This layer is foon penetrated by blood-veffels, and, like the intermedium in adhefions, (fee UNION *by the Firft Intention,*) becomes an organized and living fubftance. So far thefe modes of re-union are fimilar; but in a fhort time after this layer of coagulable lymph has been thrown out upon the open and expofed furfaces of a wound, there is thrown out alfo upon the fame furfaces a quantity of pus, or the matter of fores. This fluid, like the coagulable lymph, is the immediate product of a change induced in the action of the capillary veffels exifting in the divided fubftances of the wound, a change by which they feem to become fecreting inftead of circulating tubes. The action by which pus is formed is now denominated *fuppuration:* the old furgeons gave to it the name of *digeftion.* See SUPPURATION.

"When the furfaces of the wound have been feverely injured, or when the patient is of a bad habit of body, a greater or lefs portion of thefe furfaces lofing its vitality, feparates from the remaining found part, and comes away in the form of a flough. The older furgeons, who are moft minutely accurate in the defcriptions which they have left us of difeafed appearances, call this the *deterfion* or *mundification* of the wound: the furgeons of the prefent day, *floughing*, or the *feparation of the flough.* See the article GANGRENE.

"In the healthy conditions of the body, and when the edges of the wound are uninjured, the fmooth furface of the layer of coagulable lymph which covers the bottom of the wound is, in the courfe of a few days after the fuppuration has taken place, raifed into a number of fmall eminences, like grains or papillæ. Thefe little eminences are termed *granulations*, and their formation in the healing of wounds, *the procefs of granulation.* By the older furgeons, this ftep, in the procefs of re-union by the fecond intention, was commonly termed *incarnation*, or *concarnation*, terms expreffive of the formation of a portion of new flefh." See GRANULATION.

"On the furfaces of thefe granulations, but moft frequently on the edges of the wound next to the fkin, fmall white fpecks appear; the quantity of pus which is fecreted gradually diminifhes, and the blueifh-white fpecks, by continuing to increafe in number and fize, come at laft to cover the furface of the wound. On examination, the furface of the wound will now be found to be covered by a kind of new fkin and cuticle. The formation of this new fkin has long been denominated the *procefs of cicatrization*, and the procefs of re-union by the fecond intention being now fully accomplifhed, the wound is faid to be completely *cicatrized.*" Thomfon's Lectures, p. 288.

The re-union of a wound by the firft intention is the work of one, two, or three days; while re-union by the fecond intention always requires a period of feveral days, and fometimes in difeafed conftitutions, or parts which have been much injured, of months, or of years. Thomfon, p. 290.

As the fame well-informed writer remarks in another place,

place, moſt wounds admit of being healed partly by adheſion, and partly by the proceſs of granulation. We have very good examples of this in the wounds made in amputation of the extremities, and in the extirpation of the mamma, or of other large tumours. We know, or at leaſt we have reaſon in theſe inſtances from the firſt to ſuſpect, that the whole of the wound will not heal by adheſion; but we are ignorant whether a large or a ſmall portion will be healed by that proceſs; and accordingly, we at firſt proceed in the dreſſing of ſuch wounds, as if we expected or intended that the whole ſhould heal by adheſion. We bring the edges of the wound together by adheſive ſtraps, or ſtitches, and ſupport theſe by proper bandaging. The adheſive ſtraps are of great uſe even in thoſe wounds in which it is impoſſible to bring the edges at firſt into contact. They bring and retain the edges near each other; they diminiſh the ſize of the wound; they keep ſurfaces in contact which have a diſpoſition to adhere; and ultimately, by the gradual elongation of the old ſkin, even where the diſtances between the ſizes is at firſt conſiderable, they bring the ſeparated edges to unite together. Op. cit. p. 293.

With reſpect, however, to the particular mode of dreſſing wounds which are to heal by granulations, it ſeems unneceſſary to enter into any long detail in the preſent place; becauſe the treatment is to be conducted on the very ſame principles which apply to ſores, and which we have ſo fully explained in another article. See ULCER.

We ſhall conclude this ſection of the ſubject of wounds with a few uſeful rules, which profeſſor Thomſon recommends to be obſerved in the dreſſing and examination of theſe caſes.

In examining or dreſſing a wound, we ought never to give the patient more pain from our modes of procedure, or methods of dreſſing, than is abſolutely neceſſary for his preſent good and future ſecurity. For inſtance, we ought never to probe a wound where probing can be of no uſe; and we ſhould be contented to remain ignorant of thoſe things, the knowledge of which could only gratify an idle curioſity.

Another good rule is, to have all the freſh dreſſings perfectly ready before the removal of thoſe which have been previouſly applied. A ſponge and warm water, adheſive ſtraps, pledgets of various ointments, lint, compreſſes, and bandages, are to be at hand, and not to be ſought for at the very moment when they are required for uſe.

As in many inſtances the removal of the dreſſings, and the application of others, take up a conſiderable time, we ought carefully to reflect what the poſition is which will be moſt eaſy to the patient, and at the ſame time moſt convenient to the ſurgeon.

When the bandage, adheſive plaſter, and other dreſſings, have become hard and dry, and glued together, and to the ſurrounding ſkin by blood, or other diſcharge from the wound, the ſurgeon ſhould ſoften and looſen the applications by wetting them a ſufficient length of time with warm water, which is to be preſſed out of a ſponge upon them, a baſin being held below the part for the reception of the water as it falls off the dreſſings. This duty is of much importance in ſaving the patient from a great deal of agony, which the abrupt removal of the adherent dreſſings would produce.

In removing the dreſſings which are under the bandage, we muſt be careful that the ligatures are not entangled, and that we do not pull them forcibly away. Pulling at the ligatures during the firſt dreſſings, as profeſſor Thomſon remarks, always occaſions pain; and if, in removing the dreſſings, the threads be incautiouſly torn off, a greater or leſs degree of hemorrhage may be produced, and much diſtreſs, if not danger, occaſioned. To avoid this accident, therefore, we ought always to ſearch for the ligatures previous to the removal of the dreſſings, and to ſeparate them from theſe dreſſings when they adhere, as they moſt frequently do.

Having formed and ſeparated the ligatures, we muſt next proceed to remove the adheſive ſtraps by which the edges of the wound are more immediately kept in contact. It moſtly happens, that a greater or leſs portion of theſe ſtraps is looſened from the ſurface of the wound by the fluid which exudes from it. This is the part, therefore, from which (ſays Dr. Thomſon) we ſhould firſt proceed to ſeparate theſe ſtraps, becauſe it is here that the edges of the wound may be ſuppoſed to recede fartheſt from each other, and the pus to have found the freeſt exit. But the manner in which the remaining adhering portion of ſtrap is to be ſeparated, is not, as may firſt appear, a matter of indifference. There is but one way in which it can be properly taken off, though it is one which is often neglected in practice. In removing theſe ſtraps, we are always to lay hold of them by the ends, firſt by the one, and then by the other end, and to pull them off in the direction of the wound, taking care never to raiſe the end of the ſtrap much above the level of the ſkin, nor to continue to pull by the end we hold, after we have ſeparated it as far as the wound. Were the ſtraps pulled off in a direction from and not towards the wound, the edges of the injury to which they adhere would be drawn away from each other; the ſlight adheſions which have formed between one ſide of the wound and the other would be torn, and the proceſs of re-union diſturbed and retarded. If we raiſe the end of the ſtrap, we alſo tear the edge of the wound from the ſubjacent parts to which it adheres.

Another good piece of advice given by profeſſor Thomſon is, that only one adheſive ſtrap, or at moſt two, ſhould be removed at once; and the part from which it has been removed being carefully wiped with the ſponge, and dried with a ſoft linen cloth, a freſh ſtrap is always to be applied before another is removed. It is from inattention to this rule that we ſee the ſurfaces of wounds and ſores daily torn open at each dreſſing, merely by the weight of the parts which have juſt been united.

The edges of the wound, particularly if it be a large one, ſhould always be held together by an aſſiſtant during the time of dreſſing.

When there are ſeveral wounds, only one is to be opened and dreſſed at a time, ſo that all unneceſſary expoſure of the parts may be avoided.

At each dreſſing care muſt be taken to prevent lodgments of matter, by placing the compreſſes and ſtraps of plaſter in the manner beſt adapted to preſs upon and obliterate any cavity in which the pus has a tendency to accumulate.

A pledget of ſome mild cerate or ointment is uſually applied over the adheſive plaſter, and its ſize ſhould exceed that of the wound. It is preferable to dry lint, which becomes adherent, troubleſome to remove, and often conceals and ſticks to the ligatures. If lint be neceſſary, it may be employed over the pledget. Modern ſurgeons, however, are far more ſparing of thick maſſes of lint, tow, flannel-rollers, &c. than their predeceſſors, as we have previouſly explained.

On the ſubject of bandages we ſhall here add nothing to what has been already ſtated in the foregoing ſection of this article.

In the dreſſing of wounds, ſays Dr. Thomſon, particularly

larly

larly in hofpital practice, where frequent change of linen is not at all times obtainable, it is of great confequence to the comfort of the patient, and to the general health and welfare of the other patients, that every attention fhould be paid to cleanlinefs, and that every thing filthy and offenfive fhould be removed from the room or ward as quickly as poffible. Above all things, care muft be taken not to let the matter touch the bed-clothes.

The frequency of dreffing muft be regulated by the quantity and quality of the difcharge from the wound, by the fituation of the injury, by the climate and feafon of the year, by the effects which the renewal of the dreffings feems to produce, and by the feelings, and fometimes the wifhes of the patient.

During the long-continued difcharge of pus from many wounds, the ftrength of the patient muft be fupported, and granulation and cicatrization promoted by nourifhing diet and proper cordials. The moft difagreeable, and unfortunately not an unfrequent termination of large wounds, is the formation of unhealthy granulations, attended with a general wafting of the body and hectic fever. See Thomfon's Lectures on Inflammation, p. 294, &c.

Of punctured Wounds, or Stabs.—Punctured wounds are not only dangerous on account of their frequently extending to a confiderable depth, and injuring important blood-veffels, nerves, and vifcera, but they are alfo dangerous, inafmuch as they often give rife to violent and extenfive degrees of inflammation. It is not uncommon to fee formidable collections of matter follow wounds of this defcription, efpecially when the inftrument with which they have been made has penetrated any aponeurofis, or fafcia. Stabs and all other punctures are not fimple divifions of the fibres of the body ; they are attended with more or lefs contufion and laceration, according to the particular form of the weapon, and the degree of violence with which the thruft has been made. Hence there is not the fame propenfity to union by the firft intention, which we obferve in wounds made with fharp-edged inftruments ; and when ligamentous expanfions are amongft the parts injured, it is not uncommon to fee a train of fevere local and conftitutional fymptoms follow. Immenfe agitation of the nervous fyftem fometimes enfues upon the infliction of a punctured wound ; and it has been generally attributed to the injury of tendons or nerves. This doctrine, however, is now almoft quite exploded, as furgeons fo frequently fee nerves and tendons wounded, without the occurrence of great conftitutional diforder. The truth is, that alarming nervous fymptoms do not follow punctured wounds in perhaps more than five cafes out of a hundred, in which tendons and nerves of fome fize are actually injured. It cannot, therefore, be fo much the injury of thefe parts, as other circumftances attending ftabs, which are the caufe of the fevere indifpofition fometimes fuddenly induced by fuch wounds. When they extend deeply, the confequences of the injury of large blood-veffels and vifcera will often account for the great conftitutional diforder, without having any recourfe to doctrines like the foregoing.

Punctured wounds are frequently followed by the formation of deeply-feated abfceffes and finufes, and hence the cure is often difficult, and fometimes it cannot be effected till after a confiderable time.

With refpect to the treatment of punctured wounds, we may obferve, that in this part of practice erroneous fuppofitions have commonly led to many ferious abufes. The unqualified idea, that the fevere confequences of moft punctured wounds are, in a great meafure, owing to the narrownefs of their orifices, has induced numerous furgeons to practife indifcriminately deep and extenfive incifions, for the purpofe of rendering their external communication confiderably wider. To have conftantly in view the converfion of fuch injuries into fimple incifed wounds has always been a maxim ftrongly infifted upon, and fet forth as the reafon of the above method of treatment. The doctrine even occafioned the frequent dilatation of punctured wounds by the ftill more abfurd and cruel means, the employment of tents.

Certainly, if the notion were true, that an important punctured wound, fuch as the ftab of a bayonet, is actually changed into a wound partaking of the mild nature of an incifion, by the mere enlargement of its orifice, the correfponding practice would be highly commendable, however painful it might be. But the fact is otherwife : the rough violence done to the fibres of the body by the generality of ftabs is little likely to be fuddenly removed by an additional violence—the enlargement of the wound. Nor can the diftance to which a punctured wound frequently penetrates, and the number and nature of the parts injured by it, be at all altered by fuch a proceeding. Thefe, which are the grand caufes of the collections of matter which often take place in the cafes under confideration, muft exift, whether the mouth and canal of the wound be enlarged or not. The time when incifions are proper is, when there are foreign bodies to be removed, abfceffes to be opened, or finufes to be divided. To make painful incifions fooner than they can anfwer any end is both injudicious and hurtful. They are fometimes rendered quite unneceffary by the union of the wound throughout its whole extent, without the leaft fuppuration.

It is true, as is obferved in a modern publication, that making a free incifion in the early ftage of thefe cafes feems a reafonable method of preventing the formation of finufes, by preventing the confinement of matter ; and were finufes an inevitable confequence of all punctured wounds, for which no incifions are practifed at the moment of their occurrence, it would undoubtedly be unpardonable to omit them. Fair, however, as this reafon for the ufe of the knife may appear to fome practitioners, it is only fuperficially plaufible, and a very little reflection foon detects its want of real folidity. Under what circumftances do finufes form ? Do they not form only when there is fome caufe exifting to prevent the healing of an abfcefs ? This caufe may either be the indirect way in which the abfcefs communicates externally, fo that the pus does not readily efcape ; or it may be the prefence of fome foreign body, or dead portion of bone ; or, laftly, it may be an indifpofition of the inner furface of the abfcefs to form granulations arifing from its long duration, but removeable by laying open the cavity. Thus it becomes manifeft, that the occurrence of fuppuration in punctured wounds is only followed by finufes, when the furgeon neglects to procure a free iffue for the matter after its accumulation, or when he neglects to remove any extraneous bodies. But as dilating the wound at firft can only tend to augment the inflammation, and render the fuppuration more extenfive ; and as likewife the new incifion may heal up by the firft intention before it has anfwered any purpofe at all ; the practice fhould never be adopted in thefe cafes, except for the direct objects of giving a free exit to matter already collected, and of being able to remove extraneous bodies palpably lodged in the part. We fhall once more repeat, that it is an erroneous idea to fuppofe the narrownefs of punctured wounds fo principal a caufe of the bad fymptoms with which they are often attended, that the treatment ought invariably to aim at its removal.

Recent punctured wounds have abfurdly had the fame plan of treatment applied to them as old and callous fiftulæ. Setons and ftimulating injections, which in the latter cafe fometimes act beneficially, by exciting fuch inflammation as is productive of the effufion of coagulating lymph, and of the granulating procefs, can never prove ferviceable when the indication is to moderate an inflammation which is difpofed to rife too high. The counter-opening, which muft be formed in adopting the ufe of the feton, is alfo an objection ; and though French authors have given us accounts of their having drawn their fetons acrofs patients' chefts, in cafes of ftabs, they will find fome difficulty in making the practice feem unattended with harm, much lefs productive of good. The candid and judicious furgical reader fhould not always think a plan of treatment right becaufe the patient gets well; for there is an effential difference between a cure promoted by really ufeful means and an efcape, notwithftanding the employment of hurtful ones.

For our own part, we cannot fee what good can ever poffibly arife from the ufe of fetons in cafes of punctured wounds. Will a feton promote the difcharge of foreign bodies, if any happen to be prefent ? By occupying the external openings of the wound, will it not be more likely to prevent it ? In fact, will it not itfelf act with all the inconveniences and irritation of an extraneous fubftance in the wound ? Befides, let it be recollected, that punctured wounds are rarely accompanied with the lodgment of foreign bodies. Is a feton a likely means of diminifhing the immoderate pain, fwelling, and extenfive fuppuration fo often attending punctured wounds ? It will undoubtedly prevent the external openings from healing too foon ; but cannot this object be effected in a better way ? In moft inftances where much matter is collected, and where the fuppuration is likely to laft a long while, in confequence of exfoliations, there will be no chance of the finus healing up prematurely ; and if fuch rifk fhould appear probable, it is always eafy to maintain an external opening by the daily introduction of a probe into the finus, and a fmall doffil of lint into its orifice. See Firft Lines of Surgery, edit. 3. chap. xvi.

When a furgeon is called to a punctured wound or ftab, he may often form fome opinion refpecting the depth and nature of the injury by examining the weapon with which it was done, and obferving how far the blood reaches along the blade from the point, and by attending to the quantity and quality of the fluids which may iffue from the external opening. Thus, the efcape of chyle or feces will denote that the bowels are injured ; the effufion of urine will indicate that the bladder or fome part of the urinary organs is wounded ; and the flow of much arterial blood will prove that a confiderable artery is opened. Wounds of the lungs will alfo be attended with particular fymptoms, as we fhall notice in fpeaking of wounds of the cheft. In many inftances, however, important vifcera and large deep-feated arteries are injured by ftabs, and yet no information can at firft be deduced refpecting what has happened from attention to local fymptoms alone. The faintnefs and great fudden proftration of ftrength, the faultering, low, and intermitting pulfe, the vomiting or coughing up of blood, and the coldnefs of the extremities, however, are ftill fufficient evidence that the cafe is complicated with injury of important organs, and that the patient is in a ftate of urgent danger. Thefe are matters which will be beft underftood when we come to the confideration of wounds of the cheft and belly, and therefore we fhall not dwell upon them at prefent.

From what has been already ftated, the reader muft be aware that we do not follow the bulk of furgical writers in recommending the indifcriminate dilatation of the orifices of punctured wounds ; nor do we admit the propriety of ufing the knife for the purpofe of preventing mifchief only expected and apprehended, but not actually exifting. Whenever we have had an opportunity of attending bayonet or other punctured wounds, unattended with any particular complication, we have always obferved nearly the fame principles as are now fo generally approved of in cafes of gun-fhot wounds. We have abftained from dilating the orifice of the injury, except when it was neceffary either to get at a bleeding artery in the firft inftance, or to give a freer egrefs to the difcharge in a later ftage of the cafe. We have given the preference to mild, fimple, unirritating, and fuperficial dreffings. We have not placed much faith in the utility of enveloping the parts in a tight bandage ; but, after applying the firft fuperficial dreffings, have ufually covered the limb with linen, wet with the lotio plumbi acetatis, or cold water. Whenever a roller was ufed, it was not with a view of making preffure, but of retaining the dreffings. The wound having been dreffed, we have then ufually put in practice all fuch means as are generally deemed moft efficient in preventing and diminifhing inflammation ; fuch as venefection, the exhibition of aperient and faline medicines, low diet, &c. When the pain was very fevere in the beginning, we have prefcribed opiates, and on the accefs of much fwelling, have always been careful to let the bandage be flack. We believe that, on the whole, the application of fuperficial dreffings and cold wafhes is moftly the beft practice for the firft twenty-four hours after the receipt of a punctured wound. But if after this period the pain fhould appear to increafe, and the fwelling to become more and more confiderable, the furgeon may then remove the bandages, and apply from fix to a dozen leeches to the neighbourhood of the wound. He muft alfo fubftitute for the cold lotion the ufe of fomentations, and emollient poultices, under which is to be laid over the orifice of the wound a fmall pledget of fpermaceti cerate, or other fimple ointment. The poultices and fomentations are to be renewed morning and evening, and the leeches may be repeated, if neceffary, three or four times.

By purfuing this antiphlogiftic fort of treatment, fuppuration may be fometimes entirely prevented, and the formation of large deep abfceffes frequently averted. Should extenfive collections of matter, however, take place, proper openings are to be then made without delay, either by dilating the original wound, or by making one or more incifions in other places, as may feem moft advantageous. The cafe, in fact, is then to be treated upon the very fame principles which are obferved in the management of abfceffes in general.

Of contufed and lacerated Wounds.—The inftruments which have the effect of producing what is termed a *contufion*, are either of an ordinary defcription, fuch as a cudgel, a ftone, &c. or they confift of balls, bullets, and other metallic bodies, which are impelled into the flefh with immenfe velocity by the explofion of gunpowder. The latter occafion particular kinds of injury, well known by the name of *gun-fhot wounds*, which are a clafs of cafes fo highly interefting, that although they are ftrictly only examples of feverely contufed wounds, furgeons have always found it expedient to treat of them as diftinct and peculiar cafes. Indeed, when it is recollected how many difficult, intricate, and momentous queftions the fubject of gun-fhot wounds embraces, the neceffity of confidering it by itfelf is immediately manifeft.

The blunt weapons, or obtufe hard fubftances, which, being applied with violence to any part of the living body, bruife, rupture, and otherwife hurt the fibres and veffels, may produce two different fpecies of injury. Firft, they may more or lefs forcibly comprefs and crufh the parts upon

upon which they act, so as to disorder the texture of those organs which are situated under the integuments, without, however, causing any breach of continuity in the skin itself. This is the case which is usually called a *bruise*, or *contusion*. Secondly, acting with a certain degree of violence upon the same parts, they may produce a solution of continuity which is named a *contused wound*. The latter effect more commonly follows when the surface of the contusing weapon or body is not very broad. The cases which rank as simple bruises have been described in another volume of this publication, (see CONTUSION,) and therefore we shall not detain the reader with any observations upon them in the present place.

The majority of wounds are attended with some degree of contusion. Those which are inflicted by the blunt edge of a sabre, or by the obtuse point of a bayonet or foil, are as much contused wounds as they are punctured ones; and hence, like other contused wounds, they do not often admit of being united by the first intention.

It must be confessed, indeed, that most of the endeavours to re-unite the sides of a contused wound, however skilfully directed, generally fail. An agglutination of the parts at most only takes place at the bottom of the wound, in which situation the flesh has suffered less contusion, the violence having spent itself, as it were, upon those parts upon which it first operated: hence suppuration of the external portion of the wound is mostly unavoidable. Still the attempt at re-union ought to be made; for if only the bottom of the wound should heal by the first intention, it will be a great advantage gained, more especially when the surface of a bone has been exposed and uncovered by the injury. However, in bringing the sides of contused wounds nearer together, the surgeon is not to attempt to do it with the same closeness and accuracy as in the instance of an incised wound. The injured parts would not bear the pressure, and the means requisite for this purpose; and it may be laid down as an established rule that nothing is more hurtful in cases of contused wounds than much pressure, either from strips of adhesive plaster, or a tight roller. Sutures in these cases are also totally unjustifiable; and we think we have seen several examples, in which a rash determination of the surgeon to close large contused wounds by stitches, tight strips of plaster, and bandages, has had no inconsiderable share in bringing on the rapid and fatal gangrene which carried off the patients. When we say, therefore, that a contused wound ought to be closed, and that its opposite surfaces should be brought nearer to each other, in order that the chance of some part of the injury uniting by the first intention may be taken, we do not mean to recommend dragging the parts together by main force, or placing them in a state of constriction. On the contrary, we think that they ought to be left quite unconfined, the adhesive plaster being used very sparingly, with considerable spaces between the strips, and so put on as rather to hold the loose parts together than to press and draw them into contact with each other. The wound then is not to be entirely covered with sticking-plaster, a practice which is hurtful even in incised wounds, but merely a strip applied at particular points, where the application promises to have great effect in hindering the wound from gaping, without producing any dangerous constriction of the parts. That a strip of adhesive plaster may frequently be used with striking advantage in contused and lacerated wounds experience daily proves; and the benefit must not surprise us, when we remember that by preventing the wound from gaping in the manner it would otherwise do, we not only afford an opportunity for parts of it to re-unite, but at once diminish an inevitable cause of inflammation and suppuration, *viz.* the exposure of a large raw surface to the air.

Contused and lacerated wounds not only differ from incised wounds in the circumstance of their being more disposed to suppurate, and more difficult to heal by the first intention, they differ also in the particularity of not bleeding much, sometimes even when the largest arteries are lacerated, as must be the case when whole limbs are torn away, in consequence of becoming entangled in different kinds of machinery.

This indisposition to hemorrhage is not altogether a favourable omen, because though the patient runs less chance of bleeding to death in these cases than in cut wounds, yet the very circumstance of the large vessels not pouring out blood evinces that the violence, contusion, and other injury done to the parts, in addition to the mere division of them, must have been excessively severe, and that the dangers of the subsequent inflammation, suppuration, and sloughing of the parts, more than counterbalance the present security from bleeding.

We shall not find, in all the records of surgery, any facts more extraordinary than those which have been published at different periods on the subject of whole limbs being torn away, not only without hemorrhage, but without any other fatal effects. The cases of limbs torn off related by Cheselden, in the Philosophical Transactions, by La Motte, in his Traité des Accouchemens, by Mr. Carmichael, in the fifth volume of the Edinb. Med. Commentaries, and others in the second volume of the Mém. de l'Acad. de Chirurgie, are some of the most remarkable.

As far as our observations extend, all lacerated and contused wounds should be treated according to common antiphlogistic principles. When the injury is extensive, and attended with a great deal of contusion, venesection is to be practised, and the oozing of blood from the surface of the wound may be encouraged by the use of fomentations. With respect to dressings, they should always be of a mild unirritating quality. After lessening, by a strip or two of adhesive plaster, the exposed cavity of the wound, when this is large and the surrounding skin loose, the part may be covered with pledgets of the unguentum ceræ, over which should be laid an emollient poultice. As the first dressings should not be removed for at least 24 or 36 hours, care ought to be taken to put into the poultice a sufficient quantity of sweet oil, to prevent it from becoming soon hard. Afterwards, however, the dressings may be changed once, twice, and even thrice a day, in bad cases, with advantage; for as soon as the sloughs begin to separate, and suppuration to take place, the necessity for changing the dressings and poultices more frequently is self-evident. In severe cases, fomentations may be used at the periods of dressing; and it will be found that nothing is so effectual in relieving the pain arising from the inflammation which has been induced. The employment of leeches also should not be forgotten, as a valuable means of palliating the inflammatory symptoms. Professor Asalini, of Milan, has lately written strongly in praise of the good effects which are produced by the application of cold washes to parts which have received contused wounds (see his Manuale di Chirurgia); and we believe the plan is particularly useful in the first instance, when it is a great object to check the increase of extravasated fluids in the surrounding parts. But afterwards we think emollient applications are the best; and, indeed, it may be questioned, whether the employment of cold lotions at first would not sometimes be objectionable, inasmuch as they must tend to stop the oozing of blood from the surface of the wound; a thing which is considered by many surgeons extremely beneficial, and an object which they think ought to be promoted even by the use of fomentations.

ations. This is a point, however, which comparative and unprejudiced experience is alone capable of deciding. If, in cafes of lacerated and contufed wounds, the furgeon is lefs frequently, than in incifed wounds, called upon to take meafures for ftopping bleeding immediately after the accident, he finds greater occafion for attending to another important duty, impofed upon him in his profeffional attendance upon wounded perfons in general: we allude to the early removal of all foreign bodies and extraneous fubftances from the wound. Cuts are ufually made with clean fharp inftruments; but contufed and lacerated wounds often occur in a manner which renders them particularly likely to contain dirt, gravel, bits of glafs, porcelain, &c. We have feen one cafe in which the patient could not ufe his arm for a twelvemonth, in confequence of fome fragments of a broken bottle not having been taken out of a wound of the hand in the firft inftance. The wound did indeed heal up; but the pieces of glafs occafioned fo much pain and inconvenience, that the part could not be ufed. New incifions were unfuccefsfully made for their removal, and the fingers were becoming permanently bent and contracted when we laft faw the patient. Whether the foreign bodies have been fubfequently extracted we know not; but the cafe deeply impreffed us with the importance of always removing extraneous fubftances while a wound is frefh, and beft admits of the requifite examination.

With regard to lacerated wounds, the fame practical remarks apply to them which have been offered on the fubject of contufed wounds; but the prognofis is generally confidered as more unfavourable, and in warm climates tetanus is alleged to be a very frequent confequence of thefe injuries. See TETANUS.

The bites of rabid animals afford examples of a moft dangerous defcription of lacerated and contufed wounds, the peril, however, originating not from the mechanical injury itfelf, but from the cafe being complicated with the infertion into the wounded part of a poifon or virus, the effects of which, when they do occur, almoft bid defiance to the power of the medical art. See HYDROPHOBIA.

As foon as the furface of a contufed or lacerated wound has thrown off its floughs, fuppurated, became clean, and evinced a tendency to form granulations, the poultices are to be difcontinued, and fimple dreffings employed. Thefe are afterwards to have their quality altered, according to the appearances which the fore may affume; but any further directions refpecting the management of the cafe, after it has arrived at this ftage, muft be quite fuperfluous here, as ample inftructions will be found in the article ULCER.

Some contufed and lacerated wounds would inevitably be followed by the rapid mortification of the limb, and the patient run the greateft rifk of lofing his life, were amputation not to be performed immediately after the receipt of the injury. Thefe are generally examples in which the foft parts are extenfively and deeply wounded, and large blood-veffels and nerves alfo injured. The fize, however, of the wound feems of itfelf fometimes to be a caufe of gangrene; for we remember a brewer's fervant, who, when fitting on the fore-part of a dray-cart, met with an injury, by which the fkin covering the front of the tibia was torn from the knee to the ankle, and though no other mifchief appeared to have been received, the whole limb and even the fcrotum rapidly mortified, and the man loft his life. It fhould be known, that thefe are cafes of what M. Larrey calls traumatic gangrene, in which he and fome other modern furgeons conceive that amputation may often be done with fuccefs, though the mortification has not ceafed to fpread at the time of the operation. (See SURGERY.) This practice had alfo its advocates in former days; but fince the time of Mr. S. Sharp and Mr. Pott, the rule of never attempting amputation before a line of feparation has formed between the dead and living parts, has been acknowledged, taught, and refpected, in every fchool of furgery. For an account of the treatment of contufed and lacerated wounds which have ended in mortification, the reader muft turn to the article GANGRENE.

Of Gun-fhot Wounds. — Strictly thefe cafes ought, perhaps, to be claffed with other wounds, attended with much contufion and laceration of the parts; but the injuries which are received in modern warfare from the employment of fire-arms are fo numerous, complicated, and various, that the fubject undoubtedly merits feparate confideration. A general defcription of thefe accidents, and of the method of treatment, will be found under the head of GUN-SHOT *Wounds*. Since that article was written, however, fo much valuable information has been laid before the public by feveral diftinguifhed army and navy furgeons, that it becomes neceffary for us to avail ourfelves of the prefent opportunity to notice fome practical points of the firft-rate importance in military furgery.

Amongft the obfervations on the fubject of *Gun-fhot Wounds* in a former volume, the reader will find a ftatement of fome of the fentiments which were entertained by the late Mr. Hunter concerning the treatment of thefe injuries. It will there be found, that this celebrated furgeon, as well as a few other eminent practitioners, was far from being an advocate for immediate amputation, even in cafes in which he acknowledged that there was no poffibility of ultimately faving the injured limb. It was his opinion, that more patients died when the operation was done early, than when it was performed in a later ftage, after inflammation had fubfided, and fuppuration had been fairly eftablifhed. Such precepts, however, do not coincide with the refults of modern experience; and, as in numerous inftances, the decifion for amputation or for delay involves the queftion of life or death, we think that every opportunity ought to be taken of refuting this part of Mr. Hunter's writings.

According to the united obfervations of all well-informed experienced army furgeons, it may now be fet down as an eftablifhed rule in military furgery, *that in every cafe in which a limb is fo fhattered and injured, that no probability of its being finally faved prefents itfelf, amputation ought to be done at once, without any delay.* For nearly the laft two hundred years, there have always been fome men of talents and experience, who not only recommended, but actually adopted this judicious practice. Du Chefne, who wrote in 1625, advifes the performance of amputation in cafes of fevere injuries of the limbs; and it is worthy of remark, that *he directs the operation to be performed before inflammation and other conftitutional fymptoms have fupervened.* (See Traité de la Cure générale et particulière des Arcbufades, Paris, 1625, p. 143.) Wifeman, the father of Englifh furgery, not only recommended and practifed immediate amputation, but the fame thing was not unfrequently done by the military furgeons of his time. (Chirurgical Treatifes by R. Wifeman, 3d edit. London, 1696, p. 410.) The celebrated Le Dran, in his excellent little manual of military furgery, declared himfelf an advocate for *immediate* amputation in all cafes in which that operation from the firft appears to be indifpenfable. (See Traité ou Réflexions tirées de la Pratique fur les Plaies d'Armes à feu, Paris, 1737.) Ranby, who was ferjeant-furgeon to king George II., entertained opinions fimilar to thofe of Le Dran, with regard to to the advantages and neceſſity of immediate amputation, whenever the injury is ſuch as to remove all reaſonable hope of ultimately ſaving the limb. See Ranby's Method of treating Gun-ſhot Wounds, edit. 3. p. 29. London, 1781.

The following account of this intereſting ſubject is principally abſtracted from the third edition of Cooper's Dictionary of Practical Surgery, publiſhed in the year 1818 :— After the battle of Fontenoy, in the year 1756, the Royal Academy of Surgery in France offered a prize for the beſt diſſertation on the gun-ſhot injuries requiring immediate amputation, and on other caſes of the ſame nature, where the operation, though deemed inevitable, might be delayed. The prize was adjudged to the diſſertation of M. Faure, the main object of whoſe paper was to recommend delaying the operation. The ſide of the queſtion eſpouſed by M. Faure has found ſome modern advocates of diſtinguiſhed talents and celebrity. Suffice it to mention the names of Hunter, baron Percy, and Lombard. It is, however, only juſtice to M. Faure to ſtate in this place, that though he regarded immediate amputation as full of danger, he admitted that there were ſeveral kinds of injuries of the extremities in which it was indiſpenſably and immediately required. "The enumeration," ſays Dr. Thomſon, "which this author has given of theſe injuries is more full and diſtinct than any which had been publiſhed before his time; and, what may appear ſingular, *it does not differ in any eſſential reſpect from the enumerations given by later writers*, who in combating his opinions have repreſented him as an enemy to amputation in almoſt all injuries of the extremities." See Report of Obſervations made in the Military Hoſpitals in Belgium, p. 169.

Although in France the academy of ſurgery thought proper to decree the prize to M. Faure, whoſe doctrine thus received the higheſt approbation, yet in that country very oppoſite tenets were ſet up by ſome men of diſtinguiſhed talents and extenſive military practice. Thus Le Dran, conſulting ſurgeon to the French army, in his work on gun-ſhot wounds, publiſhed in 1737, expreſsly ſtates, "that when the amputation of a limb is indiſpenſably neceſſary in the caſe of a gun-ſhot wound, it ought to be done without delay." (Aphoriſm 9.) M. La Martinière, in particular, wrote ſome excellent arguments in reply to M. Bilguer; arguments which would do honour to the moſt accompliſhed ſurgeon of the age in which we live. (See Mémoire ſur le traitement des plaies d'armes à feu, in Mém. de l'Acad. de Chirurgie, tom. xi. p. 1. edit. in 12mo.) M. Boucher, of Liſle, was an advocate for the ſame ſide of the queſtion. (See Obſ. ſur des plaies d'armes à feu, &c. in Mém. de l'Acad. de Chirurgie, tom. v. p. 279, &c. edit. in 12mo.) Schmucker, who was many years ſurgeon-general to the Pruſſian armies, publiſhed in 1776 an eſſay on amputation, in which he particularly mentions, that during his ſtay at Paris in 1738, the ſurgeons of the Hôtel-Dieu had been in the habit of performing immediate amputation in ſevere injuries of the extremities. *He alſo declares himſelf an advocate for operating immediately, in all caſes in which amputation from the firſt appears to be neceſſary*, and inſiſts, in a particular manner, on the increaſed danger which he had ſeen ariſe from the operation during the ſecond period. He gives, as Dr. J. Thomſon has obſerved, a minute and circumſtantial enumeration of thoſe injuries, both of the upper and lower extremities, in which he conceived amputation to be neceſſary, and in many of which he had actually performed it with great ſucceſs. Schmucker appears to Dr. Thomſon to have given a better account than any preceding military ſurgeon of the injuries of the thigh; and from the reſults of his experience, he was led to believe, that *though compound fractures of the lower part of the thigh-bone might, in favourable circumſtances, be cured without amputation, yet that this operation is peculiarly neceſſary in all caſes in which the fracture is ſituated in or above the middle of that bone.* (See Unterſuchung über die Abnehmung der Glieder von J. L. Schmucker. Vermiſchte Chirurgiſche Schriften, band i. Berlin, 1785.) With the foregoing high authority we have to join one of not leſs celebrity, namely, that of M. Larrey, who has proved moſt convincingly, that when amputation is to be done in caſes of gun-ſhot wounds, nothing is ſo pernicious as delay. See Mémoires de Chirurgie Militaire, tom. ii. p. 451, &c.

The principles inculcated by M. Larrey are, in point of fact, the ſame as thoſe which were ſo ſtrenuouſly inſiſted upon by Mr. Pott, in his remarks on amputation. Mr. Pott, indeed, was not an army ſurgeon, and what he ſays was not particularly deſigned to apply to military practice, but he has repreſented, as well as any body can do, the propriety of immediate amputation for injuries, which leave no doubt that ſuch operation cannot be diſpenſed with.

Mr. John Bell, amongſt the moderns, alſo defended the propriety of early amputation, long before the ſentiments of later writers were ever heard of. He diſtinctly ſtates, that "amputation ſhould, in thoſe caſes where the limb is plainly and irrecoverably diſordered, be performed upon the ſpot." (See Diſcourſes on the Nature, &c. of Wounds, p. 488. edit. 3.) Indeed, notwithſtanding all the modern pretenſions to novelty upon this intereſting topic, we muſt acknowledge, with Dr. Thomſon, that the evidence in favour of the advantages of immediate amputation has always preponderated over that for delay. See Report of Obſ. made in the Military Hoſpitals in Belgium, p. 225.

The ſtrongeſt body of evidence upon this matter, however, is adduced by M. Larrey, whoſe ſituation at the head of the medical department of the French armies has afforded him moſt numerous opportunities of judging from actual experience.

"If we are to be told," ſays he, "that the amputation of a limb is a cruel operation, dangerous in its conſequences, and always grievous for the patient, who is thereby mutilated; that, conſequently, there is more honour in ſaving a limb, than in cutting it off with dexterity and ſucceſs; theſe arguments may be refuted by anſwering, that amputation is an operation of neceſſity, which offers a chance of preſervation to the unfortunate, whoſe death appears certain under any other treatment; and that if any doubt ſhould exiſt of amputation being abſolutely indiſpenſable to the patient's ſafety, the operation is to be deferred, till nature has declared herſelf and given a poſitive indication for it. We are alſo juſtified in adding, that this chance of preſervation is at the preſent day much greater than at the epoch of the academy of ſurgery. We learn from M. Faure, that of about three hundred amputations performed after the battle of Fontenoy, only thirty were followed by ſucceſs, whilſt, on the contrary, ſays M. Larrey, we have ſaved more than three-fourths of the patients on whom amputation has been done, and ſome of whom alſo had two limbs removed. This improvement is aſcribed by M. Larrey, 1ſt, to our now knowing better how to take advantage of the indication and favourable time for amputating; 2dly, to the dreſſings being more methodical; 3dly, to the mode of operating being more ſimple, leſs painful, and more expeditious, than that formerly in vogue."

To the preceding authorities againſt delaying amputation, in caſes of gun-ſhot wounds requiring ſuch operation, we have to add that of Mr. Guthrie, deputy inſpector of military

tary

tary hofpitals, whofe opportunities of obfervation, during the late war in Spain, were particularly extenfive. Mr. Guthrie, however, does not recommend amputation to be done immediately, if the patient be particularly depreffed by the fhock of the injury directly after its receipt. "If a foldier, at the end of two, four, or fix hours after the injury, has recovered from the general conftitutional alarm occafioned by the blow, his pulfe becomes regular and good, his ftomach eafy, he is lefs agitated, his countenance revives, and he begins to feel pain, ftiffnefs, and uneafinefs in the part: he will now undergo the operation with the greateft advantage, and if he bears it well, of which there will be little doubt, he will recover in the proportion of nine cafes out of ten, in any operation on the upper extremity, or below the middle of the thigh, &c. If, on the contrary, the operation be performed before the conftitution has recovered itfelf, to a certain degree, from the alarm it has fuftained, the additional injury will moft probably be more than he can bear, and he will gradually fink under it and die." (On Gun-fhot Wounds, p. 24. London, 1815.) As far as our experience goes, however, all delay is improper when the neceffity of amputation is undoubted, at leaft all delay beyond the fhort period, during which the faintnefs immediately arifing from the injury ufually lafts. In the campaign in Holland, in 1814, the moft fuccefsful amputations were thofe done in the field hofpitals directly after the arrival of the patients. On this point, however, hardly any difference of fentiment prevails, becaufe all naval and military furgeons agree, and mean, that amputation is not to be performed till the faintnefs and depreffion of the powers of life, directly following the wound, have been fufficiently obviated for the patient to bear the operation well. The feeming difference, therefore, on this matter, between Mr. Guthrie and Mr. Hutchifon, is not very material. (See Hutchifon's Practical Obf. on Surgery, 1817.) It appears from fome returns, collected by Mr. Guthrie, that in the peninfula, the comparative lofs, in fecondary or delayed operations, and in primary or immediate amputations, was as follow:

	Secondary.		Primary.
Upper extremities - -	12	to	1
Lower extremities - -	3	to	1

The great fuccefs attending amputation on the field of battle was alfo convincingly proved after the battle of Touloufe. Here of 47 immediate amputations, 38 were cured, while of the 51 delayed operations, on that occafion, 21 had fatal terminations. P. 42—44.

Laftly, we have to notice, amongft the advocates for immediate amputation, Mr. Hennen, a furgeon employed with our army in Spain and the Netherlands. "The queftion," fays he, "of immediate amputation has of late attracted an attention, which its great importance naturally calls forth; but it appears to me, that an idea has been impreffed upon the minds of practitioners in civil life, that doubts as to the propriety of the practice had exifted among the Britifh army furgeons. For my own part, I have never known any differences of opinion on the point. In books, it is true, it has been moft amply difcuffed before the prefent generation were in exiftence; but in Britifh practice all doubts have long been at an end. It is but juftice to Britifh furgeons, both naval and military, to declare, that immediate amputation is neither a new doctrine nor a recent practice among them, &c." See Hennen's Obf. on fome important Points in the Practice of Military Surgery, p. 45. Edinb. 1818.

If, however, military furgeons have definitively fettled the great queftion, that in all cafes in which a limb cannot be faved, the fooner amputation is done the better, they neither have, nor probably will ever be able pofitively to fettle and define the exact degrees of injury which, in every inftance, ought to be followed by putting the former rule in practice. In fact, no part of furgery is more difficult, than that in which the queftion of the poffibility or impoffibility of faving wounded limbs is fubmitted to the judgment and determination of the practitioner. Some injuries, indeed, are fo bad, that no difficulty in making a decifion is experienced; but there are other cafes, in which the damage done to the parts is lefs violent and extenfive, and in which the exact degree of mifchief is not at firft apparent. There are, in fhort, numerous doubtful examples, in which the formation of a right judgment is equally difficult and important.

The annexed remarks will convey the fentiments of fome of the lateft writers on the fecond great queftion in military furgery. What are the exact cafes in which amputation fhould be done immediately, and what are thofe in which the operation may be deferred?

Of Cafes in which Amputation fhould be done immediately.— Firft cafe. A limb carried away by a cannon-ball, or the explofion of a howitzer, or bomb, requires amputation without any lofs of time: the leaft delay puts the patient's life in danger.

In this cafe, the neceffity of the practice is inculcated by M. Faure himfelf, as well as by Schmucker, Richter, Larrey, Dr. Thomfon, and every modern writer upon gunfhot wounds.

If the operation be not fpeedily done, pain commences, fever occurs, and the functions become difordered; the irritation then increafes, and convulfive motions take place. If the patient fhould not be a victim to thefe firft fymptoms (continues Larrey), gangrene of the ftump is occafioned, the fatal confequences of which it is extremely difficult to prevent.

Second cafe. When a body propelled by gunpowder ftrikes a limb, in fuch a manner as to fmafh the bones, violently contufe, lacerate, and deeply tear away the foft parts, amputation ought to be immediately performed. If this meafure be neglected, all the injured parts will foon be feized with gangrene: and befides, as M. Larrey has explained, the accidents which the gravity of the firft cafe produces will alfo here be excited. It is only doing juftice to the memory of M. Faure to ftate, that this fecond cafe was one which he alfo particularly inftanced as demanding the immediate performance of amputation. See Prix de l'Acad. Royale de Chirurgie, tom. viii. p. 23. edit. 12mo.

Third cafe. If a fimilar body were to carry away a great mafs of the foft parts, and the principal veffels of a limb (of the thigh for inftance), without fracturing the bone, the patient would be in a ftate demanding immediate amputation; for, independently of the accidents which would originate from a confiderable lofs of fubftance, the limb muft inevitably mortify. Mr. Guthrie alfo fays, "a cannon-fhot deftroying the artery and vein on the infide (of the thigh), without injuring the bone, requires amputation." (P. 185.) When, however, the femoral artery or vein is injured by a mufket-ball, or fmall cannifter-fhot, this gentleman recommends tying the veffel above and below the wound in it, if the nature of the cafe be evinced by hemorrhage. But he believes, that when both vein and artery are injured, amputation is neceffary. (P. 186.) An injury of the femoral artery, obferves Mr. Guthrie, requiring an operation, and accompanied with fracture of the bone of the moft fimple kind, is a proper cafe for immediate amputa-

tion;

tion; for although many patients would recover from either accident alone, none would furmount the two united, and the higher the accident is in the thigh, the more imperious is the neceffity for amputation.

Fourth cafe. A large bifcayen ftrikes the thick part of a member, breaks the bone, divides and tears the mufcles, and deftroys the large nerves, without, however, touching the main artery. According to M. Larrey, this is a fourth cafe requiring immediate amputation.

Mr. Guthrie alfo fays, that "if a cannon-fhot ftrike the back part of the thigh, and carry away the mufcular part behind, and with it the great fciatic nerve, amputation is neceffary, even if the bone be untouched, &c. In this cafe, I would not perform the operation by the circular incifion, but would preferve a flap from the fore part or fides, as I could get it, to cover the bone which fhould be fhort." Guthrie on Gun-fhot Wounds of the Extremities, p. 184.

Fifth cafe. If a fpent cannon-fhot, or one that has been reflected, fhould ftrike a member obliquely, without producing a folution of continuity in the fkin, as often happens, the parts which refift its action, fuch as the bones, mufcles, tendons, aponeurofes, and veffels, may be ruptured and lacerated. The extent of the internal diforder is to be examined; and if the bones fhould feel through the foft parts as if they were fmafhed, and if there fhould be reafon to fufpect from the fwelling, and a fort of fluctuation, that the veffels are lacerated, amputation ought to be immediately practifed. We learn from M. Larrey, that this is alfo the advice of M. Percy, an eminent French army furgeon. Sometimes, however, the veffels and bones have efcaped injury, and the mufcles are almoft the only parts difordered. In this circumftance, we are enjoined to follow the council of M. La Martinière, who recommended making an incifion through the fkin. By this means, a quantity of thick blackifh blood will be difcharged, and the practitioner muft await events. According to M. Larrey, fuch incifion is equally neceffary in the preceding cafe before amputation, in order to afcertain the extent of the mifchief which the parts have fuftained.

It is to fuch injury done to internal organs, that we muft afcribe the death of many individuals, which was for a long while attributed to the commotion produced by the air put in motion by the ball, when this, in grazing upon different parts of the body, alters them, or cuts off the column of air which is to ferve for refpiration, juft at the moment when it is about to enter the cheft. See Ravaton's Traité des Plaies d'Armes à Feu.

But to return to the object of our prefent confideration. M. Larrey expreffes his belief, that what have been erroneoufly termed *wind contufions*, if they are attended with the mifchief above fpecified, require immediate amputation. The leaft delay makes the patient's prefervation extremely doubtful. The internal injury of the member may be afcertained by the touch, by the lofs of motion, by the little fenfibility retained by the parts which have been ftruck, and, laftly, by practifing an incifion, as already recommended.

Sixth cafe. When the articular heads are much broken, efpecially thofe which form the joints of the foot or knee, and the ligaments, which ftrengthen thefe articulations, are broken and lacerated by the fire of a howitzer or by a bifcayen, or other kind of ball, immediate amputation, fays M. Larrey, is indifpenfable. According to this experienced writer, the fame indication would occur, were the ball lodged in the thicknefs of the articular head of a bone, or were it fo engaged in the joint as not to admit of being extracted by fimple and ordinary means. (See alfo Guthrie on Gun-fhot Wounds, p. 197.) Putting out of confideration cafes in which the injury has been done by a clean cutting inftrument, or in which a fmall ball has paffed near or partially injured a joint, another experienced army furgeon alfo lays it down as a law in military furgery, that *no lacerated joint, particularly the knee, ankle, or elbows, fhould ever leave the field unamputated, where the patient is not obvioufly finking, and confequently where certain death would follow the operation.* (Hennen's Military Surgery, p. 42.) And in another place he tells us: "In my own practice, I have met with only two cafes, where the limb was faved after a ferious injury of the knee-joint; and in one of them only was the perfect ufe of it reftored. I never met with an inftance where the ankle or elbow-joint was perfectly reftored after fevere injury, though fome where the limb has been faved. Of the fhoulder-joint the recoveries are more frequent." P. 159.

Fractures extending into the joints, and accompanied with great laceration of the ligaments, were cafes of gun-fhot injuries pointed out by M. Faure as indifpenfably requiring immediate amputation. (See Prix de l'Acad. de Chir. tom. viii.) Thus we fee, that this author was not fo averfe to early amputation as feveral modern writers have reprefented.

It is only in this manner, that the patients can be refcued from the dreadful pain, the fpafmodic affections, the violent convulfions, the acute fever, the confiderable tenfion, and the general inflammation of the limb, which, M. Larrey obferves, are the invariable confequences of bad fractures of the large joints. But, adds this author, if the voice of experience be not liftened to, and amputation be deferred, the parts become diforganized, and the patient's life is put into imminent peril.

It is evident, fays he, that, in this cafe, if we wifh to prevent the patient from dying of the confequent accidents, amputation fhould be performed before twelve or at moft twenty-four hours have elapfed: even M. Faure himfelf profeffed this opinion, in regard to certain defcriptions of injury. Mém. de Chir. Militaire, tom. ii.

With refpect to wounds of the knee, the fentiments of Mr. Guthrie nearly coincide with thofe of M. Larrey. "I moft folemnly proteft (fays Mr. G.) I do not remember a cafe do well, in which I knew the articulating end of the femur, or tibia, to be fractured by a ball that paffed through the joint, although I have tried great numbers, even to the laft battle of Touloufe. I know that perfons wounded in this way have lived; for a recovery it cannot be called, where the limb is ufelefs, bent backward, and a conftant fource of irritation and diftrefs, after feveral months of acute fuffering, to obtain even this partial fecurity from impending death; but if one cafe of recovery fhould take place in fifty, is it any fort of equivalent for the facrifice of the other forty-nine? Or is the preferving of a limb of this kind an equivalent for the lofs of one man?" On Gun-fhot Wounds, p. 196.

Mr. Guthrie admits, that fractures of the patella, without injury of the other bones, admit of delay, provided the bone is not much fplintered.

Seventh cafe. According to M. Larrey, if a large bifcayen, a fmall cannon-fhot, or a piece of a bomb-fhell, in paffing through the fubftance of a member, fhould have extenfively denuded the bone, without breaking it, amputation is equally indicated, although the foft parts may not appear to have particularly fuffered. Indeed, the violent concuffion produced by the accident has fhaken and diforganized all the parts; the medullary fubftance is injured, the veffels

are

are lacerated, the nerves immoderately ſtretched, and thrown into a ſtate of ſtupor; the muſcles are deprived of their tone; and the circulation and ſenſibility in the limb are obſtructed. Before deciding, however, M. Larrey cautions us to obſerve attentively the ſymptoms which characterize this kind of diſorder. This caſe can be ſuppoſed to happen only in the leg, where the bone is very ſuperficial, and merely covered at its anterior part with the ſkin.

The following are deſcribed as the ſymptoms: the limb is inſenſible, the foot cold as ice, the bone partly expoſed, and on careful examination, it will be found that the integuments, and even the perioſteum, are extenſively detached from it. The commotion extends to a conſiderable diſtance; the functions of the body are diſordered; and all the ſecretions experience a more or leſs palpable diſturbance. The intellectual faculties are ſuſpended, and the circulation is retarded. The pulſe is ſmall and concentrated, the countenance pale, and the eyes have a dull moiſt appearance. The patient feels ſuch anxiety, that he cannot long remain in one poſture, and requeſts that his leg may be quickly taken off, as it incommodes him ſeverely, and he experiences very acute pain in the knee. When all theſe characteriſtic ſymptoms are conjoined, ſays M. Larrey, we ſhould not heſitate to amputate immediately; for the leg would be attacked with ſphacelus the ſame day, and the patient would certainly periſh.

M. Larrey next adduces ſeveral intereſting caſes in ſupport of the preceding obſervations.

Eighth caſe. When a large gynglimoid articulation, ſuch as the elbow, or eſpecially the knee, has been extenſively opened with a cutting inſtrument, and blood is extravaſated in the joint, M. Larrey deems immediate amputation neceſſary. In theſe caſes, the ſynovial membranes, the ligaments, and aponeuroſes, inflame, the part ſwells, and erethiſmus rapidly takes place; and acute pains, abſceſſes, deep ſinuſes, caries, febrile ſymptoms, and death, are the ſpeedy conſequences. M. Larrey has ſeen numerous ſubjects die of ſuch injuries, on account of the operation having been poſtponed with a hope of ſaving the limb. In his Mémoires de Chirurgie Militaire, tom. ii. ſome of theſe are detailed.

Although a wound may penetrate a joint, yet if it be ſmall and unattended with extravaſation of blood, M. Larrey informs us, it will generally heal, provided too much compreſſion be not employed. This gentleman believes in the common doctrine of the pernicious effect of the air on the cavities of the body; yet, in this place, a doubt ſeems to affect him: ſpeaking of the leſs danger of ſmall wounds of joints, he ſays, "a quoi tient cette différence, puiſque l'air pénètre dans l'articulation dans l'un comme dans l'autre cas?"

When two limbs have been at the ſame time ſo injured as to require amputation, we ſhould not be afraid of amputating them both immediately, without any interval. We have, ſays M. Larrey, ſeveral times performed this double amputation with almoſt as much ſucceſs as the amputation of a ſingle member. He has recorded an excellent caſe in confirmation of this ſtatement. Mém. de Chirurgie Militaire, tom. ii. p. 478.

When a limb is differently injured at the ſame time in two places, and one of the wounds requires amputation, (ſuppoſe a wound of the leg with a ſplintered fracture of the bone, and a ſecond of the thigh, done with a ball, but without any fracture of the os femoris, or other bad accident,) M. Larrey recommends us, firſt to dreſs the ſimple wound of the thigh, and amputate the leg immediately afterwards, if the knee be free from injury. When it is neceſſary to amputate above this joint, the leſs important wound need not be dreſſed till after the operation, provided it can be comprehended in the ſection of the member, or be ſo near the place of the inciſion as to alter the indication. When the wound demanding amputation is the upper one, the operation of courſe is to be done above it, without paying any regard to the injury ſituated lower down.

M. Larrey, however, approves of deferring the operation, when delirium, convulſions, and inflammation, prevail on the firſt receipt of the injury. In this circumſtance, we are adviſed to take meaſures for appeaſing theſe accidents; the progreſs of nature is to be carefully obſerved; and the firſt moment of quiet is to be taken advantage of for the performance of the operation. See Larrey's Mém. de Chirurgie Militaire, tom. ii. p. 451, &c.

Ninth caſe. To the foregoing ſpecies of gun-ſhot wounds, pointed out by M. Larrey as urgently requiring immediate amputation, are to be added compound fractures of the thigh from gun-ſhot violence.

"Gun-ſhot fractures of the thigh," ſays Dr. J. Thomſon, "have been univerſally allowed to be attended with a high degree of danger; indeed, till of late years, very few inſtances have been recorded of recovery from theſe injuries. Ravaton acknowledges, that in his long and extenſive experience, he had never ſeen an example of recovery from a gun-ſhot fracture of the thigh; and Bilguer, in his calculations with regard to thoſe who recover from gun-ſhot fractures, ſets aſide thoſe of the thigh-bone, as being of a nature altogether hopeleſs. In the preſent improved ſtate of military ſurgery, inſtances not unfrequently occur of recovery from this fracture; but of theſe, the number will be found, I believe, to be exceedingly ſmall, in compariſon with thoſe who die, particularly when the fracture has had its ſeat above the middle of the bone, &c."

According to the obſervation of Percy, ſcarcely two of ten recover of thoſe who have ſuffered gun-ſhot fractures of the thigh-bone. Mr. Guthrie ſays, that "upon a review of the many caſes which I have ſeen, I do not believe that more than one-ſixth recovered ſo as to have uſeful limbs; two-thirds of the whole died either with or without amputation; and the limbs of the remaining ſixth were not only nearly uſeleſs, but a cauſe of much uneaſineſs to them for the remainder of their lives." See Guthrie on Gun-ſhot Wounds, p. 191.

"In fractures by muſket-bullets of the lower part of the thigh-bone (ſays Dr. Thomſon), recovery not unfrequently takes place; and both Schmucker and Mr. Guthrie conceive, that they are injuries in which amputation may be delayed with ſafety. It would be very agreeable, that this opinion ſhould be confirmed by future experience; but it appears to me, that before it can be received as a maxim in military ſurgery, much more extenſive and accurate obſervation than we yet poſſeſs will be required, with regard to the proportion of thoſe who recover without amputation, or after ſecondary operations, and of thoſe who recover after primary amputation. Of thoſe who had ſuffered this injury, we ſaw, comparatively, but a ſmall number recovering in Belgium, and they had been attended with ſevere local and conſtitutional ſymptoms." See Report of Obſervations made in the Military Hoſpitals in Belgium, p. 247, *et ſeq.*

Balls often produce fiſſures of ſeveral inches in length in the thigh-bone. This is a ſtate, obſerves Dr. Thomſon, which muſt be very unfavourable to recovery; and his concluſion is, that in general, even in fractures of the lower part of the thigh-bone, a greater number of lives will be preſerved in military practice by immediate amputation,

 than

than by attempting the cure without that operation. " When the bone appears, on a careful examination, to be broken without being much fplintered, and when the patient can be removed eafily to a place of reft and fafety, it may be right to attempt to preferve the limb; but if the bone be much fplintered, or if the conveyance is to be long or uncertain, it will, in moft inftances, I am convinced, be a much fafer practice, even in fractures of this part of the thigh-bone, to amputate without delay.

" Mufket-bullets, in paffing through the femur, near to the knee-joint, produce fiffures of the condyles, which generally communicate with the joint. Thefe cafes, like thofe in which the bullets have paffed directly through the joint, require immediate amputation.

" The writings of military furgeons contain but few hiftories of cafes in which the thigh-bone had been fractured above its middle by the paffage of mufket-bullets. Thefe are cafes, I believe, which have generally had a fatal termination; and the danger attendant upon the amputation which they require, feems long to have deterred furgeons from attempting to afcertain what advantages might be derived from the employment of that operation. Schmucker recommends and ftates, that he had practifed with fuccefs immediate amputation in thofe cafes, in which a fufficient fpace was left below the groin for the application of the tourniquet. It is curious to remark, in the hiftory of amputation, how long furgeons were in difcovering the eafe and fafety with which the femoral artery may be compreffed by the fingers, or pads, in its paffage over the brim of the pelvis. Boy, from the immediate danger, protracted fuffering, and ultimate want of fuccefs, which he had obferved to follow this kind of injury, urges ftrenuoufly the propriety of immediate amputation: Mr. Guthrie's opinion, with regard to the dangerous nature of thefe injuries, and the advantages to be derived in them from immediate amputation, coincides in every refpect with thofe of Schmucker and Boy. He obferves, that thofe whofe thigh-bone has been fractured in its upper part by a mufket-bullet, generally die with great fuffering before the end of the fixth or eighth week; and that few even of thofe efcape, in whom that bone has been fractured in its middle part. Of the few whom we faw, who had furvived gun-fhot fractures in the upper part of the thigh-bone in Belgium, fcarcely any one could be faid to be in a favourable condition. In all, the limbs were much contracted, diftorted, and fwollen, and abfceffes had formed round and in the neighbourhood of the fractured extremities of the bones. In fome inftances, thefe abfceffes had extended down the thigh; but more frequently they paffed upwards, and occupied the region of the hip-joint and buttocks. In feveral inftances in which incifions had been made for the evacuation of matter, the fractured and exfoliating extremities of the bones fometimes comminuted, and fometimes forming the whole cylinder, could be felt bare, rough, and extenfively feparated from the foft parts which furrounded them. In other inftances, thefe extremities were partially inclofed in depofitions of new bone, which, from the quantity thrown out, feemed to be prefent in a morbid degree. It was obvious, that in all of thefe cafes, feveral months would be required for the re-union of the fractured extremities; that in fome much pain and mifery were ftill to be endured from the proceffes of fuppuration, ulceration, exfoliation, and ejection of dead bone; that in fome cafes, the patients were incurring great danger from hectic fever, and from diarrhœa; that the ultimate recovery in moft of them was doubtful; and that of thofe in whom this might take place, there was but little probability that any would be able to ufe their limbs! The fight of thefe cafes (fays Dr. Thomfon) made a deep impreffion upon my mind, and has tended to increafe my conviction, that this is, of all others, the clafs of injuries in which immediate amputation is moft indifpenfably required." See Report of Obfervations made in the Military Hofpitals in Belgium, p. 254—258.

Dr. Thomfon adds, that what has been faid of the danger of fractures produced by mufket-bullets in the upper part of the femur is true, in a ftill greater degree of thofe which have their feat in the neck or head of that bone. In fuch inftances, Dr. Thomfon joins the generality of modern army furgeons, in ftrongly recommending amputation at the hip-joint.

Of Gun-fhot Wounds in which Amputation may be deferred.—If, fays M. Larrey, it be poffible to fpecify the cafes in which amputation ought to be immediately performed, it is impoffible to determine *à priori* thofe which will require the operation fubfequently. One gun-fhot wound, for example, will be cured by ordinary treatment, while another, that is at firft lefs fevere, will afterwards render amputation indifpenfable, whether this be owing to the patient's bad conftitution, or the febrile complaints which are induced. However this may be, the fafe rule for fulfilling the indication that prefents itfelf, is to amputate confecutively only in circumftances in which every endeavour to fave the limb is manifeftly in vain. Upon this point, M. Larrey's doctrine differs from that of M. Faure.

The latter practitioner admits cafes, which he terms *cafes of the fecond kind*, in which he delays amputation, not with any hope of faving the limb, but in order to let the firft fymptoms fubfide. The operation done between the fifteenth and twentieth day, appears to him lefs dangerous than when performed immediately after the receipt of the injury. At the above period, according to M. Faure, the commotion occafioned by the gun-fhot injury is difpelled; the patient can reconcile himfelf to amputation, the mere mention of which fills the pufillanimous with terror in a greater or leffer degree; the debility of the individual is no objection; and it is laid down as an axiom, " that the confequences of every amputation, done in the firft inftance, are in general extremely dangerous." In fupport of this theory, M. Faure adduces ten cafes of gun-fhot injuries, in which, after the battle of Fontenoy, the operation was delayed, in order that it might afterwards be performed with more fuccefs; a plan which, according to the author, proved completely fuccefsful. See Prix de l'Acad. de Chirurgie, tom. viii. edit. in 12mo.

This divifion of the cafes for amputation into two claffes, not confiftent with nature, obferves M. Larrey, has been the caufe of a great deal of harm. Very often the partifans of M. Faure have not dared to refort in the firft inftance to amputation, the dangers of which they exaggerate; while, on other occafions, they amputate confecutively, without any fuccefs.

The effects of commotion, inftead of increafing, gradually diminifh and difappear after the operation. It is proved, fays he, that the commotion, fo far from being a counter-indication to immediate amputation, is a reafon that fhould incline the furgeon to operate. Such was the fentiment of La Martinière and Boucher.

Neither ought the patient's alarm to be a reafon for poftponing the operation; for according to M. Larrey, the patient juft after the accident will be much lefs afraid of the rifk which he has to encounter, than after the expiration of the firft four-and-twenty hours, when he has had time to reflect upon the confequences of the injury, or of amputation. This remark has been made by the illuftrious Paré.

 " Expe-

" Experience," ſays M. Larrey, " has proved, both to the army and navy ſurgeons, that the bad ſymptoms which ſoon follow ſuch gun-ſhot injuries as muſt occaſion the loſs of a limb, are much more to be dreaded than thoſe of immediate amputation. Out of a vaſt number of the wounded, who ſuffered amputation in the courſe of the firſt four-and-twenty hours after the memorable naval battle of the firſt of June, 1794, a very few loſt their lives."

M. Larrey next acquaints us, that when he was ſent to the army of Italy in 1796, he had alſo the pain of ſeeing in the hoſpitals great numbers of the wounded fall victims to the confidence which many of the ſurgeons of that army placed in the principles of M. Faure. General Bonaparte ſaw, that the *ambulance volante* was the only thing that, in the event of freſh hoſtilities, could prevent ſuch accidents; and in conſequence of his orders, M. Larrey formed the three diviſions d'ambulance, which are deſcribed in his Mémoires de Chirurgie Militaire.

Since this period, it has always been cuſtomary in the French armies, on the day of battle, to make every preparation for performing amputation as ſpeedily as poſſible. The mere ſight of theſe *ambulances*, (always attached to the advanced guard,) ſays M. Larrey, encourages the ſoldiers, and inſpires them with the greateſt courage.

M. Larrey deſires us to interrogate the invalids who have loſt one or two of their limbs, and nearly all will tell us, that they ſuffered amputation a few minutes after the accident, or in the firſt four-and-twenty hours.

" If M. Faure now retains any partiſans," ſays M. Larrey, " I recommend them to repair to the field of battle the day after an action; they would then ſoon be convinced, that without the prompt performance of amputation, great numbers of ſoldiers muſt inevitably loſe their lives. In Egypt, this truth was particularly manifeſted."

Admitting, ſays M. Larrey, that by a concurrence of fortunate circumſtances, which are not always to be calculated upon, ſome patients eſcape the danger of the firſt ſymptoms, this proves nothing in favour of doing the operation afterwards: it muſt be ſeen what nature will do towards the event of the caſe.

If at the end of twenty or thirty days the prognoſtic is as bad as it was previouſly, amputation cannot be avoided. Thus all the ſufferings which the patient has endured have been undergone for nothing, and the operation will now be attended with conſiderable riſk, inaſmuch as the patient may lie in a dangerouſly weakened ſtate.

If nature revives at all, no doubt the ſucceſs of the operation becomes more probable; but in this caſe, the ſurgeon, inſtead of having recourſe to amputation, ſhould redouble his efforts to preſerve the limb.

Caſes demanding Amputation conſecutively.—M. Larrey gives us the annexed information upon this ſubject.

Firſt caſe. *A ſpreading Mortification.*—If the diſorder be owing to an internal and general cauſe, it would then be raſhneſs in the ſurgeon to amputate before nature had put limits to the diſeaſe. This kind of gangrene, according to M. Larrey, is diſtinguiſhed from that which is named *traumatic*, by the ſymptoms which precede and accompany it. Theſe ſymptoms are ſimilar to thoſe which are obſerved in nervous ataxia, or adynamia. Here the operation ought to be deferred, and endeavours made to combat the general cauſes with regimen and internal medicines.

But when the gangrene is *traumatic*, the limb, ſays M. Larrey, ſhould be immediately cut off above the diſorganized part. Several facts in ſupport of this advice are related by this experienced ſurgeon in his Mémoire ſur la Gangrene Traumatique. See Surgery.

How contrary this advice to that inculcated by Sharp, Pott, and nearly all eminent ſurgeons of the preſent time!

A particular caſe of gangrene has been pointed out by Mr. Guthrie as demanding the early performance of amputation, and a deviation from the old rule of waiting till the mortification has ceaſed to ſpread. It is when gangrene occurs after wounds of the large blood-veſſels of a limb. See Guthrie on Gun-ſhot Wounds of the Extremities, p. 63, &c.

Second caſe. *Convulſions of the wounded Limb.*—Amputation of the member, performed immediately the firſt ſymptoms of tetanus manifeſt themſelves, more eſpecially thoſe of chronic tetanus, was propoſed and even practiſed by Larrey with partial ſucceſs. He ſuppoſed, that all communication between the original injury, and the reſt of the body being thus cut off, the general diſorder might ceaſe.

Third caſe. *Bad State of the Diſcharge.*—It often happens, that in gun-ſhot wounds, complicated with fractures, notwithſtanding the moſt ſkilful treatment, the diſcharge becomes of a bad quality; the fragments of bone lie ſurrounded with the matter, and have not the leaſt tendency to unite; the patient is attacked with hectic fever, and a colliquative diarrhœa. Under theſe circumſtances, life may ſometimes be preſerved by amputation.

Fourth caſe. *Bad State of the Stump.*—In hoſpitals, ſays M. Larrey, the cure of amputations is ſometimes prevented by a fever of a bad character. The ſtump ſwells, the integuments become at firſt retracted, and then reverted and diſeaſed a good way upward. The wound changes into a fungous ulcer, the cicatrization of which is hindered by the deep diſorder of the bone, and the ulceration of the ſoft parts. The extremity of the bone projects. In order to remedy this laſt evil, it has been propoſed to ſaw off the projecting part of the bone, and with this even to amputate all the fleſh beyond the level of the ſkin. M. Larrey condemns ſuch practice, as unneceſſary and dangerous, and he recommends giving nature time to effect the exfoliation of the diſeaſed projecting part of the bone, and heal the wound.

Of poiſoned Wounds.—Theſe injuries are eſſentially different from every other deſcription of wound, their great particularity depending upon the introduction of a venomous matter into the wounded parts, or its depoſition upon the ſurface of the injury; and, in general, the poiſon is inſerted by the weapon with which the ſolution of continuity is produced. Sometimes, however, the contrary happens, when previous cuts, or ſcratches of the fingers, which are not healed, become infected with a virus, in the diſſection of bodies, or in the dreſſing of venereal ulcers. Nay, there has lately been recorded in the public papers a remarkable inſtance, in which a nobleman's ſervant died, as is alleged, from the effects of the poiſon of a torpid viper, the fangs and poiſoned apparatus of which he had been handling and exhibiting to ſome viſitors, at a time when he happened to have a ſlight cut upon one of his fingers. The caſe is extraordinary, not only on account of the way in which the infection was contracted, but alſo on account of the fatal event, which is very uncommon in animals of the magnitude of the human ſubject, as we ſhall hereafter notice.

Pricks with the point of a diſſecting-knife, when the inſtrument is covered with putrid, infectious, irritating matter, may be conſidered as a claſs of poiſoned wounds. Sometimes, however, ſuch accidents are followed by no injurious effects; and when the ſubject is ſtrong and robuſt, a little inflamed tumour occurs in the ſituation of the puncture, the part feſters, burſts, and then heals up. But, as Richerand obſerves, obferves, when the accident befals a young man, who has been much weakened by hard ftudy, any kind of excefs, or fome previous difeafe, it frequently happens that no local fymptoms are feen. At the end of 24 or 36 hours, fometimes rather fooner, fometimes later, the axillary glands become affected with fwelling, and a painful phlegmonous inflammation takes place in them. The wound afterwards fefters; the parts around it exhibit appearances of a flow fort of inflammation, and the confequent fwelling of the hand is rather œdematous than inflammatory. Next often fucceed naufea and propenfity to vomit, proftration of ftrength, a fmall accelerated pulfe, and all the ufual fymptoms of typhus fever. Under thefe circumftances, if, inftead of a tonic plan of treatment, which is ftrongly indicated, the evacuating method be adopted, the patient very foon falls a victim.

Experience fully proves, that in ftrong vigorous habits, nature refifts with energy the introduction of poifons into the fyftem.

In the cafes under our confideration, tonic and cordial remedies are to be given in moderation. At the fame time, care is to be taken to clear out the primæ viæ, when they appear to be difordered. Abroad, it is the common practice alfo to apply a grain of cauftic potaffa, or a drop of the liquid muriate of ammonia, to the little wound itfelf.

The ftings of venomous infects, fuch as the bee, wafp, hornet, &c. are commonly treated of with poifoned wounds. The pain of the injury is alleged to depend lefs upon the introduction of the fting, which fometimes breaks and is left behind, than upon the infertion of a venomous fluid into the part. It is faid indeed, that the experiments made by profeffor Dumeril prove, that when the little cyft, fituated at the bafe of the fting, is removed, the introduction of the fting itfelf into the flefh caufes no particular pain. At the bafe of the fting there is a kind of veficle, or refervoir, for containing the poifonous fecretion, which is expelled and flows out along the fting, at the inftant when the latter penetrates the parts which are ftung. The venom of the bee is ftated to be neither of an acid nor of an alkaline nature. When applied to mucous furfaces, and even to the tunica conjunctiva of the eye, it produces no difagreeable fenfation; but if the point of a needle, after being dipped in it, be introduced into the flefh, a very acute pain is immediately excited. Various kinds of oil, honey, ammonia, fpirit of wine, and feveral other reputed fpecifics, appear to deferve no fuch character, fince they are found, after unprejudiced trials, to have no power of neutralizing the venom, nor of appeafing the actual pain arifing from the fting.

When, therefore, a perfon has been ftung by one or feveral bees, we are recommended to begin with extracting the ftings, taking care, however, previoufly to cut off with a pair of fciffars the little veficle at their bafe containing the venomous fecretion. This is to be done, left in the endeavours to remove the fting more of the venom fhould be compreffed out of the little refervoir into the wound. The part is afterwards to be covered with fnow, or bathed with ice-cold water, or fome cooling fedative lotion. In fhort, the cafe is to be treated on common antiphlogiftic principles, experience having fully proved that no fpecific has yet been difcovered for the fting of the bee, and other venomous infects. For other opinions and obfervations on this fubject, fee the article Bee.

Bite of the Viper.—Of all the venomous reptiles which are met with in Europe, there are none which inflict fo dangerous a bite as the viper or adder. Its upper jaw is furnifhed with two moveable fangs, which are very fharp-pointed, grooved longitudinally, and at their root are connected with a veficle which contains the venomous fluid. When the animal is irritated, the fangs become raifed, and the poifon flows along the grooves in them into the bitten part. The danger of the injury is in fome meafure proportioned to the fury of the animal; for when it is very much exafperated, it clofes its jaws with greater force, and more of the venom is compreffed into the wound. The degree of danger is alfo influenced confiderably by the greater or lefs fpace of time that has elapfed fince the reptile emptied the receptacles of its venom, by biting another perfon or animal. The injury likewife is generally found to produce lefs ferious confequences, in proportion to the greater fize of the animal which has been bitten. The experiments of Fontana prove, that the bite of a fingle viper will kill a moufe, a pigeon, or any other fmall animal; but that it muft be the bites of feveral to kill a man, and of a ftill larger number to deftroy an ox. It is alfo fuppofed by many writers on this fubject, that in all animals, whatever may be their fize, the degree of danger is confiderably greater, if they fhould be much frightened on the occafion, the proftration of ftrength produced by fear being conjectured to facilitate in a peculiar manner the pernicious operation of the venom. When a dog is bitten fuddenly and unexpectedly, he is, *cæteris paribus*, much lefs hurt than when he has received the injury in a conteft with the reptile, whofe very afpect has more or lefs alarmed him. The bite of the viper is thought to prove generally more or lefs fevere, in proportion to the heat of the weather.

The danger of the injury depends lefs upon the laceration of the parts, which, however, is confiderable, than upon the kind of venomous inoculation with which it is attended. The fymptoms which are excited come on almoft immediately. The perfon who has received the bite fuffers acute pain, and an inflammatory fwelling fpreads up the limb with remarkable rapidity, accompanied with a tendency to gangrene, as is indicated by the appearance of livid fpots. Affections of the heart, attended with great weaknefs and vertigo, denote that the action of the poifon extends to the whole fyftem. But thefe general effects do not arife, as Fontana wrongly imagined, from the venom having a power of coagulating the blood in the veffels, but in all probability from its operation upon the nervous fyftem.

The beft plan of counteracting the baneful effects of the bite of the viper confifts in introducing a few drops of the fluid muriate of antimony into the wound, and a fmall hair pencil may be ufed for the infertion of the cauftic, if the punctures fhould happen to be deep. Indeed, when the bottom of the wound cannot be cauterized without dilating it, the latter ftep is deemed proper by the generality of furgical writers. The furrounding parts may be rubbed with a liniment compofed of hartfhorn and olive-oil; and cordial medicines are to be exhibited, efpecially ammonia.

The amputation of the bitten part is rather too fevere a mode of preventing the ufual ill confequences of the bite of a viper to deferve recommendation. The ancients, with a view of counteracting the introduction of the poifon into the body, were accuftomed to apply a ligature round the limb above the injury; but it is a painful expedient, becaufe it cannot hinder the abforption of the venom, and the general conftitutional affection, unlefs the band be put on with fufficient tightnefs to impede the circulation. This, however, is the method which was adopted by Ambroife Paré, after he had been accidentally bitten by an adder.

The moft important object in the treatment is the prompt application of remedies; for the introduction of the virus into

into the conftitution ought to be prevented, if poffible. This is more likely to be accomplifhed than any aim at neutralizing the venomous fluid, after its effects have extended to the whole animal economy.

Even when the bite of a viper is entirely neglected, it very rarely proves fatal to the human fubject. In many cafes, the patients have recovered favourably under the mere ufe of olive-oil and of ammonia. Thefe two medicines have been recommended as fpecifics both in the Tranfactions of the Royal Society, and by the celebrated Bernard de Juffieu; and amongft the cafes in proof of their efficacy, authors ftill continue to quote the example of a dealer in vipers, who was quite indifferent about being bitten by thefe animals. He ufed to bathe the part in olive-oil, and at the fame time drink feveral ounces of this fluid. And in another inftance, which is frequently cited, a ftudent of botany, while herborizing, was bitten by a viper in a place where no medicine was at hand, except the eau de luce. Juffieu, who was prefent, introduced a few drops of this remedy into the wound, and adminiftered a tea-fpoonful of it internally in a glafs of water. The eau de luce is nothing more than the liquor ammoniæ, containing a fmall quantity of the oleum fuccini.

In France, and in other parts of the continent, the eau de luce is ftill looked upon as the internal medicine, on which moft reliance can be placed.

In this country, arfenic, in ftrong dofes, has been particularly recommended for its beneficial effects in counteracting the operation of the poifon of fnakes. The Tanjore pill, which has long been famous in India for its virtues in preventing the fatal fymptoms arifing from the bites of ferpents in hot countries, was known to have arfenic as one of its ingredients. Mr. Ireland, an army furgeon, happened to be at St. Lucia, in the Weft Indies, when feveral men of the 62d regiment were bitten by the coluber carinatus of Linnæus, the bite of which had already proved quickly fatal to feveral men of the fame corps. Mr. Ireland immediately adminiftered Fowler's folution of arfenic in ftrong dofes, and the refults of the cafes, in which he had an opportunity of trying it, were highly favourable to the practice, as the men's lives were preferved by it. (See Medico-Chir. Tranf. vol. ii. p. 393, &c.) Perhaps the prompt excifion of the bitten part, or the free ufe of the actual cautery, fhould alfo be invariably put in practice, for the bites of the more deadly kinds of ferpents, in conjunction with the exhibition of arfenic. But the ordinary confequences of the bite of a common adder are not ferious enough to require fo fevere a proceeding as the excifion or amputation of the parts would often be. Some obfervations on the ftructure of the viper will be found in the article Coluber, and other remarks on the bite of this animal will be feen in the articles Poison and Viper.

The worft poifoned wounds ever met with in this climate are thofe produced by the bite of a mad dog, and other rabid animals; but for a particular account of this highly interefting fubject, we muft refer to Hydrophobia.

Wounds of different Parts of the Face, Eye, Eye-lids, Ears, &c.—The countenance being the part in which any deformity is peculiarly confpicuous, it is always a great defideratum, in cafes of wounds of the forehead, cheeks, nofe, lips, &c. to prevent as much as poffible the formation of ugly fcars. Hence it is an invariable maxim to endeavour to heal wounds of the face by the firft intention.

As cuts of the face can hardly be very deep, adhefive plafter is generally fufficient for holding their oppofite edges together; but when the wound is fituated in the lips, thefe parts are fo inceffantly in motion, that furgeons find it beft to maintain the fides of the divifion in contact by means of the twifted future, a defcription of which is given in the article Harelip.

When the edges of a wound of the lips are much contufed and lacerated, fome authors recommend them to be pared off, in order to increafe the chance of union, and leffen the disfigurement of an uneven cicatrix.

Punctures of the tranfparent cornea of the eye are in themfelves much lefs ferious accidents than fimilar injuries of the fclerotic coat, which are almoft unavoidably combined with a wound of the choroides and retina. Hence, the latter cafes are frequently followed by a confiderable degree of inflammation. Sometimes the cryftalline lens itfelf is injured, and afterwards grows opaque.

Incifions made in the tranfparent cornea with very fharp inftruments may not give rife to any ferious confequences; and notwithftanding the efcape of the aqueous humour, the cryftalline lens and vitreous humour may remain in their natural fituation. The form, thicknefs, and denfity of the cornea are circumftances which produce a fpontaneous approximation of the edges of the wound to each other, and which, in fact, are extenfively in contact. But the coaptation is rendered very exact, and a quick re-union much promoted, by drawing down the upper eye-lid, fo as to fhut the eye; in which ftate, the cartilaginous tarfus of the upper eye-lid makes an uniform compreffion on the cornea, in a manner which is extremely ufeful. Cuts of the fclerotica are not in general fo fimple. The choroides and retina may be at the fame time either divided or expofed. In the firft cafe, the expulfion of the whole of the vitreous humour, and a total diforganization of the eye, are to be apprehended from the immediate fpafmodic contraction of the mufcles of this organ; and, in the fecond, a violent and dangerous ophthalmy is to be expected. When, in the inftance of a large wound of the fclerotica, choroides, and retina, the contents of the eye-ball are difcharged, the organ inflames, and gradually fhrinks into a much fmaller mafs, which is moveable, and capable of fupporting an artificial eye.

Contufed wounds of the eye-ball are moftly followed by a deftruction of the functions of the organ, either in confequence of the concuffion of the retina, or of the inflammation to which thefe injuries ufually give rife. However, in a few cafes, even contufed wounds of the eye have united very favourably, and without the lofs of vifion. Sometimes the folution of continuity extends through the fclerotica, while the conjunctiva itfelf is not ruptured. Delpech affirms, that he has feen feveral fuch cafes, in which the latter membrane prefented the appearance of an ecchymofis oppofite the divifion of the fclerotica, and confined the humours of the eye, which otherwife would have been loft. Précis des Maladies Chir. tom. i. p. 349.

Nothing is more likely than gun-fhot wounds to produce a violent concuffion of the retina, and an incurable paralyfis of this nervous expanfion. The fmalleft particle of lead, which either ftrikes or penetrates the eye-ball, may occafion thofe effects. Every other fevere contufion of the eye may act in the fame way. When the extravafation of blood originating from an accident of this kind is not attended with a ferious concuffion of the retina, the effufed blood will be abforbed, and the functions of the eye reftored.

In all cafes of wounds of the eye, fays M. Delpech, there are three fundamental indications; firft, to prevent the expulfion of the vitreous humour and cryftalline lens; fecondly, to promote the quick re-union of the wound by placing its edges very accurately together; and thirdly, to do every thing in our power to avert inflammation. The two firſt objects cannot be fulfilled without keeping the eye-lids continually cloſed. The prompt re-union of the wound is one of the moſt effectual means of preventing inflammation; but when this affection cannot be entirely hindered, it is to be reſiſted by the kind of treatment which is explained in the article OPHTHALMY.

Wounds made with pointed inſtruments may paſs through the eye-lids into the orbit, and thence through the thin bones which compoſe this cavity into the brain; or the weapon may penetrate directly between the eye-ball and ſide of the orbit into the brain. Injuries of this deſcription generally prove fatal on the ſpot, though ſometimes the patient lingers for a few hours.

In many inſtances, an injury by a ball, inflicted in the neighbourhood of one eye, produces paralyſis of the other. "Pierre Rouſſillier, of the 25th regiment of the line, in the ſervice of Napoleon, (ſays Mr. Hennen,) was wounded on the 18th of June, at Waterloo. The ball entered the right eye; the left, though not in the ſlighteſt degree injured to appearance, was completely blind. Rare, however, are the caſes where death does not follow all wounds, particularly ſmall punctured ones, going directly forward into the orbit, as this did. I felt under the zygoma, and all along the neighbourhood of this poor fellow's wound; but in the puffy ſtate of the parts could not detect the courſe of the ball. He himſelf was confident it had gone into his brain. He returned to France convaleſcent. Garengeot (Traité des Operations, vol. iii. obſ. 20.) gives us an intereſting caſe from the lectures of Petit, in which a ſoldier received a wound towards the great angle of the eye. It was deemed but of little conſequence, and healed under the common hoſpital treatment. The man expreſſed a wiſh to leave the hoſpital, although cautioned by the ſurgeon, and had ſcarcely reached the door when he was ſeized with rigors, obliged to return, and died in two days. On diſſection, the ball was found lodged under the ſphenoid cells and the hole of the optic nerve. The effect on this man's ſight is not mentioned." Hennen's Obſ. on Military Surgery, p. 360.

Wounds of the lower part of the forehead, or eye-brow, are ſometimes followed by the diſorder named *ptoſis*, in which the upper eye-lid hangs down more or leſs over the eye; but more commonly they give riſe to an oppoſite complaint, called *lagophthalmus*, in which, from a contraction of the cicatrix, the ſkin is drawn up, and the upper eye-lid cannot be made to cover the eye. See thoſe terms.

Wounds of the eye-brows ſometimes cauſe a ſpecies of blindneſs named the gutta ſerena. This conſequence is commonly thought to be owing to an injury of the nervous filament, which comes out of the orbit at the notch in the ſuperciliary ridge. It is very probable, however, that the affection of the eye is not altogether dependent on the injury of the nerve; for the blindneſs very often occurs when the cut is not ſituated near the track of the nerve, and frequently does not occur when the nerve is known to be wounded. According to Richter, it is when the wound is nearly or quite healed that the event is moſt likely to happen.

Scarpa has ſet down the gutta ſerena, ariſing from an injury of the ſupra-orbitary nerve, as abſolutely incurable; but we know that this ſtatement is not altogether correct; for Mr. Hey has recorded in the Med. Obſ. and Inquiries, vol. v. an example of amauroſis which got well, though it originated from a wound of the eye-brow. See GUTTA *Serena*.

Mr. Hennen ſays, he has met with one or two caſes of amauroſis from wounds of the ſupra-orbitary nerve. The perfect diviſion of the nerve did no good; but after ſome time the eye partially recovered. On Military Surgery, p. 366.

Wounds of the eye-lids ſcarcely admit of an effectual application of adheſive plaſter, and their edges are generally brought together with a ſuture. There are ſome practitioners, however, and amongſt them is M. Delpech, who conſider the uſe of ſutures, even in theſe caſes, quite unneceſſary. Précis des Maladies Chir. tom. i. p. 346.

Sabre-ſtrokes, directed obliquely downward againſt the face, very often produce a wound with a flap, which ſhould be immediately laid down in its proper ſituation again. When the flap is large and muſcular, Richter thinks it beſt to uſe a ſuture at one or two points, as the ſtrips of adheſive plaſter are apt to become diſplaced, eſpecially if the patient is reſtleſs, and then the flap of ſkin, not being ſufficiently retained, ſlips downwards, and the part is not healed without deformity. However, it certainly has always appeared to us that a ſuture in this inſtance may be diſpenſed with, if care be taken to aſſiſt the effect of the adheſive plaſter with a compreſs and bandage. Firſt Lines of the Practice of Surgery, p. 291. edit. 3.

Sabre-wounds ſometimes break and ſplinter the bones of the face. The fracture, however, ſeldom extends far, becauſe moſt of theſe bones are ſoft and ſpongy. Notwithſtanding ſuch injury of the bones, the wound of the ſoft parts frequently admits of being united, if care be taken to extract all the ſplinters, and put the ſurfaces of the diviſion of the bones as evenly together as poſſible. Unleſs the fragments are quite detached they ſhould never be taken away, but be replaced as well as circumſtances will permit. Their removal is not an eaſy matter, it occaſions an unpleaſant disfigurement, and experience proves that all diviſions of the bones of the face heal with particular readineſs. (Anfanſgr. der Wundarzneykunſt, b. ii. p. 244. edit. 3.) A very terrible ſabre-wound of the face is recorded by Mr. Hennen. The weapon ſtruck an officer nearly acroſs the eyes, one of which it deſtroyed; it then divided the parts downwards and inwards to ſuch an extent, that the pharynx could be ſeen. Yet the injury healed in a very favourable manner, as indeed do all wounds of the face, owing to its great vaſcularity. See Obſ. on Military Surgery, p. 370.

In ſome horrid caſes, where the lower jaw is ſwept away by a cannon-ſhot, life is preſerved; but, in general, the patient ſinks under the accumulated tortures of his ſituation. "It is ſtill, however, our duty," as Mr. Hennen obſerves, "to try every expedient; and after the ragged parts and ſplinters of bone are removed, the veſſels within reach ſecured, and the ſuppurating proceſs fairly eſtabliſhed, we may endeavour to aſſiſt nature, faithfully following any effort ſhe may make to fill up the chaſm, but without allowing ourſelves to count upon a ſhowy or complete cure." (Op. cit. p. 373.) This gentleman ſaw a horrid-looking caſe, in which nearly one half of the face was carried away by a round ſhot at Waterloo, in a very fair progreſs of contraction. Larrey has likewiſe recorded a ſimilar cure; and the writer of this article once witneſſed in Holland a moſt extraordinary recovery of the ſame nature. It was the caſe of a ſoldier, wounded at the aſſault of Bergen-op-Zoom, in 1814, who was afterwards brought into one of the military hoſpitals of Oudenboſch. All the lower jaw, and a large part of the upper, were in this inſtance completely torn away. There was very little hemorrhage, and no veſſels required the ligature.

For ſome obſervations on wounds of the tongue, we beg to refer to the article TONGUE.

When a part of the noſe is divided, but not entirely detached, it is the duty of the ſurgeon to replace it as expeditiouſly as poſſible. When adheſive plaſter does not appear to be be capable of securing the part in its proper situation, a suture may be employed. Writers usually advise keeping the nostrils pervious with soft flexible tubes, chiefly with a view of giving vent to the mucus which is secreted by the inflamed Schneiderian membrane, and which, if it could not readily escape, might prove exceedingly annoying to the patient. Putting out of the question Garengeot's extraordinary case, and a few others to which we have already adverted in a previous part of this article, we have many facts on record, proving not only that most incised wounds of the nose admit of union, but also that contused ones, attended with an almost complete detachment of the part, may often be united. In one instance, the cartilaginous portion of a young man's nose was nearly bit off by a horse, the separated piece only hanging by a thin portion of skin; yet after being replaced, and three stitches made, the part was united without any material deformity. Richter's Chir. Bibliothek, 6 band, seite 538, and Cooper's First Lines of Surgery, p. 282. edit. 3.

As the parotid duct passes beneath the integuments of the cheek over the masseter muscle, it is much exposed to wounds, which, if not properly treated, end in what are termed salivary fistulæ. Having considered this subject in a separate article, (see *Salivary* FISTULA,) we shall not dwell upon it at present. A late writer informs us, that in injuries of the parotid duct he has sometimes derived advantage from making the division complete by a clean incision across the duct into the mouth, and closely bringing together the edges of the wound on the outside of the cheek. The natural flow of saliva into the mouth kept the wound from healing up on the inside of the cheek. Hennen's Military Surgery, p. 374.

With respect to wounds of the external ear, experience has fully proved that they are cases which usually terminate favourably. Incised wounds and sabre-cuts of the ear mostly heal extremely well. Ravaton has recorded a case in which the ear united again, although it had been nearly separated from the head; and another instance of such success is mentioned in Cooper's Dict. of Surgery, art. *Wounds*. These and many other facts which might be quoted leave no doubt of the propriety of always making an attempt to unite parts, whenever the least connection between them remains.

Surgical authors differ in their statements about the effects of the total loss of the external ear upon the power of hearing. Thus it is asserted by M. Richerand, that the external ear, which is a sort of instrument calculated for concentrating the rays of sound, may be totally cut off without deafness being the consequence. For a few days after the loss, he says, the hearing is rather hard; but the infirmity gradually diminishes, the increased sensibility of the auditory nerve compensates for the imperfection of the organic apparatus, and the acuteness of the sense is entirely restored. (Richerand, Nosographie Chirurgicale, tom. ii. p. 122. edit. 2.) However, if we are to credit the statement of other writers, the recovery is far less complete than M. Richerand represents it to be. Thus Leschevin notices, that they who have lost the external ear, or have it naturally too flat, or ill-shaped, have the hearing less subtile. The defect can only be remedied by an artificial ear, or an ear-trumpet, which receiving a large quantity of the sonorous rays, and directing them towards the meatus auditorius, thus does the office of the external part of the ear. Prix de l'Acad. Royale de Chirurgie, tom. ix. p. 120. edit. 12mo.

Wounds of the external ear, whatever may be their size and shape, do not require a different treatment from that of the generality of other wounds. The re-union of the divided part is the only indication, and it may be in most instances easily fulfilled by means of methodical dressings. Such writers as have recommended sutures for wounds of the ear, (says Leschevin,) have founded this advice upon the difficulty of applying to the part a bandage that will keep the edges of the wound exactly together. The cranium, however, affords a firm and equal surface, against which the external ear may be conveniently fixed. Certainly, it is not more easy to secure dressings on the nose than the ear; and yet cases are recorded in which the cartilaginous part of the nose was wounded, and almost entirely separated, and the union was effected without the aid of sutures. See Mem. de M. Pibrac sur l'Abus des Sutures, in Mem. de l'Acad. de Chir. tom. iii.

In wounds of the ear, then, we may conclude that sutures are generally useless and unnecessary. As examples may occur, however, in which the wound may be so irregular and considerable as not to admit of being accurately united, except by this means, it should not be absolutely rejected. An enlightened surgeon will not abandon altogether any curative plans; he only points out their proper utility, and keeps them within the right limits. When sticking-plaster, simple dressings, and a bandage, that makes moderate pressure, appear insufficient for keeping the edges of a wound of the ear in due contact, the judicious practitioner will not hesitate to employ sutures.

When a bandage is applied to the external ear, it should only be put on with moderate tightness, since much pressure gives considerable uneasiness, and may induce sloughing of the part. In order to prevent these disagreeable effects, M. Leschevin advises us to fill the space behind the ear with soft wool or cotton, against which the part may be compressed without risk. Op. cit. p. 119.

In the application of sutures, the ancients have cautioned us to avoid carefully the cartilage, and to sew separately, one after the other, the skin of both sides of the ear. They were fearful, that pricking the cartilage would make it mortify, "ce qui est souvente-fois arrivé," says Paré. But notwithstanding so respectable an authority, the moderns make no scruple about sewing cartilages. In wounds of the nose, Verduc expressly directs the skin and cartilage to be pierced at once in applying sutures, and the success of the plan is put out of all doubt by a multitude of facts. The same treatment may also be safely extended to the ear. See Leschevin's Obs. in Op. cit., and Cooper's Dict. of Pract. Surgery, art. *Ear*.

Wounds of the Throat.—As Mr. John Bell has observed, there are several anatomical points which should be well remembered by the surgeon in all cases of wounds about the throat. First, it is to be recollected, that the arch of the aorta lies in the upper part of the chest in front of the trachea; and that where the carotid arteries come out of the chest to go up along the neck, they are scarcely at the sides of the trachea; they rather run before it. But, that as the arteries mount up the neck, they incline more to the side of the trachea; and that at the upper part of the neck, they are entirely behind that tube; for they incline towards the angle of the lower jaw, and having reached it, they begin there to give off their branches both to the head and neck. Hence we see the reason why a wound at the lower part of the neck is very often fatal, while a wound higher up is generally less dangerous. The suicide seldom strikes at the lower part of the neck; and it is from the accidental circumstance of his cutting very high up, near the chin, that the carotids escape.

Secondly, as the same author has explained, it should be remembered, that the carotid artery, the great jugular vein, and the par vagum, or eighth pair of nerves, lie very closely

 connected

connected with each other, being all inclosed in one mass of cellular substance, which forms something like a sheath for them. Now, says Mr. John Bell, since this eighth pair is one of the greatest nerves of the viscera, and since, by experiments upon animals, we know well that a wound of it is more fatal than a wound of the brain itself, this puts an end at once to all questions about the way of managing wounds of the carotid artery, or of the great vein. No doubt these may sometimes be partially wounded and the nerve escape; but, in general, the nerve will be cut along with them; and, at all events, the fatal consequences which would arise from including this nerve in a ligature, make it absolutely necessary that whenever the carotid is tied, it be first carefully separated from every other part. See John Bell's Discourses on Wounds, p. 415. edit. 3.

That the internal jugular vein, or the carotid artery itself, may sometimes be partially injured, without a wound of the par vagum, or the patient instantly perishing, has now been fully proved. The writer of this article knew of a case, which happened in the campaign in Holland in 1814, where the internal jugular vein was ruptured by the passage of a musket-ball down the neck; and yet the patient lived more than an hour after the accident, and when he died it was from suffocation, in consequence of the pressure of a large mass of extravasated blood upon the trachea. M. Larrey has related a very singular case: an officer received a gun-shot wound, which cut the external carotid at its separation from the internal, and in its passage through the parotid gland. Pressure made by an intelligent soldier at the moment, and subsequent bandages, saved the patient. (See Mémoires de Chir. Militaire.) This case is singular, because it is very uncommon for hemorrhage from so large a vessel as the external carotid to be permanently stopped by simple pressure, nor should we recommend the method to be imitated; for there is not in all surgery a better rule than that of trusting only to the ligature in every wound of a great artery. Mr. Hennen, however, informs us, that he knew of an English officer, who was also saved in India from the effects of an arrow wound in the carotid by the same means. (Obs. on Military Surgery, p. 180.) Such a mode of treatment we believe would fail a thousand times in succession; and the alleged cures would be more valuable, if it were always quite impossible to mistake hemorrhage from a branch for a bleeding from the trunk itself.

The writer of this article is acquainted with an army surgeon, in whose veracity he perfectly confides, who states, that he was once called to a soldier who had wounded the trunk of the carotid with a bayonet. The vessel was instantly taken up, and the man's life saved. In a modern publication may also be found another example, in which the carotid burst, and was taken up on the spot by Mr. Fleming, a naval surgeon. See Medico-Chir. Journal, vol. iii. p. 2.

Without positively maintaining, as Mr. J. Bell does, that it is impossible to cut through the trachea so as to open the œsophagus, without wounding the carotid artery, the jugular vein, and the eighth pair of nerves, we join him in believing that such an accident must be exceedingly rare. How then are we to explain the many alleged cures which are said to have been effected, notwithstanding the windpipe and œsophagus are stated to have been both cut through? We are to account for these extraordinary narratives in the manner so well pointed out by Mr. John Bell. "The fact is (says he), that neither the œsophagus nor the trachea is touched in the least degree, but the wound is much above them; for a suicide always strikes immediately under the chin. This wound, as far as I have observed, commonly falls in the line which divides the neck from the chin; that is, the place where the os hyoides lies, and he commonly cuts the os hyoides away from its connection with the thyroid cartilage, or pomum Adami. In that case, the thyroid cartilage, forming the uppermost part of the larynx, is not touched; the rima glottidis lies below the wound quite safe. The wound indeed separates the epiglottis from the glottis; but it leaves the glottis and the larynx quite safe. It only separates the larynx from the root of the tongue; it is properly a wound in the root of the tongue; it is rather a wound of the mouth than of the throat; and when the food comes out, along with spittle and froth, it is by rolling over the root of the tongue." On Wounds, p. 417.

That, however, the trachea and œsophagus may be both cut in a few cases, without immediate death from hemorrhage, we decidedly believe, because there are too many facts on record to admit of any doubt on the subject. See Default's Journal and Saviard, obs. 58. Hennen's Military Surgery, p. 386.

In these high wounds of the throat, it is the superior thyroid artery which is most frequently cut. This vessel, after quitting the external carotid at the angle of the jaw, passes along the side of the upper part of the trachea, inclining forward towards the thyroid gland in its descent, and being therefore much exposed to the edge of the razor. The bleeding from this artery is profuse, and if not speedily stopped is as fatal as hemorrhage from the carotid itself. In some of these cases, the bleeding also proceeds from branches of the lingual artery.

Wounds of the carotid artery, or jugular vein, commonly prove immediately fatal from loss of blood, before any assistance can be obtained. If a surgeon, however, were to arrive in time to render aid, it would be his duty immediately to apply a ligature both below and above the wound of the vessel. This is the only plan which affords any chance of saving the patient's life, and, as we have already noticed, it has actually been done with success in a few uncommon instances, in which the surgeon was not too late. In passing the ligatures beneath either of those vessels great caution is requisite; for the eighth pair of nerves lies close to it, included in the same sheath of cellular substance, and the inclusion of so important a nerve in the ligature would have fatal consequences. Its situation on the outside of the artery, between it and the jugular vein, should therefore be always carefully remembered. According to Richter, the internal jugular vein has actually been tied with success. Small wounds of the same vessel, if we are to credit the accounts of this author, may sometimes be healed by means of a graduated compress, which must be retained on the part with a bandage, or, if that prove irksome, with the finger. One thing, however, is essential; namely, the pressure must on no account be remitted, until the wound in the vessel is closed. Richter's Anfangsgr. der Wundarzn. b. iv. p. 173., and Cooper's First Lines of Surgery, p. 386. edit. 3.

M. Pelletan once saw a wound of the throat, which proved fatal in consequence of hemorrhage from the external jugular veins; and the same eminent surgeon met with another curious instance, in which a boy, who was convalescent after a cut of his throat, suddenly fell down in a state of suffocation and died: on examining the parts after death, it was discovered, that the left side of the epiglottis had been detached from the glottis and root of the tongue, and that in this loose unconnected state it had fallen upon the rima glottidis, and closed it so completely as to cause instantaneous suffocation. See Leveillé's Nouvelle Doctrine Chir. tom. i. p. 342, 343.

Wounds of the trachea are either fimple or complicated. In both defcriptions of cafes, the ufual fymptoms are, an emiffion of air between the lips of the wound, lofs of the voice, and fometimes emphyfema. Such injuries of the windpipe as are not complicated either with hemorrhage, emphyfema, or lofs of fubftance, may for the moft part be eafily cured by means analogous to thofe which are employed for the cure of wounds in general. The re-union is ftill more eafily accomplifhed, when the trachea is divided longitudinally, than when it is cut tranfverfely. If the wound be of a certain fize, and attended with hemorrhage, the firft indication is to tie the bleeding veffels, and, in particular, to obviate the inconvenience and danger which would refult from the infinuation of the effufed blood into the windpipe; an occurrence which has fometimes proved fatal. (Wilmer's Cafes and Remarks in Surgery, p. 92.) In order to prevent fuch an unfavourable event, fome furgical writers recommend the external wound not to be clofed while any oozing of blood continues, fo that this fluid may readily find an external outlet, inftead of falling into the trachea. (Laffus, Pathologie Chir. tom. ii. p. 291.) To us it appears, that the beft mode of preventing the occurrence is to bring the edges of the wound of the trachea into contact by a fuitable pofition of the patient's head, and, if requifite, even by a future.

The greater fenfibility of the larynx, its complicated ftructure, and the number and fize of its blood-veffels, *ceteris paribus*, render wounds of it much more dangerous than thofe of the trachea. In the firft volume of the Mémoires de l'Acad. de Chirurgie in 4to. many cafes may be confulted which furnifh proofs of this obfervation. In general, however, wounds of the thyroid cartilage heal very favourably, when not accompanied with injury of other important parts.

Tranfverfe wounds, dividing only the anterior half of the upper part of the trachea, ufually have a favourable termination, and when the cafes are of this defcription, the carotids and jugular veins for the moft part efcape injury. Gun-fhot wounds of the trachea are more dangerous, but experience proves that they alfo frequently end well.

The greater number of tranfverfe wounds of the trachea, which have not divided this tube completely through, readily admit of cure by the ftrict obfervance of a proper pofition. When the patient's chin is brought downward and forward towards the fternum, and the head is maintained in this pofture with pillows, the edges of the wound in the trachea become fpontaneoufly approximated to each other, and in time will grow together.

The manner in which the employment of futures aggravates the cough, and inflames the wound, often neceffitates the furgeon to withdraw them when they have been applied. It may alfo be truly afferted, that befides the irritation which they create in the trachea as extraneous fubftances, they are (to fay the beft of them) very unneceffary. Nothing has a greater tendency to impede the union of a wound of the trachea than the difturbance of a frequent convulfive cough; and the irritation of futures always increafes this hurtful fymptom in a much greater degree than they can do good by maintaining the edges of the wound in contact. In fact, unlefs the greater portion of the diameter of the trachea be divided, there never can be fuch a fpace between the edges of the wound, that they cannot be brought together with the affiftance of a judicious pofture of the head.

When the patient is much afflicted with inceffant coughing, and the inflamed ftate of the wounded parts appears to operate as the caufe of this difagreeable fymptom, relief is to be obtained from bleeding, and the exhibition of foothing and aperient medicines. In cafes in which no particular local irritation can be fufpected of giving rife to the cough, the furgeon may prefcribe the almond emulfion, fpermaceti mixture, and opium, which will frequently be found remedies of the moft decided efficacy.

In order to prevent the entrance of the difcharge and blood into the trachea in particular inftances, the plan has been tried of making the patient lie on his fide, with his face turned downwards. (See Mém. de l'Acad. de Chir. tom. i. p. 581.) But, although the cafe here referred to ended well, we believe, as already explained, that nothing prevents the entrance of blood or matter into the trachea fo effectually as keeping the edges of the wound of this tube accurately in contact, which is to be principally effected by bringing the chin down towards the breaft. This is an object which is far more difficult of accomplifhment, where the patient lies on his fide, than when he remains, as is moft ufual, upon his back.

When a wound has detached the upper portion of the trachea from the lower one, and it is not immediately fatal from the injury of other important parts, the bleeding veffels are firft to be tied, and the two ends of the trachea are then to be brought into contact. In this fort of cafe, we believe that the employment of a future is warrantable, on account of the immenfe feparation of the divided parts, and the inefficacy of pofition alone to prevent it. But, even in fuch a cafe, one ftitch will be quite enough when the chin is properly approximated to the fternum, and the needle fhould never be introduced through the membranous lining of the windpipe, as it is very fenfible, and much difpofed to inflammation.

The hoarfenefs and weaknefs of the voice, fometimes remaining after the wound is healed, often gradually difappear.

Many furgical writers recommend the patient to refrain from making forcible expirations, and from drawing the head fuddenly backwards, for a certain time after the wound is healed. By fuch caufes, it is afferted, the recent coalefcence of the wound may be eafily deftroyed.

Wounds made with bullets, which ftrike the fide of the neck and lacerate the trachea, have frequently been obferved to terminate well. (Mém. de l'Acad. de Chir. tom. iii. p. 151, &c. edit. 12mo.) Ravaton mentions feveral inftances, which not only got well, but were alfo followed by a recovery of the voice.

Sutures are not applicable to thefe cafes. A ftrict adoption of the pofition recommended above, and the application of an emollient poultice contained in a fine linen bag, are the chief local chirurgical meafures. The ufe of leeches, venefection, faline medicines, and antiphlogiftic remedies of every defcription, will alfo be generally proper. (See Firft Lines of Surgery, p. 387. edit. 3.) Opium is likewife not to be forgotten as an extremely ufeful medicine in cafes of wounds about the throat: it not only appeafes the cough with which fuch injuries are often accompanied, but tends to quiet the great mental and nervous anxiety which in examples of attempted fuicide exifted previous to the infliction of the wound, and generally continues for fome time afterwards in a very aggravated degree. Indeed, many of the unhappy perfons who attempt to deftroy themfelves by cutting their throats, ftill retain for a good while after the failure of the firft attempt, a determination to take another opportunity of accomplifhing their fatal purpofe; hence fuch patients cannot be too clofely watched, and nothing like a razor or a knife fhould ever be put within their reach. The neceffity of a conftant vigilant attendant is alfo

alfo neceffary, in order to hinder the dreffings from being pulled off, and the wound torn open again, by the reftlefs movements or actual violence of the patient.

In cafes in which the whole diameter of the trachea is cut through, the French furgeons have propofed the introduction of a flexible catheter from one of the noftrils into the larynx and trachea, in order to infure a paffage for refpiration, which, they fay, without this means is liable to be completely intercepted when the outer wound is clofed, in confequence of the two portions of the windpipe being drawn away from each and not correfponding. (Richerand, Nofogr. Chir. t. iv. p. 170. edit. 4.) This, however, would not be the practice to which we fhould give a preference; firft, becaufe the introduction of a flexible catheter is a thing which cannot always be accomplifhed with facility; fecondly, becaufe its ufe in this way is conftantly productive of confiderable irritation; and, thirdly, becaufe we deem the employment of a future the beft means of hindering one part of the trachea from becoming feparated far from the other, and thus of infuring a paffage for refpiration.

With refpect, however, to the introduction of a flexible catheter from one of the noftrils into the œfophagus, for the purpofe of giving food and medicines to the patient, without any motion or difturbance of the wounded parts, we confider the method entitled to the higheft praife in all cafes of ferious wounds, either of the larynx, the trachea, or the œfophagus. When a perfon fwallows, the mufcles concerned in the elevation and depreffion of the larynx act in a fudden convulfive kind of manner, and caufe a moft injurious difturbance of the wound. But when nourifhment and medicines are injected into the ftomach through a flexible tube, introduced from one of the noftrils down the œfophagus, this hurtful action of the mufcles is entirely prevented; the inftrument may be kept there without any annoyance or irritation, and the requifite quantity of aliment, and whatever internal remedies may be indicated, can be given with the utmoft convenience. We confider this ufe of flexible catheters as conftituting a very material improvement in the treatment of fevere wounds of the throat. The military furgeon, in particular, fhould never be without thefe inftruments; and whoever has read the relations of M. Larrey, in his Mémoires de Chirurgie Militaire, will fee, that fometimes in bad wounds of the throat, the patient's chance of recovery depends almoft entirely upon the aid to be derived from the fkilful employment of an elaftic gum tube.

Wounds of the œfophagus may either amount to a total or partial divifion of that tube; they may be either with or without a total divifion of the trachea; and with or without injury of other important parts in the vicinity. Hence fuch wounds are fometimes abfolutely fatal; and, in general, when they admit of cure, nature has a greater fhare than art in bringing it about. Some benefit, however, is to be derived from good furgery, and infinite harm may refult from bad.

A total divifion of the œfophagus muft prove immediately fatal. The inevitable fimultaneous injury of other important parts would render fuch a cafe at once mortal. The celebrated Pruffian furgeon, Schmucker, has treated fmall wounds of the pharynx and upper part of the œfophagus with fuccefs. Wounds dividing half or even two-thirds of the tube are alfo ftated to have been cured. (Mém. de l'Acad. de Chir. tom. iii. p. 151. edit. 12mo.) The poffibility or impoffibility of a cure muft obvioufly depend upon what other parts of confequence are injured.

Incifed wounds, which divide the front of the œfophagus, muft derive additional danger from the fimultaneous divifion of the whole circle of the trachea; and, indeed, fo much would the internal jugular vein, par vagum, and carotid artery, be expofed to the edge of the knife in a cut of this kind, that it is difficult to conceive how they can ever efcape. Mr. John Bell, as we have feen, believed that they never could; and were it not for the many examples publifhed, fome of them by fuch a man as Default, and for an inftance which was lately in St. Bartholomew's hofpital, we fhould have joined Mr. J. Bell in thinking, that all reports of this kind were miftakes, arifing from the wound extending through the root of the tongue into the mouth, and not actually injuries of the œfophagus itfelf.

A punctured wound, penetrating the fide of the œfophagus, may not be complicated with injury of the trachea, and therefore may not be attended with fo much peril as an incifion. But although ftabs injuring the œfophagus are not regularly and certainly mortal, they are always to be regarded as dangerous cafes.

Should the cafe be one of thofe fortunate incifed wounds which leave the great veffels uncut, though the injury of the œfophagus be complicated with a complete divifion of the trachea, the furgeon can leffen the fpace between the edges of the wound in the œfophagus by bringing the divided portions of the trachea together. This effect muft refult from the manner in which the pofterior part of the windpipe is connected with the œfophagus. But for this purpofe, a future is only to be ufed in fuch a ftate of the wounded trachea as amounts to a total divifion of the tube; for in all other cafes, a proper pofition of the head, and the ufe of adhefive plafter to the external wound, fhould be the means with which the furgeon ought to be content, with a view of bringing the margins of the wound of the trachea near to each other.

In cafes of wounds of the œfophagus, it was recommended, as long fince as the time of Ravaton, to inject nourifhment and medicines into the ftomach, through a fmooth tube of a fuitable fize, introduced down the pharynx. In one cafe of paralyfis of the œfophagus, which occurred in this country, a fmall frefh eel-fkin was paffed down this canal, by means of a whale-bone probang, in order that medicines and food might be injected into the ftomach. (Hunter, in Tranf. for the Improvement of Med. and Chirurgical Knowledge.) The many cafes, however, in which Default advantageoufly employed an elaftic gum catheter for the fame objects had a principal influence in eftablifhing the practice. The inftrument was introduced through one of the noftrils, and was often left in the œfophagus for feveral days together. (See Œuvres Chir. de Default par Bichat, tom. ii.) The introduction of elaftic gum catheters down the pharynx and œfophagus is not only highly neceffary in examples of paralyfis, and wounds of thofe paffages, but it is an exceedingly ufeful practice in wounds of the trachea, where the convulfive action of the mufcles in deglutition would otherwife create a very hurtful difturbance of the injured parts. (Firft Lines of Surgery, p. 38, 39. edit. 3.) The practice is alfo fometimes abfolutely neceffary in many complicated wounds about the face, fuch as thofe produced by the difcharge of a piftol into the mouth, and attended with extenfive laceration of the tongue, cheeks, and fauces, and a comminuted fracture of the lower and upper jaw-bones. We believe, indeed, that in all fractures of the lower jaw, the introduction of a flexible catheter from one of the noftrils into the œfophagus is an extremely judicious meafure, becaufe the action of deglutition has a greater effect in difplacing the broken bone and difturbing the procefs of union than any other circumftance.

Gun-ſhot wounds of the neck ſometimes occaſion an immediate loſs of the uſe of the arm on the affected ſide; a circumſtance which may in general be accounted for by the injury of ſome of the cervical nerves, in their deſcent to and from the axillary plexus. See Hennen's Military Surgery, p. 378, and Thomſon's Report of Obſervations made in the Military Hoſpitals in Belgium, p. 75, 76.

Wounds of the Thorax, or Cheſt.—Some of theſe injuries penetrate the cavity of the thorax; others are more ſuperficial, only affecting the ſkin and muſcles, and not extending through the pleura coſtalis. When the latter caſes are produced by ſharp-cutting inſtruments, and the only indication is to accompliſh an union of the divided parts, as happens in inciſed wounds of the ſkin, latiſſimus dorſi, pectoralis major, &c. ſuch injuries are not materially different from any ſimple wounds of other parts of the body, and require a ſimilar mode of treatment.

But where much violence has been applied to the parietes of the cheſt, and the concuſſion has operated ſo forcibly as to affect the heart, lungs, and other important organs, the wound, although ſimple in appearance and not penetrating the cheſt, may nevertheleſs be followed by alarming ſymptoms, either at firſt or conſecutively; ſuch as inflammation of the lungs, ſpitting of blood, and difficulty of breathing, as is frequently obſerved in contuſed and gunſhot wounds of the parietes of the cheſt. A violent blow on the dorſal vertebræ is alſo ſaid to have given riſe to a dilatation of the heart, and an aneuriſm of the aorta. Laſſus, Pathologie Chir. tom. ii. p. 305.

Thus profeſſor Thomſon, in his account of the wounded whom he obſerved after the battle of Waterloo, remarks, "We ſaw more inſtances than one in which a ball, in paſſing acroſs a portion of the parietes of the thorax, without penetrating that cavity, had excited an alarming and dangerous degree of inflammation of the pleura. In one of theſe, the ball had taken an oblique direction along the lower part of one of the ſides of the cheſt. In another it had ſtruck againſt a ſtrong leathern belt that was ſuſpended over the right ſhoulder, made a deep indentation in this belt without penetrating it, and produced a ſeverely contuſed wound at the inner extremities of the firſt and ſecond ribs of the right ſide. This patient ſuffered much from inflammation. The injured portions of the ribs had exfoliated and come out, and the motion of the lungs in inſpiration and expiration was perceptible from the ſinking and riſing of that part of the parietes which had been deprived of its bony ſupport. In another remarkable caſe, the ball entered above the middle of the clavicle, and paſſed out at a point directly behind. Neither at the firſt, nor at the time we ſaw this caſe, was there any reaſon to believe that the ball had wounded the pleura. Inflammation, however, of this membrane came on, which terminated in ſuppuration. The operation for empyèma was performed, and about four pints of pus evacuated." Reports of Obſ. in the Mil. Hoſpitals in Belgium, p. 82.

In wounds of the cheſt, it is often difficult to pronounce with certainty whether they penetrate into the ſac of the pleura; but all doubts with regard to this point are removed the moment we obſerve air coming out of the wound upon coughing. That the lungs have been wounded may be inferred with nearly equal correctneſs in every caſe, in which a perſon ſpits blood immediately or ſoon after receiving a wound of the cheſt.

It rarely happens that a wound penetrates the cavity of the thorax without producing more or leſs injury of the lungs, and the danger of the latter accident is in proportion to its depth, its ſituation, and the ſize of the weapon with which it was inflicted. A wound of the lungs with a ſmall ſword ſeldom gives riſe to much effuſion of blood in the cheſt, unleſs ſome of the large veſſels of thoſe organs happen to be hurt. Putting this circumſtance out of preſent conſideration, the uſual ſymptoms which the patient ſuffers are, a ſpitting of blood, cough, and difficulty of breathing, ſucceeded by a good deal of ſymptomatic fever.

"To diſcover whether the wound has injured the lungs or not, (ſays a late writer,) is a point which has given to the older ſurgeons great room for employment of their ingenuity in deviſing poſſible caſes, and has occaſioned no ſmall waſte of time and wax-tapers in aſcertaining the exit of air through the paſſage. A practical ſurgeon will require but little inveſtigation; bloody expectoration *immediately* on receiving the wound, and the terrible ſymptoms of dyſpnœa, ſenſe of ſtricture and ſuffocation, inſupportable anxiety and faintneſs which ſucceed, ſoon enough diſcover the fact; and if by good fortune no intimation is given in this way, happy is the ſurgeon, and thrice fortunate the patient.

"The immediate danger in wounds of the lungs is either from debility from hemorrhage, or ſuffocation from the blood flowing into the air-cells and cavity of the thorax. The effuſion of air forming emphyſema is alſo a troubleſome, but (as Mr. Hennen believes), taking it abſtractedly, is not a dangerous ſymptom of thoſe injuries; neither (ſays he) is it by any means ſo frequent as has been ſuppoſed. The ſymptoms that I have now enumerated, whether ſingle or in combination, may be deemed the primary effects of wounds of the thorax. Violent inflammatory affections of the lungs and the membranes ever ſubject to relapſe; long and tedious ſuppurations and exfoliations of the bones are the ſecondary, and though not ſo rapidly fatal are often as certainly ſo as the others. Diſeaſes which, although we cannot ſtrictly call them pulmonary conſumption, agree with it in many points, particularly in cough, emaciation, debility, and hectic, are often the conſequences." Obſ. on Military Surgery, p. 395.

When the weapon is broad, and it has entered the ſubſtance of the lung, the hemorrhage is conſiderable; blood is immediately extravaſated in the cavity of the thorax, and alſo flows out of the external wound; the patient has a violent paroxyſm of coughing, in which ſome of the blood is ejected from the mouth; the air comes out of the cheſt with a hiſſing noiſe; and if the outer wound be not parallel to that of the lungs, emphyſema takes place. As we have already ſtated, the danger of ſuch an injury depends upon the depth of the wound, and the ſize of the veſſels which are opened. Some patients recover, while others die inſtantly, or in a very ſhort ſpace of time.

As an intereſting author remarks, it is a thing really wonderful, "that the thorax, containing the heart, lungs, and great veſſels, ſhould be ſo often wounded with ſo little danger. Many no doubt die, but numbers eſcape; for a wound of the ſubſtance of the lungs is far from being mortal. The blood may ſuffocate the patient; the fever and pain may waſte him; he may die of the inflammation, or of the oppreſſion of the lungs; or there may be time for a large ſuppuration, or a lingering hectic to cut him off; but ſtill, if his wound be only in the edges of the lungs, he is in ſome degree ſafe. He is only in danger when the thick ſubſtance of the lungs is perforated, and falls into abſceſs, or when the root of the lungs is wounded; for there the large veſſels of the lungs being opened, the great effuſion of blood, like that from a wound of the heart itſelf, muſt kill, even by the quantity of blood loſt to the general ſyſtem. But beſides, this blood, being thrown into the

trachea

trachea, deluges the lungs; the patient fpits up a frothy blood; blood, inftead of air, occupies the bronchiæ; fo that he ftruggles for breath but a few moments, and then expires." John Bell's Difcourfe on the Nature and Cure of Wounds, p. 257. edit. 3.

We fhall next confider the treatment of penetrating wounds of the cheft. In thefe cafes, the patient may die inftantaneoufly of internal hemorrhage and fuffocation; or he may be cut off by the effects of inflammation within the cavity of the thorax. If (fays Mr. John Bell) the patient be fpitting blood and breathing high, but not much oppreffed, or his oppreffion increafing very flowly, there are hopes that he may be faved. If there be no great veffel wounded in the lungs fo as to fuffocate him at once, it is probable that the fmaller veffels which are opened by the wound will gradually ceafe to bleed; and after four or five days of alarming cough, with bloody expectoration, that fymptom will ceafe; and in order that he may the fooner be relieved from his danger, *he muft be bled very freely*. Let it be the intention to reduce him very low by quick bleedings; and let thefe bleedings (fays Mr. John Bell) have the effect of continued internal hemorrhage, without the dangers of it. Let them deprefs him to the fame low condition to which the inward bleeding would moft likely have brought him; and the fyftem being emptied in this direction, there will be lefs danger of immediate fuffocation in the lungs, and but little fear of the fucceeding inflammation rifing too high. It is only by thefe repeated bleedings that the patient can be faved: the vafcular fyftem muft be kept low in action, and fo drained as to prevent the lungs from being oppreffed with blood.

One thing (continues the fame author) is very clear, that if the furgeon bleed only when the cough and bleeding from the lungs return, he never can do wrong. The patient, lying ftruggling before him, is to lofe a given quantity of blood; if it be allowed to flow out into the lungs he may be fuffocated; if it be drawn from the arm, this fuffocation is prevented. If he be kept low enough by bleeding, there will be no blood to fpare for this extravafation into the lungs, &c. (Op. cit. p. 259, 260.) We repeat, in all cafes of penetrating wounds of the cheft, and efpecially in injuries of the lungs, the free ufe of the lancet is the only thing which can be depended upon in the early part of the treatment. By it, internal hemorrhage is reftrained; and by it, the dangers of the fubfequent inflammation of the thoracic vifcera are to be averted. The records of furgery furnifh abundant proof of the neceffity of fuch practice, and the extent to which the bleeding muft be carried is fometimes furprifing. Thus, in a cafe in which a mufket-ball had entered the left fhoulder, paffed through the lungs, and come out below the left nipple, a profufe hemorrhage of arterial blood took place from the mouth, and threatened immediate fuffocation. This hemorrhage was checked by repeated bleedings, which were reforted to on every frefh attack of the hemorrhage, and pufhed till relief was obtained. Leeches were applied to the fide in great numbers, and the antiphlogiftic plan of treatment was ftrictly purfued. Two hundred and fifty ounces of blood were in this cafe drawn off by the lancet in eighteen days. (See Thomfon's Reports of Obf. made in the Military Hofpitals in Belgium, p. 86.) In every inftance of a penetrating wound of the cheft, and more particularly when the lungs are injured, the firft bleeding fhould be copious. As Mr. Hennen recommends, from thirty to forty ounces of blood fhould be taken from the arm by a large orifice. If the patient fhould faint, we ought not to adminifter cordials to him, but allow him to revive gradually. We fhould avail ourfelves of this opportunity of extracting without pain all foreign bodies within reach, whether cloth, ball, iron, wood, fplinters of bone, &c. Should there be reafon to think that fuch extraneous fubftances are lodged, and that by an enlargement of the orifice of the wound they might be extracted, the practice ought to be immediately adopted.

The next object is to drefs the wound itfelf. "If it is a gun-fhot (fays Mr. Hennen), a light mild dreffing will be fufficient; but if incifed, the lips of it fhould be clofed at once, and this treatment will be found to afford the moft certain preventive to emphyfema (fee EMPHYSEMA), future hemorrhage, and collections of matter. (See EMPYEMA.) I fcarcely recollect an inftance where it was neceffary to remove the adhefive ftraps, or (where it was a gun-fhot) the ufual dreffings. We now lay the man down, and let him remain as quiet as poffible, and in as cool and airy a fpot of the barn, church, or hofpital, as we can find. He will often require no farther aid; but if the cafe is very fevere, he will probably lie for fome hours in a ftate of comparative eafe, till the veffels again pour forth their contents, and induce frefh fpitting of bloody froth, and a repetition of all the fymptoms of approaching fuffocation. The lancet muft again be had recourfe to; and if by this management, repeated as often as circumftances demand, the patient furvives the firft twelve hours, hopes may begin to be entertained of his recovering from the immediate effects of hemorrhage. In the after-treatment of a wound of the nature here defcribed, we fhall be confiderably affifted by the aid of medicine; but until the danger of immediate death from hemorrhage is over, we muft not think of employing any thing except depletion by the lancet: it, and it only, can fave the life of the wounded man." Hennen's Obf. on Military Surgery, p. 398.

When the paroxyfms of pain, the fenfe of fuffocation, and return of hemorrhage, fays Mr. Hennen, have become more moderate, and recur at longer intervals, we may have recourfe to means of lefs immediate influence, and fpare the lancet. In this view, the moft powerful medicine that we can adminifter is the different preparations of digitalis, in fuch form as may beft agree with the patient; and if the pain and efforts to cough are fevere and fpafmodic, we muft have recourfe to the aid of opiates. To this courfe of medicine fhould be added a rigour of diet, amounting to the total prohibition of every thing folid, and admitting of fluids only of the mildeft nature and leaft irritating quality; and even thofe in fmall quantities, and duly acidulated. Should we be fortunate enough to preferve our patient during the firft fix or feven days, a relaxation in this rigour may be cautioufly admitted; but a departure from the general plan, or an omiffion of bleeding on the rifing of the fymptoms, can only tend to accelerate the event that our efforts are defigned to counteract. Mild faline purges, and an emollient enema, fhould be occafionally adminiftered if required, and the patient kept in a ftate of the utmoft quiet and feclufion from all external impreffions, and in a cool atmofphere. (Op. cit. p. 400.) The plan of exciting a counter-irritation on the furface of the cheft, by means of blifters, fhould alfo never be omitted, when much cough and pain in the breaft continue after bleeding has been fully practifed. In fome examples, the inflammation occafioned by penetrating wounds of the cheft terminates in fuppuration within the lungs, or the fac of the pleura. The fymptoms, however, which indicate fuch an occurrence, and the mode of treatment, are fo amply explained in another part of this work (fee EMPYEMA), that we fhall not enter into the fubject again.

There is one circumftance which fometimes deceives the furgeon,

furgeon, and leads him to fuppofe that the cafe is a penetrating wound of the thorax when it is not fo. We allude to the occafional examples in which a mufket-ball pierces the fkin and mufcles on the outfide of the cheft, runs round the ribs, and makes its exit nearly oppofite the point of entrance. Here the abfence of bloody expectoration and other fymptoms of injured lungs, together with the direction of the commencement of the track of the ball, will fometimes convey ufeful information to the difcerning practitioner.

There is alfo another fource of deception as to the actual penetration of balls into the cavities of the body: this is when they ftrike againft a handkerchief, linen, cloth, &c. and are drawn out of the wound unperceived in a fold or pouch of thofe materials. M. Larrey, Mr. Hennen, &c. have publifhed examples of the occurrence.

Wounds of the cheft are fometimes complicated with the lodgment of extraneous fubftances in that cavity, and this fometimes without occafioning fatal confequences, either immediately or fubfequently. Thus Mr. Hennen informs us, that in examining the bodies of foldiers who have died from thofe injuries, he has frequently found pieces of wadding, of clothes, fpiculæ of bone, and balls, and, in one cafe, fome charpie ufed as a dreffing, either loofe in various parts of the lungs, or lying in facs, formed by a depofition of coagulating lymph. In fome more fortunate patients who recovered, fuch matters were difcharged or extracted from the wounds; and in certain other lucky examples they were ejected by the convulfive efforts to cough, which their irritation had excited. (Obf. on Military Surgery, p. 390.) The fame author relates the following interefting cafe, to prove that a much larger mafs than a bullet may pafs even through the lungs, without doing away all chance of recovery.

A foldier of the guards was wounded through the thorax at Waterloo, between the third and fourth ribs of the right fide. On his arrival at Bruffels, he was placed in an hofpital and dreffed. Nothing remarkable occurred for the firft five days; and the only fingularity in the appearance of the wound was its large fize, capable of admitting three fingers conically placed. Blood and air were freely difcharged from it. On turning the man to examine him, and renew the dreffings, a tumour was difcovered on the fcapula, from which was extracted his breaft-plate, about two-thirds of which were rolled up by the force of the blow into a figure fomewhat refembling a candle-extinguifher, with the mufket-bullet contained within it. The other third was broken off; but it had alfo paffed through the wound, and was extracted. The man furvived the injury three weeks, and afforded great hopes of his perfect recovery; but in a guft of paffion, he one night tore the dreffings off his wound, and was found dead the next morning. The body was not examined. Op. cit. p. 392.

Balls have been found in the fubftance of the lungs twenty years after their entrance, the patient being all that time in perfect health, without any fymptom characterizing the peculiar fituation of fuch foreign bodies. There are alfo on record inftances in which a ball has rolled about in the cavity of the thorax on every motion of the body. (See Baron Percy's Manuel do Chirurgien d'Armée, p. 25; Magatus's Bibliotheca Chirurgica; and Hennen's Military Surgery.) In general, however, balls lodged in the thorax become as it were encyfted and fixed by the depofition of coagulable lymph around them, and the formation of a fort of fac.

Several authors have noticed, that when a penetrating wound of the cheft is of a certain fize, a portion of the lungs fometimes forms a protrufion between the ribs. In the majority of fuch cafes, there can be no doubt of the propriety of immediately reducing this fort of hernia, and keeping it fo replaced by means of a fuitable apparatus. We learn, however, from the obfervations which have been collected on this fubject, that the protruded part of the lung has fometimes been tied, or cut away, without any ill confequences. Fabricius Hildanus records the cafe of a man who was wounded with a fword between the fifth and fixth ribs, near the fternum, and in whom a piece of lung protruded. On examination it prefented a livid appearance, and the difcoloured part was therefore cut away with a heated knife. The reft was reduced, after feparating the two ribs, from each other, as far as poffible, by a wooden wedge. Notwithftanding this extraordinary method of treatment, the patient foon recovered, and lived without experiencing any oppreffion in refpiration. See Centur. 2. Obf. 32. p. 108.

The livid appearance of the lung, as M. Laffus obferves, arifes from its expofure to the air, and the manner in which it is ftrangulated between the two ribs. It affords no proof either that the protruded part is gangrenous, or that it ought to be cut away. (Pathol. Chir. tom. ii. p. 309.) A writer (fays he) who is very little known, and whofe cafe we fhall relate, confeffes his having miftaken this livid difcolouration for a fign of mortification. A man received a ftab between the third and fourth ribs, on the right fide of the cheft, and by the way in which the fword had been withdrawn, the wound was rendered very large. A portion of the lungs protruded, fwelled confiderably, and remained in this ftate three or four days without any attempt being made to reduce it. The part then became fhrunk and quite dry, when the whole of what was exterior to the ribs was cut off. On dipping the piece of lung in water, however, it immediately refumed its natural colour, which, no doubt, it would alfo have done had it been reduced inftead of being amputated. The patient neverthelefs got quite well, and fuffered afterwards no difficulty, notwithftanding the hard laborious life which he was obliged to lead. Obf. Medicinales et Chirurgicales par Loyfeau, p. 25.

A fimilar miftake was made on a patient who had received a wound which penetrated the anterior and inferior part of the cheft. A fmall bit of the lungs protruded, which was fuppofed to be a piece of omentum, and was immediately included in a ligature. Ruyfch being confulted, perceived the miftake, and he recommended dreffing the wound, and leaving things as they were, until the tied portion of lung had become detached. No bad fymptoms followed, and the patient perfectly recovered. (Obf. Anat. Chir. obf. 53.) We met with a protrufion of a long piece of the lungs in a foldier, who had been wounded with a lance at the battle of Waterloo. The part was at leaft four inches in length, and fhaped like a tongue. As it was confiderably contufed and torn, we doubted the prudence of returning it in that ftate into the cheft. We thought, therefore, of cutting it off, but fearful that it might bleed freely, we firft made a fmall incifion into it, in order to afcertain the fact; and as a good deal of blood began to flow from this little incifion, we firft tied the protruded part clofe to the ribs, and then removed all that was exterior to the ligature. The patient was fo well on the day of the operation, and alfo the next morning, that he would not remain in bed; but we were informed that he did not ultimately recover.

A wound of one of the intercoftal arteries immediately produces a degree of hemorrhage, which is manifeft externally, and often confiderable. The blood flows out of the wound, and alfo into the cavity of the cheft. It iffues

per

per saltum, like that of all wounded arteries, and it gushes out both in inspiration and expiration, but without any hissing noise, and not blended with mucus and air, like the blood which is discharged from a deep wound of the lungs.

We should not have expected much hemorrhage from the intercostal artery when wounded by a ball, much less should we have expected that it was ever possible to take up that vessel with a tenaculum. Yet a late writer observes, "whenever the tenaculum can be used to an intercostal artery injured by a ball, it should at once be applied, and the vessel secured by ligature." (See Hennen's Obs. on Military Surgery, p. 401.) Professor Thomson heard only of one hemorrhage from the intercostal artery after a gun-shot wound received at Waterloo, and this was a secondary bleeding on the fifteenth day. It was stopped by a compress. See Obs. on the Military Hospitals, &c. p. 83.

This sort of bleeding can only be stopped by compression, and in order that the plan may be effectually practised, it is sometimes necessary to enlarge the wound by an incision. When the finger is put under the wounded artery the bleeding ceases, which obviously proves that there is no occasion for needles, nor for any particular inventions for stopping the hemorrhage. According to M. Lassus, it will be quite enough to introduce between the ribs a tent, or dossil of charpie, which is to be kept in the wound four or five days. The bleeding having stopped, the wound will discharge for some days a reddish purulent fluid, and if the lung be not perceptibly injured, the cure will be speedily effected by ordinary treatment.

The method which has been tried for stopping hemorrhage from a wound of the internal mammary artery is analogous to the foregoing. A man was stabbed with a sword, which entered obliquely between the cartilages of the ribs. The wound was not extensive; but the effusion of blood in the cellular membrane of the lateral and anterior part of the thorax was considerable. An incision was made in the integuments covering the mass of blood, and several coagula were removed. The hemorrhage was then stopped by introducing some agaric, which was fastened to a spatula, and by means of this instrument, pressed from within outward, under the cartilage of the rib, near the side of the sternum. The wounded artery was thus very exactly compressed, and the plan was continued several days and nights successively under the direction of a surgeon. Lassus, Pathol. Chir. tom. ii. p. 312.

An extravasation of a considerable quantity of blood in one of the cavities of the pleura is followed by such a train of alarming and urgent symptoms, that the patient dies of suffocation unless the fluid be discharged. This may be accomplished either by making the patient lie on his wounded side, if the wound can thus be made depending, and it be sufficiently ample, or enlarging it with a bistoury, when it is too narrow, or by making another opening in the thorax when the wound is situated too high up. (See EMPYEMA.) If the hemorrhage still continue, and be considerable, after the first extravasated blood has been discharged, the patient generally perishes; but when the bleeding ceases, and the lungs are not extensively injured, he may recover. Nothing but the urgency of the symptoms of suffocation, arising from a dangerous degree of pressure upon the lungs and diaphragm, can justify a hasty determination to make an opening for the evacuation of the extravasated blood, or the equally pernicious plan of leaving the original wound open for the same purpose. If the surgeon require arguments in support of this remark, they are to be derived from the equivocal, uncertain, and irregular character of the symptoms of an extravasation of blood in the thorax, and from the effect which even the discharge of such blood may have in renewing the hemorrhage, and making room for another effusion, in cases where the injured vessels are large. The blood, however, must be discharged when the symptoms of suffocation are urgent, and evidently owing to the pressure of the extravasation on the organs of respiration. The practice of making an opening will always be unsuccessful, when the wound of the lungs, besides being deep enough to give rise to an extravasation, is also complicated with emphysema of those organs, and the effusion of a considerable quantity of blood into their cellular and parenchymatous texture. In short, in a wound of this serious description, it does not constantly happen, that the only curative indication is to discharge the extravasated blood. The degree of danger depends upon the nature of the wound of the lungs, which is invisible, and of which it is sometimes difficult to form a correct judgment. Frequently an extravasation of blood in the pericardium, without injury of the heart, but a case which is always fatal, has been mistaken for an extravasation in the cavity of the left pleura. Sometimes, also, we may be deceived, and believe in the existence of an extravasation, while the symptoms of suffocation under which the patient labours may be owing to the substance of the lungs being changed as it were into a solid mass, by the effusion of blood and coagulating lymph in their texture, and the consequent compression of the air-cells.

Although it must be acknowledged, that the diagnosis of an extravasation of blood in the chest is not free from difficulties, the following are usually regarded as the symptoms which characterize the case, either in the primary or secondary form. In the first place it is obvious, that there must generally be a wound of the lungs, which is indicated by the issue of frothy blood from the wound, by the passage of air through the wound into and out of the chest, and by the patient spitting blood, or coughing it up in large quantities. If, however, the blood come from the intercostal artery, no blood will be coughed up. At the moment of receiving the wound, the patient falls into a state of syncope, and though the bleeding may not be very considerable, he is affected with cold sweats, and his pulse is feeble and small. In the course of a few days, notwithstanding a low diet, repeated bleedings, and perfect quietude, respiration becomes short, difficult, and laborious, and inspiration is observed to be performed more easily than expiration. The patient usually lies upon the side in which the extravasation is; and this side seems rather larger and broader at its lower part than the opposite side, on which the patient cannot lie without an aggravation of all his sufferings. When he tries to sit up in bed, he cannot remain in this position, unless he bends his body very much forwards, in order to facilitate respiration. About the xiphoid cartilage and the lateral parts of the chest, he feels a weight, attended with a frequent cough, and a sensation of suffocation. According to Valentin, a large ecchymosis, or violet-coloured spot, makes its appearance in some individuals in a later stage of the case about the angles of the false ribs; but this symptom is far from being constant, and it did not occur in an instance of extravasation of blood in the thorax recorded by Dr. Thomson. (Reports of Observations made in the Military Hospitals in Belgium, p. 85.) In general, blood escapes from the wound, unless the opening be very small, or situated in the upper part of the chest. Lastly, it is remarked, that the symptoms of suffocation proceeding from inflammation of the lungs subside, or are evidently lessened by venesection, which is not the case when they depend upon an extravasation.

If it be true that some patients have had their breathing very little oppressed, notwithstanding an extravasation of blood in one of the cavities of the pleura, and that others have been able to lie with equal ease either on the sound or diseased side (see Thomson's Report, p. 87.), which is not common, we must conclude from these unusual cases, that we ought not to form our opinion from any one symptom in particular, but from the assemblage of a great many. Lassus, Pathol. Chir. tom. ii. p. 319.

On the subject of extravasations of blood in the thorax, the following are the sentiments of a distinguished writer: "Whatever may be the cause of this inward bleeding, the surgeon should attend to the following directions. He should first put his finger into the wound; perhaps it may discover the cause, or may evacuate the blood. If the blood do not follow the finger, then some tube must be introduced, and the tube for so simple an operation need not be a nice one. If he cannot get the tube into the thorax, and the breathing continue oppressed, he must enlarge the wound, and enlarge it freely. To be afraid of exposing the lungs to air when they are already torn with a bullet and loaded with blood is childish and useless theory, very unlike the proper management of such wounds. If the wound in the thorax be not too high above the third or fourth rib, and if no posture of the patient, however willing or able to turn himself, will bring the blood easily in that way, or if the wound be contused, oblique, and difficult to dilate, an operation must be performed, which, as it is commonly practised for pus in the breast, is called the operation of *Empyema* (see this word); that is, a very free incision must be made in the line betwixt two of the ribs; then the pleura must be punctured with a lancet, and a tube introduced. Or, in plain language, whenever it is found that the natural wound will not empty the thorax, a new wound should be made in what is called the chosen point, or the point of election, *i. e.* low, betwixt the seventh and eighth ribs, that there may be an easy flow. But whenever the wound is about the middle of the thorax, it should rather be dilated, which both changes the nature of the wound and gets out the blood. When this blood proceeds from a wound of the intercostal artery, such free incisions are the more necessary; they allow us to see the artery, to feel the jet of its warm blood by putting in the finger, and this allows us to press it with a compress, or tie it with the needle and thread." (See John Bell's Discourses on Wounds, p. 263, 264. edit. 3.) However, notwithstanding this author, and a few other surgeons thus talk of taking up the intercostal artery, we much doubt the possibility of the thing, nor do we know of any well-authenticated case on record where it has actually been done.

The propriety of some other parts of this advice is also questionable, especially that relating to thrusting tubes into the cavity of the thorax. The necessity of cutting into the chest at all in order to let out extravasated blood, in an early stage of a wound of the thorax, is positively denied by Scarpa, as we shall find from an extract we shall have to make from his work in speaking of wounds of the belly. On the contrary, Scarpa, Larrey, Assalini, Hennen, &c. all agree, that wounds of the chest should be closed, and superficially and lightly dressed. At all events, we may safely assert, that in these cases nothing but the urgency of the danger, unequivocally arising from the pressure of the mass of extravasated blood on the organs of respiration, can ever justify the practice of either making another opening into the chest, or of enlarging the original one. Of the method of keeping the wound open with tubes or tents, we have a very unfavourable opinion.

In every case of extravasation of blood in the chest, the discharge of it when respiration is dangerously oppressed is not the only indication. There is another one of at least equal importance: we allude to the adoption of a rigorous antiphlogistic treatment, in order to avert and diminish the dangers arising from inflammation of the pleura and lungs.

Besides extravasation of blood in the cavity of the pleura, there is another complication which sometimes attends wounds of the chest, and is particularly deserving of the attention of the practitioner. We mean the case of emphysema, or what Mr. John Bell calls "the tumour formed by air blown out from the lungs into the common cellular substance, or confined within the thorax, and oppressing the lungs." It is not, however, our wish to detain the reader long on this interesting disorder, because by turning to the article Emphysema, he will find a statement of all the principal knowledge which exists upon the subject.

Emphysema arises from the air escaping, first from the lungs into the thorax; then from the thorax through the wound in the pleura costalis into the cellular substance on the outside of the chest; and afterwards, the air inflates the cellular membrane over the whole body. As Mr. John Bell has related, emphysema is frequent after a fractured rib, because there is a wide laceration of the lungs, and no exit for the air; while it is less frequent in large wounds with a knife or broad-sword, because in such cases the air has an open and unimpeded issue. It is very common after deep stabs with the bayonet or small-sword; and it sometimes arises in gun-shot wounds, though, as far as our experience extends, it is not so frequent in these particular instances, as Mr. John Bell describes. Mr. Hennen thinks it does not occur in more than one case out of fifty (p. 402.), which is, perhaps, a calculation considerably below the real state of things.

When the lungs are wounded, the air escapes from them at every inspiration into the cavity of the pleura, whence the next expiration it is compressed, and forced through the breach of continuity in the pleura into the cellular substance on the outside of the chest; for it cannot return into the wounded lung, because this is already full. Every new inspiration draws more air from the wounded lung, and every new expiration drives more air out into the cellular substance. There is no other outlet for the air, which spreads under the skin with wonderful rapidity. The emphysematous crackling tumour makes its first appearance over the broken rib, or over the wounded point of the thorax; it then extends over the whole chest, and next over the neck and face, filling particularly the eye-lids, so that the eyes are absolutely closed. It afterwards extends itself over the belly, down the thighs, and to the private parts, and no part escapes this tumour, except the palms of the hands and the soles of the feet. More air is every moment drawn out from the wound of the lungs, and driven under the skin; and the patient is every moment more and more oppressed, till at last the breathing is quite interrupted, the pulse flags, the extremities grow cold, and the patient, if he be not relieved by some operation, must die. John Bell, p. 267, 268.

The moment that the lungs are wounded, (says this author,) they fall down, and continue in this collapsed state until the wound heals, which it does in the course of a very few days; but from the moment in which lungs are wounded, the use of the wounded lobe is lost, so that if the wound be in the right side of the lungs, the breathing is performed entirely by the left; only half the quantity of air is inspired, and the breathing is difficult.

If the lungs, when wounded, were to continue in perpetual

tual motion, (fays Mr. J. Bell,) I do not know how we fhould expect a cure; for the air would be continually ftreaming through the wound, and the wound itfelf alternately dilating and contracting, like that in an artery, could not heal. But as the wounded lung lies in a collapfed ftate, the edges of the wound are in contact with each other. P. 269.

That the lung of one fide, which remains unhurt, is fufficient to fupport the fyftem, we learn from various accidents; from thofe cafes in which, either owing to the incifions made by the furgeon, or to the nature of the wound, the cheft has been freely opened, the lungs of one fide have collapfed, and yet the patient has lived with tolerable eafe, and ultimately recovered. We learn it alfo from cafes of emphyfema, where the lungs are oppreffed with air, and from cafes of empyema, or pus, within the cavity of the cheft, obftructing the expanfion of the lungs. (See EMPYEMA.) And efpecially, (fays Mr. J. Bell,) we are fure of it from the very gradual decay of thofe who die with large fuppurations within the cheft, in whom we find after death, that on one fide there remains nothing but one fmall knob or tubercle of the lungs. Koelpen de Empyemate Obf. p. 135.

That the breathing fhould be eafier in a free and open wound of the cheft than in a punctured wound, or that in the cafe of a punctured wound the patient fhould be relieved by a free incifion, no one need wonder; for in a punctured wound there is no way for the blood or air to efcape from the thorax, while yet at every ftroke of refpiration, more and more blood and air is drawn out from the lungs, till at laft the blood, and efpecially the air, are fo condenfed, that they not only oppres that fide of the lungs, but by hindering the free play of the diaphragm, and loading the mediaftinum, they opprefs alfo the other lung, the difficulty of breathing increafes, the extremities grow cold, and the patient dies.

Whatever danger then depends altogether upon emphyfema itfelf depends upon the manner in which the confinement of air in the cheft oppreffes not only the wounded, but alfo the oppofite lung, the diaphragm, &c. The extenfive inflation of the cellular membrane in other parts of the body is a circumftance which creates a terrible disfigurement, but perhaps very little peril in itfelf. Sometimes, however, it proceeds to fuch a pitch, that even the interftitial cellular fubftance of the lungs themfelves becomes inflated, and then fuffocation is inevitable.

On the treatment of emphyfema we fhall merely remark at prefent, that the chief means, both of relieving the organs of refpiration from compreffion, and of hindering the further increafe of the diffufion of air in the cellular membrane, confifts in practifing an incifion in the thorax at the part where the air firft efcapes from that cavity. For other practical obfervations we refer to the article EMPHYSEMA.

The exiftence of adhefions between the pleura coftalis and pleura pulmonalis, previoufly to the receipt of a wound of the cheft, muft make an important difference with regard to the fubfequent ftate of the lungs, and particularly with regard to their condition in the cafe of emphyfema. Such adhefions muft of courfe render a collapfe of thefe organs impoffible, and alfo prevent the air from infinuating itfelf between the furface of the lungs and the infide of the cheft. Whether thefe occurrences can be perfectly prevented will of courfe depend upon the extent of the adhefions. They would, however, be certainly averted altogether, were the wound to happen juft at a part of the cheft where the pleura coftalis and pleura pulmonalis happened to be adherent.

From fome remarks which have been delivered, the reader will fee, that wounds opening both cavities of the cheft, unlefs fuch adhefions exift, muft produce immediate fuffocation, in confequence of both lungs becoming collapfed. That this would really happen is the belief of the majority of the beft modern writers, and there are feveral facts reported which tend to confirm the accuracy of the opinion. A late author, however, conceives, that the finking of the lung is not an uniform confequence of a penetrating wound of the thorax. He obferves, that we have fometimes ocular proof of this, not only by the clofe contact in which the lungs lie to the wound difcoverable at firft fight, but by protrufions which occafionally happen. From experiments on brutes, fays he, we derive no fatisfactory elucidation; for in fome, where incifions on each fide have been made through the intercoftal mufcles, much greater than the natural paffage of the air, the lungs, fo far from collapfing, have expanded again, the animal has lived, and in ten days run about as well as ever. And in our own fpecies, the recoveries from wounds of the thorax on both fides, larger than the orifice of the glottis, dangerous as they are, are not few. Hennen's Obf. on Military Surgery, p. 404, 405.

Wounds of the heart generally prove immediately fatal, though it is true there are to be found in the records of furgery many curious exceptions to this obfervation. A foldier received the thruft of a fword, which entered one of the cavities of that organ, as was afcertained after death; yet he lived nine days after the accident. (Rhodius, Obf. Medic. centur. ii. obf. 39.) A young man, twenty-fix years of age, was ftabbed with a fword in the right fide, between the third and fourth true ribs. He became exceedingly weak, had great difficulty of breathing, and died in four or five days. On opening the body, it was difcovered that the heart had been completely transfixed, the weapon having paffed from the right into the left ventricle, through the feptum. The cavity of the cheft was full of blood, and it was thought that the prolongation of life had been owing to the clofure of the wound with coagula. (Saviard, obf. 113.) Haller, as Mr. Hennen obferves, has recorded in his Bibliotheca Chirurgica, vol. ii. p. 378. an example in which a needle was found in the heart of an ox; and through the kindnefs of Mr. Hammick, furgeon of the royal naval hofpital at Plymouth, Mr. Hennen was lately fhewn a preparation, in which a pin was lodged in the human heart, but without any trace of the mode in which it got there. The patient had complained of a pain in his cheft, about three months previoufly to his death, and died of carditis. (Obf. on Mil. Surgery, p. 429.) Ploucquet gives inftances in which a ball was lodged in the heart of a ftag, in the heart of a healthy dog, and in the anterior ventricle of the human heart, where it is ftated to have remained for years. Another inftance has alfo been recently publifhed, in which a ball was found lodged in the right ventricle of the heart, near its apex, included in a great meafure in the pericardium, and refting upon the feptum. See the article *Cas Rares*, Dict. des Sciences Medicales.

Guattani mentions a cafe in which a patient lived eight years after a wound of the aorta (De Aneurifmatibus); and in the Medical Records and Refearches, 1798, is the extraordinary cafe of a penetrating wound, in which a bayonet paffed through the colon, ftomach, diaphragm, part of the lungs, and the right ventricle of the heart, and yet the patient furvived the accident for upwards of nine hours. Mr. Hennen alfo refers to another inftance, related by M. Chaftenet, of a wound of the right ventricle, which did not prove fatal till the 15th day after the injury. (See Journ. de Med. Militaire, Paris, 1782, tom. ii. p. 359.) For additional obfervations on this fubject, however, we muft be content with referring to Mr. Hennen's publication.

 As

As wounds of the diaphragm can hardly happen without the fimultaneous injury of feveral other important parts, thefe cafes muft neceffarily be attended with confiderable danger; and indeed, when the tendinous centre of the diaphragm is injured, the accident is deemed by feveral writers of modern date as inevitably fatal. (Laffus, Pathol. Chir. tom. ii. p. 321. Callifen, Syft. Chir. Hodiernæ, Pars ii. p. 696.) The following are faid to be ufual fymptoms of a wound of the diaphragm:—The patient is immediately feized with exceffive anxiety and agitation. He feels acute pain in the hypochondria, and is obliged to keep himfelf bent forwards; and he is further afflicted with a cough, hiccough, convulfive fpafms, and great difficulty of breathing. Delirium enfues, the mufcles of the face are convulfed, the fingultus grows worfe and worfe, and the cafe terminates fatally in the courfe of a few days.

Dangerous, however, as wounds of the diaphragm muft generally be, on account of their being for the moft part complicated with injury of fome of the abdominal or thoracic vifcera, there is no doubt that the danger has been exaggerated. "Wounds of the thorax (fays Dr. Thomfon) are not unfrequently complicated with wounds of the abdomen. In various inftances of this kind (which this gentleman faw in the Netherlands after the battle of Waterloo), there exifted undoubted proofs of the fact that wounds of the diaphragm are not neceffarily fatal; for it muft have been perforated once, if not twice, in feveral of the cafes we faw, in which balls had paffed acrofs the lower part of the cheft, and the fame thing muft have happened alfo, I conceive, in moft of the cafes in which the liver had been wounded. In one cafe, the ball had entered the right hypochondriac region, under the edge of the falfe ribs, and come out on the right fide of the fpine, on a level with the fuperior edge of the os ilium. This patient fpit blood for fome days, and voided it alfo by ftool. On the examination after death of a patient who died thirty days after receiving the wound, and in whom a ball had entered the cheft on the lower and outer part of the right papilla, and had come out of the abdomen on the left fide of the umbilicus, the right lobe of the lung was found wounded, and the diaphragm and the upper part of the right lobe of the liver perforated. But neither in thefe cafes, nor in feveral others of wounds of the diaphragm which we faw, did any peculiar fymptoms, fuch as the rifus fardonicus, or convulfive motions of the cheft, prefent themfelves to our notice." See Report of Obf. made in the Mil. Hofpitals in Belgium, p. 93.

In the treatment of wounds of the diaphragm, abftractedly confidered, very little can be done; bleeding and antiphlogiftic remedies appear the only means which promife any effectual good. With thefe, however, we may fometimes ufefully conjoin opiates.

Extenfive wounds and lacerations of the diaphragm occafionally give rife to a particular and incurable fpecies of rupture, in which fome of the abdominal vifcera form a protrufion in the cavity of the cheft. This accident is termed a phrenic hernia, and fome account of it will be found in the article HERNIA.

Wounds of the Belly, or Abdomen.—Wounds of the abdomen are divided into two principal claffes: in one the folution of continuity is confined to the integuments, mufcles, &c. exterior to the peritoneum; in the other this laft membrane is penetrated, and frequently fome of the vifcera alfo which are included in it. Wounds affecting the parietes of the abdomen, but not extending through the peritoneum, whether of the punctured, incifed, or contufed kinds, have no effential difference from wounds of other parts, and the obfervations which have been offered on the fubject of wounds in general are in every refpect applicable to all fuperficial wounds of the belly. It is worthy of remark, however, that the parietes of the abdomen are always weakened in confequence of wounds, and difpofed to allow the vifcera to form protrufions. Strong as the cicatrix may be, the point where it is fituated continues fubject to a hernia, which feldom fails to occur, unlefs the weakened part be properly fupported with a belt or bandage. This accident may follow a fimple punctured wound; but it invariably takes place in every inftance where, in confequence of a fevere contufion, the parietes of the abdomen have loft their tone, and yield to the impulfe made againft them by the parts which they contain. It was thus that a cooper's wife, whofe hiftory is given by Sennertus, after being violently ftruck on the abdomen by a piece of green elaftic wood, which flipped out of her hufband's hands, fuffered fuch a relaxation of the contufed part, that the anterior parietes of the abdomen yielded fo as to form an enormous pouch, containing, during pregnancy, the gravid uterus itfelf.

After accomplifhing the re-union of a fuperficial wound of the belly by means of an eligible pofition, adhefive plafters, and a bandage, we fhould therefore recommend the patient to wear a belt, or any other means of making preffure on the part which muft be fupported. Should the wound have been confined to the fkin, however, and the mufcles not have been at all divided, there would be no rifk of a hernial protrufion afterwards, and of courfe the ufe of a belt, or any fort of bandage, would then be unneceffary.

If fuperficial wounds of the abdomen are unattended with any particular danger or peculiarity, the fame obfervation cannot be made with refpect to penetrating wounds, or thofe which pafs through the peritoneum. We have feen that penetrating wounds of the cheft give rife to a variety of dangers, fometimes depending upon the effufion of blood into the bronchiæ and air-cells of the lungs, or into the cavity of the pleura; fometimes upon the confequences of that extraordinary complication emphyfema; but more efpecially upon the great tendency of the pleura and lungs to inflammation. The principal dangers of penetrating wounds of the belly arife alfo partly from internal hemorrhage within the cavity of the peritoneum; partly from the irritation which is produced by the occafional extravafation of the contents of the vifcera; but in a ftill greater degree, from the ftrong difpofition of the peritoneum to become affected with violent and extenfive inflammation, in confequence of any injury or irritation. There are, fays Mr. John Bell, a thoufand occafions on which this delicacy of the peritoneum may be obferved. The wound of the fmall fword, and the ftab of the ftiletto, explain to us how quickly the peritoneum, and all its contained bowels, inflame from the moft minute wound, although it be almoft too fmall to be vifible on the outfide, and fcarcely within; for, upon diffection, no inteftines are feen wounded, and no feces have efcaped into the abdomen. In thofe who die after lithotomy, we find the cavity of the peritoneum univerfally inflamed. The operation of Cæfarean fection is fatal, not from any lofs of blood, for there is little bleeding, nor from expofure to the air, for they alfo die in whom the womb burfts, and where the air is not allowed to enter; but merely from that inflammation which fucceeds to wounds of the peritoneum, fmall as well as great, of which we have fometimes a melancholy proof in the operation of hernia, in which the ftitching the wound, according to the whimfical improvement of fome modern furgeons, or where the mere tying of the fac, as in the practice of the old rupture-doctors and caftrators, often raifed fuch inflammation as fpread very quickly over the abdomen, and ended in gangrene.

grene. This inflammation may, no doubt, come on from the flighteft fcratch in the peritoneum itfelf; yet, in general, it arifes rather from the wound of fome of the vifcera. If an inteftine be wounded, it may pour out its feces into the abdomen; if the liver, fpleen, or kidneys be wounded, thefe pour out blood; if the bladder, then the urine filters into the cavity of the belly. The extravafated food, feces, urine, blood, &c. act there as irritating extraneous fubftances, which no activity of the abforbents can remove, and which foon caufe a fatal inflammation of every peritoneal furface within the abdomen. See John Bell's Difcourfes on the Nature and Cure of Wounds, p. 310. edit. 3.

Apprized by melancholy experience of the vaft difference which the penetration of the peritoneum makes in the nature of a wound of the abdomen, furgeons have betrayed confiderable anxiety to be able to afcertain at firft, in every inftance, whether the injury partakes of this ferious defcription or not. But although the nature of the cafe is felf-evident, when the wound in the parietes of the abdomen is large, and attended with protrufion of the vifcera, it is often extremely difficult to judge whether the weapon has gone through the peritoneum or not, when the wound is a fimple ftab, unaccompanied with protrufion of the vifcera, or with any effufion of their contents.

The generality of furgical authors have laid down a variety of criteria for determining the queftion, whether the cafe is a penetrating wound? Some of thefe writers lay much ftrefs on comparing the direction of the wound with the natural thicknefs of the parietes of the abdomen at the injured part, and the breadth of the injury with that of the weapon. When the inftrument has acted perpendicularly upon a point, where the parietes are thin, and the wound, though made with a narrowifh weapon, like a fword, is yet of a certain breadth, there can indeed be little doubt of the cafe being a penetrating wound. But the impoffibility of knowing in what direction the thruft has been made, and of procuring the weapon, in order to compare its diameter with that of the wound, generally renders this mode of difcrimination ufelefs in actual practice.

If a probe (fay other writers) will readily enter perpendicularly to a certain depth, in a place where the parietes of the abdomen are thin, the circumftance is a proof that the cafe is a penetrating wound. But if the probe cannot be thus introduced, we are by no means juftified in concluding that the wound does not penetrate. As the layers of mufcles do not bear the fame relative pofition to each other which they did at the time of the accident, they foon ftop the paffage of the probe; and in whatever pofture we put the patient, it is next to impoffible to put the parts exactly in the fame pofition in which they were at the time of the receipt of the injury. Befides, when the wound is oblique, a probe which is not very flexible cannot eafily be made to follow its track. The employment of this inftrument is alfo not free from objections, founded on its creating pain and irritation, or even a renewal of hemorrhage and effufion of blood in the cellular membrane.

An abfurd propofal has been made to inject a mucilaginous fluid into the wound, the paffage of which into the belly would be a fure indication of the cavity of the abdomen being penetrated. It is obvious, however, that the injected liquid may not enter, though the cafe be a penetrating wound, owing to the change in the relative pofition of the layers of the abdominal mufcles. The fluid may alfo continue in the wound in confequence of its paffing into the cellular fubftance; and thus it may make the furgeon fuppofe that it enters the abdomen, when in reality it does not pafs down even to the peritoneum. Nor can the mildeft injection be thus thrown into the cavity of the peritoneum without the utmoft rifk of exciting that fatal kind of inflammation which we have already mentioned, as the danger moft to be dreaded in all wounds of the abdomen.

The figns then of a penetrating wound of the abdomen are fallacious, and the employment of fuch means as the probe and injections, with a view of afcertaining the real nature of the cafe, is not exempt from danger. Many fpafmodic affections, which occafionally follow the receipt of a wound of the belly, are only equivocal, as they are fometimes owing entirely to the great fenfibility of the patient. The protrufion of the abdominal vifcera, and the difcharge of fluids which they are known to contain, are the only fure figns of a penetrating wound. It is eafily conceivable at the fame time, that a wound may penetrate the cavity of the belly, and yet thefe fymptoms may not occur, either becaufe the external wound is too fmall to allow of the efcape of any of the vifcera or their contents, or becaufe the weapon or ball, after piercing the peritoneum, has actually touched none of the bowels, or has merely glided over their furface. But penetrating wounds, which are unattended with protrufion of the vifcera, or extravafation of any fluid in the cavity of the abdomen, are lefs alarming than feveral complicated wounds which do not penetrate. If in fuch cafe, fays Richerand, the patient or by-ftanders were to inquire about the nature of the injury, we fhould avoid giving a pofitive opinion, informing them of the infufficiency of the means formerly practifed, in order to afcertain the precife depth of the wound, and explaining the objections to the probe and injections. It fhould alfo be mentioned to them that the antiphlogiftic treatment, which is the beft in fimple wounds which do not penetrate, is the only plan which could be adopted, were it certain that the injury had extended into the cavity of the abdomen. Nofographie Chir. tom. iii. p. 327—335. edit. 4.

In the following defcription of the treatment requifite for the different cafes of penetrating wounds of the belly, we fhall follow the order chofen by M. Richerand, and confider,

Firft, the cafes in which the vifcera, though uninjured, protrude at the wound.

Secondly, the cafes which are complicated both with injury and protrufion of the vifcera.

Thirdly, penetrating wounds unaccompanied with protrufion, but yet attended with injury of one or more of the vifcera, as is indicated by particular fymptoms, and efpecially by the iffue of certain kinds of matter from the external wound.

And laftly, we fhall conclude with noticing the fubject of extravafations, and fome wounds of particular organs and vifcera.

1. *Of Wounds of the Belly, attended with Protrufion of the Vifcera.*—When, in confequence of a divifion of the parietes of the abdomen by a cutting inftrument, or their laceration by a bull's-horn, the inteftines protrude between the lips of the wound, the firft indication is to reduce the parts, and then to take meafures for preventing a recurrence of the protrufion. The reduction is generally eafy, if care be taken to relax the abdominal mufcles by a judicious pofture. In fome cafes, however, the wound is fo narrow that the thing is more difficult, and here, inftead of puncturing the bowel, in order to diminifh its fize by difcharging the air which it contains, (as advifed by many writers,) we decidedly recommend a moderate enlargement of the wound. This fhould be cautioufly executed with a probe-pointed curved biftoury, introduced along the groove of a director; or, if there be room, under the guidance of the left fore-

finger.

finger. In this manner, and with due care, the wound may always be fufficiently dilated without the protruded parts being cut. Authors alfo recommend the incifion for this purpofe to be directed upwards; for (fay they) the further the cut is from the lower part of the belly, the lefs liable will the patient afterwards be to hernia. The inteftines fhould invariably be returned without delay, in every inftance in which they are free from wound or gangrene. Should they even be flightly wounded or inflamed, no time fhould be loft in abfurdly applying fomentations, &c. to them in their protruded ftate. The natural warmth and moifture of the cavity, into which they are to be replaced, will be far more congenial than any topical remedies. Should the parts, however, have any dirt or fand upon them, the moft which ought to be done before their reduction is to wafh them with warm milk and water.

The reduction having been effected, the patient is to lie upon his back, with the thighs bent upon the pelvis, and he muft ftrictly avoid making any exertion, left it bring on another protrufion. The wound is to be clofed with adhefive plafter, and the uniting bandage; but if the wound fhould be large, and thefe means ineffectual, it would alfo be proper to employ futures. The ftitches, however, fhould always be as few as poffible. This method of fewing up wounds of the belly made a long fubject in all the old works on furgery, under the appellation of *Gaftroraphe* (fee that article); but at the prefent day, futures are comparatively fpeaking almoft rejected from practice, or are only employed when the oppofite furfaces of wounds cannot be kept in contact without them. Nor are they then ever ufed, except the chance of union by the firft intention ftill forms a temptation for the trial of the plan; for when a wound muft heal by the granulating procefs, ftitches can never be of the leaft utility.

When the omentum protrudes through a penetrating wound, and is ftrangulated by the narrownefs of the opening, it foon contracts adhefions. Richerand recommends us to cut off all this membrane which exceeds the level of the integuments, and to leave in the wound the reft, which, he afferts, will act like a ftopper, and hinder future herniæ. Were the wound, however, quite recent, fo that adhefions could not yet have formed, the propriety of dilating the opening, and reducing the piece of omentum, would be unqueftionable. Whenever, alfo, the omentum is found, and free from conftriction, it fhould be reduced. In cafes where a portion of this membrane is not only protruded, but gangrenous, writers authorize the excifion of the dead part, and reducing the reft after the cut veffels have been tied fingly with fmall filk ligatures. We apprehend, however, that in general, whenever the omentum has been out fo long as to flough, adhefions within the wound have had time to form; an event which would embarrafs the operator, and even render the fafety and propriety of the attempt to reduce the living portion of the protruded membrane very queftionable. Should the omentum, or inteftine, however, be not adherent to the neck of the hernial fac, though gangrenous, (as occurred in an inftance cited by Scarpa, Traité des Hernies, p. 268.) the propriety of trying to reduce it would be undeniable.

2. *Wounds of the Belly, with Injury and Protrufion of the Vifcera.*—Penetrating wounds of the abdomen, attended with protrufion of the inteftines, are always to be regarded as dangerous cafes; but the danger is much more ferious, if, befides being protruded, the bowels are alfo wounded. Under fuch circumftances, we have the authority of numerous writers on furgery, as a fanction of the practice of fewing together the edges of the divifion in the protruded inteftine; a practice, however, which, as we fhall hereafter explain, does not meet with the approbation of that excellent modern furgeon, profeffor Scarpa, of Pavia. Every one, however, allows, that the attempt would be highly improper and rafh, were the bowel only wounded, without forming a protrufion. It is this laft occurrence which creates a material difference in eftimating the poffibility of the plan, the queftion of its neceffity being at prefent excluded from confideration. When the parts are protruded, no enlargement of the external wound is neceffary to render the application of a future practicable; the plan creates no difturbance and irritation of the peritoneum and contiguous vifcera; there is no doubt concerning the actual exiftence of the injury, no difficulty in immediately finding out its precife fituation.

But though many authors are fo generally agreed about the propriety of ufing a future in the cafe of a wounded and protruded bowel, they differ exceedingly, both as to the right object of the method, and the moft advantageous mode of making the ftitches. Some, having little apprehenfion of extravafation after the reduction of the gut, advife only one ftitch to be made, (frequently only through the mefentery,) and they employ the ligature chiefly with a view of confining the injured bowel near the external wound, fo that whatever part of its contents may be effufed, there will be a ready paffage for the matter outward. Other writers wifh to remove the poffibility of extravafation, by applying numerous ftitches, and attach little importance to the plan of ufing the ligature, principally for the purpofe of keeping the inteftine near the external wound.

When the wound of a bowel is fo fmall that it is clofed by the protrufion of the villous coat, the application of a future muft evidently be altogether needlefs; and fince the ligature could not fail to caufe irritation, as an extraneous fubftance, the employment of it ought unqueftionably to be difpenfed with.

Suppofing, however, the breach in the inteftine to be fmall, but yet fufficient to let the feces efcape, what method ought to be adopted? The following practice has been tried. As Mr. A. Cooper was performing the operation for a ftrangulated hernia, at Guy's hofpital, an aperture, giving iffue to the inteftinal contents, was difcovered in a portion of the found bowel, juft when the part was about to be reduced. The operator, including the aperture in his forceps, caufed a fine filk ligature to be carried beneath the point of the inftrument, firmly tied upon the gut, and the ends cut off clofe to the inteftine. The part was then replaced, and the patient did well. Mr. Travers, who has related this fact, approves of the plan of cutting away the extremities of the ligature, inftead of leaving them hanging out of the external wound. It appears that when the firft practice is followed, the remnant always finds its way into the inteftine, and is difcharged with the ftools, without any inconvenience. But when the long ends are drawn through the outer wound, and left in it, they materially retard the procefs of healing. See Travers's Inquiry into the Procefs of Nature in repairing Injuries of the Inteftines, &c. p. 112, 113.

Let us now inquire what ought to be the conduct of a furgeon, were he called to a patient, whofe bowel is divided through its whole diameter, and protruded at the external wound? Various have been the fchemes and propofals for the treatment of this fort of accident; and fince experience has furnifhed few practitioners with an opportunity of feeing fuch a cafe in the human fubject, a variety of experiments have been made on animals, in order to determine what treatment would be the moft fuccefsful. Ramdohr, indeed, is ſtated by Mœbius to have had occaſion to try on the human ſubject a plan, on which a vaſt deal has been ſaid and written. He cut off a large part of a mortified inteſtine, and joined the ſound ends together, by inſerting the upper within the lower one, and fixing them in this poſition with a ſuture; the ligature being alſo employed, to keep them at the ſame time near the external wound. The patient recovered, and the feces afterwards paſſed entirely by the rectum in the natural way. See Halleri Diſputat. Anat. vol. vi. Obſ. Med. Miſcellan. 18.

About a year after the operation, the patient died, when the anatomical preparation of the parts was ſent by Ramdohr to Heiſter. They were preſerved in ſpirits of wine, and exhibited, according to this laſt author, an union of the two ends of the bowels together, and their conſolidation with a part of the abdomen. Now it has been queſtioned by a late writer, whether the union here ſpoken of ever really happened. When the upper end of the bowel is introduced into the lower, the external ſurface of the former is put in contact with the inner one of the latter; a ſerous membrane is placed in contact with a mucous one. Theſe heterogeneous ſtructures, he alleges, are not diſpoſed to unite. The mucous membrane, when inflamed, more readily ſecretes a kind of mucus, which muſt be an invincible obſtacle to adheſion. He thinks it, therefore, more than probable, that, in the caſe related by Heiſter, the invagination was maintained by the union of the inteſtine with the correſponding part of the abdominal parietes. Several experiments on living animals have convinced him that this happens, and that the mucous membrane will not unite with the external peritoneal coat. This impoſſibility of producing an immediate union between mucous and ſerous membranes may, of courſe, be urged as an objection to Ramdohr's practice. (Richerand, Noſographie Chirurg. tom. iii. p. 344. edit. 4.) Another equally ſtrong objection is, that the upper end of the bowel cannot be put into the lower one, unleſs it be ſeparated from a part of the meſentery. Here the diviſion of the meſenteric arteries may cauſe a dangerous bleeding. In vain did Boyer tie ſeven or eight of theſe veſſels: his patient died with an extravaſation in the abdomen. (Op. cit. tom. iii. p. 343.) Mœbius attempted to repeat Ramdohr's operation on a dog; but he could not ſucceed in inſinuating the upper part of the divided bowel into the lower one, on account of the contraction of the two ends of the inteſtinal tube, and the ſmallneſs of the canal. Mœbius was, therefore, obliged to be content with merely bringing the ends of the bowel together with a ſuture: the animal died, however, of an extravaſation of the feces.

Dr. Smith, of the Philadelphia Medical Society, alſo tried to repeat Ramdohr's method; but could not ſucceed. He divided the inteſtine of a dog tranſverſely, and having inſerted a piece of candle into that portion of the bowel which was ſuppoſed to be uppermoſt, he endeavoured to introduce the ſuperior within the inferior; but the ends became ſo inverted, that it was found utterly impoſſible to ſucceed. The ſcheme was, therefore, given up, and only one ſtitch made, the ligature being then attached to the external wound, in the manner adviſed by Mr. John Bell. The dog died, and on examination there was found a conſiderable quantity of feces and water in the abdominal cavity.

Two more trials were made of Mr. John Bell's plan by Dr. Smith, on the inteſtines of dogs: in both inſtances the animals died, the inteſtines being much inflamed, and feces effuſed in the abdomen. See Dr. Smith's Theſis.

Mr. Travers likewiſe tried the ſame experiment. "I divided the ſmall inteſtine of a dog, which had been for ſome hours faſting, and carried a fine ſtitch through the everted edges, at the point oppoſite to their connection with the meſentery. The gut was then allowed to ſlip back, and the wound was cloſed. The animal ſurvived only a few hours.—*Examination.* The peritoneum appeared highly inflamed. Adheſions were formed among the neighbouring folds, and lymph was depoſited in maſſes upon the ſides of the wounded gut. This preſented two large circular orifices. Among the viſcera were found a quantity of bilious fluid, and ſome extraneous ſubſtances, and a worm was depending from one of the apertures. By the artificial connection of the edges in a ſingle point of their circumference, and their natural connection at the meſentery, they could recede only in the intervals, and here they had receded to the utmoſt." In another experiment, Mr. Travers increaſed the number of points of contact, by placing three ſingle ſtitches upon a divided inteſtine, cutting away the threads, and returning the gut. The animal died on the ſecond day.—*Examination.* Similar marks of inflammation preſented themſelves. The omentum was partially wrapped about the wound; but one of the ſpaces between the ſutures was uncovered, and from this the inteſtinal fluids had eſcaped. On cautiouſly raiſing the adhering omentum, the remaining ſtitches came into view. Here again the retraction was conſiderable, and the intervening elliptical aperture proportionally large. On the ſide next to the peritoneum, however, the edges were in contact, and adhered, ſo as to unite the ſections at an angle.

From ſuch experiments, the concluſion drawn by Mr. Travers is, that appoſition at a point or points is, as reſpects effuſion, more diſadvantageous than no appoſition at all; for it admits of retraction, and prevents contraction, ſo that each ſtitch becomes the extremity of an aperture, the area of which is determined by the diſtance of the ſtitches. (P. 116. 119.) This gentleman, therefore, maintains, *that the abſolute contact of the everted ſurfaces of a divided inteſtine, in their entire circumference, is requiſite to ſecure the animal from the danger of abdominal effuſion.* (P. 121.) The ſpecies of ſuture employed, ſays Mr. Travers, is of ſecondary importance, if it ſecures this contact. (P. 134.) And, among other obſervations, we find, "wounds amounting to a *direct* diviſion of the canal are irreparable, and, therefore, invariably fatal." P. 133.

In the Dictionary of Practical Surgery will be found ſeveral reaſons for not entirely agreeing with theſe concluſions. We cannot admit that a total diviſion of the inteſtinal tube is certainly and invariably fatal, becauſe we muſt then not only diſbelieve the mode of union in Ramdohr's caſe, which we undoubtedly do, but we muſt alſo diſbelieve the reſult of that caſe, and of ſome others which we would cite, were this a publication expreſsly allotted to ſurgery. Nor are we at all convinced of the utility of applying numerous ſtitches to a divided bowel, in order to keep the edges of the wound together. Were a caſe to preſent itſelf to us, in which a bowel was protruded, and partly cut through, we ſhould at moſt apply only a ſingle ſuture, made with a common ſewing-needle, and ſome fine ſilk; and even of the ſafety and utility of a ſingle ſuture we entertain doubts. If the bowel were completely cut acroſs, we would alſo attach its ends together merely by one ſtitch of the ſame kind; and we ſhould do ſo without feeling at all aſſured that the practice of a ſuture would be at all right. We perfectly coincide, however, with Mr. Travers reſpecting the advantage of cutting off the ends of the ligature, inſtead of leaving them in the wound, as we believe he is right in regard to the little chance there is of the injured inteſtine

teſtine receding far from the wound; and if the ends of the ligature are then of no uſe in keeping the bowel in this poſition, they muſt be objectionable as extraneous ſubſtances. Dict. of Pract. Surgery, edit. 3. art. *Wounds.*

The following is the proceſs by which, according to Mr. Travers, a divided inteſtine is healed, when ſutures are employed: "It commences with the agglutination of the contiguous mucous ſurfaces, probably by the exudation of a fluid, ſimilar to that which glues together the ſides of a recent fleſh wound, when ſupported in contact. The adheſive inflammation ſupervenes, and binds down the everted edges of tbe peritoneal coat, from the whole circumference of which a layer of coagulable lymph is effuſed, ſo as to envelope the wounded bowel. The action of the longitudinal fibres being oppoſed to the artificial connection, the ſections mutually recede, as the ſutures looſen by the proceſs of ulcerative abſorption. During this time, the lymph depoſited becomes organized, by which further retraction is prevented, and the original cylinder, with the threads attached to it, is encompaſſed by the new tunic.

"The gut ulcerates at the points of the ligatures, and theſe fall into its canal. The fiſſures left by the ligatures are gradually healed up; but the oppoſed villous ſurfaces, ſo far as my obſervation goes, neither adhere nor become conſolidated by granulation, ſo that the interſtice, making the diviſion internally, is probably never obliterated." Travers on Injuries of the Inteſtine, &c. p. 128.

The celebrated Scarpa publiſhed, a few years ago, ſome highly intereſting remarks on the proceſs employed by nature in repairing ſolutions of continuity in the inteſtinal canal, eſpecially in caſes of hernia with gangrene; and the reſults of his inveſtigations are alſo both curious and inſtructive, in relation to what happens, and what ought to be done, in wounds of the abdomen. (Sull'ernie Memorie Anatomico-Chirurgiche, &c. Milano, 1809.) He obſerves, that the leaſt fatal conſequence of a mortification of the bowel is the eſcape of the excrement through the wound, or *artificial anus;* an afflicting and diſguſting infirmity, but one which does not preclude all hope of a radical cure, even though a conſiderable portion of the inteſtinal canal may have been deſtroyed by ſphacelus. The recorded examples of ſuch cures are abundant, and yet, ſays Scarpa, nothing has yet been written which will ſerve to convey an exact idea of the ſimple and admirable means which nature employs in accompliſhing them. Surgeons generally ſuppoſe, that after the detachment of the dead parts, the two orifices of tbe bowel remain gaping, and acquire adheſions to the margins of the external wound; that afterwards, in proportion as this contracts, they come gradually nearer together, and in the end touch each other ſo accurately, that the feces are capable of paſſing directly from the ſuperior into the inferior portion of the gut. But this theory cannot ſatisfy thoſe who have attentively examined, in ſome caſes of mortified herniæ, the reſpective ſituation of the two orifices of the inteſtine, and their relation to the external wound. In fact, the two ends of the bowel are conſtantly found lying in a parallel manner by the ſide of each other: the upper with its orifice open, and directed towards the external wound by the feces which iſſue from it; the lower, on the contrary, as it gives paſſage to nothing, always has a tendency to become leſs capacious, and retracted into the cavity of the abdomen. The contraction of the external wound cannot have the leaſt effect in changing the direction of theſe two orifices, nor conſequently in applying them to each other. Even ſuppoſing there were ſome natural tendency to this approximation, the upper orifice, being wider than in the natural ſtate, and directed outwards, could never accurately coaleſce with the lower one, which is ſhrunk, and retracted within the belly. The feces then could never paſs from one into the other without the effuſion of a large part of them outwardly, and an incurable fiſtula, diſcharging the inteſtinal contents, would in every inſtance be the conſequence.

Scarpa had an opportunity of examining the body of a young man, who, in conſequence of eating a large quantity of indigeſtible food, died about ten months after having been operated upon for a congenital hernia, attended with mortification of the protruded bowels, at a period when he had recovered, with the exception of an occaſional diſcharge of a very ſmall quantity of feces from an inconſiderable fiſtulous opening. He alſo diſſected two other caſes. From all theſe it appears, that the breach in the inteſtinal canal is not repaired by the orifices of the upper and lower portions of the bowel re-uniting, coaleſcing, and running as it were into each other; nay, that they meet at a very acute angle, the axis of one not correſponding with that of the other, and they never lie laterally together. On the contrary, Scarpa's inveſtigations ſatisfactorily prove, that a funnel-ſhaped membranous canal (what he terms the *imbuto membranoſo*), compoſed of the remains of the hernial ſac, conſtitutes the medium of communication between the upper and lower orifices of the bowel, which, in an early ſtage of the caſe, becomes adherent to the peritoneum about the neck of the hernial ſac. The baſe of the funnel-ſhaped membranous cavity correſponds to the bowel, and its apex tends towards the wound or fiſtula. It farther appears, that the feces, in order to get from the upper into the lower part of the bowel, have to paſs through the funnel-ſhaped cavity in quite a ſemicircular track, and that between the orifices of the bowel, directly oppoſite to the aperture between the cavity of the inteſtine and that of the funnel-ſhaped membrane, a conſiderable projection or jutting angle is formed, which makes a material additional obſtacle to the direct paſſage of the feces, from the upper into the lower portion of the inteſtinal tube.

Scarpa thus explains the formation of the funnel-ſhaped membranous cavity, that conſtitutes the channel of communication betwixt one part of the bowel and the other: "The hernial ſac, as every ſurgeon knows, does not always partake of gangrene with the viſcera contained in a hernia: and even when it does ſlough, ſince the ſeparation of the dead parts happens on the outſide of the abdominal ring, there almoſt always remains in this ſituation a portion of the neck of the hernial ſac perfectly ſound. We may ſay, therefore, that in all caſes immediately after the detachment of the mortified inteſtine, whether it happen within or on the outſide of the ring, the two orifices of the gut are enveloped in the neck of the hernial ſac, which ſoon becoming adherent to them by the effect of inflammation, ſerves for a certain time to direct the feces towards the external wound, and to prevent their effuſion in the abdomen. In proportion as the outer wound diminiſhes, the external portion of the neck of the hernial ſac alſo contracts; but that part which embraces the orifices of the inteſtine gradually becomes larger, and at length forms a kind of membranous funnel or intermediate cavity, which makes the communication between the two parts of the bowel. This adheſion of the neck of the hernial ſac round the two orifices of the gut does not hinder the latter from gradually quitting the ring, and becoming more and more deeply placed in the cavity of the abdomen." Scarpa then cautions ſurgeons not to fancy from this account, that there is any occaſion to paſs a ligature through the meſentery for the purpoſe of fixing it near the ring, even were the gangrenous

grenous bowel perfectly free and inadherent to the neighbouring parts. The truth is, that the adhefive inflammation, which alfo commences immediately after the operation, fixes the parts near the wound before they can be drawn away by any retraction of the bowel or mefentery; and in the courfe of the firft 24 hours the two orifices of the divided inteftine are conftantly enveloped in the remains of the hernial fac. In a cafe of this kind, where the mortified bowel was not at all adherent to the neck of the hernial fac, Scarpa introduced a ligature through the mefentery in the ufual way, and on withdrawing it at the end of 24 hours, and paffing his finger to the bottom of the wound, he found the circumference of the two orifices of the bowel every where adherent. When a ligature through the mefentery had not been practifed, and no effufion, he alfo invariably difcovered the bowel adherent to the neck of the hernial fac, in every fubject who had died foon after the operation for a ftrangulated hernia, complicated with gangrene, and whom he examined after death. Certainly, he obferves, it muft be allowed that the orifices of the divided inteftine do retract, and become farther from the ring; but they do fo very flowly, and always draw along with them the neck of the hernial fac to which they contract early adhefions.

Our limits oblige us to pafs over many other interefting obfervations relative to the caufes which facilitate or retard the re-eftablifhment of the continuity of the inteftinal canal, and on the neceffity of the funnel-fhaped membrane as a fubftitute for the portion of bowel deftroyed by gangrene. We fhall next notice the comparifon of the artificial anus, arifing from a mortified hernia, with that which is the refult of a penetrating wound of the abdomen, as made by the intelligent Scarpa. "Why," he inquires, "is it fo common to fee the continuity of the inteftinal canal re-eftablifhed after a mortified inguinal or crural hernia, while the artificial anus is always incurable, when it is formed in confequence of a penetrating wound of the abdomen with protrufion of the inteftine, whether a part of the canal be deftroyed by gangrene, as in the inftance related by Mofcati (Mém. de l'Acad. de Chir. t. 8.), or whether it be totally or partially divided by the wounding inftrument, as in the examples recorded by Stalpart-Wander Wiel (Obf. Rar. t. ii. obf. 25.), Cabrole (Oper. Med. obf. 13.), Fabricuis Hildanus (Centur. 1. obf. 74.), &c.?" Scarpa will not even allow as an exception to this remark the cafe recited in the 2d vol. of the Œuvres Chir. de Default; becaufe he conceives the details are not fufficiently explicit.

In order to refolve this problem, fays he, we have only to compare a wound of the belly complicated with protrufion and mortification of the bowel, with a mortified inteftinal hernia, and draw a parallel between the circumftances which accompany the two cafes, and conftitute their chief differences. 1ft, In a hernia, the two extremities of the mortified gut are always enveloped in the remains of the hernial fac, which form in front of the two orifices a kind of funnel-fhaped canal. There is nothing like this at the extremities of a bowel divided either by a cutting inftrument which has penetrated the abdomen, or by mortification, which has complicated a wound of this defcription. 2dly, In thefe laft inftances, the wounded or burft inteftine becomes adherent to the edges of the external wound; confequently, it cannot retract into the abdomen, and the feces, which defcend out of the upper portion, being as it were on a level with the fkin, muft neceffarily all efcape out of the external wound. This is precifely what actually happens, it being known that artificial ani of this kind are always incurable. After a mortified hernia, on the contrary, it is upon the facility with which the bowel becomes fituated farther from the wound, drawing along with it the remains of the hernial fac, that the formation of an intermediate cavity between the two orifices of the gut depends, and which is to make the communication between them. What happens after penetrating wounds of the belly, with injury of the bowels, is alfo feen in ventral herniæ, which have formed under the cicatrix of a long-cured wound of the abdomen, when fuch herniæ are unfortunately attacked by mortification. Large, old, umbilical, and ventral herniæ, though furnifhed with a hernial fac, generally give rife to incurable artificial ani whenever they flough. Scarpa explains the caufe of this circumftance, by adverting to the very intimate adhefion which exifts in fuch herniæ between the fac and the aponeurofes and integuments of the abdomen, and which tends to hinder the formation of the funnel-fhaped membranous cavity in front of the orifices of the inteftine, and which alone can eftablifh a communication between them.

It follows, fays Scarpa, from the foregoing and other facts, that the retraction of the neck of the hernial fac, and of the two orifices of the bowel, is effential to the re-eftablifhment of the continuity of the inteftinal canal, when a breach has been made in it by mortification. Hence, he thinks, that in future every body will confider the plan of paffing a ligature through the mefentery, in order to keep the two ends of the gut near the outer wound, not only as ufelefs, but even as dangerous. The adhefions of the neck of the hernial fac to the inteftine, before the occurrence of gangrene, muft almoft always render the ligature ufelefs. And even when the adhefion does not exift at the period of cutting through the floughs, Scarpa afferts that the ligature is equally unneceffary. Indeed, fays he, immediately after the operation, while nature is effecting the feparation of the dead from the living parts, the latter invariably contract, in a very fhort time, clofe adhefions to the neck of the hernial fac, either on a level with a ring, or a little within it, and there is no danger of the feces being extravafated in the abdomen. If the latter accident has fometimes happened in fubjects who have died of hernia with gangrene in a few days, it has been becaufe the feces could not make their way outward quick enough, and therefore occafioned a burfting of the bowel in the abdomen, within the ring and beyond the extent of the hernial fac. If, in fome other cafes, the two orifices of the bowel have been found in the dead fubject not adherent to the neck of the hernial fac, and the feces extravafated, Scarpa thinks it has happened only after death, when the relaxation of the whole abdomen has let the ends of the bowel quit the neck of the hernial fac, to which it had not yet acquired any adhefions. But he conceives that nothing like this can ever happen in the living body, owing to the alternate action of the diaphragm and abdominal mufcles, which comprefs all the vifcera, and tend to propel them outward.

Hippocrates writes, "Si quod inteftinorum gracilium difcinditur, non coalefcit." (Sect. 4. Aphor. 24.) This aphorifm, fays Scarpa, taken in its true fenfe, is the expreffion of an inconteftible fact. It is very true, that wounds of the inteftinal canal follow in their cicatrization quite a different courfe from fimple wounds of the fkin, mufcles, or any other parts of the body. Their edges are never obferved to become immediately applied to each other, and therefore, ftrictly fpeaking, they do not re-unite. Their cure is altogether completed through the medium of the furrounding parts; that is to fay, by the adhefions which the inteftines contract with the great fac of the peritoneum lining the parietes of the abdomen, or with the productions of this membrane which compofe the external covering

covering of the greater part of the vifcera. Littre relates, that a lunatic ftabbed himfelf with a knife in eighteen places about the abdomen, eight of which wounds penetrated into this cavity, and evidently injured the bowels. The man, however, recovered in two months; but in another paroxyfm of mania he threw himfelf out of the window, and was killed. On opening his body, all the cicatrices of the inteftinal canal were found adherent to fome point of the furface of the adjacent vifcera or parietes of the abdomen. There was not a fingle one which feemed to be formed by the direct contact of the edges of the inteftinal wound with each other. Acad. Roy. des Sciences de Paris, 1705.

The peritoneum, when irritated by any caufe whatfoever, has a fingular difpofition to inflame round the point of irritation, and to contract adhefions with the parts which are contiguous to it in the fame fituation. Thus, when one or feveral convolutions of inteftines have been divided by a cutting inftrument, or pierced by a ball, they always become united for a certain extent to the furrounding parts, all of which are covered with the peritoneum. (See alfo Platner's Inftit. Chir. § 694.) Thefe adhefions, which are the only means employed by nature for blocking up accidental openings in the inteftinal canal, are promoted by the preffure which the abdominal mufcles and diaphragm alternately make upon the vifcera in the actions of infpiration and expiration.

In a fubfequent part of his work, Scarpa delivers his own fentiments on the different plans which have been propofed for effecting the re-union of a divided inteftine. If, fays he, we compare Ramdohr's operation with the fimple and effectual proceffes employed by nature for re-eftablifhing the continuity of the inteftinal canal after herniæ with mortification, we are compelled to acknowledge on this point, as well as on many others, that art continues very inferior to nature.

In the firft place, fays Scarpa, the introduction of one part of the bowel into the other is impracticable in a great many cafes of mortified herniæ, in confequence of the adhefions which the found part of the inteftine has contracted with the neck of the hernial fac, during the inflammatory period of the ftrangulation. Secondly, it is hardly ever poffible, without inconvenience, to draw a confiderable portion of the inteftinal canal out of the belly, for the purpofe of introducing, with all the requifite precautions, the upper end of the bowel into the lower. This cannot be done without handling for too long a time, and more or lefs roughly, the bowel, which is already irritated; which circumftance, together with the pricks of the needle, and the dragging of the ftitches, is more than an adequate caufe for the production of a fatal inflammation. The danger will be ftill farther increafed, if, according to the experiments of fome modern furgeons, the two ends of the bowel are fewed together over a piece of a calf's trachea, or a fmall hollow cylinder of tallow, or ifinglafs, a pafteboard tube, &c. Whatever may be the foreign body put within the bowel, it may, by obftructing the courfe of the feces, bring on violent inflammatory fymptoms, and deftroy the patient in the moft agonizing fufferings.

Scarpa then adverts to the experiments made on dogs by Dr. Thomfon of Edinburgh, and Dr. Smith of Philadelphia, which tend to prove that the two extremities of a divided bowel may be united by means of a future, and then returned into the cavity of the belly, without endangering the animal's life. (See alfo Boyer's experiments on this fubject, in the Mém. de la Societé de Médecine de Paris, tom. i.) It is alleged (fays Scarpa), that there is no rifk of the ligatures falling into the cavity of the abdomen after their detachment; but that by one of the operations of nature which cannot be explained, the threads are voided with the feces after the cure. Scarpa notices that the particulars of the way in which thefe futures were made is not given; and how (fays he) have the above gentlemen fucceeded in applying the orifices of the divided bowel accurately to each other, which is extremely difficult, efpecially in dogs? In whatever light the fubject is viewed (he obferves), "I doubt whether it be poffible to re-unite, by means of any future, the extremities of a divided bowel after mortification in hernia, or at leaft to do it with any probability of fuccefs. Such experiments, even when they fucceed in the beft poffible manner, merely prove that certain operations, which would moft frequently be ufelefs or fatal on man, may be fuccefsfully practifed on other animals."

On the contrary (fays Scarpa), in the circumftances which have been fuppofed, nature is daily obferved to fucceed in re-eftablifhing the continuity of the inteftinal canal, by means equally fimple and mild. She prepares herfelf (as it were) for this work before gangrene actually takes place, by forming adhefions between the ftrangulated bowel and the neck of the hernial fac. After the feparation of the mortified parts, fhe draws back into the abdomen the extremities of the divided bowel, and out of the remains of the hernial fac, fhe forms a fort of funnel-fhaped membrane, which ferves at firft for directing the feces outwards, and afterwards for tranfmitting them from the upper orifice of the inteftine into the lower, by making them follow a femicircular track from before backwards. For two or three inftances of the complete fuccefs of Ramdohr's operation, an almoft innumerable multitude of cures effected altogether by the powers of nature could now be cited. Thus, fays Scarpa, in the prefent ftate of our knowledge, we fhould congratulate patients who, in thefe unfortunate circumftances, fall into the hands of furgeons either incapable of undertaking an operation, or little folicitous about healing up the wound.

It may perhaps be imagined (continues Scarpa), that Ramdohr's operation is better calculated for certain cafes of penetrating wounds of the abdomen, as, for inftance, where the inteftine has been completely divided with a cutting inftrument, or by the effects of gangrene arifing from long expofure to the air. Scarpa here allows that it would be very defirable to find out fome operation which could be ufeful in thefe circumftances, which are the more unfortunate, becaufe they do not furnifh nature with the means of re-eftablifhing the continuity of the inteftinal canal, as in cafes of mortified herniæ. But he doubts whether in fuch inftances Ramdohr's operation could be undertaken with any probability of fuccefs; for the complete divifion of the inteftine is almoft always the refult of an enormous wound, which having interefted feveral vifcera leaves little or no hope of recovery. Suppofing the bowel fhould not have been divided with the cutting inftrument, but that it is protruded and gangrenous from long expofure, it muft be remembered, that in this cafe it will have contracted adhefions to the lips of the wound, even before the feparation of the mortified part; confequently, the bowel cannot be drawn farther out of the belly, fo as to allow one end of it being introduced into the other. To undertake fuch an operation then, would be to expofe the patient to much greater perils than that of an incurable artificial anus.

According to Scarpa, it is little to have proved that Ramdohr's operation is impracticable when the inteftine has been completely divided; he proceeds farther, and has no hefitation in afferting, that *in all cafes of penetrating wounds*

of

of the abdomen, attended with injury of the inteftine, whether the canal be opened longitudinally or tranfverfely, a future is always an operation not merely ufelefs, but even dangerous and fatal: In whatever manner it is practifed, one cannot avoid the evils which muft originate from the punctures, however few, and from the paffage of the ligatures through the coats of the inteftine; a part endued with exquifite fenfibility, and whofe external tunic is much difpofed to inflame, and rapidly to communicate the inflammation to all the other abdominal vifcera. It has been unfortunately proved, by the experience of feveral ages, that in moft of the cafes in which the inteftine has been ftitched in penetrating wounds of the belly, the patients have died in the greateft agony. If a few have efcaped the dangers of this operation, it has been becaufe in them the ftitches foon cut their way out, and were voided with the feces which continued to efcape from the wound until it was entirely healed.

All furgeons of experience, and particularly thofe of large hofpitals, have often feen wounds of the right or left iliac region accompanied with injury of the great inteftine. They may alfo have noticed, in thefe examples, that after the fubfidence of the local and general inflammatory fymptoms, the wound ftill continues to difcharge the feces for a certain time; but that afterwards it contracts, and the excrement refumes its ufual courfe. Thefe wounds almoft always heal completely: firft, becaufe the adhefion of the large inteftine to the parietes of the abdomen prevents the feces from being extravafated in the cavity of the peritoneum; and fecondly, becaufe the ample capacity of the fame bowel always prefents a ready paffage for the feces, notwithftanding the progreffive and fometimes quick clofure of the external opening.

If, in the inftance of a penetrating wound of the belly attended with a wound of the fmall inteftines, it were in the furgeon's power (as indeed it is) to return the bowel into the abdomen, fo that the opening in it may exactly correfpond with the wound in the abdominal parietes, there could not be a doubt of its quickly acquiring adhefions to the peritoneum, which lines the part around the internal orifice of the external wound: hence the feces would readily efcape through the outer wound, and at length it would happen, after a certain time, as in wounds of the large inteftines, that the artificial anus would gradually clofe up, and the feces refume their natural track. The narrow diameter of the fmall inteftines would not make an infurmountable obftacle to the paffage of the feces, provided they be, as they ufually are in this portion of the inteftinal canal, fufficiently fluid; and befides (fays Scarpa) is it not proved by experience, that they refume their natural courfe, after the cure of an artificial anus, even when a confiderable noofe of the fmall inteftines has been deftroyed by gangrene, and when the two ends form by their re-union a very acute angle? In all cafes, the patient's life would be faved, and the worft that could happen would be his being afflicted the reft of his days with a fiftula difcharging feces.

Encouraged by thefe principles, which are the natural deductions of a comparifon of wounds of the large inteftines with thofe of the fmall ones, Scarpa feels no hefitation in admitting the poffibility of curing the latter, without having recourfe to a future. He obferves, that it would not be difficult for him to quote examples of fuch cures. Amongft others, he has lately feen one which deferves to be mentioned here. A portion of fmall inteftine, protruded through a penetrating wound of the abdomen, happened to be punctured with a bodkin by a country furgeon, in his endeavours to return the part into the belly. The feces, however, were not extravafated in the cavity of the peritoneum, but were for a long while difcharged through the wound. The opening in the bowel always correfponded exactly to that in the parietes of the abdomen, although no future was practifed, nor any ligature put through the mefentery in order to keep it in this fituation. The feces afterwards gradually refumed their natural courfe, the wound at the fame time became fmaller, and in the end healed up. The young man, the fubject of this cafe, now enjoys very good health, and fuffers no inconvenience which can juftify a fufpicion of any obftruction in the paffage of the feces.

The inceffant preffure made by the abdominal mufcles and diaphragm upon all the vifcera, is a caufe why the wounded inteftine, inftead of quitting the external wound, enters it, and contracts adhefions to its lips. If, however, a too timorous furgeon were afraid of entirely trufting, on this point, to the wife providence of nature, he might (Scarpa thinks) without inconvenience pafs a ligature through the mefentery, behind the portion of wounded bowel, as is ufually and quite unneceffarily done in cafes of mortified hernia. Forty-eight hours, or thereabouts, would be time enough for the inteftine to contract adhefions, through the medium of the peritoneum, to the inner edges of the wound. After this period, the ligature would be completely ufelefs, and it ought to be withdrawn, as there would now be no chance of extravafation of the feces in the belly. At the fame time one fhould neglect no remedies, internal as well as external, which may be of ufe in moderating the patient's fufferings, diminifhing the energy of the circulation, and bringing the inflammation down to the degree requifite for the formation of adhefions. One ought alfo to keep open the external wound with the fame precautions, and according to the fame indications which are to be attended to in the treatment of an artificial anus. The principal object of thefe precautions is, to let the treatment be fuch that the wound may only diminifh in proportion as the evacuation from the lower part of the inteftinal canal increafes.

Here it may be *à propos* to obferve, that the conduct of a furgeon in the treatment of penetrating wounds of the abdomen, attended with injury of the fmall inteftines, is exactly the reverfe of what it ought to be in the treatment of penetrating wounds of the cheft, accompanied with injury of the lungs.

In the latter, fays Scarpa, phyfiology, agreeing with experience, teaches us that no means fhould be omitted for effecting the immediate union of the wound, (as it is termed, *by the firft intention,*) care being taken to check the force of the circulation by repeated bleedings and every antiphlogiftic remedy, in order to prevent or diminifh, as much as poffible, internal hemorrhage. If, notwithftanding all thefe means, blood fhould be extravafated between the pleura and lungs, it preffes equally upon every point of thefe vifcera, refifts their motion, and thereby contributes to ftop the bleeding. If, after the wound in the lungs is healed, the extravafated blood be not in too large quantity, it will be gradually removed by the abforbents. In the contrary cafe, it will form a fwelling beneath the external cicatrix, and prefent itfelf externally (fee Difcours fur les Principales Maladies obfervées à l'Hôtel Dieu de Lyon, &c. par M. Petit, p. 299.); or elfe a counter opening muft be practifed at the inferior part of the cheft. See Empyema.

We are to act quite differently in the treatment of a penetrating wound of the belly, with protrufion and injury of the inteftine; for in this cafe, the chief indication, that on which the patient's fafety mainly depends, confifts in keeping the external wound open, in order that the feces may find a ready outlet. The wounded bowel foon contracts adhefions

adhefions to the inner lips of the wound of the belly, and then we have nothing to fear from an extravafation of the inteftinal matter in the cavity of the peritoneum. Afterwards, in proportion as the feces refume their natural courfe, the external wound is to be allowed to diminifh, and entirely heal up. See Scarpa Sull'ernie Memorie Anatomico-Chirurgiche, &c. mem. 4.

In every inftance in which the abdomen has received a penetrating wound, attended with injury and protrufion of a portion of the inteftinal canal, the difplaced part is to be reduced, whether it be ftitched or not. This fhould be accomplifhed as fpeedily as poffible, before the bowel has fuffered much from expofure, conftriction, &c. and alfo before any adhefions have formed at the inner orifice of the external wound; adhefions which would render the reduction of the protruded part impracticable. Of courfe, if the wound fhould be too fmall to admit of the reduction being effected without handling and bruifing the bowel immoderately, it ought to be carefully enlarged with a curved biftoury, guided on a director. Indeed, according to Scarpa's principles, one would fuppofe that in every cafe of this kind the wound, if not free, fhould be dilated, as by this means the iffue externally of whatever efcapes from the breach in the inteftine after its reduction would be facilitated. The reft of the treatment confifts in the rigorous adoption of antiphlogiftic meafures, more efpecially a low diet, and copious and repeated venefections, with a view of counteracting the danger of peritoneal inflammation. With refpect to the dreffings, they cannot be too fimple, and they ought always to be light and fuperficial. A pledget of any common unirritating ointment is all that is requifite, and it muft be renewed as frequently as the quantity of the difcharge, &c. from the wound may render neceffary.

3. *Penetrating Wounds of the Belly, attended with Injury of the Bowels, but with no Protrufion.*—A wound of the inteftines is indicated by the difcharge of blood with the ftools, and fometimes by the efcape of fetid air, or of inteftinal matter from the external wound. Such an injury, however, when the wounded bowels lie concealed in the belly, does not always admit of being known with certainty immediately after occurrence. In the majority of examples, there is at firft no efcape either of air, or of the contents of the bowels, from the external wound; the quantity of blood voided per anum may be inconfiderable, and of courfe none at all will generally be difcharged for fome time after the accident. Wounds of the fmall inteftines, efpecially of the duodenum and jejunum, are indeed ufually followed by great anxiety, palenefs of the countenance, fyncope, cold perfpirations, a fmall intermitting tremulous pulfe; but then thefe fymptoms are only equivocal, and furnifh no pofitive information, becaufe feveral of them may happen in nervous fubjects, from a mere fuperficial unimportant cut or ftab. Our inability, however, to fay affuredly, in every cafe, whether the bowels are injured or not, is a thing of no practical importance; becaufe when the nature of the accident is not clearly manifefted by fome peculiarity or feverity of the fymptoms, the cafe fhould invariably be treated on common, fimple, antiphlogiftic principles; and alfo, when circumftances leave not the fmalleft doubt of the inteftines being hurt, the fame treatment is the only rational one which can be purfued. Wounds of the fmall inteftines are reckoned much more dangerous than thofe of the large; and the nearer the injury is to the pylorus, the greater, generally fpeaking, is the degree of danger. Such cafes are alfo much more frequently, than injuries of the large inteftines, the caufe of extravafation. In the latter examples, the fymptoms are commonly milder, and either the paffage of the inteftinal contents outward through the wound more eafy and certain, on account of the bowel being naturally lefs moveable than the other inteftines; or their paffage in their natural courfe more ready, by reafon of the greater capacity of that part of the inteftinal tube.

A wounded inteftine is faid to prefent fome particular appearances, to which the generality of writers have paid no attention. "If a gut be punctured, the elafticity of the peritoneum, and the contraction of the mufcular fibres, open the wound; and the villous or mucous coat forms a fort of hernial protrufion, and obliterates the aperture. If an incifed wound be made, the edges are drawn afunder and reverted, fo that the mucous coat is elevated in the form of a flefhy lip. If the fection be tranfverfe, the lip is broad and bulbous, and acquires tumefaction and rednefs from the contraction of the circular fibres behind it, which produces, relatively to the everted portion, the appearance of a cervix. If the incifion is according to the length of the cylinder, the lip is narrow, and the contraction of the adjacent longitudinal, refifting that of the circular fibres, gives the orifice an oval form. This everfion and contraction are produced by that feries of motions, which conftitutes the periftaltic action of the inteftines." Travers on Injuries of the Inteftines, p. 85.

According to this gentleman, fome of thefe appearances were defcribed by Haller, in Element. Phyfiol. lib. 24. fect. 2. and Opera Minora, tom. i. fect. 15.

Having witneffed the facility with which confiderable injuries of the inteftinal tube were repaired, Mr. Travers was defirous of afcertaining more fully the powers of nature in the procefs of fpontaneous reparation, and of determining under how great a degree of injury it would commence, as well as the mode of its accomplifhment. For thefe purpofes, he divided the fmall inteftine of feveral dogs as far as the mefentery. All thefe animals died, in confequence of the inteftinal matter being extravafated, if they had been lately fed, or if they had been fafting in confequence of inflammation, attended with a feparation of the ends of the divided bowel, everfion of the mucons coat, and obliteration of the cavity, partly by this everfion, and partly by a plug of coagulated chyle.

In one particular inftance in which Mr. Travers made a divifion of the bowel half through its diameter, a fort of pouch was formed round the injured inteftine. "A pouch, refembling fomewhat the diverticulum in thefe animals, was formed oppofite to the external wound, on the fide of the parietes, by the lining peritoneum; on the other fide, by the mefentery of the injured inteftine, that inteftine itfelf, and an adjacent fold, which had contracted with it a clofe adhefion. The pouch, thus formed and infulated, included the oppofed fections of the gut, and had received its contents, &c. The tube at the orifices was narrowed by the half everfion, but offered no impediment to the paffage of fluids." (P. 96.) Whether, under thefe circumftances, the functions of the alimentary canal could have been continued, Mr. Travers profeffes himfelf incapable of deciding. Among the inferences which this gentleman has drawn from the experiments detailed in his publication, the tendency of the two portions of a divided bowel to recede from each other, inftead of coalefcing to repair the injury, merits notice, inafmuch as it tends to fhew that the only means of fpontaneous reparation confift in the formation of an adventitious canal, by the encircling bowels and their appendages. The everted mucous coat, which is the part oppofed to the furrounding peritoneum, is alfo indifpofed to the adhefive inflammation.

When, however, the wound of the inteftine is fmaller, the

the obſtacles to reparation are not abſolutely inſurmountable. Here retraction is prevented, and the proceſſes of everſion and contraction modified by the limited extent of the injury. If, therefore, the adheſive inflammation unite the contiguous ſurfaces, effuſion will be prevented, and the animal eſcape immediate deſtruction. But union can only take place through the medium of the ſurrounding parts.

According to Mr. Travers, it is the retraction immediately following the wound that is a chief obſtacle to the reparation of the injury; for if the diviſion be performed in ſuch a way as to prevent retraction, the canal will be reſtored in ſo ſhort a time, as but ſlightly to interrupt the digeſtive function. In confirmation of this ſtatement, a ligature was tightly applied round the duodenum of a dog, which became ill, but entirely recovered, and was killed. "A ligature, faſtened around the inteſtine, divides the interior coats of the gut, in this effect reſembling the operation of a ligature upon an artery. The peritoneal tunic alone maintains its integrity. The inflammation, which the ligature induces on either ſide of it, is terminated by the depoſition of a coat of lymph, which is exterior to the ligature, and quickly becomes organized. When the ligature, thus encloſed, is liberated by the ulcerative proceſs, it falls of neceſſity into the canal, and paſſes off with its contents." P. 103, 104.

It appears alſo from Mr. Travers's experiments and obſervations, that longitudinal wounds of the bowels are more eaſily repaired than ſuch as are tranſverſe. In a dog, a longitudinal wound, of the extent of an inch and a half, was repaired by the adheſive inflammation. Here the proceſs of everſion is very limited; the aperture bears a ſmaller proportion to the cylinder of the bowel; and the entire longitudinal fibres reſiſt the action of the circular, which are divided, and can now only ſlightly leſſen the area of the canal. P. 108.

When the wounded bowel lies within the cavity of the abdomen, no ſurgeon of the preſent day would have the raſhneſs to think of attempting to expoſe the injured inteſtine, for the purpoſe of ſewing up the breach of continuity in it. In fact, the ſurgeon ſeldom knows at firſt what has happened; and when the nature of the caſe is afterwards manifeſted, by the diſcharge of blood per anum, an extravaſation of inteſtinal matter, &c. it would be impoſſible to get at the injured part of the bowel, not only becauſe its exact ſituation is unknown, but more particularly on account of the adheſions, which are always formed with ſurpriſing rapidity. But even if the ſurgeon knew to a certainty, in the firſt inſtance, that one of the bowels was wounded, and the preciſe ſituation of the injury, no ſuture could be applied, without conſiderably enlarging the external wound, drawing the wounded inteſtine out of the cavity of the abdomen, and handling and diſturbing all the adjacent viſcera. Nothing would be more likely than ſuch proceedings to render the accident, which might originally be curable, unavoidably fatal. We muſt agree upon this point with Mr. John Bell, who ſays, "When there is a wounded inteſtine, which we are warned of only by the paſſing out of the feces, we muſt not pretend to ſearch for it, nor put in our finger, nor expect to ſew it to the wound; but we may truſt that the univerſal preſſure, which prevents great effuſion of blood, and collects the blood into one place, that very preſſure, which always cauſes the wounded bowel and no other to protrude, will make the two wounds, the outward wound and the inward wound of the inteſtine, oppoſe each other point to point; and if all be kept there quiet, though but for one day, ſo lively is the tendency to inflame, that the adheſion will be begun, which is to ſave the patient's life." Diſcourſes on Wounds, p. 361. edit. 3.

When the extravaſation and other ſymptoms, a few days after the accident, evince the nature of the caſe, a ſuture can be of no uſe whatever, as the adheſive inflammation has already fixed the part in its ſituation, and the ſpace, in which the extravaſation lies, is completely ſeparated from the general cavity of the abdomen by the ſurrounding adheſions.

When the bowel is not protruded, and the opening in it is ſituated cloſely behind the wound in the peritoneum, a ſuture is not requiſite; for the contents of the gut, not paſſing onward, will be diſcharged from the outer wound, and not be diffuſed among the viſcera, if care be taken to keep the external wound open. There is no danger of the wounded bowel changing its ſituation, and becoming diſtant from the wound in the peritoneum; for the ſituation which it now occupies is its natural one. Nothing but violent motion, or exertions, could cauſe ſo unfavourable an occurrence, and theſe ſhould always be avoided. The adheſions, which take place in the courſe of a day or two, at length render it impoſſible for the bowel to ſhift its ſituation. See Dict. of Pract. Surgery, edit. 3. art. *Wounds.*

In a penetrating wound of the abdomen, as a late author remarks, whether by gun-ſhot, or a cutting inſtrument, if no protruſion of inteſtine takes place, (and this, it muſt be obſerved, in muſket or piſtol wounds, rarely occurs,) the lancet, with its powerful concomitants, abſtinence and reſt, particularly in the ſupine poſture, are our chief dependence. Great pain and tenſion, which uſually accompany theſe wounds, muſt be relieved by leeches, if they can be procured, by the topical application of fomentations, and the warm bath; and if any internal medicine is given as a purgative, it muſt, for obvious reaſons, be of the mildeſt nature. The removal of the ingeſta, as a ſource of irritation, is beſt effected by frequently repeated oleaginous glyſters; indeed, on the firſt infliction of a wound of the abdomen, the contents of the inteſtinal canal and ſtomach are generally evacuated ſpontaneouſly, the ſtools being ſometimes tinged with blood. Their accumulation muſt be guarded againſt by a rigorous diet; for to the general ſtate of fulneſs of the veſſels induced by food, is added its local and mechanical ſtimulus in the undigeſted form. By this treatment, penetrating wounds, in which ſeveral plicæ of inteſtines have been neceſſarily implicated, have been happily cured. Authors abound with inſtances of this kind, and Mr. Hennen has ſeen ſeveral: among others, he was witneſs to the recovery of a ſoldier, who had been ſhot through the abdomen with a ramrod, at the ſiege of Badajos in 1812, which paſſed in anteriorly, and actually ſtuck in the vertebræ, from which it was not diſengaged without the application of ſome force. Garengeot and Lamotte alſo record cures, after the paſſage of ſwords completely through the body. See Hennen's Obſ. on Military Surgery, p. 436, 437.

In all penetrating wounds of the belly, the dreſſings cannot be too ſimple and light.

In ſome inſtances, the ball, or part of the weapon which has inflicted the wound, remains within the abdominal cavity, and is afterwards evacuated by the natural paſſages.

Balls, ſays Mr. Hennen, frequently paſs clean through the abdomen, evidently wounding the inteſtines, but without occaſioning any protruſion of them at either of the orifices. Theſe caſes, like all others of thoſe parts, are extremely dangerous, but are not neceſſarily mortal. They require the moſt guarded attention, and the utmoſt watchfulneſs of the approach of inflammation, which often comes on moſt inſidiouſly. The mildeſt poſſible application ſhould be employed to the wounds, and no plugging with tents

 or

or introduction of medicated dreffings thought of. (P. 440.) At firft a common linfeed poultice, and afterwards fimple pledgets, are as eligible dreffings as any which can be mentioned.

Extravafation in the Abdomen.—Wounds of the abdomen may be complicated with extravafations of blood, chyle, excrement, bile, or urine. None of thefe complications, however, are half fo frequent as an unreflecting and inexperienced practitioner might apprehend. The employment of the phrafe *cavity of the abdomen* has paved the way to much erroneous fuppofition upon this fubject, and has induced many abfurd notions, which even the fenfible obfervations long ago publifhed by Petit (le fils) have fcarcely yet difpelled.

As a modern writer has obferved, "there is not truly any cavity in the human body, but all the hollow bowels are filled with their contents, all the cavities filled with their hollow bowels, and the whole is equally and fairly preffed. Thus, in the abdomen all the vifcera are moved by the diaphragm and the abdominal mufcles, upwards and downwards, with an equable continual preffure, which has no interval; and one would be apt to add, the inteftines have no repofe, being kept thus in continual motion; but though the action of the diaphragm, and the re-action of the abdominal mufcles, are alternate, the preffure is continual; the motion which it produces (they produce) is like that which the bowels have when we move forwards in walking, having a motion with refpect to fpace, but none with regard to each other, or to the part of the belly which covers them; the whole mafs of the bowels is alternately preffed, to ufe a coarfe illuftration, as if betwixt two broad boards, which keep each turn or inteftine in its right place, while the whole mafs is regularly moved. When the bowels are forced down by the diaphragm, the abdominal mufcles recede: when the bowels are pufhed back again, it is the re-action of the abdominal mufcles that forces them back and follows them; there is never an inftant of interruption of this preffure, never a moment in which the bowels do not prefs againft the peritoneum; nor is there the fmalleft reafon to doubt that the fame points in each are continually oppofed. We fee that the inteftines do not move, or at leaft do not need to move in performing their functions; for in hernia, where large turns of inteftines are cut off by gangrene, the remaining part of the fame inteftines is clofely fixed to the groin, and yet the bowels are eafy, and their functions regular. We find the bowels regular when they lie out of the belly in hernia, as when a certain turn of inteftine lies in the fcrotum, or thigh, or in a hernia of the navel; and where yet they are fo abfolutely fixed, that the piece of inteftine is marked by the ftraightnefs of the rings. We find a perfon, after a wound of the inteftine, having free ftools for many days; and what is it that prevents the feces from efcaping, but merely this regular and univerfal preffure? We find a perfon on the fourth or fifth day with feces coming from the wound! a proof, furely, that the wound of the inteftine is ftill oppofite, or nearly oppofite, to the external wound. We find the fame patient recovering without one bad fign! What better proof than this could we defire, that none of the feces have exuded into the abdomen?

"If in a wound of the ftomach the food could get eafily out by that wound, the ftomach would unload itfelf that way, there would be no vomiting, the patient muft die; but fo regular and continual is this preffure, that the inftant a man is wounded in the ftomach he vomits, he continues vomiting for many days, while not one particle efcapes into the cavity of the abdomen. The outward wound is commonly oppofite to that of the ftomach, and by that paffage fome part of the food comes out; but when any accident removes the inward wound of the ftomach from the outward wound, the abdominal mufcles prefs upon the ftomach, and follow it fo clofely, that if there be not a mere laceration extremely wide, this preffure clofes the hole, keeps the food in, enables the patient to vomit, and not a particle, even of jellies or foups, is ever loft, or goes out into the cavity of the belly.

"How (proceeds Mr. J. Bell), without this univerfal and continual preffure, could the vifcera be fupported? Could its ligaments, as we call them, fupport the weight of the liver? Or, what could fupport the weight of the ftomach when filled? Could the mefentery or omentum fupport the inteftines; or could its own ligaments, as we ftill name them, fupport the womb? How, without this uniform preffure, could thefe vifcera fail to give way and burft? How could the circulation of the abdomen go on? How could the liver and fpleen, fo turgid as they are with blood, fail to burft? Or, what poffibly could fupport the loofe veins and arteries of the abdomen, fince many of them, *e. g.* the fplenic vein, is (are) two feet in length, is (are) of the diameter of the thumb, and has (have) no other than the common pellucid and delicate coats of the veins? How could the vifcera of the abdomen bear fhocks and falls, if not fupported by the univerfal preffure of furrounding parts? In fhort, the accident of hernia being forced out by any blow upon the belly, or by any fudden ftrain, explains to us how perfectly full the abdomen is, and how ill it is able to bear any preffure, even from its own mufcles, without fome point yielding, and fome one of its bowels being thrown out. And the ficknefs and faintnefs, which immediately follow the drawing off of the waters of a dropfy, explain to us what are the confequences of fuch preffure being even for a moment relaxed. But perhaps one of the ftrongeft proofs is this, that the principle muft be acknowledged, in order to explain what happens daily in wounds; for though in theory we fhould be inclined to make this diftinction, that the hernia, or abfcefs of the inteftines, will adhere and be fafe, but that wounded inteftines, not having time to adhere, will become flaccid, as we fee them do in diffections, and fo, falling away from the external wound, will pour out their feces into the abdomen, and prove fatal; though we fhould fettle this as a fair and good diftinction in theory, we find that it will never anfwer in practice. Soldiers recover daily from the moft defperate wounds; and the moft likely reafons that we can affign for it are, the fulnefs of the abdomen, the univerfal, equable, and gentle preffure, and the active difpofition of the peritoneum ready to inflame with the flighteft touch. The wounded inteftine is, by the univerfal preffure, kept clofe to the external wound, and the peritoneum and the inteftine are equally inclined to adhere. In a few hours that adhefion is begun which is to fave the patient's life, and the lips of the wounded inteftine are glued to the lips of the external wound. Thus is the fide of the inteftine united to the inner furface of the abdomen; and though the gut cafts out its feces while the wound is open, though it often cafts them out more freely while the firft inflammation lafts, yet the feces refume their regular courfe whenever the wound is difpofed to clofe." John Bell's Difcourfes on Wounds, p. 323—327, edit. 3.

The foregoing extract, though drawn up in the moft carelefs ftyle, contains fuch obfervations as are well calculated to make the reader underftand that the abdomen is in reality not a cavity, but a compact mafs of containing and contained parts; that the clofe manner in which the various furfaces are conftantly in contact muft powerfully oppofe extravafations; and that in fact it often entirely prevents them.

them. The paſſage cited impreſſes us with the utility of that quick propenſity to the adheſive inflammation which prevails throughout every peritoneal ſurface, and which not only often has the effect of permanently hindering effuſion of the contents of the viſcera, by agglutinating the parts together, but which, even when an extravaſation has happened, beneficially confines the effuſed fluid in one maſs, and ſurrounds it with ſuch adheſions of the parts to each other as are rapid in their formation, and effectual for the purpoſes of limiting the extent of the effuſion, and preventing the irritation of the extravaſated matter from affecting the reſt of the abdomen.

It is to M. Petit that we are indebted for the introduction of more correct modes of thinking upon the foregoing ſubject. See Mém. de l'Acad. de Chirurgie.

But notwithſtanding the influence of the reciprocal preſſure of the containing and contained parts againſt each other, and the uſeful effect of the quickly ariſing adheſive inflammation in all penetrating wounds of the belly, complicated with the injuries of the viſcera, we are not to ſuppoſe that extravaſation never happens, but only that it is much leſs frequent than has been commonly ſuppoſed. Mr. Travers, with much laudable induſtry, has endeavoured to trace more minutely than any preceding writer the particular circumſtances under which effuſions in the abdomen are likely or unlikely to happen. "It being admitted (ſays he) that there are caſes in which effuſion does take place, it is eaſy to conceive circumſtances which muſt conſiderably influence this event. If, for example, the ſtomach and bowels be in a ſtate of emptineſs, the nauſea which follows the injury will maintain that ſtate. If the extent of the wound be conſiderable, the matter will more readily paſs through the wound than along the canal. A wound of the ſame dimenſions in the ſmall and the large inteſtines will more readily evacuate the former than the latter, becauſe it bears a larger proportion to the calibre. Inciſed and punctured wounds admit of the adheſion of the cut edges, or the everſion of the internal coat of the gut, ſo as to be in many inſtances actually obliterated; whereas lacerated or ulcerated openings do not admit of theſe ſalutary proceſſes. Again, in a tranſverſe ſection of the bowel, contraction of the circular fibre cloſes the wound, whereas in a longitudinal ſection, the contraction of this fibre enlarges it. Such (ſays Mr. Travers) are the circumſtances which, combined in a greater or leſs degree, increaſe or diminiſh the tendency to effuſion." On Injuries of Inteſtines, &c. p. 13, 14.

After the details of ſome experiments and caſes, the preceding author makes among other concluſions the following:

1. That effuſion is not an ordinary conſequence of penetrating wounds.

2. That if the gut be full, and the wound extenſive, the ſurrounding preſſure is overcome by the natural action of the bowel tending to the expulſion of its contents.

3. That if food has not recently been taken, and the wound amounts to a diviſion of the gut, or nearly ſo, the everſion and contraction of the orifice of the tube prevent effuſion.

4. That if the canal be empty at the time of the wound, no ſubſequent ſtate of the bowel will cauſe effuſion, becauſe the ſupervening inflammation agglutinates the ſurrounding ſurfaces, and forms a circumſcribed ſac; nor can effuſion take place from a bowel at the moment full, provided it retains a certain portion of its cylinder entire, the wound not amounting nearly to a ſemi-diviſion of the tube, for then the everſion and contraction are too partial to prevent an extravaſation.

5. That when, however, air has eſcaped from the bowel, or blood has been extravaſated in quantity within the abdomen at the time of the injury, the reſiſtance oppoſed to effuſion will be leſs effectual, although the parietal preſſure is the ſame, as ſuch fluids will yield more readily than the ſolids naturally in contact. P. 25, 26. 100.

6. That though extravaſation is not common in penetrating wounds, it follows more generally in caſes where the bowel is ruptured by blows, or falls upon the belly, while the integuments continue unwounded. P. 36.

7. That when the bowels are perforated by ulceration, there is more tendency to effuſion than in caſes of wounds. P. 38, &c.

Mr. Travers explains the reaſon of the greater tendency to effuſion, in caſes of inteſtines burſt by violence, and in thoſe of ulceration, "by the difference in the nature of the injury which the bowel ſuſtains when perforated by a ſword or bullet, as in the one caſe, or burſt or ulcerated in the other. A rupture by concuſſion could only take place under a diſtended ſtate of the bowel, a condition moſt favourable to effuſion, and from the texture of the part, a rupture ſo produced would ſeldom be of limited extent. The proceſs of ulceration, by which an aperture is formed, commences in the *internal* coat of the bowel, which has always incurred a more extenſive leſion than the peritoneal covering. The puncture or cut is merely a ſolution of continuity in a point or line; the ulcerated wound is an actual loſs of ſubſtance. The conſequence of this difference is, that while the former, if ſmall, is glued up by the effuſion from the cut veſſels, or, if large, is nearly obliterated by the full everſion of the villous coat, the latter is a permanent orifice." P. 46.

Blood is more frequently extravaſated in the abdomen than any other fluid. Extravaſations of this kind, however, do not invariably happen, whenever veſſels of not a very conſiderable ſize are wounded. The compact ſtate of the abdominal viſcera, in regard to each other, and their action on each other, oppoſe this effect. The action alluded to, which depends on the abdominal muſcles and diaphragm, is rendered very manifeſt by what happens in conſequence of operations for herniæ attended with alteration of the inteſtines, or omentum. If theſe viſcera ſhould burſt or ſuppurate after being reduced, the matter which eſcapes from them, or the pus which they ſecrete, is not loſt in the abdomen, but is propelled towards the wound of the ſkin, and there makes its exit. The inteſtinal matter effuſed from a mortified bowel has been known to remain lodged the whole interval between one time of dreſſing the wound and another, in conſequence of the ſurgeon ſtopping up the external wound with a large tent. When the above-mentioned action or preſſure of the muſcles is not ſufficient to keep the blood from making its eſcape from the veſſels, ſtill it may hinder it from becoming diffuſed among the convolutions of the viſcera, and thus the extravaſation is confined in one maſs. The blood, effuſed and accumulated in this way, is commonly lodged at the inferior and anterior part of the abdomen, above the lateral part of the pubes, and by the ſide of one of the recti muſcles. The weight of the blood may propel it into this ſituation, or perhaps there may be leſs reſiſtance in this direction than in another. In opening the bodies of perſons who have died with ſuch extravaſations, things may put on a different aſpect, and the blood ſeem to be promiſcuouſly extravaſated over every part of the abdomen. But when ſuch bodies are examined with care, it will be found that the

the blood does not infinuate itfelf among the vifcera till the moment when the abdomen is opened, and the mafs previoufly lies in a kind of pouch. This pouch is frequently circumfcribed, and bounded by thick membranes, efpecially when the extravafation has been of fome ftanding. Sabatier, Médecine Opératoire, tom. i. p. 28—30.

It is of the higheft confequence to a practical furgeon to remember well that all the parts contained in the abdomen are clofely in contact with each other, and with the inner furface of the peritoneum. This is one grand reafon why extravafations are feldom fo extenfively diffufed as one might imagine, but commonly lie in one mafs, as Petit, Sabatier, and all the beft moderns, have noticed. The preffure of the elaftic bowels, of the diaphragm, and abdominal mufcles, not only frequently prefents an obftacle to the diffufion of extravafated matter, but often ferves to propel it towards the mouth of the wound. The records of furgery make mention of numerous inftances in which perfons have been ftabbed through the body without any fatal confequences, and fometimes without the fymptoms being even fevere. In Mr. Travers's publication many cafes exemplifying this obfervation are quoted from a variety of fources. Fab. Hildan. Obf. Chirurg. cent. v. obf. 74. Œuvres de Paré, liv. x. chap. 35. Wifeman's Surgery, p. 371. La Motte's Traité Complet de Chirurgie, &c. &c. In fuch cafes, the bowels have been fuppofed to have eluded the point of the weapon, and this may, perhaps in a few inftances, have been actually the fact; but in almoft all fuch examples there can be no doubt that the bowels have been punctured, and an extravafation of inteftinal matter has been prevented by the oppofite preffure of the adjacent vifcera. Such refiftance and preffure may alfo have occafionally obliged inteftinal matter, or blood actually extravafated, to pafs through the wound of the bowel into its cavity, and thus be fpeedily removed. Certain it is, fuch copious evacuations of blood *per anum* have followed ftabs of the abdomen as could hardly proceed from the arteries of the inteftines. This way of getting rid of an extravafation muft be rare, however, compared with that by abforption.

The pouch or cyft including extravafated blood or matter, as mentioned by Sabatier, is formed by the fame procefs which circumfcribes the matter of abfceffes. (See SUPPURATION.) It is in fhort the adhefive inflammation. All thefe furfaces in contact with each other, and furrounding the extravafation and track of the wound, generally foon become fo intimately connected together by the adhefive inflammation, that the place in which the extravafation is lodged is a cavity entirely deftitute of all communication with the cavity of the peritoneum. The track of the wound leads to the feat of the effufed fluid, but has no diftinct opening into the general cavity of the abdomen. The rapidity with which the above adhefions form is often very great, almoft incredible.

Urine and bile are more frequently difperfed to a great extent among the abdominal vifcera than blood. The latter fluid, indeed, muft often coagulate; a circumftance that muft both tend to ftop further hemorrhage, and confine the extravafation in one mafs.

Symptoms and Treatment of Extravafations in the Abdomen.—1. *Blood.*—Wounds of the fpleen, and of fuch veins and arteries as are above a certain fize, almoft always prove fatal from internal hemorrhage. The blood generally makes its way downwards, and accumulates at the inferior part of the abdomen, unlefs the exiftence of adhefions happen to oppofe the defcent of the fluid to the moft depending fituation. The belly fwells, and the fluctuation of a fluid is perceptible through the anterior part of the abdominal parietes. The patient grows pale, lofes his ftrength, is affected with fyncope, and his pulfe becomes weaker and weaker. In fhort, the fymptoms ufually attendant on hemorrhage are obfervable. The vifcera and veffels in the abdomen being continually compreffed on all fides by the furrounding parts, the blood cannot be effufed without overcoming a certain degree of refiftance; and unlefs a veffel of the firft magnitude, like the aorta, the vena cava, or one of their principal branches, has been wounded, the blood efcapes from the veffel flowly, and feveral days elapfe before any confiderable quantity has accumulated in the leffer cavity of the pelvis.

In thefe cafes of extravafated blood, the fymptoms, which perhaps had difappeared under the employment of bleeding and anodyne medicines, now come on again. A foft fluctuating tumour may be felt at the lower part of the abdomen, fometimes on the right fide, fometimes on the left, occafionally on both fides. The preffure made by the effufed blood on the urinary bladder excites diftreffing inclinations to make water; while the preffure which the figmoid flexure of the colon fuffers is the caufe of obftinate conftipation. In the mean time, the quantity of extravafated blood increafing, irritation and inflammation of the peritoneum are induced. The pulfe grows weaker, debility enfues, the countenance is moiftened with cold perfpirations; and, unlefs inftigated by all the antecedent circumftances, the furgeon practifes an incifion for the difcharge of the fluid, the patient falls a victim to the accident.

In the year 1733, Vacher, principal furgeon of the military hofpital at Befançon, fuccefsfully adopted this mode of treatment. Petit (the fon) afterwards tried the fame plan, though it did not anfwer, (as is alleged,) in confequence of the inflammation having advanced too far before the operation was performed. Long before the time of Vacher and Petit, a fuccefsful inftance of fimilar practice had been recorded by Cabrole.

Indeed, when the fymptoms leave no doubt of there being a large quantity of blood extravafated in the abdomen; when the patient's complaints are of a very ferious nature, and are evidently owing to the irritation and preffure of the blood on the furrounding vifcera; and when a local fwelling denotes the feat of the extravafation, there cannot be two opinions about the propriety of making an incifion for its evacuation.

Surgeons, however, fhould recollect, that a fmall extravafation of blood may exift without producing any confiderable irritation, provided no opening be made into the cyft with which it becomes furrounded. On the contrary, when fuch cyft is opened, the air then having free accefs to the blood contained there, that part of the fluid which cannot be difcharged is apt to putrefy, and become fo irritating, as to excite inflammation of the furrounding parts.—Even though there may be an evident extravafation of blood, the bad fymptoms are alfo fometimes entirely owing to the injury done to the parts within the abdomen, and neither to the preffure nor the irritation of the effufed blood.

But fometimes, as we have already noticed, the accumulated blood at firft neither irritates the adjacent parts by its quantity nor quality. An inflammation, however, of the parts furrounding the extravafation at length takes place. The tenfion, irritation, and pain, which in the firft inftance arofe from the wound itfelf, and fubfided, feem now to be renewed. When the extravafation is at the lower and anterior part of the abdomen, the patient experiences pain about the hypogaftric region. He is alfo conftipated, and as he

fuffers

suffers great irritation of the bladder, he feels frequent propensities to make water, but cannot relieve himself. At last a tumour makes its appearance, attended with a fluctuation more or less distinct.

In this instance, it seems proper to give vent to the accumulated blood. If this fluid should be found coagulated, injections of warm water would facilitate its discharge. Sabatier, Médécine Opératoire, tom. i.

2. *Chyle and Feces.*—These are not so easily extravasated in the abdomen as blood, because they do not require so much resistance on the outside of the stomach and intestines, to make them continue their natural route through the alimentary canal, as blood requires to keep it in the vessels. Extravasations of this kind, however, sometimes happen when the wound is large and the bowel distended at the moment of the injury, or when, as Mr. Travers has likewise explained, air is extravasated, or blood effused in the abdomen; these fluids being incapable of making effectual resistance to the escape of the intestinal matter. (See an Inquiry into the Process of Nature in repairing Injuries of the Intestines, &c. p. 26.) Nothing is a better proof of the difficulty with which chyle and feces are extravasated than the operation of an emetic, when the stomach is wounded and full of aliment. In this instance, if the resistance to the extravasation of the contents of the stomach were not considerable, they would be effused in the abdomen, instead of being vomited up. A peculiarity in wounds of the stomach and intestines is, that the opening which allows their contents to escape may also allow them to return into the wounded viscus.

Extravasation of intestinal matter in the abdomen is attended with a severe train of febrile symptoms; dryness of the mouth, tongue, and fauces; considerable pain and swelling of the belly; convulsive startings; and hiccough and vomiting, with which the patients are generally attacked on the day after that on which the wound was received. Sabatier de la Médécine Opératoire, tom. i. p. 34.

In these cases, general means are the only ones which can be employed; venesection, fomentations, low diet, perfect rest, anodynes, &c. All solid food must be most strictly prohibited. The close state of the viscera may also be increased by applying a bandage round the body.

If the symptoms are not speedily assuaged, the abdominal viscera become affected with general inflammation and gangrene, and the patients die in the course of a few days.

3. *Bile.*—Bile, on account of its great fluidity, is more easily extravasated extensively in the abdomen than either blood or the contents of the stomach and intestines. Besides, the gall-bladder has the power of contracting itself so completely as to expel the whole of its contents. Notwithstanding these circumstances, however, extravasations of this kind are exceedingly uncommon, doubtless on account of the small size of the gall-bladder, and its deep-guarded situation, between the concave surface of the liver and upper part of the transverse arch of the colon.

Sabatier informs us, that he has only been able to find one example on record. This case, after having been communicated to the Royal Society of London by Dr. Steward (N° 414, p. 341. Abridgm. tom. vii. p. 571, 572.), was inserted as an extract in the third volume of the Edinburgh Essays, and also in the third volume of Van Swieten's Commentaries on the Aphorisms of Boerhaave. (Transl. p. 65. edit. 1754.) An officer received a wound, penetrating the cavity of the abdomen, and entering the fundus of the gall-bladder, without doing any material injury to the adjacent parts. The abdomen was immediately distended, as if the patient had been afflicted with an ascites, or tympanitis; nor did the swelling either increase or diminish till the patient's death, which happened a week after the infliction of the wound.

There was no rumbling noise in the abdomen, though it was exceedingly tense. There were no stools, and very little urine was discharged, notwithstanding purgatives and glysters, and a good deal of liquid nourishment, were given. The patient never had one instant of sound sleep, but was always restless, though anodynes were exhibited. There was no appearance of fever, and the pulse was always natural till the last day of the patient's life, when it became intermittent. The intestines were found, after death, very much distended, the gall-bladder quite empty, and a large quantity of bile extravasated in the abdomen.

Sabatier met with an opportunity of observing the symptoms of an extravasation of bile, in consequence of a wound of the gall-bladder. The patient's abdomen swelled very quickly; his respiration became difficult, and he soon afterwards complained of tension, and pain in the right hypochondrium. His pulse was small, frequent, and contracted; his extremities were cold, and his countenance very pale. The bleedings which were practised the first day gave him a little relief; but the tension of the abdomen, and the difficulty of breathing, still continued. A third bleeding threw the patient into the lowest state of weakness, and he vomited up a greenish matter. On the third day, the lower part of the belly was observed to be more prominent, and there was no doubt of an extravasation. M. Sabatier introduced a trocar, and gave vent to a green blackish fluid, which had no smell, and was pure bile, that had escaped from the wound of the gall-bladder. After the operation, the patient grew weaker and weaker, and died in a few hours. On opening the body, a large quantity of yellow bile was found between the peritoneum and intestines; but it had not insinuated itself among the convolutions of the viscera. A thick gluten connected the bowels together, and they were prodigiously distended. The gall-bladder was shrivelled, and almost empty. Towards its fundus, there was a wound about a line and a half long, corresponding to a similar wound in the peritoneum. The wound which had occurred at the middle and lower part of the right hypochondrium, between the third and fourth false ribs, had glided from behind forward, and from above downward, between the cartilages of the ribs, until it reached the fundus of the gall-bladder.

Sabatier takes notice, that the symptoms of the two cases which have just now been related were very similar. Both the patients were affected with an exceedingly tense swelling of the belly, unattended with pain or borborygmus, and they were both obstinately constipated. Their pulse was extremely weak the latter days of their indisposition, and they were afflicted with hiccough, nausea, and vomiting.

M. Sabatier seems to think one thing certain, *viz.* that wounds of the gall-bladder, attended with effusion of bile, are absolutely mortal, and that no operation can be of any avail. Médécine Opératoire, tom. i. p. 34—37.

We are, however, to infer the contrary from the extraordinary case lately published by Mr. Fryer of Stamford. A boy, about thirteen years old, received a violent blow from one of the shafts of a cart, on the region of the liver. The injury was succeeded by pain, frequent vomiting of bilious matter, great sinking, coldness of the extremities, and a weak, small, fluttering pulse. The belly was fomented, and purging clysters thrown up. On the third day, symptoms of inflammation began, attended with considerable pain about the liver, great tension and soreness of the

the abdomen, and frequent vomiting. The pulſe was quick, ſmall, and weak, the ſkin hot and dry, the tongue much furred, the urine high coloured; and there was ſome difficulty of breathing, and great thirſt. Eight ounces of blood were taken away, the fomentations continued, and a few grains of calomel were directed to be given every four hours, until the bowels were properly opened. Afterwards the effervefcing mixture, with ten drops of laudanum, was exhibited every four hours.

On the following day, the patient had had ſome motions, and was much better; but as his ſickneſs continued, he was ordered a grain of opium every four hours. About a week afterwards, he complained of a great increaſe of pain, which was ſomewhat relieved by a bliſter. He was now completely jaundiced, and his ſtools were white, but the tenſion, pain, and ſickneſs, were abated.

Two days afterwards, a fluctuation was perceived in the abdomen, which in another week became conſiderably diſtended with fluid. The patient now did not complain of much pain, but appeared to be ſinking faſt; a puncture was made in the ſwelling, and thirteen pints of what appeared to be pure bile were evacuated. The bowels then ſoon became regular, and the appetite good. In twelve days, the operation was repeated, and fifteen pints of the ſame bilious fluid were drawn off. Nine days afterwards, another puncture was made, and thirteen pints more let out; and ſix were diſcharged in another fortnight. From this period the boy went on well, and perfectly recovered under the uſe of light tonic medicines. See Medico-Chirurgical Tranſactions, vol. iv. p. 330.

A previous accidental adheſion of the gall-bladder to the peritoneum might alſo certainly prevent the extravaſation of bile, and its dangerous effects. Calliſen, Syſt. Chir. Hodiernæ, tom. i. p. 718.

Mr. Hennen has never known a patient recover after a wound of the gall-bladder; and indeed, ſays he, it is difficult to imagine a caſe where the injury could happen without an effuſion of bile into the abdominal cavity, except a previous adheſion had taken place to the parietes. A caſe, however, is mentioned in the "Opuſcules de Chir." of M. Paroiſſe, where a leaden ball had lodged in the gall-bladder two years.

4. *Urine.*—Urine being of a very fluid nature may, like the bile, be eaſily extravaſated in the abdomen, when the bladder is wounded at any part which is connected with the peritoneum. If the urine in this kind of caſe be not drawn off with a catheter, ſo as to prevent it from iſſuing by the wound of the bladder, the patient ſoon periſhes. There are many inſtances recorded of the bladder being injured even by gun-ſhot wounds which were not mortal. (See Larrey's Mém. de Chir. Mil. eſpecially tom. iv.) Such wounds, however, might only have injured the ſides or lower part of the bladder. But in operating for the ſtone above the pubes, the bladder has undoubtedly been occaſionally cut at the part of the fundus which is covered with the peritoneum. However, as the accident was known in the firſt inſtance, the right treatment was adopted, and ſuch patients have recovered. Sabatier, Médécine Opératoire, tom. i. p. 37.

Wounds of the bladder are particularly characterized by a diſcharge of bloody urine and difficulty of making water. They muſt always be regarded as dangerous caſes, both on account of the riſk of the effuſion of ſo irritating a fluid in the abdomen, and of the chance of extravaſation in the cellular membrane. Under proper treatment, however, they often admit of cure. The effuſed fluid ſhould, if poſſible, be diſcharged by a depending poſture, or ſuitable punctures or inciſions, and its recurrence prevented by the introduction of a catheter, which is to be left in the urethra. The patient muſt alſo be allowed little drink. As for the tenſion and pain of the belly, the perpetual attendants of a wounded bladder, they may be greatly relieved by the uſe of the warm bath. (Calliſen, tom. i. p. 719.) Bleeding and other antiphlogiſtic means are not to be omitted. See Dict. of Pract. Surg. art. *Wounds.*

Extraneous bodies, particularly balls, as Mr. Hennen obſerves, are frequently carried into the bladder itſelf, either as it riſes above the pubes or through the openings in the pelvis, or work their way into it, and either come off by the natural paſſage, or are removed by a ſurgical operation reſembling lithotomy. Wounds of the bladder, he remarks, are dangerous in proportion as it is full of urine at the time of their receipt, or as the upper and anterior, or lower and poſterior part of the viſcus may be wounded. If the inteſtines are implicated in the wound, it is highly dangerous. Inflammation from wounds of theſe parts runs rapidly into gangrene, which is chiefly brought on by the effuſion of urine in the cellular membrane. "If there is a free extenſive paſſage, much of this danger will be obviated; and after the firſt effuſion from the bladder has taken place, the judicious uſe of the elaſtic gum catheter affords us an admirable aſſiſtance againſt this accident. "Indeed," ſays Mr. Hennen, "without this uſeful inſtrument, our practice in wounds of this nature, and in thoſe affecting the urethra, would be merely confined to looking on and moderating ſymptoms, inſtead of preventing them." (P. 460.) The reſt of the treatment conſiſts in letting out, without delay, the effuſed urine by proper inciſions, and employing the antiphlogiſtic plan, in the full ſenſe of the expreſſion, together with mild ſuperficial dreſſings or poultices, and the utmoſt attention to cleanlineſs.

A deep wound of the liver, Mr. Hennen conſiders as fatal as one of the heart itſelf. Slighter injuries of this organ, he ſets down as ſometimes recovering. He ſays, that the uſual ſymptoms which characterize wounds of the liver are, yellowneſs of the ſkin and urine, derangement of the ſtomach and of the alimentary canal, and cutaneous affections, particularly great and diſtreſſing itching. The diſcharge from the wound is generally yellow and glutinous; but he has ſeen it of a ſerous nature, and ſometimes very nearly allied to unmixed bile.

Wounds of the liver, ſays another writer, may cauſe a large effuſion of blood from the outer wound, or in the abdomen, a cadaverous yellow countenance, pain in the ſhoulder, ſlow pulſe, dulneſs of the eyes, great anxiety, cold ſweats, and finally death, which happens the more quickly and certainly, the greater the wound is, and the nearer it is ſituated to the place where the large veſſels enter this organ. But ſmall wounds of the liver, particularly of its convex ſurface, when it is adherent to the peritoneum, admit of cure. Calliſen, tom. i. p. 718.

The treatment is to be at firſt conducted entirely on antiphlogiſtic principles, veneſection, and mild aperient medicines in particular being employed. Afterwards ſmall doſes of the pil. hydrarg. and tonic medicines will tend to re-eſtabliſh the health.

A wound of the ſtomach may be known by the diſcharge of aliment from the external opening; by the vomiting of blood; the pain, the anxiety, and other ſymptoms of violent nervous irritation. Large wounds of this organ, eſpecially thoſe about the cardiac orifice, or great curvature, or ſuch as extend through both ſides of the viſcus, are for the moſt part fatal in a few days: but when the wound is differently ſituated, and properly treated, it may often be cured. In certain inſtances, however, a fiſtula remains, through which

a part

a part of the food ſometimes eſcapes. Two caſes of wounds of the ſtomach are recorded by Dr. Thomſon, in his Obſ. on the Military Hoſpitals in Belgium. One was from a muſket-ball; the other from a pike. They were treated on the mild, unirritating plan, adapted for wounds of the inteſtines, and both ended well. "The hiſtories of the Bohemian, Pruſſian, and Engliſh 'cultrivores,' from ſome of whom the knives have been cut out, and from others diſcharged ſpontaneouſly, through the coats of the ſtomach and parietes of the abdomen, as well as many other inſtances on record, are (as Mr. Hennen obſerves) very encouraging in caſes of injuries of this organ." M. Hevin, in the Mém. de l'Acad. de Chir. tom. i. p. 144. has collected a number of intereſting inſtances of recovery, both from inciſed and gun-ſhot wounds. But (ſays Mr. Hennen) the induſtrious Ploucquet, in the articles "Ventriculus" and "Pantophagi," has exceeded all others for the vaſt number of caſes he has amaſſed. In our own Philoſophical Tranſ., Lowthorpe's Abridgment, vol. vi. p. 192. or in the modern one, by Drs. Hutton, Shaw, and Pearſon, vol. iv. p. 66. an inſtance is given, where the ſtomach of a horſe was wounded and ſewed up, and a ſimilar inſtance in the human ſpecies: both recovered. More recently ſutures have been applied to its wounds in Holland and France, as may be ſeen in the "Annales de Litterature," &c. by Kluyſkens, vol. 2. and in the "Traumalogia" of Schlichting, &c. Notwithſtanding theſe narratives, however, we have no doubt of the raſhneſs of ſuch practice, and all that can be ſaid about it is, that the patients had to overcome both the injury and the bad treatment of it. Not unfrequently a wound of the ſtomach has become fiſtulous. Richerand gives a very curious caſe of this kind, where the opening remained for nine years; Etmuller, in the 5th vol. of Haller's "Diſputationes Chirurgicæ," gives an inſtance, where it continued open for ten years; and Wenker, in the ſame volume, relates a caſe where a wound of the ſtomach continued open twenty-ſeven years. (See Hennen on Military Surgery, p. 481, &c.) Copious bleeding, abſtinence, and reſt, are the beſt remedies in the early ſtage of all ſuch caſes.

Wounds of the ſpleen moſtly prove fatal by the profuſe hemorrhage ariſing from them. Mr. Hennen, however, aſſures us, that he has ſeen ſome ſlight wounds of this viſcus terminate favourably. It has ſometimes been cut out of brutes, without any fatal or even any bad conſequences; and there is a recent inſtance recorded, in which it protruded from an inciſed wound, the ſurgeon removed it, and the patient got well. (See Medico-Chirurg. Journal, vol. i. 1816.) It has alſo been tied and cut out in ſome other inſtances with ſucceſs. See caſes in Gooch's Chir. Works, vol. i. p. 97; Leveillé's Doctrine Chir. tom. i. p. 400; alſo ſome references in Thomæ Bartholini Anatome, p. 158. 8vo. Lugd. Bat. 1686, &c.

Wounds of the ſpleen have ſcarcely any ſymptom which is peculiar to them. According to Celſus, however, there is great pain in the ſhoulder, as in wounds of the liver. The looſe ſtructure of the ſpleen, and the magnitude of its veſſels, muſt always render its injuries highly dangerous.

Wounds of the pancreas, according to Calliſen, are not characterized by any peculiar ſymptom, except the effuſion of a fluid analogous to the ſaliva. The pancreas, like the duodenum, can hardly be wounded, without the weapon having at the ſame time injured other viſcera. (Syſt. Chir. Hodiernæ, tom. i. p. 719.) Gooch ſets down wounds of the pancreas as mortal, if its duct or blood-veſſels be injured. Chir. Works, vol. i. p. 99.

Wounds of the kidneys and ureters are always dangerous, on account of the hemorrhage and effuſion of urine. When the latter fluid inſinuates itſelf within the peritoneum, or into the cellular membrane, the patient has but a very diſcouraging chance of preſervation. Small wounds of the kidney, however, may be cured, though a fiſtula will ſometimes remain. The danger of wounds of the kidney is well pointed out in M. Hevin's Eſſay on Nephrotomy, in the Mém. de l'Acad. de Chir., and a great maſs of evidence is produced on the ſubject. The recoveries which Mr. Hennen has ſeen, after wounds of the kidneys, he obſerves, are very few indeed. "If the patient has ſurvived the firſt hemorrhage, the fever and peritoneal inflammation, with inceſſant hiccough and vomiting from ſympathy of the diaphragm and ſtomach, have generally cut him off; and if he has for a time eſcaped, excruciating pains, profuſe ſuppuration from fiſtulous ſores, hectic, and emaciation, have terminated his exiſtence. Where the cure has been effected, there is reaſon to think that the ureter has been but ſlightly bruſhed, and the body of the kidney itſelf left untouched. The remedies conſiſt in veneſection, mild purgatives, as manna, oil, &c. frequent emollient enemas, the warm bath generally, and local fomentations, &c. with a diet of the mildeſt kind, but much reſtricted in fluids, the indulgence in which, even in ſmall quantity, ſhould be avoided." The ſame author properly condemns all ſtimulants, bliſters, and diuretics; and he recommends light dreſſings, ſo as to allow the urine to eſcape freely. The integuments near the wound he alſo adviſes to be greaſed, ſo as to prevent the irritation of the urine from making them inflame and ulcerate. See Obſ. on Military Surgery, p. 454.

The ſubject of wounds is one of infinite length, and this muſt apologize for the extent of the preſent article, in which a great deal is ſtill omitted. Had we introduced a full account of the wounds of every part of the body, our obſervations would have formed a production more than twice as long as that which we have now finiſhed; but we thought that ſo minute and elaborate a paper would hardly be deſirable in a work not expreſsly allotted to the conſideration of ſurgery.

Wounds *in Horſes*. The moſt terrible wounds theſe creatures are ſubject to are thoſe got in the field of battle. The farriers that attend camps have a coarſe way of curing theſe; but it is a very expeditious and effectual one. If the bullet be within reach, they take it out with a pair of forceps; but if it lie too deep to be come at, they leave it behind, and dreſs up the wound in the ſame manner as if it were not there.

They firſt drop in ſome varniſh from the end of a feather, and when the bottom is thus wetted with it, they dip a pledget of tow in the ſame varniſh, which they put into the wound, and then cover the whole with the following charge: Take a quarter of a pound of powder of bole armenic, half a pound of linſeed-oil, and three eggs, ſhells and all; add to theſe four ounces of bean-flour, a quart of vinegar, and five ounces of turpentine; this is all to be mixed over the fire, and the wound covered with it. This application is to be continued four or five days, then the tent put into the wound is to be dipped in a mixture of turpentine and hog's-lard; by this means a laudable matter will be diſcharged, inſtead of the thin ſharp water that was at firſt. Then the cure is to be completed by dreſſing it with an ointment made of turpentine, firſt well waſhed, and then diſſolved in yolks of eggs, and a little ſaffron added to it.

This is the practice in deep wounds that do not go through the part; but in caſes where the bullet has gone quite through, they take a few weavers' linen thrumbs, made very knotty; theſe they make up into a kind of link, and dipping it in varniſh, they draw it through the wound, leaving

leaving the ends hanging out at each fide; by means of thefe they move the link or fkein three or four times a day, always wetting the new part that is to be drawn into the wound with frefh varnifh. They put on a charge of the bole armenic, &c. as before defcribed, on each fide of the wounded part, and continue this as long as the wound difcharges thin watery matter, or the fides continue fwelled. After this they drefs it with the ointment of the turpentine, yolks of eggs, and faffron, till it is perfectly cured.

The other methods are, the dreffing of the wound with an ointment made of wax, turpentine, and lard, and covering it with linen rags wetted with cream; or the dreffing with a mixture of yolks of eggs, honey, and faffron, and covering it up with cream and baum-leaves beaten together.

When the wound is fo dangerous as to require the affiftance of internal medicines, they give the following pills: Take affafœtida, bay-berries, and native cinnabar, of each a pound; beat up the whole into a mafs with brandy, and roll it into pills of fourteen drachms each. Thefe are to be laid in a fhady place to dry, after which they will keep ever fo long without any damage. The horfe is to take two of thefe every other day, or, if neceffary, every day, till he has taken eight or ten of them, and he is to ftand bridled two hours before and after the taking of them.

When the wound feems at a ftand, not appearing foul, and yet not gathering new flefh, there muft be recourfe had to the following powder, whofe effect in bringing new flefh is wonderful: Take dragon's blood, and bole armenic, of each two ounces; maftic olibanum, and farcocolla, of each three drachms; aloes, round birth-wort, and common iris-root, of each one drachm and a half; make the whole into a fine powder. This is fometimes ufed dry, fprinkling it on the wound; but fometimes it is mixed with turpentine, fometimes with juice of wormwood, and fometimes with honey of rofes, and either way does very well.

When the wound grows foul, and requires a detergent to cleanfe it, the common liquor for this purpofe is a phagedenic water, which they make of lime-water, and fublimate in this manner: Take two pounds and a half of newly-made and unflaked lime, put it into a pewter veffel, and pour on it five quarts of boiling water. When the bubbling is over, let it ftand to reft two or three days, ftirring it often with a ftick; then pour it clear off after due time for the lime to fettle, and filtre it through fome whited-brown paper, made for the lining of funnels, on this occafion. To a quart of the clear lime-water, thus prepared, add eight ounces of fpirit of wine, and one ounce of fpirit of vitriol; when thefe are well mixed, by fhaking them together, then add an ounce of corrofive fublimate in fine powder: mix all well together, and keep the whole in a bottle, to be ufed for the cleanfing of thefe foul wounds, and on any other occafions, where a detergent of this powerful kind may be neceffary. It will keep good many years.

If this water will not thoroughly cleanfe the wound, but there ftill will remain a quantity of foul matter in it, and there is danger of a gangrene, they add to it as much arfenic in fine powder as there was of the corrofive fublimate; that is, at the rate of an ounce to a quart and half a pint.

Thefe are all the medicines which the farrier need carry with him on account of wounds; and they are all fuch as may be prepared at home, and will continue good fo long as he has occafion to keep them, or much longer; and what is left of one year will ferve for others.

When the neceffary applications are thus fettled, it may not be improper to add the general rules by which they conduct themfelves in the cure.

1. The wound muft be probed at firft, but very gently, and afterwards as gently and as feldom as may be, for the horfe's flefh is the moft eafy of all others to be contufed in wounded parts, and to fall into a gangrene from the hurt. 2. The wound muft be kept continually as clean as poffible, and free from proud flefh. 3. The neceffary revulfion muft always be made by bleeding, as foon as the wound is dreffed the firft time; this prevents inflammation, and a great many other bad accidents. 4. If the wound be in fuch a place that the horfe can get at it with its tongue to lick it, great care muft be taken to prevent his doing fo, as it will greatly retard the cure. 5. The farrier never is to proceed to fuppuration in any cafe in which the humours can be either diffolved or repelled, and efpecially in parts that are full of finews and ligaments, or that are near the bones. 6. If a wound be accompanied with a great contufion, or if it be of a round or circular figure, incifions are often neceffary about its edges, and fometimes the application of cauftics. 7. The wound muft be always carefully covered, for the accefs of the air retards the cure. 8. The callous lips of a wound muft always be cut to the quick, before they can be united together. Thefe may ferve for general rules, that hold good in all cafes: and to thefe may be added fome that are principally applicable to peculiar circumftances of the wounds.

Wounds of the breaft are to be cured with tents and folds of foft linen laid over them, fteeped in the following mixture: Take verdigrife, vitriol, and alum, of each one ounce; vinegar, eight ounces; honey, a pound; let all thefe be boiled together till they become red.

Wounds in the belly can only be cured by fewing up the peritoneum with ftrong woollen thread, not filk, leaving the extremities without the fkin. The fkin is to be fewed together with ftrong hempen thread waxed, joining the lips of the wound together, by this means, in form of a buckle. This is to be covered with the common ointment for wounds; and if an inflammation comes on, chalk diffolved in vinegar is to be added.

If the wound be fuch that the guts come out at it, the horfe may ftill be recovered, if proper caution be ufed: the guts are to be immediately returned into their place; but they muft not in this be touched with the hand, but with a fponge dipped in warm water. And, in order to the making them more readily get into their places, it is proper to make the creature vomit, by thrufting down his throat a feather dipped in oil. If the wound through which they fell is not big enough to return them eafily by, it muft be enlarged by cutting; but if the guts are found to be bruifed or wounded, it is in vain to attempt any thing, for death muft follow.

There is alfo a certainty of death when, after a wound of any kind in the belly, the horfe voids blood at the fundament.

When a horfe is wounded near the groin, he eafily falls into convulfions; in this cafe, he is to be kept from drinking as much as poffible: he is alfo to be covered well up, and kept quiet, and to have green things given him to eat.

Wounds on the knees are very difficult to cure, becaufe the part is in motion almoft continually, and there is very little flefh to work upon. When the wounds are but flight, and in the mufcular parts of the body, a mixture of honey and tallow, boiled together, will often prove a cure; when the wound is more confiderable, turpentine melted in a little common oil, and applied hot, is the general remedy.

If a wound happens between the fhoe and the hoof, care muft be taken that no foreign matter be left in it, and it muft be dreffed with any of the ointments that have verdigrife in them; and a charge of bruifed elder-leaves is very proper

proper to be applied over all. If the wound be deep and narrow, it muſt be enlarged at the orifice, and turpentine and wax, melted in lard, muſt be poured into it. The ſame rule of opening the orifice holds good in all deep and narrow wounds.

If a nerve happens to be cut, it muſt be cloſed, and a defenſative muſt be applied, to prevent a concourſe of humours to the part; a fomentation made of oil, wine, and honey, mixed together, is alſo very proper, wherever a nerve is hurt, and a poultice may be applied over all, made of marſhmallow-roots boiled ſoft, with bread and milk.

If the horſe happens to be wounded by a piece of wood, bone, or any other hard ſubſtance, part of which remains in the wound, this muſt be carefully taken out, whatever pain it may coſt the creature to do it, and the wound muſt then be dreſſed with the common wound-ointments. In this, or any other caſe of a freſh wound, the waſhing it with oil of turpentine is an excellent method of preventing ill conſequences.

Wounds *in Trees*, ſuch as are cauſed in lopping and pruning their branches, or otherwiſe. Mr. Nichol, in his "Practical Planter," has ſhewn, that lopping of ſtrong branches becomes not neceſſary, and that all wounding in pruning ſhould be performed on or towards the extremities of boughs which have inferior laterals to partake of and divert their luxuriance of growth from injuring the ſtem or leader. It is alſo ſhewn, that from this mode little ill is to be apprehended, and conſequently that the treatment of ſuch wounds is ſimple, and which is ſo much the better for the plant and the intereſt of its owner. Such wounds require no other attention than being lopped clean off with a ſharp knife or bill; and, if the ſaw is uſed, being afterwards ſmoothed with the knife. And it were to be wiſhed, for the ſake of much timber, which otherwiſe might have been rendered more valuable, that wounds of another deſcription had been unneceſſary, or had never been inflicted. The writer here alludes to the neceſſity of lopping by the bole all ſtumps, &c. occaſioned by formerly-injudicious pruning, and the wanton folly of thoſe who lop large branches by or near to the ſtem, when ſimply ſhortening them at a proper diſtance would anſwer a better purpoſe. But ſince it becomes neceſſary to clear formerly-injured trees of ſtumps, &c. in order to prevent farther decay, it alſo becomes a duty to follow the moſt rational and ſimple mode of treatment. With this view, it is briefly obſerved, that whenever it becomes neceſſary to lop a ſtump by the bole, or to ſhorten any branch larger than the wriſt or ankle; in the former caſe, the wound ſhould be to the quick, that is, to the level of the bark, on the ſtem at leaſt; and in the latter, *obliquely* acroſs the branch, ſo as, from its poſition, to prevent moiſture from lodging: being careful to prevent laceration, by notching the bark underneath, before the amputated part falls down, or to one ſide. In both caſes, the face of the wound and edges of the bark are to be made perfectly ſmooth with the knife; and in a few hours after, or ſo ſoon as they are quite dry, let the wound be carefully plaſtered with tar, (ſuch as is uſed for ſheep-ſmearing,) or laid over with white or blue lead, which has been well mixed up with oil, and rendered rather thicker than is commonly uſed for painting. The tar is, however, certainly preferable, being of a more healing nature; and if laid on in a thin ſtate, it is not ſo apt to ſcale off by the action of the weather as the paint. This operation ſhould be performed in the *fall* of the year; at which time, the wound is not ſo apt to crack, and likewiſe dries ſooner than at any other ſeaſon. If, however, in the courſe of the enſuing ſummer, or at any ſubſequent period, the tar or paint is found to rend or ſcale off, care muſt be taken to renew and keep the plaſter ſound and ſmooth, until the bark grow over and cover the wound; and this ſhould be more particularly obſerved in reſpect of wounds on the trunk.

In the caſe of *polling* a tree, lopping an upright branch, or in training for ſhip-timber, ſtopping the leader, &c. when, from the upright poſition of the wounded part in queſtion, plaſtering or painting, as above, might be deemed inſufficient to prevent water from penetrating, and of conſequence injuring the wood at the part affected; yet by this treatment, infection, or the farther decay of the reſt of the tree, will be prevented. But there are ſome who ridicule the idea of uſing plaſter of any kind, urging for argument that the bark grows as faſt together of itſelf without this aid, and why bury in the heart of the tree a load of rubbiſh? But they certainly have not conſidered, that a decayed part of the vegetable being buried in its heart, cannot poſſibly again be renovated, or become ſound timber; but, on the contrary, muſt operate to the corruption of the reſt. And this queſtion, why bury in the tree a load of rubbiſh? leads, it is ſaid, to a deciſion in favour of uſing tar, ſince, beſides that the body incloſed is quite thin, it is of a genial, healing nature, acts as a cement to the fracture, and afterwards becomes equally ſound as the wood.

And this may be demonſtrated by examining fir-trees which have been wantonly hacked *deeply*, had holes bored into them for faſtening gates to, which have afterwards been removed, and above all in the operation of extracting roſin; in all which caſes, the wound is cloſed up by the reſinous juice of the tree, and generally becomes perfectly ſound as the reſt of the wood, although a blemiſh may be the conſequence. Wherefore, with reſpect to reſinous trees, nature prevents the neceſſity of our interference in the cure of wounds, other than the fracture of limbs; which it is certainly our duty to amputate, in order to prevent farther decay and unſightly appearance; but ſhe will haſtily cover the wound with the plaſter ſuperior to any we can prepare.

Wound-*Wort*, in *Botany*, the name given to ſeveral ſpecies belonging to different genera.

Wound-*Wort of Achilles*. See Achillea.

Wound-*Wort*, *Clown's*, a ſpecies of *ſtachys*. See Stachys.

Wound-*Wort*, *Hercules's*, or *All-heal*, the *laſerpitium chironium* of Linnæus. This is a native of the warmer climates, and bears the colds of our own. Both the ſeeds and roots of this ſpecies are conſiderably warmer than thoſe of the *garden* and *wild* parſnep. The roots and ſtalks have a ſtrong ſmell and taſte, reſembling thoſe of opoponax: and Boerhaave relates, that on wounding the plant in ſummer, he obtained a yellow juice, which, being inſpiſſated a little in the ſun, agreed perfectly, in both reſpects, with that exotic gum-reſin. Lewis. See Laserpitium.

Wound-*Wort*, *Saracen's*, *ſolidago*. See Solidago.

Wound-*Wort*, *True Saracen's*, a ſpecies of *ſenecio*. See Senecio.

WOUNICS, in *Geography*, a town of Auſtrian Poland; 32 miles E.S.E. of Cracow.

WOUTERS, Francis, in *Biography*, was born at Liere, in Brabant, in 1614. He was a ſtudent in the ſchool of Rubens, but applied himſelf principally to landſcape, and became one of the moſt eminent of his time. He choſe for his models the ſcenes of his native country, and particularly the foreſt of Soignes, near Bruſſels; embelliſhing the views he choſe with groups of figures repreſenting hiſtorical or allegorical

allegorical ſubjects. Sometimes he attempted hiſtory, but not ſuccefsfully. He was in favour with the emperor Ferdinand II.; but coming to England with his ambaſſador in 1637, he was appointed chief painter to the prince of Wales, afterwards Charles II. On the breaking out of the rebellion he returned to Antwerp, and became director of the academy there, where in 1659 he was killed by the accidental diſcharge of a gun.

WOUVERMANS, Philip, was a remarkable and melancholy inſtance of thoſe mis-ſhapen and unhappy combinations of talent, induſtry, and ill-fortune, which have occaſionally diſgraced the world of connoiſſeurſhip. He was the ſon of an indifferent hiſtorical painter, and was born at Haerlem in 1620. Having obtained poſſeſſion of his father's ſtore of pictorial knowledge, he was placed with John Wynants, the landſcape-painter, under whoſe inſtruction he ſoon acquired a conſiderable degree of power in embodying the creations of his own fancy, and to this acquiſition he added much by an attentive ſtudy of nature.

There is but little known of his private life. Celebrity, which now attends his name, formed no part of his enjoyments; indeed they appear to have been few, and confined to his affection for and attention to his art and his family, which was numerous. His pictures, beautiful as they are, agreeable in their compoſition and colour, and exquiſite in their finiſh, exhauſted his time without raiſing him above indigence and obſcurity. The more free, ſlight, and looſe works of Peter de Laer, called Bamboccio, abſorbed the admiration of the Dutch collectors, while the elegant and delightful productions of Wouvermans remained unnoticed and unknown. Time has adjuſted the balance, and the united voice of the taſteful now ſheds a luſtre over the name of the latter; too late, alas! for his gratification or benefit.

The neglect which he endured, and the ſeverity of labour required to complete ſo many pictures as he has left, in ſo high and perfect a degree of finiſhing, exhauſted his health, and he died at the early age of 48; having burnt a ſhort time before his death all his ſtudies and drawings, to prevent, as he declared, his children from being induced to follow a profeſſion which had been but a ſource of poverty and miſery to himſelf.

The ſubjects of his pictures are drawn from the common ſcenes of nature, but are ſometimes of a more elevated caſt than thoſe choſen by the generality of his compatriots, particularly his hawkings and huntings, where cavaliers and high dames, with appropriate ſcenery, rich trappings to their horſes, and numerous retinues, are introduced with great taſte and propriety. His encampments and battles are compoſed with the ſame ſkill and ſuavity; indeed the latter is a principal characteriſtic of all his works, whatever be their ſubjects, from the humble hay-cart to the richeſt combination of materials which the gay palace, its garden, and ſplendid adornments, afforded him. Farriers' ſhops, fairs of horſes, travellers on their road, or at inn-doors, &c. &c. were equally rendered agreeable by his delightful arrangements of chiaro-oſcuro and of colours, and by the exquiſitely firm full touch with which they are executed. His works are numerous, and when in good preſervation ſell at very conſiderable prices.

Wouvermans, Peter, the younger brother of Philip, was alſo an artiſt of conſiderable talent, though by no means equal to him. He was alſo born at Haerlem, about the year 1625. He was trained under R. Rogman, but principally followed his brother's ſtyle, and adopted his claſs of ſubjects. But though his pictures are frequently ſold for Philip's, yet they are not ſo delicate or ſpirited, and may be eaſily diſtinguiſhed from his by a cultivated eye. There was alſo another brother, a few years younger than Peter, who followed the ſame line of art with rather more talent; ſo that we cannot be ſurpriſed at the number of pictures which bear the name of Wouvermans. John died in 1666, at the age of 38.

WOXEN, in *Geography*, a large and noiſy current of Sweden, formed by the diſcharge of the lake of Saima into the Ladoga, which forms a vaſt cataract about a mile from its mouth.

WOXNA, a town of Sweden, in Helſingland; 40 miles W. of Soderhamn.

WOXTORP, a town of Sweden, in the province of Smaland; 27 miles N.W. of Wexio.

WOYE, a town of Germany, in the principality of Culmbach; 5 miles S.E. of Hof.

WOYTZ, a town of Sileſia, in the principality of Neiſſe; 2 miles E. of Ottmuchau.

WRA, a town of Sweden, in the province of Smaland; 48 miles W.S.W of Wexio.

WRACK. See Wreck.

Wrack, in *Natural Hiſtory*. See Wreck.

Wrack, in *Agriculture*, a name ſometimes given to a marine plant, which is of great utility as a manure. With this plant ſurgeons ſometimes make a cataplaſm, by bruiſing a quantity of it, and applying it in caſes of ſcrofula, or white-ſwelling, but more particularly glandular tumours. Where this cannot be got, ſea-water and oat-meal formed into a poultice have ſupplied its place. There is no reaſon why the tumours and ill-conditioned ſores of brute animals ſhould not be benefited by ſimilar applications. See Wreck.

It is frequently termed *ſea-wrack*, *ſea-tangle*, and *ſea-oak*. See Sea-*Weed*.

WRAGBY, in *Geography*, a ſmall market-town in the wapentake of Wingrove, Lindſey diviſion of the county of Lincoln, England, is ſituated at the junction of the turnpike-roads leading from Lincoln to Louth and Horncaſtle, and is diſtant 11 miles N.E. by E. from Lincoln, and 144 miles N. by W. from London. George Villiers, duke of Buckingham, who poſſeſſed this manor in the reign of Charles II., obtained from that monarch a charter to hold a weekly market on Thurſday and two annual fairs, which are now well frequented. Sir Edmund Turnor, who purchaſed the manor of the duke, erected and endowed an alms-houſe for ſix clergymen's widows, and ſix other deſtitute perſons, for whoſe uſe he built a chapel, with an augmentation to the vicarage of 40*l. per annum* for prayers to be read in it twice every day: this chapel was conſecrated by biſhop Gardiner July 18, 1697. Here is alſo a free-ſchool, founded and endowed in 1633 by William Hanſard, eſq. The population of Wragby is ſtated, in the return of the year 1811, to be 709; the number of houſes 103. The manor is now poſſeſſed by Edmund Turnor, eſq. who has a ſeat in the adjacent pariſh of Panton, called Panton-hall, which was built by Hawkſmoor, a pupil of ſir John Vanbrugh, in the year 1724: conſiderable additions have been made to it from the deſigns of Mr. Carr, architect at York; and the adjoining country has been greatly improved by ornamental plantations. Two miles north of Wragby is Halton Lodge, the ſeat of colonel Caldicot, in whoſe family the manor of Halton has been veſted for ſeveral generations.—Beauties of England and Wales, vol. ix. Lincolnſhire; by J. Britton, F.S.A. 1808.

WRAIN-Bolts, in *Ship-Building*, are iron ring-bolts, uſed when planking ſhips, &c. with two or more fore-lock holes near the end, for taken-in the ſet, as the plank, &c. works nearer the timbers.

Wrain-*Staves*, a ſort of ſtout billets of tough wood, tapered

tapered at the ends fo as to go into the ring of the wrain-bolt, to make the fets neceffary for bringing-to the planks or thick ftuff to the timbers.

WRAM, in *Geography*, a town of Sweden, in the province of Skone; 13 miles W.S.W. of Chriftianftadt.

WRANGLER, SENIOR, a technical term in the univerfity of Cambridge, for the ftudent who paffes the beft examination in the fenate-houfe, and confers lafting reputation. They who follow next in the fame divifion are refpectively termed fecond, third, fourth, &c. wranglers. In a fimilar manner, they who compofe the fecond rank of honours are defignated by the titles of firft, fecond, third, &c. optimi. Thofe of the laft order are diftinguifhed by the denominations of firft, fecond, third, &c. junior optimi.

WRANGON, in *Geography*, a fmall ifland in the gulf of Finland. N. lat. 59° 34′. E. long. 25°.

WRANNY, a town of Bohemia, in the circle of Schlan; 7 miles N.N.W. of Schlan.

WRANOW. See FRAIN.

WRAPPER, in *Botany*. See VOLVA.

WRASSE, in *Ichthyology*, the name of a fifh called by authors *turdus vulgaris*, and by fome *tinca-marina*, the *fea-tench*, and fometimes *old-wife*.

The wraffe, or *labrus tinca* of Linnæus, refembles the carp in figure, and is covered with large fcales. Its ufual fize is about five or fix inches in length, and it grows to the weight of four or five pounds: its colour is very variable; red, yellow, and brownifh, being very frequently mixed in the fcales; and it has five or fix longitudinal lines, alternately of a pale yellow, an olive colour, and a dufky red. Its nofe is long, and bent upwards, and it has thick and flefhy lips extended over the jaws. Its mouth is fmall, and its teeth, which are difpofed in two rows, the firft conic, the fecond very minute, are not very fharp; in the throat, juft before the gullet, are three bones, two above of an oblong form, and one below of a triangular fhape; with the furface of each rifing into roundifh protuberances: thefe are of fingular ufe to the fifh for grinding its fhelly food before it arrives at the ftomach; the dorfal fin confifts of fixteen fharp and fpiny rays, and nine foft ones, longer than the others: the pectoral fins are large and round, and compofed of fifteen rays, the ventral of fix; the firft fharp and ftrong; the anal of three fharp fpines, and nine flexible: its tail is rounded at the end, and is formed of fourteen foft branching rays; the membranes of the fins and tails are variegated with red and blue fpots, and the anterior rays of the back-fin are prickly. It is caught in plenty on the Englifh fhores, and is fold among the poorer fort of people in Wales and Cornwall; but is not efteemed a very delicate fifh. It is found in deep water, adjacent to the rocks; it will take a bait, though its ufual food is fhell-fifh, and fmall cruftacea. Willughby's Hift. Pifc. p. 320. and Pennant. See LABRUS.

WRASSE, *Bimaculated*, *labrus bimaculata* of Linnæus, has a body pretty deep, and of a light colour, marked in the middle on each fide with a round brown fpot, and another on the upper part of the bafe of the tail: the lateral line is incurvated; the branchioftegous rays are fix; the firft fifteen rays of the dorfal fin are fpiny, the other eleven foft, and lengthened by a fkinny appendage; the pectoral fins confift of fifteen rays; the ventral of fix, the firft fpiny, the fecond and third ending in a flender briftle; the anal fin is pointed; the four firft rays being fhort and fpiny, the reft long and foft. This is an inhabitant of the Mediterranean.

Mr. Pennant has defcribed fome other fpecies of wraffe, as the *trimaculated*, *ftriped*, and *gibbous*, taken on the coaft of Anglefea, and another called *ballan*, numbers of which appear during fummer near Scarborough, which is of the form of the common wraffe, except that between the dorfal fin and the tail it has a confiderable finking; above the nofe a deep fulcus; and on the fartheft cover of the gills a depreffion radiated from the centre. Pennant's Brit. Zool. vol. iii. p. 246, &c. See LABRUS.

WRATENI, in *Geography*. See FRATING.

WRATH, CAPE, a cape in the N.W. extremity of Scotland, in the parifh of Durnefs, which affords excellent pafture for fheep. In its vicinity are vaft caverns.

WRBOWALNOI, a town of Bohemia, in the circle of Konigingratz; 16 miles S.W. of Biezow.

WREAK, or WREKE, a river of Leicefterfhire, which paffes by Melton Mowbray, and runs into the Soar, 7 miles N.E. of Leicefter.

WREATH, in *Agriculture*, a fmall roll formed of any kind of light fubftance, fuch as ftraw, hay, &c. and ufed for different purpofes.

WREATH, in *Natural Hiftory*. See TURBO.

WREATH, in *Heraldry*, a roll of fine linen, or filk, (like that of a Turkifh turban,) confifting of the colours borne in the efcutcheon; placed in an achievement, between the helmet and the creft, and immediately fupporting the creft.

WREATH *Stick-Band*, in *Agriculture*, a band formed of any kind of twifted ftick, ufed for tying up fagots, and other fuch purpofes.

WRECK, WRACK, *Sea*-WRECK, or *Sea*-OAK, the *fucus veficulofus* of Linnæus, in *Natural Hiftory*, a foft, very flippery, marine plant, common among rocks that are left dry at the ebb tide, with leaves fomewhat refembling thofe of the oak-tree; the ftalk running along the middle of the leaves, and terminated by watery bladders containing either air or a flippery fluid: the veficles begin in March to fill with a thin juice; and about the end of July they burft, and difcharge a matter as thick as honey.

In fome places it is ufed to manure the ground. In Normandy, and other parts, they burn it; and of the afhes make a kind of foda, or potafh, which they ufe in the making of common green glafs, to promote the fufion or vitrification of the other materials. See SEA-*Weed*.

Dr. Ruffel relates, that he found this plant an ufeful affiftant to fea-water in the cure of diforders of the glands; that he gave it in powder to the quantity of a drachm, and that in large dofes it naufeated the ftomach; that by burning in the open air, it was reduced into the black faline powder; which feemed, as an internal medicine, greatly to excel the officinal burnt fponge; which was beneficially ufed as a dentifrice, for correcting laxities of the gums; and which indicated a remarkable degree of detergent virtue by its effect in cleaning the teeth: that the juice of the veficles, after ftanding to putrefy, yielded, on evaporation, an acrid pungent falt, amounting to above a fcruple from two fpoonfuls; that the putrefied juice, applied to the fkin, finks in immediately, excites a flight fenfe of pungency, and deterges like a folution of foap; that one of the beft applications for difcuffing hardnefs, particularly in the decline of glandular fwellings, is a mixture of two pounds of the juicy veficles, gathered in July, with a quart of fea-water, kept in a glafs veffel for ten or fifteen days, till the liquor comes near to the confiftence of very thin honey: the parts affected are to be rubbed with the ftrained liquor twice or thrice a day, and afterwards wafhed clean with fea-water. Lewis's Mat. Med. See ÆTHIOPS *Vegetabilis*.

WRECK, in *Sea Language*, denotes the ruins of a fhip which had been ftranded or dafhed to pieces on a fhelf, rock, or lee-fhore, by tempeftuous weather.

Wreck, *Wreccum*, called alfo *Ship*-Wreck, or *Ship*-Wrack, in *Law*, &c. is when a fhip perifhes in the fea, and no man efcapes alive out of it.

The civilians term it *naufragium*. The goods in the fhip which are brought to the land by the waves belong to the king, or him to whom he affigns the right thereof. Thus, in the Stat. Prærog. Reg. 17 Edw. II. cap. 11. "Rex habebit *wreckum maris* per totum regnum, balænas et fturgiones captas in mari, vel alibi intra regnum, exceptis quibuflibet privilegiatis locis," &c.

Thus alfo the matter ftood by the ancient common law; but the rigour of the law of wrecks has been gradually foftened in favour of the diftreffed proprietors. Accordingly it was firft ordained by king Henry I. that if any perfon efcaped alive out of the fhip, it fhould be no wreck; and afterwards king Henry II. by his charter, May 26, A.D. 1174, declared, that if on the coafts of England, Poictou, Oleron, or Gafcony, any fhip fhould be diftreffed, and either man or beaft fhould efcape or be found therein alive, the goods fhould remain to the owners, if they claimed them within three months; but otherwife fhould be deemed a wreck, and belong to the king, or other lord of the franchife. This was again confirmed, with improvements, by Richard I., who, in the fecond year of his reign, not only eftablifhed thefe conceffions, by ordaining that the owner, if he was fhipwrecked and efcaped, "omnes res fuas liberas et quietas haberet," but alfo, that if he perifhed, his children, or, in default of them, his brethren and fifters, fhould retain the property; and in default of brother or fifter, then the goods fhould remain to the king. And by the law, as laid down by Bracton in the reign of Henry III., if not only a dog (*e. g.*) efcaped, by which the owner might be difcovered, but if any certain mark were fet on the goods, by which they might be known again, it was held to be no wreck. Afterwards, in the ftatute of Weftm. 1, 3 Edw. I. cap. 4, the time of limitation of claims, given by the charter of Henry II., is extended to a year and a day, according to the ufage of Normandy; and it enacts, that if a man, a dog, or a cat, efcape alive, the veffel fhall not be adjudged a wreck. And it is now held, that not only if any living thing efcape, but if proof can be made of the property of any of the goods or lading which come to fhore, they fhall not be forfeited as wreck. The ftatute farther ordains, that the fheriff of the county fhall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half); that if any man can prove a property in them, either in his own right or by right of reprefentation, they fhall be reftored to him without delay; but if no fuch property be proved within that time, they then fhall be the king's. If the goods are of a perifhable nature, the fheriff may fell them, and the money fhall be liable in their ftead. This revenue of wrecks is frequently granted out to lords of manors, as a royal franchife; and if any one be thus entitled to wrecks, in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and the day. In order to conftitute a legal wreck, the goods muft come to land. If they continue at fea, the law diftinguifhes them by the barbarous appellations of *jetfam*, *flotfam*, and *ligan*.

Wrecks, in their legal accrptation, are now not very frequent; the owner being feldom unable to affert his property within the year and day limited by law. And in order to preferve his property entire, our laws have made many humane regulations, very oppofite in their fpirit to thofe which formerly prevailed in all the northern regions of Europe, and a few years ago were ftill faid to fubfift on the coafts of the Baltic fea; permitting the inhabitants to feize on whatever they could get as lawful prize. To what the reader will find under Salvage to this purpofe, we fhall here add, that all perfons who fecrete any goods of a wreck fhall forfeit their treble value; and if they wilfully do any act whereby the fhip is loft or deftroyed, by making holes in her, ftealing her pumps, or otherwife, they are guilty of felony without benefit of clergy. Moreover, by the ftatute 26 Geo. II. cap. 19. the plundering of any veffel either in diftrefs, or wrecked, whether any living creature be on board or not, or the preventing the efcape of any perfon that endeavours to fave his life, or the wounding of him, with intent to deftroy him, or the putting out of falfe lights in order to bring any veffel into danger, are all declared to be capital felonies, in like manner as the deftroying of trees, fteeples, or other ftated fea-marks is punifhed, by 8 Eliz. cap. 13. with a forfeiture of 100*l*. or outlawry. Alfo by the ftatute of Geo. II. the pilfering of any goods caft afhore is declared to be petty larceny; and many other falutary regulations are made for the more effectually preferving fhips of any nation in diftrefs.

By the civil law, to deftroy perfons fhip-wrecked, or prevent their faving of the fhip, is capital; and to fteal even a plank from a veffel in diftrefs, or wrecked, makes the party liable to anfwer for the whole fhip and cargo. The laws alfo of the Vifigoths, and the moft early Neapolitan conftitutions, punifhed with the utmoft feverity all thofe who neglected to affift any fhip in diftrefs, or plundered any goods caft on fhore. Blackft. Com. book i. p. 291, &c.

In divers charters and old writings, it appears that wreck, anciently, not only comprehended goods which came from a perifhing fhip, but whatever elfe the fea caft upon land: whether it were precious ftones, fifh, fea-weed, or the like.

This wreck, in the Grand Cuftomary of Normandy, cap. 17. is called *varech*, and latined *verifcum;* and in fome of our ancient charters, *wreche*, *werec*, *werech*, and *feupwerp*, q. d. *fea-upwerp*, of *fea* and *upwerpen*, *to caft up*.

Shipwreck, in marine infurance, and as it concerns the right of *abandoning*, is generally a total lofs. What may be faved of the fhip or goods is fo uncertain, and depends fo much on accident, that the law cannot diftinguifh this from the abfolute deftruction of the whole. The wreck of the fhip may remain, but the fhip is loft. Thus alfo the goods may remain; but if no fhip can be procured, in a reafonable time, to carry them to their place of deftination, the voyage is loft, and the adventure fruftrated. But the mere *ftranding* of the fhip is not, of itfelf, deemed a total lofs, fo as to intitle the infured immediately to abandon. It is only where the ftranding is followed by fhipwreck, or in any other way renders the fhip incapable of profecuting her voyage, that the infured is intitled to abandon. If the voyage be loft, this is a total lofs, not only of the fhip and freight, but alfo of the cargo, if no other fhip can be procured to carry it to its port of deftination. Moreover, if a cargo be damaged in the courfe of the voyage, fo that what has been faved is lefs in value than the amount of the freight, this is clearly a total lofs. In cafe of fhipwreck the rule in France is, that the infured may abandon, though the goods be recovered and carried to their place of deftination, becaufe goods thus faved are generally in a bad and unmarketable condition. But if the fhip become unnavigable, the infured cannot abandon the goods, if by any other fhip they may be conveyed in time to their place of deftination.

As it is reaſonable and neceſſary that the time of the underwriter's reſponſibility ſhould be limited, this limit is fixed in ſome maritime ſtates on the continent, within which period after the loſs the inſured may abandon. In France, Spain, and Holland, the times are limited by law, according to the diſtance of the place where the loſs happens, within which the abandonment muſt be made. In England there is no time, limited by law, for abandoning: but the courts have adopted a rule better ſuited to the promotion of commerce, and more likely to prevent frauds, which is this: that as ſoon as the inſured receives advice of a total loſs, he muſt make his election whether he will abandon or not; if he determines to abandon, he muſt give the underwriters notice of this "within a reaſonable time" after the intelligence arrives; and any unneceſſary delay in giving this notice will amount to a waver of his right to abandon; for unleſs the waver does ſome act ſignifying his intention to abandon, it will be only a partial loſs, whatever may be the nature of the caſe, or the extent of the damage. If by any interference of the underwriters the inſured be actually prevented from abandoning, the underwriters are liable for all the loſs ſuſtained by the inſured to the extent of the ſum inſured. If the inſured determine to abandon, and demand as for a total loſs, he is not obliged, as in ſome foreign countries, to make a formal proteſt, but merely to give notice of the loſs to the underwriters, and of his determination to abandon. The notice of abandonment may be given, either to the underwriter himſelf, or to the agent who has ſubſcribed for him: and the abandonment ought to be made for the whole of the effects inſured, and not for a particular part. The abandonment muſt be alſo ſimple and unconditional; otherwiſe it will not transfer the entire property to the inſurers, which is of the eſſence of the abandonment. By the abandonment, the inſured yields up to the inſurers all his right, title, and intereſt in the ſhip or goods inſured, or what may be ſaved of them, which, from the notice of abandonment, become the property of the inſurers; but the abandonment of the ſhip does not, as in France, transfer to the inſurer the freight ſhe has earned. The abandonment not only intitles the underwriters to all that can be ſaved of the effects inſured; but if compenſation be made to the inſured for the injury from which the loſs aroſe, this compenſation ſhall go to the underwriters; for when they have paid the loſs, they, and not the inſured, are the real ſufferers. If the ſhip, after abandonment, arrive ſafe, the inſurers ſhall have all the profit of the voyage. Nor ſhall they, on account of the ſafe arrival of the ſhip, refuſe to pay the ſum inſured. So if the ſhip or goods inſured happen to be recovered undamaged, after the inſurer has paid a total loſs, the inſurer cannot compel the inſured to refund the money, and take back the ſhip or goods, but the inſurer ſhall ſtand in his place, and ſhall have the benefit of ſalvage. An abandonment once properly made, on ſufficient ground, and accepted by the inſurers, is abſolute and binding upon both parties, and cannot be revoked unleſs by mutual conſent; but if the ground be inſufficient, it will be void. In caſe of ſhipwreck or other misfortune, the effects that are ſaved continue, till abandonment, the property of the inſured, who is bound in juſtice, honour, and conſcience, to uſe his utmoſt endeavours to make the moſt of what may be reſcued from deſtruction; in order, as much as poſſible, to lighten the burden of the inſurers. To enable him to do this, without prejudice to his right of abandonment, our policies provide, that in caſe of any loſs or misfortune to the inſured, their factors, ſervants, or aſſigns, ſhall be at liberty to ſue, and labour about the defence, ſafeguard, and recovery of the goods and merchandizes, and ſhip, &c. without prejudice to the inſurance; "to the charges whereof, the inſurers agree to contribute, each according to the rate and quantity of his ſubſcription." Marſhall on Inſurance, vol. ii. See *Perils of the* SEA.

WRECK, in *Metallurgy*, a veſſel in which the third waſhing is given to the ores of metals.

In Cornwall, when the tin-ore has been twice waſhed, they take the head tin, or that part of the tin-ore that lies uppermoſt, out of the buddle, and throwing it into this veſſel, they pour water on it, and work it about with wooden rakes, till it is cleared from whatever other extraneous matter there may ſtill have remained mixed with it, and is, after this, fit for the blowing-houſe to be run into metal.

WRECK, in *Agriculture*, a term ſignifying the weeds thrown up by the floods upon the ſea-ſhores; alſo the dead indigeſted roots and ſtems of graſs, and other plants in ploughed lands.

WREKIN, in *Geography*, a mountain of England, in Shropſhire; about 10 miles E. of Shrewſbury.

WREME, a town of the duchy of Bremen; 5 miles N.N.W. of Carlſburg.

WREN, *Sir* CHRISTOPHER, in *Biography*, an eminent architect and mathematician, was born in 1632, at the living of his father, who was rector of Eaſt Knoyle, in Wiltſhire, and finiſhed his education at Wadham college, Oxford, into which he entered in 1646. Before this time, he had given proofs of genius by the invention of aſtronomical and pneumatic inſtruments; the former of which he dedicated to his father, at the age of 13, in a copy of elegant Latin verſes, together with an exerciſe "De Ortu Fluminum." He alſo diſtinguiſhed himſelf by the conſtruction of other philoſophical inſtruments; and in 1647 he wrote a treatiſe on Spherical Trigonometry upon a new plan. In 1650 he graduated B.A., and in 1651 wrote an algebraical tract on the Julian period. In 1653 he was elected fellow of All-Souls' college, and graduated M.A. He was one of the firſt members of the Philoſophical Society at Oxford, from which proceeded the Royal Society, and contributed by his experiments and inventions to the amuſement and inſtruction it afforded; and in 1663 he was elected a fellow of the Royal Society. In 1657 he was choſen aſtronomical profeſſor at Greſham college; but upon being appointed Savilian profeſſor of aſtronomy at Oxford, he reſigned the former office, and in 1661 returned to the univerſity, which created him doctor of laws. Wren next preſents himſelf to our view as a pre-eminent architect; and thus diſtinguiſhed, he received a commiſſion in 1663 to prepare deſigns for the repair of St. Paul's cathedral; and after his return from a tour to France in 1665, with a view to his improvement in architecture, he finiſhed thoſe deſigns; but whilſt they were under conſideration, the edifice was deſtroyed by the fire of London in 1666. This cataſtrophe afforded him an opportunity of deſigning and conſtructing a building altogether new. The contemporary deſtruction of 50 parochial churches and many public buildings furniſhed ample ſcope for the exerciſe of Wren's talents; and he would have had the honour of refounding, as it were, a new city, if the deſign which he laid before the king and parliament could have been accompliſhed without infringing on the rights of private property. On the death of ſir John Denham in 1667, he ſucceeded to the office of ſurveyor of the works; and in order to obtain leiſure for executing the various works in which he was employed, and more particularly the rebuilding of St. Paul's cathedral, he reſigned his Savilian profeſſorſhip in 1673. In 1674 he received the honour of knighthood, and in the following year the foundation of the new cathedral was laid. For a particular account of this magnificent

magnificent edifice, fee the article London. In 1680 fir Chriftopher's fcientific merits caufed him to be elected prefident of the Royal Society. In 1683 he was appointed architect and commiffioner for Chelfea college, and in the following year comptroller of the works in the caftle of Windfor. In 1685 he was introduced into parliament as a reprefentative of Plympton. To his other public trufts were added, in 1698, that of furveyor-general and commiffioner for the repair of Weftminfter abbey; in 1699 that of architect of Greenwich hofpital; and in 1708 that of one of the commiffioners for the 50 new churches propofed to be erected in and near the city of London. Having fulfilled all his duties to the 86th year of his age, the adminiftration of 1718 incurred indelible difgrace, by fuffering political confideration to have fuch influence as to deprive him of his place of furveyor to the royal works. The remaining five years of his life were fpent in honourable retirement, and devoted to fcientific purfuits, and the reading of the Scriptures. It is faid that he indulged a very pardonable vanity by being carried once every year to furvey St. Paul's cathedral. His life was prolonged to his 91ft year, and terminated in confequence of a cold which he caught in coming from Hampton-Court to London, in February 1723. His remains were interred, with fuitable funeral honours, under the choir of St. Paul's, and upon his tomb is a concife but very appropriate and expreffive Latin infcription, ending "Lector, fi monumentum requiris, circumfpice." Sir Chriftopher was twice married, and left one fon, a man of learning and piety, and a good antiquary. The edifices conftructed by Wren were moftly public, including a royal hunting-feat at Winchefter, and the modern part of the palace at Hampton-Court. Some of the moft remarkable, befides St. Paul's, are, the Monument, the theatre at Oxford, the library of Trinity college, Cambridge, the hofpitals of Chelfea and Greenwich, and of Chriftchurch, London, the church of St. Stephen, Walbrook, thofe of St. Mary-le-Bow, St. Michael, Cornhill, and St. Bride, diftinguifhed by their fteeples, and the great campanile of Chriftchurch, Oxford. Of the rank which he occupied as a man of fcience, we may form fome judgment from the fucceeding concife detail of his performances, and more particularly from the teftimony of fir Ifaac Newton, who, in his "Principia," joins the names of Wren, Willis, and Huygens, and characterizes them as "hujus ætatis Geometrarum facilé principes." As to his moral character, it is faid to have been worthy of his intellectual eminence; as with great equanimity, he was pious, temperate, modeft, and communicative of his knowledge; and few men feem to have been more generally efteemed by their contemporaries. With regard to his architectural fkill and attainments, a very competent judge, being himfelf of the profeffion, fays, that he poffeffed an inexhauftible fertility of invention, combined with good natural tafte and profound fcientific knowledge; and that his talent was particularly adapted to ecclefiaftical architecture, which afforded domes and towers to his picturefque fancy; while, in his palaces and private houfes, he has fometimes funk into a heavy monotony, as at Hampton-Court and Winchefter. Among the rich variety of Wren's towers, fteeples, and fpires, many are truly elegant. The church of St. Stephen's, Walbrook, exhibits a deviation from common forms equally ingenious and beautiful. The Monument is grand and fimple. At Greenwich, his additions to the original work of Inigo Jones are fingularly grand and beautiful. Upon the whole, fir C. Wren's architecture is perhaps the perfection of that modern ftyle which, with forms and modes of conftruction effentially Gothic, adopts for the decorative part the orders and ornaments of antiquity. Biog. Brit. Walpole's Anecd. Gen. Biog.

Wren, or *Jenny-Wren*, in *Ornithology*, the *paffer troglodytes* of Gefner, and the *motacilla troglodytes* of Linnæus, has the head and upper part of the body of a deep reddifh-brown; above each eye is a ftroke of white; the back, and coverts of the wings and tail, are marked with flender, tranfverfe, black lines; the quill-feathers with bars of black and red; the throat is of a yellowifh-white; the belly and fides croffed with narrow dufky and pale reddifh-brown lines; and the tail is croffed with dufky bars. Pennant.

This bird, though very fmall, is of a very cheerful difpofition, and has a very agreeable voice, which he throws out with great cheerfulnefs and fprightlinefs, ufually cocking up his tail all the time he is finging, and continues his fong through the winter, except during the frofts. See Song *of Birds*.

The female breeds twice in the year, firft in the latter end of April, and afterwards in the middle of June. The neft is ufually placed among clufters of mofs and ivy, in fuch a manner that it is very hard to difcover it. It is made of dry mofs and leaves put together in a very artificial manner, being clofed all round except for a fmall hole left to go in and out at. They lay a great number of eggs, not lefs than eighteen; and it has been often found that they all hatch except one or two; and thus fixteen young ones have been found together in the neft. Thefe are brought up fo well as to fhift for themfelves by the end of May; and then another brood is provided for by the middle of the month following. The young ones may be eafily raifed. They fhould for this purpofe be taken out of the neft at about fourteen days old, and fed with fheep's, calf's, or ox's heart, cut fmall, with eggs minced among it. When they are able to peck this meat for themfelves, they may be put into cages; but they muft ftill be fed for fome days, left they fhould neglect themfelves, and die of hunger after the greateft part of the trouble is thus over. See Motacilla *Troglodytes*.

When they are grown up, they may be fed with pafte, and will need no more heart. Afterward it will be a great feaft to them to give each a fpider or two at once in two or three days; and after they attain full age, they may either be left to fing their own wild notes, which are very agreeable, or if it be defired that they fhould whiftle tunes, they will eafily be taught it. Ray and Pennant.

Wren, *Crefted*, or *Golden-Crefted* Wren, *regulus criftatus*, or *motacilla regulus* of Linnæus, the name of a very beautiful little bird, the fmalleft of all the Britifh birds. Its whole weight is not more than feventy-fix grains; and the crown of its head is adorned with a very beautiful faffron-coloured or orange-red fpot, which is called its creft, and by fome its crown, and from this golden crown the bird has obtained the name of the *regulus*, *tyrannus*, *bafileus*, and other appellations of royalty. This beautiful fcarlet mark on the head is bounded on each fide by a fine yellow line. The bill is dufky; the feathers of the forehead are green; from the bill to the eyes is a narrow white line; the back and hind part of the neck are of a dull green; the coverts of the wings dufky, edged with green, and tipped with white; the quill-feathers and tail dufky, edged with pale green; the throat and lower part of the body white, tinged with green; the legs are of a dull yellow colour; and the claws are very long.

This bird frequents woods, and is found principally in oak-trees. It is common about the Peak in Derbyfhire, and is feen in autumn as far north as the Shetland ifles, but quits that country before winter. It lays fix or feven eggs, not larger than peas. This bird has been obferved fufpended in the air for a confiderable time over a bufh in flower, whilft it fung very melodioufly. The note does not much differ from that of the common wren, but is very weak. Ray and Pennant. See MOTACILLA *Regulus*.

WREN, *Yellow*. See LUTEOLA, and MOTACILLA *Trochilus*.

WRENCH. See STRAIN.

WRENTHAM, in *Geography*, a town of the ftate of Maffachufetts, in the county of Norfolk, containing 2478 inhabitants; 23 miles S.W. of Bofton.

WRESTBALKING, in *Agriculture*, the operation of turning over upon or covering a balk or rib of whole unmoved ground, by a broad furrow-flice, in the view of rendering the land more mellow and porous. The term is chiefly ufed in the eaftern diftricts of the country.

WRESTLING, a kind of combat or engagement between two perfons unarmed, body to body, to prove their ftrength and dexterity, and try which can throw his opponent to the ground.

Wreftling, *palæftra*, is an exercife of very great antiquity and fame. It was in ufe in the heroic age; witnefs Hercules, who wreftled with Antæus.

It continued a long time in the higheft repute, and had very confiderable rewards and honours affigned it at the Olympic games. It was the cuftom of the athletæ, or wreftlers, to anoint their bodies with oil, to give the lefs hold to their antagonift. See PALÆSTRA.

Ablancourt obferves, that Lycurgus ordained the Spartan maids to wreftle in public, quite naked, to break them of their too much delicacy and nicenefs; to make them appear more robuft, and familiarize the people, &c. to fuch nudities.

A wreftling match, or *neobering*, is a very common diverfion in the Mandingo countries of Africa. It is exhibited at the "Bentang," which is a large ftage found in each town, that anfwers the purpofe of a public hall or townhoufe: it is compofed of interwoven canes, and is generally fheltered from the fun by being erected in the fhade of fome large tree. It ferves alfo for a kind of lounging place, where the indolent and unemployed affemble to fmoke their pipes, and talk over the news of the day.

At the wreftling match, the fpectators arrange themfelves in a circle, leaving the intermediate fpace for the wreftlers, who are ftrong, active, young men, trained up from infancy to this fort of exertion. Being ftripped of their clothing, except a fhort pair of drawers, and having their fkin anointed with oil, or *fhea* butter, they approach each other on all fours, parrying with and occafionally extending a hand for fome time, till at length one of them fprings forward and catches his rival by the knee. Great dexterity and judgment are now difplayed; and the conteft is at length decided by fuperior ftrength. The combatants are animated by the mufic of a drum, which ferves alfo in fome meafure to regulate their motions. The wreftling is fucceeded by a dance, in which many performers affift, all being provided with little bells faftened to their legs and arms; their motions being regulated by the drum, beaten by a crooked ftick, which the drummer holds in his right-hand, occafionally ufing his left to deaden the found, and thus vary the mufic. The drum is alfo ufed to keep order among the fpectators; and when the wreftling match is about to begin, the drummer ftrikes what is underftood to fignify "ali bæ fee," fit all down; upon which the fpectators immediately feat themfelves; and when the combatants begin, he ftrikes "amuta, amuta," *i. e.* take hold, take hold.

WRETESTA, in *Geography*, a town of Sweden, in Sudermannland; 36 miles N.W. of Nykioping.

WRETSTORP, a town of Sweden, in the province of Nericia; 16 miles S.W. of Orebro.

WRETWEED, in *Agriculture*, a name fometimes given to wart-weed or fun-fpurge, a troublefome weed in fields. See WEED.

WREXHAM, in *Geography*, a market-town in the hundred of Bromefield, towards the eaft corner of the county of Denbigh, North Wales, is fituated 25 miles E.S.E. from Denbigh, $11\frac{3}{4}$ S.S.W. from Chefter, and by the road through Whitechurch 176 N.W. from London. The parifh of Wrexham is extenfive and populous, and comprifes 14 townfhips. By the returns of 1811, the population of the whole amounted to 19,495, and the houfes to 4142.

Wrexham is a place of confiderable antiquity, for it is mentioned in the Saxon Chronicle by the name of Wrightelefham. Although belonging to Cambria, yet being feparated by the ancient trench called Offa's Dyke, it came to be ranked as appertaining to the great internal diftrict of England, Mercia. In the reign of Edward I., the town and the lordfhip were granted to earl Warren; and as early as the reign of Henry VIII., the town was known for its trade, particularly for its buckle-makers. Wrexham is noted for its fairs, one of which continues for nine days, for the fale of Welfh flannels, cattle, Irifh linens, Englifh woollens, ironmongery, &c. The weekly markets are kept on Monday and Thurfday. The church of Wrexham is the moft remarkable and moft ornamented building of its kind in North Wales. It was erected in 1472, but the tower was not finifhed till 1506. It confifts of a nave, with fide aifles, and a chancel; the whole length being 178 feet, and the breadth 72: the tower rifes to the height of 135 feet; the aifles are feparated from the nave by clustered columns fupporting pointed arches; the ceiling is compofed of oak, in imitation of groined ftone. In the town is a free-fchool for educating twelve boys. Two miles weft from Wrexham is Borfham, which is noted for the great iron-furnaces of Meffrs. Wilkinfon. Notwithftanding the difficulties in the beginning, the works are now among the greateft in the kingdom. The machinery employed is very ingenious; and every article of caft-iron, from cannon down to kitchen utenfils, is fabricated in great numbers. Iron-ftone and coal are plentiful in the neighbourhood; and at a fhort diftance is a productive lead-mine. The Ellefmere canal between Shrewfbury and Chefter paffes half a mile to the weft of Wrexham. Two miles more to the weftward is the celebrated intrenchment called Offa's Dyke, which extended from the river Wye in Monmouthfhire on the fouth into Flintfhire on the north; and is fuppofed to have been formed by that Saxon chief of Mercia, to defend his country from the native Britons, who had retired among the mountains of Wales. On the eaft fide of Wrexham is Wat's Dyke, another intrenchment of the fame kind, probably intended for a fimilar purpofe, but unconnected with the work of Offa.

About feven miles S.S.W from Wrexham is Ruabon, a village with a refpectable church, containing the monuments of the ancient families of Williams and Wynn; one in particular for the firft fir Watkin, who died in 1749, is a diftinguifhed production of Ryfbrack. The learned Dr. David Powell, the tranflator and editor of fundry hiftorical works relative to Wales, was a native and vicar of Ruabon, where he died in 1590. On the eaft fide of the village is the gate leading to the park and manfion of Wynnftay, the feat of

Printed by A. Strahan,
New-Street-Square, London.

of ſir Watkin Williams Wynn, bart. The road runs through an avenue of trees of uncommon growth, in a ſtraight line for a mile, to a ſpacious lawn, on which ſtands the houſe. Erected at different periods, and in different ſtyles of architecture, Wynnſtay-hall is more diſtinguiſhed for ſize and irregularity than for beauty of architecture. The new parts erected by the firſt baronet, although only a portion of the deſign, form a plain, ſubſtantial, comfortable place of reſidence; the older parts are chiefly appropriated to menial purpoſes. The interior comprehends ſome ſpacious apartments, in which are a few valuable portraits, particularly one by Vandyke of ſir Richard Wynn, who attended Charles I. on his romantic matrimonial adventure to Spain. Adjoining to the houſe is a ſmall building, formerly uſed as a theatre. The park, from the ancient intrenchment Wat's Dyke which traverſes it, was formerly called Wat-ſtay; but when the heireſs married ſir John Wynn, who incloſed the grounds in 1678 with a ſtone-wall, the name was changed to its preſent appellation. The grounds are not greatly diverſified, but they are well wooded, and favourably ſituated for proſpects. On an eminence ſtands a fluted ſtone column, 100 feet high, on a plinth 16 feet ſquare, acceſſible to the ſummit by an internal ſtair-caſe. It was erected in memory of the late baronet by his mother, with this ſimple but eloquent inſcription: "Filio optimo mater eheu! ſuperſtes." Near the park the river Dee winds through Nant-y-Bele, or the dingle of the Marten, a place of great natural romantic beauty. Caer-ddin in this pariſh, commonly called Garthen, is a ſtrong Britiſh poſt on a lofty hill, at no great diſtance from Offa's Dyke. It is formed by a rampart and ditch, in ſome parts double, and the inner conſiſting of a thick wall. The area, containing about four acres, exhibits veſtiges of ancient buildings.—Beauties of England and Wales, Denbighſhire, by the Rev. J. Evans, 8vo. London, 1812.

WRIETZEN. See BRIETZEN.

WRIGHT, EDWARD, in *Biography*, an Engliſh mathematician, flouriſhed in the latter part of the 16th and beginning of the 17th century. Of his private hiſtory little is known, except ſome few particulars that may be collected from the Latin memoirs of his life, preſerved among the annals of Gonvile and Caius college in Cambridge. This year (1615) died, it is ſaid, at London, Edward Wright, of Garveſton in Norfolk, formerly a fellow of this college, much reſpected for the integrity and ſimplicity of his manners, and alſo famous for his ſkill in the mathematical ſciences. He was the firſt undertaker of the difficult but uſeful work, by which a little river is brought from the town of Ware, in a new canal, to ſupply the city of London with water; but by the tricks of others he was prevented from completing it. Nor was he inferior to the moſt ingenious mechanic in the conſtruction of inſtruments, either of braſs or of any other matter. He, it is ſaid, taught Iodocus Hondius the method of conſtructing his geographical charts, though Hondius concealed his name, that he might arrogate to himſelf the honour of the invention. Of this act of injuſtice, Wright complained in the Preface to his "Treatiſe of the Correction of Errors in the Art of Navigation," a work compoſed with excellent judgment, and after long experience, to the great advancement of naval affairs. For his improvement of this art he was appointed mathematical lecturer to the Eaſt India Company; and he read lectures, for which he was allowed a yearly ſalary of 50*l.* This office he diſcharged with great reputation, and much to the ſatisfaction of his hearers. He publiſhed, in Engliſh, a book on the doctrine of the ſphere, and another concerning the conſtruction of ſun-dials. He alſo prefixed an ingenious preface to the learned Gilbert's book on the load-ſtone. By theſe and other writings he tranſmitted his fame to the lateſt poſterity. It is added, whilſt he was a fellow of this college, he was called forth to the public buſineſs of the nation by the queen, about the year 1593, or, according to other accounts, 1589. He was ordered to attend the earl of Cumberland in ſome maritime expeditions; of one of which he gave a faithful account, under the form of a journal or ephemeris, prefixing to it an elegant hydrographical chart of his own invention. His poſthumous work, which was an Engliſh tranſlation of the book of logarithms, then lately diſcovered by lord Napier, a friend of Mr. Wright, was publiſhed ſoon after his death by his ſon Samuel Wright, a ſcholar of the above-named college. Death prevented the execution of ſeveral other deſigns which he had formed. Of him it may be truly ſaid, that he ſtudied more to ſerve the public than himſelf; and though he was rich in fame and in the promiſes of the great, he died poor, to the ſcandal of an ungrateful age. To the preceding extracts from the memoirs above cited, we may add, that Mr. Wright firſt diſcovered the true method of dividing the meridian line, according to which Mercator's charts are conſtructed (ſee CHART), and upon which his failing is founded. An account of it was ſent from Cambridge to Mr. Blondeville, who publiſhed it among his exerciſes in 1594; and in 1597 a demonſtration of it was given by the Rev. Mr. William Barlowe, in his "Navigator's Supply." In 1599 Mr. Wright publiſhed "The Correction of certain Errors in Navigation," written many years before, and ſhewing the reaſon of his diviſion of the meridian, the manner of conſtructing his table, and its uſes in navigation, &c. &c. In 1610 he dedicated a ſecond edition to his royal pupil, prince Henry, with farther improvements, and an excellent method for determining the magnitude of the earth. To his other works, comprehending an account of his various diſcoveries, tables, and improved inſtruments for obſervation, we ſhall add his tract on navigation, entitled "The Haven-finding Art." It is ſaid that he conſtructed, for the uſe of prince Henry, a large ſphere with curious movements, ſerving by ſpring-work to exhibit the motions of the whole celeſtial ſphere, the particular ſyſtems of the ſun and moon, their circular motions, places, and poſſibilities of eclipſing each other. (See ORRERY.) This ſphere was overlooked in the time of the civil wars, and found among duſt and rubbiſh in 1646 by ſir Jonas Moore, who was at the expence of reſtoring it to its original ſtate, and depoſited it at his own houſe in the Tower, among other mathematical inſtruments. Preface to Robertſon's Navigation. Hutton's Math. Dict.

WRIGHT, RICHARD, was a native of Liverpool, and born about the year 1735. He was bred to the humble occupation of a houſe and ſhip painter, but exerted his talents in painting ſea views, and obtained for his encouragement the premium offered in 1764 by the ſociety for the encouragement of arts, &c.; and in 1766 he gained another premium of fifty guineas, for a picture which had the greater credit of being moſt beautifully engraved by Woollett, and is known under the name of the "Fiſhery." He died about 1775.

WRIGHT, JOSEPH, one of our earlieſt painters of celebrity in this age of reſtoration of the art. He was born at Derby in 1734, and thence obtained the name of Wright of Derby, to diſtinguiſh him from R. Wright mentioned above. He came to London to ſtudy with Hudſon, but afterwards eſtabliſhed himſelf at his native place, and had very con-

ſiderable

fiderable encouragement as a portrait-painter, though his ftyle was dry and too minute. He gained much more reputation by painting fcenes of fire and candle-light, and indeed ftood unrivalled in that way till Loutherbourg fubfequently appeared. His pictures of a forge and of a blackfmith's fhop, exhibited with the fociety of artifts about the year 1765, eftablifhed his reputation. In 1773 he vifited Rome, and Italy generally, and was abfent two years. In 1782 he was elected an affociate of the Royal Academy, but refigned his diploma foon after, on Mr. Garvey's being preferred to him in an election for an academician; though he continued occafionally to exhibit with the academy. He had great induftry and profeffional fkill, living very much apart from the world. This enabled him to produce many pictures, and in 1785 he made an exhibition of twenty-four pictures of his own painting at the great room under the Piazza Covent-garden, one of which was a large work reprefenting the deftruction of the floating batteries before Gibraltar. His ftyle in all his works was peculiar to himfelf, fomewhat dry, yet not void of richnefs, and his drawing coldly correct. One peculiarity marks his pictures, and renders them eafily diftinguifhable, efpecially thofe in which the illumination proceeds from the moon or fire. He prepared his cloths or grounds with rough furfaces, caufed by fand fifted or ftrewed upon them; and then when he had painted his fcene, he dragged his pallet-knife, covered with the colour of the light, acrofs the picture, when the colour adhering to the projections on the furface, gave the glitter which characterizes that kind of illumination, and he toned the parts to due relief by glazings. No one ever gave the exact tone of moon-light fo completely as Wright of Derby. He died in 1797, aged 63.

Wright, *Mifs*, a vocal apprentice to Michael Arne, the natural fon of Dr. Arne. She had a fweet, fpirited, and active voice, but was fo young in mufic, that fhe learned the parts which fhe had to perform on the ftage, after fhe was too haftily engaged at Drury-lane, by her ear. The firft part affigned to her in that theatre was Leonora, in Bickerftaff's Padlock, in which the airs, as fet by Dibden, were fo pleafing, and fo much on the Italian model, that they eftablifhed her in the favour of the town. But the air "Say little foolifh fluttering thing" was never fung in fuch a brilliant and captivating manner by any other finger.

In 1766 fhe appeared in the Cunning Man, Rouffeau's Devin de Village, tranflated *totidem fyllabis*, and adapted to his original mufic by the author of this article, in which fhe pleafed extremely.

Soon after this, the apprentice was exalted into the wife of her mafter, the *ferva padrona*, and fung with great applaufe in Cymon, and feveral of his and other compofers' compofitions that were performed at Drury-lane; and, if we remember right, in the fummer fhe fung in Mary-le-bone gardens. But the town was fo fond of hearing her, and the produce of her talents fo alluring to her hufband, that fhe may truly be faid to have fung herfelf to death; or, like the fwans of old in the Po, to have died finging. The truth is, that her ignorance of mufic made it neceffary for her to fing at home, in rendering herfelf perfect in her parts, ten times more than fhe did in public, which brought on a pulmonary complaint, and prematurely put an end to her exiftence in 1770, at the age of 22, to the grief of her friends, and great regret of the public.

Wright, in *Geography*, a town of Virginia; 44 miles W. of Richmond.

Wright's *Town*, a townfhip of Pennfylvania, in the county of Bucks, with 562 inhabitants; 24 miles N. of Eafton.

WRIGHTIA, in *Botany*, is dedicated by Mr. Brown to his much-refpected friend William Wright, M.D. fellow of the royal focieties of London and Edinburgh, and affociate of the Linnæan fociety, "whofe ardour in the purfuit of botanical knowledge," fays Mr. Brown, "even while engaged in extenfive medical practice in the ifland of Jamaica, has long entitled him to this mark of diftinction." We heartily concur in this fentiment, and cannot but regret that Dr. Swartz did not retain for this purpofe what he has called Meriana. (See that article.)—Brown in Tr. of the Wernerian Soc. v. 1. 73. Prodr. Nov. Holl. v. 1. 467. Ait. Hort. Kew. v. 2. 68. (Nerium; Gærtn. t. 117.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juff. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five fmall, rounded, bluntifh fegments, with five or ten internal fcales at the outfide of the bafe of the corolla, permanent. *Cor.* of one petal, falver-fhaped: tube cylindrical, various in length: limb in five oblong, fpreading, oblique fegments, as long as the tube, or longer: mouth crowned with ten divided fcales, fhorter than the limb. *Stam.* Filaments five, thread-fhaped, fhort, inferted into the throat of the corolla; anthers arrow-fhaped, pointed, prominent, cohering by their middle part to the ftigma. *Pift.* Germens two, fuperior, roundifh, cohering; ftyle one, thread-fhaped, the length of the tube, dilated at the apex; ftigma contracted. *Peric.* Follicles two, almoft cylindrical, either diftinct or cohering, pointed, erect. *Seeds* numerous, inferted into the margins of each follicle, oblong, imbricated downwards, crowned at the lower extremity with filky hairs, directed towards the bafe of the feed-veffel.

Eff. Ch. Corolla oblique, falver-fhaped; mouth crowned with ten divided fcales. Stamens prominent. Follicles two, erect. Seeds imbricated downward, hairy at the lower extremity.

A genus of upright fhrubs, or fmall trees, natives of the Eaft Indies, Ceylon, the Malay archipelago, or the tropical part of New Holland. Their *leaves* are oppofite. *Flowers* white, corymbofe, nearly terminal. *Albumen* none. *Embryo* white, turning rofe-coloured by immerfion in warm water; *cotyledons* involute longitudinally. *Brown.*

1. W. *antidyfenterica.* Oval-leaved Wrightia. Br. n. 1. Ait. n. 1. (Nerium antidyfentericum; Linn. Sp. Pl. 306, excluding Rheede's fynonym. Willd. Sp. Pl. v. 1. 1236. N. n. 107; Linn. Zeyl. 45. N. indicum, filiquis anguftis, erectis, longis, geminis; Burm. Zeyl. 167. t. 77.)—Leaves obovate-oblong, fhort-pointed, fmooth. Corymbs moftly terminal. Tube of the corolla fix times as long as the calyx. Follicles diftinct.—Native of Ceylon. A handfome erect fhrub, with numerous branches. *Leaves* on fhort ftalks, fpreading, two inches, or two and a half, long. *Tube* as well as *limb* of the *flowers* each an inch in length. *Follicles* thrice as long, a little fwelling upwards; their points converging. *Brown. Burmann.*

2. W. *zeylanica.* Lanceolate-leaved Wrightia. Br. n. 2. (Nerium zeylanicum; Linn. Sp. Pl. 306. Am. Acad. v. 4. 309. Willd. Sp. Pl. v. 1. 1236. Apocynum arborefcens, nerii flore minus; Burm. Zeyl. 23. t. 12. f. 2.)—Leaves oblong-lanceolate, blunt-pointed, fmooth. Corymbs terminal. Tube of the corolla four or five times as long as the calyx. Follicles diftinct.—Native of Ceylon. Our fpecimen was given to Linnæus by Burmann. The *branches* are long and ftraight, round, purplifh. *Leaves* fmaller than the laft, about an inch and a half long, with more or lefs of a linear blunt point. *Flowers* like the preceding, but, according to Mr. Brown, the *tube* is fhorter in proportion.

3. W. *tinctoria.* Dyer's Wrightia. Br. n. 3.—"Leaves

elliptic-

elliptic-lanceolate, or ovate, pointed, ſmooth. Branches and corymbs divaricated. Tube of the corolla twice the length of the calyx. Follicles diſtinct."—Found by Koenig and Roxburgh in the Eaſt Indies. We received from Dr. Roxburgh in 1789, by the name of *Nerium antidyſentericum*, ſpecimens which anſwer to the above characters, except that the *tube* is not at all longer than the *calyx*; the *limb* moreover appears purpliſh, and is clothed on both ſides with fine pubeſcence. This plant muſt be known to Mr. Brown, and perhaps is one of the undeſcribed ſpecies of which he makes mention.

4. W. *pubeſcens*. Downy Wrightia. Br. n. 4. Prodr. n. 1.—" Leaves elliptic-oblong, pointed, downy as well as the calyx. Corymbs erect. Tube of the corolla ſcarcely longer than the calyx. Follicles combined."—Gathered by Mr. Brown in the tropical part of New Holland, and in the iſle of Timor, near Coepang.

This author ſpeaks of ſome other ſpecies, of which he has not yet publiſhed either characters or names, and which are not known to us. *Nelem-Pala*, Rheede Hort. Mal. v. 9. 5. t. 3 and 4, is preſumed to belong to the preſent genus.

WRIGHTSBOROUGH, in *Geography*, a ſettlement in the ſtate of Georgia, on a branch of the Savannah; 30 miles W. of Auguſta.

WRING-HOUSE, in *Rural Economy*, a name ſometimes applied to the place for making cyder in, in the ſouthern diſtricts.

WRINGLE-TAIL, a name given by the people of ſeveral parts of England to the *curvicauda*, a ſpecies of bee-fly, very much reſembling the bee in ſhape, but having only two wings and no ſting. It is very troubleſome to horſes, but does not ſuck their blood, but only lays its eggs in their ſkins: it is called in other countries the *whame* and the *barrel-fly*.

WRINGTON, in *Geography*, a market-town in the hundred of Brent-with-Wrington, in the county of Somerſet, England, is ſituated to the S.W. of the Mendip hills, at the diſtance of 6 miles N.N.E. from Axbridge, and 129 miles W. from London. The ſtreets are irregularly built, and moſt of the houſes are thatched. A weekly market, by a very ancient grant, is held on Tueſday; and here is an annual fair. In the market-place are the ruins of a croſs. The church, a ſpacious edifice, 120 feet in length and 52 in width, conſiſts of a nave, chancel, ſide aiſles, and a porch. The tower, at the weſt end, is 140 feet high to the top of the battlements, which are adorned with four turrets, one at each corner, and ſixteen elegant pinnacles fifteen feet in height. The church contains ſeveral ancient and modern monuments. One is of peculiar beauty: it is built of white and Sienna marble, and was erected in memory of Dr. Henry Waterland, prebendary of Briſtol, and above fifty years miniſter of this pariſh, where he conſtantly reſided: he died March 27, 1779. In the town is a free-ſchool for ſix boys and as many girls. In the return of the year 1811, the population of the pariſh is enumerated as 1109, the number of houſes as 183. Wrington is diſtinguiſhed by being the birth-place of the celebrated philoſopher, John Locke: he was born 1632, in an old thatched houſe, ſtill ſtanding on the north ſide of the church-yard: he died October 28, 1704. See LOCKE, JOHN.—Collinſon's Hiſtory of Somerſetſhire, vol. i. 1791.

WRIST, CARPUS, in *Anatomy*. See EXTREMITIES.

WRIST, *Fracture*, *Ligaments*, and *Luxation of*. See the reſpective articles.

WRIST, in the *Manege*. The bridle wriſt is that of the cavalier's left-hand. A horſeman's wriſt and his elbow ſhould be equally raiſed, and the wriſt ſhould be two or three fingers above the pummel of the ſaddle. To ride a horſe from hand to hand, *i. e.* to change hands upon one tread, you need only to turn your wriſt to that ſide you would have the horſe to turn to, without advancing your hand. But if your horſe ſtops, you muſt make uſe of both your legs. See HAND and LEGS.

WRIT, formed from the Saxon *writan*, to write, *Breve*, in *Law*, a precept of the king in writing, under ſeal, iſſuing out of ſome court to the ſheriff or other perſon, whereby any thing is commanded to be done, touching a ſuit or action, or giving commiſſion to have it done: as, the ſummoning of a defendant, taking a diſtreſs, redreſſing a diſſeiſin, or the like. Or, according to Fitzherbert, a writ is a formal letter of the king in parchment, ſealed with a ſeal, and directed to ſome judge, officer, or miniſter, &c. at the ſuit or plaint of a ſubject, requiring to have a thing done, for the cauſe briefly expreſſed, which is to be diſcuſſed in the proper court according to law. See BREVE, BRIEF, and PRECIPE.

Writs are variouſly divided, and in various reſpects. Some, with regard to their order, or manner of granting, are termed *original*, and others *judicial*.

WRITS, *Original*, are thoſe ſent out of the high court of chancery, to ſummon the defendant in a perſonal or tenant in a real action; either before the ſuit begins, or to begin the ſuit by it. See ORIGINAL.

Royal writs are held to be demandable of common right, on paying the uſual fees; for any delay in the granting of them, or ſetting an unuſual or exorbitant price upon them, would be a breach of Magna Charta, cap. 29. "Nulli vendemus, nulli negabimus, aut differemus juſtitiam vel rectum."

Original writs are either optional or peremptory, or, in the language of our law, they are either a *præcipe*, or a *ſi te fecerit ſecurum*.

WRITS, *Judicial*, are thoſe ſent by order of the court where the cauſe depends, upon emergent occaſions, after the ſuit begins.

Judicial writs are diſtinguiſhed from original, in that their teſte bears the name of the chief-juſtice of that court whence they come; whereas the original ſay, *teſte meipſo*, in the name or relating to the king.

The *original* writ is always made returnable at the diſtance of at leaſt fifteen days from the date or *teſte*, and upon ſome day in one of the four terms: and all *judicial* writs, being grounded on the ſheriff's return, muſt reſpectively bear date the ſame day on which the writ immediately preceding was returnable. See PROCESS.

Judicial writs, if erroneous, may be amended: whereas *original* writs are not amendable, if the error be by default of the party who gave inſtruction; yet a new original may be taken out, where it is not amendable.

Writs are alſo diſtinguiſhed, according to the nature of the action, into *real* and *perſonal*.

Real, are either touching the poſſeſſion, called *writs of entry*; or the property, called *writs of right*. See RECTO.

Perſonal writs, are thoſe relating to goods, chattels, or perſonal injuries.

To which may be added *mixt* writs, for the recovery both of the thing and damages.

Some writs, again, are at the ſuit of the party; ſome, of office; ſome, ordinary; ſome, of privilege. A writ of privilege is that which a privileged perſon brings to the court for his exemption, by reaſon of ſome privilege which he enjoys.

But the moſt common writs in daily uſe are, in debt, detinue,

tinue, trefpafs, action upon the cafe, account, and covenant, &c. which, as well as others, muft be rightly directed, or they will be naught.

Writs may be renewed every term, until a defendant is arrefted; but in the court of king's bench, if the *latitat* be not renewed in five terms, a new writ is to be taken out, and the plaintiff is not allowed to renew the old one.

The fheriff's bailiffs cannot execute a writ directed to the fheriff, without his warrant; and if feveral perfons are included in a writ (for four defendants may be in one writ), there muft be feveral warrants from the fheriff to execute the fame. All writs are to be returned and filed in due time, to avoid *poft-terminums.*

Attachment lies againft fheriffs, &c. for not executing a writ, or for doing it oppreffively by force, extorting money on it, or not doing it effectually, by reafon of any corrupt practice.

Writ *of Appraifement*, a writ iffued out of court for the valuation of goods feized as forfeited to the crown; or goods taken as prize of war, or found wrecked, flotfam or jetfam.

Several feizures by feveral perfons not amounting to 100*l.* may be included in one writ. (Bunbury, p. 63.) And a new writ was ordered where the firft appraifement was too high. (Ibid. 49. 185.) They are alfo required to fpecify the goods particularly, p. 89.

Writ *of Affife*. See Assise.

Writs *of Affiftance*, are writs iffued out of the exchequer, to enable officers to enter fhips, houfes, warehoufes, and other places, to fearch for fmuggled or prohibited goods. They are directed to be granted by 13 & 14 Car. II. c. 11. and are iffued on oath, that there is ftrong prefumption to believe goods of thofe kinds are harboured; but if they are executed in the night, the officers muft be accompanied by a peace-officer.

Writ *of Capias*. See Capias.

Writ *of Delivery*, a writ directing the delivery of goods out of the king's poffeffions, either by verdict or by confent. They cannot be iffued till the information is in court (Bunbury, p. 27.); and they are difcretionary in the court. (Ibid. p. 196.) A writ was granted out of the exchequer for watches, becaufe the fprings and fteel-work were liable to ruft (p. 74.); but it was refufed for tobacco-ftalks, becaufe they were directed to be burnt. (P. 196.) A writ was alfo refufed in Ladd's and in Thomfett's cafe, in the fame court, for coins; the former reported, the latter not reported.

Writ *of Diftringas*. See Distringas.

Writ *of Election to Parliament*. See Parliament.

Writ *of Entry*. See Entry.

Writ *of Inquiry of Damages*, a judicial writ that iffues out to the fheriff upon a judgment by default, in an action of the cafe, covenant, trefpafs, trover, &c. commanding him to fummon a jury to enquire what damages the plaintiff hath fuftained, *occafione præmifforum;* and when this is returned with the inquifition, the rule for judgment is given upon it; and if nothing be faid to the contrary, judgment is thereupon entered. 2 Lill. Abr. 721.

Writ *of Mainprife*. See Mainprise.

Writ *of Neifty*. See Neifty.

Writ *of Rebellion*. See Commission *of Rebellion*.

Writ *of Right*. See Recto.

Writs *Vicountiel*. See Vicountiel.

Writ, *Action of a*. See Action.

Writ, *Appeal by*. See Appeal.

Writ, *Attachment by*. See Attachment.

Writ, *Continuance of a*. See Continuance.

WRITER *of the Tallies*, an officer of the exchequer, being clerk to the auditor of the receipt, who writes upon the tallies the whole letters of the tellers' bills. See Tally and Exchequer.

WRITING, Scriptura, the art or act of fignifying and conveying our ideas to others, by letters or characters vifible to the eye.

Or, writing may be defined to be the art of exhibiting to the fight the conceptions of the mind, by means of marks or characters fignificant of the founds of language, which enable us to transfer ideas from the eye to the ear, and *vice verfâ.*

Written characters are of two forts: they are either figns for things, or figns for words. Of the former fort, are the pictures, hieroglyphics, and fymbols, employed by the ancient nations; of the latter fort, are the alphabetical characters now employed by all Europeans. Pictures were, undoubtedly, the firft effay towards writing; accordingly, we find in fact, that this was the only fort of writing known in the kingdom of Mexico, when America was firft difcovered. By hiftorical pictures, the Mexicans are faid to have tranfmitted the memory of the moft important tranfactions of their empire. (See Warburton's Divine Legat. of Mofes, vol. ii. part i. p. 67, &c. vol. iii. p. 73. Robertfon's Hift. Am. vol. iii. p. 203, &c. and Appendix, note 26. p. 440. edit. 8vo.) But as pictures could do no more than delineate external events, without exhibiting their connections, defcribing fuch qualities as were not vifible to the eye, or conveying any idea of the difpofitions or words of men, there arofe in procefs of time, for fupplying this defect, the invention of hieroglyphical characters; which may be confidered as the fecond ftage of the art of writing.

Hieroglyphics (which fee) confift in certain fymbols, which are made to ftand for invifible objects, on account of an analogy or refemblance which fuch fymbols were fuppofed to bear to the objects. Among the Mexicans were found fome traces of hieroglyphical characters, intermixed with their hiftorical pictures. But Egypt was the country where this fort of writing was moft ftudied, and brought into a regular art. However, this fort of writing could be no other than enigmatical and confufed, in the higheft degree; and muft have been a very imperfect vehicle of knowledge of any kind.

As writing advanced from pictures of vifible objects to hieroglyphics, or fymbols of things invifible; from thefe latter it advanced, among fome nations, to fimple arbitrary marks which ftood for objects, though without any refemblance or analogy to the objects fignified. Of this nature was the method of writing practifed among the Peruvians; who made ufe of fmall cords, of different colours, and by knots upon thefe, of various fizes, and differently arranged, contrived figns for giving information, and communicating their thoughts to one another. Of this nature, alfo, are the written characters which are ufed to this day in China. The Chinefe have no alphabet of letters, or fimple founds, which compofe their words; but every fingle character which they ufe in writing is fignificant of an idea: it is a mark which ftands for fome one thing or object, and confequently the number of thefe characters muft be immenfe. This Chinese *writing*, (which fee,) probably began, like the Egyptian, with pictures and hieroglyphical figures; which figures being, in their progrefs, abbreviated in form, for the fake of more eafily writing them, and greatly enlarged in number, paffed at length into thofe marks or characters which they now ufe, and which have fpread themfelves through feveral nations of the Eaft. For it is faid, that the Japanefe, the Tonquinefe, and the Coroeans, who ſpeak different languages from one another, and from the inhabitants of China, uſe the ſame written characters with them, and thus intelligibly correſpond with each other in writing, though ignorant of the language ſpoken in their ſeveral countries. Our European arithmetical figures are ſignificant marks, preciſely of the ſame nature with the Chineſe characters. Thus far nothing has appeared which reſembles our letters, or which can be called writing, in the ſenſe now given to that term. What we have hitherto ſeen were all direct ſigns for things, and made no uſe of the medium of ſound or words; either ſigns by repreſentation, as the Mexican pictures; or ſigns by analogy, as the Egyptian hieroglyphics; or ſigns by inſtitution, as the Peruvian knots, the Chineſe characters, and the Arabian cyphers. At length, in different nations, men became ſenſible of the imperfection, the ambiguity, and the tedioufneſs of each of theſe methods of communication with one another, and began to conſider the advantage reſulting from employing ſigns, which ſhould ſtand not directly for things, but for the words which they uſed in ſpeech for naming theſe things; and they alſo conſidered, that though the number of words in every language be very great, yet the number of articulate ſounds, uſed in compoſing theſe words, is comparatively ſmall. Hence they were led to invent ſigns, not for each word by itſelf, but for each of thoſe ſimple ſounds that are employed in forming words; and they obſerved, that by joining together a few of thoſe ſigns, it would be practicable to expreſs, in writing, the whole combination of ſounds which our words require.

The firſt ſtep in this new progreſs was the invention of an alphabet of ſyllables, which probably preceded the invention of an alphabet of letters, among ſome of the ancient nations; and which is ſaid to be retained, to this day, in Ethiopia, and ſome countries of India. By fixing upon a particular mark or character for every ſyllable in the language, the number of characters, neceſſary to be uſed in writing, was reduced within a much ſmaller compaſs than the number of words in the language. Still, however, the number of characters was great; and muſt have continued to render both reading and writing very laborious arts. At laſt ſome happy genius aroſe; and tracing the ſounds made by the human voice to their moſt ſimple elements, reduced them to a very few vowels and conſonants; and, by affixing to each of theſe the ſigns which we now call letters, taught men how, by their combinations, to put into writing all the different words, or combinations of ſound, which they employed in ſpeech. By being reduced to this ſimplicity, the art of writing was brought to its higheſt ſtate of perfection, and in this ſtate, we now enjoy it in all the countries of Europe.

To whom we are indebted for this admirable and uſeful diſcovery does not appear. There ſeems reaſon to conclude, from the books which Moſes has written, that, among the Jews, and probably among the Egyptians, letters had been invented prior to his age. The univerſal tradition among the ancients is, that they were firſt imported into Greece by Cadmus the Phœnician, who, according to the common ſyſtem of chronology, was contemporary with Joſhua; but according to ſir Iſaac Newton's ſyſtem, contemporary with king David. As the Phœnicians are not known to have been the inventors of any art or ſcience, though, by means of their extenſive commerce, they propagated the diſcoveries made by other nations, the moſt probable and natural account of the origin of alphabetical characters is, that they took riſe in Egypt, the firſt civilized kingdom of which we have any authentic accounts, and the great ſource of art and polity among the ancients. In that country, the favourite ſtudy of hieroglyphical characters had directed much attention to the art of writing. Their hieroglyphics are known to have been intermixed with abbreviated ſymbols, and arbitrary marks; whence, at laſt, they caught the idea of contriving marks, not for things merely, but for ſounds. Accordingly, Plato (in Phædro) expreſsly attributes the invention of letters to Theuth or Thoth, the Egyptian, who is ſuppoſed to have been the Hermes, or Mercury, of the Greeks. Cadmus himſelf, though he paſſed from Phœnicia to Greece, as ſeveral of the ancients have affirmed, was originally of Thebes in Egypt. Moſt probably Moſes carried with him the Egyptian letters into the land of Canaan; and there, being adopted by the Phœnicians who inhabited that part of the country, they were tranſmitted into Greece.

It is curious to obſerve, that the letters which we uſe at this day, can be traced back to the alphabet of Cadmus. The Roman alphabet, which obtains with us and moſt of the European nations, is plainly formed on the Greek, with a few variations. And all learned men obſerve, that the Greek characters, eſpecially according to the manner in which they are formed in the oldeſt inſcriptions, have a remarkable conformity with the Hebrew or Samaritan characters, which, it is agreed, are the ſame with the Phœnician, or the alphabet of Cadmus. If the Greek characters are inverted from left to right, according to the Phœnician and Hebrew manner of writing, they will appear to be nearly the ſame. Beſide the conformity of figure, the names or denominations of the letters, alpha, beta, gamma, &c. and the order in which they are arranged, in all the ſeveral alphabets, Phœnician, Hebrew, Greek, and Roman, agree ſo much, as to amount to a demonſtration that they were all originally derived from the ſame ſource. The letters were, at firſt, written from the right-hand to the left; and this manner of writing obtained among the Aſſyrians, Phœnicians, Arabians, and Hebrews: and from ſome very old inſcriptions, it appears to have obtained alſo among the Greeks. Afterwards the Greeks adopted the method of writing their lines alternately from the right to the left, and from the left to the right, called *bouſtrophedon*. At length, however, the motion from the left-hand to the right being found more natural and commodious, the practice of writing, in this direction, prevailed throughout all the countries of Europe. See more on this ſubject under ALPHABET, CHARACTERS, and LETTERS.

Writing was long a kind of engraving. Pillars, and tables of ſtone, were firſt employed, and afterwards, plates of the ſofter metals, ſuch as lead: but as writing became more common, lighter and more portable ſubſtances were employed. The leaves, and the bark of certain trees, were uſed in ſome countries; and in others, tablets of wood, covered with a thin coat of ſoft wax, on which the impreſſion was made with a ſtylus of iron. See BOOK, BARK, and STYLE.

In later times, the hides of animals, properly prepared and poliſhed into parchment, were the moſt common materials: our preſent method of writing on paper is an invention of no greater antiquity than the fourteenth century.

The advantages of writing above SPEECH (which ſee) are, that writing is both a more extenſive and a more permanent method of communication: nevertheleſs, ſpoken language has a great ſuperiority over written language, in point of energy or force. See Warburton, *ubi ſupra*. Blair's Lectures on Rhetoric, &c. vol. i. lect. 7.

An

An ingenious and learned writer has lately difcuffed the fubject of this article in a very elaborate manner. He obferves, that there is a difference, deferving particular attention in the inquiry, concerning the origin and progrefs of writing, between the imitative characters and fymbolic or arbitrary marks. The former derive their origin from that imitative faculty, which is fo confpicuous in the human fpecies; the latter are founded in neceffity or convenience, and become fignificant by compact: the one comprehends fymbols and marks for founds, fignificant of ideas; and the other have an immediate reference to fenfible objects which prefent themfelves to fight, and are applicable to hieroglyphical reprefentations. Accordingly all reprefentations, marks, or characters, which were ever ufed by any nation or people, muft have been either imitative or fymbolic.

This writer controverts the opinion of M. Fourmont, bifhop Warburton, and M. Gebelin, who have endeavoured to fhew, that alphabets were originally formed of hieroglyphical characters; alleging that the letters of an alphabet were effentially different from the characteriftic marks deduced from hieroglyphics, which are marks for things and ideas, like the ancient and modern characters of the Chinefe; whereas the former are only marks for founds; and that, though there be a fufficient refemblance between the Mexican picture-writing, the Egyptian hieroglyphics, and the Chinefe characters, yet thefe are foreign to alphabetic letters, and, in reality, do not bear the leaft relation to them. The hieroglyphic characters of the Chinefe are, it is faid, in their nature imitative, and do not combine into words, like arbitrary marks for founds or letters, which are very few, and of a fymbolic nature.

Letters, it is maintained, do not derive their powers from their forms, but originally their forms entirely depended on the fancy or will of thofe who made them.

Many learned men have fuppofed, that the alphabet was of divine origin; and feveral writers have afferted, that letters were firft communicated to Mofes by God himfelf; whilft others have contended, that the Decalogue was the firft alphabetic writing. But if this art had been a new difcovery in the time of Mofes, he would probably have commemorated it; nor is there any reafon to fuppofe, that God was the immediate revealer of the art, for Mofes could never have omitted to have recorded the hiftory of fo important a circumftance, as the memory of it would have been one of the ftrongeft barriers againft idolatry.

It appears, however, that the art of writing is of great antiquity, and that the ancients, who afcribed the invention of it to the gods, had very imperfect ideas of its true origin. When it is confidered that letters muft have been the produce of a certain degree of civilization among mankind, the inquirers into their original have been naturally led to feek it in the hiftory of thofe nations that appear to have been firft civilized. Accordingly, many authors have decided in favour of the Egyptians. See Letters.

Others have vindicated the claim of the Phœnicians to the invention of letters; urging the teftimony of Sanconiatho, the moft ancient and alfo the moft celebrated Phœnician hiftorian, corroborated by Pliny, Curtius, Lucan, Eufebius, &c. as well as their very early and high degree of civilization. The Chaldæans have alfo had feveral learned advocates, who have attributed the invention of letters to the patriarch Abraham: and fir Ifaac Newton, in particular, admits, that letters were known in the Abrahamic line for fome centuries before Mofes.

It is needlefs to mention the claims of the Tufcans, Indians, and Arabians. Mr. Aftle, *ubi infra*, declares in favour of the Phœnicians; and obferves, that as the Chaldæans, Syrians, Phœnicians, and Egyptians, all bordered upon each other, and as the Phœnicians were the greateft as well as the moft ancient commercial nation, it is very probable that they communicated letters to the Egyptians; the ports of Tyre and Sidon, and thofe of the Egyptians, being not far diftant from each other. This author adds, that before the time when Mizraim went into Egypt, in the year before Chrift 2188, and 160 years after the flood, Taaut, his fon, had invented letters in Phœnicia; and if this invention took place ten years before the migration of his father into Egypt, as Mr. Jackfon fuppofes, we can trace letters as far back as the year 2178 before Chrift, and 150 after the deluge recorded by Mofes: and beyond this period, the written annals of mankind, which have been hitherto tranfmitted to us, will not enable us to trace the knowledge of them, though this want of materials is no proof that letters were not known until a century and a half after the Deluge.

An opinion feems to be gaining credit among the learned, that arts and letters took their rife in the northern parts of Afia, and that they were cultivated in thofe parts, long before they were practifed in Phœnicia or Egypt. Some travelled fouthwards, others ftaid behind; and thofe who afterwards emigrated from the Eaft were generally called Scythians, and fometimes Huns, who overfpread the northern parts of Europe. Many fettlements were made in Germany long before the Chriftian era.

It has been afferted by many writers, that all alphabets are derived from one; but Mr. Aftle maintains, that there are various alphabets ufed in different parts of Afia, which differ from the Phœnician, ancient Hebrew, or Samaritan, in name, number, figure, order, and power. In feveral of thefe alphabets, there are marks for founds peculiar to the language of the Eaft, which are not neceffary to be employed in the notation of the languages of Europe.

The following alphabets, fays this learned writer, feem to be immediately derived from the Phœnician; *viz.* the ancient Hebrew, or Samaritan; the Chaldaic; the Baftulan, or that of the colony of Phœnicians or Canaanites, who are faid to have fled from Jofhua, and to have fettled themfelves, in the moft early ages, in that part of Spain now called Andalufia and Grenada; the Punic, Carthaginian, or Sicilian; the Pelafgian Greek, and its derivatives, which are written in the Eaftern manner, from right to left; and the Ionic Greek, written from left to right. This laft-mentioned branch from the Pelafgic ftock is the fource from whence not only moft of the alphabets of Europe are derived, but alfo of many others which have been adopted in different parts of Afia and Africa. From the Ionic Greek are derived the Arcadian, the Latin or Roman, the ancient Gaulifh, the ancient Spanifh, the ancient Gothic, the Coptic, the Ruffian, the Illyrian or Sclavonian, the Bulgarian, and the Armenian: the Runic is immediately derived from the Gothic.

The alphabets derived from the Roman are, the Lombardic, the Vifigothic, the Saxon, the Gallican, the Franco-Gallic or Merovingian, the German, the Caroline, the Capetian, and the Modern Gothic. The firft relates to the MSS. of Italy; the fecond, to thofe of Spain; the third, to the MSS. of Great Britain; the fourth and fifth, to thofe of France; the fixth, to Germany; the feventh, eighth, and ninth, to all the countries of Europe where Latin is read. The fix former alphabets are before the age of Charlemagne; the three latter follow it. The characters of thefe are more diftinguifhed by their names than by their forms, which indicate that they are all of Roman extraction. The Lombardic, introduced into Italy by the Lombards in 569, was ufed by the popes in their bulls, and fometimes called Roman in the eleventh century: it ceafed in the thirteenth century. The Vifigothic, or Spanifh Gothic, was introduced into Spain by the Goths or Vifigoths; it was abolifhed in a provincial fynod, held at Leon in 1091, when the Latin letters were eftablifhed for all public inftruments; though thefe characters were occafionally ufed in private tranfactions for upwards of three centuries afterwards. Saxon writing admits of various diftinctions, *viz.* the Anglo-Saxon, Britanno-Saxon, and Dano-Saxon. The Gauls, on being fubdued by the Romans, adopted their mode of writing; and by additions of their own, gave rife to the Gallican or Roman Gallic. The Franks, a people of Germany, having conquered part of Gaul, introduced their characters called Franco-Gallic, or Merovingian, becaufe this kind of writing was practifed under the kings of the Merovingian race. It took place about the clofe of the fixth century, and prevailed till the beginning of the ninth. The Caroline was derived from the improvement of Charlemagne; this declined in the twelfth century, and totally difappeared in the thirteenth, when it was fucceeded in Germany by the Modern Gothic. The Caroline writing was reftored by Hugh Capet about the year 987, and called Capetian: it was much practifed till about the middle of the twelfth century; but in the thirteenth it degenerated into the Modern Gothic. The Capetian writing was ufed in England and in Germany, as well as France, during the above-mentioned period. The Modern Gothic, which fpread itfelf over Europe in the twelfth and thirteenth centuries, is improperly fo called; becaufe it does not derive its origin from the writing anciently ufed by the Goths and Vifigoths in Italy and Spain, but it is the moft barbarous kind of writing: it took its rife in the decline of the arts among the lazy fchoolmen, who had the worft tafte; it is nothing more than the Latin writing degenerated. It began in the twelfth century, and was generally ufed (efpecially by monks and fchoolmen) in all parts of Europe, till the reftoration of the arts in the fifteenth century, and longer in Germany and the northern nations. Our ftatute-books are ftill printed in Gothic letters.

The learned are not agreed with refpect to the origin of what is called *national* writing. Some will have it, that the Roman manner prevailed throughout the Weft, until the irruption of the barbarous nations of the North, in the fifth and fixth centuries: the Goths, they fay, firft introduced their mode of writing into Italy, inftead of the Roman manner; the Vifigoths did the like in Spain; the Franks in Gaul; the Saxons in England; and the Lombards in Italy.

According to others, the Romans were in poffeffion of various forms of writing; but it is fuppofed, that the barbarous nations introduced fome of their own letters in the writings compofed of capitals and fmall letters; that the running-hand, peculiar to each nation, was ufed in grants and contracts, and found admittance likewife in manufcripts after the middle of the feventh century.

Mr. Aftle, however, is of opinion, that the different modes of writing in Italy, Spain, France, England, and Germany, were derived from the Roman alone.

While Rome continued the centre of all the provinces of the empire, her manner of writing generally prevailed in each; but the empire being difmembered, and all the weftern provinces difunited, a change was produced; the conquerors disfigured the Roman writing, and by their falfe tafte and ignorance, diftinguifhed their writing from that of their neighbours: the genius and difpofition of the different people having no fmall fhare in producing this diverfity.

This notion greatly affifts in difcovering the age of manufcripts; for if a writing is Merovingian, it cannot be fubfequent to the ninth, nor prior to the fifth century; if another is Lombardic, it muft be pofterior to the middle of the fixth, and anterior to the thirteenth; if Saxon, it cannot be earlier than the feventh, nor later than about the middle of the twelfth.

With regard to the forms of letters, many authors are of opinion that they are derived from the pofitions of the organs of fpeech in their pronunciation. Accordingly, M. Van Helmont hath taken great pains to prove, that the Chaldaic characters are the genuine alphabet of nature, becaufe, he fays, no letter can be rightly founded, without difpofing the organs of fpeech into an uniform pofition with the figure of each letter.

Mr. Nelme publifhed a work, in which he endeavours to fhew that all elementary characters or letters derive their form from the line and the circle. Mr. Gebelin deduces them from hieroglyphic reprefentations, and he hath given feveral delineations of human figures, trees, &c. in confirmation of his hypothefis. Mr. Aftle obferves, that as letters are only marks for founds, their forms entirely depended upon the tafte, fancy, will, or caprice, of thofe who firft formed them. In this point of view, they may be confidered as arbitrary marks, or fecret cyphers, which, by being made known and adopted, would become of general ufe, wherever they were received by agreement. For the number and forms of the letters of various alphabets, illuftrated by figures, we muft refer to Mr. Aftle's account, *ubi infra.*

After the moft diligent inquiry, it doth not appear, fays Mr. Aftle, that the Britons had the ufe of letters before their intercourfe with the Romans: and though, from the coming of Julius Cæfar till the time when the Romans left the ifland in the year 427, the Roman letters were familiar to the eyes of the inhabitants, he is of opinion, that writing was very little practifed by the Britons till after the coming of St. Auguftine, about the year 596.

The writing which prevailed in England from this time to the middle of the eleventh century, is generally termed Saxon, and may be divided into five kinds; *viz.* the Roman Saxon, which is very fimilar to the Roman, and prevailed in England from the coming of St. Auguftine till the eighth century; the fet Saxon, which took place toward the middle of the eighth century, continued till about the middle of the ninth, and was not entirely difufed till the beginning of the tenth century; the running-hand Saxon, which came into ufe towards the latter end of the ninth century, when learning was diffufed in England under the aufpices of king Alfred, in whofe reign many books were written in this ifland, in a more expeditious manner than formerly; the mixed Saxon, occurring in the ninth, tenth, and in the beginning of the eleventh centuries, in many MSS., which were written in England in characters partly Roman, partly Lombardic, and partly Saxon; and the elegant

elegant Saxon, which took place in England early in the tenth century, lafted till the Norman Conqueft, but was not entirely difufed till the middle of the twelfth, and is more beautiful than the writing in France, Italy, and Germany, during the fame period.

The writing introduced into England by William I. is ufually called Norman, and is compofed of letters nearly Lombardic, which were generally ufed in grants, charters, public inftruments, and law proceedings, with very little variation, from the Norman Conqueft till the reign of king Edward III.

About the reign of king Richard II. variations took place in writing records and law proceedings; the charters from the reign of king Richard II. to that of king Henry VIII. were compofed partly of characters called fet chancery and common chancery, and fome of the letters called court-hand; which three different fpecies of writing are derived partly from the Norman and partly from the modern Gothic. The modern Gothic began to take place in England in the twelfth century; the old Englifh about the middle of the fourteenth century; and fet chancery and common chancery in the decline of the fame century, and are ftill ufed in the enrolments of letters patent, charters, &c. and in exemplifications of recoveries: the court-hand was contrived by the Englifh lawyers, and took its rife about the middle of the fixteenth century, and continued till the beginning of the late reign, when it was abolifhed by law. The court-hand characters were nothing more than the Norman characters very much corrupted and deformed.

In the fixteenth century, the Englifh lawyers engroffed their conveyances and legal inftruments in characters called fecretary, which are ftill in ufe.

The French call their writing by the names of the different races of their kings, in whofe time they were written: thefe were, the Merovingian, the Carlovingian, the Capetian, the Valefian, and the Bourbonian.

The writing called Merovingian began in France foon after the time of Merovæus, fon of Pharamond; who was made king A.D. 460: this race ends with Childeric, who died in 752. The Caroline race properly began with Pepin, who was made king of France upon the death of Childeric. This prince was fucceeded by Charlemagne, A.D. 814, whofe line in France ended with Lewis V. A.D. 987. The Capetian race began with Hugh Capet, who fucceeded Lewis V., and ended with Charles IV. A.D. 1327. The Valefian race began with Philip IV. the fucceffor of Charles IV., and ended with Henry III. the laft of this line, who was flain in 1589. The Bourbonian line began with Henry IV. A.D. 1589, whofe defcendants now fill the throne of France.

The MSS. written in the northern parts of Scotland and in Ireland are in characters fimilar to the Saxon. The learned and ingenious colonel Vallancey thinks, indeed, that the Iberians, who migrated from the borders of the Euxine and Cafpian feas, and fettled in Spain, learned letters and arts from the Phœnicians: that a colony of the ancient Spaniards, by the name of Scots or Scythians, fettled in Ireland about a thoufand, or perhaps fix hundred years before Chrift, and that they brought elementary characters with them into Ireland. He obferves, that the Irifh alphabet differs from that of all other nations, in name, order, number, and power, and fuppofes, that they might have received their alphabet from the Carthaginians, who alfo fettled a colony in Ireland about fix hundred years before Chrift; and adds, that this opinion is the more to be credited, as the Irifh language appears to have a radical identity with the Punic.

In order to difcover what real pretenfions the Irifh have to the early ufe of letters, for which they eagerly contend, Mr. Aftle has examined their ftone monuments, their coins, and their MSS., and appealed to the hiftorians of that country. The letters upon the moft ancient of their monuments are apparently of Roman and Roman-Britifh original; and none of thefe infcribed monuments are fo ancient as to prove that the Irifh were poffeffed of letters before the Romans had intercourfe with the Britons; though they prove that they had letters before the arrival of St. Patrick in that kingdom, which, Mr. Whitaker, with great probability of truth, fays, were wafted over from the Caledonians, who ufed the Roman letters. Sir James Ware fays, that the Irifh alphabet was borrowed from the Britifh, and that the Saxon characters were nearly the fame as the Irifh; and adds, that Mr. Camden inclined to this opinion.

Moreover, there are no Irifh coins, infcribed with letters, till long after the twelfth century: except coins ftruck by fome of our Saxon kings, who made incurfions into that country, and ftruck money there in the Saxon manner.

The oldeft Irifh MS. which has been difcovered is the Pfalter of Cafhel, written in the latter end of the tenth century.

The teftimony of approved hiftorians is likewife unfavourable to the ancient literature of Ireland. Mr. Innes, in his Effay on the Antiquities of Scotland and Ireland, and Mr. James Macpherfon, in the third edition of his Introduction to the Hiftory of Great Britain and Ireland, maintain, that Ireland was firft peopled from Britain; and that the manners of the old Irifh were inconfiftent with the knowledge of letters.

It feems probable, that the interior parts of Europe were immediately peopled from the northern parts of Afia, and the maritime parts from Phœnicia, and the fouthern and weftern parts of that quarter of the globe. If this be the cafe, it is not furprifing that fome Eaftern cuftoms prevailed in Great Britain and Ireland, and that many Celtic words are ftill preferved both in the Irifh and in the Welfh languages.

The Norman characters, it is obferved, were generally ufed in England from the coming of William I., and the Saxon characters were entirely difufed in the very beginning of the twelfth century; but the Irifh and Scots preferved the ancient forms of their characters till the end of the fixteenth century.

The Gaëlic or Erfe language, ufed in the Highlands of Scotland, and the Iberno-Gaëlic, are nearly the fame, and their letters are fimilar to each other, as Mr. Aftle has fhewn by various fpecimens. The curious will find much information on the fubject of this article in Aftle's Origin and Progrefs of Writing, 4to. 1784.

J. Ravenau has a treatife, intitled "Des Infcriptions en Faux," in which he fhews how to revive and reftore old writings almoft effaced, by means of galls ground in white wine and diftilled, and thus rubbed over the writings.

To write without blacking the fingers: prepare the paper with a fine powder, made of three parts of calcined copperas, two of galls, and one of gum arabic; thofe being frefh mixed, rub them with a hare's foot into the pores of the paper, and then write with fair water, and the black letters will immediately appear.

To make new writing appear old, moiften it with oil of tartar *per deliquium*, more or lefs diluted with water, as you defire the ink to appear more or lefs decayed.

We may write without ink or its materials; for this purpofe, take a fine powder of calcined hartfhorn, of clean tobacco-pipes, or rather of mutton-bones burnt to a perfect white-

whitenefs, and rub it upon the paper, and then write with a filver bodkin, or the like. Boyle's Works abr. vol. i. p. 114, 115. See INK.

The difcharging of ink out of parchment, paper, &c. is commonly done by aqua fortis diluted fufficiently with water, that it may not deftroy the paper. The like may be done with oil, or fpirit of vitriol diluted. The juice of lemons, or ftrong vinegar, will take ink out of linen more fafely, as the mineral acids are apt to deftroy the linen, unlefs great care be ufed in diluting them.

We may write on iron with corrofive fublimate wetted with common water: for this purpofe, the parts of metal we would preferve untouched fhould be covered with wax, and that taken off in the proper places to make way for the corroding fubftance. Boyle, ib. p. 528.

The like may be practifed by means of aqua fortis.

Mr. Boyle mentions a method he had of copying a whole page of writing at once. But we do not find his defcription of it any where. Ib. p. 136.

A machine has been lately invented and conftructed by Meffrs. Watt and Co. of Birmingham; by means of which letters and other writings may be copied. For an account of the ftructure and ufe of this machine, we muft refer to the directions for copying with it, furnifhed by the inventors; obferving, however, that the date, at which a writing will yield a copy, is extremely uncertain, from the weather, as it is more or lefs drying, and from the ftate of the ink. In general the purpofe will be anfwered to the end of twenty-four hours, and fometimes of three or four days; but it is moft advifeable to copy letters as foon after they are written as may prove convenient. See COPYING.

Mr. Boyle informs us of a method of imitating writing on copper-plates. The copy to be engraved is to be wrote with a peculiar kind of ink, and the copper-plate being moderately warmed is rubbed over with a white varnifh, and fuffered to cool; then the paper being gently moiftened, that it may readily communicate its ink, the writing is applied to the prepared furface of the plate, and paffed through a rolling-prefs; by which means, the ink adhering to the varnifh leaves the letters very confpicuous. And hence it is eafy with a needle to trace the ftrokes through the varnifh upon the plate, which being afterwards cleaned, the letters are finifhed with the graver, and the work printed off in a rolling-prefs, as common cuts.

Mr. Boyle does not mention what the varnifh or ink, ufed by the artificer from whom he received this method, was; but he tells us, that he himfelf ufed the purer fort of virgin wax for a varnifh; and for his ink he took fine Frankfort black, carefully ground with water, till it obtained the confiftence of common ink; but no gum was added, left it fhould hinder the ink from coming off. He alfo obferves, that written characters may be taken off without the help of a prefs, by laying the moiftened paper fmooth upon the varnifhed copper, and rubbing it on hard with a convex piece of glafs. See *Sympathetic* INK.

In law, we fay, deeds, conveyances, &c. are to be in writing. A will may either be in writing, or by word of mouth.

We alfo fay, *written law*, *lex fcripta*, in oppofition to common law, which is called *lex non fcripta*. We have alfo *written* and *unwritten traditions*, &c.

Authentic writings of any contract, fealed and delivered, make the evidences thereof.

La Vayer has a curious differtation on the proof of facts by comparifon of hand-writings, in which he endeavours to fhew this method of proof to be very fufpicious and fallacious.

WRITZEN, in *Geography*, a town of the Middle Mark of Brandenburg, on a branch of the Oder; 18 miles N.W. of Cuftrin.

WRONG, in a *Logical Senfe*. See ERROR, FALSEHOOD, and TRUTH.

WRONG, in a *Legal Senfe*, *injury*, *tort*. See INJURY, and TORT.

Wrongs are divifible into two forts, *viz*. *private* and *public*. The former are an infringement or privation of the private or civil rights belonging to individuals, confidered as fuch; and are frequently termed *civil injuries*. The latter are a breach and violation of public rights and duties, which affect the whole community, confidered as fuch; and are diftinguifhed by the harfher appellation of *crimes* and *mifdemeanours*.

WRONG, *Executor of his own*. See EXECUTOR *de fon Tort*.

WRONG-*Lands*, in our *Old Writers*, feem to denote trees that will never prove timber; fuch as wrong the ground they grow in.

WRONGS, in *Agriculture*, a term applied to the crooked arms or large boughs of trees, when the fagot-wood is cut off from them.

WROTHAM, in *Geography*, a market-town in the upper half hundred of the fame name, in the lathe of Aylesford, and county of Kent, England, is fituated near the bafe of fome chalk-hills, at the diftance of 10 miles W.N.W. from Maidftone, and 24 miles S.E. by E. from London. The manor was granted by king Ethelftan, in the year 964, to the priory of Chrift-church, Canterbury. On the divifion of the poffeffions of the monks by Lanfranc, it was allotted to the archbifhops of Canterbury, who had a palace and frequently refided here, till the time of archbifhop Iflip, who pulled down the buildings for the fake of the materials, which he applied to the completion of the palace at Maidftone, which his predeceffor, John Ufford, had begun. Archbifhop Cranmer refigned the manor to Henry VIII., and it was granted by Edward VI. to fir John Mafon, who difpofed of it to the Byngs, anceftors of the lords Torrington, of whom it was purchafed by William James, efq. of Ightham, whofe defcendants ftill poffefs it. Wrotham church, the only public edifice in the town, is a fpacious well-built ftructure, and confifts of a nave, aifles, chancel, and tranfept, with an embattled tower at the weft end; the chancel is light and elegant. The fepulchral memorials are numerous; among which are feveral curious braffes, recording the family of Peckham, who were refident in this parifh during feveral centuries. The Rayner family, who refided at Wrotham-Place the whole of the 17th century, have alfo monuments here. The rectory is efteemed one of the beft livings in Kent. Of the ancient archiepifcopal palace little now remains but a gateway, and a fubftantial ftone building which formed part of the offices. The population return of the year 1811 ftates the town to contain 107 houfes, and 613 inhabitants. Here is an annual fair, and a weekly market on Tuefday. The parifh is very extenfive, comprehending the villages of Hale, Nepicar, Plaxted, Winfield, and Roughway. In a park within the limits of the parifh is a capital manfion, once the feat of fir Harry

Harry Vane, who on the reftoration of Charles II. fuffered death for the part he took againft Charles I. This eftate, on the death of lord vifcount Vane in 1789, became the property of David Papillion, efq.: it is now occupied by the earl of Delawar.—Beauties of England and Wales, vol. viii. Kent, by E. W. Brayley, 1807.

WROTZKO, a town of Pruffia, in the palatinate of Culm; 12 miles S.W. of Strafburg.

WROUGHT, in *Ship-Building*, a term applied to any piece of timber, &c. when it is trimmed and fitted for its fituation.

WROXETER, in *Geography*, a village of England, in the county of Salop, at the union of the Torn and the Severn, by Antoninus called "Uriconium," by Ptolemy "Viriconium," by the Welfh and Britons "Caer Vruach," and by the Saxons "Wrekenceafter." It was the chief city of the Cornavii, and founded by the Romans, when they fortified the bank of the Severn where fordable. It was encompaffed by a rampart and ditch; the walls were three yards thick, and were three miles in circumference. After fuffering much in the Saxon wars, it was quite ruined by the Danifh, and is now but a fmall place. Many Roman coins and other antiquities have been found here; 5 miles S.E. of Shrewfbury, and 155 N.W. of London.

WRUNG-HEADS, a former name given to the bilge of a fhip, &c. or that part near the floor-heads, which, when a fhip lies aground, bears the greateft ftrain.

WRY-NECK, (*Caput obftipum, cervix obftipa, torticollis,*) denotes that deformity of the human body, in which the neck is bent laterally, generally inclining at the fame time fomewhat forwards, fo that the head is alfo drawn to one fide and forwards, being indeed frequently quite approximated to the fhoulder. For the moft part, the neck is in this cafe altogether irregularly formed: on the fide towards which the head inclines, it feems exceedingly plump, the ftrong fhortened mufcles being bulky, and affected with confiderable fpafm; while, on the other hand, the oppofite fide, where the neck is convex, exhibits no fuch ftrong rigid mufcles, or at all events fo little of this appearance, that, notwithftanding its convex form, it feems obvioufly lefs flefhy. When the difeafe has continued a long while, and attained a ferious degree, its effects extend alfo to the head itfelf. On that fide where the irregular action of the mufcles is ftrongeft, and where confequently the head is moft drawn downwards, the half of the face is ufually more or lefs contracted, and weaker than the oppofite half, the zygomaticus major, the buccinator, the maffeter, and other mufcles, being confiderably lefs prominent. This disfigurement of the countenance has a very unpleafant appearance, and plainly indicates the diftorted pofition into which the head is drawn. The patients are alfo incapable of turning their heads properly, or of directing their faces upwards; and if thefe functions can be executed in a very imperfect way, it is not without a good deal of effort, which in general the patients prefer avoiding. Hence they moftly choofe to remain in their diftorted pofture, and inftead of trying to turn their heads with the mufcles of the neck alone, they prefer accomplifhing this object rather by turning the whole body. Hence an opportunity is given for the evil to increafe in a very rapid and afflicting degree. According to the obfervations of Richter and Bernftein, the face is commonly turned towards the oppofite fide, and only now and then towards that to which the head inclines. (Anfangfgr. der Wundarzneykunft 4ter. Band, 2te. Auflage, f. 256. Practifchen Handbuche für Wundärzte, &c. Neue Auflage, 3ter. Theil, f. 215.) Profeffor Jörg of Leipfic does not exactly coincide with thefe furgeons on this particular point; but we think that the difference is merely in terms, and not in the thing itfelf, Richter meaning that the face is *turned* towards the found fide, not that it is *drawn away*, and *made more diftant* from the fhoulder to which the whole neck and head incline. Profeffor Jörg takes a review of the action and infertions of the fterno-cleido-maftoideus mufcle, which proceeds down the neck from the maftoid procefs, and fplits into two portions; one of which is inferted into the external and anterior part of the clavicle, the other into the upper and outer furface of the fternum. The clavicular portion of this mufcle muft neceffarily tend to draw the head towards the clavicle, which is the fixed point, while the fternal portion will pull it towards the breaft; but both acting together, will draw it in a diagonal line. At the fame time that they have the effect of inclining the head forwards and to one fide, they impart to the neck the fame direction, and even flightly turn it, fo that the nofe is no longer fituated in a ftraight line directly over the fternum, but is placed to one fide of fuch a line. When, for example, fays profeffor Jörg, the right fterno-cleido-maftoideus is too fhort, and is therefore the caufe of the wry-neck, it will pull the head towards the right fide, and alfo forwards, in fuch a manner that the nofe is moved to the left of a line drawn upwards from the fternum, and the neck itfelf is at the fame time flightly turned. But when this is the cafe, the whole face muft obvioufly be fomewhat turned towards the left fide, and drawn a little way downwards and forwards. When, however, the whole head is drawn forwards, laterally, (in this cafe to the right,) and at the fame time downwards, confequently the face forwards, laterally, (in this cafe to the left,) and downwards, it cannot be faid that the face is moved in a different direction from that of the reft of the head. Although the face is turned in a different direction, ftill it is not inclined towards the oppofite fide; for, fays profeffor Jörg, if this were fo, the neck muft be much more turned than actually happens. Hence, he thinks, that a cafe has really never exifted, where the face and head have been inclined in different directions.

With refpect to the caufes of this infirmity, they are, according to feveral writers, very numerous, and it is not to be denied that they may be of different kinds. Yet, fays Jörg, "I have never feen the complaint originate in the bones: the mufcles were always the parts firft concerned. According to my obfervations, the fterno-cleido-maftoideus muft be looked upon as being the chief original caufe of this deformity, which I have never feen unattended with the particular and manifeft influence of that mufcle. When alfo feveral other mufcles gradually participate in the diforder, the fterno-cleido-maftoideus is ufually the firft affected. While it is more difpofed to an irregular action than any other mufcle of the neck, its greater ftrength makes it in fome meafure govern the reft." As children, both in the erect and horizontal poftures, frequently keep their necks unevenly, and more to one fide than the other, profeffor Jörg conceives that this will account for one fterno-cleido-maftoideus readily becoming fhorter than its fellow; the equilibrium ceafes, and a wry-neck is immediately produced. Young children often contract a habit of lying in bed conftantly upon the fame fide, whereby the mufcles of the neck become gradually habituated to an irregular kind of tenfion, which by degrees breaks the antagonizing power between the oppofite fets of mufcles. The fame thing happens, when children are conftantly carried with their head upon one and the fame fide of their nurfe. But this irregularity in the mufcles in queftion is alfo fre-

 quently

quently congenital, and then we need not ſpecify any occaſional cauſes. The evil, though it exiſts at the time of birth only in a trivial degree, afterwards quickly increaſes, and ſoon becomes ſerious. The regular equilibrium between the ſterno-cleido-maſtoidei may likewiſe be deſtroyed, when one of them is wounded, or completely cut through; when it remains preternaturally weak, in conſequence of having been the ſeat of abſceſſes, and previous ulceration; or when, from any cauſe whatſoever, its action is rendered either too feeble or too powerful.

In one patient cured by profeſſor Jörg, it is alleged that the inner portion of the left ſterno-cleido-maſtoideus was inſerted into the middle and right ſide of the ſternum, in the ſame place as the inner portion of the muſcle of this name on the right; and the above author conceived, that this preternatural attachment was probably the cauſe of the inclination of the head to the right ſide.

Profeſſor Jörg does not give much credit to the opinion, that the wry-neck is frequently brought on by a contraction of the ſkin of the neck and of the platyſma myoides; the firſt of theſe parts being very yielding, and the ſecond very thin and elaſtic. But, he thinks, that when theſe parts, or any other muſcles of the neck, are ſhortened and ſpaſmodically contracted, it is generally as a conſequence of the affection of the ſterno-cleido-maſtoideus, which is the part originally diſordered.

The ſame writer will not deny alſo, that the malformation of the bones may be the firſt cauſe of this infirmity. If, ſays he, the dorſal and lumbar vertebræ are liable to curvature, why ſhould the cervical ones not be ſo, and thereby deſtroy the equilibrium between the muſcles of the neck? Yet, he thinks, the cauſe of the diſorder muſt lie much more rarely in the bones than the muſcles, ſince he has never ſeen one inſtance of it. He admits alſo, that there can be no doubt that the bones ſooner or later ſhare in the effects of the diſeaſe; that they become bent to one ſide, and even cemented together by anchyloſis.

As in every other diſorder, the practitioner muſt endeavour to find out the original cauſe of the complaint; and, therefore, the queſtion ariſes, how can it be known whether the muſcles and the integuments, or the bones, are the firſt cauſe of the deformity? The cauſe may be aſcribed to the muſcles, when there is obviouſly ſomething wrong about them; when they are hard and contracted on one ſide, and ſoft and little prominent on the other; and when thoſe which are ſhrunk and ſhortened become ſtill harder and more painful, on putting the head in a ſtraight poſition, to the doing of which they alſo make more or leſs reſiſtance. We may be more certain of the thing, when no diſeaſe of the bones in any part of the body, and no cauſes of ſuch complaint, can be detected; for when the bones are about to ſoften, or are already ſoftened, the latter affection muſt be preceded by certain occaſional cauſes, and accompanied with the uſual ſymptoms. The diſcovery of theſe, according to profeſſor Jörg, is not difficult to the practitioner, at leaſt not impoſſible. The diſorder, on the other hand, may be referred to the bones, when no particular defect about the muſcles is apparent, when they are no where remarkably hard and contracted, and when the caſe is attended with ſymptoms and veſtiges of a partial or general ſoftening of the bones. When this is the caſe, the muſcles are uſually much leſs altered than when they conſtitute the original cauſe of the deformity; and the head can be more eaſily raiſed, turned, and moved about.

Another queſtion is, what degree has the diſorder already attained, and have the bones materially participated in the affection or not? Perhaps the cervical vertebræ are anchyloſed? Although it may at firſt ſeem eaſy to anſwer theſe queſtions, yet it is not always ſo eaſy. The prognoſis and treatment, however, are to be regulated by the deciſion; and we can never ſpeak ſatisfactorily of the caſe, unleſs we have inquired into the whole of its progreſs.

When the bones are affected, that is to ſay, when in conſequence of the wrong poſture of the neck a change has taken place in their form; when they, as is moſt uſual, on the ſide towards which the head is inclined, are lower than on the other; or when their proceſſes are diminiſhed or abſorbed; the practitioner can frequently feel and ſee that the defect lies in the texture of the bones. The depreſſions thus produced may ſometimes be plainly ſeen, or, at all events, can be felt with the finger. When the head and neck are put into the right poſition, theſe depreſſions become ſtill more obvious, as well as the alteration of the ſpinous proceſſes. In order to derive from ſuch examination any preciſe knowledge, we muſt indeed be well acquainted with the anatomy of the neck. Profeſſor Jörg then gives us ſome directions how to move the head and neck, and how to place our fingers in trying to aſcertain whether the cervical vertebræ are anchyloſed. We paſs theſe over, becauſe we place very little confidence in their accuracy or utility.

The profeſſor next notices the influence which the deformity has over the whole organization of the body. An imperfection in the formation of the head is the firſt and principal effect derived from the infirmity. In caſes of wry-neck, he has never ſeen the face and head altogether well conſtructed. The half of the face which was neareſt to the contracted ſterno-cleido-maſtoideus was always ſmaller, and leſs prominent, than the other. Frequently the lower jaw, the zygoma, and the eye, were more ſunk on this ſide than the other, and hence the countenance preſented a very diſtorted emaciated appearance. The foregoing author has alſo conſtantly found the raiſing of the head, and other motions of this part, materially prevented. The patients always ſtoop to one ſide in a moſt awkward kind of poſture. None of them can turn their heads well. Whenever they want to look laterally, they are obliged to turn their whole bodies. Hence many of them become diſqualified for certain occupations, and even if they are capable of work, they labour with more difficulty than other perſons. The preternatural dragging downward of the head, and the curvature of the cervical vertebræ, one would think (ſays profeſſor Jörg) would have a bad effect on the functions of the brain and ſpinal marrow. He has, however, never ſeen this happen; but on the contrary, in the worſt forms of the complaint, he has not found the brain at all affected. Still he does not venture to conclude that things are always ſo. Our limits oblige us to paſs over ſome other remarks on the preceding topic, in order to begin the conſideration of the method of treatment.

We find then that the wry-neck moſtly ariſes from an affection of the muſcles, and eſpecially from irregular action in the ſterno-cleido-maſtoidei, the equilibrium between which is deſtroyed: hence the treatment is generally directed againſt the muſcles, particularly thoſe above-mentioned. It is ſeldom that it is neceſſary to do any thing for the bones. For this reaſon, the prognoſis is generally favourable, and this the more ſo the younger the patient is, and the more yielding the contracted ſterno-cleido-maſtoideus happens to be found. Indeed, when the patient is farther advanced in life, and not more than twenty-five or thirty years of age, we ſhould not totally deſpair of being able to render aſſiſtance, if no anchyloſis exiſt, and not too much deformity of the cervical vertebræ. What kind of a prognoſis nofis can be made, when the bones are originally concerned in the production of a wry-neck, muft depend upon the nature and degree of the morbid affection of thofe parts.

In the treatment of a wry-neck, we muft endeavour to foften and relax the contracted mufcles, and ftrengthen thofe which are ftretched and tenfe. The firft indication, Jörg thinks, may be fulfilled by the ufe of oily emollient liniments two or three times a day; the fecond by the employment of fpirituous ftimulating embrocations. When common applications of the laft kind are unavailing, we are advifed to ufe fpirit of ammonia, tincture of cantharides, &c. It is alfo neceffary to perfevere for a long time in thefe remedies, even though the fkin may become red and tender. Jörg is an advocate likewife for applying compreffes to the parts dipped in fuch ftimulating fluids, and kept conftantly wet with them. Thus he calculates on maintaining the effects of their operation without interruption.

If the complaint be confiderable in degree, and the head and neck much diftorted, we are advifed to combine with the foregoing means what are termed *manipulations*, which confift in manual endeavours to obtain an elongation of the contracted mufcles, efpecially the fterno-cleido-maftoideus. In thefe manœuvres, we are directed to rub with one hand the mufcle upwards, and at the fame time to try to move the head in the fame direction. With the other hand we are to bring the head into its natural pofition, and keep it there, fo that the contracted mufcles may be extended as much as poffible. The greater their fpafmodic contraction is, the more muft we rub them in the direction above fpecified, even as long as a quarter or half an hour at a time; and the plan muft be repeated once, twice, or thrice a day, until the head will remain quite ftraight, or until that fide of the neck, which was previoufly convex, has become concave, and *vice verfâ*. Befides thefe *manipulations*, the head and face fhould be moved together into a perfectly upright pofture, laterally, and efpecially towards the fide to which they could not be turned, owing to the contracted ftate of the mufcles. By thefe means, the patient will foon acquire the faculty of moving the neck to one fide, which muft always be a defideratum in the treatment.

Profeffor Jörg fays, he has not deemed it neceffary to mention electricity and galvanifm as remedies, which may be joined with thofe above recommended. Whoever likes to try them, however, fhould only apply them to thofe mufcles which are in a ftate of tenfion; for every ftimulus muft be improper for fuch as are contracted.

This author does not fay much in favour of the warm bath as a remedy for wry-necks, in which cafes he owns he has never made trial of it. All his patients have been children from one to nine years of age; and he thinks it would have been difficult, and even dangerous in fome circumftances, to have immerfed them fufficiently in the warm water to cover their necks. Thefe are the only reafons which he gives for not having tried fo important a remedy for the wry-neck as the warm bath.

One of the principal means for the cure of a wry-neck confifts in a mechanical apparatus, by which the head is brought into a ftraight pofition, the contracted mufcles are elongated, and others, which are on the ftretch, kept in a ftate of reft and relaxation. It may be faid, indeed, that the patient fhould be able to put his head and neck in this pofture himfelf, and that no mechanical apparatus is requifite. But fuch pofture can only be adopted by making a great effort, and even then imperfectly. Hence the beft inclined patients foon give up the attempt, and the head becomes depreffed again. For children who cannot be perfuaded to obferve regularly the defirable pofition, the apparatus is more effential than for many adults. Several other writers had entertained this opinion previoufly to profeffor Jörg. Köhlers, Bernftein, and other authors, recommend a variety of mechanical contrivances for the cure of the wry-neck. None of thefe, however, have anfwered the expectations of profeffor Jörg, who has felt himfelf called upon to make an invention of his own. In the conftruction of his machine, he went upon the following principles: 1. That its operation fhould be effected by means of a fpring. 2. That the action of the ftretched enfeebled fterno-cleido-maftoideus fhould be ftrengthened, and the equilibrium between it and its fellow thereby re-eftablifhed.

The apparatus confifts of a leather pair of ftays, and of a band or fillet which goes round the head. On the centre of the fore-part of the ftays is a kind of pulley, or wheel, which admits of being turned to the right or left, and then becomes fixed by means of a fpring. From this apparatus a band proceeds up the patient's neck to the fillet, placed round the head, and to which it is faftened directly behind the ear, clofe to the maftoid procefs. This band lies in the fame direction as the lengthened fterno-cleido-maftoideus mufcle, and when drawn towards the breaft by the wheel, it produces the fame effect as would arife from an increafe of ftrength in the action of that mufcle. In fhort, it pulls the maftoid procefs downwards and forwards towards the fternum, counteracts the influence of the oppofite mufcle of the fame name, and thus rectifies the pofition of the head.

But this band, fays profeffor Jörg, does not merely draw down the fide of the head which is too elevated, it alfo tends to put the neck in a ftraight pofition. It was above explained, that a wry-neck is always more or lefs twifted, in confequence of the contraction of one of the fterno-cleido-maftoidei, and thus the mouth does not lie in a direct line perpendicularly above the centre of the fternum, but to one fide of this point. The action of the preceding band, by drawing forwards as well as downwards towards the middle of the breaft, the maftoid procefs evidently tends to counteract the effect produced by the wrong action of the faulty mufcle of the oppofite fide.

Profeffor Jörg makes his patients wear the apparatus day and night, and he does not even take it off when the frictions are made. The band is to be tightened and regulated according to the effects produced. Particular care, however, muft be taken not to make it too tight at firft.

When by perfeverance in the ufe of this apparatus, and the other means above recommended, the neck has been put into a proper pofition again, it ufually happens that the head itfelf continues inclined too much forward; an effect which the contracted fterno-cleido-maftoideus, and its antagonift the band, both tend to promote. Something, therefore, muft be done for the alleviation of this deformity. With this view, Jörg removes the above band from the breaft, carries it under the arm, and through a ring at the fide of the leather ftays or corfets, and thence to the fillet round the head, where it is faftened in the fame place as before. In this manner, the head will be confiderably elevated, while ftill the object of counteracting the fhortened fterno-cleido-maftoideus of the oppofite fide is not neglected. The ring hinders the band from hurting the axilla, and keeps it from following the motions of the fhoulder. The preceding author lets his patients, towards the latter part of the treatment, wear the apparatus in this way a long while; yet fometimes he applies it in both modes alternately, with

a defign

a defign of habituating the mufcles of the head and neck to different poftures.

Together with this treatment, profeffor Jörg enjoins attention to every thing which tends to improve the health, efpecially a proper nourifhing diet, pure air, &c. One thing he infifts upon as effential, *viz.* that during work or repofe, fleeping or awake, the patient conftantly keep the head and neck in the right pofition. Hence children muft be moft vigilantly obferved, as they foon forget what is told them; and the pofture in which they lie when afleep muft be attended to, as it is frequently a bad one. Jörg recommends laying their heads on firm round bolfters filled with horfe-hair, and placeing them on the fide on which the mufcles are contracted. The bed fhould be flat, and not fink, in order that the fhoulder may not be depreffed. In this pofition, the head will be preffed and inclined towards the oppofite fide. The patients muft alfo be forbidden to do any kind of labour which will oblige them to hold their heads in a hurtful pofition; but Jörg rather commends dancing and the military exercife, as accuftoming the patient to hold his head as he ought to do.

When the bones are concerned, the above apparatus and treatment will not be effectual; and particular machinery adapted to the cafe muft be employed.

Frequently the curative means are prematurely difcontinued, and the diforder recurs. It is commonly imagined, that when the head and neck can be brought ftraight, every thing is accomplifhed. But, as Jörg remarks, it is wrong to confider this period the completion of the cure; for, when the head and neck can be kept every day feveral hours in a right pofture, without any machinery, the convalefcents foon become fatigued, as it cannot be at firft done without exertion. It is only when both fterno-cleido-maftoidei feem to be formed alike; when one is not tenfer than the other; and when, confequently, the equilibrium betwixt them is re-eftablifhed; when alfo one fide of the neck is as prominent and well-formed as the other; and when the head can be brought into the right pofition naturally, and without any effort; that the cure ought to be regarded as accomplifhed. The machinery may now be gradually relinquifhed with fafety. At firft it is to be taken off for an hour at a time every day, and the period of its difcontinuance is to be lengthened by degrees, until at length it is entirely laid afide. For the foregoing excellent obfervations we are indebted to profeffor Jörg of Leipfic, whofe publication on the deformities of the human body is entitled in German "Ueber die Verkrümmungen des Menfchlichen Körpers und eine rationelle und fichere Heilart derfelben." Leipfic, 1816, 4to.

This author has not mentioned or given any opinion refpecting the plan which was propofed by Mr. Sharp, of dividing and even cutting out a portion of the fterno-cleido-maftoideus mufcle, which appears to act with too much power.

Mr. Gooch cured a patient by merely dividing the fkin and platyfma myoides mufcle; a kind of cafe which Jörg thinks unfrequent. Mr. Gooch alfo fometimes employed machinery with fuccefs.

Wry-neck, a difeafe of the fpafmodic kind in fheep, in which the head is drawn forcibly to one fide, and the animal difabled from walking. The cure is to be effected by the ufe of calomel with opium in pretty full dofes; putting the animal into a dry well-graffed pafture during the time, and avoiding cold and moifture.

Wry-neck, *Jynx*, in *Ornithology*, a bird called alfo the *torquilla*, which Linnæus has made a diftinct genus of the *picæ*, under the denomination of *yunx:* the characters of which are, that the bill is flender, round, and pointed; the noftrils are concave and naked; the tongue is very long, very flender, cylindric, and terminated by a hard point; and the feet are formed for climbing.

There is only one fpecies, *viz.* the *jynx torquilla*. The colours of this bird are elegantly pencilled, though its plumage is marked with the plaineft kinds: a lift of black and ferruginous ftrokes divides the top of the head and back; the fides of the head and neck are afh-coloured, beautifully traverfed with fine lines of black and reddifh-brown; the quill-feathers are dufky, but each web is marked with ruft-coloured fpots; the chin and breaft are of a light yellowifh-brown, adorned with fharp-pointed bars of black; the tail confifts of ten feathers, broad at their ends and weak, of a pale afh-colour, powdered with black and red, and marked with four equidiftant bars of black: the irides are of a yellowifh colour.

The wry-neck, Mr. Pennant apprehends, is a bird of paffage, appearing with us in the fpring before the cuckow. Its note is like that of the keftril, a quick-repeated fqueak: its eggs are white, with a very thin fhell; this bird builds in the hollows of trees, making its neft of dry grafs. It has a very whimfical way of turning and twifting its neck about, and bringing its head over its fhoulders, whence it had its name *torquilla*, and its Englifh one of wry-neck: it has alfo the faculty of erecting the feathers of the head like thofe of the jay. It feeds on ants, which it very dexteroufly transfixes with the bony and fharp end of its tongue, and then draws them into its mouth. Ray and Pennant.

WRYNOSE, in *Geography*, a mountain of England, on which are three ftones, marking the boundaries of the three counties of Lancafter, Cumberland, and Weftmoreland; 12 miles S. of Ravenglafs.

WSCHESTAD, a town of Bohemia, in the circle of Kaurzim; 10 miles N.W. of Kofteletz.

WSETIN, a town of Moravia, in the circle of Hradifch; 23 miles N.E. of Hradifch.

WUIPENS. See Wippingen.

WULDA, a town of Bohemia, in the circle of Bechin; 12 miles S.W. of Crumau.

WULFEN, a town of Weftphalia, in the bifhopric of Ofnabruck; 8 miles E.N.E. of Ofnabruck.

WULFENIA, in *Botany*, was fo named by profeffor Jacquin, in honour of his highly deferving friend, and conftant botanical correfpondent, the Rev. Francis Xavier von Wulfen, profeffor of natural philofophy and mathematics at Klagenfurt, in Carniola, to which charge he was appointed in 1762, and where he died March 17, 1806, aged feventy-eight. Amid the duties of his profefforfhip, and the more ferious calls of his ecclefiaftical ftation, which he fulfilled by the moft exemplary and active benevolence and charity to all within his reach, his favourite purfuit was the ftudy of the botany and mineralogy of the furrounding country. His numerous contributions to the publications of Jacquin, on the rare plants of Carniola and Carinthia, conftitute a treafure of the moft valuable and original information. He writes with the ardour of a real lover of nature, and we have nothing to difapprove, except fomewhat of the diffufe, and what Linnæus terms "oratorical," ftyle, in the defcriptive parts of his writings, where terfenefs and precifion are moft defirable, however agreeable the graces of oratory, and the expreffion of tafte and feeling, may be in any accompanying remarks. The *Flora Lapponica* of Linnæus is our ftandard of perfection in this refpect. Wulfen was an accomplifhed fcholar, a man of the moft amiable and elevated character, who adorns every thing that he touches, and who lived and died beloved and revered by men of all ranks, and of every perfuafion. As he lived remote from the fcientific circles of Europe, it is no wonder if, in the abftrufe ftudy of cryptogamic botany, he fell into fome errors, efpecially relative to the *Lichen* tribe, a part of which the writer of this article prefumed to correct, in a paper printed in the Tranfactions of the Linn. Soc. v. 2. p. 10, certainly without intending any difrefpect for the excellent author, though a German writer of a more vulgar ftamp, by mif-tranflation and mifreprefentation, tried to excite them to enmity, but in vain. He may be pardoned for the fake of the great man whom he, though unfkilfully, meant to defend, and for his own fervices to fcience, though of inferior pretenfions. Wulfen is reported to have left behind him in MS. a complete *Flora Norica*, defcriptive of the vegetable productions of a particular part of Carniola, an *Agroftographia*, and feveral other works, rich in practical and fcientific obfervations. Of thefe, it is to be hoped the learned world will not be deprived.—Jacq. Mifc. Auftr. v. 2. 62. t. 8. f. 1. Schreb. Gen. 16. Willd. Sp. Pl. v. 1. 78. Vahl Enum. v. 1. 86. Mart. Mill. Dict. v. 4. Sm. Tranf. of Linn. Soc. v. 6. 96. (Bonarota; Mich. Gen. 9. t. 15. Pæderota; Juff. 120. Lamarck Dict. v. 4. 692. Illuftr. t. 13, but not the original *Pæderota* of Linnæus. See Tr. of Linn. Soc. as above.)—Clafs and order, *Diandria Monogynia*. Nat. Ord. *Perfonatæ*, Linn. *Scrophulariæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, linear-awlfhaped, equal, erect, permanent fegments. *Cor.* of one petal, ringent: tube gibbous, and nearly globofe at the bafe: limb two-lipped; upper lip fhorteft, undivided, or flightly notched, vaulted, acute; lower longeft, deflexed, three-lobed. *Stam.* Filaments two, thread-fhaped, afcending, fhorter than the upper lip; anthers roundifh. *Pift.* Germen fuperior, ovate-oblong, compreffed; ftyle thread-fhaped, twice as long as the calyx; ftigma capitate. *Peric.* Capfule ovate, compreffed, furrowed at each fide, of two cells and two divided valves, burfting at the fummit. *Seeds* numerous, roundifh.

Eff. Ch. Corolla tubular, ringent; upper lip vaulted; lower three-cleft. Calyx in five deep fegments. Capfule of two cells, and two cloven valves.

Obf. This genus is certainly next akin to VERONICA, under which article we have recorded a remark to that effect made by Mr. Brown. The effential difference, however, between thefe two genera refides in the limb of the *corolla*, which in *Veronica* is wheel-fhaped, its lower fegment narroweft; a character of more importance than the proportion of the tube, that part being, in a few fpecies, nearly as much elongated as in the prefent genus. If any of thofe fpecies fhould prove to have a ringent *corolla*, whofe upper lip is vaulted, and the lower three-lobed, they muft be removed to *Wulfenia;* but we difcover nothing of this in *V. fibirica* or *virginica*, whofe limb is truly that of a *Veronica*. Whether the throat be bearded in every fpecies of *Wulfenia*, we are not certain; nor is that circumftance material, any more than the valves of the *capfule* being cloven or not, the fame difference exifting between different fpecies of *Veronica*, as has already been mentioned in its proper place. The five-cleft *calyx*, indicated by Linnæus as the mark of *Pæderota*, is found in the two *Veronicæ* juft named, as well as in fome lefs ambiguous fpecies, as *V. auftriaca*, *multifida*, *Teucrium*, and *latifolia*, though in thefe laft the fifth fegment varies in fize, is occafionally abfent, and is always unequal to the others.

1. W. *Bonarota*. Blue Leafy Wulfenia. Sm. n. 1. Vahl n. 1. (Pæderota Bonarota; Linn. Sp. Pl. 20. Willd. Sp. Pl. v. 1. 77. Jacq. Auftr. append. t. 39. P. cærulea; Linn. Suppl. 84. Lamarck Illuftr. v. 1. 48. t. 13. f. 1. Bonarota montana italica, chamædryos folio, flore cæruleo; Mich. Gen. 19. t. 15. f. 1; alfo f. 2, with rounder leaves, and a more denfe fpike. Chamædrys montis Sumani; Bauh. Hift. v. 3. 289.)—Stem leafy. Upper lip of the corolla entire. Leaves roundifh-ovate.—Native of the mountains of Italy and Carniola; perennial: a ftranger in our gardens, as well as the two following. The *root* is fomewhat creeping. *Stems* fimple, erect, five or fix inches high, downy like the reft of the herbage, each bearing four or five pair of roundifh-ovate *leaves*, about an inch long, with broad, rather fhallow ferratures. *Clufter* terminal, folitary, ovate-oblong, of feveral pretty blue *flowers*, accompanied by lanceolate *bracteas*. *Calyx* hairy. The *corolla* is decidedly ringent, with a concave upper lip, and the valves of the *capfule* fplit at the fummit, each into two fharp points.

2. W. *Ageria*. Yellow Leafy Wulfenia. Sm. n. 2. Vahl n. 2. (Pæderota Ageria; Linn. Mant. 171, excluding Bauhin's fynonym. Willd. Sp. Pl. v. 1. 77. P. lutea; Scop. Ann. 2. 41. Lamarck n. 3. excluding the reference to Bauhin. Linn. Suppl. 84. P. Bonarota; Jacq. Hort. Vind. v. 2. 55. t. 121. Bonarota montana italica, chamædryos folio minùs crenato, fpicâ luteâ; Mich. Gen. 19.)—Stem leafy. Upper lip of the corolla cloven. Leaves ovato-lanceolate, elongated at the point.—Native of Carniola and Italy, in places where, according to Scopoli, the former is not found. Great confufion refpecting thefe two plants has long exifted. Linnæus and Scopoli fometimes confidered them as varieties of each other, and when they made them diftinct, they mifapplied their fynonyms. The prefent is faid to be diftinguifhed by the emarginate, or cloven, upper lip of the *corolla*, which, neverthelefs, Jacquin's figure does not exprefs, and which is but flightly perceptible in our dried fpecimens. The *leaves* differ materially in their more elongated form, and narrower, more copious, ferratures; the lower ones being alternate, as noticed by Scopoli, is but a cafual occurrence. The *corolla* is of a pale fulphur-colour, not blue. *Calyx* fmooth. The *ftyle* in both thefe fpecies is full as long in proportion to the *calyx* and *corolla* as in the following, though defcribed, in the generic character of *Pæderota* by Linnæus, as only the length of the *ftamens*.

The fpecific name of *Ageria*, given by Linnæus to what had much better have been called *lutea*, is intended to commemorate Nicholas Agerius, a friend of John and Cafpar Bauhin, who fent our *W. Bonarota* to the former, and is mentioned by him in feveral places. His name occurs in Linn. Sp. Pl. 1670, as the original difcoverer of *Verbafcum Thapfi*. Haller fpeaks of him as having publifhed, at Strafburg, in 1625, a quarto differtation *de Zoophytis;* and another in 1629, *de Animâ vegetativâ;* works not mentioned in fir Jofeph Banks's rich catalogue, and therefore, doubtlefs, very rare.

3. W. *carinthiaca*. Carinthian Wulfenia. Sm. n. 3. Willd. n. 1. Vahl n. 3. Jacq. Mifc. Auftr. v. 2. 60. Ic. Rar. t. 2. (Pæderota nudicaulis; Lamarck Dict. v. 4. 692. Illuftr. v. 1. 48. t. 13. f. 2.)—Stem naked. Leaves crenate.—Found by Wulfen, in a rich foil, among limeftone rocks, on the loftieft and moft craggy mountains of Carinthia, flowering in the middle of July. The *root* is creeping, perennial, half as thick as the middle finger. *Leaves* feveral together in a tuft, all radical, obovate, obtufe, four or five inches long, doubly or unequally crenate, fmooth and fhining, except the ftrong mid-rib, which is hairy, at the back; their bafe tapering into a winged *footftalk*.

Flowers large and handsome, of a fine blue, crowded numerously into a dense cluster, supported by an upright, round, firm, unbranched, leafless, though somewhat scaly and slightly hairy, solitary, radical *stalk*, twice or thrice the height of the leaves. After flowering, the *cluster* becomes three or four inches long, and the permanent *calyces* turn reddish. The *capsules* are each one-third of an inch in length, brown, abrupt, scarcely exceeding the calyx, soon splitting into four parts at the top. The error of the specific name in Lamarck's synonym, *P. Wulfenia*, for *P. nudicaulis*, in Vahl and Willdenow, is copied by the former from the latter.

WULFRADT, in *Geography*, a town of the duchy of Berg; 3 miles N.E. of Medman.

WULFSDORP, a town of the duchy of Holstein; 11 miles N.N.W. of Lubeck.

WULFSFELDE, a town of the duchy of Holstein; 12 miles N.W. of Lubeck.

WULFTEN, a town of Westphalia, in the bishopric of Osnabruck; 2 miles S.W. of Osnabruck.

WULLED, a town of Arabia, in the province of Yemen; 46 miles S.E. of Loheia.

WULLERSDORFF, a town of Austria; 2 miles S.E. of Gunderstorff.

WULLI, *Mountains of*, mountains of Persia, which extend from the vicinity of Shatzan, across to the lake of Vaikind, and form one range with that on the N. of Mekran, called Gehelabad by La Rochette.

WULPERODE, a town of Westphalia, in the principality of Halberstadt; 4 miles W. of Osterwick.

WULTZESHOFEN, a town of Austria; 1 mile S.W. of Laab.

WULVESHEVED, or WULVESHEAD. See WOLFESHEAD.

WUMBLE, in *Rural Economy*, the provincial name of an auger. It is sometimes written wummle and wimble.

WUMME, in *Geography*, a river of the duchy of Bremen, which runs into the Weser, about 6 miles N.W. of Bremen.

WUNALACHTIKOS, a tribe of Delaware Indians.

WUNNENBERG, a town of Westphalia, in the bishopric of Paderborn, which received its name from a victory which Charlemagne gained in the year 974 over the Saxons; 14 miles S. of Paderborn. N. lat. 51° 29'. E. long. 8° 7'.

WUNSCHELBERG, or HRADECK, a town of Silesia, in the county of Glatz. Here are manufactures of thread, cloth, and variety of stuffs; 10 miles N.W. of Glatz. N. lat. 50° 19'. E. long. 16° 15'.

WUNSCHUECH, a town of Stiria; 8 miles S. of Gratz.

WUNSEES, a town of Germany, in the principality of Bayreuth; 13 miles W. of Bayreuth.

WUNSIEDEL, a town of Germany, in the principality of Bayreuth, on the Fichtelberg; near it are mines of copper and iron, and quarries of marble; 34 miles E. of Bayreuth. N. lat. 50° 3'. E. long. 12° 3'.

WUNSTORF, a town of Westphalia, in the principality of Calenberg, the chief place of a county, which became extinct in the year 1533; 10 miles W.N.W. of Hanover. N. lat. 52° 27'. E. long. 9° 32'.

WUNT, in *Agriculture*, a term provincially applied to the mole.

WUNT-*Hillock*, a word signifying a mole-hill. See MOLE and MOLE-*Hill*.

WUNTZ, in *Geography*, a town of the county of Henneberg; 6 miles N.W. of Meinungen.

WURBEN, a town of Silesia, in the principality of Schweidnitz; 4 miles N. of Schweidnitz.

WURBENTHAL, a town of Silesia, in the principality of Troppau; 13 miles W. of Jajerndorf. N. lat. 49° 57'. E. long. 17° 15'.

WURFE, in *Commerce*, a denomination distinguishing a certain quantity of inferior silver coins in Germany; thus, a wurfe denotes 5 pieces of 17 or of 7 creutzers; and 12 wurfe of 17 creutzer pieces make 17 florins, and 12 wurfe of 7 creutzer pieces make 7 florins.

WURGLAU, or GUERGALA, in *Geography*. See WERGELA.

WURL, a river of Westphalia, which runs into the Ems, near Rietberg.

WURLITZHAIDT, a town of Germany, in the principality of Culmbach; 7 miles S.E. of Hof.

WURMBEA, in *Botany*, is dedicated by Thunberg to the honour of baron Frederick van Wurmbs, secretary to the Academy of Sciences at Batavia, whom he celebrates for great skill in Natural History, and other scientific pursuits, and who rendered him important services in his expedition to Japan.—Thunb. Nov. Gen. 18. t. 1. Schreb. Gen. 239. Willd. Sp. Pl. v. 2. 265. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 325. Poiret in Lamarck Dict. v. 8. 802. Lamarck Illustr. t. 270. (Melanthii species; Juss. 47. Thunb. Prodr. 67.)—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronariæ*, Linn. *Junci*, Juss.

Gen. Ch. *Cal.* none; unless, like Thunberg, we take the corolla for such. *Cor.* of one petal, tubular, permanent: tube with six angles, abrupt at the base: limb in six deep, lanceolate, acute, equal, erect, or spreading segments, usually about the length of the tube. *Stam.* Filaments six, thread-shaped, erect, inserted into the mouth of the tube, and shorter than the limb; anthers roundish, of two lobes. *Pist.* Germen superior, triangular, furrowed, smooth; styles three, awl-shaped, triangular, the length of the stamens; stigmas obtuse. *Peric.* Capsule invested with the withered corolla, oblong, with three angles and three furrows, consisting of three cells, separating from the top half way down. *Seeds* numerous, round.

Eff. Ch. Calyx none. Corolla in six deep equal segments, with an hexagonal tube. Stamens inserted into the mouth of the tube. Capsule superior.

Obs. Under the genus MELANTHIUM, (see that article,) we have expressed a determination of reducing the present genus to that. By a casual oversight, however, the species which compose *Wurmbea* were there omitted. Having examined them with more attention, and particularly with respect to ORNITHOGLOSSUM, which the reader will find in its proper place, our opinion has changed. The latter genus, to which *Melanthium indicum* perhaps really belongs, has most resemblance to *Wurmbea* in habit, and in the general aspect of the *flowers*; though most widely estranged therefrom in its generic character, founded on the insertion of the *stamens*. If *Ornithoglossum* be retained, *Wurmbea* must. No difficulty attends its essential character, which is obvious enough, in the pale sexangular tube, abrupt or gibbous at the base, as if furnished with six small spurs. The Linnæan herbarium shews, that Linnæus himself had established the present genus, and dedicated it to his friend Sparrmann, by whom his specimens were brought to Europe. There is a singular remark in Thunberg, of *Wurmbea* having, " without all doubt," been produced from *Melanthium ciliatum*!

1. W. *pumila*. Dwarf Wurmbea. Willd. n. 1. (W. capensis α; Thunb. Nov. Gen. 19. t. 1. f. 7.)—Cluster of three

three or four flowers. Tube the length of the limb.—Native of the Cape of Good Hope, in fandy ground, at the foot of fmall hills, flowering in Auguft or September. The *root* is a fmall globular bulb, as in all the reft, funk deep into the earth. Whole *herb* but an inch high, with two or three fhort, fheathing, lanceolate *leaves*. *Clufter* hardly rifing above the foliage, of three or four, rarely more, erect white *flowers*, on longifh partial ftalks, not feffile, or fpiked, if Thunberg's figure be correct, like the other fpecies. The margins of the fegments of the *flower* are purple, and there are fpots of the fame colour juft above the mouth of its tube. The *ftamens* are white. *Thunberg*.

2. W. *campanulata*. Bell-flowered Wurmbea. Willd. n. 2. Ait. n. 2. (W. capenfis γ; Thunb. Nov. Gen. 19. t. 1. f. β. Lamarck f. 1. Melanthium monopetalum; Linn. Suppl. 213. Ker in Curt. Mag. t. 1291.)—Tube of the corolla bell-fhaped, the length of the limb, which is twice as long as the ftamens. Spike denfe, cylindrical.—Native of the fame country. Sent to Kew garden, by Mr. Maffon, in 1788. It flowers in the green-houfe in May and June. The *bulb* is ovate. *Stem* folitary, fimple, leafy, from three to five inches high; zigzag, tapering, and pale, in the part which is below the furface of the ground. *Leaves* three or four, alternate, widely fpreading, or recurved, much longer than the ftem, but not elevated above it, tapering, channelled, rather glaucous, fmooth; their bafe dilated and fheathing. *Spike* terminal, erect, two or three inches long, of numerous, feffile, white *flowers*, whofe limb is rather concave, its edges brown in our fpecimens, anfwering to Thunberg's defcription, though that circumftance is not expreffed in the Botanical Magazine. *Stamens* white, fpreading, not half the length of the limb, with yellow *anthers*.

3. W. *purpurea*. Purple Wurmbea. Banks MSS. Ait. n. 2. (W. capenfis β; Thunb. Nov. Gen. 19. Andr. Repof. t. 221. W. campanulata β; Willd. n. 2. Melanthium fpicatum; Curt. Mag. t. 694.)—Tube of the corolla much fhorter than the widely fpreading limb.—Native of the Cape. Sent to Kew in 1788, by Mr. Maffon. This has the herbage of the laft, but the *fpike* is rather more lax, and the *flowers* all over of a dark violet purple, except the yellow *anthers*, have a much fhorter *tube*, and longer *limb*.

4. W. *longiflora*. Long-flowered Wurmbea. Willd. n. 3. (W. capenfis δ; Thunb. Nov. Gen. 19. t. 1. f. α. Lamarck f. 2.)—Spike taller than the leaves. Tube of the corolla twice the length of the limb.—Found at the Cape of Good Hope, on fandy hills in various places. A taller larger plant than any of the preceding; its *leaves* much broader at the bafe. *Spike* three or four inches long, rather lax, many-flowered, with a zigzag angular *ftalk*. *Flowers* entirely white; their *tube* near an inch long; *limb* about half that length, widely fpreading. *Stamens* full half the length of the limb. That all thefe fpecies fhould have been confidered as varieties only, appears as ftrange as any other particular in the hiftory of the prefent genus. The Linnæan herbarium proves the *Melanthium monopetalum* of the *Supplementum* to be not this, but the *W. campanulata*.

WURMBERG, in *Geography*, a town of the duchy of Stiria; 6 miles N.W. of Pettau.

WURMSEE, a lake of Bavaria; 13 miles S.W. of Munich.

WURST, a Ruffian meafure. See WERST.

WURSUREE, in *Geography*, a town of Hindooftan, in Guzerat; 32 miles N.E. of Chitpour.

WURTEMBERG, late a duchy and now a kingdom of Germany, bounded on the north by the bifhopric of Spire, the palatinate of the Rhine, the county of Hohenlohe, and territories of the city of Hall in Swabia; on the eaft by the county of Limburg, the territories of the imperial towns Gemund and Ulm, and county of Oettingen; on the fouth by Auftrian Swabia, the territories of Furftenberg, Zwifalten, Rothweil, and the Brifgau; and on the weft by the marquifates of Baden Baden, and Baden Durlach: about 64 miles from north to fouth, and about as much from eaft to weft, comprehending about 3200 fquare miles. This kingdom confifts of a great number of counties and lordfhips, fome of which were purchafed, fome devolved to it by marriage, and others were acquired by conqueft. It is beyond difpute the moft confiderable and fertile part of the circle of Swabia, and may indeed be faid to be, after Saxony, one of the beft countries in all Germany. From its natural difpofition, the country confifts of three tracts, which are all remarkably different. Of thefe, the loweft and warmeft is the north, called Unterland, reaching from Heilbronn to Stuttgard. This duchy abounds fo in grain, that it exports confiderable quantities; but this grain is chiefly fpelt, rye and wheat being much lefs cultivated here. Of all the other forts of grain, however, here is alfo a fufficiency, even for export. Flax and hemp are alfo cultivated, and the former of thefe thrives beft in the cold parts. The valleys, fome of which are feven or eight miles in length, are covered as it were with forefts of fruit-trees, of which there is no fcarcity in the other parts of this country, cyder and perry being the liquors drank in common by the country people, when wine happens to be dear. This duchy abounds likewife in very rich, palatable, and wholefome wines, called by the general name of Neckar wines, though each has a particular title of its own, which it receives from the parts where it grows. The grapes alfo, which yield the beft wines, bear the appellation of the countries whence the fets were firft brought, as the Chiavenna, Valteline, Tyrolefe, and Hungarian. The vineyards of the duchy of Wurtemberg have been greatly improved by fhoots from France, Italy, Greece, Hungary, Cyprus, and even Schiras in Perfia. The cultivation of filk was revived under duke Charles. The forefts of this country are confiderably leffened. The confumption of oak, in particular, has been very large. The mountains of the Black foreft on the W. and thofe of the Alt on the S. and E., not only diverfify the face of the country, but fupply timber, food, and wines. Moft parts of the country abound in game; near Frudenftadt, and near Konigfwart, are mines of filver and copper; of filver at Konigftein, and of copper at Guttach: near Hornberg iron is alfo found. Of minerals, *terra figillata*, which is reckoned preferable to that of Malta, and a fine clay for earthenware, as alfo porcelain, which is worked at Calw; fine variegated marbles, fome of which are equal to thofe of Italy; and remarkably tranfparent alabafter, agate, cryftalline pebbles, black amber, or rather obfidian, fine mill-ftones, &c.: and at Sulz there are faltworks. Among the baths in Wurtemberg, the moft celebrated is that of the Wildbad. The principal rivers are, the Neckar, the Enz, and the Nagold. The number of inhabitants in this ftate is known to precifion, an exact inquiry being made every year by the general fuperintendants, and reported to the annual fynod; they are now about 600,000. The ftate contains 68 cities and towns, with about 1200 boroughs, market-towns, villages, and hamlets. The revenue is computed at 245,000*l.*, and the military force at 6000. The eftablifhed religion of this country is Lutheranifm, and though duke Charles Alexander embraced the Roman, yet in the years 1729, 1732, and 1733, he gave affurances to the ftates, in formal inftruments,

ments, that no change or innovation ſhould be made in the Lutheran religion in any part of the whole duchy, and that in all the churches and ſchools throughout the duchy, and the countries thereto belonging, no other religion than that of Lutheraniſm ſhould be taught: that no Catholic churches, chapels, altars, or images, ſhould be erected or ſet up, nor any ſuch as were decayed or forſaken again uſed. The Calviniſts only are tolerated here, and their place of worſhip at Stuttgard is a private houſe. In this duchy are alſo ſome Waldenſes, who are either huſbandmen or farmers, and live in the Italian villages, as they are called, ſome few towns alone excepted; where they have eſtabliſhed manufactures of hats and ſtockings, and are allowed the public exerciſe of their religion. The toleration of the Jews here was aboliſhed by an edict of duke Chriſtopher, that of two or three families at Stuttgard excepted, under the particular protection of the court. The church is governed by four ſuperintendants, ſtyled abbots, and 38 rural deans; a ſynod is annually held in the autumn. Education, and particularly that of eccleſiaſtics, is favoured by laudable inſtitutions; the ſeminary of Tubingen uſed to accommodate about 300 ſtudents; and at Stuttgard there is a public academy. Here are manufactures of pottery, glaſs, woollen, linen, and ſilk, which, with the natural products of the country, ſupply a conſiderable export. The imports are by Frankfort on the Maine. The chief city is Stuttgard, and the ſecond town is Tubingen. The other towns are numerous, but ſmall; and the villages are thickly placed in a populous and flouriſhing country. The origin of the princely houſe is ſomewhat obſcure and uncertain. It is certain, however, that there were counts of Wurtemberg at the beginning of the twelfth century. In 1802 Wurtemberg was created an electorate of the empire; and in 1806 was erected into a kingdom. The caſtle of Wurtemberg, which gave name to the duchy, is ſituated 4 miles E. from Stuttgard. By the treaty of Preſburg in 1805, the king of Wurtemberg acquired ſeveral important reſerves.

WURTZBURG, a town of Germany, in the county of Erbach; 3 miles E. of Erbach.

WURTZEN, a mountain of Carinthia; 8 miles S. of Villach.

WURWAMA, a town of Hindooſtan, in Guzerat, on the ſouth ſide of the gulf of Cutch; 40 miles N.E. of Noanagur.

WURWAY, a river of North Wales, which runs into the Vurney, 3 miles S. of Llanvilling, in the county of Montgomery.

WURZACH, a town of Germany, in the county of Waldburg, on the Aitrach; 26 miles N.W. of Kempten. N. lat. 48° 0′. E. long. 9° 52′.

WURZBACH, a river of Germany, which runs into the Klein Enz, 2 miles E. of Wildbad.

WURZBURG, a duchy, late a biſhopric, bounded on the north by the county of Henneberg and principality of Coburg; on the eaſt by the biſhopric of Bamberg, the margravate of Anſpach, and the county of Caſtel; on the ſouth by the county of Hohenlohe; and on the weſt by Mergentheim, county of Wertheim, electorate of Mentz, and the biſhopric of Fulda; about 80 miles in length, and 64 in breadth. The territory of Wurzburg is fertile in corn, paſtures, and divers ſorts of fruits and plants, as alſo in wine, the very beſt Franconian vines growing in it. The prevailing religion is the Roman Catholic; but there are alſo Lutheran and Calviniſt churches within the eccleſiaſtical juriſdiction and territory of Wurzburg, which from time to time preferred to the diets of the empire grievous complaints of oppreſſion and injuſtice. In the ſixteenth century, this biſhopric abounded with Proteſtant inhabitants. The biſhopric was not founded here till 741. In the year 1752, pope Benedict XIV. granted them the privileges of bearing the archiepiſcopal pall and croſs; but in other reſpects they were ſuffragans to the archbiſhops of Mentz. This prince and biſhop maintained five regiments of foot and horſe, military affairs being ſubject to the aulic council of war. In 1806 Wurzburg was ſecularized, ſoon after erected into a duchy, and given to the archduke Ferdinand. The number of inhabitants is computed at 200,000. By the treaty of Preſburg in 1805, the new kingdom of Bavaria, to which Wurzburg had been before aſſigned, acquired ſeveral important additions.

WURZBURG, a city of Germany, and capital of a duchy, late reſidence of the biſhop. It is ſituated on the Maine, well fortified, and defended by a fortreſs, ſituated on a rock without the town; in which fortreſs is an epiſcopal palace, and a church, ſuppoſed to be the oldeſt in Franconia. The town is divided into four quarters and four ſuburbs, in which are, a new palace, built in the beginning of the eighteenth century, a cathedral, ſeveral collegiate and pariſh churches, colleges, abbeys, and convents. The univerſity was founded in the year 1403; and, after falling to decay, reſtored again in 1582. In Auguſt 1796, Wurzburg was taken by the French, but given up to the Auſtrians the month following; 50 miles E.S.E. of Frankfort on the Maine. N. lat. 49° 50′. E. long. 9° 59′.

WURZELBAU, or WURTZELBAU, JOHN PHILIP, in *Biography*, a German aſtronomer, was born at Nuremberg in 1651, and being diverted from his ſtudies by a change of circumſtances, devoted himſelf to mercantile purſuits. But in the midſt of theſe occupations, he reſerved his ſpare hours for reading, and acquainting himſelf with the French, Italian, and Spaniſh languages. His chief attention was directed to mathematics and aſtronomy. In 1684 and 1685 he made obſervations on an eclipſe of the moon, which were printed; and in 1689 tranſmitted to the Royal Society communications pertaining to aſtronomy. In 1691 devoting himſelf more ſeduloully to the ſtudy of geometry and aſtronomy, the emperor Leopold, apprized of his merits, raiſed him and his heirs to the rank of nobility in 1692. In 1699 he was choſen one of the foreign aſſociates of the Academy of Sciences at Paris, and in 1706 he became a member of the Academy of Berlin. Declining a removal to Dreſden, with the offer of an annual ſalary of 1000 dollars and free lodging, he occupied himſelf in aſtronomical obſervations with inſtruments of his own invention and conſtruction; and he built, at his reſidence in Nuremberg, an obſervatory conſiſting of an octagon turret, covered with copper, and reſting on iron bars, which was placed on the top of the houſe, and which was moveable to every part of the heavens: it was furniſhed with an azimuth quadrant of five feet radius, a ſextant of ſix feet, and other inſtruments; of which obſervatory he publiſhed an account at Nuremberg, 1697, fol. He publiſhed alſo other works, ibid. 1713, fol. and ibid. 1719, fol. Having publiſhed ſolar tables, &c. he died at Nuremberg in 1725. He publiſhed alſo various obſervations in the Phil. Tranſ. vol. xv. xvi. xvii. and vol. xxx.; and alſo at Nuremberg. Montucla. Weidler. Gen. Biog.

WURZEN, or WURTZEN, in *Geography*, a town of Saxony, in the territory of Leipſic; the bailiwick of which extends over ſeventy-ſix villages, and twenty-two noble eſtates; anciently the ſee of a biſhop, but in 1661, the eſtates of the foundation were annexed to the Leipſic circle. The town is ſituated on the Mulda; though not large in itſelf, it is much increaſed by its fauxbourgs, which contain the

the citadel and cathedral. The beer brewed here is the chief article of trade, and is exported in great quantities; 14 miles E. of Leipfic. N. lat. 51° 19′. E. long. 12° 42′.

WUSEN, a town of Pruffia, in the province of Ermeland, on the Paffarg; 25 miles W. of Heilfberg.

WUSHUTEE, or MEECH, a general term applied to all that country of the province of Mekran in Perfia, lying to the weftward, and on the parallel of Punjgoor or Panger, and forming the northern boundary of the Sandy Defert. It is reprefented to be a mountainous diftrict, producing in fome of its villages grain, fufficient for the confumption of the few wandering fhepherds who inhabit them. Water is plentiful, except in April, May, and June; dates are alfo produced, and camels, fheep, and goats, are procurable, but not in great number. The people are rather a fmall delicate race: their arms are, a match-lock, fword, and fhield; and each village has its own chief, who fettles difputes that arife among the inhabitants.

WUSLACH, a town of Pruffia, in the province of Ermeland; 10 miles E. of Heilfberg.

WUSTENSAXEN, a town of Germany, in the principality of Wurzburg; 5 miles N. of Bifchofsheim.

WUSTERHAUSEN, a town of the Middle Mark of Brandenburg; 11 miles S.S.E. of Berlin.—Alfo, a town of the Middle Mark of Brandenburg, on the Doffe; 36 miles N.W. of Berlin. N. lat. 52° 53′. E. long. 12° 31′.

WUSTERSDORF, a town of Auftria; 9 miles S.W. of Laab.

WUSTHAL, a town of Germany, in the circle of the Lower Rhine; 4 miles N. of Rothenbach.

WUSTRO, a town of Weftphalia, in the principality of Luneburg Zelle, on the Jetze and the Dumme; 40 miles S.E. of Luneburg.

WUTACH, a river of Germany, which croffes the county of Stuhlingen, and runs into the Rhine, 10 miles below Lauffenburg.

WUTTOOR, a town of Hindooftan, in Dowlatabad; 6 miles E. of Junere.

WUTZKOW, a town of Hinder Pomerania: it is the laft poft ftage bordering on Poland; 30 miles E. of Stolpe.

WYACONDA, a river of Louifiana, which runs into the Miffiffippi, N. lat. 39° 46′. W. long. 91° 48′.

WYALUSING, a townfhip of Pennfylvania, in the county of Luzerne, with 576 inhabitants; 320 miles N. of Wafhington.

WYALUSING *Creek*, a river of Pennfylvania, which runs into the E. branch of the Sufquehanna, N. lat. 41° 40′. W. long. 76° 20′.

WYANDOT, a town of North America, belonging to the United States: a tribe of Indians called Wyandots inhabit the neighbourhood; 6 miles S. of Sandufky.

WYASTON, a village in the hundred of Appletree, Derbyfhire, England, fituated 3 miles from Afhborne, and 137 from London. In the year 1811 it contained 16 houfes, and 69 inhabitants.

WYAT, *Sir* THOMAS, in *Biography*, an Englifh poet, was the fon of Henry Wyat, efq. of Allington-caftle in Kent, and born in 1503. Having finifhed his education at Cambridge and Oxford, he travelled, as an envoy, into various parts of Europe, and acquired the favour of Henry VIII. whofe good will was of very fhort duration; for either from a fufpicion of his connection with Ann Boleyn, or the ill offices of Bonner, he was for fome time imprifoned. After his liberation he retired to his caftle of Allington, and being employed to conduct the ambaffador of Charles V. from Falmouth to London he was feized with a fever, of which he died at Sherburn in 1541. In an elegy on his death, his character was highly drawn in an encomium by the earl of Surrey, with whom he was intimate, as his fellow-labourer in polifhing Englifh poetry; though his ftrains are faid to have been inferior to thofe of the earl of Surrey. Mr. Warton diftinguifhes him by the appellation of the firft polifhed Englifh fatirift. His reputation was high, and Leland publifhed a book of Latin verfes on his death. His poems were printed with the editions of thofe of Surrey in 1559 and 1565, and fince by Dr. Sewel, in 1717. His verfion of David's Pfalms is much commended by Surrey and Leland; but it is not extant. Warton's Hift. of Eng. Poetry. Gen Biog.

WYBERTON, in *Geography*, a village and parifh in the wapentake of Kirton, Holland divifion of the county of Lincoln; 2 miles from Bofton, and 115 from London. It was returned in the year 1811 as containing 74 houfes, occupied by 353 perfons.

WYBOLDSTON, a village in the hundred of Barford, Bedfordfhire, England, fituated 8 miles from Biggleswade, and 2 miles from St. Neot's. The population is not feparately returned, being included in the parifh of Eaton-Socon.

WYBORG. See VIBORG.

WYBUNBURY, or WIBBUNBURY, a village in the hundred of Namptwich, county palatine of Chefter, is fituated on the borders of Staffordfhire, about 3 miles E. from Namptwich. The church is a handfome ftructure, and contains a great variety of monuments and other fepulchral memorials. A fchool was built here nearly two centuries ago by fubfcription; the endowments are but fmall, though increafed by occafional donations: the fchool is for boys, fome of whom are taught reading only, others reading, writing, and arithmetic. The population return of the year 1811 ftates this village to contain 76 houfes, and 353 inhabitants. The parifh of Wybunbury is very extenfive, and comprehends eighteen townfhips.—Lyfons's Magna Britannia, vol. ii. Chefhire, 1810.

WYCH-HOUSE, a houfe in which falt is boiled. (See SALT.) In the places where there are falt-fprings, and falt-works are carried on at them, the work-houfe where the falt is made is always called the wych-houfe; and hence we may naturally conclude that *wych* was an old Britifh word for falt, which is the more probable, as all the towns in which falt is made end in *wych*; as *Namptwych*, *Droitwych*, *Middlewych*, &c.

WYCHERLEY, WILLIAM, in *Biography*, was born at Cleve, in Shropfhire, about the year 1640; and in France, whither he went for his education, he conformed to the Roman Catholic religion. Upon his return to England a little while before the Reftoration, he entered, without matriculation, as a gentleman-commoner at Queen's college, Oxford, and leaving it without a degree, took chambers in the Middle Temple. However, he abandoned the law, and addicted himfelf to the compofition of comedies, the firft of which was entitled "Love in a Wood, or St. James's Park," which brought him into notice in 1672; fo that he became a favourite of the duchefs of Cleveland, and of Villiers, the duke of Buckingham. He was alfo honoured by the attention of the king, and by promifes of future promotion. His majefty, however, was difpleafed by his marriage with the countefs of Drogheda, and the connection was unhappy. On occafion of her death, however, fhe fettled her whole eftate upon him, and his title being difputed, he was involved in law expences and other incumbrances, which occafioned his being committed to prifon. Having remained in prifon for feven years, he was liberated by king James II., who, delighted by feeing his comedy of the

the "Plain Dealer," gave orders for the payment of his debts, and fettled upon him a penfion of 200*l.* a year.

His circumftances were ftill embarraffed, and though by his father's death he became a tenant of the eftate to which he fucceeded, he was not emancipated from his difficulties. Some time after he married a young woman, on whom he fettled a jointure of 1500*l.*, humouroufly ftipulating with her that fhe fhould not take an old man for her fecond hufband, which condition, it is faid, fhe promifed faithfully to obferve. He died in 1715, at the age of 75.

Befides the two comedies already mentioned, he compofed "The Gentleman Dancing-Mafter," and "The Country-Wife." The laft and the Plain Dealer are faid to be the moft noted. His plays, though commended by lord Rochefter, are ftrongly marked with his own character,—"fome wit and ftrength of delineation, with much coarfenefs and licentioufnefs." He attacks vice, it is faid, with the feverity of a cynic, and the language of a libertine. A volume of poems publifhed in 1704 was fo unfuccefsful, that he applied to Pope, who was a mere youth, to correct the verfification. Dr. Johnfon remarks, that "when Pope was fufficiently bold in his criticifms, and liberal in his alterations, the old fcribbler was angry to fee his pages defaced, and felt more pain from the detection than content from the amendment of his faults." The pofthumous works of Wycherley, in profe and verfe, were publifhed by Theobald in 1728, 8vo., but they are utterly forgotten. Biog. Brit. Johnfon's Life of Pope. Gen. Biog.

WYCK, John, was the fon of Thomas Wyck, a painter of fhipping and views of towns, of no very great celebrity, who was in England in the time of Charles II. John was born at Haerlem about the year 1640, and diftinguifhed himfelf as a painter of battles and fieges, and fometimes of huntings and proceffions. He imitated the ftyle of Wouvermans and Vander Meulen, but never obtained their neatnefs or finifh, though his colour is oftentimes very agreeable. His execution is better upon a fmall than a larger fcale. He died at Mortlake in 1702.

Wyck, in *Geography*, a part of the city of Maeftricht, on the E. fide of the Meufe, ftrongly fortified. See Maestricht.—Alfo, a fmall fea-port of Ruffia, on the W. coaft of the ifland of Efel.

Wyck *op Zee*, a town of Holland, near the fea; 3 miles W. of Beverwick.

Wyck *te Duerftede*, a town of Holland, in the department of Utrecht, fuppofed to be mentioned by Tacitus, by the name of "Batavodurum," and faid to have been built by Battus, prince of the Catti. It was granted, with its territory, to Rixfride, the feventh bifhop of Utrecht, and his fucceffors, for the zeal he had fhewn in converting the infidels. Trithemius relates, that it was anciently three leagues in circumference, and had 55 parifh-churches, and that it had been deftroyed by the Normans and Danes three feveral times; 13 miles S.E. of Utrecht.

WYCLIFFE, a fmall village and parifh in the wapentake of Weft Culling, North Riding of Yorkfhire, England, is fituated two miles N.E. from Greta-bridge; and in the year 1811 was returned as containing 26 houfes, and 140 inhabitants.

WYCOMBE, High, or *Chipping-Wycombe*, a large market and borough town in the hundred of Defborough, Buckinghamfhire, England, is fituated 34 miles S.S.E. from the county town, and 29 miles W. by N. from London, on the banks of a fmall river, which rifes at Weft Wycombe, and, in its courfe through this parifh, turns feveral corn and paper mills. A weekly market on Fridays has been held from time immemorial, and is a great mart for corn and other articles: here is alfo an annual fair. This borough has fent members to parliament from the 28th year of Edward I.: the right of election is vefted in the mayor, aldermen, bailiffs, and burgeffes; and the number of voters is about 180. Edmund Waller, the poet, was one of the reprefentatives in 1625; fir Edmund Verney, king Charles's ftandard-bearer, who fell at the battle of Edgehill, was elected to the parliaments of 1639 and 1640; and Thomas Scott, the regicide, was a member during the protectorate of Cromwell. The firft incorporation of the town appears to have been in 1461; but the mayor and aldermen are mentioned in a record of the reign of Edward III.: the earlieft charter now extant bears date 1586. The corporation confifts of a mayor, twelve aldermen, a recorder, and other officers; formerly here was a high fteward, but the office was annulled by a charter of Charles II.; yet fince that time it has been held (by virtue of former charters) by the earl of Bridgewater, lord-chancellor Jefferies, and the marquis of Wharton. According to the population return of the year 1811, the town contained 494 houfes and 2490 inhabitants: the parifh is extenfive, and includes feveral hamlets, which make an addition of 2266 to the population, and 449 to the number of houfes. The manor of Wycombe having paffed through a variety of families, was fold, together with the manors of Loakes and Windfors, or Chapelfee, by Thomas Archdale, efq. in 1700 to Henry Petty, lord Shelburne, who bequeathed all his eftates to his nephew, John Fitzmaurice, afterwards earl of Shelburne. His fon, who in 1784 was created earl Wycombe and marquis of Lanfdown, fold thefe manors by auction, which were purchafed by the prefent proprietor, lord Carrington. The manor-houfe of Loakes, fituated near the town, was confiderably enlarged and improved by lord Shelburne, and the marquis of Lanfdown beftowed much expence in laying out the gardens and pleafure-grounds. The houfe has been almoft wholly rebuilt by the prefent noble owner, from the defigns of James Wyatt: it is now called Wycombe-abbey. The parifh-church of High Wycombe is mentioned by Warton as having been built in the reign of Henry II.: the prefent fabric is of much later date, and the tower was built in 1522. Between the aifle and the chancel is an ancient oak fcreen, which, by an infcription, appears to have been put up in 1460, at the expence of the Redhead family. In the chancel is a monument to Henry Petty, earl of Shelburne, who died in 1751. It was executed by Scheemakers, at the expence of 2000*l.*, which was bequeathed by his lordfhip for that purpofe. In the fouth aifle is a very handfome monument by Carlini, for Sophia, countefs of Shelburne, (firft wife of the late marquis,) who died in 1791, with a female figure reclining on an urn. In the church are memorials of the families of Archdale, Lluelyn, Shrimpton, and Bradfhaw. William Bradfhaw, who died in 1614, was 103 years of age. In the church-yard is the tomb of Robert Williams, the late fexton, who died in 1793, at the age of 102. Two hofpitals for lepers were founded in this town in the early part of the 13th century: one of them was granted by queen Elizabeth to the corporation; and the lands are now applied to the maintenance of an hofpital or alms-houfe for poor people, and a grammar-fchool.

Wycombe, *Weft*, is a populous village and parifh in the hundred of Defborough, fituated about two miles N.W. by W. from High Wycombe, on the road to Oxford. It was anciently called Haverindon. The manor was from a remote period till the Reformation attached to the fee of Winchefter: the prefent proprietor is fir John Dafhwood King, who has a feat here, named Weft Wycombe-houfe, which was built by fir Francis Dafhwood, but was much enlarged,

enlarged, and furnifhed with a profufion of ornaments by his fon lord Le Defpencer. The parifh-church ftands on the fummit of a fteep hill, at a fmall diftance from the village, within the fcite of an ancient circular intrenchment. It was rebuilt in 1763, (except the tower and chancel, which are parts of a more ancient ftructure,) by lord Le Defpencer, who fitted it up in the Grecian ftyle: the ceiling is painted with Mofaic ornaments. Near the eaft end of the church is an hexagonal building, erected by his lordfhip. One fide of this building is infcribed to the memory of John, earl of Weftmoreland, and another to George, baron of Melcombe Regis, whofe legacy to lord Le Defpencer, for the purpofe of erecting a monument to his memory, was the caufe of his lordfhip's building this fingular maufoleum. Within it are feveral receffes for monuments, and niches for arms and bufts. The population of this parifh, in the return of the year 1811, is ftated to be 1362; the number of houfes 273. —Lyfons's Magna Britannia, vol. i. Buckinghamfhire, 1806. Beauties of England and Wales, vol. i. Buckinghamfhire, by J. Britton and E.W. Brayley, 1801.

WYDAW, a river of Denmark, which runs into the North fea, near Tondern, in the duchy of Slefwick.

WYDRAUGHT, a water-courfe, or water-paffage, to carry off the filth and fuillage of a houfe; properly a fink, or common-fewer.

WYE, in *Geography*, called by Leland, in his Itinerary, a "pratie market townlet," is now only a confiderable village of the county of Kent, England, as its market has been long difcontinued. In the Domefday-book it is written *Wi*, and by that appellation it was granted by the Conqueror to the abbey of Battle, in Suffex, which he had founded in remembrance of his victory over Harold, it having been previoufly a part of the demefne lands of the Saxon kings. "The Chronicles of Battle abbey affirm," fays Lambard, "that there were fometime two-and-twenty hundreths fubject to the jurifdiction of this manor." The extenfive grant of the royal manor of Wye, with all its appendages, liberties, and royal cuftoms, was confirmed to the abbey of Battle by different fovereigns, and it continued parcel of its poffeffions till the period of the diffolution. Queen Elizabeth, in her firft year, granted it, together with various eftates in the vicinity, to her kinfman, Henry Cary, lord Hunfdon, to hold *in capite* by knight's fervice. The church of this parifh was made collegiate by archbifhop Kemp, who was a native of the place, and is fuppofed to have rebuilt this edifice at the fame time that he founded the adjoining college, in the year 1447. It confifts of a nave, aifles, and chancel, with a large embattled tower at the fouth-eaft angle; the nave is feparated from the aifles by four pointed arches on each fide, rifing from eluftered columns; the chancel was rebuilt at the commencement of the laft century, and has a femicircular eaft end.

The ancient college, now the grammar-fchool, founded by archbifhop Kemp, ftands on the eaft fide of the churchyard. He endowed it for a provoft and fix fellows, "two of whom had an additional ftipend for the duty of the church, and care of a grammar-fchool," in which all fcholars, both rich and poor, were to be inftructed gratis. Another fchool was inftituted here about the year 1708, under a bequeft of lady Joanna Thornhill, who, among other charities to the poor of Wye, directed that the refidue of her eftates fhould be applied to the inftruction of their children. Sir George Wheeler added to this foundation, and gave the college as the refidence for the mafter of the grammar-fchool, and for the mafter and miftrefs of lady Thornhill's fchool. The college buildings form a quadrangle, and the old hall is a large vaulted room, now ufed for the fchool. The population of this parifh in the year 1811 confifted of 1322 perfons, who occupied 224 houfes. In this parifh is Ollantigh, where archbifhop Kemp was born in 1380, and where towards the end of his life he built a chapel, or oratory. Here alfo it is conjectured was born Thomas Kemp, bifhop of London, and nephew of the archbifhop. John Sawbridge, a patriotic alderman of London, was likewife a native of this place, where he was born March 17, 1732, and where he died in 1795. His fifter, Mrs. Macaulay Graham, an Englifh hiftorian, derived her birth from this place on the 23d of March 1731. (See GRAHAM, MACAULAY.) About one mile N.E. from Ollantigh, a Roman burying-place was difcovered in the year 1703, and feveral fkeletons, urns, and other veftiges of interments, have been difcovered, and are now preferved at Heppington, in this county.—Hafted's Hiftory, &c. of Kent, 12 vols. 8vo. Beauties of England, &c. Kent, by E. W. Brayley, 8vo. 1806.

WYE, a river of South Wales, is rendered particularly noted, in confequence of the high praifes beftowed on it by topographers, tourifts, and poets. The fhores of this famed ftream are diftinguifhed by bold, rocky, and woody fcenery, and adorned by feveral towns, feats, caftles, and abbeys. The poet Gray fays, "its banks are a fucceffion of namelefs beauties." Taking its fource on the fouth fide of the mountain called Plinlimmon, in Montgomeryfhire, within a quarter of a mile from the fpring-head of the river Severn, the river takes a courfe in general to the S.E. between the counties of Brecknock on the W. and Radnor on the E. Entering Herefordfhire, it winds by and partly through the capital of that county; and then turning fouthward, it forms the boundary between Gloucefterfhire on the E. and Monmouthfhire on the W., until it unites its ftream with that of the Severn, a few miles below Chepftow. At its fource, the fcenery is wild, romantic, and bare; but after defcending to Buallt, the fcenes are extremely beautiful. In the valley of Glafsbury, the ftream is fo confiderable as to have required in 1783 a ftone bridge of feven arches, which twelve years afterwards was fwept away by the floods. At Hay, where it enters Herefordfhire and receives the waters of the Dulas, the Wye is fo much increafed in the winter feafon as to be navigable for barges. From thence to Hereford it winds through a continuation of rich and beautiful fcenes, and paffes by many pleafant villages and country-feats. Bradwardine, a village, where in ancient times ftood a caftle, on the right or fouth bank, gave name to Thomas Bradwardine, archbifhop of Canterbury, who was ftyled from the depth of his learning "the profound doctor." About three miles lower down is Moccas-court, the modern refidence of fir George Cornwall, bart. About fix miles below Hereford the Wye receives the Lug, one of the three principal rivers of the county, flowing in general fouth-eaft from the borders of Radnorfhire. "Near the conflux of the Lux and Wye," fays Camden, "to the eaft, a hill called Marclay-hill did, in the year 1575, roufe itfelf as it were out of fleep, and for three days together, fhoving its prodigious body forward, with a horrible roaring noife, raifed itfelf, to the great aftonifhment of all beholders, to a higher place." Two miles below the influx of the Lug, but on the weft fide of the Wye, is Holme-Lacy, the ancient feat of the Scudamores, the heirefs of whom married the late duke of Norfolk. The manfion occupies the fcite of an abbey, which was founded in the time of Henry III. Five or fix miles lower down, and on the fame fide of the Wye, is Harewood, a remnant of the foreft of that name, felected

by

by Mafon as the fcene of his drama of Elfrida; for there Ethelwold, the confidante of king Edgar, had his caftle, in which the fair Elfrida was concealed. Five miles farther down, on the eaft bank of the river, is Rofs, confecrated in the poetry of Pope by his fafcinating defcription of what could be and actually was accomplifhed by the "Man of Rofs," with "five hundred pounds a year." The memory of this worthy man, John Kyrle, is preferved by a monument in the church of Rofs. On the weft fide of the river are the remains of Wilton caftle, a Norman ftructure, once the refidence of the Greys. Following the courfe of the Wye on the weft, on the fummit of a bold promontory clothed with wood appear the lofty towers of Goodrich caftle, of great antiquity; for in 1204 it was granted by king John to Marfhall, earl of Pembroke. The views from the caftle are extenfive and highly interefting. At Coldwell rocks the fcenery of the Wye is peculiarly grand, the prominences are overhung with oaks and fhrubs, and feparated by deep fhadowy dells. From Symond's-gate or Yat, the fummit of a lofty hill, the fpectator difcovers a fingularly grand view of the windings of the river, and its romantic banks. Soon afterwards, entering a fhort way into Monmouthfhire, the Wye bathes the walls of the capital, near which is Troy-houfe, the ancient feat of the duke of Beaufort, and affuming a fouthern direction, runs along the limit between that county and Gloucefterfhire. The courfe of the river, in the latter part of the range, is lefs irregular than that through Herefordfhire, but it is not lefs interefting. About a mile diftant from its eaft bank, on an eminence, ftands St. Briavel's caftle, once of great extent and great ftrength, erected by Miles, earl of Hereford, in the reign of Henry I. Lower down the ftream and on the weft bank is the curious village of Llandogo, difperfed among trees on the fide of a hill. Proceeding down the river by an eafy bending courfe, in the midft of very picturefque fcenery, appear the dilapidated and highly picturefque remains of Tintern abbey, at the opening of a valley on the weft bank. This venerable ruin is apparently inclofed by fteep hills and hanging woods, which are feparated by the broad ftream in the bottom. Paffing much fcenery equally beautiful, the eaft bank of the river prefents a fcreen of rocks, called Thorn and Black Cliffs, to which the tide reaches, and afterwards marfhy lands appear on both fides. Next appear the rocks belonging to the celebrated grounds of Piersfield. Thefe refemble the projecting baftions of a caftle, and powerfully reverberate founds that ftrike againft them. A little lower down is the Lover's Leap, a precipitous rock; and the next fweep of the river brings before the eye the noble remains of the caftle of Chepftow, perched on the fummit of a lofty perpendicular cliff, impending over the weft fide of the river. The fituation of the caftle and the town of Chepftow is peculiarly picturefque. The beauties of the fcene are, in the opinion of Mr. Wyndham, "fo excellent, that the moft exact critic in landfcape would fcarcely wifh to alter a pofition in the affemblage of woods, cliffs, ruins, and water." Chepftow caftle is undoubtedly ancient, and Roman-Britifh bricks are difcovered in the walls; but its foundation can be traced only to Fitzofborne, earl of Hereford, who erected it for the defence of the poffeffions he received from William of Normandy. Notwithftanding the height and rapidity of the tides at Chepftow, a bridge has long been eftablifhed there acrofs the Wye. It was formerly conftructed wholly of timber, but is now made of caft-iron. Although the tide be fenfibly perceived only about Tintern abbey, five miles above Chepftow, yet the water rifes in the river at this town to a very extraordinary height. Formerly not lefs than feventy feet, as it is afferted; but fifty-fix feet is the greateft rife obferved during the laft hundred years. The tide fetting up the Briftol channel from the Atlantic is, by the gradual contraction of its courfe, forced to fwell up in a very uncommon manner; and its progrefs is ftill farther impeded by the advance of the land on the north of the entrance of the Wye, up which river, as well as more directly up the Severn, it rufhes with peculiar force. In defcending the Wye from Chepftow, the high impending rocks have a very ftriking effect. At the conflux with the Severn, three miles below the town, the eftuary of the latter river appears, bounded by the diftant hills of Gloucefterfhire and Somerfetfhire. The general character of the river Wye is thus reprefented by Mr. Coxe: "It is diftinguifhed by its ferpentine courfe, the uniform breadth of its channel, and the fcenery of its banks. In the navigable part from Hereford downwards, the banks for the moft part rife abruptly from the edge of the water, and are clothed with forefts and broken cliffs. In fome places they approach fo near that the river occupies the whole intermediate fpace, and nothing is feen but wood, rock, and water: in others they alternately recede, and the eye catches an occafional glimpfe of hamlets, ruins, and detached buildings, partly feated on the margin of the ftream, and partly fcattered on the rifing grounds. The general character of the fcenery, however, is wildnefs and folitude: and if we except the populous diftrict of Monmouth, no river perhaps flows for fo long a courfe through a well-cultivated country, the banks of which exhibit fo few habitations." Large hoys fitted to navigate the Severn can, with the tide, afcend the Wye to Brookfwear, a populous village midway between Monmouth and Chepftow, where they receive from and transfer into fmall craft the various commodities with which they are loaded. The Wye as well as the Severn furnifhes a confiderable quantity of falmon.—Beauties of England and Wales, North Wales, by the Rev. J. Evans, 8vo. 1810. Ditto, Monmouthfhire, by J. Britton, 1808. Hiftorical Tour in Monmouthfhire, by the Rev. William Coxe, 2 vols. 4to. 1801. Obfervations on the River Wye, by the Rev. William Gilpin, 8vo. 1789.

Wye, a river of England, which runs into the Derwent, near Bakewell.—Alfo, a river of Maryland, which runs into the Chefapeak, N. lat. 38° 54′. W. long. 76° 20′.

WYENOKE, a town of Virginia.

WYERSDALE, Nether, a townfhip in the hundred of Amoundernefs, county palatine of Lancafter, England, is fituated four miles N.N.E. from Garftang, and was ftated in the return of the year 1811 to contain a population of 713 perfons, occupying 145 houfes.

Wyersdale, *Over*, a townfhip in the hundred of Lonfdale South of the Sands, Lancafhire, England, is fituated fix miles N.N.E. from Garftang, and in the year 1811 contained 154 houfes and 802 inhabitants. A colony of Ciftercian monks were for fome time fixed here, but about A.D. 1188 they removed into Ireland, and founded the abbey of Wythney.

Wyersdale *Foreft*. See Lancashire, *Forefts in*.

WYFFLERS, in *Military Language*, fubordinate officers in the Englifh infantry, whofe bufinefs, in the time of queen Elizabeth, appears to have been to drill the men, to inftruct them how to carry their arms, and to arrange them according to their ranks in proper order.

WYFORDBY, or Wyverby, in *Geography*, a fmall parifh in the hundred of Framland, county of Leicefter, England, is fituated three miles E. from Melton Mowbray; and in the population report of 1811 was returned as containing

taining 20 houſes, and 97 inhabitants. It includes the hamlet of Brentingby.

WYGBYGERA, a town of Sweden, in Angermannland; 30 miles N. of Hernoſand.

WYGELN, a high mountain of Norway.

WYHAM, a pariſh in the wapentake of Ludborough, in Lindſey diviſion of the county of Lincoln, England, is ſituated 7 miles N.N.W. from Louth; and was ſtated in the year 1811 to have a population of 87, occupying 10 houſes.

WYHOMICA, or WYHONIEC, a town of Lithuania; 20 miles N.N.E. of Pinſk.

WYK, a town of Sweden, in the province of Smaland; 65 miles N.N.W. of Calmar.

WYKA, a town of Sweden, in Dalecarlia; 14 miles S.E. of Fahlun.

WYKE, anciently denoted a farm, hamlet, or little village.

WYKE, in *Geography*, a tything in the pariſh of Worpleſdon, hundred of Woking, county of Surrey, England, is ſituated 6 miles W. by N. from Guildford, and was returned in the year 1811 as containing 30 houſes, and 125 inhabitants.

WYKE *Regis*, a pariſh in the hundred of the ſame name, in Dorcheſter diviſion of the county of Dorſet, England, is 2 miles W.S.W. from Weymouth. The population in the year 1811 was returned as 570, the number of houſes as 134. The church, which is the mother-church to Melcombe Regis, is a ſpacious building, with a lofty tower, ſerving as a land-mark. From this village there is a ferry to Portland iſle.

WYKE-*Hamon*, a pariſh in the hundred of Cleley, Northamptonſhire, England. The church is in ruins. The population is included with that of the adjoining pariſh of Wykens, or Wyke Dyve.

WYKEHAM, in *Biography*. See WILLIAM *of Wykeham*.

WYKEHAM, or *Wycombe*, in *Geography*, a townſhip in the hundred of Eaſt Goſcote, county of Leiceſter, England; 5 miles N.E. by N. from Melton Mowbray. The population, including the adjoining townſhip of Caldwell, was in 1811 ſtated to be 95, occupying 25 houſes.

WYKEHAM, a townſhip in the eaſt diviſion of the wapentake of Pickering Lythe, North Riding of the county of York, England, is 6 miles S.W. by W. from Scarborough; and in the year 1811 contained 87 houſes, and 511 inhabitants. About the year 1153, Pain Fitz Oſbert built and endowed a priory for Ciſtercian nuns at this place. At the diſſolution there were nine religious perſons in the houſe, with an eſtate of 25*l.* 17*s.* 6*d.* *per annum*. Henry VIII. granted the houſe to Francis Poole.

WYKEHAM, *Eaſt*, is a pariſh in the Wold diviſion of Louth-Eſke hundred, in Lindſey part of Lincolnſhire, England, ſituated 7 miles N.W. by W. from Louth. The church is in ruins. The population was ſtated, in the return of the year 1811, to be 23, the number of houſes 4.

WYKEHAM, *Weſt*, is a pariſh in the eaſt diviſion of the wapentake of Wraggoe, in Lindſey diviſion of Lincolnſhire, England, adjoining to the foregoing. The church is alſo in ruins.

WYKEN, a pariſh in the county of the city of Coventry, Warwickſhire, England, is 3 miles N.E. by E. from the city; and, according to the population return of the year 1811, contained 13 houſes, and 72 inhabitants.

WYKENS, or WYKE-DYVE, a pariſh in the hundred of Cleley, county of Northampton, England, ſituated 7 miles S.E. by S. from Towceſter, and 3 miles W.S.W. from Stony-Stratford, Bucks. This pariſh is united with that of Wyke-Hamon, and in 1811 the joint population was returned as 385, the number of houſes as 57.

WYL. See WEYL.

WYLAM, a townſhip in the pariſh of Ovingham, Tyne-dale-ward, county of Northumberland. In the year 1811 it contained 159 houſes, and 795 inhabitants; 9 miles W. from Newcaſtle.

WYLDE, JOHN, in *Biography*, the author, or rather the compiler of a tract on muſic in the MS. of Waltham Holy Croſs, now in the poſſeſſion of the marquis of Lanſdown, entitled "Muſica Guidonis Monachi." It is the firſt in the volume, but not written by Guido, as the title ſeems to imply, but an explanation of his principles; it is divided into two books, and appears to have been compiled by the præcentor of Waltham abbey, John Wylde, pr. "Quia juxta Sapientiſſimum Salomonem dura eſt." The author does not confine himſelf to the doctrines of Guido, but cites later writers. The baſis of the tract, however, is the Micrologus, and his other writings, in which he treats of the monochord, the ſcale, the harmonic hand, the explanation of which he calls *manual* muſic, eccleſiaſtical tones, ſolmiſation, clefs, with a battle between B flat and B natural, are the ſubjects of the firſt book, conſiſting of twenty-two chapters.

The ſecond book, or diſtinction, contains thirty-one chapters. In the firſt he ſpeaks of a Guido Minor, ſurnamed Augenſis, as a writer on the eccleſiaſtical chant. He had mentioned this author in the ſeventh chapter of the firſt book; but who he was, or when he lived, we are unable to diſcover. It ſeems, however, as if ſome ſuch muſical writer had exiſted, and that his name, by the ignorance or inattention of the ſcribes of ancient MSS., had been confounded with that of Guido d'Arezzo.

In ſeveral of the ſucceeding chapters he treats of intervals and their ſpecies, offering nothing new or ſingular, except where he draws a parallel between the tone and ſemitone, and Leah and Rachel, Jacob's wives, which, it is preſumed, will excite no great curioſity in our readers.

Attention is engaged, however, in the tenth chapter, by a "Cantilena," as the author calls it, of the Great Guido. It is a kind of ſolfeggio, or exerciſe for the voice, through all the intervals, which is only rendered valuable, perhaps, by the ſuppoſition of its having been produced by the celebrated author of the muſical alphabet. See SERRA.

WYLIA, in *Botany*, another new umbelliferous genus of profeſſor Hoffmann's, (ſee WENDIA,) dedicated by its author to Dr. J. Wylie, privy counſellor to the emperor of Ruſſia, inſpector of medicine and ſurgery in the Ruſſian army, &c. &c., author of a *Pharmacopæia Caſtrenſis Ruthena*, in which his highly commendable aim has been to indicate the medical properties, and to fix the names of the native plants of Ruſſia.—Hoffm. Gen. Plant. Umbellif. v. 1. 3. t. 2.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juſſ.

Gen. Ch. *General Involucrum* of one ovato-lanceolate, membranous, half-claſping leaf, fringed with hairs; *partial* of five ovate, nearly entire, concave, two or three-ribbed leaves, bordered with a pellucid fringed membrane. *Perianth* of five minute teeth, permanent. *Cor.* univerſal irregular; flowers of the diſk perfect, fertile, as well as the female ones which form the radius; ſome male flowers are either interſperſed in the diſk, or diſpoſed in ſeparate umbels: *partial* of five petals; unequal in the flowers of the radius, the outermoſt very large, either obovate and flattened,

tened, or inversely heart-shaped, with a long claw; equal in those of the disk. *Stam.* Filaments five, thread-shaped, at first inflexed, and concealed in the hollows of the petals, afterwards prominent; anthers roundish. *Pist.* Germen ovate-oblong, more or less tapering; styles erect, thread-shaped, nearly equal, standing on a cup-shaped base; stigmas simple. *Peric.* Fruit linear-oblong, beaked, somewhat compressed, crowned with the erect, permanent styles, and their cup-like, slightly notched basis. *Seeds* two, linear-oblong, hispid, striated, the ribs elevated, continued into the beak with intermediate furrows; valves of the beak parallel to the fruit.

Eff. Ch. General and partial involucral leaves ovate. Flowers polygamous, radiant. Calyx five-toothed. *Fruit* oblong, somewhat compressed, beaked; valves of the beak parallel to the fruit.

Obs. The chief differences which have led professor Hoffmann to separate this genus from SCANDIX, (see that article,) appear to be the nearly entire leaves of the partial *involucrum*, which are laciniated in *Scandix;* the radiant *corolla*, and, as he says, the valves of the beak being parallel, not contrary to the fruit; that is, as we presume, compressed in a contrary direction in one genus to what they are in the other. For this we rely on the learned and judicious author not having materials sufficient to verify his observation. We must remark, that the *involucral leaves* in *Wylia*, though not laciniated, have a notch or two at the end, and precisely accord in texture with those of *Scandix*. Many of the umbels in this genus are simple, or occasionally two or three together, resembling a compound umbel.

1. W. *australis*. Southern Wylia. Hoffm. n. 1. t. 2. f. 1. (Scandix australis; Linn. Sp. Pl. 369. Sm. Fl. Græc. Sibth. t. 285, unpubl. See SCANDIX n. 6.)—Umbels simple, or in pairs, of few flowers. Radiant petals obovate, nearly entire. Beak of the fruit almost straight.—Native of fields in Italy and the Levant, as well as in Tauria, about Sudak, flowering in May. *Root* annual. *Herb* slender. *Stem* round, sometimes quite smooth, sometimes more or less hairy. *Leaves* triply pinnate, with linear acute segments, and hairy, or rather fringed *footstalks*. *Umbels* small and dense, on long stalks; the lower ones opposite to the leaves, solitary and simple; upper in pairs, rarely three together, and even in that case not constituting a real compound umbel, as an examination of specimens will readily shew. *Flowers* white, moderately radiant. Largest *petals* sometimes slightly emarginate. *Fruits* from six to ten perfected in each umbel, their beaks nearly or quite straight, quadrangular, rough with short erect bristles.

2. W. *radians*. Radiating Wylia. Hoffm. n. 2. t. 2. f. 2. (Scandix australis β; Marsch. Taur.-Caucas. v. 1. 424. S. falcata; Londes Journ. de la Soc. des Natural. de Moscou, for 1806, 57. t. 5.)—Umbels aggregate, from two to five, many-flowered. Radiant petals elongated, wavy. Beak of the fruit incurved.—Frequent in Tauria, flowering in May. This is considered by the authors who have described it as about equally related to the foregoing and to the *grandiflora*. We have no other guide than a beautiful engraving, copied by Hoffmann from the figure above cited, with the addition of the magnified and dissected fructification. By this it appears that the partial *umbels* are rather more numerously assembled, making more apparently compound *umbels*. The *flowers* are more conspicuously radiant. *Fruits* more numerous in each *umbel*, from twelve to twenty, with strongly incurved rough beaks. We confess ourselves unable to determine these two species clearly by the specific differences of professor Hoffmann, which we subjoin for the satisfaction of our readers.

W. *australis*, caule petiolis umbellisque hirsutis, corollis petalisque radiantibus obovatis integris.

W. *radians*, caule petiolisque pilosis, umbellis glabris, corollis petalis fructibusque radiantibus.

The hairiness is evidently variable, and the other characters, perhaps from some typographical error, do not contrast with each other.

3. W. *grandiflora*. Large-flowered Wylia. Hoffm. n. 3. t. 2. f. 3. (Scandix grandiflora; Linn. Sp. Pl. 369; see SCANDIX n. 10. Marsch. Taur.-Caucas. v. 1. 230.)—General umbels of from three to five very hairy rays. Radiant petals slightly emarginate.—Native of fields in Tartary and Georgia, flowering in May and June. Having discovered a specimen of this in our collection since the article SCANDIX was written, we are enabled to compare it with the descriptions of authors, and to select the following particulars:—The *root* is annual, tapering. *Stem* about a foot high, round, purplish, slightly branched, quite smooth in our specimen; Hoffmann says clothed with long hairs. *Leaves* much like the last; their *footstalks* somewhat hairy. *Umbels* terminal; the *general* ones sometimes on short stalks, each composed of from three to five long, slender, coarsely and abundantly hairy rays, with a leafy, simple or divided, linear leaf, in the place of a general involucrum. *Partial umbels* of numerous short smooth rays; their *involucrum* of several, mostly double-pointed, ovate, white-edged, fringed leaves. *Flowers* remarkably radiant; their largest *petals* obovate, not always emarginate, each furnished with a long claw. Beak of the *fruit* rather scaly, as Hoffmann delineates it, than hairy. His figures, in this and the other species, except *radians*, exhibit the parts of fructification only.

4. W. *iberica*. Georgian Wylia. Hoffm. n. 4. t. 2. f. 4. (Scandix iberica; Marsch. Taur.-Caucas. v. 1. 425. S. falcata; ibid. 230, excluding the synonym.)—General umbels of four or five very smooth rays. Radiant petals emarginate, with an inflexed point. Stem somewhat hairy at one side.—Native of Georgia. Annual. Very nearly related to the last in habit and size. The *stem* is, as in that, sometimes quite smooth. The rays of both general and partial *umbels* are said to be always very smooth. Radiant *petals* of a smaller proportion, and, as it seems to us, essentially distinguished by their sharp inflexed points. The beak of the *fruit* is described as marked with two hairy lines, and not hairy in every direction. We have seen no specimen.

WYLSTER, in *Geography*. See WILSTER.

WYMERING, a parish in the hundred of Portsdown, Hampshire, England, returned in the year 1811 as containing 121 houses, and 740 inhabitants; 4 miles W. from Havant.

WYMINGTON, or WIMMINGTON, a parish in the hundred of Willey, county of Bedford, England, is situated 12 miles N.W. by N. from the county town, and about 3 miles from Higham Ferrers, Northamptonshire. Wymington church, a fine structure, was built by John Curteys, then lord of the manor, and mayor of the staple at Calais, who died in 1391, as appears from an inscription on his tomb. The brasses of himself and his wife are on a slab of black marble under canopies, and are well preserved. The population of the parish, in the return of 1811, was stated to be 235, the number of houses 40.

WYMOA BAY, a bay on the S. coast of Atooi, one of the Sandwich islands. N. lat. 21° 57′. E. long. 200° 20′.

WYMONDHAM, or WINDHAM, a market-town in the hundred

hundred of Forehoe, and county of Norfolk, England, is ſituated 9 miles W.S.W. from Norwich, on the great road to London, from which it is diſtant 100 miles N.E. by E. This place has been ſuppoſed to be of Roman origin; and ſome writers have conſidered it as the Sitomagus of the Itinerary, though there are not the ſmalleſt traces to ſupport that opinion. The name is purely Saxon; and the conſequence of the town aroſe from the erection of a monaſtery here in the time of Henry I. A.D. 1130, by William de Albini, who amply endowed it with lands, which were confirmed with additions and privileges annexed by the reigning monarch. From the regiſter of St. Alban's, this religious houſe appears to have been originally founded as a cell for black monks of the Auguſtine order; and its annual revenues at the diſſolution amounted, according to Dugdale, to 211*l.* 16*s.* 6*d.* By the inquiſition made at that period, the monaſtery was found in a regular ſtate; and the abbot and monks in general were declared to have led blameleſs lives. The abbey-church was a large, handſome, cruciform building, erected ſoon after the year 1130. It conſiſted of a choir, nave, tranſept, north and ſouth aiſles, with a tower ſtanding in the centre, ſtill called the abbey-ſteeple, and another at the weſt end. When the monaſtery was deſtroyed, the ſouth aiſle, over which were lodgings for ſupernumerary monks, was demoliſhed: but the king granted the inhabitants leave to build another. Anxious to preſerve their noble church, they alſo obtained the following parts, which had been condemned by the act for removing ſuperſtitious buildings:—The abbey, ſteeple, veſtry, monks' lodgings over the ſouth aiſle, St. Margaret's chapel, the chapel of the Bleſſed Virgin, the chapel of St. Thomas à Becket, and the choir. Theſe were granted on condition that the inhabitants paid the king for the *lead* at the rate of 4*l. per* fodder, of twenty-four ſquare feet.

The preſent church conſiſts of a nave with aiſles, a large weſtern tower, and another at the interſection of the nave with the tranſepts. The ancient parts of the building diſplay ſemicircular arches with ſhort columns, large piers, &c. which appear to be parts of the original ſtructure. At the eaſt end, and on the ſouth ſide of the porch, are ſome fragments of walls. The north aiſle, porch, and towers, are of a much later ſtyle than the nave and ſouth aiſle. The church is curious, and highly intereſting to the architectural antiquary and draughtſman. In it is a large font, ornamented with bold ſculpture, and raiſed on ſteps. The remains of the founder were interred in the choir in 1156. The families of Albini, earls of Arundel, of Knevet, and of Clifton, are depoſited in this church. Several guilds were founded here, the revenues of which have been appropriated to other purpoſes. Wymondham pariſh is extenſive, and comprehends ſeveral hamlets, which are called the outſoken diviſion, whilſt the town is divided into ſeveral parts called the inſoken diviſion. Many of the inhabitants are employed in various branches of weaving. The diſtinguiſhed family of Wyndham, or Windham, derives its name from this place.

North of the town is Kimberly-hall, the ſeat of lord Wodehouſe. The houſe is ſeated in an extenſive and beautiful park, which contains a fine piece of water, and ſome noble maſſes of foreſt-trees. In the houſe is a portrait of Vandyck, by himſelf, when a young man.—Blomefield's Hiſtory, &c. of Norfolk, 11 vols. 8vo. Beauties of England, Norfolk; by J. Britton, 8vo. 1809.

Wymondham, a pariſh in the hundred of Framland, county of Leiceſter, England, ſituated 6 miles E. from Melton Mowbray, and 104 miles N.N.W. from London. It is very ancient, and was formerly ſurrounded with walls: the inhabitants ſtill poſſeſs an exemption originally granted to the duchy of Lancaſter. In the return of the year 1811, the population was ſtated to be 437, occupying 81 houſes.

WYMONDLEY, or Wymondesley, *Great*, a pariſh in the hundred of Brinkwater, county of Hertford, England, ſituated within three miles E.S.E. from Hitchin. The manor was given by William the Conqueror to a noble Norman, named Fitz-beck, by the ſervice of grand ſergeantry; that the lords of the ſaid manor ſhould preſent to the kings of England the firſt cup of drink at dinner on the day of their coronation: the cup becoming the property of the ſaid lords. This ſervice has continued with the manor: lieutenant-colonel Cracherood performed the office of cupbearer at the coronation of George III. The population of the pariſh was, in the return of 1811, ſtated to be 212, and the number of houſes 46.—Beauties of England and Wales, vol. vii. Hertfordſhire, by E. W. Brayley.

Wymondley, or *Wymondeſley*, *Little*, is alſo a pariſh in the ſame hundred, adjoining to Great Wymondley, and containing, in the year 1811, 34 houſes, and 188 inhabitants. A priory of Auſtin canons was founded here by Richard de Auguſtine, in the time of Henry III.: the ſcite was granted to James Needham, gent., clerk of the king's works, in whoſe deſcendants it continued till the death of George Needham, eſq. in 1726. It was then ſold to Samuel Vanderplank, eſq., and was lately the property of Chriſtopher Clitherowlſy, who married Mr. Vanderplank's granddaughter.

Wymondley-houſe, in this vicinity, formerly the reſidence of a private gentleman, is now an academy for the education of Proteſtant Diſſenting miniſters. This inſtitution originated at Northampton in 1729, by the endowment of William Coward, eſq. a Weſt India merchant. The celebrated Dr. Doddridge was the firſt tutor, which office he held twenty-two years. In 1752 the academy was removed to Daventry, and thence back to Northampton; and finally in 1799 to this place, having been previouſly united with an academy in London, under the ſucceſſive tuition of Mr. Eames, F.R.S., Dr. Jennings, Dr. Savage, Dr. Kippis, and Dr. Rees, ſupported by the ſame fund, and unfortunately for the intereſts of literature and ſcience diſcontinued. The library contains a valuable aſſemblage of upwards of 10,000 volumes of the beſt authors in divinity, criticiſm, claſſics, mathematics, topographical antiquities, &c. with a cabinet of medals, a collection of natural hiſtory, and other curioſities. This valuable library conſiſts principally of a rich collection of books, bequeathed by the late Rev. Mr. Miles, F.R.S., and appropriated to the London Academy, and augmented by numerous purchaſes.—Beauties of England and Wales, vol. vii. by E. W. Brayley. And Private Information.

WYNANTS, John, in *Biography*, an able and eminent landſcape-painter, born at Haerlem in 1600. Whether he were his own inſtructor or not does not appear, or how he qualified himſelf to attain that ſtation among the artiſts of his country which he ſo juſtly holds. His pictures are taken from the ſimple ſcenes of nature which ſurrounded his birth-place, and which he has repreſented with great vivacity and reality, though they ſometimes are overcharged in their contraſts of colouring. A ſandy bank, with broken patches of graſs and plants, with ſtunted trees beſide it, and a winding road paſſing over the bank, preſents from his pencil an agreeable and intereſting effect. Sometimes we find the entrance of a wood, with a cottage or hovel beſide

beside it, treated by him with great attention to the varied effect of colour in nature, and a dexterous management of chiaro-oscuro; and always with the most free and skilful touch, though generally upon a small scale. As he painted with facility, his works are not rare, though they bear a good price when in perfect preservation. Wynants established an academy, which produced many excellent painters. Among others of great celebrity, were Adrian Vandevelde and Philip Wouvermans, both of whom occasionally embellished their master's pictures with figures. He died in 1670, aged 70. He left numerous beautiful etchings of landscapes.

WYNNE, *Mrs.* CASSANDRA FREDERICA, the finest harpsichord player of her time. She was the daughter of signora Pompeati, the second female singer in Gluck's opera of "La Caduta de Giganti," performed in 1746, on the suppression of the rebellion; but though she nominally performed the part of second woman, she acted and sung in so masculine and violent a manner, that no female symptoms were discoverable. But this lady was better known afterwards by the name of Madame Cornellys, whose concerts, ridottas, assemblies, and masquerades, in Soho-square, were the gaiest and most fashionable amusements in London during many years.

The little Frederica, daughter of the Pompeati, was an élève of Paradie's, (some say his daughter,) and the first early player, the neatest, and the best which had ever appeared in our country during infancy, performing at six years old, with the utmost precision and firmness, propped up by cushions, the whole book of her master's twelve excellent lessons, probably composed expressly as progressive exercises for her use, with many lessons by Scarlatti and Alberti.

In 1769, when grown up, she went into Italy, where she was the wonder and subject of eloge in that mother and seat of arts. We have often heard her perform at different periods of her life, and continued to think her improved to the last.

WYNNE, ———, esq., a Yorkshire gentleman, one of the best dilettanti performers on the violin that we have heard. He was a man of fortune, and of an ancient family. To gratify his passion for music, he went into Italy early in life, where he married, and remained in different great cities till he had almost totally forgotten his mother-tongue. He likewise travelled through Germany, and having two daughters, he had always a music-master on his establishment, not only to instruct them, but to accompany himself. When he was last in England, he had Pfeifer with him for these purposes, a worthy German, and an excellent musician and performer on several instruments, who died in London of a consumption.

Besides being a good performer on the violin, Mr. Wynne had studied composition sufficiently to compose trios, which were far above the common run of trios at that time in point of taste and invention, and well put together.

WYNSBACH, in *Geography*, a town of Austria; 4 miles E. of Schwannastatt.

WYNSTER. See WINSTER.

WYOMING, a settlement and fort on the river Susquehanna. In the year 1778, this fort was attacked by a party of British and Indians. The garrison were soon overpowered, and fell a prey to Indian barbarity; after a bloody military execution of a great part, the rest were shut up in the barracks, to which they set fire, and consumed the whole; 2 miles above Wilkesbarre.

WYONOKE CREEK, a river of North Carolina, which runs into the sea, N. lat. 36° 30′.

WYRARDSBURY, or WRAYSBURY, a parish in the hundred of Stoke, and county of Buckingham, England, is situated near the banks of the Thames, 3 miles S.W. from Colnebrooke, and 3 miles N.W. from Staines, Middlesex. The manor belonged to the priory of Ankerwyke, in the same parish, which was founded in the reign of Henry II. for Benedictine nuns by Gilbert de Montfichet and his son Richard. In 1538 the priory was given to Bisham abbey, and after the dissolution it was granted to lord Windsor. Having afterwards reverted to the crown in exchange, it was given by Edward VI. in 1540 to sir Thomas Smith, the celebrated statesman, who resided at Ankerwyke. It was afterwards for many years the seat of the Salter family, of whom it was purchased by the Lees; and by marriage with an heiress came into the possession of sir Philip Harcourt, ancestor of the present proprietor, John Simon Harcourt, esq. There are no remains of the conventual buildings. Soon after the dissolution a mansion was built on the scite by lord Windsor, or sir Thomas Smith: the hall of this mansion still remains. Near the house is a remarkably large yew-tree, which at six feet from the ground measures thirty feet five inches in girth. In the parish-church are monuments of the Harcourt family; and also of Thomas Wright, esq. and Thomas Gill, esq. aldermen of London, who died within a fortnight of each other in the year 1798. The population return of the year 1811 states this parish to contain 120 houses, and 560 inhabitants. The parish was inclosed by an act of parliament passed in the year 1799: a parcel of the waste was allotted for the purpose of holding a fair on the Friday in Whitsun week, pursuant to ancient custom.—Lysons's Magna Britannia, vol. i. Buckinghamshire.

WYRE, a river of Lancashire, which runs into the Irish sea, 9 miles W. of Garstang. N. lat. 53° 53′. W. long. 2° 56′.—Also, a river of France, which joins the Semoy, 3 miles E. of Chiny.

WYRIL POINT, a cape of England, on the coast of Durham. N. lat. 55° 3′.

WYSAUKING CREEK, a river of Pennsylvania, which runs into the E. branch of the Susquehanna, N. lat. 41° 46′. W. long. 76° 27′.

WYSOCKS, a township of Pennsylvania, in the county of Luzerne, containing 619 inhabitants.

WYSOKIE, a town of Lithuania, in the palatinate of Brzesk; 16 miles N. of Brzesk.

WYSTIEZE, a town of Lithuania, in the palatinate of Brzesk; 8 miles N.E. of Brzesk.

WYSZOCK, a town of Lithuania, in the palatinate of Brzesk; 44 miles S.E. of Pinsk.

WYTA, or WITA *Plena*, signified a forfeiture of a hundred and twenty shillings. "Si pundbreche fiat in curia regis, plena wita sit; alibi, quinque marcæ."

To swear according to the wyte, *secundum witam jurare*, was to purge one's self by the oaths of so many witnesses, as the nature of the crime, and the punishment, or wyte, did require.

Hence, also, *bloodwite*, *legerwite*, *ferdwite*, *childwite*, *wardwite*, &c. See FERD-*Wite*, CHILD-*Wite*, &c.

WYTE, WYTA, or WITE, WITA, in our *Ancient Customs*, a pecuniary penalty, or mulct.

"Jurat secundum witam, quod nec fuerat furti conscius, nec coadjutor in eo." Leg. Inæ.

The Saxons had two kinds of punishments, *were* and *wyte*; the first for the more grievous offences.

The

The *wyte* was for the lefs heinous ones. It was not fixed to any certain fum; but left at liberty, to be varied according to the cafe.

Hence alfo *wyte*, or *wittree*, one of the terms of privilege granted our fportfmen; fignifying a freedom or immunity from fines or amerciaments: or, as it is vulgarly conceived, from being liable to be begged for fools, for lack of wit.

WYTHE, in *Law*, the fame as waif.

WYTHE, in *Geography*, a county of Virginia, between the river Kanhawa and North Carolina, with 8356 inhabitants, including 1157 flaves.

WYTHERS. See WITHERS.

WYTOOTACKEE, in *Geography*, an ifland in the South Pacific ocean, about 10 miles in circumference; difcovered by captain Bligh in 1789. S. lat. 18° 52′. E. long. 200° 19′.

WZETIN. See USETIN.
