CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

X

X

X, A double consonant, and the twenty-second letter in the English alphabet; which, however, begins no English word.

The *x* of the Latins, and ξ of the Greeks, are compounded of *c s*, and $\kappa \sigma$; whence, to this day, the letter *x* in the English and French has the same sound with *c s*, or *k s*. Thus we pronounce *Alexander* exactly as if written *Alecxander* or *Aleksxander*.

The Italians have no *x* at all in their language, but both speak and write *Alessandro*. The Spaniards pronounce the *x* like our *c* before *a*; viz. *Alexandra*, as if it were *Alecandro*. The Portuguese pronounce it like *ss*.

In foreign words, used in English, we sometimes soften the *x* into a double *s*; as *Brussels*, for *Bruxellers*, &c.

The letter is not known in the Hebrew, or other oriental languages; but in lieu of it, they write the two simple letters of which it is compounded. And the like do the modern Germans.

Peter Diaconus relates, that the letter X was introduced into the Roman alphabet in the time of Augustus; and that, before his reign, the Romans supplied the want of it by the letters C and S. But Mr. Asle observes, that this is a mistake; the letter X being found in the Duilean pillar, inscribed in the year of Rome 494, and 259 before Christ. *Origin and Progress of Writing*, p. 78.

X is also a numeral letter, and signifies ten; as represent- ing two V's placed one at top of the other. See V.

X *Supra denos numero tibi dat retinendos.*

When laid flat, thus X, it signifies a thousand; and when a dash is added over it, X̄, it signifies ten thousand. I before X denotes the subtraction, and after X the addition of unit: thus, IX = 9, and XI = 11. X before L or C

VOL. XXXIX.

denotes the subtraction of 10 from 50, or 100: thus, XL = 40, and XC = 90.

X on the French coins denotes those struck at Amiens.

We often meet with the Greek letters X and P joined in this manner X̄ on ancient medals. The first we find are on some large brats coins of the Ptolemies, kings of Egypt, where it was placed on a civil account.

Some writers have taken it for a date, and others for the initial letters of a proper name; but as no reasons are assigned for either of those conjectures, Mr. Ward rather supposes it an abbreviation of the word $\chi\rho\eta\mu\alpha$, *money*, impressed on those pieces, to denote their currency as money; which might be thought proper, as they have not the heads of kings stamped upon them, like their silver and gold coins; but always that of a Jupiter on the front, and an eagle perched on a thunderbolt on the reverse.

This character was afterwards applied to a very different purpose by Constantine the Great, who made use of it to denote $\chi\rho\iota\sigma\tau\omicron\varsigma$, both in his coins and military ensigns; in which he was followed not only by some succeeding emperors, but also by private persons, who out of devotion put it on their lamps and other utensils.

It afterwards came to be used merely as a critical note, to point out remarkable passages in manuscripts; and then it stood for the initials of $\chi\rho\eta\sigma\tau\iota\mu\omicron\varsigma$, *useful*; as we learn from Isidore, Orig. lib. i. cap. 20. See Phil. Trans. N^o 474. sect. 1.

X, with a P, or Greek R, in the middle of it, is also the monogram of the name of CHRIST, which constantly occurs in the catacombs or burial-places of the ancient Christians, and which was the chief ornament of the Labarum or military standard of Constantine, and the succeeding emperors. See LABARUM.

B

XABEA,

XABEA, in *Geography*, a sea-port of Spain, in the province of Valencia, near the coast of the Mediterranean; 38 miles N.N.E. of Alicante.

XABOLECTORA, in *Ancient Geography*, a name given by P. Mela to Aborras, a river of Mesopotamia.

XACA, in *Geography*. See JACA.

XACRE, a cape on the fourth-east coast of the island of Candia; 18 miles S.E. of Setia.

XAGUA BAY, a large bay on the south coast of the island of Cuba. This is one of the best ports in the West Indies, and is 15 miles in circumference, surrounded with mountains, which break off the force of the winds. N. lat. 22° 10'. W. long. 81° 20'.

XAINTES, SANTOS, or *All-Saints' Islands*, as having been discovered on that holiday by the Spaniards; three small islands in the West Indies, situated to the fourth-east of Guadeloupe. The most westerly of them is called Terra de Bas, or the Low island, and the most easterly, Terra de Haut, or the High island. The third, which lies exactly in the middle between the other two, seems to be nothing more than a large barren rock, but is of use in assisting to form a very good harbour. The island of Terra de Bas is about nine miles in circumference, but the other is larger. These islands have constantly a fresh breeze, let the wind blow from what quarter it may; and on the Terra de Bas is a neat wooden church, with two very convenient creeks both for anchorage and landing. They are about six miles distant from Guadeloupe, and 15 from Mariegalante. N. lat. 15° 56'. W. long. 61° 32'.

XALAPA, a considerable town of Mexico, or New Spain, in the fertile province of Tlascala, formerly famous for the fair held on the arrival of the stated fleets from Europe; and since the declared freedom of commerce, a considerable mart for European commodities. It is situated on the southern skirts of a mountain, in a beautiful climate, the soil being partly clay and partly stony, while pure waters issue from a white sand, and fertilize the country. The population consists of 243 Spanish families, 182 Mexizos, and 361 Indians. When north winds prevail at Vera Cruz, it always rains at Xalapa; but the climate is esteemed very healthy. The purging powder of the country is made of the root of a plant, to which the town gives the name of Jalap; 30 miles E. of Puebla de los Angeles. N. lat. 19° 50'. W. long. 98° 26'.

XALISCO, a province of Mexico, in the audience of Guadalajara. It is washed by the South Pacific ocean on the fourth and west; bounded on the east by Guadalajara Proper and Mechoacan; and separated from Chiamaletan on the north, by a narrow strip of land belonging to Guadalajara, and running out into the sea. It is not above fifty leagues in extent either way. It abounds with Indian wheat and silver mines, but has very few cattle of any sort. From this province is brought the oil of the infernal fig-tree, as the Spaniards call it, much used in medicine.

XALISCO, a town of Mexico, which gives name to a province; 9 miles N.W. of Compostella Nueva. N. lat. 21° 25'. W. long. 106° 26'.

XALON, a river of Spain, which rises in a mountain near Medina Celi, and runs into the Ebro, about six miles above Saragossa.

XAMACA, a river of America, which runs into the gulf of Mexico, 18 miles from Vera Cruz.

XAMBRINA, a town of Spain, in the province of Leon; 2 miles S.E. of Tordeillas.

XAMDELLILAH, an Arabian term, used as a grace or thanksgiving after meat.

The greatest men of that nation will often call in the

meanest, even the beggars, to eat with them; who, as soon as they have done, always rise and pronounce this word, which signifies, God be praised. Pococke's Egypt, p. 183.

XAMI, a name given by some of the old writers to the *aceration* of the Greeks, or carob-tree. See CHARNUB.

XAN, in *Geography*, a river of the principality of Georgia, which runs into the Kur, 6 miles E. of Gory.

XANGA, a river of Africa, in the kingdom of Monogallo, which runs into the Indian sea, opposite to the island of the same name.—Also, one of the Querimba islands in the Indian sea, near the coast of Africa. S. lat. 10° 45'.

XANILA, a town of Fezzan, in the road to Egypt; 140 miles E.N.E. of Mourzouk.

XANQUE, or GUYAPO, a river of Mexico, which runs into the Spanish Maine, 30 miles W. of Cape Camaron.

XANTEN, or SANTEN, a town of France, in the department of the Roer, near the Rhine; 7 miles N.E. of Guelndres.

XANTHE, in *Botany*, so called from *ξανθος*, yellow, in allusion to its yellow juice.—Schreb. Gen. 710. Willd. Sp. Pl. v. 4. 877. Mart. Mill. Dict. v. 4. (Quapoya; Aubl. Guian. 897. Juss. 256. Lamarck Dict. v. 6. 21. Illustr. t. 831.)—Class and order, *Dioecia Monadelphia*. Nat. Ord. *Guttifera*, Juss.

Gen. Ch. Male. Cal. Perianth of one leaf, in five or six small, deep, imbricated, roundish, concave, acute segments, with a pair of minute opposite scales at the base. Cor. Petals five, roundish, spreading, larger than the calyx. Stam. Filament one, columnar, erect; anthers five, two-lobed, forming a peltate concave disk, full of gluten, their under side burling, and discharging the pollen.

Female. Cal. like that of the male, permanent, inferior. Cor. as in the male. Stam. Filament none; anthers five, prismatic, erect, imperfect. Pist. Germs superior, roundish, with five furrows; style none; stigmas five, roundish, emarginate, seated on the germs. Peric. Capsule small, globose or oval, with five furrows, five cells, and five valves, burling at the furrows, their membranous partitions adhering to the central column. Seeds numerous, oblong, imbedded in the pulp, inserted in a double row upon the five-angled columnar receptacle.

Obs. It appears that one-fifth is frequently added to the parts of fructification, in the male as well as female flowers.

Eff. Ch. Male. Calyx in five deep segments. Petals five. Filament columnar. Anthers five, two-lobed, forming a peltate disk.

Female. Calyx and Corolla like the male. Stigmas five, sessile. Capsule of five cells, with many pulp seeds.

1. *X. scandens*. Twining Xanthe. Willd. n. 1. (Quapoya scandens; Aubl. Guian. 898. t. 343.)—Leaves obovate, fleshy. Capsule globose.—Native of the forests of Guiana, flowering in November. The stem is shrubby, with knotty branches, twining round neighbouring trees. Leaves opposite, on short stalks, simple, entire, thick, and smooth, three or four inches long, with a thick mid-rib, and a short blunt point, but no branching veins. Panicles at the ends of the drooping branches, compound, three-forked, smooth. Flowers small, yellow; their partial stalks longer than the calyx. Petals fleshy. Capsule about the size of a black currant, fleshy, crowned with the black stigmas all meeting in a point. Seeds red. Every part of the plant, when wounded, discharges a transparent, white, viscid, resinous juice. The Indians call this species *Quapoy*. See QUAPOYA.

2. *X. parviflora*. Small-flowered Xanthe. Willd. n. 2. (Quapoya Pana-panari; Aubl. Guian. 900. t. 344.)—Leaves elliptic-oblong. Flowers nearly sessile. Capsule elliptical.—Native of the same country. Differs from the preceding in having thinner leaves; smaller flowers, with shorter partial stalks; and an oblong, thicker, yellowish fruit. The bark and leaves, if cut or broken, discharge a yellow glutinous juice, which, when dried, resembles Gamboge, and is, like that substance, soluble in water. *Aubl.*

XANTHICA, *Ξανθικα*, in *Antiquity*, a Macedonian festival, so called because it was observed in the month Xanthus, at which time the whole royal family with the army was purified. See LUSTRATION.

XANTHIUM, in *Botany*, most unquestionably the *Ξανθιον* of Dioscorides, book 4. chap. 138, as appears by his very apt description, owes its name to the use made of unripe fruit by the Greeks, to dye the hair yellow. Our common English species, *X. strumarium*, is evidently the identical plant of Dioscorides, and its specific name alludes to a reputed virtue of curing tumours.—Linn. Gen. 487. Schreb. 635. Willd. Sp. Pl. v. 4. 373. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1017. Prodr. Fl. Græc. Sibth. v. 2. 234. Ait. Hort. Kew. v. 5. 268. Pursh 581. Juss. 191. Tourn. t. 252. Lamarck Illust. t. 765. Gært. t. 164.—Clafs and order, *Monocia Pentandria*. Nat. Ord. *Compositæ nucamentacæ*, Linn. *Corymbifera anomala*, Juss.

Gen. Ch. Male flowers compound. Common Calyx of many imbricated, slender, equal scales, as long as the numerous florets. Cor. compound, uniform, equal, hemispherical, consisting of numerous, tubular, funnel-shaped, monopetalous, upright, five-cleft florets. Stam. Filaments in each flower five, united into a cylinder; anthers erect, parallel, distinct. Common Receptacle small, with chaffy scales between the florets.

Female flowers below the male, on the same plant, doubled. Cal. involucrium two-flowered, of two opposite, acutely three-lobed leaves, (their middle lobe longest,) beset with hooked prickles, and closely enfolding, as well as united to, the germens, except the lobes, which are free. Cor. none. Pisl. Germen oval, bifid; styles two pair, capillary; stigmas simple. Peric. Drupa dry, ovate-oblong, cloven at the point, clothed all over with hooked prickles. Seed. Nut of two cells.

Eff. Ch. Male, Common Calyx imbricated. Florets of one petal, funnel-shaped, five-cleft. Receptacle chaffy.

Female, Calyx two-leaved, two-flowered. Corolla none. Drupa dry, muricated, cloven. Nut of two cells.

Obs. Linnæus remarks, that the fruit of *Xanthium* could scarcely have been well understood, without a previous knowledge of that of *Ambrosia*. These genera in fact belong to that ambiguous tribe, whose habit, qualities, and in part the structure of their male flowers, all associate them with the compound or syngeneisous order; while the disunion of their flowers, and the general nature of their female flowers, and fruit, necessarily refer them to the *Diclines*, or in the artificial system of Linnæus, the class *Monocia*.

1. *X. Strumarium*. Common Burweed, or Small Burdock. Linn. Sp. Pl. 1400. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 2544. Fl. Dan. t. 970. Bigelow Bot. 221. (*Xanthium*; Fuch's Hist. 579. Camer. Epit. 926. *X. seu Lappa minor*; Matth. Valgr. v. 2. 545. *Bardana minor*; Ger. Em. 809.)—Stem without thorns. Leaves heart-shaped; three-ribbed at the base.—Native of dung-hills, and rich moist ground, in various countries of Europe, as well as North America, flowering

towards autumn. In this island it is of very rare occurrence, though occasionally met with about London, and in the west. Dr. Sibthorp noticed the plant in many parts of Greece, where the soil is rich and rather wet, and found it called, by the modern Greeks, *καλλιτρούρα*; a name alluding to its bur-like property, rather than to the quality on which its ancient appellation is founded. The root is annual. Herb branched, rough, dark green, rather fetid, of a coarse rank habit, with furrowed, rather hairy, branches. Leaves alternate, stalked, heart-shaped, acutely lobed, and toothed or serrated; their two lateral ribs marginal, for a small space, at the base, as in the great Burdock, *Arctium Lappa*, and a few other plants. Male flowers globular, green, few together, in axillary or terminal clusters, about the upper part of the branches; female in axillary sessile tufts. Fruit elliptical, double-pointed, hard, near an inch long, beset with firm, prominent, awl-shaped, hooked prickles, which attach themselves to the coats of animals, and thus serve to disperse the seeds.

2. *X. orientale*. Oriental Burweed. Linn. Sp. Pl. 1400. Willd. n. 2. Ait. n. 2? Linn. Fil. Dec. 33. t. 17. "Schkuhr Handb. v. 3. 239. t. 291."—Stem without thorns. Leaves ovate, slightly three-lobed, somewhat triple-ribbed; wedge-shaped at the base.—Native of Ceylon, Japan, and China, from which last country it was imported, according to the younger Linnæus, with other seeds for the Upsal garden, in 1761. Sir Hans Sloane is recorded by Ray as having introduced this *Xanthium* into England in 1685; but their plant seems to have been a slight variety of the first, figured by Morison, sect. 15. t. 2. f. 2, found in America, and not answering to the distinctive characters of the present species, though Morison, and others who speak of this variety, are cited by Linnæus and Willdenow. The true *X. orientale* is an annual herb, of a more slender habit than the *Strumarium*, and more harsh, though less hairy. Their essential differences are indicated in our specific characters. The most remarkable seems to be the taper base of the leaves, in the present species, and the union of their three ribs, at a greater or less distance, above the insertion of the footstalk. The fruit is twice as large as the foregoing, with peculiarly strongly hooked thorns.

3. *X. echinatum*. Compound-thorned Burweed. "Murray in Comm. Goett. for 1784, with a figure." Willd. n. 3.—"Stem without thorns. Fruit oval; its prickles hooked, crowded, compound at the base." Annual.—Its native country unknown. *Willdenow*. We have not seen either a specimen or figure.

4. *X. spinosum*. Spinous Burweed. Linn. Sp. Pl. 1400. Willd. n. 4. Ait. n. 3. (*X. spinosum*, *atriplicis folio*; Morif. sect. 15. t. 2. f. 3. *X. lufitanicum spinosum*; Herm. Parad. 246, with a figure. *Volkam. Norib. 404*, with a figure. *X. lufitanicum*, *laciniatum*, *validissimis aculeis munitum*; Magnol. Hort. 208. t. 20.)—Stipulas thorny, three-cleft. Leaves lanceolate, three-lobed; hoary beneath.—Native of the south of France, as well as of Italy, Spain, and Portugal. It might be raised here as a tender annual, and planted out in a border, were there sufficient beauty in its copious, long, flame-coloured thorns, to entitle it to a place in the flower-garden. The leaves are not inelegant. Their upper surface is of a fine green, nearly smooth; the lower downy and white. The thorns are in fact stipulas, an inch long, very sharp, standing in pairs at the base of each footstalk, separating just above their origin into three spreading needle-like points. Flowers small and inconsiderable. Fruit oval, covered with

copious, small, hooked prickles. The wild plant makes a conspicuous appearance in winter, on banks about Montpellier.

For *X. fruticosum*, Linn. Suppl. 418, see FRANSERIA.

XANTHUM, in *Agriculture*, a term under which the lesser burdock is sometimes known by writers, and which is found to be a very troublesome weed. See WEED.

XANTHOCHYMUS, in *Botany*, received that name, either from Dr. Roxburgh or Mr. Dryander, in allusion to the remarkable yellow juice of its fruit; the word being compounded of *ξανθος*, yellow, and *χυμος*, juice.—Roxb. Coromand. v. 2. 51. Ait. Hort. Kew. v. 4. 420.—Class and order, *Polyadelphia Polyandria*. Nat. Ord. *Guttifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five roundish, unequal, obtuse, flattish, spreading, slightly imbricated, permanent leaves. *Cor.* Petals five, orbicular, nearly sessile, opposite to the calyx-leaves, and twice as long. Nectary of five broad, short, abrupt, porous glands, opposite to the petals, alternate with the stamens, inserted into the receptacle under the germen. *Stam.* Filaments twenty, united into five oblong, linear, flat bodies, alternate with the nectaries, and above twice as long; anthers stalked, roundish, of two lobes and two cells. *Pist.* Germen superior, globose; style scarcely any; stigmas five, spreading horizontally, obtuse, deciduous. *Peric.* Berry globose, succulent, with five ovate seeds, immersed in the pulp, some of which are generally abortive.

Eff. Ch. Calyx of five leaves. Petals five. Nectaries five, abrupt. Stamens united into five sets, alternate with the nectaries. Berry with from one to five seeds.

1. *X. pistorius*. Painter's Golden-apple. Roxb. Coromand. v. 2. 51. t. 196. Ait. n. 1.—Native of moist valleys, among the Circar mountains of Hindoostan, flowering in the hot season, and ripening fruit in November, December, and January. A large tree, whose tall trunk is covered with dark rough bark, and whose numerous, smooth, rather angular branches form an ample evergreen head. Leaves opposite, stalked, about a foot long and two or three inches broad, elliptic-oblong, acute, entire, coriaceous, smooth, and shining, with a strong mid-rib, and many transverse, parallel, fine, interbranching veins. *Footstalks* an inch in length, angular, channelled, corrugated. *Stipulas* none. *Flowers* an inch in diameter, five or six together, in stalked umbels, each umbel opposite to a leaf, or situated nearly where a last-year's leaf has been. *Partial stalks* simple, smooth, near two inches long. *Petals* white. *Stamens* and *Pistil* green. *Nectaries* and *Anthers* yellow. *Fruit* globular, drooping, somewhat pointed, orange-coloured, smooth, two inches or more in diameter. *Seeds* about the size and shape of almonds.

"The ripe apples," says Dr. Roxburgh, "are eaten by the natives. They are very inviting to the eye, and in taste little inferior to many of our apples in England. I have no doubt, if meliorated by culture, they would prove a delicious fruit." The green, but full-grown, fruit yields a large quantity of a gum, very like *Gummi Gutta*, Gambia. The best way to obtain it is by cutting the apples across, and to scrape off the juice, as it rapidly issues. When recent, it is of the consistence of very rich cream, bright yellow, considerably acrid, and somewhat nauseous to the taste. In a few days it hardens, and becomes less acrid. It makes a pretty good water-colour, either by itself, as a yellow, or mixed with other colours, to form green, &c. It has no particular smell when burnt. A milky juice exudes from the bark of this tree when wounded, which soon thickens, and in thickening assumes a yellow tint. It has no smell,

and, when first taken into the mouth, little taste; but after a while, a sense of dryness and acrimony extends a little way down the throat. This juice, like that obtained from the fruit, is perfectly soluble in spirits. *Roxburgh*.

The tree above described is no very remote relation of the Mangosteen, the most delicious fruit of India; so that Dr. Roxburgh's advice of improving it by culture may be well worthy the attention of horticulturists, if any be found in that part of the world where such experiments are practicable. The most obvious would be to obtain pollen of the Mangosteen, which, like that of many other plants, would probably bear carriage, and to impregnate with it some flowers of the *Xanthochymus*, whose progeny might thence perhaps be much altered.

XANTHON, a name given by some of the ancients to a species of marble of a yellowish-green colour, much used in ornamenting the inner parts of houses; and from its equal hardness with the Tænarium marble, and the equal high polish it was capable of, supposed by the workmen to be of the same species.

The word *xanthon* is of very dubious meaning, but is supposed as the name of this marble to have expressed a green colour, as this was otherwise called *marmor herbosum*. See TÆNARIUM and HERBOSUM *Marmor*.

XANTHORRHIZA, in *Botany*, received its name from the late M. L'Heritier; *ξανθος*, yellow, and *ρίζα*, a root, alluding to the colour of that part. We follow Marshall, Schreber, and Martyn, in correcting the original orthography.—Schreb. Gen. 727. Mart. Mill. Dict. v. 4. Lamarck Illustr. t. 854. (Zanthorhiza; L'Herit. Stirp. Nov. 79. Willd. Sp. Pl. v. 1. 1568. Ait. Hort. Kew. v. 2. 199. Pursh 212. Juss. 234. De Cand. Syst. v. 1. 386. Poiret in Lamarck Dict. v. 8. 838.)—Class and order, *Pentandria Polygynia*. (Polygamia Monocœcia; Schreb.) Nat. Ord. *Mulsiflague*, Linn. *Ranunculacea*, Juss. De Candolle.

Gen. Ch. *Cal.* none; uncles, with the French botanists, we take the corolla for such. *Cor.* Petals five, ovate, acute, spreading, deciduous. Nectaries five, abrupt, two-lobed, spreading, inserted into the receptacle, alternate with the petals, and about half as long. *Stam.* Filaments five to ten, awl-shaped, very short; anthers roundish. *Pist.* Germens several, seven to eleven, pericarp, oblong; styles awl-shaped, incurved; stigmas acute. *Peric.* Capsules as many, inflated, ovate-oblong, bluntish and compressed at the top, where they burst, terminated obliquely by the styles, each of one cell and two valves. *Seeds* solitary, oblong, compressed, small, pendulous from the top of the capsule.

Obs. Many of the flowers want either the stamens or pistils.

Eff. Ch. Calyx none. Petals five. Nectaries five, abrupt, stalked. Capsules five, or more. Seeds solitary, pendulous.

1. *X. apifolia*. Parsley-leaved Yellow-root. (Zanthorhiza apiifolia; L'Herit. Stirp. Nov. 79. t. 38. Willd. n. 1. Ait. n. 1. De Cand. n. 1. Pursh n. 1.)—Native of shady banks of rivers, from Virginia to Georgia, flowering in May. *Pursh*. Mr. Aiton says it was introduced, about the year 1766, by John Bush, esq. into the English gardens, where it is hardy, flowering in the early spring. Here it flowered unnoticed, or at least undescribed, till M. L'Heritier published his magnificent and learned work. The stem is shrubby, bushy, about a yard high, each branch crowned with a tuft of dark green, smooth, shining, long-stalked, pinnated leaves, whose leaflets, an inch or an inch and half long, are acute, rhomboid-lanceolate, sharply and unequally serrated in their fore-part. *Flowers* in long panicked clusters, from the

fame bud as the leaves, of a dark copper-coloured purple, like *Veratrum nigrum*, and though not gay or brilliant, not inelegant, when contrasted with the foliage. The root and stem are internally of a bright lemon-colour. The affinity of this plant to *Cimicifuga*, *Aëaa*, *Helleborus*, &c. would lead us to suspect, though there is no remarkable fetor, that its properties might be active, and accordingly it seems that the American physicians have employed it successfully in practice, as a tonic or stimulant. Probably its qualities may not be dissimilar from those of *Helleborus trifolius* of Linæus; *Copis trifolia*, Salisb. Tr. of Linn. Soc. v. 8. 305. Pursh 390. Bigelow Am. Med. Bot. v. 1. 60. t. 5; the root of which the last-mentioned writer informs us is purely and intensely bitter, strengthening the stomach and other viscera, and promoting digestion. It makes a yellow tincture, like that of Gentian in flavour and medical virtues.

XANTHORRHEA, from $\xi\alpha\sigma\delta\omicron\varsigma$, yellow, and $\rho\epsilon\alpha$, to flow, a name given by the writer of this to the Yellow Gum plant of New Holland, which constitutes a most distinct and peculiar genus. Of this Mr. Brown has made us acquainted with seven species.—Sm. Tr. of Linn. Soc. v. 4. 219. Brown Prodr. Nov. Holl. v. 1. 287. Ait. Hort. Kew. v. 2. 271.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Asphodeli*, Juss. *Asphodelæ*, Brown.

Gen. Ch. Cal. none, unless the corolla be taken for such. Cor. inferior, of one petal, in six deep, nearly equal, oblong, permanent segments; the three inner ones concave, converging at the base. Stam. Filaments six, inserted into the lower part of the corolla, linear, flat, smooth, and naked, longer than the segments; anthers versatile. Pist. Germen superior, ovate, with the rudiments of many seeds in each cell; style cylindrical, with three furrows; stigma simple. Peric. Capule projecting beyond the closed permanent corolla, ovate, with three blunt angles, woody, almost horny, polished, acute, of three cells, and three valves, the partitions from the middle of each valve. Seeds one or two in each cell, bordered, compressed, with a hard black shell; the scar at the base, naked; embryo transverse; albumen soft and fleshy.

Eff. Ch. Corolla inferior, in six deep segments, permanent. Filaments flat, linear, naked. Capule triangular, polished. Seeds one or two, compressed, bordered.

Mr. Brown, from whose examination, of the living plants, we have improved our generic description above, remarks, that the species of this genus have a peculiar habit, so striking, that where they abound, they give a singular character to the face of the country. The body of the root is sometimes elevated into a thick, scarred, black stem, often divided or branched, and several feet in height, exuding a fragrant yellow resin: in other instances it is very short, scarcely rising above the surface of the ground. Leaves very numerous, crowded, narrow, grassy, of great length, linear, somewhat triangular, or two-edged, spreading every way; recurved at the extremity; dilated, and half-veining at the base; rigid and elastic when dry. Flower-stalk terminal, quite simple, round, often many feet in length, smooth, firm, hard, and durable. Spike terminal, solitary, cylindrical, dense, many-flowered, resembling a catkin, sometimes equal in length to the stalk itself. Flowers sessile, closely crowded, small, white, each accompanied by numerous, imbricated bractæas, tapering at the base into a claw, the innermost gradually smallest. Capules of a shining chestnut, partly black.

“The structure of the seeds agrees with *Borya*, Labill. Nov. Holl. t. 107. Brown Prodr. v. 1. 286; nor are these two genera very dissimilar in foliage or inflorescence. They

are placed at the end of the *Asphodelæ*, because of their fleshy albumens, and the black crustaceous skin of their seeds.” Brown.

1. *X. arborea*. Arboreous Yellow-gum. Br. n. 1.—“Stem arborescent. Leaves two-edged; triangular beyond the middle; striated in front. Stalk scarcely the length of the very long spike. Bractæas and corolla beardless.”—Native of the country near Port Jackson, New South Wales. Each division of the thick stem is crowned with a large tuft of innumerable long, slender, drooping leaves, in the centre of which the flower-stalks stand solitary. See n. 3.

2. *X. australis*. Southern Yellow-gum. Br. n. 2.—“Stem arborescent. Leaves compressed longitudinally. Stalk shorter than the elongated spike. Bractæas subtending the tufts of flowers elongated.”—Native of the island of Van Diemen, where it was gathered by Mr. Brown. We have seen no specimen.

3. *X. Hassile*. Spear Yellow-gum. Br. n. 3. Ait. n. 1. (Yellow resin-tree; White’s Voyage, 235. t. at p. 249.)—Stem very short. Leaves compressed longitudinally. Stalk many times longer than the eighteen-inch spike. Bractæas, and outer segments of the corolla, downy at the point.—Native of New South Wales, from whence we received specimens in 1790, by favour of Dr. John White. It is said to have been sent, in 1803, to Kew garden, by Philip Gidley King, esq. A green-house plant, flowering in April and May. In the description given by Dr. White, at the place above quoted, he evidently confounds this species and the *X. arborea*; for he says “it is about the size of an English Walnut-tree. The trunk grows pretty straight for about fourteen or sixteen feet, after which it branches out into long spiral leaves, which hang down on all sides, and resemble those of the larger kinds of grass, or sedge. From the centre of the head of leaves arises a single footstalk, eighteen or twenty feet in height, perfectly straight and erect, terminating in a spike of a spiral form. This large stalk is used by the natives for making spears and fish-gigs, being pointed with the teeth of fish, or other animals.” The first part of this description appears to belong to the *arborea*; the latter, regarding the inflorescence, to the *Hassile*; which might easily, perhaps, except by a scrutinizing botanist, be supposed different stages of growth, or varieties, of the same plant. Such a mistake may be more easily accounted for than that of the great Linæus, in combining nearly the whole genus of *Aloe* into one species. The Yellow Resin is produced by the present, and some other, species of this genus, by spontaneous exudation from the trunk; or promoted sometimes, as we judge from the appearance of certain specimens, by fires kindled by the savage natives of the country. The juice, fluid at first, soon hardens in the sun, into a concrete brittle form, of a dull orange colour. Burnt on hot coals, it emits a fragrant smoke, smelling like a mixture of balsam of Tolu and Benzoin, approaching in some degree to Storax. This resin is perfectly soluble in spirit of wine, but not in water, nor even in essential oil of turpentine, unless digested in a strong heat. The varnish which it makes with either is weak, and of little use. Dr. White found this Yellow Gum a good pectoral medicine, in many cases. If burnt in a room, the scent, though pleasant to some people, soon proves oppressive, and the smoke irritating to the lungs. Olive gum, used by the Italians, is preferable for fumigation.

4. *X. media*. Intermediate Yellow-gum. Br. n. 4.—“Stem rather short. Leaves (longitudinally?) compressed. Stalk very long, many times exceeding the eighteen-inch spike. Bractæas and corolla beardless.”—Observed by Mr. Brown

Mr. Brown near Port Jackson. He is not quite confident of its being a distinct species from the last.

5. *X. minor*. Lesser Yellow-gum. Br. n. 5.—“Stem none. Leaves triangular; flat in front; rather concave beyond the middle. Stalk many times longer than the spike. Bractæas scarcely longer than the tufts of flowers, all, like the corolla, beardless.”—Gathered by Mr. Brown, in New South Wales. The *spike* of this species measures from five to eight inches. *Brown*.

6. *X. bracteata*. Long-bracteated Yellow-gum. Br. n. 6.—“Stem none. Leaves triangular; below the middle somewhat elevated in front; beyond it rather concave. Stalk many times longer than the spike. Bractæas subtending the tufts twice or thrice the length of the flowers, lanceolate and divaricated, all, like the corolla, beardless.”—From the same country. The *spike* is only from three to six inches in length. *Brown*.

7. *X. pumilio*. Dwarf Yellow-gum. Br. n. 7.—“Stem none. Leaves below the middle flattish, with a slightly elevated ridge on both sides; beyond it triangular and channelled. Stalk many times longer than the ovate spike. Bractæas nearly equal, beardless as well as the corolla.”—Gathered by Mr. Brown, in the tropical part of New Holland. The *flower-stalk* itself is, in this species, only a foot high. *Brown*.

XANTHOXYLUM, received its name from governor Cadwallader Colden, because of the yellow hue of the wood, to which ξανθός, *yellow*, and ξύλον, *wood*, alludes. We make no scruple to follow the example of professor Martyn, in restoring the proper orthography; nor is it requisite to burthen our readers with a perpetual indication of the original blunder, under every species, though that blunder has the sanction of Linnæus, and perhaps of all the authors, except Martyn, that we may have to quote. They generally write the word *Zanthoxylum*, or *Zanthoxylon*.—Linn. Gen. 519. Schreb. 684. Willd. Sp. Pl. v. 4. 753. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 382. Pursh 209. Swartz Ind. Occ. 570. Juss. 374. Lamarck Dict. v. 2. 38. Illust. t. 811. Gært. t. 68. (Fagara; Duham. Arb. v. 1. 229. t. 97. Swartz Prodr. 33.)—Class and order, *Dioecia Pentandria*. Nat. Ord. “*Hederaceæ*,” Linn. rather his *Dumoseæ*. *Terebinthaceis affinis*, Juss.

Gen. Ch. corrected. Male, *Cal.* Perianth very small, in three or five deep, concave, rather acute segments. *Cor.* Petals three or five, oval, erect, concave, thrice the length of the calyx. *Stam.* Filaments three or five, awl-shaped, erect, longer than the petals; anthers roundish, two-lobed, furrowed.

Female, *Cal.* like the male, inferior, permanent. *Cor.* like the male, deciduous. *Pist.* Germens from two to five, roundish, each terminating in an awl-shaped style, longer than the petals; stigmas obtuse. *Peric.* Capsules from one to five, stalked, each of one cell, and two coriaceous valves, bursting at the inner margin. *Seeds* solitary, roundish, polished, pendulous from an upright bristle-shaped stalk.

Eff. Ch. Male, *Calyx* in three or five small deep segments. Petals three or five.

Female, *Calyx* like the male, inferior, permanent. Petals three or five. Capsules from one to five, of two valves, and one cell. Seeds solitary, pendulous.

Obj. This genus is distinguished from FAGARA, (see that article,) by having separated *flowers*, either three-cleft, or five-cleft, and pendulous *seeds*. Botanists appear to have mistaken its real character, taking the *corolla* for a *calyx*. To this error Linnæus and Duhamel led the way,

and Jussieu, Willdenow, and others, have followed them. Yet Linnæus in his *Gen. Pl.* subjoins to his generic description a more correct statement, altogether superseding the former; and Willdenow admits species from Swartz, whose *petals* by their presence contradict his essential character. We have not seen living specimens of *Xanthoxylum*, but the descriptions of Browne and Swartz leave little doubt of the correctness of the above characters. We are much tempted to unite the two genera in question, but as they really have not been sufficiently investigated, and Gærtner seems to have discovered a distinctive mark of *Xanthoxylum*, in the stalked pendulous *seeds*, we leave them for future inquiry. The whole genus is shrubby or arborescent, with alternate, pinnate, sometimes only ternate, entire, or somewhat crenate *leaves*, and clustered, or panicled, *flowers*. The *stem* is, in most instances, armed with prickles, that are sometimes very formidable. The *wood* is hard, and serviceable for many purposes.

SECT. 1. *Stem without prickles.*

1. *X. ternatum*. Three-leaved Yellow-wood. Swartz Ind. Occ. 570. Willd. n. 1. (Fagara trifoliata; Swartz Prodr. 33.)—Prickles none. Leaves ternate, obovate, slightly emarginate, shining; dotted beneath.—Received by Sir Joseph Banks from the island of Dominica. A *shrub*, six feet high, with roundish, subdivided *branches*, angular when young. *Leaves* on smooth, spreading, channelled *shoots*. *Leaflets* on small partial stalks, entire, rigid, veiny; contracted at the base; paler beneath, and minutely dotted with black. *Clusters* axillary, compound. *Flowers* small, whitish. *Germens* three, contiguous, like one three-lobed gemma. *Stigmas* three, sessile. *Capsules* three, each of two hemispherical valves, with two internal, membranous, whitish valves. *Seeds* solitary, roundish, polished. *Swartz*.

2. *X. emarginatum*. Emarginate Yellow-wood. Swartz Ind. Occ. 572. Willd. n. 2. Ait. n. 1. (Fagara emarginata; Swartz Prodr. 33. Lauro affinis, terebinthi folio alato, ligno odorato candido, fere albo; Sloane Jam. v. 2. 24. t. 168. f. 4.)—Prickles none. Leaves pinnate, ovate, emarginate, veiny. Flowers triandrous.—Native of mountains in the interior parts of Jamaica, where it is vulgarly called *Lignum vorum*, a corruption of *Lignum Rhodium*, the smell of every part of the shrub resembling the latter when rubbed, or held near the fire. The *stem* is woody, branched, round. *Leaflets* about three pair, rarely with an odd one, above an inch long, veiny, rather coriaceous, and shining. *Clusters* terminal, somewhat compound, erect. *Flowers* minute, whitish. *Calyx* in five deep, ovate, acute, permanent segments. *Petals* only three, ovate, concave, spreading, twice the size of the calyx. *Stamens* three, very short. *Germens* three-lobed, with three sessile *stigmas*. *Capsule* seldom more than one perfected, with two internal, as well as external, valves, and one orbicular, black, shining seed. *Swartz*.

3. *X. acuminatum*. Pointed-leaved Yellow-wood. Swartz Ind. Occ. 575. Willd. n. 3. (Fagara acuminata; Swartz Prodr. 33.)—Prickles none. Leaves pinnate, elliptical, pointed, coriaceous. Flowers triandrous.—Native of mountainous parts of Jamaica. A *shrub*, with round spreading *branches*. *Leaflets* three or four pair, laurel-like, shining. *Gymes* terminal, subdivided in a forked manner. *Flowers* crowded, small, white. *Calyx* of three minute ovate leaves. *Petals* three, obtuse, concave, one line and a half long. *Stamens* three, shorter than the *corolla*. *Fruit* globose, the size of a pepper-corn, only one *capsule*, out of three, coming to perfection.

SECT. 2. *Stem prickly.*

4. *X. punctatum*. Dotted Yellow-wood. Willd. n. 4. “Weit

XANTHOXYLUM.

"West St. Croix 236."—Stem prickly. Leaves ternate, or pinnate, oblong, finely crenate; dotted beneath.—Native of the island of Santa Cruz. *Willdenow.*

5. *X. spinifolium*. Prickly Triandrous Yellow-wood. Swartz Ind. Occ. 574. Willd. n. 5. (*Fagara spinifolia*; Swartz Prodr. 33.)—Stem prickly. Leaves pinnate, with many pair of sessile, ovate, pointed leaflets; prickly beneath, as well as the branches. Flowers triandrous.—Native of dry mountainous situations in Jamaica. A *shrub*, about six feet high, with a round, branching, upright stem. *Spines* (rather we presume *prickles*) scattered, prominent, needle-like, as long as the finger-nail; those of the main stem stronger, and thicker at the base. *Leaves* a foot long, with a compressed *footstalk*, round and prickly at its base, and, if we understand right, furnished with a pair of prickles before each pair of *leaflets*, which are nearly sessile, eight or ten pair in all, ovate, with a short emarginate point, veiny, rigid, smooth, and shining, very minutely crenate at the edges, their mid-rib occasionally prickly. *Cymes* terminal, with minute, white, crowded *flowers*. *Calyx* with three ovate acute segments. *Petals* three, ovate, larger than the *calyx*. *Filaments* scarcely any. *Anthers* ovate, converging. *Germen* in three distinct lobes. *Stigmas* three, sessile, obtuse. *Fruit* not observed. *Swartz.*

We have been more full in our descriptions of Dr. Swartz's four species, that the reader may compare their characters with *Fagara*. Nothing is said of their *flowers* being separated, or dioecious.

6. *X. Clava Herculis*. Great Prickly Yellow-wood. Linn. Sp. Pl. 1455, excluding the synonymy of Duhamel. Amœn. Acad. v. 3. 16. Willd. n. 6. Ait. n. 2. Swartz Obf. 375. (*X. spinifolium*, *lentifolii longioribus foliis*, *euonymi fructu capsulari*; Cat. Car. v. 1. t. 26, according to Linnæus. *X. aculeatum*, *fraxini sinuifolii et punctatis foliis*; Pluk. Phyt. t. 239. f. 4.)—Stem with broad angular prickles. *Leaflets* ovate, pointed, crenate; nearly equal at the base: common *footstalk* prickly. *Flowers* terminal, panicle.—Native of woods in the West Indies and Carolina, flowering in March and April. It is marked by Mr. Aiton as a green-house plant, cultivated ever since Miller's time, flowering in April and May. The *trunk* is woody, often, according to Swartz, 30 or 40 feet high, armed with very powerful *prickles*, which are thick at their base, angular and sharp at the point. *Leaves* a foot long, pinnate, as in all the following species; their common *footstalks* armed with scattered straight prickles, one-third of an inch long: *leaflets* about seven pair, on short partial stalks, unequally divided by their smooth mid-rib, and somewhat falcate, an inch and a half or two inches long, bordered with shallow unequal notches, smooth and rather shining. *Clusters* terminal, compound. *Flowers* polygamous, there being some united ones, though not perfecting seed, on one tree, and others entirely female, on another. The former have a minute five-toothed *calyx*. *Petals* five, thrice as long, ovate, erect, or a little incurved. *Filaments* five, twice the length of the petals, and inserted between them. *Anthers* oblong, cloven at the base. *Germen* roundish, abortive, with five awl-shaped erect *styles*, and simple *stigmas*. The female *flowers* have a five-toothed *calyx*; five concave *petals*; no *filaments*. *Germens* five, united into a roundish body. *Styles* none. *Stigma* peltate, slightly convex, a little elevated, with five furrows. *Capsules* five, combined, or one of five lobes, each lobe having two valves, and containing a roundish, black, shining *seed*. Our description of the fructification is taken from Dr. Swartz. The *leaves* bear but a

flight resemblance to the *Mastic-tæc*, or any other species of *Pistacia*, being decidedly crenate.

7. *X. aromaticum*. Aromatic Yellow-wood. Willd. n. 7. (*Euonymo adfinis arematica*, five *Xanthoxylon spinifolium*, *fraxinellæ foliis cheufanicum*; Pluk. Amalth. 78. t. 393. f. 2.)—Stem with opposite prickles. *Leaflets* ovato-lanceolate, serrated; unequal at the base: common *footstalk* prickly. *Panicles* terminal.—Native of Chufan. "A *shrub* with straight prickles. *Leaflets* two, three, or four pair, pointed, one inch and a half long, marked with pellucid dots; rounded near the base, at the upper edge; contracted at the lower. *Common footstalk* beset with strong, nearly opposite, prickles." *Willdenow*, from a dried specimen, without *flowers*. Plukenet says, "the fruit is a single, round, rough, or warty *capsule*, tasting strongly of camphor, lined with a white, smooth, insipid membrane, containing a black polished *seed*, with a hollow whitish fear, in which lies the thread connecting the seed with its capsule." This very accurate description determines the genus. He adds, that the Chinese use this fruit instead of pepper.

8. *X. rhoifolium*. Stomach-leaved Yellow-wood. Lamarck n. 2. Willd. n. 8. (*Euonymo affinis aromatica*, five *Xanthoxylon spinosissimum*, *fraxini anguliere folio punctatum*; Pluk. Amalth. 76. t. 392. f. 1.)—Stem prickly. *Leaflets* lanceolate, finely serrated; nearly equal at the base: common *footstalk* downy and prickly. *Panicles* axillary.—Brought from the islands of Chufan, like the preceding. *The leaves* are a foot long. *Leaflets* nine to eleven pair, with an odd one, each three inches in length, pointed, dotted; slightly downy beneath. *Footstalk* sometimes without prickles. *Willdenow*. Plukenet's figure represents the *panicle* much like the preceding, but lateral. *The capsules* seem to be one, two, or three from each *flower*.

9. *X. juglandifolium*. Walnut-leaved Yellow-wood. Willd. n. 9. (*X. americanum*, five *Herculis arbor aculeata major*, *juglandis foliis alternis parum sinuifolis*; Pluk. Phyt. t. 239. f. 6?)—Stem prickly. *Leaflets* oblong, pointed, obscurely serrated; unequal at the base: common *footstalk* somewhat prickly. *Panicles* terminal.—Native of Hispaniola and Nevis. *Leaves* pinnate, with an odd one; *leaflets* alternate, coriaceous, two or three inches long, marked with distant, scarcely visible, pellucid dots; their edges entire to the naked eye, but under a magnifier appearing furnished with close distant serratures; contracted near the base, at the upper edge; rounded at the lower, rather downy beneath. *Common footstalk* beset with a few short scattered prickles. *Panicles* terminal, much branched, dense, downy. *Capsules* four or five, rather downy, pointed. *Seeds* black.

10. *X. rigidum*. Rigid Yellow-wood. Willd. n. 10.—"Stem prickly. *Leaflets* elliptical, entire, emarginate, pointed; their veins hairy beneath; mid-ribs and *footstalks* prickly."—Native of South America. *Humboldt and Bonpland*. *Leaflets* four pair, coriaceous, on very short stalks; the upper ones largest, two inches long; lower but half an inch; their base rather unequal; sometimes having a short, obtuse, crenate point; their upper side polished, reticulated with veins; under paler, with one long, reddish, awl-shaped prickle on the mid-rib of each, of which there are several on the common stalk. *Flowers* not seen. *Willdenow*.

11. *X. hermaphroditum*. Cayenne Yellow-wood. Willd. n. 11. (*Fagara pentandra*; Aubl. Guian. v. 1. 78. t. 30.)—Stem prickly. *Leaflets* elliptic-oblong, pointed, entire; nearly equal at the base: common *footstalk* without prickles. *Panicles* terminal, repeatedly compound. *Flowers* united.

united.—Gathered by Aublet, in the forests of Cayenne, flowering in May, and bearing fruit in August. A tree, whose trunk is 40 or 50 feet high, and two feet and a half in diameter, with a prickly bark. The wood is white, hard, and compact. *Leaflets* about five pair, nearly sessile, smooth; the largest six inches long, and an inch and a half broad. *Panicles* large and much branched, composed of numerous, small, white flowers, having *filaments* and *pistils* in the same individual. *Capsules* three, four, or five from each flower, reddish, each containing a black, shining, oily seed. These capsules have a pungent aromatic flavour, and the Creoles call them negro's pepper.

12. *X. fraxineum*. Ash-leaved Yellow-wood, or Common Tooth-ache Tree. Willd. n. 12. Arb. 413. Ait. n. 2. Pursh n. 1. (*X. Clava Herculis* L.; Linn. Sp. Pl. 1455. *X. ramiflorum*; Michaux Boreal.-Amer. v. 2. 235. *Fagara fraxini folio*; Duham. Arb. v. 1. 229. t. 97.)—Stem prickly. *Leaflets* ovate, very minutely serrated; equal at the base. *Umbels* axillary.—Native of shady woods, near rivers, from Canada to Virginia and Kentucky, flowering in April and May. A tincture of the bark and capsules is recommended in rheumatism and the tooth-ache, whence its English name. *Pursh*. A large deciduous shrub, whose branches are armed with sharp, conical, compressed, brown prickles, very broad at the base. *Leaflets* four or five pair, with an odd one, an inch and a half long, on short partial stalks; contracted at each end; more or less distinctly crenate, or bluntly serrated; smooth above; soft and downy beneath. Their common footstalk is described without prickles; but in our specimens it is always furnished with some, and occasionally with very numerous ones. The flowers are small, yellowish-green, in little dense umbels, just above the scars of last year's footstalks, accompanied by a tuft of downy young leaves. The mode of inflorescence abundantly distinguishes this species from all the rest. It is hardy in our gardens, flowering in March and April, before the leaves appear. The bark is used in America, as a powerful sudorific and diuretic, whence its use, as above-mentioned, in rheumatic disorders. This is the species most popularly taken for *X. Clava Herculis*, as appears by the herbarium of Jacquin, purchased formerly by Sir Joseph Banks, and even by that of Linnæus. The two species, nevertheless, are widely different.

13. *X. tricarpum*. Three-grained Yellow-wood. Michaux Boreal.-Amer. v. 2. 235. Pursh n. 2. Ait. n. 4.—Stem prickly. *Leaflets* stalked, oblong-oval, pointed, very smooth, finely serrated; oblique at the base: common footstalk prickly. *Capsules* three, sessile.—In the woods of Carolina and Florida, flowering in July. *Michaux, Pursh*. Introduced into the English gardens in 1806, by Mr. John Lyon. A hardy shrub. *Aiton*.

14. *X. heterophyllum*. Various-leaved Yellow-wood. (*Macqueria Commerloni*; Jusq. 374, under *Xanthoxylum*.)—Young branches prickly; their leaves with very numerous serrated leaflets, on prickly common stalks: old ones unarmed, their leaves of seven entire leaflets, on unarmed common stalks. *Panicles* axillary. *Capsules* solitary.—Gathered in the isle of Bourbon, by Commerlon, some of whose specimens are in our possession. Nothing can be more paradoxical than the appearance of this shrub. We must rely on its discoverer for the accuracy of his specimens, as the two branches, so very different in appearance, are not connected together; though we cannot doubt their generic identity. The young branch is slender, covered with innumerable, sharp, ascending prickles, of various sizes, a line long at most. *Leaves* alternate: common footstalk of

each five or six inches long, round, straight, channelled, beset with numerous prickles, like those of the branch, but smaller: leaflets from 40 to 60, or more, opposite or alternate, ovate, bluntish, smooth, crenate or bluntly serrated, one quarter or one-third of an inch in length, of a fine green, paler beneath, marked with pellucid dots; their mid-ribs bearing one or two prickles at the back. The older or flowering branches are stout, rugged, unarmed, leafy at their extremities only. *Leaves* alternate, rather crowded, altogether destitute of prickles, each consisting of three pair of obovate, bluntly pointed, entire, coriaceous, veiny, smooth leaflets, with an odd one; the lowermost smallest: common footstalk channelled, smooth. *Panicles* compound, rather shorter than the leaves; their stalks unarmed, compressed, and angular. *Capsules* only one, perfected in each flower, brown, the size of a pepper-corn, rugged, full of pellucid dots lodging a pungent aromatic camphorated oil, and very bitter. *Seed* black, polished, with a bivalve elastic tunic, or lining of the capsule.

For *X. trifoliatum*, Linn., see PANAX Aculeatum.

XANTHURUS INDICUS, in *Ichthyology*, the name of a fish called by the Dutch *geel-fardt*.

It is of the size and shape of the bream; its jaws are armed with straight and very sharp teeth, which stand almost straight out; its back is yellow, and its tail very strongly tinged with that colour; its belly is of a blueish-white; its head brown, and its fins of a fine red. It is caught with hooks among the rocks on the shores of the East Indies, and is a very wholesome and well-tasted fish. *Ray*.

XANTHUS, in the *Natural History of the Ancients*, the name of an iron-ore of the hematites or blood-stone kind, and usually accounted a species of it, and called by others *Elatites*.

It was of a pale yellowish-white, or the colour of the French pale yellow ochre, used by our painters; but like all other ferruginous bodies it became red by burning.

Theophrastus gives us expressly the etymology of the name, observing that it was called so from its colour; the Dorians calling a yellowish-white ξανθος, xanthos.

XANTHUS, in *Ancient Geography*, a famous river of Asia Minor, in the Troade. According to Pliny, it had its source in mount Ida, and discharged itself at the port of the Achæans into the Hellespont, after having joined the Simois.—Also, a river of Asia Minor, in Lycia, which had its source in mount Taurus, and watered the towns of Xanthus and Patara, and ran into the Mediterranean, near the last of these places. This river was anciently called Sirbes, according to Strabo, and he says that the temple of Latona was situated ten stadia above its mouth, and sixty stadia farther was the town of Xanthus.

XANTHUS, or *Xanthopolis*, a town of Asia Minor, and the largest in Lycia. It was situated seventy stadia from the mouth of the river on its bank. Pliny reckons fifteen miles from this town to the mouth of the river. Under Appian, the inhabitants of Xanthus were such enthusiasts for liberty, that when it was taken by Brutus they burnt it, and preferred death to submission to the conqueror. He adds, that the same circumstance occurred with regard to Harpalus, general of Cyrus the Great, and Alexander the Great. It subsisted in the time of Strabo.—Also, a town of the isle of Lesbos.

XANTIPPE, in *Biography*. See SOCRATES.

XANTON, in *Geography*, a town of France, in the department of the Vendée; 5 miles E. of Fontenay-le-Comte.

XANXUS, in *Natural History*, a name given by some authors to a large species of sea-shell, somewhat like that with which the Tritons of old were painted. It is found in great abundance near Ceylon, and is used there in medicine as an alkali and abortif in the same cases in which we give the testaceous powders.

XAPARACO, in *Geography*, a town of Mexico, in the province of Mechoacan; 85 miles W.N.W. of Mechoacan.

XARAMA, a river of Spain, which runs into the Tagus, a little below Aranjuez.

XARAYES, or ZARAYOS, *Laguna de Los*, a supposed lake of Brasil, formed by the river Paraguay; about 108 miles in length, and 21 in breadth. This is merely an inundation of the river, and exploded as a lake. S. lat. $17^{\circ} 45'$.

XATHOS, in *Ichthyology*, a name given by Appian to the fish called by the generality of authors the *erythrinus*, or *rubellio*.

XATIVA, now St. FELIPE, in *Geography*. See St. Felipe.

XAVIER, a town of Spain, in Navarre, the native place of the celebrated missionary of that name; 3 miles E. of Sanguesa.

XAVIER. See SABI.

XAVIER *Gogo*, a town of Africa, in the country of Whidah; 12 miles N.N.E. of Sabi.

XAVIER, *Saint*. See SAINT *Xavier*.

XAVIER *Zante*, a town of Africa, in the country of Whidah; 14 miles N.W. of Sabi.

XAUXA, a town of Peru, in the bishopric of Guamanga, containing two churches; 90 miles E. of Lima. S. lat. 12° . W. long. $75^{\circ} 30'$. See JAUIJA.

XAUXA, a river of South America, which rises in the Andes, about 75 miles N. from Atun Xauxa, and uniting with the Apurimac, forms the Ucayale.

XAUXAVA, a town of Morocco, on a river, and at the foot of a mountain, both of the same name; 15 miles N. of Morocco.

XEBEC, in *Sea Language*, a small three-masted vessel, navigated in the Mediterranean sea, and on the coasts of Spain, Portugal, and Barbary. The fore and main masts are called block-masts, being short, and formed square at the head, to receive sheaves, to reeve the jeers, &c. The mizen-mast is fitted with a top-mast, &c. similar to a small English ship, and which has been lately added, to keep them better to the wind. The xebecs have no bowsprit, but a sort of boomkin, woulded and confined to the prow, nearly horizontal (see GALLEY), to the outer end of which lead the bow-lines. The fore-mast rakes much forward, has no stay, and the shrouds set up, similar to the runners in English cutters or sloops, to toggles fixed in the sides. These shrouds are easily shifted when the vessels go about. The main-mast is nearly upright, and rigs as the fore-mast. Each mast carries a latteen-sail, the largest side of which is bent to a yard that hoists by a pulley round the mast, at about one-third its length; the yards are worked at the lower end by bow-lines, and the sail extended by a sheet at the clue. The upper lee-yard-arm is worked by a brace, and the strain supported by vangs nearer the mast. The mizen-mast carries a latteen-sail, similar to the main and fore mast. Vessels with latteen-sails will lie one point nearer the wind than a square-rigged vessel. Xebecs, particularly in France, have been rigged similar to polacres; but they never fail so well as they did in their primitive situation.

The xebec, generally equipped as a corfair, is constructed with a narrow floor, to be more swift in pursuit of

the enemy; and of a great breadth, to enable her to carry a great force of sail for this purpose, without danger of overturning. As these vessels are usually very low built, their decks are formed with a great convexity from the middle of their breadth toward the sides, in order to carry off the water, which falls aboard, more readily by their scuppers. But as this extreme convexity would render it difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating along the deck from the sides of the vessel toward the middle, on which the crew may walk dry-footed, whilst the water is conveyed through the grating to the scuppers.

When a xebec is equipped for war, she is occasionally navigated in three different methods, according to the force or direction of the wind. Thus, when the wind is fair, and nearly astern, it is usual to extend square sails upon the main-mast, and frequently upon the fore-mast; and as those sails are rarely used in a scant wind, they are of an extraordinary breadth. When the wind is unfavourable to the course, and yet continues moderate, the square yard and sails are removed from the masts, and laid by, in order to make way for the large latteen yards and sails, which soon after assume their place; but if the foul wind increases to a storm, these latter are also lowered down and displaced, and small latteen yards, with proportional sails, are extended on all the masts. The xebecs, which are generally armed as vessels of war by the Algerines, mount from sixteen to twenty-four cannon, and carry from three hundred to four hundred and fifty men, two-thirds of whom are generally soldiers. Falconer.

XEBEROS, in *Geography*, a town of South America, in the audience of Quito; 40 miles S.W. of La Laguna.

XEJUI, a river of Paraguay, which runs into the Paraguay.

XEKIAS, in *Biography*, a name given by the Chinese and Japanese to an Eastern philosopher of mythological origin and character, called also Buddas among the Indians, Somonacodom in Siam, and after his death Foc or Fotoki, who fascinated the whole northern and eastern region of Asia, as well as part of the southern, with his pantheistic doctrine. It is probable, as some have said, that he lived about 600 years before Christ; and having first appeared in the southern part of India, on the borders of the Indian ocean, disseminated his philosophy by means of his disciples to all India. It is said that he spent twelve years in solitude, when he was instructed by the Tolopoin, called by the ancients "hylobii," *i. e.* sylvan hermits; and that in his 30th year he devoted himself to contemplation, and attained to the intuitive knowledge of the first principles of all things, from which he took the name of Foc, which signifies, "something more than human." His mystical philosophy was delivered to his innumerable disciples under the veil of allegory. The Japanese add, that in his contemplations, during which his body remained unmoved, and his senses unaffected by any external object, he received divine revelations, which he communicated to his disciples.

Buddas, or Xekias, in his esoteric doctrine, taught the difference between good and evil; the immortality of the souls of men and brutes; different degrees of rewards and punishments in a future world; and the final advancement of the wicked, after various migrations, to the habitations of the blessed. Amidas, who, according to the Chinese, is Xekias himself, presides in these habitations, and is the mediator, through whose intercession bad men obtain a mitigation of their punishment. These dogmas are contained in an ancient book, called Kio, which all the Indians beyond the Ganges, who follow the doctrine of Xekias,

receive as sacred, and which is illustrated by innumerable commentaries.

The doctrine which Xekias delivered towards the close of his life to his esoteric disciples was very different. Vacuum, or void, was, according to his instruction, the principle and end of all things, simple, infinite, eternal, but destitute of power, intelligence, or any other similar attribute; and that to be like this principle, by extinguishing all passion and affection, and remaining absorbed in the most profound contemplation, without any exercise of the reasoning faculty, is the perfection of happiness. The first principle in this system cannot be pure nihilism, which admits of no properties; probably, it is First Matter, without variable qualities, whence all things are supposed to arise, which is not to be perceived by the senses, but contemplated as the latent divinity, infinitely distant from the nature of visible things, yet the origin of all substances. The emanations from this fountain became, in the popular theology, objects of the grossest superstition and idolatry.

The doctrine of Foe, or Xekias, was embraced by innumerable disciples. Among these, one of his most eminent successors was T'amo, a Chinese, who was so entirely devoted to contemplative enthusiasm, that he spent nine whole years in profound meditation, and was on this account deified.

According to the Branvins, Xekias had neither father nor mother; and as no Indian city claims the honour of his birth, he was probably a foreigner, who migrated to the southern part of India from some neighbouring maritime country, perhaps from Lybia; whither he came with some Egyptian colony, and who had been instructed in the Egyptian mysteries. It is not improbable, that at the time when Canbyles conquered Egypt, and dispersed almost the whole nation, this impostor might have passed over into India, and propagating his doctrine among an ignorant and superstitious people, became an object of universal veneration. XEL, in the *Materia Medica of the Ancients*, a name given to the fruit *fel*.

XELSA, in *Geography*, a town of Spain, anciently a Roman colony, called Julia Celsa.

XELVA. See CHELVA.

XENDAY, a town of Japan, in the island of Nippon; 115 miles N.N.E. of Jedo. N. lat. 39°. E. long. 141° 52'.

XENEXTON, a word used by Paracelsus, to express a sort of amulet to be worn about the neck, to preserve people from infection in the plague.

XENIA, *Ξενια*, q. d. *gifts*, in some *Ancient Customs*, were gifts, or presents, made to the governors of provinces, by the inhabitants thereof.

The word occurs pretty frequently in charters of privileges; where *quietos esse à xenis* denotes an exemption from making such presents to kings and queens, upon their travelling through such precincts.

XENIA, in *Geography*, a township of Ohio, in the county of Greene, with 1429 inhabitants.

XENIL, a river of Spain, which rises in Grenada, and runs into the Guadalquivir, about three miles below Ecija.

XENINEPHIDEI, a word used to express a sort of imaginary spirits, mentioned by the adepts, as delighting to discover the occult qualities of bodies to men.

XENISMI, *Ξενισμοι*, in *Antiquity*, sacrifices offered at the Athenian festival Anaceia.

XENOCRATES, in *Biography*, a famous Grecian phi-

loopher, was born at Chalcedon, in the first year of the 96th Olympiad (B.C. 396), and attached himself at first to Æschines, but afterwards became a follower of Plato, and succeeded Speusippus in the chair of the old academy (B.C. 339). His temper was gloomy, his aspect severe, and his manners were little tinged with urbanity. Plato took pains to correct these obliquities of his disposition and character; and as he highly respected his master, he probably improved by his instruction, so that he was reckoned as one of his most esteemed disciples. Xenocrates was held in such estimation among the Athenians for his virtues, and especially his integrity, as well as his wisdom, that in a public trial his simple avowal was accepted instead of an oath, which was usually required; and that even Philip of Macedon found it impossible to corrupt him. Dreading his influence, and the temptation of a bribe, he declined all private intercourse with the Macedonian sovereign, and was honoured by him with this testimony; that of all persons who had come to him on embassies from foreign states, Xenocrates was the only one whose friendship he was not able to purchase. On occasion of being employed as an ambassador to the court of Antipater, for the redemption of several Athenian captives, he waded the honour of accepting the invitation of this prince to sit down with him at supper, in the words of Ulysses to Circe, cited from Homer's *Odyss.* (l. x. v. 383); thus translated,—

“What man, whose bosom burns with generous worth,
His friends enthral'd, and banish'd from his sight,
Would taste a selfish, solitary joy?”

The patriotic spirit expressed in this appropriate passage gratified Antipater so much, that he immediately released the prisoners. As another example of his moderation, it is alleged, that when Alexander, wishing to mortify Aristotle, on account of some accidental pique, sent Xenocrates a magnificent present of 50 talents; he accepted only 30 minæ, returning the residue to the donor with this message; that the whole sum was more than he should have been able to spend during his whole life. In this instance, he also manifested a superiority to that kind of jealousy and revenge which might have actuated meaner minds, when it is considered that Aristotle had instituted a school in the Lyceum, in opposition to the academy over which Xenocrates presided. In the use of food he was singularly abstemious; his exaltation was invincible by the seducing arts of Phryne, a celebrated Athenian courtesan; and his humanity was testified by the shelter which he afforded to a sparrow that was pursued by a hawk, and fled into his bosom, where he allowed it to remain till its enemy was out of sight, alleging that he would never betray a suppliant. In the employment of his time, he allotted a certain portion of each day to his proper business, one of which he devoted to silent meditation. His high sense of the importance and utility of mathematical studies was sufficiently evinced by his refusing to admit into his academy a young man who was ignorant of geometry and astronomy, because he was destitute of the haudles of philosophy. Upon the whole, Xenocrates was eminent, both for his purity of morals, and his acquaintance with science; and he supported the reputation of the Platonic school by his lectures, his writings, and his conduct. His life was prolonged to the third year of the 116th Olympiad (B.C. 314), or the 82d year of his age, when he accidentally fell in the dark into a reservoir of water.

His philosophic tenets were Platonic; but in his lectures he adopted the language of the Pythagoreans. In his system, unity and diversity were principles in nature, or gods; the former being the father, and the latter the mother of the universe.

universe. The heavens he represented as divine, and the stars as celestial gods; and besides these divinities, he taught that there are terrestrial demons, of a middle order between the gods and men, partaking of the nature both of mind and body, and, like human beings, capable of passions, and liable to diversity of character. He probably conceived with Plato, that the superior divinities were ideas, or intelligible forms, proceeding immediately from the Supreme Deity, and the inferior gods, or demons, to be derived from the soul of the world, and, like that principle, compounded of a simple and a divisible substance, or of that which always remains the same, and that which is liable to change. Diogen. Laert. Plut. de Virt. Mor. De If. et Osir. De Anim. Gent. Cicero de Nat. Deor. Brucker's Hist. Phil. by Enfield, vol. i.

XENODOCHUS, formed of ξένος, *stranger*, and δεχόμενος, *I receive*, an ecclesiastical officer of the Greek church, the same with the hospitaler, or a person who takes care of the reception and entertainment of strangers.

St. Isidore, a priest and solitary, surnamed *Xenodochus*, lived in the fourth century. He was thus called, because entrusted with that office in the church of Alexandria.

XENOPARACHUS, formed of ξένος, *stranger*, and παραρχός, of παραίχην, *I furnish*, among the Romans, an officer who provided ambassadors with all kinds of necessaries, at the public expense.

XENOPHANES, in *Biography*, the founder of the Eleatic sect, was born at Colophon, about the 56th Olympiad (B.C. 556); and having left his country, took refuge in Sicily, where he gained a subsistence by reciting, in the court of Hiero, elegiac and iambic verses, which he had written against the theogonies of Hesiod and Homer. From Sicily he removed to Magna Græcia, where he became a celebrated preceptor in the Pythagorean school, without adhering strictly to the doctrines of Epimæides, Thales, and Pythagoras. His life was prolonged to the advanced age of 100 years, that is, till the 81st Olympiad (B.C. 456), during 70 years of which he occupied the Pythagorean chair of philosophy. In Enfield's *Philosophy of Brucker* we have the following summary of the doctrine of Xenophanes:—In metaphysics, he taught, that if ever there had been a time when nothing existed, nothing could ever have existed. That whatever is, always has been from eternity, without deriving its existence from any prior principle; that nature is one and without limit; that what is one is similar in all its parts, else it would be many; that the one infinite, eternal, and homogeneous universe, is immutable and incapable of change; that God is one incorporeal eternal being, and, like the universe, spherical in form; that he is of the same nature with the universe, comprehending all things within himself; is intelligent, and pervades all things; but bears no resemblance to human nature either in body or mind.

In physics, he taught, that there are innumerable worlds; that there is in nature no real production, decay, or change; that there are four elements, and that the earth is the basis of all things; that the stars arise from vapours, which are extinguished by day, and ignited by night; that the sun consists of fiery particles collected by humid exhalations, and daily renewed; that the course of the sun is rectilinear, and only appears curvilinear from its great distance; that there are as many suns as there are different climates of the earth; that the moon is an inhabited world; that the earth, as appears from marine shells, which are found at the tops of mountains, and in caverns far from the sea, was once a general mass of waters; and that it will at length return into the same state, and pass through an endless series of similar revolutions.

The doctrine of Xenophanes concerning nature is so obscurely expressed by those who have transmitted an imperfect account of it, that it has been misunderstood and misrepresented. Some have confounded it with the atheistical system of Spinoza; by others it has been accommodated to the ancient doctrine of emanation; and others have maintained its similarity to the Pythagorean and Stoical notions of the soul of the world. The truth seems to have been, according to Brucker's statement, that he held the universe to be one in nature and substance; distinguishing in his conception between the matter of which all things consist, and that latent divine force, which he considered not as a distinct substance, but an attribute, and yet necessarily inherent in the universe, and the cause of all its perfection. This view of his notion is consistent with the language he used, and with the account of his doctrine, preserved by Sextus Empiricus, that God is of the same nature with the universe; τὸ Θεῖον συμπύκνως πᾶσι. When he asserted that there is no motion in nature, it is probable that he understood the term motion metaphysically, meaning merely that there is no such thing in nature as passing from nonentity to entity, or the reverse. Accordingly, the ancients more generally applied the term motion to a change of nature than to change of place. Brucker is of opinion that the notion ascribed to Xenophanes concerning the nature and origin of the celestial bodies, as meteors daily renewed, must have been founded on a misconception and misrepresentation of his opinion on the subject. See **ELEATIC Philosophy**.

XENOPHILES, an able Greek musician, who professed the philosophy of Pythagoras, and who lived at Athens, where he arrived at the great age of 105. It is Lucian who gives this account of his extraordinary longevity from Ariloxenus.

XENOPHON, the son of Gryllus, an Athenian, was distinguished as a philosopher, commander, and historian. His engaging appearance whilst he was a youth induced Socrates to admit him into the number of his disciples. Under his tuition he made rapid progress in that kind of wisdom for which his master was so eminent, and which qualified him for all the offices of public and private life. Having accompanied Socrates in the Peloponnesian war, and manifested his valour in defence of his country, he afterwards entered into the army of Cyrus as a volunteer; but his enterprise against his brother proving unfortunate, Xenophon, after the death of Cyrus, advised his fellow-soldiers to attempt a retreat into their own country rather than to surrender themselves to the victor. His advice was regarded, and he was chosen as their commander. In the exercise of this duty he acquired by his prudence and firmness a high degree of honour; and the memorable adventure is related by himself in his "Retreat of the Ten Thousand." Having joined Agesilaus, king of Sparta, after his return into Greece, and fought with him against the Thebans in the celebrated battle of Cheronea, he displeased the Athenians by this alliance; and he was publicly accused for his former engagement in the service of Cyrus, and condemned to exile. Thus ignominiously treated, the Spartans took him under their protection, and provided for him a comfortable retreat at Scillus, in Elis. In this asylum he enjoyed the pleasures of domestic life with his wife and two children for several years, and availed himself of the leisure that was thus afforded him by writing those historical works which have rendered his name immortal. On occasion of a war between the Spartans and Eleans, he was obliged to abandon this agreeable retreat, and to join his son, who was settled at Lepeus. From hence he afterwards removed with his whole family to Corinth, where, in the second year of the

105th Olympiad (B.C. 359), his life terminated, at the age of about 90. As a philosopher, he was an orator to the Socratic school by his integrity, piety, and moderation; and in his whole military conduct, he was distinguished by an admirable union of wisdom and valour. As a writer, he has presented to succeeding ages a model of purity, simplicity, and harmony of language, expressing sentiments truly Socratic. By his wife Phiteia he had two sons, Gryllus and Diodorus; the former of whom ended his life with military glory in the battle of Mantinea. The news of his son's death was communicated to him whilst he was offering sacrifice; and upon receiving it, he took the crown from his head, uttering with a sigh these memorable words, "I knew that my son was mortal;" but when he heard that he had fought bravely, and died with honour, he again put on the crown, and finished the sacrifice. As an historian, he may be considered in his "Hellenics" as the continuator of Thucydidēs, and as having brought down the affairs of Greece to the battle of Mantinea. His "Cyropædia," or "Institution of Cyrus," is generally regarded as a work of fiction rather than of real history, exhibiting, under the name of the elder Cyrus, the picture of a perfect prince, according to his own conception of the character. His "Anabasis" (or Ascens) is an account of that memorable expedition of the younger Cyrus, in which he himself appears so conspicuous. This work appeared under the name of Themistocles of Syracuse, to whom Xenophon himself ascribes it; nevertheless it has been universally ascribed to Xenophon: but if this be the case, it must have been written from memory, long after the events, which are differently related by Diodorus. Among his political works we may enumerate his accounts of "The Republic and Laws of Sparta;" "Of the Republic of Athens and its Revenues;" his "Praise of Agesilaus;" and his "Hiero, or Dialogue on Tyranny." Of a miscellaneous class, he wrote a treatise on "Oeconomics;" "On Hunting;" and "On the Office of Master of the Horse." The character of Xenophon, portrayed in his writings, seems to have exemplified virtue and humanity, kind and generous feelings, and a considerable degree of piety blended with superstition. In his Anabasis he exhibits a singular degree of credulity and regard to celestial warnings, which, in his view of them, governed his conduct, and were miraculously verified by the event. For his preference of the Spartan to the Athenian government and manners, derogating from his patriotism, the only apology is his banishment. His style has been always admired for its purity, simplicity, and clearness; and his works are reckoned amongst the most popular of the Greek classics, and have passed, collectively and separately, through several editions. Laertius. *Ælian. Hist. Var. Fabr. Bib. Græc. vol. ii. Brucker's Philol. by Enfield, vol. i.*

XENOXUA, in *Geography*, a town of European Turkey, in Macedonia; 36 miles S.E. of Akrida.

XEQUETEPEQUE, a town of Peru, in the government of Truxillo, on the Pacsa Mayo; 55 miles N. of Truxillo.

XERANTHEMUM, in *Botany*, from ξηρός, dry, and ἄνθος, a flower, a name well adapted to express the dry and durable nature of the flowers of the present genus, one of the tribe popularly denominated Everlasting Flowers.—*Linn. Gen. 420. Schreb. 551, excluding Xeranthemoides of Dillenius. Willd. Sp. Pl. v. 3. 1901. Mart. Mill. Dict. v. 4. the first section only. Sm. Prodr. Fl. Græc. Sibth. v. 2. 172. Ait. Hort. Kew. v. 5. 20. Tourn. t. 284. Juss. 179, excluding Elichrysum of Tournefort. Lamarck Illustr. t. 692. f. 1. Gært. t. 165.—Class and*

order, Syngenesia Polygamia-superflua. Nat. Ord. Compositæ nucamentacea, Linn. Corymbifera, Juss.

Gen. Ch. *Common Calyx* imbricated; scales numerous, elliptic-lanceolate, scarious, permanent, the inner ones much longer than the disk, coloured, forming a radiant crown to the whole compound flower. *Cor.* compound, somewhat unequal; florets of the disk very numerous, all perfect, tubular, funnel-shaped, much shorter than the calyx, in five equal spreading segments; those of the circumference fewer, female, tubular, somewhat two-lipped, with five unequal segments. *Stam.* (in the perfect florets) Filaments five, capillary, very short; anthers forming a cylinder rather longer than the corolla. *Pist.* (in the same florets) Germen short; style thread-shaped, longer than the stamens; stigma cloven: in the female florets, *Stam.* none. *Pist.* Germen and style as in the perfect florets; stigma simple, club-shaped. *Peric.* none, except the calyx scarcely at all altered, except being closed. *Seed* in both kinds of florets alike, oblong; down a row of taper-pointed narrow scales. *Recept.* flatish, clothed with linear acute scales, rather longer than the florets.

Eff. Ch. *Receptacle* scaly. Down of taper-pointed scales. Calyx imbricated, its inner scales forming a coloured spreading radius.

Obf. Gærtner has long ago observed, what indeed no one could overlook, that the essential character of this genus, as given by Linnæus, answers to his first species only, *X. annuum*. This stands in the *Syst. Veg.* making a section by itself, characterized by a chaffy receptacle; whereas the other sections, "with a naked receptacle," receive all the numerous species besides, and directly contradict the generic character, "*receptaculum paleaceum*." Gærtner, Jussieu, and Willdenow, have properly corrected this oversight, as we have shewn under *ELICHRYSUM*. The true *Xeranthemum*, therefore, would be left with a solitary species, sufficiently well marked indeed to be so distinguished, as far as the Linnæan species go. But our great master is proved to have confounded several together, under his *X. annuum*. Willdenow distinguishes three species, two of which we cannot separate, but we shall subjoin a fourth. They were all known to Tournefort, who indeed divides them still further, mistaking double or white flowered varieties as species. The *root* of the whole genus is annual. *Herb* erect, rigid, alternately branched, clothed with fine, white, close, cottony down, easily rubbed off. *Leaves* alternate, sessile, lanceolate, acute, undivided, entire; tapering at the base. *Flowers* solitary, on long, terminal, slightly scaly, stalks. *Outer scales of the calyx* roundish, membranous and shining, at least at the edges; inner oblong, spreading while in flower, purple or brownish, occasionally white, very brilliant and ornamental.

1. *X. annuum*. Purple Xeranthemum, or Everlasting Flower. *Linn. Sp. Pl. 1201. Willd. n. 1. Ait. n. 1. Prodr. Fl. Græc. n. 2045. Jacq. Austr. t. 388. Mill. Illustr. t. 67. Mill. Ic. t. 279. (X. flore simplici, purpureo, majore; Tourn. Inst. 499, with perhaps the five following of that author. X. incanum non scetens, flore majore; Morif. sect. 6. t. 12. f. 2. Parmacia austriaca; Cluf. Hist. v. 2. 11. Ger. Em. 607. πικραλίον of Dioscorides, according to Dr. Sibthorp.)*

2. *Linn. Sp. Pl. 1201. (X. inapertum; Willd. n. 2. Ait. n. 2; excluding the synonym of Morison. X. capitulis inapertis; Hall. Enum. 709. t. 23. X. n. 122; Hall. Hist. v. 1. 52. Parmacia Imperati; Ger. Em. 606, no figure. Jacca oleæ folio, minore flore; Bauh. Pin. 272.)*

Outer calyx-scales roundish-elliptical, awned, smooth at

the keel; inner lanceolate, spreading. Crown of the feed lanceolate, shorter than the calyx.—Native of dry hilly ground in Austria, Hungary, France, Italy, and Greece; β is found in Switzerland, Spain, and Germany. This species is a hardy annual, common in our gardens, ever since the time of Gerard and Lobel, flowering in July and August. The first variety, and especially the femidouble kind, figured by Philip Miller in his *Icons*, is preferred for cultivation. The flowers with their stalks, dried quickly, preserve their shining purple colour very long, and make part of the winter decorations of a chimney-piece; but for this purpose, the back of every coloured scale of the calyx should be drawn, while fresh, over the edge of a blunt knife, to keep the flower open after it is dried. The stem is erect, branching, bearing linear-lanceolate, white, cottony leaves, and numerous flowers, an inch or more in diameter. The outer calyx-scales are membranous and shining, pale, quite smooth, each with a red or brownish mid-rib, most conspicuous upwards, and terminating in a small awn-like point.

In the variety β the flowers are of a smaller diameter, and the calyx spreads less; but we do not find that its outer scales are more acute, though somewhat variable in that respect; the inner are less strikingly purple, and turn browner as they fade. This variety we have from the Valais, as the undoubted plant of Haller, sent by the late Mr. Davall. Both kinds have a pleasant aromatic scent, different from the strong odour of the following.

2. *X. cylindraceum*. Cylindrical Xeranthemum. Sm. Prodr. Fl. Græc. n. 2046. (*X. orientale*, flore minimo, calyce cylindraceo; Tourn. Cor. 38. *X. oleæ folio capitulis simplicibus, incanum, fetens, flore purpurascente minore*; Morif. v. 3. 43. sect. 6. t. 12. f. 1.)—Outer calyx-scales elliptical, pointless, woolly at the keel; inner lanceolate, erect.—Native of Germany and Asia Minor. Gathered by Dr. Sibthorp on the Bithynian Olympus, or in its neighbourhood. Seeds of this species were given to Mr. Davall by professor Lachenal at Basle, for the common *X. annuum*, as figured by Haller; but on seeing the real plant of that author, above described, from the country of the Valais, he allowed them to be distinct. Mr. Davall first detected the true specific difference, in the woolly scales of the calyx, which, moreover, want the red mid-rib of the preceding species. Morifon indeed describes this mid-rib, which proves that he confounded *X. annuum* β , as many other people have done, with our *cylindraceum*; for Mr. Davall observed the strong disagreeable smell in his specimens, by which Morifon characterizes the plant before us.

3. *X. orientale*. Oriental Xeranthemum. Willd. n. 3. Ait. n. 3. (*X. annuum* γ ; Linn. Sp. Pl. 1221. *X. orientale*, fructu maximo; Tourn. Cor. 38. *X. oleæ folio, capitulis compactis*; Morif. v. 3. 44. sect. 6. t. 12. f. 4. *Jacea oleæ folio, capitulis compactis*; Bauh. Pin. 272. *J. incana, folio oleæ*; Dalech. Hist. 1193. Lob. Ic. 545. f. 1.)—Outer calyx-scales roundish, membranous; inner ovate, pointed, erect. Crown of the feed ovate, awned, longer than the calyx.—Native of Armenia and Syria. The leaves of this species appear to be broader and more elliptical than either of the foregoing. But its most striking difference is visible in the ovate scales, forming the crown of the feed, each of them ending in a long point, far overtopping the upright radiant scales of the calyx. We have never seen a specimen, but the figures above cited render the plant sufficiently intelligible. Willdenow describes the flowers the size of *X. annuum*, or larger. Surely Lamarck's t. 692. f. 2. cannot be intended for this plant! We know nothing auferable to that figure.

XERANTHEMUM, in *Gardening*, contains plants of the herbaceous, flowering, annual kinds, in which the species cultivated are, the annual xeranthemum, or common eternal flower (*X. annuum*); the reflexed-leaved eternal flower (*X. retortum*); the golden eternal flower (*X. speciosissimum*); the silvery eternal flower (*X. fefamoides*); the prolificus eternal flower (*X. proliferum*); the leafy-flowered eternal flower (*X. vestitum*); and the imbricated eternal flower (*X. imbricatum*). As to the species of Xeranthemum, see the preceding article.

The first is an herbaceous flowering plant, of which there are varieties with large white flowers, with double white flowers, with double purple flowers, and with double violet-coloured flowers.

Method of Culture.—In the first sort and varieties, the culture is readily effected by sowing the feeds in pots of light fresh mould, in the autumn or spring, or at other seasons for a succession, plunging them in a moderate hot-bed, to bring forward the plants. In the spring they may also be sown in patches where they are to remain, or in beds to be afterwards removed. When the plants have a few inches growth, they should be pricked out in rows a foot apart on beds, or into the borders, clumps, or other places where they are to grow. They should afterwards be kept clean from weeds, and have occasional waterings immediately after pricking out, and afterwards in dry weather.

The other sorts are raised by planting cuttings of the young shoots in the summer, in pots filled with light mould, giving them a little water and shade; or, which is better, plunging them into a hot-bed, and covering them with hand-glasses. When they are become firmly established in the autumn, they should be carefully removed into separate pots, being replaced in the hot-bed till re-rooted, after which they should have the management of other shrubby green-house plants.

The first sort produces a fine effect in the borders, clumps, &c. while growing, as well as in pots when the flowers are taken off; and the other sorts afford variety in green-house collections, among other potted plants of the same kind.

XERASIA, in *Medicine*, the name of a disease, a species of alopecia, in which the hair falls off through a dryness of the part, and want of due nourishment.

XERASIA, in *Animals*, denotes a certain kind of diseased state, which consists in a dryness of the hairs, caused by the want of due and sufficient nourishment and support, from which they decay and fall off. It is met with in such animals as have been starved, and kept and fed in a stinted manner only on poor sorts of food. It is to be removed by a better and more full kind of fodder, and other sorts of keep, and by being turned into a good salt-marsh pasture. See *SURFEIT*.

XERUARQO, in *Geography*, a town of Mexico, in the province of Mechoacan; 45 miles N.E. of Mechoacan.

XERES, a town of South America, in Paraguay, now in ruins. S. lat. 20° 5'.

XERES de Badajos, or *Xeres de los Caballeros*, a town of Spain, in Estremadura; 72 miles N.N.W. of Seville. N. lat. 38° 17'. W. long. 6° 52'.

XERES de la Frontera, a town of Spain, in the province of Seville, on the Guadalete; near which a battle was fought between the Moors and Goths, in the year 712, in which Roderick, the last king of the Goths, lost his life. The environs are celebrated for that excellent wine corruptly called sherry. The best and richest sort of sherry is called "pagarette," from the Spanish word *pago*, a district, and particularly applied to this vintage. In one aranzado (an acre of vineyard) they plant 1800 vines at regular distances.

tances. It is reckoned a good year if it gives three butts *per acre*, middling if two, and bad if but one: some years, however, it yields four or five. The number of inhabitants is estimated at 40,000, of whom one-twentieth, Mr. Swinburne says, are religious; 15 miles N.E. of Cadiz. N. lat. 36° 41'. W. long. 6° 15'.

XERES de la Frontera, a town of Mexico, in the province of Zacatecas, with a garison of Spaniards to protect the mines; 25 miles S. of Zacatecas.

XERES de Guadiana, a town of Spain, in the province of Seville, near the frontiers of Portugal; 74 miles W. of Seville.

XERES Nueva, a town of South America, in the province of Venezuela.

XERES. See **CHULUTECA**.

XERICA, a town of Spain, in the province of Valencia; 7 miles N.W. of Segorbe.

XERIFF, in *Commerce*, a money of account in Morocco, which is divided into eight paels.

XERITO, in *Geography*, a small river of Spain, which runs into the Alagon.

XEROCHLOA, in *Botany*, from *ξηρος*, *dry*, and *χλωα*, *a grass*.—Brown Prodr. Nov. Holl. v. 1. 196.—Clafs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Eff. Ch. Calyx two-flowered, of two unequal valves, parallel to the hollow of the receptacle, and half sunk therein; the outer valve smallest. Corolla of both flowers longer than the calyx, of two valves, awl-shaped, membranous, awnless. Stamens in the outermost flower. Styles in the inner one, combined at the base. Nectary none. Seed enclosed in the inner, paper-like, valve of the corolla.

This genus consists of perennial, rushy, dry, smooth grasses. *Leaves* awl-shaped, straight and stiff, with a very short *stipula*. *Stem* terminated by alternate sheaths, each containing from two to four short *spikelets*, of few *flowers*. *Xerochloa* is akin to *Apluda*, whose character requires correction. *Brown*.

1. *X. imberbis*. Beardless *Xerochloa*. Br. n. 1.—*Spikelets* awl-shaped, slightly curved. Inner valve of the male flowers smooth.—Gathered by Mr. Brown, in the tropical part of New Holland.

2. *X. barbata*. Bearded *Xerochloa*. Br. n. 2.—*Spikelets* lanceolate, straight. Inner valve of the male flowers bearded.—Native of the same country. *Brown*.

XERODES, in *Animals*, a term which is applied, and which serves to express any sort of tumour that is attended with the property of exsiccation or dryness. See **TUMOUR**.

XEROMYRON, formed of *ξηρος*, *dry*, and *μυρον*, *ointment*, a word used by the ancients to express what they do at other times call in express words a dry ointment. It was a composition of warm aromatic drugs, or of other things fit for external use, but without the fatty ingredients, by which they were usually reduced into the form of ointments.

XEROPHAGY, *Ξεροφαγια*, formed of *ξηρος*, *dry*, and *φαγια*, *I eat*, among the *Ancients*, the feeding only on dry victuals, which was the practice of the athletes.

In the first ages of the church, some, not contented with simple fasting, added the xerophagy thereto; abstaining not only from flesh and wine, but also from all fresh, succulent, and vinous fruits. And some even brought themselves to bare bread and water.

Tertullian, in his book *De Abitinentia*, cap. 9. speaks of the xerophagia as a thing commendable in time of persecution.

XEROPHTHALMIA, *Ξεροφθαλμια*, compounded of *ξηρος*, *dry*, and *οφθαλμος*, *eye*, a kind of ophthalmia, in

which the eyes itch, and are red, but without swelling or watering.

XEROPHYLLUM, in *Botany*, from *ξηρος*, *dry*, and *φυλλον*, *a leaf*, a genus founded by Michaux upon *Helonia asphodeloides* of Linnæus.—Michaux Boreal.-Amer. v. 1. 210. Willd. Enum. 402.—We confess ourselves unable to make out any sufficient reason for this measure, either in the author's description, or in the plant itself. Mr. Pursh probably was equally puzzled; for he has not even cited the *Xerophyllum* of Michaux, as a synonym under the above *Helonia*. It seems the bases of the *flamens* are dilated in the *asphodeloides*, more than in other species of **HELONIAS**. See that article.

XEROPHYTA, so named by Jussieu, from *ξηρος*, *dry*, and *φυον*, *a plant*, alluding to the arid habit of this little shrub.—Juss. Gen. 50. Willd. Sp. Pl. v. 2. 15. Lamarck Illustr. t. 225.—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Bromelia*, Juss.

Gen. Ch. *Cal.* none. *Cor.* of one petal, superior; limb in six deep ovate-oblong, acute, permanent segments; the three outer ones narrowest, spinous-pointed, stoutest, externally glandular. *Stam.* Filaments six, inserted into the lower part of each segment, thread-shaped, very short, equal; anthers erect, linear, half as long as the corolla. *Pist.* Germen inferior, turbinate; style one, short; stigma tumid, oblong, undivided. *Peric.* Capsule oval, rough, crowned with the faded corolla, with three cells, and many seeds.

Eff. Ch. Corolla in six deep segments, permanent; three outermost narrowest, spinous-pointed. Stamens inserted into the base of each segment. Stigma club-shaped. Capsule inferior, of three cells, with many seeds.

1. *X. pinifolia*. Fir-leaved *Xerophyta*. Willd. n. 1.—Gathered by Commerçon, in Madagascar. A hard rigid shrub, whose stem is round, alternately branched; the wood formed of parallel tubes, as in the generality of the monocotyledonous tribe: *branches* quarter of an inch in diameter, thickly clothed with the imbricated, deeply furrowed, permanent sheaths of the last year's foliage, each crowned with the reflexed base of a leaf, by which the whole branch assumes a singular scaly appearance. *Leaves* alternate, two inches, or more, in length, linear, rigid, channelled, striated, with thick entire edges, and a pungent spinous point; their base sheathing, fibrous, and somewhat woolly. *Flowers* terminal, one or two at the end of each branch, on simple stalks, an inch long, rough, like the *germen*, with minute prominent glands, of which some traces are also found on the backs of the three outward segments of the corolla. The colour, of the inner segments at least, appears reddish. Each flower is about half the size of a snowdrop. Nothing is known of the ripe fruit, in which perhaps some better marks, than have hitherto been given, may be found, to distinguish the essential characters of this genus from those of **HYPOXIS**. See that article.

XEROPKIN, in *Commerce*, a silver coin of Goa, in the East Indies, which is worth 3s. 1½d. sterling, nearly.

XEROTES, in *Botany, *Ξεροτης*, *dryness*, a name chosen by Mr. Brown to express the arid rushy habit of this genus, in preference to *Lomandra*, by which it is designated in the work of M. Labillardiere. This latter appellation, formed of *λωμα*, *a border*, or rather *fringe*, and *αντε*, *a male*, is designed to indicate the occasionally bordered anthers. It might perhaps have been allowed to remain, as well as many other names which are liable to some exception, though the anthers are not properly fringed.—Brown Prodr. Nov. Holl. v. 1. 259. (*Lomandra*; Labill. Nov. Holl. v. 1. 92.)—Clafs and order, *Dioecia Hexandria*. Nat.*

XEROTES.

Nat. Ord. *Tripetaloides*, Linn. *Junci*, Julf. *Juncea*, Brown.

Gen. Ch. Male, *Cal.* Perianth of six regular, ovate, coloured leaves; the three innermost, or perhaps all the six, connected at the base. *Cor.* none, unless the calyx be so called. *Stam.* Filaments six, very short, inserted into the base of each leaf of the calyx; anthers orbicular, peltate. Some rudiments of a *pisfil*.

Female, *Cal.* Perianth of six separate, permanent leaves. *Cor.* none. *Stam.* imperfect. *Pist.* Germen superior, ovate, with three furrows; styles three, short, combined at the base; stigmas obtuse. *Peric.* Capsule cartilaginous, coated, of three cells and three valves, with partitions from the centre of each valve. *Seeds* solitary, peltate.

Eff. Ch. Male, Calyx of six leaves; three innermost combined at the base. Corolla none. Anthers peltate.

Female, Calyx of six separate, permanent leaves. Styles three. Capsule superior, coated, of three cells; valves with central partitions. *Seeds* peltate, solitary.

This New Holland genus consists of perennial herbs, of a dry rigid texture, and a peculiar aspect, resembling the *Junci* and *Calamariae*. *Root* fibrous. *Stem* none, or generally very short; sometimes divided, and clothed with sheathing foliage. *Leaves* grassy, linear, either flat or channelled, rarely thread-shaped; their base dilated, membranous, half sheathing; their extremity sometimes toothed. *Flowers* terminating the stem, or radical stalk, either panicled, racemose, spiked, or the capitate. Inner leaves of the calyx often different from the outer in texture or size. When the flowers are sessile, they are invested with imbricated membranous bractees; the male ones are sometimes stalked, without bractees. Bark of the capsule at length separating, and occasionally a little pulpy. In some species, the skin of the seed adheres too loosely, as to resemble a distinct tunic. The embryo is longitudinal, straight, in the bottom of a cartilaginous albumen. *Xerotes* is allied in many points to the PALME. See that article. *Brocn.*

SECT. 1. *Female flowers in solitary beads. Leaves entire at the extremity.*

1. *X. flexifolia*. Spiral-leaved Xerotes. Br. n. 1. (*Dracæna obliqua*; Thunb. *Dracæn.* 6. t. 1. f. 2.)—Stem somewhat branched. Leaves shorter than the branches, two-ranked, twisted; their edges rough with minute teeth; their points withering, acute. Male spikes interrupted, somewhat branched longer than the leaves.—Native of New South Wales, from whence specimens were sent us by Dr. White. The stem is about a foot high; woody at the base; more or less branched above, clothed with numerous, narrow, smooth, striated leaves, an inch or an inch and a half long, spreading in two directions; their sheathing bases imbricated, and bordered with a long, thin, torn, stipulaceous membrane at each side. *Male flowers*: small, whitish, in long, mostly branched, rigid-stalked spikes or clusters, separated into little whorl-like tufts, accompanied by brown scaly bractees. *Female flowers* rather larger, in round solitary heads, terminating short leafy branches in the forks of the stem.

2. *X. mucronata*. Pointed Xerotes. Br. n. 2.—“Stem somewhat branched. Leaves shorter than the branches, but longer than the male spikes, two-ranked, straight, or slightly twisted; their points withering, acute; their margins roughish, with very minute teeth; dilated and entire at the base.”—Gathered by Mr. Brown, near Port Jackson, New South Wales, as well as the foregoing.

3. *X. collina*. Hill Xerotes. Br. n. 3.—“Leaves taller than the stem, narrow and straight; rough with marginal teeth; withering and very acute at the point; dilated and

jagged at the base. Head of female flowers sessile.”—Found by Mr. Brown, on the southern coast of New Holland.

4. *X. glauca*. Glaucous Xerotes. Br. n. 4.—“Leaves taller than the stem, narrow and straight; withering and bluntish at the point; rough with marginal teeth; dilated and jagged at the base. Tufts of flowers in the male spikes sessile.”—Gathered on the fourth coast of New Holland by Mr. Brown.

5. *X. leucocephala*. White-headed Xerotes. Br. n. 5.—“Male, as well as female, flowers capitate. Receptacle woolly. Leaves narrow, smooth-edged, longer than the perfectly simple stalk, bearing one or two heads of flowers. Stem short.”—Gathered by Mr. Brown, in the tropical part of New Holland.

SECT. 2. *Female flowers racemose or spiked: male ones racemose or panicled; partial stalks scattered; flowers drooping.*

6. *X. pauciflora*. Few-flowered Xerotes. Br. n. 6.—“Flowers few in the male cluster, in distant whorls. Leaves very narrow, acute and smooth; dilated and entire at the base; shorter than the divided stem.”—Found by Mr. Brown, near Port Jackson, New South Wales.

7. *X. filiformis*. Thread-shaped Xerotes. Br. n. 7. (*Dracæna filiformis*; Thunb. *Drac.* 4. t. 1. f. 1.)—Leaves thread-shaped, femicylindrical, elongated; flattened in front; rough-edged; finely striated at the back; round at the point. Male cluster scarcely branched. Stem short.—Gathered near Port Jackson, New South Wales, by Dr. White, and Mr. Brown. The root is woody. *Stem* scarcely any. *Leaves* several, a span or more in length, erect, rigid, very slender; flattened and whitish in front, with a green, striated, central furrow; convex at the back. We do not find that the point is always, as Mr. Brown says, round or cylindrical. *Clusters* much shorter than the leaves, branched in our specimens, as in Thunberg's figure, erect, lax, with rough stalks. *Flowers* scattered, or in pairs, drooping, whitish, small; the outer segments of the calyx smaller, and more membranous than the inner. *Bractees* awl-shaped, acute, at the base of the partial stalks. Mr. Brown notices three varieties: α . male perianth nearly globular, twice the length of the partial stalk; β . male perianth nearly globular; partial stalk longer than that part, or the bractees; γ . male perianth turbinate; partial stalk shorter than it, or the bractees. The leaves seem variable in breadth and flatness.

8. *X. tenuifolia*. Fine-leaved Xerotes. Br. n. 8.—“Leaves thread-shaped, elongated; channelled in front; deeply striated at the back. Male clusters somewhat divided, their branches alternate. Stem short.”—Observed by Mr. Brown, on the southern coast of New Holland.

9. *X. gracilis*. Slender Xerotes. Br. n. 9.—“Leaves very long and narrow, channelled; striated beneath; flat and entire at the point. Male panicles lax, alternately branched; partial stalks solitary. Stem short.”—Found by Mr. Brown at Port Jackson.

10. *X. denticulata*. Small-toothed Xerotes. Br. n. 10.—“Leaves elongated, thread-shaped, compressed, channelled, with two or three terminal teeth. Male clusters simple or divided. Stem short.”—Gathered by Mr. Brown at Port Jackson. We have some specimens which answer to this description, in the teeth of their leaves, but they seem nearly akin to *X. filiformis* to be separated from that species, and they exactly accord with Thunberg's fig. 1, drawn from a dried specimen. We are not, however, certain of their being Mr. Brown's *denticulata*.

11. *X. lasa*. Loose-flowered Xerotes. Br. n. 11.—“Leaves elongated, linear, flat, entire at the point. Male panicles

XEROTES.

panicles loose, with whorled branches, and distant clusters; partial stalks solitary, shorter than the nearly globular perianth, but longer than their minute bractæa."—Gathered by Mr. Brown, in the same country with the two last.

SECT. 3. *Flowers either spiked or panicled, their branches and tufts opposite or subopposite. Male perianths sessile, imbricated with bractæas. Capsule smooth. Leaves toothed at the end.*

12. *X. rigida*. Rigid Xerotes. Br. n. 12. Ait. Epit. 376. (*Lomandra rigida*; Labill. Nov. Holl. v. 1. 93. t. 120.)—Stem very short. Stalks and spikes much shorter than the foliage. Leaves two-ranked, cartilaginous; convex beneath; abrupt, with two marginal teeth, at the end; smooth at the edges; dilated and entire at the base.—Gathered by Mr. Brown in the southern part of New Holland. M. Labillardiere found it in Van Lewin's land. *Root* woody. *Leaves* a span in length, full a quarter of an inch in breadth, spreading in two directions, thick, rigid, smooth; greatly dilated, and bordered with a membrane, at the base; singularly abrupt, and three-pointed, at the end. *Common flower-stalk* terminal, thick, sharply two-edged, sometimes triangular, smooth. Tufts of *flowers* one above another, not numerous, forming an interrupted, branched, upright spike; each tuft accompanied by several unequal, lanceolate, acute bractæas. Three alternate *stamens*, according to Labillardiere, are longer than the rest, and bear cloven, not bordered, *anthers*.

13. *X. montana*. Mountain Xerotes. Br. n. 13.—“Stem none. Leaves elongated, linear, flat, membranous, smooth-edged; their sharp point with two very short lateral teeth. Female spike undivided, many times shorter than its stalk.”—Found by Mr. Brown, near Port Jackson.

14. *X. fluviatilis*. River Xerotes. Br. n. 14.—“Stem none. Leaves elongated, narrow, channelled, smooth-edged, two or three toothed, with an acute sinus, at the extremity. Female spikes simple or divided. Bractæas rather rigid, twice as long as the tufts of flowers.”—Gathered by Mr. Brown in the same country, but, as appears by the name, in the vicinity of rivers.

15. *X. longifolia*. Long-leaved Xerotes. Br. n. 15. Ait. Epit. 376.—Stem none. Leaves elongated, linear, coriaceous, erect; irregularly toothed at the point; rough-edged. Panicles lanceolate, rather dense, with opposite branches. Flower-stalk flattish. Anthers uniform.—Gathered near Port Jackson, by Mr. Brown; at the Cape of Van Diemen, by M. Labillardiere. The *leaves* are a foot and a half long, somewhat striated; dilated at the base, and bordered in that part with a membrane, which at length separates, and becomes torn. *Stalk* from nine to twelve inches high, two-edged. *Flowers* more numerous and crowded than in *X. rigida*, n. 12, with long taper-pointed bractæas. *Capsule* ovate, acute, thrice as long as the calyx, chestnut-coloured; pale yellow at the base; its coat separating in irregular fragments.

16. *X. Hylrix*. Porcupine Xerotes. Br. n. 16.—Stem none. Leaves elongated, linear, lax, smooth-edged; somewhat toothed at the extremity. Stalk rather convex on both sides. Male panicles repeatedly compound, with whorled branches. Bractæas leafy, rigid, spinous pointed.—Sent from the neighbourhood of Port Jackson, among the first botanical communications from thence, by Dr. White. It has also been gathered there by Mr. Brown. We have seen the living plant in some garden near London, possibly at Kew, and were much struck with the delightful fragrance of its copious panicles of male flowers, resembling the scent of *Crassula coccinea*, *Mesembryanthemum nodiflorum*, or a Bergamot Pear. Yet it does not occur in

Hort. Kew. The *leaves* are a foot and a half or two feet long, spreading. *Flower-stalks* of the male plant numerous, erect, two-edged, though convex at each side, from one to one and a half feet high, somewhat zigzag occasionally, each bearing a flattish panicle, from six to fourteen inches long, composed of numerous triangular branches, from four to eight in a whorl, beset with numerous tufts, or whorls, of sessile flowers, accompanied by several chaffy, inner bractæas, and subtended by about three long, spreading, external ones, with needle-like points. The *flowers*, and whole panicle, are of a delicate straw-colour, with a tinge of brown about the calyx or anthers. We have not seen the female plant. This species well deserves a place in the green-house, for the singularity of its appearance, as well as for its fine smell.

17. *X. arcuaria*. Sand Xerotes. Br. n. 17.—“Stem none. Leaves elongated, linear, smooth-edged, jagged and toothed at the end. Male panicle simple, with opposite branches. Tufts of flowers globose. Bractæas awl-shaped, reflexed. Flowers obtuse.”—Discovered in the tropical part of New Holland, by Mr. Brown.

SECT. 4. *Male panicle subhorrid. Flowers stalked, in drooping tufts. Capsule rugged. Leaves entire at the point.*

18. *X. difflans*. Diffant-flowered Xerotes. Br. n. 18.—“Stem none. Leaves very long, channelled, very rough at the edges. Male panicle with undivided branches, and distant tufts of flowers. Partial stalks shorter than the calyx.”—Native of the tropical part of New Holland. The male panicles are a foot long; calyx about a line and a half. *Brown*.

19. *X. media*. Intermediate Xerotes. Br. n. 19.—“Stem none. Leaves very long, channelled, smooth-edged. Branches of the male panicle undivided. Flowers five or six in each tuft; their partial stalks scarcely so long as the very short calyx. Female spike divided in the lower part, each branch bearing one head of flowers.”—From the same country as the last. *Calyx* only one-third of a line in length; male panicle six inches. *Brown*.

20. *X. decomposita*. Compound Xerotes. Br. n. 20.—“Stem none. Leaves very long, channelled, smooth-edged. Male panicle repeatedly compound. Tufts of few flowers. Partial stalks hardly so long as the calyx.”—Found also in the tropical part of New Holland. Male panicles a foot long. *Brown*.

21. *X. multiflora*. Many-flowered Xerotes. Br. n. 21.—“Stem none. Leaves very long, channelled; smooth at the back and edges. Male panicle with undivided branches, each bearing from one to three many-flowered tufts. Partial stalks longer than the calyx.”—Found by Mr. Brown in the same country as the four preceding species.

22. *X. amula*. Rough-long-leaved Xerotes. Br. n. 22.—“Stem none. Leaves very long, channelled, erect; rough at the back and edges. Male panicle with undivided branches, each bearing from one to three many-flowered tufts. Partial stalks longer than the calyx.”—Found by Mr. Brown, in the country near Port Jackson, New South Wales. The roughness of the leaves seems chiefly to distinguish this species from the last. We have seen no specimens of either.

23. *X. Banksii*. Bankian Xerotes. Br. n. 23.—“Cauliscent. Leaves two-ranked, flat, rough-edged. Female panicle dense, about the length of its two-edged stalk; branches quadrangular, very short.”—Gathered by Sir Joseph Banks, in the tropical part of New Holland, where it was not found by Mr. Brown.

SECT. 5. *Flowers of each sex in a cylindrical catkin-like spike.*

24. *X.*

24. *X. bastilis*. Spear-stalked Xerotes.—“Stem none. Spike very long. Stalk round. Leaves elongated.”—Gathered by Mr. Brown, on the southern coast of New Holland. The habit of this species appears, by the above characters, to differ widely from the rest of its genus, rather approaching a *XANTHOIRHÆA*. See that article.

XEROTRIBIA, formed of ξηρος, dry, and τριβω, I rub, a term used by authors to express a dry friction, a rubbing of some affected part with the hand or otherwise, to recall the warmth and circulation.

XERTE, in *Geography*, a river of Spain, which passes by Placentia, and runs into the Alagon.

XERTIGNY, a town of France, in the department of the Vosges; 7 miles E. of Epinal.

XERUMENHA, or *JERUMENHA*, or *Gerumenha*, a town of Portugal, in Alentejo; 10 miles S. of Elvas. N. lat. $38^{\circ} 35'$. W. long. $6^{\circ} 58'$.

XERXENA, in *Ancient Geography*, a country of Asia, on the confines of Lesser Armenia, of which it makes a part. Strabo.

XERXES, in *Biography*, was the son of Darius I. by Atossa, the daughter of Cyrus; and on the death of his father, succeeded to the crown of Persia, in the year 485 B.C. Having in the second year of his reign subdued the revolted Egyptians, and committed them to the government of his brother Achæmenes, he determined to renew the invasion of Greece, in which Darius had been disappointed; and for the success of his expedition, he formed an alliance with the Carthaginians, on condition of their making an attack on the Greek colonies in Italy and Sicily, so that they might not have it in their power to assist the mother-country. His preparations were immense, and occupied several of the first years of his reign. Having provided a large navy, he formed a project of cutting a canal through mount Athos, of sufficient breadth to admit two galleys abreast; and to this undertaking, which some have regarded as a fiction, he devoted three years. He also constructed a bridge of boats across the Hellespont, in order to convey his army from Asia to Europe; and as the first bridge which had been laid was demolished by a storm, he not only manifested his childish rage by ordering 300 lashes to be inflicted on the sea, and a pair of fetters to be thrown into it, but his tyrannical and cruel disposition by beheading those to whom the conduct of the work had been committed. The number of sea and land forces which he employed in this expedition is said to have amounted to two millions and a half, to which we may add as many more attendants. When he ascended a high tower at Abydos, and took a view of the immense number that covered the sea and surrounding plain, his pride and triumph are said to have given way to tears, when the reflection occurred, that the brevity of human life was such as not to allow one of this countless host to survive the lapse of 100 years. Without detailing the events of this disastrous expedition, which are the proper subjects of history, we shall merely mention that it terminated in the defeat of Xerxes's navy at Salamis, and the subsequent overthrow and dispersion of Mardonius's army of 300,000 men; and specify some traits of the disposition and character of this ambitious despot. For his ignominious treatment of Leonidas, we refer to his article. Upon his taking possession of Athens, he wreaked his vengeance on the buildings and the temples, and dispatched a special messenger to his uncle Artabanus, to inform him of this inglorious triumph. Having erected a throne on a lofty mountain, in order to view the expected victory at Salamis, the event produced such consternation, that he suddenly left Mardonius and the army, and hastened to the Hellespont, where

VOL. XXXIX.

finding his bridge shattered by storms, but still haunted with terror, he intruded himself in a fishing-boat, and hastened to Sardes; but when Mardonius was defeated, and all his hopes of conquering Greece were frustrated, he quitted Sardes, after having given orders for the demolition of all the temples in the Greek cities of Asia, and proceeded with all possible expedition to the Persian frontier. The other traces of his disgraceful expedition were the records of the cruelties and debaucheries exercised by himself and his family. So much at length did Xerxes become the object of contempt and hatred, that a conspiracy was formed among his own guards, which terminated in his murder during sleep, in the 21st year after his accession, B.C. 465. Herodotus. Diodorus. Anc. Un. Hist.

XESTA, $\Xi\sigma\tau\alpha$, an Attic measure of capacity, answering to the Roman sextary.

XESTES; an ancient Greek liquid measure, which is = 2 cotyli. See *MEASURE*.

XIAMETLA, in *Geography*, a town of Mexico, in the province of Xalisco; 30 miles S.E. of Purification.

XIASSI, a town of the duchy of Warsaw; 20 miles S.S.E. of Posen.

XIBACA, a town of Japan, in the island of Niphon; 120 miles S.W. of Meaco.

XICOCO, called also *Sikoko*, and *Sikokf*, an island of Japan, about 90 miles in length, and about half as many in breadth, divided into several provinces, situated near the fourth-west extremity of Niphon, from which it is separated by a strait, full of small islands, and to the north-east of Ximo. It has several convenient harbours, and many towns within the country. N. lat. $33^{\circ} 30'$. E. long. 132° .

XICONA. See *XICONA*.

XILCA. See *CHILCA*.

XILOA. See *QUILOA*.

XILOCA, a river of Spain, which rises in the fourth part of Aragon, about 7 miles N.E. of Albaracin, and at Calataud changes its name to Xalon.

XILOTEPEC, a town of Mexico, in the province of Guatteca; 90 miles S.S.W. of Panco.

XILVAN, a town of the principality of Georgia; 20 miles N. of Gory.

XIMABARA, a town of Japan, on the fourth coast of the island of Ximo, on a gulf to which it gives name; 33 miles E. of Nangafaki. N. lat. $32^{\circ} 45'$. E. long. $132^{\circ} 7'$.

XIMAGUINO, a town of Japan, in the island of Xicoco; 10 miles S. of Awa. N. lat. $33^{\circ} 50'$. E. long. $130^{\circ} 30'$.

XIMENA, a town of Spain, in the province of Seville. Near this town Craffus is said to have concealed himself in a cave, till Marius and Cinna were overthrown by Sylla; 24 miles E. of Medina Sidonia.

XIMENES, FRANCIS, Cardinal, in *Biography*, was born in 1437, in Old Castle, and educated at Alcalá and Salamanca. Renouncing preferments which he obtained in his youth, he assumed the habit of St. Francis, in a monastery of the Observantines, one of the most rigid orders of monks in the Romish church. Distinguished by his austerities and devotional practices, he became confessor to queen Isabella; and still retaining his customary modes of living, he so far engaged her respect and attachment, that he was nominated by her to the archbishopric of Toledo, the richest benefice in Europe next to the papal fee; but his real or affected reluctance to accept this high preferment could be overcome only by the authority of the pope. In this elevated station he maintained his strict adherence to the rigours of the order to which he belonged, and so far from relaxing

in his feverities, he indulged them to the extreme of self-mortification and penance. Having thus acquired a complete mastery over his own passions, and possessing political talents in a very high degree, he was thought peculiarly fitted to exercise dominion over others; and accordingly Ferdinand and Isabella entrusted him with a principal share in the administration. When a strong party was formed among the Castilians to deprive Ferdinand of the authority as regent, devolved upon him by the will of the queen, he was deserted by every person of distinction except Ximenes and two nobles; and after he had resigned it to the archduke Philip, he again acquired it upon Philip's death in 1506, by the influence of Ximenes. In 1507 Ximenes was created a cardinal by pope Julius II.; and in the following year he undertook the conquest of Oran, and of other places on the coast of Barbary, with an armament, the expence of which he offered to defray out of his own revenues, and he succeeded in this enterprise. Such was Ferdinand's confidence in the abilities and integrity of the cardinal, that when he was dying in 1516, he appointed him regent of Castile until the arrival of his grandson Charles. Although he was then in his 79th year, he took an active part in securing the throne to Charles, though in his own judgment he disapproved the king's conduct, who in his assumption of power contended the declared opinion of the Cortes. With no less firmness and inflexibility, he prosecuted a plan for extending the royal authority, which the nobility had very much circumscribed. The measures which he adopted for this purpose excited violent opposition, but he persisted, and ultimately succeeded. During his administration he was also engaged in two foreign wars; one for the preservation of the kingdom of Navarre, in which he was successful, and another against Horuc Barbarossa, who advanced himself from the condition of a corsair to the sovereignty of Algiers and Tunis, in which the Spaniards were totally defeated. When Charles was prevailed upon by Ximenes to visit Spain, the cardinal took a journey towards the coast to meet his majesty; but being disabled to proceed by the attack of a disorder, supposed to be the effect of poison, he requested an interview with the king; but Charles having conceived prejudices against him, returned a cold answer, with permission for his retirement to his diocese, that he might finish his days in tranquillity. In a few hours after the receipt of this letter, he expired November 1517, at the age of 80 years.

Ximenes was held in high estimation by his superstitious countrymen, under a delusive idea that he possessed the gift of prophecy, and a power of working miracles. But his more unequivocal claims to their respect were founded on his extraordinary talents and learning, his liberal patronage of literature, and the munificence of his public charities, to which he devoted the immense revenues of his archbishopric. At Alcalá he built the magnificent college of St. Ildefonso, endowed with forty-six professorships, and conducted under excellent regulations. Here he printed the Complutensian Polyglott, (see POLYGLOTT,) the Mozarabic liturgy, and the theological works of Toftatus. Here he also established a splendid monastery for the education of indigent females of quality, which served as a model for that of St. Cyr, under Lewis IV. The granaries which he constructed remained without decay for centuries; and upon the whole he was justified in declaring on his death-bed, that to the best of his knowledge he had not misapplied a crown of his revenue. Robinson's Charles V. vol. ii.

XIMENES, in *Geography*, a town of Spain, in the province of Leon; 10 miles S. of Astorga.

XIMENESIA, in *Botany*, Cavan. Ic. v. 2. Co. Ait. Hort. Kew. v. 5. 85, a genus which can by no means be separated from PALLASIA. (See that article, n. 3.) Nothing can be more trifling as a generic, or even specific distinction, than the difference between the syngeneisous orders of *Polygamia-superflua*, and *P. frutranca*, of the Linnæan system, provided the form of the *flowers* be alike. The *pyxis*, of which rudiments are found in several genera of the latter, may occasionally become perfect, as it does now and then in *Helianthus*, and thus overlets the distinction.

XIMENIA, owes its name to Plumier, who consecrates this genus to the memory of the Rev. Father Francis Ximenes, a Spanish monk, one of the twelve Franciscan friars who first preached Christianity to the Mexicans. Being well skilled in the language of the country, he collected a great store of information concerning the properties and medical uses of the plants and animals of New Spain, and especially of Mexico; whence he composed a work, printed in four books, at Mexico, in 1615, which is quoted with approbation by De Laet, in many parts of his own publication. It is some consolation to find any of these apostles turning their minds to the study of their Maker's works; as we cannot suppose such to have been contaminated with that infernal spirit, which renders the whole history of the Spaniards in America a foul reproach to humanity, and to Christianity itself, so prostituted or so misunderstood!—Plum. Nov. Gen. 6. t. 21. Linn. Gen. 190. Schreb. 255. Willd. Sp. Pl. v. 2. 338. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 352. Juss. 259. Lamarck Illustr. t. 297. Poir. in Lam. Dict. v. 8. 804.—Class and order, *Oëandria Monogynia*. Nat. Ord. *Aurantia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very small, in four pointed, permanent segments. *Cor.* Petals four, oblong; hairy internally; their lower half erect, forming a tube; their upper part revolute. *Stam.* Filaments eight, erect, short; anthers erect, longer than the filaments. *Pist.* Germen superior, oblong; style thread-shaped, the length of the stamens; stigma obtuse. *Peric.* Drupa nearly ovate. *Seed.* Nut solitary, roundish.

Eff. Ch. Calyx four-cleft. Petals four; hairy internally; revolute at the upper part. Drupa superior. Nut solitary.

Obf. Plumier's figure represents but three *petals*. Linneus has left a note, that his correspondent Allamand found but seven *stamens*. Swartz and Jacquin describe eight.

1. *X. americana*. Thorny Ximenea. Linn. Sp. Pl. 497. Hort. Cliff. 483. Willd. n. 1. Ait. n. 1. Swartz Obs. 149. (*X. multiflora*; Jacq. Amer. 106. t. 177. f. 31. *X. aculeata*, flore villosa, fructu luteo; Plum. Ic. 260. t. 261. f. 1. Heynssholt Spinosa; Aubl. Guian. 324. t. 125? and *H. inermis*; *ibid.* 325?)—Branches spinous. Leaves oblong. Stalks many-flowered.—Native of the neighbourhood of Carthagena, as well as of Hispaniola, flowering in September and October, and ripening fruit in December. *Jacquin*. Of the rocky shores of Hispaniola, flowering in July. *Swartz*. We believe Linneus never saw any specimen of this, except in Clifford's herbarium. That before us was given to the younger Linneus by sir Joseph Banks. Though Miller might have the plant at Chelsea in 1759, it would now probably be vainly sought for in any collection. The *stem* is either shrubby or arborescent. Young *branches* spinous, round, striated. *Leaves* two or three together, in alternate tufts, from buds of many years' duration, italked, elliptic-oblong, obtuse with a minute point, rarely emarginate, entire, single-ribbed, smooth on both sides, about two inches long. *Footstalks* quarter of an inch

inch long, smooth. *Thorns* lateral, erect, longer than the footstalks, awl-shaped, stout, but sparingly produced. *Flower-stalks* axillary, or rather from the same bud as the leaves, not half their length, deflexed, round, divided into from three to five smooth, single-flowered partial stalks. *Calyx* spreading quadrangular. *Petals* four, whitish, flaggy from the base almost to the apex, on the inflexed; smooth externally. *Fruit* the size of a small apple, yellow when ripe. Jacquin says the pulp is sweetish, eaten by children and negroes, and that the smell of the *flowers* is extremely sweet, as well as powerful, something like burnt frankincense. Aublet compares them to cloves. His figure, if it belongs to the same plant as ours, is very faulty; but we rather presume it must be a species nearly akin, whose *flowers* are really axillary, and, like the *fruit*, only one-third the size of the Linnæan plant; their *petals* finely downy, not flaggy, all over their inner surface. Still, without seeing a specimen, we dare not describe it as distinct.

2. *X. elliptica*. Elliptical Ximenea. Forst. Prodr. 27. Willd. n. 2.—“*Thorns* none. Leaves elliptic-lanceolate. Stalks many-flowered.”—Found by Forster in New Caledonia. This is known only by the above characters, which are not so discriminative as could be wished, the *thorns* being variable in the original species, and in the plant of Aublet.

3. *X. inermis*. Jamaica Ximenea. Linn. Sp. Pl. 497. Willd. n. 3. (Amyris? arborefcens, foliis ovatis glabris, vetustioribus confectis; petiolis submarginatis; floribus solitariis; Browne Jam. 209.)—“*Thorns* none. Leaves ovate. Stalks single-flowered.”—Native of Jamaica. Browne describes it as a bushy tree, not above eight or nine feet high; its *trunk* about four and a half inches in diameter. *Leaves* oval, not above an inch long, standing very thick upon the smaller branches. *Petals* hairy on the inside towards the base. *Drupa* ovate-oblong.

M. Poiret describes, in Lamarck's Dictionary, a plant by the name of *X. ferax*, n. 3, which we can scarcely refer to this genus; the *flowers* being five-cleft; *petals* linear, smooth on both sides; and *filaments* prominent. This is a spinous shrub, found in Hispaniola, with nearly orbicular, coriaceous leaves, above an inch long, and either solitary or umbellate axillary flowers. The *thorns* are three or four inches long, very sharp, sometimes leafy.

Jussieu speaks of a *X. egyptiaca*, as described in the *Species Plantarum* of Linnæus, though omitted subsequently in his *Systema*. We are unable to discover this, and Jussieu, like Calpar Bauhin, unhappily omits to cite pages. We do, however, find in Linnæus's copy of Plumier's *Genera Plantarum*, which once belonged to the French botanist Inard, a note of the latter under *Ximenea*, that “the *Agiballid* of Alpinus, *Pl. Egypt.* 38, appears to belong to this genus.” The rude wooden cut does indeed countenance such an opinion, especially the *flowers*; but the author compares the *fruit* to that of *Sambucus Ebulus*, describing it moreover as bitterish and astringent. Now *Sambucus* has nothing in common with *Ximenea*. The plant of Alpinus, which was brought from Ethiopia, may be a thorny *Lycium*, but we cannot refer it to any known species.

XIMO, or KUSIU, in *Geography*, an island of Japan, and second in size and eminence, situated to the S.W. of Nippon, from which it is divided by a narrow channel. Its circumference is supposed to be upwards of 300 miles, exclusive of the bays and creeks. It has considerable numbers of cities and towns, with some good harbours. N. lat. 32° 40' to 34°. E. long. 130° 50' to 133° 30'.

XIMONOSEQUI, a sea-port town of Japan, on the

S.W. coast of Nippon, with a good harbour, capable of containing 300 vessels. It is a place of trade, and surrounded with walls. N. lat. 33° 56'. E. long. 132° 20'.

XINGU, a river of South America, which rises somewhere near S. lat. 17°, and is first called “Paranatinga;” it afterwards takes a northerly course of about 900 miles, and runs into the Amazons river, 20 miles E. of Paru, in the government of Para.

XIPHIAS, $\Xi\phi\iota\alpha\varsigma$, the name of the *sword-fish*; which see. This fish is cut in pieces by the Sicilians, and salted. The process was anciently performed particularly at the town of Thurii, in the bay of Tarentum, and hence the fish was called “Tomus Thurianus.” (Plin. l. 32. c. 11.) Besides the Xiphias Gladius, described under the article *Sword-Fish*, Dr. Shaw has enumerated some other species, such as the following:—

PLATYPTERUS, or sword-fish with extremely broad back-fin, and very long sharp-pointed thoracic appendages; the *Guebœu* of Marcgrave, and *Scomber gladius* of Black. This species, in the appearance of the long and sharp-pointed process of the upper jaw, is nearly allied to the common sword-fish, but in other respects materially differs from it. It is found twenty feet in length, and sometimes much longer. Its general colour is a silvery bluish-white, except on the back, head, tail, and fins, which in the living animal are of a deep blue. The strength of this fish is such that it pierced the bottom of an East Indian ship with such force as completely to imbed its snout almost to its base; and if it had not been killed by the violence of the effort, but had been able to withdraw its snout, the ship must have been leaky, and thus have foundered. This power of transfixing vessels is mentioned by Pliny. This fish is found not only in the Brazilian and East Indian seas, but also in the Northern ocean; and it is said to be a great enemy to whales, with which it has frequent combats. Dr. Black says, that when this species does not exceed four feet in length, it is considered as an eatable fish; but when it exceeds that length, it is too coarse.

MAKAIRA, the blackfish sword-fish with snout of middling length, and two bony tubercles on each side of the tail. This is a species lately discovered, and described by Cope under the title of “Makaira.” This fish was cast on the isle of Rhé, near Rochelle in France. Its length was 330 French centimetres, and its weight 365 kilogrammes; its colour was blackish. It was eaten by many of the inhabitants of Rochelle, and found to be tolerable food, though somewhat dry; the flesh was white. The “round-snouted sword-fish” is also described by Cope, from the sword or snout preserved, with the fore-part of the head, in the Paris Museum. Shaw's Zoology, vol. iv. part i.

XIPHIAS is also used to express a fiery meteor, in form of a sword. See ACONTIAS.

XIPHIAS, in *Astronomy*. See DORADO.

XIPHIDIUM, in *Botany*, from $\Xi\phi\iota\varsigma$, a sword, alluding to the sword-shaped leaves. The name occurs in Pliny, and was adopted by Loefling for the present genus, which Linnæus, in publishing Loefling's papers, sunk in IXIA (see that article); but subsequent writers have restored it, the *germen* being superior, and the *corolla* of six separate petals.—Schreb. Gen. 37. Willd. Sp. Pl. v. 1. 248. Vahl Enum. v. 2. 162. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 107. Aubl. Guian. 33. Swartz Ind. Occ. 79. t. 2. Juss. 59. Lamarck Illust. t. 36.—Clafs and order, *Triandria Monogynia*. Nat. Ord. *Enfatæ*, Linn. *Iridibus affinis*, Juss. *Hemodoraceæ*, Brown?

Gen. Ch. *Cal.* none. *Cor.* inferior, of six petals, regular, permanent; the three outer ones largest. *Stam.*

Filaments three, linear, opposite to the three inner petals; anthers ovate. *Pist.* Germen superior, globose; style thread-shaped; stigma simple. *Peric.* Capsule at first fleshy, then dry, roundish, with three furrows, and three cells. *Seeds* numerous, roundish, pointed, inserted into a fleshy, central, nearly globular, receptacle.

Eff. Ch. Corolla regular, of six petals. Capsule superior, of three cells, with many seeds.

Obs. The regularity of the flower readily distinguishes this genus from *WACHENDORFIA*. See that article.

1. *X. floribundum*. Many-flowered Xiphidium. Swartz *Prod.* 17. *Ind. Occ.* 80. *Vahl* n. 1. (*X. albidum*; Lamarck *Illustr.* v. 1. 131. *X. album*; Willd. n. 1. *Ixia*; Linn. in *Loeffl.* It. 179.)

2. *X. cæruleum*; Aubl. *Guian.* 33. t. 11. Willd. n. 2. *Ait.* n. 1.—Native of South America, as well as of Tobago and St. Kitt's. Mr. Masson is recorded by Dr. Swartz as having gathered the white-flowered kind, &c. at the foot of some hills, near Sandy Point, in the last-mentioned island: β was found in Guiana, by Aublet. We have a specimen of the latter from Miller's herbarium, gathered in some part of South America. The root is perennial, somewhat creeping, jointed. Stem a foot or more in height, round, simple, as thick as the little finger; leafy in the lower part; more or less minutely hairy. Leaves numerous, alternate, sessile, somewhat sheathing, sword-shaped, pointed, entire, or minutely serrated, striated with numerous longitudinal ribs. Cluster compound, terminal, erect, of many spreading, simply racemose, branches, more or less hairy, with a very minute bractea under each partial flower-stalk. Flowers not half an inch in diameter. Three outer petals green, and often downy at the back; white or blue in front, as the three inner ones are on both sides.

Swartz and Vahl have united the two supposed species of other authors. The latter asserts the blue-flowered variety to be sometimes entirely smooth in its leaves as well as flowers.

XIPHILINUS, JOHN, in *Biography*, was born at Trebizond, in the 11th century, and having passed the earlier period of his life in a monastery on mount Olympus, was advanced to the patriarchate of Constantinople, which office he held till his death in 1075. Besides a sermon printed in the *Bibliotheca Patrum*, he is reputed by some to be the author of an "Abridgment of the History of Dion Cassius," in Greek, written faithfully, which was printed at Paris in 1592, fol.

XIPHION, or XIPHUM, in *Botany*, $\xi\iota\upsilon\omicron\nu$ of Dioscorides, so called from the sword-shaped leaves, appears evidently, by the account of that ancient writer, to be *Gladiolus communis*, Linn. *Sp. Pl.* 52, our Common Corn-flag. *Xiphium* nevertheless is retained by Linnæus as the specific name of a common, but very elegant and fragrant bulbous *Iris*, with blue and yellow flowers. To this it seems he was led by Tournefort, who applies the name of *Xiphion* to the whole tribe of bulbous-rooted species of *Iris*, of which he makes a separate genus, characterized by the root. This is rather unfortunate, as the Linnæan *Iris Xiphium* has rather awl-shaped than sword-like leaves.

XIPHOIDES, $\xi\iota\upsilon\omicron\iota\delta\epsilon\varsigma$, in *Anatomy*, a cartilage placed at the bottom of the sternum, called also *eniformis*.

It is about an inch long, and shaped like the point of a sword. Whence its appellation, from $\xi\iota\upsilon\omicron\varsigma$, sword, and $\iota\delta\iota\omicron\varsigma$, figure.

XIPHONIE PRONOTORIUM, in *Geography*, a promontory of Sicily, near port Xiphonium.

XIPHOS, $\xi\iota\upsilon\omicron\varsigma$, among the Athenians, a capital punishment, by beheading with the sword.

XIPIXAPA, in *Geography*, a town of South America, in the audience of Quito; 80 miles N.W. of Guayaquil.

XIQUACAN, a town of Mexico, in the province of Mechoacan; 50 miles S.E. of Zacatula. N. lat. $18^{\circ} 4'$. W. long. $102^{\circ} 34'$.

XIQUENA, a town of Spain, in the province of Murcia; 15 miles W.N.W. of Lorca.

XIQUITO, a town of Japan, in the island of Ximo; 16 miles S. of Naka. N. lat. $32^{\circ} 20'$. E. long. $133^{\circ} 13'$.

XIR, a word used by the chemists to express mercury.

XISINUM, a word used by some of the chemical writers to express vinegar.

XIVERT, in *Geography*, a town of Spain, in Valencia; 7 miles N.W. of Segorbe.

XIVRY LE FRANC, a town of France, in the department of the Moselle; 9 miles S. of Longwy.

XIXONA, a town of Spain, in Valencia. In the neighbourhood of this town a great number of persons are employed annually to collect the drug called Kermes, and a small district, called *de la Grana*, produces some years to the value of 30,000 dollars; 13 miles N. of Alicante. N. lat. $38^{\circ} 32'$. W. long. $0^{\circ} 42'$.

XIZABRAS, mountains of South America, in the province of Venezuela.

XOANA, in *Ancient Geography*, a town of India, on this side of the Ganges.

XOCHIOCOTZO, in *Botany*, a name used by some authors for the tree which produces the liquid amber, and is called the sweet gum by the inhabitants of the West Indies.

XOCHITENACATL, in *Ornithology*, a name given by some to the toucan, or American great-beaked magpye.

XOCHITENACATL *Alia*, the name of a bird described by Nieremberg, of the nature of the toucan, or Brazilian magpye.

It is of the size of a pigeon; its beak is large and thick, and is black and pointed; its wings and tail are variegated with black and white; it has a large black mark reaching from its back to the breast; the anterior part of the wings is yellow, the rest of its body of a pale colour, and the legs and feet brown. It always is found among the sweet-flowering trees, and is not uncommon in many parts of South America. Ray.

XOCOTLAN, or XOCUTLÁN, in *Geography*, a town of Mexico, in the province of Xalisco; 15 miles S.W. of Purification.

XOCOXOCHITL, the Indian name of the clove-berry-tree, or the *castia caryophyllata*, the bark of which is used in medicine.

XODRACE, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

XOES, an island of the Mediterranean, on the coast of Egypt, near the mouth of the Nile, called "Xebenniticum;" and also a town of the same name. Steph. Byz.

XOIS, a town of Egypt, in the Nome, denominated Xoites Nomos. Ptolemy.

XOLA, in *Geography*. See SOOLOO.

XOLO. See GILOLO.

XOMOTL, in *Ornithology*, the name of an American bird, of which the Indians are very fond, making a part of their garments of its feathers.

Nieremberg has given a short account of it. It is a web-footed fowl; its back and the upper part of its wings are black, and its breast is brown. When it is angry, it raises up the feathers of its head in form of a crest. Ray.

XORULLO,

XORULLO, or **JORULLO**, *Volcano of*, in *Geography*, a basaltic cone of New Spain, which appeared above ground on the 15th of September 1759, and which is at this day 249 fathoms or 1494 feet above the surrounding plain. It is situated in the province of Mechoacan, at the distance of eight leagues from Pafquaro the capital, towards the S.W.; the volcano of Colima being in the same direction, but at a greater distance. A delicious and fertile vale, eight leagues in length from N. to S., and three in breadth, was called Xorullo by the Indians, a word in their language signifying *paradise*; but upon the eruption of the volcano, this valley assumed an infernal aspect, blackened with perpetual smoke, covered with deformed rocks and ashes, the trees consumed, the earth full of deep breaks and openings, and now forming a hill of considerable height, crowned with a volcano. A rivulet which fertilized the valley is now so hot as to burn men and animals who attempt to pass it, which is peculiarly inconvenient, as it is in the direct road to the copper-mines in this quarter. Before this catastrophe, there were constantly heard horrible subterraneous noises, and earthquakes were felt, which excited consternation in the inhabitants.

XOXOUHQUITCPATLI, an American name of a stone of the jasper kind, and of a beautiful green, but usually pale, and sometimes with a mixture of grey, and variegated in several places with spots of a deeper green.

It is found among the several kinds of *lapis nephriticus*, with which that country abounds, and most of which the Indians celebrate for their virtues against diseases; they are not, however, acquainted with any medicinal virtues of this species.

XV. VIR, *Quindecimvir*. See **QUINDECIMVIR**.

Authors, and especially antiquaries, make use of such abbreviations, which they borrow from medals, and other monuments of antiquity, where those names are so expressed.

XUAREZIA, in *Botany*, according to De Theis, is a genus dedicated, in the *Flora Peruviana*, p. 20, to Gaspar Suarez, a Spanish botanist, who has devoted himself to the study of the plants of Italy.

XUCAHA, or **XUCAAH**, the name of a plant much famed for its virtues among the ancient Arabians, but unknown at this time.

XUCAR, in *Geography*, a river of Spain, which rises in New Castile, and runs into the Mediterranean, 20 miles S. of Valencia.

XUCHES, or **ZUCHIS**, in *Ancient Geography*, a town of Africa, in Libya. Steph. Byz.

XULLI, in *Geography*, a town of Peru, in the diocese of La Paz, near the west coast of lake Titicaca, chiefly inhabited by Indians, and governed by Indian magistrates; 100 miles N.N.W. of La Paz. S. lat. 16° 25'. W. long. 70° 6'.

XULI, a small island in the Pacific ocean, near the coast of Peru. S. lat. 16° 50'.

XULLA, or **XULLOE**, an island in the East Indian sea, about 42 miles long, and from 10 to 15 broad. The English some years since formed a settlement in this island, but from the badness of the soil, and some other circumstances, they were induced to abandon it, and remove to Balam-bangan, on the coast of Borneo. S. lat. 1° 53'. E. long. 125°.

XULLABELLA, an island in the East Indian sea, about 25 miles long, and 6 broad. S. lat. 2° 15'. E. long. 126° 12'.

XULLAMANGOLA, an island in the East Indian

sea, about 30 miles long, and 10 broad. S. lat. 1° 54'. E. long. 125° 42'.

XUN, a city of China, of the second rank, in Se-tchuen; 150 miles S.W. of Pao-king. N. lat. 30° 18'. E. long. 103° 20'.

XUNDALE, a town of South America, in the province of Popayan; 8 miles S.W. of Sante Fe de Antioquia.

XUQUI. See **JUGUI**.

XUTHIA, in *Ancient Geography*, a country of Sicily. Diod. Sic. It is represented as a town by Steph. Byz.

XUXUY, in *Geography*, a town of La Plata, which chiefly trades in cattle, sold to the miners of Potosi, and brought in considerable number to the great fair of Salta; but now in a declining state. See **JUJUY**.

XYLAGIUM, a name given by some authors to the lignum sanctum, or guaiaicum.

XYLANDER, **WILLIAM**, in *Biography*, whose family name was *Holtzmann*, was born in indigent circumstances at Augsburg, in 1532, and enabled by public liberality to study at Tubingen and Basil, in the latter of which places he took the degree of M.A. in 1556. In 1558 he was invited to undertake the Greek professorship at Heidelberg; where, with all the disadvantages of penury, he pursued his literary labours, and acquired an amplitude of erudition, which comprehended the learned languages, history, poetry, music, philology, and physics. The works by which he is chiefly known are Latin translations, (with notes,) of Dion Cassius, Plutarch, Strabo, and Cedrenus. His life was prematurely terminated in consequence of hard study, in 1576, at the age of 44 years. Moreri.

XYLARIA, in *Botany*, from *ξύλον*, wood, a name given by some cryptogamic botanists to the first section of the genus **SPHERIA** in Perfoon. (See that article.) The idea appears to have been suggested by the old name of *Hypoxydon*, belonging to one of the species. But it may also apply to the woody and durable texture of that and some others of the same section.

XYLENOPOLIS, the *Town of the Woods*, in *Ancient Geography*, a town of India, at one of the mouths of the river Indus, according to Pliny, who reports that it was built by Alexander. M. D'Anville thinks that this town is the same with Hyala. It subsisted in the time of Pliny.

XYLINA, **IXIL**, a town of Asia, in the Colchide, and country of the Lazii. It was situated on the right bank of the Acinafis, near its mouth in the Euxine sea, north of Chordyla.

XYLINE, a town of Cappadocia, in Cappadocian Pontus. Ptol.

XYLINES, a people of Africa, in Libya interior, E. of the Agagines, from the foot of mount Arvalle, as far as mount Aranges. Ptol.

XYLO-ALOE, compounded of *ξύλον*, wood, *άλος*, aloes, in *Medicine*, the lignum aloes; called also *agallochum*. See **ALOE**, and **CALAMBAC**.

XYLO-BALSAMUM, *Ξυλοβάλσαμον*, compounded of *ξύλον*, wood, and *βάλσαμον*, balsam, a name which naturalists, &c. give to the wood of the tree, which yields that precious gum known to the Latins by the name of *opobalsamum*, and, among us, by the name of *balsam*, or *balm of Gilead*.

We have branches of this tree brought from Cairo. They are very straight, brittle, unequal, and full of knots; their bark is reddish without, and greenish within. The wood is whitish, and full of pith; and, when broken,

broken, yields an agreeable smell, resembling that of the balsam.

The *xylo-balsamum* is reputed good to strengthen the brain and stomach, and to expel poison.

XYLOCRACTA, or **XYLOCRACTE**, in the *Materia Medica*, a name by which some authors have called the carob, or filiqua dulcis, the sweet pipe-tree.

This was called by some of the Greek writers *xyloceraton*, the tree bearing pods, and from a corruption of this name the other has been formed.

XYLOCARPASUM, in *Natural History*, a name given by some authors to a poisonous kind of wood.

It was the wood of that tree whose gum was called *carpasum* and *opocarpasum*.

XYLOCARPUS, in *Botany*, from $\xi\upsilon\lambda\omicron\varsigma$, wood, and $\kappa\alpha\rho\pi\omicron\varsigma$, fruit, alluding to the woody texture of the seed-vessel.—“Koenig in *Naturf.* v. 20. 2.” Schreb. *Gen.* 253. Willd. *Sp. Pl.* v. 2. 329. Mart. *Mill. Dict.* v. 4. Poiret in Lamarck *Dict.* v. 8. 806.—Clafs and order, *Oñandria Monogynia*. *Nat. Ord.* *Tribilata*, Linn. *Melia*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, club-shaped, coriaceous, somewhat coloured, with four roundish teeth. *Cor.* Petals four, ovate-oblong, rather coriaceous, widely spreading, twice the length of the calyx. Nectary erect, ovate, inflated, somewhat fleshy, with eight marginal segments. *Stam.* Filaments no other than the eight segments of the nectary, linear, obtuse, emarginate, shorter than the petals; anthers eight, attached to the inner side of the filaments, and of the same length, linear-oblong, abrupt. *Pist.* Germen superior, ovate, smooth, slightly rugged at the base; style very short and thick; stigma abrupt, broad, bordered, its margin furrowed, its disk furrowed cross-wise, and perforated. *Peric.* Drupa large, globose, dry, with a thick coat; externally smooth, marked with four or five furrows; internally woody and fibrous. *Seeds.* Nuts eight, ten, or more, angular, unequal, irregular; their outer skin soft, and rather silky; inner woody and fibrous; kernel in some degree woody, brittle, with a prominent embryo.

Ess. Ch. Calyx oblong, with four teeth. Petals four. Nectary inflated, with eight teeth bearing the anthers. Drupa superior, dry, woody, with four or five furrows. Nuts numerous, angular, irregular.

1. *X. Granatum*. Indian Wooden-pomegranate. Koenig as above. Willd. n. 1. (*Granatum litoreum*; Rumph. *Ambon.* v. 3. 92. t. 61. *Cadul gaba* of the natives of Ceylon. *Candalanga* in the *Tamul* language.)—Native of muddy thickets on the sea-shores of Amboyna, Ceylon, and other parts of the East Indies, among *Rhizophora* trees, flowering in November, and bearing fruit in January and February. A tree varying greatly in size, sometimes little more than a shrub; its wood elegantly veined, but so twined and knotty, that no large handsome pieces can be procured. The trunk is erect, with a hard, deeply cracked bark; the head dense, roundish, or oblong. Larger branches scattered; smaller generally opposite, numerous, clothed with a greyish bark. Leaves opposite, stalked, spreading, oblong, obovate, or elliptical, acute, entire, rather larger than those of an apple-tree; dark-green, smooth and shining on the upper side; veiny beneath, with a prominent midrib. Footstalks short, roundish, spreading, a little curved, rugged, of a chestnut-brown. Clusters scattered or axillary, stalked, rather spreading, shorter than the leaves; their subdivisions opposite, or three-forked, with round, smooth, red, tough, naked stalks; the ultimate ones shorter than the flowers, which are small, yellowish, or dirty white. Their nectary somewhat resembles a Lily of the Valley, but these

flowers have no smell. The fruit is larger than a pomegranate, sometimes the size of a child's head of three years old, and contains from eight or ten to twenty angular unequal nuts, bigger than chestnuts, which do not appear to be used as food. There is a very remarkable disproportion between the magnitude of the flowers and fruit. Rumphius, from whom, as well as from Koenig, we take our description, hints that the flowers are perhaps dioecious. It is certain that most of those, so numerous in each cluster, must be abortive, or there would not be room to perfect the fruit.

XYLOCASIA. See **CASSIA**.

XYLOCOCUM, in the *Materia Medica*, a name given by some of the later Greek writers to the carob-tree, or filiqua dulcis.

XYLOCOLLA, a word used by some of the ancient writers to express what was more usually called *taurocolla*, glue made of the ears and genitals of a bull.

XYLOCOPIA, $\xi\lambda\omicron\kappa\omicron\sigma\omicron\upsilon\sigma\iota\varsigma$, among the Greeks, a punishment with a cudgel. See **FUSTIGATION**.

XYLODON, in *Botany*, from $\xi\lambda\omicron\varsigma$, wood, and $\omicron\delta\omicron\upsilon\varsigma$, a tooth, an appellation given by Perfoon to the third species of his genus *SISTOTREMA*, *Syn. Fung.* 550. (See that article.) The lamelle of that genus, (which is intermediate, as he justly says, between *Boletus* and *Hydnum*, though, in our opinion, most akin to the latter,) are of a firm, woody, and durable nature, and divided into many compressed irregular teeth.

XYLOGLYCON, a name given to the carob, or filiqua dulcis, by some of the old Greek writers.

The word expresses a sweet or sweet-fruited tree.

XYLOIDES, or **HYLOIDES**, a term used by many of the ancient writers to distinguish those plants which had woody stalks, though they never grew up to any considerable size; such as the garden-thyme, marjoram, and the like.

XYLOMA, so called from the firm or woody substance of the whole fungus, and the jagged or radiating margin of one of the most common species, *X. acerinum*; the word being apparently composed of $\xi\lambda\omicron\varsigma$, wood, and $\lambda\omicron\mu\alpha\varsigma$, a fringe, or border.—*Perf. Syn. Fung.* 103. *Obf. Mycol.* v. 2. 100.—Clafs and order, *Cryptogamia Fungi*. *Nat. Ord.* *Fungi Angiocarpi*.

Ess. Ch. Flat, nearly orbicular. Receptacle various, hard, somewhat fleshy internally; either remaining closed, or bursting unequally.

Sect. 1. *Compound. Several receptacles combined. Rather large.*

1. *X. salicinum*. Sallow-leaf Xyloma. *Perf. n.* 1. “*Disp. Meth.* 5. t. 2. f. 4.”—Thick, tuberculated; internally cartilaginous, and white at the base.—Frequent on the leaves of *Salix caprea*. This, according to Perfoon, is generally closed, but he has found it in the spring, as delineated in the work quoted, breaking, in the upper part, into several portions, like the shell of a tortoise, from whose interstices the fine powdery seeds flew off like smoke. The breadth of the whole fungus is about half an inch; its colour black.

2. *X. andromeda*. Marsh-rosemary Xyloma. *Perf. n.* 2.—“Oblong, thickish, with rib-like elevations, polished.”—Found in summer on the leaves of *Andromeda polifolia*, which hence appear as if pitch had been dropped upon them. Sometimes each fungus is as long as the whole leaf; sometimes only half as long. Its thickness is considerable with regard to the size. The lower stratum is white and firm, as in the foregoing.

3. *X. acerinum*. Maple Xyloma. *Perf. n.* 3. (*Sphæria maculiformis*; Ehrh. *Crypt. n.* 219. *Beitr.* v. 7. 101.)—Dilated, somewhat orbicular, thin, flat, black, slightly corrugated towards the centre.—Frequent on the leaves of

Acer platanoides, and *A. campestre*, in the autumn. It consists of numerous, black, opaque, inseparable patches, feathered over the upper side of the leaf, each about a quarter or one-third of an inch in diameter; the margin sometimes variously and elegantly notched, or fringed, and always circumscribed by a very striking yellow, or tawny, discoloration of the leaf. Perfoon says he has observed the surface of this species, though usually almost even and uniform, cracking into waved bordered fissures. We can see something of this in a specimen from professor Schrader.

4. *X. punctatum*. Sycamore Xyloma. Perf. n. 4. Obf. Mycol. v. 2. 100.—Dilated, thin, imperfectly orbicular, somewhat convex, black. Receptacles unequal, aggregate, parallel, oblong, blunt, superficial.—Frequent on the fading or fallen leaves of *Acer Pseudoplatanus*, which are rarely without this parasite in autumn and winter. The patches are from half an inch to an inch wide, closely united with the leaf, slightly convex above, and rather concave at the under side, which is somewhat blackened by them, especially at the circumference of each. The wrinkles, or receptacles, are shaped like the clefts of an OPEGRAPHA (see that article); but much more shallow, as well as more uniform in colour.

5. *X. stellare*. Starry Xyloma. Perf. n. 5. Obf. Mycol. v. 2. 100.—“Thin, pithy; the margin fringed with radiating fibres.”—Found by Perfoon, on the leaves of *Phytoloma spicatum*, though rarely. About half an inch broad, more or less, of a handsome appearance, with an uniform smooth disk, very black; the marginal fringe either black, or greyish. No distinct receptacles have yet been noticed.

6. *X. rubrum*. Red Xyloma. Perf. n. 6. Obf. Mycol. v. 2. 101.—“Aggregate, orbicular, somewhat confluent, red.”—Generally found in autumn on the leaves of *Prunus domestica*, rarely on *P. spinosa*. At first sight the red colour of this species, all the others being black, causes it to be taken for an *Ecidium*, or *Uredo*; but on examination the internal substance proves to be solid, uniform, scarcely containing distinct receptacles, or seed-vessels; its genus, however, is reckoned by Mr. Perfoon as very doubtful. The patches are each from two to four lines broad, rather thick, with darker-coloured superficial dots, visible only with a microscope. Perfoon.

SeR. 2. Simple. Receptacles solitary, scattered; generally rounded, like a *Peziza*; or dot-like. Smaller.

7. *X. pezizoides*. Cup-like Xyloma. Perf. n. 7. (*Peziza comitatis*; Sowerb. Fung. t. 118. *P. viridis*; Bolt. Fung. t. 109. f. 1.)—Rather crowded, orbicular, black; opening at length, with an upright, somewhat crenate, border, and a pale olive or greenish disk.—Found on fallen leaves of oak in December; more rarely, and in less perfection, on those of beech. The specimens are pretty uniform in size, larger than mustard-seed, closely attached to the surface of the leaf; the border of each sometimes pale, sometimes black, unless Sowerby and Bolton describe two different species.

8. *X. spherioides*. Dot-like Xyloma. Perf. n. 8.—“Scattered, dot-like, softish, with an open disk, and a collapsed inflexed border.”—On the leaves of *Salix caprea*. This at a distance resembles *Sphaeria punctiformis*; but under a magnifier it looks like some *Peziza*, with a crisped margin. The outside is black; the disk, rarely all displayed, is paler.

9. *X. hysterioides*. Oblong Xyloma. Perf. n. 9.—“Ice. of Descr. Fung. t. 10. f. 3, 4.”—“Elliptical, shining, ranged nearly parallel.”—On the fallen leaves of Hawthorn, in the spring. Each plant is one-third of a line long, ovate, or

elliptical, of a shining black; solid within. A longitudinal line seems to mark the place where it finally bursts.

10. *X. fuliginum*. Willow Xyloma. Perf. n. 10. (“*Sphaeria fuligina*; Ehrh. Crypt. n. 299.”)—“Aggregate and rather crowded, orbicular, thin, with a somewhat convex disk.”—On the leaves of *Salix caprea*, occupying nearly their whole surface. Each individual is from one-third to one-half a line broad.

11. *X. populinum*. Aspen Xyloma. Perf. n. 11.—“Aggregate, flattened, variously shaped, smooth, opaque, black.”—Found on the old leaves of *Populus tremula*, in the spring. About a line broad; the disk here and there greyish.

12. *X. concentricum*. Concentric Xyloma. Perf. n. 12. Obf. Mycol. v. 2. 101.—“Simple. Receptacles small, orbicular, depressed, somewhat conical, concentric, of a foaty grey.”—On half-decayed leaves of *Populus tremula*, forming circular patches, near an inch broad. Receptacles like small scattered dots, at first black, afterwards foaty or greyish, bursting finally at the summit.

13. *X. fagineum*. Beech Xyloma. Perf. n. 13.—“Disp. Meth. Fung. 52.”—“Minute, crowded, of a shining black, orbicular, plaited, a little depressed.”—Found on the under side of fallen and dried leaves of Beech, in the form of crowded black dots.

14. *X. alneum*. Alder Xyloma. Perf. n. 14.—“Minute, feathered, roundish, plaited.”—This species is met with in summer, upon Alder-leaves, while they are still green. It consists of a few black distant dots.

These minute productions are necessarily very obscure in their characters and economy. The present genus is marked by its internal solidity, of a corky or woody substance, having nothing of a gelatinous nature, nor are there any distinct round capsular receptacles, as in *SPHERIA*. See that article.

XYLOMELUM, so called by the writer of this, from *ξύλον*, wood, and *μέλος*, an apple, in allusion to the hardness and form of the fruit, which procured it, when first discovered, the appellation of the wooden pear.—Sm. Tr. of Linn. Soc. v. 4. 214. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 387. Tr. of Linn. Soc. v. 10. 189. Ait. Hort. Kew. v. 1. 212.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Protaceae*, Juss. Brown.

Gen. Ch. Cal. none. Cor. Petals four, regular, equal, linear; externally hairy; a little dilated and concave at the tip; revolute soon after expansion. Nectary four glands at the base of the germen. Stam. Filaments four, very short, inserted rather above the middle of each petal, and becoming prominent by its recurvature; anthers linear, inflexed, of two lateral parallel lobes, with a membranous edge; imperfect in some of the flowers. Pist. Germen superior, roundish; style erect, rigid, the length of the petals, deciduous; stigma vertical, club-shaped, obtuse, often small and abortive. Peric. Follicle woody, very thick, ovate, of one excentric small cell, and bursting into two divaricated half valves, at the point. Seeds two, roundish, compressed, each with a terminal, oblong, rather oblique, membranous wing, as long as the follicle.

Eff. Ch. Petals four, bearing the petals above the middle, regular, revolute. Nectariferous glands four. Stigma club-shaped. Style deciduous. Follicle woody, of one excentric cell, with two winged seeds.

1. *X. pyriforme*. Wooden-pear. Brown n. 1. (*Banksia pyriformis*; Gärtn. v. 1. 220. t. 47. f. 1. Lamarck Illustr. v. 1. 242. t. 54. f. 4. White's Voyage 224. t. 21. *Hakea pyriformis*; Cavan. Ic. v. 6. 25. t. 536.)—Gathered on the eastern coast of New Holland, near Port Jackson, by the first settlers in that colony. We received specimens from

Dr. White,

Dr. White, in 1789 and 1793. Mr. Brown says it grows on stony hilly ground. This, the only known species, is a tree, with opposite branches; downy and rusty when young. *Leaves* opposite, stalked, five inches long, lanceolate, acute at each end, entire, rather coriaceous, smooth, with one rib, and many prominent reticulated veins; pale and yellowish beneath; clothed, when they first come out, with dense, deciduous, rusty down: those of young plants, according to Mr. Brown, are toothed. *Footstalks* flattish, an inch long, smooth. *Stipules* none. *Spikes* axillary, opposite, catkin-like, cylindrical, dense, much shorter than the leaves, many-flowered, flaggy with rusty down. *Flowers* sessile, hardly an inch long, in pairs, each pair accompanied with one small downy *bractea*; all of them abortive, except the lowermost, so that from specimens seen in fruit only, the flowers were judged to be solitary. The *fruit* is ovate, or inversely pear-shaped, very hard, even, downy, two or three inches in length. *Seeds* and their wings brown. Mr. Brown remarks, that the greater part of the *flowers*, having a small *stigma*, and no *germen*, are necessarily abortive. Many of the *anthers* too have, as above-mentioned, an imperfect appearance; but having never seen living flowers, we cannot tell whether this be an original defect, or merely owing to their having long ago performed their office. It is possible that the rusty hue of the flowers and young leaves, so rich and beautiful in our specimens, may partly, if not altogether, be owing to drying. This plant, though procured for Kew garden, by Sir Joseph Banks, in 1789, appears never yet to have bloomed there.

XYLON, is so well described by Pliny, book 19, chap. 1, as to leave no doubt of its being our Cotton. (See GOSYPIUM.) He says it served to make the choicest garments of the Egyptian priests. Dr. J. R. Forster, the famous botanist and circumnavigator, published in 1776 a most learned little volume, to prove Cotton the true *Byssus* of the ancients. See also Matth. Valgr. v. 1. 376.

XYLON, *ἔυλον*, among the Athenians, a punishment inflicted, by putting the offender into the stocks.

XYLOPHYLLA, in *Botany*, very expressively named by Linnaeus, after Rumphius, from *ξύλον*, wood, and *φυλλον*, a leaf, in allusion to the hardness and rigidity of its foliage, which indeed serves the purpose of both leaves and flower-stalks.—Linn. Mant. 147. Schreb. Gen. 200. Willd. Sp. Pl. v. 1. 1500. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 336. Juss. 387. Poiret in Lamarck Dict. v. 8. 812. Lamarck Illustr. t. 855. Gertn. t. 108. (Phyllanthus; Browne Jan. 188.)—Class and order, *Monocotyledonae*. (Pentandria Trigynia; Browne, Linn. Schreb. Willd.) Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male. *Cal.* Perianth in six deep regular segments; the three innermost largest. *Cor.* Petals none, unless the calyx, or its inner segments, be taken for such. Nectary of six globular glands. *Stam.* Filaments united into a very short column; anthers three or six, roundish; two-lobed.

Female, on the same plant, and in the same situation, as the male. *Cal.* and Nectary as in the male. *Pist.* Germen superior, sessile, roundish; styles three, short, spreading; stigmas three-cleft. *Peric.* Capsule roundish, with three furrows, three cells, and six elastic valves. *Seeds* two in each cell, roundish.

Eff. Ch. Male. Calyx in six deep segments; three of them interior. Petals none. Nectary of six globular glands.

Female, Calyx and Nectary like the male. Styles three.

Stigmas three-cleft. Capsule of three cells, with six elastic valves. Seeds two in each cell.

Obf. Dr. Sims, in Curt. Mag. 1021, has justly indicated this genus as too near PHYLLANTHUS (see that article); where the *seeds* are erroneously said to be solitary. Whether the difference between their *nectaries* be permanent, we have not seen enough to determine. At any rate, these two genera must stand next to each other, in the Linnaean artificial system, as well as in every natural one.

1. *X. longifolia*. Long-leaved Sea-side Laurel. Linn. Mant. 221. Willd. n. 1. Swartz Obf. 112. (Xylophyllus ceramica; Rumph. Amboyn. v. 7. 19. t. 12.)—Leaves linear, alternately toothed. Flowers solitary at each tooth.—Found only on the lofty, stony, cold mountains of the island of Ceram. The *trunk* is shrubby, scarcely so thick as a man's arm, dividing above it into many round *branches*, as thick as the finger. These end in numerous, alternate, drooping, long, linear, acute *leaves*, or perhaps winged branches, with blunt alternate teeth, usually an inch distant from each other. The *flowers* are solitary, nearly sessile, at each notch. Of their structure nothing is known; nor of the *fruit*, except what Rumphius relates, and this, as Dr. Swartz observes, does not agree with the genus before us, Linnaeus having merely adopted this remarkable plant as a *Xylophylla*, on account of its habit, which is striking enough. Rumphius says, "the *calyx* resembles a small clove, and is red, bearing a roundish-oblong *fruit*, resembling a Bay-berry, or the *Abrus* of Alpinus, (and Linnaeus), green, hard, with a small point. When opened, a small *nucleus* is found, resembling a grain of rice, fixed on the stalk, and tasting sweet, like a Filiberd, being enclosed in a white skin." It is very unlikely that the kernel of any species of this genus should be eatable.

2. *X. latifolia*. Broad-leaved Sea-side Laurel. Linn. Mant. 221, excluding the synonym. Willd. n. 2. Ait. n. 1. Swartz Obf. 113. Curt. Mag. t. 1021. (Geniophylla asplenifolia; L'Herit. Sert. Aug. t. 39. Phyllanthus n. 1. Browne Jan. 188. Hemionitidis affinis, americana epiphyllanthos, &c.; Pluk. Phyt. t. 36. f. 7.)—Leaves rhomboid, crenate; notches crowded, each bearing one or more stalked flowers.—Native of lime-stone rocks, near the sea-side, in the West Indies. Mr. Waller is recorded in Hort. Kew. as having first sent this elegant and singular shrub to his friends in England, in 1783. If we mistake not, the marquis of Rockingham, who died in 1782, received it from Mr. Waller some time before; the original having been long one of the dowager marchioness's finest plants. It flowers in a stove copiously in August and September. The *stem* is four or five feet high, with a round bushy head. *Leaves* a foot long, alternate, stalked, alternately pinnate; *leaflets* twelve or more, nearly sessile, one and a half or two inches long, ovate-rhomboid, acute, hard and rigid, erect, striated, smooth; entire towards the base. *Flowers* copious, small, green, on simple crimson stalks; those of the female flowers much the longest. Both *stamens* and *pistil* sometimes occur in the same flower, according to Dr. Swartz.

3. *X. Arbuscula*. Lanceolate-leaved Sea-side Laurel. Swartz Prodr. 28. Willd. n. 3. (Phyllanthus speciosa; Jacq. Coll. v. 2. 360. Ic. Rar. t. 616. Swartz Ind. Occ. 1107. Schneev. Ic. t. 30?)—Leaves pinnate, lanceolate, pointed, crenate; notches crowded, each bearing one or more stalked flowers.—Native of the sloping sides of lofty mountains, in the fourth part of Jamaica. Swartz. We can discern no real specific difference between this and the last. The *leaves* indeed are narrower, more elongated and less falcate, but those characters vary. Dr. Swartz

XYLOPHYLLA.

lays a strels on the *flowers* being polygamous in *latifolia*, monoecious in *Arbuscula*; but nothing is more variable than this circumstance. It is difficult to say which of the two Schneevoght's figure represents.

4. *X. falcata*. Sickle-leaved Sea-side Laurel. Swartz Prodr. 28. Willd. n. 4. Ait. n. 2. Andr. Repof. t. 331. (*Phyllanthus* *Epiphyllanthus*; Linn. Sp. Pl. 1392. *Ph. americana* planta, flores e singulis foliorum crenis profrens; Comm. Hort. v. 1. 199. t. 102.)—Leaves scattered, linear-lanceolate, somewhat falcate, distantly toothed. Flowers nearly sessile, many together at each tooth.—Native of the Bahama islands. Cultivated for above 120 years past in the stoves of England and Holland, flowering in July and August. The *stem* is five or six feet high, shrubby, with round *branches*. *Leaves* not pinnate, with a flat stalk, as in the two last, but scattered irregularly over the branches, each proceeding from a scaly bud, simple, five or six inches long, one-third of an inch wide, rigid, striated, tapering at each end; entire towards the base; alternately toothed in the upper part, the teeth an inch or more asunder. *Flowers* crimson, on short stalks, some male and some female in each tuft; the latter fewest.

5. *X. angustifolia*. Narrow-leaved Sea-side Laurel. Swartz Prodr. 28. Willd. n. 5. Ait. n. 3. (*X. elongata*; Jacq. Hort. Schönbr. v. 3. 53. t. 348. Poiret n. 7. *Phyllanthus* n. 2; Browne Jam. 188. *Ph. americana*, angustiori et longiori folio, ramosa, caulescens; Pluk. Phyt. t. 247. f. 4. *Ph. angustifolia*; Swartz Ind. Occ. 1111.)—Leaves pinnate, linear-lanceolate, rather distantly toothed, scarcely curved. Flowers on short stalks, polygamous, one or more from each tooth.—Native of stony rocky situations, in the western part of Jamaica. Swartz. Cultivated in the English stoves before 1789, flowering in July and August. Aiton. This agrees with our second and third species, in having several alternate *leaflets*, on a flat or channelled, bordered *common stalk*; but scarcely half so many on each stalk as in those; and of a longer narrower form, not copiously crenate, but sparingly and rather distantly toothed, more in the manner of *X. falcata*. The *stem* is only two feet high. The *flowers* are less copious than in the last-mentioned species, and, according to Dr. Swartz, there are some perfect, intermixed with the male and female ones. Their colour is red; the male ones palest. (Jacquin's figure expresses the contrary.) Plukenet's engraving, such as it is, manifestly agrees with this species, and with no other. Linnæus, no doubt, confounded this, and, at one time, the *latifolia* also, with the *falcata*. Browne's synonyms are settled by his own species, though unmarked.

6. *X. linearis*. Linear Sea-side Laurel. (*X. angustifolia* β; Swartz Prodr. 28. Willd. n. 5. *Phyllanthus linearis*; Swartz Ind. Occ. 1113.)—Leaves pinnate, linear, tapering, pliant, crenate; their common stalk bordered. Flowers several from each notch.—Native of shady stony banks of rivers, in the western part of Jamaica. Swartz. The stem is scarcely a foot high, erect, with round branches. Common *footstalks* four or five inches long, scattered, compressed, (rather depressed,) bordered. *Leaves* linear, rather broadest in the middle; tapering at the base; ending in a very long acute point, striated, paler beneath, two inches long, of a thinner substance than the foregoing species, which circumstance, added to its humbler stature, and different colour, has induced Dr. Swartz to consider it as distinct. The *flowers* are white, monoecious, from three to six at each notch of the leaves, on capillary stalks, four lines in length.

7. *X. montana*. Mountain Sea-side Laurel. Swartz

Prodr. 28. Willd. n. 6. (*Phyllanthus montana*; Swartz Ind. Occ. 1117.)—Leaves somewhat two-ranked, elliptic-lanceolate, coriaceous, deeply crenate. Flowers nearly sessile, many from each notch. Branches round; two-edged at the extremity.—Found on lime-stone rocks, in the western part of Jamaica. A *shrub*, six feet high, much and irregularly branched; the *branches* often forked, round, nearly erect, with annular scars; ultimate ones permanent, glaucous-ashcoloured, compressed and two-edged at the summit. *Leaves* alternate, imperfectly two-ranked, nearly sessile, either blunt or acute, obliquely striated, rigid, brownish-green, smooth, with deep many-flowered notches. *Flowers* monoecious; the males eight or ten, pale red; females solitary among the males, deep purple. Clearly distinguishable from all the species which it otherwise resembles, by the permanency, and woody texture, of the ultimate branches. Swartz.

8. *X. ramiflora*. Siberian Sea-side Laurel. Ait. Hort. Kew. ed. 1. v. 1. 376. ed. 2. n. 4. Willd. n. 7. (*Pharanceum*? *suffruticosum*; Pallas It. v. 3. 716. t. E. f. 2.)—Leaves elliptical, stalked. Flowers axillary.—Native of the deserts of Siberia, from whence it was procured for the English gardens, in 1783, by the late Mr. Bell. It is a hardy shrub, flowering in July and August. Pallas, who never saw the plant alive, merely guessed at its genus. By his figure, its habit is altogether that of a *Phyllanthus*. The *stem* is bushy, with many straight, wand-like, leafy branches, each a span long. *Leaves* scattered, thin, hardly an inch in length, blunt, crenate, or somewhat wavy. *Flowers* six or eight together, making a little axillary tuft, accompanied by minute red *stipules*, or *bractææ*. Segments of the *calyx* five, concave, white, with a coloured margin. *Anthers* five, thick, obtuse, furrowed at the outside. *Germen* in the same flower, as we presume from Pallas's description, very small. *Styles* three, thread-shaped, simple, the length of the *filaments*. The genus of this species is, at best, very doubtful, as Willdenow has already remarked.

Phyllanthus and *Xylophylla* are so totally different in habit, and the latter is, in this respect, so very peculiar, that a clear character between them is much to be desired. The true *Xylophyllæ* are all of West Indian origin. The tropical *Phyllanthi* are natives of the East Indies; a few hardy species grow in North America.

XYLOPHYLLA, in *Gardening*, contains plants of the tender exotic kind for the stove, in which the species cultivated are, the long-leaved love flower (*X. longifolia*), the broad-leaved love flower (*X. latifolia*), and the falcated love flower (*X. falcata*).

The first is a branching angular plant, but the second has round branches; and the last is woody in the stems and branches.

Method of Culture.—These plants are increased by sowing the seeds in pots in the early spring, and plunging them in a hot-bed: when the plants are come up two or three inches in growth, they should be pricked out in separate pots, replanting them in the bark-bed: they may afterwards be managed as other stove-plants of a similar growth.

They are also, some of them, capable of being raised by off-sets, slips, and cuttings, assisted by a hot-bed in the same manner.

They require the constant protection of the stove in winter, but in the hot summer months may be set out in their pots in a sheltered situation, being taken in on the approach of cold nights.

They afford variety, and are curious in stove collections among other plants of similar growths.

E

XYLOPIA,

XYLOPIA.

XYLOPIA, in *Botany*, altered by Linnæus from *Xylopicrum* of Browne, a name which the latter took from Plukenet, whose *Xylopicron*, formed from $\xi\lambda\lambda\omicron\varsigma$ and $\pi\iota\mu\epsilon\lambda\omicron\varsigma$, alludes to the bitterness of the wood. M. De Candolle, in following Linnæus, observes, that this abbreviation entirely destroys the sense. It certainly does to those who do not trace out the source of the word. If the original had been constructed in the most unexceptionable manner, we might have hazarded its restoration; but *Xylopi* is now too firmly established to be lightly disturbed, and in finding nothing can be better.—Linn. Gen. 469. Schreb. 375. Willd. Sp. Pl. v. 3. 1270. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 336. Juss. 284. De Cand. Syst. v. 1. 499. Poir. in Lamarck Dict. v. 8. 810. Lamarck Illust. t. 495. Gært. t. 69. (Xylopicron; Pluk. Almagr. 395. Xylopicrum; Browne Jam. 250.)—Clasf and order, *Polyandria Polygynia*. (Gynandria Polyandria, Linn.) Nat. Ord. *Coadunata*, Linn. *Anonac.*, Juss. *Anonaceæ*, De Candolle.

Gen. Ch. Cal. Perianth inferior, of one leaf, in from three to five deep, broad, ovate, coriaceous, rather acute, permanent segments. Cor. Petals six, sessile, linear-lanceolate, coriaceous, much longer than the calyx; the three outermost largest. Stam. Filaments none; anthers numerous, oblong, quadrangular, abrupt, parallel, crowded, seated on the tumid, nearly globose, receptacle, in several rows. Pist. Germens several, on short stalks, compressed; styles tapering, crowded together; stigmas simple. Peric. Capsules several, stalked, coriaceous, compressed, bluntly angular, of one cell and two valves, bursting at the top. Seeds one or two, obovate, polished, tunicated at the base.

Ess. Ch. Calyx lobed, coriaceous. Petals six; the three outermost largest. Capsules stalked, angular, compressed, of two valves. Seeds one or two, tunicated.

The plants composing this genus are trees or shrubs, with oblong or lanceolate (entire) leaves, and axillary, bracteated, simple or divided flower-stalks. The wood is bitter; bark and fruit aromatic. De Candolle, who describes eight species, of which the first is still the least understood.

Linnæus, by a misapprehension of the true character of his own class of GYNANDRIA, (see that article,) has placed this genus far asunder from *Anona*, *Uvaria*, &c., to which it is closely allied, both in natural and artificial distinctions. Few genera have hitherto been left underfoot.

1. *X. muricata*. Rough-leaved Bitter-wood. Linn. Sp. Pl. 1367. Willd. n. 2. De Cand. n. 1. Ait. u. 1. (X. frutescens; Gært. v. 1. 339. t. 69, excluding the synonym of Aublet. Xylopicrum n. 1; Browne Jam. 250. t. 5. f. 2.)—Leaves ovate-lanceolate, pointed; clothed with close-pressed hairs beneath. Branches zigzag, nearly smooth. Stalks with several flowers. Fruit muricated.—Found by Dr. Patrick Browne, at the foot of the mountains, in Sixteen-mile walk, Jamaica. His specimen, drawn in the plate above-cited, is in our hands, but stripped of the leaves. This deficiency is supplied by another very large and perfect one, gathered in Jamaica, by Mr. Masson. The latter M. De Candolle unfortunately did not see, when the writer of this was favoured with too short a visit from this learned and amiable man. It is become necessary to correct some errors in the description, whose source is unknown to us. The leaves are certainly not "bearded at the point," nor do we perceive in what sense they are termed "strigose beneath." These are Willdenow's expressions, adopted by De Candolle. Sir Joseph Banks sent a living plant of this species to Kew garden, in 1793; but if it survives, it has not yet flowered. This is a small tree, fifteen

or twenty feet high, with alternate, round branches, zigzag when young, quite smooth, except towards the very extremity, which is slightly silky. Leaves alternate, on short thick stalks, spreading, rather ovate than lanceolate, with a blunt or emarginate, smooth point; their length two inches, or a little more; their margin entire, slightly revolute; their upper surface smooth and shining, reticulated with veins; under paler, more opaque, clothed with fine, scattered, close, silky hairs, after a while deciduous: mid-rib stout, rough with minute tubercles at the base. Flower-stalks copious, axillary, solitary, short, knotty, bearing from two to five flowers. Calyx three-lobed, scarcely downy. Petal: half an inch long, densely silky on both sides; the three innermost very narrow, triangular-awls shaped. Capsules, by Gærtner's account, which in the main agrees with that of Linnæus, nearly ovate, but angular and compressed, sometimes as many as fifteen, coriaceous, covered with little points, of one cell and two valves, containing one or two oval seeds, each with a cup-like tunic at the bottom. Browne made no remarks on the bark or wood of this tree. We perceive little bitterness in either, though some aromatic flavour in the bark. This species being the type of its genus, we have thought a full description requisite.

2. *X. frutescens*. Shrubby Silky Bitter-wood. Aubl. Guian. 602. t. 242, excluding the synonyms of Linnæus and Browne. Willd. n. 2. De Cand. n. 2. "Dunal Monogr. 120." Lamarck t. 495, copied from Aublet, excluding the fruit, which is Gærtner's figure of the foregoing. Poir. n. 2. (X. fetosa; Poir. n. 4, according to De Candolle. Embira seu Pindaiba; Pif. Bras. 71. Ibra; Marcgr. Bras. 99.)—Leaves lanceolate, pointed; glaucous and silky beneath. Branches silky. Stalks with few flowers. Capsules smooth.—Found by Marcgraf in Brazil, flowering in February; by Aublet in Cayenne and Guiana, bearing flowers and fruit in August. M. De Candolle has examined a specimen, and we, having seen none, are obliged to rely on him and the other authors here cited for the specific distinctions between this and the first species. The smoothness of the fruit, the silkiness of the branches, and narrowness of the leaves, appear sufficient to ascertain the present plant. Marcgraf says the bark affords a tough kind of cordage. The fruit, equal in size to hazel-nuts, is aromatic and acid, serving, when powdered, instead of pepper.

3. *X. salicifolia*. Willow-leaved Bitter-wood. "Humb. and Bonpl. unpublished. Dunal Monogr. 121. t. 17." De Cand. n. 3.—"Leaves oblong, with a bluntish point; silky beneath. Stalks short, single-flowered; with small bractæas."—Found by the celebrated travellers baron Humboldt and M. Bonpland, near Espinal, in South America. A tree with blackish branches, marked with white dots. Leaves narrow, an inch and a half or two inches long, three or four lines broad, on short stalks, single-ribbed, without veins; smooth and green above; villous beneath, with close-pressed, silky hairs, of a rufous grey. Capsules from five to seven, gibbous, slightly pointed, not bursting. Seeds one or two. De Cand.

4. *X. higyrisifolia*. Privet-leaved Bitter-wood. "Dunal Monogr. 121. t. 18." De Cand. n. 4.—"Leaves oblong, rather acute, smooth on both sides. Stalks short, with few flowers, and small bractæas."—Gathered by Humboldt and Bonpland, at Buga, in South America. The branches are round, blackish, rugged, rough with whitish points. Leaves an inch and a half long, four lines broad, on very short stalks, single-ribbed, veinless; somewhat shining above; paler beneath; the young ones silky at the under side. Stalks axillary, with three or four flowers, and roundish, fifteen

eave *bracteas*. *Calyx* small, three-cleft. Three outer *petals* longest, spreading at the points. *Capsules* corrugated, not bursting. *Seeds* one or two. *Dunal*. *De Cand.*

5. *X. glabra*. Smooth Bitter-wood. Linn. Sp. Pl. 1367. Willd. n. 3. De Cand. n. 4. "Dunal Monogr. 121. t. 19." Lunan Hort. Jam. 97. (Xylopicrum n. 2; Browne Jan. 251. Xylopicron arbor, barbadensisibus *Bitter-wood*; Pluk. Phyt. t. 238. f. 4.)—Leaves ovate-oblong, pointed, quite smooth on both sides. Stalks single-flowered, solitary or in pairs. Fruit smooth.—Brought from Barbadoes by Mr. James Reece, who was sent to the West Indies by the earl of Portland, to procure plants for the royal garden at Hampton-Court. *Plukenet*. This species, therefore, may have been alive in England. Dr. Patrick Browne met with it in the mountains, at the back of Bull-bay, in Jamaica, where it grew to a considerable size, being fifty or sixty feet high. He never saw the flowers in perfection. "The wood, bark, and berries," says this author, "have an agreeable bitter taste, not unlike that of the orange-feed; and would probably prove excellent medicines. Wild pigeons feed much upon the berries, and owe their delicate bitterish flavour to this food. I have eaten many of the berries just off the tree, and found them agreeable to the palate, and grateful to the stomach. The bark and wood are agreeably bitter while fresh, but that delicacy diminishes greatly after they are dried. The wood is easily wrought, and good timber, but must not be exposed to the weather." *Browne*. Mr. Lunan, in his *Hortus Jamaicensis*, adds nothing to this account, but carefully distinguishes this Bitter-wood from QUASSIA, (see that article,) with which some persons have confounded it. M. De Candolle observes, that the *branches* of *X. glabra* are round, smooth, scarcely dotted; and that even the young *leaves* are smooth on both sides; the full-grown ones are two inches long, and one broad, obtuse with a point. *Calyx* smooth, with three very obtuse lobes. Unexpanded *petals* oblong, clothed externally with close-pressed pubescence, their length four lines. *Plukenet* represents the *flower-stalks* solitary, opposite to each leaf.

6. *X. nitida*. Shining-leaved Bitter-wood. "Dunal Monogr. 122. t. 20." De Cand. n. 6.—"Leaves oblong-lanceolate, smooth; polished on the upper side. Stalks branched, many-flowered. *Calyx* nearly entire."—Found by Joseph Martin, on the Oyac mountains of Cayenne, sloping down to the sea. A tree of a middling size, with straight, round, rugged, not hairy or downy, *branches*. *Leaves* somewhat elliptical, two or three inches long, and nine or ten lines broad; green, smooth, and very shining above; veiny, pale, and rather silky, with minute close hairs beneath; the margin a little revolute. *Clusters* small, corymbose, of four or five *flowers*, whose stalks are embraced by little roundish *bracteas*. *Calyx* coriaceous, brown, pitcher-shaped, scarcely divided. Bud of the *petals* oblong, triangular, acute. *Fruit* unknown. *De Cand.*

7. *X. acuminata*. Long-pointed Bitter-wood. "Dunal Monogr. 122. t. 16." De Cand. n. 7.—"Leaves oblong-elliptical, very long-pointed, perfectly smooth. *Capsules* on long stalks, single-valved, with two seeds."—Native of Cayenne. *Branches* round, rugged, smooth. *Leaves* on very short footstalks, four to six inches long, two inches wide, remarkably pointed, revolute, rather coriaceous; a little shining above. *Flowers* unknown. *Capsules* ovate, nine or ten lines in length, pointed, each tapering down into a long stalk, imperfectly bivalve, smooth and even. *Seeds* obovate, black, fisted, convex at the outside, flat at the inner. *De Cand.*

8. *X. prinoides*. Winter-berry Bitter-wood. "Dunal

Monogr. 122. t. 15." De Cand. n. 8.—"Leaves oblong-lanceolate, smooth, membranous, pointed; bluntish at the extremity. *Flowers* solitary. *Capsules* with two valves."—Native of Cayenne. *Branches* wand-like, slightly rugged. *Leaves* on short stalks, smooth on both sides, three or four inches, (the author, by mistake as we presume, says three or four lines), in length, and from twelve to fifteen lines broad; shining above; rather glaucous beneath. *Stalks* single-flowered, axillary, very short, each bearing an extremely minute *bractea*. *Calyx* deeply three-cleft. *Petals* ovate, acute, scarcely two lines long, being the smallest of this genus, or perhaps natural order. *Capsules* stalked, imperfectly bivalve. *Seeds* two, flat at the inner side, convex at the outer. *De Candolle*.

XYLOPICRUM. See XYLOPIA *supra*.

XYLOPOLIS, in *Ancient Geography*, a town of Macedonia, in Mygdonia. Ptolemy.

XYLOSMA, in *Botany*, from *ξύλον*, wood, and *σμύρα*, a smell, a name given by Dr. George Forster to the *Myroxylon* of his father; the latter appellation having been appropriated by Linnæus to a different genus. (See MYROXYLON.)—Forst. Prodr. 72. Schreb. Gen. 703. Willd. Sp. Pl. v. 4. 834. Mart. Mill. Dict. v. 4. Poiret in Lamarck Dict. v. 8. 817. Lamarck Illustr. t. 827. (Myroxylon; Forst. Gen. t. 63. Juss. 444. Lamarck Dict. v. 4. 192.)—Class and order, *Dioecia Polyandria*. Nat. Ord. uncertain. Juss.

Gen. Ch. Male, *Cal.* Perianth in four or five deep, roundish, minute, spreading segments. *Cor.* *Petals* none. *Nectary* minute, annular, finely crenate, surrounding the stamens. *Stam.* Filaments numerous (20—50), capillary, twice the length of the calyx; anthers roundish, small.

Female, on a distinct tree, *Cal.* as in the male. *Cor.* *Petals* none. *Nectary* as in the male, surrounding the germen. *Pistil.* Germen superior, roundish-ovate; style very short, cylindrical; stigma obtuse, flat, obscurely three-cleft. *Peric.* Berry? dry, oblong, imperfectly divided into two cells by a partition from the bottom. *Seeds* two in each, triangular, convex at the back, flat at the sides.

Ess. Ch. Male, *Calyx* in four or five deep segments. *Petals* none. *Nectary* annular, crenate. *Stamens* from twenty to fifty.

Female, *Calyx* and *Nectary* as in the male. *Style* very short. *Stigma* slightly three-cleft. *Berry* dry, of two incomplete cells. *Seeds* two to each cell.

1. *X. suaveolens*. Serrated Sweet-wood. Forst. Prodr. n. 380. Willd. n. 1. (Myroxylon suaveolens; Forst. Gen. 63. n. 1.)—Leaves ovate, serrated.—Native of the Society islands of the South seas. The inhabitants employ this wood, to give a fragrant scent to cocoa-nut oil, for anointing their hair. We know not whether this be the precious Red Sanders Wood of the South sea islands, for a specimen of which we are indebted to Sir Joseph Banks, whose scent resembles that of the East Indian wood of the same name. The tree which produced it was, as long as possible, kept from the knowledge of our European voyagers.

2. *X. orbiculatum*. Entire-leaved Sweet-wood. Forst. Prodr. n. 381. Willd. n. 2. (Myroxylon orbiculatum; Forst. Gen. 63. n. 2.)—Leaves roundish, entire.—Native of Savage island. We have never seen a specimen of either species.

XYLOSTEON, a name by which some authors have called the small red-berried double-fruited *chamæcerafus*.

XYLOSTEUM, Dod. Pempt. 411. Tourn. 609. t. 379. Juss. 212. Pursh 161. (Chamæcerafus; Tourn. ibid.) a word formed of *ξύλον*, wood, and *ὄστειον*, bone, being synonymous with a Swiss name for the same shrubs, which allude

alludes to the hardness of their wood, and perhaps to its tubular form, filled with pith, as a bone is with marrow. The authors who retain this genus split the LONICERA of Linnæus, (see that article,) into several, without necessity or utility, offering, in our opinion at least, great violence to nature.

XYLOSTROMA, so called from ξύλον, wood, and στρώμα, a stratum, or layer, because this fungus forms indeterminate expansions, like cloth or leather, in the inside of the trunks or branches of trees.—Tode Fung. Mecklenb. v. 1. 36.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi angiocarpi*?

Eff. Ch. Expanded, coriaceous, two-fided, shapeless, concealed; surface smooth and even. Seminal globules very minute, attached to internal fibres.

1. *X. giganteum*. Oak Leather. Tode as above, t. 6. f. 51. Sowerb. Fung. t. 358. (*Racodium Xylostroma*; Perf. Syn. Fung. 702. Fungus coriaceus quercinus hæmatodes; Raii Syn. 25. "F. ampliflumis; Scop. Pl. Subterr. 116. t. 44." *Byssus candida* β; Lightf. Scot. 1004.)—This singular production is found in the centre of the trunks of growing oaks, spreading in the form of a piece of cloth or leather, with numerous ramifications, through some of the largest trees. But whether it is, like the *Boletus lachrymans*, or Dry Rot, in wrought timber, the cause of their decay, or its consequence, we have not sufficient information to decide. Tode's observations countenance the former opinion. He says the wood of the trees, occupied by this fungus, becomes rotten and perfectly dry. Its smooth surfaces are owing to the smoothness of the fissures, through which it spreads in a tender state, and its branching indeterminate figure arises from the irregularity and subdivision of those fissures. The inside is spongy, or partly hollow, occupied with branching fibres, bearing numerous little ovate capsules, or receptacles, whose apex appeared to Mr. Sowerby to have an opaque lid. The whole fungus is very durable, remaining unchanged for many years. Its hue is generally an uniform buff or pale tan colour; but Persoon notices a whitish variety, more compact than the usual kind; and a saffron-coloured one, found by Schrader. We cannot well reduce the *Xylostroma* to any other genus of this natural order. The *Racodium*, Perf. Syn. 701, defined as "expanded and soft, resembling cloth in its densely interwoven fibres," seems to us but a vague assemblage; the first species being *Byssus nigra*, which some make a *Lichen*, others a *Conferua*; the second a *Mucor*.

XYLOSTROTON, formed of ξύλον, wood, and στρώτος, laid, among the Ancients, an appellation given to Mosaic or chequered work.

XYLUS, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

XYMETHUS, a town of Africa, in the interior of Cyrenaica. Ptol.

XYMPATHESIS, a word used by some of the old medical writers for sympathy.

XYNERESIS, formed of ξύς, or συν, together, and αἴρεσις, I seize, a word used by Hippocrates, and others of the ancients, to express a firm cohesion or connection of any two things. Some use it to express that firm shutting together, or clenching of the teeth, which happens in convulsions.

XYNIA, in *Ancient Geography*, a borough of Thessaly, on the confines of Perrhæbia, near a lake of the same name. Livy.

XYNOECIA, formed of ξύς, or συν, with, and οἰκία, I inhabit, a feast among the ancient Athenians, instituted on occasion of Theseus's uniting all the petty communities of

Attica into one commonwealth; the assemblies of which were to be held at Athens, in the Prytæum.

XYPHOID, in *Anatomy*, a name given to the cartilage, which forms the inferior extremity of the sternum. See the description of the *sternum*, in the article LUNGS.

XYRIS, in *Botany, an ancient name, of unknown derivation, ξύρις, or rather ξυρίς of the Greeks, supposed to belong to our *Iris fœditissima*, transferred by Gronovius to the present genus, as one of nearly similar habit and characters. They are not, however, of the same natural order.—Linn. Gen. 29. Schreb. 39. Willd. Sp. Pl. v. 1. 254. Vahl Enum. v. 2. 204. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 255. Pursh 33. Juss. 44. Kunth Nov. Gen. et Sp. v. 1. 255. Poir. in Lamarck Dict. v. 8. 818. Lamarck Illustr. t. 36. Gært. t. 15.—Class and order, *Triandria Monogynia*. Nat. Ord. *Ensatæ*, Linn. (rather *Tripetaloidæe*.) *Junci*, Juss. *Reftiæceæ*, Brown, Kunth.*

Gen. Ch. (corrected from Brown and Gærtner), Cal. Perianth inferior, of three concave chaffy leaves; the outermost hooded, deciduous; the two lateral ones keeled, compressed, curved, acute, converging, permanent. Cor. Petals three, large, spreading, flat, crenate; with narrow claws, as long as the calyx. Nectaries three, feathery, alternate with the petals; suspected by Brown and Kunth to be barren stamens. Stam. Filaments three, inserted into the claws of the petals, much shorter than the limb, thread-shaped, erect; anthers oblong, incumbent. Pist. Germen superior, obovate, three-lobed; style one, thread-shaped, rather longer than the claws of the petals, three-cleft at the summit; stigmas obtuse, entire, or jagged. Peric. Capsule roundish, of one cell and three valves, with three more or less prominent receptacles, running down the middle of each valve. Seeds numerous, minute, roundish or elliptical, acute.

Eff. Ch. Calyx of three unequal leaves; the two lateral ones permanent. Petals three, equal. Nectaries three, feathery. Capsule superior, of three valves, with central receptacles. Seeds numerous.

A genus of perennial herbs, with fibrous roots. Leaves radical, numerous, sword-shaped, or thread-shaped; dilated, equitant, and membranous at the base. Flower-stalk perfectly simple, wrapped in a sheath at the bottom. Head terminal, solitary, its scales membranous, single-flowered, closely imbricated; the outer ones sometimes empty, and unlike the rest. Anthers posterior. Brown. Flowers almost invariably yellow.

Linnæus was acquainted with but one species, *X. indica*. Several others have been determined by various authors, inasmuch that Willdenow defines four, and Vahl ten in all. Mr. Brown has fifteen from New Holland alone, and there is a new one from South America. The author just mentioned divides this genus into two sections. Those species which belong to the first section have a capsule of one cell, whose receptacles are separate at the base; of these there are thirteen found in New Holland. The second section is characterized by a capsule incompletely divided into three cells, the receptacles being combined in their lower part. Of this there are two New Holland species. It is utterly impossible for us to follow this arrangement, few people having seen half the species in any state, much less their ripe capsules. We are possessed of ten, which appear to be distinct, and which can be referred, with tolerable certainty in general, to as many described species. For the remainder we shall cite our authorities.

1. *X. indica*. East India Xyris. Linn. Sp. Pl. 62, excluding the synonyms of Gronovius, Morifon, and Pifo. Linn.

Ethn. Zeyl. 14. Willd. n. 1. Vahl n. 1. (*Gladiolus indicus*, flore tripetalo; *Rudb. Elyf. v. 2. 17. f. 8.* *Gladiolo lacustris accedens malabarica*, e capitulo botryoide florifera; *Pluk. Almag. 170. t. 416. f. 4.* *Kotsjlettipullu*; *Rheede Hort. Malab. v. 9. t. 71.* *Ranmotha*; *Herm. Zeyl. 41.*)—Stalk furrowed, with many angles. Head ovate.—Native of the East Indies, and perhaps of Sierra Leone. The leaves are described by Vahl as sometimes a foot long, equalling the flower-stalks, lax, acute, almost the breadth of the nail; but he never saw any so broad as in Rheede's figure. The flower-stalks are several, rather more slender than a pigeon's quill, furnished with six or eight furrows, and twisted in the lower part. Head rather smaller than a Hazel-nut, with roundish scales. Our specimens, gathered by the late Mr. Smeathman at Sierra Leone, have no leaves, but the stalk and head answer exactly to the above description. The scales are from twenty-five to thirty in each head, rounded, or nearly orbicular, convex, closely imbricated, obtuse, brown, but little polished, divided lengthwise into three nearly equal spaces, or regions, (as is the case in most of the species that we have seen); the middle region here is slightly hoary or downy, the side-ones smooth. The flowers are pale. The head in these specimens is nearly globose; not oblong, as in Gertner's figure, marked *X. indica*. A few of the lowest scales are flatter and rather smaller than the rest, apparently always barren, or unaccompanied by flowers. Whatever Mr. Pursh's *X. indica* may be, it cannot belong to this species. He describes the leaves very long and grassy, twisted as well as the stalks.

2. *X. pubescens*. Downy-sheathed Xyris. Poir. n. 2.—“Stalk striated, almost cylindrical, enveloped in a downy sheath. Leaves greatly elongated.”—Received by professor Desfontaines, from the West Indies. Nearly related to *X. indica*, but differing in several characters peculiar to itself. The roots are long, as thick as the finger, with soft, rather fleshy, nearly simple, fibres, as thick as a raven's quill; and producing from the crown a great number of soft, flaccid, alternate, somewhat imbricated, very smooth leaves, a foot or foot and a half long, half an inch wide, entire, pointed; dilated at the base. Stalks straight, rather slender, twisted at the lower part, where they are each embraced by a cylindrical, striated, downy sheath, three or four inches long, terminating in a little short acute leaf. Head of flowers oval, obtuse, the size of a large pea, formed of numerous, imbricated, very close, unequal, whitish scales; the outer ones a little dilated, oval, nearly flat, scarcely pointed; the inner narrower, obtuse, rather concave. Poir. See our *X. anceps*, which has also a very long leafy-pointed sheath, but it is quite smooth.

3. *X. macrocephala*. Great-headed Xyris. Vahl n. 2.—“Stalk with one acute angle. Head and scales ovate; the latter grey at the back.”—Native of Cayenne. Described from the herbarium of professor Desfontaines. The leaves are eighteen inches long; as broad as the nail, or broader. Stalks taller than the foliage; round in the lower part; somewhat two-edged further up, with one convex and one acute side. Head when in fruit twice as big as a Hazel-nut, ovate, with obtuse scales. This differs from the rest in the breadth of its leaves, and the size of the head. Vahl.

4. *X. platycaulis*. Broad-stalked Xyris. Poir. n. 4.—Stalk compressed, dilated, striated, smooth; twisted below; with a lax, cloven, abrupt sheath at the base. Heads globose, abrupt at the summit.—Gathered by Commerçon in Madagascar. Leaves wanting in the specimens. Stalks a foot high; two or three lines broad. Sheath at least three inches long, smooth, striated, rather lax, cloven lengthwise,

obliquely truncated at the summit. Head hardly so big as a pea, flattish at the top, with broad, obtuse, concave, shining, chestnut-coloured scales, the outer ones keeled towards their point. Poir. We have enlarged the author's specific character from his own description, in order the better to contrast this species with the two following, with which it appears to agree in the flatness of the stalk.

5. *X. anceps*. Small-headed Two-edged Xyris. Lamarck *Illustr. v. 1. 132.* Vahl n. 3.—“Stalk two-edged, smooth. Head nearly globose.”—Native of Madagascar, and Malabar; perhaps also of Guiana. Leaves rather rigid, narrow, but one-third or one-fourth the height of the stalks, which are several, a foot or more in height, twisted, smooth, by no means striated. Head scarcely so large as a pea, with roundish, convex, hardly emarginate, scales. Petals yellow, finely toothed. Vahl. A Guiana specimen, communicated by Mr. Rudge, remarkable for the smallness of its head in proportion to the herbage, answers precisely in every point to Vahl's description. Aquatic, or marsh-plants, such as the species of this genus, are known to grow, more than any others, in widely distant and dissimilar parts of the world. We have suspected this Guiana specimen might be Poir. n. 2; but the sheath at the base of the stalk is not pubescent.

6. *X. complanata*. Flat-stalked Xyris. Brown n. 1.—“Stalk compressed flat, dilated, nearly straight; cartilaginous and rough at the edges, four times as long as the sword-shaped, straight, bordered, roughish leaves. Spike oblong or cylindrical. Scales orbicular, tumid.”—Gathered by Mr. Brown, in the tropical part of New Holland. The stalk is a line and a half broad. We have seen no specimen.

7. *X. feabra*. Rough Xyris. Br. n. 2.—“Stalk two-edged, twisted, with rather acute and rough angles. Leaves linear, roughish. Head ovate or oblong.”—From the same country. The stalk is hardly a line in breadth. Brown.

8. *X. levis*. Smooth Xyris. Br. n. 3.—“Stalk two-edged, smooth, as well as the narrow linear leaves. Head nearly ovate. Scales imbricated every way. Keels of the calyx-leaves fringed.”—Gathered by Mr. Brown near Port Jackson, as well as in the tropical part of New Holland. The stalks are from fifteen to eighteen inches high.

9. *X. americana*. Blue American Xyris. Aubl. Guian. 40. t. 14, very bad. Vahl n. 4. Symb. v. 3. 8. Willd. n. 3. Poir. n. 6. (*Jupicai*; *Pif. Bras. 238.*)—Stalk two-edged in the upper part. Head ovate-oblong. Scales polished, emarginate, with a small callous intermediate point.—Native of moist pastures in Brazil, flowering in the rainy season, according to Pifo, whose synonym was verified by Vahl, from an inspection of Marcgraav's herbarium. Aublet found the same in wet meadows near the river Macouria, in Guiana, flowering in December; but his figure is made up, as Vahl observes, with the leaves of an *Eriocaulon*; the scales of the head, and the flowers, being moreover very ill drawn. We have never met with a specimen answering to this species. Vahl says the leaves are grassy, narrow, and acute, half the length of the stalk, which is a foot or more in height; round in the lower part, with two prominent lines running down it; compressed in the upper part, and a little dilated under the head. The latter is obtuse, rather bigger than a pea. Scales oblong, concave, cloven at the point, with a brownish, rather callous point in the notch. Vahl. The corolla is said to be blue, of which we know no other instance in this genus.

10. *X. caroliniana*. Carolina Xyris. Walt. Carol. 69. Vahl n. 5. Poir. n. 7. Pursh n. 2. (*X. Jupicai*; *Michaux Boreal-Amer. v. 1. 23*, according to Vahl.)—“Stalk two-edged. Head ovate, acute.”—Native of Carolina.

XYRIS.

Carolina. *Vahl*. Found in low grassy fields, on a sandy soil, from New Jersey to Florida. Perennial, flowering from June to August. *Heads* small. *Flowers* yellow. It is extremely variable. *Pursh*. *Vahl* thought this species distinct from the last, in having more rigid leaves, and larger heads, which are acute, instead of being remarkably obtuse. The flowers moreover are yellow, not blue. The leaves vary in length. The heads in Lamarck's specimens are longer than those of Richard's. *Vahl*. We have not seen this species, but it seems that more than one may possibly here be confounded.

11. *X. torta*. Twisted-leaved Xyris. (*X. indica*; *Pursh* n. 1, excluding the synonyms.)—Leaves linear, spirally twisted, as well as the stalk, which is two-edged below, quadrangular at the upper part. Head globose. Scales polished, rounded, somewhat emarginate, pointless, with a small silky disk.—Gathered in North America by Kalm. Linnæus confounded his specimens with *X. indica*, which he knew but imperfectly. They appear, however, to answer exactly to the *indica* of *Pursh*, who very properly gives an original specific character, instead of copying what did not agree with the plant before him. He found it in overflooded meadows, and small ponds, from Pennsylvania to Virginia; perennial, bearing yellow flowers in June and July. He calls the leaves "*longissime graminea*." In our specimens they are from one to ten inches long, a line broad, acute, many-ribbed, roughish at the edges, perfectly grassy; the outermost degenerating into broad, short, chestnut-coloured, pointed, imbricated scales. Stalks solitary, about two feet high; nearly round, though two-edged and striated, at the bottom, as well as very much twisted, even more than the leaves; the upper part is less so, more evidently two-edged; and towards the top there are four, not always equal, angles. Head the size of a large white currant, obtuse, of a shining chestnut-colour. Scales almost orbicular, convex; dilated and thin at the edges; marked at the back, just below the notch, with a pale, greenish, silky spot. Two or three of the lowermost of all are smaller, flatter, a little keeled.

12. *X. pusilla*. Dwarf Broad-leaved Xyris. Brown n. 4.—Stalk two-edged, smooth, like the short, sword-shaped, two-ranked, equitant leaves. Head orbicular, compressed, of a few shining, somewhat keeled and pointed, scales.—Gathered by Mr. Brown, in the tropical part of New Holland. Our specimens, in the herbarium of the younger Linnæus, were probably given to him when in England, by Sir Joseph Banks and Dr. Solander. The stalks are from two to six inches high, pale green, a little zigzag and twisted, somewhat quadrangular; sheathed at the base with one or two leaves, which, like those that grow from the root, are about an inch long, and two or three lines broad, slightly incurved at the point, of a pale rather shining green, with several ribs, and a finely dotted, or reticulated, surface in the dry state. Head the size of a pea. Scales orbicular, convex, of a shining chestnut-brown, pale at the edges: the two lowermost equal, without flowers, in an early state covering the whole head, and furnished with a strong, green, pointed keel.

13. *X. denticulata*. Tooth-leaved Xyris. Br. n. 5.—Stalk roundish, smooth. Leaves short, linear-awl-shaped; rough with minute marginal teeth. Head globose. Scales orbicular, shining, keeled at the summit.—Gathered in the tropical part of New Holland, by Sir Joseph Banks and Dr. Solander, who gave specimens to the younger Linnæus. This is about the size of the last, or rather taller. The root consists of very small fibres. Leaves from one to two inches long, not a line broad, their fine reticulations seeming to form the little teeth, at the margin and keel. Stalk

slender, striated or angular towards the top. Head twice the size of the last, of more numerous, bright-chestnut scales, with thin, pale, often jagged margins, and a little green short keel, or point, not extending beyond the scale. The two lowermost scales are barren, as in the preceding, and in a young state enclose the whole head.

14. *X. paludosa*. Bog Xyris. Brown n. 6.—Stalk roundish, smooth; angular at the top. Leaves somewhat tubular; that of the stalk longer than the sheath. Head nearly globular. Scales orbicular, shining, imbricated every way.—Found in the tropical part of New Holland, by Sir Joseph Banks and Dr. Solander. We have seen no specimen, nor did Mr. Brown himself meet with this or the last species, any more than with the *pauciflora* hereafter described.

15. *X. capensis*. Cape Xyris. Thunb. Prodr. 12. Fl. Cap. v. 1. 310. Willd. n. 4. *Vahl* n. 6.—Stalk solitary, thread-shaped, striated. Leaves linear, very short. Head ovate, acute. Scales ovate, obtuse, smooth.—Native of hills near Verkeerde valley, at the Cape of Good Hope, flowering in December. Stalk a foot high, or more, slender, smooth, very finely striated. Leaves few, radical, smooth, many times shorter than the stalk. Flowers yellow. Stigmas three, tumid, revolute, whitish. *Thunberg*.

16. *X. brevifolia*. Short-leaved American Xyris. Michaux Boreal-Amer. v. 1. 23. *Vahl* n. 7. *Pursh* n. 3.—Stalk thread-shaped. Leaves awl-shaped, compressed. Head globose. Scales oblong; the outermost narrowest, keeled.—Native of low boggy meadows, in Lower Carolina and Georgia; perennial, flowering in July. The smallest American species. Flowers yellow. *Pursh*. Leaves narrow, an inch and a half long. Stalk a span high, round and slender. Head the size of a black pepper-corn. Scales broadish-oblong. *Vahl*.

17. *X. pauciflora*. Few-flowered Xyris. Willd. n. 2. Phytogr. 2. t. 1. f. 1. *Vahl* n. 8. Br. n. 7.—Stalk quadrangular. Leaves linear; rough with minute marginal teeth. Head nearly globular. Scales shining, orbicular; spreading at the point, with a short triangular keel.—Gathered by Koenig and Rottler in the East Indies; and by Sir Joseph Banks, in the tropical part of New Holland. The root is a small dense tuft of pale fibres. Stalk from one to six or eight inches high, erect, straight, slender, striated, roughish. Leaves several, erect, sometimes nearly as tall as the stalk, grassy, very narrow, taper-pointed, striated, roughish, especially at the edges, where they are minutely toothed, or crenate, as in *X. denticulata*, n. 13. Head the size of a large pea. Scales chestnut-coloured, with a membranous, dilated, shining margin of a golden yellow, and each tipped with a green, triangular, projecting keel, or point, originating from the brown disk, but not extending beyond the membranous margin, with which it is incorporated. The prominence of this point, giving the head a squarrose aspect, is well expressed in Willdenow's, otherwise miserable, figure. The two lowermost scales are barren, and closely pressed to the next. *Corolla* linear.

18. *X. bracteata*. Bracted Xyris. Br. n. 8.—Stalk triangular. Leaves linear; their margins, and base of the keel, rough. Head roundish. Scales with a hoary disk, and brown membranous margin; the lower ones oblong, empty, with a linear disk.—Sent from Port Jackson, New South Wales, by Dr. White, in 1792. Mr. Brown found it in the same country, and we borrow from him the above characters of the leaves, wanting in our specimens. The stalk is a foot and a half high, slender and rusty, bluntly triangular, even, smooth to the touch, though Mr. Brown remarks that its most acute angle is roughish. Head rather
ovate

ovate than perfectly globose, one-third of an inch in length. Scales elliptical, abrupt, or partly emarginate; their disk elliptic-oblong, convex, not keeled, of a hoary or glaucous hue, finely dotted, not downy; their margin, at each side, about half as broad, membranous, of a shining brown, paler outwards. Three, four, or more, scales, at the bottom of each head, are destitute of flowers, shorter, much narrower, abrupt, oblong, not elliptical, with a peculiarly narrow disk, and have the appearance of bracts. Corolla rather large, yellow, turning white in decay.

19. *X. juncea*. Rushy Xyris. Brown n. 9.—“Stalk roundish, slightly compressed, rather zigzag, smooth as well as the awl-shaped leaves. Head globose. Scales ovate, undivided, imbricated every way; their disk of the same colour as the margin. Stigmas many-cleft.”—Gathered by Mr. Brown, in the neighbourhood of Port Jackson, New South Wales. The stalk is only eight or ten inches high. We have no specimens answering to the above characters.

20. *X. gracilis*. Slender Xyris. Brown n. 10?—Stalk thread-shaped, smooth, scarcely twisted. Leaves linear, straight, rough-edged. Head oval, of few flowers. Scales imbricated every way; their disk hoary; margin blackish. Stigmas undivided.—Sent from Port Jackson, in 1792, by Dr. White. Mr. Brown mentions only the fourth part of New Holland, and Van Diemen’s island, as the native country of this species, and yet we cannot refer our specimens to any other mentioned by him. Our plant is about half the size of *X. bracteata*, with fewer and paler flowers. Head small, elliptical, or obovate. Scales with a broad, hoary, or glaucous, disk, like that of the *bracteata*; but their membranous margin is of a darker brown, and, at the upper part of each scale, quite black, as if burnt. Several of the lowermost scales are smaller, linear-oblong, and of a more uniform brown. The stigmas are long, and undivided. Stalk somewhat compressed, seldom above a foot high; Mr. Brown says a foot and half.

21. *X. filiformis*. Thread-shaped Xyris. Lamarck Illust. 132. Vahl n. 9. Poiret n. 9.—Stalk thread-shaped, compressed. Leaves linear-awl-shaped, compressed, two-ranked. Head and scales elliptical; disk and margin uniform, with slight traces of a keel.—Gathered by the late Mr. Smeathman, as well as by Dr. Adam Afzelius, in marshy sandy ground at Sierra Leone. The root is small and fibrous. Leaves four or five, seldom more, equitant, erect, linear-sword-shaped, compressed, very narrow, tapering, but rather obtuse at the point; their surface minutely speckled, and more or less evidently reticulated, or dotted; their length, in our specimens, from one to two inches; Vahl says scarcely half an inch. Stalk solitary, six or eight inches high, very slender. Head the size of hemp-seed, but more oblong, acute at each end, of a copper-brown, not very shining; the two lowest scales empty, rather palest, most oblong, and strongly keeled; the rest elliptical, bluntly pointed, very smooth and even, without any limited disk, but sometimes marked with beautiful concentric veins; their keel scarcely discernible, except in the form of a short pale elevation, near the apex, but not projecting into a point. Corolla yellow, small.

22. *X. flexifolia*. Wavy-leaved Xyris. Br. n. 11.—“Stalk thread-shaped, twisted, smooth, as well as the zigzag, slender, slightly compressed, leaves. Head oval, with few flowers. Stigmas undivided.”—Found by Mr. Brown, on the southern coast of New Holland. Stalk from six to twelve inches high.

23. *X. teretifolia*. Cylindrical-leaved Xyris. Br. n. 12.—“Stalk, as well as the leaves, round, straight, and roughish. Head ovate, many-flowered. Scales imbricated every way, torn into many segments.”—From the same country. Stalk eighteen inches high. Brown.

24. *X. lacera*. Jagged-headed Xyris. Br. n. 13.—“Stalk round, smooth. Head nearly globular, many-flowered. Scales imbricated every way, torn into many segments.”—Discovered by Mr. Brown, on the fourth coast of New Holland. We have seen no specimens of this, or the two species immediately preceding.

25. *X. subulata*. Awl-leaved Peruvian Xyris. “Fl. Peruv. v. 1. 46. t. 71. f. b.” Vahl n. 10. Kunth n. 1.—“Stalk thread-shaped; roughish at the top. Leaves linear-awl-shaped; their sheaths woolly at the margin. Head oblong, about three-flowered.”—Native of marshy, cool, highly elevated, mountainous situations, in Peru, flowering in September. Root perennial. Plants growing together in patches. Leaves about an inch long; villous at the base. Stalk slender, about eight inches high. Flowers yellow, two or three only in each head. Vahl.

26. *X. vivipara*. Viviparous Xyris. Kunth n. 2.—“Stalk somewhat compressed; roughish at the top. Leaves linear-sword-shaped; their sheaths fringed. Head globular; at length leafy and viviparous.”—Gathered by Humboldt and Bonpland on the banks of the river Oroonoko, between the mouths of Ventuario and Guaviare, flowering in May. Root fibrous, perennial. Leaves all radical, two-ranked, from two to four inches long, erect, bluntish, sheathing, smooth, except a little roughness at the back; their sheaths keeled, striated, fringed, roughish also at the back. Stalks about a foot high, smooth, except some roughish points towards the summit; enveloped at the base with a striated, keeled, bluntish, smooth, rough-backed sheath, an inch and a half long. Head globose, rather abrupt, the size of a pepper-corn. Scales roundish-ovate, bluntish, brownish, coriaceous, smooth, rather transparent at the margin. After flowering, the head throws out from its centre a leafy crown, which becomes a young plant. Kunth.

We are not told whether this leafy tuft originates in the vegetation of one or two of the seeds; or in the germin being supplanted in the flower by a bud; or, which is the least likely, in a proliforous elongation of the stalk, independent of the parts of fructification altogether.

27. *X. operculata*. Imbricated Xyris. Labill. Nov. Holl. v. 1. 14. t. 10. Brown n. 14. Poiret n. 13. Curt. Mag. t. 1158.—Capsule partly three-celled. Stalk round. Leaves thread-shaped. Head obovate. Scales beardless, imbricated in five rows, with numerous empty ones, gradually smaller, at the base.—Sent from Port Jackson, New South Wales, by Dr. White, in 1792. Mr. Brown also observed it there; and Labillardiere in Van Diemen’s island. Neither the figure of the last-mentioned author, nor that in the Botanical Magazine, by any means represents the remarkable character of the five-ranked scales of the head, and the numerous, gradually diminishing ones, destitute of flowers, at its base; so that, but for Mr. Brown’s authority, we should have supposed our Port Jackson plant to be essentially and widely different. Dr. White’s specimens are without leaves. The stalk is about eighteen inches high, round, or slightly angular, quite smooth. Head obovate, full half an inch long, with five rows of very numerous obovate scales, whose broad convex disk is of a bronze-like hue; the margin broad and narrow, more or less jagged, with a deciduous tooth-like fringe. Flowers large, bright yellow. Stigmas obtuse.

28. *X. lanata*. Woolly Xyris. Br. n. 15.—“Stalk round, smooth. Leaves linear, narrow. Head nearly globose. Scales woolly at the extremity, imbricated in five rows, with several empty ones, gradually smaller at the base.”—Gathered by Mr. Brown, on the southern coast of New Holland.

The above great accession of new species throws much light

light on this hitherto little-known, and ill-described, genus of plants. Could they all be compared together, even in a dried state, we have no doubt that their specific characters, and the principles on which they are founded, would derive considerable improvement; and that *Xyris*, whose generic marks are so well established, would afford a beautiful display of clear and precise specific discrimination. Whether the leaves of any of the species be really toothed, in a living state, we have considerable doubt. Their foliage partakes greatly of the cellular texture, so remarkable in the neighbouring genus *Eriocaulon*; with which also they closely accord in inflorescence, and general habit. Mr. Brown, in his *Prodromus*, has elucidated both these genera, as far as concerns their numerous New Holland species, with infinitely more success than any other botanist; the one genus having previously been scarcely better understood than the other.

XYSMALOBIUM, from *ξύσμα*, a strip, or narrow shred, and *λόβος*, a pod, alluding to the shaggy coat of the seed-vessel, which is very peculiar.—Brown *Transf. of the Wernerian Soc. v. 1. 38.* *Afsclep.* 27. *Ait. Hort. Kew. v. 2. 79.*—Class and order, *Pentandria Digynia*. *Nat. Ord. Centoria*, *Linn. Apocinea*, *Juss. Afsclepiadea*, *Brown*.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, lanceolate, acute, permanent segments. *Cor.* of one petal, in five deep, ovate, spreading, rather oblique segments. Crown of the filaments in a single row of ten deep segments; five of them fleshy, roundish, opposite to the anthers, simple at the inner side; five intermediate ones smaller. *Stam.* Filaments scarcely any; anthers five, each tipped with an ovate bluntish membrane; masses of pollen ten, compressed, smooth, pendulous, with rather broad connecting processes. *Pistl.* Germens two, ovate, pointed; styles very short; common stigma pointless. *Peric.* Follicles two, inflated, clothed all over with numerous, long, slender, tapering, hairy, filamentous processes. *Seeds* numerous, imbricated, crowned with silky down.

Effl. Ch. Masses of pollen ten, smooth, pendulous. Crown simple, in ten deep segments, the intermediate ones minute. Corolla spreading. Follicles shaggy.

A genus of upright herbs, with opposite, sometimes alternate, leaves. Umbels lateral, either axillary, or between the footstalks. Flowers rather large; the limb of the corolla sometimes bearded. Only two species are at present known, both natives of southern Africa.

1. *X. undulatum*. Waved-leaved *Xyfmalobium*. *Dryand. in Ait. n. 1.* (*Afsclepias undulata*; *Linn. Sp. Pl. 312.* *Willd. Sp. Pl. v. 1. 1262.* See *ASCLEPIAS*, n. 1. *Apocynum africanum*, *lapathi folio*; *Comm. Rar. 16. t. 16.*)—Leaves undulated, naked. Corolla bearded.—Native of the Cape of Good Hope. Sent to Kew garden, in 1783, by Mr. John Graef. This is a green-house plant, flowering in July. Mr. Aiton marks it as a shrub; but *Comelin* says the thick, white, perennial root sends up every year, in the early spring, two or three thick, round, green, leafy stems. All authors speak of the leaves as opposite; but in our Linnæan specimen, gathered at the Cape by Thunberg, they are alternate, sessile, three or four inches long, ovato-lanceolate, gradually tapering to a bluntish point, with a thick mid-rib, and numerous interbranching veins; nearly smooth on both sides; undulated and roughish at the margin. Umbels axillary, stalked, much shorter than the leaves, with hairy stalks, and linear hairy bractæes. Flowers green, their segments densely bearded at the extremity, with white shaggy hairs. Follicles covered with spreading hairy filaments, an inch long. Every part of the plant, when wounded, discharges a copious milky fluid.

2. *X. grandiflorum*. Large-flowered *Xyfmalobium*.

(*Afsclepias grandiflora*; *Linn. Suppl. 170.* *Thunb. Prodr. 47.* *Willd. Sp. Pl. v. 1. 1264.* See *ASCLEPIAS*, n. 26.)—Leaves stalked, hairy. Corolla smooth.—Gathered by Thunberg, at the Cape of Good Hope, but as yet a stranger to our gardens, nor does the Linnæan collection contain a specimen. The stem is said to be simple, erect, and hairy. Flowers large, axillary, stalked; but, as far as we can gather, the umbel is not elevated on a common stalk, as in the foregoing. Corolla speckled like *Fritillaria Melegaris*, and of a similar colour.

XYSTARCHA, in *Antiquity*, the master or director of the *xyftus*.

In the Greek gymnasium, the *xyftarcha* was the second officer: the first was the *gymnasiarch*. The *xyftarcha* was his lieutenant, and presided over the two *xyfti*, and all exercises of the *athletæ* therein.

XYSTICI, among the *Ancients*, a designation given to the *athletæ*, because they performed their exercises in the *xyftus*.

XYSTIS, in *Ancient Geography*, a town of Asia Minor, in Caria. *Steph. Byz.*

XYSTRIS, in *Botany*, *Schreb. Gen. 138.* *Poiret in Lamarck Dict. v. 8. 822*, is one of those genera of proffer Schreber's, to which we have adverted under *WHEELERA*, (see that article,) as being unintelligible to all but those who may have access to the learned author's herbarium, or to some record in his manuscripts. The name is Greek, *ξύστis*, a *curry-comb*, or *scraper*.—Class and order, *Pentandria Monogynia*. *Nat. Ord. Epacrideæ* of *Brown*?

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, lanceolate, acute, spreading, hispid, permanent segments, each contracted at the base. *Cor.* of one petal: tube very short; limb in five deep, ovate, obtuse, veiny, spreading segments. *Stam.* Filaments five, bristle-shaped, erect, spreading at the summit, shorter than the corolla, inserted into the middle of its tube; anthers oblong, erect. *Pistl.* Germen superior, globose, pointed; styles two, capillary, erect, combined in the lower part; stigmas obtuse. *Peric.* Drupa globose, furrowed at the base by short, prostrate hairs, inserted into the middle of the calyx. *Seed.* Nut globose, furrowed, of ten cells; kernels oblong.

Whether this genus be founded on some New Holland specimen of the natural order of *Epacrideæ*, and whether the rigid or prickly habit of the plant suggested the name, can only be matter of vague conjecture. We acknowledge that the division of the style, and the hispid segments of the calyx, militate greatly against our ideas of the supposed natural order. In total darkness, however, any glimmering of light is welcome, and we will therefore hazard another conjecture, not altogether inconsistent with the former. As *Schreber* places *Xystris* immediately after the *Jacquinia* of Linnæus, can it possibly have been founded on *Jacquinia ruscifolia*, of whose fructification no botanist, as yet, has given any sufficient account? There seems an association of ideas between the habit of *Rufus*, and the name of *Xystris*; and the globose pointed figure of the fruit, as copied from *Plumier in Dill. Hort. Elb. t. 123*, answers to part of the above description, though the permanent calyx is drawn obtuse, and not apparently hispid.

XYSTUS, *ἔχυτος*, formed of *ξύς*, to polish, or rub, in the *Ancient Architecture*, among the Greeks, was a long spacious portico, either open, or covered over; in which the *athletæ*, and others, practised wrestling and running.

The *xyftus* made a necessary part of a gymnasium. The *athletæ*, who practised in it, were thence called *xyftici*.

Xystrus, among the Romans, was an alley, or double row of trees, meeting arbor-wise at top, and forming a shade to walk under.

Y.

Y

Y The twenty-third letter in the English alphabet, borrowed, originally, from the Greek υ .

It is occasionally both vowel and consonant. As a vowel some authors have judged it unnecessary in our language, because its found is precisely the same with that of the *i*. Accordingly, it is but little used, except in words borrowed from the Greek, to denote their origin, by representing the Greek υ ν .

The vowel *y*, however, has a place even in some words purely English; and that both in the middle of them, as in *dying, frying*, &c. and at the end, as in *lay*, &c.

Some ascribe the use of the *y*, in pure English and French words, and those that have no *y* in Latin or Greek, to this; that anciently each of those words was written with a double *ii*; which having something awkward in it, the *y* was substituted in their place.

Others say, that those words being anciently written, as well as pronounced, with a double *ii*, as they still are in the Walloon, as *paing, paifan*, &c. to avoid their being mistaken for an *u* with two dots over it, they made the second *i* longer than the first, and so formed the *y* without designing it. Some give a particular reason why words ending in *i* came to be written with *y*; viz. that the copyists found the tail of the *y* very commodious, in adorning the margins and bottoms of pages.

Y was much used by the Saxons; whence it is found for *i* in the old English writers.

When the *y* follows a consonant, and at the end of words, it is a vowel, and has the sound of *i*; and when it precedes a vowel, or diphthong, and at the beginning of words, it is a consonant.

Some have thought that *y* is in all cases a vowel; but Dr. Johnson observes of *y*, as of *w*, that it follows a vowel without any hiatus, as *rosy youth*.

The Romans used the *y* for the vowel *u*, which they had no character for, distinct from the *u* consonant; their way being to pronounce the common *u*, as we do the diphthong *ou*; and the Greek υ ν , as the English and French *u*.

Peter Diaconus observes, that Augustus first took the letters *y* and *z* from the Greeks, which were not used by the Romans before his time; *z* being written for *z*, and *i* for *y*. But Mr. Jackson shews, that the *y* was used before the time of Augustus, though probably (says Atle, Orig. and Progr. of Writing, p. 78.) it was not much older.

In our own and some other modern tongues, authors begin to dispense more and more with the precise orthography, which requires all words that have an upilon, in the Greek, to be written with a *y*. And with reason; since our Greek *y* has lost the sound it had, in the language from which we borrow it. But it is certainly ridiculous to

Y A D

use it, as many do, in words which indeed have a Greek origin, but have no *u* in the Greek, as in *eclipse*: yet some affect to do this.

Y is also a numeral letter, signifying 150, or, according to Baronius, 159; as in the verse,—

“*Y* dat centenos et quinquaginta novenos.”

When a dash was added at top, \bar{Y} , it signified 150 thousand.

Pythagoras used the *Y* as a symbol of human life; the foot representing infancy, and the forked top the two paths of vice and virtue, one or the other of which people are to enter upon, after attaining to the age of discretion.

Y, on the French coins, denotes those struck at Bourges.

Y, in *Geography*, a city of China, of the second rank, in Chan-tong; 317 miles S.S.E. of Peking. N. lat. 35° 10'. E. long. 118° 19'.

Y, a city of China, of the second rank, in Pe-tche-li; 55 miles S.W. of Peking. N. lat. 39° 25'. E. long. 115° 14'.

Y, or *Ev*, a river, or broad piece of water, which passes by Amsterdam, exhibiting the appearance of a creek of the sea rather than of a river.

YA, a city of China, of the second rank, in Se-tchuen, on the borders of Thibet; 840 miles S.W. of Peking. N. lat. 30° 9'. E. long. 102° 39'.

YABAQUE, one of the Bahama islands, situated in N. lat. 23° 30'.

YABARGULSKAIA, a town of Russia, in the government of Tobolsk, on the Irtysh; 120 miles E. of Tobolsk.

YABAY, a town of Burmah; 50 miles S.W. of Ava.

YABTONOI, a ridge of the Altaian chain in Asiatic Russia, bending in a northerly direction to the vicinity of Ochothk. The name denotes the mountains of Apples.

YACHT. See *SHIP*, and *Plate XIII. Ship-Building*.

YACHTA, in *Geography*, a fort of Russia, in the government of Irkutsk, on the borders of China; 48 miles S.S.W. of Selenginsk.

YACINTE, *St.* See *St. Yacinte*.

YACONG TALA, a number of small lakes in Thibet, situated near each other. N. lat. 30° 50'. E. long. 78° 39'.

YADAVA, in *Hindoo Mythology*, a name of the Hindoo Krishna. It is said to indicate his being of the family or tribe of Yadu.

YADI, in *Geography*, a river of Russia, which runs into the Obkskaia gulf, N. lat. 68° 25'. E. long. 72° 38'.—Also, a river of Russia, which runs into the Obkskaia gulf, N. lat. 67° 25'. E. long. 72° 18'.

YADKIN, a river of North Carolina, which rises in the

Alleghany mountains, and after a course of about 100 miles, changes its name to Pedee, in North Carolina; 9 miles S.W. of Salem.

YADRIN, a town of Russia, in the government of Kazan; 122 miles W. of Kazan. N. lat. $55^{\circ} 34'$. E. long. $45^{\circ} 44'$.

YAEAGONMEW, a town of Pegu; 58 miles S. of Prone.

YAGA. See JAFFA.

YAGARCHOCA, a lake of South America, in the jurisdiction of St. Miguel de Ibarra. It is famous for having been the sepulchre of the inhabitants of Otobalo: upon this place being taken by Huana Capac, the 12th ynca, he, instead of shewing any clemency to them on account of their magnanimity, being exasperated at the noble resistance which they made against his army, ordered them all to be beheaded, both those who had quietly surrendered, as well as those taken in arms, and their bodies to be thrown into the lake: so that from the waters of the lake being tinged of a bloody colour, it acquired its present name, which signifies "a lake of blood."

YAGATH, in *Mythology*, a deity adored by the ancient Arabian idolaters, under the figure of a lion.

YAGO, St. in *Geography*. See St. Yago.

YAGUACHE, or St. JACINTO DE YAGUACHE, a town of Peru, and principal place of a lieutenantcy, in the province of Guayaquil; 25 miles N.E. of Guayaquil.

YAGUAHS, a town of the island of Cuba; 22 miles S. of Bayamo.

YAGUARIFE, a river of Brazil, which runs into the Atlantic. S. lat. $13^{\circ} 12'$.

YAGUARON, a town of South America, in the province of Paraguay; 10 miles S.E. of Assumption.

YAGUEPURI, a river of Brazil, which runs into the Negro, 50 miles above Fort Rio Negro.

YAH, in *Hindoo Mythology*, a name of Pavana, the Hindoo god or regent of the wind; another of whose names is Vayu. See PAVANA and VAYU.

YAHANGA, in *Geography*, a small island in the sea of Japan. N. lat. $43^{\circ} 8'$. E. long. $131^{\circ} 45'$.

YAHÉBIRI, a river of South America, which runs into the Parana, S. lat. $24^{\circ} 20'$.

YAIK, a considerable stream of Asiatic Russia, which flows into the Caspian. The name has been recently changed for that of Ural, on account of a daring insurrection of the tribes bordering on the Yaik.

YAITCHNEI, a small island of Russia, in the Peninsula of Kamoi sea. N. lat. $60^{\circ} 30'$. E. long. $160^{\circ} 50'$.

YAIWA, a river of Russia, which runs into the Kama, 16 miles S. of Solikamsk, in the government of Perm.

YAK, in *Zoology*, the *bos grunniens* of the Linnæan system, or ox with cylindric horns curving outwards, very long pendant hair, and extremely villous horse-like tail, the grunting ox of Pennant, and yak of Tartary, has been lately particularly described by Turner, in his "Embassy to Tibet." He calls it the bushy-tailed bull of Tibet; and in Hindoostan it is denominated soora go. It is about the height of an English bull, which it resembles in the general figure of the body, head, and legs. He could discover no difference between them, except that the yak is wholly covered with a thick coat of long hair. The head is rather short; the horns tapering from the root upwards, and terminating in sharp points; arched inwards, and bending towards each other, but a little turned backwards near the extremities; the ears small; the forehead prominent; the eyes full and large; the nose small and convex; the nostrils

small; the neck short and curved; the withers are high and arched; the rump low; over the shoulders rises a thick muscle, like the protuberance peculiar to the cattle of Hindoostan, covered with a profusion of soft hair; the tail composed of a prodigious quantity of long, flowing, glossy hair; the shoulders, rump, and upper part of the body, clothed with a sort of thick soft wool, the inferior parts having straight pendant hair that descends below the knee, and sometimes trailing on the ground; from the chest, between the legs, issues a large pointed tuft of straight hair, somewhat longer than the rest; the legs very short. In all other respects, this animal resembles the ordinary bull. These cattle appear of a large bulk; they have a downcast heavy look, and are, as they appear to be, fullen and suspicious, and very impatient at the near approach of strangers. Their lowing is not loud, but a kind of scarcely audible grunting noise. They are pastured in the coldest parts of Tibet, on the short herbage peculiar to the tops of mountains and bleak plains. Their favourite haunt is the chain of mountains that is situated between the latitudes 27° and 28° , which divides Tibet from Bootan, and whose summits are commonly covered with snow. They are a valuable property to the tribes of itinerant Tartars, called Duckba, who live in tents, and tend them from place to place; they at the same time afford their herdsmen an easy mode of conveyance, a good covering, and wholesome subsistence. They are never employed in agriculture, but are very useful as beasts of burthen; for they are strong, sure-footed, and carry a great weight. Tents and ropes are manufactured of their hair, and caps and jackets are made of their skins. Their tails are much esteemed; and under the denomination of *chowries*, they are universally used for driving away winged insects, flies, and mosquitoes, and are employed as ornamental furniture upon horses and elephants. They supply an abundant quantity of rich milk and excellent butter, which may be kept in skins or bladders through the year, and to the utmost verge of Tartary furnishes a very material article of commercial produce. The orientals highly value a large kind of bezoar that is sometimes found in this animal's stomach. The yak is said to vary in colour, as well as in the length and form of the horns. Those with white tails are most esteemed; and sometimes their horns are as white as ivory.

In India no man of fashion ever goes out or sits in form at home without two "chowabadars," or brushers, attending him, each furnished with one of these tails, mounted on silver or ivory handles, to brush away the flies. The Chinese dye them of a beautiful red, and wear them as tufts to their summer bonnets.

Elian, according to Pennant, is the only ancient writer who takes notice of this singular species.

YAK, in *Geography*, a name given by the Ostiaks to the *Oby*; which see.

YAKE DSAKE, a lake of Thibet, about 12 leagues in circumference. N. lat. $34^{\circ} 40'$. E. long. $90^{\circ} 24'$.

YAKSAI. See AKSHAI.

YAKSHA, in *Hindoo Mythology*, a race of malignant beings of hideous form, into whom the souls of bad men are said to migrate; particularly the souls of such as in this life are addicted to fordid and base passions, or absorbed too much in worldly prosperity. In the plural, they are termed Yakshas; and are assigned as slaves or servants to Kuvera, the Pluto of the Hindoo Pantheon. Another race of beings, of a like description, is called *Rakshas*. (See that article.) Rakshini and Yakshini are the feminines of these races of demons. These names, and some note of their characters

characters and attributes, occur in the articles KUVERA, RAVENA, and SITANTA.

YAKSHNI-DEVI, a name and an inferior manifestation of the Hindoo goddess Parvati. It means goddesses of malignant beings; one race of whom are in the masculine termed *Takhsa*, which article, and others thence referred to, the reader desirous of information concerning them may consult.

YAKSIMVAR, in *Geography*, a town of Russia, in the government of Viborg, on the north-west coast of Lake Ladoga; 8 miles S. of Serdopol.

YAKUTSK, a town of Russia, in the government of Irkutsk, on the Lena, which is here about two leagues in width; but it is greatly impeded with ice, and navigable only by a few small boats, chiefly employed in supplying the town with provisions. This town is the capital of a province, to which it gives name: it contains between 500 and 600 houses, mostly of wood, with some stone churches, and is defended by a wooden fort. The best fables are found near this town and Nerhinsk; 960 miles N.E. of Irkutsk. N. lat. $62^{\circ} 5'$. E. long. $129^{\circ} 14'$.

YAKUTSK, *the Province*. The Yakutes, or, as they denominate themselves, *Sachos*, or natives of this province, are robust, and in general large; they resemble the Tartars in the cast of their features, and there is said also to be a great similarity in the idioms of these two people. Their ancient homestead extended from the Sayane mountains as far as the Angara and the Lena. Persecuted by the Burets and Mongoles, they removed down the Lena to their present rude and inclement districts, where they are found in the government of Irkutsk on both sides of that river quite to the Frozen ocean. In the year 1620 they submitted to the Russian conquerors, and at the middle of the last century they numbered upwards of 40,000 souls; but since that time they are considerably increased. Their dress is simple, and nearly the same all the year round; the only difference is, that in winter it is made of skins; over their chemise they commonly wear a large striped waistcoat with sleeves; their breeches do not extend below the middle of the thigh, but their long boots, called *Jarri*, reach above the knee. In hot weather they wear nothing but the breeches. Polygamy forms a part of the political code of this people; obliged to make frequent journeys, a Yakute has a wife in every place where he stops, but he never assembles them together. Notwithstanding this licence, they are jealous to excess, and the sworn enemies of any one who shall dare to violate the rights of hospitality. When summer commences, they leave their winter habitations, and with their families and a small number of horses, make their harvests of fodder for consumption during the frost season. They repair to a considerable distance from their yurt, and to the most fertile cantons. In their absence, the horses are left to the care of the servants, and the neighbouring pastures serve for the maintenance of all their herds. Chamans, or forcerers, are regarded as interpreters of the gods; they grant their mediation to the stupid Yakute, who implores it with trembling, but always pays for it. In the idolatry of the Yakutes, we find all the absurdities and superstitious practices of the ancient Kamtschadales, Koriaks, Tchutchis, and other inhabitants of these countries. The funerals are attended with a kind of pomp more or less magnificent, in proportion to the rank and wealth of the deceased. If a prince, he is arrayed in his finest habits, and most splendid arms. The body, placed in a coffin, is carried by the family to the tomb; deep groans announce the solemn procession; his favourite horse, and another the best in

his stud, both richly caparisoned, and led by a valet, or near relation, walk by the side of the corpse. When arrived at the burying-place, they are tied to two stakes, fixed near the grave, and while the matter is interred, their throats are cut over the corpse. This bloody libation is the homage paid to his attachment to these animals, who are supposed to follow him into the other world, where it is imagined that he will again be able to enjoy them. They are then flayed; the head and hide, in one entire piece, are fixed horizontally upon the branches of trees at a small distance from the grave; and such is the memorial that is erected. A fire is then kindled, and the last proof of friendship for the deceased consists in roasting and eating upon the spot these favoured animals: the feast being concluded the company disperses. The same ceremonial is observed for a woman, except that instead of a horse, they sacrifice her favourite cow. Their houses, like the yurts of the wandering Koriaks, are circular, spacious, and constructed with poles, fewer in number, but ranged in the same manner, and kept asunder by a sort of hoops at the top, the whole covered with the bark of the birch-tree, formed into pieces eighteen inches wide, placed in a downward direction. These pieces are edged with a kind of ribband, made of bark, and shaped into festoons, and the inside of the yurt is ornamented in the same manner. The taste of the ornaments is governed by the caprice of the proprietor, and there is in them a sort of wildness that is sufficiently amusing. The same decoration is annexed to the chairs and beds of the heads of families. The domestics lie upon the ground on mats or skins, and the fire is lighted in the middle of the house. See YUHAGHRS.

YALE, a town of the island of Ceylon; 56 miles S.S.E. of Candi. N. lat. $6^{\circ} 52'$. E. long. $81^{\circ} 20'$.—Also, a river of Ceylon, which runs into the sea, on the S.E. side of the island, N. lat. $6^{\circ} 23'$. E. long. $81^{\circ} 41'$.

YALE College. See COLLEGE.

YALEPUL, in *Geography*, a town of Ceylon, at the mouth of the Yale; 30 miles S. of Yale.—Also, a town of the island of Ceylon, near the E. coast; 96 miles S.E. of Candi.

YALLAH'S BAY, a bay of the island of Jamaica, on the S. coast, situated to the E. of Yallah's Point.

YALLAH'S Point, a cape on the S. coast of Jamaica; 12 miles S.E. of Kingston. N. lat. $17^{\circ} 53'$. W. long. $76^{\circ} 21'$.

YALLAH'S River, a river of Jamaica, which runs into the sea, a little to the east of Yallah's Point.

YALMAL, a cape on the E. coast of Russia, in the Karakoe sea. N. lat. 72° . E. long. $68^{\circ} 24'$.

YALME, a river of Devonshire, which runs into the English Channel, 7 miles S.E. of Plymouth.

YALOFFS, YALOFFS, *Jaloffs*, or *Jalloffs*, an active, powerful, and warlike race of negroes, and esteemed the most handsome of those people, who inhabit a great part of that tract of Africa which lies between the Mandingo states, on the river Gambia to the S., and the Senegal to the N. and E. See JALOFFS.

The Yaloffs differ from the Mandingoes, (see MANDING,) not only in language, but likewise in complexion and features. Their noses are not so much depressed, nor the lips so protuberant, as among the generality of Africans; and although their skin is of the deepest black, they are considered by the white traders as the most fighting negroes in this part of the continent. They are divided into several independent states or kingdoms; which are frequently at war either with their neighbours, or with one another. In

their manners, superstitious, and government, however, they have a greater resemblance to the Mandingoes than to any other nation; but excel them in the manufacture of cotton cloth, spinning the wool to a finer thread, weaving it in a broader loom, and dyeing it of a better colour. Their language is said to be copious and significant, and is often learnt by Europeans trading to Senegal. Their numerals are as follow :

One	-	-	Ween
Two	-	-	Yar
Three	-	-	Yat
Four	-	-	Yanct
Five	-	-	Judom
Six	-	-	Judom Ween
Seven	-	-	Judom Yar
Eight	-	-	Judom Yat
Nine	-	-	Judom Yanct
Ten	-	-	Fook
Eleven	-	-	Fookang Ween, &c.

Park's Travels, vol. i.

In connection with this brief account of the Yaloffs, we cannot forbear mentioning an anecdote that redounds very much to the honour of Damel, their king. On occasion of a war between Damel and Abdulkader, king of Foota Torra, a country to the W. of Bondon, the latter inflamed with zeal for propagating his religion, sent an ambassador to Damel, accompanied by two of the principal Bafreens, who carried each a knife, fixed on the top of a long pole. When they obtained admision into the presence of Damel, they announced the object of their embassy in the following singular manner :—" With this knife," said the ambassador, " Abdulkader will confend to shave the head of Damel, if Damel will embrace the Mahometan faith; and with this other knife, Abdulkader will cut the throat of Damel, if Damel refuses to embrace it—take your choice." Damel coolly replied, that he had no choice to make; he neither chose to have his head shaved, nor his throat cut: and with this answer the ambassador was civilly dismissed.

Abdulkader with a powerful army invaded Damel's country. The inhabitants of the towns and villages filled up their wells, destroyed their provisions, carried off their effects, and abandoned their dwellings as he approached. Thus he was led on from place to place, until he had advanced three days' journey into the country of the Yaloffs. Several of his men had died with fatigue and hunger by the way. This led him to direct his march to a watering-place in the woods, where his men, having allayed their thirst, lay down, overcome with fatigue, to sleep among the bushes. In this situation, they were attacked by Damel before day-break, and completely routed. Many were killed, and a greater number taken prisoners. Among the latter was Abdulkader himself, who was led, as a miserable captive, into the presence of Damel. The behaviour of Damel on this occasion is celebrated, in terms and sounds of the highest approbation, by the singing men. When his royal prisoner was brought before him in irons, and thrown upon the ground, the magnanimous Damel, instead of setting his foot upon his neck, and stabbing him with his spear, according to the custom in such cases, addressed him in the following manner :—" Abdulkader, answer me this question. If the chance of war had placed me in your situation, and you in mine, how would you have treated me?" " I would have thrust my spear into your heart," returned Abdulkader with great firmness; " and I know that a similar fate awaits me." " Not so," said Damel; " my spear is indeed

red with the blood of your subjects killed in battle, and I could now give it a deeper stain by dipping it in your own; but this would not build up my towns, nor bring to life the thousands who fell in the woods. I will not therefore kill you in cold blood; but I will retain you as my slave, until I perceive that your presence in your own kingdom will be no longer dangerous to your neighbours; and then I will consider of the proper way of disposing of you." Abdulkader was accordingly retained, and worked as a slave for three months; at the end of which period, Damel listened to the solicitations of the inhabitants of Foota Torra, and restored to them their king.

YALOVA, a town of Natolia, on the sea of Marmora, once the residence of Dioclesian; 30 miles N. of Brufa.

YALUTOROVSK, a town of Russia, in the government of Tobolsk, on the river Tobol; 108 miles S.W. of Tobolsk. N. lat. 56° 8'. E. long. 66° 32'.

YAM, in *Botany*, a large fleshy root, eatable when boiled or roasted, of which there are several species, all natives of tropical climates, and highly useful to voyagers, as they will, like potatoes, keep for a considerable time without spoiling. See DIOSCOREA.

YAM, in *Geography*. See JAMEZ.

YAMA, in *Hindoo Mythology*, is the god of the infernal regions, corresponding with the Pluto of western heathens. Yama is a very important deity: his name is of perpetual recurrence in the sacrificial ceremonies of the Hindoos; oblations and invocations to him forming a portion of many of those ceremonies. The Hindoos, as is explained under our article MARUT, have assigned regents or guardian deities to each of the cardinal and intermediate points of the world. Yama is regent of the fourth, or lower world, in which the Hindoos place the infernal regions; this corresponding with the Grecian Pluto or Minos. Under our article MENU, the great law-giver of that name is supposed to have been the same person as the Minos of antiquity. Yama has many names; and in his character and functions is found related to many important personages of sacred and profane history. Among his names are, *Dhermaraja*, or king of justice; *Pitripeti*, lord of the Pitris, or patriarchs (see PITRIS); and *Mritu*, meaning death; a name also of *Kala*, or *Siva*. (See those articles.) *Susan-yama*, and *Vaivasvata-yama*, are others of his names, derived, it is said, the first from a term denoting comeliness or beauty, the other from his solar origin; Yama being of the race of the sun, of which some explanation will be found under our article SURYAVANSA. He is also named *Sradhadewa*, or lord of the obsequies, in honour of deceased ancestors, of which a copious account is given under SRADHA. As well as the Seventh Menu, Yama bears likewise the name of *Satyavrata*. He is also named *Adhumbara*; this name is said to be derived from a species of wood, by the attrition of which fire is produced, wherewith to light the pile on which funeral obsequies are performed to Yama. Every thing connected with the important element of fire is peculiarly mythical with the Hindoos. Touching the sacrificial and other fires, the reader will find many particulars under our articles PAVAKA, SAGNIKA, SAMI, and others thence referred to. *Anbeka* is another name of Yama; it means *death*, or the *destroyer*: thus the compound *Kal-anbeka-yama* is Yama, the destroyer of Kal or Time, a personification of great boldness and extent. *Kal* is also a name of Yama. (See KAL.) Yama has other compound names, meaning the slayer of all beings, king of deities, reducer of all things to ashes, the dark-blue deity, of wolf-

like belly, the variegated being, the wonderful inflictor of pains, &c.

His abode is in the infernal city of Yamapur, whither the Hindoos believe that a departed soul immediately repairs; and receiving a just sentence, ascends to Swerga, the first heaven, or descends to Nareka, the snaky hell; or is returned to earth, according to its merits or demerits, where it assumes the form of some animal, unless its offences had been such as deserved condemnation to a vegetable or even to a mineral prison. This extensive theory of transmigration is of a very poetical tendency, affording great scope for the imagination, which the mythical and enthusiastic turn of Hindoo metaphysicians or theologians has amply indulged in.

Mr. Wilford believes Yama to be the same with Serapis; deriving the latter from a Sanskrit term, implying thirst of blood. In the Puranas, Yama is described as attended by two dogs, named Serbura and Syama; the first name signifies *varied*, and it has other appellations meaning *stained* or *spotted*. When we add that it was also called *Tri-siras*, or the three-headed, little doubt can be entertained of its being the same with the Cerberus of the Greeks. *Syama* means *black*. See SERBURA, SYAMA, and TRI-SIRAS.

As Dherma Raja, or the king of justice, Yama is described in the Puranas as having two countenances. "One, called his divine countenance, is mild and benevolent; and those only see it who abound in virtue. In this he is called an emanation of Vishnu. He is attended by a servant named Karmala, who conducts the righteous on self-moving cars into the presence of their judge. His other countenance or form is more especially named Yama. He is then depicted with large teeth and a monstrous body, and is thus seen only by the wicked. His attendant is named Kasmala, who drags the wicked with ropes round their necks over rugged paths; and at the command of Yama some are beaten, some cut to pieces, some devoured by monsters, and thrown headlong into hell. He is unmerciful, hard is his heart, and every one trembles at his sight."

Yama is the name of a celebrated legislator, whose enactments are still venerated by the Hindoos. For his profound knowledge and justice, he is said to have been made the judge of departed spirits.

In the seeming contradictions of mythologists, Yama is found to be identified, or nearly so, with both *Siva* and *Vishnu*, (see those articles,) as well as with Menu, Kala, and others. This may be reconciled, as in the mythology of Greece, by recollecting that almost all the deities melt into one. Proserpine or Hecate is given to Pluto as a help-mate, being but another form of Diana. Thus Yama has a form of Parvati assigned him, under the name and character of Pataladevi, or goddess of the infernal regions. (See PATALADEVI.) In heaven Diana is Luna, and Parvati is Swardevi, or queen of heaven. On earth they are distinguished by the names of Diana and Bhudevi, the latter meaning goddess of the earth. These similarities or coincidences could be carried to a great extent.

Some of the ceremonies still in use as propitiating Yama, or his consort *Sakti*, (which see,) have been found by Sir W. Jones and others, as strikingly resembling those of the Eleusinean goddesses; and there can be no doubt but the investigation of the mythological fables of the Hindoos has thrown great light, and may throw still greater, on many obscure and unintelligible passages of our ancient poets of Europe.

We do not find any direct representation of Yama, or

any minute description of his person and attributes, in the mythological works before the public; nor many particulars of his family. We have already noticed him as the offspring of the sun; this he shares in common with several other of the heroic personages of the Hindoos. Yama is indeed one of the many names of Surya, or the sun. The river Yamuna, or Jumna, or rather perhaps the damsel who was poetically metamorphosed into that interesting stream, is fabled as the twin sister of Yama. She is poetically called the "blue daughter of the sun." Days are especially set apart for certain ceremonies to their honour. On one, Yamuna is said to have entertained her brother; and the remembrance of it is preserved in an existing usage of Hindoo young ladies feasting and making their brothers presents on its anniversary. In the Rig-veda (see VEDA), a dialogue is given, in which Yama endeavours to seduce his beautiful sister; but his base offers are rejected by her with virtuous expostulation. In some accounts, a divinity named Swadha is described as the goddess of funeral obsequies; and as such we should expect to find her closely allied to Yama, but know little of the relationship. We have noticed her under the article SWADHA. Several other of our articles contain some particulars of Yama. See KASYA, KRITANTA, SRADHADEVA, TAPAS, and VAIVASWAT.

YAMAMAK, in *Geography*. See JAMAMA.

YAMANACHALINSKOI, a town of Russia, in the government of Caucasus, on the Ural; 20 miles N. of Guriev.

YAMASCA, a river of Canada, which runs into the St. Laurence, N. lat. 46°. W. long. 72° 45'.

YAMASCO, a town of Canada, at the conflux of the Yamasca with the St. Laurence.

YAMBLAK, one of the *Alutian islands*; which see.

YAMBO. See JAMBO.

YAMBURG, a town of Russia, in the government of Petersburg, on the Luga. The cloth manufactory at this place was instituted by Catharine II., presently after her accession to the throne: it contains 36 looms, and employs 600 persons. The cloths are sold at St. Petersburg at a low price; 20 miles E. of Narva. N. lat. 59° 15'. E. long. 28° 40'.

YAMEOS, a town of South America, in the audience of Quito, on the river Amazons; 36 miles W.S.W. of St. Joachim de Omaguai.

YAMIMKA, a river of Russia, which rises in the government of Tobolsk, and runs into the Irtysh, 14 miles S.S.W. of Kozlovo.

YAMINA, a town of Africa, in the kingdom of Bambarra, near the Niger. This town, according to Mr. Park, was large, covering the same extent of ground as Sanfanding; but having been invaded and plundered a few years since by the king of Kaarta, it was, when he was there, half in ruins. N. lat. 13° 46'. W. long. 3° 50'.

YAMON BAY, a bay on the north coast of the island of Luçon. N. lat. 14° 21'. E. long. 122° 37'.

YAMSCHEVSKAIA, a fort of Russia, in the government of Kolivan, on the Irtysh. N. lat. 51° 55'. E. long. 77° 50'.

YAMSKAIA, a gulf of Russia, in the Penzinskoi sea, between Cape Piliatchin and the continent. N. lat. 60° 20'. E. long. 154° 14'.

YAMSKOI, a town of Russia, near the gulf of Yamaskaia; 2500 miles E. of Tobolsk. N. lat. 60° 12'. E. long. 153° 34'.

YAMUMINTI, in *Hindoo Mythology*, the name of one

of the wives of the amorous Hindoo deity Krishna. Her name seldom occurs.

YAMUNA, in *Geography*, a river of India, which takes its rise, as is supposed, in the great range of mountains called Himalaya. Its source has not been accurately explored, but it probably is not more remote than that of the Ganges, which rises in the southern part of that range. The Yamuna flows through the province of Srinagara, or Serinagur, in a southerly course, nearly parallel with the Ganges, approaching its fitter stream to within forty miles, at the village of Garudavara (Gurudwar), in N. lat. $30^{\circ} 22'$; it is then of nearly equal width. The Yamuna enters Hindoostan Proper, in the province of Delhi, varying its distance from eighty to fifty miles from the Ganges. The country between them is called Doobah, a word meaning two waters, or watered by two rivers. It is a very fertile district. The rivers approximate and join at Allahabad, an important fortress and military station under the Bengal government, when the Yamuna, little inferior in magnitude, has its name and waters absorbed in the more celebrated stream. Its length, of course under its own name, is estimated at about nine hundred miles.

For many miles of its course, the Yamuna, or Jumna, as it is more properly called, was considered a boundary to the British territories, dividing them from the possessions of the Mahrattas. But from its shallowness, being fordable in many places in the dry season, it was not an important military barrier; and for the same reason is of less consequence for the operations of commerce.

The confluence of any two rivers is viewed with holy respect by Hindoos,—of these two grand streams more particularly. To heighten the mysticism, (any *ternary* connection being still more deeply venerated,) it is feigned that a third river, the Sarafwati, joins the other two by a subterranean communication at Allahabad. Frequent allusion is made to this occult union by mythological poets, who teach that these three rivers are terrene manifestations of the three great goddesses, Parvati, Lakshmi, and Sarafwati; the Sakti, as they are called, or active energies of their respective lords, Siva, Vishnu, and Brahma, who compose the Hindoo triad of divinity. Of these personages sufficient will be found in the articles given under their several names in this work. The fable of the “three plaited locks,” as this supposed union of these rivers is poetically called, often occurs in the writings of the Hindoos: it is noticed in our articles **JUNCTIONS**, **TRIVENI**, and **ZENNAR**. Under **SUCIDE**, an account is given of the supposed proneness of the Hindoos to this crime. At the confluence now under our notice, it not only loses its sin, but assumes a meritorious form. Of this, see more under **SUTTEE**.

The river goddess Yamuna is made by mythologists to be the same with Lakshmi, consort of Vishnu, and twin sister of Yama, the judge of departed spirits, and ruler of the infernal regions. Of these personages sufficient occurs under their respective names.

YAMUTHA, one of the Alientian islands. N. lat. $53^{\circ} 40'$. E. long. $180^{\circ} 29'$.

YAMYA KONDA, a town of Africa, in the kingdom of Yani.

YAMYAMA KUNDA, a town of Africa, in the kingdom of Tomani.

YANA, a river of Russia, which rises in a lake, situated in lat. $63^{\circ} 40'$, long. $131^{\circ} 14'$, and running due north, being supplied by many small streams, empties itself in the Frozen sea, N. lat. $71^{\circ} 25'$. E. long. $131^{\circ} 16'$. At its discharge

it forms five considerable rivers, which issue in a capacious bay.

YANAM, a town of Hindoostan, in the circar of Rajamundry; 28 miles S.E. of Rajamundry.

YANATONG, a town of Burmah; 40 miles S. of Mellone.

YANAUCA, a small island at the mouth of the river of the Amazons; 10 miles N. of Caviana.

YANDABOO, a town of Birman, on the Irawaddy, remarkable for its manufacture of earthenware; 70 miles W.S.W. of Ava.

YANDINSKOI, a town of Russia, in the government of Irkutsk, on the Angara; 160 miles N.N.W. of Irkutsk. N. lat. $54^{\circ} 30'$. E. long. $103^{\circ} 20'$.

YANFONG, a town of Corea; 40 miles E.S.E. of Ou-tchuen.

YANG, a town of Corea; 13 miles E. of King-ki-tao.

YANGBONRAW, a town of Pegu; 60 miles S. of Lundfey.

YANG-CONG, a river of China, which runs into the Kincha river, near Lo-choui-tong.

YANG-HO, a river of China, which joins the San-camho, N. lat. $40^{\circ} 23'$. E. long. $112^{\circ} 49'$.

YANG-KIN, a town of the kingdom of Corea; 15 miles S.E. of King-ki-tao.

YANG-LI, a city of China, of the second rank; 1157 miles S.S.W. of Peking. N. lat. $22^{\circ} 54'$. E. long. $106^{\circ} 35'$.

YANG-TCHEN, a town of Corea, in Tchufin; 150 miles S.S.W. of King-ki-tao. N. lat. $35^{\circ} 19'$. E. long. $125^{\circ} 14'$.

YANG-TCHEOU, a city of China, of the first rank, in Kiang-nan, situated on the bank of the royal canal, which extends from the Ta-kiang northwards to the river Hoang-ho, or the Yellow river: it carries on a great trade in all manner of Chinese works, and is rendered extremely populous, chiefly by the sale and distribution of the salt that is made on the sea-coasts of this jurisdiction and parts adjoining, and which is afterwards carried along small canals made for this purpose, which end in communication with the great canal; 485 miles S.S.E. of Peking. N. lat. $32^{\circ} 26'$. E. long. $118^{\circ} 54'$.

YANG-TCHUEN, a town of Corea; 35 miles W.S.W. of King-ki-tao.

YANG-TE', a town of Corea; 84 miles E. of Hantcheou.

YANG-TSE-KIANG, a river of Asia, which rises in the mountains of Thibet, and after crossing the empire of China, from east to west, empties itself into the sea, 120 miles E. from Nan-king. This river changes its name almost in every province through which it passes. See **KINCHA**.

The Yang-tse-kiang may be considered as equalling, if not exceeding in size, the **YELLOW RIVER** (which see). The sources of both these rivers are in the same range of mountains, and they approach one another in one part within a few miles. The Yang-tse-kiang, according to Mr. Barrow's statement, consists of two distinct branches, which separating from each other about eighty miles, flow in a parallel direction to the southward for the space of 70 miles, and then unite between the 26th and 27th degrees of N. latitude, just at the boundaries of the two provinces of Yunnan and Szechuen. Then striking off to the N.E. directly through the latter of these provinces, collecting the waters of the numerous rivers that descend towards it from that and another province called Quee-choo, it continues in this direction about 600 miles, and then enters the province of Hoo-quang, in the

31st degree of N. latitude. Through this province it takes a serpentine course, and receives the waters of several lakes, with which this part of the country abounds. Leaving Hoo-quang, it passes between the province of Ho-nan and Kiang-see, and with a little inclination from the E. towards the N., its copious stream glides smoothly through the province of Kiang-nan, and is disembogued into the sea, which bounds China to the E. in the 32d degree of N. latitude. The distance from thence to Hoo-quang is about 800 miles, which makes the whole length of the river about 2200 miles. The current, where the yachts of lord Macartney's embassy passed it, did not exceed in the strongest part two miles; but it was much deeper than the Yellow river. There these two great Chinese rivers, taking their sources in the same mountains, passing almost close to each other in a particular spot, separating afterwards from each other to the distance of 15 degrees of latitude, finally discharge themselves into the same sea, within two degrees of each other; comprehending within their grasp a tract of land of above 1000 miles in length, which they contribute greatly to fertilize and enrich, though by extraordinary accidents occasioning unusual torrents, they may do injury in particular instances. This tract includes the principal portion of the Chinese empire in ancient times; and lies in that part of the temperate zone, which in Europe, as well as in Asia, has been the scene where the most celebrated characters have existed, and the most brilliant actions been performed, which history has transmitted to posterity. When the gentlemen of the embassy had crossed the Yang-tse-kiang, they found that, instead of a flat country, lakes, and swamps, the ground rose gradually from the margin of the river, enriched with various kinds and tints of culture, interspersed with trees, temples, and pagodas. In the river were islands skirted with shrubbery, and rocks rising abruptly from the surface of the water. The waves rolled like those at sea, and porpoises are said to be sometimes seen leaping among them: several junks were lying at anchor. In the middle of the river is the island called "Chin-fan," (which see.) The ground to the southward of the river gradually rose to such a height, that it was found necessary to cut down the earth in some parts to the depth of near 80 feet, in order to find a level for the passage of the canal. The land in this neighbourhood is chiefly cultivated with that particular species or variety of the cotton-plant that produces the cloth usually called Nankeens in Europe. The down enveloping the seed, or cotton-wool, is whole in the common plant; but in that growing in the province of Kiang-nan, of which the city of Nan-kin is the capital, the down is of the same yellow tinge which it preserves when spun and woven into cloth. The colour, as well as the superior quality of this substance in Kiang-nan, was supposed to be owing to the particular nature of the soil; and it is asserted, that the seeds of the Nankeen cotton degenerate in both particulars when transplanted to another province, however little different in its climate. Lord Macartney's Embassy, vol. ii.

YANG-TSI, a town of Corea; 30 miles S. of King-ki-tao.

YANI, a kingdom of Africa, situated to the east of Burfali, and divided into Upper and Lower, on the north side of the river Gambia. See PISANIA.

YANIMAREW, a town of Africa, in the Lower Yani.

YANIMAZCU, a town of Africa, in the kingdom of Yani. N. lat. 13° 40'. W. long. 14° 1'.

YANKEON, a mountain of Thibet; 30 miles N. of Zuenka.

YANKJA, a town of Assyria, near the Tigris, and

not far from Bagdad. This place and also Doueffla are small straggling towns, every house being surrounded by a separate mud-wall.

YANTAC, a town of Thibet; 28 miles S.W. of Harachar.

YAN-TCHIN, or VAN-TCHIN, a city of China, of the second rank, in Quang-si; 1177 miles S.S.W. of Peking. N. lat. 23° 1'. E. long. 106° 51'.

YAN-TINCOU, a town of Thibet; 75 miles E.N.E. of Pa.

YANTRA, a word denoting a mystical figure among the Hindoos; also a mathematical instrument used in any science or art of an occult nature. An instrument used in astronomical observations, called Golayantra, or the spheric yantra, is described in the ninth volume of the Asiatic Researches, art. 6, as similar to our armillary sphere. The article now referred to by Mr. Colebrooke, president of the Asiatic Society of Calcutta, is very curious and important. The Hindoos, being so prone to mysticism, can fancy various wishes in occult figures and practices. Figures similar to the magic squares, abracadabra, &c. of western wizards, are still used and venerated by the knaves and fools of Asia; these are generally called yantra: as are peculiar figures or hieroglyphics, appropriated to certain Hindoo deities, whose followers or sectaries mark their foreheads therewith, and deem them of a sanctifying tendency. The nature of these various yantras, with suitable instructions and warnings as to their formation, uses, and purposes, are taught in a Sanskrit book, entitled "Agamafatra, or Occult Science." It may be noticed in passing, that the word Agama, meaning in the Sanskrit tongue hidden, mysterious, secret, &c. seems to have had in various languages and regions a similar meaning, as to which it may suffice to refer to our articles OGHAM, O'M, and SHASTAH.

Combined with and related to the yantra, are certain imprecations, incantations, charms, philtres, &c. called Mantra and Tantra, which occur frequently in Hindoo writings, and of which some notice is taken in this work under those words.

YAO, in *Geography*, a city of China, of the second rank, in Chen-si; 485 miles S.W. of Peking. N. lat. 35° 54'. E. long. 108° 31'.

YAO-NGAN, or YAO-GAN, a city of China, of the first rank, in Yun-nan. The territory of this city is considerable, although it contains but two cities, one of the second order, and the other of the third. It is intermixed with mountains, which are covered with fine forests and fruitful valleys, and produces abundance of musk: near the city there is a well of fat water, from which they make very white fat; 1175 miles S.W. of Peking. N. lat. 25° 33'. E. long. 101°.

YAO-TCHEOU, a town of Chinese Tartary; 380 miles E.N.E. of Peking. N. lat. 40° 43'. E. long. 122° 14'.

YAO-TCHEOU, or YAO-CHOO-FOO, a city of China, of the first rank, in Kiang-si, situated on the S.E. bank of the lake Po-yang. It has seven towns of the third rank in its jurisdiction. In this town is a large manufacture of porcelain, from whence, as well as from King-te-ching, it is sent to Nem-chang-foo; 670 miles S. of Peking. N. lat. 29°. E. long. 116° 14'.

YAP, among the *Hindoos*, is a silent meditation on the names, attributes, and powers of the Deity. Great merit is ascribed to this species of devotion, which is otherwise, though we apprehend less correctly, spelled *jap*; under which article we find we have sufficiently described it, although reference has occasionally been made to this article;

title; which is therefore thus given, chiefly to point to the more lengthened description.

YAP Island, in *Geography*, one of the group called *Carolines*; which see. In this island, a kind of crocodile is the object of their worship. Here are also a number of magicians, who impose upon the credulity of the inhabitants, by leading them to believe, that they have communication with the evil spirit; and by this imposition, they commit with impunity all sorts of crimes. They procure maladies and even death to those whom it is their interest to destroy.

YAPANDAIN, a town of the empire of Birmah, on the Iravaddy; 40 miles W. of Ava.

YAPIZLAGA, or **LLANOS DE MANSO**, a province of South America, in the vice-royalty of Buenos Ayres, of great extent, situated to the south of the Vermejo river. This country was formerly called Llanos de Manfo, or the Plains of Manfo, from a captain of that name, who in 1556 undertook to build a town: but when he thought himself in perfect security, he, with all his attendants, was murdered by the Indians; of whom there are several nations. The country is but little known.

YAPOC, a river of Surinam, which runs into the Atlantic, near Cape Orange.

YAPON, in *Botany*, a species of *ilex*. See **HOLLY**.

YARACUI, in *Geography*, a river of Venezuela, which runs into the Spanish Maine, N. lat. 10° 28'. W. long. 68° 40'.

YARANSK, a town of Russia, in the government of Viatka; 72 miles S.W. of Viatka. N. lat. 55° 36'. E. long. 48° 34'.

YARAY, a town of Africa, in the kingdom of Kayor; 80 miles S.E. of Amboul.

YARBA, a town of Africa, and capital of a country, called Yarra; 430 miles S.W. of Tombuctoo.

YARD, *Virga*, a long measure, used in England and Spain; chiefly to measure cloth, stuffs, &c.

The English yard contains three feet. It was first settled by Henry I. from the length of his own arm. See **MEASURE**.

The English yard is just seven-ninths of the Paris ell; so that nine yards make seven ells. To reduce ells, therefore, into yards, say, If seven ells give nine yards, how many yards will the given number of ells give?

Yards are converted into ells Flemish, by adding a third part; into ells English, by subtracting a fifth part; or multiplying by 8, and casting off the right-hand figure. Ells English are converted into yards, by adding a fourth. To turn ells Flemish into yards, subtract one quarter.

The Spanish vara, or yard, chiefly used at Seville, is, in some places, called *barra*. It contains seven twenty-fourths of the Paris ell; so that seventeen ells make twenty-four Spanish yards.

YARD, in *Anatomy*, the penis, or virile member; serving for the evacuating of the urine and feed.

It is also the common name for the penis in most animals.

YARD of Land, *Virgata Terre*, or *Virga Terre*, is a certain quantity of land, but that various, according to the place. At Wimbledon, in Surrey, it is only 15 acres; but in most other counties it contains 20, in some 24, in some 30, and in others 40 or 45 acres.

“Virgata terre continet 24 acras; et 4 virgatae constituunt unam hidam, et quinque hidæ constituunt feodium militare.” MS. Abbat. Malmes. See **CARRUCATE**, **HIDE**, and **KNIGHT'S Fee**.

YARD, in *Agriculture*. See **FARM-YARD**.

YARD-Manure. See **FARM-YARD**, **COMPOST**, **DUNG**, **MANURE**, and **MANURING**.

In order to prevent the vegetation of weeds in this manure, the manure is turned up in the yard in rows when it is about two feet in depth, leaving proper room between each row to put the fresh dung from the stables, cow-houses, and hog-sties. After the manure thus thrown up has got a fair heat, it is again turned over, which mostly destroys or prevents the weeds from growing, when the manure is ready for being taken out upon the land.

The uses and powers of the long and short yard dung manure are very different in different states of it.

The opinions and practice of the farmers in the county of Norfolk, in regard to the use of long or short dung or yard manure, are much divided. Comparative trials are wanting to fully ascertain this important point.

It is, however, a prevailing idea in the above county, that long dung is best for strong land, and short for light soils; but that the general practice is that of spreading short in all cases.

In Essex, too, it is now the practice of many enlightened farmers to make use of long dung or yard manure with great advantage; though what may be said to be the general custom of the district is to clamp and employ that which is in the short state. Some farmers there, however, do not like to see their yard-manure too long in the heaps, as there is loss in turning it. In the practice of dunging for wheat, it was there observed, on long and extensive experience, that it should be *long fresh* dung, as the superiority of such dung to that which the farmers so generally prefer, such as has been moved and turned over until quite rotten, was, one load of it, worth six of that of a year old and rotten, as with such dung a crop of wheat is always certain.

In Oxfordshire, and many other counties, the same is the case with many farmers, though the common practice is to mine and turn yard-manure until it is reduced into the short state, and then to apply it to the land.

On this very interesting point of management, the writer of a late work on Agricultural Chemistry has suggested, that a slight incipient fermentation is undoubtedly of use in the heaps of this sort of manure, as by means of it a disposition is brought on in the woody fibre to decay and dissolve, when it is carried to the land, or ploughed into the soil; and that this sort of fibre is always in great excess in the refuse of the farm, especially that of the yards: but that too great a degree of fermentation is very prejudicial to such mixed yard-manure, when in the heaps; and that it is better that there should be no fermentation at all before the manure is used, than that it should be carried too far, the excess of fermentation tending to destroy and dissipate the most useful part of the manure.

During the violent fermentation which is necessary for reducing farm-yard manure to the state in which it is termed *short muck* or *dung*, not only a large quantity of fluid, but likewise of gaseous material is lost; inasmuch that the dung or manure is reduced one-half, two-thirds, or more of its weight; and that the principal elastic matter disengaged is carbonic acid with some ammonia; both of which, if retained by the moisture in the soil, would be capable of becoming an useful food or nourishment of plants.

Besides the dissipation of gaseous matter when fermentation is pushed to the extreme, as in the case of short dung, there is another disadvantage attending it in the loss of *beats*, which, if excited in the soil, is useful in promoting the germination of the seed, and in assisting the plant in the first stage of its growth, when it is most feeble and most liable to disease: and the fermentation of the manure in the

foil must be particularly favourable to the wheat-crop, in preserving a genial temperature beneath the surface late in the autumn and during winter. Moreover, it is a general principle in chemistry, that in all cases of decomposition, substances combine much more readily at the moment or time of their disengagement, than after they have been perfectly formed: and in fermentation beneath the foil the fluid matter produced is applied instantly, even while it is warm, to the organs of the plant, and consequently is more likely to be efficient, than in short dung or manure that has gone through the process; and of which all the principles have entered into new combinations.

The writings of scientific cultivators allege many arguments and facts which favour the application of yard-dung in a fresh or long state; and it is supposed, that perhaps there is no subject of investigation in which there is such an union of theoretical and practical evidence and proof.

The main objection against the use of slightly fermented or long yard-dung or manure is, that weeds rise more luxuriantly and in greater numbers where it is had recourse to: but though seeds thus carried out will certainly sprout, it is but seldom that this can be the case to any extent; and if the land be not clean of weeds, any kind of manure, long or short, fermented or unfermented, will cause their rapid growth.

The application of yard-dung, or manure in the long state, is highly advantageous with regard to the quantity or extent of the improvement which may be produced, as nearly four loads of it are mostly required to form one of the short kind.

There is another question connected with this subject, which is not of less interest or importance to the farmer to have decided, which is that of the superior advantage of consuming the straw of the farm by animals, or of having it littered and trodden into dung or manure in the yards. Many of the most enlightened farmers in the first of the above counties, the writer of the account of the agriculture of it says, are against the former of these practices, though a large part of them is in the custom of it: and they have frequently, too, recourse to the method of buying oil-cake, even often at a loss, in order that their straw may be trodden into dung or manure by fattening beasts, which is an excellent management of the yard kind.

YARD-Fallen, a term used among our farriers to express a malady to which horses are sometimes subject, which is the hanging down of the penis from its sheath between the legs, the creature not being able to draw it up again. This is caused by weakness of the peculiar muscles which should act in the drawing up; and proceeds sometimes from a violent slip or strain, sometimes from a blow on the back, and sometimes from extreme weariness in long journeys.

The method of curing this is, first to wash it with oil of roses, after this with warm white wine, and finally, to anoint it with a mixture of oil of roses and honey; it is then to be returned into its place, and kept from falling down again by a little canvas bolster. It is to be thus dressed once in twenty-four hours, till the cure is perfected.

There are some other distempers to which this part is subject in a horse, as the being foul at the end, so that the creature voids his urine in the sheath; in this case, the method of cure is to draw out the penis, and cleanse the end of it from any foulness that may be found there; then it is to be washed with butter and white wine vinegar melted together: sometimes there is a discharge of yellow stinking matter from the penis; this is peculiar to stone-horses, and

principally affects them after the time of their covering of mares.

This running is attended with a swelling of the penis, and with a pain in voiding the urine; the creature also finds a difficulty in drawing up the penis into the sheath.

The method of cure is, to dissolve in a pint of white wine an ounce of roach-alum by boiling; and four or five times a day this is to be used, injecting it up into the yard with a syringe, blood-warm. This will prove a certain cure.

YARD-Foul, the filthy, furred state of the yard and sheath in animals of the horse kind, which sometimes produces disease.

It is removed by well washing and cleaning the parts, by the free use of soft-soap and water.

YARD, Mattering of, a disease in the yards of horses, produced by different causes, in which matter is formed. It is removed by the use of cooling washes, and keeping the parts clean and perfectly free from dirt and nastiness.

YARD, Sheep. See *SHEEP-YARD* and *STANDING Fold*.

YARD, Stable. See *STABLE*.

YARD, Stack. See *FARM-YARD, STACK, and STACK-YARD*.

YARD, Straw. See *STRAW-YARD*.

YARDS, in a *Ship*, are long cylindrical pieces of fir-timber, suspended to the masts of ships, &c. to extend the sails to the wind.

All yards are either square or latteen; the former are suspended athwart the masts by the flings, at right angles, and the latter at one-third their length, obliquely.

The proportional lengths of yards are as follow, particularly in the royal navy:—Main-yard, eight-ninths the length of the main-mast; fore-yard, seven-eighths of the main-yard; mizen-yard, six-sevenths of the main-yard; main-top-fail-yard, five-sevenths of the main-yard; fore-top-fail-yard, seven-eighths of the main-top-fail-yard; mizen-top-fail-yard, two-thirds of the main-top-fail-yard; topgallant-yards to 74-gun ships, two-thirds all under three-fifths of their top-fail-yards; royal-yards, half of the top-fail-yards; cross-jack-yard and sprit-fail-yard, the same as the fore-top-fail-yard; sprit-fail-top-fail-yard and driver-yard, the same as the fore-topgallant-yard; and the fludding-fail-yards, four-sevenths of their booms.

Proportion of diameters of main and fore yards at the flings is one-quarter of an inch to every foot in their length; mizen-yard, two-thirds the diameter of the main-yard; top-fail-yards, five-eighths of an inch to every yard in the length; topgallant-yards, three-fifths of an inch to every yard in the length; royal-yards, half the diameter of the top-fail-yards; sprit-fail-yard and cross-jack-yard, the same diameter as the fore-top-fail-yard; sprit-fail-top-fail-yard and driver-yard, the same diameter as the fore-topgallant-yard; and the fludding-fail-yards, one inch diameter to every five feet in the length.

The square yards are of a cylindrical surface the greater part of their length. They taper from the middle, which are called the *flings*, towards the extremities, which are termed the *yard-arms*; and the distance between the flings and the yard-arms on each side is divided into quarters, which are distinguished into the first, second, and third quarters, and yard-arms, which are regularly tapered by the following proportions. The first quarter, or that next the flings or middle, thirty thirty-ones of the given diameter; the second quarter, seven-eighths; the third quarter, seven-tenths; and the arms or ends, three-sevenths. From a middle line struck on the tree or spar the yard is to be made from, half of the several dimensions above is to be

YARDS.

let off, and the yard then fawn to its siding; it is then canted, and a middle line struck on one of those sides, and the middle and the quarters squared up thereon from the middle line on the first side, and the same diameters set off as before, then lined and fawn square to the upper side; it is then fawn eight-square the whole length.

The main and fore yards (*fig. 17. Rigging, Plate II.*) are then trimmed sixteen-square, and rounded from one quarter on each side the slings to the outer ends, except on the aft-side, which must remain eight-square two-quarters on each side the middle. The whole is then planed fair and smooth.

In merchant ships they have a sheave-hole in their arms for the topfail-sheets, and are left square the length of the sheave-hole; but this method weakens the lower yards.

Topfail-yards (*fig. 18. Rigging, Plate II.*) being trimmed sixteen-square, are rounded and planed from the first quarter on each side the middle to their outer ends, and a sheave-hole cut from their upper side, its length within each outer end for the reef-tackles. In some merchant ships a hole is cut within the cleats for the top-gallant-sheets, but is better avoided, as it weakens the yard-arms.

Topgallant-yards (*fig. 19. Rigging, Plate II.*), royal-yards, cross-jack-yards, mizen-yards, sprit and sprit-topfail-yards, fludding-fail and driver yards, are trimmed eight-square, sixteen-square, and then rounded and planed fair and smooth from end to end throughout the length.

Battening of Yards.—Main and fore yards, main, fore, and mizen topfail-yards, have oak battens nailed on their squares nearly the same length and breadth, one inch to three-quarters of an inch thick; their ends rounded and snapped, and the edges chamfered. The fore-side has no battens.

Cleating of Yards.—The sling-cleats, *a*, (*fig. 17. Rigging, Plate II.*) nailed on the fore-side of the main and fore yards, are once and a quarter the given diameter of the yard in length, with a shoulder one-third its length; the breadth one-fourth the length; the thickness two-thirds the breadth, made of elm, and nailed once the given diameter on each side the slings.

Stop-cleats, *b*, (*fig. 17. Rigging, Plate II.*) are made of oak, and nailed within the arms, on the fore-side and aft-side of the lower yards, one inch and a half to every yard in their length. Their length half the given diameter of the yard; the breadth one-fourth its length; and its thickness two-thirds its breadth. Yards for merchant ships have their cleats sometimes raised from the solid.

Topfail-yards have stop-cleats, nailed on the fore-side of the yard, once the given diameter on each side of the slings. Those within the arms, on the fore and after sides of the main and fore topfail-yards, three inches to every yard in the length; and mizen topfail-yards, two inches and a quarter.

Topgallant-yards the same as topfail-yards.

Royal-yard-cleats are once the diameter on each side the middle afunder, and twice their length within at the arms.

Cross-jack-yards have stop-cleats, nailed on the fore-side of the yard, half the diameter on each side of the slings; those at the arms, one inch and a half within their outer ends to every yard in length, and nailed on the fore and after sides.

Mizen-yards have stop-cleats nailed once the diameter afunder on the starboard-side, and once and a half the given diameter below the middle of the yard: those at the peak or outer end, once the diameter within.

Sprit and sprit-topfail-yards have stop-cleats nailed on their under sides; the spritfail-yard once the diameter on

each side the slings; the sprit-topfail-yard half the diameter on each side: those at the arms one inch and a half within their outer ends to every yard in the length; and they nail on the fore and after sides contrary to those at the slings.

Studding-fail and driver yards have stop-cleats, nailed once the given diameter afunder, at one-third the length of the yard from the inner end; those at the arms twice their length within.

Boat-yard-cleats are once the given diameter afunder at the slings; some in the middle, others one-third from the end, such as lugs, latteen, and settees, and the length of the cleat within at the arms.

Yards are fitted at their outer ends for rigging out studding-fails. Main and fore yards have four boom-irons; one on each of their outer ends, *c*, (*fig. 17. Rigging, Plate II.*) the others at one-third the length of the boom within, *d*. The outer boom-iron is composed of a ring, a neck, and straps.

The ring, through which the boom slides, is of the same diameter in the clear as its topmast-studding-fail boom; breadth three-eighths the diameter, and from five-eighths to three-quarters of an inch thick. In one side a lignum vitæ roller is fitted, one-third in length the diameter of the boom-ring. The neck is square, and connects the ring to the straps; each neck one inch longer than the diameter of the ring, and one-fourth its length in size.

The straps are made one inch and a quarter in length to every three feet of the yard; their breadth once and a half the breadth of the ring; thickness at the inner part, three-eighths of an inch: they increase in substance towards the neck, and are made to the shape of and let in their thickness into the yard-arm. They are bolted, and have two hoops made to the size of the yard-arm, one close to the end, and the other near the neck.

Inner boom-irons are made after the same proportion as the outer ones, but differ in shape. The straps are made to compass the yard at one-third the length of the topmast-studding-fail boom within the end, and the ring is separated from the strap by a collar; the upper part of the ring opens with a hinge on one side, and the heel of the boom is clasped therein.

Boom-irons fix on the yards thus: the rings are parallel with the axis of the yard, in a straight direction, with a line struck upon the yard, in the middle of the square, between the upper and fore side.

Boom-irons, on the yard-arms of ships in the merchant service, differ much in shape. The ring the boom slides through is connected by a collar to a square hoop, that lets on and nails to the yard-arms, they being left square; and sometimes a round hoop to the size of the yard-arms. Others have a straight neck, projecting from straps, with a shoulder in the middle of the neck, and the part without left square. The boom-ring has a shank on the under part, with a mortise that fits the neck, and there fastened by a screw-nut, or a spring-forelock, that goes on the neck next the ring.

Topfail-yards, main and fore, commonly have boom-irons at their outer ends, like the lower yards in merchant ships. In the navy they are mostly fitted with a boom-ring, and a sprig-eye-bolt driven in the middle of their ends, parallel to its axis; and an iron hoop let in its thickness and breadth, and nailed, to prevent splitting the yard-arm. Yards that have no inner boom-irons have faddles for the heel of the boom.

Topgallant-yards, main and fore, mizen-yards, sprit and sprit-topfail-yards, have their arms fitted with a ferrule-hoop and sprig-eye-bolts, as the topfail-yards.

Mizen-topfall and topgallant yards have hoops like the former let on their outer ends, but no eye-bolts.

Driver-yards have a sheave-hole cut through their outer end, and a hoop and eye-bolt.

The main and fore yards of large ships are sometimes made of two trees; they have each tree lined, long enough to scarf four feet beyond the first quarter, next the middle, or slings, which is in all five-eighths the length of the yard, adding four feet. The scarfs line straight, from each quarter next the middle to one-fourth the substance at the quarter next the butt, and three-fourths at the quarter next the middle, and haunches to about three inches at the butt. Each tree is then fawn as before directed, and completed thus: the scarf and haunches are trimmed straight, and out of winding on the inside, and a line struck along the middle, and a chain-coak set off, each about two feet four inches long, and one-third the diameter broad; and the butts squared across and down the sides. The coaks are raised one inch and a quarter at the butt, and sunk to the same on the other side of the middle, towards the arm; the other half is then canted thereon, set straight and out of winding, and fayed as the *masts*, (which see, and the *Plate of Masts*;) and bolted together fore and aft through the middle, in the butt of every coak; the heads are to be driven from the thinnest part of the scarf, and clenched on a ring, and the haunches nailed.

The yard is then completed as before directed, and the scarfs caulked their length and hooped; one hoop over the butt of each scarf, one in the middle of each haunch, and one over every bolt: then a fish of fir, two inches thick, and the same length and breadth as the square on the aft-side, is fayed and nailed close over all the hoopes.

Another method of scarfing yards together made of two trees, which is the strongest, and takes less trees than the former, is by providing two trees that will hold the diameter beyond the fishes, and scarf together similar to the former. Then the deficiency of the diameter towards the middle is made good by long fishes of fir, from four to six inches thick, as the size of the yard may require, extending two feet in length at each end beyond the long square on the aft-side, and each of sufficient breadth to form the eight-square on the outside. The inner surfaces of the fishes are coaked and fayed close upon the yard, the coak extending near the whole length. The yard is then finished as before directed, and hooped and bolted, as in the *Plate of Mast-making*.

YARD-ARM is that half of the yard which is on either side the mast, when it lies athwart the ship. See the preceding article.

YARDS also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. See *Dock-Yards*.

YARDLEY, in *Geography*, a village of Worcestershire, which, according to the population return of the year 1811, contained 1918 inhabitants, including 121 families employed in manufactures, and 453 houses; 7 miles S.E. of Birmingham.

YARE, a river of England, in the county of Norfolk, which rises about five miles N. from New Buckenham, passes by the city of Norwich, and runs into the German ocean near Yarmouth.

YARE. See *SEGOVIA Nueva*.

YARE, among *Sailors*, implies as much as, nimble, ready, quick, expeditious. Hence, *to be yare at the helm*, as some say, signifies to set a fresh man at the helm.

YARECA, in *Geography*. See *JARECA*.

YAREE, a town of Burmah; 40 miles S.W. of Ava.

YARENSK, a town of Russia, in the province of

Uftiug, on the Vitchezda; 92 miles N.E. of Uftiug. N. lat. 62°. E. long. 47° 50'.

YARI, a town of Brasil, in the government of Para; 60 miles N.E. of Paru.

YARIN, a word used by some of the chemical writers to express the flos æris.

YARKAN, **YARKAND**, *Irken*, or *Yarkien*, in *Geography*, a town of Cashgar, or Little Bucharia, where the grand khan of the Eluth Tartars chiefly resides. The town is large, and well built of bricks dried in the sun. The environs are fertile, and the palace of the khan large, but not handsome. In 1400 this town was taken and plundered by Timur Bec; 90 miles S.E. of Cashgar. N. lat. 38° 13'. E. long. 78° 49'.

YARKAN, or *Yarkand*, suggested to be the Oerchades of Ptolemy, a river of Asia, which passes by the town of Yarkan, and after a considerable course runs into lake Lop; 100 miles S. of Tourfan.

YARM, or **YARUM**, a market-town in the W. division of the liberty of Langbaugh, in the North Riding of the county of York, England, is situated on the banks of the river Tees, 4 miles S. by W. from Stockton, 44 N.N.W. from York, and 237 in the same direction from London. In 1811 the houses in the town and parish were 361, and the inhabitants 1431. Here is a neat modern church. A market is held on Thursday, and fairs on Thursday before the 5th of April, Holy Thursday, 2d of August, and 20th of October. At Yarm was an hospital, founded before 1185; also a house of Black friars, founded about 1271, by the family of Brus or Bruce, both of which were suppressed by Henry VIII. Over the river Tees at this place is a handsome stone bridge, communicating with the county of Durham. The town, formerly more considerable than at present, still carries on a good trade by water, particularly in corn and lead for the London market. In 1761 the town suffered severely by an inundation of the river Tees.—*Beauties of England and Wales*, Yorkshire, by J. Bigland, 8vo. Lond. 1812.

YARMOUTH, GREAT, an important sea-port, borough, and market-town, in the hundred of East Flegg, and county of Norfolk, England, is situated on the E. coast of England, near the mouth of the river Yare, whence it has its name, 22 miles E. from Norwich, and 124 N.E. from London. The number of houses in the parish, according to the returns of 1811, was 3594, and the inhabitants were 17,977. A market is held here on Saturday, and a fair in Easter week. The town, which sends two members to parliament, was incorporated by James I. It is governed by a mayor, recorder, 7 aldermen, 36 common-council-men, a town-clerk, and other inferior officers. In former times, Yarmouth was a member of the Cinque Ports, and by ancient custom appointed bailiffs, who, in conjunction with the magistrates of the town, hold a court there during the herring-fair. The corporation possess also the privileges of courts of admiralty and of record. Yarmouth is singularly situated on a long, narrow, sandy peninsula, having on the E. the German ocean, and on the W. the river Yare, which, after pointing N.E. towards the sea, suddenly bends round to the S. parallel to the shore, and opens into the sea, two miles below the town. The coast near Yarmouth and southward to Lowestoft is the most easterly part of Great Britain, Yarmouth church lying in E. long. 1° 45' from Greenwich.

The first mention of this town is in Domesday-book, which renders it probable, that it had its beginning in the early part of the Anglo-Saxon dynasty. When the sand-bank, on which it stands, and which, thrown up by the sea,

impeded,

YARMOUTH.

impeded, or at least diverted, the course of the Yare, was sufficiently consolidated, habitations were formed on it by the fishermen who resorted to the coast. By the influx of foreigners for the purchase and sale of fish the town increased, so as to become the most considerable port on the east coast of England. To provide for its security, Henry III. granted to the inhabitants permission to inclose the town with a moat and walls; works which, however, do not appear to have been commenced until 1285, the thirteenth year of his successor, Edward I. But when war with France broke out in 1545, an additional rampart was thrown up towards the sea, and further extended in 1587. In the following year, to guard against the Spanish invasion, outworks were constructed, the south moat was raised and planted with cannon, and a boom was laid across the entrance of the harbour. Coeval with the first fortification of Yarmouth was probably the castle, in the centre of the town. It served for some years as a prison; but in 1621 the whole was demolished. In 1642 the inhabitants of Yarmouth declared for the parliament; but it was only after the independents had gained an ascendancy in the state that a garrison was admitted here. During the American war, forts and batteries were constructed, and barracks for a considerable body of troops were erected for the defence of the place. Indebted for its original existence, and subsequent increase to the fishery, Yarmouth very early possessed a very numerous shipping. In the summer of 1310, when Edward II. ordered the several ports of England to send ships to Dublin, to convey troops over to Scotland, Yarmouth furnished six, while even Bristol and Gloucester, although so conveniently situated for that object, furnished only two between them. To form a fleet to be employed in the siege of Calais, in 1346, under Edward III., Yarmouth sent out forty-three vessels, carrying 1095 mariners; a number of men far exceeding those furnished by any other port in the kingdom; for London itself was called on for only twenty-five vessels, containing 662 mariners.

In 1797, when men for the navy were required in proportion to the tonnage of each port, Yarmouth was the ninth in order; but according to the Custom-house books of 1800 it had advanced to be the eighth, the ships of the port being 375, the tonnage 32,957, navigated by 2442 men, while Bristol possessed 186 ships, carrying 26,193 tons and 1674 men. Yarmouth was early distinguished, and still remains unrivalled, for the herring-fishery. About 1220 the abbot of St. Alban's purchased a large house in Yarmouth, "in order to lay up fish, especially herrings, which were bought in by his agents at the proper season, for the use of his abbey." Prior to 1238, the people of the opposite coast of Europe were in the habit of resorting to Yarmouth for a supply of herrings. These and other recorded facts shew that the method of preserving that fish, probably by salt, must have been known in England more than 200 years before the pretended invention of Beukels in Flanders, from whom *pickling* is said to have had its name. (See *HERRING-FISHERY*.) The herrings usually appear on the east coast of England about September, when the grand fishing season commences. The boats fitted out for the fishery are decked, and average from forty to fifty tons burthen, with a crew of eleven or twelve men to each. The vessels, with some tons of salt on board, proceed from four to twelve leagues out to sea. Each boat is provided with eighty or a hundred nets, twenty-one yards in length, and eight and a half in depth; all of which, fastened to a long rope, are let down into the sea at dusk, and drawn up at day-light. When fished, the fish are hung up in lofty buildings, and exposed, with

small intermissions, for about a month, to the smoke of a wood fire, and thus become red-herrings. Two centuries ago the fishery was also carried on in summer; but in the present times no herrings are found on the coast in that season. In the interval of the fishery, the boats are employed in catching mackerel and cod. Yarmouth trades very largely in the export of corn and malt, and in the woollen stuffs of Norwich. Timber, iron, and hemp, are imported from the Baltic, and ship-building is carried on at this place to a considerable extent.

The formation and the maintenance of the harbour of Yarmouth have required great exertion, ingenuity, and expence; for the present is the seventh recorded to have been made, and its yearly charge amounts to about 200*l.*, which sum is defrayed by duties exacted from goods brought in. The new works were executed by Joas Johnson, a Dutchman, who had been invited from Holland for the purpose. The principal or north pier is in length 265 yards, and the south pier, which is better constructed, 340 yards: the extent of the harbour between these piers is 1111 yards; and the depth of water, in all states of the tide, being now about twenty-four feet, instead of three feet, as was the case before the erection of the piers, vessels can always lie afloat at their moorings. The well-known Yarmouth roads are formed by ranges of sand-banks, lying out parallel to and at no great distance from the shore. The channels between the banks, some of which are dry at low water, and between them and the shore, are in general narrow, but deep enough for ships of any size. The roads consequently afford most defensible shelter in stormy weather, on a tract of coast projecting a great way into the German ocean, and peculiarly destitute of accessible harbours. But the concourse of shipping in this station has, on various occasions, produced dreadful disasters, the vessels being frequently driven from their anchors, and wrecked on the banks or on the shore.

The town of Yarmouth is in form an oblong quadrangle, consisting of four principal streets, crossed at right angles by 156 lanes, called rows, so confined in breadth, that for the conveyance of goods through them, the inhabitants have adopted narrow carts, mounted upon low wheels, and drawn by one horse, the driver standing in the front of the cart. The town is inclosed by a wall on the north, east, and south sides, in length 2240 yards, which, with the west side along the river, 2030 yards, make the circuit two miles and 750 yards. Although so populous a town, Yarmouth forms but one parish, and, until a century ago, had but one church, that of St. Nicholas, which was erected by Herbert Loisinga, bishop of Norwich, in 1123; but it was greatly enlarged in 1250. It consists of a nave, two aisles, and a transept, and had lately a spire 136 feet high, a distinguished sea-mark in the middle of a long tract of low and dangerous coast; but in 1803 it was taken down. The other public buildings of Yarmouth are, the town-hall, a handsome building, with a Tuscan portico, situated near the centre of the quay; the council-room, which also serves for assemblies; the fisherman's hospital, a quadrangle, containing twenty rooms on a floor, each intended for an old fisherman and his wife; the hospital-school for maintaining and clothing thirty boys and twenty girls, at the expence of the corporation; and the charity-school for seventy boys and thirty girls, who are clothed and educated. The quay of Yarmouth is justly the boast of the town, and is one of the finest and the most extensive in Europe. Its length from the south gate to the bridge is 1014 yards, beyond which it reaches 1016 yards farther, making its whole extent a mile and 270 yards. In many places the breadth is 150 yards, and the southern part

is decorated with a range of handsome buildings. By means of a bridge across the Yare a communication is maintained with the county of Suffolk, which stretches up the west bank of the river. As a fashionable watering-place, Yarmouth is well provided with every accommodation, and consequently much frequented. On the beach a bathing-house was erected in 1759, commanding a fine view of the roads and shipping; and in 1778 a neat theatre was opened. Opposite to Yarmouth, and for about two miles north and south of the town, the coast is nearly a level common, elevated only from two to three yards above high-water mark. From the edge of the common down to the water is a gentle slope of fine sand, intermixed with loose pebbles called shingles; and as the tides rise but about six feet, the space brought under water is only a few yards. From high-water mark to the turf of the common the sands abound with marine plants, some of them rare and curious, of which an account is given by Mr. Dawson Turner in the Historical Guide to Great Yarmouth, 12mo. 1806.—Beauties of England and Wales, Norfolk, by J. Britton, F.S.A. 8vo. Lond. 1809.

YARMOUTH, *South*, a sea-port, borough, and market-town, in the S.W. half hundred of West Medina liberty, in the Isle of Wight, and county of Southampton, or Hampshire, England, is situated at the entrance of the little river Yare, on the N.W. coast of the island, 10 miles W. from Newport, and 97 S.W. from London. The town, which is governed by a mayor, twelve burgesses, a steward, a town-clerk, &c. was incorporated by James I., and sends two members to parliament. In 1811 the houses in the borough and parish were 88, and the inhabitants 427. A market is held here on Saturday, and two fairs annually. Yarmouth is built on a bank sloping to the sea, and seems to have been formerly much larger than it is at present. The church is situated in the middle of the town. The market-house has over it the town-hall. Here was a castle, built by Henry VIII. on the site of an ancient church, which had been destroyed by the French. This fortress is defended by some pieces of cannon, and a small garrison. Between Yarmouth and Lympington a packet sails daily.—Beauties of England and Wales, Hampshire, by J. Britton and E.W. Brayley, 8vo. Lond. 1808.

YARMOUTH, a sea-port town of Massachusetts, in Barnstable bay; 50 miles S.E. of Boston. N. lat. $41^{\circ} 42'$. W. long. $70^{\circ} 10'$.

YARMOUTH, a town on the west coast of Nova Scotia; 35 miles W. of Shelburn.

YARMOUTH, *North*, a town of America, in the district of Maine, and county of Cumberland, with 3295 inhabitants; 9 miles N.E. of Portland. N. lat. $43^{\circ} 45'$. W. long. $70^{\circ} 8'$.

YARMUC, or YARUN, a town of Palestine, in the district of Saphet, on a river of the same name, which runs into the lake of Tiberias, chiefly inhabited by Christians; 24 miles S.E. of Saphet.

YARMUC, a river of Syria, anciently called *Marjyas*, which runs into the Orontes, near Apamea. In 636 a battle was fought on the banks of the river, between the Christians and the Saracens, in which the former were defeated.

YARN, denotes spun wool. See WOOL, and WOOLLEN Manufacture.

YARN, *Marking*. See MARKING.

YARN, in *Rope-Making*, is spun from hemp, and is called twenty-five, twenty, and eighteen thread yarn, which differs only in the fineness; the twenty-five being finer than the twenty, &c. It is thus distinguished, because either

twenty-five, twenty, or eighteen threads a hook, make a rope of three inches in circumference, and so in proportion.

YARN, *Spun*, on board a Ship. See SPUN.

YARNALLS, in *Geography*, a town of Pennsylvania; 20 miles E. of Sunbury.

YAROVOL, a town of Russia, in the government of Tobolsk, on the Irtysh; 52 miles N. of Tobolsk.

YARRA. See JARRA.

YARRINGLES, or YARRINGLE-*Blades*, a kind of reel, or instrument, with which hanks of yarn are wound on to clues, or balls.

YARROW, in *Botany*. (See ACHILLEA.) Perhaps this old English name originated in the Spanish *Yerba*, or *Yerua*, an herb; our Common *Achillea Millefolium* having been formerly called, in that language, *Milhojas Yerua*, or Thousand-leaved Herb, a translation of its Latin appellation.

The leaves and flowers of the common yarrow, or *achillea millefolium* of Linnæus, which is in flower on our ditch-banks, and in dry pastures, the greatest part of the summer, are greatly recommended by some of the German physicians, as mild corroborants, vulneraries, and antispasmodics, in diarrhoeas, hemorrhages, hypochondriacal, and other disorders. They promise, says Dr. Lewis, by their sensible qualities, to be of no inconsiderable activity. They have an agreeable, though weak, aromatic smell, and a bitterish, roughish, somewhat pungent taste. The leaves, having the greatest bitterness and astringency, are chiefly directed for medicinal use; the flowers have the strongest and most subtle smell, are remarkably acrid, and promise to be of the greatest efficacy, if the plant has any such efficacy, as an anodyne or antispasmodic. The virtue of both leaves and flowers is extracted by watery and spirituous menstrua; the astringency most perfectly by the former; their aromatic warmth and pungency by the latter; and both of them equally by a mixture of the two. The flowers, distilled with water, yield a penetrating essential oil, possessing the flavour of the milfoil in perfection; in consistence somewhat thick and tenacious; in colour very variable, from a greenish-yellow to a deep green and blueish-green, and fine blue, which differences depend in a great measure on the soil in which the plant is produced; the flowers gathered from moist fresh grounds yielding generally a blue oil, and those collected from dry commons a green one, with a greater or less admixture of yellow. The extract obtained by inspissating the yellowish tincture made in rectified spirit, is more agreeable in smell than the flowers, of a moderately warm penetrating taste, somewhat like that of camphor, but much milder, accompanied with a slight bitterishness and subastringency. The *achillea ptarmica* of Linnæus, called *sneezerwort*, or *bestard pelitory*, is perennial, grows wild on heaths, and in moist shady grounds, and is found in flower from June to the end of summer. The roots of this plant have a hot biting taste, approaching to that of pelitory of Spain, with which they nearly agree in their pharmacæutic properties, and for which they have been sometimes substituted in the shops. They are by some recommended internally as a warm stimulant and attenuant; but their principal use is as a masticatory and sternutatory. Lewis.

YARROW, in *Agriculture*, a plant of the herbage kind, which is common but useful in the pasture-field in many cases. It has long ago been noticed, by the writer of the "Essays on Rural Affairs," as valuable for cultivation in grass-lands in different sorts of soil. It succeeds on moist loams, but is most proper for dry burning gravels, sands, and

and chalks. It is said to possess the singular quality or property of resisting drought on the most arid soils; so that if a green spot appears in a burnt-up clove-fed pasture ground, it may almost with certainty be concluded to be covered with this plant. In pastures there is not any sort of plant which is eaten down more closely than this, by every kind of browsing domestic animal. It has been remarked with surprise, that spots of rich dry land, which were almost wholly filled with these plants, were eaten down barer than even white clover. It is a strong-rooted perennial plant, which has many fine leaves, of a highly aromatic smell, and which is considered as not only very acceptable, but uncommonly healthy, or even medicinal, both to sheep and black cattle.

It is found in the best bullock pastures and grounds, where it is said to be highly grateful to every sort of livestock of the cattle kind, and particularly so to sheep, which bite it as fast as it grows or rises: so that on tolerably well-stocked pastures or grounds it is rarely suffered to come into flower. The seeds of it are, therefore, to be obtained from some rich dry spot which is well stored with the plant; and if the soil be well supplied with good mouldy compost, it has been found that the yarrow may be made into a rough hay, from which it is easy to obtain feeds, which are of a peculiar winged form and appearance. It flowers late in the summer, and the seeds may be gathered about the month of October.

It is a plant that has not been observed in abundance in boggy or wet lands; but which, for dry rich soils, deserves the preference to most others for the purpose of being depastured. It is a plant that on the whole seems to merit the attention of the stock-farmer, at least in a much greater degree than he has yet bestowed upon it.

YARROW, Water. See **Water VIOLET.**

YARROW, in *Geography*, a river of Scotland, which rises in a mountain called *Yarrow Clough*, in the county of Selkirk, forms two lochs, St. Mary's and Lows, in its course, and runs into the Tweed, about two miles below Selkirk.

YARUM. See **YARM.**

YARUQUI, a plain twelve miles north-east from the city of Quito. This spot was pitched upon as the base of the whole operations for measuring the length of an arc of the meridian, by Ulloa, &c. Near it is a village of the same name.

YARWHELP, or **YARWIP,** an English name used in some places for the *agocephalus* of authors. See **GODWIT.**

YASASCHNA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Kitoi; 68 miles N.W. of Irkutsk.

YASASCHNAIA, a river of Russia, which runs into the Kolima, at Verchnei Kovimskoi.

YASCHAMBOU, a town of Persia, in the province of Adirbeitzan; 198 miles S.W. of Tauris.

YASSA, in *Modern History*, the name given among the Tartars to a body of laws, ascribed to the famous conqueror Gengis-Kan, which are still observed among the Tartars of Crimea, and other parts of Asia. M. de la Croix has given, in his life of Gengis-Kan, an extract of those laws, comprising twenty-one articles: the first of which inculcates the belief of one God, the Creator of heaven and earth, and to whom belong the absolute disposal and dominion of events.

YASUDA, in *Hindoo Mythology*, the name of the foster-mother of the Hindoo Krishna: it is said to mean the *giver of honour.*

YASUDERA, the name of the wife of Budlia, or

Boodh, or deity of the Hindoos, and of other people. See **BOODH.**

YATA, in *Geography*, a town on the south coast of the island of Catanduanes. N. lat. 13° 52'. E. long. 124° 29'.

YATCHEVERAM, a town of Hindoostan, in the Carnatic; 25 miles S.W. of Nellore.

YA-TCHI, a town of Corea; 25 miles S.W. of Outecheou.

YA-TCHING, a town of China, in Fo-kien; 15 miles N.E. of Fou-ning.

YATE'S RIVER, a river of Africa, which runs into the Atlantic, N. lat. 8° 8'. W. long. 12° 15'.

YATHKIED, a lake of North America. N. lat. 63° 10'. W. long. 98°.

YATI, the priesthood of the extensive sect of Jaina, in India. (See **JAINA.**) A yati is sometimes said to be more properly an ascetic, for it doth not appear that he performs any religious rite. It is his duty to read and expound to his disciples the scriptures of the Jaina system. See under **SECTS of Hindoos** for a general notice of the Jainas.

The yatis are devoted to religion from their infancy; for with the Jainas the priesthood is not hereditary, as with the orthodox Hindoos. A yati never marries, but sometimes purchases a child, adopts it, and instructs it in religious duties. Parents sometimes vow or promise their first-born to the deity, in the hope of obtaining the blessing of fecundity in their family. They serve their novice with their guru, or preceptor, and perform for him many domestic offices. After a proper period, when arrived at a sufficient age and progress in their studies, they are admitted as yatis. The ceremony on this occasion is simple. The novice is carried out of the town with music and rejoicing in procession, followed by a crowd of Sravakas, as the laity of the Jainas are called. (See **SRAVAKA.**) He is taken beneath a tree with milky juice. The pipala, or Indian fig, is usually preferred. A circle is formed on the ground, within which none but yatis are admitted. The hair, or lock, of the novice is pulled out by the root at five pulls; and camphor, musk, sandal, saffron, and fugar, are applied to the scalp: he is then stripped, and placed, with joined palms, the posture of respect and supplication, before his guru, who pronounces a mantra (see **MANTRA**) in his ear, and invests him with the dress of a yati, which consists of a cloth of three cubits for his loins, another of five cubits for his head, a coarse country blanket, called *kamly*, for his bed, a water-pot, a plate for his victuals, a cloth to tie them up in, a long stick to defend him, but not to injure others, and lastly, a broom of cotton-threads to sweep the ground where he sits or lies, to avert the destruction of any insect. The Jainas are the sect that fo especially avoid shedding blood or destroying life; a tenet that leads them to ridiculous excesses, as will be seen under our article **JAINA**, in which several particulars of the yati are also given.

YATREB, in *Geography*, the real name of Medina, in Arabia. It is called *Medina*, or the city, by way of eminence.

YATTENDON, a village of England, in the county of Berks. Here Alfred overthrew the Danes in 876; 4 miles S.E. of East Ilsey.

YATTONG, a town of Burmah; 15 miles W.N.W. of Ava.

YATTONUR, a town of the island of Ceylon; 10 miles S.W. of Candy.

YAUACA, a town of Peru, in the diocese of Lima, on the coast; 20 miles S.S.E. of Nasca. S. lat. 15°.

YAUGAR, a town of Burmah, on the right bank of the Irawaddy, opposite to Raynangong.

YAUGOS, a town of Peru, in the diocese of Lima; 80 miles S.E. of Lima. S. lat. 12° 40'. W. long. 75° 40'.

YAVI, a town of Peru, in the diocese of La Plata; 85 miles E.S.E. of Lipas.

YAW, in *Sea Language*, denotes the movement by which a ship deviates from the line of her course towards the right or left in steering. See *STEADY*.

YAWI, a small light ship's boat, rowed with four to six oars, used to convey the officers to and from the ship.

YAWNING, *OSCITATIO*, an involuntary opening of the mouth, generally indicating a troublesome weariness, or an inclination to sleep. See *LUNGS*.

YAWS, in *Medicine*, a severe cutaneous disease, which is indigenous in Africa, and has been thence conveyed to the West Indies and America; so called from the resemblance of its eruptions to a raspberry, the word *yaw* in some African dialect being the name of that fruit. Nofologists have denominated it *Frambæsia*, from the French *Framboise*, which has the same signification.

The nature of this disease has been imperfectly investigated by European practitioners; and as it is perhaps never seen in England, a brief account of it will be here sufficient.

It is not easy to discover the precise character of this eruption, from the varying language of authors. An anonymous writer, who gave the first explicit account of the disease, (see *Edinb. Med. Essays*, vol. v. part 2. art. 76.) says, they are at first "level or smooth with the skin," but soon "become protuberant like pimples." Dr. Hillary, who has copied much from this writer, describes them as "pimples," though smooth and level with the skin, but soon becoming "protuberant pustules." (On the Dis. of Barbadoes, p. 339.) And Dr. Winterbottom, who has given on the whole the most perspicuous description of the disease, calls them "*pustules*," from their first appearance. Again, as to the contents of these eruptions, the anonymous author and Dr. Hillary say, that *no pus* nor any quantity of ichor is found in them, but speak of a little *ichor* as drying upon the surface; while Dr. Winterbottom says, they are "filled with an opaque whitish fluid," and when they burst, "a thick viscid matter is discharged." There is also some difference of opinion among the writers on this disease respecting the precursory symptoms, the earlier authors asserting, that the general health is not impaired during the first stages; but others, especially Dr. Winterbottom and Dr. Daucer, affirm, that a *febricular* usually precedes it. On the whole, however, the following appears to be the most correct account of the malady, which is to be collected from the various descriptions which have been published.

The eruption of the yaws sometimes commences without any precursory symptoms of ill health; but it is generally preceded by a slight febrile state, with languor, debility, and pains of the joints, resembling those of rheumatism. After several days, minute protuberances appear on various parts of the skin, at first smaller than the head of a pin, but gradually enlarging, in some cases to the diameter of a sixpence, and in others even to a greater extent: they are most numerous, and of the largest size, in the face, groins, axilla, and about the anus and pudenda. But the crop is not completed at once; new eruptions appear in different places, while some of the earlier ones dry off. When the cuticle is broken, a foul crust is formed on the surface, from

under which, on the larger protuberances, red fungous excrescences often spring up, which attain different magnitudes, from that of a small raspberry to that of a large mulberry, which fruit they somewhat resemble from their granulated surfaces. When the eruption is most copious, these tubercles are of the smallest size; and when fewer, they are largest. Their duration and progress are various in different constitutions, and at different periods of life. Children suffer less severely than adults, and are more speedily freed from the disease. In them, according to Dr. Winterbottom, the duration of the yaws is from six to nine months; while in adults it is seldom cured in less than a year, and sometimes continues during two or three. The fungous tubercles attain their acme, according to the anonymous writer already quoted, more rapidly in the well-fed negroes than in those who are ill-fed and thin; and they likewise acquire a larger size in the former than in the latter. They are not possessed of much sensibility, and are not the seat of any pain, except when they appear upon the soles of the feet, where they are confined and compressed by the hard and thickened cuticle: in that situation they render the act of walking extremely painful, or altogether impracticable. They never suppurate kindly Dr. Winterbottom says, but gradually discharge a foetid glutinous fluid, which forms an ugly seat round the edges of the excrescence, and covers the upper part of it, when much elevated, with white sloughs. When they appear on any part of the body covered with hair, this gradually changes in its colour from black to white, independently of the white incrustation from the discharge. They leave no depression of the skin.

The period during which the eruption is in progress varies from a few weeks to several months. "When no more pustules are thrown out," Dr. Winterbottom observes, "and when those already upon the skin no longer increase in size, the disease is supposed to have reached its acme. About this time it happens, on some part of the body or other, that one of the pustules becomes much larger than the rest, equalling or surpassing the size of a half-crown piece: it assumes the appearance of an ulcer, and instead of being elevated above the skin like others, it is considerably depressed; the surface is foul and sloughy, and pours out an ill-conditioned ichor, which spreads very much, by corroding the surrounding sound skin: this is what is called the *mafter* or *mother yaw*." When arrived at its acme, however, the eruption continues a considerable time without undergoing much alteration, often without very materially injuring the functions, and it seldom proves dangerous, except from the mischievous interference of ill-directed art.

The yaws is propagated solely by the contagion of the matter discharged from the eruption, when it is applied to the wounded or broken skin of another person, who has not previously undergone the disease. For, like the febrile eruptions, the yaws affects the same person only once during life; but, unlike them, it is not propagated by effluvia. The complaint is sometimes inoculated by flies, in those hot countries, when the skin both of the diseased and the healthy remains uncovered. Hence, Dr. Bancroft says, "none ever receive it whose skins are whole; for which reason the whites are rarely infected; but the backs of the negroes being often raw by whipping, and suffered to remain naked, they scarce ever escape it." (*Nat. Hist. of Guiana*, p. 385. See also Winterbottom, p. 141—3.) In Africa it is usually undergone during childhood. The period which elapses between the reception of the contagion and the commencement of the disease is no where mentioned; but in the case of a Dane, whom Dr. Adams saw at Madeira, the patient had been absent ten months from

from the West Indies before he felt any indisposition. See Memoirs of the Med. Soc. of London.

With respect to the treatment of yaws, nothing very satisfactory is to be collected from the writings of the practitioners to whom we are indebted for the history of the disease. "The native Africans," according to Dr. Winterbottom, "never attempt to cure it until it has nearly reached its height, when the fungi have acquired their full size, and no more pustules appear." And the practitioners in the West Indies soon learned by experience, that active evacuations retard the natural progress of the disease; and that mercurials, although they suspended it, and cleared the skin of the eruption, yet left the patient still susceptible of, or rather still impregnated with, the virus, which speedily evinced its presence by a re-appearance of the symptoms more severe and tedious than before. In truth, the disease, it would seem, like the pustular and exanthematous fevers of our own climate, will only leave the constitution after it has completed the various stages of its course, and removed the susceptibility of the individual to future infection; and no medicine yet discovered has had any influence in suspending this action, or in accelerating its progress. Unless, therefore, any urgent symptoms should require alleviation, (which seldom, if ever, happens) it is advisable to dispense with the administration of medicine, and to be content with restricting the patient to a moderate and temperate regimen, during the first stage of the malady. When the eruptions begin to dry, or as soon as they cease to multiply and enlarge, the disease appears to require the same management as other slow and superficial ulcerations, accompanied with a cachectic state of the system; viz. a light but nutritious diet, a dry and wholesome air, warm clothing, moderate exercise, and a course of tonic medicine, especially of sarsaparilla, or cinchona, with the mineral acids, or with antimonials and small doses of mercury, according to the circumstances of the individual habit. The effects of mercury, however, exhibited so as to excite salivation, as the early practitioners recommend, seem to be of a very questionable nature, especially when it is unaccompanied by the vegetable decoctions; and it is certain that patients have, in some cases, soon recovered under the use of the latter, when the mercurials were omitted. The mercurial treatment, indeed, is often followed by a train of harassing symptoms, called by the negroes the *bone-ache*. "The unhappy sufferer is tormented with deep-seated pains in the bones, especially round the joints, which are occasionally aggravated to a violent degree: the periosteum becomes thickened, inflamed, and painful, and nodes are formed on the bones. When these symptoms have continued for some time, the bones are affected with caries, and even become soft and lose their form." The native Africans employ decoctions of the bark of two or three trees, which are generally purgative, as well as tonic, and likewise wash the sores with them, after carefully removing the crusts.

The *master-yaw* sometimes remains large and troublesome after the rest of the eruption has altogether disappeared. It requires to be treated with gentle escharotics, and soon assumes a healing appearance under these applications. Stronger caustics are requisite after the cure of the *crab-yaws*, or tedious excrescences, which occur on the soles of the feet.

We may add, that the anonymous writer in the Edinb. Med. Essays, and after him Dr. Hillary and others, have deemed the yaws to be the Hebrew leprosy, described by Moses. (Leviticus, chap. xiii.) In some respects, and especially in the appearance of what is called "raw flesh" in the leprosy spots, together with *whiteness of the hair*, the de-

scription of the leprosy of the Jews is applicable to the yaws. But the leprosy is described by the great legislator as beginning in several ways, or appearing under several varieties of form, in only one of which this rising of "raw flesh" is mentioned; and the two circumstances, which all these varieties exhibited in common, were a depression of the skin and whiteness of the hair. Now this change in the colour of the hair is common to the yaws and to the leuce; and it is conjoined in the latter with cutaneous depression. It seems pretty obvious indeed, that the term leprosy was used in the Scriptures to denote several diseases of the skin, against which the law of exclusion was enforced, and others to which it did not apply. An instance of the latter occurs in Gehazi, whom we find still in the employment of Elisha, and even conversing with the king, after the leprosy had been inflicted upon him, "and his seed for ever." (2 Kings, chap. v. vi. and viii. v. 4.) See Dr. Bateman's Practical Synopsis of Cutan. Diseases; and the Works above quoted.

YAXARTES, or YAKSARTES, the *Syr-Daria*, in Geography, a river of Russia, that falls into the Aral.

YAXLEY, a small market-town in the hundred of Norman-Crofts, and county of Huntingdon, England, is situated 2 miles N.E. from Stilton, and 73 miles N. by W. from London. It has of late increased in importance from its contiguity to the barracks at Norman-Crofts. The market was for a long time discontinued, but has been recently revived, and is now held on Tuesdays. It was originally granted to the abbots of Thorney, one of whom, named De Yalkeley, who died in 1294, was native of this town. Here is also an annual fair. The church is a handsome fabric, and particularly remarkable for its lofty and well-proportioned spire, which is seen at a considerable distance on all sides. The population of the parish, in the enumeration of the year 1811, was returned at 1391, occupying 171 houses.

YAYACATLAN, a town of Mexico, in the province of Tlaxcala; 10 miles E.S.E. of Puebla de los Angeles.

YAYAUHQUITOTTL, in Ornithology, the name of an Indian bird described by Nieremberg, remarkable for having two feathers of its tail much longer than the rest, and naked for a great way, but the end ornamented with black and blue hairs. The bird is of the size of the starling, and is beautifully variegated with green, blue, yellow, and grey.

Mr. Ray is of opinion, that this is the bird described by Marcgrave under the name *guaira-guainambi*.

YAYNANGHEOUM, or EARTH OIL CREEK, in Geography, a town of Burmah, on the Irawaddy, which receives its name from some wells of petroleum, in its neighbourhood. It is chiefly inhabited by potters; 15 miles S. of Pegonmew.

YAYYOS, or YANYOS, a town of Peru, and capital of a jurisdiction, in the archbishopric of Lima, which begins about 48 miles south-east from Lima, and extends about 75 miles in length along the Andes. It abounds in fruit, maize, wheat, barley, &c. and the pastures feed a great number of cattle for the markets of Lima; 80 miles S.S.E. of Lima.

YAZAMATES, a people who inhabited Kuban, after the Sarmates were for the most part given to Europe, five years before Alexander.

YAZOO, a river of the state of Georgia, which runs into the Mississippi, N. lat. 32° 38'. W. long. 91° 10'.

YAZOO, Little, a river of West Florida, which runs into the Mississippi, N. lat. 32° 13'. W. long. 91° 10'.

YAZVA,

YAZVA, a river of Ruffia, which runs into the Vifchera, 8 miles E. of Gerdin, in the government of Perm.

YBAGUE, a town of South America, in the kingdom of New Grenada.

YBAICABAL. See NERVIO.

YCA. See IGA.

YCAYALE. See UCAYALE.

YCHAN, a town of Corea; 13 miles S. of Hetfin.

Y-CHI, a town of China, of the third rank, in Chan-fi; 42 miles N.N.E. of Kiai.

YCONOMIUS. See OECONOMUS.

YDALA, in *Geography*, a town of Sweden, in Blekingen; 10 miles S.S.E. of Kongfback.

YDRIA. See HYDRIA.

YDRINUS, or HYDRINUS, a name given by some to the *opbitis*, or ferpent-ftone.

YDRUS, in *Ancient Geography*, a mountain of Hifpania. Jerome.

YE, or WYE, in *Geography*, a river of Holland, which paffes by Amfterdam, and runs into the Zuyder See, about 6 miles below.

YEA WATER, a river of Scotland, which runs into the Nith, 2 miles E. of Lochmaben.

YEADON, a township of Yorkfhire, in the Weft Riding, with 1695 inhabitants, including 476 employed in trade and manufactures; 3 miles S. of Otlely.

YEALME, a river of England, in the county of Devon, which runs into the Englifh Channel, 1 mile N.N.W. of Stoke Point.

YEANGLAW, a town of Birmah; 7 miles S. of Pegongmew.

YEANING, among *Sheep-Farmers*, a term ufed to fignify the act of bringing forth the young in animals of the fheep kind. It is faid that in the polled breeds of fheep the lambs are yeaned with the greateft eafe and facility, and in the large-horned breeds with the greateft difficulty and inconvenience. See SHEEP.

YEANING-Time, the feafon of yeaning in fheep, which is different in different breeds of them, but probably the moft early in the Dorfetfhire breed, as they may be managed fo as to lamb at a very early period. In general, however, the management is fuch, that the lambs are yeaned or brought forth from towards the latter end of February to the beginning of the following month, and later in fome cafes and fituations. When yeaned too early there is often great lofs, on account of the inclemency of the feafon, unlefs the ewes have been kept very well for fome time before it takes place. Confequently, in all fuch cafes, they fhould, for fome weeks at leaft before the yeaning time, be plentifully fupplied with proper food, fo that the health and ftrength of them and that of their young may be promoted and preferred againft this period. Proper fheltered fituations, yards, and fpofts of ground, fhould alfo be provided for this purpofe, by which the lives of numbers may be faved. See SHEEP.

In all bad cafes of yeaning, the ewes fhould be well fupplied by good oatmeal gruel and cordial drings.

YEANLING, a term applied to the young of the fheep kind when newly yeaned. See LAMB.

YEAR, ANNUS, in the full extent of the word, is a fystem or cycle of feveral months; ufually twelve.

Others define year, in the general, a period, or fpace of time, meafured by the revolution of fome celeftial body in its orbit.

Thus, the time in which the fixed ftars make a revolution is called the great year. And the times in which Jupiter, Saturn, the fun, moon, &c. finifh their revolutions, and VOL. XXXIX.

return to the fame point of the zodiac, are refpectively called the years of Jupiter and Saturn; and the folar and the lunar years.

As there is no luminary whole changes and revolutions are fo frequent and remarkable as thofe of the moon, fome have thought that all nations at firft meafured and divided time according to the various afpects of this planet. Accordingly the Egyptian year originally confifted of a fingle lunation; afterwards it included two or three months, and was defined by the ftated returns of the feafons. It has been alfo fuppofed, that feveral ages muft have elapfed before the idea of adjusting the length of the year to the courfe of the fun became general, though repeated obfervations were made on his motion in the ecliptic. The Indians, the Chaldaeans, and Egyptians, who in a very early period applied their attention to aftronomy, at length found, by comparing the motions of the fun and moon together, that one revolution of the former was equal to about 12 of the latter; and hence was formed a year of 12 lunations, in every one of which were reckoned 30 days: and hence alfo, it is faid, arofe the divifion of the ecliptic into 360 equal parts or degrees.

Year, properly, and by way of eminence fo called, is the folar year; or the fpace of time in which the fun moves through the twelve figns of the ecliptic.

This, by the obfervations of Caffini, Bianchini, and de la Hire, contains 365 days, 5 hours, and 49 minutes; which is the quantity of the year afumed by the authors of the Gregorian calendar.

But in the civil or popular account, this year only contains 365 days; except every fourth, which contains 366.

The viciffitude of feafons feem to have given occafion to the firft institution of the year. Man, naturally curious to know the caufe of that diverfity, foon found it was the proximity and diftance of the fun; and, upon this, gave the name year to the fpace of time in which that luminary, performing his whole courfe, returned to the fame point of his orbit.

And hence, as it was on account of the feafons, in a great meafure, that the year was instituted, their chief regard and attention were, that the fame parts of the year fhould always correpond to the fame feafons; i. e. that the beginning of the year fhould always be when the fun was in the fame point of his orbit; and that they fhould keep pace, come round, and end together.

This, different nations aimed to attain by different ways; making the year to commence from different points of the zodiac, and even making the time of his progrefs different. So that fome of their years were much more perfect than others, but none of them quite juft; i. e. none of them whole parts did not fhift, with regard to the parts of the fun's courfe.

We may naturally fuppofe that the commencement of the year would be determined by the date of fome confiderable event, fuch as the creation of the world, the univerfal deluge, a conjunction of planets, the incarnation of our Saviour, &c.; and of courfe it has been referred to different points in the ecliptic. The Chaldaeans and Egyptian years were dated from the autumnal equinox. The ecclefiaftical year of the Jews began in the fpring; but in civil affairs they retained the epoch of the Egyptian year. The ancient Chinefe reckoned from the new moon, neareft to the middle of Aquarius; but according to fome recent accounts, the beginning of their year was transferred (B. C. 1740) to the new moon neareft to the winter folftice. This likewife is the date of the Japanefe year. Diemfchid,

YEAR.

or Gemsciid, king of Persia, observed on the day of his public entry into Persepolis, that the sun entered into Aries; and in commemoration of this fortunate event and coincidence, he ordained the beginning of the year to be removed from the autumnal to the vernal equinox. This epoch was denominated *Neuruz*, viz. New-day, and is still celebrated with great pomp and festivity.

The ancient Swedish year commenced at the winter solstice, or rather at the time of the sun's appearance in the horizon, after an absence of about 40 days. The feast of this epoch was solemnized on the 20th day after the solstice. Some of the Grecian states computed from the vernal, some from the autumnal equinox, and others from the summer tropic. The year of Romulus commenced in March, and that of Numa in January. The Turks and Arabs date the year from the 16th of July; and the American Indians reckon from the first appearance of the new moon of the vernal equinox. The church of Rome has fixed new-year's day on the Sunday that corresponds with the full moon of the same season. The Venetians, Florentines, and Pisans in Italy, and the inhabitants of Treves in Germany, begin the year at the vernal equinox. The ancient clergy reckon from the 25th of March; and this method was observed in Britain until the introduction of the New Style, A.D. 1752, after which our year commenced on the first day of January. See *EPOCHA* and *CHRONOLOGY*.

They were the Egyptians, if we may credit Herodotus, that first formed the year, which was luni-solar, making it to contain 360 days, which they subdivided into 12 months. This year was corrected by the Thebans, who added to it five intercalary days. The Medes and Persians, who were anciently a part of the Assyrian empire, adopted the old Chaldean year of 360 days, which they afterwards reformed.

Some missionaries report, that the luni-solar year was corrected in China; that the year of the Indians contained 360 days, and was divided into 24 months. But besides this form of the year, the Indians used another, for astronomical purposes, consisting of 365 d. 15 h. 31' 15"; which Indian days and hours are equal to 365 d. 6 h. 12' 30", according to our mode of computation. Or, as this year is fideral, if you subtract 21' 35" on account of the motion of the stars in longitude, the Indian tropical year will be 365 d. 5 h. 50' 55". The Mexicans received the luni-solar year from the Indians or Chinese, and divided it into 18 months of 20 days; adding five days to the last month, and dating the year from March. That the ancient Grecian year was luni-solar, is evident from many testimonies of Hippocrates, Plato, and Pliny. The Latin year, before Numa's correction of it, consisted of 360 days, 304 of which were divided into 10 months; and to these were added two private months, not named in the calendar. Plut. in Vit. Numa. Serv. et Virgil Georg. l. i. v. 43.

It has been said that Mercurius Trismegistus added five days to the Egyptian year of 360 days. And, on this footing, Thales is said to have instituted the year among the Greeks; though that form of the year did not hold throughout all Greece. Add, that the Jewish, Syrian, Roman, Persian, Ethiopic, Arabic, &c. years are all different.

In effect, considering the imperfect state of astronomy in those ages, it is no wonder different people should disagree in the computation of the sun's course. We are even assured by Diod. Siculus (lib. i.), Plutarch in Numa, and Pliny (lib. vii. cap. 48.), that the Egyptian year itself was at first very different from that now represented.

The imperfection of the luni-solar year became more and more apparent as the arts and sciences improved; but

the necessary correction depended upon a competent knowledge of the solar year. Every nation, by degrees, invented or adopted the method of intercalating a few days at certain intervals. The author of the discovery is not certainly known: the Egyptians have claimed the merit of it; and the Theban priests have attributed it to Hermes or Thoth. It appears that they were acquainted with the year of 365 days in a very remote period. (Herodot. l. iv. c. 4. Strabo Geog. l. xvii. Syncell. Chron. p. 121.) The length of the solar year was represented in a golden circle fixed upon the tomb of Osymandes; and this circle was 365 cubits in circumference, having on each cubit a day of the year inscribed, together with the heliacal risings or settings of the stars. This Osymandes is said to have flourished either in the 13th or 11th century before the Christian era. For perpetuating the memory of this correction, though inaccurate, the first month of the year was distinguished by the title Thoth, or Sothis, which was the Egyptian appellation of the dog-star, the heliacal rising of which announced the inundation of the Nile. Hence, it is said, originated the fable, invented of the priests of Thebes, that Mercury, or Thoth, regulated the civil year by extending it, as we have already observed, to 365 days; and, in return, the first month was called by his name. See *Egyptian YEAR*, and *CANICULAR Year*.

The method of correcting the civil year, by the addition of five epagomenæ, was communicated by the Chaldeans and Egyptians to other nations; but it has not been ascertained at what epoch the solar year was observed to be almost 6 hours longer than the civil year of 365 days. The priests of Thebes claimed the merit of the discovery (Diod. Sicul. l. i. p. 59. Strabo Geog. l. xvii.); but Herodotus takes no notice of it; nor Thales, who, on his return from Egypt, taught the Greeks to form a solar year of 365 days without any intercalation. Plato and Eudexus are said to have obtained it, as a secret, from the Egyptians, about 80 years after Herodotus, and to have carried it into Greece; which shews that the knowledge of this form of the year was then recent, and confined to a few of the learned, while the old form was still retained, and the Egyptians used no intercalation until the corrected Julian year was received at Alexandria by the order of Augustus; and even at this time the Greeks and Romans, who resided in Egypt, alone obeyed the imperial mandate. The superstitious nations refused to admit any addition to a form of the year which had been so long established among them.

The reformed year of the Chinese consisted of 365 d. 5 h. 20', which were divided into 24 months, each of these equal parts including 15 d. 5 h. 14' 3". (Du Halde. Hyde. Relig. Vet. Perf.) The quantity of the Indian year was somewhat different from that of the Chinese: the lunar year contained 364 d. 22 gurris, 1 pull; and the solar year 365 d. 15 gurris, 30 pulls, 22½ puts; 60 puts = 1 pull, 60 pulls = 1 gurri, and 60 gurris = 1 day: so that their solar or rather fideral year consisted of 365 d. 6 h. 12' 7". This mode of computation is used by the Bramins, by the Moguls, and by other Mahometans in India.

YEAR, Solar, is the interval of time in which the sun finishes his course through the zodiac; or in which he returns to the same point of it from whence he had departed.

This, according to our account, is 365 days, 5 hours, 49 minutes; though some astronomers make it a few seconds, and some a whole minute less; as Kepler, for instance, who makes it 365 days, 5 hours, 48 minutes, 57 seconds, 39 thirds. Ricciolus, and Tycho Brahe, 365 days, 5 hours, 48 minutes.

YEAR.

The solar year is either *astronomical* or *civil*.

YEAR, *Solar Astronomical*, is that determined precisely by the observations of astronomy; and is of two kinds, *tropical* and *fidereal* or *astral*.

YEAR, *Tropical* or *Natural*, is the time which the sun employs in passing through the zodiac, or from one equinox, or one tropic, to the same again; which, as before observed, is 365 days, 5 hours, 49 minutes; or, more accurately, 365 d. 5 h. 48' 48". This is the only proper or natural year, because it always keeps the same seasons to the same months.

In order to find the tropical year, observe the meridian altitude, a , of the sun on the day nearest to the equinox; then the next year take its meridian altitude on two following days, one when its altitude, m , is less than a , and the next when its altitude, n , is greater than a , then $n - m$ is the increase of the sun's declination in 24 hours; also, when the declination has increased by the quantity $a - m$ from the time when the meridian altitude, m , was observed, the declination will then become a ; and as we may consider the increase of declination to be uniform for a day, we have $n - m : a - m :: 24$ hours, the interval from the time when the sun was on the meridian on the first of the two days, till the sun has the same declination a , as at the observation the year before; and this time, added to the time when the sun's altitude m was observed, gives the time when the sun's place in the ecliptic had the same situation in respect to the equinoctial points, which it had at the time of the observation the preceding year; and the interval of these times is the length of a tropical year.

If, instead of repeating the second observation the next year, there be an interval of several years, and you divide the interval between the times when the declination was found to be the same, by the number of years, you will get the tropical year more exactly.

YEAR, *Sidereal* or *Astral*, is the space of time in which the sun, going from any fixed star, returns to the same. This consists of 365 days, 6 hours, 6 minutes, 11,5 seconds.

To find the length of a sidereal year. On any day when the sun is at Z on the meridian (*Plate XXI. fig. 12.*), take the difference, Zm , between the sun's right ascension when it passes the meridian, and that of a fixed star, S ; and when the sun returns to the same part of the heavens the next year, compare its right ascension with that of the same star for two days, one when their difference, bm , of right ascensions is less, and the other when the difference, fm , is greater than the difference, Zm , before observed; then bf is the increase of the sun's right ascension in the time, t ; and as the increase of right ascension may be considered as uniform for a small time, we have $bf : bZ :: t : \text{the time, } T$, in which the right ascension is increased from b to Z ; this time, T , therefore, added to the time of the observed right ascension at b , gives the time when the sun is at the same distance, Zm , in right ascension from the star, which it was when observed at Z the year before; the interval of these times is therefore the length of the sidereal year. The best time for these observations is about March 25, June 20, September 17, December 20, the sun's motion in right ascension being then uniform. Instead of observing the difference of the right ascensions, you may observe that of their longitudes.

If, instead of repeating the second observations the year after, there be an interval of several years, and you divide the observed interval of time when the difference of their right ascensions was found to be equal, by the number of

years, you will have the length of a sidereal year more exactly.

The precession being given (see PRECESSION), and also the length of a tropical year, the length of a sidereal year may be found by this proportion; $360^\circ - 50''_{25} : 360^\circ :: 365 \text{ d. } 5 \text{ h. } 48' 48'' : 365 \text{ d. } 6 \text{ h. } 9' 11\frac{1}{2}''$ the length of the sidereal year.

YEAR, *Anomalistical*, is the time that elapses from the sun's leaving its apogee till it returns to it: and as the progressive motion of the apogee in a sidereal year, by the time which the sun takes in moving over $11''_{75}$ of longitude at its apogee; but when the sun is in its apogee, its motion in longitude is $58' 13''$ in 24 hours: hence $58' 13'' : 11''_{75} :: 24 \text{ hours} : 4' 50\frac{2}{3}''$, which added to 365 d. 6 h. $9' 11\frac{1}{2}''$, gives 365 d. 6 h. $14' 2\frac{2}{3}''$, the length of the anomalistical year. M. de la Lande determined this motion of the apogee from the observations of M. de la Hire, and those of Dr. Maskelyne. Cassini made it the same. This year is sometimes used by astronomers. See ANOMALISTICAL Year.

YEAR, *Civil*, is that form of year which each nation has contrived for the computation of time: or the *civil* is the tropical year, considered as only consisting of a certain number of whole days; the odd hours and minutes being set aside, to render the computation of time in the common occasions of life more easy.

Hence, as the tropical year is 365 days, 5 hours, 48 minutes, 48 seconds, the civil year is 365 days. And hence, also, as it is necessary to keep pace with the heavens, it is required that every fourth year should consist of 366 days.

Hence, lastly, the civil year is either *common* or *bissextile*.

YEAR, the *Common Civil*, is that consisting of 365 days. This, therefore, has seven months of 31 days each, four of 30 days, and one of 28 days; according to the well-known canon:

Thirty days hath September,
April, June, and November.

February twenty-eight alone,
And all the rest have thirty-one.

YEAR, *Bissextile*, or *Leap*, is that consisting of 366 days; or it has one day extraordinary; which day is called the *intercalary*, or *bissextile* day.

This intercalary, or additional day to every fourth year, was first appointed by Julius Cæsar; who, to make the civil year keep pace with the tropical ones, contrived that the six hours which the former wanted of being equal to the latter, should, in four years, make a whole day, and be added before the twenty-fourth, or to the twenty-third of February, which was their sixth of the calends of March. Hence, as in that year, they reckon this day twice over, or add *bis sexto calendas*, the year itself came to be called *bis sextus*, and *Bissextile*; which see.

The intercalary day, however, among us, is not introduced by telling the twenty-third of February twice over, but by adding a day after the twenty-eighth of February; which month, in that year, contains twenty-nine days. See LEAP-Year.

A farther reformation in this year was made by pope Gregory. See Gregorian YEAR, and CALENDAR.

YEAR, *Lunar*, is a system of twelve lunar months. See LUNAR.

Hence, from the two kinds of synodical lunar months, there arise two kinds of lunar years; the one *astronomical*, the other *civil*.

YEAR.

YEAR, *Lunar Astronomical*, consists of twelve lunar synodical months; and therefore contains 354 days, 8 hours, 48 minutes, 36 seconds; and is, therefore, 10 days, 21 hours, 0 minute, 12 seconds, shorter than the solar year. This is the foundation of the *Epact*; which see.

YEAR, *Lunar Civil*, is either *common* or *embolismic*.

YEAR, the *Common Lunar*, consists of twelve lunar civil months; and therefore contains 354 days.

YEAR, the *Embolismic* or *Intercalary*, consists of thirteen lunar civil months; and therefore contains 384 days. See **EMBOLISMIC**.

Thus far we have considered years and months, with a view to the principles of astronomy, on which the division is founded. By this, the various forms of civil years that have anciently obtained, or still do obtain in divers nations, are to be examined.

YEAR, *Ancient Roman*, or *Latin*, was the lunar year, which, as first settled by Romulus, only consisted of ten months; viz. 1. March, containing 31 days. 2. April, 30. 3. May, 31. 4. June, 30. 5. Quintilis, 31. 6. Sextilis, 30. 7. September, 30. 8. October, 31. 9. November, 30. 10. December, 30. In all 304 days, which came short of the true lunar year by 50 days; and of the solar, by 61 days. Hence, the beginning of Romulus's year was vague, and unfixed to any precise season; to remove which inconvenience, that prince ordered for many days to be added yearly as would make the state of the heavens correspond to the first month, without incorporating these additional days, or calling them by the name of any month. Censorinus, Varro, and other Roman authors, agree, that the ancient Latin year was divided into 10 months, which appears from a passage in Plutarch, that two intercalary months were added to every year; which two months were not inserted in the calendar. Romulus retained the former names and number of the months; but adapted their quantity nearly to the course of the sun, assigning, as we have stated, fix of them 30 days, and to the remaining four 31 days each, and he transferred the beginning of the year from April to March: December was the 10th month, as its name implies; after which the two intercalary months were inserted, but no names were affixed to them till the succeeding reign.

Numa Pompilius corrected the irregular constitution of Romulus's year, and composed two new months, January and February, of the days that were used to be added to the former year. Thus, Numa's year consisted of twelve months; viz. 1. January, containing 29 days. 2. February, 28. 3. March, 31. 4. April, 29. 5. May, 31. 6. June, 29. 7. Quintilis, 31. 8. Sextilis, 29. 9. September, 29. 10. October, 31. 11. November, 29. 12. December, 29. In all 355 days, which exceeds the quantity of a lunar civil year by one day; and that of a lunar astronomical year by 15 hours, 11 minutes, 24 seconds, but comes short of the common solar year by ten days; so that its beginning also was vague and unfixed.

Numa, however, desiring to have it fixed to the winter solstice, ordered 22 days to be intercalated in February every second year, 23 every fourth, 22 every sixth, and 23 every eighth year, making in all 90 days.

But this rule failing to keep matters even, recourse was had to a new way of intercalating; and, instead of twenty-three days every eighth year, only fifteen were added; and the care of the whole was committed to the pontifex maximus, who neglecting the trust, let things run to the utmost confusion. And thus the Roman year stood till Julius Cæsar made a reformation. See **CALENDAR**.

For the manner of reckoning the days of the Roman months, see **CALENS**, **NONES**, and **IDES**.

YEAR, *Julian*, is a solar year, containing, commonly, 365 days; though every fourth year, called *bissextile*, it contains 366.

The months, &c. of the Julian year stand thus: 1. January, 31 days. 2. February, 28. 3. March, 31. 4. April, 30. 5. May, 31. 6. June, 30. 7. July, 31. 8. August, 31. 9. September, 30. 10. October, 31. 11. November, 30. 12. December, 31. But every *bissextile* year, a day is added after the 28th of February; which month then contains 29 days.

The astronomical quantity, therefore, of the Julian year is 365 days, 6 hours; which exceeds the true solar year by somewhat more than eleven minutes; which excess, in 131 years, amounts to a whole day. So that the times of the equinoxes go backward, and fall earlier by one day in about 131 or 130 years. And thus the Roman year stood, till the reformation made in it by pope Gregory.

For this form of the year, we are indebted to Julius Cæsar; who, in the contrivance of it, was assisted by Sofigenes, a famous mathematician, called over from Egypt for this very purpose; who, to supply the defect of sixty-seven days, which had been lost through the fault of the pontiffes, and to fix the beginning of the year to the winter solstice, made that year to consist of 15 months, or 445 days; which, for that reason, is used to be called *annus confusiois*, the year of confusion. See **JULIAN CALENDAR**.

YEAR, *Gregorian*, is the Julian year corrected by this rule; that whereas, on the common footing, every secular or hundredth year is *bissextile*; on the new footing, three of them are common years, and only the fourth is *bissextile*.

The error of eleven minutes in the Julian year, little as it was, yet, by being repeated over and over, at length became considerable; and from the time when Cæsar made his correction, was grown into thirteen days, by which means the equinoxes were greatly disturbed. In the year 1582, the equinoxes were fallen ten days, and the full moons four days, more backwards than they were in the time of the Nicene council; i. e. the equinox, which in the year 325, when that council was held, fell on the twenty-first of March, was in 1582 thrown back to the tenth, and the full moon was removed from the fifth to the first of April. To remedy this irregularity, which was still increasing, pope Gregory XIII., in the year just mentioned, called together the chief astronomers of his time, and concerted this correction; and, to restore the equinoxes to their place, threw out the ten days that had been got from the time of the council of Nice, and which had shifted the fifth of October to the fifteenth. He exchanged the lunar cycle for that of the epacts; and in order to restore the spring equinox to the Nicene standard, subtracted ten days out of the month of October, in that year (1582), making the fourth to be the fifteenth; and by this means, the vernal equinox has been restored to the twenty-first of March. Moreover, it was endeavoured, by the omission of three intercalary days in four hundred years, to make the civil year keep pace with the solar for time to come. See **CALENDAR**.

In the year 1700, the error of ten days was grown to eleven; upon which the Protestant states of Germany, to prevent farther confusion, accepted the Gregorian correction. See **REFORMED CALENDAR**, and **STYLE**.

Yet is even the Gregorian year far from being perfect; for we have shewn, that in four centuries the Julian year gains three days, one hour, twenty minutes; but it is only the three days that are kept out in the Gregorian year; so

that

that there is still an excess of one hour, twenty minutes, in four centuries, which, in seventy-two centuries, amount to a whole day.

The Gregorian year is now used in most countries in Europe. From the difference between this and the Julian year arises the distinction of the old or Julian, and new or *Gregorian Style*; which see.

YEAR, *Egyptian*, called also the *year of Nabonassar*, on account of the *epocha of Nabonassar*, is the solar year of 365 days, divided into twelve months, of thirty days each, besides five intercalary days, added at the end.

The names, &c. of the months are as follow: 1. Theoth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phamenoth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epiphi. 12. Mefori; beside the *ἡμέραι επαγομένηαι*.

Hence, as the Egyptian year in every four years loses a whole day of the Julian year, because it neglects the six hours, which make a leap-day once in four years, its beginning, in the space of 1460 years, runs through every part of the Julian year; which space elapsed, they meet again; and, therefore, it is justly called the *erratic year*. And because it returns to the same day of the Julian year after 1460 Julian years, this circle is called the *Sothic period*. See *CANICULAR Year*.

This year is used by Ptolemy, in his *Almagest*; so that the knowledge of it is of great use in astronomy, for comparing the ancient observations with the modern.

This defultory form was applied by the Egyptians to civil uses, till Antony and Cleopatra were defeated; and the mathematicians and astronomers used it till the time of Ptolemy.

The ancient Egyptians, we are told by Diodorus Siculus (lib. i.), Plutarch (in the *Life of Numa*), and Pliny (lib. vii. c. 48.), measured their years by the course of the moon. At first, they were only one month, then three, then four, like that of the Arcadians; and then six, like that of the people of Acarnania. Those authors add, that it is on this account they reckon such a vast number of years from the beginning of the world; and that, in the history of their kings, we meet with some who lived 1000 or 1200 years.

But Herodotus is silent on this point: he only says, that the Egyptian year consisted of twelve months, as we have above represented it. Besides, we learn from Scripture, that from the times of the flood, the year was composed of twelve months; Cham, consequently, and his son Mirraim, the founder of the Egyptian monarchy, must have had that custom; and it is no way probable his descendants should alter it. Add, that Plutarch speaks of it with great uncertainty, and as no more than a report; and Diod. Siculus, as only a conjecture of authors whom he does not name; and who, in all probability, might have framed this hypothesis to reconcile the Egyptian chronology to that of some other nations.

F. Kircher, however, maintains, that besides the solar year, there were some of the nomes or cantons of Egypt which used a lunar one; and that in the remotest ages there were some who took a revolution of the moon, that is, a month for a year; and others, who finding the year too short, made it two months, others three, and others four, &c. (*Oedip. Egypt. tom. ii. p. 252.*) A late author observes, that Varro has affirmed of all nations, what we have here quoted of the Egyptians; and adds, that Lactantius takes him to talk on that subject. We do not know in what places of Varro, or Lactantius, he has seen this: all we can say is, that Lactantius (*Divin. Infl. lib. iii. c. 13.*), where he gives Varro's opinion, only represents him as speaking of the Egyptians. However, St. Augustine

(*De Civit. Dei, lib. xv. c. 14.*) shews, that the years of the patriarchs mentioned in Scripture are like ours, and not one of ours equal to ten of theirs, as, it appears, had been the opinion of some people.

Upon the Egyptians being subdued by the Romans, they received the Julian year, though with some alteration; for they still retained their ancient months, with the five *ἡμέραι επαγομένηαι*, and, every fourth year, intercalated another day between the 28th and 29th of August. Add, that the beginning of their year, or the first day of the month Thoth, answered to the 29th of August of the Julian year, or to the 30th if it happened to be leap-year.

This year, thus reformed, and called the fixed Egyptian year, was called the *annus Ailiacus*, as being instituted soon after the battle of Actium.

YEAR, *Ancient Greek*, was lunar, consisting of 12 months, which, at first, had 30 days a-piece, then alternately 30 and 29 days, computed from the first appearance of the new moon; with the addition of an embolismic month of 30 days, every 3d, 5th, 8th, 11th, 14th, 16th, and 19th years of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year. With this correction, though erroneous, it subsisted until the time of Herodotus and Hippocrates. Solon attempted the reformation of the calendar by the introduction of the complete and defective months; *i. e.* months of 30 and of 29 days; for two lunations made 59 days, nearly. Thus amended the year became lunar, and was adopted at Athens; but in other states of Greece the ancient form was retained.

Their year commenced with the new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus: 1. Ἑκταμηνιαίος, containing 29 days. 2. Μηνιαίος, 30. 3. Βοηδρομιαιος, 29. 4. Μουακτηριος, 30. 5. Πυθαγορειος, 29. 6. Ποσειδωνιος, 30. 7. Γαμηλιος, 29. 8. Αβδηρηνιος, 30. 9. Ελαφβολιδιος, 30. 10. Μενελαιος, 30. 11. Φαργηλιος, 29. 12. Σκιροφοριος, 30.

The Macedonians had other names for their months; so had the Syro-Macedonians, Smyrnaeans, Tyrians; so also the Cyprians, Paphians; and so the Bithynians, &c.

YEAR, *Ancient Macedonian*, is a lunar year, only differing from the Attic, in the names and order of the months; the first Macedonian month agreeing with the Attic *Μεμακτηριον*: as the Macedonian year commenced not at the summer solstice, but at the autumnal equinox. The months stand thus: 1. Διος, 30 days. 2. Απειλωνιος, 29. 3. Αουβανιος, 30. 4. Πιεργιος, 29. 5. Διτρος, 30. 6. Ξανθιος, 29. 7. Αρτεμισιος, 30. 8. Δασιος, 29. 9. Πανμος, 30. 10. Λαοιος. 11. Κορηνιος, 30. 12. Ἰππικριτιος.

YEAR, *Modern Macedonian*, is a solar year, whose beginning is fixed for the first of January of the Julian year, with which it perfectly agrees.

This year was particularly called the *Attic year*; and the intercalary month, after Posidon, was called *Ποσιδωνιος β*, or *latter Posidon*.

YEAR, *Ancient Jewish*, is a lunar year, consisting, commonly, of eleven months, which alternately contain 30 and 29 days.

It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolismic month.

Tradition reports, that Abraham preserved in his family, and transmitted to posterity, the Chaldaean form of the year, which originally consisted of 360 days (compare *Dan. vii. 25. xii. 7.* with *Rev. xii. to xiv. xi. 2, 3.*), and remained without any correction until the date of the Nabonassarean era. If any intercalation was used by the Jews, Moses

YEAR.

Moses appears to have been unacquainted with it. After the Babylonish captivity, they adopted the solar year. When they were subjected to the Syro-Macedonian yoke (B.C. 312), they were compelled to admit the lunar year into their calendar. To adjust this year to the course of the sun, they added, at certain periods, a month to Adar, and called it Ve-Adar. They composed also a cycle of 19 years; in seven of which they inserted the intercalary month, *viz.* in the 3d, 6th, 8th, 11th, 14th, 17th, and 19th. The design of this correction was, to bring the 15th day of Nisan to the equinoctial point, and to regulate the courses of the seasons, and of the feasts, in such a manner, as that the corn might be ripe at the passover, as the law required.

The names and quantities of the months stand thus: 1. Nisan, or Abib, containing 30 days. 2. Ijar, or Zius, 29. 3. Siban, or Siwan, 30. 4. Thamuz, or Tamuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tifri, or Ethanim, 30. 8. Marchefvan, or Bul, 29. 9. Cisleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolismic year, 30. Adar, in the common year, was but 29.

Note.—In the defective year, Cisleu was only 29 days; and in the redundant year, Marchefvan was 30.

YEAR, *Modern Jewish*, is likewise lunar, consisting, in common years, of 12 months, but of 13 in embolismic years; which in a cycle of 19 years are, the 3d, 6th, 8th, 11th, 14th, 17th, and 19th. Its beginning is fixed to the new moon next after the autumnal equinox.

The names, &c. of the months are, 1. Tifri, containing 30 days. 2. Marchefvan, 29. 3. Cisleu, 30. 4. Tebeth, 29. 5. Schebeth, 30. 6. Adar, 29. 7. Veadar, in the embolismic year, 30. 8. Nisan, 30. 9. Ijar, 29. 10. Sivan, 30. 11. Thamuz, 29. 12. Ab, 30. 13. Elul, 29.

YEAR, *Syrian*, is a solar year, having its beginning fixed to the beginning of October, in the Julian year; from which it only differs in the names of the months, the quantities being the same, as follows:

1. Tifirin, answering to our October, and containing 31 days. 2. Latter Tifirin, containing, like our November, 30. 3. Canun, 31. 4. Latter Canun, 31. 5. Shabat, 28, or 29 in a leap-year. 6. Adar, 31. 7. Nisan, 30. 8. Aiyar, 31. 9. Haziram, 30. 10. Tamuz, 31. 11. Ab, 31. 12. Elul, 30.

YEAR, *Olympic*, was of a singular form, the first month commenced at the new moon, that the full moon might fall on the 15th day. Four years of 360 days contain 1440 days; 48 lunations are equal to 1417 days, 11 hours, 14 minutes; a 49th lunation added to the 4th year makes 1447 days, nearly. By this adjustment, the new moon would have happened on the 8th instead of the 1st of the month. To correct this error, two days were added to the last month of every year, the 4th excepted, when one day was added. By these means, the olympic year, which consisted of 362 or 361 days, must have varied 14 days from the course of the sun in the space of an olympiad; and, at the end of 50 years, the games would have been transferred to the winter solstice; but for preventing this deviation, a month was intercalated at certain intervals. Notwithstanding this, a considerable error still remained. The olympic games were regulated by the CYCLE of *Clostratus*; which see. See also OLYMPIAD and EPOCHA.

YEAR, *Perfian*, is a solar year, of 365 days, consisting of 12 months of 30 days each, with five intercalary days added at the end.

The months are as follow: 1. Afrudia meh. 2. Ardihafest meh. 3. Cardj meh. 4. Thir meh. 5. Merded meh. 6. Schabarir meh. 7. Mehar meh. 8. Aben meh.

9. Adar meh. 10. Di meh. 11. Behen meh. 12. Affirer meh.

This year is called the *yezdegerdic* year, to distinguish it from the fixed solar year, called the *galelean* year, which the Perfians began to use in the year 1079, and which was formed by an intercalation made six or seven times in four years, and then once every fifth year.

The *yezdegerdic* year, it may be observed, is the same with Nabonassar's year, differing from it only in the names of the months, and the commencement of the epocha; for whereas the Nabonassarian began on February 26, this began on June 16. As to the galelean year, it is absolutely the best and justest of all the civil years yet invented, as being found, by calculation, to keep the solstices and equinoxes precisely to the same days, and answering very accurately to the solar motions; which no other civil year does, not even the Gregorian, for want of so commodious an intercalation. See *Perfian* CALENDAR.

YEAR, *Arabic, Mahometan, and Turkish*, called also the year of the *hegira*, (which see), is a lunar year, equal to 354 days, 8 hours, and 48 minutes, and consisting of 12 months, which contain alternately 30 and 29 days.

Though sometimes it contains 13 months; the names, &c. of which are as follow: 1. Muharram, containing 30 days. 2. Saphar, 29. 3. Rabia, 30. 4. Latter Rabia, 29. 5. Jomada, 30. 6. Latter Jomada, 29. 7. Rajab, 30. 8. Shaaban, 29. 9. Ramadan, 30. 10. Shawal, 29. 11. Dulkaadah, 30. 12. Dulheggia, 29; and in the embolismic year, 30. An intercalary day is added every 2d, 5th, 7th, 10th, 13th, 15th, 18th, 21st, 24th, 26th, 29th, in a cycle of 29 years.

The months commence not from the real new moon, but from its first appearance after conjunction.

YEAR, *Ethiopic*, is a solar year, perfectly agreeing with the Actiac, except in this, that the names of the month are different. It commences with the Egyptian year, on the 29th of August of the Julian year.

Its months are, 1. Mafcaram. 2. Tykympt. 3. Hydar. 4. Tyfhas. 5. Tyr. 6. Jacatil. 7. Magabit. 8. Mijazia. 9. Ginbat. 10. Syne. 11. Hamcl. 12. Hahafe. Intercalary days 5.

YEAR, *Athian*. See ACTIAN and EGYPTIAN YEAR.

YEAR, *Attic*. See MACEDONIAN YEAR.

YEAR, *Canicular*. See CANICULAR.

YEAR, *Yezdegerdic*. See *Perfian* YEAR and CALENDAR.

YEAR, *Galelean*. See *Perfian* YEAR and CALENDAR.

YEAR, *Nabonassar's*. See EGYPTIAN YEAR and NABONASSAR.

YEAR, *Sabbatic, Annus Sabbaticus*, among the ancients, was every seventh year; during which the Jews let their lands lie at rest. Levit. xxv. 8.

Every seventh sabbatic year, *i. e.* every 49th year, was called the *year of Jubilee* (which see); and held with solemnity extraordinary.

YEAR, *Anomalistical*. See ANOMALISTICAL and YEAR *supra*.

YEAR, *Climacteric*. See CLIMACTERIC.

YEAR, *Emergent*. See EMERGENT.

YEAR, *Enneatecal*. See ENNEATECAL.

YEAR, *Holy*. See HOLY.

YEAR, *Platonic, or Great*. See PLATONIC.

YEAR of the *Hegira*. See HEGIRA, and *Arabic* YEAR.

YEAR's Day, *New*, or the day on which the year commences, has always been very different in different nations; and yet in all has been held in great veneration.

Among the Romans, the first and last day of the year were

were consecrated to Janus; on which account it was that they represented him with two faces.

To them we owe the ceremony of wishing *an happy new year*, which appears to be very ancient. Before the first day was spent they not only visited and complimented each other, but also presented fœnæ, and offered vows to the gods for the preservation of each other.

Lucian represents it as a practice of a very ancient standing, even in his time, and refers it to Numa.

Ovid intimates the same ceremony in the beginning of his *Fasts*:

“ *Postera lux oritur, linguisque animique favete:
Nunc dicenda bono sunt bona verba die.*”

And Pliny more expressly, lib. xviii. cap. 1. “ *Primum anni incipientis diem lætis precationibus invocant faustum ominantur.*”

In Russia at the new year is annually held a feast of the dead, called Raditzli Sabal, on occasion of which every body visits the grave of his relations, lays some victuals upon it, and then hears mass, in payment for which the priests get the victuals. In our own country, the ushering in of the new year, or “ *New Year’s tide*,” with rejoicings, presents, and good wishes, was a custom observed, during the 16th century, with great regularity and parade, and was as cordially celebrated in the court of the prince as in the cottage of the peasant. On the first day of the new year, presents, called new year’s gifts, were given and received with the mutual expression of good wishes, and particularly that of a “ *happy new year*.” The compliment was sometimes paid at each other’s doors in the form of a song; but more generally, especially in the north of England and in Scotland, the house was entered very early in the morning by some young men and maidens selected for the purpose, who presented the spiced bowl, and hailed you with the gratulations of the season. In the reign of queen Elizabeth, the chief officers of state, and several of the queen’s household servants, gave new year’s gifts to her majesty, consisting, in general, either of a sum of money, or jewels, trinkets, wearing-apparel, &c. The largest sum given by any of the temporal lords was 20*l.*; but the archbishop of Canterbury gave 40*l.*, the archbishop of York 30*l.*, and the other spiritual lords 20*l.* and 10*l.* Many of the temporal lords and great officers, and most of the peeresses, gave rich gowns, petticoats, smocks, kirtles, silk stockings, cyprus garters, sweet-bags, doublets, mantles, some embroidered with pearls, garnets, &c., looking-glasses, fans, bracelets, caskets ludded with precious stones, jewels ornamented with sparks of diamonds in various devices, and other costly trinkets. These presents also consisted of books, and appropriate gifts from physicians, apothecaries, &c. The queen, though she made returns in plate and other articles, took sufficient care that the balance should be in her own favour. In the country, however, with the exception of the extensive households of the nobility, this interchange was conducted on the pure basis of reciprocal kindness and good will, and without any view of securing patronage or support; it was, indeed, frequently the channel through which charity delighted to exercise her holy influence, and though originating in the heaven, became sanctified by the Christian virtues.

We shall here add, that the rejoicings on new year’s tide were succeeded by the observance of the “ *Twelfth-day*,” called, from the idea that the Eastern magi, who are said to have visited our Saviour on that day, were kings, the “ *Feast of the Three Kings*.” The “ *Twelfth-cake*,” distributed on that occasion, was almost always accompanied by the *wassail bowl*; which see. Drake’s *Shakespeare*, vol. i.

YEAR, Civil, or Legal, in England, formerly commenced on the day of the Annunciation; *i. e.* on the 25th day of March: though the historical year began on the day of the Circumcision; *i. e.* the first of January, on which day the German and Italian year also begins.

Stowe observes, that William the Conqueror having been crowned on the first of January, that henceforth became the first of the year for historians, &c. though, in all civil affairs, they retained the ancient manner of accounting, which began the 25th of March.

The part of the year between these two terms was usually expressed both ways, as 1748-9, or 1748. But by the act for altering the style, the civil year now commences with January 1. See *New STYLE*.

Since the Conqueror, the king’s patents, charters, proclamations, &c. are usually dated by the year of the king’s reign.

The church, as to her solemn service, begins the year on the first Sunday in Advent, which is always that next St. Andrew’s day, or the 30th of November.

The Jews, as most other nations of the East, had a civil year, which commenced with the new moon in September; and an ecclesiastical year, which commenced from the new moon in March.

The month Tifri, which began about the time of the autumnal equinox, was the first month of the Jewish year, till it was changed at the time of the coming up of the children of Israel out of Egypt. For that happening in the month of Abib, afterwards called Nisan, this month was for this reason reckoned the first month of the year in all ecclesiastical matters. Before this period, Tifri was reckoned the commencement of the year, because it was thought that the world was created and first began at the time of the autumnal equinox. And for this reason, the Jews do still in their era of the creation of the world, as well as in their era of contracts, compute the beginning of the year from the first of Tifri, and all their bills and bonds, and all other civil acts and contracts, are still dated among them according to the same computation; and from this month also they began all their jubilees and sabbatical years. And therefore, although their ecclesiastical year began from Nisan, and all their festivals were computed from it, yet their civil year was still reckoned from Tifri, and the first day of that month was their new year’s day; and for the more solemn celebration of it, the feast of trumpets seems to have been appointed.

The French year, during the reigns of the Merovingian race, began on the day on which the troops were reviewed; which was the first day of March. Under the Carolingians it began on Christmas-day; and under the Capetians, on Easter-day; which, therefore, varied between the 22d of March and the 25th of April. The ecclesiastical year in France begins on the first Sunday in Advent. But for the civil, Charles IX. appointed, in 1564, that for the future it should commence on the 1st of January.

For an account of the change that took place in the year of France, see *French or Republican CALENDAR*. The French calendar was of no long duration. It was abolished in the course of thirteen years; and the Gregorian was restored, and ordered to be used in all dates after the 1st of January, 1806.

The Mahometans begin their year the minute in which the sun enters Aries. The Persians in the month answering to our June. The Chinese, and most of the Indians, begin it with the first moon in March. The Brachmans begin it with the first moon in April, on which day they hold a feast called *samvat saradi pauduga*, *q. d. feast of New-year’s day*. The Mexicans, according to D’Acosta, begin the year on

our 23d of February, when the leaves begin to grow green : their year confists of eighteen months, having twenty days each, which make three hundred and fixty days; the remaining five days are spent in mirth, and no buſineſs is ſuffered to be done, nor even any ſervice at the temples. Alvarez relates much the fame of the Abyſſinians; who begin their year on the 26th of Auguſt, and have five idle days at the end, which they call *pagoma*. At Rome there are two ways of computing the year; the one beginning at the Nativity of our Lord: this the notaries uſe, dating a *Nativitat*. The other on the 25th of March, on occaſion of the Incarnation; and it is by this the bulls are dated, *anno Incarnationis*. The Greeks begin their year of the world from the firſt of September. See *YEAR ſupra*.

Years are alſo diſtinguiſhed with regard to the epochs whence they are numbered: thus, *years of our Lord*, are thoſe reckoned from the birth of Jeſus Chriſt. *Years of the world*, are thoſe elapſed ſince the Creation. *Years of Rome*, of the *Hegira*, of *Nabonaſſar*, &c. See the difference between theſe years, under the article *ΕΡΟΧΙΑ*.

YEAR is alſo a word uſed by ſome of the chemical writers to expreſs any product of their operations, which may ſerve as a medicine, whether internally or externally.

YEAR and Day, in *Law*, &c. is a time that determines a right in many caſes, and is in ſome an uſucaption, and in others a preſcription.

Thus, in the caſe of an eſtray, if the owner, proclamation being made, challenge it not within a year and day, it is forfeit. In like manner is the year and day given in caſes of appeal, of deſcent, of entry or claim, of non-claim upon a fine, or writ of right, of the death of a man fore bruised, or wounded, of protections, eſſoins in reſpect of the king's ſervice, of a wreck, and on many other occaſions.

YEAR, Day, and Waſte, Annus, Dies, et Vaſtum, is a part of the king's prerogative, by which he challenges the profits of the lands and tenements of perſons attained for petit treaſon, or felony, for the ſpace of a year and a day, whoſeſever is lord of the manor to which they belong.

Formerly the king had only a liberty of committing waſte on the lands of felons, by pulling down their houſes, extirpating their gardens, ploughing their meadows, and cutting down their woods. But this tending greatly to the prejudice of the public, it was agreed in the reign of Henry I. that the king ſhould have the profits of the land for one year and a day in lieu of the deſtruction he was otherwiſe at liberty to commit: and, therefore, *Magna Charta* provides, that the king ſhall only hold ſuch lands for a year and a day, and then reſtore them to the lord of the fee; without any mention made of waſte. But the ſtatute 17 Edward II. *de prerogativa regis*, ſeems to ſuppoſe, that the king ſhall have his year, day, and waſte, and not the year and day inſtead of waſte; which ſir Edward Coke, and the author of the *Mirror*, before him, very juſtly look upon as an encroachment, though a very ancient one, of the royal prerogative.

This year, day, and waſte, are now uſually compounded for; but otherwiſe they regularly belong to the crown: and, after their expiration, the land would naturally have deſcended to the heir (as in gavel-kind tenure it ſtill does), did not its feudal quality intercept ſuch deſcent, and give it by way of eſcheat to the lord. *Black. Com. book iv.*

YEAR-Books, in *Law*. See *REPORTS*.

YEARS, Eſtate for, in *Law*, is a contract for the poſſeſſion of lands or tenements for ſome determinate period: and it happens when a man letteth them to another for the term of a certain number of years, agreed upon between the leſſor and the leſſee, and the leſſee enters thereon.

If the leaſe be but for half a year, or a quarter, or any leſs time, this leſſee is reputed as a leſſee or tenant for years, and is ſo ſtyled in ſome legal proceedings; a year being the ſhorteſt term which the law in this caſe takes notice of. An eſtate of this kind, even for a thouſand years, is only a chattel, and reckoned part of the perſonal eſtate; and, therefore, a leaſe for years may be made to commence *in futuro*, though a leaſe for life cannot.

With regard to emblements, or profits of land ſowed by tenant for years, there is this difference between him and tenant for life: that where the term of tenant for years depends upon a certainty, as if he holds from Midſummer for ten years, and in the laſt year ſows a crop of corn, and if it is not ripe and cut before Midſummer, the end of his term, the landlord ſhall have it; for the tenant knew the expiration of his term, and therefore it was his own folly to ſow what he never could reap the profits of. But where the leaſe for years depends upon an uncertainty; as, upon the death of the leſſor, being himſelf only tenant for life, or being a huſband ſeiſed in right of his wife; or if the term of years be determinable upon a life or lives: in all theſe caſes, the eſtate for years not being certainly to expire at a time foreknown, but merely by the act of God, the tenant or his executors ſhall have the emblements in the ſame manner as a tenant for life, or his executors ſhall be intitled to it. But not ſo, if it determine by the act of the party himſelf; as if no tenant for years does any thing that amounts to a forfeiture; in which caſe the emblements ſhall go to the leſſor, and not to the leſſee, who hath determined his eſtate by his own default. *Blackſt. Com. vol. ii.*

YEARLINGS, in *Rural Economy*, a term applied to young neat cattle of the heifer kind in the ſecond year. It is obſerved in the Glouceſterſhire Report on Agriculture, that until within theſe few years, it was there eſteemed a bad practice to let them be put ſo early to the bull, but that now it is even thought that this method improves them as milkers; and that from the increaſed value of ſtock, it is advantageous to anticipate a year, as a heifer in calf, at two years old, will be worth nearly as much as it would be if kept three. See *LIVE-Stock*.

YEARN, in *Hunting*, ſignifies to bark, as beagles properly do, at their prey.

YEARNING, in *Rural Economy*, a term applied to runnet, uſed for curdling milk in ſome places. See *DAIRY-ING* and *RUNNET*.

YEAST, YEſt, or *Barm*, the foam or flower of beer, or other liquor in fermentation.

The yeast of beer is uſed for a leaven or ferment in the making of bread: as ſerving to ſwell or puff it up very conſiderably in a little time, and to make it much lighter, ſofter, and more delicate. But when there is too much of it, it renders the bread bitter.

The uſe of yeast in bread is but of late ſtanding among us: it is not above a century ſince the avarice of the bakers firſt introduced it; and then it was only done by ſtealth. Though Pliny witneſſes it to have been uſed by the ancient Gauls.

The faculty of medicine of Paris, by a decree of the 24th of March, 1688, ſolemnly maintained it noxious to the health of the people; yet even that cenſure could not prevent its progreſs.

Common ale-yeaſt may be kept freſh and fit for uſe ſeveral months by the following method: Put a quantity of it into a cloſe canvas bag, and gently ſqueeze out the moiſture in a ſcrew-preſs, till the remaining matter be as firm and ſtiff as clay.

In this ſtate it may be cloſe packed up in a tight caſk, for ſecuring

fercing it from the air; and will keep fresh, found, and fit for use for a long time.

This is a secret that might be of great use to the brewers and distillers here, who, though they employ very large quantities of yeast, seem to know no method of preserving it, or raising nurseries of it; for want of which they sustain a very considerable loss; whereas the brewers in Flanders make a very great advantage of supplying the malt-distillers of Holland with yeast, which is rendered lasting, and fit for carriage, by this easy expedient. Shaw's Lectures.

Mr. Henry has repeatedly prepared an artificial yeast, by impregnating flour and water with fixed air, with which he has made very good bread, without the assistance of any other ferment: and he proposes this method of procuring fresh fermented bread at sea.

The process is as follows: Boil flour and water together to the consistence of treacle; when the mixture is become cold, fill a small cask with it. This cask is to be filled up in the manner represented in *Plate XV. fig. 7. Pneumatics*, and described under *PYRMONT Water*, for the impregnation of water with fixed air; and the process is to be conducted in a similar way, except that the cask is to be agitated as often as the mixture rises to about two-thirds of the capacity of the funnel *k*; and after each agitation, which should continue during several minutes, the unabsorbed air is to be let out, by withdrawing the plug from the orifice *m*, till that part of the mixture which remained in the funnel has returned into the cask. The orifice at *t* should also be larger than is necessary in the other operations, on account of the superior viscosity of the mixture. When, after repeated agitation, the mixture which has ascended into the funnel does not subside into the cask, it may be supposed incapable of absorbing more air.

Pour the mixture, thus saturated, into one or more large bottles, or narrow-mouthed jars; cover it over loosely with paper, and upon that lay a slate or board with a weight to keep it steady. Place the vessel in a situation where the thermometer will stand from 70° to 80°, and stir up the mixture two or three times in twenty-four hours. In about two days, such a degree of fermentation will have taken place, as to give the mixture the appearance of yeast.

With the yeast in this state, and before it has acquired a thoroughly vinous smell, mix the quantity of flour intended for bread, in the proportion of six pounds of flour to a quart of the yeast, and a sufficient portion of warm water. Knead them well together in a proper vessel, and covering it with a cloth, let the dough stand for twelve hours, or till it appears to be sufficiently fermented, in the above-mentioned degree of warmth. It is then to be formed into loaves and baked.

Mr. Henry adds, that perhaps the yeast would be more perfect, if a decoction of malt were used instead of simple water.

When the operation is finished, the cask, in order to prevent its contracting a disagreeable taint, should be well washed. Henry's Account of a Method of preserving Water at Sea, &c. p. 26, 1781.

YEAST, Chemical Properties of. The nature of yeast has been briefly discussed under the head of **FERMENTATION**. Since that article was written, however, some additional experiments have been published on the subject, which deserve to be noticed here.

The active and essential principle of yeast, as observed under the article *Fermentation* above alluded to, appears to be a species of *gluten*. When yeast is kept for some time in cylindrical glass vessels, a white substance, not unlike curd, separates and swims upon the surface. If this substance be removed,

the yeast loses the property of exciting fermentation. This substance possesses many of the properties of gluten, though it differs from it in others. Its colour is much whiter. It has not the same elasticity, and its particles do not adhere with the same force. It dissolves more readily in acids. Dr. Thomson considers this as the real fermentative principle, and thinks it may be considered as gluten somewhat altered, and rendered much more capable of decomposition. He thinks also that it existed in the raw grain originally, but underwent considerable modifications by the malting process, and perhaps others during the fermentation of the beer from which it separated.

The same distinguished chemist states, in support of this opinion, the experiments of Fabroni and Thenard. Fabroni, by heating the juice of grapes, and passing it through a filtre, separated an adhesive matter, which possessed the properties of gluten, and deprived of which the juice refused to ferment, though it fermented as well as usual when this principle was again added. Thenard likewise found in the juices of all the fruits he examined a substance similar to that described by Fabroni, and which, according to him, is absolutely the same with pure yeast. This substance is insipid, does not change vegetable blues, is insoluble in water, loses three-fourths of its weight when dried, and is decomposed like animal substances. When eight parts of it were distilled, they left 2.83 of charcoal, and yielded 1.61 of water, 1.81 of oil, and a quantity of ammonia, which, when saturated with muriatic acid, formed 1.46 of muriate of ammonia. The gas obtained weighed 0.33, and consisted of one-fifth of carbonic acid, and four-fifths of carburetted hydrogen, requiring 1½ times its bulk of oxygen to consume it. Nitric acid, even when much diluted, converts it into a species of tallow. With potash it forms a soap, while ammonia is disengaged. When mixed with fugar and a sufficient quantity of water, fermentation takes place, carbonic acid is disengaged, and a vinous liquor formed. By this action, the ferment loses the whole of its azote, and becomes incapable of exciting fermentation when mixed with a new portion of fugar. In farther corroboration still of this opinion, Dr. Thomson adduces an experiment of Kirchoff, which he thinks throws considerable light on the nature of yeast. Barley-meal contains both gluten and starch. Pure starch infused in hot water is not converted into fugar; nor does gluten become saccharine matter when heated in the same manner. But if a mixture of pure dried pulverized wheat-gluten and potatoe-starch be infused in hot water, the starch is converted into fugar. During the process an acid is said to be evolved. The gluten is little changed in appearance or quantity, and may most of it be separated by filtration. What is singular, however, it is incapable of inducing the same change upon starch a second time.

The following are the constituents of yeast, according to Weltrumb, as quoted by Dr. Thomson. From 15.360 parts he obtained,

Potash	-	-	-	13
Carbonic acid	-	-	-	15
Acetic acid	-	-	-	10
Malic acid	-	-	-	45
Lime	-	-	-	69
Alcohol	-	-	-	240
Extractive	-	-	-	120
Mucilage	-	-	-	240
Saccharine matter	-	-	-	315
Gluten	-	-	-	480
Water	-	-	-	13.595
				<hr/>
				15.142

Besides some traces of phosphoric acid and filica. But it is evident, as Dr. Thomson observes, that all these ingredients are not essential, and he considers the gluten only as deserving that appellation.

Some of the French chemists have considered the principle of fermentation to reside in an imperfect species of sugar, which they have denominated the *sweet principle*, and which they state to exist in combination with real sugar in all fruits containing that principle. This *sweet principle* they suppose to differ from pure sugar, in being incapable of crystallizing. A familiar example of it we have in *treacle* or *molasses*, which, according to them, is the *sweet principle* of the sugar-cane. This doctrine, however, has not met with many adherents; for, as Dr. Macculloch observes, although chemistry has not hitherto discovered the means of separating the sugar from the *sweet principle*, the results of fermentation leave no doubt that the latter consists of sugar combined with the vegetable extractive matter, or gluten, as it is denominated by most chemists. Thus molasses consists of a certain portion of *real sugar*, in such a state of combination with a variety of substances, and the fermentative principle among the rest, that it cannot be made to crystallize or be otherwise obtained in a separate state. This is demonstrated by the well-known fact, that molasses may be made to undergo the fermentative process, and to yield alcohol, in precisely the same manner as a simple mixture of sugar and yeast. The *sweet principle* of molasses, therefore, must be in fact nothing else than sugar, unless we suppose two different substances capable, by the same means, of producing the same result, which is totally unprecedented in chemistry, besides being in itself extremely improbable.

Upon the whole then, in the present state of our knowledge, we are obliged to conclude that the essential principle of yeast, or the real fermentative principle, is either identical with gluten, or closely allied to it. Of its real nature, however, and *modus operandi*, we are totally ignorant, and shall probably long remain so.

The yeast of beer is that most generally employed, and is of the utmost importance in the manufacture of bread, and of fermented liquors from malt. If carefully dried and preserved from moisture, it retains its properties for a long time, and it is a pity this practice is not more generally reported to, as fluid yeast in warm weather soon becomes acerbent and putrid, and not only loses its properties, but imparts a most disagreeable flavour to the bread, &c. with which it is mixed. Yeast may be readily dried by first separating its watery parts as much as possible, and afterwards exposing it in shallow vessels to the air, or to a gentle heat in a stove. In this way, it may be obtained in thin laminae, and requires only to be preserved in close vessels in a dry place, when it will be always ready for use, by diffusing it in a little warm water. A popular method of preserving yeast is by drying it upon bunches of twigs. See BREAD, BREWING, FERMENTATION, and WINE.

YEAST, Medicinal Properties of. Yeast has been highly extolled as an antiseptic remedy in diseases, when a putrid diathesis was supposed to prevail; as in low typhus fevers, gangrene, &c. A good method of exhibiting it, is to mix one or two table-spoonfuls of it with a quart of infusion of malt or mild porter, and to take a wine-glassful of this mixture frequently. Many practitioners also have spoken highly of the good effects of a fomenting poultice composed partly of yeast, when applied to foul and gangrenous ulcers. The good effects of this remedy, if in reality it possesses any, may probably be attributed to the carbonic acid gas generated by its agency. See FEVER.

YEATS, Mrs., in *Biography*, the celebrated tragic

actress, who, in conjunction with Mrs. Brooke, the novelist, a lady of considerable literary merit, undertook, in 1773, at all risks, the conduct and government of the opera, and all its dependencies; an enterprise for which they were but sparingly qualified. In the first place, Mrs. Yeats, though possessed of strong natural parts, and an inherent spirit of government, knew no language but English, was ignorant and indifferent about music, dancing, painting, machinery, and decorations. She and her husband had saved a considerable sum by their salaries and benefits at our national theatres, and in hopes of accumulation previous to retirement, they quitted employments for which they were extremely well fitted, and in which their success was certain, to govern a most forward family by deputation, at the extreme hazard of being ruined.

Mrs. Brooke, who had resided some time at Quebec, after its conquest, with her husband, the Rev. Dr. Brooke, chaplain to the army in that colony, indeed knew French, had a good taste in books, and wrote in a good style; but was ignorant of music, and totally unacquainted with all opera concerns. Yet it was during this female regency, that the best composers, the greatest singers, and the most capital and renowned dancers, were engaged: for during nine years, from 1773 to 1782, we had Sacchini, Truetta, and Anfosfi, to compose; Pacchierotti, Anfani, and the Gabrielli, to sing; and Madlle. Heynel, the Vestris, and Le Picq, to dance.

Mrs. Yeats did not enrich herself by her opera sovereignty; but she had the address to escape ruin. And Mrs. Brooke, who risked no property, lost no reputation by imprudence, or the want of talents in the persons she engaged.

YECATY, in *Geography*, a town of Hindoostan, in Myfore; 20 miles N. of Seringapatam.

YECORA, a town of New Mexico, in the province of Hiaqui; 50 miles E. of Riochico.

YEDACOTTA, a town of Hindoostan, in Myfore; 15 miles N. of Dindigul.

YEDAPADY, a town of Hindoostan, in the Carnatic; 8 miles N. of Sankerdurgam.

YEDAPILLY, a town of Hindoostan, in Myfore; 2 miles N.W. of Vencatighery.

YEDDIMUNGALUM, a town of Hindoostan, in the Carnatic; 18 miles E. of Tanjore.

YEDKAST. See JEZDKAST.

YEGUE HORUN, a town of Chinese Tartary; 418 miles E.N.E. of Peking. N. lat. 43°. E. long. 124° 19'.

YEHEMAGUR, a town of Hindoostan, in Lahore; 15 miles N.N.E. of Jallindar.

YEHUNGSHAUL, a town of Hindoostan, in Lahore; 40 miles W.N.W. of Lahore.

YELASURAM, a town of Hindoostan, in Palnau; 20 miles S.W. of Timerycotta.

YELCHORE, a town of Hindoostan, in the circle of Guntoor; 3 miles N.E. of Innaconda.

YELCOUR, a town of Hindoostan, in the Carnatic; 15 miles N. of Chittoor.

YELDOOR, a town of Hindoostan, in Myfore; 12 miles N.E. of Colar.

YELFOLA, a town of Spain, in Galicia; 18 miles N. of Santiago.

YELION, a word used by some of the barbarous writers to express glass.

YELL ISLAND, in *Geography*, one of the Shetland islands, 20 miles long, and about 7 broad, but intersected by a number of bays, by the inhabitants called *Voes*, which afford good harbours. The principal part of the arable land is confined to the neighbourhood of the coast; the inland parts are mountainous,

tainous, and covered with peat moss: there is but little heath, but abundance of a rough sort of grass called *lubbo*, which grows naturally, and affords tolerable pasture for sheep, horses, and black cattle. Though the crops raised are not sufficient for above eight months' consumption, yet the inhabitants, by the advantage of having plenty of fuel, and catching immense quantities of small fish, live comfortably, and as well as the generality of the peasants of Scotland. N. lat. 60° 56'. W. long. 1° 20'.

YELLAGOOD, a town of Hindoostan, in Golconda; 45 miles S.E. of Canoul.

YELLAMOODY, a town of Hindoostan, in the province of Madura; 25 miles W. of Madura.

YELLANG, a town of Burmah; 14 miles S. of Mellone.

YELLOOR, a town of Hindoostan, in Baramaul; 6 miles N.N.W. of Namcul.

YELLOW, a bright colour, reflecting the most light of any after white. See COLOUR.

The word is formed from the Italian *giallo*, or the German *gel*, which signifies the fame; or from the Latin *galbanus*, bright, gay.

There are divers yellow substances that become white, upon wetting and drying them again several times in the sun: such as wax, linen cloth, &c. (See BLEACHING.) And the same bodies, if they be already white, and continue a long time in the air without being wetted, turn yellow.

Paper and ivory, applied near the fire, become successively yellow, red, and black. Silk, when turned yellow, is whitened again with the fumes of sulphur.

YELLOW, in *Dyeing*, is one of the five simple and mother colours. See COLOUR.

The only materials used by the calico-printers for the production of fine yellows are the quercitron-bark (see QUERCUS), and the *Weld*, or *Reseda Lutetia*, which see. In order to obtain calicoes of the finest yellow or more delicate lemon colour, it is necessary to dry the pieces in the open air, as the stove would not fail to injure such colours; stove-drying having a tendency to change a yellow into an orange. In the operation of dunging the mordants for these pale yellows, care should be taken that it be not done at a higher temperature than 96° or 100°, as such a high temperature would impair their beauty. But besides, by dunging at this low temperature, the dyeing may be completed at about 110°, which will give a much livelier colour than if a higher temperature had been employed. For all the different shades of reds and yellows, the mordant employed by calico-printers is the acetate of alumine; which is prepared by a mixture of the sulphate of alumine with acetate of lead, both in a state of solution; so that, on the theory of double decomposition, sulphate of lead is formed, which precipitates while the acetate of alumine remains in solution. Of late this article has been prepared from the pyroligneous acid, by means of lime and alum, in the following manner:—The pyroligneous acid is first passed through a still, to divert it of a portion of the tar which is always dissolved in it: it is then saturated with lime or whiting; and the acetate of lime thus formed is decomposed by a heated solution of sulphate of alumine. The result of this double decomposition is sulphate of lime, which precipitates, and acetate of alumine, which is drawn from the sediment of the calcareous sulphate, and preserved for use. Mr. Parkes cautions the manufacturer against the use of lime in the process for making acetate of alumine; and he says that the true mode of making it, though more expensive, is that recommended by Berthollet, which consists in decomposing sulphate of alu-

mine by means of saccharum faturni, or acetate of lead. Mr. Parkes mentions a method of producing yellows on calico, which, though not often practised, has nevertheless a very good effect. The process is as follows:—A strong decoction of bark, thickened with gum tragacanth, is to be mixed with a portion of very pure muriate of tin; and this, when printed with the usual management, will produce a colour of great brightness and durability. This mode possesses one very important advantage; viz. that if it should be necessary to pad a piece in diluted acetate of alumine to obtain a pale lemon ground, the yellow figures previously done by the above process will not give out any part of their colour to the second mordant; whereas, whenever a strong yellow has been produced in the common way, the pattern is very apt to spread, and to become irregular, and often to stain the ground, when the piece comes a second time into the acetate of alumine. Parkes's Eff. vol. ii.

Turmeric likewise gives a good yellow; though not the best.

Woolen cloth, impregnated with a solution of alum and tartar, acquires on being boiled with the watery decoction, an elegant, but not very durable orange-yellow or gold-coloured dye. It is rarely made use of by the dyers, on account of its price, and the perishableness of its colour.

There is also an Indian wood that gives a yellow colour bordering on gold. This wood, called *fuslick*, is a species of mulberry-tree, of a deep sulphur-yellow colour, which it readily gives out both to water and spirit. The watery decoction dyes prepared woolen of a very durable orange-yellow: the colour is imbibed by the cloth in a moderate warmth, without boiling.

The *fuslet* or *fussel* of the French is a yellow wood or root, very different from our *fuslick*: it gives a fine orange dye to woolen, but the colour is extremely perishable in the air. This is called *cotinus coriaria*, or *Venice sumach*.

The leaves of many kinds of herbs and trees give a yellow dye to wool or woollen cloth that has been previously boiled with a solution of alum and tartar. There is, indeed, no colour for which we have such plenty of materials as for yellow.

Mr. Hellot observes, in his Art de Teindre, that all leaves, barks, and roots, which on being chewed discover a slight astringency, as the leaves of the almond, peach, and pear trees, ash-bark (especially that taken off after the first rising of the sap in spring), the roots of wild patience, &c. (see LEAF), yield durable yellows, more or less beautiful, according to the length of time that the boiling is continued, and the proportions of alum and tartar in the preparatory liquor: that a large quantity of alum makes these yellows approach to the elegant yellow of weld; that if the tartar is made to prevail, it inclines them to an orange; and that if the roots, barks, or leaves, be too long boiled, the yellow proves tarnished, and acquires shades of brown. Neumann's Chemical Works, by Lewis, p. 384. 434.

The Chinese are famous for their yellows in dyeing, which never change with washing. They make this dye of the flowers of the acacia, in a manner in which we might use several of our productions to a great advantage.

It is thus: they gather the flowers before they are perfectly ripe, and dry them in an earthen vessel over a gentle heat, till they crisp up in the manner of tea-leaves: they then add to them the ripe seeds of the same tree in different proportions; and then boiling them in river water, with alum, they give the yellow in any degree that they please.

They have three kinds of yellow, which they distinguish by the names of *Ngo-boang*, *king-boang*, and *hoang alone*.

The first of these is the brightest yellow: to dye five or

fix ells of silk of this colour, they use a pound of the flowers of the acacia, about two ounces of the seeds, and four ounces of alum.

The *king-hoang* is a somewhat deeper yellow: to dye this, they use the same ingredients in the same proportion as in the former case; and when the silk is dry from the dipping in this, they give it a second dipping in a slight tincture of Brazil wood: this brings it to the fine strong yellow we see.

The *hoang*, or pale yellow, is made of the same ingredients as the first, only instead of four ounces of alum they put in but three ounces: river water is found to be greatly preferable to any other for the extracting of these colours; but even in that there is great difference, some doing the business much better than others.

The Chinese are so expert in judging on this occasion, that they can tell by the taste of water whether it will or will not do; and if it taste faint they know it is faulty; but they dip the pieces twice into it instead of once, and the colour succeeds well.

The flowers of the acacia, when they have been prepared by roasting in this manner, may be kept all the year round, and employed in dyeing as occasion requires, only there is to be longer boiling for the dried flowers than the fresh ones; and it is always found that the fresh flowers give the brightest colour. *Obs. sur les Coutum. de l'Asie*, p. 254.

Greens are usually made of yellow and blue mixed. With yellow, madder red, and goat's-hair prepared with madder, are made the golden yellow, Aurora, pansy, nacarate, Isabella, and chamois colour, which are all casts or shades of yellow.

Mr. Peter Woulfe has given the following receipt for making the yellow dye:—Take half an ounce of powdered indigo, and mix it in a high glass vessel, with two ounces of strong spirit of nitre, which should be previously diluted with eight ounces of water, for preventing the indigo's being set on fire by the spirit; because two ounces and a half of strong spirit of nitre will set fire to half an ounce of indigo: let the mixture stand for a week, and then digest it in a sand-bath for an hour or more, and add four ounces more of water to it; filter the solution, which will be of a fine yellow colour. If the indigo be digested twenty-four hours after the spirit of nitre is poured upon it, it will froth and boil over; but after standing about a week, it has not that property.

One part of the solution of indigo in the acid of nitre, mixed with four or five parts of water, will dye silk or cloth of the palest yellow colour, or of any shade to the deepest, and that by letting them boil more or less in the colour. The addition of alum is useful, as it makes the colour more lasting: according as the solution boils away, more water must be added. None of the colour in the operation separates from the water, but what adheres to the silk or cloth; and consequently this colour goes far in dyeing.

Cochineal, Dutch litmus, orchil, cudbear, and many other colouring substances treated in this manner, will all dye silk and wool of a yellow colour.

The indigo which remains undissolved in making Saxon blue, and collected by filtration, if digested with spirit of nitre, dyes silk and wool of all shades of brown, inclining to a yellow.

Cloth and silk may be dyed green with indigo; but they must first be boiled in the yellow dye, and then in the blue. *Phil. Transf. vol. lxi. part i. p. 129, &c.* See DYEING.

Painters and enamellers make their yellow of masticot, or, as some write it, masticot, which is cruisse raised to a yellow colour by the fire; or with yellow ochre. Limners

and illuminers make it with saffron, French berries, orcanette, &c.

Mr. Boyle tells us a most beautiful yellow may be procured by taking good quicksilver, and three or four times its weight of oil of vitriol, drawing off, in a glass retort, the saline menstruum from the metalline liquor, till there remains a dry snow-white calx at the bottom: on pouring a large quantity of fair water on this, the colour changes to an excellent light yellow.

He says he fears this colour is too costly to be used by painters, and he does not know how it would agree with every pigment, especially oil colours. *Works abr. vol. ii. p. 91.* See VITRIOL.

Branton observes, that it was anciently the custom to paint a man's door yellow, and threw his house with salt, to declare him a traitor to his king.

YELLOW and other Colouring Matters of Flowers, in *Rural Economy*, the different colouring matters thus produced. The nature of the colouring matters of flowers has not yet been much examined into. Such colouring matters are in general very transient, especially those of the blue and red kinds. The yellow colouring matters of this sort are said to be the most permanent. It is noticed by a late writer, that the carthamus contains a red and a yellow colouring matter; that the yellow is easily dissolved by water; that from the red, rouge is prepared by a process which is kept secret; that the colours of most flowers are changed by alkalis to green, and by acids to red; that an imitation of the colouring matter may be made by digesting solutions of gall-nuts with chalk; a green fluid is produced, which becomes red by the action of an acid; and that has its green colour restored by means of alkalis.

YELLOW Copper, in *Mineralogy*, copper pyrites. See COPPER Ores.

YELLOW Earth, a soft yellow mineral substance, found at Wehraw, in Upper Lusatia, associated with clay and argillaceous iron-stone: it is sometimes used as a yellow pigment. The characters given of this substance do not seem to entitle it to be regarded as a different species from some of the ochreous clays which occur in the coal-strata in England. It is classed by professor Jameson with the lithomarge family, and is thus described by him. Its colour is ochre-yellow, of different degrees of intensity; it occurs massive; it is dull in the cross fracture, but glimmering in the principal fracture. In the large, the fracture inclines to flaty; in the small, the fracture is earthy. The fragments are tubular, or indeterminate angular. It becomes shining in the streak; it is opaque and very soft, passing into friable; it soils the fingers slightly, and adheres to the tongue; its feel is rather greasy; it is rather light, but the specific gravity is not given. Before the blow-pipe, yellow earth is converted into a black and shining enamel. We have no analysis of this earth.

YELLOW Tellurium Ore, an ore of tellurium, hitherto found only at Nagyag, in Transylvania. See TELLURIUM.

YELLOW Cow-Wheat, in *Agriculture*. See WEED.

YELLOW Dead Nettle. See WEED.

YELLOW Devil's Bit. See WEED.

YELLOW or French Berries. See AVIGNON, and LYCIUM.

YELLOW Fever, an epidemic disease of frequent occurrence in America and the West Indies. See FEVER, *Yellow*.

Vessels arriving in Great Britain or Ireland, or the islands of Guernsey, Jersey, Alderney, Sark, or Man, from places where the yellow fever is known to exist, or where it is deemed likely to break out, are subjected by various laws and orders of his majesty in council to the restraint of quarantine; the same as ships arriving from countries subjected

to the *Plague*, for the details of which, see that article in the *Addenda*.

YELLOW-Hammer, in *Ornithology*, the name of a very common English bird, called by authors *emberiza lutea*; and by Linnæus *emberiza cirinella*; and by some *hortulanus*; by others *luteus*; and by others *chloræus*.

The bill is of a dusky hue; the crown of the head is of a pleafant pale yellow; in fome almoft plain, in others spotted with brown; the hind-part of the neck is tinged with green; the chin and throat are yellow; the breast is marked with an orange-red; the belly yellow; the leffer coverts of the wings are green; the others dusky, edged with ruft colour; the back of the fame colours; the rump of a rufty red; the quill-feathers dusky, edged on their exterior fides with yellowifh-green; the tail is a little forked; the middle feathers are brown; the two middlemoft edged on both fides with green, the others on their exterior fides only; the interior fides of the two outmoft feathers are marked obliquely near their ends with white.

This fpecies makes a large flat neft on the ground, near a bufh or hedge, of mofs, dried roots, and horfe-hair; it lays fix eggs, of a white colour, with dark purple veins; and in winter frequents our farm-yards with other fmall birds. Pennant.

There is befide this another kind, which is much fmallier, and of a browner colour on the back; this is called by fome authors *zivalo*.

YELLOW Hawkweed, in *Agriculture*. See *WEED*.

YELLOW Jaundice, in *Medicine*. See *JAUNDICE*.

YELLOW, King's, is a pure orpiment, or arfenic coloured with fulphur, ufed for painting in oil and varnifh; of an extreme bright colour, and when good a true yellow: when ufed alone, it will ftand well; but mixed with white lead, and feveral other pigments, its colour flies or changes. It is fometimes mixed with blue pigments, to form a green colour. This pigment may be prepared by mixing fulphur and arfenic by fublimation: taking of arfenic powdered, and flowers of fulphur, in the proportion of twenty parts of the firft to one of the fecond, and putting them into a fublimer, and fubliming them in a fand-heat by means of a furnace particularly adapted to the purpofe. When the operation is completed, the king's yellow will be found in the upper part of the glafs, which muft be feparated with care from any foul parts adhering to it in the glafs, and levigated into an uniform powder. It may be alfo obtained from common orpiment by fubliming it in the fame manner. This pigment may be rendered warmer, or more inclined to orange, by increafing the proportion of the fulphur, and vice verfa. Handmaid to the Arts, vol. i. p. 17.

YELLOW Ladies' Bed Straw. See *WEED*.

YELLOW Meat, in *Rural Economy*, that which is much tinged with a yellow colour. It is faid to be a peculiar property in fome forts of animals, of both the fheep and cattle kinds, to afford meat which has a yellow caft or appearance.

It is fuggelted that this defect muft be hereditary, as no pature or particular food can either produce or remove it, as fheep which have been tried in the manner here defcribed and found yellow have been fent to the Thames marfhes, kept there a year, and when flaughtered have proved as yellow as gold. It may probably depend upon fome phyfical principle, which mere examination after death has not yet fhewn. Thefe remarks are equally applicable to beef as mutton, and are the refult of information on the fubject derived from a well-experienced Smithfield falefman.

YELLOW, Naples. See *GIALLOLINO*.

YELLOW Oat-Grass, in *Agriculture*, a fort of grafs which thrives well in meadows and patures, as well as upon hills where the foil is of a calcareous nature, flowering in the middle of fummer. It is a rather coarfe grafs, which, though tolerably fweet, is thought by many to be much inferior to the meadow and fefcue graffes; and which Withering has aferted not to be relifhed by cattle; but which Swayne thinks one of the beft graffes of this kind for the ufe of the farmer.

The proportional value which the grafs, at the time the feed is ripe, bears to that at the time of flowering, is as 9 to 15.

The proportional value which the grafs of the latter-math bears to that at the time of flowering, is as 5 to 15; and to that at the time the feed is ripe, as 5 to 9.

It is remarked, that this fpecies of grafs is pretty generally cultivated in many diftricts and parts of this country; and that it would appear from the above details to be a valuable grafs, though inferior to many others. See *AVENA Flavescens*, *GRASS*, and *GRASS-Land*.

YELLOW Ochre. See *OCBRE*.

YELLOW Rattle. See *WEED*.

YELLOW Scour or Milk, a difeafe in lambs, which takes place while they are young, and in which they appear quite dull and fpiritlefs; their ears inftead of being upright lie flat and afunder on their heads; they are very lank in the fides and bellies, and their breathing is very fhort and unequal. Thefe appearances are fucceeded by a purging of a yellowifh milky coloured matter, which, in fome cafes, has come on before the difeafe is noticed; but at other times, the lambs die without having had any or only a flight difcharge of excrement. The body or carcase appears well fed; the excrement in the intefines, which laft are fometimes in fome degree fwelled, refembles in colour that paffed at the anus, while the ftomach is particularly full of coagulated milk.

It is a difeafe which never appears or fhews itfelf in hard feafons, but only when the weather is warm, growing, and genial, and there is great plenty of new grafs. In general it does not affect them after they are three weeks old. It is moftly afcribed to their sucking more milk than they can digeft; and it is even faid, that they not unfrequently fuck until their ftomachs burft.

The lambs being young, and of little value, remedies to prevent or remove the difeafe are feldom tried; but thofe of the aromatic cretaceous kind, with a little opium, may often be ufed with much advantage in preventing and curing the complaint.

YELLOW Vetchling, in *Agriculture*, a plant of the rare kind, that may be cultivated by the farmer in many cafes with profit. The writer of the *Eflays on Rural Affairs* ftates, that it grows with great luxuriance on fiff clayey foils; that it continues annually, for any length of time, to afford a great weight of produce, which is of the very beft quality; that it is equally fit for pature herbage or for hay, and that it may be applied to one or other of thefe purpofes at any period as convenient; that it has likewise this advantage, that as it continues to grow with equal ftrength in the end as in the beginning of the fummer feafon, it may admit of being patured upon in the early fpring, when neceffary, without endangering the lofs of the hay-crop, which cannot be the cafe with any other plant ufully cultivated, except clover, which is unfit both for early pature and for hay; and that it is ftill more valuable, as growing to the greateft perfection on fuch foils as are wholly unfit for producing *fain-foin*, the only fort of plant yet cultivated in
the

the field, which seems to have qualities approaching to those of this plant.

The principal objection to its cultivation is the difficulty of procuring the seeds of it in plenty, which may probably be obviated by proper management. It is, however, an abiding plant, and one which increases fast by its running roots, and which may readily be propagated in this way in the field. See *LATHYRUS Pratensis*.

YELLOW-Berry Wash, is a solution of the gum of the French berries in water; and may be prepared by boiling a pound of the berries in a gallon of water with half an ounce of alum, in a pewter vessel, and filtering the fluid; and by evaporating the fluid in the boiler till the colour appears to be of the requisite degree of strength.

This is used as a washing colour in water-painting: it will stand extremely well, and being more diluted, or laid on thicker, will, in consequence of its transparency, give a variety of shades.

YELLOW Wash of Saffron. See *Tincture of SAFFRON*.

YELLOW Wash of Turmeric. See *TURMERIC*.

YELLOW Breeces Creek, in *Geography*, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 40° 13'. W. long. 76° 52'.

YELLOW Creek, a township of Ohio, in the county of Columbiana, with 491 inhabitants.—Also, a river of America, which runs into the Ohio, N. lat. 40° 34'. W. long. 80° 44'.

YELLOW River, a small river of Ireland, in the King's county, which joins the river Boyne.

YELLOW River. (See *HOANG*.) Mr. Barrow, supposing, without the possibility of exaggeration, that the breadth of the Yellow river, where Macartney's embassy passed it, about 70 miles from the sea, was only three-fourths of a mile, the mean depth five feet, and the velocity of its course four miles an hour, concludes, from these data, that the river discharges into the Yellow sea, in every hour, a volume of water equal to 418,176,000 solid feet, or 2,563,000,000 gallons of water, or 1100 times as much as appears to be furnished by the Ganges. By another computation, he estimates the quantity of mud washed into the sea by this river in every hour to be equal to 2,000,000 solid feet, or 48,000,000 in every day, or 17,520,000,000 in every year. Supposing the mean depth of the Yellow sea to be 20 fathoms, or 120 feet, the quantity of earth brought down by the Yellow river would, if accumulated together, be sufficient to fill up, even to the surface of the sea, an island one mile square in 70 days. By extending the calculation, a curious inquirer may find in what space of time the Yellow sea itself might be filled up by the successive depositions from the Yellow river alone; for supposing that sea to extend northward from that river, and to include the gulfs of Pe-che-lee and Leao-tong, the number of square miles on the surface of this extent would be about 125,000, which, multiplied by the number (70) of days necessary for consolidating one mile square, would make 8,750,000 days, or 24,000 years.

The velocity of the Yellow river at the place where the embassy crossed it was so great, as to require, agreeably to the superstitious notions of the Chinese crews, a sacrifice to the spirit of the river, in order to ensure a safe passage over it. With this view, the master presented a cock, and having wrung off his head, which he threw into the sea, consecrated the vessel with the blood spouting from the body, by sprinkling it upon the deck, the masts, the anchor, and the doors of the apartments, and stuck upon them a few of the feathers of the bird. Various kinds of provisions were then ranged across the deck; and when the

captain had made three profound inclinations of the body with his hands uplifted, he muttered a few words, as if of solicitation to the Deity. The loo, or brazen drum, was in the mean time beaten forcibly; lighted matches were held towards heaven; papers, covered with tin or silver-leaf, were burnt; and crackers fired off in great abundance by the crew. The captain afterwards made libations to the river, by emptying into it from the vessel's prow the several cups of liquids which he had provided, and concluded with throwing in also that which held the salt. All the ceremonies being finished, and the bowls of meat removed, the people feasted on it; and afterwards launched with confidence the yacht into the current. As soon as she had reached the opposite shore, the captain returned thanks to heaven, with three inclinations of the body. Sacrifices are also offered to obtain a fair wind, and to avert any impending danger.

Besides these offerings, great exertions were necessary to overcome the violence of the Yellow river, and to transport large yachts in safety to the opposite shore. Embassy to China, vol. ii.

YELLOW Sea, an extensive but shallow inland sea between Corea and China, hardly any where exceeding forty-five fathoms in depth, and often not more than twenty; with a bottom of clay or mud: the alluvion, without doubt, of the rivers that are poured into it from the mountains and plains of China. See *LEAO-TONG*.

YELLOWS, in *Animals*, is a disease which is incident to horses, neat-cattle, and sheep, in which there is a yellow jaundice-like appearance, especially in the eyes.

It is a disease that takes place in horses in all states of them, but which in those of the young kind is often unaccompanied with fever, or any sort of irritation.

It shews itself by a particular yellowness in the eyes and the inside of the mouth, with a considerable degree of constipation of the bowels in some cases.

The complaint is frequently much relieved by the use of a ball composed of one ounce of aloes in powder, with one drachm of calomel, and half an ounce of Castile soap, made up with a sufficient quantity of treacle; and the second morning afterwards giving one constituted of half an ounce each of nitre, resin, and Castile soap, made up with honey; and if the yellowness should continue in the eyes and mouth, repeating the latter after an interval of four days.

Some, however, advise to have first recourse to bleeding, clysters, and purges; in the last of which intentions the composition directed below may be found useful: One ounce and a half of Indian rhubarb, two drachms of saffron, and six drachms of foccotrine aloes, formed into a ball with syrup of buckthorn. But if the rhubarb should be thought too expensive, it may be omitted, and the same quantity of cream of tartar, and half an ounce of Castile soap, with four drachms more of aloes, be added. This may be repeated two or three times, giving intermediately the remedies directed below: Half an ounce of Æthiops' mineral, and one ounce of Castile soap, formed into a ball, and one of them given every day, washing it down with a pint of the following decoction: Madder and turmeric-root, each four ounces; burdock-root sliced, half a pound; monk's rhubarb, four ounces; and liquorice sliced, two ounces; boiled in one gallon of forge-water to three quarts; the liquor then strained off, and sweetened with honey.

In this disease, balls of Castile soap and turmeric alone are likewise often had recourse to, even to the quantity of three or four ounces or more in the day; and not unfrequently succeed in recent cases.

By means of this sort, the disease for the most part abates

abates in the course of a week or ten days, which may be known by the alteration in the eyes and mouth of the horse; but the remedies are to be continued until the yellowness is wholly removed. Should, however, the disease prove obstinate, and not give way to such modes of treatment, it will be necessary to have recourse to more powerful remedies, such as those of the mercurial purging kind, repeated two or three times at proper intervals, and then to give the balls composed of the substances directed below: Two ounces of salt of tartar, four ounces of cinabar or antimony, three ounces of filings of steel, and soap half a pound, formed with honey into balls the size of a pullet's egg, giving one night and morning in a pint of the above decoction drink.

On the recovery of the horse, some advise two or three mild purges; and if he be strong and fat, to put in a rowel.

He should have mashes and warm water frequently, and be exercised daily, and warmly covered with cloths.

In order to prevent a relapse, the first purging-ball may sometimes be used with great advantage; and a powder formed of the following ingredients be mixed, with the feeds of corn every night for a fortnight: Æthiops mineral, nitre, and aniseeds, each half an ounce, mixed together.

Salt-mashes, too, have often been found very useful in the cure of this disorder, and when taken in time rarely fail in restoring the animal.

The yellows in neat-cattle is a common disease, arising from obstruction in the gall-ducts, and consists in a diffusion of the obstructed bile through the whole body of the animal. It is first distinguished in the white of the eyes, which has a particular yellow appearance; and as it increases, the whole of the skin becomes tinged with the same yellow colour: but the ears, tail, eyes, and mouth, are the parts in which it is the most conspicuous. The animals are affected with great weakness and debility in every stage of the disease, and there is a listlessness, with indisposition to move, and a want of appetite for their food. When in the pastures, they mostly wander about by the sides of the hedges, or other fences, in a lonely manner. Milch cows are particularly subject to the disease in the spring and at the fall of the year; though they are not exempt from having it at all other seasons. The most unfavourable state of the disease is when it proceeds from an induration of some part of the liver, as there is then but little hope of the disease being permanently removed. As the changing state of the weather has often a great effect in retarding or hastening the removal of the disease, care should be taken to house the animals in all unfavourable seasons.

On the first appearance of the disease, it may often be removed by the composition directed below: Salt of tartar, Castile soap, and grains of Paradise, each one ounce; turmeric-root, and coriander-seeds, in powder, each two ounces; the whole being made into a drink, by pouring three pints of hot ale upon the ingredients in a proper close vessel, first slicing the soap in a thin manner, and covering them well up until they become about new milk warm, when two ounces of honey or treacle may be added, and the whole given as a drink. It must be repeated at the distance of every day or two, for two or three times, or as there may be occasion.

Where the beast is strong, a little blood may sometimes be taken away with advantage; but it should not be turned out into the pasture the same day.

When the disease does not give way to these remedies, it may be necessary to have recourse to a strong purge or two. After which a drink composed as below may be given: Salt of tartar, one ounce; Castile soap sliced, two ounces;

well rubbed down with an ounce of balsam of copaiva, and then two ounces each of valerian-root, ginger-root, and Peruvian bark in powder added, and the whole given in ale or gruel as above, repeating it every other day.

It is necessary to keep the bodies of the animals well open through the whole of the disease; in which intention a drink composed as below may often be useful: Barbadoes aloes, in powder, one ounce; castor-oil, four ounces; syrup of buckthorn, two ounces; mixed and given in a quart of oatmeal-gruel when about new milk warm, and repeated until the proper effect be produced, using the first saponaceous drink at the same time.

When this complaint is removed, the general health of the animals may soon be restored by the proper use of cordial strengthening drinks, formed of the different aromatic pectoral seeds in the powdered state.

The yellows is not a very common disease among sheep, and consequently has not been very accurately described; but probably confounded with many other affections to which they are subject. It is supposed by some to be in general confined to the South Down and new Leicester breeds, which, from their more tender constitutions, are more liable to complaints.

The appearances of the disease are a yellowness over the whole body, but particularly distinguishable in the white of the eye. The wool, too, has a little of the tinge, and is slightly hard. The passages of the belly are of a whitish colour, and the urine is found to tinge any thing immersed in it of a yellow hue. Sometimes there is a degree of fullness and hardness in the right-side, about the seat of the liver. The causes are any thing which has a tendency to obstruct the gall-ducts, but they are by no means evident; their effect, however, seems generally to harden the liver, and invariably to impede the passage of the bile from it into the bowels. In some cases, small stones, formed in the gall-bladder, produce it; and at other times, it is caused, as in the rot, by the swelling of the glands impeding the flow of the bile in the ducts, in which case it is mostly incurable.

The removal of the disease is to be attempted by the use of strong purgatives, and such remedies as act strongly on the stomach. A strong solution of purging salts will partly tend to produce this effect; and ten grains of ipecacuanha, given every three hours in a little warmed strong beer, is said to be attended with the most beneficial effects, when continued for five or six days together, and a dose of purging salts given after it, so as to clear the bowels. Calomel and soap may likewise be often given with great benefit, as well as some of the above saponaceous remedies.

YEMANA, or JEMAMA, in *Geography*, a country and city of Arabia, which M. D'Anville, probably misled by some map and uncertain accounts, places on a river called Altan, and which he represents as a stream in Nejed, though Niebuhr mentions it merely as a wadi or brook, which runs after rains. D'Anville says, that Jemama is in Al Kardjé, which is the grand province of Kerjé of Niebuhr, on the E. of Hedjaz and Yemen; and in this province, according to the Danish geographer, is the city of Amamé or Imamé, renowned for the prophet Moseilama, whom the historian Gibbon ascribes to Yemama, and which town is in the district of Surfa. But this cannot correspond with D'Anville's Jemama, which is in the province of Ared, bounded only by that of Lahfa on the E. Niebuhr also informs us, that Ajjana, a town of Ared, is remarkable for the new prophet Wahhab; and therefore Gibbon seems to have erred by supposing it to be the same with Yemama, the latter being probably a town of Kerjé, not far to the E. of Hedjaz. After all, the province and city of Jemama

are probably mere fictions, which should be excluded from the maps, together with the river of Altan, which, if it existed, would certainly be followed by the caravans from Lahfa to Mecca, while they seem to prefer a sandy desert. Pinkerton's Geography.

YEMBA. See EMBA.

YEMELLA, a town of Hindooftan, in Golconda; 24 miles N.E. of Rachore.

YEMEN, a province of Arabia, comprehending the finest and most fertile part of Arabia, representing, as Gibbon has observed, the Arabia Felix of antiquity, surrounded by the Red sea, or Arabic gulf, and by the province of Hadramaut, Nedsjed, and Hedsjas. Yemen is naturally divided into two parts, differing greatly in soil and climate: that bordering on the Red sea is a dry and sandy plain, nearly two days' journey in breadth, and is scorched by the most torrid heats; the other, extending immediately beyond this, is a high-lying country, full of precipitous yet fertile hills, and enjoying a much more temperate air. Yemen is, like the rest of Arabia, parcelled out among a number of different sovereigns in unequal portions. Some of them are princes of considerable power; but many are petty schieks, who are, however, perfectly independent: the most considerable of these princes is the imam, who resides at Sana. There are several other independent states, as Aden, Kaukeban, Kobail or Hafchid-u-Bekil, Abu-Arifch, a large district between Abu-Arifch and Hedsjas, inhabited by free Bedouins; Khaulan, Sahan, comprehending the principality of Saade; Nedsjeran, Kachtan, Nehhm, East Khaufan, Dsjof or Mareb, Jafa, and several others. The same intermixture of fertile and barren territory, and the same productions, appear every where through the whole province: the imam, however, seems to be master of the richest, the most agreeable, and the most interesting part of this tract of country. It would not be easy to explain distinctly the extents and limits of this sovereign's territories, as they are so interferred by the domains of a number of petty princes. The general division of Yemen into Tehama the Lowlands, and Djebal the Highlands, obtains in the imam's dominion as well as elsewhere. Upon this grand division depends the subdivision of the kingdom of Sana into thirty governments or counties. Tehama contains six of these governments, and the Highland country twenty-four: the small governments are not all alike populous or remarkable.

There are in the territory of the imam many schieks dispersed among the mountains, who acknowledge not his authority, and are but in a very slight degree dependent upon him. From the expulsion of the Turks in the year 1630, the reign of the imams began; their great ancestor Khallem Abu Mahomed was the chief author of that revolution. The throne of Yemen is hereditary; if generally approved of by the subjects, the eldest legitimate son of an imam is his rightful successor. But in the despotic governments of the East, indeed, no order can be closely observed, because there are no fundamental laws. The imam is an absolute prince, and the more so by uniting in his own person supreme authority, both spiritual and temporal, over his subjects. His jurisdiction in ecclesiastical matters, however, extends not over the dominions of other sovereigns of the same sect: these states have each a mufti, or cadi, for its spiritual use. Although the imam be absolute, he is checked in the exercise of his authority by the supreme tribunal of Sana, of which he is only president: this tribunal, consisting of a certain number of cadis, possesses the sole power of life and death. The imam may not order any of his subjects for execution, but such as have been condemned in consequence of a criminal prosecution before this court.

The cadis are generally esteemed to be persons of incorruptible integrity, of blameless lives, and devoted to the faithful discharge of their duties: they are not changed here so often as in Turkey, but hold their offices usually for life. Every petty district in the dominions of the imam has its governor: if not a prince, or one of the higher nobility, this governor is called wali and dola, or sometimes emir, when he happens to be a person of low birth. In every little town, a sub-dola, with a small garrison, consisting sometimes of five or six soldiers, resides to maintain order. The chief of a large village is a schiek; he of a small one a hakin. Every city in which a dola resides has also a cadi, dependent on the chief cadi of Sana; the cadi is sole judge in civil and ecclesiastical affairs, nor may the dola interfere to contradict his sentences, or render them inefficacious. The cadis in the provinces, no less than in the capital, are in high reputation for wisdom and integrity. The revenue of the imam is fluctuating and precarious; Niebuhr states it at about 500,000 crowns a month. This revenue arises from a land and poll tax, and from duties payable upon articles of merchandize. The military force consists ordinarily of 4000 infantry and 1000 cavalry. These armies use no artillery, nor do the Arabs know how to manage cannon. As the imam has no dread of enemies or corsairs upon the Arabic gulf, he has no occasion for a naval force; and his subjects are therefore generally unskilled in navigation. The fishermen venture far to sea in small canoes scarcely furnished with oars. The manufactures of a people of so little industry cannot but be very trifling: no sabres are manufactured in Yemen, nor any edged weapon, except a kind of crooked knives, called *jembes*. The making of match fire-locks has been attempted here within these few years: it succeeds but indifferently. It is only of late that glass works have been established at Mocha; some coarse cloth is manufactured here, but not so much as is required for the use of the country: broad cloths are neither made nor worn here. The English brought some goods of this sort to Mocha, but were obliged to carry them back to India unfold. A country which affords so few articles for sale cannot have a great trade. Coffee is almost the sole article exported from Yemen; a valuable commodity, in exchange for which many of those things which this country needs from abroad may well be obtained. All the commerce of Yemen is carried on by Mocha, except only that some small quantities of coffee are exported by Loheia and Hodeida. Agriculture seems to be farther advanced in Yemen than in the other parts of the East. Wheat, in the best cultivated districts, is said to yield an increase of fifty-fold; durra, in the Highlands, 140; and in the Tehama from 200 to 400: and the inhabitants of Tehama reap three successive crops from the same field in the same year. In many parts of Yemen, whole fields are cultivated like a garden, and watered in the rainy season by canals from the hills. The inhabitants of the plain are obliged to enclose their fields with dykes, that the water may remain for some time upon the surface of the ground. In the upper parts of Yemen, the inhabitants collect the water necessary for their fields in dams formed at the foot of the hills. In some districts of Yemen, maize and durra are planted with the hand. The husbandry of Tull and Du Hamel, says Niebuhr, although novel in Europe, is very old in Arabia. In order to guard their fields from depredation of birds and other destructive animals, the peasants watch them by turns. In the Highlands, he who watches seats himself on a tree; in the Tehama, on a sort of scaffold, with a roof raised over it. Niebuhr's Travels.

YEN, a river of China, which runs into the Hoang, 17 miles S.E. of Yen-tchang.

YEN-CHIN-TCHING, a town of China, in Chantong; 45 miles E.S.E. of Tci-nan.

YENDON, a river of England, in the county of Stafford, which runs into the Churnet.

YENGHI IMAN, a town of Curdistan; 70 miles S.E. of Kerkuk.

YENGI, a town of Corea; 25 miles N.E. of Kang.

YENISSEI, or YENISSEY, or *Eniffi*, a river of Russia, which the Tartars and Mongoles, who inhabit the superior regions of it, above the Tunguska, call Kem, and the Ostiaks, Gub or Kheses, signifying the Great river, and which is at first composed of two rivers, the Kamfara and the Veikom, originating in the Chinese Soongaria, or Bucharia, and forming a conjunction in N. lat. 51° 30', and E. long. 111°. About the mouth of the Bom-Kemtyhyug it enters on Russian ground, and hence first takes the name of Yeniffey. After various windings it turns northward, and in N. lat. 70', and E. long. 103° 30', forms a bay containing several islands; and at last, in 3° 30' of length, falls into the Frozen ocean. In autumn, when its water is at the lowest, its breadth, *e. gr.* at the town of Yeniffisk, is about 570 fathom, whereas in the spring it is 795 fathom and upwards. The coasts of the Frozen ocean, between the mouths of the Yeniffey and Oby, are called the Yuratzkoi fiore. The more considerable streams taken up by the Yeniffey are the following: on the right, the Ufs, the Tuban, the Kan, and the three Tunguskis, *i. e.* the Upper, the Middle, or Počkamenaia, and the Lower Tunguska; on the left, the Abakan, the Yelovi, and the Turukhan. In its superior regions, the Yeniffey flows over a very stony bed; and its shores, particularly the eastern, are mostly beset with lofty mountains and rocks. Its course is in general very rapid, though near its mouth it flows so gently, that the current is hardly perceptible. In the neighbourhood of Turukansk and elsewhere it forms some considerable islands; and between the cities of Yeniffisk and Krasnoyarsk several cataracts are to be seen. The Yeniffey is navigable from its mouth as far as Abakan, and affords abundance of the best fish. Near this river, as well as in some other steppes of Russia, are stone-tombs, which represent in rude sculpture human faces, camels, horsemen with lances, and other objects. Between this river and the Oby, or Ob, is a vast space extending from the north of Tomsk to the Arctic ocean, which is regarded as a steppe, being a prodigious level with no appearance of a mountain, and scarcely of a hill. The same term is applied to the wider space between the Yeniffey and the Lena, between the Arctic ocean in the N., and the river Tunguska, or Angara, in lat. 65°; and to the parts beyond the Lena as far as the river Kolyma or Covima. Tooke's *Ruff.* vol. i.

YENISSEISK, or ENISSEISK, a small town of Russia, in the government of Tobolsk, situated on the above described river, the forges of which yield a considerable tax to the Russian revenue. Its jurisdiction is extensive, and it pays annually a tribute in skins to the crown of Russia; 400 miles E.N.E. of Kolivan. N. lat. 58° 16'. E. long. 91° 50'.

YENITE, in *Mineralogy*, *Lieovite*, Werner, a mineral found in the island of Corfica, which from the great quantity of iron that it contains might properly be classed with the ores of iron. It is arranged by professor Jameson with the chrysolite family, but it differs greatly in the proportions of its constituent parts from all the other species which he has classed with this family. The appearance of this mineral resembles hornblende, or rather black epidote: VOL. XXXIX.

it occurs both crystallized and massive. The form of the crystals is that of a rhomboidal prism, the alternate angles of which measure about 113 and 67 degrees: the prisms are terminated by low four-sided pyramids, the faces of which are set on the lateral planes of the prism. It is also crystallized in rectangular prisms, bevelled on the extremities, and the bevelling planes set on the obtuse edges. These figures are also variously modified by the edges or angles being bevelled. The crystals are sometimes very minute or acicular, and sometimes half an inch in thickness; they are frequently aggregated in diverging radii, and sometimes imbedded. The prisms are striated longitudinally. The structure is imperfectly lamellar, with joints parallel to the sides, and to the short diagonal of the rhomboidal prism. The fracture of yenite is uneven, and imperfectly conchoidal, with a lustre between vitreous and resinous. The colour is black passing into brown; it does not change its colour in the streak. The hardness of yenite is about equal to that of common feldspar; it is easily frangible. The specific gravity of yenite varies from 3.825 to 4.061.

It is fusible with ease by the blow-pipe into a black glass, which has a metallic aspect, and is attracted by the magnet, but does not possess polarity; it dissolves with borax with a slight ebullition. It is acted upon by the mineral acids, but does not gelatinize with them. When exposed to heat it becomes magnetic. Its colour is changed by heat from black into dark reddish-brown, and it loses about two per cent. of its weight.

The constituent parts of yenite are,

Silex	-	from	-	28	to	30
Alumine	-	-	-	1	-	1
Lime	-	-	-	12	-	14
Oxyd of iron	-	-	-	51	-	58
with manganese	}	-	-			

Yenite decomposes gradually on exposure to the air, and is reduced to a yellowish-brown ochre. According to Brongniart, yenite occurs in dispersed crystals and groups, and in compact kidney-shaped masses, in a thick bed of a greenish substance nearly resembling yenite, but which has not been accurately examined. It is accompanied with epidote, quartz, and arsenical pyrites. This bed at Rio la Marino, in Corfica, covers a rock of primitive marble mixed with talc. At the Cap de Calamite, it is accompanied with magnetic iron-stone, garnets, and quartz.

YEN-KING, in *Geography*, a city of China, of the second rank, in Pe-tche-li; 52 miles N.N.W. of Peking. N. lat. 40° 30'. E. long. 125° 30'.

YENLADE, or STRAY, a channel between the Thames and Medway, which separates the island of Grain from the coast of Kent. It was formerly the usual passage for vessels to and from London.

YENNE, a town of France, in the department of Mont Blanc, near the Rhône, supposed to be the ancient Epanna, where Sigismund, king of Burgundy, assembled a council at the end of the fifth century; 14 miles N.W. of Chambery.

YEN-NGAN, a city of China, of the first rank, in Chen-fi, on the river Yeu; 390 miles S.W. of Peking. N. lat. 36° 44'. E. long. 108° 49'.

YEN-PING, a city of China, of the first rank, in Fokien; 820 miles S. of Peking. N. lat. 26° 40'. E. long. 117° 54'.

YEN-TCHEOU, a city of China, of the first rank, in Tche-kiang. Near this town are mines of copper, and trees that yield varnish, which give a value to the cabinet-work so much esteemed in Europe; when this varnish is once dry, it never melts again, and will bear boiling water.

The paper manufacture of this place is in equal esteem, and for which they have a great demand. Six towns of the third order are under its jurisdiction; 650 miles S.S.E. of Peking. N. lat. 29° 38'. E. long. 119° 14'.—Also, a city of China, of the first rank, in Chan-tong. The territory depending upon this capital is inclosed between two considerable rivers, which abound with fish, and make the soil very fruitful. The country is very well cultivated, the mountains are covered with woods, and the air is mild and temperate. There are twenty-seven towns within the jurisdiction of this capital; four of the second order, and twenty-three of the third; 267 miles S. of Peking. N. lat. 35° 44'. E. long. 116° 36'.

YENTCHERU, a town of Hindoostan, in the circuit of Cuddapa; 20 miles N.N.E. of Comban.

YEN-TCHING, a town of China, in Chan-tong, where a peculiar species of glass is manufactured, of so delicate a nature, that it will not endure the inclemency of the air; 45 miles S.E. of Tei-nan.

YEO. See YEovil.

YEOMAN, the first or highest degree among the plebeians of England; next in order to the gentry.

The yeomen are properly the freeholders, who have land of their own; so called from the Saxon *gemane*, or *geman*, common.

The word *youngman* is used for yeoman in the statute 33 Hen. VIII., and in old deeds it is sometimes also written *jeman*, which, in the German, signifies *any-body*.

According to Sir Thomas Smith, a yeoman is a free-born Englishman, who can lay out of his own free land in yearly revenue to the sum of forty shillings sterling.

The yeomanry of England are capable of holding lands of their own to a good value; are adjudged capable of certain offices, as constables, churchwardens, jurymen; and are also to vote in elections to parliament, and to serve in the army, and to do any other act where the law requires one that is *probus et legalis homo*.

The yeomen were famous, in ancient times, for military valour, being particularly expert at the management of the bow; whence the infantry was composed chiefly of them.

They frequently constituted the body-guard of our kings; and in process of time gave rise to the institution of *yeomen of the guard*.

In many cases, the law conceives a better opinion of the yeomanry that occupy lands, than of tradesmen, artificers, &c.

By a statute, 2 Hen. IV., it is enacted, that no yeoman shall take or wear a livery of any lord, upon pain of imprisonment, and a fine at the king's pleasure.

YEOMAN is also a title of office in the king's household, of a middle place or rank between a gentleman and a groom. Such are the yeoman of the buttery; yeoman of the scullery; yeoman of the wine-cellar, ewry, wood-yard, &c. There are also the yeoman of the mouth, yeoman of the kitchen, yeomen-porters, &c.

YEOMAN, in *Sea Language*, an officer under the boat-swain or gunner of a ship of war, usually charged with the stowage, account, and distribution of their respective stores.

YEOMEN-Warders. See WARDERS of the Tower.

YEOMEN of the Guard, properly called *yeomen of the guard of the king's body*, were anciently a body of men of the best rank under gentry, and of larger stature than ordinary; every one being required to be six feet high.

Their number has varied in almost every reign, and formerly consisted of a certain number in ordinary, and an

indefinite number extraordinary; and in case of a vacancy in the former, it was supplied out of the latter number. In the reign of king Edward VI. this corps was very numerous. In the reign of queen Elizabeth, the yeomen attending her in her different progresses were occasionally mounted. In the reign of queen Anne, the arms of half this band were arquebuses, which are said by Chamberlain to have been disused ever since the reign of king William; the other half had partisans, and those of both classes had swords. They had their wages and diet allowed them; so that in a MS. of the expences of the royal establishment for the year 1727, the charges of the table of the yeomen of the guard were 273l. 15s. But their diet has been discontinued since that reign. Their duty was to wait upon the queen in her standing-houses; forty by day, and twenty by night. At St. James's, they waited in the first room above stairs, called the guard-chamber. It is also their duty to attend the foreveign abroad by land or water.

At present there are but one hundred yeomen in constant duty, at 39l. 11s. 3d. per annum each; eight of whom are called *ufhers*, who have 10l. per annum each more than the other yeomen; six are called *yeomen hangers*, and two, yeomen bed-goers, who have the same pay as the *ufhers*; and seventy more not on duty; and as one of the hundred dies, his place is supplied out of the seventy.

The officers are, a captain, who has 1000l. per annum; a lieutenant, at 500l. per annum; an ensign, at 300l.; and four exons, at 150l. per annum each; and a clerk of the checque at the same salary.

Their origin is traced to the year 1485, when king Henry VII. ascending the throne, immediately after his coronation, instituted a guard of fifty archers to attend him and his successors. They were probably then, as they are now, called the *yeomen of the guard*.

It is observed, that this is the first instance of any established or permanent military guard in England; its kings, till that time, except in times of war and infurrection, contenting themselves with the guard of their proper domestics and retinue. And. Hist. Com. vol. i. p. 302.

Most of the writers, however, against standing armies commence that establishment with the sergeants at arms, who were first instituted by king Richard I. Their dress is that which was worn in the reign of king Henry VIII., and which on many occasions was put on by that king; it consists of a scarlet coat reaching down to the knees, guarded with garter blue velvet, and with badges of the rose and crown on their breasts and backs; their breeches also are scarlet, guarded with blue velvet; their caps are of black velvet, with broad round crowns, adorned with ribbands of the royal colours, viz. red, white, and blue.

The officers and yeomen are at the disposal of the captain; but the captain is at the appointment of the king.

YEOMAN of the Salt Stores. See ACATERY.

YEOMANRY CAVALRY, a denomination given to those troops of horse which were levied in the late war among the gentlemen and yeomen of the country, upon the same principle with the volunteer companies. The yeomanry cavalry were to be allowed pay when called out on actual service, and each corps was liable to be put upon duty within its district: all contingent expences, properly and unavoidably incurred, were to be reimbursed after an investigation at the war-office. One serjeant and a trumpeter per troop were to have constant pay, with the same allowances as serjeants and trumpeters of regular cavalry. Some accoutrements were to be furnished by the ordnance, or an equivalent

equivalent in money to be given in lieu of them, and 14s. 2d. per man for holfers.

YEOVIL, in *Geography*, a large and populous market-town in the hundred of Stone, county of Somerfet, England, is fituated on the confines of the county, at the diftance of 9 miles S.S.E. from Somerton, and 122 miles W.S.W. from London. It derives its name from the river Yeo, which rifes near Sherborne, and paffes this place under a ftone bridge of three arches, feparating the counties of Somerfet and Dorfet. The town of Yeovil confifts of upwards of twenty ftreets and lanes; many of the former are of confiderable width: the houfes in general are refpectable, and many of them are built of ftone. Part of the town is called the Borough, and is governed by a portreeve and eleven burgefles, out of whom the portreeve is annually chofen. Here is a fpacious market-houfe, feventy feet in length, and twenty in breadth, fupported by ftone pillars, in the centre of which are the remains of an ancient crofs. A confiderable market is held on Fridays for corn, cattle, pigs, butter, cheefe, and flax: here are alfo two annual fairs. The woollen trade was formerly extenfive here, but has decreased: the chief bufinefs of the town is the manufacture of leather gloves. In the return of the year 1811, the population of this parifh was eftimated at 4118; the number of houfes at 459. The church, a large ancient ftucture, confifts of a nave, chancel, two aifles, and tranfep: the length of the whole is 146 feet; the breadth 50. At the weft end is a plain tower, ninety feet high, with a ftone balustrade at the top. Diffenters have feveral meeting-houfes in the town. Here is an alms-houfe, founded in the year 1476, by the Rev. Mr. Woburne, minor canon of St. Paul's, London, and by him endowed with confiderable landed property for the maintenance of a mafter, two wardens, and twelve poor perfons of either fex. He alfo built a chapel for the ufe of his poor, and ordained divine fervice to be performed in it every day.—Collinfon's *Hiftory of Somerfetshire*, vol. iii. *Beauties of England and Wales*, vol. xiii. Somerfetshire.

YEOUNGBENZAII, a town of Birmah, on the Irawaddy; 36 miles N.N.W. of Rangoon. N. lat. 17° 30'.

YEOU-TUN-OUEI, a town of Chinefe Tartary. N. lat. 41° 8'. E. long. 121° 9'.

YEOU-YU, one of the fmall iflands in the Chinefe Archipelago; 62 miles S.W. of Macao.

YEOWAH, a town of Birmah; 15 miles S. of Pegongmew.

YEPES, a town of Spain, in New Caftile; 17 miles E. of Toledo.

YERAPATTA, a town of Hindooftan, in Myfore; 8 miles S. of Dalmacherry.

YERCO, a town of Thibet; 90 miles S.E. of Laffa.

YERE, a river of France, in the department of the Lower Seine, which runs into the Englifh Channel, at Eu.

YERGHIEEN. See **YARKAN**.

YERK, in *Horfes*, a term fignifying to ftrike out backwards. A horfe is faid to yerke, or ftrike with the hind legs, when he flings and kicks with his whole hind quarters, ftriking out the two hinder legs near together, and even to their full extent. Horfes of this fort are very dangerous, and fould be parted with as foon as poffible, whether they are of the farm or the faddle kind.

YERKIE, in *Geography*, a town of Ruffia, on an ifland at the mouth of the Volga, where veffels take their departure for the Cafpian fea. Here fhips formerly entered and cleared, but the ifland is now almoft overflowed, and the

trade of the place much decayed fince 1747; 60 miles S. of Aftrachan.

YERMA. See **JERMAH**.

YERMUK. See **YARMUC**.

YERTNAGOODAM, a town of Hindooftan, in the circar of Rajamundry; 17 miles S.W. of Rajamundry.

YERVA-MORA, in *Botany*. See **BOSEA**.

YERVILLE, in *Geography*, a town of France, in the department of the Lower Seine; 12 miles N.N.E. of Caudebec.

YESCOKING CREEK, a river of North Carolina, which runs into Pamlico found, N. lat. 35° 29'. W. long. 76° 14'.

YESD. See **YEZD**.

YESD, a town of Perfia, in the province of Larifan; 40 miles N. of Lar.

YESDECAST. See **JEZDKAST**.

YESID, a town of Perfia, in the province of Chufifan, or Kuzifan; 18 miles N. of Toftar.

YEST. See **YEAST**.

YETCHERADAW, in *Geography*, a town of Hindooftan, in Myfore; 9 miles E. of Rydroog.

YETEOPAUKE, a town of Hindooftan, in the circar of Cicacole; 15 miles S.W. of Coffimcootta.

YETHAN, a river of Scotland, which runs into the German fea, 10 miles N. of Aberdeen.

YETHOLM, or **ZET-HAM**, a market-town in the diftrict of Kelfo, and fhire of Roxburgh, Scotland, is fituated nine miles S.E. from Kelfo, on the fmall river Bowmont, which divides it into two parts, refpectively named Town Yetholm and Kirk Yetholm. A weekly market is held on Wednefdays; and two fairs annually. Many tinkers and gypsies refide in this town. The parifh extends about four miles in length, and two in breadth; and is bounded on the eaft and fouth by the Englifh border. The furface is hilly, but the hills are covered with verdure, and pafured by a very confiderable number of fheep. In the population return of the year 1811, this parifh is ftated to contain 213 houfes, and 1138 inhabitants. King Robert III. granted the barony of Yetholm in the fourteenth century to Archibald Mac Dougal, whose defcendant ftill enjoys it.—*Carliffe's Topographical Dictionary of Scotland*, 1813.

YETTUS, in *Natural Hiftory*, a name given by the writers of the middle ages to a fpecies of marble of a deep red, which was ufed by fome as a touch-ftone.

YEU, in *Geography*, a fmall and insignificant ifle, fituated on the W. coaft of France.

YEVA CHARREM, in *Natural Hiftory*, a name given by the people of the Eaft Indies to a kind of litharge, which is very common in that part of the world, and is faid to be made partly from lead and partly from zinc.

It is lefs heavy than our yellow litharge, and of a paler colour. It is ufed as a cauftic in all the occafions of furgery there.

YEVERING, in *Geography*, a village of England, in the county of Northumberland, where the Scots were defeated in 1415, by fir Robert Humpreuil and the earl of Weftmoreland. Near it is a mountain called Yevering Bell, belonging to thofe called Cheviot; 6 miles W.N.W. of Wooller.

YEULA, a town of Hindooftan, in Baglana; 5 miles E. of Bahbelongh.

YEVRE LE CHATEAU, a town of France, in the department of the Loiret; 6 miles S.E. of Pithiviers.

YEW, or **EUGII**, in *Botany*. (See **TAXUS**.) De Theis traces thefe Englifh words, whose antiquity cannot be

doubted, to the Celtic *If* or *Iaw*, green, alluding to the evergreen foliage of this tree. The French have retained *If* unaltered to the present day.

Yew, as some say, may be derived from the Greek *ἰστύω*, *to hurt*; and probably because before the invention of guns our ancestors made their bows of this wood: they therefore took care to plant the trees in the church-yards, where they might be often seen and preserved by the people.

Yew is also a term used by the salt-workers of Lymington, and some other parts of England, to express the first rising of a scum upon the brine in boiling.

In the places where they use this term, they add no clarifying mixtures to the brine, for it ferments in the cisterns, and all its foulness sinks to the bottom in form of a thin mud; they admit only the clear liquor into the pan, and boil this briskly till it yews, that is, till a thin skin of salt appears upon its surface; they then damp the fire, and carefully skim off this film, and clear only the scum or calcareous earth, which separates to the bottom.

They do not collect this into scum-pans, as at many of the other works, but they rake it up to one side of the pan, and take it out; they there add a piece of butter, and continue the fire moderately strong till the salt is granulated. They keep a brisker fire on this occasion at Lymington than in most of the other works; so that they will work three pans in twenty-four hours. See **SALT**.

YEW-TREE, in *Agriculture and Rural Economy*, a well-known evergreen tree, the timber of which is much esteemed for different uses and purposes in husbandry, and where toughness, elasticity, and durability, are required.

Trees of this sort may be easily propagated, in most cases, by sowing their berries when divested of the pulp in autumn, as soon as they are ripe, upon a bed of fresh undunged soil, either over the whole or in drills, covering them over about half an inch thick with the same earth; but the latter is the better mode. In the spring, the bed must be carefully cleared from weeds, and if the season prove dry, it will be proper to refresh it with water now and then, which will promote the growth of the seeds; many of which will come up the same spring, but others will remain in the ground until autumn or spring following; but when the seeds are preserved above ground till spring before they are sown, the plants never come up till the year after, so that by sowing the seeds as soon as they are ripe there is often a whole year saved.

The plants, when they come up, should be kept constantly well cleared from weeds, which, if permitted to grow amongst them, would cause their bottoms to be naked, and frequently destroy the plants when they continue long undisturbed.

In this bed, the plants may remain two years; after which, in autumn, there should be a spot of fresh undunged soil prepared, into which they should be removed about the beginning of October, planting them in beds about four or five feet wide, in rows about a foot asunder, and six inches distant from each other in the rows, observing to lay a little litter or mulch upon the surface of the ground about their roots, as also to water them in dry weather until they have taken root; after which they will require no farther care, but to keep them clear from weeds in summer, and to train them according to the purpose for which they are designed, — for timber in a straight manner.

In these beds they may remain two or three years, according as they have grown, when they should again be removed into a nursery, placing them in rows at three feet distance, and the plants eighteen inches asunder in the rows,

observing to do it in the autumn, as before directed, and continue to trim them in the summer for what they are intended; after they have continued three or four years in this nursery, they may be transplanted where they are to remain, always observing to remove them in autumn where the ground is very dry; but on cold moist land it is better in the spring.

These trees are very slow in growing, but there are many very large trees upon some barren cold soils.

It is observed in the Gloucestershire Report on Agriculture, that the yew-tree should not be suffered to grow in or near cow-pastures. The leaves are poisonous to horned cattle and horses, though the berries are esteemed inoffensive. In January 1805, in consequence of some fences being broken down by a violent wind during the night, a number of cows belonging to a farmer in Sandhurst entered an inclosed shrubbery, where there were many yew-trees growing, and continued in it till the morning. Soon after they were driven out, all of them were seized more or less with a kind of madness, or such acute pains as made them run about in a very furious manner, sometimes leaping to a considerable height, then beating their heads against whatever opposed them, and at last falling instantly dead. Oils of different sorts were poured down their throats, as there was an opportunity of securing them, which seemed to produce a good effect on some; and notwithstanding every effort, nine out of thirty died in a few hours after they were discovered. On their being opened, it appeared that the whole quantity they had eaten, put together, would not have filled a peck.

An opinion prevails, that the leaves are not poisonous in the summer: this, however, is probably erroneous, at least it is not confirmed sufficiently by fact to justify the farmer in subjecting his cattle to the experiment. If cattle come within reach of the yew-tree at that time of the year, they may perhaps reject it altogether, giving the preference to other green food, more palatable, and in plenty around them.

These trees should therefore in all cases be carefully kept out of the hedge-rows and all other parts of fields, where cattle are suffered to feed and pasture.

YEYEAPOUR, in *Geography*, a town of Hindoostan, in Lahore; 16 miles S. of Nagorcote.

YEZD, or **YESD**, a large and populous city of Persia, situated in a sandy desert, contiguous to a high range of mountains running nearly E. and W. This is the grand mart between Hindoostan, Bucharia, and Persia, and is, therefore, a place of considerable trade. The bazaar is well supplied, and the city contains 20,000 houses; besides those of the Guebres, or worshippers of fire, which are estimated at 4000. The Guebres were an industrious people, but are greatly oppressed, being taxed at twenty piastres a-head, in addition to the various other exactions of the Persian government. Many opulent Hindoos formerly resided here; but the late governor, wishing to enrich himself by plundering their property, they all fled in one night towards Candahar, where they have since established themselves. The present khan has, in vain, endeavoured to recall them, and there are now only nine Hindoos in Yezd. The city imports the greatest part of its corn from the neighbourhood of Ispahan. Cattle are also scarce, and an ass will sometimes sell as high as fifty tomanis. The manufacture of silk stuffs is superior to any in Persia; and the numuds or thick felts of Tuft, a small village, distant eight miles, are equally famous. The fort of Yezd has but a mean appearance; and the town is destitute of a wall. That

That territory which lies between Yezd and Ispahan is the most arid part of Irak. The soil is poor, light, and sandy; and here is a general scarcity of wood and water; the climate also is hot, though not unhealthy. The small towns of Ardistan, Nain, Aujdah, Mynboot, and Sezdabad, are badly built, and contain from 100 to 200 houses each. M'Kinneir's *Perfia*.

YEZDEGERDIC YEAR, in *Chronology*. See **PERSIAN Year**.

YEZDICAN, in *Geography*, a river of the Persian empire, in the province of Azerbaijan, which has its source about 60 miles to the E. of the lake of Van, and which, pursuing a N.E. course, passes under the walls of Yezdican and Kurs, and meets the Araxes a little to the N. of Nuchthivan.

YEZEDI, the name of a Persian sect, of which several tribes inhabit the mountains of Sinjar, about eight or ten miles from Nisibis. They are numerous in the vicinity of Mosul, and are said to worship, or rather deprecate, the devil, entertaining an idea that he possesses an unlimited power over mankind. They even dislike to hear the name of the evil spirit mentioned in their presence. They are the descendants of those Arabs who followed the banners of Yezid, and fought against Houssein, in the battle of Kerbela; and scheik Ade, the founder of the sect, is interred near Mosul. They adore one Supreme Being as the creator and benefactor of the human race, drink wine and other strong liquors, and circumcise like the Mahometans. The Yezedi are hated by the Turks, to whom they are mortal enemies, and who have never been able to subdue them. They lie in ambush behind the rising grounds which skirt the road between Mosul and Merdin; and as travellers are obliged to pass a lonely wild, twenty furlongs in length, they are liable, if not numerously attended, to be murdered by these miscreants. Sinjar affords abundance of pasturage, and also yields a sufficient quantity of grain for the consumption of its savage inhabitants. M'Kinneir's *Perfia*.

YFFINIAC, a town of France, in the department of the North Coasts; 6 miles S.E. of St. Briec.

YGEA, a town of Spain, in Old Castile; 12 miles S. of Calahorra.

YGGEDE, or **UGGADE**, in *Ancient Geography*, a place of Gallia Lyonnensis. Anton. Itin.

YGIN, in *Geography*, a town of Corea; 28 miles S.S.W. of Haimen.

YGRMETER. See **HYGROMETER**.

YGUALADA, in *Geography*, a town of Spain, in Catalonia; 28 miles N.W. of Barcelona.

YGUISAN, a small island among the Philippines, near the north coast of Panay. N. lat. $11^{\circ} 35'$. E. long. $122^{\circ} 32'$.

Y-HO, a river of China, which rises in Chan-tong, and runs into the Hoang, near Sou-tcheou, in the province of Kiang-nan.

YIAN-CHAN, a town of Corea; 28 miles E. of Hetfin, or Etfin.

YICHKENISHI, one of the smaller Western islands of Scotland; 1 mile N. of Benbecula.

YIELD or *Slack the Hand*, in the *Manage*. See **SLACK**.

YIELDING and Paying, a law phrase, formed by corruption from the Saxon *geldan*, or *gildan*, to pay. Hence, in Domesday, *gildare* is frequently used for *solvere*, *reddere*; the Saxon *g* being easily converted into a *y*. See **GELD**, and **GILD**.

YIETI, in *Geography*, a town of South America, in the province of Paraguay; 120 miles S.E. of Assumption.

YIN, a word used by some of the chemical writers to express verdigrise.

YISSER, in *Geography*, a river of Algiers, anciently called Serbetis, which runs into the sea at Jinnett.

YKINA, a town of Sweden, in the province of Finland; 45 miles N. of Biorneborg.

YLANE, a town of Sweden, in the government of Abo; 27 miles N. of Abo.

YLAY. See **LLA**.

YLLIGAN, a town on the north coast of Mindanao.

YLIKANNUS, a town of Sweden, in the government of Wafa; 24 miles E.N.E. of Gamla Karleby.

Y-LIN, a city of China, of the second rank, in Hon-quang; 617 miles S.S.W. of Peking. N. lat. $30^{\circ} 52'$. E. long. $110^{\circ} 44'$.

YLISTARO, a town of Sweden, in the government of Wafa; 24 miles E.N.E. of Wafa.

YLIVIESKA, a town of Sweden, in the government of Ulea; 38 miles S. of Ulea.

YLO, or **ILO**, a sea-port town of Peru, in the diocese of Arequipa, situated near the mouth of a fresh-water river of the same name, which is dry from the beginning of October to January; 25 miles W. of Moquegna. S. lat. $17^{\circ} 38'$.

YLIST. See **LIST**.

YLU M OE, a small island of Denmark, in the Little Belt. N. lat. $55^{\circ} 8'$. E. long. $10^{\circ} 7'$.

YLWISKA, a town of Sweden, in East Bothnia; 28 miles S. of Brahestad.

YNATILAN, a town on the west coast of the island of Sibiu. N. lat. $10^{\circ} 21'$. E. long. $123^{\circ} 22'$.

YNCA, **YNCAN**, or **INCA**, an appellation anciently given to the kings of Peru, and the princes of their blood; the word signifying literally, *lord, king, emperor, and royal blood*.

The king himself was particularly called *capac ynca*, i. e. great lord; his wife, *pallas*; and the princes simply *yncas*. These yncas, before the arrival of the Spaniards, were exceeding powerful. Their people revered them to excess, as believing them to be sons of the sun, and never to have committed any fault. If any person offended the royal majesty in the smallest matter, the city he belonged to was totally demolished.

When they travelled, whatever chamber they lay in on the road was walled up as soon as they departed, that nobody might ever enter in after them. The like was done to the room in which the king died; in which, likewise, all the gold, silver, and precious furniture, were always immured, and a new apartment was built for his successor.

His beloved wives, domestics, &c. likewise sacrificed themselves, and were buried alive in the same tomb along with him. See the History of the Yncas, by Garcilasso de la Vésia. See also **INCA**.

YNG, or **YN**, in *Geography*, a city of China, of the second rank, in Chan-fi. N. lat. $39^{\circ} 40'$. E. long. $112^{\circ} 49'$.

YNIESTA, a town of Spain, in New Castile; 20 miles S.E. of Alarcón.

Y-NING, a town of Corea; 33 miles E.N.E. of Tfin-tcheou.

Y-N-PING, a town of Corea; 38 miles S.W. of Koang-tcheou.

Y-N-TCHENG, a town of Corea; 25 miles E. of Ou-tchuen.

YN-YUEI,

YN-YUEI, a city of China, of the second rank, in Yun-nan; 1300 miles S.W. of Peking. N. lat. 25° 58'. E. long. 98° 24'.

YOAK, in *Agriculture*. See YOKE, and YOKING.

YOAK, *Jugum*, in *Antiquity*. The Romans made the enemies they subdued pass under the yoke, which they called *sub jugum mittere*; that is, they made them pass under a sort of furca patibularis, or gallows, consisting of a pike, or other weapon, laid across two others planted upright in the ground. This done they treated them with humanity enough, and sent them home again. See FURCA.

The same measure was sometimes dealt them by their enemies upon the same occasion. Thus Cæsar (lib. ii.) observes, that the consul L. Cassius had been killed by the Swifs, and his army defeated, and made to pass under the yoke.

YOAK of Land, *jugata terra*, in our *Ancient Customs*, was the space which a yoke of oxen, that is, two oxen, may plough in one day. See HIDE, YARD-Land, &c.

YO-CHIN, in *Geography*, a town of Corea; 10 miles N.E. of Han-tcheou.

YOCKLET. See JOCKLET.

YOCOM CREEK, in *Geography*, a river of Virginia, which runs into the Potomack, N. lat. 38° 6'. W. long. 76° 36'.

YOCOTE, a town of Hindoostan, in Dowlatabad; 27 miles S.S.W. of Mahur.

YOGESWARA, in *Hindoo Mythology*, a name of the Hindoo god Siva; which see. It means lord of ages, or of time; yug, or yog, being vast periods of time into which Hindoo chronologists arrange the past. The addition of Iswara, the powerful, a name of Siva, seems to give a satisfactory derivation. (See ISWARA.) For an account of those periods, see JOGUES. Some have derived the name of Yogeswara from lord of Yogis, supposing the sect of fancified beggars so designated as being more immediately under the protection of Siva; but this is in fact nearly the same thing, for yog signifies union or junction, and these periods of time re-unite all things in the Deity; and the Yogi by intense contemplation effects a similar union. But this metaphysical dogma cannot be explained here. See KALPA, YOGI, and YUG.

YOGI, a description of wandering fairs, much respected by many of the natives of India, though by others they are strongly suspected to partake more of the impostor than the enthusiast. There are many descriptions of these itinerants among the Hindoos; and we are not aware that the distinctions between them have been accurately pointed out. The appellation Yogi means a devout man, devoted to spiritual things, especially to the contemplation of the attributes of the Deity. It is derived from yog or yug, which, among very many significations, means primarily union or junction, and is applied in this sense to one who by intense meditation is united to the divine nature; a mysticism easily understood by the initiated and enthusiastic Hindoos, though not recognizable by others. There is a difference, we believe, between the Yogi and Sanassy, but we cannot exactly say in what it consists. In the latter part of the article SECTS of Hindoos, some particulars of these two will be found. Perhaps the Yogi may be the designation of the Vaisnava, and Sanassy of the Saiva sect. (See SAIVA, VAISHNAVA, and YOGESWARA.) Both profess poverty, purity, and austerities. When the latter are carried to any extent, the zealot is honoured with the title of Tapaswi, of whatever sect he be. Of such, and their austerities, see under TAPAS. We sometimes read of female anchorites denominated Yogni; but they are, we believe, merely enthusiastic females, who become ascetics and not

the wives of the fancified males. Among the oriental manuscripts presented to the Royal Society by sir W. Jones, is one entitled "Hatha Pradipaca, or Instructions for the Performance of the religious Discipline called Yoga."

In the Gita, Krishna describes the Yogi as being "more exalted than the Tapaswi, the zealot who harasses himself in performing penances: he is respected above the learned in science, and superior to those attached to moral works." This passage is quoted in the latter part of our article SECTS of Hindoos, but being erroneously pointed it scarcely intelligible. This article being thence referred to, we take the opportunity of correcting another error or two in it:—In the second column, the name of the Mahratta Brahman general, Purferam Bhow, is twice spelled Bhon; in the fifth column, the name of Vopadeva, the author of the Sri Bhagavata, is spelled Vapadeva; in the next column, line 21 from the bottom, a comma is wanted after Krishna. Having referred above to the article TAPAS, we will here correct an error in that also:—In second column, line 11, for inflexions read inflections.

YOHOGANY, in *Geography*. See YOUGHIOGENY.

YOIDES, in *Anatomy*, the bone of the tongue, commonly called hyoides. See HYOIDES.

YOLNGT, or JOINGT, in *Geography*, a town of France, in the department of the Rhone and Loire; 7 miles E. of Roanne.

YOITSBACH, a river of Silesia, which runs into the Queis, near Friedberg.

YOKE, in *Agriculture*, a frame of wood hollowed out and lined for receiving the neck part of the ox or other cattle in working. Yokes are constructed in different manners, as single and double, in order to be used differently. They are fixed with bows over the necks of the oxen or other cattle when in use; by which means, in the latter sort, the two animals are coupled together, and attached to the plough or other vehicle. See YOKING.

YOKE, in *Sea Language*, a name formerly given to the tiller, when communicating with two blocks or sheaves affixed to the inner end of the tiller. It is now applied to a small board or bar which fits on the upper end of a boat's rudder at right angles, and having two small cords extending from its opposite extremities to the stern-sheets of the boat, by which she is steered as with a tiller.

YOKED LEAF, in *Botany*, *folium conjugatum*, or *bina-tum*. See LEAF.

YO-KEOU, in *Geography*, a town of Corea; 38 miles S. of Haimen.

YOKING, in *Agriculture*, the practice of putting the animals into the yoke or other sort of team.

In the business of yoking or harnessing oxen for the purpose of draught, different methods have been followed by different farmers. And the modes of harnessing and yoking oxen are even different in different counties, and districts of the same county. The most common practice in the southern parts of this kingdom, is that of working them in harness in the manner of horses; while in the northern counties, the yoke and bows are still much employed. On the continent, as in France, Portugal, &c. the head is the part to which the draught is chiefly attached.

In the first case, the shoulder is made the principal point of draught; but in the second method, the neck and shoulder conjointly have the weight of the draught; and in the last mode, the principle of draught is, in one case the head, and in the other the joint power of the neck and hafe of the horn, which lord Somerville has considered a purchase as great perhaps as can be given to the animal.

It is "effected by a long leathern strap, wrapped round the

YOKING.

the base or bottom of the horns, and again fastened to the yoke." It has been observed by a writer in the ninth volume of the *Agricultural Magazine*, that with respect to the second method which has been noticed above, the "usual form of the yoke is a frame of wood fitted over the necks of the oxen, by which they are coupled, and harnessed to the plough. It consists of several parts, as the yoke properly so called, which is a thick piece of wood, lying over the neck; the bow, which compasses the neck about; the fittings and wreathings, which hold the bow fast in the yoke, and the yoke-ring and ox-chain," which is supposed "a method which is evidently founded on a total mistake in the anatomy of the ox."

And that in the first we have "imitated the gear used with the horse, without considering that the strength and agility of the ox are placed by nature in a different situation. The neck of the ox is a tower of strength; if the soil resist, he projects this part of his form with that prodigious muscular force with which nature has provided him for his own defence; but without attending to his operations, we impose a load of timber on his withers, we lacerate his flesh, and press him down to the earth."

The third or French mode of yoking is thus described in the words of Mr. Hughes. "The labourer passes a piece of wood, of about one-sixth of the weight of the English yoke, across the forehead of his cattle, having previously neatly hollowed out the extremities of it to fit the mould of the head, and lined those hollows with a piece of woolly sheep-skin, to answer the purpose of a soft pad or cushion. This light and easy yoke he braces to the horns with a small thong of leather, attaches the beam of his plough to the middle part of it, and the animal is completely equipped for his labour."

It has been observed by lord Somerville, in his *System of the Board of Agriculture*, that oxen, "whether worked in harness, or in the yoke and bow, as in England, by the joint power of the yoke and horn, as in Portugal, or by the head, as in France, they cannot fail to benefit their employer. As, however, the yoke and bow have prevailed for a considerable length of time, it is probable that the practice may still prevail, in which case the Portuguese mode of draught will apply with the utmost ease and success to our yoke and bow, so as gradually and imperceptibly to cheat oxen into its use. This in itself is an obvious advantage, because it gives two points of draught instead of one, and thereby relieving each admits of a lighter yoke, which in this country has ever been far too heavy and oppressive; and if hereafter the French method should be preferred, for which there are not wanting advocates, it is the best preparatory step to its introduction. It would be almost superfluous to remark that the strong points of an ox are in his head and neck. It is ordained by nature, that where the strength of an animal lies, there he will resort for defence; the horse to his heels, the man to his arms, and the ox to his head; and in cases of the greatest exertion, the beast ever puts his nose close to the ground."

In objection to the harnessing of oxen, it has been observed in the paper noticed above, that "the article of gear is an oppressive annual charge, from the perishable nature of the commodity employed. The tackle there recommended for twelve oxen would not amount to six-and-thirty shillings, whereas the leathern harness for the same number of animals, according to the new method, would cost six-and-thirty pounds, and the annual expence of repairs would exceed thrice the original cost of the former." And that "by the French mode of yoking, at least one-third more of the power of the animal is obtained. In the common way, the

shoulder being bruised by the unyielding bow, no vigour is exerted, excepting what is imparted by the goad; and the fineness of the neck are not brought into employment: hence the sublime and gigantic force with which he is endowed is not rendered subservient in the important duties he has to perform for the supply of human subsistence. The cattle proceed in the French team bold and erect: no pain oppresses them, and they chew the cud cheerfully as they pace along the furrow. On the contrary, in this country the painful pressure obstructs the progress of the animals, they lean against each other, scarcely capable of supporting their own weight, and the fine intelligent eye which nature has given them to express the generosity of their temper is clouded with anxiety." That "the trial of this method has at least two recommendations; it may be made at very little expence, and under the fair expectation of success." See *TEAM*.

The methods of yoking cattle in ploughs are also different in different places; but the only circumstance worthy of being considered is, whether the cattle should be yoked in pairs, or in a line before each other. It may, therefore, be useful to consider the advantages and disadvantages attending each mode, and to compare them.

The most common way of yoking cattle in ploughs is in pairs. There are some disadvantages attending this way that are obvious. In ploughing the furrows betwixt ridges, the land-cattle go upon the ploughed land, and tread it down with their feet: this, especially if the land be wet, poaches and hurts it very much. And there is another disadvantage which is very obvious. When there is but as much of the ridge unploughed as to allow the land-cattle to go upon it with difficulty, they are frequently either going into the opposite furrow, and thereby giving the plough too much land, or, which is worse, they are jostling the furrow-cattle upon the ploughed land.

In order to remove the inconveniences which attend the ploughing with cattle yoked in pairs, some yoke them in a line before each other. It is obvious, that cattle yoked in this manner, going always in the furrow, neither tread upon the ploughed land nor jostle one another. In these respects, the yoking the cattle in a line before each other seems to have the advantage. It is to be observed, however, that this method is not quite free from inconveniences. When examined, it may, perhaps, be found attended with as great inconvenience as the other. Where cattle are yoked in a line, they go all in the furrow. This makes it necessary to give the plough more land than ordinary, either by the fock or the muzzle; for if this be not done, the head and fock being in the same direction with the beam, and the cattle yoked to the middle of it, the plough will directly follow the cattle without taking any thing off from the land. Now it is inconvenient to be obliged to give the plough land either by the fock or muzzle; for when the fock is turned out of the plane of the beam, it makes the plough heavy to draw; and when the muzzle puts the draught too much to one side of the beam, it prevents the plough from going upright. The yoking of the cattle in pairs is attended with none of these inconveniences; for in this case, the quantity of land which the plough has naturally, when right made, is sufficient to make it take off a proper furrow.

There is another inconvenience that attends yoking cattle in a line, arising from the nature of the animals, which is, that as they like their ease, they are disposed to throw the burden upon their fellows. They they have a better opportunity of doing when yoked in a line before each other than when yoked in pairs. When yoked in a line,

line, each pulls by the traces of the one behind him; and therefore, though it may be known when the foremost neglects his work, by the slackening of his traces, it cannot be known when any of the rest neglect their work; for though one of them does this, yet by the pulling of the one before him his traces may be fully stretched. But this is easily discovered when the cattle are yoked in pairs; for then every one of them has a separate draught.

There is still another inconvenience that attends the common way of yoking cattle in a line before each other. When the fore cattle are all yoked to the traces of the hindmost, it is obvious, that as the beam to which the draught is fixed is much lower than his shoulders, by which the rest pull, such a weight must be laid upon his back or shoulder, as must render him incapable of giving any assistance. Besides, as the whole force is applied in the direction of the traces of the hindmost, it cannot have such influence on the plough, as when a part of it is in a direction more horizontal. When a body is to be moved forward in any direction, the nearer that the direction of the force applied approaches to the direction of the body, it acts with greater influence; and, therefore, as the plough moves horizontally, and as the direction of the united draught of a plough with the cattle yoked two abreast is more horizontal than the direction of the draught in a plough with cattle yoked in a line, the same force applied will have greater influence.

When these two different ways of yoking cattle in ploughs are thus considered and compared together, it is difficult to determine which ought to be preferred. Each of the two seems preferable to the other in a certain situation. When the land is stiff, and the labour severe, the yoking the cattle in pairs seems preferable, as it is certainly the strongest draught; and when the land is wet, and in danger of being much hurt by the treading of the cattle, the yoking them in a line before each other seems preferable; as thereby they are confined to the bottom of the furrow, which is the firmest part of the land, and prevented from doing harm.

In wet lands and seasons, as long teams answer best, for the most part, collars and trace-chains become of considerable utility in most cases in yoking of cattle; and in which ever way neat cattle are geared for work, they should constantly have bridles or bit-halters, with blinders, as by such means they are rendered docile, tractable, and easy to manage in the business of team labour. Much information on this subject may be seen in the Corrected Report on Agriculture for the County of Suffolk.

YOKULS, in *Geography*, the highest mountains in Iceland, perpetually clothed with snow. Of these, Snæfial, hanging over the sea on the S.W. part of the island, is said to be the highest, its height being computed at 6860 feet. The mountains are said to be chiefly sand-stone, pudding-stone, with petroflox, steatite, and argillaceous schistus.

YOLK, or YELK, in *Natural History*, the yellow part in the middle of an egg. See EGG.

The chicken is formed out of and nourished by the white alone, till it be grown to some bulk: after which the yolk serves it for nourishment; which it likewise does, in part, after it is hatched. For a good part of the yolk remains after exclusion; being received into the chicken's belly: and being there reserved, as in a store-house, is by the ductus intestinalis, as by a funnel, conveyed into the guts, and serves instead of milk. Willughby's Ornithol. lib. i. cap. 3.

This was even known to Pliny:—"Ipsum animal ex

albo liquore ovi corporatur: cibus ejus in luteo est." Lib. x. cap. 53.

YOLK, in *Rural Economy*, the peculiar nutritious secretion which exudes through the skins of sheep, and which by intermingling with the pile of the wool renders it soft, pliable, and in proper condition. It has somewhat the same effect on it which oil has upon a thong of leather, when kept in and perfectly saturated with it. The disposition to the production of this substance in sheep is favourable to the valuable properties of the wool, and should be attended to by the sheep-farmer in fixing and regulating his flock. It is noticed by a late writer on Agricultural Chemistry, that wool often washed in calcareous water becomes rough and more brittle than usual, as the carbonate of lime has the power of dissolving or decomposing the yolk of it, which is an animal soap that naturally defends it; that the finest wool, such as that of the Spanish and Saxon sheep, is most abundant in yolk; that M. Vauquelin has analysed several different species of yolk, and has found the principal part of all of them a soap, with a basis of potassa, that is, a compound of oily matter and potassa, with a little oily substance in excess; and that he has likewise found in them a notable quantity of acetate of potassa, and minute quantities of carbonate of potassa and muriate of potassa, and a peculiar odorous animal matter.

The same chemical writer has stated, that he found some specimens of wool lose as much as forty-five per cent. in being deprived of their yolk; and that the smallest loss in his trials was thirty-five per cent.

It is suggested in the above work, that the yolk is the most useful to the wool on the back of the sheep in cold and wet seasons; and that probably the application of a little soap of potassa, with excess of grease, to the sheep brought from warmer climates in our winter, that is, increasing their yolk artificially, might be useful in cases where the fineness of the wool is of great importance. A mixture of this sort is more conformable to nature, it is thought, than that ingeniously adopted by the late Mr. Bakewell; but that at the time his labours began, the chemical nature of the yolk of wool was not known. See WOOL, WASHING Sheep, &c.

YOLK of the Seed, *Vitelus*, in *Botany and Vegetable Physiology*, a part first described by Gærtner, and thus named by him, from its supposed analogy with the yolk of an egg. This analogy, and even the existence of the part in question, have been disputed, as Mr. Brown hints, in *Prodr. Nov. Holl.* v. 1. 306, by M. Correa de Serra, and by the writer of the present article. We have never at any time communicated on this subject with our learned and sagacious friend, now the Portuguese minister at New York; so that we are ignorant how far his objections extend, or on what they are founded. Nor does Mr. Brown know more of this matter, than a simple record of M. Correa's opinion, in *De Candolle's Flore Française*, v. 1. 157. This coincidence, however, from such a quarter, gives us great confidence in our own opinion, which was first offered to the public in *Introd. to Botany*, chap. 19, published in 1807. On a more attentive and full consideration of the question, the same sentiments were more explicitly detailed and defended in a paper read before the Linnæan Soc. Nov. 3, 1807, and printed in that Society's Transactions, v. 9. 204.

Gærtner states the *Vitelus*, or Yolk of the Seed, to be "distinct from the *Cotyledons*, as well as from the *Albumen*, and for the most part situated between the latter and the *Embryo*." (See SEED, where a reference is made to VITELUS, under which head the substance of the present article

was designed to have been inferted.) Gærtner considers the part of which we are about to treat, as "of all the internal parts of a feed the most singular, and by far the most unferquent." Its importance therefore cannot be very confiderable. The principal diagnoticks of the *Vitellus*, according to this eminent carpologist, are the following: 1st, "It is most closely connected with the *Embryo*, so as not to be separable therefrom, without injury to its own substance. 2dly, Notwithstanding this intimate connection, it never rises out of the integuments of the feed, as the *Cotyledons* usually do, in germination, so as to become a feminal leaf; but, rather like the *Albumen*, its whole substance is destroyed by the feeding plant, and converted into its own nourishment. And 3dly, If the *Albumen* be likewise present, the *Vitellus* is always situated betwixt that and the *Embryo*, in such a manner, however, that it may be separated from the *Albumen* with great ease, and without injury." For these reasons, Gærtner considers the organ in question as "allied on the one hand to the *Albumen*, on the other to the *Cotyledons*," but truly distinct in nature from both.

We presume to differ from this decision of the great writer, whose words have just been quoted, for the following reasons: 1st, The *Vitellus* is certainly not more closely connected with the *Embryo* than the greater number of *Cotyledons* are, as any person may find by examining feeds in the first stage of their germination, and as the faithful delineations of Gærtner himself every where shew. 2dly, That the *Vitellus* never rises out of the ground, is a circumstance likewise common to many *Cotyledons*, allowed by Gærtner to be such, as in various leguminous plants, as well as in *Æsculus*, *Cyamus*, *Tropæolum*, and many others. The difference between *Cotyledons* which grow up into feminal leaves, and those which remain and decay under ground, is of so little importance as to the classification of plants, that the most natural order of *Papilionaceæ*, or *Leguminosæ*, contains decided instances of both; *Lupinus* and *Vicia* affording examples of the former mode of growth, *Lathyrus* of the latter. And 3dly, The situation of the *Vitellus*, between the *Albumen*, if the latter be present as a separate organ, and the *Embryo*, is only a necessary consequence of the more intimate connection between the *Vitellus* and the *Embryo*, than either of them has with any other part, except that of the *Cotyledons* and *Embryo*, which is as strict as can possibly be. Hence we cannot consider the *Vitellus* of Gærtner to differ from the subterraneous *Cotyledons* above-mentioned. We presume their offices must be exactly similar, to perform the necessary functions relative to air or oxygen, till the leaves come forth, and assume those functions in greater perfection, with the co-operation of light. This appears to us more satisfactory than the hypothesis of Gærtner, that the organ of which we are treating affords nourishment to the *Embryo*; because this is abundantly supplied by the copious *Albumen* of a multitude of feeds, whose *Vitellus* is very inconsiderable, such as grasses; and it is recurring to two causes to explain what is evidently accounted for by one alone. If the vegetation of corn be observed, the *Vitellus* will be found to dwindle away, with scarcely any change in its very inconsiderable bulk, when the first leaves are unfolded, exactly as happens to the subterraneous *Cotyledons* of *Lathyrus odoratus*, &c. The same thing very often takes place as speedily in *Cotyledons* which rise out of the ground. Some which are more permanent, as in cruciform and umbelliferous plants, being only more of the nature of leaves. In grasses, the scale taken by Gærtner for a *Vitellus* is mostly so thin and unsubstantial, as not possibly to contain any material portion of nourishment; ample supplies of which are furnished by the plen-

tiful *Albumen* of those plants. But its expanded figure is very well calculated, like that of the leaves, for functions analogous to vegetable respiration; and it has the evident aspect of a subterraneous leaf, quickly rendered superfluous by the production of real leaves, and withering away, as the first of those leaves themselves do, when more vigorous ones come forth. It is remarkable, that the pretended *Vitellus* appears not to be necessary to all plants furnished with this distinct kind of *Albumen*, as *Palme* and *Orchideæ* have it not; while, on the other hand, no instance presents itself of a supposed *Vitellus*, and a real *Cotyledon*, or *Cotyledons*, in the same plant. Gærtner takes the *Plumula* for *Cotyledons* in *Rhizophora* (see his t. 45.), as well as in some of the *Scitamineæ*; for we cannot conceive the tubular part, embracing the *Embryo*, in *Amomum*, (see Gært. t. 12, which he erroneously calls *Zingiber*.) to be any thing but a *Cotyledon*, notwithstanding the opinion of our learned friend Mr. Brown, who, like Gærtner, terms it a *Vitellus*. The name would be of little importance, if the supposed use of it did not convey, as we presume to think, an erroneous idea; in attributing to these feeds two distinct and separate sources of nourishment. That two such distinct parts exist in this natural order, and perhaps, as Mr. Brown observes, in *Nymphaea* and *Nuphar* likewise, we are ready to admit; and we are therefore more satisfied to attribute to each a separate and appropriate office. We have had no opportunity of observing the germination of *Amomum*, or any true Scitamineous plant; but as far as we have been able to judge, it appears that the *Albumen* of every feed, when separate from the other parts, is always totally absorbed, or removed, leaving its skin empty; whereas a *Cotyledon* withers and shrinks in its whole substance, like a decaying leaf. If the albuminous matter, necessary for the temporary nourishment of perhaps every feed, in one form or other, be lodged in the substance of the *Cotyledons*, as in *Zamia*, the leguminous and cucurbitaceous tribes, and many others, such parts shrink the more, but do not lose any one particular portion of their substance, so as to have only a skin left behind. Perhaps a confusion of ideas has arisen, from the first consideration of this subject, in consequence of the term monocotyledonous as contrasted with dicotyledonous. The first had an evident reference to the *Albumen*, in corn, palms, &c.; and when Gærtner had emancipated himself from this error, he seems to have transferred the idea to the *Embryo*, which he calls *monocotyledonous*, as if he meant by that word to express its own simple form. Prepossessed with this idea, when a separate organ manifested itself, as in the *Scitamineæ*, he thought a new appellation requisite. Mr. Brown objects to the term *Cotyledon* in this case, because he says there is no point of union between the part in question and the *Embryo*. If such be the case, which we cannot understand, it would be not at all less difficult to conceive how this part could, as a *Vitellus*, supply the *Embryo* with nourishment, than it would be to imagine how it could perform any services towards that organ with respect to air, in its capacity of a *Cotyledon*.

It seems to us, that by considering the *Vitellus* of Gærtner as a *Cotyledon*, all ambiguity respecting the anatomy or component parts of any feed is removed. When the *Cotyledons* are two or more, the albuminous matter is either lodged in their substance, or forms a separate part. In the latter case, it has no more connection with the *Embryo* than is absolutely necessary, being in fact not an organic part, but a mere reservoir of food or nourishment, immediately undergoing a chemical change, after which its whole substance is speedily absorbed. Such is the economy of corn and palms; even the large *Albumen* of the cocoa-nut soon disappears,

appearing, for the evolution and fulfilment of the little *Embryo*, lodged in a cavity of its base; while the *Cotyledon* of the not very distant genus *Zamia* shrinks indeed considerably, from losing the albuminous part of its substance, but does not disappear; because the remaining part destined to perform the essential office of a *Cotyledon*, respecting air, merely decays when its purpose is answered, and sloughs off, like any other dead portion of the vegetable body.

We have already (see GERMINATION) adverted to these two different situations of the albuminous matter. That substance must be present, in some shape or other, for the nourishment of the young *Embryo*, at the first period of its evolution, when so great an alteration of bulk takes place, till it can supply itself from the earth. The idea of this nutritious substance, whether of an oily, mucilaginous, or farinaceous nature, being always, when not a distinct body, lodged in the *Cotyledons*, throws additional light on the nature and physiology of these last-mentioned parts, and in a very beautiful manner confirms their analogy with leaves. The sap of plants (see CIRCULATION of the Sap) being carried into the leaves, and there acted upon by air, light, heat, and moisture, is returned in the form of various secretions, into the different parts of the vegetable body. Under the influence of light, the upper surface of their leaves absorbs carbonic acid gas, and the under gives out pure oxygen. But in the dark, leaves absorb oxygen. So the *Cotyledons* of seeds, in their dark subterraneous situation, being moreover often guarded expressly from light by a brown or even black skin, absorb oxygen, which, as we have said in the article above cited, is known to be necessary to germination. They are already stored with albuminous matter, abounding with the carbonic principle. This, by the action of oxygen, becomes saccharine and milky, fit to be transmitted, through the returning vessels, which the *Cotyledons*, in common with *Leaves*, possess, into the stem of the *Embryo*; all these important parts having already begun to swell, from the absorption of moisture, and the stimulant effects of heat. Hence we see why light proves hurtful to incipient germination, and why carbonic acid gas may be given out by seeds during that process. It is evident that the proper functions of *Cotyledons* are best performed under ground, and that when they rise into the air and light, it is not till after their primary destination is fulfilled, and then only because, being fundamentally of the nature of leaves, they are mostly capable of assuming the functions of those organs, with respect to light. *Cotyledons* of seeds are subterraneous leaves, just like the scales of a bulbous root. Both are stored with albuminous or nutritious matter, and when acted upon by oxygen perform under ground those functions, which leaves perform in the open air, with the assistance of light. It is worthy of notice that the *Cotyledons* are so placed, in all seeds, that the oxygen gas must be imbibed by their under surface only, that very same part which, in leaves, gives out this kind of gas during the day, and probably absorbs it at night. "It would," as we have elsewhere observed, Tr. of Linn. Soc. v. 9. 213, "have evinced a strange contrariety in the constitutions of two organs otherwise so analogous, the *Leaves* and *Cotyledons*, if the upper surface of the latter, while in the unexpanded seed, had been presented to receive the oxygen gas."

By taking the *Vitellus* of Gærtner for a *Cotyledon*, we throw no new difficulties in the way of the classification of plants by this organ. Its form is always, as far as we know, simple and undivided, so that the plants in which it occurs remain only the more steadily fixed in their place of *Monocotyledones*, as opposed to the *Dicotyledones*; witness *Gramina*, *Scitamineæ*, &c. thus indeed acquiring a right to

such an appellation, which they could otherwise scarcely claim, having, according to Gærtner's principle, no *Cotyledon* at all.

YOLOTOU, or YULDUZ, or *Cyalis*, or *Chialifh*, in *Geography*, called by the Turks *Keraffer*, or the Black City, a town of Little Bucharia, situated in a country abounding with springs and fine meadows; 85 miles N.N.W. of Hami.

YOM-NIM-KIEN HOTUN, a town of Chinese Tartary, on the E. coast of the gulf of Leao-tong; 263 miles E. of Peking. N. lat. 40°. E. long. 121° 34'.

YOM-TA-HOTUN, a town of Corea; 648 miles E.N.E. of Peking. N. lat. 42° 55'. E. long. 129° 37'.

YON, a river of France, in the department of the Vendée, which passes by La Roche fur Yon.

YONGHELAHE, a river of the island of Madagascar, which runs into the sea on the west side of the island, S. lat. 23° 30'. E. long. 47° 4'.

YONG-LI, a town of Corea; 30 miles S.E. of Koang-tcheou.

YONG-NGAN, a city of China, of the second rank, in Quang-fi; 1027 miles S.S.W. of Peking. N. lat. 24°. E. long. 110°.

YONG-NGAO, a small island near the coast of China, in Quang-tong; 20 miles S.S.E. of Macao.

YONG-NING, a city of China, of the first rank, in Yun-nan, on the borders of Thibet. A little to the E. of this town is a lake; 1095 miles S.W. of Peking. N. lat. 27° 50'. E. long. 100° 24'.—Also, a city of China, of the second rank, in Quang-fi; 977 miles S.S.W. of Peking. N. lat. 25° 6'. E. long. 109° 14'.

YONG-NING, or *Yung-ning*, a city of China, of the second rank, in Koei-tcheou; 1027 miles S.S.W. of Peking. N. lat. 25° 55'. E. long. 104° 57'.

YONG-PE, a city of China, of the first rank, in Yun-nan; 1150 miles S.W. of Peking. N. lat. 26° 42'. E. long. 100° 34'.

YONG-PING, a city of China, of the first rank, in Pe-tche-li, on a river which runs into the gulf of Leao-tong. This city is advantageously situated, but its jurisdiction is not very extensive; it contains but one city of the second order, and five of the third. It is environed by the sea, by rivers, and by mountains, covered for the most part with fine trees: this makes the country less fertile, but the neighbouring bay supplies its want with great plenty of all the necessaries of life. Not far from this city stands a fort named *Chun-bai*, which is the key of the province of Leao-tong. This fort is near the beginning of the great wall, which is built, for a league together, in a boggy marsh, from the bulwark in the sea; 115 miles E. of Peking. N. lat. 30° 55'. E. long. 118° 34'.

YONG-SIN, a town of Corea; 113 miles E. of Han-tcheou.

YONG-TCHANG, or YUNG-TCHANG, a city of China, of the first rank, in Yun-nan. This city is large and populous, and is built in the midst of high mountains, on the borders of the province, in the neighbourhood of a savage people, whose genius and manners the inhabitants of this country partake of. The country produces gold, honey, wax, amber, and a vast quantity of fine silk. It has within its districts one town of the second order, and two of the third; 270 miles S.W. of Peking. N. lat. 25° 6'. E. long. 99°.

YONG-TCHEOU, a city of China, of the first rank, in Hou-quang; 882 miles S.S.W. of Peking. N. lat. 26° 10'. E. long. 111° 15'.

YONG-TONG, a town of Corea; 40 miles E. of Het-sin.

YONI, in *Metaphysics*, the name of a mysterious symbol among the Hindoos; which, although contemplated with respect and awe by that superstitious race, is yet of such a nature as not to be discussed without difficulty in the living language of a country which has happily shaken off the trammels of priestcraft; and views with pity, mixed with just abhorrence, the idolatrous propensities of those still retained in mental bondage; accompanied, as we find they were, among many ancient people, by the indecencies of impure rites, scarcely yet diffused, even in Europe, and existing in almost undiminished grossness in the still unenlightened regions of Asia.

The reader is supposed to be more or less aware of the nature of the orgia incident to the worship of such deities as Pan, Priapus, Bacchus, Venus, &c. We do not here inquire particularly into the origin of such rites. In their earlier stages, they were probably an innocent ebullition of gratitude for the experienced bounties of nature. In the lapse of time, a concourse of people of both sexes, warmed by exercise and beneficent feelings, at a genial season most likely of the year, found, as is ever the case, their unrestrained devotion sublimed into enthusiasm; and hurried by such feelings beyond the scope of unassisted reason, gave themselves up to the extravagances of mysticism, and in the end to excesses which not only Christians, but the decent of every sect and country must unite in reprobating. These Bacchic phrenzies were accordingly suppressed or mitigated as to their offensive usages and tangible abominations. Nature, in the phraseology of certain sects, was no longer propitiated through the indulgence of feelings of her own prompting, excited farther by the presence of unequivocal exhibitions. She, still personified, was more decently represented by certain symbols substituted for the earlier types. The cunning priest no longer daring to exhibit their obscenities in shameless nudity, permitted only a portion of indecency to remain in the hands and eyes of their deluded votaries, and concealed their origin and meaning in the various mysteries and hieroglyphics denominated Bacchic, Eleusinian, Phallus, Linga, Yoni, Cone, &c. &c. Some notice of these things, and of the ordinary course and consequences, will be found under the appropriate articles of our work; also in MYSTERY, MYSTICS, and others thence referred to.

By such people Nature was contemplated chiefly under her attribute or property of fecundity; and symbols of generative allusion were those under which her prolific potencies were exhibited. Those prone, like the Hindoos, to resolve almost every thing into sexual allegory, of course fancied the male and female pudenda omni-archetypal. These, in the early days of such perverted devotion, were probably pourtrayed in India, as elsewhere, without reserve; but were, in most cases, soon corrected into the comparative decency of the hieroglyphics; and the deluded people were cajoled by mummery and mystery, that became less and less understood, and therefore, perhaps, the more revered. We have said in most cases; for in Egypt and Greece the grossness of Phallism is known only in the remains of antiquity; in India it doubtless exists, but diverted of obtrusive or conspicuous delicacy; and too true it is that among Christians was the primeval infamy of the symbol and usage most tenaciously retained. We can but just allude to the discovery of this curious though lamentable fact, by Sir William Hamilton, in the neighbourhood of Naples. His

communication, with ample commentary and illustration, has been printed, but very properly not published; concealed, though not suppressed; and we therefore make no direct reference to the sufficiently intrusive, though too disgraceful volume, in which this disgusting worship is proved to exist in Christian Europe, and is traced almost all the world over.

Among the Egyptians, Greeks, and Romans, the Phallus and the Cone seem to have been the earliest of the grosser and corrected emblems; the latter contained both the Linga and Yoni, nature active and passive; and similar, familiar, or recondite meanings and allusions were thus readily revived in the minds of the vulgar and the initiated, suitable to the esoteric or isoteric nature of their capacities and feelings. These fooleries, to give them no harsher name, thus found to have existed among the people just mentioned, and others, have, with great appearance of reason, been suppositively derived from the still more ancient usages of India. Much might be said in support of this, were it worth while; and thus far the inquiry will probably be repaid, that it may bring to light many strange coincidences. If such writers as Colebrooke, Wilford, Faber, and others, who bend their minds to the development and elucidation of Eastern literature and mysteries, continue for a while in the same line of research, we anticipate a confirmation of the surmises long entertained, that nearly all the learning, science, and art, as well as the religion of Egypt and Greece, originated in India, or at least with the Brahmans; however much they may have been improved or embellished by the hands through which they reached us.

India then, or the country of the Brahmans, wherever that was, being in our judgment the region where the superstitious practices now under our consideration originated, we may expect to find its early history teeming with allusions to it. This is indeed the case; though such allusions are not, perhaps, found in its *earliest* works on theology. But as no people have changed so little as the Brahmans and their flock by the innovations of strangers, or the lapse of time, (for frequent subjugations by conquests seem to affect them but little, and persecutions serve only to confirm their prejudices,) we may expect to find their religious institutions and practices more in accordance with those of their early days than the usages of other people who have not disdained to become wiser by the operation of reason and philosophy; and who have been taught to look on the follies of their ancestors with the pity they deserve. In India, we thus find certain hieroglyphics still receiving the external adoration so little their due. There we find the infamous Brahman still teaching his ignorant suppliant to fall down and worship the Linga and Yoni; symbols, in whatever shape exhibited to the public eye, no doubt fitter for the brothel than the temple. The former of these is the attribute of Siva, the Maha-deva, or great divinity presiding over reproduction, or regeneration in the abstract; and the other of his consort Devi, or Parvati, the Magna-Mater, the Bona Dea of the East.

In preceding articles, we have necessarily touched on the character and attributes of the two just mentioned grand divinities of the Hindoos; and refer our readers to PARVATI and SIVA for our remarks thereon, and to LINGA for a brief notice of the Phallic worship of India. In this article, we propose to discuss that still offered to the Juno, the Venus, the Isis, the many-named all-absorbing goddesses of the Hindoos, whose emblem is the Yoni.

Writers on this subject generally, perhaps unavoidably, commix their speculations on the Linga and Yoni. Crude nature

nature is personified, and called Prakriti; she is declared to be nature, or the earth, the womb of nature; she is thence any thing conceiving or containing, or the power or fukti of such faculties. In its first state that *power* was rather a tendency, an aptitude, and laid dormant until excited by the *bija*, or vivifying principle, the *aura* of nature personified in Siva, who in this character is called Parusha, or the primeval male. Here we find nature passive and active: the power or aptitude of nature is symbolized by the Yoni; the vivifying principle by the Linga. Prakriti is found to be one of the names and forms of Parvati, as Parusha is of Siva. Under these names we have taken some notice of their character; but it is not easy, in the short articles to which, in these matters, we must restrict ourselves, to explain fully, were we able, the nature and allusions of these abstract personifications.

The faculty or power of containing, of which the Yoni is the type, is also called Argha by Hindoo mytics. The name is given to a cup or dish, or *vessel*, in which fruits and flowers are offered in oblation. These vessels, they say, ought always to be *boat-shaped*; and so they frequently are, but sometimes round, oval, or square; mostly, however, circular. All this is mysterious and profound. The rim of the Argha is more especially the Yoni, while the contents of the vessel represent the Linga, which is sometimes more unequivocally figured by an image of Siva standing erect in the centre of the Argha. Hence one of his names is Arghanatha, or lord of the boat-shaped vessel. We may stop a moment here to remark how readily Bryant, Faber, and the race of Noetics, would have recognized the ark, in the arga or arka, or ark, as it may without much licence be written, of the Hindoos. We do not hesitate to hint our belief that many of the fables connected with Colchis, Juno, Io, Ionia, Jonah, &c. are traceable upwards to Hindoo words: many also connected with the names of places or persons, beginning with Col or Kal, or containing its root, that are scattered in unmeaning profusion through the geography and early biography of Europe. But this is not the place to enlarge on this subject.

The Argha, as a type of the *power of conception*, excited and vivified by the Linga or Phallus, Mr. Wilford (Af. Ref. vol. iii.) supposes to be one and the same with the ship Argo, which, according to Orpheus (Argon. v. lxxi.), was built by Juno and Pallas, or, according to Apollonius (b. ii.), by Pallas and Argus, at the instance of Juno. The word Yoni, as it is usually pronounced, nearly resembles the name of the principal Etruscan goddess; and the Sanskrit phrase Arghanatha Iwara seems accurately rendered by Plutarch (on Isis and Osiris), when he asserts that Osiris was commander of the Argo. That the Sanskrit words *p'bhala*, meaning fruit, and *p'hulla*, a flower, had ever the sense of *phallus*, is not affirmed; but as these are the chief oblations in the Argha, and are confessed to be a representation of the Linga, their sounds may easily have been so transferred. We have seen, too, that Mahadeva himself, the prototype of the Linga, is sometimes placed erect in the Argha: this is to complete a mystical triumph of powers; for Vishnu, the principle of humidity and of conservation, is symbolized by a convexity or embolment in the centre of the Argha, over which the image of Mahadeva, or the p'hala and p'hulla, as representing the Linga or Phallus, are placed. The idea that the Sanskrit p'hala or p'hulla may in sense as well as sound be cognate with and the source of the Greek phallus, derives strength from the fact that Mahadeva, in his character corresponding with that of Jupiter Marina, or Neptune, bears, like his Roman kinsman, a trident, called

Trifula, and sometimes Triphala, denoting trifurcation and triforescence. Jupiter Triphylus is thus identified with the three-eyed Siva, who in this form is named Trilokana and Trifula.

That the Sanskrit language is very widely spread, and is traceable in various dialects, we have the authority of Mr. Colebrooke for believing. In the names of places, we are inclined to think its extension is proved as much as in any point: and we do not deem the idea very extravagant (lays our correspondent) that derives the name of Trafalgar, the scene of the last grand triumph of the British Neptune, from the mythological language of our fellow-subjects of India.

To return to the Yoni or Argha, we have seen that the vessel under the latter denomination is boat-shaped, and a type of the world. In the general Deluge, the generative powers of nature, male and female, reduced to their simplest elements, the Linga and Yoni, assumed this shape for the preservation of mankind. Brahma, the creative power, is represented to have been asleep at the bottom of the abyss. This alludes, we suppose, to the destruction of mankind; man being represented in the abstract by Brahma. The Yoni becoming boat-shaped, the Linga was the mast, and protected by Vishnu rode upon the waters. This, though sufficiently gross, is doubtless an arkite allegory. Every thing hollow or concave having the property of containing, remind mytics of their type the Argha or Yoni, as aspiring objects do of the Linga. Enthusiasts see these two principles; that is, they say, nature passive and active, dormant and revived, every where and in every thing,—the earth, the sea, a boat, a well, a pond, the hollow of the hand, clefts in rocks, excavations, caves, commensures of branches, &c. partake of relationship with the one,—mountains, especially if insulated and conical, pyramids, cones of any sort, fire, a mast, a tree, especially if denuded of branches, obelisks, &c.—all these connect themselves with ideas of Mahadeva and the Linga. The earth is typified by a boat; the Argha of the Hindoos, and the Cimbium of the Egyptians. Osiris is represented in a boat carried by men: in India, Mahadeva erect in the Argha refers to the same allegory. All over India, the Argha, and Linga of stone inserted in it, is found an object of worship. It is strewed with flowers, and water is poured on the Linga, and conveyed off by the rim or Yoni; the fossa navicularis or mystical boat of Isis.

Caves we have noticed as types of the Yoni, from their property of hollowness or containing, and also from the shape of their mouth. It will be recollected, that the most ancient oracle and place of worship at Delphos was that of the earth in a cave, which was called Delphi; an obsolete Greek word, synonymous, according to Mr. Wilford (Af. Ref. vol. vi.), with Yoni in Sanskrit. Similar superstitions have prevailed farther westward. Perforations and clefts in stones and rocks were called Cunni Diaboli by early Christians, who usually bestowed the appellation of devils on the deities of the heathens. One of the wonders of the peak in Derbyshire retains an appellation still coarser: but Mr. Wilford thinks improperly; for this wonderful cave, or one he says very like it, particularly noticed in the Puranas, is declared to be the sacred Yoni. The cleft called Guhyasthan, in Nepal, answers fully and literally to the coarse appellation of its relative in Derbyshire, (Guhya, or Podex,) and is devoutly worshipped by numerous pilgrims from all parts of India. Perforated rocks or stones, as well as the mouths of caves, are mystically contemplated in India. A regeneration is effected by passing through them; or, if the hole be too small, a hand or a foot thrust through, with a sufficient faith, will nearly answer the same purpose.

It is difficult to discuss such subjects as these without feeling a certain degree of contempt, pity, and wonder, at the fooleries of creatures called rational. But when we recollect that many millions, hundreds of millions probably, of our fellow mortals are, or have been, thus misled, and have been similarly misled in all parts of the world, the origin and spread of such usages become a subject not unworthy the inquiry of the philosopher: as connected probably with the history of stupendous events in sacred history, it claims also the attention of the theologian; and the total disuse of all such irrational superstition among ourselves is a matter of gratulation to us as reformed Christians. We are disposed, however, to view it in all cases as an invention and engine of priestcraft, and not much more to be charged on the religion of the Hindoos and others, than the mummeries practised at Loretto, Naples, and elsewhere, are justly chargeable on Christianity.

Connected with the symbols and rites of the Yoni, we had prepared to offer some remarks shewing the spread of similar superstitions almost all over Europe, as well as in other regions. And, indeed, although their origin and allusion are now wholly forgotten, curious observers may discern in still existing usages occasional relics of this species of devotion even in England. It is inexpedient, however, to indulge in this extended view.

Adoration of stones is found similarly spread through the superstitious ages of all nations. The Hindoos retain it with undiminished bigotry; and will affirm, and indeed go night to prove, that such objects, from the sacred monolithic subject of the Kaaba at Mecca, or the obelisks of Egypt, to the trilithic temple at Stonehenge, with many intermediate, are no other than their Linga, under various forms and denominations. The Bætilia of antiquity are nearly related to it. Under BÉTYLOS, CROMLECH, KISTVAEN, STONEHENG, and other articles of this work these referred to, the reader may, if desirous, see the extent of speculation to which the superstition connected with *Lithism*, if such a term may be allowed, has given rise.

Clefts in rocks, rent by the hand of nature, may therefore be supposed to be profoundly venerated by such enthusiasts as are Hindoo mytics. One of the most celebrated in India, as far as we have heard, is at the promontory on the island of Bombay, called by the English Malabar point. The promontory itself, thrusting its apex into the sea, which there forms a sanday, or junction, (see *JUNCTIONS*), is *Lingaic*. It used to be much resorted to, and its sin-expelling potency much relied on, before its purity and privacy were polluted and interrupted by the presence of strangers, and the increasing population of the island. The unequalled density of its present population, and the extending prevalence of foreign manners, have lessened the sanctity of this spot, now the constant resort and abode of persons who look on the local superstitions with an eye too rational or curious—or severe shall we say?—to encourage their continuance. Like the Lithic Linga temple of its neighbouring island of Elephantia, as the English call it, the Yoni of Malabar point will soon cease to be resorted to. Its fine temple is levelled to the rock whence it arose, and some of its spoils adorn the Museum at the India House. The neighbourhood of Bombay was in former times a grand assemblage of Hindoo temples. The great beauty and salubrity of the situation, the forms of the hills and islands, and other real and fanciful advantages, combined to give it high charms to the tasteful and cunning Brahman. An island rising conically is, we have seen, itself a Linga, its shores a Yoni, the ocean an Argha. The demoralizing effect of this perverted philosophy on the mind

of the simple Hindoo might be exemplified by a citation from our great dramatic poet, slightly altered:

“ — And this their life, exempt from public haunt,
Found Lingas in stones, Arghas in running brooks,
Yonis in rocks, and gods in every thing.”

Passing through such clefts as we have just noticed with a peculiar or expiatory view is, or rather has been, of extensive prevalence. We could shew it to have existed in many parts of Europe. Relics of it still exist in England. And indeed such is the recent rage of theological innovation, and the amazing increase of credulity, that a zealous sectarian need not despair of seeing these, or usages equally ridiculous, revived among us. But it would not suit the crafty Brahmans to allow rich delinquents to ease an expiation as the passage through a cleft or Yoni of rock. In certain cases of desilement, it is required that an image of pure gold be made of the female power of nature, either in the form of a woman or of a cow: in this statue, the person to be regenerated is enclosed, and is protruded through the usual channel. As this evidently must be enormously expensive, it is of course rarely resorted to. An instance is given in the Hindoo Pantheon, p. 398. of a recent case where a Yoni of gold was the medium of regeneration to two Brahmans, who had suffered pollution by coming to England. The desilement of a natural birth is done away by the protrusion of the person or head through a sacred thread called *Zennar*. (See that article.) This regeneration is essential to Brahmanical purity, and is also required of the two next tribes. The individuals thereafter are denominated *twice-born*. The fourth tribe is not allowed to be thus purified, and is therefore considered as base and unclean. See *SECTS of Hindoos*.

Enough has been said under this article to shew the mysterious bearing of its title. It is a subject which, connected with the Linga, meets the observer or inquirer directly or allusively, though not offensively, or very often in an offensive form, at every step he takes in the investigation of Hindoo literature or antiquities. Respecting the non-offensiveness of their appearances, we refer to our article *LINGA*; of which indeed this may be considered as a continuation. The subject is inexhaustible, but to us not inviting, though it must have been so to others. It might not be exaggeration, if it appear so, to say, that more speculation exists hereon in the languages of India than would fill a volume equal to our whole Cyclopædia! Reference to earlier articles descriptive of the Yoni and its attributes and allusions enables us to abridge this, which is, however, even combined with what is said in those articles, still and necessarily incomplete. See *KAMALAYONI*, *LILESWARA*, *LOTOS*, *MERU*, *PATRA*, *RADHA*, *SAIVA*, *SAMI*, *SAMI-DEVI*, and *SECTS of Hindoos*. From the article *SAMI* reference is made to this, and we take this occasion to correct an error in the former: in col. 2, line 24 from bottom, for *fiction* read *frition*.

Individuals, chiefly of the sect called Sakta, meaning worshippers of the Sakti, or female energy of Mahadeva, the deity of reproduction, propitiate the goddesses under the form of the Yoni, the mythical matrix of nature. Of this, see under *SAKTA* and *SAKTI*. Such individuals have the sectarian appellation of Yoniya. In what they differ from the Sakti, if they differ at all, we are not informed. These sects may be supposed to comprise but few persons; but this is a point on which information is obtained with difficulty. Respectable individuals, if there be any such belonging to it, are ashamed to avow being Saktas; and from persons of a different sort information is not to be relied on,

Writings,

Writings, too, on these subjects, are very obscure; their endless Scholia equally so, and can be critically understood by very few Europeans, even with the assistance of a learned native, who, aflamed probably of what he is desired to explain, will, with almost laudable delicacy or deceit, gloss over the half-revealed obscenities of his brethren.

The common tendency in the nature of the adoration of the Linga and of the Yoni might, one would think, have united their worshippers in a community of object and view. But such are the anomalies and perversities of the human mind, that it appears to be an historical fact, that the Lingajas and Yonijas have actually not only disputed and quarrelled respecting the comparative merits of their respective hieroglyphics, or, in other terms, the paramount potentiality of the archetype; but that bloody wars have arisen between them on the question, which, as far as now appears, seems really to have been one of physiology: the only instance, probably, in which such a question hath ever operated as a cause of holy war, manifold as those causes unhappily have been. The Yonijas insisted, it seems, on a superior influence in the female over the male nature in the production of a perfect offspring. The consequent disputes and warfare the Hindoo writers have, as usual, recited in extravagant allegories, which we should call obscene, but which they consider as awfully sacred.

"This diversity of opinion," says Wilford, "seems to have occasioned the general war which is often mentioned in the Puranas (see PURANA), and was celebrated by the poets of the West as the basis of the Grecian mythology: I mean that between the gods led by Jupiter, and the giants, or sons of the earth, or, in other words, between the followers of Iswara (see ISWARA) and the Yonijas, or men produced, as they asserted, by Prithu, a form of Vishnu (see PRITHU and VISHNU); for Nonnus (Dionys. b. xxiv. v. 241.) expressly declares, that the war in question arose between the partisans of Jupiter and those who acknowledged no other deities than water and earth. According to both Nonnus and the Hindoo mythologists, it began in India, whence it was spread over the whole globe, and all mankind appear to have borne a part in it.

"These religious and physiological contests were disguised in Egypt and India under a veil of the wildest allegories and emblems. On the banks of the Nile, Osiris was torn in pieces; and on those of the Ganges, the limbs of his consort Isi, or Sati, (see OSIRIS, ISIS, ISI, and SATI,) were scattered over the world, giving names to the places where they fell, and where they are still superstitiously worshipped. In Sanskrit books, we find the Grecian story concerning the wanderings of Bacchus; for Iswara, having been mutilated through the imprecation of some offended Nunnis, (see MUNI and SAMI-DEVI,) rambled over the whole earth, bewailing his misfortune; while Isi wandered also through the world singing mournful ditties in a state of distraction. There is a legend in another book, of which the figurative meaning is more obvious. When Sati, after the close of her existence as the daughter of Daksha, sprang again to life in the character of Parvati, or mountain-born, (see MERA and MENA,) she was re-united in marriage to Mahadeva. This divine pair had once a dispute on the comparative influence of sexes in producing animated beings, and each resolved, by mutual agreement, to create apart a new race of men. The race produced by Mahadeva was very numerous, and devoted themselves exclusively to the worship of the male deity; but their intellects were dull, their bodies feeble, and their complexions of different hues. Parvati had at the same time created a multitude of human

beings, who adored the female power only. These were well-shaped, with sweet aspects, and fine complexions. A furious contest ensued between these Lingancitas and Yonijas: the former flood their ground pretty well at first, but were in the end defeated, and shamefully routed in the battle, through the potency of the sacred Yoni. Mahadeva enraged was about to destroy them by the fire of his eye: but Parvati interposed; and to appease him, made use of the same artifice that Banbo did to put Ceres into good humour, and shewed him the prototype of the Lotos. Mahadeva smiled, and relented on condition that the Yonijas should instantly leave the country.

"It is evident that this strange tale was invented to establish the opinion of the Yonijancitas, or votaries of Parvati or the Yoni, that the good shape, strength, and courage of animals depend on the superior influence of the female parent, whose powers are only excited and put into action by the male *aura*. But the Lingancitas maintain an opposite doctrine. There is also a sect of Hindoos, by far the most numerous of any, who, attempting to reconcile the two systems, tells us, in their allegorical style, that Parvati and Mahadeva found their concurrence essential to the perfection of their offspring; and that Vishnu, at the request of the goddess, effected a reconciliation between them: hence the *navel* of Vishnu, by which they mean the *as inica*, is worshipped as one and the same with the sacred Yoni." Wilford, in Af. Ref. vol. iii.

YONIJIA, the name of a sect of Hindoos, who worship the hieroglyphic of Parvati, called *Yoni*; which see.

YONKERS; in *Geography*, a post-township of the state of New York, in West Chester county, on the E. bank of the Hudson, above New York island, 20 miles N. of New York, extending near eight miles along the Hudson, and having a medial breadth of near three miles. The surface is broken, but the lands are cultivated and productive. In 1810 the whole population consisted of 1365 persons, with 93 electors, and 204 taxable inhabitants.

YONNE, a river of France, which rises about four miles S. from Château-Chinon, in the department of the Nievre, passes by or near to Monceaux, Clamecy, Coulanges, Cravant, Auxerre, Joigny, Villeneuve, Sens, Pont fur Yonne, &c. and joins the Seine at Montereau.

YONNE, one of the nine departments of the central region of France, formerly *Yonne*, E. of Loiret, in N. lat. 47° 50', about 70 miles long, and from 30 to 40 broad, containing 7740 kilometres, or 373 square leagues, and 333,278 inhabitants; bounded on the N.E. by the department of the Aube, and on the S.E. by the department of the Côte d'Or, on the S. by that of the Nievre, on the W. by that of the Loiret, and on the N.W. by that of the Seine and Marne. The river Yonne, from which it receives its name, crosses it from S.E. to N.W. It is formed of the Auxerrois, formerly reckoned a part of Burgundy. Its capital is Auxerre. It is divided into five circles, or districts, 34 cantons, and 484 communes. The circles are, Sens, comprehending 57,285 inhabitants; Joigny, 81,933; Auxerre, 103,882; Tonnerre, 47,394; and Avallon, 42,784. According to Hassenzratz, its extent in French leagues is 29 in length, and 25 in breadth: its circles are 7, its cantons 69, and its population consists of 364,969 persons. In the 11th year of the French era, the total of its contributions was 3,093,023 fr.; and its expenses, administration, judiciary, and for public instruction, were 207,935 fr. 66 cents. The soil is various; it has some dry and indifferently fertile tracts, diversified with little hills; the western part is of a clayey soil, covered with woods and pools:

pools: the cantons to the S. and E. are planted with vineyards; and the northern district is tolerably cultivated. The department, in general, is fertile, producing grain in abundance, with wine, fruits, and excellent pastures.

YOOL ISLANDS, a cluster of small islands in the Pacific ocean, so called by captain Forreft, in the year 1774. In 1788 they were by Mr. Meers called Tattee islands.

YOO-MIOU, a large town of the Birman empire, situated on a small river, which enters the Irawaddy at a place called Yoo-wa. An extensive tract of country is inhabited by a people called Yoo, who are said to be exceedingly ugly, having protuberant bellies, and white teeth. These Yooos are subjects of the Birman state, and observe the same religious worship. They speak the language of Tavay, which is merely a provincial dialect of the Birman tongue. Symes's Embally to Ava, vol. ii.

YOPA, a town of Mexico, in the province of Culiacan; 100 miles E.N.E. of Culiacan.

YOPAS, LAS, or *Yopez*, a river of Mexico, which rises in Tlalcala, and runs into the Pacific ocean, N. lat. 17° 10'.

YO-PING, a town of Corea; 33 miles S.W. of King-ki-tao.—Also, a town of Corea; 28 miles S.S.E. of Tin.

YORK, the *Eboracum* of the Romans, is the capital of the great county to which it gives name, the see of an archbishop, who is primate and metropolitan of England, and the second city in rank in the kingdom. It is of unquestionable antiquity, and eminently distinguished in English history by the important political, ecclesiastical, and military transactions which have occurred within its walls, or with which it has been in other ways intimately connected. Seated in the midst of a vast plain, by the side of a river which was navigable for the largest ships of ancient times, and too remote from the open sea to be immediately exposed to predatory invasion, York must have early attracted the attention and become the favourite abode of the chiefs of the northern states, and of their successful invaders from foreign lands. Eboracum was accordingly selected by Roman emperors and commanders as a principal residence during their protracted contests with the ungovernable inhabitants of the northern parts of Britain. The metropolis of a shire unparalleled in the kingdom for extent, population, and productions, York is placed at the point of junction, although independent of them all, of the three ridings or districts into which the shire is subdivided. The cathedral is situated in N. lat. 53° 58', and in W. long. from Greenwich 1° 7'. The city is distant, by the shortest roads, from London, N. by W. 108 miles; from Edinburgh, S.S.E. 201 miles; from Durham, S. by E. 67 miles; from Hull, W.N.W. 38 miles; and from Liverpool, E.N.E. 100 miles. The nearest point of the sea-coast on the E. is at Bridlington bay, distant 33 miles, and on the W. at Lancaster 90 miles. The position of the city is central, with respect to both the limits of the county, and the great body of the population, industry, and commerce, by which it is distinguished. The ancient station of Eboracum was confined between the river Ouse on the W. and the collateral stream, the Foss, on the E., which falls into the Ouse at the southern extremity of the old city. In later times, however, the limits were extended considerably on the opposite sides of both rivers. Such a position, defended on three sides by rivers and marshes, and accessible by an enemy on the N. side alone, although in the midst of a plain, but consequently overlooked by no neighbouring eminence, would, even in the modern art of war, be susceptible of powerful defence: in ancient times it might have been rendered

nearly impregnable. In constructing the walls, and laying down the streets, on ground previously occupied by their camps, it was the practice of the Romans to preferre as much as possible the form and distribution of the prior intrenchment. Of this practice frequent instances are found in Britain, as well as in Gaul, and other parts of the continent. The same, notwithstanding the many changes to which the city has been subjected, may still be traced in York, where evident remains of Roman architecture are yet preserved, and where monuments of antiquity of various classes have often been discovered.

In its present state, the plan of York forms an irregular pentagon, extending from S. to N. about 1340 yards, and from W. to E. about 1360 yards: the area within the walls is therefore about 300 acres. It is divided into four wards, which take their names from the four gates. Bootham-gate-ward, in the N.W., contains three parishes; Micklegate-ward, on the W. side of the Ouse, contains six parishes; Monk-ward, in the N.E., five parishes; and Walmgate-ward, on the S.E., seven parishes. But the clofe of the cathedral is not included in any ward. Some of these parishes extend beyond the walls; and the two churches of St. Lawrence and St. Maurice, situated on the outside of the city, are still commonly reckoned to belong to it. The number of churches, exclusive of the cathedral, is therefore twenty-three. In former times they amounted to forty-five. Although no regular plan can now be traced in the distribution of the streets, yet some of them are of respectable appearance, having of late years been much improved by widening and paving; and new and handsome buildings, public and private, have been erected. The river Foss, long a piece of stagnated water, has again been rendered navigable, and now materially contributes to the ornament of the city as well as to the health of the inhabitants.

York, still inhabited by many genteel families, maintains its importance in no inconsiderable degree; but in point of population and wealth, it has been far excelled by many manufacturing and trading towns in the county, of comparatively modern foundation. According to the reports of the population of the kingdom in 1811, the inhabitants of York were then only 18,217, and the houses 2743.

Civil History.—York, under its romanized name, *Eboracum*, early appears in British history. In the year 208, the emperor Severus, with his sons Caracalla and Geta, visited Britain; and returning from an expedition against the northern insurgents in the following year, Severus resided at Eboracum, while his troops were employed in constructing across the isthmus, between the mouths of the Eden and the Tyne, the great wall of defence still known by his name. In this enterprize, he followed the example and completed the fortification of his predecessor Hadrian, which had been formed in the year 121. While Severus's great work was in progress, the emperor died at York in 210; and his successor Caracalla, more intent on the destruction of his envious brother Geta than on the enlargement or the preservation of the Roman dominion in Britain, soon afterwards returned to the continent. During his residence in York, Severus struck money, on which he styled himself *Britannicus*; and also issued a decree respecting the recovery of slaves, which decree is still preserved in the Roman code, dated at Eboracum, on the 3d of the nones of May, in the consulate of Faustinus and Rufus, corresponding to the year A. D. 209.

Turning his arms against the Caledonians, and other Britons, who struggled for freedom in the north, Constantius fixed his head-quarters in York, and there ended his life in 306. York was also the scene of the inauguration of his son

son and successor Constantine, who, learning in Asia the indisposition of his father, hastened to York, where he arrived in time to receive his last instructions; and was there proclaimed emperor by the army.

Among the towns specified in the geography of Ptolemy, the Itinerary of Antoninus, and the much later work of Richard of Cirencester, Eboracum is ranked first as a colony, and afterwards as a municipal town. As a colony, or settlement of veteran troops, the inhabitants were citizens of Rome, and governed by the laws of the state. When advanced to the highest station, that of municipium, the inhabitants retaining the privileges of Roman citizens were no longer under those particular laws, but invested with the power of self-government, under magistrates of their own appointment. Besides Eboracum, Britain contained but one other municipal town, Verulamium. In the list of Roman troops stationed in York, the sixth legion, called the victorious, appears to have been there for three successive centuries, down to 446, when the Romans finally renounced all dominion in Britain. The British name of York is lost; but although softened into Eboracum by the Romans, and by their colonies, who copied from them, traces of the original may still be perceived in the *Kair-Ebrauc* of Nennius and Henry of Huntingdon, and in the *Cair-Effroc*, or *Efroc*, of the Welsh. In British compound appellations of places, the descriptive part precedes the proper name: in the language of the Saxons a contrary mode prevailed. Hence *Cair-Effroc* was by them converted into *Efroc-wyc*, and *Yevor-wyc*, from which the present name of York seems to be derived.

York was the capital of Deira, one of the districts into which the *Provincia Maxima* of the Romans, or the county of Northumberland, was divided; and there, in the beginning of the seventh century, resided Edwyn, who re-united those kingdoms, and acquired the principal ascendancy over Saxon-England. To this prince are ascribed the construction of the castle, and the foundation of the city of Edinburgh (Edwyn's burgh), now the capital of Scotland. He also founded a cathedral in York; but in 633 he fell in the defence of his dominions, against the combined attack of the Saxons of Mercia and the Britons of Wales. Under Oswald, who came to the crown in the following year, Northumberland was again united into one kingdom; and afterwards governed by the celebrated Egbert, who, in 827, out of the Saxon heptarchy, formed the great kingdom of England. After a long series of disasters from Danish invasion, and the internal disorders of the kingdom, York was exposed to utter destruction from the memorable expedition of Harold Hardrad, king of Norway. On the death of Harold of England, an unsuccessful attempt was made by the people of York to place Edgar Atheling on the throne. For this step, William of Normandy besieged the city in 1070, which, after many months, was compelled by famine to surrender. The conqueror inflicted the most horrible vengeance on the inhabitants, the surrounding country was laid waste, and castles were erected within the walls, to keep the conquered citizens in subjection. With the exception of the contests between the metropolitans of York and Canterbury, little is recorded of the former city until 1137, when the cathedral church, thirty-nine parish-churches, and the greater part of the houses, were accidentally burnt down. About 1160, one of the first parliaments of England was held there by Henry II.; and in the reign of his successor, Richard I., in 1190, occurred the horrible massacre of the Jews, which was perpetrated and accompanied with circumstances of peculiar atrocity. In 1299, the courts of justice were removed from London to York by Edward I. during

his expeditions against Scotland. In his reign this city was classed among the sea-ports of England, and required to furnish one ship for his use. In the languinary contests between the houses of York and Lancaster, the former city naturally espoused the cause of the white rose; and in 1483, Richard III. was a second time crowned in the cathedral. The year 1509 was distinguished by the establishment of a printing press in the minister-yard of York, near the place where the royal presses were afterwards erected in 1642, while king Charles resided in the city. Nothing of moment relative to York is afterwards recorded until the 31st year of Henry VIII., when commissioners were appointed there to conduct the suppression of the northern monasteries. Adhering to the royal cause, the city was, in 1644, besieged by the parliamentary forces under sir Thomas Fairfax. But on the approach of prince Rupert, the siege was raised; and on the 2d of July, the important battle of Marston-moor, about five miles off, was fought, in which the royal party was completely defeated. Returning to the siege, Fairfax, at the end of six weeks, obtained possession of the city, on most honourable terms for the garrison and inhabitants. Notwithstanding the zeal for the royal cause manifested by the citizens of York, their charter was suppressed by Charles II., and never restored. A new charter, however, confirming all the former rights of the city, was granted by his successor James II. in 1685. Down to the 30th of July, 1688, the inhabitants of York continued to express the most determined attachment to James; and on that day, the mayor, aldermen, and commons, congratulated him, in the most energetic terms, on the birth of a young prince.

Civil Government.—The government of York is vested in a mayor, who, like the mayors of London and Dublin, and the provost of Edinburgh, is authorized by the act of Richard II. to assume the title of lord; a recorder, two city-council, twelve aldermen, two sheriffs, seventy-two common-council-men, and six chamberlains. What is styled the privy-council, or the upper house, consists of the lord-mayor, aldermen, and sheriffs, together with those citizens who have passed the office of sheriff. This body, whatever may be its number, is usually called the twenty-four. The mayor, whose office ceases on the 3d of February, is chosen annually from those aldermen who have not borne that office twice, nor within the six preceding years; and during his mayoralty takes precedence of all persons within his jurisdiction. York was early distinguished among the cities of England: in the *Domesday-book* it appears to be exempted from the payment of geld, except when the same is paid by London and Winchester, and from paying reliefs. In 1396 king Richard appointed two sheriffs, instead of three bailiffs, for the government of the city, which was then constituted a county within itself. The earliest charters of York now preserved are, one granted in 1199, and another by Henry III., who died in 1272: but both recite preceding charters of Richard I., Henry I., and Henry II. Representatives in parliament for the city of York appear in the summons and returns of the 23d of Edward I. For the parliament called to assemble at Shrewsbury, on the 30th of September 1283, which was but the 11th year of Edward, two representatives were summoned from a number of cities and towns, among which York stands the fourth in order; those before it being London, Winchester, and Newcastle-upon-Tyne. Under the jurisdiction of the lord-mayor, aldermen, and sheriffs, besides the city, is a considerable district on the W. of the river Ouse, called the Ainstey, in ancient writings, *Ancity*; but its origin and import are now unknown. This tract was once a hundred or wapentake of the West Riding of Yorkshire; but in the 27th year

year of Henry VI. it was annexed to the jurisdiction of the magistrates of York, and has ever since been comprehended in the county of the city of York. The whole district was anciently a forest, but laid open in the reigns of Richard I. and John: it contains 22 parishes subdivided into a number of townships; the inhabitants of the whole amounting, in 1811, to 8205 persons. In all parliamentary assessments the city is called on for three-fifths of the amount, and the Ainstey for two-fifths. Doubts having long been entertained whether the inhabitants of this district could vote for the representatives of Yorkshire in parliament, a decision was obtained in the house of commons in 1735, declaring, "that the persons whose freeholds lie within that part of the county of the city of York, which is commonly called the Ainstey, have a right to vote for knights of the shire for the county of York."

Ecclesiastical History.—The earliest notice respecting the recognised establishment of Christianity in Eboracum, or York, exists in the list of bishops, or pastors, who composed the synod or council of Arles, now Arles, in the south of France, about A.D. 314. The bishops who then appeared on the part of the British church were, Eborius de civitate Eboracensi, Restitutus de civitate Londinensi, and Adelfius de civitate Colonia Londinensium. By the retreat of the Romans in the middle of the 5th century, and the subsequent overwhelming invasions of the Saxons, Christianity was almost entirely suppressed in the northern parts of the kingdom. At last, about 628, Edwin, king of Northumbria, having married Ethelburga, the sister of Ebald, the converted king of Kent, was, by her persuasion, aided by Paulinus, who attended her to York, induced also to embrace the Christian religion. Paulinus was consequently publicly appointed bishop, or, as some say, archbishop of the renovated church of York. The appointment was confirmed, and the new prelate formally invested with the ensigns of his office, by pope Honorius. In former times, jealousies and contentions occasionally took place between the metropolitans of York and Canterbury; to appease which it was often necessary to appeal to the pope. Under the archbishop of York are placed the bishops of Durham, Chester, Carlisle, and the Isle of Mann; and he is styled in general primate and metropolitan of England: but the archbishop of Canterbury assumes the same titles over all England. At the coronation the latter crowns the king; but the queen has that ceremony performed on her by the archbishop of York. By the removal of the seat of government to the southern parts of the kingdom, and particularly after the Norman Conquest, the prelates of Canterbury and Winchester, situated near the throne, soon acquired an ascendancy over their brothers of York in political favour and power. Among the latter, however, were many men of eminence in the history of the church and of the state. Wilfrid, appointed in 669, founded the celebrated monastery of Ripon. Egbert, the brother of Eadbert, king of Northumberland, was the patron of Alcuin, the enlightened secretary of Charlemagne. In 930 Wulfstan was deprived for aiding Anlof, the Danish king of Northumberland, against Edred of England. Aldred, who succeeded in 1060, was the last prelate of the Saxon race; for dying in 1070, he was succeeded by Thomas, a Norman. Gerard, appointed in 1100, as well as his predecessor, refused obedience to the see of Canterbury; but pontifical authority compelled him to submit. Obedience was again denied by Thurstan, who had been appointed in 1114; but at last he retired to a monastery. In 1153 succeeded William, afterwards canonized. Roger, suspected of being privy to the death of Becket, was acquitted on his oath of purgation. In 1190 the see was filled by Geoffrey

Plantagenet, son of Henry II. and the Fair Rosamond. His successor, Walter de Grey, is said to have transmitted a prodigious sum to Rome for his infatuation: but for this apparent simony he atoned by purchasing the manor of Thorpe for the country-residence of the archbishops of York, and by contributing materially to the erection of the cathedral. While the see was occupied by John Thoresby, appointed in 1352, in order to remove the contentions between the two archbishops, pope Innocent VI. established the distinction before-mentioned in the metropolitan dignity. Richard Scroope, who succeeded to the see in 1398, was, in 1405, beleagued for the active part he took in opposition to Henry IV. after the murder of Richard II., who, on various occasions, had shewn a particular favour for York. The fifty-second prelate, appointed in 1464, was George Neville, brother of the famous earl of Warwick, and distinguished by the misfortunes of his latter years, no less than by the unbounded magnificence of his installation. Christopher Bainbridge, appointed in 1508, and ambassador to Rome, was created a cardinal; but was soon after poisoned by an Italian priest, his steward. His successor, in 1514, was the celebrated cardinal Wolsey. By the exertions of archbishop Heath, appointed in 1555, the see recovered a great part of the revenues it now enjoys, which had been alienated by the arbitrary and avaricious measures of Henry VIII. As a Roman Catholic, he was deprived of his dignities by Elizabeth, who, however, respected his merits, and allowed him to retire to his estate at Cobham. In 1641 the see was filled by John Williams, who, after warmly espousing the royal cause, openly joined the parliament. After him the see remained vacant for ten years until 1660, when, on the restoration of Charles II., it was conferred on archbishop Frewen. Archbishop Dolben, who succeeded Richard Sterne, was an ensign in the army in his youth, and bled in the royal cause at Marston-moor: he died in 1688. The last prelate was Dr. Markham, who had been head-master of Westminster-school, and preceptor to the prince of Wales. Dying in 1808, he was succeeded by the present archbishop, the honourable Edward Vernon.

Antiquities.—That Eboracum possessed temples, palaces, theatres, and the other public edifices with which the politic Romans were in the habit of adorning the principal, and even in some cases the minor cities within their dominions, cannot be doubted; but all such structures have long disappeared. The most remarkable monument of Roman occupation now to be seen is what is called the multangular tower, being a polygon forming the N.W. angle of the Roman wall, near the N.E. bank of the Ouse. The lower part of this tower is faced with rows of regularly squared stones, separated at broad intervals by layers of flat bricks. The upper part of the tower, pierced with loop-holes, is of much later date. Various Roman inscriptions have been and continue to be discovered in York: some are mentioned by Camden, who was the first to record them. In digging for a cellar, in the beginning of the last century, in what is called the manor, or the ruins of St. Mary's abbey, on the outside of Bootham-bar, was found a small bust in bronze. In the environs of the city, particularly on the London road, which follows the course of the ancient Roman way, sepulchral urns of various kinds have been discovered. Coins, seals, fibulæ, and many other relics of Roman antiquity, are abundantly found within and around the city. The coins bear the names of all the emperors, from Augustus to Gratian. In 1807 a small vault of Roman construction was discovered, four feet below the surface, on the outside of Micklegate-bar, containing a stone coffin, with a human skeleton entire, a lacrymatory, &c. In 1813 two large

stone coffins were found without Bootham-bar; and are now preserved in the cathedral. In 1814 was laid open a beautiful tessellated pavement, within Micklegate-bar, but without the Roman town; but unfortunately a part of it only was preserved; this was the first ever found in York. The walls of the city, which probably succeeded to the Roman fortifications, and which are now in rapid and disgraceful decay, still retain sufficient evidences of their ancient strength and importance. When they were erected is now unknown; but their construction on the Roman foundations is generally ascribed to Edward I., about 1280: in the time of Henry VIII. they were in complete repair. The oldest part of the present walls appears to be that adjoining to Walmgate-bar, at the S.E. corner of the city, on the road to Hull, where the remains of the Red tower are still visible. During the last siege of York, in the civil wars, by sir Thomas Fairfax, in 1644, these walls were so shattered as to require three years to repair them: but since that period they have been shamefully neglected by those whose duty it is to preserve them.

York is distinguished among the cities of England for its ancient gates, or bars, as they are termed. Of these, Micklegate-bar, on the S.W. side of the present city, under which is the road from London, is the most remarkable. It consists of a lofty square embattled tower, with loop-holes, &c. and guarded by an adorned work, with bastion-turrets, &c. Bootham-bar, at the N. entrance of the city, not far from the Roman tower, is almost wholly constructed of materials formerly employed in Roman buildings. Monk-bar, on the N.E., and the Walmgate-bar on the S.E., seem to be of equal date, and were probably erected by Edward III. The whole circuit of the ancient walls is nearly two miles and three-quarters.

Castle: Clifford's Tower.—Nearly at the junction of the Ouse and the Foss, on an eminence, is the site of the ancient castle, accessible only from the city on the N., and strengthened on the other sides by the Foss, carried round it in a deep moat. Prior to the Norman Conquest, York possessed a castle, by some supposed to have stood on the W. side of the Ouse. It is, however, much more probable, that the principal fortrefs occupied the position here described, on which William of Normandy erected his castle, which was restored by Richard III. Ceasing to be regarded as a place of strength, it was converted into the prison for the county of York: but becoming ruinous, the whole was, in 1701, taken down, and the present grand structures, still retaining, although very incongruously, the original name, were erected. Within the inclosure of the ancient castle on the N.W. is a high mount, surrounded by a deep ditch, rising 90 feet above the river Ouse, and 30 above the site of the castle. On the summit stands Clifford's tower, consisting of four segments of circles joined together, and so called, it is said, from the first governor, after its erection by William the Conqueror, to whose castle it served as the keep. In the time of Henry VIII. this tower was in a ruinous state: but on the commencement of the disorders in the reign of Charles I., it was repaired and fortified by the earl of Cumberland, who mounted some pieces of artillery on the platform. In the year 1684, the powder-magazine within the tower exploded, and the building was reduced to its external walls, as now existing. Corresponding to Clifford's tower, on the W. side of the Ouse, is another mount, called the Old Baile, or *Vetus Ballium*; also the site of an ancient fortrefs.

Public Buildings.—At the head of the public edifices of York is necessarily placed the venerable minster, or cathedral, which, considered in its totality, is unparalleled in

England. The earliest erection of a *stone* edifice for the service of the Christian religion in York is always ascribed to Edwin, king of the Northumbrians. This church was founded about A.D. 628; but it was completed by bishop Wilfrid, after 669, who covered the roof with lead, and filled the windows with glass. This last invaluable substance must have been imported from the continent; for it was not till 674 that glass-makers were first introduced into England by Benedict Biscop, to glaze the windows of his new monastery at Bishop-Wearmouth. That the cathedral of York suffered with the other parts of the city by the ravages of the Danes in 867 is most probable: but it is not noticed until 1069, when it was destroyed, with a great part of the city, in a conflagration occasioned by the Norman garrison, when attacked by the united Danes and Northumbrians. To punish the refractory people of the city and vicinity, William of Normandy expelled the ecclesiastics, and seized the revenues of the see: but these were soon restored, and his chaplain and treasurer, Thomas, a Norman, was promoted to the archbishopric. By this prelate the cathedral was rebuilt in a magnificent style; but in 1137 it was again destroyed by fire, together with the abbey of St. Mary, and 39 parish-churches. Having for a number of years lain in ruins, archbishop Roger, the strenuous opponent of Becket of Canterbury, began in 1171 to rebuild the choir with its crypt, which he lived to finish. In 1227, his successor, Walter de Grey, erected the transept, with the exception of the N. part, which was the work of John le Romaine, the treasurer, who also raised a central steeple in 1260. In 1291, the son of the preceding being advanced to the see, commenced the nave, which, together with the two noble western towers, was completed by archbishop William le Melton. In 1361, the present beautiful choir was commenced by archbishop Thoresby, who contributed largely to defray the charges of the work. More money having been collected than was required, the surplus was, in 1370, employed to construct the present noble central tower, in the place of one erected by John le Romaine. Thus, in the course of 150 years, the cathedral of York was brought into a form nearly as it now appears. It is a grand and interesting edifice; and consists of a nave with side aisles, a large and lofty transept with aisles, a choir with aisles, and a large space east of the choir, called the lady-chapel, with aisles. Beneath the altar is a crypt; on the fourth side are three apartments called vestries and treasury; and at the end of the north transept is a fine chapter-house, with a corresponding vestibule. The west end is adorned by two elegantly ornamented towers, whilst another, of larger dimensions, rises at the centre of the transept. All these parts of the church are on a large and magnificent scale; and though not in an uniform style, yet the nave and choir are of corresponding height and width, and very similar in their windows, columns, and other members. The W. front is more richly adorned than any other part of the edifice. Its two towers diminish in dimensions as they ascend, and have been ornamented with several statues, of which now only very few remain. Each tower is surmounted by eight pinnacles; and in the south tower is a set of celebrated bells. In the front are three entrances; that in the centre is divided into two by a pillar. The entire length of the cathedral is above 524 feet; that of the nave, from the west end to the screen at the entrance of the choir, is 250 feet; the length of the choir to the altar-screen 150 feet; and that of the lady-chapel, at the east end, 65 feet. The transept is in length 222 feet. The breadth of the nave, with its side aisles, is 103 feet; that of the nave itself being 63. In the centre of the nave the height to the roof

is 91½ feet; in the transept 103 feet; and in the choir 101 feet. The elevation of the central tower or lantern is 213 feet; that of the towers at the W. end 196 feet. The great windows which occupy the principal part of the W. and E. ends of the church are particularly beautiful. The great E. window, especially, is of uncommon dimensions and richness. It was executed about 1405, at the expense of the dean and chapter; and the glass painted, &c. by John Thornton, of Coventry, glazier, who engaged to finish it in three years, and for which he was paid four shillings *per week*. Spacious, lofty, and light, the interior of this cathedral has a most imposing effect. For although the choir be separated from the body of the building by a screen furnished by the organ, still from the W. end the eye ranges over all, quite to the great terminating window in the E. The nave consists of a double range of eight lofty pointed arches, supported by slender clustered columns. A similar arrangement prevails in the choir; but the transept is of a different age, style, and character, to all the other parts of the church.

Great labour has been bestowed in the carving of the stalls of the choir, which are of oak. The screen behind the altar is stone, divided into eight pointed arches, the upper parts of which are perforated and glazed. At the entrance of the choir is a very elaborate screen of tabernacle work, perhaps of the time of Henry VI. It is covered with niches, canopies, pediments, pinnacles, &c. and contains statues of fifteen English monarchs; *i. e.* eight on one side of the entrance, and seven on the other side. The whole has been of late years suitably repaired. The central tower, or lantern, as it is usually called, is supported by four lofty arches resting on strong massive clustered piers.

Among the monuments of prelates and other eminent persons preserved within the cathedral of York, is distinguished that of archbishop Walter Grey in the fourth transept. It exhibits his effigy in his pontificals, covered by a magnificent canopy, supported by slender pillars. The whole was enclosed with a handsome railing by the late Dr. Markham. But the most elegant of all is the monument of archbishop Bowet, appointed in 1423, of great height, and in the most florid style of the pointed architecture. A full-length statue, with emblems and an inscription, commemorates the late Sir George Saville. Attached to the fourth side of the choir is a range of low buildings, styled the vestries; in one of which are preserved sundry emblems of the ancient metropolitan dignity of York cathedral. Among these is a famous antique horn, as it is termed, although formed out of an elephant's tooth, by the possession of which the church holds lands of great value, said to have been granted by Ulphus, a Saxon prince of Deira. In the same place is preserved the silver pastoral staff, presented by Catharine of Portugal, dowager of Charles II., to her confessor, who had been appointed popish archbishop by James II. in 1687. Adjoining to the S.W. angle of the transept was a small building, formerly used as a library. A library for the use of the ecclesiastics of the cathedral is believed to have been founded by Egbert the archbishop in 740, and his successor Albert; but the whole was consumed by fire in 1060. By this misfortune no small loss was sustained by the lovers of learning; for according to certain writings of Alcuin, the secretary of Charlemagne, many valuable classic and other works were contained in it. To supply in some measure its place, another library was collected by archbishop Thomas, the Norman; but that also was destroyed by the flames in 1137. From this period, the cathedral is not known to have been furnished with many books until the private collection, consisting of upwards of 3000 volumes, of

archbishop Matthew, was bestowed on it by his relic in the beginning of the 17th century. By various subsequent bequests, presents, and purchases, a large collection of valuable books and manuscripts has been formed, and placed in what was formerly the chapel of the archiepiscopal palace, on the north side of the cathedral. This building has been lately repaired in a style suitable to that of the church, and commodiously adapted to its present destination. Connected by a short passage or vestibule with the N.E. angle of the transept of the cathedral is the chapter-house, an octagon room, 63 feet in diameter, and nearly 63 in height. This building differs from many others of the same kind, in having no central pillar to support the roof: but the pressure of the arched roof upon the walls is effectually counteracted by buttresses at each external angle. From the similarity of the style of building with that of the nave of the cathedral, founded in 1291, the chapter-house is supposed to have been erected about that time. The buildings belonging to the cathedral were formerly separated from the city by walls; and some remains of the gates of communication may still be discovered. Of those buildings, the principal was the archiepiscopal palace, situated on the north of the church. It was erected by the first Norman prelate appointed in 1070; but after a lapse of about 500 years, the great hall was taken down by the Protestant archbishop Young, for the sake, it is said, of the lead on the roof. Since that time other parts of the palace have been leased out. In former times to the see of York belonged various places of residence; but now that of Bishopthorpe alone is occupied. This is agreeably situated on the side of the river Ouse, about three miles south-west from the city. It was purchased and appropriated to the see by archbishop Walter de Grey, in the early part of the 13th century; since whose time it has undergone many important alterations and improvements. The principal front and the vestibule are in the pointed style of architecture, and in the interior are several spacious and elegant apartments, besides the chapel and library. In the minister-yard still remains the residence of the dean of the cathedral, a spacious and convenient edifice of respectable appearance.

Of the parish-churches in York, that of St. Margaret in the south-east quarter of the city is remarkable for the porch attached to it, but which is of much higher antiquity than any other part of the edifice. It was removed from the church of St. Nicholas, formerly situated without Walmgate-bar, but ruined during the siege of York in 1644. The arch of the porch is femicircular, and exhibits alternately the signs of the zodiac and the emblems of the months. The churches of St. Denys and St. Lawrence have also an appearance of considerable antiquity. Next to the cathedral, the church of St. Michael-le-Belfrey is the largest and the most regular in the city, supported by light pillars and pointed arches. The present building was erected on the removal of the former in 1535. The church of All Saints, on the pavement, is distinguished by its open octangular turret, erected on a square tower, in which, according to tradition, a large lamp was suspended in the night, to guide travellers over the broad forest of Galtres, which extended on the north and east of the city. York contains places of meeting for various classes of dissenters from the established church; that for the Society of Friends, lately erected, is large and commodious. A handsome chapel for the use of the Roman Catholics was built in 1782.

Of the numerous religious establishments formerly existing in and near York many vestiges still remain. Of these,

YORK.

the principal was St. Mary's abbey, situated on the bank of the river Oufe, on the outside of the city wall. The foundation of the monastery is of uncertain date; but the church, of which some considerable ruins still remain, was rebuilt in 1270. Having fallen to decay after the general suppression of religious houses, Henry VIII. ordered a palace to be erected out of the ruins, for the residence of the lord-president of the north of England, to be designated the 'king's manor.' This was enlarged by James I. Previously to the Revolution it became an object of popular outrage: but some years afterwards the king's Mint was established in it, and much gold and silver, distinguished by the initial letter Y, was struck there for William III. The site of the abbey and the manor have long been leased from the crown by lord Grantham and his predecessors. Connected with the religious system of former times, it may be noticed, that adjoining to the walls of York, immediately without Micklegate-bar on the London road, is an establishment called the Nunnery. The building was originally acquired in 1686, as a place of education and living for young ladies of Roman Catholic families. The establishment at present consists of the superior and twenty assistants, who wear the dress and conform to the regulations of nuns in Catholic countries, with twelve lay-sisters, and a chaplain. From sixty to seventy boarders are usually accommodated in the institution.

The Guild-hall and the Mansion-house are situated near the river Oufe, in the north-west quarter of the city. The hall, built in 1446, is a noble room, ninety-six feet long, forty-five broad, and twenty-nine feet six inches high. In it are held the law-courts and the courts of municipal justice. The Mansion-house was erected in 1725, and contains every necessary accommodation for the lord-mayor. In the same quarter of the city are the assembly-rooms, the theatre, the subscription library, the principal hotels, &c. As a fortress, York castle has long ceased to be of importance: it is now occupied by several structures. That on the W. side of the area is the county-hall, rebuilt in 1777, in which the assizes are held, and other county business is transacted. The centre building is the prison for debtors and criminals: the third building on the E. contains the record-office, and various apartments necessary for the transaction of the business of the county. Of all these buildings it is but justice to say, that in their construction external elegance and taste have been properly combined with a due attention to their several destinations. The arrangement and management of the prisons have been frequently the subject of commendation. The new city-goal, an extensive stone structure near the Old Baile, on the west side of the river Oufe, and the house of correction, are also deserving of attention.

The charitable establishments for the poor and the sick in York are very numerous, and well conducted. Among these, the county-hospital and the city-dispensary are highly commendable. Schools for the education of youth of both sexes are not wanting in York. In 1647 a petition was presented to the crown from the inhabitants of the city and the county, and from other parts of the north, for the establishment of an university in York: but the unsettled state of the affairs of the kingdom then prevented due consideration of the request; nor has it since been renewed; although, for various important reasons, York seems peculiarly adapted for a place of literary and scientific retirement and study. A seminary or college for the education of ministers and lay-gentlemen among Protestant dissenters, which formerly subsisted at Manchester under the successive care of the Rev. Dr. Barnes and Mr. Walker, and was liberally supported by

voluntary subscription, was on the death of the latter professor removed to York, where it is conducted with great reputation by the Rev. Messrs. Wellbeloved, Kenrick, and Turner.

Bridge.—Communication between the original city of York, and the suburb styled Micklegate-bar on the fourth-west side of the river Oufe, is maintained by a handsome stone bridge, which has lately been erected from the designs and under the direction of Peter Atkinson, esq. of York. In 1154 the bridge was wood: but in 1268 it was probably of stone; for then was founded on it St. William's chapel, in atonement for the death of several persons on the spot in a fray with the people of the town. In 1564 a flood following an intense frost swept away two arches of the bridge, with the houses built on them.

On the south-east side of York, going out by Walmgate-bar, near the village of Hellington, is an establishment for the reception and relief of persons disordered in mind; which has, for some time, been the subject of general approbation. This was called the Retreat, founded by the respectable Society of Friends, and originally intended for members of their class alone. The first idea of this admirable institution was suggested in 1791, by the unfortunate death of one of their society, at a common receptacle for the insane. In 1794 land was purchased, and the building commenced, on a commanding eminence. The general arrangement, management, and system of treatment of the unfortunate patients, have been imitated, as the most perfect of their kind, in various parts of the kingdom and America. See an "Account of the Retreat," 8vo.—Eboracum, or History and Antiquities of York, by Francis Drake, F.R.S. folio, 1736. Description and History of the City and Cathedral of York, 12mo. 3d ed. 1790. Description of York, 12mo. 1816. A Guide to the Cathedral of York, 12mo. 1815, is a rational and judicious vade mecum.

YORK, Custom of. See RATIONABILI parte bonorum.

YORK, in *Geography*, a county of the United States, in the district of Maine, containing 23 towns, and 41,877 inhabitants.

YORK, a district of South Carolina, containing 10,032 inhabitants, including 3164 slaves.

YORK, a county of Pennsylvania, south-west of Susquehanna. It contains 22 townships, and 31,958 inhabitants.

YORK Borough, a town of Pennsylvania, in York county, containing 2847 inhabitants.

YORK, a township of Pennsylvania, in York county, containing 1649 inhabitants.

YORK, a county of Virginia, with 5187 inhabitants, including 2931 slaves.

YORK, a town of United America, in the district of Maine, and county of York, containing 3046 inhabitants; 50 miles N.N.E. of Boston. N. lat. 43° 7'. W. long. 70° 40'.

YORK, a township of Ohio, in the county of Belmont, containing 1349 inhabitants.

YORK, the capital of Upper Canada, situated on the lake Ontario. It is likely to become a city of great importance, as it possesses great facilities for commerce and navigation. It lies in about 43° 35' N. lat., within an excellent harbour of the same name, made by a long peninsula, which embraces a basin of water sufficiently large for containing a considerable fleet. Vessels may ride safely at its entrance during the winter. On the extremity of the peninsula, which is called Gibraltar Point, are erected commodious block-houses and stores commanding the entrance into the harbour. On the main land opposite

YORK.

posite to the Point is the garrison, situated on a point made by the harbour and a small rivulet, which being improved by sluices, affords an easy access for boats to go up to the stores. The barracks being built upon a knoll are well situated for health, and command a delightful prospect of the lake to the west, and the harbour to the east. The government-house has a striking appearance from the lake, and is well calculated for the residence of a governor. Its situation is commanding, about two miles above the garrison, being the head of the harbour. The town is increasing; the society of the place is respectable. The public buildings are designed for the legislative council, house of assembly, and courts of law. The gaol is in a healthy situation. The town is furnished with every convenience, and the market is well supplied with good beef, mutton, venison, fish, &c. The wheat supply is from Montreal: the land around York is in general sandy; but bears good crops of every description. The plan of the town is one mile and a half in length; the streets are tolerably uniform; and the river Don empties itself into the harbour, a little above the town, running through a marsh, which, when drained, will afford excellent meadows. The country round this place is capable of great improvement, and renders it fit for a seat of government. See Boulton's Sketch of Upper Canada, ch. viii.

YORK, a river of Virginia, formed by the union of the North Anna and South Anna, which runs into the Cheapsack, near its mouth.—**Alfo**, a river of America, in the district of Maine, which runs into the sea, a little below York.

YORK Bay, a bay on the fourth-west coast of the island of St. Vincent; 2 miles N.W. of Kingstown bay.—**Alfo**, a bay formed by the union of the East and Hudson's rivers below New York. It communicates with the sea by a channel, called the Narrows.

YORK Fort, a fortress at the mouth of Nelson's river, in Hudson's bay. N. lat. 57° 2'. W. long. 92° 46'.

YORK Island, a small island, near the east coast of the island of Antigua; about half a mile N.N.E. of Frier's Head.—**Alfo**, one of the Gallapagos islands, in the Pacific ocean.

YORK Islands, three small islands, in the South Pacific ocean, near York Cape, on the north coast of New Holland.

YORK Minster, a lofty promontory on the coast of Terra del Fuego, so called by captain Cook in 1774. It forms the north-west point of entrance into Christmas sound. S. lat. 55° 26'. W. long. 70° 25'.

YORK Point, a cape in the straits of Magellan. N. lat. 53° 39'. W. long. 73° 32'.

YORK River, a river of America, in the province of Maine, which runs into the Atlantic, N. lat. 43° 7'. W. long. 70° 40'.

YORK Road, a road for ships in the straits of Magellan, near the coast of Patagonia. The only danger of falling into the bay, that is formed by two points in this road, arises from a reef that runs off to about a cable's length from the western point, which once known may be easily avoided. To anchor in this bay, it is safest to bring York Point E.S.E.; Bachelor's river N. by W. half W.; the west point of the bay or reef N.W. half W.; and St. Jerom's found W.N.W. at the distance of half a mile from the shore. There is good watering about a mile up Bachelor's river, and good wooding all round the bay, where the landing also is, in all parts, very good. There is plenty of celery, cranberries, muscels, and limpets, many wild-fowl, and some fish, but not enough to supply a ship's company with a fresh meal. S. lat. 53° 39'. W. long. 73° 52'.

YORK, New, one of the United States of America, situated, according to the statement of Melish, between 40° 33' and 45° N. lat., and 3° 43' E. and 2° 43' W. long. from Washington; extending from N. to S. 198 miles, and from E. to W. 256; and comprehending an area of 46,000 square miles, or 28,440,000 acres. This state is bounded on the N. by lake Ontario and Canada; on the S. by Pennsylvania, New Jersey, and the Atlantic ocean; on the E. by Vermont, Massachusetts, and Connecticut; and on the W. by Upper Canada, lake Erie, Pennsylvania, and New Jersey. This territory, according to Spafford's "Gazetteer of New York," comprises an area of 46,085½ square miles, equal to 29,494,720 acres; but this computation includes all the inland rivers and lakes, one half of lake Champlain, and the St. Lawrence; excluding only all the waters below New York island, and that part of the lakes Ontario and Erie which belong to this state. This statement gives 20.8 persons to a square mile. New York is at present divided into 45 counties, and 452 townships, including four incorporated cities; viz. New York, Albany, Hudson, and Schenectady, as exhibited in the following

Topographical Table.

* Laid out since the census was taken.

Putnam county was erected in June 1812, from the S. end of Dutchess county, and is formed of the towns of Philips or Philipstown, Carmel, Frederick, Patterton, and South-East. Courts are held in the Baptist meeting-house in the town of Carmel, and this county sends one member to the house of assembly. The towns are, Carmel the chief, including, in 1810, 2020 inhabitants, the electors being 153; Frederick, with 1811 inhabitants, and 98 electors; Patterton, with a population of 1446, and 110 electors; Philips, with 3129 persons, and 165 electors; and South-East, in which the population is 1887, and the number of electors 161.

Warren county was erected from the N.W. extremity of Washington, March 12, 1813. It comprises the towns of Bolton, Caldwell, Chester, Hague, Johnburgh, Luzerne, Queensbury, and Thurman, the last of which is divided into two towns, called Athol and Warrenburgh. The chief town is Caldwell, with a population of 560 persons, and 60 electors; Athol has 443 inhabitants, and its electors are 20; Bolton has 726, and 30 electors; Chester 937, and 120 electors; Hague 398, and 21 electors; Johnburgh 651, and 82 electors; Luzerne 1015, and 85 electors; Queensbury 1948, and 197 electors; and Warrenburgh 887, with 41 electors.

The face of this state exhibits a great variety. To the S.E. its surface is agreeably uneven; in the middle, mountainous; to the N.W. undulating; flat towards the lakes; and hilly towards the southern extremity.

Of the mountains in this state, the chain called Catskill, or Catskill, is the largest and most extensive, and this presents a bifurcation of the Appalachian ridge, which at the Highlands occupy a tract of about 16 miles in width, lying obliquely across the Hudson, and penetrated by that river. These ridges preserving their general direction stretch across Dutchess county, the eastern parts of Columbia and Rensselaer counties, and exhibit some lofty summits. The Taconic mountains are lofty and very rugged, and Hoosack and Williamstown are mountains which deserve the appellation. But the Catsberg or Catskill mountains present some summits that are higher than any others of the Appalachian chain, if we except the White-hills in New Hampshire. At the Highlands, the summit of Butter-hill is 1432 feet above the level of the river; that called the Crow's-nest 1330; Bell-hill 1391. About 60 miles N., the Round-top is elevated 3655 feet above the level of the river; the High-peak 3487. These summits are in Windham, Greene county, about 20 miles W. of Hudson, and in full view from that city. A turnpike-road which crosses this range of mountains near those summits, winds up till it reaches the astonishing altitude of 2274 feet. Upon this spot the view is inexpressibly grand. The general altitude of the Catskill mountains may be estimated at about 2000 to 3000 feet across Greene county. From Greene they

pass into Schoharie county with ridges less rugged; and towards the southern part, their continuity is less distinctly defined. Until after forming the falls of the Mohawk, this range traverses Herkimer county, forming a rugged tract, and diminishing in altitude till they cross the St. Lawrence into Canada, at the Thousand Islands. These mountains have obtained from the early Dutch inhabitants the name of Helderberg, or clear mountain, presenting, instead of lofty summits of granitic and schist mountains, an elevated plain of considerable and very uniform altitudes. Around lake George, and to the W. of lake Champlain, we find the Peruvian mountains, which furnish the northern sources of the Hudson, and form the height of land that separates the waters of the Hudson and St. Lawrence. The highest of these is probably that called White-face, which commands a view of Montreal, at the distance of near 80 miles. The altitude of this summit is little short of 3000 feet from the level of lake Champlain. These mountains obtained the name of Peru from the French inhabitants, in allusion to their supposed mineral treasures. With some few exceptions, the whole country S. of the Highlands is underlaid by rocks of granite, with superstrata of other rocks, which appear in the elevated tracts. There are some tracts of lime-stone and some of sand-stone, but these are so inconsiderable in extent as to furnish no objection against denominating this the granitic region. Some ranges of hills on the W. of the Hudson, composed of sand-stone, are underlaid by granite; and the Catskill mountains are a mass of sand-stone, similar to the Alleghany mountains in Pennsylvania, intermixed with lime; the Helderberg, with some particles of sand-stone, occasionally interperfed. N. and E. of the Highlands the rocks are chiefly schist that form the substratum, while calcareous ridges of great extent occupy the surface. The hills on the eastern border of Columbia and Rensselaer counties are formed chiefly of fragile schist, intermixed with quartz, and occasional superstrata of lime-stone. On the eastern declivities of these hills lime-stone predominates, forming the marble quarries of Stockbridge, Lansborough, &c. in Massachusetts. The north-western continuation of the Catsberg or Catskill presents a kind of calcareous granite, in which the absence of the felspar is supplied by primitive lime-stone. The Peruvian mountains are principally granitic, though ridges of lime-stone, slate, flint, and sand-stone, appear in conglomerate masses, and these are most abundant in mineral treasures. The whole level county of the small western lakes is calcareous. The Taconic hills that border the south-eastern part of Columbia county are granitic.

The rivers of this state are numerous and extensive; and so are its lakes and creeks. The Hudson and the Mohawk are the most considerable rivers, to which we may add the Sacandaga, a branch of the Hudson and Scroon rivers, connected with Scroon and Brant lakes. The creeks of the Hudson and Mohawk are numerous. The Susquehanna rises in this state; and its western branch, the Tioga, is a river of some note, and claims distinction from several creeks belonging to the former river. The Delaware, which receives several rivers and creeks, forms a part of the western boundary of New York; and the Alleghany, a principal branch of the Ohio, has its origin in this state, and its creeks, large and small, are too numerous for our recital. The Chatauga lake discharges itself into Connewongo creek. The Cataaraugus and Buffalo creeks run into lake Erie; Tonewanda and Ellicott's creeks into Niagara river, forming a part of the western boundary of the state. Lake Ontario, half of which is in this state, receives the Genesee, the Oswego, and Black rivers, which convey into this lake the

the waters of several other rivers and creeks. The St. Lawrence washes more than 100 miles of the north-western boundary, and it receives a number of rivers and creeks. Half of lake Champlain also belongs to this state, and it is supplied by several streams. East river also belongs to this state.

The *climate* and *seasons* must in such an extent of country be very various, so that it is difficult to accommodate any general observation to the whole state. In the eastern territory, or wholly S. of the Highlands, where the prevailing winds are southerly through the warm seasons, the weather is very variable; and the changes of temperature, governed by the winds, frequent and sudden. In the northern part of the state, the weather is less variable; but the winters are long and severe, with a clear and settled sky. This region, extending from the southern extremity of lake George, and westward to near lake Ontario and the St. Lawrence, may be distinguished as the region of the "northern climate." That of the "western climate" comprises the great western territory of this state, extending from the Catsberg or Catskill mountains to the great lake. Here south-westerly winds prevail in a considerable proportion throughout the year. A gentle current of air, that may be traced from the gulf of Mexico, and reaching to a distance of more than 1000 miles, prevails almost constantly from the S.W.; and northerly and easterly winds are almost wholly unknown. In this district, the average temperatures are about three degrees higher than in similar latitudes in the eastern climate. Such is the general character of the western climate of the United States, and the distinction is said to terminate, or nearly so, with the region about lake Ontario. The western climate of this state is therefore warmer than the eastern by about 3° of Fahrenheit; and this is attributed to the greater prevalence of warmer currents of air from the S.W. In the region about Albany, the rigours of winter commence about the 20th of December, and end with February, or about the 10th of March, when the ice usually breaks up in the Hudson. From the middle of March to the end of April, the weather is very variable; the changes of temperature great and sudden, though it be generally rainy, with long-continued storms of easterly winds. May is also a variable month; June assumes a summer character; in July, southerly winds are diminished, and drought prevails; August is more showery, and more uniformly temperate, than any month of the year, and affording health and plenty. The former part of September resembles August, and terminating with mild and pleasant weather. October is an agreeable month; early frosts occur about the 26th of September, though corn ripens till the middle of October; and from the 15th to the 25th of this month the foliage of the forest-trees is destroyed, and early falls of snow commence about this time. December is usually cold and showery, and storms from the N. and E. are frequent, and of long continuance. It is observed, that a general modification of temperature, favourable to agricultural interests, has occurred within the last 10 or 15 years.

This state affords facilities for *inland navigation* superior to any other, combining both the objects and the means of intercourse. The connections of the rivers Hudson, Mohawk, Oswego, Delaware, Ohio, Susquehanna, Alleghany, Mississippi, and St. Lawrence, by creeks and streams, and canals with the lakes Oneida, Erie, George, Champlain, Ontario, &c. are peculiarly favourable to internal navigation and commerce. The canal at Rome, which connects the waters of the Mohawk and lake Ontario, and which was completed in 1797, deserves particular mention; and it

should be noticed to the honour of this state, that the western inland lock navigation company is formed for the direct purpose of improving the navigation of the western waters; and that the project of a great western canal for connecting lake Erie and the Hudson by a boat navigation is a very important object.

The state of New York has few *bays*, exclusively of those of Long island, which are very numerous. It has many islands, among which Nassau, or Long island, claims the first place, as it affords more than 100 miles of sea-coast, many excellent harbours, and many advantages for commerce. Its bays are both numerous and large, and it has immediately dependent upon it many subordinate islands. The islands in the bay of New York, as well as that upon which New York itself is situated, and Staten island, and those belonging to the Hudson, Mohawk, Niagara, and St. Lawrence rivers, to lake Ontario, Champlain, George, &c. might be enumerated if our limits would allow. In this connection we might also mention a variety of bridges that serve to facilitate communication and intercourse between the various parts of this state.

The *soil* and *agriculture* of New York deserve our particular attention. The soil is of various characters in different parts of the state. In some districts it is deep and warm, and well adapted to grain or grass; in other parts it is of a looser texture, and is found in various proportions by the admixture of vegetable remains; forming a thick vegetable mould, with a small proportion of earth, and called by the farmers in that country "black muck." This is soon exhausted, and as it rests on a substratum, called "hard-pan" by the farmers, that is cold and stony, it is incapable of being restored or reclaimed by any manure or art of husbandry. The west end of Long island is rich, fertile, and highly cultivated; but the eastern part has a large proportion of sandy barren plains. Below the Highlands, the soil is principally dry and warm, having a gravelly or sandy substratum, or granitic rock. North of the Highlands to the Mohawk, the soil is dry and warm, being either a gravelly or sandy loam in general; and both those which we have mentioned are stated to be a medium soil. But on the eastern border of the state, the rocks are principally schistose, and a schistose gravel forms most of the soil, which is warm and productive, though not deep. The alluvial flats of Columbia and some part of Rensselaer counties are very extensive and rich; and the valleys, presenting a warm gravelly soil, are also extensive, and furnish much good medium soil. West of Albany are extensive sandy plains, interperfed with marshes, and rather cold and wet till we approach the Helderberg hills. This plain is generally underlaid by clay; but the Helderberg hills are calcareous, and present a better soil, though broken and much diversified.

The agricultural products of this division of the whole territory of the state consists of all the various productions of this country. The west part of Long island, and the counties of West Chester and Dutchess, are well cultivated. The latter is one of the best farming counties in the state. The introduction of gypsum as a manure has marked a new era in the agriculture and rural economy of this region. The west side of the Hudson is considerably behind the eastern. The southern part of Washington county has a warm gravelly medium soil, and abundant crops. Saratoga has much good but more waste land. Its general character is more sandy; and, like that of Albany, rests on clay. Around lake Champlain there is a large extent of clayey soil, extending to the hills that skirt the Peru mountains. With the exception of the alluvial flats, which are extensive and rich, the soil of the country of the Mohawk may be generally

generally denominated a stiff loam, till we go west of the Catskill hills to the Little Falls. Here it assumes a new character. The soil of the mountainous tract of the western region is much diversified: the hills are rocky; the valleys deep and narrow, or spacious and rich. This tract furnishes considerable black muck, or deep vegetable mould, in the valleys. A very large proportion of the soil of this country may be denominated a rich mould, variously intermixed with earth of different kinds; and much of the soil is well adapted for grain and graze. No part of the state is more rapidly advancing in agricultural improvements than this western region. The soil of the level country east of lake Ontario, and along the St. Lawrence, is a warm sandy loam, with a large proportion of the first rate of medium for agriculture.

The rotation of crops lately introduced into this country marks a new era in its agriculture. We shall close this detail with remarking, that the exertions of the agricultural society of this state have been very beneficial, though its publications need more general circulation.

The *botanical productions* of this state are numerous and various. Its forest-trees are luxuriant. The region of the western climate is principally wooded with deciduous trees, and of the loftiest growth. Those of the eastern or Atlantic climate are generally deciduous, but less lofty. The most common forest-trees are, oak, maple, beech, walnut, butternut, chestnut, birch, tilia or bals-wood, poplar, cherry, sycamore or button-wood, alii, elm, salicifera, hornbeam, sumach, elder, pine, spruce, larch, fir, hemlock, cedar, and in some parts, locust laurel, mulberry, black-walnut, cucumber-tree, crab-apple, and common thorn, of many varieties. The state of New York is essentially agricultural. Wheat is the first object of the farmers; and they also cultivate rye, maize, oats, flax, hemp, peas, beans, &c. and most of the domestic grasses are cultivated with success. Fruits are abundant and various; such as apples, affording cyder of the best quality, peaches, pears, plums, cherries, &c. The garden-fruits are as various as those of any state in the Union.

The *domestic zoology* of the state presents the horse, the cow kind, the merino and other kinds of sheep, which furnish good wool, and swine. The wild animals, not to mention the mammoth, the moose, and the bison, now extinct in this state, are, the deer, bear, wolf, and fox; and more rarely, the otter, the wolverene, the wild-cat, racoon, martin, the weasel, hare and rabbit, squirrel and mouse, &c. The lakes and rivers supply abundance of fish, such as the salmon-trout, trout, sturgeon, chad, herring, pike, and many others. The oysters are in high repute. The number of birds stationary and migrating is very great. Serpents are found in small numbers, and the rattle-snake does not frequently occur; other snakes are numerous. It is needless to mention the insects, of which the number and variety are considerable.

The *mineralogy* comprehends iron-ore, salt, gypsum, limestone, marble, slate, native brimstone, coal, ores of lead, copper, zinc, tin, asbestos, mill-stones, marle and peat, clays, alum, swine-stone, &c. Calcareous petrifications are very common in the calcareous regions. Siliceous sand for the manufacture of glass, plumbago, a variety of ochres, mica, singlars, magnesian stones, amianthus, black flints for muskets, molybdena, iron and copper pyrites, emery, magnetic ores of iron, ores of zinc, ores containing silver and antimony, and rock crystals, are severally found in various parts of this state. Its mineral waters are held in high estimation.

The *constitution* of this state was adopted by a convention of delegates April 20, 1777, and revised in 1801; and its

character is republican. The constitution of the United States was acceded to in this state in 1788: The supreme executive power is vested in a governor and lieutenant-governor, elected every three years by free-holders possessing a clear estate of 250 dollars; as are the senators also. The supreme legislative powers are vested in a senate and house of assembly, which meet at least once in each year. The senators are elected for four years; the members, or representatives, as they are called, who compose the house of assembly, are elected annually. The number of senators is limited to thirty-two; that of members is not to exceed 150. For the convenience of electing senators, the state is divided into four great districts: the southern, which elects five senators, and comprehends six counties; the middle, eight; the eastern, nine; and the western, twenty-two. The general election is held annually. A census of the electors is taken every seven years, and the representation apportioned according to the numbers in the respective counties, increasing the number of representatives each year by the addition of two, until they amount to 150. The senators are divided into four classes, elected at different periods, so that some new senators are chosen annually. The governor is commander-in-chief of the militia, and admiral of the navy, of this state: he has power to convene the legislature; to grant pardons and reprieves for crimes, except treason and murder; and can suspend the execution of sentences in those cases till the sitting of the legislature, which alone has a right to pardon. A council of revision consists of the governor, the chancellor, the judges of the supreme court, or any two of them, whose duty it is to revise all bills about to be passed into laws; and if they object in writing to a bill, a re-consideration takes place, and the same must be amended or approved by two-thirds of both houses before it can then become a law: and this is the negative of the executive power. If the council neglect to return a bill, in ten days it becomes a law, unless the legislature has previously adjourned. A council of appointment consists of the governor, and a senator from each of the four great districts, chosen annually by the legislature. In this council, the governor presides, with only a casting vote. The right to nominate is vested concurrently in the governor and the other members of the council. The list of officers annually appointed by this council is enormous, and consists of most of the subordinate officers of the state.

The chancellor holds courts of equity, and appoints the officers of his court. The supreme court is a court of law. It consists of a chief-justice and four associate judges. County courts consist of a first judge and a number of associate justices. Circuit courts are held in the respective counties by a judge or justice of the supreme court, and the judge and justices of the county. Justices of the peace have cognizance of trials for the recovery of debts to the value of twenty-five dollars; and in New York to the value of fifty dollars. The right of habeas corpus is preserved, and the trial by jury.

The great officers of state are, the governor, lieutenant-governor, a secretary of state, comptroller, treasurer, surveyor-general, attorney-general, council of appointment, commissioners of the land-office, the regents of the university, &c. for the department of state.

Judiciary officers of state, a chancellor, five judges of the supreme court, and a judge of probates.

For the general convenience and the better administration of justice, the whole territory of this state is subdivided into counties, and these into towns.

From the report of the comptroller to the legislature of this state in 1811, the productive funds of this state, in-

vested in stock of banks, United States stock, &c. securities on lands, &c. &c. amounted to 4,191,803 dollars 25 cents, producing an annual revenue of 278,489 doll. 96 cents. To this amount of funds should be added the school fund, amounting to 483,326 doll. 29 cents, producing an annual income of 36,427 doll. 64 cents. The state also owns about 1,000,000 acres of land, which, valued at two dollars *per acre*, amount to 6,675,129 doll. 54 cents. The expenses of government for the year 1811 amounted to 268,366 doll. 22 cents. This estimate draws an excess of revenue amounting to 10,123 doll. 74 cents, and including the balance in the treasury, Feb. 16, 1811, of ready funds, to the amount of 34,129 doll. 86 cents.

The militia of this state consists of every able-bodied male inhabitant between eighteen and forty-five years of age; and the laws have made an honourable exception in favour of those whose religious opinions are averse to war. Agreeably to the annual return of the adjutant-general for 1809, the enrolled infantry amounted to 95,324; the artillery, 3102; the cavalry, 3642; giving a total of 102,068.

The constitution provides for the free exercise of religion in this state in the following terms: "And whereas we are required by the benevolent principles of rational liberty not only to expel civil tyranny, but also to guard against that spiritual oppression and intolerance, wherewith the bigotry and ambition of weak and wicked priests and princes have scourged mankind: This convention doth further, in the name and by the authority of the good people of this state, ordain, determine, and declare, that the free exercise and enjoyment of religious profession and worship, without discrimination or preference, shall for ever hereafter be allowed within this state to all mankind. Provided, that the liberty of conscience hereby granted shall not be so construed as to excuse acts of licentiousness, or justify practices inconsistent with the peace or safety of this state. That no minister of the gospel, or priest of any denomination, shall ever hold any civil or military office or place within this state." In April, 1804, a law was passed authorizing all religious denominations to appoint trustees, for the purpose of superintending the temporal concerns of their respective congregations. And these trustees become a body corporate by that general act, capable of all legal transactions in behalf of the congregation.

All denominations, therefore, are left at liberty to support their own ministry, and maintain the order of their worship, in such way as is most agreeable; and every congregation may designate from three to nine of its members as trustees, who are, with little trouble, invested with corporate powers in behalf of the whole, and authorized to hold estates producing an annual revenue of 3000 dollars. This free toleration has not produced more sects in this than in other states less tolerant of religious opinions. There are many sects however; and in the enumeration of those, no regard is paid to comparative numbers. There are, English Presbyterians, Dutch Reformed, Congregationalists, Episcopians, Quakers, Baptists, Methodists, German Lutherans, Moravians, Roman Catholics, Shakers, Jews, and a few of the Universal Friends, or the followers of *Jemima Wilkinson*, Scotch Cameronians, Anabaptists; and Christian charity would include some Indians, beside those who profess Christianity. But it is worthy of remark, that many of the above sectarian distinctions exist merely in name, while their tenets differ less, perhaps, than those of the same religious society, in the individual opinions.

The manners and customs of this state have undergone a considerable variation during the period that has elapsed from its first settlement to the present day. Among those

who planted the colony of New York, and who for many years afterwards settled in it, a large proportion consisted of Dutch families, who migrated hither from the Dutch Netherlands, and transferred to the societies which they established here, the rural economy of the population of the Netherlands, of Holland, and of the banks of the Rhine. Soon after their arrival, various parts of this state presented buildings resembling those of their native country, and habits of neatness, order, industry, and frugality, which they had practised from their youth. After the conquest of the English in 1664, multitudes flocked hither from various nations of Europe, and produced a considerable change in the original and discriminating character and customs of this colony. In 1685 it had a numerous accession of French Protestants. In 1710 it was augmented by about one hundred families of poor Palatines from Germany; sixty or seventy of which settled Germantown on the east bank of the Hudson, and some at Elopis, now Kingston. Other early German emigrants settled on the Mohawk, in Orange county, on Long island, and in many other parts where their descendants are now found. The early English settled principally at New York and in Long island. The French, at New Rochelle, in West Chester county, and on Staten island. The Scotch fixed themselves, during the more early periods, about Albany, and in Washington county. Massachusetts supplied also the east part of Long island with inhabitants, whose posterity form a large share of the present population. But the Dutch were the original proprietors and first colonists, and therefore their possessions were the greatest and the most valuable: nor did they, or the Germans, next to them in number and importance, altogether abandon their discriminating manners and habits. The Revolution, however, produced a material change in this state, and the change, though effected by sanguinary conflicts, was not unfavourable to its general character. The prosperity that succeeded the peace widely diffused a spirit of enterprise and of emigration; and was followed by a surprising increase of population and wealth. Hence arose those various traits of national character, and those diversified habits, manners, and customs, which have distinguished this state. It is observed, that the new character imparted by the influx of emigrants is beneficial to the state; more especially as the New England people have introduced their improved agriculture, their spirit of enterprise, their ingenuity in the arts, and their social habits. In this state, it is said, there are about 100,000 freeholders; and freehold estates are known to produce for their proprietors from 30,000 down to 50 dollars *per annum*; and this fact is alleged as forming a peculiar feature of the civil habits, manners, and customs of the population of this state.

The English language is chiefly prevalent in this state; though the Dutch and German are in use among people of Dutch and German descent: but these and other dialects are declining, in consequence of the intercourse and influence of a large majority of those who speak English. Some few instances, however, occur, in which public worship is performed in the Dutch, German, and Welsh dialects.

The taste for literature and science is gradually increasing, and is promoted by a variety of publications; and by the progressive improvement of school education, for which a liberal fund is provided, which has been already mentioned. We are informed by the writer of communications, of which we avail ourselves in the compilation of this article, that there are about a hundred printing establishments in this state, and sixty-nine gazettes, besides a very considerable number of other public journals, which contribute to diffuse various kinds of knowledge. The advancement of literature is promoted by

an institution established in 1787, intitled "Regents of the University of the State of New York;" being a society of twenty-one gentlemen, possessing adequate powers derived from the legislature for superintending colleges, academies, and schools. The university of New York is acquiring distinction, and the Columbia college claims high reputation. See COLLEGE.

In this state there are fifteen banking companies, with a very considerable sum of capital stock, which is said to have amounted in 1811 to 12,380,000 dollars; and 11 incorporated assurance companies. The manufactures of this state, consisting of woollen, linen, and cotton cloths, leather, paper, hats, iron, &c. are in an improving condition, and are said to have amounted, in 1811, to 30,000,000 dollars, of which 12,000,000 were produced by household industry and enterprise. If we judge of the commerce of this state by the returns of 1810, it must appear to be very considerable. The domestic exports of that year amounted to 10,928,573 dollars, and the foreign to 6,313,757, making a total of 17,242,330 dollars; and it is laid that the port of New York yields about one-fourth of the revenue of the United States, arising from commerce. The exports, exclusive of articles from foreign countries, consist principally of beef, tallow, pork, hams, lard, wheat, maize, rye, butter, cheese, pot and pearl ashes, flax-seed, peas, beans, horses, cattle, lumber, flour and meal, bread and biscuit. The foreign exports are composed of important articles. Wheat, which is the national staple, is exported annually to a very great amount; and about 6,000,000 of bushels on an average, after deducting the supplies for the country, are sent to market from the surplus product of this state. The average annual payments into the treasury of the United States, for duties on imports, tonnage, &c. exceed 4,000,000 of dollars from the district of New York.

The Societies for promoting Agriculture and the Arts in this state are numerous. It has also several Medical Societies; an Historical Society; and also an Academy of Arts lately established at New York. Bible and Missionary Societies are instituted in New York, Albany, and some other counties; and the Charitable and Humane Societies abound. In the city of New York alone there are about forty benevolent institutions; and there are societies of the same kind, as well as those of a literary nature, in Albany, Hudson, Schenectady, Troy, Poughkeepsie, Kingston, Newburgh, Utica, and most of the large towns.

The State-Prison, or Penitentiary, is about two miles from the city-hall, in the city of New York, on the E. bank of the Hudson: it was built in 1796-7, and together with its buildings and courts comprises four acres of ground. The immediate government of the prison is committed to seven inspectors. The convicts are all dressed in uniform, the sexes kept separate, and all are comfortably clothed and fed. Great care is taken of their morals, in the benevolent hope of a reformation.

The Natural Curiosities of this state comprehend the cataracts or falls of Niagara, of the Mohawk, of the Hudson, of West Canada creek, of Black river, Seneca river, Genesee river, and some others of less note. It is probable, that the southern and western parts of this state were occupied by a considerable proportion of Indians at a remote period. So long ago as the year 1535, the country about the lake Onondaga was considered as a favourite situation by the wandering tribes: but their condition was not much known till about the year 1635. At that time, the Iroquoise, or Five Nations, occupied the countries from lake Erie to Ontario, the St. Lawrence, around lake Champlain, and the whole of that watered by the Hudson down to the Highlands, were

very numerous and warlike. Such was their ascendancy, that the Indians of the lower country of the Hudson, on the Connecticut, the Delaware, and Susquehanna rivers, were in a kind of subjection to them. Onondaga was the principal settlement, and the seat of Indian power. Their combination consisted of Onondagas, Oneidas, Mohawks, Cayugas, and Senecas; and it was then so powerful as to be able to send several thousand warriors on distant expeditions. The first Christian colonists, availing themselves of Indian wars, which they promoted, taught the Indians to despise and abhor those for their hypocrisy and perfidy whom they had first considered as beings of a superior order; and thus originated the implacable enmities which not only continued but increased when the French and British became rival nations. About the year 1690, the English erected a strong fort at Onondaga; and in 1696, the French sent a considerable force against the Indian settlement, and succeeded in destroying it. From this time, colonies of each of these nations were planted there at different periods. But we forbear, to pursue their history, and to trace the sanguinary conflicts that served mutually to irritate and incense Indians and professed Christians. At this time, the principal settlements of the Indians are at Oneida and Onondaga, on the Genesee and Alleghany rivers, Buffalo creek, and Tufcarora, besides other places which we have not room to enumerate in detail. But we must hasten to finish this sketch of the New York state by a brief abstract of its history.

Soon after the discovery of America, towards the commencement of the 16th century, the present state of New York was possessed by the Iroquoise, and Canada by the Algonquins, two rival nations of Indians. About the year 1608, the French planted colonies in Canada, which they had laid claim to from having first failed up the St. Lawrence as far as the present Montreal. In 1609 Champlain, the founder, discovered lakes Champlain and George, when he defeated a small party of the Iroquoise. In 1608 Hudson, an Englishman, discovered the East and North rivers, ascending up the latter as far as the present Albany; and soon after he held his right to the Dutch. In 1614 the States General of Holland erected a fort at Albany, and granted an exclusive trade on Hudson river to the Dutch West India company; and in 1629, Wouter van Twiller, the first governor, arrived, and took the command of New Netherland, as it was then called. The English, who still laid claim to this country, objected to the sale of Hudson; and in 1663-4, the English king granted the whole to his brother James, duke of York and Albany, afterwards James II. A small armament subdued the colony for England, which then took the name of New York, as did the city also. In 1673 New York was conquered by the Dutch, but restored in 1673-4. The duke's grant was confirmed, and the colony assigned to the English by treaty; and this right they held till the Revolution. From the surrender of the province in 1664 to 1683, the duke of York possessed full sovereignty. He appointed the governor and the council, who made rules and orders that were acknowledged as laws. These were called the duke's laws; they were collected and arranged about 1674, and a copy of them is deposited among the records of the state. Those, it is said, which were made in 1683, and after the duke's accession to the throne of England, when the people were admitted to a participation of the legislative power, are defaced or lost. No regard is now paid to any laws made here antecedently to 1691, when the first legislative assembly was organized. New York was then divided into nine counties, and the house consisted of seventeen delegates. The second legislative assembly was convened in 1708. We shall not minutely

YORK.

trace the series of events that occurred in this state before the year 1776, when, on July 4, the thirteen united colonies were declared independent. This was followed in 1777 by the formation and adoption of the state constitution, by a convention of delegates, which was revised in 1801. In 1783, New York was evacuated by the British, and general Washington made his public entry Nov. 25. In 1787 the present constitution of the United States was proposed by the convention, and acceded to by this state in 1788, by a majority of 30 to 25 votes. General Washington was elected president of the United States, and Congress met at New York for the first time under the new federal constitution, March 4, 1789. In 1797 Albany was made the capital of the state. In 1801 the legislature divided the state into thirty counties, and these into towns. An academy of the fine arts was founded in New York. In 1807 a steam-boat was established on the Hudson for passengers, between New York and Albany; and in 1811 their number was 5. In 1809-10, the capitol was built at Albany, at an expense of 115,000 dollars, and was first used by the legislature in the session of 1809-10.

YORK, *New*, a county in the American state of the same name, comprises the island of Manhattan, or York island, on the E. side, and near the mouth of Hudson river. It is about $14\frac{1}{2}$ miles long from N. to S., and in breadth varying from half a mile to two miles; its area is about $21\frac{1}{2}$ square miles, or 13,920 acres. It is situated between $40^{\circ} 42'$, and $40^{\circ} 52'$ N. lat., and $0'$ and $8'$ E. long. from the city of New York. It is bounded on the N. and E. by Haarlem and East rivers, S. and W. by the Hudson, or by York bay, and the state of New Jersey. The limits of the county, town, and city of New York are the same; and the only legal subdivisions are the wards, ten in number. The jurisdiction of the city and county of New York extends to low-water mark on the opposite shores of the waters that surround this county. The agriculture of New York county is highly respectable, and its horticulture is in the first style of the country. The whole population of the county probably exceeds 100,000; by the census of 1810, it amounted to 96,373. This county sends 11 members to the house of assembly.

YORK, *New*, a city of America, the capital of a county of the same name, is situated on the E. bank, at the confluence of Hudson and East rivers, at the fourth end of New York island. N. lat. $40^{\circ} 42' 40''$. W. long. from Greenwich $74^{\circ} 0' 45''$. The compact part of this city extends along the Hudson about two miles, and along East river, from the S.W. angle of the battery, near four miles: its circuit is about $7\frac{1}{2}$ miles. The streets of the ancient part are irregular; but the northern part has been recently laid out to greater advantage. Many of the streets are spacious, running in right lines, and intersected by others at right angles. The surface has at present a gentle ascent from the Hudson and East rivers, and commands a fine view on the right and left of the town, the above-named rivers, and their crowds of shipping. The principal streets are, Broadway, opening to the N.E., and extending through the whole length of the city, Greenwich-street, Pearl-street, &c. &c. The usual tides at New York are about six feet, and the depth of water is sufficient for the largest ships; and the harbour, which is safe and good, is capacious enough for the largest fleets, and very rarely obstructed by ice. The houses of this city are well built of brick, and its public buildings are numerous and elegant. The first of these that deserves mention is the city-hall, in which are held the courts for the city and county of New York. This building stands on elevated ground, and its structure is ornamental to the city.

The whole number of the churches, or houses for Christian worship, is 37, besides a Jewish synagogue. Of these, eight are Presbyterian, eight Episcopal, four Dutch Reformed, three Scots Presbyterian, three Methodist, two for Friends or Quakers, two Baptist, two German Lutheran, one French Protestant, one Moravian, one Roman Catholic, two African. The New York hospital is an extensive establishment; the custom-house adjoins the battery at the S.W. angle of the city; the gaol and bridewell are opposite to the Park, and the alms-house is on the same square with the gaol, bridewell, and city-hall. The college is about midway between the Park and the river Hudson; and St. John's church, reckoned the most elegant in the city, is in Hudson-square, farther north. The state-prison is two miles N. of the battery, on the bank of the Hudson. Here are also a library and theatre, six market-houses, and many other buildings that might, if space were allowable, be enumerated. There are eight banking-companies in this city; and their houses and offices, together with those of the insurance, manufacturing, and other companies, and those of various societies, add to the number of edifices that adorn the metropolis. The population, which by the census of 1810 was estimated at 96,373, is supposed to amount to more than 100,000. The city and harbour of New York have been lately fortified against naval assaults at a very great expense: but we should be tedious in minutely describing the works which have been constructed for this purpose. The number of charitable establishments, and of schools for education in this city, is very great, and does honour to the disposition and liberality of its inhabitants. The markets, which are kept every day, are well supplied with the productions both of land and water. The public walks and amusements in the vicinity of this city afford attraction to its stated inhabitants, and to those who occasionally resort hither. The theatre, reading-rooms, public-gardens, park, and walks on the battery, afford amusement, and contribute to activity and health.

The city of New York is governed by a mayor, recorder, aldermen, and assistants, who constitute the common council. Each ward chooses an alderman and assistant. The mayor, deputy-mayor, recorder, and aldermen, are ex-officio justices of the peace, and justices of oyer and terminer; and the mayor, aldermen, and commonalty, are authorized to hold a court of record or of common pleas; and this is called the mayor's court, and deemed of great importance. For the manufactures, commerce, literary institutions, &c. &c. of the city of New York, we refer to the account already given of the state of *NEW YORK*. Melish. Morfe. Spafford's Gazetteer of New York, 1813.

YORK, *New*, a post-town of Virginia; 167 miles S.W. of Washington.

YORK *Town*, or YORK, a township of West Chester county, in the state of New York, 45 miles N. of New York, bounded N. by Duches county, E. by Somers and Newcastlle, S. by Newcastlle, W. by Cortlandt; in length N. and S. 10 miles, and nearly 4 miles wide. The general surface is hilly, but productive, and well distributed into arable, pasture, and meadow lands. In 1810, here were 269 taxable inhabitants, 142 electors, and in all 1924 inhabitants.

YORK *Town*, a town of the state of Virginia, capital of the county of York, on the right bank of York river, about 10 miles from its mouth, containing about 800 inhabitants. In the year 1781, the British army under lord Cornwallis surrendered themselves prisoners of war to the united forces of America and France near this town, and was the occasion of a peace which followed soon after. A marble

YORKSHIRE.

column, with a suitable inscription and trophies, was ordered by Congress to be erected on the spot in commemoration of the event; 8 miles E. of Williamsburgh.

YORKSHIRE, a county in the northern part of England, which, for extent, for its number of inhabitants, and for its natural and artificial productions, is by far the most considerable in the kingdom. In its general form the county is an irregular quadrangle; the longest diagonal extends from N.W. to S.E. about 130 miles, and the shortest from S.W. to N.E. about 90 miles. The area of the county comprehends about 5,960 square miles, or above 3,814,000 statute acres. Yorkshire, taken at its extreme points, is situated between the parallels of $53^{\circ} 18'$, and $54^{\circ} 40'$ N. latitude, and between $2^{\circ} 40'$ of W. and $0^{\circ} 10'$ of E. longitude from Greenwich. On the N., the E., and part of the S. sides, it is distinctly defined by rivers and by the sea. On the N. it is separated in its whole extent, from the county of Durham, by the river Tees. From the mouth of this river to the entrance of the Humber, the whole E. side is washed by the German ocean. By the estuary of the Humber and the river Trent, it is divided from Lincolnshire on the S. The limits between Yorkshire, and the counties of Nottingham, Derby, and Chester on the S., and those separating it from Lancashire and Westmoreland on the W., are merely conventional, being indicated by no natural feature of the country; the latter, however, in general, coincide with the mountainous range which distinguishes the northern from the southern provinces of England. At a very early period of the Saxon dominion, the great county of York was subdivided into three districts, still recognized, and still under the corrupted name of ridings. These are termed north, east, and west, in reference to their relative positions with respect to each other, and to the capital city of the county. The North Riding is subdivided into 12 wapentakes, the East into 7, and the West into 11 wapentakes; the whole county thus containing 30 wapentakes and 563 parishes. The wapentake, a division adopted in certain northern counties of England, corresponds generally to the cantred or hundred of the southern provinces. The whole county comprehends one archiepiscopal city, York, and 59 market-towns, of which 13 are parliamentary boroughs. Of those left in the North Riding are 5, *viz.* Malton, Northallerton, Richmond, Scarborough, and Thirsk; the East Riding contains three boroughs, Beverley, Heydon, and Hull; in the West Riding the five boroughs are, Aldborough, Boroughbridge, Knaresborough, Pontefract, and Ripon. Yorkshire lends thirty members to parliament; *viz.* two for the county, two for the city, and two for each of the boroughs just named. According to the official reports made in 1811, the number of houses and inhabitants in the county was the following:—In the North Riding 33,567 houses, and 152,445 inhabitants; in the East Riding (York city included), 31,420 houses, and 167,353 inhabitants; and in the West Riding, 129,575 houses, and 653,315 inhabitants. From this statement, Yorkshire, at that period, contained altogether 194,562 houses, and 973,113 inhabitants, or on an average 163 persons for each square statute mile.

General Appearance, Soil, and Climate.—Yorkshire is an extensive and interesting county: in its geographical features, and geological characteristics, it presents important themes for inquiry and disquisition. Its ancient history, and the numerous antiquities with which it abounds, afford other and not less interesting topics for investigation and comment. The manufactures, commerce, and trade of the county; its mineral productions, and agricultural practices, are also entitled to the most careful and critical develop-

ment of the topographer. It is, however, to be regretted, that neither of these subjects has hitherto been satisfactorily elucidated by a local historian; whence we shall be necessitated to refer to and cautiously analyse several detached and imperfect works, to render a short topographical account of this widely-extended county in any degree useful to the general reader. In the sequel these works will be referred to.

Yorkshire presents a great variety of surface: mountains, hills, vales, moors, fens, rocks, coast, and rivers, are its component parts; but these are greatly diversified. The North Riding consists principally of two hilly regions, separated by a comparatively low tract, which opens on the S. into the spacious plain or vale of York. The hilly parts are commonly termed, from their position and their nature, the E. and the W. moorlands. Those on the E. bounded by the valley of the river Tees on the N., and by the sea on the N.E., occupy a space of 30 miles from W. to E. by about half as much from N. to S. They consist in general of bleak heath, interspersed with loose blocks of stone, or with peat-moss and bog. The whole is destitute of wood, excepting in a few intersecting dales or valleys, where cultivation is practicable. Of these dales a few are of moderate extent, particularly Elkdale and Bildale, in the eastern parts toward the sea. The western extremity of these moorlands, in the district of Hamilton, produces heath intermingled with large quantities of coarse grass. Between the N. edge of the moorlands and the river Tees is the fertile district of Cleveland. Several productive valleys intersect the W. moorlands, of which Wenleydale is the most considerable. Watered by the river Ure, the bottom of the valley furnishes rich grazing grounds, bordered on each side by sloping inclosed fields, which reach up the hills for more than a mile from the river. In the East Riding the face of the country, although varied, is less boldly characterized than that in the N. It is divided in the middle into two extensive plains, by the Wolds, a range of hills stretching N. and S. Towards the sea the coast of this Riding is in general low when compared with that of the North Riding; but in several places it rises to cliffs of considerable height, as at and in the vicinity of Flamborough-head. The S.E. part of this Riding consists chiefly of a tract of fen and marsh, about 20 miles in length, and four in breadth, which spreads from the sea to the Humber. This part of the Riding, forming the wapentake of Holderness, runs out to the S.E. and S., and terminates its course at the Spurn, a well-known point on the N. shore of the Humber. A succession of easy risings forms the eastern ascent of the range of the Wolds; but on other sides they are steep; and the whole have an agreeable and peculiar appearance. Considered with respect to extent and population, to manufactures and trade, the West Riding is by far the most important division of Yorkshire. Its surface is very irregular, varying from the low marshy tracts in the E. to the rocky mountainous country in the W. The level marshes are the continuation of those already mentioned in the East Riding, and extend westward nearly to the great N. road through Doncaster. Still farther westward lies the middle division of the West Riding, gradually and beautifully swelling into hills, and extending to Sheffield, Bradford, and Outley. Beyond these towns, the country becomes rugged and mountainous, and is composed chiefly of black moors, which terminate in the lofty range of hills bordering on Lancashire. These hilly and mountainous tracts are not, however, without many beautiful and romantic valleys, among which are those watered by the rivers Aire, Nid, and Wharfe. Several of the smaller dales are well-

YORKSHIRE.

well-wooded and inclosed, and have numerous villages interperfed.

The foil of Yorkshire is not lefs variegated than the furface. In the E. moorlands of the North Riding, wherever the ground is covered with ling or heath, the upper foil is invariably black moor or peat; but the fubfoil is various, and confifts of clay, free-ftone, and hardened fand. In that part of the moors called Hamilton, the foil confifts generally of fine loam on lime-ftone rock. In the interfecuting dales, black moory earth, fand, and grit-rock, more or lefs, prevail; but the vale of Cleveland, along the river Tees, is compofed chiefly of ftrong tenacious clay. Lime-ftone, or a calcareous rock, is the general bafis of the W. moorlands; and the beneficial effects of this fubfoil are evident in the grafs and other ufeul productions with which the furface is generally covered. In the extenfive traët of plain ftyled the Vale of York, which occupies the interior parts of the county, and comprehends portions of all the three Ridings, confiderable changes of foil are found. In the N. part towards the river Tees, a rich gravelly loam prevails. The flopes of the high grounds on the E. and W. are in fome places cold, and abound in fprings; but in the greateft part the foil is ftrong and fertile. Of the Eaft Riding, the moft ftriking feature is the range of hills called the Wolds, compofed of chalk; but the furface is in general a light free loam, interperfed with chalky gravel, often very fhallow. The great plain between the Wolds, the fea, and the lower part of the Humber, contains many extenfive traëts of fertile cultivable land, efppecially in the N. and E. quarters; but the fouthern diftricts, towards the river, are covered with marfhes and fens, fufceptible, where draining can be praëficed, of material improvement. In the continuation of thofe fens, fituated on the W. of the Wolds, called the Levels, the foil is either clay or fand, with moorifh traëts interperfed; but on the banks of the Darwent and the Oufe ftrong clay and loam prevail. In the extenfive Weft Riding foils of every kind are to be found, from deep ftrong clay and rich loam to the poorelt peat-earth. Clay and loam, but mingled with fome fand and moor, prevail in the E. diftrict of this Riding, while the middle divifion confifts chiefly of loam on a lime-ftone bafis. Similar foils extend through the W. parts, but are frequently interrupted by traëts of moor of different kinds.

In a country of fuch extent, and of fuch variety of foil, elevation, and exposure, as Yorkshire, an accordant variety of climate, with regard to temperature, humidity, and falubrity, muft naturally be experienced. The E. moorlands, advancing high and bold into the German ocean, are neceffarily expofed to the cold, moiit, and impetuous winds from the N. and E. The climate there, however, is rather difagreeable than unhealthy; for the high grounds are frequently involved in fogs and vapours from the fea. Among the W. moorlands the climate is ftill more fevere; but its effects on the productions of the furface are powerfully counteracted by the calcareous rock of which thofe mountainous traëts confift. By their diftance from the fea, combined with their much greater elevation, the fnow remains on them confiderably longer than on the E. moorlands. But the greateft obftacle to agricultural labours in the W. parts of the county is the almoft inceffant rain which falls among the mountains. On them are accumulated and condensed the vapours collected by the oppofite winds, which prevail on the contrary fides of the ifland. By the humidity thus produced, no attempt to raife corn-crops among thofe high lands can fucceed. In the intermediate plains and gently-fwellng traëts of the centre of the county, the

climate is, on the contrary, in general mild and temperate, in proportion to the remotenefs from the mountainous quarters. The low grounds on the banks of the Darwent, are, however, fo moiit, although warm, as to be much better adapted to pafurage than to corn-land. What is faid of the climate of the W. parts of the North Riding is equally applicable to the correfponding portion of the W.; for there the climate is alfo rainy, cold, and ftormy. At Sheffield, although on the S. border of the county, the quantity of rain which falls in a year is about 33 inches. It is, indeed, found by experience, that the lofty traëts which feperate Yorkshire from Lancashire and Cheshire are fully as fubject to fog, rain, and ftorms, as any other portion of England. But notwithstanding thefe circumftances, the air is pure and healthy. The middle and lefs-elevated traëts of the Weft Riding are equally healthy, milder, and lefs humid; holding a defirable medium between the tempeftuous blafts of the mountains in the W., and the dull fogs and damps which ufually befet the low marfhy country in the E. On the oppofite fides of the Wolds, in the Eaft Riding, a different temperature is experienced; for by thofe hills the W. divifion is in general fheltered from the cold damp winds from the fea and the entrance of the Humber, which prevail over the E. divifion. On the Wolds themfelves the air is fharp, and the fnow remains for a confiderable time on the ground. But the mildnefs of the climate in the W. Levels is abundantly compensated, in regard to falubrity, by the vapours of the marfhes.

Mountains.—The E. moorlands of the North Riding form a peculiar feature in the county; for they are wholly detached by their pofition, and by their fubftance, from the mountains in the W. Some points of the E. moorlands rife nearly 900 feet above the level of the fea; but the moft remarkable fummit of the whole is Rofebury Topping. This fingular hill, fituated midway between Stokesley and Guifborough, towards the N.W. edge of the moors, hoots up in a conical form, to the height of 1488 feet above the fea. By its detached pofition and fuperior elevation, it commands, in all directions, a profpect at once extenfive and interefting. The hill feems to reit on a bafis of alum-rock, interperfed with iron-ftone; and its pinnaced fummit indicates to the furrounding country the approaching changes in the weather; for when the fummit is involved in clouds, rains feldom fail to defend on the neighbouring low grounds. It is, however, on the W. borders of the county, that the moft elevated mountains are found. Thefe are a portion of the chain, which, commencing in the S. in Staffordshire, extend northward, with increasing elevation, through Derbyshire, Lancashire, Weftmoreland, Cumberland, and Northumberland, into Scotland. In that portion of this range which belongs to Yorkshire are feveral fummits of very confiderable elevation above the fea. Of thefe, the moft remarkable are, Pennigant, which riles, according to barometrical meafurement, to the height of 3930 feet; Ingleborough, 3987 feet; and Whernfide, 4052 feet. The laft mountain is the higheft in England; for Crofsfell on the borders of Cumberland is in height only 3839 feet; Skiddaw, 3530; and Snowden, the higheft in Wales, 3568. Bennevis, a detached mountain in the N. of Scotland, and the moft elevated in Britain, riles to the height of 4387 feet. Pennigant, fituated about 7 miles N. from Settle, is fteep and towering. Ingleborough confifts of a bafis of lime-ftone, but towards the fummit the grit-rock appears. The E. and S. fides of this mountain are very fteep, and of difficult accefs, on account of a deep morafs at the bottom; but the W. and N. fides, particularly the former, may be afcended

YORKSHIRE.

ascended with ease. Continually receiving vapours from the Irish sea on the W., Ingleborough is seldom free from clouds, and the whole mountain abounds with springs: whence it is covered with verdure, and sheep graze on the most elevated parts. In the vicinity appear Pennigant, distant 6 miles to the E., and Whernside 5 miles to the N. On the N.W. are the mountains of Westmoreland, and on the W. spreads out the low land of Lancashire, bounded at the distance of 24 miles by the Irish sea, of which a great portion may, in clear weather, be descried. In the midst of a circle of hills rises Whernside, on which account, although more elevated, the views from it are not equally interesting with those from Ingleborough. Near the summit are several small lakes or pools, there called tarns, one of which is about 180 yards in length by nearly an equal breadth. In the East Riding, the only hills of note are the Wolds, which exhibit themselves to advantage, in rising out of the low country around them; but at no point are they supposed to exceed 600 feet in height.

Rivers.—Along the whole length of the North Riding, from W. to E., the county is bounded by the river Tees. Rising in the mountains of Westmoreland and Cumberland, it pursues a very indirect course into the German ocean below Stockton, where it spreads out into an estuary three miles in breadth. The river Tees is navigable for ships of considerable burthen up to Stockton; but the channel is serpentine and intricate, and the current is rapid. Commodious anchorage is, however, found at the entrance, in winds from the W. and S. A few inconsiderable streams from the W. moorlands fall into the river Tees; but the great body of the waters of Yorkshire take their course in the opposite direction, and unite with the Humber. Of these rivers, the most northern is the Swale, which, rising in the W. moorlands, enlivens the romantic Swale dale, and, after visiting Richmond, bends S.E. until it reaches Boroughbridge, where it unites with the Ure. The latter river, proceeding from the same moors, passes near to Ripon, and in some part of its course separates the North and West Ridings. Having received the Swale, about six miles below Boroughbridge, the Ure takes the name of Ouse, from an insignificant rivulet which joins it on the W. side. Under this last appellation the combined stream, still farther augmented by the waters of the Nid, traverses the city of York, where it becomes the limit between the West and the East Ridings; and being navigable for large barges up to that city, it receives on its W. side the rivers Wharf and Aire: at last, after a very wandering course to the southward, in conjunction with the Trent, it disappears in the estuary of the Humber. The Aire, already mentioned, a very considerable stream, issuing from the mountains of Craven, facilitates by its waters the important manufactural commerce of Leeds. Receiving on the W. side the current of the Calder, which performs the same service to Wakefield, the joint stream conveys an important accession to the Ouse. Still farther to the S. the Don pursues its course from the W. mountains to Sheffield, where it bends to the N.E. by Rotherham and Doncaster, to its influx into the Aire. Before it be lost in the Humber, the Ouse receives on the E. the Darwent, which, having its sources in the E. moorlands, flows in general S.W. by Malton, across the western parts of the E. district. Two small streams still deserve notice in Yorkshire, not so much for their length of course, or volume of water, as for their great utility in forming the principal ports of the county. In the E. moorlands of the North Riding rises the Eike, which after watering Elkdale opens into the German ocean through the

harbour of Whitby. The river Hull traverses the East Riding from N. to S. passing near to Beverley, and, at its influx into the Humber, forms the secure though not capacious harbour of Kingston, which, from the river, is generally also called Hull.

Canals of Yorkshire.—See CANAL.

Coasts and Harbours.—The sea-coast of Yorkshire, though very extensive, affords but very few harbours of any importance. The mouth of the river Tees, as already stated, is frequented as a place of anchorage in winds from the south and the west. Vessels also often resort to other spots on the coast when the wind blows off the land, such as to Robinhood's bay to the southward of Whitby, to Filey bay on the north-west, and Bridlington bay on the south-west of Flamborough-head.

The principal harbour on this coast is that of Whitby. (See WHITBY.) Scarborough bay is serviceable in westerly winds; and the pier, a noble stone structure, furnishes easy access and safe protection for ships of considerable burthen; for at spring-tides, the depth of water at the entrance is from twenty to twenty-four feet: for want of a back-stream, however, the harbour is in danger of being filled with sand. The entrance of the Humber affords to shipping less protection than from its locality might be expected; for the shores on both sides of Yorkshire on the N.E. and of Lincolnshire on the S.W. are low, and the channel is much incumbered with sand-banks and shallows. Notwithstanding these disadvantages on its north bank, just at the point where the estuary turns its direction from E. to S.E., is situated the much-frequented and important harbour of Kingston-upon-Hull. The natural accommodation of the river has proved very insufficient for the increased shipping belonging and trading to the port, which ranks as the fifth in the kingdom. Docks of great capacity have therefore been excavated, in which vessels lie afloat or dry, as may be required. From this port, the produce of the great manufacturing districts in the interior of the country are exported to foreign parts; and these foreign commodities are transferred to smaller vessels, to be in their turn distributed over the interior of the kingdom. The most remarkable projection of the coast of Yorkshire is the bold and lofty promontory, called Flamborough-head. The cliffs rise perpendicularly over the sea to the height of 100 and 150 yards. They are composed of a mouldering lime-stone rock, of uncommon whiteness; and at the bottom are pierced by a number of caverns, some of them entering a great way into the rock. A new light-house is placed about 400 yards west from the extremity of the promontory. About south by east eleven leagues from Flamborough-head is another point of great consequence to mariners. This is the Spurn-point, which, running out southwards, low and narrow, forms the north limit of the mouth of the Humber. The light-house is situated in N. lat. 53° 41', and E. long. 0° 17'.

Agriculture.—From what has been already noticed respecting the mountainous and the marshy tracts comprehended within the capacious limits of Yorkshire, agricultural improvements in them must be comparatively very limited. In other districts, however, particularly in the spacious plains forming the central parts of the county, every species of amelioration of the soil which the industry of the inhabitants, availing themselves of the natural means within their command, could apply, has been generally brought into action. The farms are of very unequal extent and rental, conformably to the nature of the soil and to the situation of the farmer with respect to a market. It is remarkable, that in the North Riding leases are unusual; but although the husbandman labours on so precarious

YORKSHIRE.

rious a possession, changes of occupants of farms are by no means common. In the vale of York one-third of the land is computed to be in tillage, and two-thirds in grass; but in Cleveland, along the fourth bank of the river Tees, the country is equally divided between corn and pasture. In the environs of Thirsk, where the dairy is the chief object of pursuit, fully three-quarters of the land are devoted to it. In the valleys or dales which intersect the east moorlands, about one-fifth of the surface is in tillage; but in those of the west, a much smaller quantity is usually ploughed: those parts although inclosed are therefore generally in pasture. In few districts of England have improvements in agriculture been more generally or skilfully introduced than of late years in the East Riding. The farms are commonly large, and vary in annual rent from two or three hundred pounds to a thousand; but in the marshy tracts, called the levels, they are mostly small. By drainage there, and in the flat country, in the vicinity of Hull, large tracts, formerly flooded, now produce plentiful crops of corn; the value of the land being thus increased to ten times its former worth. In the hilly range of the Wolds, barley and oats have in many places been superseded by wheat. In the West Riding the farms are generally small, but in the environs of the manufacturing towns a great portion of the ground is occupied by the inhabitants for the use of their families. To the eastward of Leeds, Wakefield, and Rotherham, the greatest part of the Riding is cornland; but this tract contains no small proportion of common fields. The soil, however, is good, and improvement may be easily introduced. In addition to grain of all sorts, flax is cultivated in the marshlands to considerable extent; and in the environs of York mustard is now a valuable article of cultivation; though it is still considered as the produce of Durham. The horses of Yorkshire, and in particular those of the North Riding, have long and universally been famed. Cleveland furnishes an excellent breed for the coach and the plough; the northern parts of the vale of York others for the coach and saddle; and many of both kinds are bred in the southern parts and the marshes. The East Riding also rears horses of peculiar value. A smaller but hardy and useful kind is bred in the dales of the east moorlands: many of an equally servicable description are also produced in the moorlands on the west. The horned cattle of Yorkshire are of various kinds, adapted to the nature of their pastures, and to the uses for which they are employed. The north parts of the vale of York and the district of Cleveland produce the Tees-water breed, which is ranked among the largest in the kingdom. In the plains where cattle are chiefly kept for the purposes of the dairy, the milk, and not the form or strength of the race, is the main object of attention with the farmer. The sheep in the various parts of the county are also extremely different in their nature and properties. In the North Riding, the flock has of late years been considerably improved by the intermixture of the Northumberland and other breeds. The sheep of the west moorlands are small; but the wool is tolerably fine: those of the east moorlands are still smaller, but with a very coarse wool. Many of the old sheep-walks on the Wolds, in the East Riding, are now broken up, and converted into corn-land. In the West Riding, by the introduction of the Leicestershire breed, the sheep have in many places been highly improved. Those bred on the west moors and hills of this Riding, when brought down early to pasture in the low grounds, become very valuable for food.

In many parts of Yorkshire, great amelioration of the soil has been produced by hollow-draining; irrigation,

and burning the surface, have also been advantageously adopted. In certain tracts, bones bruised in a mill are usefully employed in composts for manure. Considering its great extent, the North Riding of Yorkshire contains but a small proportion of woodlands; the whole having been estimated at about 25,000 acres, of which the vale of York, with its boundary hills to the north, contains about 11,000. Large full-grown timber is accordingly very scarce, excepting on the estates of the earl of Carlisle, C. S. Duncombe, &c. and some other land proprietors. But the oak-timber of this Riding, produced on hard rocky ground, if not of great size, is solid and durable; and hence the valuable qualities of the shipping built at Whitby and Scarborough. The planting of the Wolds in the East Riding has been successfully begun by several proprietors. In the West Riding, the quantity of oak and ash is very considerable; and both are much used for ship-building, and for the various demands of the manufacturers: much is also consumed in the coal and other mines. In the vicinity of Sheffield, the duke of Norfolk possesses above 1500 acres of woodland. According to a calculation made in 1799, the waste lands in this Riding amounted to upwards of 400,000 acres, of which one-third seemed to be proper only for planting. No great progress in that operation has, however, yet been made.

Manufactures.—The manufactured productions of Yorkshire, especially of the West Riding, are of the very first importance to the county and to the kingdom, as well as to the multitudes to whom they furnish employment and wealth. The principal inducement for the establishment of those great works in the interior of the country was the plentiful supply of water and fuel for giving motion to machinery, and for the various other operations of the several branches of industry. Leeds, situated on the north bank of the river Aire, has long been celebrated as the centre of the manufacture of woollen cloth; and it is still the great mart for that staple article of the commerce of Yorkshire. (See LEEDS, and WOOLLEN MANUFACTURE.) The white cloth is chiefly made at and about Dewsbury, among the hills which separate the valleys of the Aire and Calder, and in the vicinity of Wakefield. The mixed cloth is principally made in the villages comprehended in the parish of Leeds to the westward of the town; in the vale of Calder west from Wakefield; and also in the environs of Dewsbury. In the year 1806, the number of yards of broad cloth manufactured in the West Riding of Yorkshire is stated at 10,079,256, and of narrow cloth at 6,193,317. But in 1810 the broad cloth was only 9,826,048 yards, and the narrow cloth had increased to 6,951,762 yards. In 1811, however, the quantity of both sorts of cloth had sensibly diminished; for the yards of broad cloth were only 8,671,042, and those of narrow cloth 6,180,181; one of the many effects produced on the industry, and consequently on the well-being of the county and of the kingdom at large, by the hostilities in which Britain was then deeply involved on both sides of the Atlantic. The cutlery and plated goods of Sheffield are in all their branches carried to a perfection and an extent of which it is not easy to furnish a satisfactory account. The cutlery, consisting of edge-tools of every description, files, anvils, saws, &c. is not confined to that town, but manufactured in all the neighbouring villages. The plated goods, consisting of teapots, coffee-pots, tankards, candle-sticks, and many other articles of household use, are all prepared within the town. In it are also several founderies for iron, brass, and white metal.

Minerals, &c.—Excepting the alum on the borders of the east moorlands, and the lead of the vicinity of Richmond towards

YORKSHIRE.

wards the opposite quarter, the North Riding of Yorkshire furnishes but few mineral substances of peculiar value. Copper of good quality, it is true, was wrought about the middle of the last century near Middleton-Tyas; but the works have for some time been discontinued. Copper was also discovered about twenty years ago at Richmond. In the vale of the river Swale, twelve miles above that town, are several very profitable lead-mines. The iron-stone of the east moorlands has not hitherto been applied to any useful purpose. It appears, however, from ancient records, that as early as the beginning of the thirteenth century, iron was wrought and forged in Kofedale. Ayton, a few miles S.W. from Scarborough, is the only place where forges are now established, and those are but inconsiderable. The great alum works are principally situated on the sea-coast on both sides of Whitby, and in the vicinity of Guilborough. See **WHITEY** and **ALUM**.

Various parts of the North Riding produce coal, particularly in the plain between Easingwold and Thirsk; and in the west moors, the coal hitherto discovered seems adapted only to the burning of lime: the north part of the Riding is consequently furnished with that mineral from the adjoining county of Durham. Good free-stone for building appears in many parts of the Riding: a few miles west from Whitby is a quarry from which have been drawn the blocks employed in constructing the new piers of that town. Limestone, and a species of marble not inferior to the Derbyshire, are found in different places; and loose blocks of red granite are seen on the surface in certain parts of the west moorlands.

In the East Riding, the chalk of the Wolds is the only mineral substance of importance hitherto discovered or brought into use; but the mineral productions of the West Riding are of peculiar value; for it contains lime, coal, iron, and lead, in great abundance. None of them, however, are found in the low level tracts in the east division of the Riding. The lime-stone extends all to the westward of a line running northward from Doncaster to Tadcaster. The tracts situated between the rivers Aire at Leeds and Calder at Wakefield are the principal seats of the coal-mines, which abound likewise in the neighbourhood of Bradford, Barnsley, and Sheffield. Near Bradford also there are very considerable iron-mines. Lead is principally extracted from the mines of Grassington, the property of the duke of Devonshire.

Yorkshire contains several mineral waters of great virtue and celebrity. The chalybeate and sulphureous springs of Harrogate have long been in high repute. See **HARROGATE**.

Scarborough, on the sea-coast of the East Riding, has long been celebrated for its mineral springs, which issue from the foot of a lofty cliff on the shore, a little way to the southward of the town. See **SCARBOROUGH**.

Ancient History, Remains, &c.—The great county of York was but a part of the territory of the British tribe, called in Roman history the Brigantes: they are not however mentioned by Cæsar. It appears that they were first overpowered by Cerealis, in the reign of Vespasian, in the year 71 of the Christian era. In 78, the Roman arms were carried beyond the river Tay in Scotland, where Agricola encountered the Caledonians, under Galgacus: but, contrary to the usual practice of the Romans, after a signal victory over the natives, as it is represented by Tacitus, his son-in-law and professed panegyrist, the Roman commander, retreated into the southern part of the country previously subdued. Having established a chain of posts across the

narrow isthmus, between the firths of Forth and Clyde, Agricola was in the year 85 recalled by Domitian. From that period, until the arrival of the emperor Adrian himself in Britain in 120, little is known of the transactions in the northern parts of the island. That Adrian should deem it necessary to repair in person to so remote a portion of the empire, which then comprehended the richest provinces of the world, is however a proof that the Britons, although overpowered, were by no means reduced to patient subjection. Renouncing, therefore, a great part of the country included within the chain of forts of Agricola, Adrian constructed an earthen rampart across the island, between the mouths of the rivers Tyne and Edon. While these operations were in progress, the emperor fixed his residence in Eboracum, or York; but scarcely had he returned to the continent when the northern Britons, breaking through the second rampart thrown up against them, joined with the Brigantes in an endeavour to regain their independence. To repress those attempts, Lollius Urbicus was sent into Britain, who, repelling the natives beyond the Roman bounds, constructed a wall and towers on the line between the Forth and the Clyde, first fortified by Agricola. From this event, which happened about 140 until 183, Britain seemed to be tranquil: but then, while the empire was subject to the monster Commodus by the exertions of the natives, and the discontented spirit of the legions themselves, the power of the Romans in Britain was reduced to a very precarious situation. Pertinax, who had served in the island, and who, by his military talents, was fully qualified to restore the discipline and spirit of former times, was soon cut off by the licentious and disorderly Prætorian guards of Rome; and in 196, Septimius Severus became sole master of the empire. The Caledonians still continuing their efforts to rid themselves of the Roman yoke, Severus, although thus far advanced in life, and very unfit for the service of the field, found it necessary to repair to Britain. (See **YORK**.) In 207 he arrived at Eboracum, in the full determination to quell the restless spirit of the natives. After an expedition into the northern parts of the island, in which the loss of the Romans is admitted by their own historians to have been prodigious, he fixed his head-quarters in Eboracum; and commanded the rampart thrown up by Adrian between the Edon and the Tyne, to be powerfully strengthened, as Urbicus had done on the northern rampart with a continued wall and forts of stone. Taking advantage of his absence from the frontiers, the Caledonians again had recourse to arms: but in 211, while Severus was preparing in Eboracum to repel their assaults, he died, and his sons and successors Caracalla and Geta soon afterwards returned to Rome. Whatever might have been the inclinations of the Brigantes, however gladly they would have combined with their countrymen of the north, yet by the presence of the imperial court, officers, and troops, every effort on their part must have been instantly discovered and repressed. Under Carausius, Britain enjoyed some semblance of independence; but his assassination in the midst of his spirited projects enabled Constantius to subject Britain again to the Roman arms. Dying in Eboracum in 307, Constantius was succeeded in the western portion of the empire by his son Constantine, who was present at his death, and was immediately proclaimed emperor by the legions. For many years, the Brigantes with the other southern provinces of Britain seem to have been submissive to their masters; but in 364, the northern nations renewed their incursions, while the opposite part of the island was harassed by the predatory de-

cents

YORKSHIRE.

cents of the Saxons. Tranquillity was at last restored by Theodosius, whose fon of the same name obtained the purple, and after a short reign died in 393. Diffension within and assault from without were now fast hastening on the overthrow of the mighty empire of Rome; and in the middle of the fifth century of our era, the Romans finally relinquished all possession, power, and authority in Britain. Of their long protracted residence in Yorkshire, many unquestionable evidences are found in the capital, and in other parts of the county. The roads established by that extraordinary people may yet be traced, traversing the county in various directions. The whole system of the Roman policy and discipline was certainly directed to the perfection of their military power.

One great line of probably Roman road, which traverses the county of York from S. to N., is now called the Watling-street, (a name apparently Saxon,) which was opened from the Rutupian port, in the neighbourhood of Sandwich, in Kent, in various directions, all the way to the wall of Severus. Entering Yorkshire near Bawtry, it has been traced by Doncaster, (Danum, or the station on the river Don,) over Seawley and Pigburn Leas, to Barnsdale, through Pontefract to Castleford, supposed to be the position of the ancient Legiolium, a little below the junction of the rivers Aire and Calder. From this point, the road was conducted by Calcaria, now Tadcaster, to Eboracum, or York. From this city it probably followed the N.E. side of the river Ouse, crossing it near to Ifurium, now Aldborough, below Boroughbridge, and thence by Leeming-lane to Catterick-bridge, adjoining to which vestiges of Cataractorium are to be seen; then turning more to the northward, it passed over the Tees at Pierfe-bridge into the county of Durham. Another military road is supposed to have been laid out from Mancunium, now Manchester, in a N.E. direction, by Wakefield, to join the former line between Doncaster and York. North-eastwardly from York a road seems to have been formed by or near Malton, terminating on the sea-coast at Dunley bay, the Dunus bay of Ptolemy. This road is still called Wade's causeway, from the Saxon chief Wada, as Camden thinks, who resided on the coast in a castle, perhaps originally erected by the Romans. A branch of this road is supposed to have led to Scarborough, when the sheltered beach furnished a convenient place for Roman shipping. The straight course of an ancient road may be traced, although over the high grounds of the Wolds pointing from York towards Bridlington bay, corresponding probably to the Sinus Gabrantovicorum of the Romans; a branch has also been observed tending towards Hunmonby and Filey bay. Another line may also be followed in a direction to Patrington (Prætorium) and the Spurn-point, which seems to correspond with the Ocellum Promontorium of Ptolemy. From Lincoln (Lindum colonia) a Roman road may be traced running N. to the S. bank of the Humber near Winttringham, where are still seen vestiges of the station, ad Abum. On the N. bank, Brugh indicates the position of another ancient station, from which a branch of road probably communicated with York. This, however, is not the course indicated in the itineraries, which point out a much more convenient course from Lincoln to York, across the river Trent at Littleborough, the ancient Segelocum.

The vestiges of Roman works and occupation distributed over various parts of Yorkshire are by far too numerous to be mentioned in this place: it must therefore be sufficient to point out two, Cataractorium and Ifurium. About five miles below Richmond in Swaledale is the present village of Catterick, so named from the Cataractorium of the Romans, of which the vestiges are visible on the S. bank of the river,

a little lower down the valley. Ifurium exhibits the most remarkable proofs of Roman habitation. Sixteen miles above York, and nearly one mile below Boroughbridge, on the S. bank of the river Ure, is Aldborough, so called in allusion to the old town, to which it has succeeded, named by the Romans Ifurium.

Castles.—Of these many still remain in Yorkshire, although in several cases they are either nearly demolished, or by later alterations, bear but little resemblance to their original form and structure: in some, indeed, the name alone is preserved. Of York castle, the keep, or Clifford's tower, is almost all that is to be seen above the surface of the ground. Scarborough castle is situated on a projecting precipitous cliff, 300 feet above the sea, and cut off by a deep natural hollow from the high ground behind it. Richmond has long been distinguished by its extensive castle, which was erected soon after the Norman Conquest by Alan, a kinsman of William the Conqueror, on receiving the vast possessions of the Saxon, Edwin, earl of Chester. Crake or Creyke castle, although belonging to the county of Durham, is situated only twelve miles N. from York, is of great antiquity; for so early as in 685, it was bestowed on St. Cuthbert by Egfrid, king of Northumberland. Six miles W. from Doncaster, are the castle and village of Conisburgh, or more properly Coningburgh. The castle, one of the most interesting edifices of the kind in the N. of England, a building of great extent and strength, is commanded by the high ground on which the village is placed. The area of the castle is in circuit about 700 feet, encompassed by a very deep ditch, now filled with trees. Of Knareburgh castle, once a fortress of importance, but few remains are now to be seen. It is believed to have been erected by Serlo de Burgh, who received the manor as a reward for his services at the Conquest. Pontefract castle, the scene of many transactions of note in English history, in particular of the murder of Richard II., is built on a lofty rock. Sheffield castle, formerly of great strength from its situation, between and at the meeting of the rivers Don and Sheaf, was levelled to the ground by the parliament in the civil wars. The ancient castle of Skipton, in the W. part of the county, is still in a habitable state. It now belongs to the earl of Thanet; but was formerly the residence of the powerful family of Clifford, of which Henry, the fourteenth lord, was, in 1525, created earl of Cumberland. Near the E. bank of the Darwent, S.E. from York, are the remains of the magnificent castle of Wresle, supposed to have been erected by Percy, earl of Worcester, in the reign of Richard II., towards the end of the 14th century. Originally the castle formed a quadrangle, having a tower at each corner, and a fifth over the entrance. Wresle was one of the places of residence of the great earls of Northumberland, where they lived in a style of splendour and magnificence, formed on the model and with the state of the royal household. Notwithstanding the zeal evinced by the earl of Northumberland in the cause of the parliament, the castle was, in 1650, dismantled. Three sides of the quadrangle were demolished, and an accidental fire in 1796 completed its destruction. The site belongs to the earl of Egremont.

Seats.—To describe the number of admirable structures of modern times, with which the county of York is adorned, would require a volume. In this place merely to notice some of the most eminent seats is all that can be attempted. About 13 miles N.N.E. from York is situated Cattle-Howard, the princely mansion of the earl of Carlisle, of the illustrious house of Howard. On the site of the ancient castle of Hinderkelf the present building was erected, about a century ago, by sir John Vanbrugh, the celebrated

YORKSHIRE.

architect of Blenheim. Castle-Howard, in its general arrangement and appearance, bears an evident resemblance to that superb structure, and indicates the genius of that distinguished artist. In extent of front it exceeds Blenheim, and in exterior display of magnificence it is, perhaps, superior. The interior, spacious and lofty, is enriched with a very valuable assemblage of paintings by masters of the greatest celebrity; and the collection of antique statues, busts, &c. is peculiarly interesting. The surrounding park and grounds are distributed and ornamented in a way fuitable to the grandeur of the structure they inclose. Duncombe-park, the seat of Charles Slingsby Duncombe, esq., 22 miles N. from York, also erected by Vanbrugh, is splendid in itself, and splendidly adorned with paintings of the most eminent artists. Harewood-house, the residence of the earl of Harewood, six miles N. from Leeds, is a magnificent structure, commenced in 1760, in which are combined grandeur of design and ornament, with convenience and accommodation of arrangement. One of the greatest ornaments, not of Yorkshire only, but of the kingdom, is Wentworth-house, once the habitation of the distinguished patriot Charles marquis of Rockingham, from whom it descended to his nephew and heir the present earl Fitzwilliam. It is situated in a spacious park, four miles N.W. from Rotherham, and seven N.N.E. from Sheffield. The mansion extends in front about 600 feet, forming altogether a structure of uncommon magnificence. Nor is the interior deficient in appropriate arrangement and splendour. In approaching the house, the attention of the visitor is arrested by a noble mausoleum, raised in 1788, by the present earl, to the memory of his uncle, the marquis. This monument is placed on an eminence, and is in itself 90 feet in height, divided into three parts. The square Doric basement supports a similar structure of the Ionic order, with open arches on the sides exhibiting a sarcophagus; the whole surmounted by a cupola. Within the basement story is a chamber containing a statue of the marquis, by Nollekens. Around the walls are busts of eight of his principal political friends, C. J. Fox, sir G. Saville, &c. Wentworth-house, erected by the earl of Strafford in 1730, but now the seat of Henry Vernon, esq., is a noble fabric. Towards the southern border of the county, midway between Doncaster and Worktop, is Sandbeck, the superb mansion of the earl of Scarborough, erected nearly fifty years ago.

Ecclesiastical State.—A very important change in the condition of the ecclesiastical establishments in Yorkshire, and over England in general, was introduced by William I. Prior to the Conquest the Saxon prelates, with their archdeacons and other delegates, sat in the courts with the ears and sheriffs for the administration of justice; receiving with the lay-judges a share of the fines imposed on offenders. According to the original charter, however, still preserved among the records of the cathedral of Lincoln, the Conqueror declared, that no bishop or archdeacon should, in future, hold ecclesiastical pleas in the hundred-court, nor suffer any cause of a spiritual nature to come under the cognizance of secular persons. Whoever, therefore, offended against the canons of the church was to be tried by a tribunal, to be appointed by the bishop of each diocese. It was also strictly enjoined on all sheriffs, royal officers, or other lay persons, not to encroach on the episcopal jurisdiction. These regulations were afterwards confirmed, in a general council of the nation, by the bishops, abbots, and all the principal nobility; but those nobles and prelates were then almost all Normans or other foreigners. To this artful separation of the ecclesiastical from the civil jurisdiction, the jealousies, contrarities, contests, and open

ruptures, by which the kingdom was, on various occasions, brought almost to its ruin, must be ascribed. In addition to the dissensions occasioned in this way, the dispute respecting the superiority of the see of Canterbury over that of York was conducted with peculiar animosity, between the Norman prelates of both. In 1070, Thomas, a canon of Bayeux in Normandy, appointed to York, repaired to Canterbury for consecration from the hands of archbishop Lanfranc, who had been previously installed; but refusing to swear obedience to the see of Canterbury, the consecration did not take place. The famous Gregory VII. making it now a rule to confer the pall on no prelate who did not appear in person before him, the two contending English archbishops were required to present themselves in the court of Rome, where the dispute was referred for decision to a synod of the clergy of England. By this council, assembled at Windfor in 1072, a sentence amounting to a compromise was pronounced. The rights claimed by Canterbury were confirmed; but Lanfranc dispensed with the oath of obedience from Thomas of York. In his profession of obedience, however, Thomas acknowledged that the archbishops of York and their suffragans were bound to obey the mandate of the primate of Canterbury, when required to attend him in council, wherever it should be held. On the appointment to York of Thurstan, chaplain and secretary of Henry I. in 1115, the dispute was again revived; but in 1121, Thurstan, who had obtained favour at Rome, was permitted by Henry, whom his pertinacity had irritated, to return to York. It does not, however, appear that he ever made any satisfaction for his resistance to the claims of Canterbury; or that a profession of obedience to that see was ever made by any of his successors. From this time, therefore, York maintained its independency, and, a few years afterwards, had certain suffragan bishops placed under its authority. Roger of York, in 1162, procured a bull from Rome, granting him the privilege of crowning the kings of England, possessed by some of his predecessors, and of having his cross carried erect before him throughout the whole kingdom. But in 1165, in the reign of Henry II., the latter privilege was by pope Alexander III. restricted to Roger's peculiar province. Opposing claims were nevertheless advanced on both sides, until Edward III. by influence and management procured from Rome a confirmation of the arrangement he had accomplished between the contending prelates. Then was introduced the casual and silly distinction, still preserved, in the titles of the two metropolitans, by which the archbishop of York is styled primate of England, and his brother of Canterbury primate of all England.

The county of York is wholly and immediately under the superintendance of the archbishop, whose suffragans are the bishops of Carlisle, Chester, Durham, and the Isle of Man. The latter, styled bishop of Sodor (the southern isles of Scotland) and Man, presiding over a diocese not formerly pertaining to England, has no seat in the house of peers. Under the archbishop, ecclesiastical affairs are conducted by archdeacons; an office first introduced into the diocese, as it is said, by Thomas the Norman, appointed in 1070.

Fertile and extensive as is the county of York, the number of religious houses erected within its bounds, in former times, was prodigious. "These were in all," according to Burton, (*Monasticon Eboracense*), "106; viz. abbeys 14, priories 44, alien priories 7, cells 13, and houses of friars of various orders 28." Of those establishments the ruins of many houses still exist; some of them exhibiting very picturesque and attractive monuments of ancient devotion and liberality. St. Mary's abbey adjoining York gives sufficient indications

tions of its original grandeur. The abbots of St. Mary's and of Selby, both of the Benedictine order, were alone entitled to wear the mitre on the N. side of Trent. But for an account of these abbeys, and that of Whithy, the reader is referred to the description of the several towns in which they are situated. Of some others, erected in detached situations, a few may be here noticed. About three miles S.W. from Ripon are the magnificent and picturesque ruins of Fountain's abbey, of the Cistercian order, founded in 1132; and so named, not from any abundance of springs of water at the place, but from the village of Fontaines in Burgundy, where St. Bernard, the great patron of the order, was born. But the structure, of which the remains are so great an ornament to the country, was commenced in 1204. Built in the most elegant style of the ancient pointed architecture, the tower and the walls of the church still remain; the roof only being ruined. The length of the church was 351 feet, and that of the transept 186. The great tower, singularly situated at the N. end of the transept, is in height 166 feet. The whole edifice may be considered as one of the finest specimens of the simple but majestic style of the time of Henry III. and his successor Edward I. The abbey now forms a peculiar ornament to the celebrated grounds of Studley-Royal. On the N. bank of the river Aire, three miles to the westward of Leeds, are the remains of Kirkstall abbey, founded in 1147, by a colony of Cistercian monks from Fountain's abbey. The venerable remains of the Cistercian abbey of Rievall, or Rievaulx, are situated in a valley, about three miles northwards from Duncombe-park, from which they appear with peculiar advantage. Of the very ancient monastery of Ripon no part now exists. The collegiate church, or minster, still an interesting edifice, was partly rebuilt in the middle of the 14th century. Roche abbey, situated near lord Scarborough's feat of Sandbeck, in a deep narrow vale, is now reduced to a few arches, and a portion of the nave.

Authorities. — *Monasticon Eboracense*, or the Ecclesiastical History of Yorkshire, by John Burton, M.D. F.S.A. folio, 1758. *Topographical Dictionary of Yorkshire*, by Thomas Langdale, 8vo. 1809. *Eboracum, or the History and Antiquities of the City of York*, by Francis Drake, F.R.S. and F.S.A. folio, 1736. *History of Cleveland*, by the Rev. Rennie, Brown, and Sheriff, 8vo. 1794.

YORKSHIRE Cows, in *Rural Economy*, a term sometimes applied to a large short-horned breed of these cattle, which afford much milk, but which is not of the most rich kind, and which are much produced on the fine pastures in that district. See *Cow* and *LIVE-Stock*.

YORKSHIRE White, in *Agriculture*, a perennial grass that thrives well in most situations, and which grows very generally on all soils, except those that are of the most barren and dry qualities. It flowers in the middle of the summer, and is well calculated for sheep, as it answers uncommonly well when closely fed down. It is said not to be much relished by neat cattle, and considered injurious to horses, which, in some cases, are supposed to become affected with a profuse discharge of urine and general weakness in consequence of the use of it. But should any hay, made from this grass, be accidentally given to these animals, and produce these effects, an immediate change of the fodder will

prevent any further bad consequences. Its foliage is rather soft and woolly.

The proportional value which the grass at the time the seed is ripe bears to that at the time of flowering, is as 11 to 12.

It is a useful sort of grass in many cases of laying land down to pasture and other such purposes. See *HOLCUS Lanatus*.

YO-SANPOO, in *Geography*. See *SANPOO*.

YO-TCHEOU, a city of China, of the first rank, in the province of Hou-quang, situated on the Yang-tse river, and on the Tong-ting lake. This lake, which resembles a sea, is remarkable for the greatness of its circuit, which is more than 210 miles; for the quantity of its water, especially in certain seasons, in which the two great rivers of the provinces swelled with rains, discharge themselves into it, passing out on the other side sensibly diminished; and for its astonishing quantity of fine fish which are caught therein. The great number of barks and merchandizes which are brought thither render it one of the richest cities in the empire; its districts contain one town of the second order, and seven of the third; some on the east side of the lake, and others on the west. The country round is every where extremely fruitful, and full of different kinds of orange and lemon trees; 675 miles S. of Peking. N. lat. 29° 23'. E. long. 112° 35'.

YOUB, EL, a town of Algiers; 50 miles S.W. of Tremecen.

YOUGH GLADES, a post-town of Maryland; 173 miles N.W. of Washington.

YOUGHAL, a sea-port, borough, and post-town of the county of Cork, Ireland, situated at the mouth of the river Blackwater, in the eastern part of the county. Youghal is an ancient corporation, and sends a member to the united parliament. It is one of the towns belonging to the duke of Devonshire, as heir of the eldest branch of the Boyle family. It has a considerable corn trade, and is much frequented for bathing. There is a collegiate church, the wardenship of which is united to the see of Cloyne. Youghal is 115 miles S.W. from Dublin, and 25 E. from Cork.

YOUHIOGENY, a river of America, which rises in the north part of Virginia, and runs into the Alleghany, at Pittsburgh.

YOVIS, a town of Africa, in the county of Whidah; 9 miles E.N.E. of Sabi.

YOULE, a river of Madagascar, which runs into the sea on the west coast, S. lat. 20° 20'. E. long. 44° 40'.

YOUNG, EDWARD, in *Biography*, a celebrated poet and clergyman of the established church, was born at his father's living of Upham, in Hampshire, in 1684, and removed from Winchester school to New college, in the university of Oxford in 1703, and afterwards to Corpus Christi college. In 1708 he obtained a law-fellowship at All Souls by the patronage of archbishop Tenison, and at this time poetry was the chief object of his pursuit. His first performance in this department was "An Epistle to Lord Lansdown," one of the twelve peers created at the same time in 1712; and this was followed in the next year by his "Last Day," to which he prefixed a dedication to queen Anne, extolling the peace of Utrecht. From this circumstance he was regarded as a court-writer with a fixed stipend, under which character Swift alludes to him in his "Rhapsody on Poetry."

"Where Y — must torture his invention
To flatter knaves, or lose his pension."

His next production was "The Force of Religion, or Vanquished Love," founded on the story of lady Jane Gray; and in 1714 he inscribed a poem on the death of the queen and the accession of George I. to Addison, who was then secretary to the lords justices. In 1719 he became tutor to the eldest son of the earl of Exeter; but soon abandoning that connection by the solicitations of the duke of Wharton, he graduated doctor of civil laws in this year, and wrote his tragedy of "Buffsir, King of Egypt," which was dedicated to the duke of Newcastle, and favourably received; and in the same year he dedicated in a very complimentary strain to lord chancellor Parker, his poetical "Paraphrase on Part of the Book of Job." In the year 1721 his tragedy, "The Revenge," was exhibited with great applause, and dedicated to the duke of Wharton, whom he avows as his peculiar patron, and from whom he received some pecuniary favours. His satires, entitled "The Love of Fame, or the Universal Passion," were separately published, from 1725 to 1728, and as they became popular, he derived from them considerable profit. In 1726 he addressed his poem, entitled "The Intalment," to sir Robert Walpole, on his receiving the honour of the Garter; and he availed himself, on the accession of king George II., of his recommending an attention to the navy, to compose two odes, one inscribed "To the King, Pater Patriæ;" introducing another under the title of "Ocean." Having attained his 44th year, he took orders, and in 1728 was nominated one of the royal chaplains; and this change of his views and pursuits induced him to withdraw from the stage his tragedy of "The Brothers," which was under rehearsal. His next publications were adapted to his new profession; and among these were his "True Estimate of Human Life," exhibiting the dark side of the picture; and a sermon preached before the house of commons on the 30th of January, entitled "An Apology for Princes, or the Reverence due to Government;" a subject not unappropriate to his situation as royal chaplain. In 1730, Dr. Young was presented by his college to the rectory of Welwyn, in Hertfordshire; and in the following year he married lady Elizabeth Lee, widow of colonel Lee, and daughter of the earl of Lichfield. Before this time he had resumed his poetical pen, and written "Imperium Pelagi, a Naval Lyric;" "Two Epistles to Mr. Pope, concerning the Authors of the Age;" and "The Sea-Piece," in two odes, dedicated to Voltaire. By his wife, who died in 1741, he had one son; and this circumstance, together with some other domestic losses that occurred about the same period, increased that melancholy and depression of mind to which he was constitutionally inclined. When he married lady Lee, she had a son, and also two daughters, the eldest of whom, denominated by him Narcissa, falling into a decline, went to the south of France, and died at Lyons in 1736. Her husband, Mr. Temple, supposed to be the poet's Philander, died in 1740; and his own lady died in 1741. If he referred to these events in the annexed lines, he must have taken a chronological licence hardly allowable even to a poet:

"Infatiate archer! could not one suffice?
Thy shaft flew *thrice*, and *thrice* my peace was slain;
And *thrice*, ere *thrice* yon moon had filled her horn."

It is certain that he began to write his "Night Thoughts" in the year 1741; and the occasion, as he declares, was real, and not fictitious. The seventh of these poems is dated in 1744, and the interval must have been occupied in the composition of them. Notwithstanding

the sublime strains in which the author expresses his pious feeling, he is not regardless of the patronage of distinguished persons, for to such he inscribes them. On this work Dr. Young bestowed much attention and labour, and he valued it as the chief of his productions. Among his other works, we may mention a poem written as an expression of his loyalty in 1745, and entitled "Some Thoughts occasioned by the present Juncture, inscribed to the Duke of Newcastle;" "The Centaur not fabulous, in Six Letters to a Friend, on the Life in Vogue;" an overcharged picture of the existing manners; and "A Sermon preached before their Majesties," with a dedication to the king, 1758. Dr. Young, notwithstanding his genius and piety, and his solicitude to obtain preferment, seems to have been disregarded; and though archbishop Secker expresses his surprise that he had been overlooked by persons in power, he declines any interference in his favour. It should be recollected, however, that the attention which he paid to Frederick, prince of Wales, during his variance with his father, was not forgotten; nor indeed would his junction of the poetical and clerical character be any recommendation to George II. But the reason of his name's being struck out of the list of court-chaplains on the accession of his present majesty is not known; it is the more unaccountable, as he was soon after appointed clerk of the closet to the princess dowager of Wales.

In his retreat at Welwyn he maintained a respectable and dignified character; and though the cast of his mind seems to have been gloomy, he was an agreeable and lively companion. The close of his life, however, was rather disconsolate than cheerful. The conduct of his only son, supposed to be the Lorenzo of the Night Thoughts, who is said to have been a rake and free-thinker, afforded him renewed opportunities for reproof and sarcasm, and must have been the occasion of poignant grief; though Mr. H. Croft vindicates his character, alleging that he was only eight years old when his father began that poem. But others have asserted that he was alarmed and grieved on his account; and that, notwithstanding the favourable change which took place in his sentiments and character, his father would not admit him to any interview in his latter years; and even on his death-bed he refused to see him, though he assured him of his forgiveness, and made him his heir. Towards the close of his life, he surrendered himself to the influence of a housekeeper, and from some mismanagement in his concerns, and a growing disposition to avarice, he became irritable in temper and depressed in spirits. His last production was a poem, entitled "Resignation," printed in 1762, which indicated the decline of his mental powers. His life was prolonged to the year 1765, and he then died in his 84th year. He was interred in the church of Welwyn, and his son erected a monument near the remains of both his parents.

Dr. Young is known principally, if not wholly, as a poet; and his compositions in this department are distributed into satires, tragedies, and night thoughts. His satires are founded on the questionable principle, that the love of fame is the universal passion of mankind; and as he did not excel in judgment, they are exercises of wit and invention rather than grave exposures of vice and folly. As a dramatic writer, he is charged with not understanding or not adhering to nature, and with indulging his imagination and feeling, and running into exaggeration of character and bombast of expression. The only tragedy that has kept possession of the stage is his "Revenge," the Zanga of which is said to have no competitor for theatrical effect.

effect among the personages of modern tragedies. His "Night Thoughts" were deemed original in design and execution. Whatever were the causes that produced them, they are adapted to excite devout feeling, and to produce moral effect, though they are justly complained of as in some places unintelligible, and as affording too much scope for criticism. To many readers, the theology on which they are founded and which they express is too awful and severe, and not so well calculated to soothe and pacify the human mind under trouble as the gentler and more consolatory dictates of Christianity. They are sometimes tedious and prolix. They will never be neglected as long as taste and susceptibility of virtuous and religious impressions remain. The lyric attempts of Dr. Young are said to have been singularly unfortunate. From the edition of his works published in his life-time in 4 vols. 8vo., he himself excluded several compositions which he thought of inferior merit. Biog. Brit. Croft's Life of Young in Johnson's English Poets. Gen. Biog.

YOUNG, PATRICK, (*Patricius Junius*, Lat.), an eminent scholar, was born in 1584, at the seat of his father, sir Peter Young, who had been co-tutor with Buchanan to James VI. of Scotland, at Seaton in Lothian. Educated in the university of St. Andrew's, and accompanying his father in the suite of king James, he was employed for some time as librarian and secretary, by Dr. Lloyd, bishop of Chester. In 1605 he assumed the degree of M.A. which he had before taken at St. Andrew's, and entering into orders, became chaplain at All Souls' college. During his residence at Oxford he occupied himself in the study of ecclesiastical history and antiquities, and also the Greek language; and upon his removal to London, he obtained a pension of 50*l.* a year, and was occasionally employed by the king and persons in power in writing Latin letters. His patron was Montagu, bishop of Bath and Wells, who procured for him the appointment of librarian to the king. In 1617 he was introduced at Paris, by the recommendation of Camden, to the learned men of that city; and upon his return, he assisted Thomas Rhead in making a Latin version of the works of king James. In 1620 he married, and afterwards was advanced to several preferments in the church; and succeeded Rhead in 1624 as Latin secretary. Unknown by any publication, he was nevertheless honoured as a person of distinguished literature, who rendered acceptable and useful services to learned men. In this way, he was the coadjutor of Selden in the examination of the Arundelian marbles; and when they were published by this celebrated antiquary, he dedicated the work to Young. He was also employed in collating the Alexandrian MS. of the Bible with other copies; and as the result of his labours, he communicated many various readings to Grotius, Usher, and other persons. It was his intention to have edited a fac-simile of this MS., but his design was never executed. He published, however, in 1633, from this MS. the "Epistles of Clemens Romanus," and he proposed editing the curious MSS. from the king's library; but the civil wars, and the seizure of the royal library, prevented the accomplishment of his purpose. During the troubles of this period, he sought an asylum with a son-in-law, at Bromfield in Essex, where he died in 1652.

Young is said to have indulged to excess a disposition to oblige, which led him to lend valuable MSS. belonging to the royal library to foreigners and others; and he has been charged with betraying his trust, by not returning MSS. which he removed to his own house in contemplation of the pillage of the library, and these were sold among his other effects. To obviate this imputation, it has been alleged

that he purchased for himself many MSS. from Greeks who visited this country. Smith's Vit. Erudit. Viror. Gen. Biog.

YOUNG is a name borne by many persons connected with and remarkable in some way or other for useful talents in the arts. Charles Young, organist of Catharine-cree church, near the Tower, father of three daughters, who were all public singers: Cæcilia, the eldest, was an élève of Geminiani, spoke Italian well, sung in many of Handel's later operas, and was afterwards married to Dr. Arne; the second Miss Young, Isabella, was married to the ingenious and excellent composer Mr. Lampe, who set the Dragon of Wantley; and the third Miss Young, Esther, afterwards Mrs. Jones, sung on the stage at Covent-Garden theatre to the time of their deaths. Charles, the father of these ladies, was, we believe, the son of Anthony Young, a musician and music-feller in St. Paul's church-yard, commonly called Tony Young, who has been said by some of the family to have set "God save great George our King." But at the time of the rebellion of 1745, when this air was revived, which Dr. Arne's mother assured us was written and set for king James II., when the prince of Orange was hovering over the coast previous to the Revolution; no claim was then made by the descendants of Anthony Young, or of any other composer of this air, which no one durst sing or own after the abdication of king James, without incurring the penalty of treason to king William; so that the song or hymn lay dormant, and the author concealed for near sixty years, before it was applied to king George II.

There is a quibbling glee in the first volume of Purcell's catches on two persons of the name of Young, father and son, who lived in St. Paul's church-yard; the one was an instrument-maker, and the other an excellent performer on the violin:

"You scrappers that want a good fiddle well frung,
You must go to the man that is old while he's Young,
But if this same fiddle you fain would play bold,
You must go to his son, who'll be Young when he's old.
There's old Young and young Young, both men of
renown,
Old fells, and young plays, the best fiddle in town;
Young and old live together, and may they live long,
Young to play an old fiddle, old to fell a new fong."

Another Young, of the same family, the proprietor of a music-shop in St. Paul's church-yard till the middle of the last century, had a relation, an excellent performer on the violin, known by the name of *Chin-Young*, from the length of that feature, who led at almost all the concerts within Temple-bar, particularly at the Blue-coat school chapel, Christ's hospital, on a Sunday evening, where there used to be a performance of sacred music.

Miss Young, afterwards the hon. Mrs. Scot, and her sister Mrs. Bartleman, both public singers, seem to have been the last remains of the musical family of Young.

YOUNG. See GENERATION, CONCEPTION, GESTATION, EMBRYO, FETUS, DELIVERY, CHILD, &c.

In the army, that regiment, or officer, is said to be the *younger, junior*, which was last raised, or whose commission is of latest date, whatever be the age of the man, or however long he may have served in other capacities.

YOUNG *Plantations, Securing and Sheltering of*, in *Rural Economy*. See PLANTATION and SHELTERING.

YOUNG *Frederick's Island*, in *Geography*, a small island among Queen Charlotte's islands, in Port Ingraham.

YOUNG *Nick's Head*, a cape on the east coast of New Zealand, so called from Nicholas Young, a boy on board the

the Endeavour, who discovered it in 1769. It forms the south-west point of Poverty Bay.

YOUNG Point, a cape on the east coast of St. Vincent. N. lat. 13° 12'. W. long. 61° 9'.

YOUNG'S Island, a small island near the south coast of the island of St. Vincent; 2 miles S.E. of Kington Bay.

YOUNGE, NICHOLAS, in *Musical History*, an Italian merchant, the editor of "Musica Tranalpina," 1588; Madrigales of four, five, and six parts, chosen out of divers excellent Authours; with the first and second part of La Virginella, made by Maister Bird upon two Stanzas of Ariosto, and brought to speak English with the rest. The editor having opportunities of obtaining from his correspondents the newest and best compositions from the continent, had them frequently performed at his house, for the entertainment of his musical friends.

The second collection of the same kind was published by the same editor in 1597; in which, among others, there are three madrigals by Crow, three by Luca Marenzio, and six by the elder Ferrabosco. These two collections being selected from the works of Palestrina, Luca Marenzio, and other celebrated masters on the continent, seem to have given birth to that passion for madrigals which became so prevalent among us afterwards, and which the composers of our own country endeavoured with such zeal to gratify.

If allowance be made for the wretched state of lyric poetry in England at the time the madrigals published in Younge's two collections were translated, which was long before the publication of the sonnets of Spenser or Shakspeare, the undertaking seems to have been tolerably executed. Indeed, sometimes with such care and felicity as to transfer the expression of the original words into that of the version. The Italians themselves, at this time, had but little melody or rhyme in their music; but their poetry having been long cultivated, and brought to a much greater degree of perfection than ours could then boast, it indicated to the musical composer traits of melody, more airy and marked, perhaps, than we could derive from the prosody or phraseology of our own language. The translator of these madrigals, whoever he was, for the editor does not tell us, seems in general to have imitated the original Italian measure and structure of verse, as well as ideas; and though they abound with *conceits*, to which not only Italian poets, but those of all the rest of Europe were then so much addicted, the general taste of the times was indulged in poetry as well as music, and metre and melody were at once furnished with new models.

However, the perpetual double rhymes in Italian madrigals and sonnets have so much distressed our translator to supply them in English, that, as the preservation of the original music obliged him to render his version *totidem syllabis*, his embarrassments on this account are sometimes truly ridiculous. It seems as if the constant double rhymes in Italian poetry, which throw the accent on the penultima, instead of the final syllable, of a verse, gave a peculiar cast to the melody in which it is clothed, and rendered it specifically different from that of English songs, in which but few double rhymes occur. The constant and regular mixture of masculine and feminine rhymes in French poetry may likewise have had a latent effect on the vocal melody of France, different from that of the other two neighbouring nations. But, after mentioning these suspicions, we shall leave the further investigation of so subtle a subject to philosophers, not only possessed of the necessary knowledge, but an equal zeal for the cultivation of philology, poetry, and music. No. 7, in Younge's second publication of Italian madrigals Englished, in which the old Saxon termination of the present

tenfe of the indicative mood of our verbs is conveniently preserved, was doubtless not thought the worst, as it is applied to several compositions in the collection.

"In vayne he seeks for beauty that excelleth,
That hath not sene hir eyes where love feorneth,
How sweetly here and there the same she turneth.

He knows not how love heateth, and he quelleth,
That knows not how the sighes, and sweet beguileth,
And how she sweetly speakes, and sweetly smileth."

These madrigals were celebrated, nearly forty years after their publication, by Peacham, who has pointed out the peculiar excellence of several, particularly those of Luca Marenzio, which, he says, "are songs the muses themselves might not have been ashamed to have composed;" and of those by Alfonso Ferrabosco, the father, he says, "they cannot be bettered for sweetness of ayre and depth of judgment." Upon the ditty (words) of one of these, "I saw my Ladie weeping," (he says) Maister Byrd and Alfonso, in a friendly emulation, exercised their invention." The words of the Nightingale, and Fayre Sufanna, were so much admired, that they seem to have been set by all the best composers of the times. A few lines of each will perhaps convey to the reader an adequate idea of the poetical beauty of these favourite songs.

The Nightingale.

"But my poore hart with sorrowes over-swelling,
Through bondage vyle, binding my freedom short,
No pleasure takes in these his sports excelling,
Nor of his song receiveth no comfort."

Fayre Sufanna.

"To them she sayd, if I, by craft procur'd,
Do yeld to you my body to abuse it,
I lose my soule; and if I shall refuse it,
You will me judge to death reproachfully.
But better it is in innocencie to chuse it,
Then by my fault t'offend my God on hyc."

Indeed, in more than twenty sets, published between the years 1588 and 1624, during a period of near forty years, including almost four hundred and fifty madrigals and songs in parts, it would be difficult to find any one of which the words can be perused with pleasure. The sonnets of Spenser and Shakspeare, many of which are worthy of their authors, were indeed not published till about the end of the sixteenth century; but afterwards, it is wonderful, that, except one by Shakspeare, none of them were set by our best musical composers of their time.

YOUNGOULE, in *Geography*, a sea-port town, on the west coast of the island of Madagafcar. S. lat. 23° 30'. E. long. 47° 4'.

YOUNGSTOWN, a township of the state of Ohio, in the county of Trumbull, with 773 inhabitants; 66 miles N. of Pittsburgh.

YOUNGSTOWN, an inconsiderable settlement called a village in Cambria, Niagara county, and state of New York, 1 mile from Fort Niagara, and 6 from Lewiston, containing about six or eight houses.

YOUNKERS, among *Sailors*, are the younger sailors, otherwise called *foremast-men*; whose business is to take in the top-sails, furl the sails, sling the yards, &c.

YOURE, in *Geography*. See URE.

YOURI, a town of Africa, in the kingdom of Cashna. N. lat. 16° 15'. E. long. 11° 2'.

YOUTH, *Adolescence.* See AGE and ADOLESCENCE.

The renovation of youth has been much fought after by chemical adepts; and many of them pretended to various secrets for this purpose: but unluckily the death of the pretenders proved a sufficient refutation of their doctrine. Paracelsus talks of the mighty things he could do with his *ens primum*; and even Mr. Boyle tells us some strange things about the *ens primum* of balm. (Boyle's Works abr. vol. i. p. 75.) But Mr. Boyle gives these wonderful stories on the credit of a French chemist, and not on his own.

YOUTH, *Juventus, or Juventas,* in the *Pagan Theology*, a goddess worshipped among the Romans, who, together with the gods Mars and Terminus, kept her place in the Capitol along with Jupiter, when the other deities were turned out; whence the Romans drew a lucky omen for the durableness of their empire. Mem. Acad. Inscrip. vol. i. p. 71. seq.

This state of life was, by the ancients, compared to autumn. In which sense, Horace speaking of one approaching to puberty, says,

“ ——— Jam tibi lividos
Distinguet autumnus ramos,
Purpureo varius colore.”

The moderns, on the contrary, when they speak of one in the autumn of his age, mean one that is upon the decline; and choose rather to use the comparison of the spring, to denote youth.

YOWRY, in Geography, a small island in the East Indian sea, near the north coast of New Guinea, on which a nutmeg-tree was found growing by captain Forreil. S. lat. 15°. E. long. 130° 45'.

YPAWA, a river of Bohemia, which runs into the Elbe, near its source.

YPERLEE, a river of France, which rises near Ypres, and runs into the canal of Nieuport.

YPOLOTE, a town on the E. coast of the island of Paraguy. N. lat. 8° 46'. E. long. 118° 21'.

YPRES, or IPRES, a city of France, in the department of the Lys, situated on the river Yperlee, from whence it takes its name. Before the year 800, it was only a chateau, which was sacked and ruined by the Normans. Baldwin III. comte of Flanders, repaired the chateau, and built a town about the year 960, which was afterwards enlarged by Thierry, comte of Flanders, and Ferrand, the son of Sanchez, king of Portugal. In the year 1325, the inhabitants revolted with most part of the neighbouring towns against Louis de Nevers, comte of Flanders, and pulled down the old wall to build a new one, in which they inclosed the faubourgs, which had become so extremely populous, from weavers and other tradespeople, that in the year 1242, the number of persons amounted to 200,000. In the 14th century, the inhabitants of Ypres, for the most part weavers, were exceedingly troublesome to their neighbours, being unwilling that any people should carry on trade besides themselves. In the year 1383, the rebels of Ghent, assisted by the English, under the command of the bishop of Norwich, besieged this town with great vigour for six weeks, but were compelled to retire; and the English being obliged to quit Flanders, Philip the Hardy, duke of Burgundy, having become master by a marriage with the heiress of the late comte Louis, enlarged it, and surrounded it with walls. It was erected into a bishopric under the archbishop of Malines, by pope Paul IV. in the year 1559. The town-house is a very large building, forming a square, and is said to have been built by the English, 600 feet

in front; it has a very handsome tower, in which were kept their public archives from the year 1342. Besides the cathedral, it has several other churches, and some religious houses. The inhabitants carried on formerly a great trade in woollen cloth, but by the severity of the duke of Alva, the principal manufacturers were driven to England, from which time that branch of trade declined. At this time they carry on a considerable manufacture of linen of excellent fabric; 4 miles N.W. of Lisle. N. lat. 50° 48'. E. long. 2° 53'.

YPSILOIDES, *Ψυλλοειδης,* in *Anatomy*, the third genuine suture of the cranium; thus called from its resembling a Greek ψ , or upsilon.

Some also call it $\lambda\alpha\mu\delta\omicron\iota\delta\omicron\iota\delta\eta\varsigma$, *lamdoïdes*.

There is also a bone at the root of the tongue, called *ypsiloïdes*, and *hyoides*. See **HYOIDES**.

YQUETAYA, in Natural History, a plant growing in Brazil, long used as a medicine in that country; and lately discovered to the Europeans by a French surgeon.

It has been since found in France; where, being cultivated and examined by Marchant, it appears to be no other than the common water-betony, or scrophularia aquatica.

It has this remarkable property, that it takes away from senna all its ill taste and smell; which property of correcting the infusion of senna was before wholly unknown.

To use this plant, it must be dried ten or twelve days in the shade, and afterwards exposed to the sun, till quite dry.

YRAME, in Geography, a town of Arabia, in the province of Yemen; 100 miles N.N.E. of Aden.

YRIARTE, Don JOHN DE, in Biography, was born in the Isle of Tenerife in 1702, and having completed his education at Paris and Rouen, settled at Madrid; where he occupied several literary offices, and particularly that of librarian to the king. His life terminated, to the regret of those who knew his worth, in 1771. Among his learned works, the principal are, “*Palæographia Græca*,” 4to.; “*Miscellaneous Pieces in Spanish, with Latin Poems*,” 2 vols. 4to.; “*A Catalogue of Greek MSS. in the Royal Library*,” and “*A Catalogue of Arabic MSS. in the Escorial*,” 2 vols. fol. Nouv. Dict. Hist.

YROUER, in Geography, a town of France, in the department of the Yonne; 5 miles S. of Tonnerre.

YRSEE ABBEY, a princely abbey of Germany, in the circle of Swabia, founded in the year 1182. The territory includes the village of Yrsee, and seven others. In 1802, this abbey was given among the indemnities to the elector of Bavaria; 3 miles N.W. of Kaufbeuren.

YRVILLAC, a town of France, in the department of the Finistère; 3 miles S. of Landerneau.

YRUN, a town of Spain, in Guipuzcoa; 2 miles S. of Fontarabia.

YRVON, a river of Wales, in the county of Brecknock, which runs into the Wye, at Builth.

YS, in Ichthyology, a name given by Athenæus, and some other of the Greek writers, to the fish called *mus* and *fus* by others. It is the capricus of later writers. See **GOAT-FISH**.

YSAMBRA, a word used by some as a name for hellebore, and by others to express a species of posion prepared in Spain, of which hellebore is an ingredient.

YSARD, in Zoology, a name given to the chamois.

YSCHÉ, in Geography, a river of France, which runs into the Dyle, 6 miles S. of Louvain.

YSENDYCK, or ISENDYCK, a town and fortrefs of Flanders, situated on the side or arm of the Scheldt, called the

the Blic: it was built near a town called Gasterneffe, swallowed up by an inundation of the sea some centuries ago, whose inhabitants came to establish themselves at this place. The Dutch made themselves masters of it in the year 1604, and since that time it has been strongly fortified, which is much assisted by its situation, being surrounded by morasses, which they can lay under water at pleasure; 8 miles E. of Sluys. N. lat. $51^{\circ} 21'$. E. long. $3^{\circ} 28'$.

YSIPIORTAM, in *Ancient Geography*, a place of Asia, in Armenia, which had a Roman garrison.

YSNI, in *Geography*. See ISNY.

YSOPUS, a term used by some to express the chemical art of separation.

YSPAR, a name by which some of the chemical writers call iron.

YSSANDON, JEAN, in *Musical Biography*, born at Lefart, in the Comté de Foix, wrote "A Treatise on Practical Music, divided in Two Parts." This book is become very scarce, and deserves to be reprinted. It was first printed by Ballard in 1582. Laborde.

YSSEL, in *Geography*. See ISSEL.

YSSENCEAUX. See ISSENCEAUX.

YSTAD, or YDSTAD, a sea-port town of Sweden, on the fourth coast of the province of Schonen, from whence a packet sails to Stralfund. It was formerly well fortified, and contained two churches. The harbour is neither large nor safe; 26 miles S.E. of Lund. N. lat. $55^{\circ} 22'$. E. long. $13^{\circ} 44'$.

YSTLA, a town of North America, in the province of Mexico.

YSTWITH. See ISTWITH.

Y-TCHANG, a town of Corea; 35 miles W.N.W. of Kang-tcheou.

Y-TCHUUN, a town of Corea; 15 miles S.S.W. of Ou-tcheou.—Also, a town of Corea; 55 miles N. of King-ki-tao.

YTHAN, a river of Scotland, a few miles N. of the Don, that joins the sea, about two miles from Aberdeen, which falls into the German ocean. The Ythan is a stream formerly celebrated for its pearl fisheries, of which some relics are now found.

YTHER, a river of Wales, which runs into the Wye, 3 miles N. of Buith.

YTERON, a small island in the gulf of Bothnia. N. lat. $63^{\circ} 4'$.

YTTA BERGON, a small island on the W. side of the gulf of Bothnia. N. lat. $61^{\circ} 48'$. E. long. $17^{\circ} 13'$.

YTTRIA, or ITRIA, in *Chemistry*, is a peculiar elementary substance usually considered as an earth.

Ytria has been hitherto met with in a peculiar mineral named GADOLINITE, so named from professor Gadolin, who first analysed it, and in YTRO-TANTALITE, both minerals found only in Sweden. See those articles.

Ytria has the appearance of a fine white powder, without taste or smell. It does not affect vegetable blues. Its specific gravity is considerably higher than that of the other earths, being no less, according to Ekeberg, than 4.842.

Ytria is insoluble in water, yet, like alumina, it is capable, according to Klaproth, of combining with nearly one-third of its weight of that fluid when precipitated from a state of solution by the muriatic acid.

In solutions of the pure alkalis it is likewise insoluble; but in the carbonate of ammonia, and indeed in all the alkaline carbonates, it dissolves readily. It combines with acids, and forms with them salts, which, as far as they are known, are described below.

Ytria is not affected by light, and probably does not

combine with oxygen. According to the experiments of Klaproth, it does not combine readily with sulphur.

Sir Humphrey Davy found, that when potassium was passed through red hot yttria, it was converted into potash, while grey metallic particles were perceived mixed with the alkali, which were considered to be the metallic basis of the earth or yttrium. Nothing further, however, is known respecting this metallic basis.

The Salts of Ytria are but little known. The following only have been examined.

Nitrate of Ytria.—This salt was first formed by Ekeberg, and has been more lately examined by Vauquelin. It may be prepared by dissolving yttria in nitric acid. The solution has a sweet astringent taste, and can scarcely be made to crystallize. Exposed to the air, it deliquesces. When sulphuric acid is poured into the solution, crystals of sulphate of yttria are instantly precipitated.

Carbonate of Ytria.—This salt may be formed by precipitating yttria from its solution in acids by means of an alkaline carbonate. It is white tasteless insoluble powder, composed, according to Klaproth, of

Carbonic acid	-	18
Ytria	-	55
Water	-	27
		<hr/>
		100

According to Vauquelin, however, it loses only 32 per cent. when calcined.

Phosphate of Ytria.—Vauquelin formed this salt by mixing a solution of the phosphate of soda with the sulphate, nitrate, or muriate of yttria. The phosphate of yttria precipitated in the form of gelatinous flakes.

Sulphate of Ytria.—Sulphuric acid dissolves yttria readily. As the solution proceeds, the sulphate crystallizes in small brilliant grains. Ekeberg fuses these crystals to be flat six-sided prisms, terminated by four-sided summits. Dr. Thomson obtained these in the form of long slender rhomboidal prisms. Their colour is amethyst-red; their specific gravity 2.791. They are soluble in about 30 parts of water at 60° . A red heat partly decomposes them. Oxalic acid, prussiate of potash, and infusion of nutgalls, occasion a precipitate in the aqueous solution of this salt. It is decomposed by the phosphate of soda. The sulphate of Glucina is readily distinguished from this salt by its being colourless, lighter, and more soluble in water. According to Berzelius, the sulphate of yttria is composed of

Sulphuric acid	-	50.0
Ytria	-	50.0
		<hr/>
		100.0

Arseniate of Ytria.—When yttria is dissolved in arsenic acid, and the solution boiled, arseniate of yttria precipitates in the form of a white powder. Arseniate of potash also precipitates yttria from acids.

Chromate of Ytria.—Chromic acid dissolves yttria cold in considerable quantity, and with effervescence. The solution has an astringent and pungent taste, and, like most of the chromates, has an orange-red colour, passing into yellow. The solution is quite neutral. When evaporated, it forms minute prismatic and cubic crystals. It is very soluble in water.

Acetate of Ytria.—Ytria dissolves readily in acetic acid, and the solution on evaporation yields crystals of the acetate of yttria, the form of which is usually that of thick six-sided plates,

plates, obliquely truncated. Their colour is amethyst-red, and they are not altered by exposure to the air.

Succinate of Yttria.—Yttria is not precipitated from its solution in acids by the succinates, unless the two salts be concentrated, in which case small cubic crystals fall, which are the succinate of yttria.

Oxalate of Yttria.—When oxalic acid, or the oxalate of ammonia, is dropped into a solution of yttria in an acid, a white insoluble powder falls, which is the oxalate of yttria. According to Vauquelin, this salt is composed of

Oxalic acid	-	-	57.5
Yttria	-	-	42.5
			<hr/>
			100

Tartrate of Yttria.—Yttria is precipitated from its solution in acids by the tartrate of potash, but the precipitate is dissolved by the addition of water.

Dr. Thomson infers, from the analyses above-mentioned, and more especially from the analysis of the sulphate and carbonate by Berzelius and Vauquelin, that the combining weight or weight of the atom of yttria is 50, oxygen by 10, and consequently that it is composed of

Yttrium	-	-	80
Oxygen	-	-	20
			<hr/>
			100

and the weight of the atom of yttrium will be 40.

With respect to the salts of yttria in general, it may be said, that many of them are little soluble; that they are capable of being precipitated from acids by the phosphate of soda, the carbonate of soda, the oxalate of ammonia, the tartrate of potash, and the prussiate of potash; and lastly, that the sulphate of yttria may be distinguished from the sulphate of lime by its greater solubility, and by its sweet taste.

YTRIUM, the metallic basis of yttria. See YTRIA *supra*.

YTTRO-TANTALITE, in *Mineralogy*, *Tantal yttria*, Brongniart, an ore of tantalum, combined with the newly-discovered earth called yttria, and found at Ytterby, near Roslagen, in Sweden. The colour of ytthro-tantalite is a dark iron-black; when pulverized it is greyish: it occurs in nodules, about the size of a hazel-nut, and also crystallized in oblique six-sided and four-sided prisms. It occurs also in granular distinct concretions. Its fracture is compact or finely granular, and it has a shining metallic lustre. Ytthro-tantalite scratches glass, but yields with difficulty to the knife. The specific gravity of this mineral is 5.13. It decrepitates with the blow-pipe, but at length melts into a greenish-yellow slag. According to Vauquelin, the constituent parts are,

Oxyd of tantalum	-	-	45
Oxyd of iron and yttria	-	-	55
			<hr/>
			100

Ytthro-tantalite is nearly allied to gadolinite, the other mineral in which yttria is found, and occurs with it at Ytterby, in a bed of flesh-red felspar in gneiss.

YTZAIMPATLI, in the *Materia Medica*, a name given by some to the cevadilla, or *bordeum causticum*, the *caustic Indian barley*.

YU, in *Geography*, a city of China, of the second rank, Vol. XXXIX.

in Pe-tche-li; 87 miles W. of Peking. N. lat. 39° 52'. E. long. 114° 14'.—ALFO, a city of China, of the second rank, in Ho-nan; 442 miles S.S.W. of Peking. N. lat. 33° 22'. E. long. 112° 38'.—ALFO, a city of China, of the second rank, in Ho-nan; 377 miles S.S.W. of Peking. N. lat. 34° 16'. E. long. 113° 14'.—ALFO, a river of China, which rises in Ho-nan, 12 miles N. of Pi-yang, and joins the Hoai, 20 miles E.S.E. of Sin-fai.—ALFO, a river of China, which rises about 26 miles W. from Ngran-fou, in Kiang-fi, and runs into the Kan-kiang, 7 miles N.N.E. of Lin-kiang.

YUCATAN, a province of Mexico: it is a peninsula, surrounded on the W. and N. by the gulf of Mexico, between the bay of Campechy on the S.W., and that of Honduras on the S.E., having the little province of Tabasco on the S.W., and that of Vera Paz, in the audience of Guatemala on the S., where it is joined on the continent by an isthmus not 120 miles broad. The climate is pretty warm in summer, which begins about April, and ends in September. It rarely rains here during the winter season, though the weather is tolerably cool, except in January and February, which are almost as hot as in the middle of summer. It is, however, very healthy, especially a large mountainous tract, extending from Salamanca on the W., to the eastern boundary, and where the natives live to a great age. The fourth side of this ridge is ill-peopled, and worse cultivated, for want of water; but the north part is very populous, being rendered pleasant by gentle breezes, though the sun is very hot. The days and nights are nearly equal all the year. The soil when properly cultivated produces great quantities of corn, cotton, and indigo. All sorts of cattle, wild-beasts, honey, wax, and fowls, are here in great plenty; and on the coasts are found large pieces of amber; but as no mines were ever discovered in this country, the Spaniards are not fond of making settlements here, so that it abounds mostly with Indians, subject to the Spaniards, who employ them in making salt, in the bay of Campechy. This peninsula has very few rivers, but wells without number, and considerable lakes; and wherever they dig up the land, abundance of shells are found, which with the lowness of the country, and shallowness of the sea about it, has induced many to think that the greatest part of it was once under water. The capital of Yucatan is Campechy, in the bay of which, and of Honduras, the former lying on the west, and the latter on the east side of this province, the English cut their logwood.

YUCCA, in *Botany*, is the *Yucca*, *Tuca*, or *Jucca*, of the original inhabitants of America. Gerard appears first to have published this name in England. Caspar Bauhin follows him. Linnaeus, *Phil. Bot.* 164, lays to the charge of Tournefort the introduction of *Yucca*, as a scientific generic appellation, but we do not find it in his work. Dillenius however adopts it in his *Nova Genera*, and *Hortus Elthameris*, and Linnaeus rather overlooks that approoves of the barbarism.—Linn. Gen. 170. Schreb. 226. Willd. Sp. Pl. v. 2. 183. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 291. Pursh 227. Juff. 49. Poirer in Lamarck Dict. v. 8. 824. Lamarck Illustr. t. 243. Gærtn. t. 85. (Yucca; Dill. Nov. Gen. 111. t. 5. Ponted. Anthol. 294. t. 6. f. N. O. Cordylina; Van Royen Lugd.-Bat. 22.)—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Lilia*, or perhaps *Bromeliæ*, Juff.

Gen. Ch. *Cal.* none. *Cor.* bell-shaped, in six deep, ovate, very large, equal, moderately spreading segments, connected by their claws. *Nectaries* none. *Stam.* Filaments six, inserted into the base of the corolla, very short, swelling upwards, reflexed; anthers minute, roundish. *Pist.*

Germen superior, oblong, bluntly triangular, with six furrows, rather longer than the stamens; style none; stigma obtuse, with three furrows, its lobes cloven, the centre pervious. *Peric.* Berry oblong, bluntly hexagonal, fleshy, perforated at the summit, of six cells; three of the partitions thicker than the three intermediate ones. *Seeds* very numerous, in a single row, separated from each other by transverse membranes, roundish-obovate, flat, depressed, attached, by their pointed base, to the inner angle of the cell.

Effl. Ch. Corolla inferior, bell-shaped, its segments without nectaries. Stamens club-shaped. Style none. Berry hexagonal, of six cells. Seeds numerous, flat.

Obs. We have, like Schreber, adopted Gærtner's idea of the fruit, which Linnæus does not appear to have seen in perfection, and which Dillenius confesses himself to have judged of from the unenlarged germen only. Analogy might well lead these authors to presume it a capsule, which, from the structure of the germen, might be judged to consist of three cells. This idea was moreover supported by an account which Ray had somehow obtained from the East Indies; where indeed no *Yucca* grows wild, and therefore this account cannot implicitly be trusted. Gærtner received, from professor Hermann of Strasburg, the ripe fruit of *Yucca draconis*; and this being the only authentic instance of the seed-vessel of any one of the genus passing under the investigation of a critical botanist, we must rely on it as affording the only certain type of the genus in this particular. Jussieu appears to have followed Linnæus; but the discovery of the true nature of the fruit, rather favours his opinion above-mentioned, of the affinity of *Yucca* to his *Bromelia*. This is a handsome perennial genus, more or less caulescent, with numerous, long, simple, rigid or coriaceous, pungent leaves; and copious, panicle, white, liliaceous, very elegant though generally inodorous flowers. Some of the species are tolerably hardy in our gardens, but they do not very readily or constantly blossom.

1. *Y. gloriosa.* Common Adam's-needle. Linn. Sp. Pl. 456. Willd. n. 1. Ait. n. 1. Pursh n. 4. Curt. Mag. t. 126c. Andr. Repof. t. 473. (*Y.* five *Jucca*, peruana; Ger. Em. 1543. *Yuca indica*, foliis aloes, flore albo; Barcl. Ic. t. 1194.)—Caulescent. Leaves lanceolate, straight, furrowed; their edges smooth and entire.—Native of Peru and North America. On the sea shore of Carolina, flowering in July and August; the whole plant about ten feet high. *Flowers* white. *Pursh.* The stem in our gardens is seldom two feet in height, somewhat branched, thick, tough, crowned at the summit of each branch, if divided, with a profusion of crowded leaves, spreading in every direction, each a foot and a half or two feet long, tapering to a hard spinous point; contracted in the lower part, but dilated at the very base, where they half clasp the stem; their upper surface is of a fine green, smooth, furrowed longitudinally, especially towards the end; the under paler, and more even; the edges quite even and smooth. *Panicle* terminal, compound, erect, composed of perhaps an hundred drooping flowers, not much inferior in size and beauty to those of the White Water-Lily, but more cream-coloured, tinged at the base and points with crimson, destitute of scent. *Partial stalks* about an inch long, round, smooth, with a pair of membranous bractæ at the base. *Stigma* in three distinct, spreading, cloven lobes. We cannot but think, notwithstanding Mr. Ker's opinion, that Andrews's figure belongs to this species, and not to *aloifolia*. This is evinced by the furrows and margin of the leaves, as well as by the structure of the stigma; though we must allow the whole

representation to be less happy and characteristic than that in the Magazine.

2. *Y. recurvifolia.* Drooping-leaved Adam's-needle. Salisb. Parad. t. 311. Pursh n. 3.—Caulescent. Leaves linear-lanceolate, furrowed, recurved and drooping; their edges at length somewhat filamentous.—Native of the fandy shores of Georgia, where it was found by M. Leconte, flowering in July and August. The flowers are of a greenish-yellow, with a tinge of purple. *Stem* about three feet high. *Pursh.* This species is recorded in the *Paradysus Londinensis*, as having flowered, in the late Mr. Swainson's garden at Twickenham, in 1805; yet it is not admitted by Mr. Dryander, or Mr. Aiton, into the *Hortus Kewensis*, or its *Epitome*. The flowers are said by Mr. Salisbury to have a strong smell, mixed with something like a citron flavour. The three inner segments of the corolla are a little the broadest. *Stigma* moist like the last. The edges of the leaves split off in a few disjointed filaments, in the manner of *Y. filamentosa*, though far less remarkably. We have seen no specimen. Mr. Pursh having observed this, as well as the *gloriosa*, in a living state, in North America, chiefly induces us to admit it into our list of species; garden plants being always less to be trusted in any doubtful question.

3. *Y. aloifolia.* Aloe-leaved Adam's-needle. Linn. Sp. Pl. 457. Willd. n. 2. Ait. n. 2. Pursh n. 5. Curt. Mag. t. 170c. (*Y.* *arborescens*, foliis rigidioribus rectis ferratis; Dill. Elth. 435. t. 323.)—Caulescent. Leaves linear-lanceolate, even, straight; their edges bordered with fine callous notches.—Native of South America, according to most authors; of the coast of Carolina and Florida, flowering in August. *Pursh.* It was introduced, more than a hundred years ago, into the English and Dutch gardens, and is generally treated as a green-house shrub, though said to succeed and flower better, in mild seasons, in the open ground. The stem is generally simple, and rises to the height of fifteen to eighteen feet, even in our conservatories, being for the most part naked, round, three or four inches in diameter, marked with scars where leaves have been. The upper part, for the space of a foot or more, is thickly beset with leaves, spreading in every direction, the lower ones pointing downwards, the upper ones nearly upwards, a few in the middle only being horizontal. The leaves are all straight, narrower and stiffer than in *Y. gloriosa*, and distinguished by their crenate edges, as well as even surface. The panicle also is more dense and cylindrical, from two to three feet high. *Flowers* white, externally tinged with purple. *Stigma* abrupt, of three shorter, less dilated and spreading, lobes. Mr. Ker truly remarks, in the Botanical Magazine, that this species will thrive for many years with very little earth, in pots not more than a foot deep. Its flowering is a rare occurrence, and after that event, the head decays at the top, throwing out lateral shoots, and the plant becomes branched; but its elegant simplicity is destroyed, and we believe no more flowers, at least in our gardens, are ever produced.

4. *Y. draconis.* Drooping-leaved Adam's-needle. Linn. Sp. Pl. 457. Willd. n. 3. Ait. n. 3. (*Y.* *draconis* folio, ferrato reflexo; Dill. Elth. 437. t. 324. Tacori; Cluf. Exot. 48.)—Caulescent. Leaves linear-lanceolate, even, reflexed, crenate. Segments of the corolla spreading, somewhat recurved.—Native of South Carolina, according to Mr. Aiton, who marks this species as a hardy shrub, flowering in October and November. We have never seen an authentic specimen of the flowers, but in the very admirable plate, communicated to Dillenius by his friend Sprekelson of Hamburg, and published in the Hort. Elth. as above, the corolla is represented with more lanceolate, flat, spreading,

ing, and in some measure reflexed, segments, than in any of the foregoing. The *leaves* are described longer, narrower, and thinner than in the last species, reflexed, being bent downwards, and pendulous, from about the middle, or rather nearer the base; they are moreover shining, of a deeper green, less concave, and with longer more slender terminal spines. They are an inch broad, and above two feet long. Dillenius says the marginal notches are rather finer than in the last. The Linnæan specific definition implies the reverse. Commelin's plate in his *Praludia Botanica*, t. 16, exhibits very large and distant spinous teeth, at the edges of the *leaves*, such as we have never seen, even in young plants. We have therefore refrained from citing this author under the present species, as well as his t. 14. of the same work, and Plukenet's t. 256. f. 4. under the last; because, though they may be right, such figures afford no information or instruction. Clusius says the Indians use the fibres of the leaves of the species of which we are treating, obtained by maceration and beating, as a fine kind of thread, like flax or silk; and they also make strong cordage of the same, for tying the rafters of their huts together. Such qualities merit further inquiry.

5. *Y. filamentosa*. Thready Adam's-needle. Linn. Sp. Pl. 457. Willd. n. 4. Ait. n. 4. Pursh n. 1. Curt. Mag. t. 900. (*Y. foliis lanceolatis, acuminatis, integerrimis, margine filamentosis*; Trew's Ehret 9. t. 37. *Yucca*, five *Jucca*, vera, foliis filamentosis; Moril. fect. 4. t. 23. f. 2.)—Stem none. Leaves lanceolate, entire, coarsely filamentous at the edges.—On the shores of Virginia and Carolina, and in the western parts of the same countries, flowering in July and August. *Pursh*. A hardy perennial in our gardens, flowering, though not very constantly, in autumn. The *leaves* are numerous, a foot long, spreading in the form of a rose from the crown of the root; their points spinous, but short; their surfaces both striated, a little glaucous, rough to the touch with minute harsh prickles; their edges beset with long recurved threads. *Flower-stalk* solitary, erect, from four to five feet high, round, smooth, leafless, bearing several scattered, oblong, membranous, reddish-brown *bractees*, such as also accompany the partial stalks. *Panicle* compound, lax and spreading, of numerous large and handsome, pendulous, cream-coloured, bell-shaped *flowers*, represented of much too yellow a hue in the Botanical Magazine. Their segments are taper-pointed. *Filaments* rough, or glandular, with very small *anthers*. *Stigma* with spreading, somewhat recurved and cloven, lobes, like *Y. gloriosa*.

6. *Y. angustifolia*. Narrow-leaved Dwarf Adam's-needle. Pursh n. 2.—Stem none. Leaves linear, elongated, rigid, sparingly filamentous at the edges. Fruit obovato-cylindrical.—Gathered by Mr. Nuttall, on the banks of the Mississippi, flowering in July and August. Perennial. *Leaves* very narrow. *Stalk* from two to three feet high. *Fruit* large. *Pursh*. This appears not yet to have been brought to England.

The name of *Yucca* may be found applied, by the older botanists, to several plants which have no botanical affinity to the present genus; such as Morison's fect. 4. t. 23. f. 3, where the *leaves* are digitate; and *Jatropha Manihot* of Linnæus. (See *JATROPHA*.) Such plants agree in the essential quality of their fleshy *roots*, which when grated and washed, yield a farinaceous substance, of which the natives of America and the West Indies appear to have made a kind of bread, long before our European corn was introduced among them.

Yucca, in *Gardening*, contains plants of the succulent, evergreen; shrubby, hardy, and tender kinds, in which the

species cultivated are, the common Adam's-needle (*Y. gloriosa*), the thready Virginian yucca (*Y. filamentosa*), the aloe-leaved yucca (*Y. aloifolia*), and the dragon-tree-leaved yucca (*Y. dracaonis*).

These are all succulent evergreen shrubby plants, some of them having a fleshy nature and great regularity of growth.

Method of Culture.—These plants are all capable of being raised by offsets or suckers, from the roots and heads of the old plants, as well as by seed.

The offsets and suckers may be taken off any time in the spring or summer seasons, being laid in some dry place for a few days, till the wounded part cauled by the separation from the plant is dried and healed over; when they may be planted out separately in pots of light sandy compost, and be placed in a shady situation till they have taken root in a perfect manner. When assisted by a hot-bed, they often succeed better.

The seed obtained from abroad should be sown in the spring in pots of light earth, plunging them in a hot-bed, in which the plants soon come up; and when they are two or three inches high, they should be pricked out separately in small pots of light sandy mould, replunging them in the hot-bed to forward their growth, assisting them with moderate waterings and fresh air daily, and hardening them by degrees to the full air, so as to be set out in June to remain till October, when they should be removed into the greenhouse for the winter.

Some plants of all the sorts should constantly be preserved in pots.

They are all very ornamental; the two first after they have been hardened, in the dry borders, where the soil is light, and where the situation is warm and sheltered; and the others in green-house collections, among other potted plants.

YUE, in *Geography*, a city of China, of the second rank, in Yun-nan; 1105 miles S.S.W. of Peking. N. lat. 25° 22'. E. long. 103° 22'.

YUEN, a river of China, which runs into the lake Tongting, 17 miles E. of Tchang-te.—Also, a city of China, of the second rank, in Hou-quang; 850 miles S.S.W. of Peking. N. lat. 27° 23'. E. long. 109°.

YUEN-KIANG, a city of China, of the first rank, in Yun-nan, on the Ho-ti river; 1250 miles S.W. of Peking. N. lat. 23° 37'. E. long. 101° 44'.

YUEN-TCHEOU, a city of China, of the first rank, in Kiang-si; 750 miles S. of Peking. N. lat. 27° 50'. E. long. 114°.

YUEN-YANG, a city of China, of the first rank, in Hou-quang, on the river Han; 517 miles S.S.W. of Peking. N. lat. 32° 50'. E. long. 110° 29'.

YVERDUN, or **IFERTEN**, a town of Switzerland, in the Vaudois, and capital of a bailiwick, in the canton of Berne, situated on the lake of Neuchâtel, otherwise called the lake of Yverdun, at the mouth of the river Orb, which divides into two branches, forming a good port, and an island, on which the town is situated. The two faubourgs communicate with the town by bridges. It is ancient, and in the Theodosian table called "Castrum Ebredunense," and "Ebrudunense," by which it is understood to have been a place of strength. The Romans maintained here a *prefectus barbariorum*, and there yet exists a society of boatmen, of ancient standing, and numerous, who have a particular police, privileges, and laws of navigation. From the Romans it duked to the kings of Burgundy, and afterwards to the dukes of Zahringen. In the year 1259, it was taken by Peter of Savoy, who reduced it by famine, and it continued

in that family till the year 1536. In this year, the troops of Berne, when they had reduced the rest of the Vaudois, laid siege to this town, and after a few days, became masters, since which Yverdun has been subject to Berne. The police is administered by a great and little council, composed of thirty-six members, the president of whom has the title of *banneret*. It has a large and strong castle, flanked with four towers, built in the 12th century, by Conrad, duke of Zähringen: other public buildings are, a college for the instruction of youth, an hospital, divers magazines, &c. and in the town-house is a library, formed not long since by contribution. The environs were formerly a morass, which has been drained, and is now become good and fertile land. Near the town is a sulphureous medicinal spring, and in the year 1730, a building, for the purpose of bathing, was erected by the magistrates. In the middle of the last century, a company was formed, for the purpose of making a navigable canal from the lake of Yverdun to the lake of Geneva, but it was never finished. The bailiwick is one of the most considerable in the canton of Berne, containing about 25 parishes and 20 lordships, and is about 15 miles in length. The fertility is moderate: the wine is not of the best quality; 34 miles S.W. of Berne. N. lat. 46° 48'. E. long. 6° 14'.

YVES, or IVO, in *Biography*, bishop of Chartres, was born in the 11th century, of a noble family, in the territory of Beauvais, and studied theology under Lanfranc, prior of Bec. Being made abbot of St. Quentin, he opened a theological school, which became famous; and having superintended this institution for fourteen or fifteen years, and maintained a regularity among those who attended it conformable to the ancient canons, he was justly regarded as one of the chief founders of the order of canons-regular. Upon the death of Geoffrey, bishop of Chartres, he was chosen as his successor, and the election was confirmed by Urban II. in 1091. The discipline he maintained in his see was exemplary, and in the duties of it he was employed for 25 years, his episcopate and his life terminating in 1116. Besides sermons, a brief chronicle of the kings of France, and two collections of ecclesiastical decrees, he has left 287 epistles, from which may be learned the manners of the times in which he lived. Of these we have a summary by Dupin. A collection of his works was printed at Paris in 1647. His name is highly respected in the church of Rome, and pope Pius V. issued a bull in 1570, empowering the canons-regular of Latran to celebrate an anniversary for "the blessed Yves." Dupin. Moreri.

YVETOT, in *Geography*, a town of France, in the department of the Lower Seine. This was once a place of consequence, and the capital of a kingdom; 18 miles N.W. of Rouen.

YUFTS, or *Russia Leather*, as it is called in England, are the chief products of the tanneries in Russia; and the principal places in which they are prepared, next to Moscow and Petersburg, are, Arfamas, Kostroma, Yaroflaf, Pfcove, Kazan, Vologda, Nishney-Novgorod, Vladimir, Ekatarinenburg, &c. Mr. Tooke has described the process by which they are prepared:—The raw ox-hides are first laid in running water, or in large tanks full of water dug in the earth for that purpose, to soak for a whole week; but in summer not so long. During this time they are daily taken out of the water, and scraped at a scraping-bench, or wooden horse. Having now been duly steeped, they are put into a ley, thus prepared:—In other vats, likewise dug in the ground, and under cover, they mix two parts of good ashes with one part of unslacked lime, in boiling water, and sink the wet hides in this ley on

a grating, which being suspended by cords, can be raised or let down at pleasure. In this vat the hides are laid again for about a week, though in warm weather less, in cold perhaps even longer. The sign that they have lain long enough in the ley is, that the hair can without difficulty be rubbed off with the hand, so that none remains. If the hides, after the expiration of a week, are not in that condition, fresh ashes are put into the ley, and the skin sunk in it. But if at length the hair be sufficiently loose, the hides are entirely taken out of the ley, and all the hair scraped off on a stretching-block, by means of blunt iron scrapers with two handles. The hair is washed clean, and sold for domestic uses. The hides, thoroughly cleansed from hair, are suspended in vats of clean water on a running stream, where they remain three days, diligently turning them to and fro, in order to purge them from the ashes and ley; afterwards they are hung up, and left to drain. The hides must now be scraped on the flesh side. To this end they employ either the aforesaid scraping-iron, or others sharper in various degrees. After this treatment, the hides are trampled. But calves-hides have another sort of preparation, which the yuft-tanners, in the interior towns of the empire, who mostly practise it, call *rakfcha*. This preparation is performed with the white excrement of dogs dried, which is dissolved in boiling water, and to a hundred hides about four vedros full of excrement is the rule. If here the right proportion with the water be not found, the hides corrupt in this slime, the object whereof seems to be the complete freeing of the skin from the salts that adhere to it from the ley. The hides are left to lie twice twenty-four hours. With this is stirred a four gruel of oatmeal with warm water, and to three omicks, or eights of a chetverik, three or four vedros of dregs of the common quas, which the people make of meal and a small portion of malt, put in the thin gruel, that it may quickly sour with the hides. To ten hides, the tanners usually reckon forty pounds of meal.

After the hides have soured, which is done in large vats, they are laid in other vats, and well steeped for two or three days in a strong tan-juice, sok, thoroughly boiled from good bark. When this is done they are brought straight to the tan. In the tan-pits, in which often some hundreds of hides are lying, is poured half water and half tan, or water boiled with tan, and a grating is hung in with cords, having one hide after the other spread upon it, thick strewed with good fine-pounded tan, and the grating constantly let deeper into the pit, till it be nearly full; yet so that the tan-liquor is always above the hides, which are then again sprinkled over with tan. In this tan the hides continue to lie a week; those of full-grown animals longer. On being taken out, they are washed and trampled on, which two workmen in a summer's day can perform with three hundred hides. The next day they are laid, in the manner above-described, in fresh tan. Thus they generally get four times successively fresh tan, and are every time rinsed clean. In the last tan they lie three weeks, or longer, are then finally washed, hung up, and, when they have tolerably drained, delivered to those workmen whose business it is, in particular workshops, to dye, dress, and wax the yufts, and to deliver the goods finished. It is to be observed, that the Russian yuft-tanners seldom use oak-tan, and never willingly. The choicest and best tan is that of the *tschernotal*, as they call it, or the black willow; and also the young bark peeled off from other shrubby willows, which are collected by the boors, dried in bundles, and brought in cart-loads to market. To ten hides, the tanners compute one and a half fathom of these bundles of willow-bark,

YUFTS.

bark, as they are laid one upon another for sale, through all the tans. It must not, however, be imagined that the excellence of the Russian yufts depends on this; for in Siberia, where are no oaks, and but few willows of any size, they tan yufts with only birch-bark, which are not much worse than the Russian. The bark is made small by either ordinary tan-mills, turned by horses or by water; or the tanner himself, in many towns where there are no mills, causes it, at unnecessary expence and labour, to be pounded in wooden mortars, or excavated blocks, with pebbles, almost like those in the tan-mills, by day-labourers.

The dyeing of the yufts is performed in two ways, and of two colours. The commonest and most natural custom of giving the colour to the hides is, by sewing them together in pairs, the hair side inwards, while they are yet moist, round the edges, with rushes or stripes of bark, thus forming them into a bag or sack; into this sack the colour is put, the sack well shook, and the superfluous dye let to run out, whereupon the skins are dried. From this method of dyeing them, it seems to proceed that the yufts are called and taken by pairs. The other process, whereby much trouble, time, and colour are saved, and the edges of the skin entirely preserved, is the following: Each skin is hung upon a horse over a long trough, so that the hair side, which must be flained, appears outwards, pouring the dye upon it out of the dye-kettle, till the whole skin is dyed. The two colours given to the yufts are red and black. The red dye is thus prepared: Pound brasil-wood (sandal) in the pounding-mill, or with hand-pebbles, as fine as the tan, and boil it in kettles. Previous to the dyeing, steep the skins in alum-water. It is calculated, that to each small yuft-skin a half, and to a large one a whole pound of logwood is put. But the latter are mostly coloured black. To a hundred yufts to be dyed red, four pounds of alum is sufficient. For dyeing black the brasil-wood is likewise used; but in the red dye, to a hundred skins three pounds of good iron vitriol is dissolved. After the first tincture the skins are dried, and afterwards on tables done over again with the same dye and rolled up, that they may thoroughly imbibe the dye. For heightening the colour this tincture is sometimes thrice repeated. When the skins are now tolerably dried, by hanging, that the colour may not fade, with the flesh side outwards, the yufts, still somewhat moist, are smeared over on tables that have ledges. There was a time when it was commanded by authority to use nothing but dolphin and seal-blubber for smearing them; but by that the yufts are harsher, and have not that yuft smell, which foreigners prize so much, unless the birch-tar, deggot, prepared in Russia, at least be mixed with it. At present this birch-tar alone is used for smearing. This done, the skins are cleaned from all impurities that may remain, and are sent to the dressing-house, where skilful workmen scrape them first with scraping-irons, having two handles, with the edge cross-wise on a stretching-bench, that a soft thin leather remains with a clear glossy surface, free from all impurities. Other workmen then take the clean-scraped yufts on large clean tables, sprinkle them on the flesh side with a gentle shower of fresh water from their mouths, and lay them slightly rolled up to moisten. This done, the skins are taken separately one after another, folded together, and worked and calendered in all directions, to make them soft and pliant. They are then carried with a kind of wooden curry-comb, with sharp irons fixed in leathers, like a card for carding wool, the skin being folded with the hair side outwards, by which the whole surface of the yufts acquire the cross-strokes or trellis-like marks they are always seen to

have. Some work the skins with the hands first dry, not sprinkling them till they are mangled with the card. Lastly, those skins which are too harsh and stiff to the feeling, are more or less sprinkled with linseed-oil, and thus are ready for the merchant.

In this connection we shall introduce from the same author an account of the Russian method of preparing and dyeing their fassian, maroquin, or Morocco leather, which are dyed at Astrachan of three colours, red, yellow, and black. The treatment of the red fassians, which are the most famous, is usually as follows:—The raw hides are first laid in large vats, and have river water poured upon them, in which they are left to soak for three or four times twenty-four hours. They are then taken out, the water is drained and squeezed from each skin, and are scraped one by one on the stretching-bank with scraping-irons, uraki, quite gently on the flesh side, in order to take away the grosser impurities, but principally for opening the skin, and to qualify it for the ensuing operation.

They now proceed to make the hair fall clean off, chiefly by the application of lime. To a hundred hides is stirred in about half a bushel of unslaked lime in vats with river water, and the hides are laid in so as that the lime may as much as possible be equally distributed over all of them. The Astrachan Tartars let the hides lie in this lime-pit frequently three weeks; but it is well known, that their fassians are so harsh and liable to crack, and even scorched by it, that they are fit for nothing, and can only impose upon an inexperienced purchaser. They then take out skins, wash them, and carefully scrape off the hair, now become loose, with wooden scrapers. It often happens, that the hair is not perfectly loosened by the first lime-ley, but that many tender stubbles and small hairs are left remaining. In this case, the hides must be put into fresh lime-ley, and be left perhaps two weeks in it; the hair then comes off, and the hair side of the skin gets a green and very white appearance, but the substance is then also very soft, and the fassians, by this corrosion of the lime, are very little durable in comparison of other kinds of leather.

The method now for taking the lime again out of the hides, is the second treatment with dog-excrement, or white gentian, which is carefully collected for this purpose. This excrement, which is indispensably necessary, is pounded, put into a narrow not very large vat, warm water poured upon it, the mass thoroughly stirred, and the cleaned hides are put with it into another vat, so as that the dissolved album grecum is spread and insinuated over and between every skin. In these ingredients, the skins must lie only twenty-four hours, or if the quantity of album grecum prove not rich, somewhat longer. The proportion here to be observed cannot be accurately ascertained; for the fassian-makers are guided generally by eye-measure, and observe only that the water be very thick and turbid, and consequently acid enough. The hides come out of this corrosive much softer and thinner than they were, and are now freed from the force of the lime; but no time must be lost in endeavouring to extract the corrosive likewise, that the hide may not be even more ruined by it than by the lime. They are generally very careful that the hides lie not too long in this corrosive, which they judge of by their eye from the pliancy and suppleness of them. As soon as the skins are lifted out, the unclean moisture is carefully and forcibly pressed out, and they are laid without loss of time in a vat, wherein wheat-bran is stirred to a tolerably thick gruel with warm water; in this they lie again about thrice twenty-four hours, whereby all the former defects are completely remedied, and the substance of the
skin

YUFTS.

skin is softer and mellow. All these particulars are in some measure of no other service than to bring off the hair thoroughly clean from the skin.

Now follows the proper preparation of the skins taken out of the wheat-bran. This is done chiefly by honey. To eighty hides they take about twenty-five pounds of raw honey, boil it in a kettle, pour as much water to it as is necessary for giving it a due consistence, and stir it for a pretty long time boiling on the fire. They then let the kettle cool, till they can but just bear the hand in it, and then pour the still hot honey-water on the hides lying singly in little trays, by ladle-fuls, till they have thoroughly imbibed the honey-water. When all the skins are duly drenched, they are thrown into a dry vat all together, laying at top a board with weights upon it, and covering the whole vat with felt, carpets, or furs, that the vapour during the fermentation may not escape; and in this manner, the skins must ferment once more thrice twenty-four hours. By this means they acquire the grain. From the honey-vat they are rinsed clean in luke-warm water, wrung as dry as possible, and steeped immediately in a moderately strong pickle or brine made of common salt, in which they must be left five or six days. This time being elapsed, the skins are taken out of the pickle, and hung upon clean poles, that the brine may drain out, as it would be thought injurious to squeeze it out with the hands. This done, the skins have received their whole preparation, and may now be dyed red, but not yellow; because for the yellow saffians, as was said before, the preparation is of another kind.

For giving the red saffians the colour, nothing is used but cochineal, or, as the Tartars call it, kirmifs, and that in the following method: First, they boil a quantity of the herb *salvia ericoides*, by the Tartars called tshagan, plentifully growing on the arid Aitrachan salt-steppes. To about four Russian vedros of water is put of this dried herb somewhat less than a pound, and it is set to boil for a whole hour, whereby the water acquires a dark greenish colour, but betrays no acrimony to the taste. The saffian-maker only takes care that the water be not too deeply tintured, and that when dropped on the thumb-nail shews only a scarce perceptible green; and in case it have adopted too many particles of the colour, it is drawn off, and fresh water put, in which the herb must boil again, till the decoction has received the due degree of saturation. The herb is then with a scoop taken clean out of the kettle, and then the previously nicely powdered cochineal thrown into a kettle of four Russian vedros to about half a pound, well stirred, and fresh fire added, in which great attention must be paid, that the red scum, which arises from boiling, does not boil over, therefore constantly some is taken and again poured in, in order by this refrigeration to prevent the over-boiling, and to allay the foam. After boiling for about an hour and a half, the water has obtained a strong tincture; but as much of it is boiled away, the kettle is filled up again with the remaining decoction of the herb tshagan, and the thus attenuated colour boiled afresh, till it is seen that the cochineal is perfectly dissolved, and the colour become thoroughly bright. Upon this, to the whole kettle is put about two lots of pounded and burnt alum into the dye, with which it is to boil about a quarter of an hour, and then the fire is taken from under the kettle, leaving only some hot embers, that the dye may retain as much heat as the hand can but just bear. This done, the skins prepared for dyeing are taken in hand, the dye poured by ladles into trays, one skin folded together after another, with the hair side outwards, and then are worked in their portion of dye so long, till they have uni-

formly absorbed all the dyeing particles, and only somewhat of a pale moisture remains. The leathers being thus for the first time stained are quickly squeezed out, hung up singly across poles, and when they are all done, they are directly taken for the second time, and imbued in the same manner with dye, and this treatment is repeated for the third and the fourth time; so that each skin gets four ladles of the dye. From the fourth dye the skins are no more pressed out, but hung up entirely wet, to be ventilated, upon poles.

After the dye, the skins are once more curried with the leaves of the tan-tree, which the Armenians call belgê. The crushed or pounded dry leaves, which the Aitrachan saffian-makers get from the Terek, are stirred in broad troughs to a thick gruel with river water, and the coloured skins laid in it, between each of them, leaving a sufficiency of the leaf-ooze; the tanner then goes barefoot on the troughs upon the skins lying on one another. In this tan, or quas, as the workmen call it, the saffians lie eight days and nights, adding fresh tan every other day; so that four tans are necessary.

Here it must be observed, that some Armenians who prepare saffians, for enhancing the quality of the red colour of their saffians, to half a pound of cochineal add two lots, or rather more of sorrel, (or lutor, or loter, as they call it,) in the dye-kettle, but it is usually omitted in Aitrachan, on account of its high price; for which reason the Aitrachan saffians are excelled by the Turkish in beauty of colour. Secondly, it is to be known, that instead of the leaves of the tan-tree, bruised nut-galls are held to be still more serviceable for giving the saffians the tan. By this means, the colour is so durable as never to pass away but with the leather; whereas the saffians prepared with the tan-tree begin soon to be discoloured. But the nut-galls are likewise too dear in Aitrachan to be customarily used by the saffian-makers. The Kazan Tartars colour their saffians with red wood, and tan them with the shrub *uva urbi*, but it makes the worst saffians of all, as they presently fade.

When the saffians are lifted out of the tan, still the last work remains. They are first left some time in the air to dry, they are afterwards scraped on the stretch-bank with sharp scrapers on the flesh side, quite smooth and clean, then washed in running water, each skin duly stretched with pegs all round the edges, and thus left till they are dry.

The skins must now be smoothed on the hair side with a wooden instrument for that purpose; and lastly, they are laid on a thick felt, where, with an iron heckle that has blunt points, those little pittings, which the saffians are generally seen to have, are impressed on the same side. And thus they are ready for sale, without being smeared with linseed-oil, as is mentioned in Gmelin's travels, which would infallibly spoil them.

The yellow saffians are little made in Aitrachan, as the demand for them is much less, and there are but few saffian-makers who know much of the matter. The dye which they make use of for this purpose is of the berries of a sort of *zhamnus* (perhaps *lycioides*), which are brought from Persia under the name of *ulochar*, and usually bought for six to nine rubles the pood. The Kazan Tartars colour their ordinary yellow saffians with the flowers of the yellow camomile, which they gather under the name *fare tshet-schiak*, i. e. yellow-flower.

In preparing the yellow saffians, they observe in Aitrachan the following difference of treatment: 1. They make no use whatever of honey in the preparation. 2. They never

never at all put the hides into the salt brine. 3. Instead of the honey-preparation and the pickling, they lay the hides before the dyeing, in the foregoing manner, in the tan of the leaves of the kitzliar tan-tree, leaving them in it eight days. 4. For preparing the dye, they have no need of the herb tſchagan, but the berries alone are boiled in clear water, of which to four Russian vedros of water about ten pounds are requisite, and heighten the colour afterwards with three lots of alum to every pound of berries. The dyeing is performed in the same manner as has been related with the red, and after the dyeing there is no need to lay the saffians in the tan, as having before received it. Nothing more is necessary than to scrape them clean, to work them thoroughly, to polish and to ornament them. The yellow saffians usually are sold at one ruble twenty kopeeks; but the red at somewhat more, on account of the 'dearneys' of the dye, generally one ruble eighty kopeeks.

YUG, or YOG, the more correct mode of writing the word *jogus*, by which the Hindoos distinguish the poetical or mythological ages of the world. We have noticed these wild speculations under the more popular word *jogues*; to which, to GENTOOS, KALKI, KALPA, and YOGESWARA, we refer those desirous of farther information hereon.

YUGASIRI, in *Hindoo Mythology*, is the name of the wife of *Vairava*, an incarnation of *Siva*. See those articles.

YUHAGHIRS, in *Geography*, a Russian tribe, which occupies the northernmost parts of the territory of the Yakutes, bordering on the Frozen ocean, from the Yama to the Koly-ma. They were known to the Russian conquerors as early as the Yakutes; but on account of their wild and impassable deserts, could not be brought into entire subjection until the year 1639. They had never seen a horse, though that species of animals was found among the Yakutes; and therefore they appear to have been for a long time confined to their cold, fenny, and mountainous districts. The whole people, at the revision before the last, says Mr. Tooke, paid taxes only for about 1000 heads; but it was so easy for them in their deserts to evade the payment, that their entire population may be computed at a much higher number. See YAKUTSK.

YVIA, a town of France, in the department of the North coasts; 4 miles E.N.E. of Pontriun.

YVICA. See IVICA.

YUKANLOOT, a town of Candahar; 10 miles E.N.E. of Sufia.

YULDUZ. See YOLOTOU.

YUMA, or YUMBA, or *Long Island*, one of the Bahama islands: about 50 miles in length, of very unequal breadth. N. lat. 23° 20'. W. long. 74° 50'.

YUMA, in *Mythology*. See TSCHEREMISSES.

YUMAR, the name of the object of worship among the Votjaks; similar probably to Yuma, Yummel, and Yummala, among other tribes of the ancient Finns.

YUMBA BAY, in *Geography*, a bay on the E. coast of the island of Hispaniola, S. of Cape Spada.

YUMETOS, a cluster of small islands, among the Bahama islands, about 20 miles S.W. from Yuma.

YUMFONG, a small island, near the coast of China, about three miles from the island of Tſeng-ming. N. lat. 31° 42'. E. long. 121° 17'.

YUMMALA, in *Mythology*, an idol deity of the Finns, who had a rich temple in Permia, or Biermia, supposed to have extended from the White sea to the mountains of Ural. This temple was decorated with a profusion of gold and jewels. See PERMIANS.

YUMMEL, an appellation by which the Lieflanders and

Esthoniens worshipped the true God; in subordination to whom they only admitted inferior deities as beneficent and malicious spirits.

YUN, in *Geography*, a city of China, of the second rank, in Yun-nan; 1262 miles S.W. of Peking. N. lat. 24° 32'. E. long. 99° 35'.

YUN, or *Yong-pe*, a city of China, of the first rank, in Yun-nan; 1135 miles S.W. of Peking. N. lat. 26° 44'. E. long. 100° 34'.

YUNA, a river of Hispaniola, which runs into the So-mana bay.

YUNCHA, a town of South America, in the province of Tucuman; 60 miles S. of St. Jago del Estero.

YUNG-KANG, a city of China, of the second rank, in Quang-fi; 1140 miles S.S.W. of Peking. N. lat. 22° 56'. E. long. 107° 26'.

YUNG-NGAN-POU, a fortress of China, in Chen-fi, on the borders of Tartary; 110 miles N. of Ling-tao.

YUNG-NING, a city of China, of the second rank, in Chan-fi; 300 miles S.W. of Peking. N. lat. 37° 35'. E. long. 110° 30'.

YUNGUS, or VUNGUS VICUS, in *Ancient Geography*, a place of Gaul, on the route from Reims to Treves. Anton. Itin.

YUN-HING, in *Geography*, a city of China, of the first rank, in Ho-nan. The country within its district is very large, and is partly flat, and partly mountainous, especially to the north and south; it is watered by several rivers, which render the soil very fruitful. There are two towns of the second rank, and twelve of the third under its jurisdiction; 430 miles S. of Peking. N. lat. 33°. E. long. 113° 52'.

YUN-LEAN-HO, a canal of China, formed of the river Pay-ho, or rather the river itself made navigable from Hiam-ho to Tien-tſin, in the province of Pe-tche-li, for the purpose of conveying corn towards Tong-tcheou and Peking. The name in the Chinese language is said to mean corn bearing.

YUN-NAN, a province of China, bounded on the N. by Se-tchuen and Thibet, on the E. by Quang-fi and Koei-tcheou, on the S. by Laos, and on the W. by Ava and Pegu; about 300 miles in length, and 250 in breadth. This province is reckoned one of the most fertile and opulent in China. Its inhabitants are brave, robust, affable, and fond of the sciences, which they cultivate with success: its rivers, gold, copper, and tin-mines; its amber, rubies, sapphires, agates, pearls, precious stones, marble, musk, silk, elephants, horses, gums, medicinal plants, and linen, have procured it a reputation which renders it respectable to the Chinese. Its commerce is immense, as well as its riches, which are said to be inexhaustible. This province contains 21 cities of the first class, and 55 of the second and third. Sir George Staunton estimates the population at eight millions.

YUN-NAN, a city of China, of the first rank, and capital of Yun-nan, situated at the north extremity of a lake. It was formerly celebrated for its extent, and the beauty of its public edifices. Here were seen magnificent buildings, vast gardens, tombs, triumphal arches, and elegant squares; but the Tartars, in their different invasions, destroyed all these monuments; and the city at present contains nothing remarkable: it is, however, the residence of the governor of the province. It comprehends in its district four towns of the second class, and seven of the third; 1152 miles S.S.W. of Peking. N. lat. 25° 6'. E. long. 102° 28'.

YUNTAI, an island near the coast of China, in the Eastern

ZABERN, CONRAD DE, in *Biography*, born in Germany about 1450, was a very learned man, and much respected for his morals. He wrote two treatises on music; the first of which is entitled "De Monochordo," and the second "De Modo bene Cantandi." He was much beloved by the emperor Frederic III.

ZEBERN, in *Geography*. See BERGZABERN.

ZABI, or ZABA, in *Ancient Geography*, a place of Africa, in Mauritania Sitifensis, on the route from Carthage to Cæzarea, between Aræ and Macri. Anton. Itin.

ZABII, or ZABIANS. See SABEANS and SABAISM.

ZABIN, in *Geography*, a town of Lithuania; 30 miles N.E. of Minsk.

ZABIRNA, in *Ancient Geography*, a river of Asia, in Mesopotamia, which discharges itself into the Tigris.

ZABLOTOW, in *Geography*. See SABLITOW.

ZABLOWICZE, a town of Lithuania; 86 miles E. S. E. of Pinsk.

ZABOLA, a town of Transylvania; 10 miles N. of Cronstadt.

ZABORE, a town of Russia, in the government of Irkutsk; 36 miles S. S. W. of Kirensk.

ZABRZEH. See HOHENSTADT.

ZABULISTAN. See SABLESTAN.

ZABULON. See ZEBULON.

ZABULON, *Tribe of*, in *Ancient Geography*, was bounded on the N. by the tribes of Asher and Naphtali, on the S. by the torrent of Kishon, on the E. by the sea of Galilee, and on the W. by the ocean. Almost all the towns of this tribe were on the plain of Galilee.

ZABULON, a town of Judea, situated on the plain of Galilee, in the tribe of the same name, according to Joshua and the book of Judges. Josephus says, that Cestius, though he admired its beauty, took, pillaged, and burnt it. It was situated S. E. of Ptolemais.

ZABUR, a country of Asia, in Babylonia, in which was the town of Seleucia.

ZABUS, ZABATUS, or *Zerbis*, (*Great Zab* or *Zarb*), a river, which is the same with the Lycus, flowed from a source towards the 36th degree of latitude, and directed its course first to the N. W., then to the W., afterwards to the S. W., and finally to the S., discharging itself into the Tigris, about lat. 35° 45'. Xenophon says, that this river, at its entrance into the Tigris, appeared to the Greeks comparable to the Tigris itself. See ZAB.

ZABUS *Minor*, or *Caprus*, (*Lesser Zab*, or *Atun-Sou*), a river of Asia, which had its source E. of Arbelles, and ran towards the S. W., discharging itself into the Tigris, over against Cæne, below or S. S. E. of the greater Zabus. See ZAB.

ZACA, in *Geography*, a town of Egypt; 17 miles N. E. of El Arish.

ZACANTHA, in *Ancient Geography*, a town of Hispania, in Iberia, said by Steph. Byz. to have been taken by Hannibal, and to have been called Zacynthus or Saguntum.

ZACAPA, in *Geography*, a town of Mexico, in the province of Vera Paz; 42 miles S. of Vera Paz.

ZACAPULA, a town of Mexico, in the province of Chiapa; 130 miles S. E. of Chiapa dos Espagnols.

ZACATECAS, a province of Mexico, bounded on the north by New Biscay, on the east by Guatteca, on the south by the provinces of Mechoacan, Guadalaajara, and Chiametlan, and on the west by Chiametlan and Culiacan. It is well inhabited, and abounds with large villages. Part of it lies in the temperate and part in the torrid zone: it is about 100 leagues in length, and 45 in breadth. The

western part of it is an arid tract, and would not be inhabited were it not for the mines, which were formerly reckoned the richest in America; but the eastern part abounds with corn, and fruits of various kinds, and its forests are full of deer.

ZACATECAS, the capital of the fore-mentioned district, the importance of which has declined with the mines. It formerly contained about 12,000 families of Spaniards and mixed breeds, though consisting chiefly of one street, in a deep passage between high rocks, crowned with cottages. Luis de Potosi on the S. E. is said by Alcedo to contain only 1600 families of Spaniards, Mulattoes, and Indians, though it has six magnificent churches. The ridge of St. Peter, five leagues from the city, contained rich mines of gold and silver; but they are now in part exhausted, and the fuel has become scarce. The opulence of this city has in course declined, and the chief trade is in goat-skins and tanned leather.

ZACATECAS. See ST. LOUIS DE Zacatecas.

ZACATLAN, a town of Mexico, in the province of Tlaxcala; 30 miles N. of Puebla de los Angeles.

ZACATULA, or SACATULA, a town of Mexico, in the province of Mechoacan, on a river of the same name, near the Pacific ocean; 95 miles S. of Mechoacan. N. lat. 18° 35'. W. long. 103°.

ZACATULA, a small but fertile province in the dominion of Mexico.—ALGO, a river of Mexico, which runs into the Pacific ocean, near the town of Zacatula.

ZACCARIA. See TEVO.

ZACCIA, PAOLO, in *Biography*, an eminent physician, was born at Rome in 1585, and in the progress of life was distinguished by his learning, and by his skill in music, painting, poetry, and eloquence, as well as in the more appropriate sciences relating to his own profession. He was physician to pope Innocent X., and celebrated among his contemporaries by various publications; of which the principal is intitled "Questiones Medico-legales, in quibus omnes materiae medicæ quæ ad legales facultates videntur pertinere, proponuntur, pertractantur, resolvuntur;" a work which has been often reprinted. He was also the author, in Italian, of two esteemed works, "Del Vitto Quadragesimale," 1637, the subject of which is the regimen of diet in Lent; and "De' Mali Ipocondriachi," 1639, a diffuse treatise on hypocondriacal affections. He died in 1659, aged 75. Haller. Eloy. Gen. Biog.

ZACCONI, P. LODOVICO, of Pefaro, author of an ample treatise of music, entitled "Prattica di Musica," the first part of which was printed at Venice, 1592, and the second in 1596; a publication in which the author not only proposes to give instructions for the regular composition, but the accurate performance of every species of music. The idea is splendid; but the world has been so frequently deceived by the titles of books, that authors are obliged to abate in their promises, in proportion as the expectations of the public are diminished. If arts and sciences could be acquired by the dead letter of silent instruction, every one who could read, in Italy, might, during the times under consideration, have been a musician. But though no ingenious occupation was perhaps ever yet completely taught by books, without a master, or by a master, without books, yet they are excellent helps to each other. It is hardly possible for a didactic work to satisfy all the doubts that arise in an inquiring mind during solitary meditation; particularly in the first stages of a student's journey through the rugged roads of science. But when he has made some progress, if he should be separated from his guide, the way becomes daily so much more fraught and smooth, that by

the help of these kinds of charts, he will be enabled to advance with tolerable speed and facility by himself.

Zacconi's work, though sometimes dry and tedious, contains much useful and practical knowledge. And as he is almost the only Italian writer on the subject of music who has not bewildered himself in inquiries concerning the systems of the ancient Greeks, or the philosophy of sound, he has had the more leisure for analysing the art, and facilitating the student's progress. This author regarded Okenheim, Josquin, Isaac, Brumel, Mouton, and Senefio, as ancients compared with Willaert, Morales, Cipriano, Zarlino, and Palestrina; and these last, ancient with respect to himself and contemporaries; and says (lib. i. cap. xi.), that as the ancient Greeks and Romans produced their musical effects by mere melody, united with poetry, and Josquin and other early contrapuntists, by notes of different lengths, harmonized and worked into perpetual fugue; so the more modern, though the rules of harmony are the same, by a different disposition of concords, inversions, and other contrivances, produce a greater variety of effects.

He likewise observes (cap. xxiii.), that "every age has vainly thought its music brought to as great a degree of perfection as was possible; but it was always found that the next age continues to change, and still to think the same. Okenheim, the master of Josquin, and even in the days of Josquin, John Mouton, his scholar, had the same ideas of their own improvements; yet, since their time, music has not stood still, but made great advances towards perfection, being more light and pleasing."

The change in musical *modes* has continued to our own time, and will doubtless continue to the end of *all* time; for melody, being a child of fancy and imagination, will submit to no theory or laws of reason and philosophy; and therefore, like love, will always continue in childhood.

Zacconi's chief labour and merit in the third book have been the explanation of the moods, and correction of errors in the notation of old composers, to which his work will serve as a useful collection of errata. In Book I. he dwells much on the superiority of the singing and fingers of his own time, over all that preceded them; and has a long chapter upon the manner of gracing and embellishing a melody, where he tells us, "Che stile si tenghi nel far di *gorgia*; dell' uso de i moderni *passaggi*, come si *forischino* le cantilene;" and speaks of *aconciature*, as the modern Italians do of *riffioramenti*, or graces. The divisions, however, into which he breaks passages, in order to *embellish* them, if adopted by an operator of the present times, would be like a modern fine lady appearing at court in the furbelows and flounces of queen Elizabeth, or a fine gentleman in the peruke of sir Cloudfley Shovel.

ZACHAN, or SOCHAN, in *Geography*, a town of Hinder Pomerania; 14 miles E. of Stargard. N. lat. 52° 13'. E. long. 15° 28'.

ZACHAREVSKAIA, a fort of Russia, in the government of Ekaterinoflav, on the Konkija; 28 miles W. of Mariupol.

ZACHARIE, JUSTUS FREDERICK WILLIAM, in *Biography*, was born at Frankenhausen in Thuringia, in 1726; and during the course of his elementary education at his native place, he distinguished himself by various poetical pieces. In 1743 he went to Leipzig to study jurisprudence, but directing his chief attention to the belles lettres, he produced his mock-heroic poem, entitled "Renommitten," which Eichorn, in his History of Literature, says, was the commencement of heroico-comic poetry among the Germans. In the following year, he was admitted as an associate by the young men who contributed to the work published under

the title of "Amusements of Reason and Wit." From Leipzig, where he remained about three years, he removed to Gottingen, where, attracting the notice of professor Klaproth, he was recommended by him to be a member of the German society. In 1748 he was appointed tutor at the Caroline college at Brunswick, and in 1761 he became professor of poetry in that institution; to which, in the succeeding year, were annexed the offices of inspector of the typographic and bookfelling establishment belonging to the Orphan House, and director of the Brunswick Intelligencer. From 1768 to 1774, he was editor of the New Brunswick Gazette; in 1775 he was appointed to the diaconate of St. Syriac, at Brunswick; and he died in the month of June, 1777, in the 51st year of his age. His biographer states, that "he possessed a very fertile and vivid imagination, with a fine taste, improved by observation and acquaintance with the world. As a poet, he composed with uncommon facility, and tried his talents in almost every species, but was the most successful in the descriptive and heroico-comic. His burlesque poems were distinguished from every thing of the kind that had before appeared in Germany." A collection of Zachariae's poetical works was published at Brunswick in 1763—1765, 9 vols. 8vo. Gen. Biog.

ZACHARIAH, or ZECHARIAH, one of the minor prophets, who commenced the exercise of his gift in the 8th month of the 2d year of Darius, the son of Hystaspes; and on account of the precision and clearness of his predictions, he has been intitled "the sun among the minor prophets." The most remarkable of his prophecies are those that relate to the advent of the Messiah, and to the destruction of Jerusalem. Dupin.

ZACHARIAS, POPE, a native of Greece, succeeded Gregory III. in 741; at a time when the Roman territory was threatened with an invasion by Luitprand, king of the Lombards, and when the sons of Charles Martel were too much engaged by domestic broils to undertake its defence. The pope, therefore, tried how far he might avail himself of the authority of religion in averting the storm; and by a solemn embassy and personal visit, he not only obtained peace, but induced Luitprand to restore to the Roman see four cities which he had taken from it. He also interposed, in 743, with Luitprand on behalf of the exarch of Ravenna, and prevailed with him to desist from an invasion of the exarchate, and to grant peace, as well as to give back the fortrefs of Cesena to the exarch; and in the same year he held a council at Rome to settle some matters of discipline, particularly such as related to the clergy. During the pontificate of Zacharias in the year 746, Carloman, the eldest son of Charles Martel, who had surrendered his dominions to his brother Pepin, went to Rome, and assumed the monastic habit, with which he was solemnly invested by the pope. Rachis, the successor of Luitprand, who, upon his accession to the throne in 747, was peaceably disposed towards the pope and the Romans, took up arms against them; but his hostile purposes were averted by the remonstrances of Zacharias, and those of some of his principal clergy and nobility, who visited his camp, in order to obtain peace; nor were they successful merely in this object; but the result of their interview was Rachis's resignation of his crown, the assumption of the monastic habit conferred upon him by the pope, and retirement to the monastery of Monte Casino, where Carloman resided. In 752 Pepin applied to the pope for permission to seize the crown of France, and to set aside Childeric III.; the pope consented, and Childeric was provided for in a monastery. Zacharias, having displayed talents in the exercise of his office, which gave

him rank among the greatest of the popes, and having established an estimable character by his liberality to the poor, and by his munificence in public works, died in 752, in the 11th year of his pontificate. Some of his decrees and epistles, and also his translation of the dialogues of St. Gregory from Latin into Greek, are extant. Bower.

ZACHAROVA, in *Geography*, a fort of Russia, in the government of Irkutsk; 32 miles N.N.E. of Kirensk.

ZACHAU, a town of Brandenburg, in the Middle Mark; 10 miles E. of Brandenburg.

ZACHAW, FREDERIC WILHELM, in *Biography*, an able musician and organist at Halle, in Saxony, was born at Leipzig in 1665. He had the honour and good fortune to have Handel for his scholar. He is still celebrated by the Germans as a master, who had established an admirable school of music at Halle, and as one who was deeply skilled in all the arcana of composition and performance.

ZACHEO, or **DESCIHO**, in *Geography*, a small island in the West Indies, between Hispaniola and Porto Rico; about 27 miles N.E. of Mona.

ZACHTLEVEN, CORNELIUS, in *Biography*, was born at Rotterdam in 1606, and became an admirable painter of scenes of humour, imitating the style of Bronwer; but in subjects of a more sober description, which he also painted, such as farm-houses, kitchens, and the recreations of villagers, &c. he chose the more light and agreeable style of Teniers for his model; and in that style attempted to embody the same description of persons and compositions. In neither, however, of his imitations did he attain an equal degree of spirit or of truth with his prototypes. His works are well composed, and the touch with which they are executed is bold and free; they are not often met with, but are thought deserving of a place in the best collections.

ZACHTLEVEN, HERMAN, was the younger brother of Cornelius, and was born at Rotterdam in 1609. He is said to have been the pupil of Van Goyen, but did not follow the style of that master. His principal occupation appears to have been in painting views of the banks of the Rhine and the Meuse. These he executed in a very neat manner, but with a mean and common-place style of selection and imitation. The tones and hues of his pictures are generally cold, but fresh; and as he appears to have had great knowledge of aerial perspective, his distances are well preserved; and the forms drawn with great care and minuteness. He never left Flanders, though it has been asserted that he went to Italy. His drawings are numerous, and are carefully preserved in the best collections. He died in 1685, aged 76. Both he and his brother Cornelius employed the etching-needle, and left several neatly executed plates, from designs of their own.

ZACINTHA, in *Botany*, whether so called by Matthioli, the author of the name, because this plant was originally found in the isle of Zante, or for what other reason, does not appear.—Matth. Valgr. v. 1. 457. t. 46c. Schreb. Gen. 534. Willd. Sp. Pl. v. 3. 1624. Ait. Hort. Kew. v. 4. 468. Sm. Prodr. Fl. Græc. Sibth. v. 2. 145. Tournef. 269. Poiret in Lamarck v. 8. 831. Gært. t. 157.—Clafs and order, *Syngenesia Polygamia-æqualis*. Nat. Ord. *Compositæ-semiflosculosæ*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* double: the outermost short, erect, of several lanceolate leaves, membranous at the edges; innermost larger, simple, furrowed, of eight permanent, linear, acute, converging leaves; at length swelling and very prominent at the base. *Cor.* compound, imbricated, uniform: florets equal, perfect, of one petal, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.*

German ovate-oblong; style thread-shaped, the length of the stamens; stigmas two, reflexed. *Peric.* none, except the interior calyx, which becomes woody, clofed, depressed, with a point, having eight rounded protuberant angles, each scale enfolding one of the marginal fides. *Seeds* solitary to each floret; the marginal ones ovate-oblong, incurved, compressed at the fides, gibbous at the back, tapering below, striated; longitudinally channelled, and villous, in front; central ones oblong, slightly incurved, quadrangular, compressed at the back, striated, smooth. Down sessile, somewhat feathery. *Recept.* naked.

Eff. Ch. Receptacle naked. Seeds of the circumference incurved; of the centre straight. Down very short, finely feathery. Outer calyx membranous; inner with eight protuberances.

1. *Z. verrucosa*. Warty Zacintha. Gært. n. v. 2. 358. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 820, unpublished. (*Lapsana Zacintha*; Linn. Sp. Pl. 1141. *Cichorium verrucatum*, Zacintha; Clus. Hist. v. 2. 144. *C. verrucarium*; Ger. Em. 289.)—Native of Italy, Crete, Lemnos, and Zante, as well as of mount Athos. *Sibthorp*. The root of this, the only known species, is annual. *Stems* somewhat leafy, round, smooth, branched and forked, spreading, from a span to eighteen inches high. *Leaves* runcinate, smooth; the radical ones largest and most numerous. *Flowers* yellow, small. The swelling part of the *calyx*, after flowering, assumes a purple colour. See *LAPSANA* and *RHAGADIOLUS*.

ZACO, in *Geography*, a territory which probably belonged to the province of Adiahen, and was generally comprehended between the Tigris and the Caprus, or Little Zab. The ridges or mountains of Zaco are a part of the Kurdistan region, on which was the road along the Tigris, between Mosul and Jezirah. These ridges were lofty, steep, and rocky, and the path rugged and difficult of ascent. It was part of the road of the 10,000 Greeks in their retreat. The present town of Zaco stands near the northern part of the ridge, denominated from it; and it is the most considerable place that occurs between Mosul and Jezirah; and is surrounded by a fertile district, which produces a great variety of excellent fruits. Zaco stands in an island of the river Kurnib, which descends from the Kurdistan or Carduchian mountains, and falls into the Tigris, a few miles below the town.

ZACONDA, a town of Africa, in the country of Ante, where the Dutch built a fort. It was a considerable town at one time, till in a war between the people of Ante and Adom, it was burnt down by the latter; since which it has never been thoroughly repaired.

ZACUTO, or **ZACUTUS LUSITANUS**, in *Biography*, a physician, was born at Lisbon in 1575, and educated at Salamanca and Coimbra. In his 20th year he took the degree of doctor, and settling in his native city, practised with reputation for thirty years. As he was a descendant of Jewish parents, his dread of the Inquisition, after the edict of Philip IV. against the Jews was issued in 1625, induced him to retire to Holland, where he openly professed the religion of his family, and maintained a character highly respectable, both in his profession as a physician, and in his moral conduct. He died at Amsterdam in the year 1642; and left behind him a collection of works, amounting to 2 vols. fol. The principal of his works are, “*De Medicorum Principum Historia*,” lib. vi. in which he approves himself a strenuous advocate of Galen and the Greek physicians; “*Praxis Historiarum Malorum*,” lib. v.; and “*Praxis Medica admiranda*,” lib. iii. In all his works he blends acuteness of observation with a certain degree of superstitious

superstitious credulity; but they are nevertheless consulted and quoted. Haller. Eloy.

ZACYNTHUS, in *Ancient Geography*, an island of the Ionian sea, W. of that part of the Peloponnesus on which is the Sinus Chelonitis. It is now called *Zante*. Strabo makes its compass 160 stadia. It had many forts, and was very fertile. In this isle was a town of the same name, situated in the eastern part, with a citadel. According to Dionysius of Halicarnassus, it derived its name from Zacynthus, son of Dardanus, who, accompanied by a number of Phrygians, settled here. According to Thucydides, the first Greeks known in this island were Achæans, who came hither from Achaia. It passed under the dominion of Philip, king of Macedon, who surrendered it to Amynter, king of the Athamans, who confided the government of it to Philip of Megalopolis, by whom it was transferred to Hierocles of Sicily. After the defeat of Antiochus at Thermopylæ, Hierocles sold it to the Achæans. Livy says, that the town and citadel were assaulted and captured by Levinus; and Pausanias informs us that it was called Plophis. According to Scylax it had one port; and Pliny says that it was very fertile, and that its port was named Hyrie; but P. Mela distinguishes Hyrie from Zacynthus.

ZACYNTHUS, a town of Africa, in Libya. Steph. Byz.
ZACYNTHUS, an epithet used by the ancients to a liquid bitumen, from the island Zante.

ZAD, in *Geography*, a name given to the Niger of Africa, in Bornou, which is described in Horneman's Journal as flowing eastwards. Its breadth was given to him for one mile, and he was told that it flowed towards the Egyptian Nile, through the land of the heathens. The course here given is directly towards the Congo; and it is said, that Zad is the name of the Congo at its mouth, and it is the name of the Congo for at least 650 miles inland.

ZADADRUS, in *Ancient Geography*, a river of India, on this side of the Ganges; which received the waters of the Hypasis and Adris, according to Ptolemy.

ZADAN, in *Geography*, a town on the west coast of the island of Celebes. S. lat. 2° 55'. E. long. 119° 9'.

ZADAON, a river of Portugal, which runs into the Atlantic, near Setuval.

ZADELSDORF, a town of Saxony, in the circle of Neustadt; 3 miles S.S.E. of Auma.

ZADONZK, a town of Russia, in the government of Voronez, on the Don; 92 miles N. of Voronez. N. lat. 53° 4'. E. long. 39° 14'.

ZADRACARTA, in *Ancient Geography*, a very large town of Asia, the capital of Hyrcania, according to Arrian.

ZADRAMA, a town of Arabia Felix, the capital of the Cinædocolpites. Steph. Byz.

ZADRAN, in *Geography*. See HATVANY.

ZADRIS, in *Ancient Geography*, a town of Asia, in the interior of the Colchide. Ptol.

ZADURA, in the *Materia Medica* of the ancients, a name given to a foreign root, which was round and smooth, and of the colour of ginger.

It was at that time imported from the Indies, and greatly esteemed in pestilential cases.

ZÆA, or **ZEA**, in *Ancient Geography*, a very ancient town of Greece, in Bœotia. Steph. Byz.

ZÆTIA, or **ZETIA**, a town of Arcadia, N. of Megalopolis. It had two temples, one of Ceres, another of Diana.

ZÆZAR, in *Geography*, a town of Spain, in the province of Murcia; 22 miles N.W. of Murcia.

ZAFANIN, a town of Fez, near the coast of the Mediterranean; 35 miles S.E. of Melilla.

ZAFARANBOLI, a town of Natolia; 28 miles S. of Amasieh.

ZAFFABEN, a word used by some of the chemical writers to express putty.

ZAFFE IBRAHIM, in *Geography*, a town on the east coast of Madagascar. S. lat. 17°.

ZAFFER, **ZAFFRE**, or **SAFFRE**, in *Chemistry*, is the residuum of cobalt, after the sulphur, arsenic, and other volatile matters of this mineral have been expelled by calcination: so that it is a kind of calx or oxyd of cobalt, mixed with a portion of siliceous matter, of a grey or reddish colour; in which state it is imported from Saxony. It is used to produce a very fine blue colour, when it is melted with fusible and vitrifiable matters.

The blue colour produced by the vitrification of zaffer proceeds from the earth or calx of a semi-metallic substance contained in cobalt, called by chemists *regulus of cobalt*. This is proved by melting zaffer with a reducing flux, like any other roasted ore, by which means the regulus will be obtained. The scoria in this fusion has also a blue colour, proceeding from a portion of the calx of the regulus that is not reduced, but is vitrified together with the scoria. The calx, therefore, or metallic earth of the regulus of cobalt, is the sole cause of the blue colour produced by zaffer.

But as this is contained in cobalt in various quantities, some zaffers produce more blue than others. The heterogeneous fixed matters contained in cobalts contribute, according to their quantity, not only to the greater or less intensity of the blue colour, but also to its lustre and beauty; and, therefore, those who manufacture zaffer from cobalt make frequent essays of the roasted ore, by mixing it with vitreous matters, in order to discover the intensity and beauty of the blue colour.

Good cobalt calcined would form too deep a blue, and almost a black glass, if it were not previously mixed with a certain quantity of vitreous frit. In the manufacture of zaffer, therefore, the calx of cobalt, the strength of which has been determined by previous essays, is mixed with such a quantity of sand, or of powdered flints and quartz, that with the addition of some saline flux, a deep blue glass may be formed. See COBALT.

The zaffer that is commonly sold, and which comes from Saxony, is a mixture of oxyd of cobalt with some vitrifiable earth: it is of a grey colour, and some zaffers are clearer than others, according to the intensity of the colour which they are capable of producing.

Zaffer is employed in the manufacture of pottery and of porcelain, for painting the surface of the pieces of ware, upon which it is applied, together with some saline flux, previously to the baking or glazing, that the same fire may vitrify this colouring material.

The blue of zaffer is the most solid and fixed of all the colours that can be employed in vitrification; it suffers no change from the most violent fire. It is successfully employed to give shades of blue to enamels, and to the crystal glasses made in imitation of some opaque and transparent precious stones, as the lapis lazuli, the turquoise, the sapphire, and others of this kind.

To prepare zaffer for use in the glass-trade, put it in gross pieces into earthen pans, and let it stand half a day in the furnace; then put it into an iron ladle to be heated red-hot in the furnace; take it out while thus hot, and sprinkle it with strong vinegar: and when cold, grind it on a porphyry to an impalpable powder, then throw this into

water

water in glazed earthen pans; and when it has been well stirred about, let it fettle and pour off the water: repeat this washing often, and the foulness of the zaffer will be thus wholly separated. Dry the powder, and keep it for use.

ZAFFRAM, a word used often by authors to express saffron, but sometimes as the name of other things of a yellow colour; thus ochre was called by this name.

ZAFFRAMEN, a word used by some medical writers to express saffron.

ZAFRA, in *Geography*, a town of Asiatic Turkey, in the government of Marasch; 15 miles S.W. of Tarsus.—Also, a town of Asiatic Turkey, in the government of Trebifond, on the Black sea; 50 miles N.W. of Trebifond.—Also, a town of Spain, in Estremadura; 22 miles E. of Xeres de los Caballeros.

ZAFRANIA, in *Colours*, a term used by the Greeks to express the yellow of saffron. The barbarous writers of the after-ages translated it into the Latin *crocietas*, or saffron colour.

The later Greek writers only use it, and they have taken it literally from the Arabians, Avicenna, and Sérapio. This was a term used by them to express the colour of the fine bole-armenic of Galen, which they tell us stained paper to a fine and beautiful gold colour.

ZAGA, in *Botany*, Poiret in Lamarck Dict. v. 8. 831. (*Zaga* Pohon, or *Corallaria latifolia*, Rumph. Amboin. v. 3. 175. t. 110.)—This is one of those trees, whose hard red seeds are used for ornament, in the form of necklaces, bracelets, &c. by the natives of tropical climes, and even by the inhabitants of the most polished countries of Europe, as fashion, from time to time, is pleased, in her capricious wisdom, to ordain. Such are the beautiful red and black seeds of *Abrus precatorius*, of which there is a pearly white variety, of rare occurrence. Such also are those much larger seeds, of the same combination of colours, produced by the West Indian genus *ORMOSTA*. (See that article.) The *Zaga* of Rumphius and Poiret is evidently a papilionaceous plant, with pinnate leaves, composed of about three pair of elliptic-oblong, entire, stalked, rather large leaflets, with an odd one. Flowers in paniced terminal clusters. Legumes elliptic-oblong, pointed, hard and smooth, each containing one, rarely two, hard, shining, round seeds, all over of the colour of red coral, larger than those of *Adenanthera pavonina*, being as broad as the fore-finger nail, and destitute of the defined circumscribed area, for which the seeds of the *Adenanthera* are remarkable.

ZAGALA, in *Geography*, a town of Spain, in Estremadura; 25 miles S. of Alcantara.

ZAGAN, a town of the principality of Georgia, in the province of Kaketi; 3 miles N. of Tefisi.—Also, a town of Persia, in the province of Irak; 12 miles S.W. of Hamadan.

ZAGARA, a mountain of Greece, in Livadia, anciently called Helicon.

ZAGATHAI, a name given from the second son of Zingis to Great Bucharia; which see.

ZAGATIS, in *Ancient Geography*, a river of Asia, in the Colchide, according to Arrian, who fixes its mouth between Athenæ and Anchiane Regia.

ZAGAWA, in *Geography*, a city of Africa, in Bornou, on a river which runs into the same lake, where the Niger is by some supposed to be lost. N. lat. 19° 10'. E. long. 25° 50'.

ZAGGOS, a mountain of Africa, in which are some mines of salt; 100 miles S. of Algiers.

ZAGHARA, a town of Africa, in Bornou.

ZAGI. See **ZEGI**.

ZAGILLONITIS, in *Ancient Geography*, a country of Asia, in Cappadocia. Strabo.

ZAGING, in *Geography*, a town of Austria; 3 miles N. of St. Polten.

ZAGIRA, in *Ancient Geography*, a town of Asia, in Paphlagonia, at a small distance from the sea. Ptol.

ZAGLIA, in *Geography*, a town of the island of Corfica; 8 miles S.E. of Calvi.

ZAGORA, a town of European Turkey, in Romania, on a lake which communicates with the Black sea; 12 miles S.W. of Burgas.

ZAGORA, in *Ancient Geography*, a town of Asia, in Paphlagonia, on the coast of the Euxine sea, between Carusa and the mouth of the river Halys, according to the Periplus of Arrian.

ZAGOROLO, in *Geography*, a town of the Popedom, in the Campagna di Roma; 3 miles W. of Palestrina.

ZAGOROW, a town of the duchy of Warlaw; 20 miles S. of Kalifch.

ZAGRAB. See **AGRAM**.

ZAGROS, MOUNT, a mountain of Persia, in the province of Irak, along the brink of which extends the district of Kurrend, from the vicinity of Holwan to the village of Goor. It is covered with forests of oak, and inhabited by an extraordinary race of men, among whom subsist customs similar to those of the Kadmusia in Syria, described by Volney. It is said that in their nocturnal festivals, the garments of the fair sex, at the expiration of a certain period, are thrown into a heap, and jumbled together. The lights are then extinguished, and the clothes being regularly distributed among the men, the candles are relighted; and it is settled by the rules of the society, that the lady must patiently submit to the embraces of the person who has become possessed of her dress, whether father, son, husband, or brother. The lights are then once more extinguished, and all of this licentious tribe pass the remainder of the night in the indulgence of the most promiscuous lust.

ZAGRUS, or **ZAGRIUS MONS**, in *Ancient Geography*, a mountain of Asia, in Media. It made a part of mount Taurus, commencing in Armenia, and extending as far as the Chalontide, between Media and Adiabene. Pliny. It is reckoned by Ptolemy one of the most considerable countries in Media. According to Strabo, it was this chain of mountains which touched the Niphates, and separated Media from Babylonia.

ZAGU, in the *Materia Medica*, the name given by some authors to the sago-tree, the *todda pauna*, or *palma fructu pruniforme*.

ZAGUANANAS, in *Geography*, a river of considerable length in New Mexico, which flows from the same sources with the Rio Bravo, and joins the *Colorado*; which see.

ZAGYTIS, in *Ancient Geography*, a country of Africa, in Libya. Steph. Byz.

ZAHARA, in *Geography*, a town of Spain, in the province of Seville. In 1407, this town was taken from the Moors; about two years after the Moors retook the town, but not being able to reduce the citadel abandoned it. In 1481, it was surprized by the Moors, in a dark stormy night; most of the inhabitants were put to the sword, and the rest sent slaves to Grenada; 36 miles S.E. of Seville. N. lat. 36° 50'. W. long. 5° 33'.

ZAHARA. See **SAHARA**.

ZAHIA, a word used by the Arabian physicians to express a sort of dysentery, in which there was a very large

large discharge of blood from the rectum, attended with an evident sensation of abrasion, or pain in the bowels.

ZAHNA, in *Geography*, a town of Saxony; 8 miles N.E. of Wittenberg. N. lat. 51° 56'. E. long. 12° 54'.

ZAHRADKA, a town of Bohemia, in the circle of Czeclau; 17 miles S.S.W. of Czeclau.

ZAHRINGEN, an ancient citadel in the Brisgau, which gave the title of duke to a noble family that became extinct in the 13th century; 1 mile N. of Friburg.

ZAIBAC, one of the many names by which the ancient chemists have called mercury.

ZAIDIR, a name by which some of the chemical writers have called verdigrise, or the rust of copper; and others, the metal itself; and some brasis.

ZAIM and **TIMAR**, lordships granted under those names in the Ottoman empire for life, as military rewards and encouragements. Those who possess a zaim, or timar, are honoured with the title of aga; they are bound to a military personal service, and obliged to bring with them to war one or more *gébélis*, horsemen or foot-soldiers, armed and equipped according to the revenue and extent of the lordship. The timar differs in no respect from the zaim, except that it is of less value, and that the aga who possesses it does not arm as many horsemen and foot-soldiers as the other. The number of zaims in Turkey in Europe is 914, and that of the timars is 8356. Nearly the same number is reckoned in Asia, which furnishes, with the *gébélis*, a militia of upwards of 60,000 men, better disciplined, and more inured to war than the spahis and the janizaries. This militia for a long time constituted the principal force of the Ottoman empire: to this principally the first sultans were indebted for the astonishing success of their arms, and the rapid progress which they made in a little time in Asia, in Europe, and even in Africa.

On the death of a zaimat, or a timariot, the sultan is to draw a year's revenue from the lordship, and nevertheless, give it up again to the son of an aga, a spahis, or any other military man, especially to him who, by a brilliant action, has distinguished himself in battle, who has first mounted to the assault, penetrated into the enemy's intrenchments, killed a great number of infidels, or contributed to put them to the rout. But since the sultans prefer to the fatigues of war and the dangers of battle the tranquillity of their seraglio, and the pleasures of their harems; and more especially since avarice and a love of gain have caused to be put up to auction the places intended for the recompence of valour and merit, the lordships are become the patrimony of the rich and of intriguers. Thus the best institutions degenerate; thus the Mussulman, formerly intrepid and valiant, becomes merely a vile plunderer, or a ferocious assassin; and the Ottoman armies, so formidable to their enemies, are become an object of contempt or pity, and this vast empire would no longer exist, if some European power were not interested in its support.

ZAIN, in *Horses*, a term used by the French to signify a horse of a dark colour, neither grey nor white, and without any white spot or mark upon him in any part. See *HORSE*.

ZAINAH, in *Geography*, a town of Algiers, in the province of Constantina; supposed, from some considerable ruins, to have been Zama, an ancient and royal city of Numidia; 25 miles S.E. of Seteef.

ZAINE, or *Wadel Berber*, a river of Africa, which runs into the Mediterranean, N. lat. 36° 54'. E. long. 9° 16'.

ZAIRA KAKONGO, an island in the Atlantic, at the mouth of the river Zaïre.

ZAIRAGIA, or **ZAIRAGIAN**, a kind of divination in use among the Arabs; performed by means of divers wheels, or circles, placed concentric to one another, and noted with several letters, which are brought to answer to each other, by moving the circles according to certain rules.

This is also called *zariab*, because the circles of this machine, which are called *mutaxariat*, *laflak*, &c. are intended to correspond to the orbs of the planets, and the atmospheres of the several elements.

ZAIRE, or **SAIRE**, in *Geography*, a river of Africa, which rises in the country of Matamba, about S. lat. 10°, and takes a northerly course to lat. 3°, in the kingdom of Congo; after which it takes a south-westerly direction, and runs into the Atlantic, S. lat. 6°. E. long. 12° 20'.

It has been an important question, with regard to which geographers have entertained various opinions, what are the course and termination of the Niger. The ingenious geographer, Mr. Rennell, on comparing the various accounts of the progress of the Niger beyond Houffa, declared his opinion to be, that its waters had no communication, either with the river Nile, as was thought, or with the sea, as others imagined; but that they were spread out into a great lake in Wangara or Ghana, and evaporated by the heat of the sun. (See *NIGER*.) Mr. Park, the late African traveller, directed his particular attention to this subject, and was induced to conclude that the Congo would be found to be the termination of the Niger from the following considerations: 1. The total ignorance of all the inhabitants of North Africa respecting the termination of that river. If the Niger ended any where in North Africa, it is not easy to account for this total ignorance, and for his so generally describing it as running to the Nile; and in fact, to a country with which they had not any acquaintance. A second consideration has been already suggested under the article *ZAD*. A third is deduced from the general supposition that the river of Dar-Kulla, mentioned by Mr. Browne in his "Travels," was the Niger, or at least that it communicated with that river; and this, it is said, would be exactly the course which the Niger ought to take in order to join the Congo. 4. The quantity of water discharged into the Atlantic by the Congo cannot be accounted for on any other principle, but that it is the termination of the Niger. If the Congo derived its waters entirely from the S. side of the mountains, which are supposed to form the belt of Africa, one would naturally suppose, that when the rains were confined to the N. side of the mountains, the Congo, like the other rivers of Africa, would be much diminished in size; and that its waters would become pure. On the contrary, the waters of the Congo are at all seasons thick and muddy. The breadth of the river, when at its lowest, is one mile, its depth is fifty fathoms, and its velocity six miles *per* hour. 5. The annual floods of the Congo commence before any rains have fallen south of the equator, and agree correctly with the floods of the Niger, calculating the water to have flowed from Bambarra at the rate of three miles *per* hour. Mr. Park, during his residence in Scotland, became acquainted with a Mr. George Maxwell, formerly an African trader, who was well acquainted with the whole western coast of Africa, more especially S. of the equator, and had published a chart of the river Congo. Mr. M. had been led by a variety of circumstances to conjecture that the source of the Congo lay considerably inland, and far to the north; and from a perusal of Mr. Park's travels

he concluded, that the Congo and the Niger were one and the same stream. Mr. Maxwell's reasoning confirmed Mr. Park in his opinion; and in this opinion he persevered to the end of his life.

Since the discoveries of Mr. Park, it is very generally allowed that the course of the Niger is from west to east; and his opinion with regard to its termination in the Congo, or, as it is sometimes called, the Zaire, has received a considerable degree of confirmation from the account of the Congo given by Mr. Maxwell. "Before ever the Niger came to be the topic of conversation," says Mr. M., "it struck me, that the Congo drew its source far to the northward, from the floods commencing long before any rains take place S. of the equator; since it begins to swell perceptibly about the latter end of October, and no heavy rains fet in before December, and about the end of January, the river must be supposed to be at its highest. At no time, however, can the rains to the southward of the line be compared with those in the Bight of Guinea, where ships are obliged to have a house erected over them during these months."—"If the Niger has a sensible outlet, I have no doubt of its proving the Congo, knowing all the rivers between Cape Palmas and Cape Lomas to be inadequate to the purpose; nor need the immense course of such a river surprise us, when we know that the river St. Lawrence, contemptible in size compared with the Congo, encompasses the whole of North America, issuing through a chain of lakes. But instead of seven or eight lakes, the Congo may be supposed to pass through seventeen or eighteen; which will solve any difficulty as to the floods of the Niger not immediately affecting the Congo." He adds, the river Congo, compared with other rivers, must rank as the third or fourth in magnitude. Considering the force of the current it produces in the sea, carrying out floating islands sixty or seventy leagues from the coast, the Amazon or Plata only can cope with it. At the distance of 600 miles from its mouth, the Congo traders report that it is as large at the place from which they came, and that it went by the name Enzaddi, as it does among all the nations upon the coast. If the shallow water opposite to Suenda should be thought to detract from the assumed size of the Congo, it should be considered, that the river there is spread out ten miles in width, the middle channel of which has never been accurately sounded. "It has long been my opinion, that Leyland's or Molyneux island at Embomma, (a settlement on the banks of the Congo, distant thirty leagues from its mouth), either of which might be rendered as impregnable as Gibraltar, at a very small expence, could be a choice station for establishing an extensive commerce with the interior of Africa. Indeed, if the idea of the Congo being the outlet of the Niger prove to upon trial, we may consider it as an opening designed by Providence for exploring those vast regions, and civilizing the rude inhabitants." The Congo appears from other testimonies to be a river of the first class, and larger, probably, than the Nile. The waters of the Congo, it is said, may be distinguished at sea more than thirty leagues from the coast; and the water is fresh at the distance of thirty miles. If these accounts are thought to be exaggerations, it is a general opinion among navigators that this river has a wonderful size and force. All accounts concur in representing that the stream of the Congo is of a more uniform height, and subject to much less variation from the dry and rainy seasons, than any tropical river which is known; and that on a comparison with such rivers, it may be considered to be in "a perpetual state of flood." The average rising of the Ganges in the rainy season is stated by

major Rennell to be thirty-one feet, being almost the same with that of the Nile; whereas, the difference between the highest point of the Congo about February, and the lowest, in September, is only about nine feet; and the river, at the latter period, has all the appearance to a stranger of being in full flood. It is this remarkable peculiarity which distinguishes the Congo from other great rivers of a similar description, and which leads to important conclusions with regard to its origin and cause. "In support then of the hypothesis which identifies the Congo with the Niger, the following arguments deduced from the preceding facts and observations may be alleged: 1. The great magnitude of the Congo. 2. The probability that this river is derived from very remote sources, perhaps considerably north of the equator. 3. The fact, that there exists a great river N. of the equator (the Niger), of which the termination is unknown, and which may, perhaps, form a principal branch of the Congo.

"Such being the evidence in favour of the hypothesis respecting the Congo, the objections must be admitted to be weighty and formidable: the principal of these are, 1. That it supposes the course of the Niger to be through the vast chain of the mountains (anciently *Montes Lunæ*), the great central belt of Africa."—"It is difficult to understand how the Niger could penetrate this barrier, and form a passage southwards. 2. The course of the Niger, estimated from its source in the mountains of Senegal, (supposing it to be the same river with the Congo, and to flow by Wangara and Casina, through the centre of Africa into the Atlantic), would be considerably more than 4000 miles. But the course of the Amazon, the greatest river in the old or new world, is only about 3500 miles; and although the existence of a river considerably greater than any yet known may be within the limits of physical possibility, yet so improbable a supposition ought not to be adopted upon slight or conjectural reasoning, or upon any thing much short of distinct and positive proof."

The editor of Mr. Park's *Travels*, &c. in 2 vols. 8vo. 1816, which we are now citing, very laudably expresses a hope, "that this distinguished river, which hitherto has been only known as one of the greatest marts of the Slave Trade, may at length be rendered conducive to objects of civilization and science; and that some use will now be made of this great inlet into Africa, for the purpose of exploring a part of that continent which as yet is entirely unknown; or, at least, of obtaining more complete and authentic information relative to the Congo itself, which must unquestionably be considered as a very curious and interesting subject of inquiry."

Another opinion with regard to the termination of the Niger has been advanced by M. Reichard, a German geographer, and published in the "Ephemerides Geographiques," at Weimar, in August 1808. This opinion is, that the Niger, after reaching Wangara, takes a direction towards the south, and being joined by other rivers from that part of Africa, makes a great turn from thence towards the south-west, and pursues its course till it approaches the north-eastern extremity of the gulf of Guinea, where it divides, and discharges itself by different channels into the Atlantic; after having formed a great Delta, of which the Rio del Rey constitutes the eastern, and the Rio Formosa, or Benin river, the western branch. This hypothesis, though it diminishes the distance which the Niger has to flow in its course to the Atlantic, does not remove the objection arising from the Niger's being conceived to penetrate the Kong mountains. But we must not pursue this subject

any farther. For the lengths of the course of the most noted rivers, see RIVER.

ZAKA. See SCHAREDSJE.

ZAKEPH GADHOL, *Rex Pauperrimus*, one of the Hebrew accents, sometimes denoting no kind of pause, and marked over a letter thus (זָ).

ZAKEPH *Katon Rex*, one of the Hebrew accents, constituting either a comma or femicolon, and marked over a letter thus (זָ).

ZAKERZEZIN, in *Geography*, a town of Kurdistan; 26 miles N.N.W. of Van.

ZAKIEH, a town of the Arabian Irak, on the Tigris; 10 miles N. of Korna.

ZAKLIKOW, a town of Austrian Poland, in Galicia; 40 miles S. of Lublin.

ZAKROCZYN, or SAKROTSCHIM, a town of the duchy of Warlaw, on the Narew. In 1794 the confederate Poles were defeated here by the Russians; 40 miles N.W. of Warlaw.

ZAL ALEKSANDROVSKOI, a bay of the Caspian sea; 260 miles S.S.E. of Astrachan. N. lat. 43°. E. long. 51° 14'.

ZALA, in *Botany*, so called by Loureiro, Cochinch. 405, from *ζαλα*, a *tempesl*, or agitation of the sea, because the plant floats, and is driven about, at the mercy of the winds and waves. This is no other than the *PISTIA* of Linnæus (see that article); where the generic characters, as corrected by Schreber, come sufficiently near to those of Loureiro, to leave no doubt in the mind of the reader, allowance being made for the peculiarities of structure in so singular a flower.

ZALA, in *Ancient Geography*, a town situated in the vicinity of Amalæa, which was a town of the Peloponnesus, in Achaia Propria.

ZALA, in *Geography*. See WADAN.

ZALACA, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptol.

ZALACUS, a town of Africa, in Mauritania Cæsariana. Ptol.

ZALACUS *Mons*, (*Van-nasb-reefs*), mountains of Mauritania, at some distance from and to the S. of the river Chinalaph. Ptol.

ZALAKNA, in *Geography*, a town of Transylvania; 14 miles W. of Weissenburg.

ZALAMEA, a town of Spain, in the province of Seville; 38 miles W.N.W. of Seville.

ZALAMEA *de la Serena*, a town of Spain, in the province of Extremadura. This town was anciently called Ilipa, and many vestiges remain of its former splendour; 27 miles N.E. of Llerena.

ZALANTZ, a town of Hungary; 10 miles S.E. of Cafchau.

ZALANTZ, in *Ancient Geography*, a town of Africa Propria, S. of Adrumetum. Ptol.

ZALESCE, in *Geography*, a town of Austrian Poland, in Galicia; 32 miles S. of Lemberg.

ZALEUCUS, in *Biography*, a philosopher and legislator of Greece, and founder of the Locrian state, flourished in the 7th century B.C. He was of obscure birth, and lived in servitude as a shepherd; but his extraordinary abilities and merit attracted notice even in his humble station, and advanced him to the government. His laws were deemed severe, but being adapted to the circumstances and manners of the Locrians, their constitution was for several ages highly celebrated. His discipline was rigorous, so that he prohibited the use of wine, otherwise than as a medicine;

VOL. XXXIX.

and he ordained, that adulterers should be punished with the loss of their eyes. When his son had incurred this penalty, he blended paternal lenity with a pretence of maintaining the authority of the laws, by ordering his son to be deprived of one eye, and by submitting to the loss of one of his own eyes. In order to secure the permanent stability of his system of legislation, he required that a person who proposed a change in any one of them should come before the assembly with a cord about his neck, that he might be instantly strangled, if upon examination the old law were preferred. Valer. Max. Diod. Sic. Laert. Brucker by Enfield.

ZALGIN, in *Geography*, a town of the island of Cuba; 47 miles N. of St. Jago.

ZALIKARA, the most considerable city of Mingrelia, situated on the right bank of the Hippus, which rises in the highest mountain of the Soane, not far from the source of the Phasis, flows through Letighuani, divides Mingrelia from Iberia, and enters the Phasis near the Tredia: an open place, at the confluence of the Hippus and Phasis, well peopled by different nations, particularly Jews.

ZALISCUS, in *Ancient Geography*, a river of Asia, in Galatia. The mouth of this river in the Euxine sea lay between Cyrtafia and Galorum.

ZALISSA, a town of Asiatic Iberia. Ptol.

ZALLANT, in *Geography*. See SALLAND.

ZALSSING, a town of Austria; 5 miles N.W. of Aggipach.

ZALUZJANSKIA, in *Botany*, so named by Necker, in "Act. Palat. v. 3. phys. 303," according to Willd. Sp. Pl. v. 5. 538, is no other than *MARSILEA quadrifolia*, which the reader will find in vol. xxii. The above name is designed, as we presume, to commemorate a Polish botanist, author of *Methodi Herbaria*, published at Prague, anno 1592, in 4to., and at Frankfort in 1604. This work is spoken of by Haller, *Bibl. Bot.* v. 1. 387, as a transposition of the arrangement of Dodonæus, without any improvement or additional information.

ZAM, in *Geography*, a town of Grand Bucharia; 85 miles N.W. of Balk.

ZAMA, a town of Peru, in the diocese of Arequipa; 30 miles N. of Arica.

ZAMA, in *Ancient Geography*, a town of Africa Propria, 5 journeys from Carthage. This town, to which ancient authors give the title of royal and a fortress, is famous in the wars of Jugurtha and Juba, and more especially on account of a battle between the Carthaginians under Hannibal and the Romans, commanded by Scipio, in the year 551 of the Republic. At the time when this town was in a flourishing state, it was assigned to Numidia. Cornelius Nepos says, that it was 300 miles from Adrumetum. Appian says 3000 stadia. It was situated on a plain, and owed its strength to its fortifications more than to its situation. Hirtius says, that it was the ordinary residence of king Juba, where he had his wives, children, and treasures. Pliny says, that it became a Roman colony.

ZAMA, a town of Cappadocia, in the prefecture of Chamane.—Also, a town of Asia, in Mesopotamia. Ptol.

ZAMAMIZON, a town of Africa Propria, between the town of Tabraca and the river Bagradas. Ptol.

ZAMBOSE, or CUMANA, in *Geography*, a river of Africa, which rises in the interior parts of Mocaranga, and runs into the Indian sea at several mouths: the principal of which takes the name of Luabo. S. lat. 16°. E. long. 37°.

ZAMBOZIN, a town of Congo; 24 miles S.S.W. of St. Salvador.

ZAMBRANO, JUAN LUIS, in *Biography*, a Spanish painter,

painter, was born at Cordova in 1599. He was a disciple of Paolo de Cespedes, and was a successful follower of the style of that master. His principal works are in the cathedral at Cordova, and in the church of the convent of Los Martyros, where he painted two altar-pieces, representing the stoning of St. Stephen, and the martyrdom of St. Acifelo and St. Victoria. In the colegio di Santa Catalina is a fine picture by him of a guardian angel, and a St. Christopher, which Palomino describes as designed in the great style of M. Angelo. He passed the latter part of his life at Seville, where he painted several altar-pieces for the church of St. Basil, and died in that city in 1639, at the age of 40.

ZAMBROKRI, in *Geography*, a town of Hungary; 14 miles S.W. of Rosenberg.

ZAMBROW, a town of the duchy of Warsaw; 80 miles N.E. of Warsaw.

ZAMECH, a name given by some writers to the lapis lazuli.

ZAMETUS, in *Ancient Geography*, a mountain of Arabia Felix. Ptol.

ZAMFARA, or ZANFARA, in *Geography*, a town of Africa, and capital of a kingdom of the same name; 170 miles E.N.E. of Wangara. N. lat. 18° 20'. E. long. 16° 15'.

ZAMIA, in *Botany*, from *ζῆμια*, *damage*, or *loss*. This name, which first occurs, as the appellation of a genus, in the Gen. Pl. ed. 6. of Linnæus, is taken from Pliny, who uses it for such cones of the fir as "split while they are upon the tree," and, as he says, "require to be taken off, that they may not injure the rest." This should seem to apply to the male catkins, however false the physiology of Pliny, and the practice founded upon it, may be. Our *Zamia* answers to his, merely in the cone-like form of its fructification, which, being male on one plant, and female on another, exhibits in the former the appearance of loss, or sterility, like the male catkins of the fir.—Linn. Gen. 574. Suppl. 68. Schreb. Gen. 778. Willd. Sp. Pl. v. 4. 845. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 410. Brown Prodr. Nov. Holl. v. 1. 348. Pursh 648. Juss. 16. Poir. in Lamarck Dict. v. 8. 831. Lamarck Illustr. t. 892. Gært. t. 3.—Clafs and order, *Dioecia Polyandria*. Nat. Ord. *Filices*, Linn. Juss. *Cycadeæ*, Perfoon, Brown.

Gen. Ch. Male, *Cal.* Catkin ovate, tessellated-scales horizontal, obtuse, thickened towards the end, permanent. *Cor.* none. *Stam.* Filaments none; anthers numerous, sessile, crowded on the under side of each scale, especially towards the extremity, elliptical, smooth, of two valves and one cell, splitting lengthwise.

Female, *Cal.* Catkin ovate, tessellated: scales horizontal, obtuse, more or less peltate, permanent. *Cor.* none. *Pist.* Germens two, oval, sessile, horizontal, inflexed, on the under side of each scale, near the extremity; style very short, somewhat conical; stigma obtuse, undivided, pervious. *Peric.* Drupa roundish, somewhat angular, of one cell. *Nut* hard, roundish or elliptical, of one cell.

Eff. Ch. Male, Catkin tessellated. Scales abrupt. Anthers oval, sessile at the under side of each scale. Female, Catkin tessellated. Scales peltate. Drupas two, at the under side of each scale.

Obs. Mr. Brown, to whom we are obliged for the remark of the style being finally pervious, records an idea of the late Mr. Dryander, that the American *Zamia*, which constitute the original genus, having more perfectly peltate scales to the male catkin, and the anthers assembled in two distinct masses might possibly form a distinct genus from

the Cape and New Holland species; more especially as in these American plants, the leaflets are each manifestly articulated with a projection from the main rib of the leaf; whereas in the others they are either very obscurely jointed, or perfectly decurrent. We conceive, however, that they all together compose a very distinct genus, which cannot, without violence to nature, be divided. It is nearest akin to *Cycas*, but differs essentially in the female part of the fructification being a catkin, whose scales bear two germens underneath; instead of an assemblage of fronds, or leafy receptacles, bearing an indeterminate number upon their margins. The herbage is perennial, generally without a stem. Leaves abruptly pinnate, singularly hard, rigid, and often spinous; rarely lobed. Catkins radical, stalked.

It being extremely difficult to obtain and to compare good specimens of the different species, as well as to detect and define their essential characters, authors have not very clearly described them. Jacquin has published magnificent figures of several; but their most satisfactory marks require to be fought at an earlier period of their growth, and in more minute parts, than he has generally exhibited.

1. *Z. cycadifolia*. Sago-palm-leaved *Zamia*. Jacq. Fragm. 27. t. 25, 26. Willd. n. 1.—Leaflets very numerous, two-ranked, linear, entire, with simple spinous points; common stalk femicylindrical, channelled, downy. Catkin of the fruit elongated, somewhat cylindrical.—Native of the Cape of Good Hope. Cultivated in the Imperial gardens at Schoenbrunn, but not mentioned by Mr. Aiton as known to our English collectors. The thick globular scaly head of the root, near a foot in diameter, bears numerous spreading pectinate leaves, very much resembling, at first sight, those of *Cycas revoluta*. The stalk of each, in its naked part, two feet long, as thick as a swan's quill, all over downy, as is also its leafy portion, and the young leaflets themselves. The full-grown leaflets are from 50 to 80, rigid, parallel, acute, pungent, each about three inches long; the lowermost gradually shorter, and rather more distant. The ripe fruit, brought from the Cape, is ovate-oblong, about fifteen inches in length, and five in diameter, brown, each scale bearing two ovate, angular, orange-coloured drupas, about an inch long, their points directed towards the base of the scale. Nut not much smaller, ovate, angular.

2. *Z. pungens*. Needle *Zamia*. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 1. Willd. n. 2. Poir. n. 3. (*Palma fobolifera ægyptia*, foliis lævioribus, fructu nigro; Till. Pif. 129. t. 45.)—Leaflets awl-shaped, spreading, straight, rigid, pointed, entire; their outer margin rounded at the base; common stalk nearly cylindrical, unarmed.—Native of the Cape of Good Hope, from whence it was brought by Mr. Maffon, to Kew garden, in 1775, but has not yet flowered. The leaflets are very thick and coriaceous, much fewer than in the preceding species, mostly opposite, four or five inches long, and one broad; their under surface somewhat striated; the upper smooth and shining; margin quite entire; point simple, spinous, stout and rigid.

3. *Z. tridentata*. Three-toothed *Zamia*. Willd. n. 3.—Leaflets linear, obscurely furrowed, smooth, with three spinous teeth at the end; common stalk femicylindrical, channelled.—Supposed to be a native of the Cape of Good Hope. The leaflets are fourteen to sixteen pair, linear, tapering at each end, with two lanceolate, pointed, terminal teeth, and a third situated a little lower at the outer edge. Common stalk smooth. Willdenow. No other author appears to know this species. We have specimens in the herbarium of the younger Linnæus, without name, indication of their native country, or any traces of fructification, which answer

ZAMIA.

answer to the above characters; except the *leaflets* being more numerous, sometimes with a simple spinous point only, on the same stalk with others that have two or three, very rarely four; and in one instance the leafy part of the common *footstalk* is shaggy with soft hairs. Each *leaflet* is two, or two and a half inches long, thick-edged and slightly revolute, entire, except the above-mentioned points; smooth on both sides; furrowed beneath; tapering at the base, and somewhat decurrent at its insertion. See n. 15.

4. *Z. angustifolia*. Narrow-leaved Zamia. Jacq. Coll. v. 3. 263. Ic. Rar. t. 636. Willd. n. 4. Poiret n. 6.—Leaves linear, elongated, entire, obtuse, with two terminal callous points; common stalk femicylindrical. Fruit ovate, pointed.—Native of the Bahama islands; cultivated at Schoenbrun, where it was raised from seed, and bore flowers and fruit, the catkins being about eight months in going through their different stages. The *root* is scarcely bigger than a large radish; its ovate crown enveloped in a few pointed, very broad, scales. *Leaves* about a yard high, with slender stalks and *leaflets*; the latter drooping, a span long, and two lines broad. *Catkins* three inches long, on stalks about the same length; the male ones most slender, and nearly cylindrical. *Fruit* three inches long, of a thick ovate, or elliptical figure, with a blunt point. *Drupas* concealed, red.

5. *Z. tenuis*. Slender Zamia. Willd. n. 5.—“*Leaflets* linear, obtuse, somewhat revolute; tapering at the base; with one or two obsolete teeth near the extremity; common stalk triangular, smooth.”—Native of the Bahama islands. Willdenow saw a living male plant. *Leaflets* about fourteen pair; the upper ones furnished, near the point, with one or two very inconspicuous teeth. An intermediate species between the last and the following; agreeing nearly with *Z. angustifolia* in the form of its *leaflets*, but they are broader, and their *stalk* is triangular: the *leaflets* are narrower than those of the following, neither are they minutely ferrated towards the point; but the *stalks* are similar. Willdenow.

6. *Z. media*. Intermediate Zamia. Jacq. Hort. Schoenbr. v. 3. 77. t. 397, 398. Willd. n. 6. Poiret n. 7.—*Leaflets* linear-lanceolate, obtuse, flat; obscurely ferrated towards the point; common stalk triangular, smooth.—Native of the West Indies; cultivated at Schoenbrun. The crown of the *root* is as big as the fist. *Leaves* two feet long, besides their naked *stalk*, which is half as much. *Leaflets* from fourteen to twenty pair; five inches long, and one-third or half an inch broad, flat, for the most part entire, except a few shallow distant ferratures towards the extremity, which is bluntish, and without any spinous termination. *Female catkins* on short thick stalks, ovate, with a blunt point. *Fruit* oval, brown, rough, three inches long. *Jacquin*. That author considers the present species as allied, on the one hand, to his *angustifolia* (see n. 4.), and on the other to *integrifolia*, n. 8. Still we cannot question its being specifically distinct from both.

7. *Z. debilis*. Lax-leaved Zamia. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 2. Willd. n. 7.—(Palma prunifera humilis non spinosa, infusæ Hispaniolæ, fructui jujubino similis, osculo triangulo; Commel. Hort. v. 1. 111. t. 58.)—*Leaflets* lanceolate, acute, pointless, ferrated towards the point; common stalk triangular, smooth.—Native of the West Indies, from whence it is said to have been imported, in 1777, by the late Messrs. Kennedy and Lee. It flowers in the stove, in July and August. The *leaflets* are five or six pair, half an inch broad; though only two and a half or three inches long, and are distinguished from all the foregoing by their conspicuous ferratures, all

indeed near the end, the greater part of the leaflet being entire: the upper side is smooth and shining; under furrowed or striated. *Commelin* originally raised this species from seed in the Amsterdam garden, and was informed that the *fruit* was reddish, growing partly underground.

8. *Z. integrifolia*. Dwarf Zamia. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 478. ed. 2. n. 3. Willd. n. 8. Pursh n. 1. Poiret n. 5, excluding the reference to *Commelin*. Jacq. Coll. v. 3. 261. Ic. Rar. t. 635. Lamarck t. 892, copied from *Jacquin*. (*Z. pumila*; Linn. Sp. Pl. 1659, excluding all the synonyms.)—*Leaflets* smooth, striated, lanceolate; rounded, obtuse, and finely ferrated at the end; tapering at the base. Common stalk smooth, somewhat quadrangular.—Native of East Florida, from whence it was introduced into the English stoves, by the celebrated John Ellis, esq. in 1768. *Jacquin* says it grows also in Hispaniola. The crown of the *root* is sometimes as thick as a man's arm, dividing below into several stout branches and fibres. *Leaves* usually about eighteen inches long; sometimes twice as much. *Leaflets* from ten to twenty pair, opposite or alternate, each two and a half or three inches long, varying in breadth from one-quarter to three-fourths of an inch, entire, rather shining, strongly striated on both sides, with many parallel ribs; the extremity rounded and pointless, with a greater or less number of slight tooth-like ferratures in proportion to its width. *Catkins* on short stalks, ovate, clothed with dark brown pubescence; the male ones about two inches long. *Fruit* three inches long, elliptical, pointed, downy; its *scales* finally widely separating, each of them peltate and angular, supported by a rather slender angular stalk, above an inch in length, and remaining long after the fruit is fallen. Each *drupa* is elliptical, about half an inch, or more, in length, with a small quantity of sweet orange-coloured pulp, and a large, rather pointed, nut. The *leaflets* are too strongly ferrated in Lamarck's plate; and rather broader and more luxuriant than usual in *Jacquin's*, otherwise admirable, representation. The male *catkins* are very frequently produced; the female ones we know only from dried specimens, and the works of *Jacquin*.

9. *Z. muricata*. Prickly-stalked Zamia. Willd. n. 9.—“*Leaflets* oblong, pointed, smooth, striated; ferrated from the middle to the extremity; common stalk spinous.”—Gathered by Humboldt and Bonpland, in South America, near Porto Cabello. *Leaflets* about four pair, six inches long; tapering at the base; striated and ribbed on both sides; sharply ferrated in their upper half. *Footstalk* channelled, armed with very short, blunt, scattered spines. Willdenow.

10. *Z. furfuracea*. Broad Rusty-leaved Zamia. Linn. fil. MSS. Ait. Hort. Kew. ed. 1. v. 3. 477. ed. 2. n. 4. Willd. n. 10. Poiret n. 2. (Palma americana, foliis polygonati brevioribus, levitè ferratis, et nonnihil spinosis, trunco crasso; Pluk. Phyt. t. 103. f. 2. et t. 309. f. 5. P. americana, crassis rigidique foliis; Herm. Parad. 210. t. 210. Palmifolia fructu clavato polyphyren; Trew Ehret, 5. t. 26.)—*Leaflets* elliptic-oblong, pointless; copiously ferrated from the middle to the extremity; striated and hairy beneath; common stalk spinous.—Native of the West Indies. Plukenet saw it in the royal gardens at Hampton-Court in king William's time. It is still preserved in our stoves, flowering towards autumn. The crown of the *root* is often a foot in diameter. *Leaves* from one to two feet long, exclusive of their prickly stalks. *Leaflets* usually eight or nine pair, three or four inches long, and one or one and a quarter broad, very rigid and coriaceous; shining, and roughish to the touch, on the upper side; more

furrowed, and clothed with shaggy, chaffy pubescence, which gives them a rusty or tawny hue, underneath. Their ferratures, or teeth, are numerous, obtuse, very irregular. *Catkins* ovate, hoary and downy, about three inches long, on *stalks* about the same length. Hermann says this plant produces a white infusid gum.

11. *Z. spiralis*. Spiral Zamia. Salisb. Prodr. 401. Willd. n. 11. Ait. n. 5. Brown n. 1.—Leaflets numerous, linear, very smooth, somewhat curved, with a few spinous teeth at the extremity. *Catkins* smooth, with pointed scales; those of the male ones wedge-shaped.—Native of New South Wales, from whence seeds were sent, in 1791, by Dr. John White, to the writer of this, and plants were raised from them in the following year, by the late Mr. Fairbairn, in Chelsea garden, being the first introduction of this species into Europe. The whole cone, filled with these nuts, was about half as large as a man's head; the nuts themselves about the size of small chestnuts. They were said to be eaten roasted by the natives of New South Wales, but on being tried by our English settlers, occasioned sickness. Their flavour is certainly inferior to a chestnut, and even to the nuts of *Cycas revoluta*, ripened in the bishop of Winchester's stove at Farnham castle. The plants soon grew to a considerable size, and according to Mr. Aiton, this species flowers in the stove, in July and August. The leaves are very smooth, of a fine green, a yard or more in length, spreading, each composed of from thirty to forty pair of long narrow leaflets, tipped with from three to five spinous teeth. *Footstalks* said to be somewhat spiral. The *catkins* are stalked, cylindrical, about five inches long, and two in diameter, squarrose, smooth, not downy nor hairy: *scales* of the male ones obovate-wedge-shaped, an inch long, with a short, broad, sharp, ascending, polished point; their upper side smooth and naked; under nearly covered with an uninterrupted heart-shaped assemblage of crowded, oval *anthers*, the size of poppy-seed: *scales* of the female *catkins* stalked, gibbous, two-edged and depressed, larger than the male ones, each tipped with an erect, sword-shaped, pungent, smooth point, an inch long, and, as the fruit ripens, extended to three inches, the gibbous fleshy part of the scale being then also much enlarged. *Germens*: two, ovate, sessile, close together, at the inner edge of this fleshy part of the scale, and directed horizontally inward. *Drupas* roundish, gibbous, an inch or inch and a half in diameter, orange-coloured, with a rather thin pulp, at least in the dried state, and a large, ovate, hard nut, not bursting, whose kernel, after keeping twenty-five years, is horny, semitransparent, and as hard as the shell. Mr. Brown suspects there may be two species confounded under *Z. spiralis*; one found in the neighbourhood of Port Jackson, to which our description and synonyms entirely belong, and which is from two to four feet high; the other, often ten feet in height, noticed by Mr. Brown on the southern coast of New Holland, and which we have never seen. Mr. Brown remarks, that in both, the *catkins*, usually solitary, sometimes grow two together.

12. *Z. longifolia*. Tall-leaved Zamia. Jacq. Fragm. 28. t. 29. Willd. n. 12. Poir. n. 10.—Leaflets numerous, elliptic-lanceolate, pointless, entire, clothed with shaggy down. Scales of the male *catkins* wedge-shaped, with abrupt quadrangular points.—Native of southern Africa, above a hundred miles from the Cape of Good Hope. Cultivated at Schoenbrunn. The crown of the root is scaly, a foot in diameter, smooth. Leaves slightly spreading, from five to seven feet high; their *stalks* quadrangular, without spines; *leaflets* from forty to fifty or sixty pair, two-ranked, three or four inches long and one broad, coriaceous; striated beneath; clothed on both sides, as well as the leafy part of

their common stalk, with a cobweb-like down, easily rubbed off; the lower ones only somewhat pointed. This species has not flowered in Europe; but the male *catkin*, brought from Africa, and represented in Jacquin's magnificent plate, is elliptic-oblong, near two feet in length, and five inches in diameter, brown, smooth, composed of innumerable wedge-shaped scales, covered underneath with *anthers*, and each tipped with a quadrangular, or pyramidal, abrupt, prominent point, without any of the pyramidal termination seen in the last.

13. *Z. lanuginosa*. Woolly-scaled Zamia. Jacq. Fragm. 28. t. 32, 31. Willd. n. 13. Poir. n. 9.—Leaflets lanceolate, smooth, spinous-pointed, with a few unilateral spinous teeth. Radical scales woolly.—Native of southern Africa, from whence a single plant was brought long ago to the Imperial stove at Schoenbrunn. After twelve years' culture, it had made but slow progress, and shewed no signs of fructification. The root consists of numerous, very thick, tap-shaped radicles; its crown being as large as a man's head, and covered with imbricated, deltoid, pointed scales, two or three inches broad, all clothed with soft, dense, hoary wool. Leaves a yard high, or more, dark green, very smooth and shining, with unarmed quadrangular *stalks*, and from twenty-five to thirty pair of linear-lanceolate *leaflets*, each four inches long, with a short spinous point; their margins all entire, except being often furnished with one, two, or three broad, spinous, tooth-like lobes, always at the lower edge of each leaflet, by which this species is at first sight readily distinguished. Professor Willdenow suspected it might not be distinct from *Z. cycadis* (see our 15th species); but we see no reason to concur in that opinion.

14. *Z. horrida*. Grey Thorny Zamia. Jacq. Fragm. 27. t. 27, 28. Willd. n. 14. Ait. n. 6. Poir. n. 8.—Leaflets lanceolate, glaucous, acute, spinous-pointed, with a few unilateral, lanceolate, spinous teeth. Radical scales smooth.—Native of southern Africa, a hundred miles above the Cape of Good Hope. Cultivated at Schoenbrunn, and introduced into the English green-houses, in 1800, by John Liptrap, esq., who possessed, for several years, a splendid collection of exotics at Mile-end; but it does not seem to have blossomed either here or in Germany. The scaly crown of the root is as large as the preceding, but the scales are not woolly. The leaves and their stalks are all over finely glaucous, which distinguishes the plant from the rest of its genus. The *leaflets*, as well as their lateral spinous lobes, are longer, and more pointed, than in *Z. lanuginosa*; the points and bases green, as the whole surface becomes when rubbed. A ripe female cone, brought from its native country, is fifteen inches long and eight thick, brown, tessellated, and warty, but not spinous. *Drupas* orange-coloured, oval, each with a thick, elongated, obtuse point, in the place of the *style*. Nut oval, somewhat triangular. This species is, as Willdenow observes, very nearly related, in size and general habit, to the last, but differs in its smooth crown of the root, and glaucous colour of the herbage.

15. *Z. cycadis*. Bread-tree Zamia. Linn. Suppl. 443. Ait. n. 7. Poir. n. 4. (*Cycas caffra*; Thunb. Nov. Act. Upsal. v. 2. 284. t. 5).—Leaflets lanceolate, spinous-pointed, smooth, entire; tapering at the base. Scales of the *catkins* abrupt, obtuse, pointless.—Native of the north-east part of southern Africa, far above the Cape of Good Hope, from whence living plants were sent to Kew, by Mr. Masson, in 1775. This is the species figured by Gertner. It grows on the sides of hills, in dry open spots, especially where the ground has been cleared by burning, and flowers in August, or the following months. The crown of the root is round and large, imbricated with scales, and, according to

Linnæus,

Linnæus, downy; with age, the plant acquires, like the palm tribe, a thick scaly stem, as tall as a man. The leaves are from a span to two feet long, of rather numerous and crowded leaflets, each two or two and a half inches in length, and one-quarter or one-third of an inch in breadth; smooth and even above; striated beneath; the younger ones, or rather those of young plants, tipped with a sharp tooth or two, besides the terminal spine. Common stalks smooth. *Catkins* stalked, ovate: the male a span long; its *foales* somewhat triangular, very obtuse, rugged, smooth; flat on the upper side; keeled underneath, and covered with *anthers* the size of millet-feed: female *catkin* larger than the male, near a foot long, green and smooth; its *foales* stalked, with a quadrangular, peltate, thick termination, lodging a pair of ovate angular *drupas*, with a red pulp. Nut of each the size of an acorn, not very hard, with a white solid kernel. Thunberg says, the older plants, which have acquired a stem, are broken off, or cut down, by the Caffres and Hottentots; and the pith, which is of considerable thickness, being tied up in the skin of a sheep or calf, previously well rubbed with grease, is buried in the ground. After remaining there a month, or longer, it is taken up in a putrefying state, and being bruised between two stones, and moistened with water, forms a sort of paste, which is made into little round cakes, about an inch in thickness. These are baked in wood-ashes, and are esteemed a great luxury; though, as the author observes, not very tempting to people of more refined habits, especially if they happen to have witnessed the whole process of preparation.

We are not without a suspicion that Willdenow's *Z. tridentata* (see n. 3.) may be this very species. This is more probable, at least, than his own conjecture, of Jacquin's *lanuginosa*, n. 13, being *Z. cycadis*.

Authors, even the most intelligent, use the term *frond*, instead of *leaf*; in their descriptions of this genus, because Linnæus considered *Zamia* as either a Palm, or a Fern. But its fructification is by no means cryptogamic, or obscure; nor do the leaves bear the flowers of either fern. There is a curious coincidence of structure and appearance between its *anthers*, and the supposed *capsules* of some of the spiked or racemose *Filices*, especially of *Botrychium* (the *Osmunda lunaria*, &c. of Linnæus); indeed the likeness is so great, that we can scarcely persuade ourselves that the two parts in question are not destined to answer the same purpose.

ZAMIA, in Gardening, comprises some low plants of the tender palm kind, among which the species chiefly cultivated in this climate are, the dwarf pinnated palm (*Z. pumila*), the thorny dwarf palm (*Z. spinosa*), and the entire leaved palm (*Z. integrifolia*).

The first is the finest sort, but the other two are occasionally preserved in some stove collections among other plants of the same class.

Method of Culture.—They may be raised from seeds, and by other means, in pots plunged in the bark-beds of hot-houses and stoves, where they must constantly be kept in light rich earth or mould, having the management of other exotics of similar kinds.

They afford variety in all such collections of tender plants.

ZAMIANSK, in Geography, a fort of Russia, on the Volga; 20 miles N.W. of Aitrachan.

ZAMIN, a town of Grand Bucharra; 50 miles N.E. of Samarcand.—Also, a river of Asia, which rises about 70 miles S. of Kogend, and after a N.W. course of about 150 miles, loses itself in the earth.

ZAMIRÆ, in Ancient Geography, a people of India that were Anthropophagi, near mount Mœander. Ptol.

ZAMOLXIS, in Biography, a celebrated person among the Scythians, was, as some have supposed, a slave of Pythagoras, who, having attended him into Egypt, obtained his freedom, and taught his master's doctrine among the Getæ. It has been also said, that in order to enforce the belief of the immortality of the soul, he dug a subterraneous apartment, and concealed himself in it for three years; but re-appearing as one risen from the dead, he there established his authority as a teacher. But Herodotus, who relates this fabulous story, as a common tradition, gives it no credit, but expressly says, that so far from being a Pythagorean, he flourished at a much earlier period than Pythagoras. The general testimony of the ancients furnishes reason for concluding, that Zamolxis was a Thracian, who, at a very remote period, taught the Scythians the doctrine of the immortality of the soul, and that after his death, they enrolled his name among the divinities, with whom they assured themselves they should associate in the invisible world. Herodotus relates, that at certain festivals, they chose several persons by lot, who were to be deputed as messengers to Zamolxis; and that they put them to death, by throwing them up into the air, and catching them, as they fell, upon the points of their spears; and this story is thought to be the more credible, because it is well known, that the practice of offering human sacrifices prevailed among the Scythians and the Thracians. Herodotus. Brucker by Enfield, vol. i.

ZAMORA, in Geography, a town of Spain, in the province of Leon, on the Duero; the see of a bishop, suffragan of Compostella. In the year 967, this town was taken by the Moors and destroyed; but afterwards rebuilt and fortified. It is now a frontier town against Portugal, and place of arms. The streets are narrow, and the general appearance of the town is gloomy; 120 miles N.W. of Madrid. N. lat. 41° 50'. W. long. 6°.—Also, a town of Algiers, founded in honour of a Mahometan saint. Here is a small garrison; 28 miles W. of Seteef.—Also, a town of Mexico, in the province of Guadalupe; 80 miles N.W. of Mechoacan. N. lat. 20° 54'. W. long. 103° 40'.—Also, a town of South America, in the audience of Quito, on a river of the Amazons. In the neighbourhood are some gold-mines; 200 miles S. of Quito. S. lat. 4°. W. long. 78° 46'.

ZAMOSCIE, or SAMOSTZIC, a town and fortrefs of Austrian Poland, in Galicia, built by the famous great chancellor, John Zamoyfki. It has a stately cathedral, and several other churches, a decayed university, a charitable foundation called Mons Pietatis, and several valuable privileges; but the fortifications are now in a bad condition. The proprietor of this town, &c. styled himself prince Zamoscie. It now belongs to Austria; 60 miles N.W. of Lemberg. N. lat. 50° 31'. E. long. 23° 15'.

ZAMPALA, a river of Mexico, which rises in the province of Tlafcala, and runs into the gulf of Mexico, N. lat. 19° 40'.

ZAMPALA, Chempoalla, or Zempoala, a city of Mexico. When Cortez landed in the year 1519, the chief or lord of this place, who was tributary to Montezuma, offered his service to the Spaniards. It was at that time a large city and exceedingly populous, the lowest account reckoning the inhabitants at 20,000 or 30,000. It was the capital of a country called Totonacapan, now the N.E. part of the province of Tlafcala; 90 miles E. of Puebla de los Angeles. N. lat. 20° 10'. W. long. 97° 50'.

ZAMPERINI, ANNA, in Biography, of Venice, arrived in England in 1767, as a buffa singer, a *partie eguale*, with the

the Guadagni, sister to the great singer and actor Guadagni, who had been here in early youth.

The Zamperini was a very pretty woman, coquetish, and an affected singer. Her first appearance on our stage was in *La buona figliuola* Maritata of Piccini, of which the music was so difficult to perform, and not easy to hear, that it was never sufficiently repeated for the public to be familiarly acquainted with it. They were glad, therefore, as well as the performers, to return to *La buona figliuola*, for their own relief from a too serious attention.

The sister of Guadagni, an elegant singer, and graceful actress, the original performer of the part of *Cocchina* in Italy, being superseded in that part by the Zamperini, occasioned a great rupture between Guadagni just arrived here in 1769 for the second time, and the honourable patentee and imprisario of the opera; which generated faction and a party spirit that destroyed the comfort of the opera, serious and comic, at a time when the public, in a state of tranquillity, would have been more delighted than at any other period.

We never heard the Zamperini sing serious music, but are told by M. Laborde (*Essai for la Mus.*), that "having a natural talent for music, and great spirit and fire in her action, though her excellence of performance was principally manifested in comic operas, yet she sung equally well in the serious. After performing with great applause in London, Lisbon, and Italy, she quitted the stage, and was well married."

ZAMPERI, DOMENICO, called *Domenichino* in the History of Painting, was born at Bologna, in 1581, and placed when very young under the tuition of Denis Calvert; but being ill treated by him, he prevailed upon his father to permit him to enter the school of the Carracci, at the time when Guido and Albano were both students there. He soon distinguished himself, but more by his care and assiduity than by brilliancy of talent. He here attached himself to Albano, and, when he left the Carracci, they travelled together to Parma, Modena, and Reggio, to study the works of Correggio and Parmeggiano, and soon afterwards they both went to Rome. In that city his first patron was cardinal Agucchi, who employed him in his palace, and commissioned him to paint three pictures for the church of S. Onofria, of subjects from the life of S. Jerome. His former master, An. Carracci, also employed him for some time to assist in his great work at the Farnese gallery; and he painted from his own designs, in the loggia in the garden, the Death of Adonis, when Venus springs from her car to assist her unfortunate lover.

As the health of A. Carracci became rapidly impaired, and he was necessitated to refuse many commissions offered to him, he recommended them to his scholars; and had the satisfaction of seeing Guido and Domenichino employed by the cardinal Borghese to paint the frescoes in S. Gregorio, which have subsequently become so celebrated, and of which the Flagellation of S. Andrea by the latter is so justly admired. The cardinal Farnese also employed him to paint some frescoes in the chapel of the abbey at Grotto Ferrata; among them is that picture of the Cure of the Demoniac Youth, which has been compared with and by many preferred to the one of Raphael in the Transfiguration. Another cardinal, Aldrobrandini, availed himself of the established renown of Domenichino, and engaged him to paint in fresco ten pictures of the history of Apollo, in his villa at Frascati, which added greatly to his reputation. Soon afterwards he completed the work which more than any other has served to immortalize his name, his well-known picture of the Communion of S. Jerome, painted

for the principal altar of the church of S. Girolamo della Carità. This fine production ranks with the best of any age. It is said with great semblance of truth, that the arrangement of its composition was borrowed of Agostino Carracci, who painted the same subject for the Certosa at Bologna. But if Domenichino did borrow the thought, he has amply made amends by the mode in which he has adorned it. It received its due meed of applause at the time, and was ranked as the work next in value to the Transfiguration by Raphael; but while the merit of its author thus excited the admiration of the public and most of the artists of Rome, it elicited in the minds of several, and among them of Lanfranco, the bitterest spirit of envy and malignity, which was actively exerted against him. He was reviled as a plagiarist, and the execution of his pictures condemned as heavy and ungraceful; and in spite of their powerful effect, the influence of his adversaries so far prevailed, that for a time he failed of commissions, and had serious thoughts of changing his profession for that of sculpture. The celerity and freedom with which Lanfranco invented and painted, and all those machinists who applauded the means of art above the end, were opposed to the slow and uncertain power of invention possessed by Domenichino. But upon this subject Lanzi justly observes, that if Domenichino had had the good fortune which he merited, he would, like the Carracci in Bologna, have soon triumphed over his adversaries, admitting that he was an imitator, but not a servile one, and that if his works were more slow in their birth than those of his enemies, they merited a much longer existence. "The public," he adds, "is just in its judgment, but before its tribunal a good cause is not sufficient of itself unless able pleaders give it credit. Domenichino timid and solitary, master of little, had not then sufficient means to protect himself against the torrent which overwhelmed him, and report seemed to verify the remark of the cardinal Agrecchi, that his worth would not be duly appreciated till after his death. Impartial posterity does him justice, and there is now no gallery which is regarded as complete without some specimen of his talents."

The virulence of these persecutions disgusted and disturbed Domenichino so much, that he returned to Bologna, and there he tranquilly passed some years in the delightful practice of his art. Among the most renowned of his productions about this period are his pictures of the Martyrdom of S. Agnes, for the church of that saint, and the Madonna della Rosario, both large works, and of sufficient merit to attract the insipidity of the French, and for a while they adorned the walls of the Louvre; but they are now returned to their original destinations. When malice and envy had exhausted themselves, and fame added fresh laurels to the brow of Domenichino, he was invited back to Rome by pope Gregory XV., who appointed him his principal painter, and architect to the pontifical palace. The cardinal Montotto engaged him to paint the vault of S. Andrea della Valle, where he represented the four Evangelists with Angels; and in the chapel of cardinal Bandini, in the church of S. Sylvestro, in the Quirinal, he painted four pictures, which rank amongst his best: the subjects are, Either before Abaferus, Judith with the Head of Holofernes, David playing and singing before the Ark, and Solomon and his Mother Bathsheba seated on a Throne. The former are certainly of a very high class of art, and though lacking the simplicity and grandeur of M. Angelo or Raffaele, yet they are full of rich and fine forms, particularly those of the angels, &c. which accompany the figures. The latter are not of so elevated a style, but are more familiar, and wrought with fine colour: they are engraved by Jacomo Frey.

Frey. About the same time he painted four of the Cardinal Virtues in the angles of S. Carlo Catenari, which have been preferred to us by the graver of G. Andran.

Domenichino not only excelled in historical painting, in works both great and small, but he has also left us many landscapes of extraordinary excellence in point of tone; seldom can fo much be said of their compositions. They are generally feleſt in ſcenery, of a grave and dignified character, and are executed with boldneſs and freedom, and enriched with figures. A very fine one may be ſeen in the collection of the marquis of Stafford. He is univerſally eſteemed as the beſt among the diſciples of the Carracci, and Nicolo Pouſſin is ſaid to have preferred him before them: but that favour, if we except the Communion of S. Jerome, his works will ſcarcely be found to ſupport. M. Fufeli has remarked, that “expreſſion which had languiſhed after the death of Raphael ſeemed to revive in Domenichino; but his ſenſibility was not ſupported by equal comprehension, elevation of mind, or dignity of motive.” His forms are by no means fo pure or graceful, or his actions fo natural and unconſtrained, as thoſe of that divine painter. His invention does not appear to have been vivid, but his ſtudy was unremitting, and with all his defects he well deſerved the title of a great painter, and certainly has not ſince been equalled. He died in 1641, aged 60.

ZAMPOGNA, in the *Italian Muſic*, is uſed to denote any inſtrument that ſounds like a flute; and particularly a bagpipe, being an aſſemblage of divers pipes of different ſizes. It is alſo taken for a common flute.

ZAMRECOTTA, in *Geography*, a town of Bootan; 34 miles S.E. of Damfong.

ZAMZEVRIZI, a town of the principality of Georgia, in the province of Carduel; 15 miles S.W. of Gori.

ZANA, a river of Peru, which runs into the Pacific ocean, S. lat. 7°.

ZANAATHA, in *Ancient Geography*, a town in the interior of Arabia Petræa. Ptol.

ZANCHI, BASILIO, in *Biography*, an elegant Latin poet, was born at Bergamo in 1501, and purſued his ſtudies under Gioviſta Rapicio with fo much ardour, that at the age of ſeventeen he made a collection of Latin poetical epithets, which was afterwards publiſhed. Before he had attained the age of twenty he viſited Rome, and was much noticed by the poets of that city. According to the practice which then prevailed he changed his baptiſmal name Pietro into L. Petreius; but afterwards, returning to Bergamo, and entering, in 1524, among the canons-regular of Lateran, he aſſumed that of Baſil; devoting his attention to ſacred literature, and publiſhing ſome works on the ſcriptures. In the progreſs of his life he frequently changed his reſidence; and was every where reſpected, on account of his learning and talents, by the principal ſcholars of the age. Under the ſevere decree of pope Paul IV. iſſued in 1558, which commanded, under the threatened penalty of the priſon or galleys, all the religious to return to the cloiſters to which they belonged, Zanchi was impriſoned, and fell a ſacrifice to the rigour of confinement. One of his biographers ſays, that he had few equals in the ſweetneſs, and fewer in the elegance of his poetry; ſpecimens of which occur in his eight books of poems, one of which bears the title of “De Horto Sophiæ,” and deſcribes the moſt remarkable facts and doctrines of the Catholic religion. Some of his poems are inſerted in the “*Deliciae*,” and the “*Carmina Poetarum Italarum*.” He alſo publiſhed a kind of *Lexicon*, entitled “*Latinarum Verborum ex variis auctoribus Epitome*.” Moreri. Gen. Biog.

ZANCHI, GIROLAMO, an Italian Proteſtant, was born in

1516 at Alzano, in the territory of Bergamo, and entered among the canons-regular of Lateran at the age of fifteen, in which connection he remained for ten years. But Peter Martyr having communicated to him, and others of his fraternity, the opinions of the reformers, he departed with him from Italy in 1530, and went to Geneva. From Geneva he removed to Straſburg upon an invitation to ſupply a vacancy in the profeſſorſhip of ſacred literature, which he accepted in 1553, and which he occupied for about eleven years. Having ſigned the Augſburg confeſſion, with ſome reſtrictions, he was aggregated to the chapter of St. Thomas, in Straſburg. Although his diſpoſition was moderate and conciliatory, he was engaged in ſome diſputes with the zealous Lutherans, who determined to procure his expulſion. With this view, they acquired his ſignature of a formulary, to which he aſſented in the following terms: “Hanc doctrinæ formulam ut piam agnoſco, ita etiam recipio.” The ambiguity of this declaration was not ſatisfactory to his adverſaries, and he was therefore induced to reſign, and to accept an invitation to a church in Chiavenna. The articles with regard to which he was ſuſpected by the Lutherans were predeſtination, the perſeverance of the ſaints, the eucharift, ubiquity, images, antichriſt, and the end of the world. Having reſided at Chiavenna from the year 1563 to 1568, he removed to the theological chair at Heidelberg, when he took the degree of doctor. When Frederick III., who was a zealous Lutheran, ſucceeded the elector palatine, and removed the Heidelberg profeſſors, Zanchi declining offered ſettlements at Leyden and Antwerp, took a place in count John Caſimir’s college at Newſtadt. Upon the reſtoration of the expelled profeſſors, Zanchi, on account of his age, was declared “emeritus;” and having loſt his ſight, died at Heidelberg in 1590.

Highly eſteemed among Proteſtants in general on account of his learning and invincible attachment to their principles, John Sturmius affirmed of him, “that he ſhould not be at all anxious for the cauſe of reformed religion, if Zanchius alone were to diſpute in the council of Trent againſt all the fathers preſent.” Bayle.

ZANCLE, in *Ancient Geography*, a town of Sicily, on the ſtrait which ſeparates this iſland from Italy. According to Herodotus, the Meſſenians, driven from the Peloponneſus by the Lacedæmonians, tranſplanted themſelves into Sicily, took poſſeſſion of Zancle, and gave it the name of Meſſana, whence Meſſina.

ZANDENDORF, in *Geography*, a town of Germany, in the margravate of Anſpach; 2 miles S.W. of Cadolzburg. ZANDHOP, a town of Pruſſia, in Ermland; 16 miles S.E. of Heilsberg.

ZANE, a town of Virginia; 9 miles S.S.E. of Wincheſter.—Alſo, a townſhip of Champaign county, in the diſtriſt of Ohio, with 645 inhabitants.

ZANES, in *Ancient Geography*, a town of Upper Mæſia, fortified by Juſtinian, ſo as to render it one of the ſtrongeſt bulwarks of the empire.

ZANESVILLE, in *Geography*, a townſhip of the ſtate of Ohio, in the county of Muſkingum, on the Scioto, with 2154 inhabitants.

ZANETTI, ANTONIO, in *Biography*, of Venice, maeltro di capella to the duke of Moçena, the latter end of the 17th and beginning of the 18th century, for whom, and for the theatres in Venice, he produced fix or ſeven operas that were much eſteemed in thoſe days.

ZANETTI, FRANCISCO, was born in the year 1740, maeltro di capella in the cathedral at Per gia in 1770. He had previously paſſed ſome time in London, where ſome elegant and eaſy ſonatas of his compoſition were publiſhed

by

by Bremner. He lost his place in the church at Perugia, by having appeared on the Alberti stage at Rome, as a singer in an opera of his own composition, and that, merely to supply the place of the principal tenor, who had run away, and to prevent the piece from being stopped: he however married afterwards a pretty woman, who sung well, and indemnified him for the loss of his place.

Since his marriage he has composed several successful operas, in which signora Zanetti has performed the principal female part, particularly one at Milan in 1785, in which she was much applauded, as well as her husband's music. He has composed much natural and pleasing music for instruments; as six violin trios, six quintets for three violins, and two violoncellos, &c.

ZANFARA, in *Geography*. See ZAMFARA.

ZANGARISA, a town of Naples, in Calabria Ultra; 6 miles N.E. of St. Severina.

ZANGESAIR, or SANGUSEER, a sea-port of Hindoostan, in Concan, with a good harbour, but not much frequented; 15 miles S. of Seevrodroog. N. lat. $17^{\circ} 38'$. E. long. $72^{\circ} 54'$.

ZANGUEBAR, a name given to a large territory of Africa, bordering on the Eastern sea, including many kingdoms; the name is said to import "the coast of the negroes," all the inhabitants being blacks, with curled woolly hair; extending from two degrees north to the twenty-first degree of south latitude. The principal kingdoms on the coast have been separately spoken of and described. Of the country in general little is known; the whole tract is represented as barren and unhealthy, the lands lying low, and intersected with rivers, lakes, thick woods, forests, and marshy grounds. The fruits of it are very unwholesome, their rivers, for the most part, covered or choked up with weeds, bushes, and thickets; all which so stagnate the air, and corrupt the products of the earth, and render the inhabitants so sickly and indolent, that they receive little or no benefit from its produce. The Bedouin Arabs are the only people who make advantage of it by breeding multitudes of cattle, and living mostly upon their flesh and milk; whilst the negroes, or Zanges, content themselves with feeding upon wild beasts and fowl, which swarm all over those parts. To supply the want of corn, pulse, roots, and other wholesome food, of which they are destitute, the Divine Providence hath interspersed that whole country with mines of gold, easily got, by the help of which they can purchase all the necessaries and conveniences of life from other parts: but this is the very circumstance that makes them so extremely jealous of letting strangers penetrate into the inland; more especially since the Portuguese have made themselves masters of such a number of places along this coast. They are in their nature fierce and stout, ignorant and brutish, without religion, especially the negroes; upon which last account they have the name of Caffers. As for the Bedouins, they have some kind of religion, or rather observe a variety of superstitious rites, but are no less ignorant and uncivilized than the Caffers; yet they chiefly herd among themselves, and live at a great distance from the coasts, and by the sides of lakes and rivers, for the convenience of pasture for their numerous herds. They go all naked, both Caffers and Arabs, excepting that they wrap a piece of cotton cloth round their middle, which descends a little below the knee; but those who live along the coasts are somewhat more civilized, affect a little more finery in their dresses, and instead of cotton cloth cover themselves with the skins of wild beasts, more or less rich, according to their rank, with

the tails of animals trailing behind on the ground; they likewise adorn their necks, arms, and legs, with a variety of beads, bugles, and other trinkets, of amber, jett, glass, and other materials, which they purchase from the merchants with their gold, furs, ivory, and other commodities. There are among these coasts a great number of Mahometans, but a much greater number still among the islanders along the coast; they being for the most part descended from those Arabs who were banished out of their country. The countries are, Melinda, Mongala, Jubo, Mofambique, and some others.

ZANHAGA, or ZANZAGA, or *Zenhaga*, a province of Africa, in the country of Sahara, bordering on the Atlantic.

ZANIA, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptol.

ZANNA, the name of a medicinal earth, described by Oribasius: he says it is found in Armenia, in that part which borders on Cappadocia; and that it is very drying, and of a pale colour, and easily diffused by water, falling into a fine powder like lime.

It is called by the natives *zarina*, and the mountain from which it is taken is near the city Baganona. It is of a drying and astringent nature.

ZANNICHELLI, JOHN JEROME, in *Biography*, a physician and naturalist, was born at Modena in 1662, and settling in the medical department at Venice, he published a work on the preparation of chemical medicines, entitled "Promptuarium Remediorum chymicorum." In 1702 he was created, by a patent of the duke of Parma, doctor of medicine, surgery, and chemistry. He afterwards formed a museum of natural history, and made many journeys in order to collect fossils and other subjects for this repository. Some of his excursions were undertaken by public authority, as he was nominated by the chamber of health, physician-naturalist to all the states of Venice. He died in 1729. During his life-time he published several tracts relating to botany and lithology; and after his death his son John James edited from his MSS. "Opuscula Botanica Posthuma," 1730, and "Istoria della Piante che nascono nel lidi intorno à Venezia," 1735, being a description, with figures, of the plants on the Venetian shores. Haller. Eloy.

ZANNICHELLIA, in *Botany*, was so named by Micheli, in compliment to John Jerome Zannichelli, an eminent apothecary at Venice, who spared no expence or labour, even at an advanced age, in the study of botany, on account of which he undertook several hazardous and difficult journeys. He was particularly devoted to the observation of marine productions, as well animal as vegetable. In pursuit of these he was Micheli's companion and guide, among the islands and shores of the Adriatic; and has wrote an account of the plants there to be found; which, with the history of some of his mountain tours, were printed after his decease. Zannichelli published a pamphlet on the medical qualities of *Rufcus*, as well as various chemical and geological works. He died in 1729, aged 67. His son, John Jacob Zannichelli, wrote on the properties of the horse-chestnut, as well as an account of his own and his father's museum. — Mich. Nov. Gen. 70. t. 34. Linn. Gen. 476. Schreb. 616. Willd. Sp. Pl. v. 4. 181. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 229. Sm. Fl. Brit. 955. Prodr. Fl. Græc. Sibth. v. 2. 225. Pursh 4. Juss. 19. Poiret in Lamarck Dict. v. 8. 836. Lamarck Illustr. t. 741. Gærtn. t. 19. (Graninifolia; Dill. Gen. 168.) — Clafs and order, *Monococcia Monandria*. Nat. Ord. *Inundate*, Linn. *Naiades*, Juss.

Gen. Ch. Male, *Cal.* none. *Cor.* none. *Stam.* Filament one, simple, elongated, erect; anther ovate-oblong, erect.

Female, close to the male. *Cal.* Perianth of one leaf, inferior, hollow, swelling, oblique, with two or three teeth. *Cor.* none. *Pist.* Germens from four to eight, stalked, oblong, converging; styles as many, simple, rather spreading; stigmas ovate, peltate, flat, spreading outwards. *Peric.* none. *Seeds* as many as the germens, naked, stalked, oblong, compressed, a little incurved, beaked with the permanent styles, tuberculated at the back, with a simple coriaceous coat.

Obf. Schreber speaks of some solitary, dispersed, male flowers, furnished with a single-leaved calyx, whose orifice is oblique, acute at the posterior part, and entire. He follows Gærtner in considering the coat of each seed as a capsule; but the latter allows there is scarcely any internal coat, or integument, to the kernel, and the outer one is destitute of valves; so that although the style be permanent, we rather follow Linnæus than other authors; and we conceive that if the existence of a naked seed be admitted in any instance, it must be in the present; there being only a simple covering to the embryo, which is indispensible.

Eff. Ch. Male, Calyx none. Corolla none. Filament elongated, erect. Anther oblong.

Female, Calyx of one leaf. Corolla none. Germens four, or more. Stigmas peltate. Seeds stalked, naked.

1. *Z. palustris*. Marsh Horned-Pondweed. Linn. Sp. Pl. 1375. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1844. Pursh n. 1. Mill. Illustr. t. 77. Fl. Dan. t. 67. (*Z. palustris* major, foliis graminicis acutis, flore cum apice quadrifidulari, embryonis clypeolis integris, et vasculo non barbato, capsulis seminum ad costam dentatis; Mich. n. 1. t. 34. f. 1. Potamogeto filimis, graminifolia, ramosa, ad genicula polyceratos; Pluk. Phyt. t. 102. f. 7.)—Anther of four cells. Stigmas entire.—Native of ponds, ditches, and rivulets, in Italy, as well as other parts of Europe, from Sweden to Constantinople, flowering in summer. It is found also in Virginia, near the sweet springs, according to Clayton and Pursh. The root is annual. Stem slender, floating, branched, round, leafy, and smooth, with the habit of a *Potamogeton*. Leaves linear, grassy, sessile, narrow, acute, and entire, two or three inches long. *Bractea* membranous, tubular, axillary, including a pair of green flowers, one male, the other female. Anther tawny. Seeds blackish when ripe, rugged or toothed at the back.

2. *Z. dentata*. Toothed Horned-Pondweed. Willd. n. 2. Poir. n. 2. (*Z. palustris* minor, foliis graminicis acutifimis, flore minimo cum apice bicapsulari, embryonis clypeolis circumcrenatis, et vasculo barbato, capsulis seminum ad costam asperis; Mich. n. 2. t. 34. f. 2.)—Anther of two cells. Stigmas toothed.—Found in the neighbourhood of Florence, with the foregoing, as well as in mountain pools in the adjacent country. Rather smaller than the first species, with shorter leaves; but most essentially different in having only two cells to the anther, and remarkably toothed stigmas. The seeds also are tuberculated all over, not merely toothed at the back, or keel.

Loureiro has a *Z. tuberosa*, Fl. Cochinch. 543, to which he attributes "ovate-oblong single-seeded berries." It grows in the waters of Cochinchina, and has tuberous perennial roots, radical, sword-shaped leaves, spiked flowers, the calyx of the female in six deep segments. We agree with M. Poir. that it would be too hazardous to admit this species without examination. Loureiro had probably never seen a real *Zannichellia*.

ZANOE, in *Ancient Geography*, a town of Palestine, in Vol. XXXIX.

the mountains of the tribe of Judea.—Also, a town of Palestine, in the plain of the tribe of Judea. Joshua.

ZANONA, in *Geography*, a small island in the Mediterranean; 2 miles N.E. of Ponza.

ZANONIA, in *Botany*, bears that name in memory of an Italian botanical writer of the 17th century, James Zanoni, superintendent of the public garden at Bologna. He published in 1675 a folio volume, in Italian, entitled *Istoria Botanica*, with 80 plates, of new or rare plants, accompanied by descriptions. Monti gave an enlarged edition of this work, in Latin, in 1742. Zanoni died in 1682, aged 67. Plumier, who speaks of him as a learned and critical investigator of the plants of the ancients, published a *Zanonia*, in his Nov. Gen. 38. t. 38, which Linnæus has reduced to *COMMELINA* (see that article, sp. 12.); and which some botanists reckon a *Tradescantia*.—Linn. Gen. 523. Schreb. 690. Willd. Sp. Pl. v. 4. 769. Mart. Mill. Dict. v. 4. Jusf. 397. Poir. in Lamarck Dict. v. 8. 837. Lamarck Illustr. t. 816.—Class and order, *Dioecia Pentandria*. Nat. Ord. *Cucurbitaceae*, Linn. Jussif.

Gen. Ch. Male, *Cal.* Perianth of three ovate spreading leaves, shorter than the corolla. *Cor.* of one petal, in five deep, spreading, pointed, inflexed, equal segments. *Stam.* Filaments five, spreading, the length of the calyx; anthers simple.

Female, on a separate plant, *Cal.* Perianth as in the male; seated on the germs, deciduous. *Cor.* as in the male. *Pist.* Germen oblong-clubshaped, inferior; styles three, spreading, conical, reflexed, permanent; stigmas divided, crisped. *Peric.* Berry large, elongated, abrupt; tapering at the base; encompassed near the top with a crisped suture, of three cells. *Seeds* two in each cell, rounded-oblong, flat, in the centre of a lanceolate scale, or wing.

Eff. Ch. Male, Calyx of three leaves. Corolla in five deep segments.

Female, Calyx superior, of three leaves. Corolla in five deep segments. Styles three. Berry of three cells, with a lid. Seeds winged, two in each cell.

1. *Z. indica*. Climbing Indian Cucumber. Linn. Sp. Pl. 1457. Willd. n. 1. Poir. n. 1. ("Pinar-valli; Rheede Hort. Mal. v. 8. t. 49, male; t. 47, 48, female.")—Native of Malabar and Ceylon. A stranger in the gardens of Europe, nor do we recollect having ever seen a specimen, Linnæus having, in this instance, confided entirely in the *Hortus Malabarius*, which was very rarely his custom. The herbaceous branching stem appears to climb by means of simple, spiral, axillary tendrils. Leaves alternate, stalked, ovate-oblong, acute, entire, smooth. Flowers in lax drooping clusters, which in the male appear to be somewhat compound. Fruit oblong, abrupt, obscurely triangular, with the flavour of a cucumber according to Rheede. There can be little doubt of this genus belonging to the gourd tribe, whether it answers to all the characters which authors have been pleased to apply to that tribe or not. The opening of the fruit betrays some analogy to *Momordica operculata*.

ZANORI, in *Geography*, a town of Mexico, in the province of Culiacan; 80 miles N. of Culiacan. N. lat. 25° 40'. W. long. 108° 10'.

ZANOTTI, FRANCIS MARIA, in *Biography*, a mathematician and philosopher, was born at Bologna in 1692, began his education among the Jesuits, and pursued a course of natural philosophy at the place of his nativity. Declining the prosecution of jurisprudence, to which he directed his first attention, he devoted himself to the study of philosophy, laying the foundation in an acquaintance with mathematics, and commencing with the works of Descartes

and Malebranche. But being desirous of studying the works of Aristotle and Plato in the original language, he applied with diligence to acquire a knowledge of the Greek, so that he became able not only to read but to write it. Thus furnished, he obtained leave to give lectures in philosophy; in the course of which he instituted a comparison between the system of Descartes and that of Newton, avowing a decided preference to the latter; more particularly as it respects optics and astronomy. It was by his advice, and under his direction, that Algarotti undertook to compose a popular treatise on light and colours. Declining to go to Padua for the purpose of giving lectures, he was appointed librarian to the Institute at his native place, and afterwards secretary, in which office he drew up in Latin an account of the transactions of the academy, with a history of its institutions, which he continued till the year 1766. This work was rendered peculiarly pleasing and instructive by the clearness of his arrangement, and the excellence of his style; in both which respects he seems to have formed himself on the model of Fontenelle. To these transactions he was himself a contributor; communicating a method of squaring different spaces of the hyperbola, and several important discoveries with regard to the circle, sphere, and circumscribing figures. Of these discoveries he transmitted an account to the Academy of Sciences at Montpellier, of which, as well as of the Royal Society of London, he had been elected a member. He also discovered a method of separating indeterminate quantities, detected several errors in philosophy, and prosecuted a variety of experiments; on these and other subjects he delivered papers to the Bologna Institute, which were published in his commentaries. Several of his papers on the central forces were also inserted in the Transactions of the Academy. His theorem on the means of determining the velocity of a body drawn or repelled from its centre, in any point of its orbit, were held in high estimation by Paul Frisius, who availed himself of it in the composition of his work on universal gravity. On the subject of the "Vis viva," which in his time engaged particular attention, he wrote three dialogues in Italian, distinguished for perspicuity and elegance. In these he adopted the opinion of Descartes in opposition to that of Leibnitz, who conceived that this force was not to be estimated from the velocity, as he asserted, but from the square of the velocity. The properties of numbers likewise engaged his peculiar attention; and he shewed, that if any multiple of the number 9 be taken, the sum of the figures forming that multiple will be also a multiple of 9. In his speculations on moral philosophy, he defended the Peripatetics against Maupertuis; and his adversary Analdi, in his "Vindicia Maupertusiana;" accused him of depreciating the Catholic religion, as he ascribed too great influence to the Stoic philosophy in alleviating the misfortunes of human life. This controversy gave occasion to many publications. Zanotti was a poet as well as a mathematician and philosopher, and wrote verses both in the Tuscan and Latin languages; aiming, in imitation of the most celebrated poets of Italy, to blend the suavity of Petrarch with the energy and vigour of Dante. Many of his Italian poems were published by Eustasio Manfredi; and some of his Latin elegies were edited by J. Antonio Vulpi; who says of them, that Catullus himself would not have been ashamed to acknowledge them. Both his Italian and Latin poems were afterwards published separately, first at Florence, and lastly at Bologna; and in this edition are contained imitations of Tibullus, Ovid, and Virgil, as well as of Catullus. After the death of Beccaria, Zanotti, whose modesty was no less conspicuous than his talents and acquirements, accepted the office of president of

the Institute, which he deemed peculiarly honourable, as it was a token of esteem conferred upon him by his countrymen. Among the learned men with whom he maintained intercourse of friendship or correspondence were the famous anatomist Morgagni, Voltaire, and pope Benedict XIV. He died in the month of January 1777. For an account of his works, which, besides those to which we have already referred, were numerous, we refer to "Fabroni Vite Italorum Doctrina excellentium;" and for an abstract of their titles, and time and place of publication, to Gen. Biog.

ZANOTTI, GIOVANNI PIETRO, was born at Paris, though of Italian parentage, in 1674. He was sent young to Bologna, and became a pupil of Lorenzo Paffinelli. Under that master he acquired an agreeable tone of colouring, a mellow pencil, and an intelligent acquaintance with the principle of the chiaro oscuro. He painted several altar-pieces for the churches at Bologna, of which the most esteemed are, the Incredulity of St. Thomas, in the church of S. Tommaso del Mercato; the Resurrection, in S. Pietro; the Nativity, in La Purita; and a large picture in the palazzo publico, representing the ambassadors from Rome swearing fidelity to the Bolognese. He resided great part of his life at Cortona, where he also distinguished himself by several pictures painted for the churches, particularly Christ appearing to the Magdalen, Christ bearing his Cross, and the Murder of the Innocents.

Zanotti was a laborious and intelligent writer on art. Of his numerous publications the most considerable is his "Storia dell' Accademia Clementina di Bologna," published in two vols. 4to. in 1739. He died in 1765, aged 91. Bryant's Dict.

ZANOTTI, L'ABATE GIANCALISTO, of Bologna, a disciple of Padre Martini, was born in 1770, of whose composition at the annual performance of the musical students, who were members of the celebrated Philharmonic Society in Bologna, founded in 1666, we heard a *dixit*, in which there were all the marks of an original and cultivated genius. The movements and even passages were well contrasted; and to make use of the language of painters, there were discernible in it not only light and shade, but even mezzo tints. He proceeded from one thing to another by such easy and insensible gradations, that it seemed wholly the work of nature, though conducted with the greatest art. The accompaniments were judicious, the ritornels always expressed something, the melody was new and full of taste, and the whole was put together with great judgment, and even learning. We have very seldom been more pleased or completely satisfied than by this production; and yet the vocal parts were but indifferently executed, for there were then no great figures at Bologna. We expected to have heard of future works by this most promising young composer, who was one of the *maestri di capella* in the church of San Petronio; but as that has not happened, we fear he did not long survive this performance.

ZANOW, in *Geography*, a town of Pomerania; 6 miles E.N.E. of Coslin.

ZANTE, an island in the Mediterranean, near the coast of the Morea, about 12 miles in length, and six in breadth, chiefly inhabited by Greeks, till lately under the Venetians, who appointed a governor, called *provveditor*, and two counsellors. The Greeks have 40 churches, besides convents, and a bishop; the Roman Catholics have three convents and a bishop. By the treaty of Campo Formio, Zante was given to France; but in 1799 it was taken by the united fleets of Russia and Turkey, and in the year 1800 connected with other neighbouring islands, to form a republic of the Seven islands, named the Ionian, which are to pay a tribute to the

the Porte, and guaranteed both by the Turks and Russians. Corfu, Cephalonia, and some others lately in the possession of Venice, were of this number. The island produces excellent wine, and that species of grapes called currants, olives, figs, melons, peaches, and other choice fruits: towards the coasts, the island is in general mountainous, but level in the interior parts. It is much subject to earthquakes. N. lat. $37^{\circ} 40'$. E. long. $21^{\circ} 4'$.

ZANTE, a town and capital of the island of Zante, situated on the N.E. side, with a harbour safe and commodious for vessels of any size. The town stretches between the harbour and the foot of a mountain about a mile in length, but narrow; the streets are not paved, and the houses in general low. On a mountain above the town is a citadel, which commands the harbour, and contains a little city within its walls. It is to be ascended with difficulty, is strong, and well supplied with stores, and furnished with a garrison. This is the residence of the governor and officers. Zante is the see of a Greek and Latin bishop. There are several churches, and the Jews have a synagogue; 21 miles S.S.W. from the town of Chiarenza in the Morea. N. lat. $37^{\circ} 50'$. E. long. $21^{\circ} 8'$.

ZANTHENES, in *Natural History*, a name given by the ancients to a fossil substance found in Media. Pliny quotes Democritus for saying, that if rubbed in palm wine and saffron, it became soft as wax, and yielded a very sweet smell.

ZANTHER, in *Geography*, a town of Pomerelia; 10 miles S. of Marienburg.

ZANTHORRIZA, in *Botany*, L'Herit. Stirp. Nov. t. 38. See XANTHORRIZA.

ZANTHOXYLUM, Linn. Gen. 519. See XANTHOXYLUM.

ZANTHOXYLUM, in *Gardening*, contains plants of the hardy and tender exotic shrubby kinds, in which the species cultivated are, the Canada tooth-ache-tree, or Hercules's club (*Z. clava Hercules*), and the Chinese tooth-ache-tree (*Z. trifoliatum*).

The first is a plant of the tree kind, of which there is a variety; the ash-leaved tooth-ache-tree, with oval-oblong folioles, and prickly mid-ribs.

And the last is a woody branching plant.

Method of Culture.—These plants may be increased by seeds and layers. The seeds should be sown in the spring, either in an east border, or in pots placed in the morning sun all the summer, being sheltered in a frame in winter; and in the spring following removed to the full air till October, giving proper waterings all the summer; and towards winter be placed again under shelter from frost till March, when the young plants may be potted separately; and thus continued for a year or two, being sheltered in the winter, when they may be transplanted into the shrubbery, where they are to remain.

The layers of the young wood may be laid down in autumn or early spring, and when they have stricken root be taken off and managed as the seedlings.

They also succeed by cuttings in spring or summer, planted in pots, assisted by a hot-bed, in which they soon strike, when they should be inured to the full air; and the young plants will be fit for planting out in the autumn, or the spring following.

The first is a very ornamental plant in the borders and other dry parts of shrubberies, and the latter among potted plants in the green-house collections.

ZANTOCH, in *Geography*, a town of the New Mark of Brandenburg; 8 miles E. of Landsberg.

ZANZALUS, in *Biography*. See BARADEUS.

ZANZIBAR, or ZANGIBAR, in *Geography*, an island of Africa, in the Indian sea, near the coast of Zanguebar, governed by a king, who is tributary to the Portuguese. S. lat. 6° . E. long. $41^{\circ} 15'$.

ZANZOUR, a town of Africa, in the country of Tripoli; 15 miles W.N.W. of Tripoli.

ZAOIE, a town of Egypt, on the left bank of the Nile; 13 miles N. of Beniuef.

ZA-OSTROG, a town of Morlachia, near the coast; 15 miles S.E. of Macarika.

ZAOZERSKOI, a town of Russia, in the government of Novgorod, on the Sula; 28 miles W. of Tcherepovetz.

ZAPATA, or SAPATA, a kind of feast, or ceremony, held in Italy, in the courts of certain princes, on St. Nicholas's day, in which people hide presents in the shoes or slippers of those they would do honour to; in such manner, as to surprize them on the morrow, when they come to dress.

The word is originally Spanish, *capato*; and signifies a shoe, or slipper.

It is done in imitation of the practice of St. Nicholas; who used, in the night-time, to throw purses of money in at the windows, for portions to poor virgins in their marriage.

F. Menestrier has described these zapatas, their origin, and different usages, in his *Treatise des Ballets Anciens et Moderns*.

ZAPATERO, in *Geography*, a small island of Mexico, in lake Nicaragua, near the west coast; 30 miles S.E. of Grenada.

ZAPATILLA LAGOON, a bay on the east coast of Yucatan. N. lat. $18^{\circ} 52'$. W. long. $89^{\circ} 32'$.

ZAPETRA, in *Ancient Geography*, a town of Asia, in the mountains of Comagene, upon a small river, which discharged itself into the Euphrates, S. of that town.

ZAPFENDORF, in *Geography*, a town of Bavaria, in the bishopric of Bamberg; 9 miles N. of Bamberg.

ZAPHOR, a name given by some writers to *Zaffer*; which see.

ZAPOROGEAN COSSACKS, in *Geography*. See COSSACKS.

ZAPOTITLAN, a town of Mexico, in the province of Tlascalala; 62 miles S.E. of Puebla de los Angeles.

ZAPOTLAN, a town of Mexico, in the province of Mechoacan; 25 miles N. of Colima. N. lat. $20^{\circ} 10'$. W. long. $104^{\circ} 36'$.

ZAPPANIA, in *Botany*, was so named by Scopoli, in honour of Paul Anthony Zappa, an Italian botanist, to whom the public garden at Pavia was indebted for many valuable communications. The French, not always exact in orthography, will have it *Zapania*, and they have misled our more accurate countryman Mr. Brown, who follows Jusseu and Lamarck in adopting this genus, in his *Prodr. Nov. Holl. v. 1. 514*. Scopoli published it in his *Deliciae Floræ et Faunæ Insularum*, v. 1. 34. t. 15. The species, on which he founds the genus, and which he erroneously suspected might be the *Lantana involucrata* of Linnæus, is the *Verbena globiflora* of L'Heritier. (See *VERBENA*, n. 3.) We do not find it necessary or expedient to retain *Zappania* as a distinct genus.

ZAPUNTELLO, in *Geography*, a town of the island of Melada, which sometimes gives name to the island.

ZAQUALPAN, a town of Mechoacan, in the province of Mechoacan; 6 miles S. of Zacatula.

ZARA, a city and sea-port of Dalmatia, see of an arch-bishop, situated in a district, called "The County of Zara," which was purchased of the king of Naples, in the year

1409, by the Venetians, in whose hands it afterwards continued. Zara is surrounded on all sides by the sea, except that it has a communication eastward with the continent, by means of a draw-bridge, commanded by a fort. It is reckoned one of the best fortifications in Dalmatia, and deemed almost impregnable. The citadel is divided from the town by a very deep ditch, hewn out of a rock. The harbour, which lies to the north, is capacious, safe, and well guarded. The rain is carefully preserved in cisterns, to supply the want of fresh water. In the castle resides the governor or proveditor of Dalmatia, whose office is only triennial. It now belongs to the kingdom of Italy; 28 miles N.W. of Scardona. N. lat. 44° 22'. E. long. 15° 38'.

ZARA *Vecchia*, *Old Zara*, or *Biograd*, or *Alba Maritima*, a town of Dalmatia, now little better than a village. In the time of the Romans it was a place of considerable figure, and received a new set of inhabitants by a numerous colony of that people. In the middle ages it was called *Belgrad*, or *Alba Maris*, and more anciently *Blandona*. According to some it was ruined by Attila; but we know with more certainty that it was destroyed in the war between the Venetians and the Hungarians, by the doge Ordelafo Falieri. Some banditti afterwards mixing with the inhabitants that remained, the republic, to check their excesses, ordered a general massacre of the robbers, in which the ancient inhabitants were not spared. Here was also a bishop's see, which, on the demolition of the town, was removed to Scardona; at present its inhabitants consist only of a few peasants; 18 miles S.E. of Zara.

ZARA. See SCHIAREDSJE.

ZARA, in *Ancient Geography*, a town of the Moabites, taken by Alexander Jannæus.—Also, a town of Asia, towards Armenia, upon the route from Arabissum to Satala, between Eumææ and Dagalassum. Anton. Itin.

ZARAIK, in *Geography*, a town of Russia, in the government of Riazan, on the Oser; 24 miles S.W. of Riazan. N. lat. 54° 30'. E. long. 38° 24'.

ZARAMA, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptolemy.

ZARANDA, a name anciently given to the Euphrates.

ZARANG, the *Zarange* of Ptolemy, in *Geography*, a populous city of Persia, in the province of Segestan or Seistan, situated pleasantly on the banks of the Hearmund. This was the customary residence of Jacob Ben Lath, the conqueror of the caliph of Bagdad, and stood a long siege against Timur, by whom it was at last taken. Zarang is supposed to be the same with the present Dooshak, the old name having been lost in the revolutions to which this province has been subject for more than a century, and to which its present desolated state may, in a great measure, be attributed. For a further account of it, see SEGESTAN.

ZARANIS, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptolemy.

ZARATE, AUGUSTINE DE, in *Biography*, a Spanish historian, was sent by Charles V. in 1543 to South America, as comptroller-general in Peru and Terra Firma; and having collected all the memoirs he could procure, he composed his work "Del Descubrimiento y Conquista de la Provincia del Peru," first printed at Antwerp in 1555, 8vo. and reprinted at Seville, 1577, folio: the first edition being regarded as most authentic. It has been translated into Italian and French, and is commended as a work of reputation and credit by Dr. Robertson. Moreri. Robertson's America.

ZARATE, in *Geography*, a town of South America, in the province of St. Martha; 15 miles S. of Teneriffe.

ZARAYOS, or SHARAYOS, a supposed lake of America, in the course of the river Paraguay, which only exists during the annual inundations, that are on a far grander scale than those of the Ganges, and may be said to deluge whole provinces.

ZARCA, a town of Egypt, on the east branch of the Nile; 10 miles S. of Damietta.

ZARCHIAS, or TCHARKAS, a town of Persia, in the province of Chorasan, or Khorassan; 150 miles N. of Herat.

ZARCOIA, a town of Persia, in the province of Segestan; 12 miles W. of Zarang.

ZARDAM. See SARDAM.

ZARE, a town of Persia, in the province of Chorasan, or Khorassan, on the north side of a lake so called; 70 miles S. of Herat.—Also, a lake of Persia, in the province of Segestan; 60 miles N. of Zarang. See ZERREH.

ZARED, in *Ancient Geography*, a torrent beyond Jordan, on the frontier of the Moabites. This torrent had its source in the mountains, E. of the country of Moab, and proceeding from the E. to the W. discharged itself into the Dead sea. The Israelites passed it 38 years before their departure from Kadesh-Barnea. Numb. xxi. 12. Deut. ii. 13, 14.

ZAREPHATH. See SAREPTA.

ZARESH-SHEKER, or SARAT-AFER, a city of Reuben, beyond Jordan. Josh. xiii. 19.

ZARETHÆ, or ZARETE, a people comprised under the name of Scythians, on this side of the Imaus, south of mounts Massæi and Alani. Ptol.

ZAREX, a port of Laconia, on the Argolic gulf, S. of Cyphanta. Near this port was a temple of Apollo, with a statue of this god, holding in his hand a lyre. To the south, and parallel to the coast, was a mountain called Zarex.

ZARFA, in *Botany*, a name given by Leo Africanus, and others, to the *lotus*, or nettle-tree.

ZARGIDAVA, in *Ancient Geography*, a town situated on the bank of the river Hierafus, in the interior of Lower Mæsia, a little above Tamafava.

ZARIASPA, or ZARIASPE, a town of Asia, in Bactriana, watered by a river of the same name, which discharged itself into the Oxus. Strabo. It was also called Bactra. Steph. Byz.

ZARIFU, a word by which some of the chemical writers have expressed tin.

ZARIK, in *Geography*, a town of European Turkey, in the Morea; 22 miles E. of Mistra.

ZARIMA, a town of South America, in the province of Quito; 220 miles S. of Quito. S. lat. 3° 36'. W. long. 79° 36'.

ZARJON, a town of South America, in the government of Buenos Ayres; 300 miles N.N.W. of Buenos Ayres.

ZARLINO, GIUSEPPE *da Chioggia*, maestro di capella of St. Mark's church at Venice, and the most general, voluminous, and celebrated theorist and writer on music in the Italian language during the 16th century, was born in 1540, and author of the following musical treatises, which, though separately printed, and at different periods, are generally bound up together in one thick folio volume:—"Institutioni Harmoniche," Venice, 1558, 1562, 1573, and 1589; "Dimostrazioni Harmon." Ven. 1571, and 1589; and "Supplimenti Musicali," Ven. 1588. We discover by these dates, that Zarlino first appeared as an author at the age of 18; and from that period till he had arrived at 49, he was continually revising and augmenting his works.

The

The musical science of Zarlino, who died in 1599, may be traced in a right line from the Netherlands: as his master Willaert, the founder of the Venetian school, was a disciple of John Mouton, the scholar of the great Josquin.

A commentary upon the voluminous writings of this author would occupy too large a portion of our work; and to refer the reader to the analysis of his several treatises by Artusi would be doing him little service, as the writings of Artusi would be difficult to find. There are few musical authors whom we have more frequently consulted than Zarlino, having been encouraged by his great reputation, and the extent of his plan, to hope for satisfaction from his writings concerning many difficulties in the music of the early contrapuntists; but we must own, that we have been more frequently discouraged from the pursuit by his prolixity, than enlightened by his science: the most trivial information is involved in such a crowd of words, and the suspense which it occasions is so great, that patience and curiosity must be invincible indeed to support a musical inquirer through a regular perusal of all his works.

He begins his *Institutes* with a panegyric upon music, in the usual strain; then we have its division into mundane and humane, faithfully drawn from Boethius; after this, there is a great waste of words, and parade of science, in attempting to explain the several ratios of greater and less inequality, proportion, and proportionality, &c. where, in his commenting on Boethius, we have divisions of musical intervals that are impracticable, or at least inadmissible, in modern harmony.

In his account of the ancient system, he discovers much reading; and that is what he chiefly wishes the reader should know.

In describing the diatonic genus, in which the tetrachord is divided into tone major, tone minor, and major semitone: $\frac{9}{8}$, $\frac{7}{8}$, and $\frac{1}{2}$, for which division, commonly called the syntonous, or intense of Ptolemy, he constantly contends, we have the substance of his dispute with Vincenzo Galilei, which will be mentioned hereafter. The second part of his *Institutes* is chiefly employed in measuring and ascertaining intervals by means of the *monochord*, and an instrument called the *mesolabe*, which is said to have been invented either by Archytas of Tarentum, or Erastobenes, for the purpose of halving an interval. Whether the practical musicians of antiquity applied these calculations or imaginary divisions to their flutes and lyres, we know not; but of this we are most certain, that the greatest performers of modern times are Aristoxenians, and make the *ear* the only instrument of calculation; which, by means of harmony, and the constant opportunities of comparison which the base or other accompaniment affords them, during performance, is rendered a much more trusty guide than it could be in playing a single part. It seems, however, as if the ancient instruments, upon which all the tones are *fixed*, had more need of the assistance of calculation and mathematical exactness in regulating their intervals than those of the violin-tribe at present; which, except in the open strings, which often lead the performer to erroneous intonation, depend on the strength and dexterity of the musician's hand, and accuracy of his ear, *during performance*. See an ingenious and useful work, called "Essay upon Tune," published at Edinburgh, 1781; where the imperfections in the scales of modern instruments are clearly shewn, and remedies for correcting them prescribed.

The elements of counterpoint, and fundamental rules of composition, which chiefly concern the practical musician, are given in the third part of the *Institutes*; and these are more ample, and illustrated with more examples, than in any

preceding writer; particularly the laws of canon and fugue, for which no instructions have been given by Franchinus, though they were in such high favour during his time. P. Aaron and Vicentino have indeed started the subject, but the pursuit of it was left to Zarlino.

In the fourth part of the *Institutes* we have a short historical account of the inventors of the several ecclesiastical modes: it is, indeed, a mere skeleton of assertions or conjectures without proof, more derived from traditional than written evidence. He here likewise gives instructions for composing in all these modes, in which he religiously keeps within their legal limits, and submits to all the restraints which antiquity had prescribed.

Padre Martini, faggio di contrappunto, in recommending the study and imitation of ancient masters, has well described the difficulties they had to encounter; where, after confronting the ecclesiastical scales with the secular, we have the following passage: "From an attentive and comparative view of these scales, any one desirous of learning the art of counterpoint for the service of the church, will see what diligence and efforts were necessary to unite the different qualities of canto-fermo and canto-figurato; and by carefully examining the examples given of both, will discover what artifices were used by ancient masters to avoid such sounds as differed from the canto-fermo, and with what parsimony they admitted such accidents as canto-figurato requires, particularly in the third and fourth tones; where, instead of modulating into B *mi*, the 5th of the mode or key, as is constantly practised at present, they have passed to the key of A in the fourth tone, and C in the third, by which means they have been able, dexterously, to unite the different qualities of canto-fermo with those of canto-figurato."

He gives excellent rules for composing motets and madrigals; but it is remarkable, that he advises the composer to make the *tenor* proceed regularly through the sounds of the mode he shall choose; and above all, that this part be so much the more smooth, regular, and beautiful, as the rest are to be built upon it; whence, says he, its sounds may be called the nerves and ligaments of all the other parts: by which it appears that the cantilena, or principal melody, was not given, as it is by modern composers, to the *soprano*, or *highest* part; that *castrati* were not so common as at present; and that the *tenor* being the kind of voice most easily found, and more generally good than that of any other pitch, was judiciously honoured with the principal melody.

Zarlino says, that so great was the rage for multiplying parts in musical compositions, that some masters, not content with three or four, which sufficed to their predecessors, had increased them to fifty; from which, he truly observes, nothing but noise and confusion could arise. However, in another part of his book, he tells us, that Adriano Willaert had invented masses *à Due Cori*, over a *tre*, or, as some call them, *à Cori Spezzati*, which had an admirable effect. We know not how Okenheim disposed his thirty-six parts in the motet already mentioned; but they would have furnished nine choirs of four voices each. In the large churches of Italy, where the performers are divided into two bands, placed in opposite galleries, all the imitations and solo parts are distinctly heard, and when united in at least eight *real* parts, completely fill the ears of the audience with all the charms of congregated sound.

ZARMISOGETUSA REGIA, in *Ancient Geography*, a capital town of Dacia, upon the river Sargetia. When this city became a Roman colony, it joined to its ancient name "Colonia Ulpia Trajana," or that of "Augusta Dacia."

roundish, stalked, longer than the glumes; angular and compressed at the base.

Obf. Two out of the four valves of the female corolla appear to belong to an abortive flower. *Schreber.*

Eff. Ch. Male flowers in distinct spikes. Calyx a two-flowered beardless glume. Corolla beardless.

Female, Calyx a glume of two valves. Corolla of four valves. Style one, thread-shaped, pendulous. Seeds foliary, imbedded in an oblong receptacle.

1. *Z. mays.* Common Maize, or Indian Corn. Linn. Sp. Pl. 1378. Willd. n. 1. Ait. n. 1. Pursh n. 1. (*Fruentum indicum*; Camer. Epit. 186. *F. afaticum*, turcicum et indicum; Ger. Em. 81, 82. Morif. sect. 8. t. 13. f. 1, 2, 3.)—Leaves entire.—Native of America. Cultivated there, as well as in the southern countries of Europe. One of the largest of the family of corn or grasses. *Root* annual, of innumerable fibres. *Stem* erect, somewhat branched, round, stout, jointed, leafy, from five to ten feet high. *Leaves* sheathing, lanceolate, concave, acute, ribbed, two or three feet long, and three or four inches broad. *Male flowers* in numerous, aggregate, terminal spikes, each three or four inches long, greyish, downy, with purple anthers. *Female ones* below, in a generally simple, cylindrical spike, covered by the large sheaths of the upper leaves. *Styles* six or eight inches long, very numerous, of a shining yellowish or reddish hue, hanging down like a long silken tassel. *Seeds* white, yellow, red, or purplish, forming a heavy, tessellated, cone-like, naked spike, from six to ten inches long. There are innumerable varieties, in the size, figure, colour, and qualities of the grain, which, though valuable for many purposes, and yielding an abundant crop, is far inferior to wheat as a bread corn. It requires a richly manured soil. Mr. Pursh mentions a variety, brought lately by governor Lewis from the Mandan nation, on the Missouri, which promises to be particularly valuable, as ripening earlier than any other fort, and yielding an excellent produce. See MAIZE.

2. *Z. Curagua.* Chili Maize. "Molina Chil. German edition, 107." Willd. n. 2.—Leaves serrated.—Native of Chili. Annual. Smaller in all its parts than the foregoing. *Molina.* Of the qualities or history of this species, we have no further account.

ZEA, in Gardening, contains a plant of the hardy herbaceous annual kind, of which the species cultivated is the maize, or Indian corn (*Z. mays*).

It has a large strong, herbaceous stalk, which sometimes rises to the height of ten or twelve feet; and there are varieties; with yellowish-white seeds, with deep yellow seeds, and with purple-blue seeds. This plant is mostly cultivated in the garden and pleasure ground for the sake of its singular tall growth.

Method of Culture.—These plants may be raised by sowing seed in the spring, as March or April, in a dry warm situation, where the plants are intended to remain, in patches of two or three seeds or more in each, about an inch and a half deep: when the plants are come up, they should be thinned out to one or two of the strongest. But to have the plants more forward, so as to produce ripe feed-spikes more effectually, some should be sown in a hot-bed at the same time, and when the plants are three or four inches high, be forwarded by pricking them out upon another hot-bed, either under a deep frame, or an awning of hoop arches, to be covered with mats occasionally, allowing them plenty of free air; and when they have sufficient growth, as in May, they may be transplanted, with balls of earth about their roots, into the full ground in the borders or shrubbery

clumps, in warm sunny situations, being well watered; and when the summer proves warm and dry, they often produce perfect heads, and the seeds ripen in a good manner.

As the plants mostly run up in tall stalks, it is proper to support each with a tall neat stake, especially where much exposed to wind and rain.

These plants in the different varieties have a fine effect in the back parts of borders, clumps, and other places, in warm sheltered situations.

It is observed by a late writer, that he has planted a small quantity of this sort of grain in his garden, and it turned out superior to his expectations; and he is of opinion, that this crop may be raised to advantage in the field on some light soils, particularly the poor sands of Norfolk and Suffolk, or on any hot burning lands; as the countries where it grows naturally are light hot soils. And he adds, that he prefers the drill method of culture for it in this country; as the small hillocks in planting the feeds separately make the land unfitly and improper for other crops. But to raise the greatest produce in corn, the hills are, he conceives, the best way; however if the crop is intended chiefly for fodder, then drills are best. The feed is to be put about an inch deep in the ground. And that when the corn first appears above the surface, the hillocks or drills must be examined, to see whether it all comes up properly; and if it has not, there must be fresh feeds put into the vacant places to prevent a loss in the crop. And as soon as the plants take root in the ground, the crop should be examined again to see whether any have died away, or the birds have taken the feed. The plants must also be thinned to two on a hill, and good plants substituted for weak ones.

In the cultivation while growing in the hill-way, the hoe must be used at every operation to the plants, and earth be given to them, as the land cannot be made too light for this crop; but when in drills, the corn must be hoed in the same manner as garden peas.

He also further observes, that when the corn gets out of the milk, the blades below must be all pulled off while green: tie them up in small bunches, about the size of a birch-broom, and hang them on the top of the stalks of the corn; for at the same time that the blades are pulled, the tops must be cut off, and set up in round bunches to dry, and tied round the topmost part to keep them from falling: when these are dry, they must be harvested. The blades are generally ready in four or five days, but the tops take longer; when these blades and tops are properly harvested, they are excellent food. And it is suggested, that as these processes will be finished about the end of August, the land might be ploughed and then sown with rye. If seeds were required, he is of opinion that it would be very proper to sow the feeds at that time on this poor hot land; as the warm season would be over, and the feeds would have sufficient time to take root before winter. If only rye was wanted, he would eat it with sheep in the spring or during the winter. But the stalks must, he says, stand, for the corn to ripen after the rye is sown; and the corn ought to hang on the stalk till it is hard. In America, it is often December before the white corn can be pulled, or September for the yellow corn: if it is pulled before it is hard, and the cob is perfectly dry, it will mould and spoil, and the corn will be apt to rot, therefore great care should be taken not to pull it too soon.

This sort of corn is, it is said, given to horses, cattle, and hogs, without shelling, and only husked in the ear; but when given to fowls, or intended for sale, it is rubbed off by burning a cob in the fire till hard, and then rubbing the corn with

with it. It is a sort of grain which is sometimes given to pigs, but more frequently when ground to fowls. Count Rumford has shewn in his Essay on Food, that this is perhaps the most nutritious grain, except wheat, either as human sustenance, or as provender for brute animals. See MAIZE.

ZEAL, in *Geography*. See ZIA.

ZEAGONG, a town of Birmah; 12 miles N.N.W. of Raynangong.

ZEAL, ΖΕΛΟΣ, Ζηλος, the exercise of a warm animated affection, or passion, for any thing.

Some will have jealous *zeal* to be properly a mixed or compound sensation, where one affection is raised or inflamed by another. On these principles, jealousy may be defined an affection arising from love and indignation, which cannot bear a thing to be given to another, that a person desires for himself, or one whom he loves and favours. Others make it consist in an eager study, or desire, to keep any thing inviolate; or a fervour of mind, arising from an indignation against those who abuse or do evil to a person beloved.

The Greek philosophers make three species of *zeal*. The first, of *envy*; the second, of *emulation*, or imitation; the third, of *piety*, or devotion; which last makes what the divines call *religious zeal*.

Josephus speaks much of a party, or faction, called the *Zealots*, or *Zealots*, which arose among the Jews during the war with Vespasian and Titus. Lib. xiv. cap. 6. Antiq. and lib. iv. cap. 12. de Bello Judaico.

ZEALAND, or ZEELAND, or *Seeland*, (in Danish *Sjeland*), in *Geography*, the largest island belonging to the kingdom of Denmark, bounded on the north by the Scagerrack, on the east by the Sound, on the south by the Baltic, and on the west by the Great Belt; about 65 miles in length from north to south, and where widest 60 from east to west, though in some parts scarcely 30, and in no part above 20 miles from the sea: reckoned about 700 miles in circumference. The coast is much interfeeted with large bays; and within the country are several lakes, which, as well as the rivers, abound in fish. The country is pleasant; the soil is generally fertile, and produces corn, chiefly barley and oats, more than sufficient for the inhabitants, with excellent pastures; and in most parts is plenty of wood, except towards the centre of the island, where the inhabitants generally use turf for fuel. The fields are separated by mud-walls; the cottages are of brick or white-washed; sand-hills are sometimes destructive on the coast; and the best protection from their ravages, says Cateau, is the *elymus anemaria*. Copenhagen is the capital. N. lat. 55° 2' to 56° 6'. E. long. 10° 58' to 12° 40'. See DENMARK.

ZEALAND, *State of*, one of the former UNITED Dutch States, and now part of the recently established kingdom. It consists of islands which are formed by those branches and outlets of the Scheldt, called *Zeeuwfche Stromen*, or *Sea Streams*; on the north it is bounded by Holland, eastward by Brabant, southward by Flanders, and westward by the North sea: its name sufficiently indicates its natural position and situation. The islands of Walcheren and Schouwen, on the western coast, are defended against the violence of the sea, by downs or sand-hills, and on the other sides, like the rest of the islands of Zealand, by vast dykes, which, at the bottom, have a breadth of 25 German ells, and at the top are so wide, that two carriages may pass abreast: the height is also proportioned to their thicknels; notwithstanding which, in high tides and stormy weather, the waves in many places force a passage, or even flow over them: the first formation of these dykes must have been attended with

immense expence, the very repair and maintenance of them requiring large sums. Emannul van Meteren, in the sixteenth book of his Commentaries, says, and confirms it by the attestations of the workmen employed in them, that the dykes in this province alone, if placed in one direction, would form a length of 40 miles, each mile to be reckoned at 1400 rods, and that the expence of one rod with another was a pound Flemish, or six Dutch guilders. Thus the charge of the outward dykes taken together amounts to 340,000*l.* sterling. Though the inhabitants of the other provinces, and foreigners in general, complain of the air being heavy, disagreeable, and unhealthy, yet no people look better, or enjoy a more confirmed state of health, than the natives who are born and bred up in it. The soil too is very fruitful, and famed for its excellent wheat, as likewise for madder, the cultivation of which furnishes out great employment for the inhabitants of Zealand: it abounds also in good fruits, and its rich pastures are covered with flocks of fine sheep. The waters around the islands supply them with plenty of fish, particularly with oysters, lobsters, and mullets, of an uncommon size and goodness. Zealand enjoys likewise an affluence of all kinds of provisions, but fuel is very scarce there, especially turf, which, being brought from other provinces, bears a high price; great quantities of English coals are used here. In the whole province are 121 towns and villages, some of which are very large. The inhabitants are reckoned the most wealthy in all the Netherlands, which is, in a great measure, owing to their traffic by sea, and for this, indeed, they have every convenience that can be desired. (See HOLLAND.) The right bank of the Scheldt, called the East Scheldt, divides this province into two quarters, *viz.* into that on the east and that on the west of the said river. The quarter on the West Scheldt is composed of five islands, *viz.* Walcheren, South Beveland, North Beveland, Wolferdyk, and St. Joostland. The quarter of the East Scheldt contains four islands, *viz.* Schouwen, Duiveland, Tholen, and St. Philip's Land.

ZEALAND, *New*, two islands in the South Pacific ocean, first discovered by Tasman, a Dutch navigator. In the year 1642, he traversed the eastern coast from lat. 34° to 43°, and entered the strait called Cook's Strait; he was attacked by the natives soon after he came to an anchor in the place, to which he gave the name of Murderer's Bay, and never went on shore: he gave the country the name of Staaten Land, in honour of the states-general, and it is now generally distinguished in our maps and charts by the name of New Zealand. As the whole of this country, except that part of the coast which was seen by Tasman from on board his ship, had from his time to the voyage of the Endeavour, in the year 1770, remained altogether unknown, it was by many supposed to be part of a southern continent. It is, however, now known to consist of two large islands, divided from each other by a strait or passage, which is about four or five leagues broad. The northernmost of these islands is called by the natives *Eaheinomauwe*; and the southernmost *Tovy*, or *Tavai Poenamoo*. The latter is the name of a lake, and signifies the water of green talc. This lake is situated in the northern part of the island, and the country adjoining it only is known to the natives under this name. From my observation, says captain Cook, and from other information, it appears to me, that the New Zealanders must live under perpetual apprehensions of being destroyed by each other; there being few of their tribes that have not, as they think, sustained wrongs from some other tribe, which they are continually upon the watch to revenge; and perhaps the desire of a good meal may be no small incitement. They will even prefer their enmity from father to

son, and the son never loses sight of an injury done to his father. The method of executing their horrible designs is by stealing upon their enemies in the night; and if they find them unguarded, (which however is but seldom the case,) they kill every one indiscriminately, not even sparing the women and children: the dead bodies they either devour on the spot, or carry them home for that purpose. If they are discovered before they can execute their bloody purpose, they generally steal off; and sometimes are pursued and attacked by the other party in their turn. They never give quarter, or take prisoners. This perpetual state of warfare renders them so circumspect, that they are never off their guard either by night or day. According to their system of belief, the soul of the man whose flesh is devoured by the enemy is doomed to perpetual fire; while the soul of him whose body has been rescued, as well as those who die a natural death, ascend to the habitation of the gods. They do not eat the bodies of their friends who have been rescued. Their common method of disposing of the dead is by burying in the earth; but if they have more of their slaughtered enemies than they can eat, they throw them into the sea. They have no such things as morals, or other places of public worship; nor do they ever assemble together with this view. But they have priests who alone address the gods in prayers for the prosperity of their temporal affairs. Whatever the principles of their religion may be, they are strongly inculcated from their infancy: of this I had a remarkable instance in the youth who was first destined to accompany Taweharooa. He refrained from eating the greatest part of the day on account of his hair being cut; though every method was tried to induce him to break his resolution; and he was tempted with the offer of such victuals as he was known to like best. He said, that if he ate any thing that day, the Eatooa would kill him: however, towards evening the cravings of nature got the better of the precepts of religion, and he ate, though but sparingly. Notwithstanding the divided and hostile state in which the New Zealanders live, travelling strangers who come with no ill design are well received, and entertained during their stay; which, however, it is expected will be no longer than is requisite to transact the business that they come upon. Polygamy is allowed amongst the people: the women are marriageable at a very early age; and one who is unmarried is but in a forlorn state: she can with difficulty get a subsistence, and is in a great measure without a protector, though in continual want of a powerful one. The New Zealanders seem to be perfectly satisfied with the little knowledge they are masters of without attempting in the least to improve it; nor are they remarkably curious either in their observations or inquiries. Tovy Poenamoo is for the most part a mountainous, and to all appearances a barren country, and thinly peopled. Eaeleinomauwe has a much better appearance; it is indeed not only hilly, but mountainous, yet even the hills and mountains are covered with wood, and every valley has a rivulet of water; the soil in these valleys and in the plains, of which there are many that are not overgrown with wood, is in general light, but fertile, and fit for every kind of European grain, plants, and fruit. From the vegetables that were found here, there is reason to conclude the winters are milder than in England, and the summer not hotter, though it was more equally warm: dogs and rats are the only quadrupeds that were seen, and of the latter only a few. The inhabitants breed the dogs for the sole purpose of eating them. There are seals and whales on the coast, and a sea-lion was once seen. The birds are, hawks, owls, quails; and there are song-birds, whose note is wonderfully melodious. There are ducks and

snags of several sorts, not unlike those of Europe; and the gannet, which is exactly the same. The sea-coast is visited by albatrosses, sheer-waters, pintados, and penguins. The insects are, flesh-flies, beetles, butter-flies, sand-flies, and musquitoes; and the neighbouring sea abounds with fish, which are equally delicious and wholesome food. Captain Cook seldom came to anchor but they caught enough, with hook and line only, to supply the whole ship's crew; and when they fished with nets, every melf in the ship, except those who were too indolent, falted as much as supplied them when at sea some time after. The fish was not less various in kind than plentiful in quantity; there were many sorts they had never before seen, but the sailors readily gave names to all of them. The highest luxury which the sea afforded was the lobster, or sea cray-fish. Here were also several species of the skate, or stingray: soles, flounders, and shell-fish, were abundant. This country abounds with forests filled with very large, freight, and clean timber. There is one tree about the size of an oak, which was distinguished by a scarlet flower, that appeared to be composed of several fibres; the wood of which was hard and heavy, excellently adapted to the use of the mill-wright: and another which grows in swampy ground, very straight and tall, bearing small bunches of berries, and a leaf resembling that of a yew-tree; the wood of which is very tough, and thick enough to make masts of any size: about 400 species of plants were found, all of which are unknown in England, except garden night-shade, fow-thistle, two or three kinds of fern, and one or two sorts of grass. They found wild celery, and a kind of cresses, in great abundance on the sea shore, and of eatable plants raised by cultivation, only coccos, yams, and sweet potatoes. There are plantations of many acres of these yams and potatoes. The inhabitants likewise cultivate the ground; and the Chinese paper mulberry-tree is to be found, but in no abundance. There is only one shrub or tree in this country which produces fruit, and that is a kind of a berry almost tasteless; but they have a plant which answers all the uses of hemp and flax. There are two kinds of this plant, the leaves of one of which are yellow, and the other deep-red, and both of them resemble the leaves of flags; of these leaves they make lines and cordage, and much stronger than any thing of the kind in Europe. These leaves they likewise split into breadths, and tying the slips together form their fishing-nets. Their common apparel by a simple process is made from leaves, and their finer by another preparation is made from the fibres. This plant is found both on high and low ground, in dry mould, and deep bogs; but as it grows largest in the latter, that seems to be its proper soil.

The men of this country are as large as the largest Europeans. Their complexion is brown, but little more so than that of a Spaniard. They are full of flesh, but not lazy or luxurious, and are stout and well shaped. The women possess not that delicacy which distinguishes the European ladies, but their voice is singularly soft, which, as the dress of both sexes is similar, chiefly distinguishes them from the men. The men are active in a high degree; their hair is black, and teeth are white and even. The features in both sexes are regular; they enjoy perfect health, and live to a very advanced age; they are of the gentlest dispositions, and treat each other with the utmost kindness, but they are perpetually at war, every little district being at enmity with all the rest, and towards their enemies they are implacable, never giving quarter. They have neither black cattle, sheep, hogs, nor goats; so that their chief food being fish, and that not at all times to be obtained, they are

in danger of dying through hunger: they have a few, and but a very few dogs; and when no fish is to be got they have only vegetables such as fern-root, clams, yams, and potatoes to feed on; and if by any accident these fail them, their situation must be deplorable. This will account for their shocking custom of eating the bodies which are slain in battle, for he who fights through mere hunger will not scruple to eat the adversary he has killed. The inhabitants of New Zealand are modest and reserved in their behaviour and conversation. The women, indeed, were not dead to the softer impressions; but their mode of consent was, in their idea, as harmless as the consent to marriage with us, and equally binding for the stipulated time. If any of the English addressed one of their women, he was informed, that the consent of her friends must be obtained, which usually followed on his making a present. This done, he was obliged to treat his temporary wife at least as delicately as we do in England. They anoint their hair with oil, melted from the fat of fish or birds. The poorer people use that which is rancid, so that their smell is very disagreeable: but those of superior rank make use of that which is fresh. They wear combs, both of bone and wood, which are considered as an ornament when stuck upright in the hair. The men tie their hair in a bunch on the crown of their head, and adorn it with the feathers of birds, which they likewise sometimes place on each side of the temples. They commonly wear short beards; the hair of the women sometimes flows over the shoulders, and sometimes is cut short. Both sexes, but the men more than the women, mark their bodies with black stains called *Amoco*; in general the women stain only the lips, but sometimes mark other parts with black patches; the men, on the contrary, put on additional marks from year to year, so that those who are very ancient are almost covered. Exclusive of the *Amoco*, they mark themselves with furrows: these furrows make a hideous appearance, the edges being indented, and the whole quite black. The ornaments of the face are drawn in the spiral form, with equal elegance and correctness, both cheeks being marked exactly alike, while the painting on their bodies resembles fillagree work, and the foliage in old chased ornaments, but no two faces or bodies are painted exactly after the same model. These Indians likewise paint their bodies, by rubbing them with red ochre, either dry, or mixed with oil. Their dress is formed of the leaves of the flag, split into slips, which are interwoven, and made into a kind of matting, the ends which are seven or eight inches in length hanging out on the upper side. One piece of this matting, being tied over the shoulders, reaches to the knees; the other piece, being wrapped round the waist, falls almost to the ground. These two pieces are fastened to a string, which, by means of a bodkin of bone, is passed through, and tacks them together. The men wear the lower garment only at particular times. What they consider as the most ornamental part of their dress is the fur of dogs, which they cut into stripes, and sew on different parts of their apparel. As dogs are not in plenty, they dispose these stripes with great economy. They have a few dresses ornamented with feathers; and one man was seen covered wholly with the red feathers of the parrot. The women never tie their hair on the top of their head, nor adorn it with feathers; and are less anxious about dress than the men. Their lower garment is bound tight round them, except when they go a-fishing, and then they are careful that the men shall not see them. The ears of both sexes are bored, and the holes stretched so as to admit a man's finger. The ornaments of their ears are, feathers, cloth, bones, and sometimes bits of wood: a great

many of them use nails, which were given them by the English for this purpose; and the women sometimes adorn their ears with the white down of the albatross, which they spread before and behind the hole, in a large bunch. They likewise hang to their ears by strings, chiefs, bodkins, the teeth of dogs, and the teeth and nails of their deceased friends. The arms and ancles of the women are adorned with shells and bones, or any thing else through which they can pass a string. The men wear a piece of green talc, or whalebone, with the resemblance of a man carved on it, hanging to a string round the neck.

The houses are from sixteen to twenty-four feet long, ten or twelve wide, and six or eight in height. The frame is of slight sticks of wood, and the walls and roof are made of dry grafs, pretty firmly compacted. Some of them are lined with bark of trees, and the ridge of the house is formed by a pole, which runs from one end to the other. The door is only high enough to admit a person crawling on hands and knees; and the roof is sloping. There is a square hole near the door, serving both for window and chimney, near which is the fire-place. A plank is placed near the door, adorned with a sort of carving, and this they consider as an ornamental piece of furniture. The side walls, and roof, projecting two or three feet beyond the walls at each end, form a sort of portico, where benches are placed to sit on. The fire is made in the middle of a hollow square in the floor, which is inclosed with wood or stone. They sleep near the walls, where the ground is covered with straw for their beds. Besides the fern-root, which serves them for bread, they feed on albatrosses, penguins, and some other birds. Whatever they eat is either roasted or baked, as they have no vessels in which water can be boiled. No plantations of coconos, potatoes, and yams, were seen to the southward, though there were many in the northern parts. The natives drink no other liquor than water, and enjoy perfect and uninterrupted health. When wounded in battle, the wound heals in a very short time, without the application of medicine; and the very old people carry no other marks of decay about them than the loss of their hair and teeth, and a failure of their muscular strength, but enjoy an equal share of health and cheerfulness with the youngest.

The canoes of this country are not unlike the whale-boats of New England, being long and narrow. Those of the larger sort seem to be built for war, and will hold from 30 to 100 men; one of these measured near seventy feet in length, six in width, and four in depth. It was sharp at the bottom, and consisted of three lengths, about two or three inches thick, and tied firmly together with strong plaiting: each side was formed of one entire plank, about twelve inches broad, and about an inch and a half thick, which were fitted to the bottom part with equal strength and ingenuity. Several thwarts were laid from one side to the other, to which they were securely fastened, in order to strengthen the canoes. These vessels are rowed with a kind of paddles, between five and six feet in length, the blade of which is a long oval, gradually decreasing till it reaches the handle; and the velocity with which they row with these paddles is surprising: their sails are composed of a kind of mat or netting, which is extended between two upright poles, one of which is fixed on each side. Two ropes fastened to the top of each pole serve instead of sheets. The vessels are steered by two men, having each a paddle, and sitting in the stern; but they can only fail before the wind, in which direction they move with considerable swiftness.

These Indians use axes, adzes, and chisels, with which last they likewise bore holes. The chisels are made of jasper, or of the bone of a man's arm; and their axes and adzes of a hard black stone. Their tillage of the ground is excellent, owing to the necessity they are under of cultivating, or running the risk of starving. A long narrow flake, sharpened to an edge at bottom, with a piece fixed across, a little above it, for the convenience of driving it into the ground with the foot, supplies the place both of plough and spade. The soil being light, their work is not very laborious, and with this instrument alone they will turn up ground of six or seven acres in extent. Their fish-hooks are of shell or bone; and they have baskets of wicker-work to hold the fish. Their warlike weapons are, spears, darts, battle-axes, and the patoo-patoo, in which they chiefly confide. This is fastened to their wrists by a strong strap, lest it should be wrenched from them, and the principal people generally wear it sticking in their girdles, considering it as a military ornament and part of their dress, like the poinard of the Asiatic and the sword of the Europeans. The spear, which is pointed at each end, is about twenty-six feet in length, and they hold it in the middle, so that it is difficult to parry a push from it. Whether they fight in boats or on shore, the battle is hand to hand; their contests must be bloody. The war-dance consists of a great variety of violent motions and hideous contortions of the limbs, during which the countenance and tongue perform their parts. This horrid dance is always accompanied by a song, every strain of which terminates with a deep and loud sigh.

The employment of the men is supposed to consist in cultivating the ground, making nets, catching birds, and fishing; while the women are engaged in weaving cloth, procuring fern-roots and shell-fish, and dressing food. With regard to religion, they acknowledge one superior being, and several subordinate. Their mode of worship could not be learned, nor was any place proper for that purpose seen. There was indeed a small square area, encompassed with stones, in the middle of which hung a basket of fern-roots on one of their spades. This they said was offered to the gods, in the hope of a plentiful crop of provision. The inhabitants of the southern district said they disposed of their dead by throwing them into the sea; but those of the north said they buried them in the ground: captain Cook's crew, however, saw not the least sign of any grave, or monument; but the body of almost every inhabitant bore the marks of wounds which they had given themselves, in token of grief for the loss of their friends and relations. Some of these scars were newly made, which is a proof that their friends had died while the ship's crew were there, yet no one saw any thing like a funeral, as the islanders conceal every thing respecting the dead with the utmost caution. A great similitude was observed between the dress, furniture, boats, and nets of the New Zealanders, and those of the inhabitants of the South Sea islands, which furnish a strong proof that the ancestors of both were natives of the same country. The language of New Zealand and Otaheite is radically the same; and that of the northern and southern parts differs chiefly in the pronunciation. S. lat 34° to 48°. W. long. 181° to 194°. Cook's Voyages by Hawkefworth, vol. iii.

ZEAMAH, a river of Algiers, which runs into the Mediterranean, 6 miles S.S.E. of Cull.

ZEAN, a town of Hindoostan, in Doobab; 20 miles S. of Canoge.

ZEB, or ZIB, a town of Syria, near the sea-coast, an-

ciently called Achsaph, Achzib, and Ecdippa; 9 miles from Acre.

ZEBAIDE, a town of Persia, in the province of Farfistan; 80 miles E. of Schiras.

ZEBDAINEH, a village of Syria, built on the spot where it is said by some that Cain slew his brother Abel; 14 miles N.W. of Damascus.

ZEBE, or ZAAB, in *Ancient Geography*, a town which once formed a part of Mauritania Sitifensis; it was situated at the foot of the chain of mount Atlas.

ZEBEE, in *Geography*, a river of Abyssinia, which runs into the Indian sea.

ZEBEER, a town of Arabian Irak; 12 miles W. of Bassorah.

ZEBEN. See SZEBEN.

ZEBET, a word used by some of the chemical writers to express dung.

ZEBID, in *Geography*, a city of Arabia, in the province of Yemen. Zebid was once the place of a sovereign's residence, and the most commercial city in all Tehama; but since the harbour of Ghalefka was choked up, its trade has been transferred to Beit el Fakih and Mocha, and this city now retains nothing but the shadow of its former splendour. Viewed from a distance, it appears to some advantage, by means of the mosques and kubbets, of which it is full. Several of those mosques were erected by different pachas, who resided here during the short period while this part of Arabia was in the possession of the Ottoman Porte. Zebid had once eight gates; of these only five are now standing, and the river is gradually breaking down a part of them. The walls of the old city are demolished, and the very ruins are sold by poor people, who gather out the stones, and sell them for building new houses. The present buildings occupy about one half of the ancient extent of the city. Zebid is still distinguished for an academy, or university, for the Sunais, as that of Damar is for the Scidites, in which the youth of Tehama, and a part of Yemen, study such sciences as are cultivated among the Mussulmen. This is besides the feat of a dola, a musti, and three cadis; 52 miles N. of Mocha. N. lat. 14° 12'. E. long. 43° 15'.

ZEBIO, a mountain of Italy, which sometimes emits flames; 6 miles S. of Modena.

ZEBLICCIUM MARMOR, in *Natural History*, a name given by several authors to a soft green marble, variegated with black and white; and though the authors who have described it have not observed it, yet it no way differs from the white ophites of the ancients. See OPHITES.

ZEBOIM, in *Ancient Geography*. See SEBOIM.

ZEBRA, in *Zoology*. See EQUUS ZEBRA.

ZEBU, a name given by M. de Buffon to a variety of the bos taurus of Linnæus, or bison of other writers, or the camel. This variety resembles the Indian ox, or bos Indicus, but is extremely small, being found in some parts of India of a size scarcely larger than a great dog. In colour it differs like the common cattle, being either grey, brown, white, &c., or variously spotted. The Indian ox, which is found in many parts of India, as well as in the Indian and African islands, and particularly in Madagascar, is of a reddish colour, of a very large size, and is distinguished by a very large protuberance over the shoulders.

ZEBU, in *Geography*. See SIBU.

ZEBULUN, or ZABULON, in *Scripture Geography*, one of the Jewish tribes in Lower Galilee, on the S. of the tribes of Apher and Naphtali, having the Mediterranean on the W., the sea of Galilee on the E.; separated on the N. from Apher by the river Jephthael, and on the S. from Issa-

char by that of Kishon. Its ports, on account of its vicinity to the sea, were numerous, and its commerce extensive. Its cities were, Zebulun the capital, Bethsaida, Magdalen, Joppa, Jotapa, Cinnereth, (since Tiberias, on the lake of that name,) Cartha, Bethulia, Rimmon, Dothaire, Danna, Sommeron, Tabor, both the city and mount, Sopha, Saffa or Siporis, Nazareth, Cana the lesser, commonly called Cana of Galilee, Iconium, and Sicaminum or Porphrem, anciently Hiepha, or Ceipha, situated northwards at the foot of mount Carmel.

ZEBULUN, or *Zabulon*, the capital of the fore-mentioned tribe, situated on the Mediterranean, near the mouth of the Jephthael, and once styled Zabulon Andron, or of men, on account of its extraordinary populousness. It was adorned with fine buildings, after the manner of Tyre, Sidon, and Berytus, and much admired on that account by Cestius, the Roman general, who nevertheless took, plundered, and burnt it to the ground. In the early ages of Christianity it was the see of a bishop, but now it is a poor place, in ruins.

ZECHARIAH, or the *Prophecy of Zechariah*, in *Biblical History*, a canonical book of the Old Testament.

Zechariah was contemporary with Haggai, and prophesied in the second year of Darius Hystaspes. The design of the first part of this prophecy is the same with that of Haggai, viz. to encourage the Jews to go on with rebuilding of the temple, by giving them assurance of God's assistance and protection: from whence the author proceeds to foretel the glory of the Christian church, the true temple of God, under its great high priest and governor, Jesus Christ, of whom Zerubbabel and Joshua the high priest were figures. The latter part of the prophecy, from chap. ix., probably relates to the state of the Jews under the Maccabees, and then foretels the rejection of the Messiah, and some remarkable incidents that should happen to them in the latter ages of the world.

Mr. Mede, and some other learned men, think, that the 9th and following chapters of Zechariah are parts of the prophecy of Jeremiah.

ZECHIN, or **ZECCHINO**, in *Commerce*. See **SEQUIN**.
ZECHINI, in *Geography*, a small island in the Grecian Archipelago; 2 miles S.E. of Stanchio. N. lat. 36° 43'. E. long. 26° 51'.

ZECHLIN, a town of Brandenburg, in the mark of Prenzitz; 9 miles E. of Wittstock.

ZEDIC, a town of Africa, capital of a district in Tripoli, situated in a bay of the Mediterranean, called the bay of Zedic; 150 miles E.S.E. of Tripoli.

ZEDLISCHT, a town of Bohemia, in the circle of Pilsen; 5 miles N.W. of Hayd.

ZEDOARY, **ZEDOARIA**, or *Kempferia Rotunda* of Woodville, or *Curcuma Zerumbet* of Dr. Roxburgh, in the *Materia Medica*, a medicinal root, belonging to a plant growing in the East Indies (the *amomum Jacqo nudo*, *spica laxa truncata*, of Berg. Mat. Med.), whose leaves are like those of ginger, only longer and broader.

The *Curcuma Zedoaria* of Dr. Roxburgh, with small bulbs, and with the long palmate tubers inwardly yellow, leaves broad lanceolar, subsessile on their sheaths, sericeous underneath, and the whole plant green, is the *AMOMUM Zedoaria* of Linnæus and Willdenow; which see. It is a native of various parts of India; flowers during the hot season, April and May, when the plant is destitute of leaves: soon after they appear. The dry root, it is said, agrees pretty well with the drug known in England by the name of zedoaria rotunda. The Sanskrit name implies that the drug is used as an antidote to poison.

The *Curcuma Zerumbet* of Roxburgh, with small bulbs, and palmate tubers pale straw-colour; leaves green-petioled, broad-lanceolar, with a purple cloud down the middle; and flowers shorter than their bractæas, is the *AMOMUM Zerumbet* of Retzius; which see. This is a native of various parts of India, and its flowering-time the hot season, before the leaves appear. The pale colour of the roots, crimson coma, and ferruginous mark down the centre of the leaves, which is a constant mark in this elegant species, readily point it out from every other. The dry root appears to be the zedoaria of the shops in England. See *Asiatic Researches*, vol. ii. p. 332—334.

The root is brought over in oblong pieces, about the thickness of the little finger, and two or three inches in length; or in roundish ones (the *zerumbet* of the Paris Pharmacopœia), about an inch in diameter; it is of an ash colour on the outside, and white within. The difference of these, in strength, if any, is very inconsiderable, and therefore the college allows both to be used indiscriminately.

This root has an agreeable camphoraceous smell, and a bitterish aromatic taste. It impregnates water with its smell, a slight bitterness, a considerable warmth and pungency, and a yellowish-brown colour: the reddish-yellow spirituous tincture is in taste stronger, and in smell weaker, than the watery. In distillation with water, it yields a thick, ponderous essential oil, smelling strongly of the zedoary, in taste very hot and pungent: the decoction, thus deprived of the aromatic matter, and concentrated by inspissation, proves weakly and disagreeably bitter and sub-acrid. A part of its odorous matter rises also in the inspissation of the spirituous tincture; the remaining extract is a very warm, not fiery, moderately bitter aromatic, in flavour more grateful than the zedoary in substance.

Zedoary-root is a very useful warm stomachic; and has been commended in colics and hysterical affections, for promoting the menses, &c. It has been employed by some as a succedaneum to gentian root; but from the above analysis it appears to be not entirely similar to that simple bitter; its warm aromatic part being the prevailing principle, in virtue of which its spirituous extract (the most elegant preparation of it), has been made an ingredient in the cordial confection of the London Pharmacopœia. Lewis's Mat. Med.

Cartheuser, who ascribes its virtues to a camphoraceous volatile oil, considers it as a general remedy for most of the chronic diseases with which human nature is affected; but as the camphor contained in it can avail but little, and its effects as a bitter or aromatic are so very inconsiderable, this root is now deemed to possess very little medicinal power, and might be safely expunged from the *matæria medica*. Cullen. Woodville.

The zedoary wash, which is a cooler yellow than saffron, though full as bright, and valuable for many purposes in painting with water-colours, may be prepared by boiling an ounce of the root in a quart of water, till the water is sufficiently tinged to make a stain on paper, of a full yellow colour; and straining the liquor through a linen filter. This wash may be dried in shells, and will again dissolve and spread kindly with the addition of water.

ZÉEDLITZ, in *Geography*, a town of Silesia, in the principality of Neisse; 3 miles N. of Ottmichau.

ZEFERDEN. See **STUFFERDAM**.

ZEFR, a word by which some of the chemical authors express pitch.

ZEFRIÒ, in *Geography*, a mountain of Naples, in Calabria Ultra; 10 miles N.E. of Bova.

ZEGEDIN, or **SZEGED**, a town of Hungary, near the conflux of the rivers Maros and Theisse. It is strong, and a place

a place of some trade, particularly in cattle. In the year 1503, all its defence was a moat and rampart; but falling some time after into the hands of the Turks, they erected a brick fort. In 1686, the Imperialists dispossessed the Turks of it; 68 miles N. of Belgrade. N. lat. $46^{\circ} 15'$. E. long. $19^{\circ} 56'$.

ZEGGO, a town of Africa, in the country of Melli, in the road from Kong to Cahna; 100 miles N.N.W. of Malel. N. lat. 14° . E. long. 8° .

ZEGHAMA, a town of Dar-Fur; 60 miles N. of Cobbe.

ZEGHEN, a town of Fezzan; 65 miles N. of Mourzouk.

ZEGI, **ZAGI**, a word used by Avicenna and others to express all the several vitriolic minerals. See **CHALCITIS**, and **COLCOTHAR**.

ZEGMA, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates, opposite to Romkala.

ZEGUTI, a town of Imiretia; 20 miles S.W. of Cotatis.

ZEGZEG, a city of Africa, and capital of a country of the same name, situated to the east of Agades; 370 miles N.N.E. of Cahna. N. lat. $20^{\circ} 45'$. E. long. 16° .

ZEHDENICK, a town of Brandenburg, in the Ucker Mark, on the Havel. In it is a convent for ladies of noble descent, consisting of a domina and six sisters. It carries on a large trade in wood and corn: in the pastures, near the town, iron-ore is met with in great abundance, and accordingly there is a mill here for that purpose, which is driven by the Havel. At this place likewise is a foundery, where bombs, grenades, bullets, mortars, pots, weights, and even small cannon are cast; 28 miles S.S.W. of Prenzlau. N. lat. $52^{\circ} 58'$. E. long. $13^{\circ} 22'$.

ZEH DIN, a town of Brandenburg, in the New Mark; 40 miles E. of Oderberg.

ZEHERECH, a word used by some of the chemical writers to express flowers of bræs.

ZEHISTA, in *Geography*, a town of Saxony, in the margravate of Meissen; 3 miles S. of Pirna.

ZEHRENDORF, a town of Brandenburg, in the Middle Mark; 3 miles S. of Zossen.

ZEIDURE, a district of Algiers, between Tremecen and Oran.

ZEIL, a town of Bavaria, in the bishopric of Bamberg; 12 miles W.N.W. of Bamberg. N. lat. $50^{\circ} 1'$. E. long. $16^{\circ} 40'$.—Also, a town and castle of Germany, which gives name to a county; 4 miles N. of Leutkirch.

ZEILA, or **ZELLA**, or **Sejla**, a sea-port town of Africa, in the kingdom of Adel, situated on the coast of the Arabian sea, at the mouth of the Hanazo, or Hawah, which forms a bay, called the Bay or Gulf of Zeila. It receives a governor from the dola of Mocha. N. lat. $10^{\circ} 45'$. E. long. $44^{\circ} 20'$.

ZEILSHEIM, a town of the duchy of Wurzburg; 4 miles N. of Volkach.—Also, a town of the duchy of Wurzburg; 4 miles E.N.E. of Arnstein.

ZEINDEROOD, or **ZENDEROOD**, a river of Persia, in the province of Irak, which has its source in the Kohizard, or Yellow mountain, where an aqueduct may yet be seen, by which Abbas the Great attempted to unite its waters with those of the Karoon. The Zeinderood passes through the city of Ispahan, and is said to be absorbed in the irrigation of the neighbouring territory, or to lose itself in a lake, 15 miles S.W. of Laurian. On this river are three bridges, two of which are in good repair; particularly that of the Char Baug (four gardens), so called

from its connecting the upper and lower Char Baug, the name given to a spacious avenue, which runs from the royal square to the foot of the mountains E. of Ispahan.

ZEISELMAN, a town of Austria; 3 miles E. of Tulln.

ZEISPERG, a town of Austria; 3 miles E.N.E. of Crems.

ZEITHAYN, a town of Saxony, in the margravate of Meissen, famous for a pleasure-camp which king Augustus II. made there, in 1730, at the expence of five millions of six-dollars. On the spot which was used for this camp, and the exercising of the army, are erected six large pyramids; and medals have likewise been struck upon it, and a grand representation thereof engraved on copper; 8 miles W.N.W. of Grossenhayn.

ZEITLOSS, a town of the duchy of Wurzburg, on the river Sinn; 10 miles N. of Gmunden.

ZEITON, a town of European Turkey, in Thessaly, on a gulf to which it gives name. Here are about 400 Christian families, but the greater part of the inhabitants consists of Turks; 48 miles S.S.E. of Larissa. N. lat. $39^{\circ} 6'$. E. long. $22^{\circ} 58'$.

ZEITON, a gulf or bay of the Egean sea, on the E. coast of Thessaly, N.W. of the island of Negroponte.

ZEITOON, a town of Persia, in the province of Fars or Faristan, containing about 2000 inhabitants, and situated in a pleasant valley, fertilized by both the branches of the river Tab, which here form a junction. Zeitoun is about fifteen miles distant from Behaban, the capital of the mountainous district of Khogilsea, which extends from the valley of Ram Hormuz to the vicinity of Kazeroon.

ZEITOUN, a town of Asiatic Turkey, in the government of Sivas, on the Kizilermak; 33 miles W. of Samfoun.

ZEITRABRA, a term used by some of the chemists to express any thing that is fluxile.

ZEITZ, in *Geography*, a town of Saxony, in the bishopric of Naumburg, anciently the see of a bishop, founded by the emperor Otho I. afterwards transferred to Naumburg, after this town had been sacked and almost destroyed by the Vandals in the year 982; 15 miles E.S.E. of Naumburg. N. lat. $51^{\circ} 3'$. E. long. $12^{\circ} 2'$.

ZEKELHEIB, a town of Hungary; 8 miles N.N.W. of St. Job.

ZELA, a town of Persia, in the province of Segestan; 25 miles S.W. of Ferah.

ZELA, **ZIELA**, or **Zeleja**, in *Ancient Geography*, a town of Thrace, afterwards called Flaviopolis.—Also, a town of Asia, in Cappadocia Pontus, near the Lycus. It was celebrated by the defeat of Triarius, the Roman general, and afterwards by that of Pharnaces. Here was a famous temple, represented upon some medals, consecrated to the goddess Anahis, a Persian divinity, whose pontiff was very powerful under ancient kings; but in process of time his authority and revenues were diminished. The town and the ministers of the temple were dependent on Pithodiris, who possessed a part of the territory; other parts were ceded to the pontiffs of Zela and Comanes, and the rest was annexed to the Roman province. According to Strabo, Zela and its territory were situated to the left of the river; the sacred lands of the temple, and the domains of the pontiff, were in the environs of the town. He adds that it was fortified and built in the retrenchment of Semiramis; and in the first times it had only some houses near the temple; but Pompey made it a town.

ZELAH, or **SELA**, a city of Benjamin (Josh. xviii. 28.), where Saul was buried in the tomb of his father, Kish. 2 Sam. xxi. 14.

ZELAN, in *Geography*, a mountain in the county of Tyrol; 20 miles N.E. of Trent.

ZELANDY, a small island in the East Indian sea, near the W. coast of Sumatra. N. lat. $0^{\circ} 53'$. E. long. $98^{\circ} 14'$.

ZELANICA, a cape on the N. coast of Nova Zembla. N. lat. 78° . E. long. $77^{\circ} 24'$.

ZELATE, a town of the country of Candahar; 30 miles N.E. of Candahar.

ZELBL. See SCHELEBY.

ZELEEFA, a town of Africa, in the country of Tunis; 10 miles S.E. of Cairoan.

ZELEH, a town of Asiatic Turkey, in the government of Sivas, anciently a town of Pontus, and called Zela. Near this place the Romans, under Triarius, were defeated by Mithridates; and Pharnaces, son of Mithridates, was afterwards defeated by Julius Cæsar; 21 miles W.S.W. of Tocat. See ZELA.

ZELEIA, in *Ancient Geography*, a town built, according to Homer, at the foot of mount Ida. It was watered by the Tarsius, and had to the S. the lake Aplnitis. According to Strabo, it had also in ancient times an oracle, but in his time it was not consulted.

ZELEM, in the *Materia Medica of the Ancients*, a name given by Avicenna and others to a fruit common in Africa in their time, and much esteemed by the people of that country, and called there by some *piper nigrorum*, the black people's pepper, or negro-pepper.

Avicenna tells us, that the zelem was a fattish seed, of the size of a chick, and of a high flavour, in colour yellow on the outside, and white within, and that it was brought from Barbary.

He adds, that there was another plant, properly called *fulful alsuaden*, that is, *piper nigrorum*. This, he says, was a seed contained in pods like kidney-beans, and was black, and of a pungent and acrid taste.

ZELENN, in *Geography*, a small island in the Frozen ocean, near the S.W. coast of Nova Zembla. N. lat. $70^{\circ} 50'$. E. long. $56^{\circ} 24'$.

ZELENOIKOLOK, a fort of Russia, in the government of Caucasus, on the Ural; 44 miles N. of Guriev.

ZELÉS, in *Ancient Geography*, a town of Hispania, in Bætica, upon a strait which separated Hispania from Africa, according to Strabo. This author reports, that the Romans transported the inhabitants into Mauritania, together with others drawn away from Tingis, established the town of Julia Joga.

ZELETAWA, in *Geography*. See SCHELETA.

ZELEZENSKAIA, a fort of Russia, in the government of Kolivan, on the E. side of the Irtisch. N. lat. $53^{\circ} 25'$. E. long. $75^{\circ} 40'$.

ZELITO, or ZILITO, a fort of South America, in the harbour of Carthageana.

ZELL, a town of Austria; 14 miles N.N.W. of St. Wolfgang.—Also, a town of Bavaria, in the bishopric of Bamberg; 10 miles W. of Bamberg.—Also, a town of Germany, in the principality of Culmbach; 12 miles S.S.W. of Hof.—Also, a town of the duchy of Wurzburg; 3 miles N. of Schweinfurt.

ZELL. See LIEBENZELL.

ZELL *im Ham*, a town of Germany, on the Moselle; 25 miles N.E. of Treves. N. lat. $50^{\circ} 4'$. E. long. $7^{\circ} 7'$.

ZELL in the *Pitzgau*, a town of the archbishopric of Salzburg, on the Zeller See; 30 miles S.S.W. of Salzburg.

ZELL in *Zillertal*, a town of the archbishopric of Salzburg, on the Zeller; 50 miles S.W. of Salzburg.

ZELL *am Hammerbach*, a town of Germany, situated in the vale of Hammerbach. The town was imperial, and

affessed twenty-one florins till 1802, when it was given to the margrave of Baden; 9 miles W. of Freudenstadt. N. lat. $48^{\circ} 23'$. E. long. $8^{\circ} 7'$.

ZELLA, in *Ancient Geography*, a town of Africa, which was ruined during the war of Cæsar against Scipio. Strabo.

ZELLANG, in *Geography*, a town on the W. coast of the island of Celebes. S. lat. $4^{\circ} 20'$. E. long. $120^{\circ} 3'$.

ZELLE, or ALTENZELLE, a town of Saxony, in the circle of Erzgebürg; 2 miles W. of Nossen.

ZELLE, a city of Westphalia, in the principality of Lüneburg. This is a fortified and well-built town, situated on the Aller, which is here navigable, and behind the New Town is joined by the Fuhsee. The town itself, in conjunction with the suburb of Fritzenweife, consists of 564 houses; but including the other suburbs, fummer-houfes, and buildings without the gates, the number of them amounts to about 1400. At this place was held the high court of appeals for the several territories of the electoral house of Brunfwick-Lüneburg, together with the chancery and chief tribunal of the principality of Lüneburg. Here also stands the provincial house for the diets of the principality, together with one of its superintendencies, and a special superintendency which is administered by the general superintendant, who is always first minister of the town church. The other public edifices in it are, the Guildhall, the riding-house, the mews, and the armoury. The magistracy is possessed of the lower jurisdiction in the town, and likewise in some parts of the suburbs. At this place, too, are manufacturers and artificers in various branches, particularly in gold and silver. The prince's seat, near the town, is walled and moated in, and was the residence of the Zelle line of Brunfwick-Lüneburg, which failed in 1705. It was built by duke Henry, in the year 1485, and afterwards improved; 40 miles S. of Lüneburg. N. lat. $53^{\circ} 42'$. E. long. $10^{\circ} 14'$.

ZELLENERBERG, a town of France, in the department of the Upper Rhine; 9 miles N. of Colmar.

ZELLER SEE, a lake of Germany, in the archbishopric of Salzburg; 28 miles S.S.W. of Salzburg.

ZELLERFELD, a town of Westphalia, in the Harz Forest; silver to the value of 20,000 imperial crowns is annually coined in this town; 6 miles S.S.W. of Goslar.

ZELLERNDORFF, a town of Austria; 3 miles S.E. of Schrottental.

ZELLHOFEN, a town of Austria; 10 miles N.W. of Grein.

ZELLIA, in *Ancient Geography*, a country of Upper Pannonia, inhabited by the Slavi.

ZELLIN, in *Geography*, a town of the New Mark of Brandenburg; 13 miles N.W. of Cultrin.

ZELLINGEN, a town of the duchy of Wurzburg; 8 miles N. of Wurzburg.

ZELLITZ, a town of the duchy of Stiria; 8 miles W. of Marburg.

ZELON, a town of Thibet; 27 miles S.W. of Lassa.

ZELOTTI, BATTISTA, in *Biography*, was born at Verona in 1532. He was a pupil of Titian, according to Vasari, and a fellow-student with Paolo Veronese, with whom he co-operated in several important works at Venice. He particularly excelled in fresco, and that induced Paolo to court his assistance in many of the great works in which he was engaged. In consequence many of his works are given to Veronese, and those in the hall of the Council of Ten, in the palazzo S. Marco, have been engraved by Le Febvre as the works of that master. His picture of the Holy Family, in the Carara collection, is painted with the strength and warmth of Titian, and others of his works in oil

oil are deservedly esteemed and admired, particularly the Conversion of S. Paul, and Christ with his Disciples in the Fishing-boat, in the cathedral at Vicenza. He fell short of the grace and taste of Veronese, yet his invention was not lacking in energy; his touch is free and animated, and his compositions managed with skill and judgment. He died in 1592, aged 60.

ZELPHI. See ZENDA.

ZELPITSCH, in *Geography*, a town of Iltria; 10 miles N.E. of Mitterburg.

ZELTURINSKOI, a fort of Russia, in the government of Irkutsk; 72 miles S.S.E. of Tunginkoi.

ZELUIA, a town of Lithuania, in the palatinate of Novogrodek; 25 miles N.W. of Slonim.

ZEM, a river of Albania, which runs into the Moraca, 12 miles W. of Cattaro.

ZEMA, a word used by many of the old writers for a decoction or apozem.

ZEMARAIM, or SEMARAIM, in *Ancient Geography*, a city of Benjamin near Bethel. Josh. xviii. 22.

ZEMARITES, an ancient people of Syria, mentioned by Strabo, who places them on a plain, two leagues to the N. of mount Libanus, and gives them the term of Simyra.

ZEMASARUM, a word used by some of the chemical writers as a name for cinnabar.

ZEMBLA, NOVA, *Novaya Zemlia*, or *New Land*, in *Geography*, a Russian island, or rather a group of five islands, with the intervening channels always filled with ice, situated in the Frozen or Northern ocean. Of the numerous islands in this ocean, *Novaya Zemlia* and *Kalgeva* are the most considerable; but both are uninhabited, and frequented only by fishermen and hunters. The former is indeed well supplied with water; but is rocky, unfertile, and destitute of wood, furnishing vegetation only for a few stunted bushes and polar plants. It abounds, however, with rein-deer, white bears, and blue foxes; and the shores swarm with morfes, walruses, and various kinds of fish. Its magnitude is estimated at 950 versts in length, 520 in breadth, and 3090 in circumference, without following the sinuosities, and 425,509 German miles of superficies, according to Mr. Storch. On the northern side it is entirely encompassed with ice mountains; and to the south is the sea of Cara, Kara, or Karfoge, in which the tide flows about two feet nine inches. Among the lakes of this island there is one of salt water. From the middle of October till February the sun is not at all visible; but they have the advantage of numerous and strong north-lights and of much moon-light. In summer they have no thunder-storms. The snow falls in many places to the depth of four arshines. For two months, viz. June and July, the sun never sets. Between this island and the main land is the famous passage known by the name of Vaggat's or Waygat's straits.

ZEMECH, a word used by some writers as a name for *lapis lazuli*.

ZEMENIE, in *Geography*, a town of European Turkey, in Romania; 16 miles S.W. of Gallipoli.

ZEMIA, Ζημία, among the Athenians, is sometimes taken in a large and general sense for any kind of punishment; but more frequently for a pecuniary mulct or fine laid upon the criminal, according to the degree of his offence.

ZEMLIANSK, in *Geography*, a town of Russia, in the government of Voronez; 44 miles N.N.W. of Voronez. N. lat. 52° 12'. E. long. 38° 42'.

ZEMLIN, or SEMLIN, a fortress of Slavonia, in the union of the Save and the Danube, opposite Belgrade. Here is a lazaretto, where travellers and merchandise from the Levant are detained to prevent infection. The number

of inhabitants is about 1200 Rascians, Greeks, Jews, Armenians, and Turks: during a fire at Zemlin, Joseph II. emperor of Austria, assisted in person to suppress it.

ZEMME, a town of Grand Bucharia, on the Gihon; 60 miles S. of Bucharia.

ZEMOKARTLI, a town of Turkish Armenia, in the government of Cars; 50 miles N. of Ardanoudji.

ZEMORGET, or ZERMOGETE, a small island in the Red sea, 30 miles from the coast of Egypt. This island was called by the ancients "Ophiodes," from the abundance of serpents, and the island of topazes from the number of those precious stones found there. N. lat. 23° 25'. E. long. 53° 5'.

ZEMOVAH, a town of Pegu; 50 miles S. of Prone.

ZEMPHYRUS, in the *Materia Medica of the Ancients*, a name give to a precious stone, the fragments of which they use as a cordial and sudorific.

It appears by their accounts, that this stone was blue; and hence many have too hastily judged, that it was the lapis lazuli; but in truth it was the sapphir.

The word *zemphyrus* is no where used but in the writings of the later Greeks, and it is plainly formed, as most of their names of things are, on the Arabian word expressing the same thing. This Arabian word is *semphir*; and this, in Avicenna and Serapio, is always used as the name of a sapphir, never as that of any other gem. We find also by their accounts, that this sapphir was not the sapphir of the ancient Greeks, but the fine blue pellucid gem we now know by that name; for the sapphir of Theophrastus, and the other old writers, was only a kind of lapis lazuli.

ZEMPLIN, in *Geography*, a town of Hungary; 16 miles N.E. of Patak.

ZEMPOALA. See ZAMPALA.

ZEMZEM, the holy well of Mecca, which see.

ZENANICH. See SELANIEH.

ZENATI, a river of Algiers, formed by the union of two streams, which soon after changes its name to Seiboufe.

ZENDA, a general term coined by Paracelsus, by which he and his followers express extraneous or equivocal generation, or the production of bodies without a seminal principle. The word *zerunda* is used to express this particular sort of generation of men, and *zelpbi* in regard to other animals.

ZENDAVESTA, by contraction *Zend*, and, as it is vulgarly pronounced, *Zundavestow* and *Zund*, in *Antiquity*, denotes the book ascribed to ZOROASTER. (see his article,) and containing his pretended revelations; and which the ancient Magians and modern Perfes, called also Gauris, observe and reverence in the same manner as the Christians do the Bible, and the Mahometans the Koran, making it the sole rule of both their faith and manners. See MAGI, PERSES, GEBRES, &c. See also GENTOOS.

The word, it is said, originally signifies any instrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it.

Zendavesta is compounded of *Zend*, denoting the letters of the book, and *Avesta*, signifying the language in which it was written. See PERSIA, *Language of*.

M. Anquetil du Perron, to whose account we shall refer more at large in the sequel of this article, has taken pains, in the 37th volume of the work cited below, to prove that Zoroaster lived under Hytaspes, the father of Darius, in the sixth century before Christ.

The Zendavesta, or *Zend*, contains the system of doctrine and duty, which is said to have been supernaturally communicated

municated to Zoroaster, and which his followers hold in very extraordinary veneration. A copy of this book is kept, says Dr. Prideaux, to this day in every oratory and fire-temple, and portions of it are read at stated times by the priests to the people: and to this they appeal as the standard of the good and evil of their actions. This work, ascribed among other numerous writings to Zerdusht, or the Persian Zoroaster, and esteemed by his followers as of sacred authority, is said to have been written in the Persian language, and to have consisted of two parts; one of which contains their forms of devotion and order of ceremonies, the other the precepts of religion and morality. A compendium of it, called the *Sadda* or *Sadder*, is read to the people on every sacred day by their priests. There is, however, much reason to question, whether this book be of such ancient date as the time of Zoroaster; and it has been suggested as probable, that it was written about the time when many Jews and Christians resided among the Persians; that is, about the 4th or 5th century. In proof of its being later than the time of Zoroaster, but written since the days of Mahomet, it is alleged, that the word *sbaitam* occurs in it, which is peculiar to the Arabs; for in other oriental languages it is written *fatam*, or *fatou*.

Dr. Hyde gives us the following account of it. The *Zend* is the general name of the book, which is also called the book of Abraham; and it consists of twenty-one or twenty-two separate parts, with distinct names. Its contents were originally written on twelve hundred skins; and the ancient copies of it, like the original, are in the pure old Persian language; but the later copies are in the same language, mixed with modern Persian or Arabic words, serving to explain such as were becoming obsolete. Some parts of the *Zend* contain the original text, and others contain Zerdusht's second thoughts subjoined, for more fully explaining his doctrine. Some writers suggest, that Zerdusht first intended to comprise his book in four parts, *viz.* the *Zend*, containing the liturgy and chief doctrine of his religion, and the *Pazend*, or commentary upon the former; and that the farther additions were occasioned by the opposition of adversaries, and unforeseen circumstances that occurred. The character in which the *Zend* is written is that of the old Persian, called Pehlavi; and the *Pazend* character differs in a small degree from this.

Dr. Hyde has given a catalogue of the several parts of the *Zend*, each of which is called *nosb* or *nusb*.

In process of time, when the old Persian language became antiquated, and little understood, one of their deities or bishops (about A.D. 1500) composed the *Sadda*, which is a compendium, in the vulgar or modern Persian tongue, of those parts of the *Zend* that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaster, serving as an authoritative rule of faith and practice for his followers. This *Sadda* is written in a low kind of Persian verse, and, as Dr. Hyde informs us, it is *honorum et malorum sarrago*, having many good and pious things, and others very superstitious and trifling.

The *Zend* contains a reformed system of Magianism; teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darkness, out of which he made all other things; that there are in a state of conflict, which will continue till the end of the world; that then there shall be a general resurrection and judgment; and that just retribution shall be rendered unto men according to their works; and that the angel of darkness with his followers shall be con-

signed to a state of everlasting darkness and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darkness shall no more interfere with each other. The *Zend* also enjoins the constant maintenance of sacred fires and fire-temples for religious worship, the distinction of clean and unclean beasts, the payment of tithes to priests, which are to be of one family or tribe, a multitude of washings and purifications, resembling those of the Jewish law, and a variety of rules and exhortations for the exercise of benevolence and charity.

Dr. Prideaux charges the *Zend* with allowing the worst kind of incest; and Dr. Hyde also intimates that it was allowed by Zoroaster, till it was at length abolished; but no authority has been cited to justify this charge.

The above-mentioned doctrines of the *Zend* are accommodated to the eastern taste by a great intermixture of fable.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David: the author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the Creation and Deluge with Moses, differing indeed with regard to the former by converting the six days of the Mosaic account into six times, comprehending in the whole three hundred and sixty-five days; and speaks also of Abraham, Joseph, Moses, and Solomon. Moreover, Dr. Baumgarten (Univ. Hist. Suppl. vol. ii. p. 367, &c.) asserts, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Christians, and Mahometans; whence, and from other circumstances, he concludes, that both the history and writings of this prophet were probably invented in the later ages, when the fire-worshippers under the Mahometan government thought fit to vindicate their religion from the suspicion of idolatry.

The Zoroaster, says the abbé Foucher, (see ZOROASTER,) who was the author of the *Zend*, is represented by him as an apostate Jew, a subtle philosopher, and an obsequious artful courtier, who insinuated himself into the favour of Darius Hytaspes; and he says that his great design was to reconcile the Hebrew with the Persian religion by a mixture of the leading and essential doctrines of each, to revive the credit of the Magi, and to accommodate, by a proper colouring, the Jewish religion to the weakness and prejudices of the Medes and Persians, by taking from it that exclusive character that rendered it offensive to other nations, and mixing with it the reveries and visions of the ancient Zoroaster. See Hyde's *Religio Veterum Perfarum*. Prideaux's *Conn. of the Old and New Testament*, vol. i. p. 317, &c. edit. 9. Univ. Hist. vol. ii. p. 206, &c. fol.

The account more lately given both of the Persees and *Zend*, by M. Anquetil du Perron, differs in several particulars from that of Dr. Hyde. This gentleman made a voyage to India, and employed himself between the years 1755 and 1761 in studying the Persian and Sanskrit languages, and in collecting and translating manuscripts, many of which he brought with him, and deposited in the king of France's library. His account was read to the Royal Academy of Sciences at Paris, and a translation of it was published in the *Gentleman's Magazine* for 1762, and also in *Dodley's Annual Register* for 1762, part ii. p. 101—127. Of the Persees or Parsses, the disciples of Zoroaster, he says, a very numerous body has been established more than nine hundred years in Guzerat, to which place they came fugitives from Kerman, A.D. 767, on account of the Ma-

U hometan

ZENDAVESTA.

hometan persecutions, where their genius for commerce and industry, which are their known characteristics, procured for them very considerable settlements. Concerning the hierarchy of the Parfies, this writer observes, that their ministers of religion are divided into five classes, *viz.* erbeds, mobeds, destours, destour mobeds, and destouran destours, or destours of destours. An erbed is a person who has submitted to the purification directed by the law, who has read, during four days without interval, the *Izefchne* and the *Vendidad*, and who is instructed in the ceremonies of the worship established by Zoroaster. If the erbed afterwards continues to read publicly the *Zend works*, which constitute the liturgy, and to perform the ministerial functions, he becomes a mobed, though he does not understand the *Zendavesta*; but if he contents himself with studying the law, the *Zend*, and the *Pehlvi*, or *Pehlvi*, without exercising the ministerial functions, he is called a destour.

The destour mobed is he who unites the qualifications of the mobed and destour; and the destouran destour is the principal destour of a city or province, who decides cases of conscience, and determines points of law, and to whom the Parfies pay a tithe of their revenues.

As for those *Zend writings*, which the Parfies attribute to their legislator, and for which they have the same veneration as the Jews have for their Hebrew text, M. du Perron inclines to think, though he does not affirm, that they are really the works of Zoroaster, whose reputation has been acquired by laws that have subsisted two thousand five hundred years.

The law, which was either framed or regulated by Zoroaster, was divided, as we are told by modern authors, into twenty-one *nohs*, or parts: seven treat of the creation and history of the world; seven of morality, and civil and religious duties; and seven of physic and astronomy. Among the Parfies it is an universally received tradition, that Alexander the Great condemned these twenty-one volumes to the flames, after having caused them to be translated into Greek. Those which escaped are, the *Vendidad*, the *Izefchne*, the *Vispered*, the *Jefchts*, and the *Neafchs*, in *Zend*, and some other *Pehlvi* translations of *Zend originals*. The Parfies have also a great number of prayers, which they call *nerengs*, and which in general are written in modern *Perfic*, with *Zend* characters, which they affect to use in all writings that treat of religion, though composed in modern *Perfic*. The writings of Zoroaster, which still remain, speak of the creation of the universe, of the terrestrial paradise, and the dispersion of mankind; of the cause of the respect paid to fire, of the origin of evil, natural and moral; of the angels appointed to the government of the universe; of several particulars relating to the end of the world, and the resurrection, &c. &c. They also contain predictions with respect to the latter times, some excellent moral precepts, and a very extensive ceremonial code.

The *Zend*, according to Du Perron, is not the name of Zoroaster's writings, but merely of the characters, though generally used to signify the language itself, in which they were written: the language of the original text is called *Avesta*, and is a dead language, and was entirely unknown to the Parfies before the time of Zoroaster, who, he apprehends, brought it from the mountains; and is totally different from the *Pehlvi* or ancient *Perfic*, spoken in the time of Zoroaster. He farther supposes, that the works of Zoroaster, still extant in the *Pehlvi*, were translations made into that language during the life of this legislator, or soon after his death.

The *Pazend*, which Dr. Hyde makes to be the name of a work, is, according to Du Perron, the name of a language, which is a dialect or corruption of the *Avesta*, and almost extinct, except that a few words of it are preserved in the *Pehlvi* translation. The characters of the *Avesta* and *Pehlvi* are different; the former, which are properly the *Zend* letters, being much the neatest; the *Pazend* has no peculiar alphabet, but adopts that of the *Zend* or *Pehlvi* indifferently. (On this subject, see *Language of PERSIA*.) For M. du Perron's account of the eighteen MSS. of which he brought duplicate copies with him, and an abstract of their contents, we must refer to the *Ann. Reg. &c. ubi supra*.

This writer has published a translation of the *Zendavesta*, with remarks and illustrations, &c. in 3 vols. 4to. at Paris, in 1771.

The *Zend*, as fir W. Jones suggests (*Works*, vol. iii. p. 115, 8vo.), bore a strong resemblance to Sanskrit, and the *Pehlvi* to Arabic, being a dialect of the Chaldaic. Sir W. Jones, from a perusal of two vocabularies, exhibited in this work, one in *Zend*, and another in *Pehlvi*, and derived from a collection of traditional pieces in modern Persian, was confirmed in his opinion concerning the Chaldaic origin of the *Pehlvi*; and in perusing the *Zend glossary*, he was surpris'd to find, that six or seven words in ten were pure Sanskrit. M. Anquetil, he says, most certainly, and the Persian compiler most probably, had no knowledge of Sanskrit, and could not therefore have invented a list of Sanskrit words: it must therefore be an authentic list of *Zend words*, which had been preserved in books or by tradition; and hence it follows that the language of the *Zend* was at least a dialect of the Sanskrit, approaching perhaps as nearly to it as the *Pracrit*, or other popular idioms, which are known to have been spoken in India 2000 years ago. As soon as M. Anquetil published the above-mentioned work, fir W. Jones immediately discovered that the work was spurious, and by no means to be attributed to Zoroaster; in consequence of which he published in the same year, "Lettre à M. A—— du P—— dans laquelle est compris l'Examen de sa Traduction des Livres attribués à Zoroastre." This letter is contained in the 10th volume of his works, ed. 8vo. In Germany this version of M. Anquetil has met with more success, and has not only been translated into German, but applied to the purposes of explaining the New Testament. This use of it has been suggested by Michaelis, and exemplified in the illustration of the introduction to St. John's gospel, and particularly of the term "word," which is used in the *Zendavesta* in the same sense as by St. John and the Gnostics for the name of a person, and determines the proper translation of *λογος*. (Michaelis by Marsh, vol. i. p. 161.) Several other persons, besides fir W. Jones, have questioned the authenticity of the work which M. Anquetil has translated, or its being a genuine remain of Zoroaster.

Mr. Richardson, in his "Dissertation on the Language, Literature, and Manners of the Eastern Nations," originally prefixed to his Persian, Arabic, and English Dictionary, 1778 (chap. i. sect. 2.), is very severe, both on Dr. Hyde and M. du Perron. Those fragments of the supposed works of Zoroaster, which Dr. Hyde has given us under the title of *Salders*, are, he says, the wretched rhymes of a modern *Parfi* destour or priest, who lived about three centuries ago; whilst the publications of M. Anquetil du Perron carry palpable marks of the total or partial fabrication of modern times. The *Zend* language, he says, is not genuine; and M. du Perron has produced no discovery which can stamp his publication with authority.

He adds, the specimens of old Persian in Hyde's *Religio Veterum*

Veterum Perfarum are simply modern language in ancient characters.

In the "Memoirs of the Royal Society of Gottingen for 1799," *i. e.* "Commentationes Societatis Regiæ Scientiarum Gottingensis, &c." we have a memoir by M. Christopher Meiners, who enters into a critical examination of the authenticity and antiquity of the books published by M. Anquetil du Perron, as genuine writings of Zoroaster; and alleges many plausible arguments to prove them recent and spurious. He shews, that they contain a multitude of fables, totally unknown to the ancient Persians, and contrary to the spirit of their laws and religion; and also many opinions and ceremonies, which had their first rise many ages after Zoroaster. The dissertations of professor Meiners, relating to the Zendavesta, are printed in the 8th volume of the *Novi Commentarii Soc. Reg. Gotting.*; and in the 1st and 3d volumes of the *Commentationes*.

Some have thought that the truths which are observable in Zendavesta, Vendidad Sadi, and other writings of the eastern nations, were derived from the disciples of Nestorius, who were found very early on the coast of Malabar. But this, Mr. Bryant thinks, is a groundless surmise; because the religious sects, among which these writings have been preserved, are widely separated, and most of them have no connection with Malabar or the Christians of that quarter. And besides, the Brahmins and Banians adhere closely to their own rites, and abhor all other persuasions; and they are influenced by customs and seruples, which prevent their intercourse with other people. In their writings there occurs no trace of Christianity, or of its founder; and thence Mr. Bryant infers, that whatever truths may be found in the writings of these people, they were derived from a higher source, and by a different channel. See *Anal. of Anc. Mythology*, vol. iii. p. 599, &c.

We shall terminate this article with adding, that Dr. Hyde presented the copy of part of the Zend writings in his possession to the university of Oxford; and that the whole Zend was afterwards brought from India by Mr. Frazer, and is lodged with his other oriental MSS. in the Radcliff library at Oxford.

ZENDERO, in *Geography*. See GINGIRO.

ZENDEROD. See ZEINDEROOD.

ZENDGIN SERAI, a town of Grand Busharia; 30 miles S. of Samarcand.

ZENDORFF, a town of the duchy of Stiria; 12 miles E. of Landberg.

ZENECHDON, a term used by the Arabian physicians for a preparation of arsenic, for external use; *zeech* being their name for arsenic.

ZENEXTOR, one of the many names by which the chemists have called mercury.

ZENGAN, ZENIGAN, or *Zinjan*, in *Geography*, a town of Persia, in the province of Irak, said to have been fortified many years before the Christian era, and at one time to have contained 20,000 houses. It was entirely destroyed by Timur Bec when he first passed through that part of Persia; but being informed that it had long been the seat of learning and science, on his return from Turkey he in part rebuilt it. Since that time it has been frequently sacked and destroyed by the Tartars and the Turks. It contained in the 17th century about 2000 houses. It is a large, and now apparently a prosperous town, capital of the extensive district of Khunseh, which is 71 miles down an uneven country, full of deep ravines, from hence to the banks of the Kizilo-

zen, or golden stream, the natural boundaries of Irak and Azerbaijan; 21 miles N.W. by W. of Sultania.

ZENGI. See SEGNA.

ZENGHI, a river of Armenia, which runs into the Aras, 10 miles S. of Erivan.

ZENGIFUR, a word by which some of the chemical writers have expressed cinnabar.

ZENGITZA, in *Ancient Geography*, a promontory of Africa, in Ethiopia, upon the gulf of Barbary. Ptolemy.

ZENGUIA, in *Geography*, a town of Syria, in the pachaic of Aleppo, on the Euphrates; 55 miles N.N.E. of Aleppo.

ZENHAGA. See ZANHAGA.

ZENI, a word used by many of the chemical writers as a name for vitriol.

ZENIC, or ZENIK, in *Zoology*, a species of wasel. See VIVERRA.

ZENICON, the name of a poison, composed of several ingredients, and used to poison the tips of the arrows with which the Celtic hunters shot at the beasts they pursued for food. The poison was known to be of that quick spreading nature, that as soon as the beast was fallen, the huntsman ran up to it, and cut out a large piece of the flesh about the wound immediately, to hinder the venom from spreading farther. The antidote to this poison was supposed to be the leaves of oak, beech, and other trees.

ZENIEH, in *Geography*, a town of Asiatic Turkey, in Caramania; 15 miles of Selefkeh.

ZENITH, in *Astronomy*, is derived from an Arabic word signifying *point*, and is that peculiar point in the visible celestial hemisphere, which, at a given time, is vertical to a spectator, situated on any part of the earth's surface, and from which, if a perpendicular line were demitted through the place of the spectator, it would proceed to the centre of the earth. Of all the points in the apparent concavity of the visible hemisphere, the *zenith point* is the most interesting; it is not only the pole of the local horizon of every place, and of all parallels of altitude, but is the point to which all the grand circles of the sphere are referred, and through which not only the great circles connecting the cardinal points, but all the circles of azimuth pass and intersect one another; and further, it is the only point in the celestial expanse that is not affected by atmospheric refraction. If the earth had no annual or diurnal motion, nor any nutation of its axis, the zenith of each place on the earth's surface would be so many fixed points in the heavens; but as none of these is the case, the actual zenith of every place, except over the two poles of the earth, is continually changing. The annual orbit of the earth is indeed so small in comparison of the distance of a star from it, that the parallax arising therefrom is too small to be appreciable with certainty even by the best instruments; but the effect of nutation of the earth's axis is very perceptible, as is also the aberration of light occasioned by the earth's progress in its annual orbit; and these will both conspire to render the *apparent* a little different from the *true* zenith. It is, however, the earth's diurnal motion that produces the principal change in the celestial situation of the zenith; for as this planet revolves on its axis, any given place on its surface has a corresponding succession of zeniths, which describe a circle, at the distance of its co-latitude from the nearest pole; and hence a succession of stars situated in this circle will appear to transit the zenith in a direction contrary to that of the earth's diurnal motion in every sidereal day, or time of one entire rotation. Hence, though the zenith of any place may be considered as a fixed point in the heavens,

as to its *direction*, when viewed by a spectator; yet as it has reference to the apparent place of a heavenly body, it is not fixed, because the earth's motion is continually carrying the spectator's eye in a circle that produces the optical effect of an apparent circumpolar revolution of the celestial bodies. Whatever point of the hemisphere is at any moment vertical to an observer on any part of the globe, *that point* is the *zenith* for the time *then passing*, and will again be the zenith, or very nearly so, after an interval of one complete rotation of the earth; and, therefore, strictly speaking, in every place there are as many successive zeniths in this period, as there are appreciable points in the circle generated in the heavens by the superior end of the vertical line carried round by the globe in rotation.

Because every point of the horizon is just 90° distant from the existing zenith, in every place, and at all times, it will be readily apprehended, that the complement of the altitude of any heavenly body will, at any instant, be the angular distance of that body from the zenith of the place of observation; but as this distance varies inversely with the altitude, it is more properly called the *co-altitude* than the *zenith-distance*, the former being a variable, and the latter a limited quantity. The *zenith-distance* of any star is properly the complement of its *meridian* or *greatest* altitude in any given place, and as the latitude of the place varies, so will the *zenith-distance* of the same body, but inversely; the distance of the zenith to the pole being always the complement of the latitude. Hence it is obvious, that when the *zenith-distance* of a star is observed by any instrument that measures it accurately, the latitude of the place may be inferred from the tabular polar distance of that star, as well as from the declination, which is its complement; and, therefore, it is a matter of no importance in theory, whether the altitude or *zenith-distance* of a body transiting the meridian be taken, for the purpose of ascertaining its place in the heavens, when the latitude of the observer is known, or for the purpose of determining the latitude of the place, when the declination, or polar distance of the body, is known. Accordingly, in the circular instruments that have been recently introduced into observatories, and that will reverse in position, it is usual to number the divisions and subdivisions so, that when they read altitudes with the graduated plane facing the east, they read *zenith-distances* (on the meridian) when the same is made to face the west, and *vice versa*; so that not only are the opposite errors of collimation of the telescope and of the bubble or plumb-line thus corrected, but when atmospheric refraction is allowed for, the sum of the two readings, or of the averages of several, will be exactly 90° , or otherwise 180° , if the observations be truly taken, and the instrument duly adjusted for zero and collimation; which check is of great practical importance in the delicate operations of the astronomer.

ZENITH-SECTOR is an *astronomical* instrument, by means of which the angular distance of a star is accurately measured from the zenith point of any given place towards the north or south. The first instrument made use of for this purpose was contrived by Dr. Hooke, with a view of determining the annual parallax of a fixed star, agreeably to the suggestion of Galileo. The telescope, which Dr. Hooke, in the year 1669, made the essential part of his instrument, was thirty-six feet long, the principle of achromatism not being at that time practically applied, so as to allow of considerable power with a short focal distance of the object-glass; but the length of the radius of his arc of measurement promised advantages over every other instrument, which justified the conception and execution of the

plan, though its accomplishment failed of corresponding success. Indeed, the nice arts of constructing achromatic telescopes, and of dividing the arc of a circle with extreme precision, had neither of them yet been perfected. From the Cutlerian Lectures we learn, that the first observation with this instrument was made on the 6th of July of the above-mentioned year, on the star denominated γ Draconis, which, on that evening, was found to pass at the distance of $2' 12''$ to the north of the zenith of Gresham college; which was also found to be the case on the 9th of the same month: but on the 6th of August next following, the distance was only $2' 6''$; and on the 21st of October after only $1' 48''$, or $1' 50''$; whence it was concluded, that the measurement of a *zenith-distance* taken by this instrument was liable to an error of $24''$, or perhaps more; and it was considered, therefore, that the instrument was quite incompetent to the purpose for which it was intended. But an original idea once suggested, as the basis of useful speculation, is not readily abandoned, even under an apparent want of successful application. The Hon. Samuel Molyneux afterwards availed himself of the manual skill of the ingenious Graham, and by the assistance of Dr. Bradley put up a *zenith-sector* at Kew, in the year 1725, which turned out to be much more accurate than its predecessor, though the focal length of the object-glass of its telescope was only $24\frac{1}{2}$ feet. With this instrument, and with one of about one-half its focal length, were made two of the most important discoveries in astronomy that have graced the annals of this science; *viz.* the *nutations* of the earth's axis, and the *aberration of light* in its passage from the heavenly bodies. As the history of astronomical discoveries, and that of astronomical instruments, are mutually illustrative of each other, and as a detail of the *minutiae* is always interesting, that connect great results with primary measures, that might otherwise be considered as insignificant, we will make no apology for introducing here Dr. Bradley's own account of his proceedings, as inserted in the Philosophical Transactions of London, N^o 406. p. 149 of the Abridg.

"The following observations," says the author, "were begun by the honourable Samuel Molyneux at Kew, continued and repeated by myself at Kew and Wantstead, in hopes of verifying those that Dr. Hooke formerly communicated to the public, concerning the *parallax of the fixed stars*. (London, 1674.) Therefore the same star was made choice of by Mr. Molyneux, almost the same method followed, and his instrument constructed upon principles nearly the same, but greatly exceeding the doctor's in exactness, which was chiefly owing to our curious member (of the Royal Society) Mr. George Graham, to whom the lovers of astronomy are also indebted for several other exact and well-constructed instruments. Mr. Molyneux's apparatus was completed and fitted for observing about the end of November, 1725; and on the 3d day of December following, the bright star in the head of Draco (marked γ by Bayer) was for the first time observed, as it passed near the zenith, and its situation carefully taken with the instrument. The like observations were made on the 5th, 11th, and 12th days of the same month; and there appearing no material difference in the place of the star, a farther repetition of them at this season seemed needless, it being a part of the year wherein no sensible alteration of parallax in this star could soon be expected. It was chiefly, therefore, curiosity that tempted me (being then at Kew, where the instrument was fixed) to prepare for observing the star on Dec. 17th, when, having adjusted the instrument as usual, I perceived that it passed a little more southerly this day

day than when it was observed before. Not suspecting any other cause of this appearance, we first concluded, that it was owing to the uncertainty of the observations, and that either this or the foregoing were not so exact as we had before supposed; for which reason we proposed to repeat the observation again, in order to determine from whence this difference proceeded; and upon doing it on Dec. 20th, I found that the star passed still more southerly than in the former observations. This sensible alteration the more surprised us, in that it was the *contrary way* from what it would have been had it proceeded from an annual parallax of the star; but being now pretty well satisfied that it could not be entirely owing to the want of exactness in the observations, and having no notion of any thing else that could cause such an apparent motion as this in the star, we began to think that some change in the materials, &c. of the instrument itself might have occasioned it. Under these apprehensions we remained some time; but being at length fully convinced, by several trials, of the great exactness of the instrument, and finding by the gradual increase of the star's distance from the pole, that there must be some regular cause that produced it, we took care to examine nicely, at the time of each observation, how much it was: and about the beginning of March, 1726, the star was found to be 20'' more southerly than at the time of the first observation. It now, indeed, seemed to have arrived at its utmost limit southward, because in several trials made about this time, no sensible difference was observed in its situation. By the middle of April, it appeared to be returning back again towards the north; and about the beginning of June, it passed at the same distance from the zenith as it had done in December, when it was first observed.

"From the quick alteration of this star's declination about this time, (it increasing a second in three days,) it was concluded, that it would now proceed northward, as it before had gone southward of its present situation; and it happened as was conjectured; for the star continued to move northward till September following, when it again became stationary, being then near 20'' more northerly than in June, and no less than 39'' more northerly than it was in March. From September the star returned towards the south, till it arrived in December to the same situation it was in at that time twelve months, allowing for the difference of declination on account of the precession of the equinox.

"This was a sufficient proof that the instrument had not been the cause of this apparent motion of the star; and to find one adequate to such an effect seemed a difficulty. A *nutaton of the earth's axis* was one of the first things that offered itself upon this occasion; but it was soon found insufficient; for though it might have accounted for the change of declination in γ Draconis, yet it would not at the same time agree with the phenomena in other stars; particularly in a small one almost opposite in right ascension to γ Draconis, at about the same distance from the north pole of the equator; for, though this star seemed to move the same way as a nutation of the earth's axis would have made it, yet in changing its declination but about as much as γ Draconis in the same time, (as appeared upon comparing the observations of both made upon the same days, at different seasons of the year,) this plainly proved that the apparent motion of the stars was not occasioned by a real nutation, since, if that had been the cause, the alteration in both stars would have been near equal.

"The great regularity of the observations left no room to doubt, but that there was some regular cause that pro-

duced this unexpected motion, which did not depend on the uncertainty or variety of the seasons of the year. Upon comparing the observations with each other, it was discovered, that in both the fore-mentioned stars, the apparent difference of declination from the *maxima* was always nearly proportional to the versed sine of the sun's distance from the equinoctial points. This was an inducement to think, that the cause, whatever it was, had some relation to the sun's situation with respect to those points. But not being able to frame any hypothesis at that time, sufficient to solve all the phenomena, and being very desirous to search a little farther into this matter, I began to think of erecting an instrument for myself at Wanstead, that, having it always at hand, I might with the more ease and certainty inquire into the laws of this new motion. The consideration, likewise, of being able by another instrument to confirm the truth of the observations hitherto made with Mr. Molyneux's was no small inducement to me; but the chief of all was the opportunity I should thereby have of trying in what manner other stars were affected by the same cause, whatever it was. For Mr. Molyneux's instrument being originally designed for observing γ Draconis, (in order, as I said before, to try whether it had any sensible parallax,) was so contrived, as to be capable of but little alteration in its direction, not above seven or eight minutes of a degree; and there being few stars within half that distance from the zenith of Kew bright enough to be well observed, he could not, with his instrument, thoroughly examine how this cause affected stars differently situated with respect to the equinoctial and solstitial points of the ecliptic.

"These considerations determined me; and by the contrivance and direction of the same ingenious person, Mr. Graham, my instrument was fixed up, August 19, 1727. As I had no convenient place where I could make use of so long a telescope as Mr. Molyneux's, I contented myself with one of but little more than half the length of his, (viz. of about $12\frac{1}{2}$ feet, his being $24\frac{1}{2}$.) judging from the experience which I had already had, that this radius would be long enough to adjust the instrument to a sufficient degree of exactness; and I have had no reason since to change my opinion: for from all the trials I have yet made, I am very well satisfied that when it is carefully rectified, its situation may be securely depended upon to half a second. As the place where my instrument was to be hung in some measure determined its radius, so did it also the length of the arc, or limb, on which the divisions were made to adjust it; for the arc could not conveniently be extended farther than to reach to about $6\frac{1}{2}^\circ$ on each side my zenith. This indeed was sufficient, since it gave me an opportunity of making choice of several stars, very different both in magnitude and situation; there being more than two hundred inserted in the British Catalogue, that may be observed with it. I needed not to have extended the limb so far, but that I was willing to take in *Capella*, the only star of the first magnitude that comes so near my zenith.

"My instrument being fixed, I immediately began to observe such stars as I judged most proper to give me light into the cause of the motion already mentioned. There was variety enough of small ones, and not less than twelve that I could observe through all the seasons of the year; they being bright enough to be seen in the day-time, when nearest the sun. I had not been long observing, before I perceived that the notion we had before entertained of the stars being farthest north and south, when the sun was about the equinoxes, was only true of those that were near the solstitial colure; and after I had continued my observations a few months,

mouths, I discovered what I then apprehended to be a general law observed by all the stars, *viz.* that each of them became stationary, or was farthest north or south, when they passed over my zenith at six of the clock, either in the morning or evening. I perceived likewise, that whatever situation the stars were in with respect to the cardinal points of the ecliptic, the apparent motion of every one tended the same way, when they passed my instrument about the same hour of the day or night; for they all moved southward while they passed in the day, and northward in the night; so that each was farthest north, when it came about six of the clock in the evening, and farthest south, when it came about six in the morning.

"Though I have since discovered, that the *maxima* in most of these stars do not happen exactly when they come to my instrument at those hours; yet not being able at that time to prove the contrary, and supposing that they did, I endeavoured to find out what proportion the greatest alterations of declination in different stars bore to each other, it being very evident that they did not all change their declination equally. I have before taken notice, that it appeared from Mr. Molyneux's observations, that γ Draconis altered its declination about twice as much as the fore-mentioned small star almost opposite to it; but examining the matter more particularly, I found that the greatest alteration of declination in these stars was as the sine of the latitude of each respectively. This made me suspect that there might be the like proportion between the *maxima* of other stars; but finding that the observations of some of them would not perfectly correspond with such an hypothesis, and not knowing whether the small difference I met with might not be owing to the uncertainty and error of the observations, I deferred the farther examination into the truth of this hypothesis, till I should be furnished with a series of observations made in all parts of the year, which might enable me not only to determine what errors the observations are liable to, or how far they may safely be depended upon, but also to judge whether there had been any sensible change in the parts of the instrument itself.

"Upon these considerations, I laid aside all thoughts at that time about the *cause* of the fore-mentioned phenomena, hoping that I should the more easily discover it, when I was better provided with proper means to determine more precisely what they were.

"When one year was completed, I began to examine and compare my observations; and having pretty well satisfied myself as to the general laws of the phenomena, I then endeavoured to find out the cause of them. I was already convinced that the apparent motion of the stars was not owing to a *nutaton* of the earth's axis. The next thing that offered itself was an *alteration* in the *direction* of the *plumb-line*, with which the instrument was constantly rectified; but this, upon trial, proved insufficient. Then I considered what *refraction* might do, but here also nothing satisfactory occurred. At last I conjectured that all the phenomena hitherto mentioned proceeded from the *progressive motion of light*, and the *earth's annual motion in its orbit*. For I perceived that if light was propagated in time, the apparent place of a fixed object would not be the same when the eye is at rest, as when it is moving in any other direction than that of the line passing through the eye and object; and that when the eye is moving in different directions, the apparent place of the object would be different."

The author then proceeds to deduce from his observations the relative velocities of light, and of the earth in its annual orbit; shews what variation in the right ascension

and declination of stars differently placed may arise out of the *aberration* of light; and concludes that light, agreeably to such deductions, must travel from the sun to the earth in about $8' 7''$ of time. (See *ABERRATION, LIGHT, and STARS.*) The discovery of the earth's *nutaton* was not, however, published until the year 1737. See *NUATION.*

After our readers have seen what important discoveries and deductions have been derived from Graham's zenith-sector in the hands of a skilful astronomer, they will be naturally disposed to become acquainted with its construction, which we will now proceed to describe.

Zenith-Sector by Graham.—The zenith-sector that we have said Graham made for Mr. Bradley, afterwards Dr. Bradley, was removed to Greenwich, when the proprietor became astronomer royal, and is the same instrument which Dr. Maskelyne used with great success in adjusting, by comparison, the zero of the large quadrants. It still remains at Greenwich, and is yet capable of measuring zenith-distances to the accuracy of half a second, according to Bradley's original report, or even less. *Fig. 1. of Plate XXXIII. of Astronomical Instruments,* is a representation of the essential parts of this instrument: A B represents the iron tube of the vertical telescope, which is supported by two small metallic cylinders projecting at right angles from the superior end, one of which is seen at *a*, and the other is hidden by the tube. These cylinders, which constitute the axis of motion, rest in a pair of Ys, attached to the solid wall facing the north, and also occasionally to another pair fixed to a wall facing the south; which additional pair allows the ends of the cylinders, or axis of motion, to be reversed in position. The brass bar C D is fixed to the same wall to which the pair of Ys are attached, at opposite sides of the room, and bears a cock to which the micrometer-screw E is fixed, which measures the fractional portion of a minute on its head *b*; and the second screw *c* is made to relieve it. The ends of these screws press against studs inserted into the tube of the telescope, while the weight F pulls a string round the fixed pulleys G and H, by means of a pliable cord, attached to the tube at the point *d*, and keeps the telescope home. The graduated arc I K contains $12\frac{1}{2}^\circ$, each subdivided into twelve parts, or five minute spaces, and is fixed exactly at right angles to the tube, over the point where the wires intersect the field of view. This arc was originally of brass, but Sisson put on an arc of steel, containing gold pins to receive the dots of division. A plumb-line suspended from the superior end of the tube, over the centre of one of the cylinders *a*, and having an adjusting screw *e*, to bring the point of suspension to the upper dot, falls near the face of the arc, and indicates the distance from zero at the middle of the arc; if the plumb-line covers one of the dividing dots of the scale, when a star near the zenith is cut by the horizontal wire, then the quantity is read by the plumb-line and arc alone; but otherwise the fractional portion is ascertained by means of the micrometer-screw, which is made to press against the tube until the suspended line coincides with the next nearest dividing dot of the scale. The value of the micrometer-head, which is divided into thirty-four equal parts, was ascertained by trying how many revolutions of the screw would measure a degree, or other portion of the arc, exactly; and on an average of several trials made in different parts of the arc, it was ascertained, that one revolution was not precisely $34''$, but $33''$.6328, and one of its divisions on the head, therefore, only $0''.9892$, instead of $1''$, as was intended by the maker. The instrument had originally a single lens for its object-glass; but at the request of the late Dr. Maskelyne, Mr. Dollond substituted

stituted an achromatic object-glass, which has modernized the instrument, and put it nearly on a level with the new instruments which have lately been constructed and erected in the Royal Observatory by Troughton, on the best principles. If the zenith-sector had been made to reverse in position in the same situation, *i. e.* without being carried across the room, its use would have been more convenient, and the observations more certain, inasmuch as the same distance would have been preserved between the axis of motion of the telescope, and the point acted upon by the micrometer-screw, without any refuting allowance. Besides, the instrument would have been less liable to accidents; and reversed observations might probably have been made on the same evening. When Bird afterwards made a zenith-sector for the Oxford Observatory, he noticed these inconveniences, and obviated them by making the tube of the telescope turn round in its own place, so that the positions of the axis can be reversed by an azimuthal motion that carries the plumb-line round at the same time; and when the plumb-line will cover the dot at zero during this whole motion, the telescope is truly vertical.

The adjustment for collimation is effected by an apparatus that moves the wires in the eye-piece, as in the transit-instrument, and may be thus effected: Let the graduated arc face the east, and view a star passing in or near the zenith, the proper time for doing which may be known from the star's right ascension, by means of a sidereal clock, or by conversion of solar into sidereal time, and note the distance from zero when the plumb-line is quiet, which it will lose be if the plummet is immersed in a goblet of water, and mark down this quantity as read partly by the divisions on the scale, and partly by the micrometer-head; which call the *eastern* measure with N. or S. annexed, accordingly as the star passes to the north or south side of the zenith point: then reverse the position, and on a succeeding night, which will be 3' 56" sooner on every successive night, measure the zenith-distance of the same star in like manner with the graduated scale facing the west; and call it the *western* measure: then if the two quantities thus measured be similar, the collimation for zenith-distance will be true; but if otherwise, one half of the difference of the two readings will be the *error* of collimation, which may be either corrected by the proper apparatus at successive trials, or, which is perhaps better, may be allowed for in each observation. When the instrument has been used for several observations, it will be still better to take an average of all the observed errors, as ascertained by different stars, and to apply it with its proper sign in future single observations, so long as the instrument remains in all respects unaltered. It is hardly necessary to observe, that in using this instrument, when a star is very near the zenith of any place, the micrometer alone, without reference to the graduated scale or arc, will give the due measure. How the latitude of any place may be very accurately determined from the measured zenith-distance of a star, of known declination, will be seen presently.

Zenith-Sector by Ramsden.—While the trigonometrical survey of England was carrying on, it was found desirable to have a portable zenith-sector to assist in measuring an arc of the meridian, and as Ramsden had one in a half-finished state, that had been ordered by the duke of Richmond, the parties were prevailed on to have this finished for the purpose, which was nearly done in Ramsden's life-time, in the year 1801, and completed in April 1802 by his successor Berge. It was first tried at Greenwich, and then removed to the Isle of Wight, where the operations began, and from whence they were continued northward from station to sta-

tion, as described in the "Trigonometrical Survey," by captain William Mudge, and published from time to time by Mr. Faden, of Charing-Crofs. The original account of this complex instrument has reference to six large plates, and is too long for us to copy. (See vol. ii. p. 6. *5th seq.* of part ii.) Fig. 2. of our Plate XXXIII. of *Astronomical Instruments*, gives a reduced perspective view of this instrument, from an examination of which a better idea will be formed of its general construction than by any detailed account we can give of its parts without the additional plates.

Captain Mudge says, "that Mr. Ramsden has here obviated the inconveniences attendant on the use of former sectors; and has also diminished, in a very considerable degree, the errors unavoidably resulting from their imperfect construction. The principles, he adds, on which he has founded the several improvements, consist in the means of uniting the sectorial tube to its axis, so as to ensure the permanency of the length of its radius, when erected for observations; more accurate methods of adjusting the instrument vertically; and an easy way of placing the face of its arc in the plane of the meridian." The frame exhibited in our figure consists of two parts; the external stand of mahogany, which supports the apparatus to which the sectorial tube is attached; and an inner frame, containing that apparatus with the tube itself. The stand, or outer frame, is in the shape of an obtruncated pyramid, having a base six feet square, and its vertex three. It unites strength with simplicity of construction. The inner frame, within which the sector is suspended, is supported at top in every lateral direction, while its lower extremity is terminated by a cone resting in a metallic concavity, on which it turns in azimuth; and it can be kept in any position by a clamping apparatus acting with an azimuth circle, made fast to the bottom of the external frame. The telescope of the sector has an object-glass nearly eight feet long, with an aperture of four inches, near which is made fast the transverse axis of motion, similar to that of a transit-instrument. The wires of the eye-piece of the telescope are illuminated by reflected light, entering the axis in the usual way; and a plumb-line, with the ghost apparatus for adjustment to zero, is made a leading feature in the construction. The arc is divided into 15°, which was the concluding work done by Berge, and each degree is subdivided into 5' spaces, as in Graham's instrument. A second telescope, of 29 inches focal length, is attached to the long tube, and moves in the plane of the divided arc to any given elevation, but partakes of the azimuthal motion when the long vertical telescope is turned round: with this 29-inch telescope horizontal angles are measured, by the help of the azimuth circle, which therefore is divided for this purpose. Besides these essential parts, there are various appendages and bracing parts, rendered necessary by the size of the instrument, particularly a microscopic tube reaching up to the upper dot of the plumb-line, and bent at both ends into a horizontal position for convenience of the observer. This contrivance required reflectors, both of the light, and of the image of the piece of mother-of-pearl that is bisected by the wire, constituting the plumb-line. The micrometer measures minutes and seconds in the usual way, and the plummet is immersed in a small vessel of water to prevent vibration. We mention these particulars *generally*, not only because their particular uses and modes of application have been previously described, when we explained other instruments, such as CIRCLES, EQUATORIALS, TRANSIT-INSTRUMENTS, &c.; but because this instrument has furnished hints to others who have copied in part, or wholly, several

ZENITH.

several of Ramsden's contrivances. It was moreover necessary to introduce various weights, pulleys, cords, springs, &c. to facilitate and keep steady the motions of the different acting parts, which, together with the reading microscopes, lamps, rods, and adjusting screws, give the instrument the appearance of great complexity.

The manner of adjusting the instrument for observation is thus performed, according to Mr. Mudge's own words: *viz.* "The feet of the external stand should be first carefully brought into a horizontal plane; and when they are so, the azimuth circle will be necessarily parallel to it, having its centre under the middle of the opening in the mabogany frame screwed on the top of the stand. This being done, and the instrument set up, the plane of the arc should be brought parallel to one of the sides of the stand, in which situation the internal frame is to be clamped to the azimuth circle, and the wire brought to its proper distance from the limb, by means of the adjusting screw attached to one of the sliders, which carries the concave receptacle and conical point. The dot at zero should then be brought exactly under the plumb-line, as seen through the magnifier, and the point on the micrometer-head, at which its index stands, noted. The instrument is then to be turned half round; and if the same dot on the arc still continues bisected, it will afford a proof of the internal stand being upright in one direction. But if the dot should not continue bisected by the plumb-line, it must be made to do so, and the revolutions, or parts of a revolution, counted; half of which is to be turned back on the micrometer-head. The same dot, zero, is then to be brought under the plumb-line (wire), by

means of the other adjusting screw, beneath the azimuth circle. If the stand is pretty accurately set up, one operation is sufficient for bringing the interior frame upright in one direction, *viz.* either in that of the meridian, or the one at right angles to it. The arc is then to be turned round 90°, and the same operation gone through. This being properly done, the interior frame is made perfectly upright. The next step to be taken is that of placing the long level on its axis above, and rectifying that axis by means of the Y plate screws. If this be done carefully, the bubble will remain between the pointers of the level, whatever position the sector may be placed in. Having thus rectified the instrument, by making the internal frame upright, and the axis horizontal, the only remaining point to engage attention is, placing the plumb-line at a proper distance from the arc: this is done by means of the screw acting on the spring just under its point of suspension. If great care be used in going through these several adjustments, the instrument may, at any future time, be accurately adjusted for observation by turning the proper screw belonging to the azimuth circle, and bringing the arc to its usual distance from the wire."

In order to shew the accurate results that may be obtained from an instrument of this description, and also the care that is necessary in using it, and in clearing the observations of errors arising from natural causes, we will subjoin a few Tables that were found useful in the grand trigonometrical operations, by means of which, in the years 1802 and 1806, the meridian arcs were compared with the corresponding terrestrial measurements.

TABLE shewing the Runs of the Micrometer-Screw over every Five Minutes in the First Degree on each Side of Zero.

ZENITH.

Besides these observations, various others were taken of different stars in Draco, Cygnus, Urfa Major, Hercules, Perseus, and Auriga, from an average of all which the final results were obtained; but before the true or mean zenith-distances can be exactly known, the apparent measures must be corrected by certain equations for aberration, nutation, semi-annual solar equation, precession, and refraction; the Tables proper for which are chiefly given under our article DECLINATION. It was deemed sufficient for our purpose in this place to confine ourselves to the consideration of the observations made on γ Draconis alone, which being a star of the second magnitude, and very near the zenith of London, and of the southern parts of England, was considered as the best object. We will therefore subjoin the reduction of the observations made on this star by way of illustrating their application in practical astronomy.

Reduction of the Observations contained in Table I.

	Face of Limb West.	Face of Limb East.	
Greenwich Observatory, 1802.	{	April 16. - - - - - \circ 2 28.37	April 22. - - - - - \circ 2 19.05
		19. - - - - - \circ 0 29.92	23. - - - - - \circ 0 20.54
		25. - - - - - \circ 0 28.55	Mean E. - - - - - \circ 2 19.79
		Mean - - - - - \circ 2 28.94	Mean W. - - - - - \circ 2 28.94
			2) \circ 4 48.73
Apparent Mean of both positions - - - - -	=	\circ 2 24.36	
And also, half the difference, or collimation - - - - -	=	4.57	
Then in Bode's Catalogue Dec. N. of γ Draconis, 1801 - - - - -	=	51 31 5.	
Subtract for annual diminution .7 + .3 - - - - -	=	1.	
True declination - - - - -	=	51 31 4.	
And $2' 24'' .36 + 0.03''$ (sum of Equations) true zenith-distance - - - - -	=	2 24.39	
The true latitude of Greenwich Observatory, as deduced from γ Draconis - - - - -	=	51 28 39.61	

When the reductions are thus made for the observations taken at the other places, the zenith-distances and corresponding latitudes will stand thus, viz.

	Zenith Distance.		North Latitude.
Dunnose	$1^{\circ} 50'$ 5.24" N.		$50^{\circ} 37'$ 7".36
Clifton	$1^{\circ} 56'$ 26.64 S.		$53^{\circ} 27'$ 30.64
Arbury-Hill	$0^{\circ} 42'$ 22.75 S.		$51^{\circ} 15'$ 26.75
Delamere For.	$1^{\circ} 42'$ 18.09 S.		$53^{\circ} 13'$ 19.09
Burleigh Moor	$3^{\circ} 3'$ 19.09 S.		$54^{\circ} 34'$ 20.09

In obtaining the latitudes of the two last places, the declination of γ Draconis is diminished $3''$ to bring it to the year 1806, and in all the cases where S is annexed to the zenith-distance, it is added to the declination. The reductions are made to the first of January of the respective years, and the latitudes come out very nearly the same as those determined from terrestrial measurement, and also from an average of all the observed stars.

"From the observations made at the station in Delamere forest with the zenith-sector in 1806, combined with those at Dunnose, 1802, taken with the same instrument," says the author of the Survey, "it is found, that the difference in latitude of those is $2^{\circ} 36' 12'' .2$ (by γ Draconis alone in our examples $2^{\circ} 36' 11'' .73$), making a difference of $1''$ between the calculated and observed amplitudes, which, setting aside the consideration of the spherical figure of the earth, is at the rate of $\frac{1}{10}$ ths of a second in one degree. Perhaps, under the consideration of each meridional line being obtained independently of the other, and admitting that neither of them can be measured with perfect accuracy, together with the chances of the amplitudes being in some small degree either in excess

or defect, we may consider the result as sufficiently consistent and satisfactory, and may take 60823 fathoms, in latitude $52^{\circ} 34'$, or the centre of England, as the length of 1° ." Trigonometrical Survey, vol. iii. p. 332, &c.

ZENITH-MICROMETER is an instrument of very recent date, and is scarcely yet known to the generality of astronomers. It differs from the zenith-sector in this respect; that the measures taken with it are all taken within the tube of the telescope, whereas those taken by the zenith-sector are all external: consequently the range of the zenith-micrometer's scale is confined to the extent comprised within the field of view, which will always be inversely as the magnifying power of the glasses used; hence the greater the power of the telescope, the smaller the number of stars that will pass within the range of the micrometer-screw; but then corresponding accuracy may be expected from the great powers and delicate construction of modern micrometers; and what is wanting in the extent of the scale will be made up by superior precision. The telescope, which constitutes the basis of the zenith-micrometer, may be either of the reflecting or refracting construction; and within a short space of time one of each description has been constructed; the former by Troughton, for the Greenwich observatory, and the latter by Dollond, for the use of those geodæic commissioners, who are employed by the English government to ascertain the proper line of demarcation across the American lakes. We will give a short account of each of these instruments, such as will enable our readers to form an opinion of their respective merits, as prototypes for future imitation.

Zenith-Micrometer by Troughton.—It is probable that the first

ZENITH.

first idea of a zenith-micrometer occurred to Mr. Troughton, and certain that he was the first who executed one, and gave it its name. It was in 1806 that he proposed it to Dr. Maskelyne, and in 1812 that he erected it at the Royal Observatory, as an appendage to the mural circle.

The telescope of this instrument is a Newtonian reflector, the tube of which forms the vertical axis, through which axis a plumb-line passes centrally from end to end; and, therefore, is not made to vibrate by turning. The tube or axis, 10 feet long, and 5 inches diameter, at the lower end terminates in a pivot, while the upper end is received by a right angle, against the sides of which it is gently pressed by two springs; contrivances which produce free and steady azimuthal motion.

All the zenith instruments require for collimation two positions, which in the sectors are called *face east* and *face west*; two at 180° distance from each other are equally necessary for the micrometer, and in that under consideration are indicated by the contact of stops, without regarding any divisions.

The large mirror at the lower end, as well as the pivot, are perforated, in order that the plumb-line may pass freely through them, the latter sustaining the plummet in a water vessel several inches below. The axis of the mirror is somewhat inclined to that of the tube, for the purpose of placing the plane mirror out of the way of the plumb-line, which latter, as before observed, occupies the centre. The rays of light, thus rather obliquely reflected up the tube, are turned into a horizontal direction by the plane mirror, and come to a focus a little beyond the side of the tube, where, with appropriate adjustments, is fixed a double micrometer for measuring zenith-distances.

When the instrument is stopped with the micrometer toward the south, one of the moveable wires is made to bisect a star a little before it comes to the centre of the field of view; then the instrument is turned to the opposite stop with the micrometer towards the north, which may be done in three seconds, and then the other moveable wire is made to bisect the star. It is evident now, that the opening between the wires is double the zenith-distance of the star, and if the axis was truly vertical, the middle between them is the point zenith. The revolutions of the screws are counted in the field of view, and the parts to the third decimal figure read off upon the micrometer heads, which revolutions and parts are to be reduced to angular measure.

The plumb-line is suspended from a fixed point at the upper end, and near the lower end is a rectangular arrangement of microscopes with adjustments, which, together with the adjustments of the pivot, accomplish the means of bringing the axis and plumb-line coincident with each other, and of assuring the vertical position of the former.

The conception of this instrument was not confined to a reflecting telescope, it was seen that a refracting one would succeed equally well: in the latter case, the pivot at the lower end must be perforated to receive the eye-glass, and the plumb-line should be exterior to the main tube, but inclosed in a smaller one to protect it from the action of the wind. In the case of the Greenwich instrument, of which the foregoing is a description, the reflector was preferred on account of its allowing the central position of the plumb-line, which, being free from vibration, shortens the time required for adjustment; a consideration indeed of very little value; for it is now known (but was not then) that instruments properly constructed, and used with care, which they now are at our national establishments, seldom or never

want re-adjustment. A better cause for adopting the reflector was, that the horizontal view is more easy than the vertical one, especially as in the former the hands and whole body are unembarrassed, and fit for action. But whichever construction of the telescope is employed, we know that Troughton considers the zenith-micrometer as one of the most elegant of his inventions.

Zenith-Micrometer by Dollond. — The zenith-micrometer which is represented in Plate XXXIII. by *figs. 3, 4, 5, and 6*, has great advantages in the simplicity of the construction and use, that former instruments for the same purpose do not possess, and is portable: the plan was proposed by Mr. Pond, the astronomer royal, and the instrument executed by Mr. Dollond for transatlantic measurements. It is drawn from a scale of two inches to the foot, and is represented without a stand or support. It can be applied to either, as occasion may require. The component parts are these; *viz.* an achromatic refracting telescope *AA*, (*figs. 3, 4.*) of 42 inches focal length, with an aperture of $2\frac{3}{4}$ inches; a micrometer *B*, with two screws, each moving a separate wire through the field of view, which is extended to two degrees. The transverse axis *C* is 18 inches long, and glazed for a telescope, with cross wires that adjust, so that when the principal telescope *A* is taken out, (and for which there is a provision,) the line of collimation may be truly adjusted to the pivots, and when replaced will be correctly at right angles to the principal telescope. The use of the axis being formed into a telescope, is, for the purpose of placing the instrument correctly in the meridian, by a mark that must be found to the east, and also by another to the west, so that when the star has been observed with one of the micrometer wires, and the instrument is changed for the purpose of observing the same star with the other micrometer wire, it may be correctly replaced, the mean of the two observations being the correct zenith-distance. The instrument is also furnished with a plumb-line *D*, and with a dot at *E*, the image of which is brought to the place of the plumb-line by a lens; this is known by the name of the *ghoff* adjustment. The plumb-line is suspended from a piece at *F*. The two screws *GG* are used for bringing the dot carried by the telescope, to coincide with the plumb-line; and is observed to be so by the lens at *H*. This contrivance affords one of the greatest advantages of the instrument, as it enables the observer, at the moment before he observes the conjunction of the star with the micrometer wire, to ascertain the correct position of the instrument by the plumb-line; for the correctness of the observation will depend on the accuracy with which the plumb-line is made to coincide with the dot; and by this method the *error of division is done away*. The level (*fig. 6.*) is used for levelling the axis, and the circular piece (*fig. 5.*) with the *Ys a a* attached, in which the pivots of the transverse axis rest, may be applied to a mahogany-framed stand, or on a stone pier, or bracket: it is represented as it was made for a mahogany stand (which had adjusting screws at the feet); it consists of two strong brass plates, and is furnished with a circular motion for bringing the instrument into the meridian, which motion is given by a pinion *b*; and it is made fast by the four screws *e, e, e, e*. The two adjusting screws *G G*, *fig. 3.* must also be attached to a bracket or framed piece in the stand; and the support for the water, in which the plummet is immersed, may also be applied to this bracket. The wires are illuminated through the axis in the same manner as in the transit-instrument. The value of the micrometer-screws is to be found in the usual manner, and reduced into seconds.

The foregoing are the distinguishing properties of this instrument,

instrument, and as the method of using it may be understood sufficiently from what we have said of the zenith-sector, from which it differs only in the small range of its scale, it will be unnecessary to give any further explanation of either its adjustments or practical application.

Other Instruments.—Besides the zenith-sectors and zenith-micrometers, which we have above described, there are other instruments, which may be used as substitutes for these, at the same time that they may be used for their own respective purposes. Of these, the transit-circles of large dimensions, particularly those which move with their pivots supported by stone piers, claim our principal notice. As the professed use of these circles is to ascertain both right ascensions and declinations at the same time, and as zenith-distances are only complements of altitudes taken in any latitude, it is obvious, that those instruments that measure altitudes accurately, at all elevations, will also measure zenith-distances, or their complements; and in fact, the divisions are now numbered in such way, that altitudes and zenith-distances are read alternately in the reversed positions. Of this description is the excellent circle of Mr. Groombridge at Blackheath; but the large circle at Greenwich, not having a plumb-line or level used, nor being capable of reversal, is not of the same class; though a very superior instrument for its own purpose of measuring polar distances from the exact polar point, without any reference to latitude, altitude, or zenith-distance.

We have also before us an 18-inch transit-circle with a 3½-feet telescope, very lately made by Mr. Thomas Jones, of Charing-Cross; the axis of which is supported by a cast-iron frame, that very conveniently admits of measures being taken in or near the zenith, as well as in any other degree of elevation. This instrument comprises many new and useful contrivances, but they cannot be described under this head, consistently with our general plan of dividing our subjects.

ZENITH is a word used by some writers to express the first appearance of the menses in young women.

ZENKABAD, in *Geography*, a town of the Arabian Irak; 22 miles S. of Sherban.

ZENKOV, a town of Russia, in the government of Tchernigov; 140 miles S.E. of Tchernigov. N. lat. 50°. E. long. 34° 14'.

ZENN, a river of Franconia, which runs into the Rednitz, near Vacha, in the margravate of Anspach.

ZENN. See LANGENZENN.

ZENNA, the name of a mystical thread worn by Brahmans, and by many individuals of other tribes of Hindoos. So prolix and minute are the authors of the Ordinances of the Hindoos, that rules for almost every occurrence of life, however trifling, have been laid down. Not that any thing connected with the zennar has been deemed trifling by those who ordained it, by those who wear it, or those who revere it. On the contrary, the individuals to be so distinguished, the mode of manufacturing the sacred article, and its investiture, with many particulars, have occupied the attention of lawgivers, and are attended to with great respect by their obedient followers.

Brahmans affect to consider the zennar as of highly mysterious and sacred import, and do not consider an individual as fully a member of his tribe until he have assumed this holy emblem. A Brahman should be invested with it at the age of eight years, by the hands of his father, who, with his Guru, or spiritual preceptor, twirls that first put on. A Khetriya receives it at eleven, from a Brahman. A Vaisya at twelve years of age. A Sudra is on no account permitted to wear it. A description of these four grand

divisions, comprising the whole race, will be found under *SECTS of Hindoos*.

The zennar must be made by a Brahman: it is composed of three threads, each measuring ninety-six hands, twisted together, and folded into three; then twisted again four as to consist of nine threads: these are again folded into three without twisting, and each end fastened with a knot. It is put over the left shoulder next the skin, and hangs down the right thigh as low as the fingers can reach. Of these cords a Brahman wears four; the other privileged tribes but three. Some writers call this the Brahmical, or priestly, or sacerdotal thread; but not, it would appear, in strict correctness; it not being confined to the priestly tribe, but worn, as we have seen, by three out of the four sects of Hindoos.

In the Institutes of Menu (see MENU), c. 11. v. 36. the revered legislator ordains, that "in the eighth year from the conception of a Brahman, in the eleventh from that of a Khetriya, and in the twelfth from that of a Vaisya, let the father invest the child with the mark of his class."

The two next verses allow, on particular occasions, the assumption of the sacrificial thread, as it is often called, in the fifth, sixth, or eighth years respectively; or it may, in like manner, be delayed until the individual be double the age mentioned in verse 36. "After that, all youths of these three classes, who have not been invested at the proper time, become outcasts, degraded from the Gayatri, and condemned by the virtuous," v. 39. Of the Gayatri, see under our article O'M.

In ancient books, the three first classes, from being thus invested with this sacrificial thread, are called *twice born*; a regeneration being effected by this mystical second birth. But it has been thought, that in later times, the Brahman only has the advantage of being thus *born again*. The term *twice born* is very common; a *third birth* is sometimes mentioned: this, we believe, is at the decease, or the burning of the body. "The first birth is from a natural mother; the second, from the ligation of the zone; the third, from the due performance of the sacrifice: such are the births of him who is usually called twice born, according to a text in the Veda. Among them, his divine birth is that which is distinguished by the ligation of the zone and sacrificial cord; and in that the Gayatri is his mother." Menu, ii. 169, 170.

This cord is never taken off; even when sleeping and bathing, it is worn and disposed of in a particular manner. When worn out, it is committed to the water with due and appropriate ceremony, and another is as duly put on. It is seen on the most ancient of Hindoo sculptures, and on many of the figures; for instance, in the cavern temple at Elephanta. (See MAHAKALA.) It has several other names; among them Janvi, or Jahnvi, Maurvi, &c. The latter is applied to the cord of the military tribe, being made from the leaves of a species of hyacinth, called murva, of which bow-strings are also made: the Brahman's cord is made of cotton. The name Jahnvi given to this sacred, triple, mystical, regenerating thread, has been derived from Jahn, an ascetic, who, in a very extravagant way, gave a second birth to the equally sacred, triple, mystical, regenerating river Ganga (the Ganges), which is hence called Jahnvi. Of this we have taken some notice under JAHNU; and of the triple union of the Ganga, and other sacred rivers, under TRIVENI.

Brahmans, and their enthusiastic followers, are very mystical concerning regeneration, and have divers modes of effecting the second birth, in cases where the purity derived from the ligation of the zone, or investiture with the sacrificial thread,

thread, hath been lost by the contaminations of unlawful acts, as from accidental defilements. Of this, see under our article *YONI*.

ZENO, in *Biography*, called the *Eleatic*, in order to distinguish him from *Zeno* the Stoic, was a native of Elea, in Magna Græcia, and said to have been the adopted son of Parmenides, whose disciple he was, flourished about the year 463, B.C. and chose to live in his native city rather than at Athens, for the sake of maintaining his independence. He is represented as a zealous friend of civil liberty, and as having lost his life in his opposition to a tyrant. It is said, that having been detected in a conspiracy against the petty tyrant of the place of his nativity, he endured the most cruel torments, because he would not betray his accomplices; and that at length his countrymen, roused by his fortitude, fell upon the usurper and stoned him to death. To him the invention of the dialectical art has been erroneously ascribed.

According to Aristotle, *Zeno* taught that nothing can be produced either from that which is similar or dissimilar; that there is only one being, and that is God; that this being is eternal, homogeneous, and spherical, neither finite nor infinite, neither quiescent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are composed of four elements, heat and moisture, cold and dryness; and that the body of man is from the earth, and his soul an equal mixture of these four elements. He argued with great subtlety against the possibility of motion. If Seneca's account of this philosopher deserves credit, he reached the highest point of scepticism, and denied the real existence of external objects.

Upon the whole, his sentiments seem to have been so fluctuating and unstable, and his method of arguing so versatile, that it is not certain whether he allowed or denied a properly divine nature. Molsheim, not improperly, applied to the doctrine of *Zeno* the words of Terence:

“ ——— Incerta hæc, si tu postules
Ratione certa facere, nihilo plus agas,
Quàm si des operam, ut cum ratione infanias.”

“ Things thus uncertain, if by reason's rules
You'd certain make; it were as wise a task
To try with reason to run mad.” COLMAN.

Bayle depreciates the practical philosophy of *Zeno*, on account of his vindication of the warmth with which he resented reproach, by saying, “ If I were indifferent to censure, I should also be indifferent to praise.” His works, though unknown to the moderns, were held in high estimation among the ancients. *Diog. Laert.* Bayle. *Brucker* by *Enfield*, vol. i.

ZENO, the founder of the *Stoic* sect, was born about the year 366, before Christ, and died, as it is said, in the 1st year of the 129th Olympiad, or 264 B.C. For an account of him, see the article *STOICS*.

ZENO, Roman emperor of the East, was a descendant of an Iaurian family of distinction, and at first bore the name of “ *Trafalissæus*.” Being a commander of the Iaurian troops in the service of *Leo I.*, he married *Ariadne*, a daughter of the emperor, who created him a patrician, and raised him to the chief command of all the armies in the East. Upon the death of *Leo* in the year 474, the empire was transmitted to his grandson by *Zeno* and *Ariadne*, and *Zeno*, by the influence of the dowager-empress *Verina*, was appointed his colleague, and when the young emperor died, *Zeno* possessed the whole imperial power. But *Verina*, being incensed by his scandalous conduct,

formed a conspiracy against him, so that *Zeno* was obliged to seek refuge, first at Chalcædon, and afterwards in Iauria, his native country. *Basiliscus*, the empress's brother, who had assumed the empire, became so unpopular, that *Zeno* was restored, and the degraded emperor perished in prison. About this time the western empire terminated; and *Zeno*, receiving deputies from the Roman senate, who recognized Constantinople as the seat of universal empire, and requested the title of patrician for *Odoacer*, proclaimed king of Italy, was flattered with the title of sole Roman emperor, and commenced an amicable correspondence with *Odoacer*. The remaining period of his reign was both turbulent and inglorious. The insurrections against his government were numerous, and his temper, which was naturally severe, was thus rendered more hostile and cruel towards those whom he considered as his enemies. The irritability of his disposition proved eventually a collateral cause of his death, by aggravating a disorder in his bowels, which proved fatal in the year 491, at the age of 65, after a reign of seventeen years and three months. His widow *Ariadne* married very soon after his death. His reign was famous for the conflict of faith, called the *HENOTICON*, or *Henoticon*, (which see.) *Gibbon's Hist. Rom. Emp.* vols. vi. vii. viii.

ZENO, in *Geography*, a river of Italy, which runs into the Taro, opposite Fornovo, in the duchy of Parma.

ZENOBIA, *Queen*, in *Biography*, was a native of Syria, in the third century, who claimed descent from the Macedonian kings of Egypt. This female was celebrated for the beauty of her person, the harmoniousness of her voice, her mental talents and literary acquisitions, and her distinguished heroism and valour, as well as her modesty and chastity. “ Her manly understanding,” says *Gibbon*, after recounting her personal beauties and excellencies, “ was strengthened and adorned by study. She was not ignorant of the Latin tongue, but possessed in equal perfection, the Greek, the Syriac, and the Egyptian languages: she had drawn up for her own use an epitome of oriental history, and familiarly compared the beauties of *Homer* and *Plato*, under the tuition of the sublime *Longinus*.” She was allied by marriage to *Odonatus*, king of *Palmyra*, and delighted in those exercises of war and the chase to which he was devoted. Many of his victories have been ascribed to her military skill and valour. After the death of her husband, about the year 267, she assumed the sovereignty of the East, and governed with equal vigour and policy; so that by her success in warlike expeditions, as well as by the wisdom and firmness of her administration, she aggrandized herself in Asia, and her authority was recognized both in *Cappadocia* and *Bithynia*, when *Aurelian* succeeded to the Roman empire. Envious of her power, and determined to dispossess her of some of the rich provinces that were comprehended within the extent of her dominion, he marched at the head of a powerful army to Asia, and having defeated the queen's general *Zabdas*, near *Antioch*, she retreated to *Emesa*, whither she was pursued by *Aurelian*. Under the walls of that city another engagement with *Zenobia*, which was commanded and animated by herself, took place, in which the emperor was again victorious. The queen, thus unfortunate, withdrew the relics of her vanquished forces to *Palmyra*, her capital; and was pursued thither by *Aurelian*. The favourable terms that were offered to *Zenobia* being refused, the city was besieged; which, after long resistance, the queen determined not to surrender; but as the apprehended famine within the walls, she mounted a swift dromedary, and hastened towards the *Euphrates*, with a view of seeking an asylum in the Persian territories. But being overtaken in her flight, she was brought back to *Aurelian*, who

who received her with a stern countenance, and questioned her how she could dare to re-fit the emperors of Rome. She replied, "Because I could not acknowledge as such a Gallienus and others like him; but I recognize by that title you who know how to conquer." At Emesa, the fate of Zenobia was submitted to the judgment of a tribunal, at which Aurelian presided; and the Roman soldiers demanded her death. She, in a manner unworthy of her former fame, saved her own life by throwing the blame of her resistance on her ministers and counsellors; Longinus was one of these, who, with several others, was put to death, in the year 273.

Zenobia was referred to grace the triumph of Aurelian; and on the appointed day she preceded, on foot, a magnificent chariot, which she had designed in the days of her prosperity for a very different kind of entry into Rome. She was encircled, it is said, with chains of gold, and almost sunk under the load of jewels with which she was adorned. Afterward she was treated with humanity by the victor; and had assigned to her an agreeable residence near the Tiber, where she passed the remainder of her days as a Roman matron. Whether she contracted a second marriage with a Roman senator, as some have affirmed, is uncertain; but however this be, her surviving son Vballat withdrew into Armenia, and possessed a small principality granted to him by the emperor, and her family was not extinct in the fifth century. Gibbon's Hist. of Rome, vol. ii.

ZENOBIA, *Zelebi*, in *Ancient Geography*, a town of Asia, in the Euphratenus, upon the banks of the Euphrates, five miles from fort Mambri, and on this side of the small town of Sura. According to Procopius, it was founded by Zenobia, wife of Odonatus, prince of Palmyra. After it had been ruined, Justinian re-established it, and re-peopled it, and made it one of the bulwarks of the empire. After having rebuilt the town and fortified it, he embellished it, constructing magnificent churches, public baths, galleries, and lodgments for the soldiers. It was situated S.E. of Nicephorium.

ZENOBIA, a place of Italy, near the palace of Adrian, assigned to queen Zenobia for her residence.

ZENOBII ISLAND, the name of seven islands in the Indian ocean, upon the coast of Arabia Felix, at the entrance of the Sathalite gulf. Ptolemy.

ZENODOTIUM, a town of Asia, in Osrhoené, in the vicinity of Nicephorium, according to Appian. Steph. Byz. This town, says Plutarch, was forcibly taken by Crassus, who ruined it, and sold the inhabitants by auction.

ZENONIS CHERSONESUS, a town mentioned only by Ptolemy, and placed by him in the Tauric Chersonesus, along the western coast of the Palus Mæotis. M. Peyssonnel thinks this was not a town, but an isthmus, called at present Zeniské.

ZENSON, in *Geography*, a town of Italy, in the Trevisan; 9 miles E.N.E. of Trevigio.

ZENSUS, in *Arithmetic*, a name which some authors give to a square number, or the second power.

The higher powers they call *zenfizenjus*, *zenzicibus*, *zenfzenjus*, *zenfurdofolidus*, &c. See POWER.

ZENTA, in *Geography*, a town of Hungary, on the river Theys; memorable for a signal victory obtained, in the year 1697, by prince Eugene, over the Turks, commanded by the emperor Muthapha II. in person: 20,000 Turks were killed, 10,000 wounded, and 3000 taken prisoners; 52 miles N. of Belgrade.

ZENTA, a district of Dalmatia, on the confines of Albania.

ZENTILMANDAIK, a town of Asiatic Turkey, in Natolia; 8 miles N. of Eregrî.

ZENUPH, in the *Jewish Antiquities*, a kind of tiara worn by the kings of Judah. See CIDARIS.

ZEOBID, in *Geography*, a town of the Arabian Iraq, on the Euphrates; 28 miles S. of Bagdad.

ZEOLITE, in *Mineralogy*, a mineral so named by Cronstedt, from the Greek word *ζέω*, *to foam*, on account of its intumescing and foaming very much before the blow-pipe. Haiüy makes two distinct species of the zeolite, which he denominates mesotype and fibbite. Werner makes four sub-species of zeolite, which he calls mealy zeolite, fibrous zeolite, radiated zeolite, and foliated zeolite. Besides this he makes zeolite a generic name, placing it at the head of what he calls the zeolite family, in which arrangement he is followed by professor Jameson, who classes with the zeolite family the following minerals: prehnite, (see PREHNITE,) zeolite, apophyllite, cubicite, called by Haiüy analcime, chabasite, crossite, laumontite, dipyre, natrolite, and wavelite. (See WAVELLITE.) In the classification of specimens at the British Museum, these minerals, so nearly allied in chemical composition, and in many of their external characters, are arranged together under the appropriate denomination of zeolitic substances, by which the confusion incident on making the same word represent both a genus and species is avoided. These substances, except wavelite, are composed of siliceous, alumine, lime, or an alkali, and a considerable portion of water. To the latter, they owe the property of intumescing before the blow-pipe, that many of them possess. Some of these minerals form a jelly when dissolved in acids. Zeolitic minerals occur principally in the cavities of volcanic and basaltic rocks. Of the different members of the zeolite family, prehnite has been already described. (See PREHNITE.) Zeolite, comprising mealy zeolite and fibrous and radiated zeolite, are the various mesotypes of Haiüy, mealy zeolite being the *mesotype alterée aspect terreux* of the French mineralogist. This mineral is white, inclining to yellowish, greyish, or reddish, and is sometimes red. It occurs massive, and kidney-shaped, and corrolloid. Sometimes it forms a crust over other zeolites. The lustre is dull or feebly glimmering; it is opaque, very soft, and rather sectile; it has an earthy fracture, sometimes inclining to fibrous. It is very light, and easily frangible, and feels rough and meagre. It appears to be zeolite in a decomposing state. It intumesces before the blow-pipe, and forms a jelly with acids. The constituent parts are,

Siliceous	-	-	-	-	60
Alumine	-	-	-	-	15.6
Lime	-	-	-	-	8
Oxyd of iron	-	-	-	-	1.8
Loss by exposure to heat	-	-	-	-	11.6

97

Fibrous Zeolite, Mesotype, Haiüy, is of a snow-white colour, passing to greyish, yellowish, or reddish-white, and sometimes into red and yellowish-grey, yellowish-brown, or ochre-yellow. It occurs massive, in kidney-shaped balls, and in capillary crystals. The external surface of the kidney-shaped varieties is rough and dull; internally it is strongly glimmering, passing into glittering, and the lustre is pearly: it is faintly translucent. The structure of this mineral is fibrous, either diverging on one side or stellate, and passes from delicately fibrous to coarse or to narrow radiated. It is brittle, breaking into splintery or wedged-shaped

ZEOLITE.

shaped fragments; it yields easily to the knife. The specific gravity is from 2.158 to 2.197. Before the blow-pipe it intumesces, and forms a jelly with acids. It may be distinguished from needle zeolite by its inferior lustre, fibrous structure, and low degree of transparency and hardness, and also by its want of regular crystallization.

Needle Zeolite, Mesotype, Häuy; and *prismatic mesotype* of some mineralogists. Its colours are, greyish, yellowish, or reddish-white: it occurs both massive and crystallized. The crystals are acicular-rectangular four-sided prisms, terminated by low four-sided pyramids, the faces of which are set on the lateral planes of the prism. Sometimes there are only two terminating planes, forming an acute bevelment, set on obliquely. The rectangular prism is sometimes truncated on the edges, forming an octahedron, with four large and four small planes. The lateral planes of the crystals are longitudinally striated, but the acuminating planes are smooth. Sometimes the crystals are diverging, and sometimes promiscuously aggregated. The crystals are externally shining or splendid, internally glistening; the lustre is vitreous, inclining to pearly. The structure is lamellar, with joints parallel to one of the sides of the prism; also at right angles to the axis, and parallel to the two diagonals of the prism. Of these, the first cleavage only is generally visible. The cross fracture is imperfectly conchoidal; the lustre between vitreous and pearly. It is translucent or transparent, with double refraction. It yields to the knife, but scratches calcareous spar, and is brittle. The specific gravity varies from 2.17 to 2.27. This mineral, like the preceding, intumesces before the blow-pipe, and gelatinizes with acids. It becomes electric by heat; the extremity of the crystal, terminated by a pyramid or bevelment, shews positive the bottom of the crystal negative electricity. According to Vauquelin, the constituent parts of mesotype are,

Silice	50.24
Alumine	29.50
Lime	9.46
Water	10
	99.2

Needle zeolite, or mesotype, is distinguished from radiated zeolite, or stilbite, by its vitreous lustre, distinct prismatic concretions, and greater transparency and brittleness. The latter has also more of a nacry lustre.

Radiated Zeolite, Stilbite, Häuy, is generally of a yellowish or greyish-white colour, and rarely passes into reddish-white or red. It occurs massive in angular pieces, and globular, and also crystallized in broad, rectangular, four-sided prisms, rather acutely terminated by four planes set on the lateral edges of the prism. Of these planes two adjoining ones are more inclined to the axis of the prism than the other two. The summits of the terminating planes are sometimes more or less deeply truncated. Sometimes the prism is so thin as to form a long six-sided table, bevelled on the shorter terminal planes. The crystals are aggregated in diverging radii, and frequently so closely joined to each other, that the pyramidal terminations of each crystal are only visible. The broader lateral planes of the crystals are smooth, and the smaller longitudinally striated. The structure is lamellar, with joints in one direction, parallel to the axis of the prism. The surfaces of the broader lateral planes are splendid and pearly; internally the lustre is more or less shining, and is pearly. The crystals are translucent, or semi-transparent. The diverging

radii of the aggregated crystals are more or less broad, passing from fibrous to foliated. It is brittle, and the fragments are wedge-shaped and splintery. Stilbite scratches calcareous spar. The specific gravity of this mineral is from 2.13 to 2.16. It intumesces before the blow-pipe, yielding a phosphoric light: it becomes white when laid on a glowing coal: it does not gelatinize with acids. The constituent parts are,

Silice	40.98
Alumine	29.09
Lime	10.95
Water	16.50
	97.52

Foliated Zeolite, Stilbite, Häuy.—The colours of this mineral are nearly the same as those of the preceding, being chiefly yellowish and greyish-white, and rarely milk-white, snow-white, reddish-white, or red; it sometimes is yellowish-grey, and pinchbeck-brown. It occurs both massive, disseminated, globular, amygdaloidal, and crystallized. The form of the crystals is a low, very oblique, four-sided prism; sometimes truncated on the acute lateral edges, and also on the angles of the acute lateral edges. Sometimes all the angles are truncated. It occurs also in low six-sided prisms, and equi-angular six-sided tables; also in eight-sided prisms. The crystals are generally small; the lateral planes are transversely striated, and the terminal planes are smooth. It has a pearly lustre, which is either shining or splendid. The pinchbeck-brown variety has a semi-metallic lustre. It has a foliated and slightly curved structure, with a single cleavage, parallel with the terminal planes of the prisms. Sometimes a conchoidal cross fracture may be observed. It is brittle, and the fragments are angular and blunt-edged, and sometimes tabular. The massive varieties are strongly translucent; the crystals are translucent, semi-transparent, or transparent. It yields to the knife, but scratches calcareous spar. The specific gravity of this mineral is 2.2; and, like the preceding mineral, it intumesces and melts before the blow-pipe, giving out a phosphoric light: it does not form a jelly with acids. According to Meyer, the constituent parts are,

Silice	58.3
Alumine	17.5
Lime	6.6
Water	17.6
	100

According to Vauquelin,

Silice	52.6
Alumine	17.5
Lime	9
Water	18.5
	97.6

All these zeolitic substances, classed as mesotype and stilbite by Häuy, pass by imperceptible gradations into each other, and occur, as we have before observed, in basaltic and volcanic rocks.

The easy fusibility of zeolites was at one time regarded as rendering their occurrence in volcanic rocks a subject of difficult explanation; but the experiments of sir James Hall, referred to under SYSTEMS of Geology, demonstrate

ZEOLITE.

the possibility of crystalline arrangements taking place under compression in substances that would be diffipated by heat under the common pressure of the atmosphere. It is probable, however, that many zeolitic substances which occur in basalt or lava have been infiltrated into the cavities at a later period, and are even forming at the present day in ancient lavas and basalts.

Some of the minerals classed with the zeolite family have been described in our preceding volumes. See *APOPHYLITE*, or *ICTHYOPHTHALMITE*.

Analcime, or *Cubicite*, formerly called by Werner *cubic zeolite*, is generally white, sometimes reddish-white, or red. It occurs sometimes massive, but more generally crystallized in perfect cubes, or with the angles more or less deeply acuminate, or in twenty-four-sided crystals, like those of the leucite, having each of the sides equal and similar trapeziums. The structure presents slight indications of cleavage, parallel with the sides of a cube. The fracture is compact and flatly conchoidal, passing into fine-grained, uneven. It is translucent, semi-transparent, or transparent, and has a shining lustre, between vitreous and pearly. It is sufficiently hard to scratch glass, but is easily frangible. The specific gravity of cubicite is 2.44. It becomes electric by rubbing. Before the blow-pipe it melts into a transparent glass. According to Vauquelin, the constituent parts of this mineral are,

Silix	-	-	-	-	58
Alumine	-	-	-	-	18
Lime	-	-	-	-	2
Soda	-	-	-	-	10
Water	-	-	-	-	8.5
					96.5

This mineral occurs most frequently in cavities in rocks of the trap formation, accompanied with zeolite; but it is sometimes found in metallic veins in schistose rocks, accompanied with various ores, and with calcareous spar and quartz. The name *analcime* was given to it by Häuy, signifying a body with little power, on account of the feeble electricity excited in it by friction.

Chabasite, *Chabasie*, Häuy, is nearly allied to cubicite, and was formerly classed with it. The crystallization is different; the form is not perfectly cubical, but slightly rhomboidal, the angles of the rhomboid being 94° and 86°, either perfect, or with the obtuse lateral edges truncated, and sometimes both the six obtuse lateral edges and six obtuse angles are truncated. The crystals are transparent or translucent. The lustre is vitreous, and externally splendid, internally glistering; the fracture is imperfectly conchoidal, or fine-grained, uneven. It scratches glass a little. The specific gravity of this mineral is 2.7. It is fusible into a white spongy enamel. According to Vauquelin, the constituent parts are,

Silix	-	-	-	-	43.33
Alumine	-	-	-	-	22.66
Lime	-	-	-	-	3.34
Soda with potash	-	-	-	-	9.34
Water	-	-	-	-	21
					99.67

The situation in which this mineral occurs is nearly the same with that of analcime. The name was given it by Häuy, from chabazion, an unknown stone mentioned in the poems of Orpheus.

Laumontite, *Zeolithe efflorescente*, Häuy.—Its colours are, yellowish-white, snow-white, and greyish-white. It occurs massive and crystallized in octahedral prisms, with edges apparently rounded; the summits of the crystals are dihedral. The crystals are small, lining drusy cavities. The structure is lamellar, and has a two-fold cleavage: it is transparent or translucent when fresh; but on exposure to the atmosphere soon becomes opaque, losing its hardness, and yielding to the pressure of the finger. When fresh it scratches glass. The specific gravity is 2.23. Bournon. It forms a jelly with acids. Before the blow-pipe it intumesces, and is changed into a white enamel. According to Vogel, the constituent parts are,

Silix	-	-	-	-	49
Alumine	-	-	-	-	22
Lime	-	-	-	-	9
Water	-	-	-	-	17.5
Carbonic	-	-	-	-	2.5
					100

This mineral, which agrees in its principal characters with zeolite, was first found in Brittany, by M. Gillet Laumont, after whom it has been named by Werner. It has been found also at Paisley, in Renfrewshire, in amygdaloid, accompanying cubicite. Laumontite disintegrates so rapidly, that for its preservation it requires to be kept in well-closed bottles.

Crofs-Stone, *Harmotome*, Häuy, occurs in small crystals: the form is generally a broad rectangular prism, terminated on each extremity by four rhombic faces, with their acute angles set in the lateral edges of the prism. Sometimes the edges of the rhombic faces are bevelled in one direction. But the name *crofs-stone* is derived from the frequent occurrence of two prisms intersecting each other, having one common axis. The broader planes by this intersection project, and form the figure of a crofs when the prism is viewed at the end, or in the direction of the axis. The colour of *crofs-stone* is generally a greyish-white, which passes into smoke-grey: it is sometimes a yellowish-white, passing into cream-yellow, and red. It is translucent or transparent, with a lustre between vitreous and pearly. The fracture is uneven, or imperfectly conchoidal. It is supposed, by professor Jameson, to have an imperfectly foliated structure. It scratches glass feebly. The specific gravity is 2.33. Before the blow-pipe it emits a yellowish phosphoric light, and melts with intumescence into a colourless glass. It does not gelatinize with acids. This mineral differs from other members of the zeolite family, by containing barytes as an ingredient in its composition. According to Klaproth, its constituent parts are,

Silix	-	-	-	-	49
Alumine	-	-	-	-	16
Barytes	-	-	-	-	18
Water	-	-	-	-	15
					98

Dipyre, Häuy; *Schmelzstein*, Werner.—Its colours are, light pearl-grey, greyish-white, or reddish-white. It occurs massive and crystallized, in aggregated, slender, octahedral, acicular prisms. The structure is lamellar, with joints parallel to the sides, and to the diagonal of a rectangular prism. The lustre is intermediate, between vitreous and pearly: it is translucent. This mineral is sufficiently hard to scratch glass; but is very frangible. The specific gravity

vity is 2.630. Before the blow-pipe it intumescs, and melts with great ease, giving out at the same time a phosphoric light from this double effect of heat upon it. Hæuy gave it the name of *diypre*, on account of its easy fusibility: it was called *schmelzstein* by Wernær. Its constituent parts are,

Silex	-	-	-	-	60
Alumine	-	-	-	-	24
Lime	-	-	-	-	10
Water	-	-	-	-	2
					96
					—

It is said by Brongniart to occur in steatite, along with iron pyrites, near Maulcon, in the Western Pyrenées.

The other members of the zeolite family are described in the preceding volumes. See NATROLITE and WAVELITE.

ZEOPILOS, a word used by Quercetan as the name of an antimonial medicine.

ZEOPHYRUM, in the *Materia Medica*, the name of the *triticum æstivum*, or *hordeum nudum*, as it is called by some authors, the naked barley.

ZEPHANIAH, a canonical book of the Old Testament, containing the predictions of Zephaniah, the son of Cushi, and grandson of Gedaliah; being the ninth of the twelve lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was contemporary with Jeremiah. He prophesies chiefly against Judah, who continued very corrupt, notwithstanding the king's pious zeal for reformation, and the good example he gave to his subjects.

ZEPHAT, in *Ancient Geography*. See SEPHAAT.

ZEPHIRA, in *Geography*, a small island in the Grecian Archipelago, near the N. coast of Antiparos.

ZEPHIRE, in *Ancient Geography*, an island situated on the coast of that of Crete, before the promontory Samonion. Mela.

ZEPHRON, or ZEPHRONIA. See ZIPHON.

ZEPHYRI FÆTUS, a term used by Hartman, and some other writers, to express a mole, or false conception.

ZEPHYRINUS, *Pope*, in *Biography*, succeeded Victor in the Roman see in the year 201. A persecution at the commencement of his papacy obliged him to conceal himself, and when he was at liberty to exercise his functions, he was engaged in the suppression of prevalent heresies, which disturbed the latter years of his pontificate. He died in the year 218 or 219. Bower.

ZEPHYRIUM, in *Ancient Geography*, a promontory of Asia, on the confines of Cilicia Propria. According to Strabo and Ptolemy, this promontory and that of Sarpedon formed the mouth of the river Calycadnus.—Also, a town at the extremity of this promontory.—Also, a promontory of the isle of Cyprus, towards the S.W., at the extremity of a peninsula, which on the W. incloses the gulf, at the bottom of which was Paphos.—Also, a promontory of Italy, on the eastern coast of Brutium, between the promontory of Hercules and the town of the Locri. Strabo.—Also, a promontory of Africa, in the Cyrenaica, upon the coast of the Pentapolis. Ptolemy. Strabo distinguishes two promontories of this name on the coast of Cyrenaica.—Also, a town of Asia, on the coast of Paphlagonia.—Also, a town of Asia, in the interior of Cappadocian Pontus. Arrian gives it a port, and states it to be 120 stadia from the isle of Arrenthias, and 90 stadia from the town of Tripolis.—Also,

a promontory on the coast of Egypt, between Campé and Alexandria, where was a chapel of Venus Arfinoe, and hence she took the name of Zephiritis.—Also, a promontory of Asia Minor, on the coast of Caria, in the vicinity of the town of Myndus. Strabo.—Also, a town of the Tauric Chersonesus; situated on the sea-coast, N.E. of Theodosia. Pliny.—Also, a promontory on the eastern coast of the isle of Crete.

ZEPHYRIUM Jugum, a sacred mountain of Hispania, upon which was a fortress.

ZEPHYRUS, or ZEPHYR, Ζεφύρος, the west wind; a wind blowing from that cardinal point of the horizon opposite to the east.

The poets personify it, and represent Zephyrus as the mildest and most gentle of all the deities of the woods: the character of his personage is youth and gentleness.

It is also called *Favonius*, and *occidens*; and, by many, has been confounded with the *Africus*. See WIND.

ZEPS, in *Geography*, a town of the duchy of Warfaw; 20 miles E. of Wladislaw.

ZERA, a town of Italy, in the Veronese; 7 miles S. of Verona.

ZERANIA REGIO, in *Ancient Geography*, a country of Thrace. Steph. Byz.

ZERBITA, in *Geography*, a town of South America, in the government of New Grenada; 30 miles W.S.W. of Pamplona.

ZERBST, a town of Germany, in the principality of Anhalt Zerbst. It is the residence of the prince, and the largest and handsomest town in the whole principality of Anhalt. The residence-house here is remarkably grand. In the town are two Lutheran churches, one of which is used by the Calvinists, together with an university, common to all the princes of Anhalt, and founded in 1582, out of a school: it has a rector, with three Calvinist and one Lutheran professors. The principal trade is in beer, with manufactures of gold and silver; 8 miles N.N.W. of Dessau. N. lat. 52° 3'. E. long. 12° 10'.

ZERDA, in *Zoology*, a name given by the Moors to an animal which inhabits the desert of Sahara, extending beyond mount Atlas.

This is the *canis cerdo* of Linnæus, with a straight tail, a palish or yellowish-white body, with prolonged upright ears, internally rofe-coloured. It is the fennec of Bruce, and a beautiful African and Asiatic animal, and is principally found in Arabia.

Pennant classifies it under the genus of dog; and describes it as having a pointed visage, long whiskers, large bright black eyes, very large ears of a bright rofe colour, internally lined with long hairs, and orifice so small, as not to be visible, probably covered with a valve or membrane; legs and feet like those of a dog, and taper tail; its colour is between a fraw and pale brown; its length from nose to tail ten inches, its ears three inches and a half long, tail six, and height not five. It burrows in the sandy ground, and is so excessively swift, that it is very rarely taken alive; feeds on insects, especially locusts; sits on its rump; is very vigilant; barking like a dog, but with a shriller sound, and chiefly in the night; and is never observed to be sportive.

M. Buffon says of this animal, that it is found to the south of the Palus Tritonides, in Lybia; that it has something of the nature of the hare, and something of the squirrel; and that it lives on the palm-trees, and feeds on the fruits: hence probably it derives its name fennec from φοῦξ, a palm-leaf. Bruce's Travels, vol. v.

ZERDUSHT, in *Biography*. See ZOROASTER.

ZEREA, in *Geography*, a town and fortrefs of Perfia, in Farfifitan: this town was taken by the troops of Timur Bec, with great slaughter; 18 miles N.N.E. of Schiras.

ZEREB, a town of Perfia, in the province of Segeftan; 130 miles N.W. of Zarang.

ZEREWICA, a town of Lithuania; 5 miles S.W. of Slonim.

ZERIB, a town of Kurdifitan; 25 miles W. of Gulamerik.

ZERICHUM, a name given by fome of the chemical writers to arfenic.

ZERKI, in *Geography*, a town of Kurdifitan; 30 miles S.W. of Bethis.

ZERKWITZ, a town of Lufatia; 2 miles W. of Lubbenau.

ZERMA. See SURMA.

ZERMAGNA, a river of Dalmatia, which runs into the Adriatic, oppofite Pago.

ZERMONY, a town of Lithuania; 10 miles N.W. of Lida.

ZERNA, a mountain of Carinthia; 3 miles N.W. of Millatt.

ZERNA, a word ufed by fome of the chemical writers to exprefs an ulcerated lepra or impetigo. The chemical authors ufe it alfo as a name for the foulnefs which they call the *lepra metallorum*, or leprofies of metals.

ZERNEMBL, or TSCHERNEMBL, in *Geography*, a town of the duchy of Carniola, on a fmall river which runs into the Kulpa; 4 miles S.S.W. of Rudolfswerth. N. lat. 45° 50'. E. long. 15° 5'.

ZERNESIUM COLONIA, in *Ancient Geography*, a colony of Dacia, founded by Trajan.

ZERNETZ, in *Geography*, a town of Switzerland, in the Upper Engadine. In the late war it was taken by the French, and foon after retaken by the Auftrians; 8 miles N. of Zultz.

ZERNITZ. See CZERNETZ.

ZERO, a river of Italy, which runs into the fea, 7 miles N. of Venice.

ZERO, denotes the point from which the feale of a thermometer is graduated. Thus Cælius's and Reaumur's thermometers have their zero at the freezing-point, while the thermometer of Fahrenheit has its zero at that point at which it ftands when immerfed in a mixture of fnow and common falt. In Wedgwood's pyrometer, the zero corresponds with 1077° of Fahrenheit's, each degree of which is equal to 130° of Fahrenheit. Confequently 180° Fahr. = 100° Celf. = 80° Reaum. = 150° De Lifle = $\frac{1}{12}$ Wedgwood. See THERMOMETER.

ZEROGERE, in *Ancient Geography*, a town of India, on this fide of the Ganges, E. of the river Namadus. Ptolemy.

ZEROWITZ, in *Geography*, a town of Bohemia, in the circle of Bechin; 3 miles W.S.W. of Potfehaken.

ZERREH, or ZURRAH, *Lake of*, a lake of Perfia, in the province of Seiftan or Segeftan, into which the river Heermund, or *Hindmund*, (the ancient Etymander,) navigable for boats from Boft to Zarang, flows through the centre of it, from the mountains of Huzara, beyond Cabul. This lake is faid to be 30 furlongs in length, and 6 in breadth, or about 100 miles long, and 20 broad at the wideft part. It is principally formed by the waters of the rivers Heermund and Ferrah, and in the dry feafon refembles more a marfh than a lake, being covered with rufhes and reeds. In the middle the water is frefh; but brackifh towards the fhore, as the fandey plains which furround it are

impregnated with falt. The lake is full of fifh and wild fowl; and in its centre there is a fortified town, called "Kookbozard," built on a high ifland, where the treasure of the principal families of Seiftan ufed to be depofited when the province was invaded. It is faid that on the borders of this lake is a town named "Naffarabad," which is defcribed as being four days' journey for a loaded camel, W. of the city of Doolhak, the prefent capital of the province.

ZERTA, or SERTA, the *Zerte*, or *Serte*, in *Ichthyology*, a fifh caught in the rivers of Italy, and fome other places, of the figure of the chub, and called by authors *capito anadromus*, and the *blike*. It feldom grows to more than ten pounds weight, and at times lives in rivers, at times in the fea; and is efteemed a very well taftef fifh, efpecially a little before the feafon of its fpawning, either frefh, falted, or prepared in various ways by pickling, &c.

The *zerte* is that fpecies of cyprinus defcribed by Gefner and others under the name of *capito anadromus*. See CYPRINUS *Vimba*.

This is the filvery-blueifh carp, olivaceous above, with the dorsal, caudal, and anal fin blueifh, the reft reddifh, and the nofe protuberant. It is a native of Germany, Ruffia, Sweden, and other parts of Europe, inhabiting rivers, and migrating into the Baltic fea.

ZERVINKA, in *Geography*, a town of Servia, on the Danube; 10 miles N.W. of Belgrade.

ZERUIS, in *Ancient Geography*, a town of Thrace, on the route from Dyrachium to Byzance, between Dymæ and Plotinopolis. Anton. Itin.

ZERUMBET, in *Botany*, a name firft ufed by Serapio, and apparently either of Arabian or Indian origin. It belongs to one of the aromatic roots of the natural order of *Scitamineæ*, the produce of the Eaft Indies, but rather to a *Kempferia*, than to the fpecies of Ginger to which Linnæus has applied it. (See ZINGIBER.) Dale has very juftly obferved on this fubject, *Pharmacologia*, 275, that in the prefent inftance, as well as innumerable others, the Arabian writers are fo brief, as well as vague, in their defcriptions, and fo contradictory amongst themfelves, that we can fcarcely tell whether they were acquainted with any particular object or not.

Wendland, Jacquin, and Poiret, (Lamarck Dict. v. 8. 857.) have moft unaccountably made a genus of *Alpinia nutans*, and called it *Zerumbet*; but this cannot on any principle be maintained.

ZERYNTHUS, in *Ancient Geography*, a town of Thrace, which had a cavern of the fame name, and which the ancients called Zerynthium Antrum. This cavern was confecrated to Hecate, to whom they facrificed dogs. Suidas.

ZERZEN, in *Geography*, a town of Arabia, in Yemen; 36 miles S.E. of Ghezar.

ZESEMITZ, a town of Bohemia, in the circle of Chrudim; 8 miles N. of Chrudim.

ZESSEL, a town of Silefia, in the principality of Oels; 5 miles N.E. of Oels.

ZEST, the woody thick fkin quartering the kernel of a walnut. Some phyficians prefcribe this zeft, dried, and taken with white wine, as a remedy againft the gravel.

The word is alfo ufed for a chip of orange or lemon-peel; fuch as is ufually fqueezed into ale, wine, &c. to give it a flavour; or for the fine thin oil that fpirts out of that peel on fqueezing it.

Hence, to zeft an orange or lemon, among confectioners, is to cut the peel from top to bottom into fmall flips, as thin as poffible; or, to zeft, is to fqueeze the peel over the furface of any thing.

ZESTO-

ZESTOLUSIA, a term used by some medical authors to express bathing in warm water, by way of distinction from *ψυχροβλυσία*, or bathing in cold water.

ZETA, or **ZETECULA**, a little closet, or withdrawing chamber, with pipes running along the walls, to receive from below either the cool air, or the steam of warm water.

The word is formed either from ζῆλος, *to be warm*; or of ζῆν, *vivere, to live*, on account of the use made hereof for love and enjoyment.

ZETA, or **Zetta**, (*Menzil*), in *Ancient Geography*, a town of Africa Propria, situated near the sea, E. of Vicus Angulii.

ZETETÆ, Ζητηταί, among the Athenians, were officers appointed upon extraordinary occasions, to inquire after the public debts, when, through the neglect of the receivers, or by other means, they were run up to large sums, and began to be in danger to be lost, if not called in.

ZETETICE, Ζητητικῆς, formed from ζῆτισις, *I seek*, or zetetic method, in *Mathematics*, the method made use of to investigate or find the solution of a problem.

The ancient Pyrrhonians were sometimes called *Zetetici*, q. d. *seekers*.

ZETIN, in *Geography*, a town of Croatia; 28 miles W.N.W. of Novi.

ZETLAND, or **SHETLAND**, the name of a cluster of islands, situated in the Northern ocean, between the 59th and 62d degrees of N. latitude, and a very little to the W. of the meridian of London. The most southern part is nearly 100 miles N.N.E. from the northern county of Scotland. These islands exceed one hundred in number, of which only thirty-four are inhabited; the others, consisting chiefly of rocks and sands, are unfitted for human support. By different writers, they have been named *Hethland*, *Hialtland*, *Zetland*, *Schetland*, and *Shetland*; which names, Dr. Edmondston says, "are of Norwegian origin, and are supposed to be descriptive of their form or appearance." The most correct and approved orthography is that of *Zetland*. The general appearance of these islands is bleak, bare, and rocky; but some interior parts of the main-land are cultivated, clothed, and cheerful. In many places on the coasts, rocks of immense size are seen to rise above the foaming waves, some of which are at considerable distance from the shores. Some of these are also perforated by vast natural arches; in other parts there are deep caverns and subterranean recesses. Two of these are called the *Seranda*, one of which extends above 300 feet in depth. Almost all the large islands are deeply intersected by tortuous bays, or voes, as they are provincially called, which afford facilities for internal communication, and excellent harbours for vessels. Several of them are commodious, and well sheltered from dangerous winds. Some of the islands have lakes, the largest of which is not more than two miles in length. The highest hill is *Mons Ronaldi*, in the parish of Northmaven; the height of which, from barometrical measurement, is 3944 feet above the level of the sea. Some of the headlands are lofty and grand, one of which, *Nofs-head*, is above 600 feet in height.

According to the population reports of 1811, the following is the enumeration of houses and inhabitants, and the names and number of parishes. The total number of houses 8230, inhabited by 9038 families, 16 houses building, and 101 unoccupied. The whole population was 46,153, consisting of 20,151 males and 26,002 females. The parishes are, 1. Aichfing and Sandfing; 2. Breffay, Burra, and Quarff; 3. Delting; 4. Dunrossness, Sandwick, Cunnibrough, and Faria isle; 5. Lerwick and Gulberwick;

6. Lunnasting, Netfing, Skerries, and Whalfay; 7. Northmaven; 8. Tingwall, Whitenefs, and Weifdale; 9. Unff; 10. Walls, Sandnes, Papa, and Fonta; 11. Yell (North) and Fellar; 12. Yell (South and Middle).

As the chief histories and topographical peculiarities of the *Zetland* islands have been fully detailed under the words *MAINLAND*, *LERWICK*, and *SCALLAWAY*, the reader is referred to each word respectively.—A View of the ancient and present State of the *Zetland* Islands, by A. Edmondston, M.D. 2 vols. 8vo. 1809.

ZETLAND *Islands*, *Forula* or *Fula*, the most western of the *Shetland* islands, and is supposed to be the "Ultima Thule" of the ancients. It is about three miles long and one and a half broad, nearly twenty miles distant from any land, W. of the clusters of *Orkney* and *Shetland*, to which it is politically annexed; it affords excellent and extensive pasture for sheep; and is inhabited by 26 or 27 families.

ZETTERITZ, a town of the principality of *Culmbach*; 11 miles S.W. of *Culmbach*.

ZETUS, a word used by some of the chemical writers as a name for vitriol.

ZEVACO, in *Geography*, a small island in the Pacific ocean, near the coast of *Veragua*. N. lat. 8°. W. long. 81° 46'.

ZEVEN. See *CLOSTER Seven*.

ZEVENAER. See *SEVENAER*.

ZEUF, or **GAER**, a town of the kingdom of *Balk*; 100 miles S.E. of *Balk*.

ZEUGITÆ, Ζευγίται, among the Athenians, the third class of the people, or those who had an estate of two hundred medimni.

ZEUGITES, in *Botany*, an ancient name, adopted by *Browne*, but no otherwise applicable to the present genus, than as far as concerns its reedy habit. The *Zeugites* of *Pliny* was a large *Boeotian* reed, so called from ζυγος, a yoke, because it was bound together, in portions of different lengths, to make the pastoral pipes; as wheat straws are, by our shepherd's boys, to this day; but the *West Indian* grass, of which we are now to give an account, has not even this coincidence with the original.—*Browne* *Jam.* 341. *Schreb.* *Gen.* 810. *Willd.* *Sp. Pl.* v. 4. 204.—Class and order, *Monocia Triandria*. (Rather *Triandria Dignia*.) *Nat. Ord.* *Gramina*, *Linn.* *Juss.*

Gen. Ch. *Common Calyx* a glume of two valves; the outer one broadest, concave, abrupt and jagged, ribbed; membranous at the edges; the inner narrower, sharper and keeled. *Male Florets* two, smallest, on a common stalk the length of the solitary female floret, within the common calyx. *Pertianth* none. *Cor.* Glume of two ovate-oblong, compressed, bluntish, awnless, equal valves. *Stam.* Filaments three, capillary, the length of the corolla; anthers oblong, cloven at each end.

Female within the larger glume of the common calyx, sessile. *Pertianth* none. *Cor.* Glume of one oblong concave valve, twice the size of the calyx, bordered towards the top with a dilated membrane, awned; the awn terminal, capillary, straight, half as long again as the glume. *Pist.* Germen oblong; style divided; stigmas long, shaggy. *Peric.* none. *Seed* solitary, oblong.

Obs. *Schreber* remarks, that this grass differs so entirely, in every character, from *Apluda*, with which *Linnaeus* combines it, that they are totally irreconcilable. We should refer both, with all other true *Gramina*, as in *Fl. Brit.* to the class *Triandria*.

Ess. *Ch.* *Common Calyx* of two valves, with three flowers; the female one sessile; the males stalked. Corolla of

of the males of two beardless valves; of the female of one awned valve. Style divided. Seed oblong.

1. *Z. americanus*. Jamaica Yoke-grass. Willd. n. 1. (*Z. arundinaceus*, ramifolus, minor, rufescens; paniculâ sparsâ terminali; Browne Jam. 341. t. 4. f. 3. *Apluda* Zeugites; Linn. Sp. Pl. 1487. Amcen. Acad. v. 5. (not 6), 412. Swartz Obf. 384.)—Native of Jamaica. Found by Dr. Browne at Cold-spring, in the mountains of New Liguanea, in a rich soil, and shady situation. His original specimens are in the Linnæan herbarium. The root is said to be perennial. Stem two feet high, much branched, ascending, round, jointed, polished, brownish, leafy, rather slender. Leaves alternate, on slender stalks, each with a long sheathing base, reclinate, or nearly pendulous, ovate, acute, entire, smooth, many-ribbed, from an inch to an inch and a half long, and from half an inch to an inch broad. Panicles terminal, from the sheaths of the uppermost leaves, compound, spreading, with smooth slender branches. Glumes green, striated, smooth. The habit is no less foreign to the genus *Apluda* than the generic characters.

ZEUGMA, *Ζεύγμα*, literally denoting a joining together; from *ζεύω*, *I join*, a figure in *Grammar*, whereby an adjective, or verb, which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

Thus Terence, "Utinam aut hic furdus, aut hæc muta facta sit." So Virgil, "Hic illius arma, hic currus fuit." In which cases, the words *facta sit* agreeing primarily with *hæc muta*, are also made to agree or extend to *hic furdus*: and the verb *fuit* is not only referred to *hic currus*, which it properly respects, but farther to *hic illius arma*.

Of this species of ellipsis, which differs from the ellipsis properly so called, in that the word which is to be understood once or oftener, has been already mentioned, Messieurs De Port Royal enumerate three sorts; viz. when we repeat the noun or verb in the same manner it has been already expressed; or when the word expressed cannot be repeated without receiving some alteration in gender, case, number, or person; or when, after a word which includes the whole, a distribution of the parts is made without repeating the verb. Latin Gram. vol. ii. p. 183.

The Latins, it may be here observed, take a liberty in constructions, which some of the nicer critics among the moderns, particularly the French, will not allow in the modern tongues.

ZEUGMA, (*Roum-Kala*), in *Ancient Geography*, a town of Asia, or a place on the right bank of the Euphrates, S.E. of Samofata, and over-against Apamea.

ZEVICO, in *Geography*, a town of Spain, in the province of Leon; 10 miles S.E. of Palencia.

ZEVIO, a town of Italy, in the Veronese; 10 miles S.S.E. of Verona.

ZEVKETI, a town of the principality of Gurjel; 25 miles S.E. of Puti.

ZEULEN, a town of Bavaria, in the bishopric of Bamberg, on the Rotach; 21 miles N.N.E. of Bamberg. N. lat. 50° 13'. E. long. 11° 16'.

ZEULENRODA, a town of Saxony, in the county of Reussen, containing two churches and 350 houses. Here is a manufacture of stuffs, and a considerable one of stockings; 10 miles W. of Greitz. N. lat. 50° 36'. E. long. 11° 51'.

ZEUS, in *Ichthyology*, a genus of fish, of the order of the *thoracici*; the characters of which are, that the head is compressed and declining; the upper lip is arched by means of a transverse membrane; the tongue is awl-shaped; the

branchiotegous membrane has seven perpendicular rays, the lowest placed transversely; the dorsal fins, in most species, furnished with projecting filiform rays; and the body is compressed, broad, thin, and of a bright colour. The species enumerated by Gmelin and Shaw are the following:

VOMER. Silvery dory, with the second ray of the dorsal fin very long. Bloch. (See **VOMER**.) Its shape is rhomboidal, length six or eight, or more, inches, body thin, without scales, tinged on the upper parts with a blueish cast, mouth with small teeth. Native of the American seas, and sometimes seen in those of the north of Europe: eatable, but not much esteemed.

GALLUS. Silvery dory, with the tenth ray of the dorsal and second of the anal fin longer than the body. Shape and length, and body, like those of the former; back tinged with a greenish hue, head large, mouth wide. Native of the American and Indian seas, esculent: when first taken grunting, like the gunnards. The abacatuja of Marcgrave.

FABER. Gold-green, fuliginous dory, with a dusky central spot on each side of the body, or with a rounded tail, brown spot on the middle of the sides and two anal fins. Linnæus. This is the common dory (see **DOREE**), which is a native of the Mediterranean, Northern, and Atlantic seas. Its head is large and long; length generally twelve or fifteen inches, and weight ten or twelve pounds; mouth wide, lower jaw longer than the upper, teeth small and sharp, eyes large, body covered with small scales, and marked by a curved lateral line, which descending pretty suddenly from the gill-covers, passes on to the tail; back arched, and furnished with a row of strong, small prickles, continued along the curve of the abdomen; two very strong and sharp spines at the base of the pectoral fins. The introduction of this fish, as excellent food, to the tables of the higher ranks, is of no remote date; Mr. Quin being considered as the founder of its peculiar reputation in the polite circles. This fish is of a very voracious nature, preying on smaller fishes and their spawn, as well as various kinds of sea-insects, the smaller shell-fish, &c. It emits a noise like that of the gunnards and scorpanas, when first taken, by violently forcing out the air from its gill-covers.

APER. Reddish dory, with rough scales and even tail; a small species about three inches long, resembling the common dory in habit; snout protuberant, and turning upwards; no perceptible teeth; eyes large, with white irides; two dorsal fins, the anterior having nine strong and sharp spines, the first low and scarcely visible, the second four times longer, and the third very long and thick; the second dorsal fin consisting of twenty-three soft rays; the vent-fin having twenty-six rays, the pectoral fins about fourteen, and the ventral six. This fish generally resides at the bottom, and is accidentally taken after great storms: it is not eatable, being small, coarse, and of an unpleasant odour. It is a native of the Mediterranean.

INSIDIATOR. Silvery dory, with sides speckled with black, and narrow extensile mouth; shape rhomboidal; smaller than *Z. ciliaris*; colour bright-silvery, blueish-green above, and speckled with black points; body without scales; lower lip retractile, and mouth capable of forming a tubular snout, for ejecting a drop of water against such insects as happen to alight on or fly about the aquatic plants near the shores of the waters it inhabits, and thus obtain its prey. A native of the rivers and fresh-waters of India.

CILIARIS. Silvery dory, with some of the rays in the dorsal and anal fin excessively long; body rhomboidal, thin, without scales, and of a bright-silver colour, with a blueish or

or greenish cast on the back, and small and sloping; lower jaw longer than the upper; teeth small and sharp; several of the last rays of the dorsal and anal fin extending farther than the tail itself, the long and flexible filaments of which Count de Ceppe imagines attract small fishes, which mistake them for worms, the dory himself lying concealed among sea-weeds, &c. and waiting for its prey: the count also conceives that they may serve to sustain the fish by circling round the stems of sea-plants, &c. A native of the Indian seas; but not esteemed as food, being small and coarse.

LUNA or OPAH. Dory with somewhat lunated tail; the body being generally either red, green, or purple, with oval white spots. This is a superb species, and found, probably wandering from the warmer regions, in the Mediterranean and Northern seas, the largest species of the kind, being between four and five feet in length, in colour varying from a bright silvery-green ground to a bright gold colour, and variegated on the sides with pretty numerous and moderately large oval white spots, while the fins and tail are bright scarlet; the skin seemingly destitute of scales and perfectly smooth.

Specimens of this fish have been occasionally thrown on the British coasts, one of which is described under the article **OPAH**. A dried specimen of this fish may be seen in the British Museum.

QUADRATUS. Grey dory, with transverse dusky or a cinereous body, and even tail. This fish, found in the sea that washes the coast of Jamaica, is described by Sir Hans Sloane, as five inches long and four broad in the middle, narrowing from thence gradually to the head and tail; mouth small, but with rows of small, sharp teeth; tongue round and cartilaginous; pupil large and black, in a white circle; seven fins; tail almost square; whole body clothed with grey or ash-coloured scales, having three or four transverse black lines; with a very crooked line from head to tail.

ZEUS, a species of scorpæna. See **SCORPÆNA PORCUS**.

ZEUXIS, in *Biography*, a celebrated ancient painter, who is said to have been a native of Heraclea, either in Greece or Magna Græcia, and to have commenced the practice of his art in the fourth year of the 95th Olympiad, B.C. 397. According to Quintilian, he is the first artist who understood the proper management of lights and shades, and to have excelled in colouring; but ambitious of imitating the strength and grandeur of Homer's manner, he is charged with giving unfitable bulk to the heads and massiveness to the limbs of his figures. Notwithstanding these alleged imperfections, he attained distinguished excellence; and in the prosecution of it he was attentive even to the minutest circumstance. Many instances occur in his history to this purpose. In his picture of Helen, executed for the Crotonians, as an ornament for their temple of Juno, he determined to combine every quality that might constitute a perfect beauty; and with this view he selected five of the handomest females of Crotona, and transferred to his picture, from their naked charms, an assemblage of all that were most perfect in their kind. This figure has been extolled as the finest specimen of art existing; and under it the painter, not unconscious of his merit, inscribed the lines of Homer, in which Priam expresses his admiration of the beauty of the real Helen. Every one who saw it, before it was placed in the temple, paid the painter a fee, which, added to the liberal recompense of the Crotonians, amply repaid him for his skill and labour. This enabled him to gratify his vanity by making presents of his pictures, for which no adequate price could be given. To such a degree

was he enriched by his art, that he was able to indulge his vanity by appearing at the Olympic games with his name embroidered in golden letters upon his mantle. Such were the failings of a man, who rendered his name illustrious by the supereminent exercise of his art. Among his most famous performances are enumerated a Jupiter on his throne, with the other gods standing round;—a Hercules in his cradle, strangling the serpents, Alcmena and Amphitryon witnessing the exploit with terror;—a Penelope, with an expression conformable to her character;—a Cupid crowned with roses, for the temple of Venus at Athens;—a Marsyas bound, afterwards placed in the temple of Concord at Rome;—and a group of Centaurs. The time of his death is not known; but as to the manner of it, the following whimsical anecdote is recorded: after having painted an old woman, whilst he was attentively surveying it, he was seized with such a violent fit of laughter, that he died on the spot. Pliny Hist. Nat. Gen. Biog.

ZEYA, in *Geography*, a river of Austria, which rises near Ennsprung, and runs into the March, 6 miles E. of Zisterdorf.

ZEYL. See **ZEIL**.

ZEYLAND, a small island near the coast of Lapland. N. lat. 70° 10'.

ZEYRING, a town of the duchy of Stiria; 6 miles N.W. of Judenburg.

ZEZARE, a river of Portugal, which rises in the east part of Estremadura, and runs into the Tagus, at Tancos.

ZEZARINE, or **KIERAZIN,** a small island in the Persian gulf, hardly half a mile in length. N. lat. 28° 8'.

ZFOKEN, a town of Saxony, in the circle of Erzgebirg; 8 miles N.W. of Grünhayn.

ZHA, a river of Africa, which forms the east boundary of Fez, and runs into the Mulloioah.

ZHEHOL, ZHEHO, or *Gebo*, a town of Chinese Tartary, in the country of the Mandshars, not far beyond the great wall, and summer residence of the emperor of China; 120 miles N.E. of Peking.

ZIA, an island in the Grecian Archipelago, anciently called "Ceos" and "Hydrassa," about 16 leagues in circumference. The inhabitants are Greeks, who have a bishop. The soil is fertile, and they have a good breed of cattle, with plenty of wild fowl, especially partridges and pigeons. The chief manufactures are, silk, camlets, and a sort of cloaks made of goats' hair. Among the productions of the island may be reckoned the velani, a species of acorn much esteemed. Of four considerable towns or cities in this island, the only one at present remaining is Carthea, or Zeia, containing about 2500 houses, with a harbour capable of receiving vessels of considerable burden, and where a whole fleet may ride in security from every gale, in every depth of water, and in very good anchoring ground. The entrance into this creek or arm of the sea is very safe by keeping it, according to the sea-phrase, open; but when once within it, ships of whatever burden may ride where they please to an anchor; 10 miles E. of Cape Colonna. N. lat. 37° 30'. E. long. 24° 24'.

ZIA, Ziba, or *Siba*, in *Ancient Geography*, a city beyond Jordan; 5 miles W. from Philadelphia.

ZIATEK, in *Geography*. See **SAATZ**.

ZIB. See **ZEB**.

ZIBA, a town of Arabia, in the province of Hedsjas; 20 miles S.S.W. of Madian.

ZIBATSKOI, a fort of Russia, in the government of Kolivan, on the Irutich. N. lat. 54° 44'. E. long. 92° 20'.

ZIBELLINA. See MUSTELA *Zibellina*, and SABLE.
ZIBER, in *Geography*, a town of European Turkey, in Bulgaria, on the Danube; 24 miles S.S.E. of Viddin.

ZIBET, or ZIBETH. See ZEBID.

ZIBETHA, in *Zoology*. See VIVERRA *Zibetha*.

ZIBETHUM, or ZIBETA, in *Natural History*, civet, a perfume contained in a bladder, in the groin of a civet-cat. See CIVET.

ZIBILÆ, a name given by some authors to a large sort of raisins, resembling the stones of dates in shape; they have much pulp, but very little moisture.

ZIBREIRA, in *Geography*, a town of Portugal, in the province of Beira; 30 miles S. of Alfayates.

ZIBRITZ, a river of European Turkey, which runs into the Danube, near Ziber, in Bulgaria.

ZIBU. See SIBU.

ZICCARA, a name of an Indian fruit, resembling a pine-cone, and containing twenty, thirty, or more kernels, of no known use in medicine.

ZICHIAN, in *Geography*, one of the tribes of mount Caucasus, collaterally related to the Tscherkessians or Circassians. The Zichians or Tichekians, called by the Russians Yasi, are the principal inhabitants of the isle of Taman. They formerly paid a small tribute to the Krimean khan; in all other respects they are governed by their own laws. The isle Atschuk or Atschuyef is likewise inhabited by Zichians. The Auchassians and Zichians are two tribes, which, properly speaking, are only one collateral branch of the Tscherkessians, have belonged to the Russian empire, as inhabitants of the Kuban, since the year 1783. See CIRCASSIA.

ZICKAR, a mountain of Algiers, anciently called "Garaphi;" 18 miles S. of Shershell.

ZIDDIM, or ASSEDIM, in *Ancient Geography*, a city of Naphtali. Josh. xix. 35.

ZIDRACH, in *Natural History*, the name given by Cuba, and some other authors, to that species of the syngnathus of Ardeï, commonly called the hippocampus.

ZIECKRA, in *Geography*, a town of Saxony, in the circle of Neustadt; 4 miles S. of Auma.

ZIEGELBACH, a river of Germany, which runs into the Rhine, near Gernsheim.

ZIEGENBALG, BARTHOLOMEW, in *Biography*, a Lutheran German divine, was born in 1683; at Pulnitz, in Upper Lusatia, and finished his education in the university of Halle. In 1705 he was ordained at Copenhagen, with a view of being sent as a missionary by Frederick IV. king of Denmark to India. In 1706 he arrived at Tranquebar, but he was there opposed and imprisoned, so that he resolved, upon his release, to return to Europe. In 1715 he landed at Bergen in Norway, and after having visited Copenhagen, in order to give an account of his mission, and to receive further instructions, he travelled through Germany and Holland into England, and from thence to India in March 1716. On his return to Tranquebar, he established a Portuguese and Malabar printing-house, in which many of his own works were printed. In the faithful and laborious discharge of his missionary duty he employed 13 years, at the close of which period his life terminated by a disorder probably owing to his intense application. This event happened in February 1719, in the 36th year of his age. His works were numerous, and of these the principal are mentioned in the Gen. Biog.

ZIEGENFELD, in *Geography*, a town of Bavaria, in the bishopric of Bamberg; 12 miles N.E. of Bamberg.

ZIEGENHALS, a town of Silesia, in the principality

of Neisse: this place is famous for its manufactures of beautiful glasses. Here are some iron-works; 10 miles S. of Neisse. N. lat. 50° 12'. E. long. 17° 17'.

ZIEGENHAYN, a town of Germany, and chief place of a county of the same name, in the principality of Hesse. It is situated in a morass, and can be occasionally inundated. In this place were kept the archives of the foreveign families of Hesse. The counts of Ziegenhayn are extinct; 15 miles S. of Fritzlar. N. lat. 50° 50'. E. long. 9° 15'.

ZIEGENRUCK, a town of Saxony, in the circle of Neustadt, on the Saal; 10 miles S. of Neustadt. N. lat. 50° 32'. E. long. 11° 42'.

ZIEGLER, JAMES, in *Biography*, a learned writer of the 16th century, was born at Landshut in Bavaria, and having studied in the university of Ingolstadt, finished his education by visiting the libraries of foreign countries, and cultivating the society of learned men. He resided several years at Rome, collecting in the history of Leo X. and Clement VII. every anecdote that tended to the discredit of the papal court; and in his conferences with learned Swedes, materials for a correct history of Scandinavia, and of the cruelties committed by Christian II. of Denmark. It appears that, besides some other posts which he occupied, he was for some time professor at Ingolstadt, and, as some say, of mathematics at Upsal. He was for a considerable time a teacher at Vienna, from whence, for fear of the Turks, he retired to Wolfgang, bishop of Passau in Bavaria, under whose protection he composed some of his works; and he died at Passau in 1549. The earliest of his publications, whilst he was a Catholic, was written against the Waldenses, and printed at Leipzig in 1512. His other works are multifarious, consisting of geographical, historical, political, mathematical, and controversial tracts, abounding with literary researches. Although he did not openly renounce the Roman Catholic religion, he favoured the cause of Luther and the reformers. Thuan. Hist. Moreri. Gen. Biog.

ZIELËNZIG, in *Geography*, a town of the New Mark of Brandenburg; This town belonged in a considerable degree to the knights of Malta; 18 miles S.E. of Custrin. N. lat. 52° 30'. E. long. 15° 16'.

ZIENWALD, a town of Saxony, in the margravate of Meissen; 4 miles S.S.W. of Lauenstein.

ZIERCKOWITZ, a town of the duchy of Stiria; 4 miles E.S.E. of Windisch Feistritz.

ZIERENBERG, a town of the principality of Hesse Cassel; 11 miles N.W. of Cassel. N. lat. 51° 22'. E. long. 9° 20'.

ZIERIA, in *Botany*, was so named by the writer of the present article, in memory of the late Mr. John Zier, F.L.S., who, as Dr. Sims records in the Botanical Magazine, "having been appointed to a professorship in a Polish university, was preparing to leave this country, but was prevented by a chronic disease, which terminated in death." That Mr. Zier was "a learned and industrious botanist," we are most ready to confirm by our own testimony. He was no less meritorious in his private character, and bore with modesty and patience those privations, which too often belong to literary merit in a foreign country, especially where canting and time-serving are out of the question. We have been informed that Mr. Zier was the coadjutor of Mr. WILLIAM CURTIS (see that article), in part, at least, of the celebrated *Flora Londinensis*; taking upon himself the technical Latin descriptions, while Mr. Curtis was engaged in those practical observations, experiments, and scientific distinctions, which make the peculiar merit of the work.

work. Mr Zier died about the year 1796, perhaps rather earlier, at no advanced period of life.—Sm. Transf. of Linn. Soc. v. 4. 216. Jackson in Andr. Repof. v. 9. 606. Sims in Curt. Mag. 1395. Poirat in Lamarek Dict. v. 8. 859.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rutaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four deep, ovate, rather acute, equal, permanent segments. *Cor.* Petals four, ovate, pointed, somewhat coriaceous, downy, equal, longer than the calyx, alternate with its segments. *Stam.* Filaments four, alternate with the petals, awl-shaped, simple, smooth, inflexed, much shorter than the corolla, each inserted into a globular gland, projecting above their base at the infide; anthers terminal, roundish, with a minute point. *Pist.* Germen superior, roundish, four-lobed; style terminal, erect, columnar, the length of the filaments, deciduous; stigma capitate, four-lobed. *Peric.* Capsules four, connected at their inner edge, each compressed, abrupt, of two valves and one cell. *Seeds* solitary, oval, compressed, each enclosed in a horny elastic tunic of two valves.

Effl. Ch. Calyx in four deep segments. Petals four. Stamens smooth, each inserted into a gland. Style simple. Stigma four-lobed. Capsules four, combined. Seeds with an elastic tunic.

We are acquainted with four species of this genus, consisting of shrubs, natives of New South Wales, with opposite, stalked, ternate leaves, and white flowers. It is allied to *Boronia*, (see *RUTACEÆ*), as well as to *Crowea*, *Eriostemon*, *Correa*, *Phebalium*, and *Melicope*, to which we refer the reader. *Zieria* is essentially characterized by the insertion of each of its *stamens* into the outside of one of four large glands, standing on the *receptacle*, at the base of the germen; as well as by the simplicity of those *stamens*, in the other part of their structure. All the species abound with resinous dots on their *leaves*, *stalks*, and *calyx*; lodging an essential oil, whose qualities are more or less acrid and aromatic.

1. *Z. lanceolata*. Lanceolate *Zieria*. Brown MSS. (*Z.* Smithii; Andr. Repof. t. 606. Curt. Mag. t. 1395. Ait. Epit. 376.)—Clusters axillary, repeatedly three-forked. Leaflets lanceolate, flat, acute. Branches and stalks warty.—Sent from Port Jackson, New South Wales, by Dr. John White, in 1795. It is said by Mr. Aiton to have been introduced into the English gardens in 1803, where it proves a tolerably hardy green-house shrub, flowering in the spring and early part of summer, and may be increased from cuttings. The *stem* is bushy, of humble growth, being scarcely three feet high, with round, purplish, leafy *branches*, rough with glandular warts, and when young, besprinkled with minute, starry, rigid pubescence. *Footstalks* warty, channelled, near an inch long, destitute of *stipulas*, each bearing three lanceolate, flat, entire, smooth, single-ribbed *leaflets*, contracted at each end, the middle one rather the largest, being two inches, or two and a half, in length. *Panicles* opposite, axillary, often two together, somewhat leafy, repeatedly forked, many-flowered, various in length, spreading, slightly downy; their stalks quadrangular, purplish. *Flowers* white, each about the size of a Privet-blossom, with yellow *anthers*. *Capsules* brown, dotted with glands. Tunic of the *seeds* white and shining. We agree with Dr. Sims in preferring an expressive specific appellation to one taken from the name of a botanist, and, therefore, as the genus in question was not established on this species more than the rest, all, except the last, having been equally considered, we are happy to set the example of an alteration, in which we can have no other motive than propriety and common advantage. We had called this

Vol. XXXIX.

species *multiflora*; but we consider the synonym in the Botanical Magazine as a publication of the unexceptionable name given by Mr. Brown.

2. *Z. levigata*. Smooth *Zieria*.—Clusters axillary, three-forked, corymbose. Leaflets linear, revolute. Branches and stalks very smooth.—Gathered by Dr. White, near Port Jackson, New South Wales. The *branches* of this pretty species are quadrangular, and very smooth, like every other part, except the *petals*. *Leaves* smaller than the foregoing, with somewhat of a glaucous hue. *Footstalks* about half a quarter of an inch long. *Leaflets* scarcely an inch, acute, polished, strongly revolute, dotted with glands, and somewhat tinged with purple. *Flowers* a little larger than the last, and much fewer, the *panicles* being always solitary, much less compound, and situated chiefly towards the upper part of each branch. The *stalks* are acutely quadrangular, and very smooth. *Calyx* brown or reddish, taper-pointed, likewise quite smooth. *Petals* downy on both sides, like a piece of woollen cloth.

3. *Z. pauciflora*. Few-flowered *Zieria*.—Stalks axillary, with one or three flowers. Leaflets linear-ovate, somewhat revolute. Branches and stalks hairy. Segments of the calyx lanceolate, taper-pointed.—Sent from Port Jackson, with the former, by Dr. White, in 1795. A small *shrub*, with slender, round, scarcely quadrangular, *branches*, which are more or less copiously clothed with erect bristly hairs. *Leaves* about half the size of the last; their leaflets dilated upwards, and obtuse, a little crenate towards the end; copiously dotted, rarely hairy, on the upper side; sometimes very hairy beneath, but occasionally quite smooth even in that part. *Flowers* very small, often quite solitary, on an axillary stalk, with a pair of small acute *bractææ*; sometimes there are three flowers on each stalk. Segments of the *calyx* broad at the base, but tapering suddenly into a long point. *Petals* minutely dotted with tufts of starry hairs, giving them a warty, or granulated, aspect. *Capsules* tuberculated, sometimes hairy; curiously reticulated at the infide. *Seeds* black, rather opaque, with a shining, white, at length convoluted, tunic, whose edge is minutely fringed. The hairy and nearly smooth varieties of this plant look different at first sight, but we cannot detect a specific distinction.

4. *Z. cythoides*. Downy *Zieria*.—Stalks axillary, three-forked, leafy. Leaflets obovate, entire, downy on both sides. Branches and stalks downy.—Native of New South Wales, from whence we obtained a specimen through the favour of earl St. Vincent in 1805. Whether this be Mr. Brown's *arborescens*, mentioned by Dr. Sims, we have at present no means of knowing, and therefore we are obliged to describe it by a name which appears to us very expressive. Every part is clothed with fine dense soft pubescence, appearing stellated and entangled under a high magnifier. *Branches* round. *Footstalks* half an inch long. *Leaflets* about an inch in length, entire, slightly revolute; their upper side peculiarly soft and velvet-like; the under most hoary. When held against the light, they appear full of pellucid dots. *Calyx* very downy; its segments broad and ovate. *Petals* about twice as long, and of the same shape, downy. We have not seen the ripe fruit.

ZIESAR, or ZIEGESAR, in *Geography*, a town of the Middle Mark of Brandenburg; 18 miles S.W. of Brandenburg.

ZIETZ, a town of the Middle Mark of Brandenburg; 10 miles S.W. of Brandenburg.

ZIEZAR, a town of Spain, in the province of Murcia; 22 miles N.W. of Murcia.

ZIFIUS, in *Ichthyology*, a name given by Albertus to the xiphias, or sword-fish. See XIPHIAS.

ZIGADENUS, in *Botany*, a genus of Michaux, *Boreal-Amer.* v. 1. 213. Pursh 241. The name, formed of $\zeta\iota\gamma\omicron\varsigma$, a yoke, and $\alpha\delta\eta\varsigma$, $\alpha\delta\eta\varsigma$, a gland, evidently alluding to the pair of glandular depressions in each petal, ought therefore to have been *Zygodenus*. We do not, however, believe that this genus can be separated from HELONIAS. See that article.

The species are,
H. glaberrima. Smooth-leaved Helonias. Ker in Curt. Mag. t. 168c. (*Zigadenus glaberrimus*; Michaux as above; 214. t. 22. Pursh n. 1. Ait. Epit. 376.)—Leaves linear, channelled, recurved. Stalk leafy. Bractees ovate, pointed as well as the petals.—In low meadows of Virginia and Lower Carolina, perennial, flowering in June and July. Pursh. Root bulbous. Leaves a span long, concave, spreading. Stalk two feet high, bearing several, gradually diminishing, leaves, and terminating in a panicle of several greenish-white flowers, the size of *Veratrum album*, each of whose petals is marked, near the base, with a double glandular, apparently nectariferous, depression. Stamens distinct from the petals. Seeds tunicated. We know not whether they be so in any other *Helonias*.

H. elegans. Elegant Helonias. (*Zigadenus elegans*; Pursh n. 2.)—Leaves linear, flat, erect. Stalk nearly naked. Bractees linear. Petals acute.—On the waters of Cokahlaishkit river, near the Rocky Mountains, found by governor Lewis, flowering in July. Radical leaves erect, linear, very long, smooth, ribbed, flat. Stalk taller than the foliage, about two feet in height, round, simple, bearing one or two short leaves. Cluster many-flowered, occasionally branched at the bottom. Bractees as long as the partial stalks, membranous, ribbed. Flowers whitish, the size of *Melanthium virginicum*. Petals ovate, acute, with something of a claw, marked at the base with two vermilion spots. Filaments shorter than the corolla. Stigmas three, reflexed. Pursh.

ZIGÆ, in *Ancient Geography*, a people of Asiatic Sarmatia, on the bank of the Tanais. Pliny.

ZIGALOVKA, in *Geography*, a town of Russia, in the government of Irkutsk; 16 miles N.W. of Tutura.

ZIGANEAH, a mountain of Algiers; 18 miles S. of Constantina.

ZIGANSK, a town of Russia, in the government of Irkutsk, on the Lena; 1472 miles E. of Tobolsk. N. lat. 67°. E. long. 120° 32'.

ZIGEIRA, or ZIGIRA, in *Ancient Geography*, a town of Africa Propria, between the town of Thabraca and the river Bagradas. Ptolemy.

ZIGER, a word used by some of the old writers to express a very fine kind of cassia, extremely aromatic to the taste, and of a purplish-black colour.

ZIGERE, in *Ancient Geography*, a town of the interior of Thrace, on the borders of Lower Mesia.

ZIGET, in *Geography*, a town of Hungary, situated between the streams of a small river, which unite below the town, and soon after run into the Drave. It is on every side surrounded by a morass, and defended by moats, walls, and bastions; 44 miles S.E. of Canifcha. N. lat. 46° 8'. E. long. 17° 56'.—Also, a river of Hungary, which runs into the Drave, 12 miles S. of Ziget.

ZIGIRA, in *Ancient Geography*, a town of Asia, in Alysia, towards the N., and at a great distance from the Tigris. Ptol.

ZIGURELLA, in *Ichthyology*, the name by which some have called the julis, a small but very beautiful fish,

common about Genoa, and in some degree approaching to the nature of the turdus or wrasse.

It is a species of the labrus, according to Artedi, and is distinguished by the name of the palmaris labrus, with two large teeth in the upper jaw. See LABRUS.

ZIGZAG TREFOIL, in *Agriculture*, a term sometimes applied by farmers to the perennial red clover, marl grass, or wild red clover. See CLOVER and TRIFOLIUM *Purpureum Perenne*.

ZIKLAG, or SICALAG, in *Ancient Geography*, a city which Achih, king of Gath, gave to David, while he took shelter among the Philistines (1 Sam. xxvii. 6.), and which afterwards always belonged to the kings of Judah. Joshua had allotted it to the tribe of Simeon. (Josh. xix. 5.) Eusebius says, that it lay in the southern part of Canaan.

ZILA, in *Geography*, a river of Moldavia, which runs into the Pruth, 30 miles S.E. of Jassy.

ZILEH, a town of Turkish Armenia; 30 miles S.S.W. of Arzinga.

ZILGA, a river of Russia, which runs into the Oka, N. lat. 53° 4'. E. long. 101° 14'.

ZILIS, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, marked in Anton. Itin. 24 miles from Tingis, between Taberna and Ad Mercuri. This was a colony established by Augustus, exempt from the jurisdiction of the kings of Mauritania, and dependent upon Bætica in Hispania.

ZILKEFEL, in *Geography*, a town of the Arabian Irak; 18 miles S.W. of Helleh.

ZILLEBA, a town of Arabia, in the province of Yemen; 35 miles E. of Lohia.

ZILLER, a river of Tyrol, which runs into the Inn, 2 miles above Rattenburg.

ZILLY. See CILLY.

ZILMISSUS, in *Ancient Geography*, a hill of Thrace, on which was a temple dedicated to the god Sabadeus. Macrobius.

ZILTAN, in *Geography*, a town of Africa, in the desert of Barca; 150 miles W. of Angela.

ZIMARA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, at the foot of mount Capotis, in the place where the Euphrates has its source.

ZIMARA, in *Geography*, a town of Asiatic Turkey, in the government of Sivas; 55 miles E. of Sivas.

ZIMBAOA, or ZIMBAO, a town of Africa, in the kingdom of Sofala, and capital of Moccaranga. S. lat. 16° 40'. E. long. 33° 40'.

ZIMBRA. See ZOWAMORE.

ZIMENT-WATER, or COPPER-WATER, in *Natural History*, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newfol in Hungary, in the great copper-mine called by the Germans *herrn grundt*.

The water in this mine is found at different depths, and is received into basons, for the purpose of separating the copper from it; in some of these it is much more saturated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common species of iron used in the experiments are, horse-shoes, nails, and the like; and they are found very little altered in shape, after the operation, except that their surfaces are more raised.

The water appears greenish in the bason where it stands; but if a glass of it be taken up, it looks clear as crystal; it has no smell, but a strong vitriolic astringent taste, inasmuch

that the lips and tongue are blistered and scorched upon talking it.

The miners are well acquainted with the virtue of this water in changing the metals; but they also use it as a medicine: whatever sickness they are seized with, they first attempt its cure by a large dose of this water, which usually both vomits and purges them very briskly.

They also use it in disorders of the eyes, in some of which it must be of great power; but in others, it is very improper; so that upon the whole they do more harm than good with it.

The copper produced from these waters is valued by the people much beyond any other copper, as being much more ductile, and running easier in the fire: the people in the neighbourhood have many vessels of it; but it is to be observed, that its ductility and hardness increase after it is taken out of the water; for while immersed in it, it is friable.

It is observed, that after great rains the springs are always fuller than at other times, and the virtues of the water considerably less.

A pound of this water, when strongest, evaporated over a gentle fire, becomes first turbid, and afterwards deposits a yellowish sediment, which evaporated to dryness, weighs two scruples and a half; and when warm water is poured upon this and filtered, six grains of yellowish earth will be left in the filtre; and the greenish solution being again evaporated to a pellicle, and the operation being several times repeated, somewhat more than two scruples of a blueish-green vitriol will be separated in small crystals.

A small quantity of oil of tartar being added to a pound of this water, the whole becomes turbid, and on filtration leaves a large residuum in the filtre, which dried, weighs about two scruples and a half, and is found to be a cupreous vitriol, with a small mixture of a neutral fat. If a pint of this water be put into a bottle, and a small piece of iron thrown into it, bubbles will appear on the iron, which will gradually be changed to a copper colour. On the second day, the water will be turbid, and afterwards whitish, and white filaments will gather about the bottom and sides of the glass, and about the iron, which will appear throughout of a coppery colour. From these experiments, we may easily understand what the true nature of the water is; that it contains a large quantity of vitriol of copper, which it probably owes to a solution of that metal, by means of the acid of the common pyrites and water: when this is known, the effects are not difficultly accounted for, there being no real change of one metal into another; but the true state of the case being, that the particles of one metal are dissolved and carried away, and those of another metal deposited in their place. A water thus impregnated is a menstruum capable of dissolving iron, and in the solution of that metal becomes so weakened as to let go the copper it before contained in small parcels. This is seen to be the case, by examining the changed metal while it lies in the water, the copper then appearing not a soft malleable and even mass, but a congeries of granules closely placed together, and resembling the small granules, or ova, in the spawn of fishes; and it is very friable and fragile while in this state.

This solution of one metal, and deposition of the particles of another in its place, is a thing very familiar in chemistry, and is seen every day in numerous instances; but in none so familiar as in a like case, or solution of iron and copper in the same menstruum. Thus, if a piece of copper be dissolved in aqua fortis, and when this solution is perfected a piece of iron be thrown into the liquor, the same thing will be seen that is in this spring, for the iron will be dissolved,

and the copper which was before dissolved in the menstruum will be slowly precipitated and deposited in the place of it. Phil. Trans. N^o 479, p. 355, &c. See on this subject the articles COPPER and VITRIOL.

ZIMEX, a word used by some of the old chemical writers for verdigrise.

ZIMITI, in *Geography*, a town of South America, in the province of Cartagena, near a lake; 60 miles S. of Santa Fé de Bogota. N. lat. 7^o 42'. W. long. 74^o 6'.

ZIMMER, an island of the Red sea, much smaller than *Foosbe*, (which see,) without inhabitants, and without water; though, by the cisterns that now remain, and are sixty yards square, hewn out of the solid rock, there is reason to imagine that this was once a place of consequence: rain, at certain seasons, falls here in abundance. It is covered with young plants of rack-tree, whose property it is to vegetate in salt water. It has also a considerable number of Saicel, or Acacia-trees. In this island there are antelopes and hæmas; and hence we may infer that water, without which these animals could not subsist, is found in some subterranean caves or clefts of the rocks, unknown to the Arabs or fishermen. Mr. Bruce found here plenty of the large shell-fish called Biffer and Surrumbac, but no other. *Foosht* bears from this island 8 miles N.W. by N. $\frac{1}{2}$ W. N. lat. 16^o 7'.

ZIMMER, in *Commerce*, a term used for reckoning in Germany, and denoting 40 pieces.

ZIMMERBACH, in *Geography*, a town of France, in the department of the Upper Rhine; 5 miles W. of Colmar.

ZIMMERMAN, JOHN GEORGE, in *Biography*, an eminent physician and miscellaneous writer, was born in 1728 at Brug, in the canton of Bern. Having completed his preparatory education at Bern, and chosen the medical profession, he placed himself in the university of Göttingen, under the tuition of the celebrated Haller; and on graduating in 1751, the subject of his thesis was the doctrine of irritability. His respect for Haller was testified in the account he gave of him in the journal of Neuchâtel, printed in 1752. Having married at Bern a relation of Haller, he settled as a physician in his native town. The retirement of his situation afforded him an opportunity of composing many pieces in prose and verse; and in 1756 he published the first sketch of his popular work "On Solitude." This publication was followed by an essay "On National Pride," in 1758; by his work "On the Experience of Medicine," in 1763, and several others; and by "A Treatise on Dyfentery," in 1766. In 1768 he accepted an invitation to occupy the vacant post of physician to the king of England for Hanover, whither he removed. In this situation, the accumulation of business furnished in some measure an antidote to that constitutional irritability of temper, and tendency to hypochondriacal complaints, which in the retirement of a small town had rendered him unhappy; and having occasion to place himself under the medical care of a surgeon at Berlin, on account of a local disease under which he laboured, his removal thither in 1771, and the notice that was taken of him by several persons of distinction, and even by the king, were favourable both to his health and spirits, and of course to his happiness. Having lost his first wife, he formed a second matrimonial connection in 1782; and to this union he was indebted for many of those comforts which counterbalanced and alleviated his afflictions. His remaining years were chiefly devoted to the completion of his work "On Solitude," which was published in four volumes. In the year 1786, Zimmerman was sent for to attend the great Frederick in his last illness; and

this visit gave him an opportunity of publishing an account of his "Conversations" with that celebrated prince. He was induced also, by the notice that was taken of him, to undertake a defence of the character of Frederick against the censures of count de Mirabeau. The severe criticisms to which these writings exposed him, and the part he took in the controversies that agitated the continent with regard to the principles that produced the French revolution, irritated his feelings and disquieted a mind like his peculiarly susceptible of contumely and reproach. His political and religious principles led him to view with jealousy and detestation those societies which, in his judgment, and in that of others of similar sentiments, aimed at the subversion of established forms and authorities, and to declare war against them. Such were his abhorrence and dread of them, that he addressed a memoir to the emperor Leopold, recommending the suppression of them by force; and he subjected himself to a prosecution for a libel by a charge brought against a person by name for an unavowed publication. His mind had arrived to such a state of irritation, that the approach of the French towards Hanover in 1794 almost subverted his reason. Dreading the consequences of their arrival, he abstained from food, wasted to a skeleton, and died absolutely worn out in 1795, at the age of 66. "Such," says his biographer, "was the melancholy end of a man whose moral and intellectual qualities rendered him in a high degree the object of private friendship and public esteem." Tiffot's Life of Zimmerman. Gen. Biog.

ZIMOVE, in *Geography*, a village of Russia, in the government of Irkutsk, where is a custom-house; 52 miles S.E. of Barguzinsk.

ZIMOVE *Tchijkoi*, a town of Russia, in the government of Irkutsk; 16 miles S.W. of Vitimskoi.

ZIMOVE *Yafschnoe*, a winter habitation of Russia, on the N. coast of Baikal lake, in the government of Irkutsk. The word *Zimove*, in Russian, means a house or inn, built at a distance from a town, for the accommodation of travellers, where are generally found a warm room, fresh bread, and a kind of liquor called *quasi*. N. lat. 55° 20'. E. long. 109° 14'.

ZIMOVE *Zamin'koi*, a town of Russia, in the government of Irkutsk, near lake Baikal; 76 miles S.E. of Vercholenk.

ZIMOVSKAIA, a town of Russia, in the country of the Cossacks, on the Choper; 48 miles W. of Arkadinkaia.

ZIN, SIN, or *Senna*, in *Ancient Geography*, a city S. of the land of promise. (Numb. xxxiv. 4.) See SIN.

ZINARI, in *Geography*, an island in the Grecian Archipelago. N. lat. 36° 59'. E. long. 26° 10'.

ZINARIA, a word used by the Arabians for a kind of vitiated bile, called aruginous bile.

ZINC, in *Chemistry*, the name of a metal, in Latin *zincum*. The ancients do not appear to have been acquainted with this metal. *Cadmia* was the name by which they seem to have known one of its ores, which was so called from Cadmus, who, it is said, taught the Greeks how to form brass by its means. It is first mentioned by Albertus Magnus, but it is doubtful if he had ever seen it. The word *zinc* first occurs in the writings of Paracelsus. This metal has been also called *spelter*.

Zinc has never been found in Europe in a state of purity, and chemists were late in discovering a method of extracting it from its ores. Henkel seems to have been one of the first who effected this about the year 1720, and he was soon followed by others. Zinc is of a brilliant white colour, with a shade of blue, and seems to be composed of a number of

thin plates adhering together. It imparts a perceptible smell and colour to the skin when rubbed by it for some time; hence it is rather soft. Its specific gravity is said to vary from 6.86 to 7.1, the lightest being esteemed the purest. When hammered, its specific gravity becomes as high as 7.19.

This metal is by no means so malleable as copper, lead, or tin; it is not however brittle. It yields, and becomes somewhat flatter, when struck with a hammer. When heated a little above 212°, it has the remarkable property of becoming very malleable, and in this state may be reduced into very thin plates, either by hammering or rolling. When heated to about 400°, it becomes so brittle that it may be reduced to powder in a mortar.

Zinc may be drawn into wire. According to Mufchenbroeck its tenacity is such, that a wire of $\frac{1}{4}$ th of an inch in diameter is capable of supporting a weight of about 26 lbs.

Zinc melts at a temperature of about 680°, according to Dr. Black. If the heat be increased it evaporates, and may be easily distilled over in close vessels: upon this property of zinc, Von Swab's method of extracting it from its ore was founded. When allowed to cool slowly, this metal crystallizes beautifully in small bundles of quadrangular prisms disposed in all directions, which, if exposed to the air while hot, assumes a blue changeable colour.

When exposed to the air, zinc soon tarnishes, but it scarcely undergoes any other change. When kept under water, its surface becomes black, the water is decomposed, hydrogen is emitted, and the oxygen combines with the metal. If heat be applied, these changes go on more rapidly; and if the steam of water be made to pass over zinc at a high temperature, it is very rapidly decomposed.

When this metal is kept melted in open vessels, it soon becomes covered with a grey pellicle of oxyd. If the heat be very strong it takes fire, and burns with a brilliant white flame, and at the same time emits a great quantity of very light white flakes. This is merely the oxyd of zinc. It was well known to the ancients, and received from them many whimsical names, such as *pompholyx*, &c. Among the alchymists it was known by the names of *nihil album*, *lana philosophica*, *flowers of zinc*, &c.

Zinc appears to combine with only one proportion of oxygen, which has been stated by different chemists to vary from 24.16 to 25 of oxygen to 100 of the metal. According to the first of these determinations, the weight of the atom of zinc will be 41.39; according to the second 40. Dr. Thomson has decided upon 41.25 as the most probable weight of the atom.

Zinc combines readily with chlorine, and forms a chloride of zinc. It may be prepared by dissolving zinc in muriatic acid, or by exposing the metal to the gas, when the two combine by a species of combustion. The chloride may be also obtained by distilling zinc-slings with the oxy-muriate of mercury, or *corrosive sublimate*; and thus obtained, it was formerly denominated the *butter of zinc*. When thus prepared, it sublimes on the application of heat, and crystallizes in needles; but according to Dr. Davy, when the common muriate is heated in a glass tube, it does not sublime even at a red heat, but remains in a state of fusion. Exposed to the air, it soon deliquesces. According to Dr. J. Davy's analysis, it is composed of

Chlorine	-	-	-	-	100
Zinc	-	-	-	-	100

But if we suppose it to be composed of an atom of zinc and

ZINC.

and an atom of chlorine, and the atom of zinc to weigh as above, its constituents should be

Chlorine	-	-	-	100
Zinc	-	-	-	91.6

Zinc readily combines with iodine by heat. The compound, or *iodide*, is white. It is volatile, and crystallizes in fine quadrangular prisms. It deliquesces in the air, and is very soluble in water. The solution is colourless, and does not crystallize. Gay Lussac has shewn, that this compound consists of one atom iodine, and one atom zinc, or by weight of

Iodine	-	-	-	100
Zinc	-	-	-	26.52

No compound of zinc with fluorine is at present known. Zinc does not combine with azote nor hydrogen; nor are we acquainted with any compound of this metal with boron and silicon.

Zinc may be combined with phosphorus by dropping small bits of phosphorus into it while in a state of fusion. Phosphuret of zinc is of a white colour, and possesses a metallic lustre, which more resembles lead than zinc. It is somewhat malleable. It emits the odour of phosphorus when filed or hammered, and if exposed to a strong heat it burns like zinc. Phosphorus also appears to combine with the oxyd of zinc, and to form a peculiar compound.

Sulphur cannot be combined artificially with zinc; but if melted with the oxyd of zinc a peculiar compound is formed. A similar compound is formed when sulphuretted hydrogen in combination with an alkali is dropped into a solution of zinc. It is at first white, but becomes darker on drying. Dr. Thomson considers this compound as a sulphuret of zinc. Mr. E. Davy ascertained, that when the vapour of sulphur is passed over zinc in fusion a yellowish compound is obtained, similar in appearance to blende.

One of the most common ores of zinc is *blende*, described below, and which is a sulphuret of zinc, composed, according to Dr. Thomson's experiments, of

Zinc	-	-	-	100
Sulphur	-	-	-	48.84

Hence he considers it as a compound of one atom zinc, and one atom sulphur.

The alloys of zinc and the metals of the fixed alkalies are speedily decomposed by exposure to the air or immersion in water. We are not acquainted with the alloys of zinc and the metallic bases of the alkaline earths.

Zinc may be combined with arsenic by distilling a mixture of it and arsenious acid. With iron, zinc combines with difficulty; the alloy when formed, according to Lewis, is hard, somewhat malleable, and of a white colour, like silver. Malouin has shewn, that zinc may be used instead of tin for covering iron plates; a circumstance which demonstrates an affinity between the two metals.

Zinc does not appear capable of combining with nickel or cobalt by fusion. The alloys of zinc with manganese, cerium, and uranium, are unknown.

For the other alloys of zinc, see the different metals; particularly for the most important of them or brass, see BRASS and COPPER.

Salts of Zinc.—Almost all the acids act with energy on zinc, in consequence of its powerful affinity for oxygen. The salts of zinc, therefore, are very easily formed, and on account of their being but one oxyd of zinc are not much liable to variation.

Nitrate of Zinc.—The nitric acid attacks zinc with such energy, that it is commonly necessary to moderate its action by diluting it with water. Even then much heat is evolved, and a strong effervescence is produced by the escape of nitrous oxyd gas. The solution is transparent and colourless, very caustic, and yields by evaporation flat, striated, tetrahedral prisms, terminated by four-sided pyramids. These crystals attract moisture on exposure to the air, and are soluble in water and alcohol. When heated they melt, and if thrown on burning coals, detonate with a red flame.

Carbonate of Zinc.—*Calamine*, one of the ores of zinc, is a native carbonate of zinc, as described below. This salt usually exists in the form of a white powder, and may be obtained by precipitating zinc from its solution in acids by an alkaline carbonate.

Phosphate of Zinc.—The phosphoric acid unites in two proportions with the oxyd of zinc. The neutral phosphate is a tasteless white powder insoluble in water. The bi-phosphate is soluble in water, if not exposed to too great a heat. It does not crystallize, and is strongly acid.

Sulphate of Zinc.—Concentrated sulphuric acid scarcely acts upon zinc without the assistance of heat; but when diluted it acts upon the metal very strongly, and hydrogen gas is given out in abundance. In this case, the water is decomposed, its oxygen combines with the metal, while its hydrogen escapes. The solution, when concentrated, yields crystals in abundance.

This salt, formerly known under the name of *white vitriol*, was discovered in Germany, about the middle of the 16th century. When quite pure, it is perfectly white. The form of its crystals is that of flat quadrangular prisms, terminated by four-sided pyramids. At a temperature of 60°, it dissolves in about 1.4 times its weight of water. In boiling water, it dissolves in any quantity whatever. The constituents of this salt are,

1 Atom of sulphuric acid	-	-	-	31.74
1 Atom of zinc	-	-	-	32.54
5 Atoms of water	-	-	-	35.72
				100.00

When heated, the crystals part with their water, and if the heat be strong, the whole of the acid likewise separates, and leaves the oxyd of zinc in a state of purity. See VITRIOL, *White*.

Muriate of Zinc.—See *Chloride of Zinc, supra*.

Sulphite of Zinc.—This salt exists in the form of crystals, soluble in water, but insoluble in alcohol. On exposure to the air, they are soon converted into the sulphate of zinc. Fourcroy and Vauquelin describe a *hypo-sulphite of zinc*, which assumes the form of four-sided prisms, terminated by four-sided pyramids. They are soluble in water and alcohol.

Borate of Zinc is a white insoluble powder. It may be formed by pouring borate of soda into the nitrate or muriate of zinc.

Arseniate of Zinc is a white insoluble powder, and may be formed by mixing solutions of the alkaline arseniates with the sulphate of zinc.

Acetate of Zinc.—This salt exists in the form of rhomboidal or hexagonal plates of a talky appearance, and is not very soluble in water. Solutions of this salt form an excellent external application to inflammations.

Oxalate of Zinc.—This salt is a white powder, little soluble

ZINC.

n water, and may be formed readily by double decomposition.

Tartrate and Citrate of Zinc.—Both these salts exist usually in the form of powders, and are but little soluble in water. They may be procured, like the oxalate, by double decomposition.

The other salts of zinc are of very little importance or interest, and do not therefore merit to be enumerated here. The salts of zinc may be distinguished in general by their forming colourless solutions in water, by their yielding white precipitates with prussiate of potash, sulphuretted hydrogen, and the alkalis, and by the characteristic circumstance that zinc is not precipitated in the metallic state by any other metal.

Uses of Zinc and its Compounds.—Neither this metal nor its compounds, if we except *brass*, are much employed in the arts nor in medicine. A chief use of zinc is in the formation of galvanic apparatus, and in electrical experiments. (See GALVANISM and ELECTRICITY.) As it is not a poisonous metal, it has been recommended instead of tin and lead for domestic purposes; but the ease with which it is oxidized makes it very unfit for all sorts of culinary apparatus.

The strong affinity of zinc for oxygen renders it of great use as a chemical agent for precipitating other metals from a state of solution in the metallic state. The oxide of zinc is used in medicine, both internally as a tonic, and externally mixed with hog's-lard as an ointment. The native carbonate is also used in the same manner as an external application. See UNGUENTUM *Calamine*, and UNGUENTUM *Zinci*.

The *sulphate* and the *acetate* are the only salts of zinc used in medicine; for the properties of which, see above.

ZINC, Ores of, in Mineralogy. The ores of zinc are generally associated with lead-ores, and exist abundantly in various parts of England; particularly in veins in the mountain lime-stone of Derbyshire, Durham, Cumberland, Yorkshire, Somersetshire, and North Wales. The ores of zinc are either oxides, carbonates, or sulphurets of zinc, and are principally known as *calamine* or *blende*. There is an ore of zinc hitherto found only in North America, called by Dr. Bruce red zinc-ore; it occurs in several of the iron-mines in Suffex county, New Jersey.

Red Zinc Ore is of a blood-red or aurora-red colour; it occurs massive and disseminated. The fresh fracture is shining, but becomes dull after long exposure to the air, and is covered with a pearly crust; the principal fracture presents a foliated structure; the cross fracture is conchoidal. It is opaque or translucent on the edges; it yields a brownish-yellow or orange streak; it is brittle. The specific gravity is 6.22. It is infusible without addition by the blow-pipe, but melts into a transparent yellow bead with borax. When pounded and mixed with potash, and exposed to heat, it melts into an emerald-green mass, which, on solution in water, yields the same colour; but on the addition of the mineral acids is immediately changed to rose-red. This ore is soluble in the mineral acids. Its constituent parts are,

Zinc	-	-	-	-	76
Oxygen	-	-	-	-	16
Oxyds of manganese and iron	-	-	-	-	8
					100

Bruce's American Mineralogical Journal, p. 69.

According to Dr. Bruce, this ore possesses advantages in the manufacture of brass over those generally used; for without any previous preparation, it affords with copper

brass of the very finest quality, possessing a high degree of malleability, and suited for the most delicate workmanship. Red zinc-ore is characterized and distinguished from red silver-ore and red lead-ore by its infusibility; the latter melting into a blackish slag before the blow-pipe. Red orpiment, with which it might be confounded, is distinguished from red zinc-ore by its volatility, and the garlic smell which it yields. This ore of zinc has greater specific gravity than red copper-ore, and its solution in acids is colourless; but those of red copper are green. *Calamine* is divided by some mineralogists into four kinds, sparry *calamine*, compact *calamine*, earthy *calamine*, and electric *calamine*.

Sparry Calamine: Zinc Carbonaté, Häüy.—Its colours are greyish and yellowish-white, and sometimes green and reddish-brown. It occurs massive, botryoidal, cellular, stalactitic, and crystallized, in acute and obtuse rhomboids, and in longish quadrilateral tables: the crystals are small. The lustre of sparry *calamine* is between resinous and vitreous. The structure is imperfectly lamellar, and sometimes radiated. It is translucent, or more or less transparent; it yields easily to the knife. The specific gravity is 4.3. It is infusible before the blow-pipe, and loses about 34 per cent. by ignition. With muriatic acid it effervesces, and is dissolved. According to Smithson, the constituent parts of this ore from Derbyshire are,

Oxyd of zinc	-	-	-	65.2	
Carbonic acid	-	-	-	34.8	
					100.

From Somersetshire,

Oxyd of zinc	-	-	-	64.8	
Carbonic acid	-	-	-	35.2	
					100.

Compact Calamine: Zinc Carbonaté, Häüy.—Its colours are, greyish, greenish, or yellowish, and often brown, from an intermixture with iron. It occurs massive, botryoidal, disseminated, stalactitic, reniform, and mamillated; it has a dull, feebly glitening, resinous lustre. The fracture is uneven and coarse-grained, or splintery, and sometimes even a flatty conchoidal. It sometimes occurs in concentric lamellar concretions; it is opaque. Its chemical characters and constituent parts are the same as of the sparry *calamine*, these minerals being only varieties differing in form from each other.

Earthy Calamine: Zinc Carbonaté, Häüy.—It is of a greyish or yellowish-white colour, sometimes snow-white; externally it is frequently covered with a tint of yellowish-brown. It occurs massive, and coating other minerals; it is opaque, and has an earthy fracture; it yields to the nail, and adheres to the tongue. The specific gravity is 3.358.

According to Smithson, the constituent parts are,

Oxyd of zinc	-	-	-	71.4	
Carbonic acid	-	-	-	13.5	
Water	-	-	-	15.1	
					100.

Electric Calamine: Zinc Oxyd, Häüy.—Its prevailing colours are, greyish, blueish, or yellowish-white; externally it is sometimes brownish or blackish. It occurs crystallized, mamillated, botryoidal, stalactitic, and massive. The crystals are six-sided prisms, with dihedral summits, or acute octahed-

ZINC.

octahedrons; sometimes truncated on the summits. The crystals are small, and either solitary, or radiating in groups, like zeolite. The lustre is shining, glitening, and vitreous: the structure is imperfectly lamellar, or divergingly fibrous. It is sometimes opaque, and sometimes translucent or transparent: it yields to the knife, but is much harder than common calamine. The specific gravity is 3.4. When gently heated it is strongly electric; it is infusible, and loses about 12 per cent. by ignition. It is soluble in muriatic acid with effervescence: the solution gelatinizes on cooling. According to Klaproth, its constituent parts are,

Oxyd of zinc - - -	66
Silic - - - - -	33
	—
	99
	—

According to Smithson,

Oxyd of zinc - - -	68.3
Silic - - - - -	25.
Water - - - - -	4.4
	—
	97.7

Calamine sometimes occurs in what are called supposititious crystals, as if it had been moulded over crystals of other minerals, and the internal crystal had disappeared. In Derbyshire, the working miners are of opinion, that the calamine destroys the lead-ores when they occur together; or, as they express it, the calamine eats up the lead. That some process of decomposition or change takes place where these ores are associated there can be no doubt; but by what means this is effected we are at present ignorant. See VEINS, *Metallic*.

Calamine, commonly called lapis calaminaris, when cleaned and roasted, is used for the fabrication of brads, forming a compound with copper. (See BRASS.) Its uses in the making of brads is of very high antiquity, being mentioned by Aristotle.

Calamine is also the most valuable ore from which metallic zinc is extracted.

The uses of calamine were not known in England before the reign of queen Elizabeth, and even so late as the year 1700 it was commonly carried out of the kingdom as ballast by the ships which traded to Holland. The calamine raised in Derbyshire about the year 1780 amounted to 1500 tons. Sixty years before that time the quantity got did not exceed 40 tons, the greater part being thrown away through ignorance of its nature and value.

The dressing of calamine consists principally in picking out all the pieces of lead-ore, lime-stone, iron-stone, heavy spar, and other minerals mixed with it in the mine. The picked calamine is then calcined in proper furnaces, and loses by calcination a third and fourth part of its weight, which is the carbonic acid. In great works, where calamine is prepared for the brads-makers, after its calcination, it is carefully picked again, the accidental ingredients being rendered more discernible by the action of fire. It is afterwards ground to a fine powder, and washed in a gentle rill of water, to free it from earthy particles with which it may be intermixed; for these being lighter are carried off by the water: it is then made up for sale.

A ton of the crude Derbyshire calamine, as dug from the mine, is reduced, by the various processes it undergoes before it becomes fit for use, to about twelve hundred weight. Part of the zinc is lost in calcination, particularly if too strong a fire be made: this is evident by the flame visible over the furnace. It would be practicable to use calamine without calcining it, for the carbonic acid would be expelled

by the heat applied in making brads; but then there would be seven or eight hundred weight put into the brads pots which would be of no use in the operation: it is therefore better to get rid of so large a quantity of unserviceable matter, and thereby avoid also an increased expence of carriage from the calamine-furnace to the places where the brads is made. Watson's Chemical Essays, vol. iv.

Blende comprises various sulphurets of zinc, differing in the proportion of their constituent parts, and the admixture of other mineral substances.

Yellow Blende, or Phosphorescent Blende: Zinc Sulphuræ Jaune, Brongniart.—The prevailing colours of this ore are yellow, passing into green, and sometimes hyacinth-red, aurora-red, or brownish-red. It occurs massive, disseminated, and crystallized. The crystals are generally small, middle-sized, and so closely aggregated, that it is difficult to determine the precise figure, which appears either the rhomboidal, the dodecahedron, the octahedron, or the tetrahedron. Yellow blende is translucent, passing into transparent, and has a splendid adamantine lustre. It yields to the knife, and affords a yellowish-grey or yellowish-white streak: it is brittle. The specific gravity rather exceeds 4: according to Karf-ton, it is 4.1.

It decrepitates before the blow-pipe, and becomes grey; but is infusible either alone or with borax. By friction it becomes phosphorescent, and, according to Bergman, acts as powerful in this respect in water as in air.

Foliated Brown Blende: Zinc Sulphuræ Brun, Brongniart.—It is of a reddish or yellowish-brown, passing into blackish-brown and dark red. It occurs massive, disseminated, and crystallized. The form of the crystals is a rhomboidal dodecahedron, either perfect or truncated on the alternate lateral angles and edges, or an octahedron, either perfect or truncated. It occurs also in tetrahedrons, perfect or truncated, and in rectangular four-sided prisms, six-fixed prisms, and acicular crystals. Sometimes the crystals are joined, forming a twin crystal. The lustre is shining or splendid, and either resinous, adamantine, or semi-metallic; it has a straight lamellar structure, with a cleavage in six directions. It is more or less translucent; it yields to the knife, and affords a yellowish-grey or yellowish-brown streak; it is brittle, and easily frangible. The specific gravity of this ore varies from 3.7 to 4. It is infusible, and yields an hepatic odour when digested in sulphuric acids. The constituent parts of blende are given as under; but some varieties of foreign blende contain silic, arsenic, and manganese, which may be regarded as accidental.

Blende from Satilberg, according to Bergman:

Zinc - - - - -	44
Iron - - - - -	5
Sulphur - - - - -	17
Silic - - - - -	24
Alumine - - - - -	5
Water - - - - -	5
	—
	100

From Allonhead, in Northumberland, according to Dr. Thomson:

Zinc - - - - -	58.8
Iron - - - - -	8.4
Sulphur - - - - -	23.5
Silic - - - - -	7.
	—
	97.7

Fibrous Blende.—The colour is reddish-brown: it occurs reniform and massive. The structure is divergently fibrous in one direction, and concentric lamellar in the other: its lustre is resinous; it is opaque or faintly translucent at the edges; it agrees in other characters with foliated blende. The constituent parts are given as under in the Journal des Mines, t. xlix. No. 13.

Zinc	-	-	-	62
Iron	-	-	-	3
Lead	-	-	-	5
Arfenic	-	-	-	1
Sulphur	-	-	-	21
Alumine	-	-	-	2
Water	-	-	-	4
				98
				—

Black Blende: Zinc Sulphuréd Noir, Haüy.—It is of a greyish or velvet-black colour, and sometimes brownish-black. When translucent, it appears blood-red; it is sometimes tarnished with various colours. It occurs massive, disseminated, and crystallized, in the same forms as brown blende; internally it is shining, sometimes splendid; and the lustre is adamantine, inclining to metallic. It has a foliated structure, and six-fold cleavage. The fragments are angular, and rather sharp-edged. It is almost always opaque. The streak is intermediate, between yellowish-grey and lightish-brown: it is easily frangible. The specific gravity varies with the admixture of ingredients in this ore, from 3.9 to 4.1. Auriferous blende from Nagyag, as given by Muller, is 5.39. The constituent parts of black blende are as under:

Zinc	-	45	53
Iron	-	9	12
Lead	-	6	0
Arfenic	-	1	5
Sulphur	-	29	26
Silex	-	4	0
Water	-	6	4
		—	—
		100	100

Blende is distinguished from tin-stone by its inferior hardness; it yields pretty easily to the knife. It may be distinguished from other ores which resemble it, by the sulphureous odour which it yields when thrown into an acid, or triturated in a mortar. The common name given to this ore by the English miners is Black Jack. It frequently occurs in the upper part of the metallic veins in Cornwall, that are rich in other ores below. Blende is not so valuable an ore of zinc as calamine: it must be freed from its sulphur by calcination before it can be applied to the making of brass. Some blendes lose one-fourth of their weight, others one-fifth by calcination. It has been for many years used for making brass at Brittol as well as calamine; but so little was this application of it known in other parts of the kingdom, that in the year 1777 we are informed by Dr. Watson, in his Chemical Essays, that its use in Derbyshire was but recently discovered; and he was requested not to divulge the purpose to which it might be applied, probably to evade the dues on minerals payable to the duchy court of Lancaster.

ZINCHI, or ZICCHI, in *Ancient Geography*, a people of Asiatic Sarmatia, upon the coast of the Euxine sea, and separated from the Sanichæ, by the river Abchæus. Arrian.

ZINCKGRABEN, in *Geography*, a town of Bavaria, in the bishopric of Bamberg; 5 miles E. of Lichtenfels.

ZINDIKITES, a sect among the Mahometans; so de-

nominated from their leader Zindik, whom Grotius makes to be one of the magi, and a follower of Zoroaster.

The Zindikites believe no providence nor resurrection: they allow no other God but the four elements; and, in this sense, they assert, that man, being a mixture of those simple bodies, returns to God when he dies.

ZINDINSKAIA, in *Geography*, a fort of Russia, on the confines of China, in the government of Irkutsk; 80 miles S. of Selenginsk.

ZINETUS, a word used by Paracelsus as a name for one of the brass-like marcasites.

ZINGANE-IS-KELESI, in *Geography*, a town of European Turkey, in Romania; 6 miles S. of Burgas.

ZINGAR, a word used by some of the chemical writers for verdigrise; and by others for the flos æris, or flowers of copper or brass.

ZINGHA, in *Geography*, a town of Africa, in Whidah; 20 miles N.W. of Sabi.

ZINGI, in the *Materia Medica*, the name of a seed, sometimes also called the anisum stellatum, or starry-headed anise.

ZINGIBER, in *Botany*, *ζιγγίβερις* of Dioscorides, a name which the Greeks seem to have taken, when they obtained the plant itself, from the Arabians. Gærtner, dissatisfied with Linnaeus's application of the ancient name *Amomum*, to a genus of the *Scitamineæ*, under which they both of them confounded very different things, substituted *Zingiber* in its place, as undoubtedly belonging to one or other of the species. But since this tribe, and its generic distinctions, have been cleared up by Mr. Roscoe, it becomes necessary to discriminate between *Amomum* and *Zingiber*, and consequently both names are employed.—Roscoe Tr. of Linn. Soc. v. 8. 347. Dryandr. in Ait. Hort. Kew. v. 1. 5. (*Amomum*; Lamarck Illust. t. 2. f. 3.)—Class and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. Brown. *Cannæ*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, tubular, sheathing, membranous, splitting at one side. Cor. of one petal: tube twice the length of the calyx, a little swelling upwards: outer limb ringent; the upper lip undivided; lower in two deep, equal, deflexed segments: inner limb a large, spreading, three-lobed lip, of which the middle segment is the largest, all of them more or less wavy and crenate. Stam. Filament one, erect, oblong, extended beyond the anther in an awl-shaped incurved beak, involute at the edges, embracing the style; anther attached by its back, below the beak of the filament, oblong, of two clove, parallel, linear lobes, meeting round the style, curling in front. Pist. Germen inferior, roundish, small, crowned with a pair of glands; style thread-shaped, embraced by the filament, and scarcely extending beyond its beak; stigma small, concave, fringed, projecting a little beyond the point of the beak. Peric. Capsule?

Ess. Ch. Anther two-lobed. Filament elongated beyond the anther, with an awl-shaped, channelled beak, embracing the style. Outer limb of the corolla ringent; inner a three-lobed lip.

Obs. Jussieu had already, after Adanson, remarked a difference between the inflorescence of the Ginger and the Cardamom tribes, though both have been comprehended by all botanists under *Amomum*. In the former, the flowers compose a dense spike, supported by a radical stalk; in the latter, they are panicled at the base of the stem. So important a difference in habit, between plants whose general structure is so uniform and simple, might lead us to look for some generic difference in the parts of fructification.

This Mr. Roscoe has detected in the *filament*, according to the

ZINGIBER.

the principle which runs through all his generic distinctions of this tribe, and which is supported throughout by the inflorescence, as well as the parts of the flower in general. Nothing more perfect has ever been accomplished in systematic botany. See SCITAMINEÆ.

1. *Z. officinale*. Narrow-leaved Ginger. Roscoe n. 1. Ait. n. 1. (*Z. majus*; Rumph. Ambon. v. 5. 156. t. 66. f. 1. Amomum Zingiber; Linn. Sp. Pl. 1. Willd. Sp. Pl. v. 1. 6. Jacq. Hort. Vind. v. 1. 31. t. 75. "Inchi; Rheede Hort. Malab. v. 11. 21. t. 12.")—Bractæes ovate, acute. Segments of the outer limb of the corolla linear, revolute. Middle lobe of the lip entire.—Native of the East Indies; naturalized in Jamaica. A stove plant in England, flowering in September. It appears to have been cultivated here by Edward lord Zouch, before the year 1605. The root is perennial, tuberous, fleshy, with long stout fibres, well known for its hot, gratefully aromatic, flavour, and cordial qualities. The whole herb is smooth, and partakes of the flavour of the root. Barren stems several, erect, herbaceous, wand-like, leafy, about three feet high. Leaves alternate, linear-lanceolate, acute, entire, single-ribbed, spreading, with long, close, sheathing, abrupt foot-stalks. Flower-stalks radical, a foot high, clothed with tubular sheathing bractæes. Spikes solitary, erect, club-shaped, enveloped in broader, shorter, less pointed, crowded bractæes, each accompanied by a solitary, sessile flower, twice its own length, of a delicate texture and short duration. The outer limb of the corolla is of a very pale yellow, or straw colour, revolute; the upper segment rather the broadest. Lip, as well as the incurved point of the filament, spotted with crimson. We have never been able to procure any specimen or account of the fruit, which is perhaps in consequence of the great increase of the roots, not often perfected, or if produced, it is most probably overlooked by the cultivators, who may find it expedient for the advantage of their crop, to cut away the stalks before they run to seed.

2. *Z. Zerumbet*. Broad-leaved Ginger. Roscoe n. 2. Ait. n. 2. Sm. Exot. Bot. v. 2. 105. t. 112. (*Z. spurius*; Koenig in Retz. Obf. fasc. 3. 60. *Z. latifolium* sylvestre; Herm. Lugd.-Bat. 636. t. 637. Amomum Zerumbet; Linn. Sp. Pl. 1. Willd. Sp. Pl. v. 1. 6. Jacq. Hort. Vind. v. 3. 30. t. 54. Lampujum; Rumph. Ambon. v. 5. 148. t. 64. f. 1. "Katou-infchi-kua; Rheede Hort. Malab. v. 11. 27. t. 13.")—Bractæes ovate, obtuse. Segments of the outer limb of the corolla straight. Middle lobe of the lip cloven, slightly wavy. Rib and sheaths of the leaves smooth.—Native of the East Indies. The roots are said to be bitter, without the flavour and pungency of the true Ginger; but the young foliage, according to Rumphius, is used in Amboyna as a pot-herb. This species is not uncommon in our stoves, being easy of culture, and flowering frequently at the end of autumn. Many persons who grow it think themselves possessed of the real Ginger. The habits of the two plants are indeed very similar, but the barren stems of the present species are rather the tallest, being four or five feet high, with elliptic-lanceolate leaves; silky beneath when young. Flower-stalks eighteen inches or two feet high, thick and firm. Spike ovate. Flowers pale yellow, without scent, each lasting but a few hours. Upper segment of the outer limb ovate, erect, concave; two lower ones lanceolate. Lip yellow, its large central lobe emarginate.

3. *Z. Cafumunar*. Cafumunar, or Hairy Ginger. "Roxb. in Asiatic Researches, v. 11. 347. t. 7." Sims in Curt. Mag. t. 1426. Ait. Epit. 376. (Cassumuniar; Dale Pharmac. 275. Cafumunar; Lewis Disp. ed. 4.

121.)—Bractæes ovate, rather acute. Segments of the outer limb of the corolla straight. Middle lobe of the lip cloven, dilated, crisped, and crenate. Rib and sheaths of the leaves hairy.—Native of the East Indies, from whence it was sent by Dr. Roxburgh to this country, and flowered in August 1811, in the stove of James Vere, esq. at Kensington Gore. The roots had long ago been introduced into the Materia Medica as a powerful stimulant and tonic, in hysterical, paralytic, and other nervous disorders, possessing a warm bitterish flavour, with the smell of Ginger; but they have long gone out of use. Their shape is less elongated and compressed than that of Ginger, and more annulated, tuberous or knotty. Herbage most like the last species, but distinguished by the hairy sheath and mid-rib of the leaves. Flower-stalks not above six or eight inches high. Spike ovate, brownish. Corolla pale yellow, distinguished from *Z. Zerumbet* by the greatly dilated, inversely heart-shaped, crisped and crenate, middle lobe of its lip; the two side lobes being erect and entire, not larger than in *Zerumbet*. The plant is said to be propagated by cuttings of the root.

4. *Z. Mioga*. Japanese Ginger. Roscoe n. 3. Ait. n. 3. (Amomum Mioga; Thunb. Jap. 14. Willd. Sp. Pl. v. 1. 7. Banks Ic. Kæmpf. t. 1. Desjoka, vulgò Mjoga, seu Mioga; Kæmpf. Am. Exot. 826.)—Bractæes ovate, acute. Spike nearly sessile. Segments of the outer limb of the corolla erect, acute. Middle lobe of the lip concave, entire.—Found near Nagasaki, and in other parts of Japan, flowering in September. Thunberg, Kæmpfer speaks of this as an eatable kind of Ginger, with a mild flavour. The leafy stems are from one to two feet, or more, in height, and with the foliage resemble those of the three foregoing species. The flower-stalk is radical, and remarkably stout, or scarcely any. Spike ovate, with numerous, large, white, pointed, striated, concave bractæes; the outer ones largest, concealing many within. The flowers smell faintly like Butter-bur, and have a yellow, very concave, undivided lip, and a white limb. Filament greenish-white, beaked, embracing the thread-shaped style, according to the generic character, as is faithfully described by Thunberg, who speaks of the fruit as a nearly ovate, obtuse capsule, with three cells and three valves, and numerous minute seeds, inserted into the central column.

5. *Z. roseum*. Rose-coloured Ginger. Roscoe n. 4. (Amomum roseum; Roxb. Coromand. v. 2. 15. t. 126.)—Bractæes lanceolate, coloured. Spike nearly sessile. Segments of the outer limb of the corolla revolute. Middle lobe of the lip flat, entire.—Native of moist valleys in Hindoostan, flowering in the rainy season. The Telings call this plant Bumacatchicay. Root creeping, cylindrical, branched, not knotty. No aromatic or other quality is recorded concerning it, or any other part of the plant. Leafy stems two or three feet high. Spikes nearly sessile at the root, ovate, two or three inches long. Bractæes loosely imbricated, erect, lanceolate, acute, of a fine rose colour, as are also the calyx, and the narrow revolute segments of the outer limb of the corolla. The lip is whitish, obovate, entire, not concave, but somewhat reflexed. Beak of the filament yellow. No account is given of the seed-vessel.

6. *Z. purpureum*. Purple Ginger. Roscoe n. 5. Ait. n. 4.—"Bractæes ovate, coloured. Segments of the outer limb of the corolla erect. Middle lobe of the lip divided."—Native of the East Indies. Introduced into the English stoves, by the right honourable sir Joseph Banks, in 1796, and observed by Mr. Roscoe in the Botanic garden at Liverpool. It flowers in September.

ZINGIBER, in the *Materia Medica*. See GINGER.

ZINGIS, otherwise JENGHIZ-KHAN, or *Genghis-khan*, in *Biography*, the founder of the Mogul empire, was the son of Bifukai, or Jesukai, a chief over thirteen hordes of Moguls in the Tartarian range between China and the Caspian sea, and born about the year 1161 or 1163, his first name being Temugin. In the year 1205 he was installed in the Mogul empire, and declared his purpose of giving a new code of laws to the nation; the object of which was the preservation of peace at home, and the conduct of war abroad. The penalty of death was denounced against murder, adultery, perjury, and the theft of a horse or ox, which were the chief articles of Tartarian property. The nation was interdicted all servile labour, the performance of which was assigned to slaves and strangers, and was consecrated to the sole profession of arms. The weapons which they were appointed to use were bows, scymetars, and iron maces; and the troops were distributed into divisions of hundreds, thousands, and tens of thousands. The soldiers and officers were made individually responsible for the safety and conduct of one another; and it was an established rule, that peace should never be granted without previous conquest. With regard to religion, Zingis established universal toleration. As for himself, his only article of faith was the existence of one God, the creator and governor of all things; but his Mogul and Tartar subjects were idolaters, Jews, Christians, and Mahometans, all of whom were allowed to practise their several rites without molestation, and without any difference of privileges. Having thus settled the affairs of the proper Mogul empire, he successively, by his own arms, and those of his lieutenants, reduced the different tribes of the desert, and rendered himself the undisputed monarch of the pastoral nations who pitch their tents from the wall of China to the Volga. For a sketch of his conquests, we refer to the article of the *MOGUL Empire*. These conquests were attended with many acts of savage cruelty. In his invasion of Kitay, the northern empire of China, he took 90 cities, destroyed by fire a number of towns and villages, and massacred many thousands of people; at the same time obliging the Kin emperor to purchase peace at the price of a Chinese prince, 500 youths and maidens, 3000 horses, and a large tribute in gold and silk. At his departure, he inhumanly ordered all the children whom he had taken in four provinces to be butchered. In a second expedition he laid siege to the capital city Yen-king, now called Peking, which, after a long resistance and grievous suffering by famine, was stormed by the Moguls, with the conflagration of the imperial palace; and after the desolation of China, its five northern provinces submitted to the dominion of the Mogul conqueror. In the bloody conflicts between Zingis and Mohammed, sultan of Kharism or Charism, all the rich and populous cities and countries of Transoxiana, Kharism, and Khorasan, were taken or laid waste by the Moguls. Mohammed died a fugitive in a desert island of the Caspian sea; but his son, Gelaeddin, boldly resisted the invader, and checked his progress, till overpowered by numbers on the banks of the Indus, he was under a necessity of spurring his horse into that rapid river, the opposite side of which he reached in safety. Zingis, admiring his heroism, and forbidding the pursuit of him, said to his sons, "Any son might wish to spring from such a father." Nevertheless he ordered all the sultan's male children to be killed. After the defeat of Gelaeddin, Zingis, remaining for some time in Khorasan, pursued his customary operations of sacrificing lives, and desolating whole tracts of country. Returning to Bokhara, or Bucharia, in 1223, he investigated the antiquities of Balk and the doctrines of Zoroaster, and held conferences with the Mahometan doctors; the result of which

was his assent to their tenets, the necessity of a pilgrimage to Mecca excepted. In 1224 he held a grand diet in the plain of Tonkat, which, though seven leagues in length, could scarcely contain the tents of all the distinguished persons that were assembled. In the following year he passed through Tartary to the borders of northern China, and subjugated the kingdom of Hya or Tangut. In the province of Shen-fi, on the mountain of Lu-pan, whither he went in order to pass the summer heats, he was taken ill; and as he perceived his end approaching, he summoned the generals of his army, before whom he declared his fourth son regent, till the arrival of his brother Oetai, whom he appointed his successor in the dignity of grand khan of the Moguls and Tartars. Recommending unanimity, and advising the conduct of the war against Kin, he expired in August 1227, at the age of 66 years. His remains were interred with great pomp under a beautiful tree which he had fixed upon in returning from a hunting expedition. He had many wives, and left a numerous progeny. "This emperor," says one of his biographers, "possessed the civil and military qualities necessary for the founder of a mighty monarchy, together with a penetrating and inquiring mind, which, with superior culture, might have placed him in the list of truly great princes. His memory now survives as that of one of the great conquerors whose deeds have astonished the world, to which they have proved the most terrible of scourges. His simple laws were long the rule of the countries he governed, and are still religiously observed by the Crim Tartars." D'Herbelot. Gibbon's Hist. Univ. Hist. Gen. Biog.

ZINGST, in *Geography*, a small island in the Baltic, near the coast of Pomerania, and a little to the west of the island of Uledom. N. lat. 54° 28'. E. long. 12° 50'.

ZINIAR, a name given by the old chemical writers for verdigrise.

ZINIAT, a word used by the old chemical writers to express either the action of fermentation, or any thing that is capable of exciting it in bodies.

ZINK. See ZINC.

ZINKOW, in *Geography*, a town of Poland, in Podolia; 32 miles N. of Kaminnec.

ZINN, JOHN GODFREY, in *Biography*, an anatomist and botanist, was born in 1726, studied under Haller at Göttingen, and became botanical professor in that university. His first experiments were undertaken in order to ascertain the sensibility of different parts of the brain; he then proceeded to the examination of the eye, which produced his esteemed work, intitled "Descrptio Anatomica Oculi Humani, Iconibus illustrata," Götting. 4to. 1755. Botany was also the subject of his assiduous study, the result of which appeared in several papers, and in a catalogue of the plants in the academical garden and vicinity of Göttingen, arranged according to the system of Haller. His premature death happened at the age of 32, in April 1758. He was a member of the Academy of Sciences at Göttingen, the Institute of Bologna, and the Royal Society of Berlin. Haller. Eloy.

ZINNA, in *Geography*, a town of the duchy of Magdeburg; 18 miles N. of Wittenberg.

ZINNIA, in *Botany*, was so named by Linnæus, in honour of Dr. John Godfrey Zinn, professor of physic and botany at Göttingen, author of a *Catalogus Plantarum Horti Academici et Agri Göttingensis*, printed there in 1757. This work, making an octavo volume, is classed after Haller's method. Its author has, besides, published various botanical and physiological treatises, and would probably have contributed much more to the advancement of science, had he not been cut off, at the early age of 32, in 1758. Haller, whose

ZINNIA.

whose disciple and successor he was, speaks of him with much complacency; but it is easy to see that his favour was greatly conciliated by Dr. Zinn's preference of his system to that of Linnæus. One principle of the learned Swede he indeed very justly approved, that plants nearly related on the whole ought not to be separated on account of a difference in one particular part. Yet in the application of this rule he surely has wandered widely from the truth, in wishing to unite *Geum*, *Comarum*, *Potentilla*, *Tormentilla*, and *Fragaria*. Such it seems was the avowed opinion of Zinn, in his *Prælectio*, published in 1755; but he has not followed it in his work above-mentioned. In that volume occurs, if we mistake not, the first figure of a *Zinnia*, under the name of a *Rudbeckia*; though the author justly declares it to constitute an indubitably new genus.—Linn. Gen. 437. Schreb. 563. Willd. Sp. Pl. v. 3. 2139. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 91. Pursh 565. Juss. 188. Lamarck Illust. t. 685. Gærtn. t. 172.—Clafs and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifolice*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* ovato-cylindrical, smooth, imbricated, with numerous, obtuse, erect, permanent scales. *Cor.* compound, radiated. Florets of the elevated disk several, all perfect, funnel-shaped, five-cleft, internally villos; those of the radius from five to ten, ligulate, roundish or oblong, abrupt, larger than the disk, permanent. *Stam.* in the perfect florets, Filaments five, very short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, Germen oblong, with two very unequal awns; style thread-shaped, cloven half way down; stigmas two, erect, obtuse: in the female florets, Germen oblong, triangular, without awns; style capillary, cloven half way down; stigmas two, recurved. *Peric.* none, except the unchanged calyx. *Seeds* in the perfect florets, solitary, oblong, quadrangular, compressed. Down of two points, one of them awned. In the female florets solitary, pointless, crowned with the permanent petal. *Recept.* chaffy, with tongue-shaped, channelled, deciduous scales, the length of the calyx.

Eff. Ch. *Receptacle* chaffy. *Seed* down of two erect unequal awns. *Calyx* imbricated, somewhat ovate. Florets of the radius from five to ten, permanent, undivided.

1. *Z. pauciflora*. Yellow Zinnia. Linn. Sp. Pl. 1269. Willd. n. 1. Ait. n. 1. (*Bidens calyce oblongo squamolo, seminibus radii corollæ non deciduâ coronatis*; Mill. Ic. v. 1. 43. t. 64. *Rudbeckia foliis oppositis hirsutis ovato-acutis, calyce imbricato cylindrico, radii petalis pistillatis*; Zinn. Gott. 409. t. 1. *Chrysozomum peruvianum*; Linn. Sp. Pl. ed. 1. 920, excluding the synonym, which is wrong, and a heap of confusion; see Feuillée 766.)—Flowers sessile. Leaves somewhat heart-shaped, sessile, clasping the stem.—Native of Peru. Cultivated by Miller, but not commonly preferred in our gardens like the following, being less hardy, and not so ornamental. The root is annual. *Stem* erect, three or four feet high, branched, angular, leafy. *Leaves* opposite, deflexed, two or three inches long, acute, roughish, entire, rough-edged, with three principal ribs; their base broadly-heart-shaped. *Florets* solitary at the ends of the branches, nearly or quite sessile, with the uppermost pair of leaves close to the base of the calyx; disk brownish; radius yellow. We perceive a difference between several specimens and figures of this plant, but cannot trace an absolute or constant specific distinction between them. In the Linnæan specimen, the small number of florets justifies the specific name, and the flower itself is quite sessile. This is undoubtedly Miller's plant, though the radiant florets are much more numerous in his figure, and the whole flower larger. A specimen under this same name of *pauciflora*, given us by

Mr. Joseph Banks, from Jacquin's herbarium, is what Zinn's figure exactly represents. The leaves are shorter, more rounded and heart-shaped, and the flower is large, with more or less of a stalk. Its radiant florets are numerous, broad, and yellow. How far these characters are permanent, culture and repeated observations must determine. We are rather inclined to suspect the Linnæan specimen, raised in the Upsal garden, is a starved one, the flowers perhaps being rendered diminutive by their lateness. It is most probable that a portion of the same seed was sent by Jussieu to Linnæus and to Miller. The plant indeed flowered at Upsal before the year 1753, when Miller says he received his seeds, because it is described, in the first edition of Sp. Pl. printed that year, from the garden specimen now before us.

2. *Z. multiflora*. Common Red Zinnia. Linn. Sp. Pl. 1269. Willd. n. 2. Ait. n. 2. Pursh n. 1. Curt. Mag. t. 149. Linn. Dec. 23. t. 12. Jacq. Obl. fasc. 2. 19. t. 40.—Flowers stalked. Leaves opposite, ovato-lanceolate.—Native of North America. Found on the banks of the Mississippi, flowering in July and August. Annual. Rays yellow, orange, and sometimes brick-red. *Pursh*. The latter colour is most common in the gardens of Europe, where this plant is treated as a rather tender annual, like the different species of *Tagetes*, being best raised on a hot-bed, and planted out so as to flower in the autumn. A yellow variety, almost equally common, is less singular and striking in colour. We are not by any means certain that this variety may not be sometimes taken for the foregoing; yet the plant of Zinn and Jacquin, of which we have just given an account, is too different in the great breadth of its leaves to be confounded with the present species. The *Z. multiflora* has a more hairy stem than the *pauciflora*, much narrower and elongated leaves, with three ribs; their surface roughish to the touch. The flowers stand each on a hollow, deeply furrowed, terminal stalk, from one to two inches long, much thicker than the stem, and gradually swelling upwards. The disk is conical and acute, composed of reddish or tawny florets, accompanied by the prominent, dark-green, or blackish, scales of the receptacle: the radius consists of ten or more broad, elliptical, usually emarginate florets, of a deep brick-red, and very smooth, above; pale, greenish, and rough beneath; reticulated with veins, and finally becoming rigid, or membranous.

3. *Z. verticillata*. Whorl-leaved Zinnia. Andr. Rep. t. 189. Willd. n. 3. Ait. n. 2.—Flowers stalked. Leaves whorled, ovato-lanceolate. Radiant florets very numerous.—Native of Mexico. Raised by Messrs. Lee and Kennedy at HammerSmith, about the year 1789. We cannot suppose this to be any thing more than a luxuriant variety of the last. Annual plants, pampered with manure, and every possible advantage of cultivation, are liable to acquire aggregate leaves, double flowers, and many other characters, which do not appear in a state of nature. These it is the business of the gardener to encourage, and of the botanist to beware of. Having seen no specimen of this plant, we can only judge by the figure, in which we cannot discover any specific distinctions. The flowers indeed are rendered very splendid, by their multiplied radius of a deep scarlet, and their disk seems broader, and less conical, or pointed, than in either of the foregoing species. This last character, if constant, is more material than any which has been mentioned.

4. *Z. elegans*. Purple-flowered Zinnia. Jacq. Ic. Rar. t. 589. Willd. n. 4. Ait. n. 4. (*Z. violacea*; Cavan. Ic. v. 1. 57. t. 81. Andr. Rep. t. 55.)—Flowers stalked. Leaves opposite, ovate-heart-shaped, sessile, clasping the stem, harsh on both sides. Scales of the receptacle jagged and fringed.

fringed. Tubular florets with a hairy disk.—Native of Mexico; said to have been brought to England from Madrid, in 1796, by the late marchioness of Bute; whose botanical acquisitions in Spain, made with no less intelligence than taste, have eminently enriched the gardens of England. This is also a tender annual, flowering from Midsummer to the end of autumn. The *herbage* is flouter, the *leaves* broader, and much more harsh to the touch, like a file, than in any other of the genus. *Flowers*, in a cultivated state at least, as large as the last, with a conical, but rather obtuse, disk; the prominent orange-coloured scales of the *receptacle* have many finely-fringed segments; the upper surface of the yellow tubular florets is densely shaggy; the *radius* consists of numerous, spreading, obovate florets, of a deep lilac, or light purple, colour, less harsh, or scarious, after flowering than in the *multiflora*.

5. *Z. tenuiflora*. Slender-flowered Zinnia. Jac. Ic. Rar. t. 590. Willd. n. 5. Ait. n. 5. Curt. Mag. t. 555. (*Z. revoluta*; Cavan. Ic. v. 3. 26. t. 251.)—Flowers stalked. Leaves opposite, ovato-lanceolate, pointed. Calyx cylindrical. Radiant florets linear, revolute.—Native of Mexico. Raised here in 1799, by the late captain Woodford, at Vauxhall. This very distinct species requires the same treatment as the rest. They may all, perhaps, succeed, in favourable seasons, as hardy annuals, but are best raised with artificial heat in the spring. The present has much narrower leaves than the last, which moreover are nearly smooth. The flowers are the smallest of their genus, and distinguished by their bright red, narrow, revolute radiant florets, very rough at the edges; the tubular florets are yellow, roughish in their disk.

ZINNIA, in *Gardening*, contains plants of the annual flowering kind, in which the species cultivated are, the few-flowered yellow zinnia (*Z. pauciflora*), and the many-flowered red zinnia (*Z. multiflora*).

These are both plants of the annual flower kind.

Method of Culture.—These annual plants are increased from seeds, which should be sown on a slight hot-bed in the early spring, as March; and when the plants are a few inches high, they should be pricked out on another bed previously prepared to receive them, where they should remain till the advance of summer, when they may be taken up and planted out in the borders of the pleasure-ground, where they blow and complete their seeds for the year following.

They have a fine effect in their leaves and flowers in these situations.

ZINNORE, in *Geography*, a town of Hindoostan, in Guzerat, on the Nerbuddah; 30 miles N.E. of Baroach.

ZINTEN, a town of Prussia, in the province of Natangen, near which the Poles were defeated in 1520; 30 miles S.S.W. of Königsberg. N. lat. 54° 23'. E. long. 20° 20'.

ZINTI, a town of South America, in the viceroyalty of Buenos Ayres, and archbishopric of La Plata; 90 miles S. of La Plata.

ZINU, a province of South America, in the viceroyalty of New Grenada, situated to the north of Choco, and west of Carthagena.

ZINU, or *Sinu*, a town of South America, and capital of a province, on a river of the same name, which runs into the Spanish Main; 90 miles S. of Carthagena. N. lat. 8° 58'. W. long. 75° 48'.

ZINWALD, a town of Bohemia, in the circle of Leitmeritz; 18 miles N.W. of Leitmeritz.

ZINZENDORF, NICHOLAS LOUIS, in *Biography*, was born at Dresden in May 1700, and was educated under the

inspection of his grandmother, who was a pious woman, accustomed to the perusal of the Scriptures. He was thus led into an early acquaintance with the principal doctrines of the Christian religion, and manifested a peculiar taste for spiritual songs. Under professor Franke at Halle, he became a good classical scholar; and his facility in composing verses was such, that he indited them faster than he could write them. Such, however, was his proneness to dissipation, and particularly gaming, that he squandered away not only his money, but all his effects. From his youth he was fond of forming religious societies, and it is said that he had established seven associations of this kind between the year 1710 and the year 1716, when he left Halle. One of his companions in forming these institutions was baron Frederick von Watteville, in intercourse with whom he first conceived the idea of attempting the conversion of the heathens. With this view they bound themselves by an oath, and determined to employ others in accomplishing this design who were properly qualified for the office. This resolution seems to have taken its rise from a baptized native of Malabar, who had been brought to Halle by the missionary Ziegenbalg. In 1716 Zinzendorf removed to Wittenberg, where he applied diligently to his studies; and in 1719 he quitted Wittenberg, in order to gratify his relations by pursuing his travels. On his tour he remained for some time at Utrecht, prosecuting his studies in history and jurisprudence; but his chief attention was directed to theology, as he had formed a purpose of becoming a preacher. From Holland he proceeded to Paris, where he associated with his friend, Henry, prince of Reufs, and endeavoured to spread his doctrine among the Catholic nobility, by some of whom they were treated with respect, while others contemptuously denominated them Janfenits and Pietists. At this time he was introduced by Father de la Tour, general of the Society of the Oratory, to the archbishop of Paris, and attempts were made, without effect, for gaining him over to the Catholic church. During his abode at Paris he formed an acquaintance with several other persons of distinction. From Paris he proceeded through Switzerland to Germany in 1720, and having arrived at Herford, in Lusatia, he found his grandmother still living, and employed himself in communicating instruction to the domestics, and corresponding with his friends. Soon after, retaining his purpose of becoming a preacher, he went to Dresden, and having received his property from those with whom it had been entrusted, he purchased the lordship of Bertholdsdorf, in Lusatia, and marrying a filier of the prince of Reufs, distinguished for her piety and virtue, he assigned to her his whole property, that he might not be incumbered and diverted from the prosecution of his design by the cares of the world. About the year 1722 he indulged the notion of a purer church discipline, of which he observed some traces among the Bohemian and Moravian brethren, who, from their earliest connection with the Waldenses and true followers of John Huss, had formed a peculiar religious community. The Christians of this description had undergone from the year 1458 to 1627 severe persecutions, so that they were almost extirpated from Germany; but a small number of them remained, under oppression, in Moravia; and about the year 1720 the sect revived: so that they held frequent meetings, read the Scriptures with their old books of hymns, celebrated in secret the holy sacrament, and introduced, at least in their houses, the ancient church discipline. One of their number, of obscure condition, obtained an introduction to count Zinzendorf, who gave them leave to settle on his estate at Bertholdsdorf. Availing themselves of this permission, a small number of them, consisting of three men, two women,

ZINZENDORF.

women, and five children, came hither from Moravia, in Whitfuntide, 1722, and erected on a hill, in a wild marshy district, a wooden habitation, exposing themselves to the derision of the adjacent inhabitants. They were so poor that the countess sent them a cow to supply milk for their children. However, they gradually gained new converts; and when the count and his consort visited this new settlement of the Moravian brethren in the month of December, he gave them a cordial welcome, and falling upon his knees, pronounced a benediction on the infant colony. Such was the origin of the village of Hernhut. (See HERNHUTERS and MORAVIANS.) The count, whilst he afforded them protection, left them at full liberty to think for themselves; more especially as he found, upon examination, nothing improper in their doctrine. From this time, count Zinzendorf, in connection with some other persons similarly disposed, took pains in giving instruction to his subjects, and educating their children; avowing himself a true Lutheran, but wishing that his people might remain totally ignorant of the disputes that subsisted among Protestant divines. In 1723 he published a small catechism, entitled "The pure Milk of the Doctrine of Jesus," which, he says, cost him more labour than all his other works. The count, devoted to the prosecution of the work he had undertaken, resided sometimes on his estate in Lusatia, and sometimes at Dresden, but declined every offer of a place at court. He employed himself in the composition and occasional publication of books adapted to his design; one of which, being a periodical work, and entitled "The German Socrates," was suppressed by order of the council, probably because it censured the prevailing indifference about religion, and called upon his fellow-citizens to live in a manner more agreeable to what their religion required, or entirely to renounce it. In 1727 he quitted Dresden, that he might be nearer his favourite object Hernhut, and that he might be at leisure to devote his whole time and attention to the improvement and increase of his congregation. With this view he made a tour through the greater part of Germany, occasionally preaching, and endeavouring to gain converts. In 1731 he extended his tour to Denmark, and being present at the coronation of Christian VI., who conferred upon him the order of Dannebrog, which five years afterwards he resigned, because he thought it improper to appear as the instructor of his flock with the insignia of his order. In this tour he acquainted himself with the state of the Danish missions in the East Indies and Greenland; and on his return he took measures for carrying into execution the design he had formed at Halle with his friend Watterville. From this commencement, in the year 1732, arose that missionary system of the Moravians which has since been so widely and so wonderfully extended. Between 1732 and 1766 nearly 4000 negroes in the Danish islands were baptized; and in 1768 the congregation of New Hernhut and Lichtenfels, in Greenland, amounted to 784 persons. When the congregation at Hernhut had increased in 1732 to 500 persons, the Saxon court became alarmed, and appointed a commission for the purpose of examining their doctrine and principles. Although they were found to be inoffensive, the count was forbidden to bring any more new emigrants from Moravia; and soon after he received an order to sell his estate and property, which was a kind of sentence of banishment from his country. He also perceived a coldness and reserve in the disposition of his friends. Accordingly he quitted Hernhut, and repaired to his friend count Reufs at Eberdorf. He now thought seriously, as he had done twenty years before, of entering regularly into the church; but the countess and his

friends dissuaded him from adopting this measure. With a view of becoming tutor to the children of Richter, a merchant at Stralsund, to which he was urged by his pecuniary circumstances, he was examined for orders, and having obtained a flattering testimonial, was formally ordained at Tübingen. But a change taking place in the circumstances of Richter, this plan did not succeed. In 1735 he made an attempt to visit Sweden, but was forbidden to enter the kingdom by an order of government; and this occasioned the composition of one of his most important works, entitled "A Letter to the King of Sweden in regard to the general Belief of himself and Congregation," which he widely circulated, and which produced various plans for extirpating the Moravian brethren from the empire. In the same year he visited Switzerland, and in 1736 he and the countess made a tour to Holland, where, at the desire of the princess dowager of Orange, he founded a new colony at Yffelstein, called Heerendyk, which was afterwards removed to Zuyit. On his return he found at Cassel a copy of a Saxon rescript, by which he was forbidden the territories of that electorate, and banished from his native country. He was thus reduced to the necessity of making various excursions; and on his return he was invited to a conference with the king of Prussia, who was so well satisfied with his doctrine and character, that he advised him to be regularly ordained. For this purpose he recommended him to the chief court preacher Jablonky, by whom he was consecrated bishop of the Moravian congregation in May 1737. In this year he visited London, and established the brotherhood in England. Here he became acquainted with John Wesley, and maintained a dispute with him on the impossibility of men's attaining moral perfection, for which the English preacher contended. Although he obtained permission to return to Hernhut, it was on condition of his making certain declarations with which he could not comply, and therefore he became a voluntary exile; and was forbidden ever to enter Saxony. In the year 1738 he undertook his first voyage to America, in the course of which he composed a work entitled "Jeremiah a Preacher of Righteousness." Upon his arrival at the island of St. Thomas, he found that all the missionaries had been thrown into prison, but he immediately procured their release, and liberty for his congregation to assemble. After his return he visited Holland and Switzerland, wrote in his own defence against the accusations of his German enemies, and held public assemblies at Geneva. In 1742 he made a second voyage to America, and preached alternately with their own minister to the Lutheran congregation at Germantown, in Pennsylvania, and built for them a place of worship. In a Latin speech at Philadelphia he laid aside the title of count, and assumed the name of Von Thunitein, which belonged to his family. The Quakers generally styled him friend Lewis. He also established the celebrated colony at Bethlehem, and made a tour among the Indians, who received him favourably, and, as a token of their friendship, gave him the wampum belt. In America, however, he suffered much abuse and calumny. In 1743 he returned to Europe; and having proceeded to Riga with a view of settling some differences among his followers at Livonia, he was arrested, conveyed to the frontiers, and ordered never to enter the imperial territories any more. In 1747 he obtained permission to return to Saxony, after an exile of ten years; and the king, having received from one of the Moravians a considerable sum of money for the castle of Barby and district of Doben, issued a declaration that the society should be allowed, in every part of his territories, the same privileges which they had enjoyed at Hernhut. In 1748

he succeeded in obtaining a commission, which, after particular examination, declared the members of the Moravian community to be true adherents to the Augsburg confession. In the following year he visited England, and obtained an act of parliament for the protection of his followers in the British dominions in America. In 1757 he made his last tour to Switzerland, and from thence proceeded to Holland. In 1760 he died at Hernhut, after an illness of four days, and his funeral was attended by 2000 of his followers, and as many spectators; and his coffin was carried to the grave by thirty-two preachers and missionaries, some of whom had come from Holland, England, Ireland, North America, and even Greenland. Count Zinzendorf was somewhat above the middle size; and his countenance combined ferociousness with animation. In early life his manners were elegant, but as he withdrew from intercourse with the world, in more advanced life they became stiff and reserved. To money he was perfectly indifferent, and as he gave to every mendicant, he was often penniless. His disposition was lively, but he was capable of long-continued and intense application. His memory was prompt and comprehensive, but as he was of a lively imagination it was not very retentive. In his style he bid defiance to all the rules of grammar, and his ambiguous mode of expression subjected him to many inconveniences, so that his meaning was often mistaken and misrepresented. To persons of the lower order he was condescending, and in his intercourse with all mild and candid. In his temper he was irritable and passionate, but placable and forgiving. His activity in doing good and serving others was indefatigable and unbounded; he often promised, it is said, with the best intentions, beyond his ability of performance; and he is charged with having used art and flattery to carry on his own purposes, and to gain converts to his cause. Mosheim, &c. Gen. Biog.

For a further account of the tenets and partisans of the sect with which he was connected, and of which he was, according to his own statement, a reformer, and not a founder, we refer to the articles HERNHUTERS, MORAVIANS, and UNITAS Fratrum.

ZINZIBER, GINGER. See ZINGIBER and GINGER.

ZINZIBER Rubrum, Red Ginger, a name by which some authors have called the official casumunar-root.

ZINZIBER Caninum, Dog's Ginger, in Botany, a name given by some of the old writers to the *periscaria urens*, or biting asmart; a plant which is very hot, and pungent to the taste, and grows in watery places. It had hence the name of *hydropiper*, water-pepper, among the Greeks, and was called *zinziber caninum*, or dog's ginger, by Avicenna and others, from its heat, and from an opinion that it would poison dogs that eat of it.

The Arabian name is *zinzibil alkebe*.

ZINZIBER Caninum is also a name given by some authors to the *capficum*, or Guinea-pepper. Ger. Emac. Ind. 2.

ZINZIG, or SINZIG, in Geography, a town of France, in the department of the Roer; 18 miles N.N.W. of Coblenz. N. lat. 50° 33'. E. long. 7° 12'.

ZINZILLA, a name by which some medical writers have called that species of the herpes, which we usually call the shingles.

ZINZOACZA, in Geography, a town of Mexico, in the province of Mechoacan, anciently the residence of a cacique.

ZYCOBERIS, in Ancient Geography, a river of Asia, in Hyrcania, which discharged itself into the Rhydage, according to Quintus Curtius. Diodorus Siculus calls it *Sibtoetes*.

ZIOLO, in Geography, a town of Italy, in the Paduan; 10 miles S.E. of Padua.

ZION, in Ancient Geography. See SION and JERUSALEM.

ZIPH, a town of Palestine, in the tribe of Judah. (Joth. xv. 24.) St. Jerom says, that in his time they shewed the village of Ziph, 8 miles from Hebron eastward. David for some time concealed himself in the wilderness of Ziph. (1 Sam. xxiii. 14, 15.) There was another city called Ziph, near Maon and Carmel of Judah. Joth. xv. 55.

ZIPHRON, or **ZEPHRONIA,** a city N. of the land of promise, now unknown. Numb. xxxiv. 9.

ZIPOETIUM, a town of Asia Minor, in Bithynia, near mount Lyperus, and which had been founded by king Ziptetus. Steph. Byz.

ZIPPORIS, a name which the ancients gave to the town of Sefora or Sauffori. It was the strongest place in Galilee, and its position might be regarded as the key of the province, according to Josephus.

ZIPSERCHLOSS, in Geography, a town of Hungary; 6 miles E. of Leutfch.

ZIRBALIS HERNIA, a term used by medical writers to express that kind of rupture which is caused by a defect of the omentum into the scrotum.

ZIRBUS, the name by which the Arabian physicians have called the omentum.

ZIRCON, in Mineralogy, *Jargon de Ceylon*, Romé de Lisle, *Zircon*, Häüy, a gem originally found in the island of Ceylon, in the sands of rivers, along with spinel, sapphires, emeralds, and iron-sand. Zircon, the gem called the hyacinth, and zirconite, are regarded by most mineralogists as varieties of the same species. They are essentially composed of the earth called zircon, (see ZIRCONIA, in Chemistry), with silica, and a minute portion of iron, which may be regarded merely as the colouring matter. The primitive form of the crystals of zircon, according to Häüy, is an octahedron, composed of two four-sided prisms, whose sides are isosceles triangles. The inclination of the planes of the same pyramid to each is 124°.12; the inclination of the sides of one pyramid to those of the other 82°.50. The angle of the summit is 73°.44. The common forms in which it occurs are rectangular four-sided prisms, rather flatly terminated by four-sided pyramids, the planes of which are set on the lateral planes of the prism under equal angles. The above figure is often truncated in the lateral edges. The angles of the prism, in junction with the pyramid, are often bevelled, and sometimes the prisms are terminated by four planes at each end, two of which at each end form very obtuse angles, and are set on the lateral planes of the prism. The crystals are generally small, and occur loose or imbedded. The surface of the crystals is sometimes rough, and sometimes smooth and shining; that of the grains is uneven, and glistening internally. Zircon is splendid or shining, with a lustre intermediate, between adamantine and resinous. The structure is imperfectly foliated, with the folia parallel to the lateral edges of the prism. The fracture is flatly conchoidal. The prevailing colour of zircon is grey; it is sometimes white, green, and brown, and occasionally yellow, blue, and red. The colours are pale; it is sometimes transparent, but more frequently semi-transparent or translucent: it refracts doubly. Zircon is harder than quartz, but softer than the diamond. The specific gravity varies from 4.5 to 4.7. It is infusible without addition by the blow-pipe.

According

According to Klaproth, the constituent parts are,

Zircon	-	-	69	63
Silex	-	-	26.50	33
Oxyd of iron	-	-	50	1
			<hr/>	
			96.	97

Hyacinth: Zircon Hyacinth, Brongniart. — The prevailing colour of this mineral is orange-red; it is sometimes yellow, grey, and green, and very rarely white. It occurs in angular grains, but more frequently in small crystals, which have the following forms. A rectangular four-sided prism, terminated by four rhomboidal faces at each end, set on the lateral edges of the prism; the prism is sometimes truncated on the edges. Sometimes it occurs in an irregular garnet-shaped dodecahedron, and sometimes in a flat octahedron. The structure is foliated; it has a double rectangular cleavage, and the folia are parallel with the diagonal of the prism. Hyacinth is transparent or translucent, and refracts doubly: the lustre is resinous-vitreous and splendid. It is very hard, scratching quartz with ease. The specific gravity varies from 4.3 to 4.7. Before the blow-pipe it loses its colour, but not its transparency, and is infusible. According to Klaproth, the constituent parts of hyacinth of Ceylon are,

Zircon	-	-	-	70
Silex	-	-	-	25
Oxyd of iron	-	-	-	0.50
Loss	-	-	-	4.50
				<hr/>
				100.

According to Vauquelin, the constituent parts of hyacinth of Expailly are,

Zircon	-	-	-	64
Silex	-	-	-	32
Oxyd of iron	-	-	-	3
Loss	-	-	-	1
				<hr/>
				99

Zirconite does not appear to differ from zircon, except in the situation in which it is found. It occurs in small crystals of a reddish-brown colour, imbedded in fensite. According to Klaproth, its constituent parts are,

Zircon	-	-	-	65
Silex	-	-	-	33
Oxyd of iron	-	-	-	1
				<hr/>
				99

Zircon and hyacinth, as we have stated, were originally found in Ceylon; they have since been found in various parts of Asia and Europe.

Zircon occurs in considerable quantities along with sapphire and iron-sand in volcanic sand, in a rivulet near Expailly in Auvergne; also near Pifa, and in the volcanic sand of the Vicentine. It has been found in trap-rocks in Bohemia, and in the vicinity of Lisbon. It was first found in its native situation at Freidrickshwarn, in the district of Christiana, in Norway, imbedded in fensite. It was also found in basalt near Expailly, and in the mountain of Anise in Auvergne, and also in volcanic scoria in the same

country. It has been found in rolled masses of fensite by professor Jamefon in Scotland, in the county of Galloway; and has since been met with in granite near Cuffel, in Dumfriesshire.

Zircon has been found in South America, and in the province of New Jersey, in the United States.

Zircon and hyacinth are characterized by their great specific gravity. Common zircon has been frequently confounded with the diamond, but the specific gravity alone would be sufficient to distinguish them; that of the diamond not exceeding 3.5. The hyacinth has often been confounded with other minerals. The oriental hyacinth of Romé de Lisle is orange-coloured sapphire. The occidental hyacinth of Dutens is yellow-coloured topaz.

Cruciform hyacinth is cross-stone; brown volcanic hyacinth is vesuvian; white hyacinth of Somma is meionite.

The hyacinth of Dessentis, mentioned by Sauffure, is a variety of garnet.

Common zircon is frequently cut and polished by the jewellers as a gem. The greyish-white and yellowish-white varieties are the most prized, on account of their resemblance to the diamond. The darker coloured varieties may be deprived of their colour by heat. It is cut into the same forms as the diamond, and exhibits faintly the same play of colours, and is not unfrequently fold as an inferior kind of diamond. The hyacinth is also employed by jewellers in various kinds of ornaments; but pale garnets and rock crystals are frequently fold for hyacinths.

ZIRCONIA, or ZIRCON, in *Chemistry*, the name of a peculiar earth, hitherto only met with in the minerals termed *hyacinth*, and *zircon* or *jargon*. See the preceding article.

Zirconia exists in the form of a fine white powder, which feels rather harsh when rubbed between the fingers. It has neither taste nor smell. It is infusible before the blow-pipe; but when heated violently in a charcoal crucible it undergoes a sort of imperfect fusion, and acquires a greyish colour and porcelainous appearance. In this state it is very hard, and its specific gravity is 4.3.

Zirconia is insoluble in water, but has a considerable affinity for that liquid. It does not combine with oxygen, azote, or any of the simple combustibles, but appears to have a strong affinity for many metallic oxyds, especially for that of iron.

It is insoluble in alkaline solutions, neither can it be fused with them by the assistance of heat; but it is soluble in the alkaline carbonates. Sir H. Davy subjected this earth to the action of galvanism, and obtained evidences of its containing a metal as its basis. To this metal he gave the name of *zirconium*. Nothing satisfactory is known respecting its nature.

No very accurate analysis of the salts of this earth have been yet made. From some experiments of Klaproth and Vauquelin, Dr. Thomson fixes the weight of its atom at 46.25, though it is probable that this is not to be absolutely relied upon.

Salts of Zirconia: Nitrate of Zirconia.—This salt may be formed by pouring nitric acid on newly precipitated zirconia. It always contains an excess of acid, and does not crystallize. It is decomposed by heat, and most of the vegetable acids, except perhaps the acetic.

Carbonate of Zirconia is a white insoluble powder. It may be formed by double decomposition with the alkaline carbonates, and solutions of zirconia in acids.

Sulphate of Zirconia.—This salt exists in the form of a white powder, but may be obtained in small needle-formed crystals. It has no taste, and is insoluble in water. It is easily decomposed by heat.

Acetate of Zirconia.—This salt has an astringent taste. It does not crystallize. It is very soluble in water and alcohol.

The other salts of zirconia are mostly white insoluble powders, very little known, and apparently possessing very little interest. With respect to the general properties of zirconia and its compounds, it may be remarked, that the alkalies and alkaline earth separate this earth from its combinations with acids. The salts of zirconia have an astringent, harsh, disagreeable taste, similar to some of the metallic salts. They are most of them insoluble in water. Those which are soluble yield white precipitates when sulphuric acid, carbonate of ammonia, oxalate of ammonia, tartrate of potash, and infusion of nut-galls, are dropped into their solutions. These properties sufficiently distinguish this earth from *alumina* and *yttria*. For further particulars respecting this earth, see the articles above referred to.

ZIRCONITE. See ZIRCON.

ZIRCONIUM, the metallic basis of zirconia. See ZIRCONIA *supra*.

ZIRJANKA, in *Geography*, a small river of Russia, which runs into the Enisei, near its mouth.—Also, a town of Russia, on the Niznei Tunguska. N. lat. 16° 16'. E. long. 106° 54'.

ZIRICZEE, a town of Holland, one of the most ancient in Zealand, and capital of Schouwen, built and surrounded with walls in the year 859, by a person named Ziringus, from whom it is called. It was the ancient residence of the comtes of Zealand, and was at that time a place of much more consequence than it is at present, the port being filled with sand. The inhabitants carry on a considerable trade in grain, salt, and fish: the town is large and populous, and has several good buildings; the church, called the "Munster," dedicated to St. Levisus, is a handsome structure. N. lat. 51° 40'. E. long. 30° 48'.

ZIRKNA, a river of Syria, which runs into the Mediterranean, 8 miles S. of Tortura.

ZIRKNITZ. See CIRKNITZ.

ZIRKWITZ, a town of Silesia, in the province of Oels; 14 miles N. of Breslaw.

ZIRL, or CIRL, a town of the county of Tyrol, on the Inn; 7 miles W. of Innspruck.

ZIRNOE, a town of Russia, in the government of Saratov; 32 miles S.W. of Saratov.

ZIRO, Lo, a town of Naples, in Calabria Citra; 9 miles E. of Umbriatico.

ZIROVAIA, a small river of Russia, which runs into the Penzinkaia gulf, 32 miles S.W. of Oklanfk.

ZIRUA, a small island in the Mediterranean, near the coast of Tunis. N. lat. 33° 39'. E. long. 11° 39'.

ZIRWITZ, a town of Silesia, in the principality of Oels; 3 miles E. of Trebnitz.

ZIRZING, a town of Austria; 6 miles E. of Steyregg.

ZIS, a river of Africa, which rises in the Atlas, passes by Sugulmeffa, and loses itself in the sands, in the country of Tahilet.—Also, a mountain of Africa, between Sugulmeffa and Fez; 40 miles S.S.E. of Fez.

ZISEL, in *Zoology*, a name given by Buffon to the earless marmott, or *mus civellus* of Linnaeus. See CITELLUS.

ZISKA, JOHN, in *Biography*, a distinguished leader among the Hussites, who was the son of a Bohemian gentleman, named "De Trocznou," and celebrated for military valour in his youth. Ziska, denoting "one-eyed," was an appellation, which he bore in consequence of having lost an eye in a combat, on occasion of the perfidious execution of John

Hufs and Jerome of Prague, at the council of Constance. Their followers took up arms, and invited Ziska to be their commander. In 1519 he accepted the invitation; and having assembled a body of peasants, he soon disciplined them so as to be equal to veteran troops. From a fortress which he constructed on an elevated situation, and called Thabor, the Hussites derived the name of Thaborites. At the siege of Rabi he lost his other eye; but though totally blind, he executed his office as commander with great vigour and success. At Auffs on the Elbe he gained a complete victory over the Catholics, and left 9000 of them on the field, retaliating the severities which they inflicted on the Reformers, by demolishing their churches, committing their priests to the flames, massacring those who were prisoners, and laying waste their country, and thus rendering his name formidable. Having made himself master of the new town of Prague, it was invested by the emperor Sigismund and other princes: but Sigismund, being defeated with great slaughter by the Thaborites, was obliged to retreat into Moravia, while Ziska laid siege to Wisrhade. When the emperor with a fresh accession of forces renewed the attack, he lost his whole army, and the town surrendered to Ziska. He also dispersed an army of crusaders commanded by an archbishop; and in 1422 he again routed the army of Sigismund. In the mean time the Hussites renounced their allegiance to Sigismund, and chose for themselves a king; but this measure was disapproved by Ziska and the Thaborites, because they were inclined to a republican government; and the new king was compelled to abdicate his crown. Such were the reputation and importance which Ziska acquired, that Sigismund proposed to him terms of accommodation; but in his journey to hold a conference with the emperor, he was seized with the plague, which terminated his life in 1524. Although the story of his having ordered his flesh to be given to the birds and beasts, and his skin to cover a drum, for the purpose of founding dismay to his enemies and courage to his friends, be fabulous, it is certain that the Bohemians regarded his memory with superstitious veneration. Un. Hist. Gilpin. Gen. Biog.

ZISPATA, in *Geography*, a bay of the Spanish Main, on the coast of South America; 80 miles S. of Carthagena.

ZISTERSDORF, a town of Austria, with a citadel. In the year 1704, this town was miserably laid waste by the Hungarian rebels; 20 miles N.E. of Vienna. N. lat. 48° 28'. E. long. 16° 43'.

ZITARA, a town of South America, in New Grenada, and capital of a district, to which it gives name, in the province of Chocoes; 120 miles S.W. of Santa Fé de Antiquia. N. lat. 6°. W. long. 76° 30'.

ZITHA, or SITHA, in *Ancient Geography*, a town of Asia, in Mesopotamia, on the bank of the Euphrates. Ptolemy.

ZITTAU, in *Geography*, a river of Germany, which runs into the Saal, 4 miles S.S.E. of Bernburg.—Also, a town of Lusatia, on the river Neisse. This town is considered as one of the best in Lusatia, and fortified in the ancient manner; it contains two churches within the walls, and three without, with three hospitals and an orphan-house; 17 miles S. of Gorlitz. N. lat. 50° 49'. E. long. 14° 56'.

ZITWA, a river of Lithuania, which runs into the Niemen, 20 miles S.E. of Lida, in the palatinate of Wilna.

ZIVAGEE, or ARCHACHERA, a town of Hindoostan, in Concan, on the Pirate coast; 30 miles S. of Severndroog.

ZIUF, a town of Africa, in the kingdom of Tunis.

ZIVOLO, in *Ornithology*, a name by which some authors have

have called the smaller species of yellow-hammer, from its conitant note, which is only *zi, zi*.

It is of the size of the common sparrow; its beak is thick and short; its breast and belly yellowish, spotted with brown; and its head, back, wings, and tail, of a dusky-brown, but two of the tail-feathers on each side have a variegation of white.

The difference between the male and female in this species is, that the male is yellow, and has some yellow spots on its neck and sides, which are wanting in the female. It is almost always seen on the ground, and feeds on seeds, &c. It seems but little if at all essentially to differ from the common yellow-hammer; and Mr. Ray has some suspicion that they are the same species.

ZIWICA, in *Geography*, a town of Austrian Poland; 35 miles S.W. of Cracow.

ZIZA, in *Ancient Geography*, a town in the interior of Arabia Petraea. Ptol.

ZIZANIA, in *Botany*, an ancient name, *Ζίζανος* of the Greeks, synonymous with the *infelix lolium* of the Latins, as well as with our Darnel, and belonging to an unprofitable weed, of the tribe of Grasses, which greatly injured the crop of corn, and into which Corn itself was supposed to degenerate. (See LOLIUM.) Our translators of the New Testament call it Tares! *Αίρα* was another Greek name for Darnel, and is still used for *Lolium temulentum* in the Morea. *Zizania* was merely adopted, as an unoccupied classical name, by Gronovius and Linnæus, for the present genus, which yields an inferior sort of grain, used by the inhabitants of some parts of North America. We cannot applaud this application of ancient names, to plants to which they could not possibly have originally belonged, though Linnæus often practised it. Gærtner has successfully opposed this principle, but did not always change things for the better.—Linn. Gen. 491. Schreb. 639. Willd. Sp. Pl. v. 4. 394. Mart. Mill. Dict. v. 4. Pursh 60. Ait. Hort. Kew. v. 5. 278. Juss. 33. Poir. in Lamarck Dict. v. 8. 863. Lamarck Illustr. t. 768. Gærtner. t. 82. (Elymus; Mitchell in Ephem. Nat. Cur. v. 8. append. 210.)—Class and order, *Monocœcia Hexandria*. Nat. Ord. *Gramina*, Linn. Juss.

Gen. Ch. Male, *Cal.* none. *Cor.* Glume of two lanceolate, membranous, ribbed, clasping valves, one rather larger than the other, and most pointed. Nectary of two ovate obtuse scales. *Stam.* Filaments six, capillary, very short, equal; anthers pendulous, linear, notched at each end, shorter than the corolla.

Female in the same panicle, larger, *Cal.* none. *Cor.* Glume of two valves, closed, except a vacancy at each side just above the base; the outer valve largest, concave, long, straight, rigid, revolute at the edges, embracing the inner at each side, and terminating in a long straight awn; the inner narrower, lanceolate, involute at the edges. Nectary of two acute scales. *Stam.* sometimes present, though minute and imperfect, with small incomplete anthers. *Pist.* Germen superior, oblong; styles two, spreading, capillary, short; stigmas feathery, projecting between the valves of the corolla. *Seed* solitary, oblong, even, polished, naked, unconnected with the glumes.

Eff. Ch. Male, Calyx none. Corolla of two valves; the outer one pointed.

Female, Calyx none. Corolla of two unequal closed valves; the outermost largest, revolute at the edges, with a terminal awn. Styles two, divaricated. Seed solitary, enclosed in the plaited corolla, but unconnected with it.

1. *Z. aquatica*. Canadian Wild-Rice. Linn. Sp. Pl. 1408, excluding the synonym of Sloane. Ait. n. 1. Pursh VOL. XXXIX.

n. 1. Lambert Tr. of Linn. Soc. v. 7. 264. t. 13. (*Z. clavulofa*; Michaux Boreal.-Amer. v. 1. 75. Willd. n. 3. *Z. palustris*; Linn. Mant. 295. Willd. n. 4. Schreb. Gram. v. 2. 54. t. 29.)—Panicle pyramidal, compound, with numerous male flowers, in the lower part; spiked and female above.—Common in all the waters, from Canada to Florida, flowering in July and August, and known by the name of *Tyfcarora*, or Wild Rice. *Pursh*. Sir Joseph Banks introduced it into this country in 1790, and still cultivates it abundantly in the ponds of his delightful villa of Spring Grove. The seeds were obtained from Canada in jars of water. Mr. Lambert is of opinion, that this grain might be cultivated in many shallow lakes of Ireland, and turn to considerable advantage. The root is certainly annual; not, as Mr. Pursh marks it, perennial; and consists of numerous, long, stout, hairy fibres. *Stems* several, two or three feet high, round, jointed, hollow, leafy. *Leaves* grassy, long, narrow, smooth, with long, close, striated, smooth sheaths. *Stipula* short, somewhat pointed, membranous, decurrent, entire. *Panicle* two feet, or more, in length, erect, and terminating in a compound, close, straight, spiked cluster, of numerous female flowers; the lower part consisting of still more numerous, drooping male ones, of a smaller size, with green or purplish glumes, and yellow anthers, composing an elegant spreading assemblage, of compound branches. We have from Mr. Frazer a mutilated specimen, of what Michaux and Willdenow call *clavulofa*, a name well expressing the appearance of the female flower-stalks, after the flowers are gone; being larger than in the common specimens. Other writers consider this is not even a variety of the plant in question, and we submit to their opinion. Linnæus, who cultivated the *Z. aquatica* at Upsal, confounded with it originally a Jamaica species, which he afterwards distinguished. But he by inadvertence, in his *Mantissa* above quoted, applies the name of *palustris* to his original *aquatica*, and cites Browne's Jamaica, who has two *Zizania*, neither of which appears to be this North American grass. We shall attempt to set this matter right under the next species.

2. *Z. effusa*. Jamaica Wild-Rice. (*Z. aquatica*; Linn. Syst. Veg. ed. 13. 714. ed. 14. 855. Willd. n. 1. *Z. n. 1*; Browne Jam. 340. *Arundo alta gracilis, foliis e viridi cæruleis, locustis minoribus*; Sloane Jam. v. 1. 110. t. 67.)—Panicle loose, much branched. Male and female flowers interperfed.—Common in all the waters, or lagoons, of Jamaica. Sloane calls it the Trumpet reed. The stems are as thick as the little finger, and appear to be several feet high. *Leaves* longer and broader than in the foregoing, with a strong mid-rib. *Panicle* large, with numerous, whorled, repeatedly compound branches, whose ultimate divisions are quite capillary, and very smooth. We have seen but a few damaged flowers. This is unquestionably a very distinct species from the last, though it does not appear that Linnæus ever described it as such. He did not, in fact, distinguish between the names of *aquatica* and *palustris*, but used one at one time, and another at a different period, for the same plant, to which he misapplied Browne's synonym. This has caused great confusion, to remedy which we are obliged to choose a new name, which has some meaning attached to it.

3. *Z. miliacea*. Millet-seeded Wild-Rice. Michaux Boreal.-Amer. v. 1. 74. Willd. n. 2. Pursh n. 2, excluding the references to Willdenow and Sloane.—“Panicle loose, much branched. Male and female flowers interperfed. Glumes with short awns. Seed ovate, smooth.”—In meadows and ditches overflowed by the tide, in Pennsylvania and Carolina, perennial, flowering in August. *Pursh*. The stem

is described as ratlier thick. *Panicle* long and large, much branched. Permanent *corolla* tumid, and, as well as the *seed*, somewhat ovate, with very short awns. We have seen no specimen of this species, but the ovate tumid *glumes*, with the similar form of the *seed*, which gave occasion to the specific name, appear to constitute a very clear distinction between this and both the preceding, nor is the figure of Sloane, which we have referred to our *essaya*, by any means reconcilable to the present plant.

4. *Z. stuitans*. Floating Wild-Rice. Michaux Boreal-Amer. v. 1. 75. Willd. n. 5. Pursh n. 3.—“Spikes foliary, axillary, about four-flowered; the upper ones male. Glumes beardless.”—On the banks of lakes Champlain and St. Laurence; perennial, flowering in July. Of humble stature, with slender, branched, floating *stems*. *Leaves* floating, linear, flat. *Spikes* bristle-shaped; the lower ones female. All the *glumes* are destitute of awns. Michaux, *Pursh*.

5. *Z. terrestris*. Land Wild-Rice. Linn. Sp. Pl. 1408. Willd. n. 5. (Katou-Tsolam; Rheede Hort. Malab. v. 12. t. 60. Raii Hist. Pl. v. 3. 617.)—*Panicle* nearly simple.—Native of sandy ground, on the coast of Malabar. *Stems* round, leafy, jointed. *Leaves* long and narrow, green, rigid, sharply pointed. *Flower-stalks* slender, from the sheaths of the leaves. *Glumes* leafy, bearing round, blackish, glassy buds, (we presume *seeds*). These bruised with the juice of Betle-nut, and applied to the tongue, are supposed to cure the thrush to which children are subject. Ray. We have seen no specimen. Linnæus described this species from the *Hortus Malabaricus* alone, and we presume its genus may, at least, be doubtful.

ZIZDRA, in *Geography*, a town of Russia, in the government of Kaluga; 60 miles S.W. of Kaluga. N. lat. 53° 43'. E. long. 34° 54'.

ZIZERIA, a word used by Apicius, and some other authors, to express the intestines of fowls of the gallinaceous kind, often used in decoctions for glysters, &c.

ZIZERS, or ZITZERS, in *Geography*, a town of the Grisons, in the Cadée league; 6 miles N. of Coire.

ZIZEVON, a town of Persia, in the province of Farfitan; 23 miles E.S.E. of Schiras.

ZIZIPHORA, in *Botany*, a mongrel name, composed, as it is said, of *Zizi*, an Indian word, and *ῥίζα*, to bear; but what is meant by *Zizi*, we are not informed. Morison appears to have received from Aleppo one of the species of this genus, under the name of *Ziziforum*, and Linnæus, with a slight correction, adopted it.—Linn. Gen. 16. Schreb. 21. Willd. Sp. Pl. v. 1. 123. Vahl Enum. v. 1. 216. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 49. Sm. Prodr. Fl. Græc. Sibth. v. 1. 12. Juss. 111. Poir. in Lamarck Dict. v. 8. 865. Lamarck Illust. t. 18. Gært. t. 66.—Class and order, *Diandria Monogynia*. Nat. Ord. *Verticillate*, Linn. *Labiate*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cylindrical, very long, striated, bristly, with five minute marginal teeth, and bearded in the orifice. *Cor.* of one petal, ringent: tube cylindrical, the length of the calyx: limb minute; its upper lip ovate, flat, reflexed, undivided; lower spreading, broadest, in three round equal segments. *Stam.* Filaments two, simple, spreading, about the length of the corolla; anthers oblong, distant. *Pist.* Germen superior, four-cleft; style bristle-shaped, the length of the corolla; stigma cloven, pointed, inflexed. *Peric.* none, except the calyx remaining unchanged, a little gibbous at the base. *Seeds* four, oblong, obtuse, gibbous at one side, angular at the other, very much shorter than the calyx.

Eff. Ch. *Corolla* ringent; its upper lip reflexed, flat, undivided. Calyx thread-shaped. *Seeds* four.

The plants of this genus are slender, generally aromatic herbs, or diminutive shrubs, of humble growth, with the habit of *Thymus*, or *Clinopodium*; but distinguished by their long and slender calyx, as well as almost capillary tube of the corolla, even more than by having only two *stamens*. Their texture is hard and rigid, and they inhabit dry sunny situations. The *leaves* are opposite and undivided. *Flowers*: whorled or capitate, red or purplish. *Root* mostly annual; sometimes perennial, and rather woody.

1. *Z. capitata*. Oval-leaved Ziziphora. Linn. Sp. Pl. 31. Mant. 317. Willd. n. 1. Vahl n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. v. 1. 10. t. 13. (Thymus humilis latifolius; Buxb. Cent. 3. 28. t. 51. f. 1. Clinopodium fistulosum pumilum Ind. Occid. fimo caule floridum; Pluk. Phyt. t. 164. f. 4.)—Flowers fasciculated, terminal. *Leaves* ovate.—Native of Syria, Tauria, and the isle of Cyprus. A hardy annual, flowering in July and August, sometimes kept in botanic gardens. Miller seems to be the first person who raised this plant in England. The *root* is fibrous, branched and zigzag. *Stem* erect, three or four inches high, when cultivated much taller, square, leafy, usually with two opposite spreading branches, besides the central part, clothed all over with fine, short, curved, hoary pubescence. *Leaves* hardly an inch long, entire, hoary, roughish at the edges, furrowed with parallel veins. *Foot-stalks* one-eighth as long as the leaves. *Braçtas* four at the top of each branch, nearly sessile, like the leaves, but larger, more pointed and fringed; somewhat heart-shaped at the base; about the length of the *flowers*, which are numerous in each head. *Calyx* half an inch long, furrowed, bristly, a little wavy, with slender, sharp, purple teeth. *Corolla* with a white, downy, zigzag tube, and pale purplish limb. *Stamens* prominent, about as long as the lower lip, with bluish anthers. We scarcely perceive any aromatic flavour in the dried plant. Plukenet was much misinformed as to this Ziziphora being of West Indian origin.

2. *Z. hispanica*. Spanish Ziziphora. Linn. Syst. Nat. ed. 10. 853. Sp. Pl. 31. Amœn. Acad. v. 4. 263. Willd. n. 2. Vahl n. 2. Ait. n. 2.—Flowers axillary. *Leaves* obovate, pointed, many-ribbed.—Gathered by Læffing in Spain. *Root* annual. The *stem* is three or four inches high, cross-branched and bushy, downy with minute recurved hairs. *Branches* leafy. *Leaves* a quarter or one-third of an inch long, fringed; tapering at the base; marked on both sides with conspicuous glandular dots: the lower ones smaller, and somewhat crenate. *Flowers* two or three together, sessile. *Calyx* tapering upwards, strongly furrowed, hispida, about the length of the leaves. *Corolla* externally downy. Linnæus considered the branches as *spikes* and the leaves as *braçtas*, but we can see no more reason for this than in any of the following species. The *leaves* in the original specimen still retain a powerful smell of Pennyroyal.

3. *Z. spicata*. Spiked Ziziphora. “An. Hist. Nat. Madr. v. 4. 254.” Vahl n. 3.—“Flowers in racemose spikes, imbricated. *Braçtas* ovate, acute, ribbed. *Leaves* lanceolate, somewhat toothed.”—Native of Spain. Annual. *Stem* from ten to eighteen inches high, throwing out from the base a branch or two as tall as itself. *Leaves* ribbed; the lower ones flaked; the upper sessile. *Flowers* several, on short stalks, standing near together. *Braçtas* broad, entire, acute, fringed. Perhaps a mere variety of *Z. hispanica*. Yet it seems to differ in having the stem leaves lanceolate, narrower than those that accompany the *flowers*, which are ovate, not obovate. Vahl. We have seen no specimen;

specimen; but this description seems to make the inflorescence of the present species really spiked rather than whorled, though it does not alter our opinion as to the last.

4. *Z. tenuior*. Spear-leaved Ziziphora. Linn. Sp. Pl. 31. Willd. n. 3. Vahl n. 4. Ait. n. 3. (Acinos *fyriaca*, folio mucronato, capsulis hirsutis; Morif. v. 3. 404. fect. 11. t. 19. f. 3; also *A. fyriaca*, tenuiore folio, capsulis hirsutis; *ibid.* f. 4.)—Flowers axillary. Leaves ovato-lanceolate, taper-pointed, acute, entire.—Native of Syria. Sent to Morifon from Aleppo, by the Rev. Dr. Huntington. We presume, from a remark of Morifon under a plant immediately following, that the two varieties here indicated, as well as perhaps a third, with a smoother calyx, his f. 2, were all sent him in feed, and that he raised the plants. If so the introduction of this species should be dated before the time of Miller. The root is annual. Stem a span high, with many square, downy, leafy branches. Leaves an inch long, nearly sessile, strongly ribbed, downy, dotted, entire, more or less fringed with strong white hairs. Flowers stalked, mostly in pairs, altogether axillary. Calyx about half the length of the leaves, hoary with fine recurved pubescence, more or less intermixed with long, prominent, bristly hairs; its lower part swelling much, as the seeds ripen. Corolla pale, hairy externally, with a dilated throat.

5. *Z. acinoides*. Basil-leaved Ziziphora. Linn. Sp. Pl. 31. Willd. n. 4. Vahl n. 5. Ait. n. 4. (Climopodium supinum incanum; Amm. Ruth. 51.)—Flowers axillary. Calyx hairy. Leaves ovate, stalked, somewhat ferrated.—Native of Siberia. Introduced into England by the late Dr. William Pitscain, in 1786. Mr. Aiton marks it as perennial. The stems are diffuse, branched, bluntly quadrangular, finely downy. Leaves scarcely aromatic, though dotted with pellucid spots, many-ribbed, rough-edged, and somewhat fringed, from half to three-quarters of an inch long, on footstalks about half or a third as much. Flowers all axillary, three, four, or more, together; on downy stalks, half the length of the footstalks. Calyx cylindrical, strongly ribbed, not downy, but beset with numerous, prominent, horizontal hairs. Corolla hairy, its limb larger than in the first and second species, scarcely so long as the third, of a light purple, or lilac, especially the lip. Anthers large, ovate, purple.

6. *Z. taurica*. Narrow-leaved Ziziphora. Bieberst. Taur.-Cauc. v. 1. 18.—Flowers axillary. Leaves linear-lanceolate, striated, obtuse, entire.—Native of mount Caucasus and its neighbourhood, among lime-stone rocks, or about the stony banks of torrents, flowering in June and July. We received specimens of this, and all the following species, from the Chevalier de Steven. The root is annual, long, tapering and zigzag. Stems one or more, scarcely divided, except at the bottom, ascending, near a span long, not composed of opposite branches crossing each other, as in *Z. tenuior*, to which the author of the Flora Taurico-Caucasica considers this plant very nearly allied. Without adverting to the greater size of the corolla, which is very likely to vary, and to the pubescence of the calyx, which certainly does, the leaves appear to be much narrower and more obtuse; not acute or spinous-pointed. The whole herb smells strongly, but pleasantly, of Penny-royal, and its leaves are dotted as in the *tenuior*. One of our specimens has broader leaves than the other, and rather shakes our opinion of its being a distinct species.

7. *Z. serpyllacea*. Thyme-headed Ziziphora. Bieberst. Taur.-Cauc. v. 1. 18. (Serpyllum orientale, folio pulegii vulgaris; Tourn. Cor. 13.)

β. Bieberst. *ibid.* (Serpyllum orientale, folio pulegii cervini; Tourn. Cor. 13. Herb. Tourn.)

Clusters terminal, capitate, somewhat leafy. Leaves lanceolate, naked, even, obtuse. Stems rather shrubby, ascending.—Native of the grassy hills of Caucasus, flowering from June to August. β of open fields in Georgia, about Teflis; communicated by the Chevalier de Steven. The stems are rather woody, their branches hoary, with fine, recurved, dense hairs. Leaves smooth, with copious pellucid dots, and the flavour of Penny-royal. They have a mid-rib, but no lateral ribs, veins, or furrows. Flowers stalked, crowded at the summit of each branch into a close tuft, some of the lowermost being axillary. Flower-stalks round, clothed with finest possible hoary pubescence, as are also the strong ribs of the calyx, whose teeth are fringed with long white hairs. Limb of the corolla rather large, and stamens prominent. The variety β, which is all we have seen, is said to differ only in having narrower, perfectly entire, leaves, which are also more crowded than in α. If there be any affinity between the two varieties, neither of them can possibly be the *Z. serpyllacea* of Curt. Mag. t. 906. See the following species.

8. *Z. dasycantha*. Hairy-headed Ziziphora. Bieberst. Taur.-Cauc. v. 1. 18. (Z. serpyllacea; Sims in Curt. Mag. t. 906. Ait. n. 5. Z. Poufchkinii; Sims in Curt. Mag. t. 1093. Ait. n. 6.)—Clusters terminal, capitate, somewhat leafy. Calyx densely hairy. Leaves ovate, obtuse, notched. Stems procumbent.—Native of mountainous parts of Georgia, towards Caucasus, flowering from July to September. Introduced into this country by Mr. Lodiges. The root is perennial, and rather woody, as is the lower part of the spreading, nearly prostrate, hairy, purplish stems. Leaves stalked, about a quarter of an inch long, roundish-ovate, ribbed and veiny, distantly ferrated, dotted, roughish with short hairs, especially the ribs beneath. Flowers numerous, crowded into very dense oval heads. Calyx in our specimens quite concealed by very long, dense, spreading, hoary hairs, much more remarkable than in any other known species. Limb of the corolla rather large. Stamens more or less prominent, though variable in length, with large anthers. The colour of the flowers may very well vary between the two extremes represented in the Botanical Magazine. The smell of the herb may also be variable. We cannot but think the original opinion of our judicious friend Dr. Sims far preferable to that which induced him to separate the above two plants. Let it should be wrong however, it is proper to announce that our specimen of *Z. dasycantha*, from the Chevalier de Steven, has little or no scent, and agrees best with *Z. Poufchkinii*. The Flora Taurico-Caucasica speaks of a variety, found in the elevated fields of Georgia, in which the leaves are rather narrower, and the hairs of the calyx shorter, as well as fewer. The author esteems this to be closely related to *Z. hispanica*, see n. 2, of which perhaps he had not examined an authentic specimen. No two species of this genus, or any other, can be more distinct, than the Linnæan *bispanica*, and the plant of which we are treating.

ZIZIPHUS, perhaps *Zizipha* of Pliny, though reckoned by him among the kinds of apples; certainly *Ziziphus* of Columella; as well as of Caspar Bauhin and others of the earlier modern botanists; ζίζυφου of the modern Greeks. Shaw, in his *Specimen Phytographia Africanae*, n. 631, traces this word to the African or Moorish name of the same fruit *Ajajfa*; but its Arabic appellation, *Zizouf*, comes much nearer.—Juss. Gen. 380. Tourn. t. 403. Lamarck Dict. v. 3. 316. Illustr. t. 185. Pursh 188.

ZIZIPHUS.

Gzertn. t. 43. (Z. excluding PALIURUS, see that article; Willd. Sp. Pl. v. 1. 1102. Sm. Prodr. Fl. Græc. Sibth. v. 1. 159. Ait. Hort. Kew. v. 2. 18. Rhamni species; Linn. Gen. 105. Schreb. 142.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Dumosa*, Linn. *Rhamnii*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, nearly flat, in five fpreading, ovate, equal, coloured, deciduous fegments. *Cor.* Petals five, minute, obovate, between the fegments of the calyx, but much fhorter, oppofite to the ftamens, fpreading horizontally. *Stam.* Filaments five, fhort, lying over the petals, and not half fo long; anthers roundifh, of two lobes. *Pift.* Germen fuperior, orbicular, depreffed; ftyle one, very fhort; ftigmas two or three, obtufe. *Peric.* Drupa oval, or roundifh, pulpy, of one cell. *Seed.* Nut folitary, the fhape of the drupa, of one or two cells, with folitary kernels.

Efl. Ch. Calyx flatfifh, in five deep fegments. Petals five, oppofite to the ftamens. Drupa fuperior. Nut of one or two cells.

Obf. We have already (fee RHAMNUS and PALIURUS) declared our determination of feparating all thefe genera, though, like Willdenow and fome others, the writer of this has united *Ziziphus* and *Paliurus*, in the *Prodromus Fl. Græc.*; an error which will be corrected in the *Flora Græca* itfelf. With refpect to fome of the fpecies, we can only rely on thofe who have defcribed the fruit, on which the diftinction chiefly depends. They are all fhrubby, and for the moft part thorny, with alternate, fimple, undivided, deciduous, ftrongly ribbed leaves, and fmall, axillary, tufted, fometimes racemofe and partly terminal, flowers, of a yellow or greenifh colour, and inconfpicuous appearance; their calyx more flat, for the moft part, than that of *Rhamnus*. The fruit is in moft instances eatable, or medicinal. In a few instances, the petals are wanting.

SECT. 1. *Thorns or prickles none.*

1. *Z. lineata.* Veiny Jujube. Willd. n. 1. (Rhamnus lineatus; Linn. Sp. Pl. 281. Amcen. Acad. v. 4. 308. Osbeck It. 219. t. 7. Engl. ed. v. 1. 353. t. 7.)—Stem erect, unarmed. Leaves roundifh-ovate, obtufe, wavy. Clusters terminal; their lower flowers axillary.—Gathered by Osbeck, on the French ifland, in the river of Canton, flowering in September. A bufhy fhrub, often as tall as a man, with copious, alternate, round, leafy, finely downy branches. Leaves alternate, on fhort ftalks, of a roundifh, abrupt, often emarginate, figure, half an inch long at moft, fmooth on both fides; dark green above; paler and yellowifh beneath, with very elegant, oblique, parallel, red veins. Flowers about the ends of the branches, ftalked, partly axillary, partly collected into terminal fmooth clusters. Calyx a little concave, or bell-fhaped, at the bafe; its fegments lanceolate, as are likewife the petals. Anthers black before they burft. Drupa fmall, oval, feated on the orbicular permanent bafe of the calyx.

2. *Z. volubilis.* Twining Jujube. Willd. n. 2. Ait. n. 1. Purf. n. 1. (Rhamnus volubilis; Linn. Suppl. 152.) Walt. Carol. 101. Jacq. Coll. v. 2. 236. Ic. Rar. t. 336.)—Stem twining, unarmed. Leaves ovate, acute, fometimes wavy. Umbels axillary and terminal, ftalked.—In deep fwamps, near the fea-coaft, from Virginia to Carolina, flowering in June. Flowers fmall, greenifh-yellow. Fruit oblong, violet-coloured. It afcends the higheft trees of *Cupreffus difticha*, in the Difmal fwamp, near Suffolk in Virginia, and is known there by the name of Supple-Jack. Purfb. The branches are round and fmooth. Leaves ftalked, drooping, one and a half or two inches long, and

near one broad, acute, and tipped with a fmall point, fmooth, with oblique parallel veins, more numerous than in the laft; their under fide rather the paleft. Flowers fmall, pale. Drupa fmall, blackifh, of a long oval fhape. Nut of two cells in the wild ftate, according to Walter, though Jacquin, in the cultivated plant, found only one. Lamarck, in an obfervation at the end of this genus, though he allows this fpecies to have the proper fruit of *Ziziphus*, gives his reafons for keeping it in *Rhamnus*; thefe are the concave calyx, and the want of a flefhy difk, or, in Linnæan language, “receptacle of the flower.” Probably the fame remarks would apply to the preceding fpecies, which Lamarck alfo excludes from *Ziziphus*. We are ready to allow that they both have more of the habit and foliage of *Rhamnus*, and their fruits are fo fmall, it may be difficult to fay whether they are drupas or berries. Not having had an opportunity of investigating this point ourfelves, we muft rely on thofe who have.

3. *Z. peruviana.* Peruvian Jujube. Lamarck n. 12.—Stem unarmed. Leaves elliptic-obovate, fparingly and minutely toothed, fomewhat angular, rather flefhy, fmooth. Petals acute, longer than the calyx.—Native of Peru. Long cultivated in the public garden at Paris, from whence the younger Linnæus procured a fpecimen, and where Lamarck faw it flowering for many fucceffive years, but without producing fruit, which led him to fuppofe the flowers might be dioecious. The plant itfelf appears now to be no longer in exiftence there, no mention being made of it in profeflor Desfontaine’s Tableau de l’Ecole de Botanique au Jardin du Roi, ed. 2. printed in 1815. This is an evergreen, branching, loofely fpreading fhrub, about three feet high, fmooth in every part. Branches a little zigzag, nearly round. Leaves fcattered, ftalked, from an inch to an inch and a half long, generally obovate, blunt, or fometimes pointed, thick and fomewhat flefhy, of a glaucous green, with a mid-rib, and a few fcattered veins, none of which feem to be vifible but in a dried ftate, and then but flightly. The margin is irregularly angular, each angle tipped with a glandular tooth. Our fpecimen has no flowers. Lamarck fays they are fmall, axillary, two or three together, or folitary, ftalked, yellowifh-white, widely expanded, five-cleft. Petals oval, pointed, flat, larger than the calyx.

4. *Z. emarginata.* Notched Jujube. Swartz Ind. Occ. 1954.—Stem erect, unarmed. Leaves roundifh-ovate, emarginate. Umbels axillary, ftalked. Petals none.—Gathered by Mr. Fahlberg, in the Weft Indian ifland of St. Bartholomew. The ftem is fhrubby, with round, erect, rigid branches, whole bark is grey and fmooth; their extremities angular. Leaves ftalked, alternate, but approaching each other in pairs, fo as to become nearly oppofite, rather membranous, very fmooth on both fides, an inch or an inch and a half long, entire, the extremity only being flightly emarginate. Footftalks fhort. Umbels oppofite. Stalks the length of the footftalks, thickened as the fruit advances. Partial ones from three to fix, rather longer, fingle-flowered. Calyx concave, with a fpreading limb, in five acute fegments, divided as it were into two cavities. Petals none. Filaments very fhort, inferted below the divifions of the calyx. Anthers ovate, embraced at each fide by the hollows in the fegments of the calyx. Stigmas two, obtufe. Drupa roundifh-ovate, fmooth, the fize of Allfpice, crowned with the permanent ftyle. Nut of two cells, with folitary kernels. Swartz.

SECT. 2. *Branches prickly.*

5. *Z. Lotus.* Lotus Jujube. Willd. n. 4. Lamarck n. 2. Ait. n. 3. (Z. fylveftris; Tourn. Inf. 627. Shaw Afric.

ZIZIPHUS.

Afric. n. 632. f. 632. *Rhamnus Lotus*; Linn. Sp. Pl. 281. "Desfont. in Act. Paris, for 1788. 446. t. 21. Mungo Park's Travels, 99, with a plate."—Prickles in pairs; one of them hooked. Leaves elliptic-oblong, lightly crenate, three-ribbed, smooth on both sides.—Native of Africa, especially of the kingdom of Tunis, "in a tract called *Jereed*, which was formerly the country of the *Lotophagi*. The Arabs know this plant by the name of *Seedra*. It has the habit of a *Rhamnus*, and the flowers of the Common Jujube. But the fruit is smaller, rounder, and sweeter; the size of Sloes, with a large lobe. This fruit is borne on every part of the branches, like Gooseberries; whereas that of the Common Jujube grows only on the slender annual shoots, thrown out from the ends of the branches. The *Z. vulgaris* is 20 feet, or more, in height, with a large furrowed stem, twisted branches, knotty at the extremities, and larger oblong leaves; but the *Lotus* is scarcely three or four cubits high, with numerous shoots from the same root, which are smoother, straighter, and paler, or whitish; the leaves small, round, and more rigid. The fruit is ripe, and fit for eating, in December and January." Such is Dr. Shaw's very intelligent account; to which we may add, that the prickles grow in pairs, both of them very straight, slender, and sharp, when young, but in process of time one becomes thick and hooked, the other much elongated, remaining quite straight. The leaves are at most an inch long, perfectly smooth, naked; and green, on both sides; their three ribs sometimes separate, sometimes more or less combined.

6. *Z. Napeca*. Smooth Indian Jujube. Willd. n. 5. Lamarck n. 11. (*Rhamnus Napeca*; Linn. Sp. Pl. 282. Rh. n. 87; Linn. Fl. Zeyl. 36. *Jujuba indica spinosa*, folio et fructu longioribus; Pluk. Almag. 199. *Prunus zeylanica spinosa*, &c.; Pluk. Phyt. t. 216. f. 6. *Vidara littorea*; Rumph. Amboin. v. 2. 119. t. 37.)—Prickles generally in pairs, hooked. Corymbs axillary, many-flowered. Leaves ovate, acute, finely serrated, smooth on both sides. Fruit elliptical.—Native of Ceylon, Amboyna, and other islands of the East Indies. We know this only by the specimen in the Linnæan herbarium, which does not quite agree with the description in the *Flora Zeylanica*, the leaves being neither oblique, unequal, nor bluntish, but exactly as represented by Plukenet and Rumphius. The branches are somewhat zigzag, round, or a little angular, with a smooth whitish bark; rough with mealy down when young, like the flower-buds, stalks, and young leaves. Prickles stout, recurved, dark brown. Leaves an inch, or an inch and a half long, elliptic-ovate, acute, tipped with a small glandular point, finely and bluntly serrated, strongly three-ribbed; paler and yellowish beneath. Footstalks quarter of an inch long, a little downy. Flowers very numerous, in dense, compound, downy or mealy, corymbose clusters, on short axillary stalks. *Drupa* like an olive, elliptical, or somewhat ovate; its flavour acid and astringent. Rumphius says, this fruit is seldom eaten but with salt, or as a sauce to fish or other food, for the purpose of exciting an appetite. Lamarck unites this species, or at least its synonyms, with the *Rhamnus Spina-Christi* of Linnæus, of which we shall speak hereafter; see n. 15.

7. *Z. Jujuba*. White-leaved Indian Jujube. Willd. n. 6. Lamarck n. 6. Ait. n. 4. (*Rhamnus Jujuba*; Linn. Sp. Pl. 282. Rh. n. 89; Linn. Fl. Zeyl. 36. *Manifanas*; Sonnerat Nouv. Guin. 134. t. 94. *Malum indicum*; Rumph. Amboin. v. 2. 117. t. 36. *Perintoddali*; Rheede Hort. Malab. v. 4. 85. t. 41.)—Prickles solitary, deflexed. Corymbs axillary, many-flowered.—Leaves roundish-ovate, obtuse; downy and snow-white

beneath.—Native of the East Indies. A flowe plant in England, flowering in April and May. When wild, it makes a tree of a moderate size. The branches, flower-buds, stalks, and backs of the leaves, are all white with fine, dense, entangled, rather itarry, pubescence. Form and size of the leaves much like the last, but rather rounder and more blunt; the margin crenate, or bluntly serrated; upper side very smooth, of a fine green. Inflorescence like the last. Flowers white; sometimes six-cleft and hexandrous. Style divided. *Drupa* globular, or somewhat heart-shaped. Nut rugged, with two green kernels. Sonnerat reckons this fruit among the best that are the produce of New Guinea. Rheede speaks of it as "agreeably acid," and more olive-shaped than in Sonnerat's figure. Cultivation perhaps may account for these differences. Hence we presume *Z. mauritiana*, Lamarck n. 7, may be but a variety of this.

8. *Z. Xylopyrus*. Wooden-fruited Indian Jujube. Willd. n. 7.—"Prickles solitary, recurved. Leaves ovate, rather acute, somewhat heart-shaped; downy beneath. Flowers corymbose."—Native of desert places, at the bottoms of hills in the East Indies. A tree, scarcely taller than a man. Branches hoary. Leaves broadly-ovate, often in some degree heart-shaped, not frequently oblique; unequally serrated; dark coloured above; clothed beneath with very fine white down. Prickles few, small, solitary under each footstalk. Flowers in axillary stalked corymbs. Calyx downy. *Drupa* dry, insipid, slightly astringent, larger than a cherry. Nut rugged. Retzius, Willd. Possibly this may be *Z. rugosa*; Lamarck n. 8, for which that author cites *Frutex bijugarius spinosus*, &c.; Pluk. Phyt. t. 29. f. 7.

9. *Z. Oenoplia*. Velvet-leaved Jujube. Willd. n. 8. Lamarck n. 5. Mill. Dict. ed. 8. n. 3. (*Rhamnus Oenoplia*; Linn. Sp. Pl. 282. Rh. n. 88; Linn. Fl. Zeyl. 36. *Jujuba aculeata, nervosis foliis, infra fericeis, flavis*; Burm. Zeyl. 131. t. 61.)—Prickles solitary, conical, recurved. Leaves unequally ovate, or half-heart-shaped, acute; silky beneath.—Native of Ceylon. A small tree, with downy branches, and short, thick, hooked prickles. Leaves two inches long, very obscurely serrated; remarkably uneven or oblique at the base, the three ribs also being much nearer one margin than the other; the under side finely silky and yellowish; the upper also silky while young, but in a less degree. Flowers in little dense, silky, axillary tufts.

10. *Z. iguanea*. Lizard Jujube. Lamarck n. 4. (*Rhamnus iguaneus*; Linn. Sp. Pl. 282. Jacq. Amer. 74. *Jujuba americana spinosa, loti arboris foliis et facie, fructu rotundo parvo dulci*; Commel. Hort. v. t. 141. t. 73.)—Prickles in pairs, unequal, divaricated. Leaves ovate, pointed, serrated, smooth on both sides. Clusters axillary, monoecious. Petals wanting. Fruit roundish.—Native of the West Indies, as well as of the neighbouring continent, in bushy, rocky, or stony places, where the *Laetaria Iguanea*, reported to be fond of this fruit, is likewise frequently to be met with. This is an inelegant trailing shrub, with round, zigzag, scarcely downy, branches. Leaves thin, pliant, three-ribbed, very smooth, two or three inches long, sometimes more, Jacquin says eight inches, though rarely, in which case they are more elliptical. The prickles are long and slender, in pairs under each footstalk; one of them always straight; the shortest sometimes curved, but not remarkably. Flowers small, yellow, according to Jacquin destitute of petals. *Drupa* roundish or ovate, yellow, twice the size of a pea, with a sweet pulp, and a rugged nut, of one cell. Willdenow seems to have omitted this species entirely.

11. *Z. sinensis*. Chinese Jujube. Lamarck n. 3. Defont. Tabl. 231.—“Young branches prickly, downy; old ones unarmed. Leaves ovate-oblong, sharply ferrated. Petals reflexed under the calyx.”—Cultivated in the public garden at Paris, and said to be a native of China. As this point is uncertain, how much better might the name of *cryptopetalis* have been chosen! Lamarck describes the present species as a *shrub*, only three or four feet high, losing its slender, unequal, bristle-like prickles as the branches advance in age. Leaves of a very pale green, crowded, three-ribbed, rather smaller than those of *Z. vulgaris* hereafter described; we presume they are quite smooth. *Footstalks* short and downy. *Flowers* small, whitish, axillary, solitary or in pairs, remarkable for having their *petals* so completely reflexed, and concealed by the *calyx*, as not to be visible when we regard the flower vertically. Lamarck.

12. *Z. rotundifolia*. Round-leaved Jujube. Lamarck n. 9. (Jujuba, five *Ziziphus*, zeylanica rotundifolia crenata minor, foliis subtus lanuginosis; Pluk. Phyt. t. 197. f. 2. Burm. Zeyl. 132.)—“Prickles in pairs; one of them recurved. Leaves roundish-oval; downy beneath.”—Native of Ceylon. Leaves small, perhaps hardly an inch long, rather more rounded than in Plukenet’s figure, slightly toothed; smooth above; cottony beneath; on very short *footstalks*. Branches slender, cylindrical. Prickles small. An Indian specimen in the Linnean herbarium, attached to *Z. Napaea*, to which it certainly is very little related, agrees in many points with this description of Lamarck, except that the very small prickles are solitary, nor are the *footstalks* very short. We know not to what other species of *Ziziphus* to refer this specimen. It is marked *Ber*, and said to afford gum lac, which is collected from it by winged insects.

13. *Z. angulata*. Angular-branched Jujube. Lamarck n. 10.—“Prickles in pairs, straight. Leaves roundish-oval, somewhat toothed, smooth on both sides. Branches acutely angular.”—Described from the herbarium of Jussieu, without fructification. The angular branches strikingly distinguish this species from all the rest. They are woolly, smooth, zigzag, square, with prominent acute angles. Leaves three-ribbed, an inch and a half broad, on short *footstalks*. Lamarck. Nothing is recorded of the native country of this plant.

14. *Z. vulgaris*. Common Jujube. Willd. n. 9. Lamarck n. 1. Ait. n. 5. Sm. Fl. Græc. Sibth. t. 241. (Z.; Dod. Pempt. 807. *Zizypha*; Camer. Epit. 167. *Rhamnus Zizyphus*; Linn. Sp. Pl. 282. Pall. Ross. v. 1. part 2. 24. t. 59. C. L. Willdich Obf. 5. Jujube Arabum, five *Ziziphus* Dodonæi; Ger. Em. 1501.)—Prickles in pairs, unequal. Leaves ovate, abrupt, bluntly ferrated, smooth. Flowers in axillary tufts. Fruit elliptical.—Native of the south of Europe. Gathered by Dr. Sibthorp about Megara, and on mount Parnassus. It has been cultivated in England ever since Parkinson’s days, but requires the shelter of a green-house, and though it may sometimes blossom, never bears fruit. Pliny says the Jujube-tree was brought, in his time, from Syria into Italy. When wild it attains the size of a small tree, with round, smooth, glaucous branches, zigzag and leafy when young. The prickles make no appearance on the young leafy shoots, but the following year they become strong thorns, one of them an inch long, the other much shorter, and sometimes, not always, recurved, as Willich well observes. Leaves rather crowded, deciduous, on short stalks, ovate, somewhat tapering into a broad blunt point, frequently emarginate; their edges copiously though bluntly ferrated; both surfaces smooth; the under paler, strongly three-ribbed; their length an inch

and a quarter or an inch and a half. Flowers yellowish, on short stalks, in little axillary tufts, not much longer than the *footstalks*. Petals obtuse, half the length of the *calyx*. Stigmas two or three. *Drupa* the size and shape of an olive, blood-red, sweet, mucilaginous, esteemed good in forenses or inflammation of the mouth and throat, but are out of use in our present practice. If Pallas’s plate above quoted be the true *Z. vulgaris*, of which we cannot help feeling some doubt, a comparison of that plate with the old wooden cut of Camerarius, may serve to shew how superior the artists of those earlier times were to some of our modern delineators and colourers.

15. *Z. Spina Christi*. Christ’s-thorn Jujube. Willd. n. 10. (*Z. africana*; Mill. Dict. ed. 8. n. 4. *Rhamnus Spina Christi*; Linn. Sp. Pl. 282. *Oenoplia pinifolia*; Cluf. Hist. v. 2. 313. Nabca, Palurus Athenæi credita; Alpin. Ægypt. 16. t. 19. Jujube five *Zizyphus africana*, mucronatis foliis, pinia gemella; Pluk. Almagn. 199. Phyt. t. 197. f. 3.)—Prickles in pairs, straight. *Corymbs* axillary, stalked, many-flowered. Leaves ovate, finely crenate, smooth on both sides. Fruit globose.—Native of Ethiopia and Palestine. Seeds collected near Jerusalem, by Hasselquist, produced the plant described by Linnaeus, a wild specimen of which, sent also by Hasselquist, is preserved in the Linnean herbarium. Miller also raised this species from Syrian seeds, so that it is entitled to a place in Hort. Kew. Respecting Plukenet’s synonym, we feel no doubt. The cut of Alpinus as much resembles *Z. Napaea*, n. 6, in the foliage, but the globose fruit agrees best with the species before us. The prickles are hardly visible on our specimen, which is a young luxuriant leafy branch, in flower. They perhaps acquire their full proportion on older branches, as in *Z. vulgaris*, n. 14. The leaves are scattered, of a broad-ovate, somewhat roundish, obtuse figure, two and a half or three inches long, and two wide, strongly three-ribbed, with transverse veins, minutely and slightly crenate rather than serrated, very smooth and even on both sides; paler beneath. *Footstalks* scarcely an inch long; downy on their upper side. *Corymbs* forked, downy, many-flowered, each on a solitary axillary stalk, shorter than the *footstalk*. Bractæas awl-shaped. In our only expanded flower, the segments of the *calyx*, as well as the *petals* and *stamens*, are strongly reflexed, quite under the base of the *calyx*. The *drupa* is said to be the size and shape of a Sloe.

ZIZITH, in the Jewish Customs, a name given by the Jews to the tufts or fringes they used anciently to wear at the four quarters of their upper garments, but which they now only wear under their clothes, fixed to a square piece of cloth, which represents the garment they anciently wore in their own country before their dispersion. The zizith of the modern Jews is a tuft made of eight threads of yarn, spun on purpose for this use, each having five knots, which take up half the length. That which is not knotted, being furled out, makes a kind of tuft or fringe. Numb. xv. 38. Deuter. xxii. 12. Leo of Modena, Cerem. of the Jews, part i. chap. 5. Calmet. Dict. Bibl. in voc.

ZIZYPHA, in Botany. See ZIZYPHUS.

ZLABINGS, in Geography, a town of Moravia, in the circle of Iglau; 28 miles W. of Znaym.

ZLATOUSTOVSKOI, a town of Russia, in the government of Upha; 60 miles W. of Tcheljabinsk.

ZLEBY, a town of Bohemia, in the circle of Czasslau; 4 miles S.E. of Czasslau.

ZLIN, a town of Moravia, in the circle of Hradisch; 15 miles N.N.E. of Hradisch.

ZLOTI, a money of account in Poland, where accounts are kept in zloti, guldens, or florins of 30 groschen or grosz,

grofz, and each grofchen is divided into 18 pfenings. The florin also contains $2\frac{1}{2}$ fchilling, 90 fchillings, or 270 pfenings. A fchilling is worth 12 grofchen, or 36 fchillings; a grofchen, 3 fchillings; and a fchilling, 3 pfenings.

ZMEINOGORSKAIA, in *Geography*, a fort of Ruffia, on the river Porobalika; 200 miles S. of Kolivan. N. lat. $51^{\circ} 10'$. E. long. $82^{\circ} 10'$.

ZMILACES, in *Natural Hiftory*, a name given by Pliny to a ftone found in the river Euphrates, refembling marble, and of a blueifh-green colour.

ZMILAMPIS, the name of a gem, defcribed by Pliny and the ancients, which they tell us was very like the Proconneftian marble, except that in the centre of the ftone there was always a blueifh fpot, refembling the pupil of an eye.

The Proconneftian marble of the ancients was of a fine clear and elegant white, variegated with irregular black veins. Pliny's defcription is fo fhort, that it has been fuppofed from him that the zmilampis was a fort of marble; he only fays of it, that it was like the Proconneftian marble, but blue in the middle. Many had inferred from this, that he meant no more by it than that this was a ftone, which had blue veins inftead of the black ones in the Proconneftian kind. But when we examine the reft of the ancients, and find that it was a fmall ftone, found in the river Euphrates, and worn in rings, and that its blue fpot was like a pupil of an eye, we may eafily determine that it was one of thofe gems which we call *oculus belli*, or *belloccio*; of which there is a vaft variety found in the rivers of the Eaft Indies, and many have a fine opaque white ground, and a blueifh or greenifh fpot for the pupil.

ZMILANTHES, a name given by Solinus and fome others to a gem called by the more correct writers *zmilampis*.

ZNAMENSKOI, in *Geography*, a town of Ruffia, in the government of Tobolsk, on the Irtifch; 28 miles N.N.W. of Tara.

ZNAYM, a town of Moravia, in the circle of the fame name, near the river Teya. This town was built about the year 1222, at a little diftance from another town, laid wafte by the Bohemians. It contains a citadel, four cloifters, and a college; the circle borders on Auftria; 68 miles S.W. of Olmutz. N. lat. $48^{\circ} 48'$. E. long. $15^{\circ} 51'$.

ZNENDEL, a river of Ruffia, which runs into the Vitim. N. lat. 53° . E. long. $115^{\circ} 14'$.

ZNIN, a town of the duchy of Warfaw; 20 miles N. of Gnefna.

ZNONIGRAD, a town of Croatia; 36 miles S. of Bihaas.

ZOAGLI, a town of Genoa; 20 miles E. of Genoa.

ZOANA, in *Antient Geography*, a town of Afa, in the Leffer Armenia, upon the route from Satala to Arabiffus, between Tonofa and Gundufa. Anton. Itin.

ZOANNES, a name given by Strabo to a people half-favage, that inhabited the mountains of the Colchide.

ZOAR, ZOARA, *Segor*, or *Bela*, a city of Pentapolis, on the fouthern extremity of the Dead fea. It was preferved by deftruction from fire by means of the interceffion of Lot. (Gen. xiv. 2.) Its name before this circumftance was Bela; but when Lot requested it to be fpared as a place of refuge for himfelf, he represented it as a *fmail* place; and hence it had the name *Zoar*, or *Segor*, which, in Hebrew, fignifies fmall or little. The Romans kept a garrifon at Zoar. St. Jerom obferves, that the name Bela was given to this city, becaufe, as foon as Lot left it, an earthquake caufed it to be fwallowed up; *bela* in Hebrew

fignifying to fwallow up. Jerom alfo fays, that the Hebrews think that Zoar bears alfo the name of Shalifa. (1 Sam. ix. 4.) They pretend that this city has been often demolifhed by earthquakes.

ZOAR, in *Geography*, a town of Arabia, in the province of Hedfias, on the fouth coaft of the Dead fea, at the mouth of the Safa; 30 miles N. of Karac.

ZOAR. See TSON.

ZOARA, a town of Africa, in the country of Tripoli; 60 miles W.N.W. of Tripoli.—Alfo, a town of Africa, in the country of Barca; 140 miles S.W. of Tolometa. N. lat. $32^{\circ} 35'$. E. long. $11^{\circ} 56'$.

ZOBAYA, a town of Mexico, in the province of Guatimala; 30 miles N. of Guatimala.

ZOBEIR, a town of the Perfian empire, in the pachalic of Bagdad, about 10 miles W. of the city of Baffora, fituated on the dry canal of the Djurre Zade, fuppofed to be the former bed of the Euphrates. It is by fome faid to be the ancient Bafra, and derives its prefent name from Zobeir, who was defeated and flain in the battle of the Camel, fought near this place.

ZOBELN, a town of the duchy of Courland; 20 miles E. of Goldingen.

ZOBERA, a town of Arabia, in the province of Yemen; 35 miles S.E. of Chamir.

ZOBERN, a town of Saxony, in the Vogtland; 8 miles W. of Oelfnitz.

ZOBIN, a town of Germany, in the principality of Ottingen Wallerftein; 6 miles W.N.W. of Nordlingen.

ZOBING, a town of Saxony, in the margravate of Meiffen; 15 miles S. of Deffau.—Alfo, a town of Auftria; 3 miles N. of Crems.

ZOBLITZ, a town of Saxony, in the circle of Erzgebirg. This place confifts of 110 houfes, and the inhabitants fubfift principally by working the ferpent-ftone, which is found here, into pitchers, bowls, tea and coffee difhes, mortars, cups, &c. The ferpent-ftone is dug juft above the town, and farther on to the eaft of it is found a red fpecies, which is reckoned among the fineft, and for that reafon is alfo confidered by the fovereign as his property, together with a yellow, green, grey, and black fort. In the electoral red quarry is alfo found afbestos of divers colours and granites; 17 miles S. of Freyberg. N. lat. $50^{\circ} 36'$. E. long. $13^{\circ} 11'$.

ZOBOWITZ, a town of Pomerelia; 14 miles S. of Dantzic.

ZOBTEN, a town of Silefia, in the principality of Schweidnitz; 9 miles E.N.E. of Schweidnitz. N. lat. $50^{\circ} 48'$. E. long. $16^{\circ} 41'$.

ZOBTENBERG, a mountain of Silefia, fituated in a country otherwife level, 2424 Paris feet above the level of the fea, near Zobten.

ZOCCO, ZOCCOLO, *Zoole*, or *Soele*, in *Architettura*. See SOCLE.

ZOCELAR, in *Geography*, a town of Croatia; 2 miles S.W. of Bihaas.

ZOCHINACAZTLIS, in *Botany*, a name by which fome authors have called the *flor auricula*, a flower of New Spain, ufed in making of the Spanifh chocolate.

ZODIAC, ZODIACUS, in *Aftromony*, a falcia, or broad circle, whose middle is the ecliptic, and its extremes two circles parallel to it, at fuch diftance from it, as to bound, or comprehend, the excursions of the fun and planets.

The word is formed from the Greek ζῶον, *animal*, by reafon of the conftellations in it, which have the forms of animals given them; others derive it from ζῶν, *life*, from

an opinion, that the planets have a great influence on animal life.

The sun never deviates from the middle of the zodiac; *i. e.* from the ecliptic: the planets all do more or less. Their greatest deviations, called latitudes, are the measure of the breadth of the zodiac; which is broader, or narrower, as the greatest latitude of the planets is made more or less. Accordingly some make it 16, some 18, and some 20 degrees broad.

The zodiac intersecting the equator obliquely makes an angle with it of 23 degrees and a half; or, more precisely, of 23° 29', which is what we call the *obliquity of the zodiac*, and is the sun's greatest declination. See ECLIPTIC.

The zodiac is divided into twelve portions, called *signs*; and those divisions, or signs, are denominated from the constellations which anciently possessed each part. But the zodiac being immoveable, and the stars having a motion from west to east, those constellations now no longer correspond to their proper sign; whence arises what we call the *precession of the equinoxes*.

When a star, therefore, is said to be in such a *sign of the zodiac*, it is not to be understood of that sign, or constellation, of the firmament, but only of that twelfth part of the zodiac, or dodecatemery of it.

Cassini has also observed a tract in the heavens, within whose bounds most of the comets, though not all of them, are

observed to keep, which, for this reason, he calls the *zodiac of the comets*.

This he makes as broad as the other zodiac, and marks it with signs, or constellations, like that; as Antinous, Pegasus, Andromeda, Taurus, Orion, the Lesser Dog, Hydra, the Centaur, Scorpio, and Sagittary.

ZODIAC, Hindoo. The early investigators of Hindoo mythology, which comprehends not only their astronomy, but every science, and almost every art, of which the Hindoos have any knowledge, were surprised to find that the days of the week were named, as with us, after the planets, and in the same order. It was natural enough to suppose that the Hindoo almanac was borrowed from the Arabians. The few Brahmans who at that time had access to Europeans of science, supposed the fame of us, when they discovered the similitude of fable and of name. But it has been made manifest by the investigations of later writers, that the Hindoo zodiac is of very great antiquity. Such of our readers as may be desirous of extended information hereon, are referred to the dissertations of sir William Jones and Mr. Colbrooke; on the Hindoo zodiac, in the 2d and 9th volumes of the Asiatic Researches; and to the Hindoo Pantheon. In both works, plates of the Hindoo zodiac are given from different authorities; and in the latter work separate engravings also of the personified planets. We will extract from it a sort of table, shewing the English and Sanskrit names, and the vehicles assigned to the several planets by the latter fabulists.

Names of Planets, &c.		Days over which they respectively preside.		Vehicles or Seats, according to the Plate of	
English.	Sanskrit.	English.	Sanskrit.	Sir William Jones.	The Hindoo Pantheon.
Sun	Surya	Sunday	Aditvar	Lion	Chariot
Moon	Soma	Monday	Somavar	Antelope	Antelope
Mars	Mangala	Tuesday	Mangalvar	Horse	Ram
Mercury	Boodh	Wednesday	Budhvar	Eagle	Carpet
Jupiter	Vrihaspati	Thursday	Vrihapatvar	Boar	Do.
Venus	Sukra	Friday	Sukervar	Camel	Rat
Saturn	Sani	Saturday	Sanivar	Elephant	Raven
Dragon's Head	Ketu			Frog	Carpet
Dragon's Tail	Rahu			Tortoise	Owl

Under the Sanskrit names of the planets we have given short articles descriptive of their mythological and historical attributes and allusions. To them (SURYA, SOMA, &c.) we therefore refer for farther particulars, and to the article VAHAN for an account of the vehicles assigned to them and other mythological personages of Hindoo fable.

ZODIACAL LIGHT, a brightness resembling that of the milky way, but less bright, and which is sometimes perceived in the heavens, at certain times of the year, after sun-set, or before its rise. Some have supposed, that this phenomenon is the same with that which the ancients called *trabes*, a term by which they denoted a meteor, or impression in the air like a beam. Thus Pliny (lib. ii.) says, "emittant trabes, quos docos vocant." The form of this light resembles that of a pyramid, lying lengthways in the zodiac, within which its point and axis are always enclosed, its base being towards the sun, and placed obliquely with respect to the horizon. In the torrid zone, the zodiacal light is frequently, or almost constantly, seen. At or near our latitude it may be seen about the time of the equinoxes. The best time for seeing it is about the 1st of March, at 7 o'clock in the

evening, when the twilight is ending, and the equinoctial point in the horizon. This phenomenon was first discovered by Descartes, and by Childrey about the year 1659. It did not engage general attention till it was described and named by M. Cassini the elder, in 1683. It was afterwards observed by M. Fatio, in 1684, 1685, and 1686, and by M. Kirch and Eimmart, in 1688, 1689, 1691, 1693, and 1694. See Mairan, Suite des Mem. de l'Acad. Royale des Sciences, 1731, p. 3.

In 1707, April 3, it was observed by Mr. Derham in Essex. It appeared in the western part of the heavens, about a quarter of an hour after sun-set, in the form of a pyramid, perpendicular to the horizon. The base of this pyramid he judged to be the sun. Its vertex reached 15° or 20° above the horizon. It was throughout of a dusky-red colour, and at first appeared pretty vivid and strong, but faintest at the top. It grew fainter by degrees, and vanished about an hour after sun-set. This solar atmosphere has also been seen about the sun in a total solar eclipse, a luminous ring appearing about the moon at the time when the eclipse was total.

M. Fatio conjectured that this appearance arises from a collection of corpuscles encompassing the sun in the form of a lens, reflecting the light of the sun. M. Cassini supposed that it might arise from an infinite number of planets revolving about the sun; so that this light might owe its existence to these bodies, as the milky way does to an innumerable number of fixed stars. It is now, however, generally supposed, that it is matter detached from the sun by its rotation about its axis. The velocity of the equatorial parts of the sun being the greatest would throw the matter to the greatest distance, and on account of the diminution of velocity towards its poles, the height to which the matter would there rise would be diminished; and as it would probably spread a little sideways, it would form an atmosphere about the sun something in the form of a lens, whose section perpendicular to its axis would coincide with the sun's equator. And this agrees very well with observation. There is, however, a difficulty in thus accounting for this phenomenon. It is very well known that the centrifugal force of a point of the sun's equator is a great many times less than its gravity. It does not appear, therefore, how the sun, from its rotation, can detach any of its gross particles. If they be particles detached from the sun, they must be sent off by some other unknown force; and in that case they might be sent off equally in all directions, which would not agree with the observed figure. The cause is probably owing to the sun's rotation, although not immediately to the centrifugal force arising therefrom.

The zodiacal light, according to M. de Mairan's ingenious and plausible hypothesis, is nothing but the solar atmosphere, a rare and subtle fluid, either luminous by itself, or made so by the rays of the sun surrounding its globe; but in a greater quantity, and more extensively about its equator than any other part. As it always accompanies the sun, it is natural to ascribe it to a solar atmosphere, extending beyond the orbit of Mercury, and sometimes even beyond that of Venus. Accordingly, the zodiacal light has been supposed to be a section of this atmosphere, which, being extremely flat at its poles, cannot be conceived to partake of the sun's monthly motion. Dr. T. Young (Lectures, vol. i. p. 502.) observes, that the only probable manner in which it can be supposed to retain its figure, is by means of a revolution much more rapid than that of the sun's motion. To that purpose, M. de la Lande remarks, that it seems now to be generally believed, that the zodiacal light is the atmosphere of the sun; for it always accompanies that luminary; and the equator of the sun is in the direction of this light: consequently he says, that in all probability the zodiacal light is an atmosphere situated round the sun, in the direction of its equator, and flattened by its rotatory motion. Astron. Paris, 1771. § 845 to 849.

The zodiacal light is more or less visible according to circumstances; but the solar atmosphere is not always visible by means of this light, though it be always seen about the globe of the sun in total eclipses.

One of the most essential circumstances for the perception of the solar atmosphere by the zodiacal light is its having sufficient length on the zodiac; for without this its brightness is entirely hid from us by the twilight.

M. de Mairan says, it may be proved from many observations, that the sun's atmosphere sometimes reaches as far as the earth's orbit, and there meeting with our atmosphere produces the appearance of an aurora borealis.

The length of the zodiacal light varies sometimes in reality, and sometimes in appearance only, from various causes.

The oblique position of this light, little different from

that of the plane of the ecliptic, does not permit us to see it distinctly, and sufficiently elevated above the horizon; but some time after sun-set, towards the end of the winter, and in spring, or before sun-rising in autumn, and towards the beginning of winter. Several causes hinder our seeing it, any more than the milky way; such as moon-light and strong twilights, among others.

M. Cassini often mentions the great resemblance of the zodiacal light to the tails of comets. M. Fatio has made the same observation; and M. Euler has lately endeavoured to prove them owing to similar causes. *Decouverte de la Lumiere Celeste que paroît dans le Zodiaque, art. 41.* Lettre à M. Cassini, printed at Amsterdam, 1686. Euler, in *Mem. de l'Acad. de Berlin*, tom. ii.

The figure of this solar atmosphere must be lenticular, or that of a flattened spheroid. M. de Mairan gives us a draught of its appearance and projection.

The extent of the zodiacal light from the sun to its point is seldom less than 45, sometimes 150 degrees in length; M. Pingré being on the torrid zone saw it 120 degrees; and its breadth varies from 8 to 30 degrees.

This light seems to have no other motion than that of the sun itself.

M. Euler observes, that if the sun has an atmosphere, the force of the impulse of light issuing from that globe must drive particles of that atmosphere before it; but as gravity is very strong at the sun, this impulse would never drive those particles beyond the limits of their atmosphere, were it not for the centrifugal force arising from the sun's motion round its axis. This being opposite to the action of gravity, diminishing its effects, the impulse of the light may considerably dilate the figure of the solar atmosphere, from what it would be if it arose from the gravity and centrifugal force of its particles only: and this dilatation will be very considerable near the sun's equator, and very small towards its poles. The action of light thus diminishing the action of gravity, M. Euler attempts to calculate how far this diminution of gravity may increase the extent of the sun's atmosphere about its equator. He finds a cubic equation, the roots of which express the semi-axis, or greatest amplitude of this atmosphere. He adds, that this equation having three real roots, it is possible that the solar atmosphere may become a ring surrounding the sun's globe, as the ring of Saturn surrounds the body of that planet. As the electric fluid is now generally acknowledged to be the cause of the aurora borealis, which M. de Mairan ascribes to the solar atmosphere, which produces the zodiacal light, and which is thrown off principally and to the greatest distance from the equatorial parts of the sun, in consequence of his rotation on his axis, and extending visibly, in the form of a luminous pyramid, as far as the orbit of the earth, falls into the upper regions of our atmosphere, and is collected chiefly towards the polar parts of the earth, in consequence of the diurnal revolution, where it forms the aurora borealis: it is no improbable conjecture, that the sun may be the fountain of the electric fluid, and that the zodiacal light, and the tails of comets, as well as the aurora borealis, lightning, and artificial electricity, are its various and not very dissimilar modifications. See *Theory of ELECTRICITY*.

ZODZISZKI, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 52 miles E. of Wilna.

ZOEGEA, in *Botany*, was so named by Linnæus, in honour of his pupil and correspondent Dr. John Zoega, who visited Iceland, and communicated from thence, as well as from the neighbouring ocean, many new or rare plants, especially of the cryptogamic tribes, to the great Swedish naturalist. Dr. Zoega wrote a *Flora Islandica*, which has

C c been

been several times printed, with Olafsen's, and von Troil's, accounts of that country. In the latter book this *Flora* is a mere catalogue of Linnæan names, the fynonyms and descriptions being omitted. He wrote also a mineralogical work on Zeolites. The plant which bears his name was raised in the Copenhagen garden, from Siberian seeds, and communicated by himself to Linnæus.—Linn. Mant. 15. Schreb. Gen. 577. Willd. Sp. Pl. v. 3. 2276. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 143. Juff. 174. Poiret in Lamarck Dict. v. 8. 868. Gært. v. 2. 452.—Clafs and order, *Syngenesia Polygamia-fruſtranea*. Nat. Ord. *Compositæ capitata*, Linn. *Cinarocephalæ*, Juff.

Gen. Ch. Common *Calyx* ovate, imbricated, of numerous lanceolate, fringed scales; the inner ones linear-lanceolate, chaffy, longest. *Cor.* compound, radiant. Florets of the disk numerous, perfect, of one petal, with a slender tube, and a limb in five deep, lanceolate, erect segments: those of the radius fewer, neuter, of one flat, ligulate, abrupt, sharply five-toothed petal. *Stam.* in the florets of the disk, Filaments five, short; anthers united into a cylindrical tube. *Pist.* in the same florets, Germen short; style capillary, very long, erect; stigma short, cloben: in the radiant florets, Germen a rudiment only, without style or stigma. *Peric.* no other than the unaltered closed calyx. *Seeds* in the florets of the disk, solitary. Down bristly. In the radius none. *Recept.* bristly.

Eff. Ch. Receptacle bristly. Seed-down of simple bristles. Florets of the radius ligulate. Calyx imbricated.

Obf. Linnæus justly observes that this genus is very intimately related to *CENTAUREA* (see that article). Indeed the only difference consists in the flat, or ligulate, not tubular, florets of the radius. How far that distinction is sufficient, some persons have doubted; especially as the presence of the radiant florets themselves in *Centaurea*, has been thought but a casual occurrence, equivalent to double flowers in other natural orders. As long, however, as the *Syngenesia* family continues to be characterized at all by the different figure of the florets, *Zoegea* must remain separate from *Centaurea*.

1. *Z. Leptaurea*. Yellow *Zoegea*. Linn. Mant. 117. Suppl. 383. Willd. n. 1. Ait. n. 1. L'Herit. Stirp. Nov. 57. t. 29. (*Z. alleppica*; Jacq. Col. v. 1. 89. Ic. Rar. t. 177.)—Native of Siberia, according to a manuscript correction of Linnæus in his own Mantissa: other authors say, of the Levant. It appears to have been cultivated in Mr. Blackburne's celebrated garden at Orford, Lancashire, before the year 1779, when the catalogue of that rich collection was printed. This plant is a hardy annual, flowering in July and August. The stem is much branched, spreading in every direction, leafy, angular and roughish, twelve or eighteen inches high. Leaves alternate, distant, roughish, entire; the lower ones pinnatifid; the rest undivided, obtuse, tapering down into a footstalk. Flowers solitary, on long terminal stalks, large, near two inches broad. Scales of the calyx delicately fringed with tawny bristles. Corolla of a shining golden yellow.

Another species is described in the *Supplement* by Linnæus himself, under the name of *Z. capensis*. This is *Relbania pedunculata* of L'Heritier. See Willd. Sp. Pl. v. 3. 2136, and is the same thing as *Athanasia pumila*, Linn. Suppl. 362.

ZOFALA, in *Geography*. See SOFALA.

ZOFFANY, JOHAN, in *Biography*, was born at Frankfurt, about the year 1735. He came to England as a painter of small portraits when he was about 30 years of age. After passing some time with very little encouragement, he

at length was fortunate enough to attract public attention by a portrait of the earl of Barrymore, and thenceforward enjoyed considerable favour and encouragement. The most considerable of his productions at this period were portraits of the most celebrated dramatic performers in their favourite characters; as Garrick, in Abel Druggier, sir John Brute, and lord Chalkstone, &c.; Foote, in major Sturgeon; and Jacob, as Jacob Gallop; Foote and Welton, as Dr. Laft and the President, in the Devil on Two Sticks; Parsons, Moody, Branſby, Aicken, and many others, whose likenesses he preserved most admirably, with all the variety of expression required for the characters they personified. One picture he painted of the members of the Royal Academy, in the hall of the Academy devoted to the study of the living figure, round which they here assembled, and it received universal applause.

He had the honour to be employed by his majesty, and painted portraits of the royal family; and he was engaged by the queen to paint for her a view of the Tribune of the Gallery at Florence. He was somewhat of a humourist, and it is said of him, that whilst he was engaged painting in the Florentine Gallery, the emperor of Germany visited the grand duke, and coming up to Zoffany in the Gallery, was much pleased with his performance, and asked him his name; and on hearing it, inquired what countryman he was; when he answered, an Englishman. Why, said the emperor, your name is German. True, returned the painter, I was born in Germany, that was accidental; I call that my country where I have been protected!

Soon after his return from Italy, he went to the East Indies, where he was much employed, and acquired a considerable fortune; but it disappeared upon his return home, and was only restored by a second adventure to the same hot-bed of wealth and disease. He again returned to England, but with diminished powers: yet he still continued to paint, and, among other works, produced an elaborate picture of the facking of the wine vaults at the Tuileries, in 1792; a disgusting display of the atrocities of that eventful period. He lived to a very advanced age, but was reduced exceedingly in intellectual powers for some years before his decease, which happened in 1808. He was a member of the Royal Academy.

ZOFFINGEN, in *Geography*, a town of Switzerland, in the canton of Berne, on the Wigger. It was at one time imperial, after which it put itself under the count of Habsburg. In the 13th century it was subject to the house of Austria, from which it was taken by the Bernois, in the year 1415, and is the principal place of a bailiwick, with considerable privileges; 26 miles N.N.E. of Berne.

ZOGNO, a town of Italy, in the department of the Serio; 5 miles N. of Bergamo.

ZOGOCARA, in *Ancient Geography*, a town of Asia, in Greater Armenia. Ptol.

ZOGOR, in *Geography*, a town of Thibet; 16 miles W.S.W. of Zuenaga.

ZOHAUB, one of the districts of the province of the Lower Kurdistan, in the pachalic of Bagdad, which has a separate hakem or governor. See SOLYMANIA.

ZOHAUK, a town of Grand Bucharia; 12 miles N.E. of Bamian.

ZOHRRA, a town of Egypt, on the left bank of the Nile; 5 miles N.N.E. of Miniet Ebn Kafib.

ZOÏKA, a town of Russia, in the government of Archangel, near the mouth of the Petchora; 160 miles N.E. of Mezen.

ZOÏLUS, in *Biography*, a carping critic belonging to the class of grammarians, was a native of Amphipolis, and lived

lived in the time of Ptolemy Philadelphus, about the year B.C. 270. His natural disposition to depreciate eminent characters is said to have been strengthened by the course of his education, as a disciple of Polycrates, who wrote an accusation against Socrates. This disposition, which he was in the habit of indulging, gave occasion to his being denominated the rhetorical dog; rhetorical, as his style was elegant, and dog, from his practice of snarling. Both his person and mind are very unfavourably exhibited by Ælian; who says of him, that being once asked, why he *spoke ill* of all mankind?—he replied, “because I cannot *do ill* to them.” Ambitious of gaining reputation, he endeavoured to acquire it by degrading others; and valued himself by having established a kind of claim to the title of “Homero-matrix,” or the fource of Homer. Suidas informs us, that he wrote nine books of grammatical remarks upon this poet. Plato and Iocrates, as well as Homer, were objects of his critical severity. Zoilus was the author of several works; particularly a history commencing from the theogony, and continued to the death of Philip of Macedon, and a history of his own city. His attack upon Homer seems to have been an unpardonable offence, and threw a shade over every other good quality he possessed; for if we may credit Dionysius of Halicarnassus, he testifies that he was actuated by the love of truth, and he ranks him with Aristotle, and other eminent philologists. But his virtues and talents, whatsoever they were, could neither secure him from poverty whilst he lived, nor guard his memory from reproach. Vitruvius reports, that when he visited Alexandria, he recited his writings against the Iliad and Odyssey of Homer to king Ptolemy, which gave the king such offence, that he would take no notice of him; and afterwards, when urged by indigence, he solicited charitable assistance, Ptolemy repulsed him with this contemptuous reflection; that if Homer, who had been dead 1000 years, could by his works give maintenance to many thousand people, a writer so much his superior might surely maintain himself. It is further said, that the king was so much displeas'd with his conduct, that he treated him as if he had been guilty of parricide; and that he was put to death, as some say, by crucifixion, and as others say by stoning; and according to another account, he was burnt alive at Smyrna. Vitruvius adds, “that whichever of these was his fate, he well deserved the punishment.” The penalty, however, if this statement be true, seems to have been much more than adequate to the offence. Ælian Hist. Var. Voss. Hist. Græc. Gen. Biog.

ZOISITE, in *Mineralogy*, *Epidote*, Häüy, a mineral fossil called by Werner after baron Von Zois of Laybach.

Common Zoisite.—Its colours are yellowish and blueish-grey; it occurs massive and crystallized in very oblique four-sided prisms. The crystals are middle-sized, and deeply streaked longitudinally. The structure is lamellar, and the joints parallel with the axis of the crystal. The internal lustre is splendent; the lustre of the cross fracture is glit-tering, and between pearly and resinous; it is translucent, hard, and easily frangible. The specific gravity is 3.31. According to Klaproth, the constituent parts are,

Silex	-	-	-	42
Alumine	-	-	-	29
Lime	-	-	-	21
Oxyd of iron	-	-	-	3

95

Friable Zoisite is of a reddish-white colour, spotted with

pale peach-blossom red; it occurs massive. The fracture is intermediate, between earthy and splintery; the fragments are very sharp-edged, and translucent on the edges; it is rather hard and brittle. The specific gravity of this mineral is 3.3. According to Klaproth, its constituent parts are,

Silex	-	-	-	44
Alumine	-	-	-	32
Lime	-	-	-	20
Oxyd of iron	-	-	-	2.50
				<hr/>
				98.50

Zoisite was first found in Carinthia, but has since been discovered in various parts of the continent of Europe, and at Glenelg in Invernesshire. It is nearly allied to tremolite, with which it was at first arranged.

ZOITIUM, in *Ancient Geography*, a town of the Peloponnese, in Arcadia; 15 stadia from Tricolons. Steph. Byz.

ZOK, SOKOR, in *Geography*. See **SOKOR Zok**.

ZOKOL, a town of Servia; 16 miles S. of Sabatz.—Alfo, a town of Bosnia; 45 miles E. of Bosnaferai.

ZOL ENGERS. See **ENGERS**.

ZOLCA, in *Ancient Geography*, a town of Asia, in Galatia, which belonged to the Paphlagonians, and was situated on the coast of the Euxine sea. Ptol.

ZOLDO, in *Geography*, a town of Italy, in the Bellunese; 18 miles N.W. of Belluno.

ZOLDORF, a town of Bohemia, in the circle of Bolef-law; 6 miles W.N.W. of Jung Buntzel.

ZOLERI, a town of the county of Tyrol; 8 miles S.S.E. of Trent.

ZOL-HUYS. See **TOL-HUYS**.

ZOLLERN, a castle of Germany, situated on a mountain, in the principality of Hohenzollern, to which it gives name; 10 miles S. of Tubingen.

ZOLLICKOFEN, a town of Switzerland, and principal place of a district, in the canton of Berne; 2 miles N.W. of Berne.

ZOLNOK, a town of Hungary, on the river Theyss; 48 miles W.S.W. of Debriczin.

ZOLOGEV, a town of Russia, in the government of Charcov; 24 miles N.N.W. of Charcov. N. lat. 50° 20'. E. long. 35° 44'.

ZOLOFITZA, a town of Russia, in the government of Archangel, on the east coast of the White sea; 60 miles N. of Archangel.

ZOLOTONOSCHA, a town of Russia, in the government of Kiev; 72 miles S.S.E. of Kiev. N. lat. 49° 30'. E. long. 31° 58'.—Alfo, a river of Russia, which runs into the Dniuper, near Zolotonofcha, in the government of Kiev.

ZOLOTTA, or **SZELOTTA**, a silver coin of Turkey, containing 30 paras, the para being = 3 aspers.

ZOMBA, in *Geography*, a town of Africa, in the kingdom of Congo; 70 miles E. of St. Salvador.

ZOMBAR, a town of Hungary; 40 miles S. of Colocsa. N. lat. 45° 56'. E. long. 19° 12'.

ZOMERAW, a town of Prussia, in Oberland; 12 miles N.E. of Bischofswerder.

ZOMUCHANA, in *Ancient Geography*, a town of Asia, in Aria. Ptol.

ZONA, or *Zona Uxoris Regie*, a very fertile country of Persia. It was so called because its revenue was destined for the accommodation of the queen. Plato.

ZONA, a word used by some authors for that species

of herpes, which others call the *zinzilla*, and we term the *shingles*.

ZONCHIO, in *Geography*, a cape of European Turkey, on the coast of the Morea; 12 miles N.N.W. of Navarin. N. lat. $37^{\circ} 12'$. E. long. $21^{\circ} 30'$.

ZONCHO, a sea-port town of European Turkey, in the Morea: the harbour is large, but not commodious; 8 miles N. of Navarin.

ZONCOLUCAN, a mountain of Mexico, in the province of Guaxaca.

ZONDAGS, a river of Africa, which runs into the Indian sea. N. lat. $31^{\circ} 20'$. E. long. 29° .

ZONDORO, a town of Hungary; 26 miles S.W. of Cafchau.

ZONE, **ZONA**, ζων, q. d. *belt, girdle*, in *Geography* and *Astronomy*, a division of the terraqueous globe, with respect to the different degrees of heat found in the different parts of it; formed by the two tropics and two polar circles, which divide the surface of the earth into five parts.

The zones are denominated *torrid, frigid, and temperate*.

ZONE, Torrid, is a fascia, or band, surrounding the terraqueous globe, and terminated by the two tropics.

Its breadth, therefore, is $46^{\circ} 56'$. The equator running through the middle of it, divides it into two equal parts, each containing $23^{\circ} 28'$.

The ancients imagined the torrid zone uninhabitable.

ZONES, Temperate, are two fasciæ, or bands, environing the globe, and contained between the tropics and the polar circles. The breadth of each is $43^{\circ} 4'$.

ZONES, Frigid, are segments of the surface of the earth, terminated, the one by the antarctic, and the other by the arctic circle; or included between these circles and the poles. The breadth of each is $46^{\circ} 56'$.

The difference of zones is attended with a great diversity of phenomena.

1. In the torrid zone, the sun passes through the zenith twice a year; and his receds from the equator towards the pole, which is above the horizon, is twice a year equal to the height of the pole.

2. In the temperate and frigid zones, the least height of the pole exceeds the greatest distance of the sun from the equator; and therefore, to the inhabitants of it, the sun never passes through the zenith; yet if, on the same day, the sun rises, at the same time, to a greater height, the height of the pole is the less, since the inclination of the circles of diurnal revolution to the horizon is less.

3. In the temperate and torrid zones, the sun rises and sets every natural day, because the distance of the sun from the pole always exceeds the height of the pole; yet every where but under the equator, the artificial days are unequal, and the inequality is the greater as the place is less distant from the frigid zone.

4. Where the temperate zones terminate on the frigid, the height of the pole is equal to the sun's distance from the pole, when in the neighbouring tropic; and consequently, once a year, the sun, in its diurnal motion, performs an entire revolution, without going down under the horizon.

5. Every where, in a frigid zone, the height of the pole is greater than the least distance of the sun from the pole; and therefore, during some revolutions of the earth, the sun is at a distance from the pole less than the pole's height; and, during all that time, does not set, nor so much as touch the horizon. Where the distance from the pole, as the sun recedes from it, exceeds the height

of the pole, or latitude of the place, the sun rises or sets every natural day.

ZONE, Cingulum, or girdle, part of the ecclesiastical drefs of the Roman Catholic ministers. The use of it being derived from the church of Rome, it was called *zona Romana*.

ZONE, Ciliary, in *Anatomy*, the black impression of the ciliary processes on the vitreous humour. See **EYE**.

ZONE, Greater and Smaller, of the Iris, arterial circles produced by the anastomoses of the arteries. See **EYE**.

ZONGHAN, in *Geography*, a town of Cochinchina, near the sea. N. lat. $14^{\circ} 30'$. E. long. $108^{\circ} 48'$.

ZONGO, or **MORENA**, a river of Africa, which runs into the Atlantic, near Old Benguela.

ZONITES, in the *Materia Medica of the Ancients*, a name given to a kind of tutty, called also *placitis*. It had the latter name from the Greek πλάκος, a crust, it being formed by way of crust on the sides of the furnaces. The latter name *zonites* was given from its being formed of several coats, which, when broken transversely, had the appearance of belts or zones. See **TSAPHARI**, and **TUMEX**.

ZONITIS CADMIA, a name given by some authors to a kind of *cadmia fornacum*, from its usually surrounding the upper parts of the furnaces like a girdle or belt.

ZONITIS, in *Entomology*, a genus of the *coleoptera* order of insects, the characters of which are, that the antennæ are setaceous; the palpi four and filiform, and shorter than the whole jaw; and the lip emarginated. There are two species; viz.

CHRYSOMELANA. Yellow, the wing-sheaths having a point in the middle, and the apex black; found in Egypt and the East.

FLAVA. Reddish, with wing-sheaths yellow, and black at the apex.

ZONNAR, a kind of belt, or girdle, of black leather, which the Christians and Jews of the Levant, particularly those of Asia, and the territories of the grand signior, are obliged to wear, to distinguish themselves from the Mahometans.

The word is corrupted from the vulgar Greek; a contraction of ζωνάριος, or ζωνή, *girdle*.

It was Motavakkel X. kaliph, of the family of the Abafides, that first enjoined the Christians, &c. to wear the zonnar.

The ordinance to this effect was published in the year of the Hegira 235.

Hence, as most of the Christians of Syria, Mesopotamia, &c. are either Nestorians or Jacobites, those sectaries are often called *Christians of the girdle*.

ZONOSBIO, in *Geography*, an Indian town, belonging to the Seneca tribe; 2 miles N. of lake Seneca.

ZONS, a town of France, in the department of the Roer, situated on the Rhine, with a castle: at this place a river-toll is paid; 13 miles N.N.W. of Cologn. N. lat. $51^{\circ} 4'$. E. long. $6^{\circ} 43'$.

ZOOGRAPHY, formed of ζων, *animal*, and γραφειν, *I describe*, denotes a description of animals.

ZOOLATRIA, Ζωολατρία, composed of ζων, *an animal*, and λατρία, *worship*, a species of idolatry, in which divine worship was offered to animals.

ZOOLOGIA, **ZOOLOGY**, Ζωολογια, compounded of ζων, *life*, or ζων, *animal*, and λογος, *speech, discourse*, a discourse or treatise upon animals, or living creatures.

Zoology makes a considerable article in natural history, comprehending what relates to the form, structure, method of living, feeding, propagating, &c. of the divers species

ZORAH, in *Geography*, a town of Africa, on the coast of Barca. N. lat. $30^{\circ} 45'$. E. long. $18^{\circ} 30'$.

ZORAMBUS, in *Ancient Geography*, a river of Asia, in Carmania. Ptol.

ZORBIG, or LITTLE ZERBST, in *Geography*, a town of Saxony, in the circle of Leipzig, with a citadel; 15 miles S. of Delfau. N. lat. $51^{\circ} 40'$. E. long. $12^{\circ} 18'$.

ZORECZA, a town of Lithuania; 80 miles E.S.E. of Pinski.

ZORGE, a town of Saxony, belonging to the abbey of Walkenried; 6 miles N.E. of Walkenried.

ZORGE, a river of Thuringia, which runs into the Helm, 5 miles W. of Nordhausen.

ZORIGA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, to the left of the Euphrates, and at some distance from it. Ptol.

ZORILLE, in *Zoology*, a species of weasel, having the back and sides marked with short stripes of black and white, the last tinged with yellow; the tail long and bushy, partly white, and partly black; the legs and belly black. This animal inhabits Peru, and other parts of South America: its pestiferous vapour overcomes even the panther of America, and stupefies that formidable enemy. Pennant. See VIVERRA.

ZORITA, in *Geography*, a town of Spain, in New Castile; 12 miles N.W. of Huete.

ZORLESCA, a town of Italy; 8 miles S.S.E. of Lodi.

ZORN, a river of France, which rises near Saverne, in the department of the Lower Rhine, passes by Brumath, and enters a canal which communicates with the Rhine, 8 miles N. of Straßburg.

ZORNDORF, a town of the New Mark of Brandenburg, where the king of Prussia defeated the Russians in the year 1758, near Custrin.

ZORNIA, in *Botany*, received that name from the late professor Gmelin of Göttingen, the compiler of a very faulty edition, at least as to the botanical department, of the *Systema Nature* of Linnæus. He chose this appellation for one of Walter's anonymous genera, which he himself knew nothing of. It has been adopted by Michaux and Pursh, and seems intended for the commemoration of Mr. John Zorn, an apothecary of Kempten, in Bavaria, who was born in the year 1739, and may possibly be still living. He has published five volumes in octavo of *Icones Plantarum Medicinalium*, each volume containing one hundred plates, with a Latin and German text. These figures are coloured in the Nuremberg stile; at which place the work appeared, between the years 1779 and 1784. There was, moreover, a Dr. Bartholomew Zorn of Berlin, who published there, in 1714, *Botanologia Medica*, a thick German quarto, with six plates. He edited also, in 1673, the *Herbarium portatile* of Thomas Pancorius, and according to Dr. Riand. Bibl. Banks, v. 5. 496, died in 1717, at the age of 78.—Gmel. *Syst. Nat.* v. 2. 1096. Michaux *Boreal-Amer.* v. 2. 76. Pursh 484. Poir. in Lamarck *Dict.* v. 8. 872. (Anonymos n. 279; Walt. Carol. 181.)—Clas and order, *Diadelphica Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, two-lipped; upper lip broad, abrupt, emarginate; lower in three deep segments, the middle one longest. *Cor.* papilionaceous: standard inversely heart-shaped, reflexed, revolute at the sides; wings ovate, erect, smaller than the standard: keel divided at the base, bluntly rectangular, the length of the wings. *Stam.* Filaments in two sets; anthers five of them oblong, five alternate ones globose. *Pist.* Ger-

men ovate; style awl-shaped, horizontal; stigma simple. *Peric.* Legume of several, roundish, compressed, single-seeded joints, hispid with barbed prickles, not bursting. *Seeds* solitary, kidney-shaped.

Ess. Ch. Calyx bell-shaped, two-lipped; the upper lip abrupt. Standard revolute. Keel angular. Five alternate anthers oblong; five globose. Legume of several single-seeded, closed, hispid joints.

Obs. The habit of this genus is so peculiar, and so unlike *HEDYSARUM*, much more resembling *STYLOSANTHES*, (see those articles), that we are very glad of any characters that may serve to keep it distinct, and we hope the above may suffice. The plants are herbaceous, with one or two pair of conjugate leaves, without an odd one. Flowers small, in axillary spikes, with large leafy bractæes. The species have not yet been well discriminated. We shall endeavour to explain them, with the help of original specimens.

1. *Z. angustifolia*. Narrow-leaved Zornia. (*Hedyfarum diphyllum* α ; Linn. Sp. Pl. 1053. Willd. Sp. Pl. v. 3. 1178. Lamarck *Dict.* v. 6. 404, excluding the variety H. n. 291; Linn. Zeyl. 134, excluding Sloane's synonym, and the variety β . H. bifolium, filiculis articulis echinatis; Burm. Zeyl. 114. Onobrychis materafapatana diphyllus minor, filiculis hirsutis; Pluk. Phyt. t. 246. f. 6. "Nelam-mari; Rheede Hort. Malab. v. 9. 161. t. 82." Raii Hist. v. 3. 404.)—Leaflets two, lanceolate, uniform. Bractæes ovate, ribbed, fringed, imperfectly reticulated, shorter than the legume, marked with glandular dots. Prickles of the legume rough.—Native of the East Indies, in a sandy soil. Root annual, tapering, warty. Stems several, diffuse, from four or five inches to a foot long, round, slender, zigzag, smooth, leafy, with short alternate branches. Leaves simply conjugate, alternate; leaflets from half an inch to an inch long, elliptic-lanceolate, entire, bluish, tipped with a small point, unequal at the base, smooth on both sides, not quite sessile at the extremity of the common foot-stalk, which is about the length of the leaflets, cylindrical, smooth, with a longitudinal furrow above. Stipules half-arrow-shaped, ribbed, entire, pointed at each end. Flowers yellow, in axillary, solitary, stalked, lax, bracted spikes, longer than the leaves, each spike of from three to eight alternate flowers. Bractæes one pair to every flower, twice as long, two-ranked, converging, flat, ovate, acute, entire, strongly fringed, three or five-ribbed, besprinkled with resinous dots, elongated at the base into a short oblique spur, permanent, their surface smooth. Legume near an inch in length, longer than the bractæes, of about four semi-orbicular joints, finely reticulated, and beset with spreading, brown, barbed prickles, which are rough with minute reversed hairs, but we cannot perceive that the surface of the legume itself is downy, at least not invariably. The resinous dots scattered over the bractæes seem peculiar to this species. Those parts are full as much fringed in this as in the *H. conjugatum* of Willdenow, though his definitions indicate otherwise.

2. *Z. reticulata*. Reticulated Zornia. (*Hedyfarum diphyllum* β ; Willd. Sp. Pl. v. 3. 1178. β ; Lamarck *Dict.* v. 6. 404. H. diphyllum; Swartz *Obs.* 285. H. n. 10; Browne *Jam.* 301, excluding the synonyms. H. minus diphyllum, flore luteo; Sloane *Jam.* v. 1. 185.)—Leaflets two, lanceolate; the lower ones elliptical. Bractæes ovate, as long as the legume, strongly reticulated and fringed, without glandular dots. Legume and its prickles downy.—Native of the dry sandy parts of the savannahs of Jamaica. Our specimens are from Browne himself. The root, though said to be annual, is somewhat woody. Herb larger than the last, and most unquestionably specifically distinct. The stems are straight, a foot long, scarcely branched. Leaflets an inch

inch or an inch and a quarter in length; those of the lower leaves half an inch broad. *Spikes* many-flowered, thrice as long as the leaves. *Flowers* yellow; the standard sometimes purplish. The *bractæas* afford a clear specific distinction, in their strongly-marked, elevated, veiny reticulations, and the total want of resinous or glandular dots, though their whole surface is minutely granulated, as it were, like those of the foregoing species. The *legumes* have three or four joints, and their surface, as well as their prickles, is downy. They are almost entirely covered by the *bractæas*.

3. *Z. conjugata*. Ovate *Zornia*. (*Hedyfarum conjugatum*; Willd. Sp. Pl. v. 3. 1178. H. *diphyllum* β ; Linn. Sp. Pl. 1053. H. n. 291, β ; Linn. Zeyl. 135. H. *bifolium*, *foliolis ovatis*, *filiculis asperis*, *geminis*, *inarticulatis*; Burm. Zeyl. 114. t. 50. f. 1. *Onobrychis maderafatana* *diphyllus*, *filiculis asperis*; Pluk. Phyt. t. 102. f. 1.)—Leaflets two, ovate, uniform. *Bractæas* ovate, ribbed, fringed, imperfectly reticulated, shorter than the legume, without glandular dots. *Legume* fringed; its disk and prickles smooth.—Native of Ceylon and Tranquebar. This species approaches the last in size, but differs in many essential points. The *leaflets* are ovate, not near so long as their common *footstalk*. *Bractæas* more pointed and elongated at the base, ribbed, but not strongly reticulated; their substance quite destitute of pellucid dots, though some of them occasionally bear little black opaque prominences, which seem the effect of injury, or are perhaps a minute parasitical fungus. *Legumes* considerably longer than the *bractæas*, though each consists of scarcely more than two orbicular joints, full twice the size of either of the preceding species, from which they differ in the smoothness of their disk and prickles, though fringed at the edge. The *flowers* are yellow.

4. *Z. latifolia*. Broad-leaved *Zornia*. (*Hedyfarum diphyllum*; Aubl. Guian. 774, excluding all the synonyms.)—Leaflets two, roundish-ovate; the lower ones orbicular. *Bractæas* linear-lanceolate, ribbed, somewhat hairy, longer than the downy legumes.—Gathered in Guiana by Aublet, from whom we have specimens, which abundantly shew his plant to be different from any of the foregoing, and justify him in saying that, with respect to it at least, Plukenet's figures are bad. This has a woody, but perhaps annual, root, and several prostrate stems, from six inches to a foot long, straight, round, downy. *Footstalks* also downy, rather longer than the *leaflets*, which in the lower leaves are about half an inch in length, nearly orbicular, obtuse; in the upper gradually more elongated, ovate, or ovato-lanceolate, acute; all of them somewhat hairy or silky, especially beneath, where also they are a little glaucous. The narrow *bractæas*, very differently shaped from any of the three preceding species, are the distinguishing characteristic of this: they have three very strong crowded ribs, originating from their point of insertion, below which is a blunt elongation downwards, most like that of *Z. reticulata*; and they are somewhat hairy, as well as slightly fringed. *Corolla* yellow. *Legume* of only two joints, unless any have been broken off, which is not apparent; the prickles downy, and the disk quite woolly. Willdenow speaks of a supposed variety of *Hedyfarum diphyllum* from Portorico, which is larger than the common kind, and whose leaves are "strigose beneath;" by which expression is probably meant bristly, or hairy. This, if not our *Zornia latifolia*, must be a hitherto non-descript species, of which we have not materials to give a definition.

5. *Z. heterophylla*. Various-leaved *Zornia*. (*Hedyfarum tetraphyllum*; Thunb. Aët. Nov. Upsal. v. 6. 44. t. 3.

Prodr. 132. Willd. Sp. Pl. v. 3. 1203. Lamarck Dict. v. 6. 405, variety δ .)—Leaflets three or four, lanceolate. *Stipulas* half-arrowshaped. *Base* of the *bractæas* elongated and acute.—Gathered by Thunberg in the interior part of the country, above the Cape of Good Hope, near Gagebofeh, flowering in November and December. The stem is herbaceous, decumbent, thread-shaped, smooth, a foot or more in length. *Footstalks* rather longer than the *leaflets*, which are three or four together, elliptic-lanceolate, acute, entire, hardly an inch long. *Stipulas* much elongated at the base, acute at each end. *Spikes* axillary, many times longer than the leaves, (at least the lower spikes,) and consisting of ten or twelve flowers, concealed by the ovate three-ribbed *bractæas*, each of which is elongated at the base into an ovate acute appendage, nearly half its own length. *Legume* longer than the *bractæas*, of four joints, fringed by Thunberg to be rough, but in what manner, or degree, is not mentioned: his figure represents them smooth and globose, which is evidently an inaccuracy.

6. *Z. tetraphylla*. Four-leaved *Zornia*. Michaux Boreal-Amer. v. 2. 76. t. 41. Pursh n. 1. (*Z. bractæata*; Gmel. n. 1. *Anonymos bractæata*; Walt. Carol. 181. *Hedyfarum tetraphyllum*; Lamarck Dict. v. 6. 405, α .)—Leaflets four, lanceolate. *Stipulas* ovate. *Base* of the *bractæas* somewhat elongated, obtuse.—Native of sandy fields in Lower Carolina. Perennial, flowering in July and August. About a foot high, much branched. *Flowers* yellow. *Pursh*. We have here ventured to distinguish this from the last-described species, by the characters afforded in the plates cited, without our having ever seen a specimen of either. We are fully aware of the hazard of such a proceeding; but as it is highly probable that a Cape plant will hardly prove, on comparison, the same species as a Carolina one; and the species of this genus very nearly resemble each other, and have been much confounded, we propose the above characters. If the figure of Michaux be exact, as to the *stipulas* and *bractæas*, there can be no doubt on the subject, and it was drawn by no less an artist than Redouté. The *stipulas* are there represented perfectly ovate, without any spur, or elongation, at the base, and not half the usual size in this genus. Those of Thunberg's plate are like the rest of the species. This is the most important difference, though the short and blunt spur of the *bractæas* is very striking also. The *flowers* seem larger in these two last, than in any of the foregoing.

On reviewing the whole genus, we cannot but repeat that the abruptly-compounded leaves afford a most important mark of difference, compared with *Hedyfarum*, nor are the yellow flowers, in this case, entirely unworthy of consideration. There is moreover too close a resemblance between all the species of *Zornia*, as to induce a persuasion of their constituting a very natural genus. The same may be said of *STYLOSANTHES*, to which we have already referred the reader as being next akin to *Zornia*.

Which of the above six species, or rather which of the first four, is entitled to a place in the *Horius Kewensis*, we cannot presume to determine. In v. 4. 340. of that work, Dr. Houttoun is recorded as having sent to Miller, before the year 1733, something which has always passed for *Hedyfarum diphyllum*. This must have come from South America, or the West Indies, and was therefore not *Nelam-mari* of Rheedé, our *Zornia angustifolia*; nor the *conjugata*, a plant of Ceylon. It must have been either the West Indian *reticulata*, or more probably perhaps the South American *latifolia*.

ZOROANDA, HAZOUR, in *Ancient Geography*, a place of

ZOROASTER.

of Asia, on a part of mount Taurus, called Nicephates, where the Tigris opened a subterranean passage, N.W. of Amida.

ZOROASTER, ZERDUSHT, or ZARDUSHT, in *Biography*, an eminent Eastern philosopher, concerning whom, as well as the age in which he lived, learned writers have entertained very different opinions. Some have ascribed this title, the derivation of which is uncertain, to many eminent persons; whilst others have maintained that there was but one Zoroaster, and that he was a Persian. Others have said that there were six celebrated founders of philosophy of this name. Ham, the son of Noah, Moses, Othris, Mithras, and others, both gods and men, have by different writers been asserted to have been the fame with Zoroaster. Many different opinions have been also advanced concerning the time in which he flourished. Aristotle and Pliny fix his date at so remote a period as 6000 years before the death of Plato: Hermippus says, that he lived 5000 years before the Trojan war; but these are idle tales, which should, without doubt, be classed with the report of the Chaldeans, concerning the antiquity of their astronomical observations. According to Laertius, he flourished 600 years before the Trojan war; according to Suidas 500. We shall in the sequel of this article detail the opinions of some of our principal modern writers on this subject. According to Brucker, the most probable hypothesis is, that there was a Zoroaster, a Perso-Median, who flourished about the time of Darius Hytaspes, and that besides him there was another Zoroaster, who lived in a much more remote period among the Babylonians, and taught them astronomy. The Greeks and Arabians are agreed concerning the existence of the Persian Zoroaster; and the ancients unanimously ascribe to a philosopher, whom they call Zoroaster, the origin of the Chaldean astronomy, which is certainly of much earlier date than the time of Hytaspes; so that it seems necessary to suppose a Chaldean Zoroaster distinct from the Persian. Concerning this Zoroaster, however, nothing more is known, than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldean astrology and magic. (See *CHALDEAN Philosophy* and *MAGI*.) All the writings which have been ascribed to the Chaldean Zoroaster are unquestionably spurious. The Persian Zoroaster was probably of Persian extraction, and born in Media. Although much of what has been related concerning this Zoroaster or Zerdusht, and the instruction which he received from the Jews, is fabulous; nevertheless it is not improbable that he might have learned some things from the Israelites who resided in Babylon, that might enable him to correct the doctrine of the Persian magi; but it is not easy to specify particulars. Several miracles are ascribed to Zoroaster, but they are of such a kind as an impostor would not find it very difficult to perform. (See *MAGI*.) To Zerdusht, or the Persian Zoroaster, many writings are ascribed; particularly the *Zend*. (See *ZENDAVESTA*.) Fragments of a work, entitled "The Oracles of Zoroaster," are still extant. Several editions of them under the form of verses have been published, and pains have been taken to explain them. Stanley has subjoined to his "Lives of the Philosophers" a correct translation of them. The philosophers of the Alexandrian school highly venerate them as genuine remains of Chaldean wisdom: but they have so many evidences in their ideas and language of their origin in that school, as to render it probable that they were written by some Platonicist, about the beginning of the second century; a period in which spurious writings were produced in order to support the sinking credit of Gentile philosophy.

The learned Dr. Hyde, and after him Dr. Prideaux and several others, are of opinion, that Zoroaster was the same with the Zerdusht of the Persians, who was a great patriarch of the Magians, and that he lived between the beginning of the reign of Cyrus, and the latter end of that of Darius Hytaspes.

Dr. Warburton (*Legation*, vol. ii. part i. p. 8.) censures Hyde and Prideaux for making an early Bactrian law-giver to be a late Persian false prophet, and says this whole story of him is mere fable, contradicting all learned antiquity, and supported only by the romantic relations of later Persian writers under the caliphs.

Dr. Baumgarten likewise (*Anc. Un. Hist. Suppl.* vol. ii. p. 365, &c.) represents it as doubtful, whether the Persian Zoroaster ever existed, calls in question the credibility of the oriental writers who give his history, and makes the whole to be a forgery in later times by the fire-worshippers of Persia.

The learned Mr. Bryant (*Anal. Anc. Mythol.* vol. ii. p. 107.) observes, that there are more persons than one spoken of under the character of Zoroaster; though there was one principal to whom it more truly related. Of men, styled Zoroaster, he says, the first was a deified personage, revered by some of his posterity, whose worship was called *Magia*, and the professors of it *Magi*. This worship was transmitted from the ancient Babylonians and Chaldeans to the Persians, who, succeeding to the sovereignty of Asia, renewed under their princes, and particularly under Darius, the son of Hytaspes, those rites which had been in a great degree effaced and forgotten. The Persians, says this learned writer, originally derived their name from the deity *Perez*, or *Parez*, the sun; whom they also worshipped under the title of *Zor-Aster*. On occasion of the distresses to which they were reduced upon the death of their last king *Yesdegerd*, they retired into *Gedrosia* and *India*, where people of the same family had for ages resided, and carried with them some flattered memorials of their religion in writing, whence the *Sadder*, *Shaster*, *Vedam*, and *Zendavesta*, were compiled; and upon these the religion of the *Brahmins* and *Persees* is founded. The person who is supposed to have first formed a code of institutes for this people is said to have been one of the *Magi*, named *Zerdusht*; the same, as Hyde and others suppose, both in character and name, with Zoroaster; but Mr. Bryant discovers no resemblance between them. There were, indeed, many persons of this name in different parts of the world, who were magi or priests, and denominated from the rites of Zoroaster, which they followed. We read of an *Assyrian*, *Medo-Persian*, *Proconnesian*, *Bactrian*, *Pamphylian*, *Chinese*, &c. Zoroaster, supposed by Dr. Hyde to have been one and the same. But Mr. Bryant thinks that their respective histories furnish evidence sufficient of their being different persons; and besides, there seems to have been one person more ancient and celebrated than the rest. As for the Zoroaster or Zerdusht of Hyde, he lived in the reign of Darius, the father of Xerxes, about the time of the battle of Marathon, and consequently not a century before the birth of Eudoxus, Xenophon, and Plato. This Zerdusht, who was the renewer of the Sabian rites, could not be the person so much celebrated by the ancients, and referred to the first ages. Xanthus Lydius makes him above 600 years prior to the reign of Darius; Suidas places him 500 years before the war of Troy; Hermodorus Platonicus, Hermippus, and Plutarch, refer him to 5000 years before that era; Eudoxus supposed him to have flourished 6000 years before the death of Plato; and Pliny places him many

many thousand years before Moses. Upon the whole it appears, that no memorial upon record is placed so high as the ancient writers have carried this personage; and though their accounts are for the most part exaggerated, yet they fully ascertain the antiquity of this person.

The title Zoroaster, Mr. Bryant conceives, originally belonged to the sun, and was metaphorically bestowed on sacred and enlightened personages. Some have thought, that the first among men to whom this title was applied was Ham; others have taken him for Chus, for Mizraim, and for Nimrod, and Huetius for Moses. But Mr. Bryant, after examining the primitive characters given of him by different writers, supposes, that they concur only in Noah, who was the first deified mortal, and the prototype in the Magian worship. This writer supposes, that, as the object of the Perfic and Chaldaic worship was the sun, and most of their titles were derived thence, Zoroaster denoted Sol Aferius; Zor being the sun, and Afer signifying star.

The abbé Foucher, in a long series of memoirs, inserted in the 25th, 26th, 27th, 28th, 30th, and 31st vols. of the *Histoire de l'Academie Royale des Inscriptions et Belles Lettres*, &c. Paris, has given an ample account of the religion of the Persians. This learned author maintains, on the authority of Pliny, that the most celebrated Zoroaster was an ancient sage, who lived under Cyaxares, king of the Medes, restored the worship of fire, was revered by the Persians as a celestial prophet, and whose extacies, prodigies, and revelations, made a great noise in the world. See ZENDAVESTA.

ZOROPASSUS, in *Ancient Geography*, a town of Asia, in Lesser Armenia, dependent on the prefecture of Marianne. Ptol.

ZORVI, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 22 miles E. of Ana.

ZOSAWA, a river of Moravia, which runs into the Friaawa, 5 miles W. of Hohenstadt.

ZOSIMA, in *Botany*, an umbelliferous genus, thus called by professor Hoffmann, in compliment to three brothers, Anastatius, Nicholas, and Zoa Zosima, distinguished for their editions of numerous works of the Greek classics. This botanical commemoration seems chiefly owing to the great propensity, ("magna propensio,") of the latter of these brothers, for natural history. We presume not to dispute the claim, because the author of this name is, doubtless, better able to judge of its propriety than we can possibly be.—Hoffm. Umbell. v. 1. 145. t. 1. B. f. 9.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferae*.

Gen. Ch. *General and partial Umbel* of many unequal rays. *General and partial involucrem* of many, linear-lanceolate, acute, unequal, villous, permanent leaves. *Perianth* of five unequal, very short, permanent teeth. *Cor. Universal* nearly regular and uniform; *flowers* partly perfect and fertile; the central and lateral ones, in each umbel, male: *partial* of five, nearly equal, spreading, inversely heart-shaped, deflexed petals; rather concave, on each side, at the keel; tapering at the base; and obliquely inflexed at the point, which is linear-lanceolate, acute, involute, channelled. *Stam.* Filaments five, spreading or deflexed, straight, longer than the involute corolla, dilated at the base; anthers versatile, roundish, two-lobed. *Pistl.* in the perfect florets, Germen inferior, ovate, compressed, villous; styles two, thread-shaped, channelled; their tumid base wavy and crenate at the margin; at length reflexed and permanent; stigmas simple, obtuse. *Peric.* Fruit roundish-obovate, compressed, finely downy, bordered; the border externally tumid, and somewhat corrugated, internally striated; emarginate at the summit, crowned with the styles

on their short, nearly sessile, crisped base; thickened at the bottom; the disk elevated and striated. *Seeds* two, of a similar shape, convex in the middle, with three elevated, narrow, central ribs, and two marginal ones; their interstices, in the upper half, occupied by four coloured stripes.

Eff. Ch. *General and partial involucrem* of many permanent leaves. Corolla uniform. Some flowers male. Calyx tumid, five-toothed. Petals nearly equal, obovate, inflexed. Fruit roundish-obovate, compressed, villous, with a corrugated border; the disk ribbed.

1. *Z. orientalis*. Oriental Zosima. Hoffm. n. 1. (Heracleum abrotanifolium; Venten. Choix de Pl. 7. t. 7. March. a Bieberit. Taur.-Aucuf. v. 1. 224. Sphondylium orientale humiliss, foliis abrotanii; Tourn. Cor. 22.)—Native of Peria, Georgia, and other countries about Caucasus, flowering in the early part of summer. The root is biennial, tap-shaped, milky. The whole herb when bruised smells like Smallage, *Apium graveolens*. Stem erect, near two feet high, cylindrical, furrowed, somewhat branched, and slightly leafy, about as thick as a swan's quill, rough to the touch with short whitish hairs. Leaves opposite, stalked, thrice pinnate, hoary with short pubescence; leaflets small, wedge-shaped, lobed; entire at the edges. Umbels two or three inches in diameter, on long stalks, terminal: *partial* ones of from twelve to fifteen flowers, which, according to Ventenat, are milk-white, but Hoffmann describes the petals of a yellowish-green. Germen downy. If the flowers are really white, we should suspect this plant to be nearly related to *Heracleum tomentosum*, Sm. Prod. Fl. Græc. Sibth. v. 1. 192, which will be exhibited in t. 281. of the Fl. Græca; but the shape of the fruit of the latter is very unlike Hoffmann's figure, nor does it better agree with the representation in Ventenat's work. This last indeed is itself so unlike Hoffmann's t. 1. B. f. 9, (he himself erroneously cites f. 7,) that we cannot but suspect some mistake. Nor are we, after all, persuaded that the plant under consideration ought to form a separate genus from *Heracleum*. In so natural a family, the skill of a botanist is shewn in combining, rather than dividing, which last is the most easy thing in the world, and the most pernicious to science. We do not, however, pretend to decide in the present case; because the generic distinctions of Umbellate plants are still *sub judice*.

ZOSIMUS, in *Biography*, a Greek historian, who held various civil offices under the younger Theodosius, about the commencement of the fifth century, and left a history of Roman affairs in six books; the first of which furnishes a slight view of the emperors, from Augustus to Diocletian; and the others detail the public events that occurred to the second siege of Rome by Alaric, and the pontificate and deposition of Attalus. Something seems to be wanting towards the end. The style of this historian is concise, perspicuous, and pure; but his prejudices against the Christian emperors have misled him; and particularly in his account of Constantine the Great. Leunclavius has attempted to justify him; and it has been allowed that he has divulged some truths which other historians have suppressed. Gibbon says, "credulous and partial as he is, we must take our leave of this historian with regret." The first edition of his work was that of R. Stephens, in 1581; others have been published by T. Smith, Gr. and Lat. Oxon. 1679, 8vo.; and the Variorum by Cellarius, 8vo. 1679, 1712.

ZOSIMUS, *Pope*, a native of Greece, was elevated to the pontifical throne in March 417, as successor to Innocent I.; at the time when the Pelagian controversy prevailed. Cælestius, the chief disciple of Pelagius, presented his confession of faith to this pope, who approved it and admitted

him to his communion. That of Pelagius was likewise approved. The African bishops, however, who were hostile to the Pelagian doctrine, interested the emperor Honorius in their favour; and obtained from the pope an anathema of the doctrine of Pelagius and Cælestius, with a sentence of excommunication if they refused to abjure their tenets. A council was assembled, in which other bishops, who concurred in the Pelagian creed, were degraded from their episcopal dignity. The fluctuations and inconsistencies of Zosimus's conduct depreciated the character of the pope, and furnished reason for questioning his infallibility. Other instances occurred, in which he was hardly able to maintain his authority. This pope died in December 418, leaving the character of an able man of business, but haughty, tenacious, and imperious. His thirteen epistles, that are extant, are written with spirit and elegance. He was canonized, as Bower says, by a mistake of cardinal Baronius, who supposed him to be a St. Zosimus in the martyrology of Bede. Dupin. Bower.

ZOSITERPUM, in *Ancient Geography*, a town of Thrace, in the province of Rhodope. Procopius.

ZOSSEN, in *Geography*, a town of Brandenburg, in the Middle Mark; 13 miles S.E. of Potzdam. N. lat. 52° 10'. E. long. 13° 17'.

ZOSTER, in *Ancient Geography*, a borough of Attica, upon the sea-coast, with a promontory of the same name, extended into the Saronic gulf; but it is not known to what tribe it belonged. Minerva, Apollo, Diana, and Latona, were honoured here. As Zoster bore some resemblance to zone, or cincture, the inhabitants pretended that the borough bore this name, because Latona, finding herself in this place, and feeling that her time was approaching, unloosened her cincture. Pauf. in Attic. c. 31.

ZOSTER, a word used by some to express that kind of herpes, called by others *zona* and *zingilla*, and by us usually known under the name of the shingles.

ZOSTERA, in *Botany*, so named by Linnæus from ζῶστis, a girdle, alluding to the ribband-like appearance of its long linear foliage.—Linn. Gen. 472. Schreb. 615. Willd. Sp. Pl. v. 4. 179. Vahl Enum. v. 1. 14. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 7. Prodr. Fl. Græc. Sibth. v. 1. 2. Pursh 2. Brown Prodr. Nov. Holl. v. 1. 338. Juss. 24. Poir. in Lamarck Dict. v. 8. 872. Lamarck Illustr. t. 737. Gært. t. 19. (Alga; Raii Syn. ed. 3. 52. Ruppia; Moehring in Phil. Trans. v. 41. 217.)—Class and order, *Monandria Monogynia*, Fl. Brit. and Vahl. (Gynandria Polyandria, Linn. Monoclea Monandria, Schreb. and Willd.) Nat. Ord. *Piperites*, Linn. *Araidea*, Juss. *Araidea affinis*, Brown.

Gen. Ch. *Cal.* Spadix linear, flat, sheathed by the base of a leaf, bearing an indeterminate number of flowers on one side. Perianth none. *Cor.* none. *Stam.* Filament none; anther sessile, erect, closely pressed to the spadix, simple, cylindrical, a little wavy, tapering at each end. *Pist.* Germen solitary, parallel to the anther, and of nearly a similar shape; style one, obliquely curved, shorter than the germens; stigmas two, linear, acute, spreading. *Peric.* Capsule pendulous, elliptical, membranous, of one cell, not bursting. *Seed* solitary, oblong, striated.

Eff. Ch. Spadix linear, sheathed by the base of a leaf, bearing the flowers on one side. Perianth and Corolla none. Anther sessile. Stigmas two, linear. Capsule with one seed.

Obs. The above is the view of the genus in question, first given by Gærtner, and confirmed from actual observation in the *English Botany* and *Fl. Brit.* Vahl adopts the same idea as ours of the place of this genus in the artificial system. The seed has a large, oval, half divided cotyledon, as we

would call it; Gærtner terms it a *vitellus*. (See the article *Yolk of the Seed*.) From this genus is to be separated the *Z. oceanica* of Linnæus, which belongs to *Caulinia* of De Candolle and Brown; *Possidonia* of König in Ann. of Bot. v. 2. 95. t. 6; *Kerneria* of Willd. Sp. Pl. v. 4. 947; but which is different from *CALLINIA* of Willdenow; see that article.

1. *Z. marina*. Common Grass-wrack. Linn. Sp. Pl. 1374. Willd. n. 1. Vahl n. 1. Fl. Brit. n. 1. Engl. Bot. t. 467. Fl. Dan. t. 15. Pursh n. 1. Brown n. 1? (Zoster; Linn. Et. W. Goth. 166. t. 4.)

β. *Fucus marinus*, seu *Alga marina graminea minor*; Raii Syn. 52. (Algoïdes; Mich. Ic. Ined. t. 60. f. 2.)

γ. *Fucus*, five *Alga marina angustifolia femiferia ramiflor*; Raii Syn. 52. (Algoïdes; Mich. Ic. Ined. t. 59?)

δ. *Potamogeton marinum* in utriculis epiphyllispermon minus; Raii Syn. 53.

ι. *Alga angustifolia vitrariorum*; Raii Syn. 53.

Leaves entire, obscurely three-ribbed. Stem slightly compressed. Native of the sea-shore, or salt muddy ditches and creeks throughout Europe, possibly of New Holland and North America also, flowering towards autumn. The root is perennial, fibrous. Stems roundish, smooth, decumbent at the base, and trailing to a great extent, throwing out tufts of fibres here and there; their branches floating and leafy, simple, a little compressed. Leaves alternate, tapering at the base into a kind of sheathing footstalk, linear, a foot, or much more, in length, flat, smooth, bluntish, quite entire, splitting longitudinally a little above the base, on the upper side, and putting forth from that fissure a linear, obtuse, flat *receptacle* or *spadix*, two inches long, covered in front with a series of naked flowers. Each of these flowers consists of a green anther, and a pistil of the same hue, parallel to it; but in such an alternate order, that the anther of each flower is contrary to that of its neighbour, and stands above the pistil of the latter. The whole herb is flaccid and tender; yet Linnæus says it is used in some parts of Sweden to make a thatch, which is very durable, and likewise to stop up chinks in wooden buildings. It serves also for manure, as well as the various kinds of sea-weed.

Whether the varieties above indicated may any of them prove distinct species, must be left for future inquiry. The β is a small slender plant, differing in nothing but its lesser dimensions from the common kind. It is well represented in one of Micheli's unpublished plates. γ is larger, more compact, and branched; we can scarcely doubt its being Micheli's t. 59. Of the others we know no more than can be gathered from Ray's *Synopsis*.

Z. oceanica of Linnæus is quite different from any of these supposed varieties, constituting a distinct genus, called *Possidonia Cavolini*, by Mr. König, in Ann. of Bot. v. 2. 95. t. 6; and well described by don Philip Cavolini of Naples, in a dissertation on these plants. De Candolle has named it *Caulinia*, but it is not Willdenow's. In Micheli's unpublished figures above cited, t. 58, is a good figure of this. We never met with any authority for its being a native of the British coast; but Mr. Horner, in a paper published by the Geological Society, in their Transactions, v. 3, mentions the submarine remains of a forest, on the Suffex coast, in the brown vegetable earth, accompanying which are found fragments of a plant, whose leaves were thought by Mr. Brown to resemble *Zostera marina*, except that, being much broader than usual, he suspected they might belong to *Z. oceanica* above-mentioned. If these leaves were sufficiently perfect to exhibit the three ribs, that question might perhaps be determined. As to the breadth, or size, of the leaves

in this whole tribe, nothing is more variable. We have *Z. ciliata* of Vahl; to which he attributes *leaves* an inch or more in breadth: whose *leaves*, in our different specimens, are but one-third or one-fourth of an inch wide, and from three inches to eight inches long. *Z. marina* differs with us from one-eighth to one-fourth of an inch in width, and if the above synonyms be all right, its variations are still greater.

Z. unincervis. Single-ribbed Grass-frack. Forik. *Ægypti- Arab.* 157. Vahl n. 2. Willd. n. 2.—“Leaves entire, single-ribbed. Stem compressed; swelling at the joints.”—Found by Forskall on the coast of the Red sea at Mocha, growing under water, and resembling overflowed grass. The stem is yellow, with bent joints. Leaves a span long, or more, narrower than in *Z. marina*, with an obscure mid-rib, unattended by lateral ones; and their base is sheathing.

Z. ciliata, Vahl n. 3; and *Stipulacea*, his n. 4; found by Forskall at the same place as the last, with whose fructification Vahl was, in both instances, unacquainted, are referred by Mr. König, in *Ann. of Bot.* v. 2. 97, not without some doubt, to a new diocious genus, denominated *Thalassia* in Dr. Solander's MSS., of whose fructification no figure has appeared, and of which the male flowers only have been observed. They are indeed sufficiently remarkable, as the following characters evince. *Sheath* single-flowered, of one leaf, in two oblong obtuse segments. *Perianth* of three ovate-oblong, obtuse leaves. *Cor.* none. *Filaments* none. *Anthers* nine, converging, linear-lanceolate, shorter than the calyx. The want of a slit in the *leaves* of these two last-mentioned plants proves them to be no *Zosteræ*.

ZOTENBERG, in *Geography*, a mountain of Silesia, in the principality of Schweidnitz, on which is a celebrated chapel; 20 miles W. of Breslau.

ZOTHECA, among the *Ancients*, the place where the animals designed for sacrifice were kept.

ZOUF, in *Geography*. See GAUR.

ZOUF, a river of Grand Bucharia, which runs into the Dehaur, 45 miles S. of Balk.

ZOU-KEOU-KIAOU, a town of China, in Pe-tcheli; 5 miles S.W. of Peking.

ZOULNOUN, a town of Asiatic Turkey, in the government of Sivas; 10 miles S.S.W. of Amafreh.

ZOUR EL HAMMAN, or *Island of Pigeons*, a small island in the Mediterranean, near the coast of Algiers. N. lat. 36° 26'. E. long. 12° 38'.

ZOUR, *Shabr e*. See SHAREZUR and SOLYMANIA.

ZOWAMORE, or ZIMBRA, an island in the Mediterranean, near the N.E. coast of Tunis, called by the ancients *Ægimurus*; 18 miles N.N.W. of Cape Bon. N. lat. 36° 50'. E. long. 11° 8'.

ZOWHAREEN, a town of Africa, in the kingdom of Tunis; 16 miles E.S.E. of Keft.

ZOW-WAN, or ZAGWAN, a town of Africa, in the kingdom of Tunis. It is a small flourishing town, built upon the north-east extremity of a conspicuous mountain of the same name. It is in great repute for the dyeing of scarlet caps, and the bleaching of linen; great quantities of both being daily brought thither for that purpose from Tunis, Sufa, and other places. The stream which is employed at present for this use was formerly, together with the river Zungler, conveyed to Carthage; and over the fountains of it there was a temple erected, the ruins of which continue likewise to this day; upon this ancient gate, which regards the fourth-east, there is a ram's head, armed, in basso relievo, with AUXILIO, in large letters, below it. This may, perhaps, instruct us, that Zow-wan, or whatever was its former name, was under the immediate influence and

protection of Jupiter Ammon; 36 miles S.W. of Tunis. N. lat. 36° 14'. E. long. 10° 6'.

ZOXO, a town of Asiatic Turkey, in the government of Diarbekir; 20 miles S.S.E. of Kerkifek.

ZOYSSIA, in *Botany*, was so named by the late professor Willdenow, in honour of the baron Charles de Zoys, a dignified ecclesiastic, resident in Carniola, who has long pursued with ardour the investigation of the botanical treasures of that country, and who is celebrated by Hoff, Wulfen, Jacquin, and other eminent writers, for the assistance which he has at various times afforded them.—“Willd. in Nov. Act. Nat. Cur. Berol. v. 3. 440.” Brown Prodr. Nov. Holl. v. 1. 208. (“Matrella; Perf. Syn. v. 1. 73.”)—Clafs and order, *Triandria Digynia*. Nat. Ord. *Gramina*, Linn. Juss.

Gen. Ch. *Cal.* Glume of one valve, single-flowered, ovate-oblong, compressed, cartilaginous, smooth, rigid, keeled, incurved, gaping at the apex of one edge; convex on one side; flattish on the other. *Cor.* Glume of two thin, membranous valves, enclosed within the calyx, awnless. Nectary none. *Stam.* Filaments three, capillary, short; anthers bifidate. *Pist.* Germen superior, linear, minute; styles two, the length of the calyx; stigmas prominent, feathery. *Peric.* none, except the permanent glumes. *Seed* solitary, linear, invested with the calyx and corolla.

Efl. Ch. Calyx of one valve, single-flowered, compressed, cartilaginous. Corolla of two membranous valves, within the calyx. Stigmas feathery. Seed linear, invested with the glumes.

1. *Z. pungens*. Sharp-pointed Zoysia. Willd. as above. Brown n. 1. (*Agroitis Matrella*; Linn. Mant. 185. Willd. Sp. Pl. v. 1. 366. “Matrella juncea; Perf. Syn. v. 1. 73.”)—Gathered in sandy ground, on the coast of Malabar, by Koenig; and near Port Jackson, New South Wales, by Mr. Brown. This is a small perennial grass, with a creeping root, enveloped in sheathing furrowed scales. *Stems* alternate, ascending, slender, thread-shaped, simple, leafy, three or four inches high. *Leaves* two-ranked, spreading, involute, sharp-pointed, smooth, an inch or an inch and a half long, with pale, furrowed, close *sheaths*, concealing the joints of the stem. *Stipula* of several spreading hairs. *Glusters* terminal, solitary, quite simple, of ten or twelve nearly sessile, alternate, erect *flowers*, remarkable for their smooth ivory-like *glumes*, about two lines in length, out of which, at the tip, project the feathery *stigmas*.

Linnaeus was inclined to make this a distinct genus by the name of *Matrella*; derived from *matrix*, and alluding to an anatomical resemblance, too obscure to be very instructive, if it were liable to no other objection. Such allusions were allowable enough while botany remained the abstruse study of philosophers and physicians; but in proportion as it becomes general and popular, they are either useless or censurable. This grass might be forced into *Agrostis* as the definition of that genus stood in Linnaeus, but has certainly no natural habit, nor any precise character, in common therewith. Mr. Brown remarks, that the *corolla*, (his *perianthium*;) is inverted, or contrary to the single-valved *calyx*; on which account, added to the nearly spiked *inflorescence*, he ranges *Zoysia* near *Rottböllia*. We cannot but think it rather more related to *Panicum Daßylon* of Linnaeus, Haller's *Digitaria*; though in fact so distinct in its nature, as not to associate well with any thing.

ZOZONISIUS, in *Natural History*, a name of one of the gems of the ancients, but of which our accounts are so short, that we can make no conjecture of what it was. Pliny only tells us, that it was found in the river Indus, and used by the magi.

ZRATSCHE, in *Geography*, a town of Bohemia, in the circle of Czaflau; 16 miles S.W. of Czaflau.

ZRIN, a town of Croatia, near the river Unna; 40 miles E.S.E. of Carlstadt. N. lat. 45° 16'. E. long. 16° 55'.

ZSCHOPA. See TSCHOPA.

ZSCHORLAU, a town of Saxony, in the circle of Erzgebirg; 10 miles S.S.E. of Zwickau.

ZSOKEN, a town of Saxony, in the circle of Erzgebirg; 8 miles N.W. of Grunhayu.

ZUAQUI, a town of New Mexico, in the province of Sonora; 8 miles S.S.E. of Pitquin.

ZUATA, a town of New Grenada; 45 miles N.N.E. of Tunja.

ZUBETH, a town of Persia, in the province of Chufistan; 105 miles N.W. of Sulter.

ZUBIA, a town of Spain, in the province of Grenada; 4 miles S.E. of Grenada.

ZUBTZOV, a town of Russia, in the government of Tver, on the Volga; 68 miles S.W. of Tver. N. lat. 55° 46'. E. long. 34° 50'.

ZUCARELLO, a town of Genoa; 7 miles N.N.W. of Albenga.

ZUCCAGNIA, in *Botany*, so named by the late abbé Cavanilles, in honour of Dr. Attilius Zuccagni, superintendent of the garden at Florence.—Cavan. Ic. v. 5. 2. Poiret in Lamarck Dict. v. 8. 875.—Clas and order, *Dicandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coloured; tube turbinate; limb in five deep, oblong, obtuse, permanent segments, the lower one a little the longest. *Cor.* Petals five, obovate, inserted into the calyx; the uppermost broadest, vaulted. *Stam.* Filaments ten, awl-shaped, ascending, hairy in their lower part, about as long as the corolla; anthers roundish, of two lobes, divided by a furrow. *Pist.* Germen superior, roundish, compressed; style capillary, of the length and position of the filaments, smooth; stigma funnel-shaped. *Peric.* Legume ovate, oblique, compressed, hairy, of one cell and two valves. *Seed* solitary, ovate, compressed, attached by its stalk to the summit of the legume. *Cavanilles*.

Eff. Ch. Calyx bell-shaped; its limb in five permanent segments. Petals five, obovate; the upper one broadest, vaulted. Legume of one cell and two valves. *Seed* solitary.

1. *Z. punctata*. Dotted Zuccagnia. Cavan. as above, t. 403. Poiret n. 1.—Native of hills in Chili, between *Portillo* and the springs commonly called *Manantiales*, bearing flowers, as well as seed, in January. It was communicated to the author by Louis Née, to whose discoveries in South America and New Holland his *Irones* are so much indebted. The stem is shrubby, four or five feet high, with numerous, twisted, glutinous branches. Leaves alternate, abruptly pinnate, of numerous, alternate, sessile, elliptical, entire, glutinous leaflets, each one-third of an inch long, marked on both sides with blackish resinous dots. *Chislers* terminal, solitary, simple, of several rather small flowers. *Partial stalks* one-third of an inch long, each with a little acute bractea at its base. *Calyx* smooth, reddish-brown, rather shorter than the corolla. *Petals* a line and a half long, saffron-coloured, with darker veins. *Anthers* deep orange. *Legume* about three lines in length, clothed with long rusty hairs. *Seed* of a shining brown. This pretty shrub does not appear to have been raised in the gardens of Europe.

ZUCCARO, or ZUCCHERO, TADEO, in *Biography*, was a painter of considerable renown, born at S. Agnolo in

Vado, in the duchy of Urbino, in 1529. His father Ottaviano Zuccaro was also a painter, but of moderate talents; and Tadeo was principally indebted to Pompeo de Fano for initiation in the art. Having, as he imagined, exhausted the store of information to be derived from his preceptor, animated by love of his art and a desire to free his father from further charge on his account, he, at the age of 14, went to Rome, unknowing and unknown. His relation Francesco d'Agnolo was then engaged painting, with Pierino del Vaga, the grotesques of the Vatican, and he had some hope of assistance from him; but his application was vain, and he was obliged to earn his daily bread by grinding colours in different shops, wherever he could find employment. He divided his time between this labour and copying from the works of Raphael, in the Palazzo Ghigi particularly, and was often compelled to sleep under the loggie of the palace, being unable to procure better accommodation. Weary at length of so much misery, he returned to his father, but soon left him to revisit the great emporium of art. Fortune now began to smile upon him; he became known to an artist named Giacomone, and having improved much with him, and acquired some credit, his relation Francesco d'Agnolo noticed him, and for a time they worked together. Afterwards he was engaged by Daniello da Parma, a scholar of Correggio and Parmegiano, to assist him in painting a chapel of Santa Maria, in a church at Vitto, in Abruzzo. The work was in fresco, and Zuccaro, according to Vasari, painted a large portion of the subjects required. When this was done, he returned to Rome, and was employed by G. Mattie to paint a façade of the Palazzo Mattei in fresco, where he executed, in chiaro oscuro, nine historical pieces relative to the history of Furio Camillo. He was then only 18, and the execution of them was a matter of surprize to all who saw them. By this his first public work he gained so much reputation, that he soon acquired considerable employment. The duke d'Urbino, hearing of his fame, sent for him to Urbino, and gave him a commission to paint in fresco the chapel of the Duomo there, which was delayed by various causes, and he returned to Rome in the time of Julius III., who employed him, under Vasari, in the Vatican, to paint in a frieze the labours of Hercules, which were afterwards destroyed by pope Paul IV. to make room for other works. Hitherto he had been principally employed upon ornamental subjects, but now a serious one was entrusted to his pencil; and he painted in fresco, for the church of Santa Maria della Consolazione, several subjects of the passion of the Saviour, which are regarded as among his best productions. He was afterwards called upon to exert his skill, by the cardinal Farnese, in the Palazzo Caprarola. This is his greatest work, and is that whereon his reputation most depends. He was liberally paid by the cardinal. The whole ornamental part of the building was entrusted to his care, and he laboured with great earnestness to make it honourable to himself and pleasing to his employer. It has been engraved by Preamer in a set of 45 plates. Tadeo Zuccaro died at Rome in 1566.

ZUCCARO, FEDERIGO, was a younger brother of Tadeo just mentioned, and born in 1543. He received his instruction from his brother, with whom he was placed at Rome, when very young, and who paid him the most affectionate attention. He soon rendered himself useful to Tadeo in his great works, and engaged also in some labours for himself. Pope Pius IV. employed him, in conjunction with F. Barrocio, in the Palazzo Belvidere, where he gained great reputation. The brothers continued to work together without rivalry, and co-operated at the Vatican and the

Villa Farnese. He was invited to Florence by the grand duke to finish the cupola, left imperfect by Vasari, and succeeded in pleasing his employer.

Gregory XIII. engaged him to paint the vault of the Capella Paolina; but having some dispute with the officers of his holiness, he avenged himself by a satirical picture which he exhibited. By this the pope was offended, and Zuccaro was obliged to fly, and leave his great work unfinished. He took refuge in France, where he was sometimes employed by the cardinal of Lorraine; and from thence he went to Flanders, where he painted cartoons for tapestries.

In 1574 he visited England, and was received very favourably. Here he painted portraits. The queen fat to him, and many of the nobility. How long he remained here is not exactly known. When he returned to Italy, he went to reside at Venice, where the patriarch Grimani employed him in his chapel to finish the fresco ornaments begun by Battista Franco, and he added some designs of his own to them. He also painted there a large picture of the Adoration of the Magi. In conjunction with the great masters then living in Venice, he was employed in the hall of the grand council of that city, and he obtained as his reward the honour of knighthood. He soon after returned to Rome, and the pope not only overlooked his indiscretion, but allowed him to complete the work he had begun in the Capella Paolina.

On the accession of Sixtus V. he was invited to Madrid by Philip II. to adorn the walls and ceilings of the Escorial; but though he painted with his usual skill, and covered immense quantities of space, he had not his usual success in affording pleasure to his patron. Philip was not gratified with his works, and Zuccaro was dismissed; not, however, without being munificently rewarded for his labours. The works he left behind him were afterwards covered over by others from the hand of Pellegrini Tibaldi. On his return to Rome he established the academy of St. Luke, for which he received letters patent from Gregory XIII., and to which, at his death, which happened in 1609, he bequeathed all his property.

The talents of the Zuccaros were more splendid than great. They designed and executed with facility; but aiming at grandeur, fell into manner; and the vice of mannerism touches also the colour and chiaro oscuro of their productions. Sometimes happy in all parts, but more frequently defective in the principal one of expression and feeling, their works please without gratifying; and though they attract, do not absorb the spectator.

ZUCCHABARI, CHADARA, in *Ancient Geography*, a town of Mauritania Cæsariensis, situated on the left bank of the river Chinalaph, and towards the north-east of mount Zalacus. This is very probably the Succabar and Colonia Augulta of Pliny.

ZUCCHARA, ZUNG-GAR, an ancient town of Africa, and the most northerly of those which lay between Zingitania and Biracium. Its magnificent ruins and its temple are the coverts of Arabs.

ZUCCHERELLI, FRANCESCO, in *Biography*, a very pleasing landscape painter, was born at Pitigliano in Tuscany, in 1702. He for some time attempted history, but abandoned it, and adhered solely to landscapes, which he adorned with very agreeably composed groups of figures. In 1752 he visited England, where he was much encouraged; but our greatest debt to him is due for his having persuaded Wilton to adopt landscape for his object, instead of portrait. For this liberal act what adequate thanks can be offered to his memory? At the foundation of the Royal Academy

he was chosen an original member. After remaining here twenty years, he returned to Italy, and settled at Florence, where he had the misfortune to be reduced to indigence, by the suppression of a monastery where he had lodged the money he had acquired. He again resumed the pencil to support himself, and died at Florence in 1788, aged 86.

ZUCCO, in *Geography*, a town of Italy, in the county of Friuli; 5 miles N.W. of Friuli.

ZUCCORA, a river of European Turkey, which runs into the Morava, near Niša.

ZUCHABARUS, in *Ancient Geography*, a mountain of Africa Propria, in which the river Cyniphus and the fountain Acaba have their source. Herodotus called it "Charitum Mons."

ZUCHIS, a lake of Africa Propria, which is, according to Strabo, 400 stadia in circuit; and on the bank of the lake is a town of the same name.

ZUCHOW, in *Geography*, a town of Poland, in Volhynia; 32 miles E. of Lucko.

ZUCKMANDEL, a town of Silesia, in the principality of Neisse, the see of a bishop; 17 miles N.N.W. of Jagerndorf. N. lat. 50° 8'. E. long. 17° 16'.

ZUCKTOK, a town of Mexico, in the province of Yucatan; 80 miles S. of Campeachy.

ZUDA, a town of Arabia, in the province of Yemen; 12 miles W. of Chamir.

ZUDISHTIRA, in *Hindoo Mythology*, is one of the heroic sons of Pandu, whose wars and adventures occupy a considerable portion of the Mahabarat, an epic poem of great celebrity in the Shanfcrit language. See MAHABARAT and SHANSCRIT.

ZUECA, in *Geography*. See GIUDUCCA.

ZUELA, ZULA, or *Zavula*, a considerable town of Africa, in the kingdom of Fezzan, said to have been anciently the capital, containing many rich merchants, situated in a fertile country. The remains of ancient buildings in this town, the number and size of the cisterns, and the construction of the vaulted caves, intended perhaps as repositories for corn, exhibit such vestiges of ancient splendour, as will probably attract, and may highly reward, the attention of the future traveller; 60 miles E.N.E. of Mourzouk. N. lat. 27° 35'. E. long. 16° 45'.

ZUENGA, a town of Thibet; 176 miles W.S.W. of Lassa. N. lat. 28° 32'. E. long. 88° 10'.

ZVENIGOROD, a town of Russia, in the government of Moscow, on the Moskva; 28 miles W. of Moscow. N. lat. 55° 40'. E. long. 35° 34'.

ZUENZIGA, a desert district of Africa, in the country of Sahara, situated to the south of Taflet.

ZVERINOGOLOVSKAIA, a fort of Russia, on the Tobol; 52 miles S. of Okunevsk.

ZUEVA, a town of Russia, in the government of Irkutsk, at the union of the Kotoi and the Angara; 60 miles N.N.W. of Irkutsk.

ZUF, a town of the country of Candahar; 50 miles N.W. of Candahar.

ZUFFERABAD, a town of Hindoostan, in the subah of Moultan, near the Ravee; 25 miles N.E. of Moultan.

ZUFFIRWAL, a town of Hindoostan, in Labore; 10 miles N.N.E. of Sealcot.

ZUFFOLO, in the *Italian Musee*, a little flute or flageolet, having a very shrill sound, like the whistling of small birds.

ZUF-FOONE, or *Mers el Fulom*, in *Geography*, a seaport of Algiers; 36 miles W.N.W. of Boujjeah.

ZUG, a canton of Switzerland, bounded on the north and

and east by Zuric, on the south by Schweitz, and on the west by Lucerne; only about ten miles long, and nearly as much in breadth. The pastures here are excellent, and it produces also a sufficiency of grain, with plenty of fruit, and some wine. On one side of the Zug lake, the country is covered with chefnut-trees, which form a very profitable branch of trade, by the sale of the nuts to the neighbouring countries. This district, on the extinction of the counts of Lenzburg, devolved to those of Kyburg, which latter also failing, it came to the counts of Habburg, and in them to the house of Austria, towards which it always manifested an inviolable attachment; but in the year 1351, the town of Zug being besieged by the Helvetic confederacy, and not only neglected by the archduke, but even recommended by him to surrender, it followed his advice, and was admitted into the confederacy, to which its territory had previously acceded. The generosity of the conquerors rivalled the courage of the vanquished; for, in consequence of their submission, the canton of Zug was rescued from the yoke of a foreign master, obtained liberty and independence, and was admitted into the Helvetic confederacy upon equal terms. This canton is the seventh in rank, and among the lesser ones the fifth; besides which, it is in a particular manner connected with Lucerne, Uri, Schweitz, and Underwalden, commonly called the five territorial confederates. The government of this little canton is exceedingly complicated; and the inhabitants of the town have somewhat more influence, and enjoy a greater share in the administration of affairs, than those of the capital burghs in the five other democratical cantons. The supreme power resides in the inhabitants of Zug, Bar, Egeri, and Meutzingen, who assemble yearly to enact laws, and choose their magistrates. The landammann, reciprocally elected from each of the four districts, continues three years in office when taken from Zug, and but two years when chosen from each of the three other districts. The general administration of affairs is entrusted to the council of regency, composed of forty members, of whom thirteen are supplied by the district of Zug, and twenty-seven selected equally from the three remaining communities. This council, as well as the landammann, resides always in the capital. Zug was the only one of the small cantons which did not send its contingent to the army, but made a shew of resistance to the imposition of the new constitution. On the 29th of April, Zug was invested by French troops, surrendered on the 30th, and on the 1st of May accepted the new constitution. The people of this canton are reckoned the most restless of Switzerland: their general assemblies are often tempestuous, though seldom attended with bloodshed.

ZUG, a town of Switzerland, and capital of the above described canton, is beautifully situated at the north-east extremity of a lake, in a fertile valley, abounding with corn, pasture, and wood. It contains two churches, a convent, a town-house, arsenal, corn-magazine, a college, hospital, &c. The titular saint of this place is Oswald, king of Northumberland in the seventh century, who was defeated and slain in 624 by Peuda, king of the Mercians. In the church is his statue, with this inscription: "Sanctus Oswaldus Rex Angliæ Patronus hujus Ecclesiæ." This king was much renowned for his charity, piety, and power of working miracles; 15 miles S. of Zurich. N. lat. 47° 6'. E. long. 8° 16'.

ZUG, a lake of Switzerland, eight miles long, and two wide, abounding in fish. It receives its name from the town on its coast.

ZUGANA, in *Ancient Geography*, a town in the interior of Arabia Felix. Ptol.

ZUGAR, a town of Africa Propria, between the rivers Bagradas and Triton.

ZUGARI, in *Geography*, a town of Naples, in Calabria Ultra; 6 miles N. of Nicotera.

ZUGLIANO, a town of Italy, in Friuli; 4 miles S. of Udina.

ZUHREE, a district of the province of Balouchistan, or Ballagistan, which is considered by some as a province distinct from Mekran or Mecran, and by others as the northern division of it. However this be, Balouchistan is a confused mass of tremendous mountains, affording pasture nevertheless for numerous flocks of sheep and herds of cattle, and producing great quantities of wheat. The territories of its chief comprehend all the countries that lie between 20° 30' and 30° N. lat., and from 65° to 69° E. long.; and Balouchistan is divided into the two mountainous provinces of Ithalawann and Sarawan, the low country of Cutch Gandava to the east, and the provinces of Zuhree and Anund Dajal, to which may be added the small districts of Sbat and Mulkung, lying north of Kelat. Zuhree, though it is entirely subject to the khan of Kelat, pays very little to him, as its revenues are enjoyed by Zadir Bukli, of the Zuhree tribe of Balouches. The chief town is Zuhree, which contains from one to two thousand houses. The second town, nearly as large, is Dadur; besides which, there are many populous villages; and upon the whole, this is spoken of as the most civilized part of Balouchistan, the capital of which is Kelat.

ZUIA, a river of Spain, which runs into the Guadiana, a little above Medellin.

ZUICK, a town of Prussia, in Natangen; 8 miles N.W. of Lick.

ZUIA. See ZUEELA.

ZUINGLE, or ZWINGLE, ULRIC, in *Biography*, the *Swiss Reformer*, was born January 1, 1484, at the village of Wildhauen, in the county of Tockenbourg; and having discovered in his youth a studious disposition, was intended by his father for the church. Accordingly he was sent for education first to Basil, and then to Berne, where attempts were made to fix him in the convent of the Dominicans; but in order to prevent their taking effect, his father removed him to the university of Vienna, which was then in high reputation. Returning from thence to Basil, he was chosen classical tutor in his 18th year, where he made very considerable advances in knowledge, and particularly in that of the profession to which he was destined, whilst he taught others; and availing himself of the lectures of Thomas Wyttembach, who, without renouncing the system of the schools, allowed his pupils to think freely for themselves. After a residence of about four years at Basil, Zuingle took the degree of M.A., and being chosen pastor of Glarus, was ordained by the bishop of Constance. Having commenced a course of liberal inquiry, he indefatigably pursued it, critically examining the New Testament as the directory of his faith, and consulting a variety of writers who had incurred the censure of the church of Rome. The consequence of this mode of study was a discovery of the deviation of the ecclesiastical system, generally adopted and established, from that of Christianity, both in doctrine and practice. But he was slow in publishing the theological sentiments which he had imbibed, and for ten years pursued a course of practical instruction at Glarus, which secured to him the respect and affection of his parishioners, so that the bigotted clergy could not succeed in their attempts to do him injury. From Glarus he removed to the celebrated abbey of Einsidlen, where he accepted the office of preacher, and where he had an opportunity of associating

with

ZUINGLE.

with persons of learning, and of contributing to the education of candidates for the ministry. Whilst he was at Glarus he exposed several superstitions of the church of Rome; and at Einsidlin he gained additional reputation by preaching against vows, pilgrimages, and offerings. Here he employed his influence to effectually, that he ordered the inscription over the abbey-gate, "Here plenary remission of sins is obtained," to be effaced, and the relics to be buried; and, among other rules which he established in a convent of females under his direction, he introduced one for obliging the nuns to read lessons in the New Testament, instead of reciting their hours. He was also intrepid and zealous in propagating rational sentiments of religion, and with this view he availed himself of a public occasion, when a crowd was assembled, to deliver a sermon designed to shew that no superior sanctity resided in any place so as to confer peculiar merit on vows addressed from it, but that their acceptance depended upon the purity of the heart and life of the worshipper. Declarations of this kind, whilst they gained the approbation of some of his auditors, excited the indignation of others, and alarmed the monks of this and neighbouring convents. Although he was regarded with jealousy and terror by those whose interest led them to oppose reformation, he was so much respected, that his ecclesiastical superiors manifested no displeasure against him; and by his correspondence with Erasmus, Glareanus, Hedio, Rheanus, and other learned persons, he established a reputation which enabled him to encourage liberal studies. In 1518 he was invited to occupy the vacant post of preacher in the cathedral of Zurich, and before he was installed he announced his proposed plan of preaching, which differed from that which had been before practised, and which gave him an opportunity of explaining the books of the New Testament in an uninterrupted series, without regard to texts that were marked for each Sunday and Saint's-day in the year. This plan was approved by the majority of the chapter, and drew together a crowded auditory, who expressed in high terms their admiration of the preacher. A circumstance occurred which afforded him a complete victory over an emissary of pope Leo X., who was employed in the sale of indulgences, inasmuch that he was obliged to quit the city and retire into Italy. Some writers, especially among the Catholics, have referred the origin of the reformation, and of the opposition of both Zuingle and Luther to the papal authority, to the disputes about indulgences; but, although this quarrel might have contributed to the promotion of it, the people were previously prepared for the event by the preaching and conduct of Zuingle, and by the judgment and prudence with which he had planned and pursued his measure for this purpose. Luther proceeded very slowly to that exemption from the prejudices of education, which Zuingle, by the force of an adventurous genius, and an uncommon degree of knowledge and penetration, easily got rid of. And we learn from the most authentic records of history, that he had explained the Scriptures to the people, and called in question the authority and supremacy of the pope, before the name of Luther was known in Switzerland. In process of time, after Luther had taken up arms against Rome, Zuingle, being then minister of the chief church in Zurich, concurred with him; preaching openly against indulgences, then against the intercession of the saints, then against the mass, the hierarchy, the vows and celibacy of the clergy, abstinence from flesh, and also many things which Luther was disposed to treat with toleration and indulgence; such as images, altars, wax-tapers, the form of exorcism, and private confession, &c. Zuingle, at an early period of his ministry, had declared his decided

disapprobation of all wars, excepting those that were undertaken for the defence of the country; and such was the influence of his opinion, that the canton of Zurich refused to concur with the other cantons in a subsidiary treaty with the French king. The result of his arguments and remonstrances to this effect was a law passed by the assembly of the canton in 1522, abolishing all alliances and subsidies for the term of 25 years. He laboured at the same time to enforce a regard to the rules of the gospel in preference to the respect that was generally manifested to those of ecclesiastical discipline. Accordingly he defended those persons who had been denounced to the magistrats for infringing on the "fast of Lent" without a dispensation; and published on this occasion his treatise "On the Observation of Lent," which contained free opinions on the obligation of fasting and keeping particular days. When the bishop of Constance remonstrated against his proceeding, and endeavoured by his charge and letters to excite apprehensions among the people, and in the council and chapter of Zurich, that he would spread through Switzerland such a flame as Luther had kindled in Germany, Zuingle obtained permission to reply; and composed a tract to prove that the gospel alone is authority from which there is no appeal, and that the decisions of the church are binding only inasmuch as they are founded on Scripture. When the bishop of Constance had prevailed with the deputies of the Helvetic diet to order the arrest of a pastor accused of preaching the "new doctrine," Zuingle, who had now adopted and openly avowed the principles of the reformation, addressed to the heads of the cantons, in his own name and that of his friend, a summary of his doctrine, annexing an intreaty that they would allow liberty for the preaching of the gospel. In a conference before the deputies of the bishop of Constance, in the presence of the great council of Zurich, held in 1523, Zuingle gave an account of his doctrine; and the colloquy terminated in the following declaration of the council: "That Zuingle, having been neither convicted of heresy, nor refused, should continue to preach the gospel as he had already done; that the pastors of Zurich and its territory should rest their discourses on the words of Scripture alone; and that both parties should abstain from all personal reflections." Zuingle, having been thus supported by the magistrats, and having obtained a public sanction of the principles of the reformation in this canton, has been charged, both by Catholics and Protestants, with allowing to the secular power an undue degree of authority in ecclesiastical matters; however it has been urged in his defence, that he did not intend to transfer to government the absolute power over consciences claimed by the popes; but that, for the preservation of order and tranquillity, he thought that the depositories of lawful authority ought to have a share in the direction of ecclesiastical affairs. Zuingle, though thus supported, proceeded with caution in promoting alterations in the ceremonies and modes of public worship, and was principally anxious to lay a proper foundation of change by enlightening the understanding and convincing the judgment of the people. When some zealous reformists instigated a mob to pull down a crucifix that had been erected at the gate of the city, and the culprits were brought before the council to be tried and punished, Zuingle interposed; and whilst he vindicated the offenders from the charge of sacrilege, he gave it as his opinion, that they deserved some punishment for having pulled down the crucifix without the authority of the magistracy. This dispute led to a general colloquy, which was held in October 1523; and the result was, that all the culprits, except Hottinger their ring-leader, and the person who had actually

ZUINGLE.

tually committed the offence, were set at liberty; but Hottinger was banished from the canton for two years; and he was afterwards put to death for heresy, in consequence of a sentence pronounced by the deputies of seven cantons at Lucerne, notwithstanding the intercession of Zurich. The question of the celibacy of the clergy was agitated in these colloquies, and though no decisive opinion was given by the council, several clergymen married, and among them was Zuingle himself, who had expressed his sentiments against the question, at the age of 40. In 1524, the council of Zurich proceeded to the reformation of public worship according to the plan proposed by Zuingle. They began with causing all pictures and statues to be removed by those whose ancestors had consecrated them; and of these several were destroyed. These measures occasioned alarm and complaint in the other cantons; and acts of hostility were meditated. Without entering into a detail of the various circumstances that occurred on one side and on the other, we shall content ourselves with observing, that fanaticism and bigotry were engaged in opposition to each other, and produced in Switzerland effects similar to those that have attended innovation and reformation in other countries. At Zurich, the total subversion of the Romish worship was accomplished, by prohibiting processions and other ceremonies, and by the abolition of the sacrifice of the mass. The latter event took place by the activity of Zuingle in 1525; and on Easter Sunday the Lord's Supper was celebrated according to his idea of this rite, which was that of a merely commemorative and symbolical service. Our reformer displayed in another instance a disinterested spirit, which reflects great honour on his memory. Although he was one of the canons who composed the chapter of the cathedral, and this body was independent of the council, and possessed its own jurisdiction and property, he prevailed with the majority of his colleagues to consecrate the large revenues of the chapter to establishments for public instruction, and to transfer its temporal power to the government. In the conduct of this event he manifested no less wisdom and moderation than disinterestedness; for the chapter charged itself with the payment of as many pastors as were necessary for the public worship of the city, to which service those canons who were capable of service were devoted. Those who were old and infirm were allowed to preserve their benefices for life; and their revenues, as they became vacant, were to be employed in founding professorships for lectures, to which admission was to be gratuitous. These liberal conditions were religiously observed, and the regulations thus framed are still continued at Zurich. The orders of mendicants, and other religious houses, were abolished; and their revenues were appropriated to the support of hospitals, and other charitable institutions, as the old members dropped off. Zuingle was afterwards commissioned to organize a system of public instruction, in which he displayed a cultivated and liberal mind.

The reputation which Zuingle had acquired, and the success which had crowned his plans and labours in the cause of reformation, were not sufficient to secure him against the prejudices of fanatics, and the hostile attacks of malignity. Attempts were made to associate him with Munzer, one of the leaders of the Anabaptists; but he happily avoided the snare that was laid for him, and instead of taking part in those violences which called forth the interposition of the civil power, and which terminated in the death of one of the persons concerned, he did all that lay in his power to prevent them; and though he could not preserve the life of one disturber of the public peace, he composed the tu-

mult occasioned by the intemperate zeal of others. Notwithstanding the singular prudence and moderation which influenced his whole conduct, his reputation excited envy, and a conspiracy was formed against his life. Under the protection of the magistracy of Zurich he was safe; but his enemies insidiously proposed a conference at Baden, in Argovia. His friends, however, were not unapprised of his danger, and well knowing that the cantons were actuated by inveterate hostility against his person as well as his doctrines, they would not consent to his leaving Zurich. At the conference, which he prudently declined to attend, enmity was avowed both against him and his adherents. Some of the cantons, however, withheld their concurrence; and this was particularly the case with respect to the canton of Berne. In this canton, the reformation had made considerable progress, so that in 1527 several of its municipalities addressed the senate for the abolition of the mass, and the introduction of the form of worship established at Zurich. The reformers at Berne summoned a convocation, to which the clergy of the other Helvetic states, and the neighbouring bishops, were invited. Zuingle's attendance was also requested; and he thought it his duty to appear in that assembly, professedly convened for the advancement of the reformation. Haller was the leader of the party in this canton, and in connection with Zuingle and other coadjutors the cause to which they were devoted obtained a complete triumph; so that the grand council of that canton fully adopted the measures of that of Zurich. Upon this, five of the cantons which were attached to the old religion entered into a solemn engagement not to suffer the doctrines of Zuingle and Luther to be preached among them. At length the hostilities that subsisted between the Catholic and reformed cantons were amicably terminated by the treaty of Cappel in 1529. The animosity, however, between these cantons was not extinguished. It broke out again with greater violence than ever; and the senate of Zurich has been charged with the first aggression, by arbitrary acts in favour of the reformed preachers in the common bailiages. Its project of secularizing the abbey of St. Gall, which belonged to the Helvetic confederacy, was a greater grievance; and on the other hand, the five associated Catholic cantons refused to concur with the others in expelling the Spaniards from the Valeline, and persecuted the reformed in their jurisdictions with the greatest severity. The sufferers sought the protection of Zurich, and the eloquence of Zuingle was employed in recommending their case to the senate. The breach widened, and a majority of the Protestants agreed in stopping the transit of provisions to the five cantons, which depended upon foreign supplies. Zuingle in vain remonstrated against this cruel act; and the five cantons took up arms, and having published a manifesto, marched into the field in October 1531. A detachment was ordered to prevent the junction of the forces of Berne with those of Zurich, and the main body advanced towards Cappel. This intelligence alarmed the people of Zurich; and they could only spare 700 men for the relief of their countrymen at Cappel. Zuingle was appointed to accompany them. A battle ensued; and though the Zurichers, animated by his exhortations, defended themselves valiantly, they at length were compelled to yield to superiority of numbers, and were entirely routed. Some died at their posts; others fled; and Zuingle received a mortal wound at the commencement of the action, and fell senseless to the ground. As soon as he had recovered sufficiently to raise himself up, he crossed his arms on his breast, and lifted his languid eyes to heaven. In this condition he was found by some Catholic soldiers, who, without knowing him, offered to bring a confessor; but

but as he made a sign of refusal, the soldiers exhorted him to recommend his soul to the holy virgin. On a second refusal, one of them furiously exclaimed, "Die then, obstinate heretic!" and pierced him through with a sword. His body was found on the next day, and the celebrity of his name drew together a great crowd of spectators. One of these, who had been his colleague at Zurich, after intently gazing on his face, thus expressed his feelings: "Whatever may have been thy faith, I am sure thou wert always sincere, and that thou lovest thy country. May God take thy soul to his mercy!" Among the savage herd some voices exclaimed, "Let us burn his accursed remains!" The proposal was applauded; a military tribunal ordered the execution, and the ashes of Zuingle were scattered to the wind. Thus, at the age of 47, he terminated a glorious career by an event deeply lamented by all the friends of the reformation, and occasioning triumph to the partisans of the Romish church.

"In the character of Zuingle," says one of his biographers, "there appears to have been united all that makes a man amiable in private society, with the firmness, ardour, and intrepidity that are indispensable in executing the great task of reformation. By nature mild, his earnestness was the result of his sense of the importance of the cause he engaged in to the best interests of mankind, not of a dogmatic or dictatorial spirit. His views were large and generous, and his opinions rose above the narrow scale of sect or party. It was no small proof of liberality in that age that he ventured to assert his belief of the final happiness of virtuous heathens, and of all good men who act up to the laws engraven on their consciences. His temper was cheerful and social, somewhat hasty, but incapable of harbouring resentment, or indulging envy and jealousy. As a reformer he was original; for he had proceeded far in emancipating himself from the superstitions of Rome by the strength of his own judgment, and had begun to communicate the light to others, whilst Luther still retained almost the whole of the Romish system, and long before Calvin was known in the world. He was more learned and more moderate than the first of these divines, and more humane and kind-hearted than the last. He wrote many works of utility in their day; and the reform, of which he was the author, still subsists unchanged among a people distinguished by their morals and mental cultivation." Life of Zuingle, by J. G. Heß. Mosheim's Eccl. Hist. Coxe's Travels in Switzerland, vol. i. See ZUINGLIANS.

ZUINGLIANS, in *Ecclesiastical History*, a branch of ancient Reformers or Protestants; denominated from their author Ulrich or Huldric Zuinglius. See ZUINGLE.

As to the eucharist interpreting *hoc est corpus meum*, by *hoc significat corpus meum*, he maintained, that the body and blood of Christ were not really present in the eucharist; and that the bread and wine were no more than external signs or symbols, designed to excite in the minds of Christians the remembrance of the sufferings and death of the divine Saviour, and of the benefits which arise from them. This opinion was embraced by all the friends of the reformation in Switzerland, and by a considerable number of its votaries in Germany. On the other hand, Luther held his doctrine, which was *consubstantiation*, with the utmost obstinacy; and hence arose, in 1524, a tedious and vehement controversy, which terminated, at length, in a fatal division between those who had embarked together in the sacred cause of religion and liberty. From this time, Zuingle propagated his doctrine concerning the eucharist in a public manner by his writings, after having entertained and taught it privately before that period. His "Commentary on true

and false Religion," containing his sentiments on this subject, was published in 1525, and followed by a learned treatise of Cœcolampadius on the same subject.

With a view of bringing this controversy, which reflected much discredit on the Protestant cause, to an amicable issue, Philip, landgrave of Hesse, invited, in 1529, to a conference at Marburg, Luther and Zuingle, together with some of the other principal leaders of their respective parties; who disputed, during four days, in presence of the landgrave. Luther attacked Cœcolampadius, and Melancthon disputed against Zuingle. Before they parted, the Swiss and German theologians signed their mutual assent to 14 articles, containing the essential doctrines of Christianity, and expressed a hope that their difference with respect to the real presence would not interrupt their harmony. The landgrave required from the two leaders a declaration that they would regard one another as brothers. Zuingle readily consented; but Luther would engage no farther than that, speaking of the Swiss, he would for the future moderate his expressions. In this conference Zuingle was accused of heresy, not only on account of his explication of the nature and design of the Lord's Supper, but also in consequence of the false notions he was supposed to have adopted relating to the divinity of Christ, the efficacy of the divine word, original sin, and some other parts of the Christian doctrine. But though he cleared himself to the satisfaction even of Luther from the greatest part of these accusations, their dissension concerning the manner of Christ's presence in the eucharist still remained. Nor did it terminate with the death of Zuingle in 1531, nor with that of Luther in 1546. Melancthon and Calvin made several attempts towards promoting a reconciliation between the contending parties. With this view Calvin proposed a system, with respect to the eucharist, more conformable to the doctrine of the Lutheran church than that of Zuingle. He acknowledged a spiritual presence of Christ in this sacrament, and supposed that a certain divine virtue or efficacy was communicated by Christ with the bread and wine to those who approached this holy sacrament with a lively faith, and with upright hearts; and to render this notion still more satisfactory, he expressed it in almost the same terms which the Lutherans employed in inculcating their doctrine of Christ's real presence in the eucharist. But whilst the followers of Zuingle asserted, that all Christians, without distinction, whether regenerate or unregenerate, might be partakers of the body and blood of Christ, Calvin confined this privilege to the pious and regenerate believer alone. Besides, the sentiments of the Zuinglians, with regard to the divine decrees, differed very little from that of the Pelagians; nor did they hesitate in declaring, after the example of Zuingle himself, that the kingdom of Heaven was open to all who lived according to the dictates of right reason; whereas Calvin maintained, that the everlasting condition of mankind in a future world was determined from all eternity by the unchangeable order of the Deity, and that this absolute determination of his will and good pleasure was the only source of happiness or misery to every individual. Moreover, Zuingle and Calvin differed in their notions of ecclesiastical government. The former ascribed an absolute and unbounded power, in religious matters, to the civil magistrate; allowing at the same time of a certain subordination among the ministers of the church, and placing at their head a perpetual president or superintendent, with a certain degree of inspection and authority over the whole body; but Calvin, on the contrary, reduced the power of the magistrate, in religious matters, within narrow bounds; declaring the church a separate and independent body, endowed with the power of

legislation for itself, and maintaining that it was to be governed, like the primitive church, only by presbyters and synods, *i. e.* by assemblies of elders, composed both of the clergy and laity, and leaving to the civil magistrate little else than the privilege of protecting and defending the church, and providing for what related to its external exigencies and concerns. These and other circumstances prevented the union of the Lutheran and reformed churches; though in process of time almost all the latter churches adopted the theological system of Calvin. *Mosh. Eccl. Hist. Eng. ed. 8vo. vol. iii. and vol. iv.*

ZULAFU, in *Geography*. See SULAU.

ZULE, a town of South America, in the new kingdom of Grenada; 5 miles S. of Pamplona.

ZULIANA, a town of the republic of Ragusa; 30 miles W.N.W. of Ragusa.

ZULLICHAU, a town of the New Mark of Brandenburg, formerly in the duchy of Crossen. This town is the capital of a district, or circle, and the seat of an ecclesiastical inspection, situated in a low plain, half a German mile distant from the Oder, and about the same distance from the Ober. The town itself consists only of 250 houses, one parish-church, and a grammar-school; but it has four large suburbs: without the walls is a feat belonging to the king of Prussia, fortified with walls and moats, which serves for the residence of the king's receiver of the prefecturate; in this part also stands the Calvinist church. Zullichau contains a good woollen manufacture; 37 miles S.E. of Francfort on the Oder. N. lat. 52° 8'. E. long. 15° 45'.

ZULPHA, or JULFA, a town of Persia, in the province of Irak, on the S. side of the Zenderoud, about a mile and a half from Ispahan, to which it is considered as a kind of suburb: it was built by Abbas I. after he had destroyed Zulpha, in Armenia. In the year 1722 this town was taken by the Afghans, under Maghmod, who demanded of the inhabitants the sum of 70,000 tomans. This suburb has been reduced from 12,000 to 600 families, which is the case with respect to most of the others; and a person may ride for miles amidst the ruins of the immense capital, Ispahan, which nevertheless still boasts of 200,000 souls. In the suburb of Julfa, there still remain nine churches, in which weekly service is performed.

ZULPHA, or *Julfa*, a town of Persian Armenia, on the Aras or Araxes, supposed to be the ancient Arriamene. This town was taken and destroyed by Abbas I., who removed the inhabitants to Ispahan, where they built a fauxbourg, called *Zulpha*, containing 4000 houses; some families, nevertheless, returned back to their native place, and took up their residence among the ruins; 60 miles N. of Tauris.

ZULPICH, or ZULCH, a town of France. This town contains three churches, and several cloisters. In the year 406, Klodwig, king of the Franks, overcame the Alemanni near this place; 18 miles S.W. of Cologn. N. lat. 50° 43'. E. long. 6° 34'.

ZULTZ, or BIALA, a town of Silesia, in the principality of Oppeln, and capital of a circle; 20 miles S.S.W. of Oppeln.

ZULUCK, a small river of Russia, in the country of the Cossacks, which runs into the Kardaï, near Babere-zovskaïa.

ZULZ, a town of the Grisons, in Upper Engadine, on the Inn; 31 miles N.N.E. of Chiavenna.

ZUM BOIRS, a town of Germany, in the county of Bregentz, on the river Bregentz; 18 miles S.S.E. of Bregentz.

ZUM *Glosterlin*, a town of Germany, in the county of Pludentz, on the river Alfens; 9 miles E. of Pludentz.

ZUM *Hofst*, a town of Germany, in the county of Bregentz, on the river Bregentz; 15 miles S.S.E. of Bregentz.

ZUM *Stein*, a town of the duchy of Berg; 3 miles N.E. of Blankenberg.

ZUM *Vogelgang*, a town of France, in the department of the Roer; 3 miles S.E. of Juliers.

ZUM *Zontags*, a town of Germany, in the county of Bregentz; 24 miles S.S.E. of Bregentz.

ZUMALA, or CUMATA, a town of Spain, in the province of Guipuscoa, near the coast of the bay of Biscay; 14 miles W. of St. Sebastian. N. lat. 43° 17'. W. long. 1° 51'.

ZUMAMPA, a town of South America, in the government of Tucuman, in the Rio Dolce; 90 miles S. of St. Yago del Eitero.

ZUMELLA, a town of Italy, in the Trevifan; 10 miles N.W. of Ceneda.

ZUMIC ACID, in *Chemistry*, a name given by Dr. Thomson to a peculiar acid principle lately obtained by M. Braconnot from rice, and which that gentleman had absurdly called *Nanceic acid*, from *Nancy*, the name of the city where he resided.

This acid was obtained by fermenting rice in water by the application of a gentle heat. An acid liquor was obtained, which on evaporation to dryness left a gummy mass, having a very sour taste. This was digested in alcohol, which on evaporation let fall crystals composed of the peculiar acid and lime. The lime was thrown down by barytes, and the barytes afterwards separated by sulphuric acid, and thus the acid obtained in a separate state.

Zumic acid is colourless, has a very acid taste, and does not crystallize. It precipitates none of the metals from their solutions, except zinc from very concentrated solutions of its salts.

With potash and soda it forms incrySTALLIZABLE deliquescent salts, soluble in alcohol. With ammonia it forms a crystallizable salt.

The neutral zumate of lime crystallizes confusedly in a form somewhat resembling a cauliflower. It is opaque, very white, has little taste, and has the appearance of having effloresced.

We do not think it necessary to detail the properties of the other compounds of this acid, which have been but little examined, and appear to be totally devoid of interest.

Dr. Thomson thinks the zumic acid is the same with the lactic acid, the latter being probably disguised as usually obtained, by the presence of some animal matter.

ZUMPANGO, in *Geography*, a town of Mexico; 90 miles S. of Mexico.

ZUMAPANO, a town of Mexico; 20 miles N. of Mexico.

ZUNAC, a town of South America, in the audience of Quito; 30 miles N.W. of Macas.

ZUNAPA, a small island in the Adriatic. N. lat. 43° 7'. E. long. 17° 7'.

ZUNCOLO, a town of Naples, in Principato Ultra; 17 miles S. of Conza.

ZUNDEL, a town of Silesia, in the principality of Neisse; 5 miles S.S.E. of Grotkau.

ZUNGER, a town of Prussia, in Pomerelia, at the mouth of the Nogat; 8 miles W.N.W. of Elbing.

ZUNG-GAR, a town of Tunis, anciently called *Zuchara*. Here are the ruins of a temple, and an aqueduct erected for the purpose of conveying water to Carthage; 48 miles S.W. of Tunis.

ZVORNICK. See ZWORNICK.

ZUPU, a town of Circassia; 160 miles E. of Theodosia.

ZUR GUGEL, a town of Prussian Pomerelia; 20 miles S.E. of Marienburg.

Zur *Osis*, a town of the duchy of Bremen; 5 miles S.S.W. of Bremervorde.

ZURA, a town of European Turkey, in Moldavia, on the Dniester; 22 miles E. of Orhei.

ZURARA, a town of Portugal, in the province of Entre Duero e Minho, at the mouth of the Ave, opposite Villa de Conde.

ZURBARAN, FRANCISCO, in *Biography*, was a Spanish painter, born at Triente da Cantos, near Seville, in 1596. He was a disciple of Pablo Roclas, under whose tuition he acquired very considerable talent, and soon enjoyed a good reputation as an artist. He adopted the style of M. A. Caravaggio, painting with great boldness, force, and truth. His first public work was painted for the convent of La Merced Calzada, from the history of S. Pedro Nolasco, by which he added much to his fame. There are many other works of his in the public edifices at Seville and Cordova, particularly in the Collegio di San Pablo. He was invited to Madrid about 1630, and was appointed principal painter to the king, and employed in the Buen Retiro, where he painted the Labours of Hercules. His productions may also be found in the Casa da Campo, and other royal palaces, as well as in private collections. Zurbaran died in 1662, aged 63.

ZUREITA, in *Geography*. See ZUWEITA.

ZURIC, or ZÜRICH, a canton of Switzerland, and the first in rank, bounded on the N. by Swabia and the canton of Schaffhausen, on the E. by the Thurgau and the county of Toggenburg, on the S. by the cantons of Schweiz and Zug, and on the W. by the county of Baden. This canton is not unaptly called an epitome of all Switzerland, as containing in it hills, valleys, plains, corn-lands, vineyards, lakes, rivers, vegetables of all kinds, and whatever else is necessary to the support of life. Grain is cultivated all over the country; but it ripens later in the mountainous parts, where the air is coldest, than in the levels or funny valleys. The hilly grounds in the E., W., and S. borders, afford a specimen of the fertile Alps, as abounding in cattle, milk, butter, and cheese; at first the wines have a taint attending them, yet they improve by keeping; and, after lying some years in the cask, become smooth, pleasant, and wholesome. Fruits also are every where found in great plenty, and very good. The most remarkable minerals and fossils are, chalk, potters' earth of several sorts and colours, sulphur, and pit-coal; some mineral springs are likewise found. The proportion of grain to the other productions of the earth will appear from the following calculation: there are 217,424 acres, of 36,000 square feet each, laid out in grain, 14,466 in vines, 94,553 in meadows, 42,549 in pasturage, and 103,772 in forests. As sufficient corn is not produced for the interior consumption, the deficiency is chiefly supplied from Swabia. In order to prevent a scarcity of this material article, a public granary is maintained, at the expence of government, for grain at the common price; but in seasons of scarcity, it is sold considerably cheaper than it can be purchased at the market. The wine is mostly consumed in the country, and little of it is spared for foreign commerce. The canton contained, in 1784, 174,572 souls, including 10,500 in the capital: this large population, in proportion to the size of the canton, is owing to the trade of Zuric; as at least two-thirds of the inhabitants derive their livelihood by spinning thread and

filk, and making linen for the manufactures of the town. The sovereign power resides exclusively in the burgeses of the town, consisting of about 2000; but a contracted disposition prevails in most of the states of Switzerland, so that they seldom confer the burghership. In Zuric, it is said, a new citizen has not been admitted for the last 150 years.

The burghers, beside the advantage of electing their magistrates, and of aspiring to the administration of affairs, enjoy the sole right of commerce; all strangers, and even subjects, being excluded from establishing manufactures in the city, or in any part of the canton.

The burghers of Zuric are divided into thirteen tribes; one of which is called Constafler, or the tribe of nobles, although at present not absolutely confined to persons of that description: it enjoys the privilege of giving eighteen members to the Sovereign Council, and six to the Senate, whereas each of the other tribes only supply twelve to the former, and six to the latter.

The legislative authority is vested by the burghers in the Sovereign Council of two hundred; consisting, however, of two hundred and twelve members drawn from the thirteen tribes, and comprising the Senate, or Little Council. This Senate, composed of fifty members, including the two burgomasters, has jurisdiction in all causes civil and criminal: in civil cases, when the demand is of a certain importance, an appeal lies to the Council of two hundred; but in criminal affairs, their sentence is final, and, when once passed, there is no reverfal or mitigation.

It is to be regretted, that in this republic, as in most other states of Switzerland, there is no precise code of criminal law. The Caroline, or code of Charles V., is ostensibly followed; but on account of its obsolete usages and extreme severity, the sentence is ultimately left to the discretion of the magistrates.

The power of the Senate, considered in a collective capacity, is very considerable: it judges finally in all criminal causes, has the care of the police, and supplies the principal magistrates. But as too great a power of individuals is dangerous in a republic, the members of this assembly are liable to be changed, and a revision or confirmation is annually made, in some instances by the Sovereign Council, in others by the particular tribes to which the senators belong. This annual revision is a great check to mal-administration, and at the same time prevents the Senate from gaining so great an influence as to be detrimental to the liberties of the people. A burgher is qualified to vote at twenty; is eligible into the Sovereign Council at thirty; and into the Senate at thirty-five. The canton of Zuric is divided into districts or bailiages, which are governed by bailiffs nominated by the Sovereign Council, exercising an authority subject to certain restrictions. The reformation was begun by Zuinglius, in the year 1517, in the town of Zuric; and in 1524, gained footing in the whole canton.

The militia of the canton amounted, in 1781, to 25,718 infantry, 1025 artillery, 886 dragoons, and 406 chaceurs; in all 28,235 effective men. The arsenal is well supplied with cannon, arms, and ammunition; and contains a reserve of muskets for 30,000 men. This canton had formerly a regiment and some companies in the service of France, a regiment in that of Holland, and some companies in the service of the king of Sardinia.

In ecclesiastical affairs the Senate is supreme: the canton is divided into fourteen districts, each governed by a dean, chosen by the synod, from three candidates proposed by the clergy of the diocese. The synod, composed of the whole clergy, and several assessors on the part of the Little Council, meets twice a year. The principal ministers and professors

ZURIC.

in the town constitute, in conjunction with several magistrates and other assessors, deputed by the civil power, an ecclesiastical and academical council: to this committee the deans recur in all concerns, which seem to exceed their jurisdiction: it determines lesser affairs, and refers cases of importance to the Senate.

During the French revolution, the canton of Zurich, after a feeble resistance, surrendered to the arms of the invaders; and the national assembly, which had been convoked, acceded to the new organization of the Helvetic constitution.

ZURIC, a city of Switzerland, and capital of a canton of the same name, situated on a large lake, where the river Limmat is discharged, which divides it into two parts; supposed to have been built on the site of the ancient Tigurum, which was destroyed by the Allemanni.

The environs are very delightful; an amphitheatre of hills gradually sloping to the borders of the water, enriched with pasture and vines; dotted with innumerable villages, cottages, and hamlets; and backed on the W. by the Udlberg, a bold and gloomy ridge stretching towards the Alps, and that chain of mountains which rises gradually to the Alps. Of the two parts into which the town is divided, the old part is surrounded with the same ancient battlements and towers which existed in the thirteenth century, and the suburbs are strengthened by fortifications in the modern style, but too extensive. The ditches, instead of being filled with stagnant water, are mostly supplied with running streams. The public walk is pleasantly situated in a lawn, at the junction of the Limmat and the Sihl, an impetuous and turbid torrent, which descends from the mountains of Einsidlin: two rows of lime-trees planted by the side of the Limmat, and following its serpentine direction, afford an agreeable shade in the heat of summer. The inhabitants are very industrious; and carry on with success several manufactures: the principal are those of linens and cottons, muslins, and silk-handkerchiefs. The manufacturers do not in general dwell within the walls; but the materials are mostly prepared, and the work is completed in the adjacent districts. For this reason, Zurich does not exhibit the activity and numbers of a great commercial city. The environs, on the contrary, are so extremely populous, that perhaps few districts in the neighbourhood of a town, whose population scarcely exceeds 10,000 inhabitants, contain within so small a compass so many souls. The streets are mostly narrow; the houses and public buildings accord more with plainness and convenience, than with the elegance and splendour of a capital. In 1780 the town contained 10,550 souls; but the population had decreased from the difficulty of obtaining the burgherhip; whereas luxury and opulence had very considerably increased. In general, however, the manners of the inhabitants are simple. Dinner is usually served at twelve: in the afternoon the gentlemen assemble in clubs, or small societies, in the town during winter, and at their respective villas in summer. They frequently smoke, and partake of wine, fruit, cakes, and other refreshments. The women, for the most part employed in their domestic occupations, or devoted to the improvement of their children, are not fond of visiting. This reserve, however, has much abated, and gives place to a more sociable intercourse. Such, however, is the prevalence of national habit, that a few families, which form a more agreeable mixture of company, are considered as differing from the established customs, and are still known by the name of the French Society. Sumptuary laws are well observed. Amongst these, the use of a carriage in the town is prohibited to all sorts of persons except strangers; and it is

almost inconceivable, that in a place so commercial and wealthy, luxury should so little prevail.

Zuric was formerly an imperial city, and obtained from the emperor Frederick II. very considerable privileges; which were acknowledged and augmented by several of his successors. The civil war between the magistrates and the people in 1335 nearly reduced the city to ruins; but the former being banished, the citizens, in 1337, established a new form of government, which was confirmed by the emperor Louis of Bavaria. The exiles, after several fruitless attempts, were at length re-admitted; but engaging in a conspiracy against the citizens, were discovered and put to death. In consequence of this execution, the nobles in the neighbourhood took up arms; and Zurich, after having ineffectually applied for assistance to the emperor Charles IV., formed an alliance with Lucerne, Uri, Schwitz, and Unterwalden, and was admitted a member of their confederacy. This event happened in the year 1351. The four cantons yielded the pre-eminence to Zurich: a privilege it enjoys at present; being the first canton in rank, and the most considerable in extent, both of territory and power, next to Berne. In the same year, Zurich was assisted by the four cantons against Albert, duke of Austria, who besieged the town, and was repulsed with great loss.

Zuric was the first town in Switzerland that separated from the church of Rome, being converted by the arguments of Zuingle.

The charitable establishments at Zurich are, the orphan-house, which is regulated with extreme attention and care; an alms-house for poor burghers; an hospital for incurables, and that for the sick of all nations, which usually contains between six or seven hundred patients; and the Allmosen-Amt, or foundation for the poor: this excellent institution puts out children as apprentices; and distributes money, clothes, and books of devotion to poor persons, as well in the town, as in different parts of the canton, at the recommendation of the respective ministers. Here is also a chirographical seminary, formed by voluntary subscriptions, to the support of which, Dr. Rhan, an eminent physician, was a liberal contributor.

At Zurich public education is a concern of the state, and under the immediate protection of government. The office of a professor gives rank and estimation, and is often held by a member of the Senate and of the Great Council. The principal literary establishments for the instruction of youth are, the Caroline college for students in divinity; *Collegium Humanitatis*, or the college for polite literature; and the school of arts: the first has twelve professors, the second two, and the last seven. The learned languages, divinity, natural history, mathematics, and in short every species of polite learning, as well as abstract science, is taught at a small expence in these respective seminaries.

In consequence of the peculiar attention paid by government, since the reformation, to the education of youth, Zurich has produced many persons, who have distinguished themselves in all departments of literature: among these we may reckon Zuingle and Bullinger, Conrad Gesner, Hottinger, Simler, Spon, Scheutzer, Heidegger, Breitinger, Bodmer, Hirtzel, Solomon Gesner, and Lavater. For each of these distinguished persons, see our biographical articles.

Dr. Hirtzel was a learned physician, and deservedly styled the Swiss Plutarch: he distinguished himself, among various publications, by the *Socrate Rustique*, and by the lives of Sultzer and Heidegger. Leonhard Meiter, professor of history and morality in the school of arts, deserves mention, on account of his numerous and valuable publications, in all which he has displayed great zeal for the promotion of

literature, correctness of taste, liberality of sentiment, and extensive historical and biographical knowledge. In his observations on fanaticism and intolerance, he has forcibly evinced their dreadful effects on government and civil society by historical facts, and approved himself an able writer in combating perfection, and in repressing the prevalent spirit of fanaticism.

The public library at Zuric contains about 25,000 volumes, and a few curious MSS., of which latter are, the original MS. of Quintilian, the Psalms in the Greek tongue, written on parchment dyed of a violet colour, the letters being silver and golden, and the marginal reference red, somewhat similar to the "Codex Argenteus" of Upfal, and supposed to have once formed a part of the "Codex Vaticanus," and several MSS. of Zuingli. Zuric is a district 41 miles S.E. of Bale, and 36 S.W. from Constance. N. lat. $47^{\circ} 18'$. E. long. $8^{\circ} 25'$. Coxe's Travels in Switzerland, vol. i.

ZURIC, a lake of Switzerland, situated in the canton to which it gives name, about 10 leagues in length, and one in breadth, of an oblong form; and though not so large as that of Constance, more thickly studded with villages and towns. The adjacent country is finely cultivated, and well peopled; and the southern part of the lake appears to be bounded with the high stupendous mountains of Schweitz and Glarus. The scenery is picturesque, lively, and diversified.

ZURIMACZOW, a town of Austria Poland; 22 miles S. of Luckow.

ZURITA, a town of Spain, in New Castile, on the left bank of the Tagus; 48 miles N.E. of Toledo.

ZURITO, a town of Peru, in the diocese of Cusco; 12 miles N.W. of Cusco.

ZURLINDEN, a town of Prussia, in the palatinate of Culm; 18 miles E.N.E. of Thorn.

ZURMENTUM, in *Ancient Geography*, a town in the interior of Africa Propria, S. of Adrumetum. Ptol.

ZURNAPA, in *Zoology*. See CAMELOPARDAL.

ZURUPALCA, in *Geography*, a town of Peru; 44 miles S. of Potosi.

ZURZACH, a town of Switzerland, in the county of Baden, on the Rhine, chiefly celebrated for its fairs, at which great quantities of goods are sold by the merchants from Germany, France, and Italy; 25 miles E. of Bale.

ZURZONZA, a town of Mexico, in the province of Mechoacan, situated on an island in a lake; 20 miles W. of Mechoacan.

ZURZURA, in *Ancient Geography*, a town of Asia, in the Greater Armenia. Ptol.

ZUSAM, in *Geography*, a river of Bavaria, which runs into the Danube, opposite Donauwert.

ZUSCHEN, a town of Germany, in the county of Waldeck; 4 miles N.W. of Fritzlär.

ZUSCHEN, or *Zuchenau*, a town of Germany, in the duchy of Westphalia; 5 miles S.W. of Medebach.

ZUSEL, a river of France, which runs into the Roer, at Susteren.

ZUSMERSHAUS, a town of Bavaria, in the territory of Augsburg; 13 miles N.W. of Augsburg.

ZUSNIN, a town of Istria; 11 miles N.N.E. of Pedena.

ZUTPHEN, a city of Holland, and capital of a county to which it gives name, situated on the river Berckel, which passes through the middle of it, fills its ditches, and immediately joins the Iffel. It takes its name from the two Flemish words "Zudt Vunen," which signify Southern Meadows. The principal buildings are, the church of

St. Walburge, the town-house, the college of the deputies of the comté, and an ancient building, which they call "s'Graven-Hof," or Palace of the Comté. Otho I. of Nassau, acquired this country in the 11th century, by his marriage with the heiress of Gerlach, count of Zutphen, since which it has ever been annexed to Guelderland; 7 miles S. of Deventer. N. lat. $52^{\circ} 10'$. E. long. $6^{\circ} 5'$.

ZUTPHEN *Islands*, a group of small islands, in the straits of Sunda. S. lat. $5^{\circ} 50'$. E. long. $105^{\circ} 42'$.

ZUTZ, a town of Switzerland, in the league of the Grisons, on the Inn. This town, though not the largest, is reckoned the principal place of Upper Engadine, because it contains the criminal court of justice. This court consists of the landamman of Sotto, one of the two communities of Upper Engadine, who is president, and sixteen jurymen, called Trouadors, taken equally from each district. Justice is said to be more equitably administered in this court than in any other throughout the Grisons, excepting at Coire. The vicinity of Zutz, and also of Scampf, is the finest part of the valley of Engadine; it there produces some rye and barley, and the mountains are clothed with verdure to their very fummits.

ZUURE-VELDT, a division of Graaf Reynet, which is an extensive plain country, stretching from the Sunday river, in Zwartkop's bay to the great Fish river, and is the same kind of good arable or pasture land as the plains of the Antiniequas division in Zwelendani; but it is now exclusively in the possession of the Kaffers, from whom it was originally taken by the Boors. The great chafms towards the sea-coast, that are filled with thickets, abound in elephants and buffaloes; and in the great Fish river are, occasionally at least, found a few of the hippopotamus, or river-horse.

ZUWEITA, or ZUREITA, a town of the Arabian Irak; 35 miles S.E. of Helleh.

ZUYDER-ZEE, or ZUIDER-SEE, a great gulf or bay of the German ocean, which extends from south to north, in the United Provinces, between Friesland, Overissel, Guelderland, and Holland. It is so called from its situation towards the south, and is said formerly to have been a lake, and that the land is swallowed up that united North Holland with Friesland.

ZUZAN, a town of Persia, in that part of Khorassan which extends from N. lat. $32^{\circ} 30'$ to $34^{\circ} 40'$, and from 56° to 62° of E. long. It is the ancient "Susa," now an inconsiderable place, situated at the same distance from Pashing as the latter is from Herat.

ZUZON, a town of Spain, in Old Castile; 22 miles N.E. of Siguena.

ZUZYGIUM, in *Botany*. See SYZYGIUM and CALYPTRANTHES, to which latter genus belongs the original *Suzygium* of Browne.

ZWAMMERDAM, or ZWADENBURGERDAM, in *Geography*, a town of Holland, on the Rhine, which was pillaged and burned by the French, in the year 1762; 6 miles N. of Gouda.

ZWARTE-BERG, as well as *Cango* and *Trada*, are divisions of Zwelendani, which are the Karroo plains, situated between the first and second chains of mountains, but being well watered by the mountain streams contain fertile patches of ground. Their great distance, however, from the Cape, and very bad roads, prevent an extensive tillage. In these plains are numerous ostriches, and herds of quachas, zebras, and hartebeests. Behind the first chain of mountains, in these divisions, are two hot springs of chalybeate water.

ZWARTE-BERG is also a division of Graaf Reynet, which

is a portion of the mountain of the same name, in the district of Zwelendam, to which it ought properly to belong. Sheep and horned cattle are the chief produce of the farmers.

ZWARTE-KOP's River is a fertile and extensive division of Graaf Reynet, lying to the southward of Zwarde-Ruggens, and capable of producing an abundant supply of grain, convenient to be delivered at a trifling expence at the bay. About 15 miles to the westward of the bay are large forests of timber-trees, near which is an appearance of a rich mine of lead. Near the bay is also a salt lake, which yields a plentiful supply of that article. Wax from the *myrica cerifera* and aloes might be furnished by this division as articles of commerce.

ZWARTE-RUGGENS, a division of Graaf Reynet, which is a stony tract of country to the southward of Camdeboo, another division lying at the foot of the snowy mountains. It is very fertile supplied with water, and produces little except succulent plants, among which are two or three species of euphorbia. Few families are found in this division, but here and there in the neighbourhood of the Sunday river, which runs through it. The cattle and sheep are small, but generally in good condition.

ZWARTKOP'S BAY. See ALGOA Bay.

ZWARTLAND, EAST, and *Twenty-four Rivers*, are two divisions of the district of Stellenboich and Drakenstein, consisting of widely-extended plains, stretching in breadth, from the Berg river to the great chain of mountains, and to the Picquet Berg, in length, to the northward. These are considered as the granaries of the colony. The crops, however, in Zwartland, are as uncertain as the rains, on which their success almost entirely depends. In the *Twenty-four rivers*, the grounds may be irrigated by the innumerable streamlets that issue from the great chain of mountains, in their course to the Berg river. These form swamps, that have been productive of very fine rice. Wheat, barley, and pulse, are the principal articles that are cultivated in those two divisions; but they have also plenty of fruit, and make a little wine for family use.

ZWELLENDAM, a tract of country in southern Africa, which lies upon the sea-coast between Breede river on the W., and Camtoos river on the E., and extends northerly to the second chain of mountains, called the Zwarde-Berg, or Black mountains. The length is about 380 and breadth 60 miles, comprehending an area of 19,200 square miles, which is occupied by 480 families, so that each family has, on an average, 40 square miles of land. The population of Zwelendam, ascertained on oath in the year 1798, consisted of 3967 Christians, and 2606 slaves and Hottentots, making a total of 6663. The flock and produce comprehended 9049 horses, 52,376 horned cattle, 154,992 sheep, 220½ leggers of wine made, 16,720 muids of wheat reaped in 1797, and 10,554 muids of barley and rye.

ZWELLENDAM, *Drofsdy*, or village of, a division of Zwelendam, situated at the foot of the first chain of mountains that runs E. and W., or parallel to the sea-coast, and distant from Cape Town about 140 miles. It is composed of about 30 houses, scattered irregularly over a small but fertile valley, down the middle of which runs a plentiful stream of water. At the head of the valley stands the house of the landroft, to which is annexed a large garden well stocked with a variety of fruits, and a spacious vineyard; the whole enclosed and planted with oaks and other trees. In the middle of the village a large church has been lately erected, which is the only place of worship in the whole district. The other divisions of Zwelendam are, the country between

the drofsdy and Gauritz river, named according to the rivers that cross it, Congo, Zwarde-Berg, Trada, Mofel bay, Autinieguas land, Plettenberg's bay, Olifant's river, Kamnaaic, Lange-Kloof, and Sitfikamma. Barrow's Southern Africa, vol. ii.

ZWENCKAU, a town of Saxony, in the principality of Merseburg, on the Elster. In the year 1429, this town was burned by the Huffites; 5 miles S. of Leipfic. N. lat. 51° 14'. E. long. 12° 18'.

ZWENTENDORFF, a town of Austria; 6 miles W. of Tulln.

ZWERCHBACHLEIN, a river of Wurtemberg, which runs into the Nagold, near the town of Nagold.

ZWERNITZ, a town of the principality of Culmbach; 10 miles S.W. of Culmbach.

ZWERNTLDORFF, a town of Austria; 6 miles E. of Weikendorf.

ZWETHAN, a town of Saxony; 20 miles S.E. of Wittenberg.

ZWETL, a town of Austria, at the conflux of the Zwetl and the Kamp; 26 miles W.N.W. of Crems. N. lat. 48° 33'. E. long. 15° 7'.

ZWETL, a river of Austria, which rises about four miles west from Weitra, and runs into the Kamp, at Zwetl.

ZWETZEN, a town of Thuringia; 3 miles N. of Jena.

ZWETZEY, a town of Croatia, on the river Mreunitza; 12 miles S. of Sluin.

ZWEYBRUCKEN. See DEUX-PONTS.

ZWEYDRITTELSTUCK, or *Piece of Two-thirds*, in Commerce, a silver coin in Germany, worth two-thirds of a six-dollar of account.

ZWIAHEL, in Geography, a town of Russian Poland; 90 miles E. of Luckow.

ZWICKAU, a town of Saxony, in Erzgebirg, on the Mulda. It has a citadel, three churches, and a Latin school, in which is a good library: here is a manufacture of cloth, and another of cards, for the use of wool-combers; with a considerable inland trade; 38 miles S.S.E. of Leipfic. N. lat. 50° 30'. E. long. 12° 25'.—Also, a town of Bohemia, in the circle of Boleflau; 4 miles W. of Gabel.

ZWIELLAUKA, a town of Moravia, in the circle of Olmutz; 26 miles W. of Olmutz.

ZWIFALTEN, a princely abbey founded in the year 1089. In 1802, it was given among the indemnities to the duke of Wurtemberg; 58 miles W. of Augsburg. N. lat. 48° 17'. E. long. 8° 30'.

ZWINGENBERG, a town of Hesse Darmstadt, situated on the Bergstraffe. In 1693, the greater part of this town was destroyed by the French, since which it has been rebuilt in a better manner; 10 miles S. of Darmstadt.

ZWINGENDORFF, a town of Austria; 2 miles S. of Laab.

ZWINGERA, in Botany, a genus taken from Aublet, dedicated under this name to the memory of several Swiss botanists of the family of Zwinger, who for three generations have cultivated this science at Basil, chiefly, indeed, with a reference to the medical qualities of plants. Theodore Zwinger, professor of anatomy and botany in that university, who died in 1724, aged 67, published in 1696 a folio German Herbal, of 995 pages, with wooden cuts, borrowed from Gesner and Camerarius, which is little known out of his own country. Some botanical dissertations also appeared under his presidency. His son Frederick gave an enlarged edition of the above Herbal in 1744; and has published in the *Ada Helvetica*, v. 1. 50, a plate and description of a very remarkable fungus, apparently belonging to

Peziza, but of which we find no notice taken by Perfoon. The *NOLANA* of Linnæus, (see that article,) was once published under the name of *Zwingera humifusa*, by John Hofer, in *Ab. Helvet.* v. 5. 267. t. 1, but this plant has had many names besides.—Schreb. Gen. 802. Willd. Sp. Pl. v. 2. 569. Mart. Mill. Dict. v. 4. (Simaba; Aubl. Guian. 400. Juff. 373.)—Clafs and order, *Decandria Monogynia*. Nat. Ord. *Terebinthaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, small, in five deep, ovate, acute segments. *Cor.* Petals five, oblong, obtuse, spreading. *Stam.* Filaments ten, capillary, dilated and hairy at the base, shorter than the corolla; anthers ovate. *Pist.* Germen superior, feated on a glandular receptacle, roundish, with five deep furrows; style longer than the stamens, thread-shaped, striated; stigmas five, simple. *Peric.* Capsules five, coriaceous, ovate, spreading, of one cell. *Seeds* solitary, ovate.

Eff. Ch. Calyx in five deep segments. Petals five. Filaments dilated and hairy at the lower part. Capsules five, coriaceous, feated on a fleshy receptacle. Seeds solitary.

Obf. The flowers are said to be occasionally only four-cleft and octandrous. This genus is not much akin, as Willdenow thought, to *QUASSIA*, but rather to *CNETHIS* (see those articles); differing from the latter in having one style instead of five. How far their fruits correspond, we know not enough of the feed-vessel of *Zwingera* to determine.

1. *Z. amara*. Bitter *Zwingera*. Willd. n. 1. (Simaba guianensis; Aubl. Guian. 400. t. 153.)—Native of the woods of Orapu in Guiana, bearing flowers and fruit in June. A shrub, not more than seven or eight feet high, whose stem is three or four inches in diameter, with a white soft wood. Branches numerous, alternate. Leaves alternate, stalked, either ternate, or pinnate, of two or three pair, with an odd one, of elliptic-lanceolate, pointed, emarginate, entire, smooth leaflets, the largest of which are three and a half inches long, and an inch, or more, in breadth. Flowers five or six together, in little axillary clusters. Petals whitish, furrounding the green disk. Fruit yellow; the inner rind green and bitter. Nothing is recorded concerning the qualities or uses of this shrub.

ZWISSEL, in *Geography*, a town of Bavaria, on the Regen; 42 miles E. of Ratibon.

ZWITTAU, or ZWITAWA, a town of Moravia, in the circle of Olmutz; 30 miles N.W. of Olmutz. N. lat. 49° 43'. E. long. 16° 16'.

ZWITTAU, a river of Moravia, which rises in the south-east part of Bohemia, and joins the Swarta, near Brunn.

ZWOL, or SWOL, a town of Holland, in the department of Overissel, situated on the river Aa, between the Iffel and the Vecht, in the country of Zallant. It is a strong place, well fortified, and furrounded with a double ditch, filled with the waters of the Aa. Its situation is very advantageous, on an eminence which commands the country, and is the ordinary passage from Holland to the provinces of Friesland, Groningen, and Overissel. It was formerly a free and imperial city, and ranked among the Hanse towns. The magistracy is composed of eight echevins, and eight common-council. The celebrated Thomas à Kempis, another wife called Hamerken, was a regular canon in a priory of Augustines in this place, and died here in 1471, aged 91; 28 miles S.W. of Covorden. N. lat. 52° 32'. E. long. 6° 1'.

ZWOLFAING, a town of Austria; 8 miles S.S.E. of Vienna.

ZWONIGRAD, a town of Dalmatia, and capital of a district; 60 miles S.E. of Segna.

ZWONITZ, a town of Saxony, in the circle of Erzgebirg; 4 miles N.N.W. of Grubenhagen.

ZWORNICK, a town of Bosnia; 63 miles S.W. of Belgrade. N. lat. 44° 37'. E. long. 18° 50'.

ZWOTA, or TZWONA, a river of Bohemia, which runs into the Egra, near Falkenanu.

ZYDACZOW, a town of Austrian Poland, in Galicia; 30 miles W.N.W. of Halicz.

ZYGENA, in *Ancient Geography*, an island in the northern part of the Arabic gulf. Ptolemy.

ZYGENA, in *Ichthyology*, a species of *squalus*, which fee; called by Willughby *balance-fish*. See also SHARK.

ZYGASTICUM, Ζυγαστικον, formed of ζυγος, a balance, among the *Ancients*, money paid for weighing things.

ZYGER, in *Geography*, a river of Hungary, which runs into the Kyros, 5 miles W. of Boros Jenó.

ZYGES, in *Ancient Geography*, a people of exterior Libya, towards the coast of the Mediterranean sea, W. of the Mareotide Nome. Ptolemy.

ZYGI, a people of Asia, of the number of those who inhabited the Cimmeric Bosphorus, between the Athæi and Heniuchi. Strabo.

ZYGIA, in *Botany*, Ζυγία of Theophrastus, the second kind of his σφινδαμνον, or Maple, remarkable for its wild and veiny wood, is spoken of as a mountain-tree, but botanists have not ascertained the precise species. Pliny's account of this matter is extracted and abridged from the above Greek author, but is not made at all more clear. He however seems to have been acquainted with a beautiful wood, of the Maple kind, which he says was compared to a peacock's tail, and grew chiefly in Ithria and Rhetia. Can this have been the *Acer Opalus* of modern authors? (See Willd. Sp. Pl. v. 4. 990.) Anguillara has long suspected that tree, which Linnæus and many other botanists have strangely overlooked, to have been the Ζυγία of Theophrastus. Its native country, and veined yellow wood, sometimes very beautiful, are in favour of this opinion. De Theis, following Bodæus a Stapel, and other commentators on Theophrastus, who are led by the obvious derivation of the name from ζυγος, a yoke, take the tree in question for our *Carpinus*, whose hard and tough wood serves to make yokes for oxen. He ingeniously supports this opinion by the Celtic origin of *Carpinus*, from *car*, wood, and *pin*, head; and further by its English synonym, *Hornbeam*, oxen being yoked by their horns. The wood of the *Carpinus*, however, is neither yellow nor beautifully veined, and it is most probable Ζυγία had some other origin, or allusion. Robert Constantine, cited by Bodæus a Stapel, seems to confound the *Acer Opalus* with *Viburnum Opulus*, which he terms "the *Opulus* of Columella, a French shrub, used for hovers." This last has nothing in common with the history of the Ζυγία.

Whatever may have been the ancient *Zygia*, Dr. Patrick Browne, finding this name unoccupied, has applied it to a Jamaica shrub, which appears to belong to *Mimosa*; see Browne Jam. 279. t. 22. f. 3. Nor is this application too unsuitable as may seem at first sight; for the author had evidently in his mind the yoked leaflets, to which he alludes in his specific definition. We do not find that Linnæus, except in manuscript, or any other author, has adopted this as a *Mimosa*. Jusseu, in his Gen. Pl. 366, ranges Browne's *Zygia*, with a few other genera, at the end of his *Leguminosæ*, adding a reference to *Mimosa Bourgois*, Aubl. Guian. t. 358, as a similar plant or genus. We do not see why it

was not placed near *Mimosa*, in the first section of that natural order. Swartz, Ind. Occ. 980, speaks of Browne's figure of the flower of *Zygia*, as exactly like his own *Mimosa comosa*, Prodr. 85; but he adds that the plants are different, without any further elucidation of the former. There is no specimen of *Zygia*, amongst the plants in the Linnæan herbarium, collected by Browne, and sent by Solander to Linnæus. In a manuscript catalogue of Jamaica plants, in Dr. Browne's own hand, given to the writer of this article by A. B. Lambert, esq., *Mimosa Zygia* stands between *Sagittaria* and *Unguis Cati*, with this remark, which is not in the author's History of Jamaica, "*folia bijugata, five sustentaculis bipartitis, singulis diphyllis.*" This plant is there called Yoke-wood. In the printed work it is denominated Horse-wood, or Hoop-wood, the wood being "pretty tough, and sometimes cut for hoops. The shrub is very common in St. Mary's, growing chiefly in low moist lands; but is sometimes found in the mountains, where it commonly rises to the height of ten or twelve feet, or better." These are all the particulars we can gather relative to Browne's *Zygia*.

ZYGIA, in the *Instrumental Music of the Ancients*, a flute peculiar to weddings, according to Apulcius. (Metam. lib. iv.) The word *zygia* is a Greek adjective, which implies *nuptial*. The *zygia* was probably a double flute; for Julius Pollux (Onomast. lib. iv. c. 10.) says, "there was also a flute air for the wedding; executed on two flutes, one longer than the other."

ZYGIA, in *Entomology*, a genus of insects belonging to the order of coleoptera, the characters of which are, that the antennæ are moniliform, the palpi unequal and filiform, the lip elongated and membranaceous, and the jaw undentated. There is one species, *vis*.

OBLONGA. Found in the East, oblong, red, with head and wing-sheaths cyanous.

ZYGIANA, in *Ancient Geography*, a country of Asia Minor, in Bithynia. Ptolemy.

ZYGIS, in *Botany*, the specific name of a species of *THYMUS*, (see that article, n. 9.) supposed to be the *ζυγίς*; of Dioscorides. De Theis, who writes this word *ζυγίς*; without any authority that we can find, derives it from *ζυγός*, the *bum of bees*, which is confirmed, apparently without his knowledge, by the modern Greek name of the same plant, *αζαζή*, the *delight of bees*. Such an appellation is peculiarly suitable to a plant well known to be highly grateful to those insects, and which is supposed to give its aromatic flavour to the famous honey of mount Hymettus, a spot where this *Thymus* abounds. Undoubtedly there are other species of the same genus, as well as of *Thymbra*, *Satureia*, &c., found in the same neighbourhood, which contribute to produce this flavour, in as powerful a degree perhaps as the above.

ZYGITÆ, in the *Roman Galleys*, a term used to express those rowers in the triremes, or three-rowed galleys, who sat on the second row, that is, above the thalamitæ, and below the thranitæ.

ZYGOMA, *Ζυγομαχία*, in *Anatomy*, a bone of the head, otherwise called os jugale; or, it is the bony arch under which the temporal muscle passes.

The word is formed from *ζυγισμός*, *I join*; so that *zygoma*, properly speaking, is the juncture of two bones. See *CRANIUM*.

ZYGOMATIC PROCESS of the temporal bone and os meæ: the parts contributing to form the *zygoma*.

ZYGOMATICUM, *Os*, the cheek-bone, so called

because it contributes largely to the formation of the *zygoma*. See *CRANIUM*.

ZYGOMATICUS, *Major and Minor*, muscles of the face, connected to the corner of the mouth. See *DEGLUTITION*.

ZYGOMATICUS is also an epithet given to the future that binds the two processes of the *zygoma* together.

ZYGOPHYLLUM, in *Botany*, so named by Linnæus, from *ζυγός*, a *yoke*, and *φυλλόν*, a *leaf*, of most of the species, being composed of a pair of leaflets, yoked, as it were, together, and somewhat resembling the foliage of the garden bean, *Vicia Faba*; whence this genus obtained, from Dodonæus and Tournefort, the name of *Fabago*. Hence also arose its English appellation of *Bean-Caper*, given by Gerard. *Fabago* was properly deemed inadmissible, being compounded of another name, though of one no longer in use as generic. We may observe moreover, that it conveys an erroneous idea; for the plant in question does not "bear beans," but leaves, resembling bean leaves.—Linn. Gen. 212. Schreb. 288. Willd. Sp. Pl. v. 2. 560. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 39. Sm. Prodr. Fl. Græc. Sibth. v. 1. 273. Juffl. 296. Lamarck Dict. v. 2. 441. Illustr. t. 345. Gartn. t. 112. (*Fabago*; Tourn. t. 135.)—Class and order, *Dicandria Monogynia*. Nat. Ord. *Grinales*, Linn. *Rutaceæ*, Jussl.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, obtuse, concave, erect leaves. *Cor.* Petals five, dilated upwards, obtuse, emarginate, rather longer than the calyx. Nectary of ten converging, pointed leaves, or scales, sometimes divided, embracing the germen, each of them attached to one of the filaments near its base. *Stam.* Filaments ten, awl-shaped, attached to the outside of the nectary, shorter than the corolla; anthers oblong, incumbent. *Pist.* Germen superior, oblong, tapering at the base; style awl-shaped, the length of the stamens; stigma simple. *Peric.* Capsule oblong, or roundish, with five angles and five intermediate furrows, five cells and five valves, the partitions linear, from the middle of each valve. *Seeds* several, roundish kidney-shaped, inserted alternately, in two rows, into the middle of the valves.

Obsl. Linnæus remarks, that the seed-vessel differs in shape in the different species, and that in some the flowers are four-cleft and octandrous. Schreber records an observation of Reichard, merely taken from the *Maniffa* of Linnæus, that *Z. album* has five *stigmas*; but we do not find this to be correct. Our fifteenth species is said to have five distinct *styles*.

Ess. Ch. Calyx of five leaves. Petals five. Nectary of ten scales, embracing the germen, and bearing the stamens. Capsule of five cells, superior.

The plants of this genus are, for the most part, shrubby, with simple or twin *leaves*, (rarely ternate or pinnate,) which are opposite, mostly stalked, entire, often scetid, of a thick or succulent texture, accommodated to the dry and sunny situations where the greater part of the species grow. A very few are found in South America, or Guinea; the rest are natives of Syria, Arabia, Siberia, and especially of southern Africa, about the Cape of Good Hope. The flowers are solitary, axillary, yellow, white, or reddish, often brilliant and rather handsome. The *seed-vessel*, though answering in general to the above description, which is made from *Z. Fabago*, is variously shaped in the different species, and in some appears to be lined with a sort of horny elastic coat, analogous to the tunic of the *seeds*, to be remarkable in the genuine *Rutaceæ*. Such is the case in *Z. microphyllum*,

the

ZYGOPHYLLUM.

the edges of whose inflexed valves seem to constitute the partitions; yet the cells do burst at the outer margin, as well as at the inner. Willdenow defines fourteen species, which we shall find a necessity of extending to sixteen.

1. *Z. simplex*. Cylindrical-leaved Bean-Caper. Linn. Mant. 68. Willd. n. 1. (*Z. portulacoides*; Forfk. *Ægypt.-Arab.* 88. Ic. t. 12. f. B.)—Leaves simple, sessile, cylindrical.—The most common of all plants in the driest parts of the deserts of Arabia, where it is known by the name of *Garmal*, and esteemed by the Arabs very good for removing specks in the eyes, for which purpose the bruised leaves are applied, mixed with water. For this we have the authority of Forskall, who sent seeds to Linnæus. These vegetated at Upsal, but the plants did not live to produce flowers. The root is simple, tapering, apparently annual. Stem prostrate, repeatedly forked, round, smooth. Leaves sessile at each joint, spreading, an inch long, obtuse, somewhat dotted. Flowers yellow, quarter of an inch in diameter, almost sessile. Petals round, with long claws.

2. *Z. cordifolium*. Heart-leaved Bean-Caper. Linn. Suppl. 232. Willd. n. 2. Thunb. Prodr. 80. Ait. n. 1.—Leaves simple, sessile, opposite, roundish, somewhat heart-shaped.—Gathered by Thunberg, at the Cape of Good Hope, from whence it was sent by Mr. Masson to Kew garden, in 1774. This is a green-house shrub, flowering in October. We have seen no specimen.

3. *Z. Fabago*. Common Bean-Caper. Linn. Sp. Pl. 551. Willd. n. 3. Ait. n. 2. (Capparis Fabago; Dod. Pempt. 747. Ger. Em. 897. Best. Eycl. æstiv. ord. 10. t. 1. f. 1. C. leguminosa; Lob. Ic. v. 2. 58. Fabago Belgarum; Dalech. Hist. 456. Telephium Diofcoridis; Column. Eeprh. 132. t. 131. Morgfani; Rauw. It. t. 113.)—Leaves conjugate, stalked; leaflets obovate. Calyx smooth. Petals entire. Capsule oblong. Stem herbaceous.—Native of Syria, Persia, Barbary, &c. A hardy, but not common, herbaceous perennial in our gardens, flowering in autumn, cultivated by Gerarde, in 1596, and seen a few years afterwards, in the garden of cardinal Aldobrandini, at Rome, by Fabius Columna, who took this plant for the *Telephium* of Diofcorides, and has left us a most faithful representation of it, too much neglected by Linnæus and recent authors, who only refer to Dodonæus. Whether Columna erred or not with respect to the name, the reader will judge by consulting the article TELEPHIUM. The root is tapering, fleshy, producing from its crown several spreading, alternately branched, leafy, round, herbaceous, smooth stems, one and a half or two feet high. Leaflets an inch long, entire, smooth, green, unequal at the base, furnished with a principal rib, and one or two smaller ones. Footstalks rather shorter than the leaflets, swelling upwards, smooth, channelled, crowned with a small, intermediate, awl-shaped point, like an abortive leaflet. Stipules between the footstalks, in pairs, membranous, ovate, pointed, oblique. Flowers yellow, on simple, axillary, opposite, nearly upright stalks, hardly so long as the footstalks. Calyx-leaves concave, quarter of an inch long, green, even, with a membranous edge. Petals rather longer, obtuse. Nectaries jagged, almost pectinate. Five of the stamens deflexed, five ascending. Capsule above an inch in length. Seeds numerous.

4. *Z. fetidum*. Fetid Bean-Caper. Schrad. Sert. Hanov. 17. t. 9. Willd. n. 4. Ait. n. 3. (*Z. insuave*; Curt. Mag. t. 372.)—Leaves conjugate, stalked; leaflets obovate. Calyx downy. Petals jagged. Capsule roundish. Stem shrubby.—Native of the Cape of Good Hope, from whence it was introduced in 1750, by Mr. Masson. This is a hardy green-house shrub, flowering all summer long, but rendered

undesirable by the strong fox-like scent of its leaves, resembling that of the Crown Imperial, and peculiarly offensive when the house is either shut up, or warmed by the sun. The shrubby stem distinguishes this species from the last; but the short, roundish, or obovate, fruit, and jagged petals, which are five times the length of the calyx, and marked with a red spot at the base of their limb, afford essential marks of difference. *Z. retrofractum* of Thunberg, cited with a mark of doubt by Willdenow, has no resemblance to either.

5. *Z. maculatum*. Spotted-flowered Bean-Caper. Ait. ed. 1. v. 2. 60. ed. 2. n. 4. Willd. n. 5.—“Leaves conjugate, stalked; leaflets linear-lanceolate.”—Native of the Cape of Good Hope, from whence it was introduced, in 1782, by George Wynch, esq. A green-house shrub, flowering in October and November. The petals are yellow, with a red heart-shaped spot, at the base of each, above which, in the three upper ones only, is a transverse red line. Aiton.

6. *Z. coccineum*. Scarlet-flowered Bean-Caper. Linn. Sp. Pl. 551. Willd. n. 6. (*Z. desertorum*; Forfk. *Ægypt.-Arab.* 87. Ic. t. 11. Fabago arabica teretifolia, flore coccineo; Shaw Afric. n. 231. f. 231.)—Leaves conjugate, on a fleshy stalk; leaflets cylindrical, smooth. Capsule oblong.—Plentiful in the arid valleys of the desert, between Cairo and Suez. The Arabs call this plant *Rottraji*. All kinds of cattle, even the camel, refuse to eat it. Forskall. The stem is shrubby, ascending, much branched, often a foot and a half high. Leaflets half or three-quarters of an inch long, obtuse, thick and succulent, quite smooth, supported in pairs on a club-shaped footstalk, somewhat more in length. Petals red, pointed. Capsule near an inch long. The shape of the capsule and leaflets, not to mention the colour of the flowers, distinguishes this species from the following.

7. *Z. album*. White Bean-Caper. Linn. Sp. Pl. 551. Mant. 379. Willd. n. 7. Ait. n. 5. Linn. fil. Dec. 1. 11. t. 6. Sm. Fl. Græc. Sibth. t. 371, unpublished. (*Z. proliferum*; Forfk. *Ægypt.-Arab.* 87. Ic. t. 12. f. A.)—Leaves conjugate, on a fleshy stalk; leaflets obovate, downy and hoary. Capsule roundish, five-lobed.—Native of Egypt, Cyprus, Barbary, &c. Forskall found it very abundantly about Alexandria; and Desfontaines near Tripoli, as mentioned by Shaw. Mr. Masson met with it in the Canary islands, and sent plants or seeds to Kew, in 1779, where this species is said to be kept in the dry stove, but not yet to have flowered. The stem is woody, diffuse, much branched, and very leafy. Leaves opposite, or aggregate, being accompanied by axillary tufts of smaller ones. The leaflets, as well as their footstalk, are thick, round, and juicy, both hoary, like the young branches, with fine, short, dense pubescence: the former are obovate, or almost globular, seldom a quarter of an inch long; the footstalk twice as much, and club-shaped. Flowers a third of an inch broad. Calyx reddish. Petals white, obtuse, crenate. Germen roundish, depressed, downy, with five rounded lobes. Capsule of the same shape; its coat, according to Forskall, pulpy, and there are only two seeds in each cell. The stigma is represented, in Mr. Ferdinand Bauer's drawing, rather slightly notched, not simple, as described by the younger Linnæus; but still less can we discern the five acute stigmas, mentioned in the *Maniffa*.

8. *Z. Morgana*. Four-leaved Bean-Caper. Linn. Sp. Pl. 551. Willd. n. 8. Ait. n. 6. (Fabago capensis frutescens major; Dill. Elth. 142. t. 116. f. 141. F. triphylla et tetraphylla, flore quadripetalo, fructu membranaceo drangulari; Burm. Afric. 7. t. 3. f. 2. Planta africana

ZYGOPHYLLUM.

frutescens, portulacæ folio, *Morgsani* sylvorum, ex brevi pediculo binis; Pluk. Amalth. 173. t. 429. f. 4.)—Leaves conjugate, nearly sessile; leaflets obovate, flat, smooth. Stem shrubby. Capsule roundish, tumid, five-lobed.—Native of the Cape of Good Hope. A green-house shrub in England, flowering most part of the summer. *Aiton*. The branches are somewhat quadrangular, very smooth. *Leaflets* an inch long, succulent, but not tumid; their common *footstalk* very short, or altogether wanting. *Stipulas* in pairs, lanceolate, pointed, reflexed. *Flower-stalks* the length of the leaves, unilateral, in pairs, declining. *Flowers* large, yellow, turning white in decay; their *petals* obovate, entire, streaked with purple at the base. *Nectaries* jagged or fringed, as in n. 3, 4, and perhaps some other species. *Capsule*, as represented by Burmann, an inch in diameter, globose, with five large, rounded, prominent lobes. We find the *petals* uniformly five, and entire; Linnaeus says four, rarely five, and somewhat emarginate. There is reason to believe he confounded more than one species under the present. He has applied a specific name, which properly belongs to *Z. Fabago*.

9. *Z. seffilifolium*. Sessile-leaved Bean-Caper. Linn. Sp. Pl. 552. Willd. n. 10. Ait. n. 7. (*Fabago capensis* frutescens minor; Dill. Elth. 142. t. 116. f. 142. F. humilis quadrifolia glabra, flore albedo fructu rotundo; Burm. Afric. 4. t. 2. f. 1. F. africana arborefcens, flore sulphureo, fructu rotundo; Commel. Rar. 10. t. 10.)—Leaves conjugate, sessile; leaflets obovate, flat, smooth. Stem shrubby. Capsule globose, undivided.—Native of the Cape of Good Hope. A green-house shrub, flowering in July and August, which appears to have been known in our gardens for above a century. Its size is inferior to the last, from which, according to Dillenius and Burmann, this species is essentially distinguished by the fruit. The capsule is either exactly globular, or, as Dillenius says, depressed like a Dutch cheese, its diameter not half an inch, nor is it furrowed, nor parted into large tumid lobes, like *Z. Morgsana*. The leaves too are smaller, and more perfectly sessile. Linnaeus defines them “rough-edged,” which we can find nothing to countenance, even in his own specimen. The flowers are drooping, orange-coloured, turning white as they fade; the petals crenate at the end, not much spreading. The nectaries are smaller, and much less conspicuously jagged than in the preceding.

10. *Z. fulvum*. Tawny Bean-Caper. Linn. Sp. Pl. ed. 1. 386. (*Z. seffilifolium* β ; Linn. Sp. Pl. ed. 2. 552. Willd. n. 10, β . *Fabago* flore luteo, petalorum unguibus rubris, fructu sulcato oblongo acuto; Burm. Afric. 6. t. 3. f. 1.)—Leaves conjugate, sessile; leaflets obovate, flat, smooth. Stem shrubby. Capsule ovate, five-angled, acute.—Native of the Cape of Good Hope. Linnaeus latterly considered this as a variety of the last, but we cannot discover on what his opinion was founded, there being nothing in his herbarium to represent *Z. fulvum*. There is indeed a specimen, referred by him at one time to *Z. Morgsana*, and at another to *coccineum*, on which, having no affinity to the latter, we are led to suspect he wrote *coccineum* by accident for *fulvum*. In this the leaves have something of a common *footstalk*, though very short. The nectaries are long and jagged, as in *Morgsana*. There is unluckily no fruit. Burmann’s figure of the capsule is so precise, that, considering the analogy of other species, so well distinguished by this part, we can have no hesitation in re-establishing *Z. fulvum*, as essentially differing from *seffilifolium*, whether our specimen be what Linnaeus intended or not. The capsule of the real plant is above an inch long, with five acute angles, and as many deep intermediate channels, and terminates in a

point, being equally unlike *seffilifolium* on one hand, and *Morgsana* on the other.

11. *Z. spinosum*. Spinous Bean-Caper. Linn. Sp. Pl. 552. Mant. 380. Willd. n. 11. (*Fabago tenuifolia spinosa, fructu rotundo; Burm. Afric. 5. t. 2. f. 2.*)—Leaves conjugate, sessile; leaflets linear, fleshy, smooth; flat above. Stem shrubby. Permanent stipulas hooked, spinous.—Native of the Cape of Good Hope. The stem is bushy, shrubby, about a foot high, branched from top to bottom; the branches acutely quadrangular. Leaves numerous, fleshy like those of a *Sedum*; the leaflets acute, scarcely an inch long, blunt, with a small point; their under side convex, or hemispherical. Stipulas in pairs, small, lanceolate, spreading, at length becoming hardened, hooked, and pungent, so as to form two, three, or four prickles at every joint. Flowers drooping, large and handsome, on longish, solitary, lateral stalks. Calyx reddish. Petals yellow, fading to white, nearly or quite entire. Nectaries entire, not fringed. Capsule, according to Burmann, “round, smooth, compressed, terminating in the very acute style.”

12. *Z. microphyllum*. Small-leaved Bean-Caper. Linn. Suppl. 232. Willd. n. 9. Thunb. Prodr. 80.—Leaves conjugate, somewhat stalked; leaflets inversely heart-shaped, smooth. Stem shrubby, with ascending branches. Capsule roundish, abrupt, of five compressed lobes. Style permanent.—Gathered by Thunberg, at the Cape of Good Hope. This is one of those hard, rigid, small-leaved, much branched shrubs, so characteristic of the botany of its native country. The branches are round, knotty, spreading, slightly hoary, or glaucous. Leaflets from one to three lines long, thick, oblique, sometimes obovate, but more frequently cloven, so as to become inversely heart-shaped; they are supported on a manifest, though short, thick footstalk. Stipulas minute. Flower-stalks thread-shaped, solitary, longer than the leaves, from the same buds. Flowers drooping, rather small, yellow. Calyx reflexed. Capsule the diameter of a pea, consisting of five rounded, vertical, compressed lobes, crowned with the spinous style, their surface rather reticulated: each of them bursts at the inner, as well as outer, edge into two elastic, or cartilaginous, valves, coated with a thin skin.

13. *Z. retrofractum*. Recurved Bean-Caper. Thunb. Prodr. 80.—Leaves conjugate, stalked; leaflets obovate, smooth. Stem shrubby, with spreading recurved branches. Flower-stalks shorter than the leaves.—Gathered at the Cape of Good Hope, by professor Thunberg, from whom we have a specimen. His short specific character was Willdenow’s only guide, when the latter reduced this plant to *Z. fastidum*, to which it has no affinity, and very little resemblance. The present, though a very distinct species, is most allied to *Z. microphyllum*, but the long, spreading, deflexed branches afford a characteristic difference of habit. The leaflets too are smaller, and seem to be always obovate, not orbiculate. Flowers very small, their little thick stalks hardly so long as the calyx. Nectaries lanceolate, entire. Germen, after the other parts of the flower are fallen, elliptic-oblong, deeply five-lobed, acute, crowned with the style; but we have none in an advanced state, to enable us to judge whether the lobes ever extend into a rounded semi-orbicular shape, like the last, as may very probably be the case.

14. *Z. afluans*. Surinam Bean-Caper. Linn. Sp. Pl. 552. Willd. n. 12.—Leaves conjugate, sessile; leaflets obovate, abrupt. Stems herbaceous, diffuse. Stipulas five at each joint.—Gathered in Surinam by Rolander, who sent seeds to Linnaeus; but the plants raised from them

died without flowering. The *stems* are a foot long, smooth, roundish, except a flatness on the upper side. *Leaves* opposite, without veins. *Stipulas* reflexed; two between each pair of leaves, at the uppermost side of the stem; one between the same pair, on the lower side; one between the leaflets of each leaf. *Linnaeus*. This last seems to answer to the little point, or rudiment of a leaflet, which occurs in several others of the broad-leaved species.

15. *Z. lanatum*. Woolly-jointed Bean-Caper. Willd. n. 13.—“Leaves ternate; leaflets papillary beneath. Styles five. Stem zigzag, woolly at the joints.”—Native of Sierra Leone. A plant of a doubtful genus, seen by the above author in a dried state only. The *stem* appears herbaceous, round and smooth, except the joints, which are remarkably woolly. *Leaves* opposite, small, on *footstalks*. *Leaflets* three, on very short partial *footstalks*, roundish, tapering at the base, pointed at the end; smooth on the upper side; beset underneath with prominent points. *Flower-stalks* axillary, solitary, single-flowered, erect; drooping after flowering. *Calyx* of five linear, obtuse leaves; downy on the inside, and at the edges. *Corolla* not present; perhaps fallen. *Filaments* but little dilated at the base. *Germs* club-shaped. *Styles* five, long, and thread-shaped. *Stigmas* obtuse. *Capssule* ovate, with five angles, five cells, and five valves with keel-like edges, bursting at the base. *Seeds* solitary. *Willdenow*. The ternate leaves afford a strong presumption against this being a *Zygophyllum*, and the want, as it seems, of *nectaries*, with the five *styles*, decide the question, in our judgment. Not having seen the plant, we leave it here for further inquiry.

16. *Z. arboreum*. Tree Bean-Caper. Jacq. Amer. 130. t. 83. Linn. Sp. Pl. 1673. Willd. n. 14.—Leaves abruptly pinnate. Stem arboreous.—Native of South America. Found by Jacquin, in uncultivated valleys about Carthagena, as well as in woods on the sandy sea-shore, flowering in July. A very handsome tree, forty feet high; the trunk being about six feet; the head dense, widely spreading, and extremely ornamental; the branches opposite, or forked. *Leaves* very numerous, opposite, four inches long, of about seven pair, without a terminal one, of alternate, sessile, elliptic-oblong, obtuse, entire, smooth, shining leaflets, an inch or more in length. *Clusters* axillary and terminal, shorter than the leaves, compound, lax, generally forked. *Flowers* large and handsome, without scent. *Calyx* yellowish-green, smooth. *Petals* orange-coloured, roundish, emarginate; their claws as long as the calyx. *Nectary* fringed; its scales gradually larger towards the upper side of the flower. *Stamens* erect, converging. *Germs* tapering at the base, into a long, thick, five-furrowed stalk. *Capssule* with five large membranous lobes. When it blossoms this tree affords a most magnificent spectacle, from the innumerable flowers, covering the bright green leafy head. Before the inflorescence appears, the leaves might incautiously be supposed doubly pinnate. The inhabitants give the name of *Guay-acan* to this tree, which is a general appellation for all kinds of hard wood that is useful for cabinet or other work. The trunk is reported to become changed into stone by lying in the earth, being incapable of corruption. *Jacquin*.

ZYGOPHYLLUM, in *Gardening*, comprises plants of the herbaceous and woody succulent exotic kind, among which the species are, the common bean-caper (*Z. Fabago*), the African bean-caper (*Z. seffilibolium*), the purslain-leaved Ethiopian bean-caper (*Z. Morgfiana*), the thorny bean-caper (*Z. spinosum*), and the white Egyptian bean-caper (*Z. album*).

The first has a deep fleshy root, and soft herbaceous stalks, which decay in the winter.

The second is of a shrubby growth, and there are varieties, with yellow-flowers, with sulphur-coloured flowers, with white flowers, with copper-coloured flowers, having mostly a reddish or brown spot near the base of each petal.

The third has also a shrubby stem, and there is a variety with flame-yellow-coloured flowers.

And the fourth has an under shrubby growth.

Method of Culture.—The first sort is raised from seeds, which should be sown in the spring in pots filled with light sandy mould, or on a hot-bed. When the plants have a few inches growth, they should be removed into separate pots, plunging them into a hot-bed, admitting air so as gradually to harden them to the open ground. They should be protected for a winter or two, and then be turned out into borders, or other parts, where the situation is warm, and the soil dry and rubbishy, as they are of a succulent nature.

The other sorts are capable of being increased by cuttings and seeds; the cuttings should be planted out in the spring or summer in pots filled with light sandy mould, and plunged in a hot-bed, being occasionally watered, when they quickly emit roots, and shoot at top; and when sown in the summer months, they may be planted in a shady place, or in pots placed in the shade, giving frequent waterings, when they will also take good root. In either method, they should be potted off separately-towards autumn, in order to be moved into the green-house or glass-case in the beginning of autumn.

The seed should be sown in the spring in pots of light earth, and be plunged in a hot-bed, where they soon come up: when a little advanced in growth, they should be pricked out in separate small pots, being watered and re-plunged into the hot-bed till well-rooted, when they should be gradually hardened to the full air, and in June set out to remain till the autumn, when they should be placed in the green-house, or some other place, where they may have protection for the winter.

The first sort affords variety in the borders, as well as among other potted plants; and the others in collections of the green-house kind.

ZYGOPOLIS, in *Ancient Geography*, a town of Asia, in the Colchide, near the town of Trapezunte.

ZYGOSTATES, among the *Ancients*, an officer who was the overseer of weights, and was to take care that tradesmen used none but what were just.

ZYGRIS, in *Ancient Geography*, a town on the coast of the nome of Lybia; and *Zygrita* are the people who inhabit this nome.

ZYMAR, a name given by some of the chemical writers to verdigrise.

ZYME, a word used by many authors to express ferment or leaven.

ZYMOLOGY, in *Chemistry*, a term used by some writers to express a treatise on fermentation, or the doctrine of fermentation in general.

Mr. Symphon has written a treatise on this subject, in which he refers the whole to the internal conflicts of acid and sulphur in bodies, and seems to think that the phenomena of hot-baths, the generation of minerals, and the production of mineral waters, the grand appearances of light, heat, and fire, and the generality of the subterranean phenomena of damps, earthquakes, and fiery eruptions, and the appearance of meteors, may be all explained by the doctrine

trine of fermentation, established on this basis. Symphon's Zymol. Chym.

ZYMOSIMETER, formed from ζυμωσις, *fermentation*, and μέτρον, *measure*, an instrument proposed by Swammerdam, in his book "De Respiratione," wherewith to measure the degree of fermentation occasioned by the mixture of different matters; and the degree of heat which those matters acquire in fermenting; as also the heat, or temperament, of the blood of animals.

ZYMOSIS, a word used by some to express fermentation, and by others for a flatulent tumour of the liver, or other of the viscera.

ZYMUM, in *Botany*, apparently from ζυμῶν, *a ferment*, a name which, De Theis says, is given to a plant of the Mauritius, by Noróna, a Spanish botanist, but without any explanation of its meaning, or application. This name is, nevertheless, retained by Aubert du Petit-Thouars, in his *Plantes des Isles d'Afrique*, fasc. 4.

ZYORY, in *Geography*. See SOUBAU.

ZYPE, a kind of island of North Holland, formed by canals cut from the Zuyder Zee to the German ocean. It

was formerly a morass, but is now converted into rich meadow land. On this spot the duke of York was posted, when he made terms with the French general Brune to evacuate Holland; having it in his power, by taking up the sluices, to inundate the country.

ZYRAS, in *Ancient Geography*, a river of Thrace, which watered the town of Dionysopolis. Pliny.

ZYRMA, a town of Thrace, near which ran the river Hebrus. Ptolemy.

ZYTHOGALA, formed of ζυθος, *cerevisia*, and γαλα, *lac*, *beer posset*, a drink recommended by Sydenham, as good to be taken after a vomit, for allaying the acrimonious and disagreeable taste it has occasioned, as well as to prevent gripes. Syden. *Observ. de Morb. acut.* p. 39.

ZYTHUM, or ZYTHOS, a sort of malt liquor, in use among the ancient Germans.

Matthioli represents the ancient *zythum*, and *curmi*, as the same with our beer and ale.

ZYTOMIERS, in *Geography*, a town and fortrefs of Russian Poland; 65 miles W. of Kiev. N. lat. 50° 16'. E. long. 28° 54'.

A, B, C, DARIA, in *Botany*, a name given by Rumphius, Herb. Amboin. v. 6. 145. t. 65, to the *Verbefina Acnella* of Linnæus, see SPILANTHUS, n. 3. The above appellation is designed to express the use made of this plant by the black school-masters at Amboyna, who cause their young pupils to chew the flowers or the root, either alone

A B E

or with Betle-nut, in order that they may more easily pronounce some of the difficult Arabic letters, such as *Tfcha* and *Ze*, both which they commonly confound with *S*. The Malay name, *Daun murit*, School-boy's herb, given to this *Spilanthus*, as well as to *Bidens pilosa* of Linnæus, has the same allusion. Such plants agree with Pellitory of Spain, *Anthemis Pyrethrum*, in a peculiar property of stimulating the mouth, accompanied by a sense of coolness, and a slight saline taste, all which together cause a great flow of saliva. Hence they are beneficial in tooth-ache arising from cold rheum, but the slight numbness and tingling of the nerves, which attend their use, should seem rather unfavourable to precise enunciation. The recent flowers of *Spilanthus oleracea*, slightly rubbed upon the gums, are perhaps the best of the whole tribe for producing the above effects.

ABDALLAH, EBN-ZOBEIR, l. 4, Heg. 63.

ABDAS, in *Biography*, a Persian bishop of the fifth century, who deserves to be exhibited in the page of history as a cautionary example of the folly of supporting any cause by persecution. Having destroyed a pagan temple belonging to the worshippers of fire, the king of Persia, instigated by the Magi, ordered him to rebuild it at his own charge; but as he refused to comply with this order, a dreadful persecution was commenced against the Christians, which lasted 30 years; and in this persecution Abdas lost his life. Bayle.

ABELICEA, in *Botany*, Ἀβελικία in modern Greek, see our ninth species of ULMUS.

ABERAERON, in *Geography*, a small town and port of Cardiganshire, much frequented by small coasting-vessels, which convey the corn and other produce of the district to
the

the English markets. The harbour has been lately much improved by the construction of a pier. A market has been lately established here.

ABEREMOA, in *Botany*, altered by Aublet from the Caribbean appellation of the same plant, Aubl. Guian. 610. t. 245; see *GUATTERIA* hereafter.

ABERPORTH, in *Geography*, a little fishing-town of Cardiganhire, pleasantly situated at the entrance of the river which flows by Blaenporth. The craft belonging to this port are chiefly employed in bringing lime-stone from Pembrokehire and other parts, which are burnt here, to supply the neighbourhood with manure, and for other purposes.

ABILDGARDIA, in *Botany*, a genus of Professor Vahl's, dedicated by him to the memory of the late Peter Christopher Abildgaard, a native of Denmark, formerly professor of the veterinary art, who contributed much information to Professor Rottböll on the subject of Grasses. Mr. Brown retains this genus, not without a hint of its too near affinity to *FIMBRISTYLIS*; see that article. We trust the barbarism of the double *a* may be dispensed with, and we have ventured to make that alteration.—Vahl Enum. v. 2. 296. Brown Prodr. Nov. Holl. v. 1. 229.—Clafs and order, *Triandria Monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperoides*, Juss. *Cyperaceæ*, Brown.

Gen. Ch. *Cal.* a single scale to each flower, ovate, pointed, concave, compressed, forming a spike, imperfectly two-ranked. *Cor.* none. *Stam.* Filaments three, rarely but one, inserted beneath the germen, gradually elongated by age, anthers linear, longer than the filaments. *Pist.* Germen superior, acutely triangular, rather contracted at the summit; style bulbous and pyramidal at the base, the bulb triangular, broader than the germen, permanent, the upper part bristle-shaped, deciduous; stigmas three, shorter than the style. *Peric.* none. *Seed* one, snow-white, nearly pear-shaped, with three angles, contracted at the base, crowned at the summit with the pointed base of the style, convex at the sides, and rough with minute dots, without any surrounding bristles. *Recept.* thread-shaped, gradually elongated, minutely cellular, dotted with brown, the edges of the cells membranous, from the permanent bases of the scales.

Eff. Ch. Glumes chaffy, imbricated, imperfectly two-ranked. Corolla none. Style three-cleft, with a triangular, pointed, permanent base. Seed solitary, pear-shaped, triangular, without any bristles at its base.

The *stems* of this genus are angular, slender, without joints; leafy at the bottom. *Leaves* narrow, channelled, sheathing. *Spikes* ovate-oblong, acute, compressed, often twisted; their *scales* closely imbricated, keeled, very smooth and polished, white, dotted with purple, the green keel of each elongated into a little point; the two lowermost narrower than the rest. *Vahl. Brown.*

Mr. Brown remarks, that the style is certainly deciduous, and the spike, when in seed, by no means perfectly two-ranked; circumstances which bring the present genus very near to *Fimbristylis*. The following are the only described species.

1. *A. monostachya*. Single-spiked *Abildgardia*. Vahl n. 1. Br. n. 1. (*Cyperus monostachyos*; Linn. Mant. 180. Willd. Sp. Pl. v. 1. 271. Swartz Obf. 29. Rottb. Gram. 18. t. 13. f. 3. *Græmen cyperoides minimum, spica simplicia compacta, radice tuberosa odorata*; Sloane Jam. v. 1. 120. t. 79. f. 2.)—Spike solitary. Scales uniform, nearly all fertile.—Gathered, by Kœnig, in shady situations in the East Indies; in the pastures, and sea marshes,

of Jamaica and Hispaniola, by Sloane and Swartz; and in the tropical part of New Holland, as well as at Port Jackson, by Mr. R. Brown. The *root* appears to be perennial, with many long simple fibres. *Herb* slender, smooth and glaucous, forming tufts, about a foot high, with linear, very narrow, *leaves*, which sometimes break off, as Vahl remarks, at a sort of joint, below the middle of each. *Stem* simple, slender, angular, and striated, taller than the leaves. *Spike* half an inch long, two-ranked, subtended by a linear rough-edged leaf, sometimes, in the Linnæan specimen, exceeding its own length. The *glumes*, or *scales*, have a green keel, accompanied by two white ribs, next to which is an assemblage of purple dots, the rest being cream-coloured. Two or three of the lower *glumes* are small, and apparently barren. There is said to be but one *flamen* to each *flower*. Sloane's synonymy seems, to us, doubtful.

2. *A. schoenoides*. Rushy *Abildgardia*. Br. n. 2.—“Spike solitary, naked. Outer scales shorter and barren; terminal ones narrower, with spreading points.”—Gathered by Mr. Brown, in the tropical part of New Holland. We have seen no specimen of this or the next.

3. *A. vaginata*. Sheathing *Abildgardia*. Br. n. 3.—“Spikes about three together; the middle one feffile. Scales pointed. Stem bristle-shaped, angular, leafless; sheathed at the base.”—Found by Mr. Brown, in the tropical part of New Holland.

4. *A. triflachya*. Three-spiked leafy *Abildgardia*. Vahl n. 2. (*Cyperus triflorus*; Linn. Mant. 180. Willd. Sp. Pl. v. 1. 272. *Schoenus cyperoides*; Retz. Obf. fasc. 4. 8.)—Spikes about three together; the middle one feffile. Stem semi-cylindrical; round, bulbous, and leafy, at the base.—Native of the East Indies, in hard dry ground. *Kœnig*. The *stems* are from one to two feet high, rushy and rigid, erect; according to Vahl, bulbous at the bottom, and wrapped with dry brown sheaths among the foliage. The *leaves* are smooth, channelled, not so tall as the stem. *Spikes* two, three, or four, twice the size of the first species, tumid, ovate, acute, twisted, of a dirty but polished white; three of them generally springing from one short leafy sheath, the two lateral ones elevated on long, flattened, striated, smooth stalks. *Stamens* three; *Vahl*. *Stigmas* long and downy.

ABINGTON, in *Geography, a town of Massachusetts, in Plymouth county, containing 1704 inhabitants.—Also, a township of Pennsylvania, in Montgomery county, having 1236 inhabitants.—Also, a township of Pennsylvania, in Luzerne county, having 511 inhabitants.*

ABUS.

ABUSCHÆHRR. See BUSHEER.

ABUTA, in *Botany*, a Brazilian name, first published by Barreire, adopted by Aublet, and recently by De Candolle, as well as Juskieu. It may remain for the present, till the characters of the genus are known. There are hitherto involved in great uncertainty, the flowers not having been observed by any botanist.—Barr. Hist. Nat. de la France Equinoxiale, 1. Aubl. Guian. 618. Juss. 286. De Cand. Syst. v. 1. 542.—Clafs and order, *Diocia Dodecandria?* (Polyandria Polygynia, Aubl.) Nat. Ord. *Menispermata*, Juss.

Eff. Cl. Male, unknown.

Female, Fl. unknown. Berries two or three, ovate, somewhat compressed, dry, single-seeded.

Lamarck and Willdenow have considered this genus as not distinct from *MENISPERMUM*, see that article; but Professor De Candolle reckons the large, dry, ovate, not kidney-shaped, berries, so termed, we presume, because of the brittle shell of their feed, as affording a sufficient character, even without the flowers. He is more inclined to refer *Abuta* to his own genus of *Cocculus*, separated by him from *Menispermum*; but their habits are somewhat different. Two species of *Abuta* are defined by this writer, but *A. amara* of Aublet, Guian. 620. t. 251, is referred, on the authority of Richard, to *Aristolochia*. These are large twining shrubs, with ovate leaves, whose pinnate ribs spring nearly from one point at the base.

1. *A. rufescens*. Reddish *Abuta*, or False Pareira-brava. Aubl. Guian. 618. t. 250. De Cand. n. 1. (*A. scandens*, amplifloro folio cordiformi, subtus tomentoso; Barr. Fr. Equin. 1. *Menispermum Abuta*; Lamarck Dict. v. 4. 100. Willd. Sp. Pl. v. 4. 828.)—Leaves ovate, acute, entire; and downy beneath.—Native of woods in Brazil, Cayenne, and Guiana. Aublet found it in almost every forest of the last-mentioned country, that he examined, bearing fruit in January. The Portuguese confound this plant with the true *Cissampelos Pareira*, and consider its root of equal efficacy in jaundice, disorders of the kidneys and bladder, as well as internal abscesses, and menstral suppressions. The climbing stem, and downy branches, reach to the tops of trees, and bear large, alternate, stalked, coriaceous, veiny, entire leaves, from four inches to a foot long; smooth above; covered beneath with prominent, reticulated, downy veins, springing copiously from five principal ribs, which radiate from nearly the base of the leaf. The footstalks are about half the length of the leaves, round, finely and densely downy. Berries elliptical, downy, an inch long, three upon each receptacle, and forming large axillary branches. There is said to be a variety whose woody parts, as well as the pubescence of the foliage, is reddish. The Creoles make a decoction of the branches of the red and white varieties indifferently, to cure obstructions of the liver, to which they are very subject. Aublet.

2. *A. candicans*. Whitish-leaved *Abuta*. De Cand. n. 2. Richard MSS.—“Leaves ovate, pointed, somewhat crenate, or minutely lobed; smooth and whitish beneath.”—Gathered in Cayenne by M. Richard, who unluckily did not meet with the flowers. The branches are round and smooth. Footstalks four inches long, round and smooth likewise. Leaves five to seven inches long, three or four broad, nearly entire, or slightly crisped, or toothed, in the margin; even and smooth above; pale or nearly white underneath, but, as it seems, quite smooth; the ribs pinnate, the two lower lateral ones close together. The inhabitants of Cayenne call this plant *Liane anère*, Bitter Vine. De Candolle.

ABYSSINIAN MUSIC. See MUSIC.

ACACIA, in *Botany*, an ancient Greek name, derived

from *ακαζα*, to point or sharpen, in reference to its thorny habit. De Theis deduces all words of this etymology from the Celtic, *ac*, a point. The *ακαζια* of Dioscorides, book i. chap. 133, was a sort of Egyptian thorn, “of a diffuse or spreading mode of growth, with a white flower, and a pod resembling lupines.” Its expressed juice, dried in the shade, was an astringent medicine much in use, and the shrub yielded also a clear white gum. This may very well have been a plant of the present genus. Willdenow, who established this genus, first separated it from the Linnæan *MIMOSA* (see that article), which has become inconveniently numerous in species, and unquestionably is capable of division by the characters of the fruit, of which Willdenow has very well taken advantage. He leaves in *Mimosa* such species as have a *lomentum*, or legume separating into single-seeded joints. Of these he defines 32, having a five-toothed corolla, and only eight stamens; and to many of them, being sensitive, the name *Mimosa* is properly appropriated. For his other genera taken from hence, see *DESMANTHUS*, *INGA*, and *SCHRANKIA*. We must observe however that the *Acacia* of Tournefort is not analogous to what is now before us.—Willd. Sp. Pl. v. 4. 1049. Ait. Hort. Kew. v. 5. 459. Pursh 305.—Clafs and order, *Polygynia Monoccia*, or rather perhaps *Polyandria Polygynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Eff. Cl. Calyx five-toothed. Corolla five-cleft. Stamens indefinite, from four to an hundred. Pistil one. Legume of two valves. Some flowers male.

Öbf. The flowers, sometimes four-cleft, have, in some instances, a corolla which separates into four or five distinct petals. We have not had an opportunity of examining a sufficient number of species to give a full generic character. Willdenow reckons up 102, in seven sections; to which Mr. Brown has made numerous additions from New Holland, partly described in *Ait. Hort. Kew.* above cited. We shall give some examples of each section.

SECT. 1. *Leaves simple*. Sixteen species in Willdenow, to which ten are here added, nine of them from *Hort. Kew.*—Of this singular tribe, first discovered by our British circumnavigators, all the species, as far as hitherto known, bear, in a seedling state, compound pinnate leaves, soon replaced by leafy or spinous simple footstalks, which latter constitute the only foliage of the adult plant. There are no proper thorns or prickles in these. Their stem is shrubby, or arborescent, as well as throughout the whole genus. We have slightly adverted to this section at the end of our article *MIMOSA*.

A. verticillata. Whorl-leaved *Acacia*. Willd. n. 1. Ait. n. 1. (*Mimosa verticillata*; L'Herit. Ser. Angl. 30. Curt. Mag. t. 110. Venten. Malmaif. t. 63.)—Leaves whorled, linear-awlshaped, rigid, spinous-pointed. Spikes solitary, cylindrical.—Gathered in Van Diemen's island, by the late Mr. David Nelson, who sent seeds to Sir Joseph Banks in 1780. Hence this singular shrub became known in the English green-houses, where it flowers in the spring, and ripens seed. The first two or three leaves of seedling plants are conjugate and pinnate, with elliptical obtuse entire leaflets: the rest are accurately whorled, simple, pungent, flattish thorns rather than leaves, six or eight in each whorl, about half an inch long, somewhat unequal, spreading horizontally. Flowers in dense, yellow, thick, obtuse spikes, which are an inch, more or less, in length, each on a simple, slender, axillary stalk, but there are sometimes two or more of these stalks together. Legume linear, compressed, corrugated, of one cell with several kidney-shaped seeds.

A. juniperina. Juniper-leaved *Acacia*. Willd. n. 2. Ait. n. 2. (*Mimosa juniperina*; Venten. Malmaif. t. 64. “*M. ulcifolia*;

ACACIA.

« *M. ulicifolia*; Wendl. Coll. 25. t. 6." Willd.)—Leaves imperfectly whorled, linear-awl-shaped, rigid, spinous-pointed. Spikes solitary, globose.—Found near Port Jackson, New South Wales, from whence Sir Joseph Banks is said to have received seeds about the year 1790. We have specimens from Dr. White. This differs from the foregoing in having its spinous leaves more crowded, and less distinctly whorled, more hairy branches, and globular heads of flowers, each flower, according to Ventenat, accompanied by a little ovate, pointed, stalked bractea.

A. acicularis. Needle-leaved Acacia. Brown in Ait. n. 3.—"Leaves scattered, roundish-awl-shaped, pointed, rigid. Stipulas deciduous. Young branches smooth. Spikes solitary, globose."—Said to have been found in New South Wales, by colonel William Paterson, from whence it was sent to Kew in 1796. It flowers at the same season as the two preceding, and requires the same treatment. If we understand this species aright, the leaves are full an inch long, being twice the length of the two foregoing, and more slender. We received specimens answering to this description before 1796, from Dr. White.

A. fulcata. Furrowed Needle Acacia. Brown in Ait. n. 4.—"Leaves thread-shaped, furrowed on all sides, with a harmless point. Heads of flowers usually in pairs. Bractæas ovate, concave, permanent, at the base of the flower-stalk. Legumes zigzag."—Observed by Mr. Brown on the south-west coast of New Holland, from whence it was introduced, in 1803, by Mr. Peter Good. This is likewise a green-house shrub, flowering from May to August.

A. suaveolens. Sweet-scented Acacia. Willd. n. 4. Ait. n. 5. (Mimosa suaveolens; Sm. Tr. of Linn. Soc. v. 1. 253. Labill. Nov. Holl. v. 2. 87. t. 236. M. angustifolia; Jacq. Hort. Schoenbr. v. 3. 74. t. 391. M. obliqua; Lamarck Journ. d'Hist. Nat. v. 1. 89. t. 5.)—Leaves linear, pointed; tapering at the base. Clusters oblong, axillary. Flowers four-cleft. Branches triangular.—Native of New South Wales. Cultivated, before 1790, by Mr. Thomas Hoy, in Sicca gardens. A green-house shrub, flowering in the spring. The acute edges of the branches are bright red. The first leaves are conjugate, pinnate, with thick elliptical leaflets, and a lanceolate common footstalk; the rest alternate, narrow, coriaceous, four or five inches long, rather glaucous, smooth, thick-edged. Flowers simply racemose, yellowish-white, fragrant, their corolla deeply four-lobed. Stamens very numerous. Legume elliptical, an inch and a half or two inches long, and one inch broad, finely glaucous.

A. striata. Double-headed Acacia. Willd. n. 8. Ait. n. 8. (Mimosa striata; Andr. Repof. t. 53. Curt. Mag. t. 1121.)—Leaves linear-obovate, obtuse; tapering at the base. Spikes globose, stalked, axillary, in pairs, divaricated.—Native of New South Wales, from whence Sir Joseph Banks is recorded to have received seeds in 1790. This requires the same treatment, and flowers at the same time, as the last, from which its capitate five-cleft flowers, and more dilated rounded-pointed leaves, at once distinguish it. Dr. Sims, in Curtis's Magazine, under this species, has given but too just reasons for retaining the genus *Mimosa* entire for the present, which principally refer to our ignorance of their fruit in a number of instances. Our learned friend, however, has since conformed to the new arrangement; and we think, with Willdenow, that enough is known for us to venture on the division this author has proposed, which may generally be supported by analogy, if not by absolute demonstration.

A. melanoxylon. Black-wooded Acacia. Brown in Ait. n. 12. Curt. Mag. t. 1659.—Leaves elliptic-lanceolate,

many-ribbed, slightly falcate. Spikes globose, in short clusters. Flower-stalks and young branches angular, powdery. "Umbilical cord coloured, plaited, nearly surrounding the seed."—Found by Mr. Brown, in Van Diemen's island. From him we adopt the singular character of the umbilical cord. This is a considerable tree, raised by John Walker, esq. of Arno's Grove, Southgate, who received the seeds under the name of Black-wood, about the year 1808. The young twigs are covered with rusty mealiness. Leaves stalked, three inches long, and one broad, slightly glaucous, usually five-ribbed. Flowers pale-yellow, their globular spikes disposed in short axillary clusters, about twice the length of each footstalk. We have no account of the legume.

A. Sophora. Sophora-podded Acacia. Br. in Ait. n. 13. (Mimosa Sophora; Labill. Nov. Holl. v. 2. 87. t. 237.)—Leaves oblong-obovate, equilateral, many-ribbed. Spikes cylindrical, axillary, in pairs. Petals four. Legumes linear, curved, pointed. Umbilical cord plaited.—Found by Labillardiere, as well as by Mr. Brown, in Van Diemen's island. Its seeds were brought by the latter to Kew Garden, and raised there in 1805, but the plants have not yet bloomed. The young leaves are represented by Labillardiere as pinnate and trijugate; the rest ovovate, two or three inches long. Spikes nearly sessile, hardly an inch long, and very slender. Flowers small. Legumes five or six inches in length, tumid, and twisted, a quarter of an inch broad. Each seed is subtended by a cup-like tunic, which we presume is the umbilical cord of Mr. Brown.

A. marginata. Marginate-leaved Acacia. Br. in Ait. n. 14.—"Leaves oblong-lanceolate, rather falcate, bordered, single-ribbed; their anterior edge somewhat narrowed, with a solitary gland. Heads about four-flowered, disposed in clusters."—Observed by Mr. Brown on the south-west coast of New Holland, from whence seeds were sent in 1803, by Mr. Peter Good. A green-house shrub, flowering from April to June. Aiton.

A. myrtifolia. Myrtle-leaved Acacia. Willd. n. 14. Ait. n. 15. (Mimosa myrtifolia; Sm. Tr. of Linn. Soc. v. 1. 253. Bot. of New Holl. 51. t. 15. Curt. Mag. t. 302.)—Leaves elliptic-lanceolate, oblique, thick-edged, single-ribbed, with a solitary gland at their anterior margin. Heads of flowers clustered, aggregate.—Native of New South Wales. Raised by Mr. Thomas Hoy, before the year 1789. A green-house shrub, flowering from February to May, or late in autumn. The stem is three or four feet high, with angular branches. First leaves conjugate, pinnate; the rest about two inches long, broadly lanceolate, pointed, very rigid, somewhat glaucous, often wavy, smooth. Flowers pale yellow, fragrant, three or four in each round head, the heads disposed variously in somewhat compound axillary clusters, nearly equal in length to the leaves. Legume linear, curved, tumid, with very thick edges.

A. hispidula. Little harsh Acacia. Willd. n. 15. Ait. n. 16. (Mimosa hispidula; Sm. Bot. of New Holl. 53. t. 16.)—Leaves elliptical, acute, oblique, minutely toothed, rough on each side and at the margin. Young branches harsh. Flowers four-cleft, in solitary axillary heads.—Native of New South Wales, from whence specimens were sent to us, with coloured drawings, in 1794, and seeds about the same time to Sir Joseph Banks. The roughness of the foliage and branches is very remarkable, caused by short, rigid, prominent hairs, or points. The leaves are sessile, an inch long, vertical, very stiff, deep-green. Heads stalked, globose, many-flowered. Legume thick-edged, elliptic-oblong, sometimes with one or two contractions. Seeds few,

A. baftulata,

ACACIA.

A. basifolata. Little Halberd-leaved Acacia.—Leaves deltoid, spinous-pointed, roughish; their upper angle glandular. Stipulas bristle-shaped, permanent. Branches rough. Flowers in solitary axillary heads.—Gathered near King George's sound, on the south-west coast of New Holland, by Mr. Menzies, to whom we are obliged for a specimen. This remarkable new species is evidently allied to the two last-mentioned, though abundantly distinct from both. The shrubby stem bears numerous, erect, round, rough, wand-like branches, beset with innumerable, spreading, vertical leaves, about a quarter of an inch long, single-ribbed, unequally deltoid, with an elongated spinous point, thick-edged, rough with minute points; their lower angle either rounded or somewhat toothed; the upper more prominent, and tipped with a gland. Stipulas slender, erect, in pairs at the base of each leaf. Flowers three or four in each of the little stalked heads, which are very numerous all along the branches.

A. decipiens. Paradoxical Acacia. Br. in Ait. n. 17. Curt. Mag. t. 1745. (Mimosa decipiens; König in Ann. of Bot. v. 1. 366. t. 8. Adiantum truncatum; Burm. Ind. 235. t. 66. f. 4. Linn. Syst. Veg. ed. 13. 790.)—Leaves triangular-wedgeshaped, spinous-pointed, smooth; their upper angle glandular. Stipulas bristle-shaped, deciduous. Branches smooth. Flowers in solitary axillary heads.—Gathered by Mr. Menzies on the south-west coast of New Holland, and not on the west side of North America, as mentioned in the Annals of Botany. Seeds were sent to Kew in 1803, by Mr. Good, and the plant is marked by Mr. Aiton as a green-house shrub, flowering from March to June. Its history is certainly curious; specimens without flowers having been taken by professor Burmann, who mistook Linnæus, for an *Adiantum*, which error was detected by the late Mr. Dryander, on seeing Mr. Menzies's specimens. Those of Burmann were reported to have come from Java, in which there may be a further mistake. At any rate this plant is nearly related to our last-described, and grows in the same country. The leaves differ in being larger, half an inch to an inch long, erect, and differently shaped, their inner, or upper, glandular angle being greatly extended, while the lower or rounded angle, seen in *A. basifolata*, is wanting. The flowers are more numerous, from seven to ten, in each round head.

A. biflora. Two-flowered Acacia. Br. in Ait. n. 18.—“Leaves triangular; the outer angle spinous; inner glandular. Stipulas bristle-shaped and spinous, permanent. Young branches downy. Heads two-flowered.”—Observed by Mr. Brown, on the south-west coast of New Holland, from whence it was sent to Kew by Mr. Good, in 1803. A green-house shrub, flowering from March to June. We have seen no specimens.

A. armata. Simple-leaved prickly Acacia. Br. in Ait. n. 19. Curt. Mag. t. 1653.—“Leaves oblong, halved, smooth, with a small point; their solitary rib near and parallel to the somewhat abrupt interior margin. Stipulas spinous. Heads solitary, globose. Branches hairy.”—Observed by Mr. Brown, on the south coast of New Holland. Sent to Kew, by Mr. Good, in 1803. A green-house shrub, flowering from April to June. Leaves dark green, an inch long, sessile. Flowers yellow, numerous.

A. alata. Wing-stalked Acacia. Br. in Ait. n. 20.—“Stem winged on two sides. Leaves decurrent, single-ribbed, tipped with a small spine; their inner margin with one glandular tooth. Stipulas spinous. Heads stalked, mostly solitary.”—Gathered by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to Kew, by Mr. Good, in 1803. This is likewise a shrubby green-house plant, flowering from April to July.

SECT. 2. *Leaves conjugate, pinnate*. Seven species in Willdenow, to which one of Mr. Brown's is to be added from *Hort. Kew*. The *Prodrromus* of this able author, when completed, will probably furnish more New Holland species to this section.

A. xylocarpa. Wooden-fruited Acacia. Willd. n. 17. (Mimosa xylocarpa; Roxb. Corom. v. 1. 68. t. 100.)—Leaves conjugate, pinnate; leaflets four pair, ovate-oblong, acute. Heads globose, many-flowered, lateral, stalked, in pairs.—Native of the mountainous parts of the Circars of Hindoostan, casting its leaves during the cold season, and flowering when the hot weather begins. This is one of the largest trees of this genus or any of its allies; the timber very hard, of a chocolate colour towards the centre, and much esteemed for purposes where hardness, toughness, and durability, are requisite, as in ploughs, the natives seldom using iron in that implement. The leaves are large, smooth, paler beneath, consisting of two divisions, or wings, and those of four pair of leaflets each, except that the innermost leaflet on each side, at the bottom, is wanting; the lower leaflets are about two inches long; the upper four or five. Heads of flowers whitish, the size of a cherry, on simple stalks, two or three inches in length. Corolla bell-shaped, five-cleft. Stamens ten. Legume only one from each head, ovate, compressed, very large and woody, three or four inches long, the stalk becoming necessarily greatly thickened. Seeds about ten, oval, ranged near the lower edge, as large as kidney-beans.

A. pulchella. Zigzag Spiny Acacia. Br. in Ait. n. 22.—“Leaves conjugate, pinnate, with a stalked gland between the wings, each of which has from five to seven pair of leaflets. Stipulas spinous, nearly equal to the leaves. Heads solitary. Branches zigzag.”—Observed by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to Kew, in 1803, by Mr. Good. A green-house shrub, flowering from April to July.

SECT. 3. *Leaves doubly pinnate*. Stem without thorns. Spikes oblong. Eleven species in Willdenow, the last of which, *A. Houstoni*, we shall remove to the following section.

A. muricata. Warty Acacia. Willd. n. 25. (A. latifolia alpecuroides, flore albo; Plum. Ic. 6. t. 11. Mimosa muricata; Linn. Sp. Pl. 1504.)—Thorns none. Leaves doubly pinnate; first division of five pair; second of many pair; leaflets abrupt. Spikes axillary, aggregate, nearly cylindrical. Branches warty.—Gathered in South America, or the West Indies, by Plumier, whose figure is the only authority for this species. The branches are round, and warty, as well as the lower part of the flower-stalks, which last are evidently axillary, not, as Willdenow says, terminal. They are longer than the large compound leaves, and bear four or five alternate dense spikes, on partial stalks. Leaflets numerous, crowded, elliptical, veiny, emarginate, about a half or three-quarters of an inch long. Flowers numerous, very small. Legumes several, spreading, four or five inches in length, linear, flat, veiny, wavy at the edges, with many oval flat seeds.

A. pallida. Pale South-American Acacia. Willd. n. 26.—“Thorns none. Leaves doubly pinnate; first division of two pair; second of twelve pair; leaflets linear, obtuse, downy. Spikes thread-shaped, much longer than the leaves.”—Gathered by Humboldt and Bonpland, in South America. Branches round, warty, divaricated. Leaflets obtuse at each end, sometimes but ten pair; clothed sparingly on the upper side, more densely on the under, with fine pubescence; the edges fringed. There is a cup-shaped sessile gland between the secondary divisions of each leaf (indications of which appear likewise in Plumier's plate of the foregoing).

ACACIA.

Footstalks hairy. *Spikes* axillary, solitary, three or four inches long, being thrice the length of the leaves. *Flowers* opposite, of five *petals*. *Willdenow*.

This seems much allied to the last, but the shape and downiness of the *leaflets*, and the solitary *spikes*, indicate a sufficient difference.

A. areolata. Sand Acacia. Willd. n. 29.—“Thorns none. Leaves doubly pinnate; first division of six pair; second of sixteen pair; leaflets linear, acute. Spikes thread-shaped, in pairs.”—Found by Mr. Bredemeyer at the Caraccas, about the sandy banks of rivers. A *shrub* ten or twelve feet high, with angular downy *branches*. *Leaflets* fringed, from sixteen to twenty-four pair. *Footstalks* clothed with hoary down; the partial ones accompanied by an acute intermediate gland. *Spikes* axillary, measuring three or four inches, generally rather longer than the leaves. *Flowers* opposite, white, fragrant. *Calyx* with four or five teeth. *Corolla* in four or five deep segments. *Stamens* twice as many, and thrice as long. *Willdenow*.

A. guianensis. Guiana Acacia. Willd. n. 32. Ait. n. 25. (*Mimosa guianensis*; Aubl. Guian. 938. t. 357.)—Thorns none. Leaves doubly pinnate, each division of about ten pair; leaflets elliptical, obtuse. Common *footstalk* with a convex gland. *Spikes* thread-shaped, axillary.—Observed by Aublet in Cayenne and Guiana, flowering in November, and bearing ripe seeds in January and February. This is a large tree, whose *trunk*, thirty or forty feet high, is a foot or more in diameter, with a smooth grey bark, and white brittle wood; the *branches* widely spreading. *Leaflets* elliptical, about half an inch long. The first divisions of the leaves are sometimes not more than seven or eight. *Stipulas* rounded, deciduous. *Spikes* axillary, from two to five together, on square simple stalks, the *flowers* small and densely crowded. *Calyx* with five teeth. *Corolla* of one petal, in five sharp lobes. *Stamens* ten, inserted into the calyx below the corolla, long, slender, with heart-shaped *anthers*, each of which bears a little leafy stalked appendage. *Legume* linear-oblong, flattish, brown, smooth, three or four inches in length, with several seeds.

A. lophantha more properly belongs to this section, though placed in the next.

SECT. 4. *Leaves* doubly pinnate. *Stem* without thorns. *Spikes* globose. Thirty-one species in Willdenow, to which we have three to add, besides *A. Houstoni*.

A. ciliata. Ciliate-winged Acacia. Br. in Ait. n. 23.—“Without thorns, hairy. Leaves doubly pinnate; first division of two pair; second of two or three pair. *Stipulas* nearly setaceous, deciduous. Heads solitary.”—Gathered by Mr. Brown, on the fourth-west coast of New Holland; and sent to Kew, by Mr. Good, in 1803. A green-house shrub, flowering from March to June, of which we have not seen either specimen or figure.

A. nigricans. Unequal-winged Acacia. Br. in Ait. n. 24. (*Mimosa nigricans*; Labill. Nov. Holl. v. 2. 88. t. 238.)—Without thorns, smooth. Leaves doubly pinnate; first division of two pair; second of two or three pair in the lower, and from five to seven pair in the upper. *Stipulas* slender-awlshaped. Heads solitary.—Native of the fourth-west coast of New Holland, from whence Mr. Good sent seeds to Kew, in 1803. A green-house shrub, flowering from May to July, said to be about six feet high in a wild state. The *leaflets* are uniform, elliptical, obtuse, one-third of an inch long. Heads axillary, stalked, one, two, or three together. *Corolla* deeply five-cleft. *Stamens* about 150. *Legumes* one or two from each head, linear-oblong, one inch and a half in length, and one-third of an inch in breadth. *Laillardiere*.

A. odoratissima. Fragrant Coromandel Acacia. Willd. n. 37. Ait. n. 27. (A. non spinosa, &c.; Pluk. Amalth. t. 251. f. 4. *Mimosa odoratissima*; Linn. Suppl. 437. Roxb. Coromand. v. 2. 12. t. 120.)—Thorns none. Leaves doubly pinnate; first division of four pair; second of ten or twelve pair; leaflets obtuse, the lowermost very minute. Heads panicled, terminal.—Native of the mountainous parts of the coast of Coromandel, flowering in the hot season. The wood is hard, and equally useful with that of *A. xylocarpa*. (See SECT. 2.) The leaves are a span long, with uniform leaflets, an inch in length, glaucous beneath, very unequal at their base. Flowers numerous, white, highly fragrant, in numerous, aggregate, stalked, globular heads. *Legume* coriaceous, about six inches in length, and one in breadth, with a central row of seeds.

A. arborea. Rough Tree Acacia. Willd. n. 38. Ait. n. 28. (A. non spinosa jamaicensis, foliis latâ basi in metæ formam fastigiatis; Pluk. Almag. 6. t. 251. f. 2. A. arborea maxima non spinosa, pinnis majoribus, flore albo, siliquâ contortâ coccinea ventricosâ elegantissimâ; Sloane Jan. v. 2. 54. t. 182. f. 1, 2. *Mimosa arborea*; Linn. Sp. Pl. 1503. Swartz Obf. 300. Browne Jan. 252. n. 3?)—Thorns none. Leaves doubly pinnate; first division of seven pair; second of seventeen pair; leaflets halved, acute. Heads axillary, stalked. *Legume* contorted, tumid. Seeds spherical.—Native of fields and woods in Jamaica, where it is called Wild Tamarind, and is one of the largest trees of that island. The wood, according to Sloane, is durable, though soft and white. Leaves of numerous, small, dark-green, smooth leaflets. Heads globular, of numerous sweet-scented flowers, whose corolla is reddish, the stamens whitish, very long. *Legume* as if beaded, four or five inches long, red; its valves of a blood-red on the inside. Seeds globular, of a shining black. This species was cultivated by Miller, but is now unknown in our gardens, nor are botanists in general well acquainted with it; Forskall and Thunberg having given the name of *Mimosa arborea* to two plants very different from this, as well as from each other.

A. Julibrissin. Smooth Tree Acacia. Willd. n. 39. Ait. n. 29. (*Mimosa Julibrissin*; Scop. Infubr. v. 1. 18. t. 8. Ait. ed. 2. v. 3. 440. M. arborea; Forsk. Ægypt.-Arab. 177. Gmel. It. v. 3. 372. t. 40.)—Thorns none. Leaves doubly pinnate; first division of about ten pair; second of many pair; leaflets halved, obtuse with a point. Heads lax, aggregate, terminal. *Legume* flat, membranous, smooth.—Native of the Levant. Forskall saw it cultivated at Constantinople, where it was called *Djal ibrim*, by the Turks; which name, denominating a silky flower, in allusion to the stamens, appears to be the origin of the specific appellation chosen by Scopoli. We have seen this species as large as a common apple-tree, covered with a profusion of blossoms, in the open ground at Turin, nor could any thing be more elegant or splendid. In England it is usually treated as a green-house plant, and flowers sparingly; though it succeeds well against a wall, with some protection in winter. The leaves are large and spreading, of numerous leaflets, half an inch long, very unequal in their two halves. Flowers lilac, with long monadelphous stamens, forming most beautiful tassels like white silk. *Legume* half a foot long, thin, pale brown, corrugated, unequal in breadth, with many small flattish seeds.

A. villosa. Downy Jamaica Acacia. Willd. n. 46. (*Mimosa villosa*; Swartz Prodr. 85. Ind. Occ. 982.)—Thorns none. Leaves doubly pinnate; first division of five or six pair; second of many pair; leaflets elliptical, oblique, downy. Stalks and branches hairy. Heads rather oblong,

ACACIA.

oblong, panicled, terminal. Legume hairy, flat.—Found by Dr. Swartz, on mountains in the south of Jamaica. Browne seems by his herbarium to have confounded this with the real *A. arborea*, just described. The present is much smaller, being merely a *shrub*, six feet high, with hairy furrowed *branches*. *Leaflets* downy on both sides, smaller and more obtuse than in the *arborea*; glaucous underneath; from ten to twelve pair in each subdivision. *Clusters* terminal, composed of many oblong and obtuse, rather than globular *spikes*, on very hairy stalks. *Flowers* small, white, with numerous capillary *filaments*, of a tawny hue, inserted into the lower part of the *receptacle*. *Legume* short, very different from that of *arborea*.

A. difcolor. Two-coloured-leaved Acacia. Willd. n. 47. Ait. n. 32. Curt. Mag. t. 1750. (*Mimosa difcolor*; Andr. Repof. t. 235. M. botrycephala; Venten. Hort. Celf. t. 1.)—Thorns none. Leaves doubly pinnate; first division of five pair; second of about ten pair; leaflets lanceolate, pale beneath. Heads in terminal and axillary clusters, much longer than the leaves.—Native of New South Wales, from whence seeds and specimens were among the first brought into this country, in the year 1788. It is now not an uncommon green-house plant in general collections, flowering at various seasons. The *branches* are angular and zigzag. *Leaves* rather stiff, their *footstalks* hairy like the young *branches*; leaflets not half an inch long, acute, smooth; dark green above; very pale beneath. *Flowers* yellow, in numerous globular heads, disposed in very conspicuous long clusters.

A. pubescens. Hairy-stem'd Acacia. Br. in Ait. n. 33. (*Mimosa pubescens*; Venten. Malmalf. t. 21. Curt. Mag. t. 1263.)—Thorns none. Branches hairy. Leaves doubly pinnate; first division of about eight pair; second of about fifteen pair; footstalks without glands; leaflets obtuse. Heads in axillary clusters, longer than the leaves.—Native of New South Wales, from whence its seeds are said to have been procured by Sir J. Banks, about the year 1790. This pretty delicate species has an arborescent stem, with drooping *branches*, and its copious fern-like *foliage* exhibits a most elegant appearance. Both sides of the *leaflets* are of a similar bright green. The whole compound *leaf* measures usually two inches; the numerous clusters of yellow capitate *flowers*, which smell like new hay, being about twice that length.

A. lophantha. Two-spiked New Holland Acacia. Willd. n. 53. Ait. n. 34. (*Mimosa distachya*; Venten. Hort. Celf. t. 20. M. elegans; Andr. Repof. t. 563.)—Thorns none. Leaves doubly pinnate; first division of ten or twelve pair; second of about twenty pair; leaflets lanceolate; top and bottom of the common footstalk glandular. Spikes oblong, axillary, in pairs.—Observed by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to Kew, in 1803, by Mr. Good. A tall *shrub*, or perhaps a *tree*, with furrowed warty *branches*. *Leaves* large, drooping, dark green, with innumerable narrow smooth *leaflets*. *Spikes* stalked, ovate or oblong, not globose, of numerous, crowded, sulphur-coloured *flowers*, having each about 200 monadelphous *filaments*. *Legume* oblong, flat, thick-edged, somewhat constricted here and there occasionally, when the seeds happen to be abortive.

A. brachyloba. Illinois Acacia. Willd. n. 54. Ait. n. 35. Pursh n. 1. (*Mimosa illinoensis*; Michaux Boreal.-Amer. v. 2. 254.)—Herbaceous, without thorns. Leaves doubly pinnate; first division of five to eight pair; second of many pair, with a gland between the lowermost. Heads globose, axillary, solitary. Legumes lanceolate, straight.—In the extensive natural meadows of Illinois and Kentucky, flower-

ing in June and July. Perennial. *Flowers* white, with only five *filaments*. *Pursh*. Stem smooth, furrowed. *Leaflets* from sixteen to twenty-four pair, linear, acute, slightly fringed at the base. *Footstalks* nearly smooth. *Heads* of flowers the size of a pea, stalked. *Legume* the length of the nail. *Willdenow*.

A. glandulosa. Glandulous Acacia. Willd. n. 55. Ait. n. 36. Pursh n. 2. (*Mimosa glandulosa*; Michaux Boreal.-Amer. v. 2. 254. Venten. Choix. t. 27.)—Herbaceous, without thorns. Leaves doubly pinnate; first division of about twelve pair; second of many pair, with a gland between each. Heads globose, axillary, solitary. Legumes oblong, curved.—On the banks of the rivers Tennessee and Mississippi, flowering in July. *Flowers* white, pentandrous. *Pursh*. This appears to be very nearly related to the last. Both are herbaceous, with perennial roots, and have been introduced into the English gardens, but we have not had any account of their success. They require the shelter of a green-house.

A. decurrens. Decurrent Acacia. Willd. n. 56. Ait. n. 37. (*Mimosa decurrens*; Venten. Malmalf. t. 61.)—Thorns none. Leaves doubly pinnate; first division of about eleven pair; partial of innumerable linear leaflets, on a winged stalk, with a gland near the base, on the common stalk. Heads globose, in axillary clusters.—Native of New South Wales. Sir Joseph Banks is said to have introduced this plant at Kew, in 1790. It flowers in the early part of summer, and is a green-house *shrub*, of an elegant fern-like aspect, with strongly angular zigzag *branches*. The *leaves*, though their common stalk is subtended by a projection from the branch, are not really decurrent. *Flowers* yellow, forming short clusters of little round heads.

A. grandiflora. Great Red Acacia. Willd. n. 61. Ait. n. 39. (*Mimosa grandiflora*; L'Herit. Sert. 30. Thornton Illust. t. 4. Andr. Repof. t. 592.)—Thorns none. Leaves doubly pinnate; first division of about fifteen pair; second of very numerous, elliptic-lanceolate, straight leaflets. Heads about five-flowered, in a terminal cluster.—Native of the East Indies, from whence it is said to have been introduced into the English stoves, by Mrs. Norman, about the year 1769. No figure of this stately plant, (Plukenet's synonym, cited by Willdenow, being too uncertain,) had ever appeared, till Dr. Thornton published his magnificent plate. The stem is shrubby, erect, slightly branched, downy, twelve feet or more in height, even in our gardens. *Leaves* large and spreading, with downy *footstalks*; their *leaflets* a quarter of an inch long, slightly fringed, bluntnish, unequal at the base, but not curved or falcate. *Clusters* solitary, large, terminal, erect, of many alternate stalks, solitary or in pairs, clothed with rusty down, each stalk bearing a head of from four to six *flowers*, whose *corolla* is but half an inch long, of a pale greenish-red; but the very numerous *filaments*, two inches in length, and of a fine shining crimson, like tassels of silk, render this one of the most beautiful of its tribe.

A. Houstoni. Houston's Purple Acacia. Willd. n. 34. Ait. n. 26. (*A. americana* non spinosa, flore purpureo, staminibus longissimis, siliquis planis villosis, pinnis foliorum tenuissimis; Houft. Ic. ined. t. 20. Mill. Ic. 4. t. 5. Amman. Herb. 584. n. 17. *Mimosa Houstoni*; L'Herit. Sert. 30. Banks Rel. Houft. 12. t. 26. *Gleditia inermis*; Linn. Sp. Pl. 1509, excluding the synonyms, except Miller's; and place of growth.)—Thorns none. Leaves doubly pinnate; first division of five or six pair; second of very numerous, linear, somewhat falcate leaflets. Heads of few flowers, in a terminal cluster.—Gathered at Vera Cruz, in South America, by Dr. Houston, who sent seeds to Miller,

ACACIA.

in 1729. These produced plants which flowered in the stove at Chelsea. The present species is certainly next akin to the last, however differently its inflorescence may have been described or delineated by authors, in which respect indeed Miller and Houttoun disagree. The plate of the former however has all the appearance of fidelity, and it is possible the partial *flower-stalks* may vary in length, or, more probably, be elongated as the flowers open. Having seen no specimens, we must be guided by the materials before us, from which we gather that the *leaves* of *A. Houttoni* have not half so many *pinne*, and that their *leaflets* are narrower, longer, more acute, and more curved. The *petals* are purple. *Legume* thick-edged, hairy, tapering at the base. The leaf in *Parad. Lond.* t. 64, cited in *Hort. Kew.* appears to belong to this species, but the *flowers*, and perhaps the *legume*, which is smooth, seem those of *A. grandiflora*. If this be the case, the smooth *legume*, not tapering at the base, would be an important addition to the specific character of *grandiflora*.

SECT. 5. *Leaves doubly pinnate. Stipulas becoming spines. Spikes elongated.* Ten species in Willdenow.

A. juliflora. Long-flowered Acacia. Willd. n. 66. Ait. n. 41. (*Mimosa juliflora*; Swartz Prodr. 85. Ind. Occ. 986, printed by mistake *piliflora*. M. diffusa, spica oblonga, filiquis longioribus compressis; Browne Jam. 252. n. 2.)—*Spines* stipulary, in pairs. *Leaves* doubly pinnate; first division of two pair, with intermediate glands; second of about twenty pair of oblong leaflets. *Spikes* axillary, two or three together, cylindrical, pendulous.—Native of very dry fields in the fourth part of Jamaica, flowering in the middle of summer. The *stem* varies from six to thirty feet in height. *Branches* long and spreading. *Spines* strong, four or five lines in length, prominent, curved upwards. *Leaves* spreading, with narrow, obtuse, smooth, ribbed leaflets. *Spikes* two or three inches long, lax, many-flowered. *Flowers* crowded, sessile, very numerous, yellow, sweet-scented. *Corolla* internally hairy. *Stamens* eight or ten, distinct. *Legume* from three to five inches long, compressed, smooth, often twisted, containing several oblong brown seeds, separated by fleshy partitions. There are numerous flowers in each spike destitute of a *pistil*. Cattle feeding on the leaves and young branches, unless gradually accustomed to them, are poisoned, and the sweet legumes are reported to be noxious. The inhabitants of Jamaica call this plant *Cafbeez*. Browne erroneously gives it the name of *Popanax*, which belongs to *Mimosa (Acacia) tortuosa*. Swartz. See Sect. 6.

A. caffra. Hottentot Acacia. Willd. n. 70. Ait. n. 42. (*Mimosa caffra*; Thunb. Prodr. 92.)—*Spines* stipulary, in pairs, incurved. *Leaves* doubly pinnate; first division of twelve pair; second of many pair; with a gland on the footstalk. *Spikes* axillary, cylindrical.—Found by Thunberg in Southern Africa. Sent to Kew in 1800, by W. Somerville, M. D. The *branches* are round and striated. First divisions of the *leaves* from seven to twelve, second from twenty to thirty, pair; *leaflets* linear, obtuse, smooth. *Footstalks* nearly smooth; the common one bearing a depressed gland above its base. *Spike* stalked, two inches long. *Legume* the same length, linear-lanceolate, flat. Willdenow.

A. Catechu. Medicinal Acacia. Willd. n. 73. Ait. n. 44. (*Mimosa Catechu*; Linn. Suppl. 409. Woodv. Med. Bot. 183. t. 66. Roxb. Coromand. v. 2. 40. t. 175. Terra Japonica; Kerr in Med. Obs. et Inq. v. 5. 151. t. 4.)—*Spines* stipulary, hooked, in pairs. *Leaves* hairy, doubly pinnate; first division of ten or twelve pair; second of many pair; with a gland at each extremity of the com-

mon footstalk. *Spikes* cylindrical, axillary, two or three together.—Native of the mountainous parts of Coromandel. A large tree, of which seeds have been sent by Dr. Roxburgh to sir J. Banks. These have vegetated at Kew, but the plants have not arrived at a flowering state. The *branches* are round, downy when young; the older ones beset with numerous pairs of small recurved thorns, originating in the *stipulas*, as in all the plants of this section. *Leaves* slender and delicate, finely hairy, pale green; their *leaflets* crowded, hardly a quarter of an inch long, linear, rounded at each end, unequal at the base. *Spikes* slender, three or four inches long, hairy, stalked, pale yellow. *Legume* oblong, acute at each end, flat, smooth, with three or four distant flat seeds. "The wood," says Dr. Roxburgh, "is good, and applied to various uses; but the natives have no idea of extracting from it, or any other, the *Catechu*, or *Terra Japonica*. Yet I believe there are many trees as fit to yield this extract, as the present." Mr. Kerr, assistant surgeon to the civil hospital at Bengal, has however described the mode of preparing the *CATECHU*, (see that article,) by boiling the interior coloured part of the wood of this species, till an inspissated extract is obtained, which is the drug in question, long supposed to be an earth produced in Japan. Another sort of *Catechu*, or *Gutta Gambir*, made in Sumatra, Prince of Wales's island, &c., has been shewn by Mr. Hunter, secretary to the Asiatic Society, in Transactions of the Linnæan Society, v. 9. 218. to be the produce of a species of *NAUCLEA*. (See that article, spec. 7.) We presume that Mr. Kerr and Mr. Hunter are equally correct, and that the two distinct kinds of *Terra Japonica*, known to druggists, are thus accounted for.

SECT. 6. *Leaves doubly pinnate. Stipulas becoming spines. Spikes globose.* Sixteen species in Willdenow.

A. macracantha. Long-thorned Acacia. Willd. n. 76.—*Spines* stipulary, in pairs, lanceolate, compressed, nearly as long as the leaves, which are doubly pinnate; first division of twelve pair; second of many pair; with a depressed gland at each extremity of the common footstalk. *Spikes* stalked, globose.—Gathered by Humboldt and Bonpland in South America. The *branches* are striated, and nearly round. *Leaflets* about thirty pair in each division, linear, obtuse, fringed. *Footstalks* downy. *Spines* two inches or more in length, sharp-pointed, spreading at a right angle. *Heads of flowers* the size of a pepper-corn, on long stalks, in pairs, either axillary, or disposed in a sort of cluster at the ends of the branches. Willdenow. This species appears very remarkable, on account of the great size of its thorns.

A. eburnea. Ivory-thorned Acacia. Willd. n. 78. (*Mimosa eburnea*; Linn. Suppl. 437. M. leucacantha; Jacq. Hort. Schoenbr. v. 3. 75. t. 393.)—*Spines* stipulary, in pairs, cylindrical-awhiskered, combined at the base, spreading. *Leaves* doubly pinnate; first division of three or four pair; second of six or more pair; leaflets distant, elliptic-oblong. *Heads* axillary, stalked, aggregate.—Sent by Kœnig from the East Indies. Jacquin by mistake makes it a native of Africa. He cultivated it at Schoenbrun, but we have not met with this species in any English stove, the following one having been miscalled by the above name. The true *A. eburnea*, of which the original Linnæan specimen lies before us, is a twisted irregularly branched shrub, whose twigs are round and zigzag, armed with tremendous straight *spines*, which are white, smooth and polished, almost like ivory, but brown and very sharp at the end: the longest measure nearly two inches; some are but a quarter that size: they taper gradually from a thick confluent base. *Leaves* about two inches long, with smooth leaflets, placed at the distance of their own width from each other. *Common foot-*
stalk

ACACIA.

stalk with two depressed glands in the upper part. *Flower-stalks* either axillary, or terminal and racemose, more or less aggregate, each bearing a globular head, of yellow sweet-scented flowers. We know nothing of the legume.

A. horrida. Awl-thorned Acacia. Willd. n. 79, excluding the synonym of Jacquin, and perhaps Forikall. (*A. maderaspatana*, foliolis parvis, aculeis e regione binis prægrandibus horrida, cortice cinereo; Pluk. Phyt. t. 121. f. 4. *A. eburnea*; Ait. n. 46, but not of Willd. *Mimosa horrida*; Linn. Sp. Pl. 1505. Vahl Symb. v. 1. 81? *M. eburnea*; Roxb. Coromand. v. 2. 54. t. 199.)—Spines stipular, in pairs, linear-awlshaped, angular, spreading, longer than the leaves; some much shorter and recurved. Leaves doubly pinnate; first division of two or three pair; second of many pair; leaflets crowded, on a hairy stalk. Heads axillary, stalked, aggregate.—Native of the East Indies, flowering in the cold season, sent by Dr. Roxburgh to Sir Joseph Banks in 1792. This is a small ill-looking tree, or large bushy shrub, whose branches spread in every direction, and are round, purplish, waxy, very rigid, armed with formidable thorns, of various sizes. Some of the latter are two inches long, white, spreading horizontally in opposite directions, scarcely combined at the base, much more slender and linear than in the *A. eburnea*, flat or channelled along their upper side; when young they are much smaller, needle-like, and hairy; others, on the same branch, and of the same age, with the large ones, are very short and hooked. The leaves are not half the size of the last species. Heads of flowers globose, with a purplish corolla, and yellow stamens. Legume linear, twisted, two inches long, smooth. The flowers are said by Dr. Roxburgh to be separated from each other, on their globose receptacle, by abrupt, fringed, chaffy scales, of which we can find no traces in our specimens.

A. tortuosa. Poponax Acacia. Willd. n. 82. (*A. americana*, siliquis teretibus ventricosis, floribus luteis; Sloane Jam. v. 2. 56. *Mimosa tortuosa*; Linn. Sp. Pl. 1505. Swartz Obs. 391. Browne Jam. 251. n. 1.)—Spines stipular, in pairs, awl-shaped, much shorter than the leaves, round, downy. Leaves doubly pinnate; first division of three or four pair; second of many pair; leaflets crowded, on a downy stalk. Heads axillary, on downy stalks, solitary or in pairs. Legume externally fleshy.—Very common in the low sandy lands of Jamaica. The stem is shrubby, with spreading wavy branches, rendering the plant useful for hedges according to Dr. Swartz; but Browne speaks of it as of little service, the smell of every part being so rank and disagreeable, that it cannot be used even for fire-wood. The taste is bitter, and the flowers have an oppressive smell. Both these authors mention the legumes as furnished with a glutinous juice under their skin, whose qualities are eminently bitter and astringent. Sloane appears to confound the *A. farnefiana* and others with this species. The true *tortuosa*, of which we have Browne's own specimen, comes near to *horrida* in botanical characters, but the leaves and leaflets are much larger; thorns smaller, not angular, but more tapering; flower-stalks downy, not smooth. There are no scales on the receptacle between the flowers, but the teeth of the long tubular calyx are very densely and finely fringed. Dr. Swartz says this is the tree really called *Poponax* in Jamaica, Browne erroneously attributing that name to *A. juliflora*. Both are frequently met with in the same situations.

A. farnefiana. Sponge Acacia. Willd. n. 83. Ait. n. 47. (*A. indica farnefiana*; Aldin. Hort. Farnes. 3. t. 2. 4. *Mimosa farnefiana*; Linn. Sp. Pl. 1506.)—Spines stipular, in pairs, awl-shaped. Leaves doubly pinnate; first division of from five to eight pair; second of many pair; leaflets crowded. Heads stalked, axillary. Legume

tumid, coriaceous.—Native of Hispaniola, from whence the seeds were brought to Italy, early in the 17th century. This shrub is occasionally seen in our groves, being esteemed for the peculiarly delicious scent of its balls of yellow flowers, which are produced during summer. A coloured figure is much wanted. The dry tumid legume distinguishes it clearly, as a species, from the last. The whole plant is smoother, nor have we ever observed the herbage to be fetid.

A. arabica. East Indian Gum-Arabic Acacia. Willd. n. 86. (*A. altera* var. &c.; Pluk. Almag. 3. t. 251. f. 1. *Mimosa arabica*; Lamarck Dict. v. 1. 19. Roxb. Coromand. v. 2. 26. t. 149. Nella Tooma of the Telingas.)—Spines stipular, awl-shaped, in pairs. Leaves doubly pinnate; first division of five pair; second of many pair. Heads axillary, about three together. Legume neck-lace-like, flat, densely downy.—Native of the East Indies, whether of Arabia also may be doubted. Dr. Roxburgh says it is abundant over every part of India, thriving best in a low, stiff, uncultivated soil, and flowering most part of the year. Besides yielding a great quantity of Gum Arabic, this tree is one of the most useful in India for its tough and hard wood, serving many valuable purposes in ship-building, wheel-carriages, &c. The astringent bark serves for dyeing, and making ink. The branches are round. Spines distinct, an inch, more or less, in length. Leaves like several of the foregoing, as are also the aggregate globular heads of yellow flowers. But the legumes afford a most striking character, being flat, four or five inches long, covered with dense hoary pubescence, like fine velvet, and remarkably contracted into numerous orbicular portions, in each of which is lodged a flattish seed. Cattle are very fond of the tender branches and young pods.

A. vera. Egyptian Gum-Arabic Acacia. Willd. n. 87. Ait. n. 48. Velling Ægypt. 6. t. 8. Bauh. Hist. v. 1. p. 2. 429. (*Mimosa nilotica*; Linn. Sp. Pl. 1506. Hasselq. Travels, Engl. ed. 250. Woodw. Med. Bot. 187. t. 67.)—Spines stipular, in pairs, linear-awlshaped. Leaves doubly pinnate; first division of five or six pair; second of many pair; common stalk glandular. Heads axillary, about three together. Legume neck-lace-like, nearly flat, smooth.—Native of the sandy deserts of upper and lower Egypt, from whence Hasselquist sent specimens to Linnæus, who seems to have described the same plant under the name of *Mimosa Senegal*. This original Gum Arabic tree was known to our earlier botanists, and Gerard appears to have cultivated it in his garden, whence it has obtained a place in Mr. Aiton's valuable work; but few persons at present are acquainted with living, or even dried, specimens, especially of the legumes. These clearly distinguish the species, being more strictly contracted into orbicular portions than the last, with an obliquity well expressed in the wooden cut of Vellingius. Their surface is brown, nearly or quite smooth, pale at the edges; the disk of each lobe rather tumid, from the swelling of the seeds. In the leaves or flowers of these two species, we cannot, from the dried specimens, detect any great difference; but the spines of *A. vera* are almost as remarkable for their length and whiteness as those of *horrida*. For the most valuable produce of this tree, see ARABIC, Gum.

SECT. 7. *Leaves doubly pinnate. Prickles scattered.* Eleven species in Willdenow.

A. cæsia. Grey Acacia. Willd. n. 97. Ait. n. 49. (*A. spinosa*, indur. orientalis, foliis subtus cæsiis, floribus globosis luteis; Pluk. Mant. 1. Phyt. t. 330. f. 3. *A. zeylanica farnefiosa*, flore luteo globoso; Burm. Zeyl. 3. *Mimosa cæsia*; Linn. Sp. Pl. 1507.)—Branches and foot-

stalks

stalks prickly. Leaves doubly pinnate; first division of seven pair; second of sixteen pair; leaflets oblong-oval; a gland on the main footstalk. Spikes globose, in terminal paniced clusters.—Native of the East Indies, from whence it was procured for Kew garden, by sir J. Banks, in 1773, but appears not yet to have flowered. We have seen no authentic specimen of this species.

A. pennata. Fine-leaved Acacia. Willd. n. 98. Ait. n. 50. (*A. aculeata multiflora*, foliis pennas avium referentibus; Burm. Zeyl. 2. t. 1. *A. zeylanica*, floeulis globosis luteis, foliis pinnatis tenuissimis incisiss, spinis minoribus; Burm. Zeyl. 3. *Mimosa pennata*; Linn. Sp. Pl. 1507.)—Branches prickly. Leaves doubly pinnate, with many pair of general divisions, and very numerous linear leaflets; a gland on the common stalk. Panicle terminal, spreading; heads stalked, aggregate; general flower-stalks, like the base of the common footstalks, prickly. Legume flat, smooth; wavy at the edges.—Native of Ceylon, and other parts of the East Indies. Sent to Kew, in 1773, by sir J. Banks. We have specimens from Dr. Roxburgh. The very delicate slender leaflets, which, in the dried plant at least, fold together, give a feathery appearance, well expressed in Burmann's plate. The panicle is very large and compound, with downy rusty stalks; its main branches only armed with small hooked prickles. The legumes, not hitherto described, but very important in discriminating this multifarious tribe, are about three inches long, tapering, though rather blunt, at each end, flat, thick-edged, wavy or sinuous at both margins. Seeds about four.

A. Ceratonia. Round-leaved Acacia. Willd. n. 101. Ait. n. 52. (*A. repens aculeata*, flore albo, foliis Siliquis; Plum. Ic. 4. t. 8. *Mimosa Ceratonia*; Linn. Sp. Pl. 1508.)—Branches, and all the stalks, prickly. Leaves doubly pinnate; leaflets three pair, roundish-obovate, oblique, three-ribbed. Panicle terminal. Heads globose. Legume flat, prickly at the edges.—Native of the West Indies, from whence the present duke of Marlborough is said to have introduced it into his rich collection, before the year 1800. The remarkable roundness of the leaflets, which would have authorized the name of *rotundifolia*, and their greater size, distinguish the present species from all we have hitherto noticed. Every part is extremely prickly, but devoid of pubescence. The heads of flowers are rather small, and, according to Plumier, white. He delineates the legume of a flat, oblong, obtuse figure, two or three inches long and one broad, fringed with hooked prickles.

A. tamarindifolia. Tamarind-leaved Acacia. Willd. n. 102. Ait. n. 53. (*A. aculeata*, flore albo, foliis Tamarindis; Plum. Ic. 4. t. 7. *Mimosa tamarindifolia*; Linn. Sp. Pl. 1509. Jacq. Hort. Schoenbr. v. 3. 77. t. 396.)—Branches prickly. Leaves doubly pinnate; first division of five or six pair; second of about fifteen pair; a gland on the common stalk; leaflets oblong. Stipulas and bractees heart-shaped. Clusters terminal. Heads globose. Legume flat, smooth.—Native of South America and the West Indies. Said to have been cultivated by Kennedy and Lee, at Hammermith, in 1774. The name is very expressive of the aspect of the leaves. The very broad heart-shaped stipulas, and the smaller, more ovate, bractees, give a peculiar character to this species. Inflorescence rather racemose than paniced, destitute of hairiness or spines, though the branches of the stem are armed with strong prominent prickles. Heads of a few white flowers, each on a long stalk, solitary or in pairs. Legumes, according to Plumier's figure, linear-oblong, flat, straight, destitute of prickles at the edges, acute, about three inches long and one broad. Seeds numerous, oval.

A. acantholoba. American Prickly-podded Acacia. Willd. n. 95.—“Branches prickly. Leaves doubly pinnate; first division of three pair; second of ten pair; leaflets linear, obtuse; downy beneath. Heads globose, nearly sessile, racemose. Legume prickly at the edges.”—Gathered in South America, by the celebrated travellers Humboldt and Bonpland. Branches round. Leaflets ten or eleven pair, clothed beneath with close-pressed hairs. Foot-stalks downy. Prickles scattered, hooked, compressed. Heads small, almost sessile, disposed in a terminal cluster. Legume an inch and a half in length, oblong, flat, membranous, smooth, beset with prickles at the margin. Willdenow. This author declares himself to have been possessed of several specimens of the *Mimosa* tribe, which were too imperfect to be enumerated or defined. We are not only in this situation, but we have several in sufficiently good condition, which on account of the incomplete descriptions of authors, especially concerning the fruit, we cannot ascertain to be described or not.

ACADEMY. The Academy of Arts at Petersburg was established by the empress Elizabeth in 1758, and annexed to the Academy of Sciences. At the suggestion of count Shuvalof, the late empress Catharine, in 1764, formed it, &c. Next col. after l. 54, add,

The academy of painting, sculpture, and architecture, at Vienna, was founded in the year 1705.

Under Academies of Nonconformist Ministers, instead of Manchester r. York, dele Exeter, and instead of Wrexham r. Llanfylling.

ACÆNA, in Botany, *axaxæ*, a thorn, alluding to the prickly fruit. This genus, supposed to consist of only one species, was described by Mutis, who communicated his account of it to Linnaeus, without any specimen, and it was published in Linn. Mant. 2. 145, 200. Some time afterwards Forster founded his *Ancistrum*, Forst. Nov. Gen. t. 2, several species of which have been described by the younger Linnaeus, Lamarck, and other writers. (See ACÆNA and ANCISTRUM.) Vahl first discovered these to be one and the same genus, and has greatly added to the number of species. We shall extract from his work a compendious view of the whole.—Vahl Enum. v. 1. 293. Linn. Mant. 2. 145. Schreb. Gen. 87. Willd. Sp. Pl. v. 1. 693. Mart. Mill. Dict. v. 1. Ait. Hort. Kew. v. 1. 67. Juss. 336. (Ancistrum; Forst. Gen. t. 2. Linn. Suppl. 10. Schreb. Gen. 25. Willd. Sp. Pl. v. 1. 154. Mart. Mill. Dict. v. 1. Juss. 336. Lamarck Illustr. t. 22. Gærtn. t. 32.)—Class and order, *Dianthia Monogynia*. Nat. Ord. *Seneciaceae*, Linn. *Rosaceae*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, permanent, with four teeth, each sometimes tipped with an upright bristly awn, barbed at the point, or the whole body of the calyx is so armed. Cor. Petals four, roundish, inserted into the border of the calyx, and shorter than its awns. Stam. Filaments two or four, thread-shaped, longer than the petals, inserted into the border of the calyx; anthers roundish. Pist. Germen superior, oblong; style thread-shaped; stigma many-cleft, tufted. Peric. none, except the permanent calyx. Seed solitary, ovate, coated with the thickened base of the calyx.

Efl. Ch. Calyx of one leaf, armed with barbed bristles. Petals four, inserted into the calyx. Stigma tufted. Seed solitary, coated with the calyx.

Obf. The petals are sometimes wanting. Flowers occasionally five-cleft, with five stamens. The stem is herbaceous, or sometimes shrubby. Leaves alternate, pinnate with an odd one, deeply serrated or cut, often hairy or silky; their common footstalks sheathing, bordered with a pair of membranous

branous combined *stipulas*. Flowers small, greenish, in a globose head, or interrupted spike. Fruit reddish, dry.

1. *A. leppacea*. Bur Acæna. Vahl n. 1. "Fl. Peruv. v. 1. 66. t. 103. f. a."—Leaflets oblong, ferrated. Flowers racemose. Fruit all over prickly. Stem erect.—Native of craggy funny spots in the district of Tarma, Peru. Stems rather shrubby, numerous, a foot high, slightly branched, round, villous. Leaflets four pair, deeply ferrated, hairy; becoming smooth by culture. Flower-stalks axillary, four times as long as the leaves, bearing from five to seven distant, stalked flowers.

2. *A. elongata*. Mutifian Acæna. Linn. Mant. 200. Vahl n. 2. Willd. Sp. Pl. v. 1. 693.—Leaflets oblong, ferrated; downy beneath; bearded at the tips of the ferratures. Spikes elongated, compressed. Fruit all over prickly. Stem nearly erect.—Found in Mexico, by the celebrated Mutis. Stem woody, perennial, with very long, ascending, somewhat compound branches, two feet in length. Leaves scattered; leaflets sessile, crowded; the lower ones very small, linear, acute, entire; from four to eight of the upper pair larger, oblong, ferrated. Spikes axillary, erect, rigid, a span long. Bractæas solitary, close to the calyx, concave, ovate-oblong. Flowers alternate, nearly sessile. Mutis.

3. *A. latebrosa*. Hairy Acæna. Vahl n. 3. Ait. n. 1. (Ancistrum latebrosum; Willd. Sp. Pl. v. 1. 155. A. decumbens; Thunb. Prodr. 6. Agrimonia decumbens; Linn. Suppl. 251.)—Leaflets oblong, cut, hairy. Stem creeping. Spikes elongated, stalked, many-flowered.—Native of the Cape of Good Hope. The germen is downy, beset with many barbed prickles, which, as the fruit ripens, project through the skin of the calyx. See Gärtner f. 2, and Lamarck f. 4.

4. *A. pinnatifida*. Deep-cut Acæna. Vahl n. 4. "Fl. Peruv. v. 1. 68. t. 104. f. b."—Leaflets oblong, deeply ferrated, almost pinnatifid; hairy beneath. Spikes cylindrical. Stem erect.—Found on dry exposed hills in Chili. Commerçon gathered what appears to be the same, at Monte Video, not, as Vahl by mistake says, at the straits of Magellan. The stem is quite simple, a span high, leafy, very hairy in the upper part. Leaves numerous at the root, and several on the stem, with eight or nine pair of leaflets, besides the odd one; the largest near an inch long, copiously and deeply cut, like *Potentilla anserina*. Spike obtuse, an inch or inch and half long, dense, many-flowered, dark purple. Germen beset with strong barbed thorns, not proceeding from its teeth.

5. *A. Sanguisorbæ*. Burnet-leaved Acæna. Vahl n. 5. Ait. n. 2. (Ancistrum Sanguisorbæ; Linn. Suppl. 89. A. diandrum; Forst. Prodr. 10. A. anserinæfolium; Forst. Gen. 2. Lamarck Illustr. v. 1. 76. t. 22. f. 1.)—Leaflets obovate, deeply ferrated; silky beneath. Spikes globose. Stem decumbent. Calyx-teeth awned.—Native of New Zealand, Terra del Fuego, and Staten-land. Introduced into Kew garden by Sir J. Banks, in 1796. Perennial and hardy, flowering in June. The stems are a span or more in length. Leaves resembling Burnet; smooth above. Heads of flowers globose, dense, on long stalks.

6. *A. ovalifolia*. Oval-leaved Acæna. Vahl n. 6. "Fl. Peruv. v. 1. 67. t. 103. f. c." Ait. n. 3. (Ancistrum repens; Venten. Jard. de Cels, t. 6.)—Leaflets elliptic-oblong; villous beneath. Spikes globose. Stem creeping. Calyx-teeth awned. Stigma unilateral.—Native of Peru, in moist shady places. Cultivated at Paris, by the late M. Cels, and at Kew by Mr. Aiton, where it is hardy, flowering in May and June. We can discover no difference

between this and the foregoing, the stigma being perhaps accidentally imperfect.

7. *A. argentea*. Silvery Acæna. Vahl n. 7. Fl. Peruv. v. 1. 67. t. 103. f. b. (Proquin; Feuill. Voy. v. 3. 55. t. 41.)—Leaflets elliptic-lanceolate, acute, ferrated; silky beneath. Spikes globose. Stem creeping.—Native of Chili, in moist ground. The Indians use it as a vulnerary. The branches are two feet long. Leaves shining and smooth above; silvery beneath. Flowers in globular heads, on long stalks. Stamens two or four. Calyx with two, three, or four terminal awns.

8. *A. lucida*. Shining Deep-cut Acæna. Vahl n. 8. Ait. n. 4. (Ancistrum lucidum; Willd. Sp. Pl. v. 1. 155. Lamarck Illustr. v. 1. 77. t. 22. f. 3.)—Leaflets in three or five deep oblong segments; hairy beneath. Spikes oblong. Stem almost buried.—Native of the Falkland islands, from whence Dr. Fothergill procured it in 1777. Commerçon gathered the same in the straits of Magellan. The stems run just under the surface of the ground, sending up numerous leafy tufts. Leaves linear-oblong, of many pairs of small, elliptic-oblong, deeply divided leaflets. Spikes partly interrupted. Fruit reddish, smooth, entirely unarmed, as well as the calyx, in our specimens. Vahl attributes four awns to the latter.

9. *A. trifida*. Three-cleft Acæna. Vahl n. 9. Fl. Peruv. v. 1. 67. t. 104. f. c.—Downy and hoary. Leaflets wedge-shaped, in three or five segments. Spikes globose. Stem erect.—Native of pastures, fields, and hills in Chili. Densely villous. Stems several, unequal, the longest measuring about a foot. Leaflets seven or eight pair; the lowermost often undivided. Flower-stalks terminal, often bearing one or two little round heads, besides the principal one. Bractæas linear. Calyx sometimes five-cleft. Stamens two to five. Fruit obovate, densely villous, with four or five angles, and as many awns. Vahl.

10. *A. magellanica*. Magellanic Acæna. Vahl n. 10. (Ancistrum magellanicum; Lamarck Illustr. v. 1. 76. t. 22. f. 2.)—Leaflets obovate, deeply ferrated, three-cleft; hoary beneath. Spikes globose. Stem erect, smooth.—Gathered by Commerçon, at the straits of Magellan. Stems rather shrubby, three or four inches high, branched, smooth; sometimes hoary at the summit. Leaves at the ends of the branches: leaflets five or six pair, scarcely half the length of the nail; the uppermost with seven or nine teeth, lower with about three, lowest of all entire. Flower-stalks axillary, at the top of each branch, erect, purplish, slightly villous at the upper part. Head twice the size of a pea. Very nearly akin to the last, but the smoothness of the stem, branches clothed with imbricated bases of the foot-stalks, crowded leaves, and smooth bractæas, distinguish this species. Vahl.

11. *A. adscendens*. Ascending Smoothish Acæna. Vahl n. 11. (A. lævigata; Ait. n. 5? Ancistrum magellanicum β ; Lamarck Illustr. v. 1. 76.)—Leaflets oblong or obovate, ferrated, nearly smooth. Spikes globose. Stem decumbent.—Gathered by Commerçon at the straits of Magellan. We do not find any specimen from him in the Linnæan collection; but Mr. Menzies has communicated some, by the name of *Ancistrum alpinum*, which appear to answer to Vahl's description, except being considerably hairy. These were gathered on the summits of the mountains near Cape Horn, along with *Viola tridentata*. (See VIOLA n. 76.) Vahl speaks of the stems as a span long, smooth. Leaflets from five to seven pair, opposite or alternate, bluntly ferrated, veiny, somewhat hairy at the rib. Flower-stalks terminal, elongated. Head the size of a cherry.

Calyx

Calyx with four awns. The hairiness of the upper side of the leaves in our plant, and the smaller size of the heads of flowers, may be owing to a very lofty or exposed situation. We merely guess this to be Mr. Aiton's *lavigata* from the synonym of Lamarck.

12. *A. cylindriciflatha*. Cylindrical-spiked *Acæna*. Vahl n. 12. "Fl. Peruv. v. 1. 68. t. 104. f. a."—"Leaflets oblong, ferrated; silky beneath. Spikes cylindrical, on nearly radical stalks. Stems subterraneous."—Found on hills in Tarma, Peru. *Herb* clothed with silky pubescence. *Leaves* radical, numerous; leaflets ten or eleven pair, obtuse, furrowed. *Flower-stalks* several, from three to nine inches high, bearing a few simple leaves. *Calyx* purplish, with four awns. *Stamens* two.

13. *A. pumila*. Smooth Dwarf *Acæna*. Vahl n. 13.—Leaflets oval, convex, ferrated, very smooth; polished on the upper side. *Flower-stalks* almost radical. Spikes cylindrical.—Gathered by Commerçon at the straits of Magellan, and by Mr. Menzies in Staten-land, near Cape Horn. The root is tuberous. *Stems* very short, or scarcely any. *Leaflets* about twelve pair, with blunt revolute teeth; veiny on both sides; paler and opaque beneath. *Flower-stalk* slightly leafy. *Spike* interrupted in the lower part. *Germs* beset with very numerous little barbed bristles.

ACALZIKE. After Tartary, add: the capital of *Akiska* (which see); a populous and commercial city, situated in an open valley, on the left bank of the Kur. The inhabitants are, Jews, Turks, Greeks, Armenians, and Georgians.

ACANTHI, in Botany, Jussieu's third natural order of his eighth class, or the thirty-sixth of his general series, named from the most celebrated and conspicuous genus which it contains. For the character of the class, see GENTIANÆ. The *Acanthi* are thus defined.

Calyx divided, permanent, often bracteated. *Corolla* mostly irregular. *Stamina* either two; or four, two of which are shorter than the others. *Style* solitary; with a two-lobed, rarely simple, stigma. *Fruit* capsular, of two cells, often many-seeded, with two elastic valves, and a partition contrary, or opposite, thereto, inserted into their middle, splitting from top to bottom into two uninterrupted receptacles, bearing seeds on each side, rendering the valves semibilocular. *Stem* either herbaceous or shrubby. *Leaves* for the most part opposite, as well as the flowers.

SECT. 1. *Stamens* four, in unequal pairs.

This contains *Acanthus* of all authors; *Dilivaria* of Jussieu, founded on *Acanthus ilicifolius* of Linnæus; but surely on the slightest possible characters; *Blepharis* of Jussieu; *A. nodratripatensis* of Linnæus, as slightly distinguished; *Tunbergia* of Linn. Suppl.; *Barleria*; and *Ruellia*.

SECT. 2. *Stamens* only two.

Justicia and *Dianthera*.

Mr. Brown, who retains this order by the name of *Acanthaceæ*, Prodr. Nov. Holl. v. 1. 472, has enriched it with many valuable remarks, and some new genera. He combines, like Professor Vahl, *Dianthera* with *Justicia*, but extracts from the latter the *Hypoxis* of Solander; with *Eranthemum*, originally founded by Linnæus; and establishes moreover two genera of his own by the names of HYGROPHILA and NELSONIA. (See those articles.) We perceive also that this intelligent writer retains Vahl's *Elytraria*. He proposes also *Aphelandra*, consisting of *Justicia pulcherrima* and its allies; *Athelema*, founded on Forskall's *Ruellia imbricata*, and various undescribed East Indian and African species, of which therefore we can give no account. LEPIDAGATHIS of Willdenow, Sp. Pl. v. 3. 400, of which we

propose to speak hereafter, is admitted by Mr. Brown, as well as a new genus of Jussieu's named *Blechnum*. Some others are less distinctly indicated. We select from the work of our learned friend the following additional observations upon the *Acanthi*, or *Acanthaceæ*.

The anthers are either of two cells, sometimes equal, sometimes unequal in their insertion, or of only one cell; and burst longitudinally. *Germs* furrowed at the base with a glandular disk. *Seeds* roundish, mostly subtended by *retinacula*, prope, or awl-shaped ascending processes from the partition. *Skin* of the seed lax. *Albumen* invariably none. *Embryo* either curved or straight. *Cotyledons* large, nearly orbicular. *Plumula* inconspicuous. These plants are chiefly tropical. Their pubescence, if any, is simple, occasionally capitate, very rarely starry. *Leaves* opposite, rarely four in a whorl, without stipules, simple, undivided, either entire or serrated; seldom sinuated, or slightly lobed. *Inflorescence* terminal or axillary, spiked or racemose, fasciculated, panicled, or solitary. The order is certainly natural, though not easily to be defined. In some instances the props of the seeds are wanting. The rudiments of a fifth stamen frequently occur. The elastic mode of bursting in the capsule is nearly universal.

The following principles by which the genera are to be discriminated, are thus proposed by Mr. Brown in succession, according to their relative importance. 1. Seeds with or without props. 2. Partition combined with the valves or separate. 3. Anthers of two cells or of one. 4. Anther-bearing stamens two or four. 5. Limb of the irregular corolla with one lip or two. 6. *Calyx* equal or unequal. Cells of the capsule containing each two or more seeds. The following is the order of Mr. Brown's genera. *Hypoxis*, *Justicia*, *Eranthemum*, *Ruellia*, *Hygrophila*, *Acanthus* including *Dilivaria* of Jussieu, and *Nelsonia*, which may be found in their proper places.

ACANTHONOTUS, in Ichthyology, a genus of fish, whose characters are, that the body is elongated, without dorsal fins, and that it has several spines on the back and abdomen. There is one species, a native of the East Indies, described by Bloch under the name of

NASUS; Snouted Acanthonotus, which is grey, with the back transversely barred with brown. This fish is of considerable length, that described by Bloch being two feet and a half; the head is large, the teeth small, forming a row along each jaw, the eyes large, and the nostrils conspicuous; the body, moderately wide for about a third of its length, tapers towards the extremity; head and body are covered with scales, of a bluish tinge, silvery on the abdomen; the pectoral fins brown, of a moderate size, the ventral of like colour, and small; the lateral line straight, nearer to the back than to the abdomen; with ten spines, strong but short, along the narrow part of the back, and towards the abdomen from twelve to thirteen others, followed by the anal fin, which is shallow, and continued into the tail, which is very small. Shaw's Gen. Zool.

ACANTHURUS, a genus of fish, consisting of such species of the Linnæan genus *Chatodon* (which see) as, in contra-distinction to the principal character of that genus, have, in general, moderately broad and strong teeth, rather than slender and setaceous ones; they are also furnished on each side of the tail with a strong spine. Their generic character is as follows: Teeth small, in most species lobated; tail aculeated on each side; habit and general appearance as in the chatodon. The species are,

UNICORNIS. Grey-brown, with a frontal horn stretching

ing forwards over the frout, and two spines on each side of the tail. See *CHETODON Unicornis*.

NASUS. Grey, speckled with black, with a rounded frontal tubercle, and two spines on each side of the tail. A native of the Indian seas, and, according to Cope, first described by Commerlon.

TEUTHIS. Blue, with the middle of the body paler, and a spine on each side of the tail. See *TEUTHIS Hepatus*.

CHIRURGUS; Lancet Acanthurus. Orange-yellow, with the body crossed on the hind part by transverse brown stripes, and a spine on each side of the tail. See *CHETODON Chirurgus*.

NIGRICANS. Blackish, sub-argenteous beneath, with a spine on each side of the tail. See *CHETODON Nigricans*.

MILITARIS. Brown, with rhombic-ovate body, and strong spine on each side of the tail. Native of the Indian and American seas.

TRIOSTEGUS; Triradiated Acanthurus. Greenish-brown, with four transverse dusky bands, and a spine on each side of the tail. Native of the Indian seas. See *CHETODON Triostegus*.

HARPURUS; Guarded Acanthurus; Rhombic-ovate brown Acanthurus, with extremely minute scales, and two spines on each side of the tail. Native of the Indian seas.

SOHAL; Dusky Acanthurus, with longitudinal violet streaks, and two spines on each side of the tail imbedded in a red depression. See *CHETODON Sobal*.

NIGRO-FUSCUS; Dusky Acanthurus, with ovate body, and spine on each side of the tail. A variety of the preceding. See *CHETODON Nigro-fuscus*.

ACHILLES; Brown, ovate Acanthurus, with a bare ovate red spot on the hind part, aculeated in the middle.

LINEATUS; Ovate-brown Acanthurus, with numerous longitudinal white stripes, and spine on each side of the tail. See *CHETODON Lineatus*.

UMBRATUS; Brown-ovate Acanthurus, with extremely minute scales, and a spine on each side of the tail. Native of the Indian seas.

MELEAGRIS; Blackish-brown Acanthurus, thickly marked with round white spots, and spine on each side of the tail. Native of the Indian and American seas.

VELIFER; Broad-finned; whitish Acanthurus, with roundish-ovate body, marked by numerous brown transverse bands, and spine on each side of the tail. Native of the American seas. Shaw's Zool.

ACANTHUS, in *Botany.* In addition to the observations of our predecessor, we would remark, what the writer of the present article has elsewhere hinted, (*Considerations respecting Cambridge, more particularly relating to its Botanical Professorship*, 37.) that every mention of this plant in Virgil accords with the Common Holly, *Ilex Aquifolium*, for far, at least, as the words of the poet indicate any thing in particular. The passages in question are,

- *baccas semper frondentis acanthi.*—Georg. 2. 119.
- *aut flexi tacuisse vimen acanthi.*—Ib. 4. 123.
- Ille comam mollis jam tum tondebat acanthi.*—Ib. 4. 137.
- Et molli circum est ansas amplexus acanthi.*—Ecl. 3. 45.
- Mixtaque ridenti colocalia fundet acantho.*—Ib. 4. 20.
- *circumtextum croceo velamen acantho.*—Æn. 1. 653.
- *pitium croceo velamen acantho.*—Ib. 1. 715.

The flexible twigs, ever-green leaves, bright or gay saffron-coloured berries, (as the term *croceus* is used with considerable latitude by Latin writers,) the head of the plant being clipped by gardeners in the early spring, all sufficiently well apply to the Holly, which is a common wild, as well as garden, shrub, throughout Italy, but of

which we can find no mention whatever in all Virgil's writings, if these passages allude to any thing else. They are acknowledged to be inapplicable to the *ακανθα* of Dioscorides, which is evidently the Linnaean *Acanthus*. They are no less so to the *ακανθος* of Theophrastus, which is a tree bearing pods, or legumes. These Greek names, simply meaning a thorny or prickly plant, are variously applied, not only to different trees or shrubs, but to many kinds of thistles. The *Acanthus Dioscoridis*, Linn. Sp. Pl. 891, a species adopted by Linnaeus from other writers, without leaving a specimen or figure, seems to be merely a narrow-leaved, or starved state of *A. spinosus*; of which *A. mollis* may, on the other hand, be a cultivated, or more luxuriant variety. The latter was found by Dr. Sibthorp in Sicily, not in Greece; the former, apparently the natural state of this herb, as described by Dioscorides, occurs in moist stony places, as well as about the borders of fields, in the southern part of Greece, and the islands of the Archipelago, and is very common in Crete.

ACARNA, a name adopted from the Greeks, whose *ακαρνα* was, like this, some sort of thistle. This name is now applied in Willdenow's Sp. Pl. v. 3. 1699, and from thence by Mr. Aiton, Hort. Kew. v. 4. 490, to a genus separated by these writers from the Linnaean *TRACTYLIS* (see that article); from which it differs in the want of a radius. The species referred to *Acarna* are, 1. *Atractylis gummifera* of Linn. Sp. Pl. 1161; 2. *A. macrocephala*, Desfont. Atlant. v. 2. 253; 3. *A. macrophylla*, ibid. 255. t. 226; 4. *A. castifolia*, ibid. 254. t. 225; 5. *A. lancea*, Thunb. Jap. 306; 6. *A. ovata*, ibid. 306; and 7. *A. cancellata*, Linn. Sp. Pl. 1162.—We can by no means concur in this alteration. Nothing is less certain than such a generic distinction as the above, when unsupported by any natural character. Willdenow has also separated from *Atractylis* the *purpurata* and *mexicana* of Linnaeus, perhaps with more propriety, their receptacles being nearly naked, and their seed-down simple, to say nothing of a difference in the structure of the radiant florets of the former, which rather invalidates than confirms the new-established genus. See *ONOSERIS*.

ACCELERANDO, l. 11, *r.* refinements.

ACCOUNT CURRENT, the personal account of a merchant or trader with each of his correspondents or customers, a copy of which account is transmitted to the person whose name it bears, shewing the state of affairs between the parties at the current or present time when made out.

ACCURSIUS, *r.* *Marianus*.
ACER, l. 6, *r.* *Tribilate Acera*. Juff.
ACERA, in *Botany*, the sixth natural order, of the 13th class in Juslieu's system; the 66th in his general series. See the characters of this class under the article *GERANIA*. The *Acera* are defined as follows.

Calyx of one leaf. *Petalis* definite, very rarely wanting, inserted around the disk, which is under the germen. *Stamina* inserted into the middle of the same disk, definite, but

often unequal in number to the petals. *Germs* simple, standing on the before-mentioned disk; *style* one, or rarely two; *stigma* one or two. *Fruit* of several cells, or several capsules, the cells or capsules three or two. *Seeds* in each solitary, or at the utmost three, attached to the inner angle, some of them frequently abortive. *Coraculum* destitute of albumen, the radicle lying on the lobes. *Stem* arborescent, or shrubby. *Leaves* opposite, without stipulas. *Flowers* racemose or corymbose; sometimes by the abortion of one or other part becoming separate in sex.

SECT. 1. *Fruit of several cells*, contains only *Aesculus*.

SECT. 2. *Fruit of several capsules*, only *Acer*.

SECT. 3. Consists of genera all on the one hand to the *Acera*, on the other to MALPIGHIE; see that article. There are *Hippocratea* and *Thryallis*.

There is some doubt, even in the mind of Jussieu himself, whether *Aesculus* properly belongs to this natural order; and he justly adverts to its great affinity to his SAPINDI, (see that article,) with which its fruit undoubtedly very closely accords.

ACERAS, so named from *α*, without, and *αρα*, a born, alluding to the want of a nectariferous spur to the lip.—Brown in Ait. Hort. Kew. v. 5. 191. Sm. Compend. Fl. Brit. ed. 2. 128.—Class and order, *Gynandria Dianthia*. Nat. Ord. *Orchideae*.

Gen. Ch. *Cal*. Perianth superior, of three ovate, concave, equal, converging leaves. *Cor*. Petals two, linear-lanceolate, concealed by the calyx, and about the same length. Nectary an oblong, flat, pendulous lip, much longer than the petals, with two pair of deep, linear, flat, dependent lobes, but no posterior spur. *Stam*. Filament none; anther erect, oblong, attached by its back, parallel to the style, of two cells, opening in front, the masses of pollen club-shaped, each attaching itself, by a taper base, to two glands in a single pouch near the stigma. *Pist*. Germen inferior, linear-oblong, twisted; style columnar, very stout; stigma below the anther, rather concave. *Peric*. Capsule oblong, with three blunt angles, twisted, of one cell and three valves, splitting by three lateral fissures. *Seeds* numerous, minute, each with a chaffy tunic.

Eff. Ch. Calyx converging. Lip without a spur, flat. Anther nearly terminal, fixed to the style, of two cells.

This genus was first established by Mr. Brown, who separates it from OPHRYs, (see that article,) on account of the converging calyx, and especially the situation of the two glands, which receive the pollen, being in one pouch, not in two distinct and distant ones. The latter character, though excellent in this instance, appears to us in others less satisfactory (see GYMNAEDIA hereafter); and even in the characters of *Aceras* and *Opbrys*, the flat lip of the former, contrasted with the convex one of the latter, seems a more obvious and natural distinction. In affinity the present genus comes nearest to ORCHIS, but wants the spur.

1. *A. anthropophorum*. Green-man *Aceras*. Br. n. 1. Sm. Compend. 130. (Ophrys anthropophora; Linn. Sp. Pl. 1343. Willd. Sp. Pl. v. 4. 63. Sm. Fl. Brit. 937. Engl. Bot. t. 29. Curt. Lond. fasc. 6. t. 66. O. n. 1264; Hall. Hist. v. 2. 133. t. 23. O. anthropophora oreades; Column. Ecphr. 318. t. 320. f. 1. O. flore nudi hominis effigiem representans; Rudb. Elyf. v. 2. 193. f. 6. Vaill. Paris. t. 31. f. 19, 20.)—Lip of the nectary longer than the germen.—Native of dry calcareous pastures, in Italy, France, Switzerland, and England, flowering in June. The root consists of two roundish-ovate, nearly equal, downy bulbs, or knobs. *Herb* smooth, of a bright, slightly glaucous, green, about ten or twelve inches high. *Leaves* several, ovato-lanceolate, all radical, except one which sheaths the lower part of the stalk. *Spike* erect, of

numerous rather scattered flowers. *Calyx* convex, green, with reddish-brown edges. *Petals* green, erect. *Lip* pale yellow, pendulous, near an inch long, in four narrow, rather spreading lobes, of which the two lowermost are usually the shortest; the whole flower having nearly the shape of *Orchis militaris*, except the want of a spur, and of a small central lobe, often observable in that plant. We have found at Valcamiera, on the Apennines, what seems a mere variety with a red lip.

2. *A. anthropomorphum*. Short-lipped *Aceras*. (Ophrys anthropomorpha; Willd. Sp. Pl. v. 4. 63.)—Lip but half the length of the germen.—Found on hills in Portugal, by professor Linck. About a span high, the spike an inch long. *Braeas* oblong, membranous, half the length of the germen, nor does the lip exceed that proportion. Willdenow thinks it can scarcely be a variety of the former. We have seen no specimen.

ACERIC ACID, in *Chemistry*, lately discovered by professor Scherer, of Vienna, in the sap of the *acer campestris*, or common maple. Its properties have been very imperfectly described. The acetate of lime is white, slightly translucent, has a weak acidulous taste, and is not altered by exposure to the atmosphere. 1000 parts of cold water dissolve 9 parts, and 1000 parts of boiling water 17 parts of this salt. Schweigger's Journal, iv. Thomson's Chemistry, iv. new edition.

ACETATES, or ACETITES, a class of salts, the characteristics of which are, that they are all very soluble in water; that they are decomposed by the action of heat; and that they afford acetic acid when distilled with sulphuric acid. Accordingly we have acetates of barytes, of potash, of soda, of lime, of ammonia, of magnesia, &c. See ACETIC Acid.

ACETIC ACID. It is now universally admitted by chemists, that the acetic acid differs in no respect from common vinegar, or what was formerly termed *acetous acid*, but in the degree of concentration only. This opinion, first advanced by Adet, has lately been fully confirmed by the experiments of Darracq and Proust. What has been said, therefore, on the subject of *acetous acid* and *vinegar* in the Cyclopaedia, is to be understood as applicable to dilute *acetic acid*; and the salts termed *acetites* are to be considered as *acetates*. The following facts are important, and deserve a place here.

The specific gravity of acetic acid does not enable us to determine its strength. The specific gravity is stated by Dr. Thomson to be a maximum when the liquid is a compound of one atom, and three atoms water. When the proportion of water is either increased or diminished, the specific gravity diminishes. Acid composed of one atom real acid and one atom water, and acid composed of one atom real acid and nine and a half of water, are stated by the same chemist to have the same specific gravity.

The following table, drawn up chiefly from the experiments of Mollerat by Dr. T., exhibits the specific gravity of acetic acid of various strengths.

Atoms.		Weight of		Sp. Gr.
Acid.	Water.	Acid.	Water.	
1	+	1	100	1.0630
		2	100	1.0742
		3	100	1.0770
		4	100	1.0791
		5	100	1.0800
		6	100	1.0763
		7	100	1.0742
		8	100	1.0728
		9	100	1.0658
		10	100	1.0637
		11	100	1.0630

Acetic

Acetic acid of the sp. gr. 1.063 is the strongest that can be procured. It crystallizes at the temperature of 55°, and the crystals melt slowly when heated to 72½°. This had been long ago observed by Courtenvaux. Lowitz has proposed an ingenious method of obtaining it of the requisite degree of strength to crystallize. This consists in making distilled vinegar into a thick paste with well-burnt charcoal, and exposing the mixture to a temperature of 212°. The watery part is driven off, and the acid remains. The acid itself may be separated by a higher degree of heat, and thus obtained in a very concentrated state. It is commonly necessary, however, to repeat the process before it can be made to crystallize.

Mr. Chenevix, by distilling the acetates, obtained a peculiar substance different from acetic acid, and which he has denominated *pyro-acetic spirit*. The acetates of potash and soda gave a greater proportion of this principle than any of the metalline acetates; but when the acetate of barytes is distilled, the whole liquid product consists of this spirit without any mixture of acid whatever. No other genus of salts tried, such as the oxalates, tartrates, or citrates, yielded this spirit, nor was acetic acid converted into it by heat.

Pyro-acetic spirit is a white and limpid fluid. Its taste is at first hot and acrid, but it becomes cooling and rather urinous. Its smell is peculiar, and is compared by Mr. Chenevix to that of a mixture of oil of peppermint and bitter almonds. Its specific gravity is .7864. It burns with a flame, white exteriorly, but of a fine blue within, and leaves no residue. It boils at a temperature of 165°. It mixes with water, alcohol, and volatile oils, in any proportion. With hot olive-oil it also mixes in any proportion; but with that oil cold it only mixes in certain proportions. When hot it dissolves wax and tallow. It dissolves also a little sulphur and phosphorus, and is an excellent solvent of camphor. It dissolves potash, and becomes dark-coloured, but it may be obtained again unaltered by distillation. Strong sulphuric acid blackens and decomposes it. Nitric acid renders it yellow, and changes its properties. Muriatic acid renders it brown. When distilled with this acid a combination takes place, and a substance is formed possessing very different properties from muriatic ether. These properties are sufficient to shew, that the pyro-acetic spirit is a distinct substance, and differs entirely from alcohol, ether, and volatile oils. Of course, therefore, as Dr. Thomson observes, it deserves a distinct place among compound combustibles.

Many attempts have been made to analyze the acid. Those most worthy of notice are by Gay Lussac and Thenard, and Berzelius. The former burnt a mixture of acetate of barytes and chlorate of potash. The results were carbonic acid and water. Berzelius's analysis was made on the same principles, but the salt he employed was supposed to be quite free from water. The following are the results of these celebrated chemists:

	Hydrogen.	Carbon.	Oxygen.	Acid.
Gay Lussac	5.629	+ 50.224	+ 44.147	= 100
Berzelius	6.55	+ 45.83	+ 46.82	= 100

If, with Dr. Thomson, we consider the results of Berzelius most entitled to credit, acetic acid consists of

3 atoms or proportions of hydrogen,	weighing	0.375
4 ————— of carbon	—————	3.000
3 ————— of oxygen	—————	3.000

Or of ten atoms or proportions, and the weight of an integrant particle, will be 6.375; and this weight, as the same

chemist has shewn, accords very well with the constitution of the acetates.

ACHARIA, in *Botany*, a genus dedicated by Professor Thunberg, to the honour of his countryman Dr. Eric Acharius, knight of the order of Wasa, a member of various learned societies, and one of the most distinguished botanists of the present day, particularly with regard to the *Lichen* tribe, which he has profoundly studied, and most learnedly illustrated. (See **LICHENES**.) Dr. Acharius is now Regius Professor of Physic, at Vadstena, in Sweden.—Thunb. Prodr. præf. n. 7. Willd. Sp. Pl. v. 4. 327. Lamarck Illustr. t. 755.—Class and order, *Monoecia Triandria*; or rather, perhaps, *Triandria Monogynia*. Nat. Ord. *Elægni*, Juss.?

Gen. Ch. Cal. Perianth inferior, of two small, ovate, acute, permanent leaves. Cor. of one petal, tubular-bell-shaped, downy, in three deep, equal, elliptical segments, permanent. Stam. Filaments three, very short, inserted into the top of the tube of the corolla, opposite to its segments; anthers roundish, of two lobes. Pist. Germen superior, roundish; style solitary, thread-shaped, half as long as the corolla; stigma three-cleft. Peric. Capsule ovate, of one cell, and three valves. Seed solitary? globose, rough. The *filamens* are most perfect in the upper flowers, the *pistil* in the lower.

Eff. Ch. Calyx of two leaves. Corolla of one petal, three-cleft. Capsule of one cell, and three valves. Seed solitary?

Obs. Nothing can be more imperfect or puzzling than the character and natural affinity of this genus, according to the materials furnished by Thunberg, especially what regards the *capsule* and *seed*. He defines the fruit, "*capsule* of one cell, with three *seeds*." Willdenow, who seems to have had no other authority than Thunberg's figure, says, "*capsule* of one cell and three valves, with a solitary *seed*," which last account best agrees with that figure. With respect to the natural order of *Acharia*, if we take for *bractæas* what Thunberg terms a *calyx*, the *flower* will indicate one of Jussieu's *Elægni*, though the *capsule* of three valves is very anomalous, and the lobed *leaves* no less so. By the specific name *tragodes*, or rather *tragioides*, and the place where the genus is introduced, Thunberg appears to have considered it as akin to **TRAGIA**, (see that article,) which idea the aspect of the *leaves*, and the somewhat monoecious *flowers*, might probably suggest.

1. *A. tragodes*. Lobed *Acharia*. Thunb. Prodr. 14. t. 1. Fl. Cap. v. 1. 160. Willd. n. 1.—Gathered by Professor Thunberg, near Van Stade's river, and in other parts of the interior of Africa, above the Cape of Good Hope, flowering in December and January. Root fibrous, annual? Stem solitary, herbaceous, erect? from four to twelve inches high, branched from the bottom to the top, smooth; branches alternate, angular, erect, somewhat zigzag, wand-like, subdivided. Leaves alternate, on stalks about their own length, about an inch long, three-lobed, finely downy; lobes obovate, variously cut. Flowers in effect monoecious, axillary, solitary, on short stalks, reflexed, small, the male about the upper part of the plant, female lower down. The corolla is about a quarter of an inch long, downy all over, as are likewise the *germen* and *style*. Capsule ovate-oblong, acute, thrice the length of the permanent corolla. Seed nearly the size of a pepper-corn, apparently black and rough.

ACHERON, l. 1, r. Theoprotia.

ACHILLINI, l. 25, for 40 r. 49.

ACHIMENES, in *Botany*, so named by Browne, possibly

sibly from α , and $\chi\mu\alpha\omega\upsilon\varsigma$, to be *vaintry*, or *tempehuaut*, meaning that the plants in question are not calculated to endure rough weather. He tells us they thrive best in the cooler parts of Jamaica. When cultivated in Europe, they require great heat. This genus is founded on two species only, and those as generically different as two plants of the same natural order can well be. See Browne's Jamaica, 270. t. 30. f. 1, and Juss. Gen. 119. The latter writer, following Browne, did not distinguish these plants. One of them is *Columnea bifida*, the other our CYRILLA; see that article.

ACHOR, last line. *r.* PORRICO instead of TINEA Capitis.

ACHROCORDES. Add. See SERPENTES.

ACHTIL, ACHELIEG, or *Martel*, a corn-measure in Germany, which contains 4 hinners, 8 metzers, 16 sechters, or 64 gefcheides. See MALTER.

ACIANTHUS, in *Botany*, from $\alpha\upsilon\varsigma$, a point, and $\alpha\omega\delta\omicron\varsigma$, a flower, because of the bristly tips of the calyx-leaves, unusual in this family.—Brown Prodr. Nov. Holl. v. 1. 321.—Clas and order, *Gynandria Monandria*. Nat. Ord. *Orchidææ*.

Gen. Ch. *Cal.* Perianth three-leaved, somewhat ringent, awned; its two side-leaves placed under the lip; upper one broadest, vaulted, erect. *Cor.* Petals two, linear-lanceolate, much smaller than the calyx. Nectary a prominent undivided lip, shorter than the petals, with two swellings at the base, but no appendage to the disk. *Stam.* Anther terminal, permanent, of two cells close to each other; mass of pollen in each cell four, or two divided ones. *Pist.* Germen inferior, oblong, angular; style erect, semi-cylindrical, without any auricles or wings at the summit; stigma in front. *Peric.* Capsule of one cell. *Seeds* numerous, minute.

Eff. Ch. Calyx somewhat ringent; its side-leaves under the lip. Lip without a spur, shorter than the petals, undivided, with two prominences at the base. Anther terminal, without appendages, permanent. Pollen powdery. Column semi-cylindrical.

This genus is next akin to MICROTIS of the same author (see that article); to whose essential character should be added, "Anther with two auricles. Column funnel-shaped."—*Acianthus* consists of little smooth herbs, with solitary, undivided, naked, downy bulbs, or tubers, throwing out a few fibres, along with a downy shoot, at whose extremity the young bulb is situated, on a partial stalk. *Stem* very short, its base enclosed in a short, tubular, pointed sheath. *Leaf* solitary, deeply heart-shaped, acute, with three ribs, and many reticulated veins; its under side red or purple. *Flowers* small, reddish, either clustered or solitary, their common stalk without bristles, except beneath each flower.

1. *A. fornicatus*. Vaulted *Acianthus*. Br. n. 1.—Flowers racemose. Awns four times shorter than the perianth. Petals nearly erect. Lip bearing longitudinal glands. Column concealed.—Native of the neighbourhood of Port Jackson, New South Wales, from whence we long ago, received specimens in spirits, as well as dried, by favour of Dr. White, and where Mr. Brown has also gathered this curious little plant. The leaf is about an inch in diameter. Common flower-stalk from three to six inches high, bearing from two to six flowers, about the size and aspect of the *Coralorrhiza*, each with an ovate bristle at its base. Lower leaves of the calyx linear-lanceolate, very narrow in comparison of the upper one. Petals linear-lanceolate, very delicate. Lip somewhat fleshy, having a longitudinal furrow, the ridges bearded horizontally

with papillary glands. This is the only species we have seen.

2. *A. exsertus*. Prominent *Acianthus*. Br. n. 2.—Flowers racemose. Awns very short. Upper calyx-leaf tapering at the base. Petals horizontally reflexed. Lip glandular at the extremity. Column prominent.—Gathered by Mr. Brown, near Port Jackson.

3. *A. caudatus*. Long-awned *Acianthus*. Br. n. 3.—Stalk with one or two flowers. Awns very long. Leaf way at the margin.—Gathered by Mr. Ferdinand Bauer, in the neighbourhood of Port Jackson.

4. *A. bifidulus*. Two-leaved doubtful *Acianthus*. Br. n. 4. (*Epipactis reflexa*; Labill. Nov. Holl. v. 2. 60. t. 211. f. 1.)—"Stalk single-flowered. Leaves two, radical, hooded. Perianth without awns, its three leaves uniform; the lateral ones reflexed. Petals? linear, narrow."—Gathered by Labillardiere, at Cape Van Diemen. Mr. Brown doubts whether this species, which he appears not to have examined, is most akin to *Acianthus*, or to another genus of his, hereafter to be noticed, named *Chiloglottis*. It agrees with the former in having four masses of pollen, a column destitute of a joint, and a lip without any appendage; with the latter in bearing two radical leaves, a perianth without awns, and very narrow petals. These last are represented in the plate, at fig. 2, as if situated on the outside of the calyx, which the description, and, if we mistake not, the other figures, shew to be an error of the draughtsman or engraver.

ACICARPHA, so named by the celebrated Jussieu, from $\alpha\upsilon\varsigma$, a point, and $\kappa\alpha\alpha\rho\alpha$, a chaffy scale, because the scales of the receptacle, as he thought, become armed with a spinous point, when the seeds, which they separately envelop, approach towards maturity.—Juss. in *Annal. du Mus. d'Hist. Nat.* v. 2. 347. Willd. Sp. Pl. v. 3. 2327.—Clas and order, *Syngenesia Polygamia-necessaria*? Nat. Ord. *Compositæ capitatae*, or rather *Aggregate*, Linn. *Corymbifera*, Jacq. 5. Juss.

Gen. Ch. Common Calyx of one leaf, in five deep, linear, spreading segments, permanent. *Cor.* compound, discoid. Florets all uniform, tubular, funnel-shaped; their limbs somewhat bell-shaped, five-cleft, obtuse; the central ones male, least numerous; those of the circumference more abundant, each furnished with stamens and pistil, but not all fertile. *Stam.* Filaments five, very short; anthers oblong, united, shorter than the limb of the floret. *Pist.* Germen oblong; style thread-shaped, longer than the corolla; stigma club-shaped, notched. *Peric.* none, except the hardened scales of the receptacle. *Seeds* solitary; oblong, destitute of crown or wing, each enclosed in a greatly enlarged, hardened, concave, spinous-pointed scale of the lower part of the cylindrical chaffy receptacle.

Eff. Ch. Receptacle chaffy. Seed-down none. Calyx in five deep segments. Florets uniform, tubular. Seeds separately enclosed in the spinous scales of the receptacle.

1. *A. tribuloides*. Caltrap *Acicarpa*. Juss. as above, 348. t. 58. f. 1. Willd. n. 1.—Leaves oblong, deeply toothed.—Gathered by Commercer, on the sea-shore at Monte Video. Root tapering, annual. Stems one or more, herbaceous, ascending or decumbent, a span long, somewhat branched, leafy, smooth. Leaves alternate, sessile, oblong, obtuse, fleshy, smooth, an inch and a half to three inches long, deeply and coarsely toothed; tapering at the base. Flower-stalks terminal and lateral, opposite to the leaves, and about as long, simple, single-flowered, erect. Flowers white, hemispherical, one-third of an inch in diameter. Fruit a globular head, armed with unequal, rigid, sharp, pale, divaricated, or recurved spines, and crowned with

with a tuft of withered male florets, like a tassel. The intermediate florets seem to be abortive, though furnished with the most conspicuous pistils.

2. *A. spatulata*. Spatulate Acicarpha. Brown Tr. of Linn. Soc. v. 12. 129.—Leaves spatulate, mostly entire.—Sent from Brazil by Mr. Sellow. A smooth, diffuse, apparently annual plant, with angular ascending branches. Leaves scattered, stalked, without stipulas, spatulate, with a very short little point, rather thick, and perhaps glaucous, an inch and a half long; the lower ones sometimes toothed from above the middle. Footstalks linear, a little dilated at the base; the lowermost longest. Heads of flowers yellow, solitary; either stalked and opposite to the leaves, or terminal and nearly sessile. Involucrum of five leaves in a simple row, longer than the flowers. Receptacle conical, slender, chaffy, with lanceolate pointed scales. Florets tubular, uniform, smooth. Those of the circumference in two or three rows, with perfect stamens as well as pistils. Tube of the corolla slender, cylindrical, closely united to the germens and base of the style; limb funnel-shaped, five-cleft, segments parallel at the edges, half-lanceolate, flat, three-ribbed. Stamens five, inserted into the corolla, alternate with its segments, their filaments, as well as the lower half of the anthers, united into a tube. Germens combined, each crowned with a five-cleft partial calyx, whose teeth, alternate with the segments of the corolla, become spinous, each germens containing one pendulous seed. Style thread-shaped, smooth. Stigma simple, obtuse, rather hairy. The numerous upper florets are rather smaller, with a membranous calyx, and imperfect germens. The ripe fruit, originating from the florets of the circumference, consists of close pericarps, combined together, not bursting, each crowned with its own enlarged spinous calyx. Seed ovate, pendulous. Albumen fleshy, large, white. Embryo nearly cylindrical, central, about the length of the albumen, with two linear cotyledons. By this account it appears that Mr. Brown differs from M. de Jussieu, in thinking the present genus belongs to the Linnæan order of *Aggregate*, and not to the *Compositæ*. This last account of the fruit is evidently more natural than the above, and the character, if Mr. Brown, which we doubt not, be correct, must be altered to "Seeds crowned with the spinous partial calyx."

ACID, ACIDIFICATION, in *Chemistry*. When these articles were written for the Cyclopædia, the theory of Lavoisier, that oxygen was the only principle of acidification, was almost universally received. Since that period, however, a great revolution has taken place in chemistry, and the doctrine in question is now no longer admitted. This indeed has been noticed in subsequent parts of this work, more especially under OXYGEN and OXYMURIATIC ACID; so that little more is necessary than to refer our readers to these articles. It may not be deemed superfluous, however, to mention here very briefly the discoveries that have led to these important changes.

The first circumstance which gave the death-blow to the doctrine of Lavoisier, was the demonstration by Gay Lussac and Thenard, and more especially by Davy, that oxy-muriatic acid, or chlorine, as it is now termed, contains no oxygen, but is a simple elementary substance. Chemists indeed had never been able to demonstrate satisfactorily that oxygen actually existed in this substance; but misled by the plausibility of the Lavoisierian doctrines, had tacitly admitted its presence from analogy; and so strongly was this belief founded, that there are a few, we believe, who adhere to the old opinions even to the present time.

More recently, however, the old opinions have been rendered still further improbable, and the new ones corroborated

by the discovery of iodine and cyanogen; the one an elementary, the other a compound substance, both which have been unequivocally demonstrated to form acids by combining with hydrogen. The analogy, also, of sulphuretted and telluretted hydrogen, compounds free from oxygen, but possessing the properties of acids, have been likewise urged in proof of the new opinions, and as quite irreconcilable with those of Lavoisier.

Our readers will find further information on this subject in the articles CHLORINE, CYANOGEN, IODINE, MURIATIC ACID, OXYGEN, and OXYMURIATIC ACID.

ACINACIFORME, FOLIUM, in *Botany*, a Scimitar-shaped Leaf, is scarcely used but for one species of *Mesembryanthemum*, which bears this specific name. (See LEAF. It is of a succulent texture, compressed, one edge convex and thin, the other straight and thick.

ACINACIFORME, *Pericarpium*, a Seed-vessel of a similar shape, is exemplified in the cells of the capsule of the same genus of *Mesembryanthemum*; see Linn. Phil. Bot. 224.

ACINUS, in *Botany* and *Vegetable Physiology*, a Grain, is technically used for each pulpy portion, containing a solitary seed, of a compound Berry. (See BACCA.) The fruit of the Raspberry, Bramble, &c., consists of several acini; and perhaps the same term may be applied to the separate portions of a Mulberry, though originating in the calyx of each flower become pulpy. In *Passiflora* the capsule is lined with very juicy acini, each lodging a single seed. Gærtner improperly extends the above term to the simple many-seeded berries of the Vine, Gooseberry, &c. The last-mentioned fruit, in an early state, rather resembles the *Passiflora*.

ACONITUM, in *Botany*, (see our former article,) has received considerable elucidation from professor De Candolle, in his *Regni Vegetabilis Systema Naturale*, v. 1. 364, where this genus is treated of as one of the natural order of RANUNCULACEÆ. (See that article.) Its generic references are, Linn. Gen. 274. Schreb. 368. Willd. Sp. Pl. v. 2. 1232. Mart. Mill. Dict. v. 1. Ait. Hort. Kew. v. 3. 321. Sm. Prodr. Fl. Græc. Sibth. v. 1. 372. Pursh 372. Juss. 234. Tourn. t. 239, 240. Lamarck Illustr. t. 482. Gærtner. t. 65. "Koelle Monogr. 1788. Erlang. in 8vo."—Class and order, *Polyandria Pentagynia*. Nat. Ord. *Multifloræ*, Linn. *Ranunculaceæ*, Juss. De Cand.

Eff. Ch. Calyx none. Petals five; the uppermost vaulted. Nectaries two, stalked, recurved. Capsules three or five.

M. De Candolle, following Jussieu's view of the subject, gives the following characters, using the term *sepala* for calyx-leaves, and *petala* for nectaries.

Calyx of five petal-like, deciduous leaves; the upper one (hood) large, concave, helmet-shaped; two lateral ones, (wings,) orbicular; two lowermost oblong. Petals five, sometimes irregular in number; three very minute, claw-shaped, often converted into stamens; two uppermost with long claws, hooded, sheltered under the helmet-shaped leaf of the calyx, dilated at the top into a bag, whose bottom, the summit, or spur, of the petal, is callous, incurved, its mouth extended into an oblong, emarginate limb, or lip. Stamens indefinite. Capsules three to five, with an indefinite number of seeds.

Perennial herbs, with tuberous roots, whose knobs in some instances bear fibres, in others are oblong, and mixed therewith. Stem leafy. Leaves stalked, deeply palmate, with from three to five segments, variously cut, cloven and toothed. Clusters terminal. Stalks single-flowered, from the bases of the bractæ, each bearing two smaller bractæ.

Flowers

ACONITUM.

Flowers large, irregular, sometimes sulphur-coloured, sometimes blue, or white.

All the species are poisonous; the *Anthora* less dangerous; the *Napelli* highly noxious. The root is always the most poisonous part, the herbage less acrid, and though in a fresh state injurious to animals, by drying, or by boiling in water, it becomes so mild, that some species, *A. septentrionale* for instance, are eatable! Dr. Storck, who found Aconite to be useful in chronic rheumatism, confirmed gout, and venereal swellings of long duration, employed *A. paniculatum*; but other physicians have often, without sufficient attention, promiscuously given every kind with blue flowers.

The twenty-eight species at this time known inhabit rough bushy or woody places, in the northern hemisphere; eleven are found in Europe, eleven in Siberia, one in Japan, one in North America, and one is common to Siberia and the western part of North America.

This is a most natural genus, but very difficult as to the determination of its species, nor has it been properly investigated. Clusius in his time was extremely well acquainted with the European kinds, and requires to be consulted in preference to all other writers.

Aconitum may be distributed by the habit, rather than by any characters, into five sections, or divisions, as follows.

SECT. 1. *Anthora*. Flowers pale yellow. Hood convex. Leaves in numerous deep linear segments. Species 1 and 2.

2. *Lycototum*. Flowers pale yellow, or very rarely blue. Hood conical, elongated, scarcely pointed in front. Leaves in wedge-shaped lobes. Species 3—10.

3. *Napellus*. Flowers blue or white. Hood convex. Leaves in numerous deep linear segments. Species 11—14.

4. *Cammarum*. Flowers blue or white. Hood conical, or very convex, with a long point in front. Leaves with wedge-shaped lobes. Species 15—20.

5. *Anabates*. Flowers blue or white. Hood convex. Stem climbing, somewhat twining. Species 21—25.

† Such as are not sufficiently described; 26—28.

†† Such as are doubtful, or uncertain; 29—35.

SECT. 1. *Anthora*.

To the above characters are added—Hood acute at the apex. Root with two oblong knobs.

1. *A. Anthora*. Whole some Wolf's-bane. (No. 5 of our former article.) Linn. Sp. Pl. 751. Willd. n. 5. Ait. n. 4. Jacq. Austr. t. 382. (Anthora Matth. Valgr. v. 2. 441. Camer. Epit. 837. Rivin. Pentap. Irr. t. 128. A. vulgaris. Clus. Hist. v. 2. 98. A. five Aconitum salutiferum; Ger. Em. 969. A. vera, flore luteo; Barrel. Ic. t. 609.)

β. *atrovirens*; and stalks smooth. (*A. salutiferum elatius pyrenaicum, foliis atro-virentibus, flore majore*; Tournef. Inf. 425.)

γ. confertiflorum; cluster cylindrical, dense, downy. (*A. tuberosum*; Patrín, unpublished.)

Hood convex, terminating in a point; spurs spiral; lips inversely heart-shaped. Leaves in numerous linear segments.—Native of rough bushy places, on the mountains of Europe; and in Switzerland, on the Apennines, and in Siberia; β on the Pyrenees; γ on mount Caucasus.

Var. α has either a simple or branched stem, which, like the flower-stalks, is either smooth, or finely downy. β has smooth dark-green leaves, a taller and smooth stem, less convex hood, with a more abrupt and pointed beak. γ is smaller, with a closer more cylindrical cluster, whose main stalk, as well as the partial ones, are clothed with velvet-like down; it may be a distinct species. *De Candolle*.

We have not followed, here or elsewhere, our learned friend, in his elaborate assemblage of synonyms, nor in his

chronological arrangement of them. To the latter we have objections, and the former would only be burthenome to our plan. We wish to give our readers an idea of his powers of discrimination, and to profit by them ourselves.

2. *A. anthoroideum*. Prominent, Whole some Wolf's-bane. (*A. pyrenaicum*; Pallas Itin. v. 2. 316, by his herbarium.)

—Hood convex; its back protruding forward, over the pointed beak; spurs spiral; lips inversely heart-shaped. Leaves in numerous linear segments.—Gathered by Pallas in Siberia. This is so like *A. Anthora*, that perhaps it may be esteemed a mere variety. It differs only in this respect, that the back, or ridge, of the hood is not merely convex, but stretched forward over the point in front. This plant varies like the former as to the density of its cluster, and the smoothness or fine downiness of the flower-stalks. *De Candolle*. We most readily concur in the opinion of its being a variety of the first species.

SECT. 2. *Lycototum*.

Flowers pale yellow, whitish, or bluish; their hood conical, elongated, obtuse, scarcely pointed in front. Root tuberous, sending out fibres. Leaves with somewhat wedge-shaped lobes, deeply toothed, or jagged, at the extremity.

3. *A. barbatum*. Bearded Wolf's-bane. Patrín, unpublished. "Perf. Enchir. v. 2. 83. Poir. Suppl. to Lamarck Dict. v. 1. 114."—Hood conical, obtuse; spurs straight; lips obovate; wings bearded with a fringe. Bractees minute. Stem downy. Leaves in five deep divisions, with linear pointed lobes.—Native of the eastern part of Siberia, about Irkoulsk. Patrín. Intermediate between *Anthora* and *Lycototum*, differing from the former in having a conical hood, from the latter in the linear lobes of its leaves; from both in the straight spurs, or summits of the bractees, (*De Candolle's petals*). Stem round, finely downy, not hispid. Leaves with long scattered hairs on the smooth stalks, and here and there on the under side; the upper appearing downy when magnified; their outline circular, divided nearly to the base into five somewhat cohering lobes, pinnatifid, with linear pointed segments. Cluster erect, long and dense. Stalks erect, downy, shorter than the flowers, having under each a linear-awl-shaped, scarcely downy; bractea, still shorter; as well as a smaller clove bractea half way up. Flowers whitish, according to Patrín; pale yellow when dry; externally downy; hood elongated; wings orbicular, with long hairs on their margin and inner surface. *Germei* downy.

4. *A. bipidum*. Rough-stalked Wolf's-bane. *De Cand.* n. 4.—Hood conical, obtuse; spurs straight; lips obovate; wings slightly bearded. Bractees awl-shaped, hairy. Stem hairy. Leaves in five deep divisions, with linear, rather acute, lobes.—Found by Pallas, in the eastern part of Siberia. *Lambert*. Differs from the last in its hispid, not downy, stem; more deeply five-cleft leaves, whose lobes are not pointed, but rather obtuse, with a little callous apex; more hairy bractees; and scarcely bearded wings. The leaves are very like *Anthora*, but with broader lobes; flowers like *Lycototum*, but with straight spurs. Stem erect, round, simple; hispid chiefly at the base, with soft, rather deflexed, hairs; the top almost smooth. Lower leaves on long hairy stalks, their outline orbicular; upper side scarcely downy; ribs of the under one hairy. Cluster simple, rarely with one small branch, cylindrical, erect. Stalks erect, shorter than the flowers, which are pale yellow, resembling the last, but less bearded. Bractees awl-shaped, flagggy, two lines long; two smaller ones in the middle of each stalk. *De Candolle*.

5. *A. squarrosum*. Spreading-lobed Wolf's-bane. *Linn.* MSS. in Herb. propr. *De Cand.* n. 5. (*A. n. 2*; *Linn.* Hort. Upsl. 152, excluding the synonyms. *A. pyrenicum*; *Linn.* Sp. Pl. 751, excluding the synonyms, and the Pyrenees

ACONITUM.

as its place of growth.)—Hood conical, obtuse; spurs spiral; lips inversely heart-shaped. Cluster drooping at the summit before expansion. Leaves in five deep divisions; lobes pinnatifid, with spreading, recurved, acute segments.—Native of Siberia and Tartary; cultivated in the Upsal garden. Very nearly allied to *Lycotoxicon*, but differing in the leaves being divided to the very base into many pinnatifid portions, whose elongated, acute, widely spreading segments are entire, not at all cut or ferrated. *Cluster* long, its upper part drooping while the flowers remain in bud. *Bractæas*, both general and partial, very small. *Stalks* shorter than the flowers, but much longer than their respective *bractæas*. The rest as in *Lycotoxicon*. *De Cand.* To this original specimen is attached a different one from Siberia, which we concur with professor De Candolle in thinking no other than *Lycotoxicon*. Hence Linnæus is no authority for *A. pyrenaicum*, which depends upon other authors, as follows. His herbarium indeed contains, if we mistake not, a specimen of this species, brought by baron Alstroemer from Spain, but confounded by Linnæus with *Lycotoxicon*.

6. *A. pyrenaicum*. Pyrenean Wolf's-bane. Lamarck Dict. v. 1. 33. Desfont. Tabl. 149. "De Cand. Franc. ed. 3. v. 4. 916. v. 5. 642." (*A. pyrenaicum*, ampliore folio tenuius laciniato; Tourn. Init. 424. A. n. 6; Camer. Epit. 831, with a figure.)—Hood conical, obtuse; spurs spiral; lips obovate. Leaves palmate below the middle, with from seven to nine three-cleft, deeply cut lobes, lying over each other.—Native of rugged meadows on the Pyrenees, among lofty thickets, flowering in July and August. Tournefort and De Candolle. Related to *Lycotoxicon*, but certainly distinct. A handsome plant, three or four feet high, downy, with large, long-stalked, almost circular leaves, whose main lobes are unequally divided, wedge-shaped at the base, separated upwards into acute, cut lobes, dilated so as frequently to overlap each other. *Cluster* long, cylindrical, dense, more or less branched at the base. *Stalks* often shorter than the flowers. *Lower bractæas* in three or five lobes; *upper* linear, in the middle of each stalk, spreading, from two to five lines long. *Flowers* pale yellow, externally covered with velvet-like down. *Germens* hairy. These characters are not very strong, but they are constant. Specimens gathered by De Candolle in the Pyrenees differed in no respect from those which have been cultivated at Paris, ever since the time of Tournefort. *De Candolle*. We have had no opportunity of enquiring what stands for this species in the gardens of England, but Miller is most likely to have received the true plant from France. Our Linnæan Spanish specimen, mentioned under the last, correctly answers, in every point, to the above description.

7. *A. lycotoxicon*. Great Yellow Wolf's-bane. Linn. Sp. Pl. 750. Willd. n. 1. Ait. n. 1. Jacq. Austr. t. 380. Balliard Fr. t. 63. Villars Dauph. v. 3. 703, from the author. (*A. lycotoxicon* vulgare, luteo flore; Cluf. Hist. v. 2. 94. *A. luteum* ponticum; Lob. Ic. 677. Ger. Em. 970. *A. reticulata* radice, flore sulphureo-albicante; Barrel. Ic. t. 599, 600. A. n. 2; Camer. Epit. 827. Matth. Valgr. v. 2. 431. *Napellus* flore luteo; Rivin. Pentap. Irr. t. 129.)—Hood conical, obtuse; spurs spiral; lips obovate. Leaves downy, divided more than half way, into from three to five lobes, which are three-cleft and jagged. Partial *bractæas* in the middle of each flower-stalk.—Native of woods, thickets, and grassy pastures, on the mountains of Switzerland, France, Germany, and Italy, flowering in summer. This is probably, as M. De Candolle indicates, the real *ακωνίσιον* *λυκοτόξικον* of Dioscorides, with whose imperfect account it sufficiently agrees. It is one of the most common of this genus, but not found in Britain. The stem

is from two to four feet high, nearly simple, or very much branched, smooth or downy. Lobes of the leaves more or less deep, either close or spreading. *Flowers* crowded or distant. M. De Candolle hints that some of these diversities may afford specific distinctions, but we can scarcely suppose this. He observes that *A. lycotoxicon* differs from *barbatum*, *bispidum*, and *ochroleucum* in its spiral spurs; from *pyrenaicum* in having from three to five, not seven to nine lobes in the leaves, and those not lying over each other, as well as in the *germens* being smooth, scarcely at all downy or hairy, and the stalks mostly longer than their flowers. From the following one, hitherto confounded herewith, it differs in having pale-yellow, not blue, flowers, and the partial *bractæas* situated half way up the flower-stalks, not near their base.

8. *A. septentrionale*. Blue Northern Wolf's-bane. "Koelle Acon. 22." Willd. n. 7. De Cand. n. 8. Ait. n. 6. (*A. lycotoxicon*; Linn. Fl. Lapp. ed. 2. 185. Tour in Lapland, v. 1. 36. 47. 278. v. 2. 123. 277. Fl. Dan. t. 123. Calceolus Lapponicus; Scheff. Lapp. 360.)—Hood conical, obtuse; spurs spiral; lips obovate. Leaves downy, divided more than half way, into from three to five divaricating sharply cut lobes. Partial *bractæas* at the lower part of each flower-stalk.—Native of mountainous thickets and pastures on the sides of the Lapland alps, and throughout Norway, as well as in some parts of Siberia, and on the Carpathian mountains. Linnæus noticed it also about the bases of the larger hills in Medelpad and Angermanland; but though he has recorded in Fl. Lapp. that the flowers are of a greyish-blue; not yellow, as described in all the accounts of *A. lycotoxicon*; yet he still supposed his to be the same species. His own specimen retains evident traces of this blue or grey colour, and answers to the distinctive characters of the *septentrionale*, as given by De Candolle. The leaves, as that excellent writer remarks, are more acutely toothed. With respect to the situation of the partial *bractæas*, they are rather on the lower part, than at the base, of the flower-stalks. The flowers are less downy, and of a thinner texture, than in *lycotoxicon*. Perhaps if living specimens were compared, better characters might be discovered, for there is every reason to presume this a distinct species. Linnæus in Fl. Lapp. speaks of the leaves being boiled and eaten with impunity; and in his Lapland Tour, v. 2. 123, records another instance of the same fact. He was justly astonished, knowing the poisonous quality attributed by all writers to *A. lycotoxicon*. Perhaps this may strengthen our opinion of these plants being truly distinct, for we find no record of the true *lycotoxicon* being used as food, in any state. Haller was one of the first botanists who suggested the propriety of separating these species; see his Hist. Stirp. Helvet. n. 1200. Yet there seems little reason for his wonder, there expressed, that this *Aconitum* should be fatal to wolves. When recent its qualities are probably very different.

9. *A. ochroleucum*. Pale Wolf's-bane. Willd. n. 4. De Cand. n. 9. Ait. n. 3. March. Taurico-Caucas. v. 2. 14, excluding the synonym of Tournefort.—Hood conical, elongated; spurs curved; lips lanceolate. Leaves deeply palmate, five-lobed, scarcely downy beneath; lobes deeply three-cleft, acutely jagged and toothed.—Found in mountainous meadows of mount Caucasus; frequent about the mineral springs of Narzana; flowering in summer. Communicated to us by Dr. Fischer. The habit entirely resembles *A. lycotoxicon*, but the surface of the herb is nearly smooth; the lobes of the leaves are more sharply toothed; and the spurs of the *necaries* are rather curved than spiral. *Stem* erect, round, pale green, three or four feet high, with straight branches. *Cluster* long, branched at the bottom.

Lower

ACONITUM.

Lower bractæ in three or five segments, often reflexed; *upper linear*; *partial ones* in the middle of each *flower-stalk*, two lines long. *Flowers* pale buff, crowded, remarkable for their long and slender *hood*, measuring above an inch. *Stalks* shorter than the flowers. *Spurs* of the *nectaries* curiously involute.

10. *A. japonicum*. Japan Wolf's-bane. Thunb. Jap. 231. Willd. n. 2. De Cand. n. 10. (Soo Hoo of the Japanese.)—Hood conical, obtuse. Leaves palmate, three-lobed; lobes obtuse, cut; their segments rounded, with a point.—Gathered in Japan by Thunberg, who describes this species as allied to *lycoctonum*. The stem is round and smooth. Leaves stalked; their lateral lobes in two segments; middle one in three; all obtuse, deeply toothed; their teeth rounded, with a point. *Cluster* short. *Thunberg*.

SECT. 3. *Napellus*.

Flowers blue or white, never buff-coloured; their hood convex, tapering into a point in front. Stem straight. Cluster cylindrical. Roots fibrous, from a rather tuberous stock. Leaves lobed in a palmate manner, many-cleft; their segments linear.

All the species of this section having been confounded under *A. Napellus*, De Candolle has thought right to lay aside that specific name entirely. But even he is doubtful whether they are not all one species!

11. *A. vulgare*. Common Monk's-hood. De Cand. n. 11. (*A. Napellus*; Linn. Sp. Pl. 751. "Koelle Acon. 14, with a figure." Woodv. Med. Bot. t. 6. Sm. Prodr. Fl. Græc. Sibth. v. 1. 372. *A. lycoctonum* 6, *Napellus vulgare*; Cluf. Hist. v. 2. 96. *Napellus*; Matth. Valgr. v. 2. 440. *N. versus caruleus*; Ger. Em. 972. *N. flore minore*; Rivin. Pentap. Irr. t. 130.)—Germens three, smooth. Wings hairy on the inside. Cluster cylindrical, elongated. Leaves in five divisions to the very base, with many linear acute segments, each with a longitudinal furrow on the upper side.—Native of mountainous meadows in most parts of Europe, from Switzerland, Germany, France, Spain, and Italy, to Greece, flowering in summer, and one of our most common garden plants ever since the days of Gerard. Dr. Leech sent us specimens from Scotland; but there is reason to doubt the plant's being really wild in Britain. De Candolle distinguishes this from all its relations, though, as he says, with difficulty, by the simple, straight, upright stem, almost always terminating in a simple cylindrical close cluster, and not corymbose; leaves with linear segments, that are hardly at all dilated at the extremity, marked with a furrow, and not resembling any others, except perhaps those of *A. tauricum*, whose cluster is the only one more dense than the present; hood convex, rather acute at the summit, but not gibbous or elevated at the back, as in *intermedium*, *rostratum*, and *variegatum*; wings hairy on the inside, which in *tauricum*, *parvicolum*, &c. are smooth; germens smooth, never more than three, not five, and hairy; capsules six lines long, and not an inch, as in *A. neubergense*. The present species however, being very common, is extremely variable; the whole surface is sometimes quite smooth, sometimes downy, especially about the flowers; the furrow on the segments of the leaves is more or less distinct; the flowers naturally blue, or (in the variety called by Schultz *bicolor*) white at the base, blue at the summit, become in gardens white, rose-coloured, purple, or variegated. De Candolle. Their most usual and well-known colour is a deep and gloomy blue; we have seen no other. Dr. Sibthorp's Greek plant must rest on his own authority, being only mentioned in his MSS., without any accompanying specimen; nor were the species of this genus so accurately noted in his time.

12. *A. strictum*. Straight Monk's-hood. "Berrh. Monogr." De Cand. n. 12.—Germens three, smooth. Wings hairy on the inside. Cluster cylindrical, elongated. Leaves in five divisions to the very base; their lobes wedge-shaped, jagged at the summit.—Native country unknown. Closely related to the last, but differing in the three or five divisions of the leaves being wedge-shaped in their lower part, and cut at the extremity into oblong lobes, which are shorter, blunter, and twice as broad as in that; the cluster is shorter, with little short branches at its base. Perhaps this may not be sufficiently distinct from the following, De Candolle.

13. *A. neubergense*. Broad-leaved Monk's-hood. De Cand. n. 13. (*A. Napellus*; Herb. Linn. Jacq. Austr. t. 382. Ehrh. Pl. Off. n. 87. "Palmfr. Suc. t. 46." *A. lycoctonum*, vel *neubergense*; Cluf. Hist. v. 2. 96. Morif. sect. 12. t. 3. f. 11. *A. purpureum neubergense*; Ger. Em. 973. *A. foliorum laciniis linearibus, supernè latoribus, lineâ exaratis*; Linn. Hort. Cliff. 214. *Moræus* in Stockh. Transf. for 1739. 43. t. 2. *Napellus flore majore*; Rivin. Pentap. Irr. t. 131.)—Germens three, smooth. Wings hairy on the inside. Cluster cylindrical, elongated, lax; stalks downy, rather spreading. Leaves in five deep, wedge-shaped, three-lobed, jagged segments.—Native of alpine meadows in various parts of Germany, Hungary, Siberia, &c., flowering rather later than *A. vulgare*, and no less common in gardens than that species, with which it is generally confounded. Clufius having originally met with this plant in the greatest abundance on the mountain called Neuberg, in Styria, De Candolle has chosen the above specific name, which is indeed preferable to the mongrel one of *neomontanum*, adopted by some writers. The species before us is said to differ from *vulgare*, in having broader leaves, whose rather wedge-shaped divisions are more connected at the base; three-cleft and cut at the extremity, into acute segments, thrice the breadth of *vulgare*, and not marked with any furrow. The cluster also is more lax, its stalks always downy, more spreading, and longer than the flowers. The capsules, according to Wahlenberg, are three, above an inch long, spreading, those in the middle part of the cluster exceeding the length of their stalks.

14. *A. tauricum*. Taurian Monk's-hood. Wulf. in Jacq. Coll. v. 2. 112. Jacq. Ic. Rar. t. 492. De Cand. n. 14. "Koelle Acon. 15." (*A. Napellus*; Bull. Fr. t. 45? De Cand. *A. lycoctonum quartum tauricum*; Cluf. Hist. v. 2. 95. *A. violaceum*; Ger. Em. 973.)—Germens three, smooth. Wings smooth. Cluster cylindrical, elongated, very dense; stalks smooth, shorter than the bractæ. Leaves in five divisions to the very base, somewhat pedate, with linear lobes.—Native of the alpine heights of Tauria, Carinthia, &c. flowering in summer. Very like *vulgare*, but the smooth wings and flower-stalks, the latter shorter than their bractæ; the short dense cluster, whose main stalk is concealed; and the pedate, more wedge-shaped; linear-lobed, scarcely furrowed leaves, are thought by De Candolle to afford sufficient differences.

SECT. 4. *Cammarum*.

Flowers blue or white; hood very convex, or conical, ending, often abruptly, in a point in front. Cluster lax, somewhat corymbose. Stem straight. Leaves deeply divided, in a palmate manner, into wedge-shaped lobes. Roots navew-shaped, intermixed with small fibres.

For the same reason as concerns the last section, the specific name *Cammarum* is here laid aside, having been variously applied by different botanists. De Candolle suspects all the species of the present section, or at least the first four, may be varieties of each other!

ACONITUM.

15. *A. intermedium*. Ambiguous Monk's-hood. De Cand. n. 15. (*A. neomontanum*; Willd. n. 9, excluding the synonym, "Hoppe Pl. Exsicc." *De Cand.* Thora italica, seu *Napellus minor*, flore cæruleo; Barrel. Ic. t. 610.)—Germs three, smooth. Wings internally hairy. Cluster lax, corymbose; stalks smooth. Hood very convex, somewhat conical.—Found in mountainous woody parts of Germany and Flanders, flowering in July. In habit like the two following, but the hairy wings; (De Candolle by mistake says *lips*.) distinguish this species from all the rest of the section. We have seen no specimen.

16. *A. paniculatum*. Panicked Monk's-hood. Lamarck Franc. ed. 1. v. 3. 646. n. 1224. Diët. v. 1. 33. De Cand. n. 16. (*A. Napello simile*, sed minus, cæruleum, præcocius; Bauh. Hist. v. 3. 656. Chab. Sciagr. 531. *Napellus*; Camer. Epit. 836. Storck Libell. 69. t. 3.)

β, cluster drooping. De Cand. (*A. cernuum*; "Koelle Acon. 17." Willd. n. 12. *A. lycocotnum octavum*, comâ nutante; Cluf. Hist. v. 2. 97. *A. maximum nutante comâ*; Ger. Em. 971. *A. septimum*; Matth. Valgr. v. 2. 436. Camer. Epit. 832.)

Germs three, smooth. Wings internally smooth. Cluster lax, corymbose; stalks downy. Hood convex.—Found in various alpine parts of Europe, flowering towards autumn. The roots are roundish, tapering downwards, bearing many long fibres. Stem erect, smooth. Leaves somewhat pedate; their lobes wedge-shaped below, acutely pinnatifid upwards. Cluster usually erect, with long downy stalks; downy; the lower ones branched. Flowers large, of a brighter blue than *vulgare*, with a convex hood, whose point is more remarkable than in the 3d section. It may be important, if any person should repeat Storck's experiments, to be aware that this is the plant he used, and not our Common Monk's-hood, *A. vulgare*.

17. *A. rostratum*. Beaked Monk's-hood. De Cand. n. 17. (*A. Cammarum*; Lamarck Diët. v. 1. 33. Willd. n. 14? *A. lycocotnum nonum judenbergense*; Cluf. Hist. v. 2. 97. *A. maximum judenbergense*; Ger. Em. 973. *A. lycocotnum*, flore maximo; Bauh. Hist. v. 3. 659.)—Germs three, smooth, or only fringed at the inner edge. Wings smooth. Cluster somewhat corymbose, of few flowers, with smooth stalks. Hood conical, elevated, abrupt in front, with a prominent beak.—Native of the Austrian and Swiss alps, flowering in summer. We have it in Mr. Davall's herbarium, but the plant seems unknown to cultivators. The roots are roundish, tapering downward. Stem a yard high, straight, round, smooth, purplish. Leaves somewhat pedate, with wedge-shaped, jagged, acute lobes. This species differs from the preceding, as well as from the following, in the very large and high hood, accompanied by a very considerable beak, being conspicuous for the greater size, and rather paler blue, of its flowers.

18. *A. hebegynum*. Downy-fruited Monk's-hood. De Cand. n. 18. (*A. Cammarum*; Linn. Sp. Pl. 751? Willd. n. 14? Ait. n. 11? Jacq. Austr. t. 424.)—Germs from three to five, all over finely downy. Wings nearly smooth. Cluster rather corymbose, of few flowers; stalks downy. Hood convex, beaked in front.—Native of rugged bushy places on the alps of Switzerland, from whence we have it; as well as of Austria and the recesses of the Carpathian mountains, flowering in summer. A large handsome species, with ample foliage, whose segments are acutely pinnatifid. Flowers dark-blue; their hood rounded, much less elevated than in the preceding. The germs clothed with fine velvet-like down afford a clear specific character. There are no means of perfectly ascertaining the *A. Cammarum* of Linneus, he having left no specimen, and his synonyms pointing

to different plants. His character of "*floribus subpentagonis*;" is all that indicates the present species, which is probably the plant of the gardens. De Candolle says all the synonyms of his first, or principal, variety of *paniculatum*, may just as well serve for *hebegynum*; but surely Storck's figure cannot be mistaken for this. The plants themselves can never be confounded, provided the germs be attended to; for which discovery we are indebted to professor De Candolle.

19. *A. variegatum*. Variegated Monk's-hood. Linn. Sp. Pl. 750. Willd. n. 13. Ait. n. 10. "Koelle Acon. 18." (*A. lycocotnum decimum*, Thora italica; Cluf. Hist. v. 2. 93. *A. lycocotnum cæruleum parvum*; Ger. Em. 971. *Napellus flore mixto*; Rivin. Pentap. Irr. t. 133.)—Germs three, smooth as well as the petals. Cluster lax; stalks smooth; the lower ones many-flowered, twice the length of their many-cleft bractæes; their lower partial bractæes cut. Hood elevated, conical, obtuse, with a short beak in front.—Native of woody rather alpine situations, in Carniola, Bohemia, and Italy, flowering in August. Root, according to Clusius, tuberosus, with ovate knobs, or rather perhaps buds. Whole herb smooth. Stem erect, with spreading branches. Lower leaves on long stalks, their outline orbicular, their upper side of a shining green, lower pale; their three or five deep principal divisions wedge-shaped at the base, dilated and many-cleft at the extremity, with oblong acute segments; upper leaves sessile; floral ones in three deep divisions, copiously, but not deeply, cut. Lower stalks of the cluster distant, each bearing three or four flowers. Partial bractæes, which are under each flower, linear. Flowers large, perfectly smooth, blue (or blue and white); the hood very large, above an inch long, and extremely convex, not at all covering the wings, its beak short; wings orbicular, fix or seven lines long; germs smooth, slender. De Candolle. This description answers to the Linnæan specimen, and nearly to our garden plant, except that we have always seen the flowers principally white, with a portion of blue on the beak and wings, and that the stem in ours is rather of the twining or wavy kind, as in the next section; by no means straight, though supporting itself. This character appears in the old wooden cuts, and may possibly have escaped M. De Candolle, only because, as he himself mentions, he had seen no other than a dried specimen. The figure of Rivinus indeed is erect, and yet, notwithstanding the annexed representation of five capsules, we can scarcely doubt that synonym.

20. *A. album*. White Monk's-hood. Ait. ed. 1. v. 2. 246. ed. 2. n. 5. Willd. n. 6. De Cand. n. 20. (*A. orientale*; Mill. Diët. ed. 8. n. 10. *A. lycocotnum orientale*, flore magno albo; Tourn. Cor. 30. *Napellus flore albo*; Rivin. Pentap. Irr. t. 132?)—Germs four or five. Hood conical, with a long claw. Cluster lax, simple. Stalks erect. Leaves in three or five deep, ovate-wedge-shaped, three-cleft, toothed segments.—Found in the Levant by Tournefort, who sent seeds to the royal garden at Paris, and from thence, according to Miller, it came to England. Hence there can be no doubt respecting Tournefort's synonym; and yet his appellation of *lycocotnum*, and the place in his *Infl.*, where he directs this species to be inserted, might favour the application of his synonym to *ochroleucum*, n. 9, as in the Flora Taurico-Caucasica. The plant of Aiton, and consequently of De Candolle, is totally different from the *ochroleucum*, and very near *variegatum*. The stem is described by Miller fix feet high, or more. We have a specimen from Dr. Schrader, sent to be compared with *Napellus*, which appears to be this very species, and agrees well with the figure of Rivinus indicated above, except the flowers being blue; but that circumstance can

ACONITUM.

be of no moment. The *stem* is round and smooth. *Leaves* smooth; their wedge-like lobes sharply pinnatifid. *Cluster* lax, with some axillary branches below. *Stalks* erect, smooth. *Hood* near an inch and a half long, obtuse, even, bent forward with a slightly recurved, notched, beak; its *claw* longer than the large round *wings*. *Germens* five, smooth.

SECT. 5. *Anabates*.

Flowers blue or white; hood convex. Cluster lax. Stem twining, climbing.

21. *A. eriophlemon*. Hairy-throated Monk's-hood. De Cand. n. 21. ("A. volubile; Koelle Acon. 21, but not of Willdenow." De C.)—Stem twining, somewhat downy with close hairs. Footstalks naked. Leaves in three or five deep, pinnatifid lobes, with lanceolate segments. Cluster lax. Germens two or three, very smooth. Stamens hairy.—Gathered by Koelle in Siberia; cultivated at Montpellier. *Stem* round, its fine close hairs scarcely visible with a microscope. *Leaves* smooth, with distant, oblong, acute segments. *Upper branches* flowering at their extremities. *Lower bractæas* in three or five divisions; upper oblong, undivided; partial ones linear. *Stalks* downy. *Flowers* pale blue, hardly at all downy; hood gradually tapering into an acute beak, with a space between it and the wings, which are fringed, but nearly or quite smooth on their inside. *Filaments* hairy! De Candolle.

22. *A. ciliare*. Fringed Monk's-hood. De Cand. n. 22. (A. volubile; Willd. n. 11, but not of Koelle. Ait. n. 9. Donn Cant. ed. 5. 135.)—Stem twining, clothed with spreading hairs. Footstalks fringed. Leaves in three or five deep pinnatifid lobes, with linear-lanceolate segments. Cluster lax. Germens five or more.—Native of woods in Siberia. We received a specimen in flower, in Sept. 1801, from the rich garden of the late Rev. Mr. Watts, of Ashill, Norfolk. The *stem* is round, slender, purplish, six feet high, varying in its degree of downiness. *Leaves* in three and figure not unlike *Malva moschata*. *Cluster* branched, lax. *Flowers* of a middle size, rather light blue, downy; hood convex, rounded, with a beak in front; spurs hooked, with an obtuse, inversely heart-shaped, lip. *Germens* five or six, elliptic-oblong, smooth. *Stamens* smooth. Our specimen rather answers to the more hairy variety of De Candolle, which he suspected might prove a distinct species; we have seen no other, and can therefore form no opinion.

23. *A. tortuosum*. Twisted Monk's-hood. Willd. Enum. 576. De Cand. n. 23. (A. n. 8; Matth. Valgr. v. 2. 437? A. comâ inflexâ, foliis latioribus; Tourn. Init. 425?)—Stem twining, smooth, as well as the footstalks. Leaves in three deep, ovate, pointed, coarsely and deeply toothed lobes. Cluster lax. Germens two or three, quite smooth, as well as the stamens.—Seen in a cultivated state only, by Willdenow and De Candolle, who knew not whence it came. The *stem* rises to the height of six or seven feet, branching, round, and smooth. *Leaves* smooth; their lobes wedge-shaped at the base; the lateral ones deeply cloven. *Flower-stalks* downy. *Lower bractæas* three-cleft; partial ones awl-shaped, placed about half way up each stalk. *Flowers* smooth, pale blue; hood convex, gradually tapering into an acute beak. The figure of Matthiæus expresses the habit, but may probably belong to some other species. De Candolle. Indeed many of that author's figures are curved, evidently to accommodate them to the dimensions of the wooden block.

24. *A. glabrum*. Smooth Twining Monk's-hood. De Cand. n. 24.—Stem twining, smooth like the footstalks. Leaves in five deep, lanceolate, wedge-shaped, coarsely and deeply toothed lobes. Cluster lax. Hood stalked, elongated,

conical, with a long, erect, cloven beak.—Native country unknown. Described from the herbarium of Professor Desfontaines. The whole herb is smooth. The *flowers* are pale blue, and remarkable for the long linear lobes which terminate the beak, and standing erect, are nearly on a level with the top of the hood, which appears to be the great peculiarity of this little-known species.

25. *A. uncinatum*. American Monk's-hood. Linn. Sp. Pl. 750. Willd. n. 15. Ait. n. 12. Pursh n. 1. Curt. Mag. t. 1119. De Cand. n. 25.—Stem somewhat twining, slightly downy. Footstalks smooth. Leaves abrupt at the base; lobes three or five, acute, with three teeth. Cluster lax. Hood stalked, elongated, convex.—In swamps, and by the sides of rivulets, on the high mountains of Virginia and Carolina, flowering in June and July. *Flowers* large, of a fine blue, and singular structure. *Pursh*. *Stem* round, somewhat branched, minutely downy. *Footstalks* smooth, round, with a longitudinal furrow. *Leaves* coriaceous, smooth, dark-green, lobed only about half down; lobes three-ribbed. *Lower stalks of the cluster* long and divided; upper simple and crowded; all downy in their upper part. *Bractæas* two, oblong, not far from the flowers, which are large, of a rich violet purple; hood tapering into a sharp beak; wings orbicular, hairy rather than fringed. *Germens* three to five, downy. Such is our Linnean specimen, from J. Bartram.

M. De Candolle saw in the herbarium of Michaux, mixed with the above, specimens, whose hood was twice as long, almost conical, without any hook or beak. This he considers as the *uncinatum* of that author, Fl. Boreal.-Amer. v. 1. 315, and possibly a distinct species.

Mr. Pursh says,—"On the foot of the Peaks of Otter, and about the sweet springs, another species occurs, with smaller flowers, and a climbing stem which sometimes attains the height of nine feet; but unfortunately I have no materials at present to give a correct description thereof."

Hence it appears that the history of this long-established genus is not yet complete. M. De Candolle enumerates three species, of which he had not sufficient information to define them correctly. These are,

26. *A. delphinifolium*, of which there are three varieties. 1. *Americanum*, found by David Nelson, in Sledge (not Hedge) island, with an erect stem, from six to twenty inches high, downy upwards; leaves like *Delphinium pentagynum*, smooth, in numerous pinnatifid segments; and blue racemose flowers, whose hood is convex, acute at the summit. 2. *Sibiricum*, gathered in Siberia by Pallas, has larger flowers, with *nectaries* but half the length of the hood. 3. *Kamtschaticum*, has from three to six rather scattered, somewhat smaller, flowers, and rather longer *nectaries*. Root of tufted fibres. De Cand.

27. *A. biflorum*. (A. grandiflorum; Fischer Hort. Gorenk. 1808. 77.)—Native of the Altai mountains. Root tuberous, ovate, the size of a pea. Stem four inches high, slender, finely downy at the summit. Leaves in five deep, palmate segments, with linear acute lobes; the lowermost on long stalks. Flowers two, terminal, nearly sessile, pale blue; hood convex, externally downy at the back, tapering into an acute beak; wings obovate, or roundish, smooth. Stamens smooth. Germens three, villous. Nectaries hooked, obtuse, with very minute lips. De Cand.

28. *A. maximum*. Pallas herb.—Native of Kamtschatka. Stem six feet high, erect, round, smooth. Leaves smooth, stalked, wedge-shaped at the base, in three or five dilated, wedge-shaped, five-cleft lobes. Cluster short, of eight or ten pale-blue flowers, on downy stalks, with a convex acute hood, like that of *delphinifolium*, but smaller. De Cand.

The seven following are scarcely to be ascertained.

29. *A. nonum*; Matth. Valgr. v. 2. 438. Dalech. Hist. 1741. f. 2. *A. comā inflexā, floribus rarioribus, et foliis elegantē diffectis*; Tourn. Inft. 425.—We should suppose this an unnatural posture of *A. Antiora*, n. 1.

30. *A. lycocotium quartum, five lycaneum*; Cluf. Hist. v. 2. 96. Bauh. Hist. v. 3. 657.—No figure.

31. *A. ramofum, parvo flore*; Bauh. Pin. 183. Bauhin cites *A. octavum*, Matth. Valgr. v. 2. 437. See our n. 23.

32. *A. fpicā florum pyramidalē*; Morif. Præl. 226. *A. pyramidale multiflorum*; Tourn. Inft. 425. *A. pyramidale*; Mill. Dict. ed. 8. n. 6.—Esteemed by De Candolle a variety of *A. vulgare*, n. 11.

33. *A. feptimum*. Matthioli; Debry Floril. Nov. t. 42, but not the plant of Matthioli.

34. *A. minus autumnale infulæ Cheufan, finicē Tjou-u*; Pluk. Amalth. 5.

35. *Napellus major cæruleus montanus, authoræ radice*; Boec. Musf. 74.—Native of Monte Cofcione, in Corfica.

ACOTYLEDONES, constitute a class of plants in the natural systems of most authors, but especially of Jussieu, in whose method this class stands first. In these the *coraculum* of the seed is defined to be destitute of cotyledons, and consequently undivided in the process of germination, though forming a root below, and more or less of a stem, or at least a frond, above. The parts of fructification in many of this tribe are obscure, anomalous, or altogether unknown. The orders in the above-mentioned writer are six; FUNGI, ALGÆ, HEPATICÆ, MUSCI, FILICES, and NAIADÆ; all which articles the reader will find in their proper places. From our account of *Musci* and *Filices* he may observe, that the denomination of the supposed natural class in question, and its essential character above-mentioned, are far from being universal or unexceptionable, though two orders having manifest cotyledons, or something equivalent; while many plants, supposed to have a solitary cotyledon, have really none at all. See the article MONOCOTYLEDONES, where this subject is discussed. See also COTYLEDONES and GERMINATION.

ACOUCHY. See AKOUSCHY.

ACOUROA, in *Botany*, apparently a vernacular name in Guiana, by which Aublet has chosen to designate a papilionaceous diadelphous plant, which Jussieu, with great reason, suspects to be a species of *PEROCARPUS* (see that article); as well as another genus, named by the same author *Vatairea*. See Aubl. Guian. 753—756. t. 301, 302.

A. violacea, the only species, is a tree, found about the margins of salt-water creeks in Guiana, bearing flowers and fruit in July. The *trunk* is twelve or fifteen feet high, and a foot in diameter, sending out from its summit many spreading branches; the bark reddish, cracked, and wrinkled; the wood whitish externally, but the heart is reddish, hard and compact. *Leaves* alternate, alternately pinnate of seven or nine ovate, pointed, entire, firm, smooth *leaflets*, gradually larger upwards, the lowermost being an inch and a half or two inches long, the uppermost or terminal one four or five. *Stipulas* small, deciduous. *Clusters* about the ends of the branches, long, compound, many-flowered. *Braçtes* small, solitary at the base of each flower. *Calyx* of one leaf, in five sharp unequal segments. *Corolla* papilionaceous, violet-coloured. *Stamens* ten, diadelphous, the odd one distinct. *Stigma* obtuse. *Pericarp* dry, reddish, nearly orbicular, concave on one side, convex on the other, not burling. *Seed* solitary, lenticular. *Aubl.*

The *Vatairea*, Aubl. t. 302, is a much larger tree, the *trunk* being fifty feet in height, with a smooth whitish bark, and light brittle wood. *Leaves* pinnate, as in the former,

but more elliptical. *Flowers* unknown. *Pod* flat on both sides, with a thick edge, chestnut-brown, of an irregularly orbicular shape, about three inches in diameter, containing one large seed; which, when beaten in a mortar with purified pork lard, is used to cure tetters or ring-worms, whence the inhabitants of Guiana call this seed *Graine à dartes*. The tree grows by river sides in that country. *Aubl.*

ACQUACKNACK. Add, containing 2023 inhabitants.

ACRE, col. 3. l. 29. The tobacco of Acre is highly esteemed; and coarse muslins, remarkable for the durability of their dye, are sold at a low rate. The inhabitants make use of wooden tubes for their tobacco-pipes, garnished with a swathing of silk, or linen, for the purpose of absorbing water. This being kept moist, cools the smoke, as it rises, by the constant evaporation. A modern traveller, in the account of his Journey from Acre to mount Carmel, mentions the exportation to Venice of the sand of the river Belus for the glass-houses of that city. (See GLASS.) At Acre there are the remains of an ancient church, with pointed arches, other instances of which, demonstrating the existence of the Gothic architecture, occur in the Holy Land.

ACROSTICHUM, in *Botany*, a Linnæan name, whose meaning therefore is to be sought in the obscure hints left by its author. He derives the word in *Phil. Bot.* 183, from *ακροσ*, *top*, and *σιστον*, *an order or row*, but its application has been thought rather difficult. We agree with De Theis, that *ακροσιστον* literally means the beginning, or the first letters, words, or lines, of a set of verses; but we cannot assent to his explanation, of its being given to these plants "because several of them bear, on the back of the leaf, lines resembling the beginnings of words;" there being in fact no such thing, nor has Linnæus described any similar marks. It seems natural to trace his ideas in the appearance of the most remarkable of the original species, four of which are delineated in *Amen. Acad.* v. 1. t. 10, and in two or three of these, the *rows* of linear appendages, or *leaflets*, at the *top* of the *frond*, sufficiently explain the meaning of Linnæus. These species indeed are now removed from the established genus of *Acrostichum*, which has undergone much alteration since its first publication, and the view of its species already given, (see ACROSTICHUM,) requires to be totally reformed. Many of them are removed to other genera, while a great number of new ones have more than supplied their places. Willdenow, the latest general writer on *Filices*, which make the most original and accurate part of his *Species Plantarum*, defines sixty-two species, under six sections, of which we shall take a general view, first, as usual, prefixing the generic synonymys and characters.—Linn. *Ed.* 559. Schreb. 756. Willd. Sp. Pl. v. 5. 100. Mart. Mill. Dict. v. 1. Ait. Hort. Kew. v. 5. 500. Sm. Mem. de l'Acad. de Turin, v. 5. 147. Traçts 230. Prodr. Fl. Græc. Sibth. v. 2. 271. Swartz Syn. Fil. 9. Ind. Occ. 1587. Spreng. Crypt. Engl. ed. 84. t. 2. f. 18. Brown Prodr. Nov. Holl. v. 1. 145. Pursh 668. Juff. 15. Lamarck Dict. v. 1. 34. Illustr. t. 865. f. 4.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorsifera*; sect. *annulata*.

Gen. Ch. *Capsules* globular, of two equal valves, bound by a jointed elastic ring, and disposed in broad, continued, indeterminate, dense masses, more or less intermixed with hairs, or fine scales, over the back of the *frond*; either entirely, or partially at the upper part of the whole, or of its segments or leaflets, which are often contracted, or otherwise changed, in their fructifying portions. *Involucrum* entirely wanting, (unless the above-mentioned hairs, or scales, be taken for such.)

Ess. Ch. *Capsules* occupying the back of the frond, in uninterrupted

ACROSTICHUM.

uninterrupted shapeless masses, either partially or entirely. Involucrum none.

The whole genus, as it now stands, is chiefly tropical, a very few species only being found in the fourth of Europe, and one in North America. None are arboreferent. The species removed from the catalogue of the genus, in our former article, are the following; and are thus disposed of by Willdenow, we believe, on the whole, very correctly.

A. lanceolatum, is *Polypodium acrostichoides*, Willd. Sp. Pl. v. 5. 156.

heterophyllum, *P. adnascens*, *ibid.* 145.

punctatum, Linn. Sp. Pl. 1524, *P. lingulatum*, 159.

spicatum, Sm. Pl. Ic. t. 49, *Lomaria spicata*, 289.

Lingua, *Polypodium Lingua*, 162.

basilatum, *P. tricuspis*, 163.

septentrionale, *Asplenium septentrionale*, 307.

australe, *A. australe*, 308.

peccinatum, *Schizæa pectinata*, 85.

dichotomum, *S. dichotoma*, 87.

digitatum, *S. digitata*, 86.

ferrugineum, *Polypodium incanum* β , 175.

polypodioides, *P. incanum* α , 174.

rufum, *Hemionitis rufa*, 129.

punctatum, Linn. Suppl. 444, altered to *punctulatum* by Swartz, Syn. 13, retains the latter name in Willd.

Sp. Pl. v. 5. 118.

areolatum, *Woodwardia angustifolia*, Sm. unjustifiably altered to *W. onocleoides*, *ibid.* 416.

marginatum, *Pteris grandifolia*, 369.

sanctum, *Polypodium sanctum*, 198.

platyneuron, *Asplenium ebeneum*, 329.

siliquosum and *thalictroides*, reduced to one species, as

Pteris thalictroides, 378; but perhaps they require

further investigation.

ivense, *Polypodium ivense*, 198. See Woodsia.

furcatum, *Mertensia furcata*, 71; a genus under by

Mr. Brown to *Gleichenia*. See that article, and

MERTENSIA.

aculeatum, *Davallia fumaroides*, 480.

barbarum, *Todea africana*, 76, our *OSMUNDA barbara*.

viviparum, *Darea vivipara*, 302.

ferrulatum, *Grammitis ferrulata*, 141.

graminoides, *G. graminoides*, 141.

To which we must add that *A. ebeneum* is made by Willdenow the variety β of *calomelanos*, 124; and *petiolatum* is reduced to *viscosum*, 103. Fifteen species therefore, out of our former list, are all that are retained by Willdenow, and the generic name remains with plants that do not by any means answer to it, though they agree correctly with the generic character.

We proceed to give examples of the several sections.

SECT. 1. *Frons simple, undivided.* Twenty-five species. We shall here venture to unite two of them, *latifolium* and *longifolium*, adding a new one, *limbellatum*.

A. nummularifolium. Money-wort *Acrostichum*. Willd. n. 1. Swartz Syn. Fil. 419 and 191. t. 2. f. 1.—Barren fronds roundish, obtuse, somewhat heart-shaped; hoary and downy beneath: fertile ones obovate. Common stalk thread-shaped, scaly, creeping.—Found by Thunberg in Java. The common stalk creeps extensively, attaching itself by copious, tufted, black radicles, and bearing several alternate simple fronds, or leaves, not an inch long, on short partial foot-stalks; these are smooth on the upper side, veinless; and the hoary down of their under surface is interperfed with flarry hairs. The fertile fronds are fewer and smaller, tapering at the base, sometimes besprinkled with flarry hairs; their

backs covered with shining-brown capsules, intermixed with flarry hairs of a rusty hue. Swartz.

A. fimbriatum. Fringed *Acrostichum*. Willd. n. 3. "Cavan. Annal. de Nat. Scienc. v. 1. 102." Swartz Syn. Fil. 11.—Frons lanceolate, fringed. Stalks brittle.—Native of shady mountainous places in the kingdom of Quito.—We have been favoured with a specimen, gathered by William Swainson, jun. esq. of Liverpool, on damp rocks in woods, among the mountains at Rio Janeiro, which answers to the above definition, but we are not authorized, without better information, to assert that it is Cavanille's plant. The fronds of ours grow eight or ten together, in tufts, with a fibrous, blackish, scarcely hairy, root: each being an inch and a half long, one-third of an inch wide, bluntish, shaggy on both sides with coarse, brittle, reddish-brown hairs, spreading copiously beyond the edges. Stalks simple, equally shaggy, rather longer than the fronds. The fertile fronds are convex above, almost hooded; their concave under surface covered with brown capsules. The size and habit of this fern resemble *Blechnum Lanceola*, of Swartz, in Stockholm Transf. for 1817, 71. t. 3. f. 2, a native of Brazil; but the latter is smooth and naked, with the proper fructification and involucrem of a *Blechnum*.

A. viscosum. Glutinous *Acrostichum*. Willd. n. 8. Swartz Syn. Fil. 10 and 193. (*A. petiolatum*; Sw. Ind. Occ. 1588.)—Frons linear-lanceolate, pointed, smooth on both sides; their ribs, as well as stalks, scaly and viscid: fertile ones linear; hairy beneath and covered with capsules to the very margin.—Found on the mossy trunks of trees, on the highest mountains of Jamaica. Root lightly creeping. Stalks crowded, slender, angular, roughish, rusty and scaly, three or four inches high. Each frond is a span long, erect, rather rigid; the barren ones linear-lanceolate, pointed, somewhat membranous, smooth, besprinkled at the back with minute, prominent, brownish, glandular dots; their ribs scaly; fertile ones on longer stalks, more linear, either smooth or slightly hairy, covered entirely at the back with pale rusty powdery capsules. The clamminess of the stalks, and the hairiness of the fertile fronds, distinguish this species from its allies. Swartz.

A. limbellatum. Narrow-bordered *Acrostichum*. (*Lingua cervina angustifolia*, *colitis et pediculis villosis*; Plum. Fil. 113. t. 129.)—Frons linear-lanceolate, wavy, pointed, smooth on both sides; their ribs and stalks hairy: fertile ones nearly linear, with a smooth naked border.—Gathered by Plumier, on mossy rocks about the source of a little rivulet, called Le Morne Rouge, near fort St. Pierre, in Martinico. The root is long, creeping, cylindrical, resembling a worm, covered with little black fibres. Frons numerous, erect, above a foot high, each of their fine transverse veins ending in a little dot, before they reach the margin; at least such is their appearance in Plumier's figure. This character, the greater height of the fronds, and the fertile ones having a smooth naked border, over which the capsules do not extend, caused Dr. Swartz to omit citing Plumier's figure under the last-mentioned species. We have no doubt of these plants being very distinct from each other. Plumier is one of the few authors whose fidelity is always to be relied on, and he is therefore the sole authority for several of Linnaeus's species of ferns, described from his plates and descriptions.

A. villosum. Shaggy Bordered *Acrostichum*. Willd. n. 10. Swartz Syn. Fil. 10. Ind. Occ. 1592. (*Lingua cervina villosa minor*; Plum. Fil. 110. t. 127. f. D.)—Frons lanceolate, wavy, pointed, shaggy on both sides: fertile ones somewhat elliptical, with a naked border; fringed at the edge. Stalks hairy, elongated.—Gathered by Plumier

ACROSTICHUM.

mier in wet woods in Hispaniola; by Swartz on the hollow mossy sides of hills in the south of Jamaica. *Root* tufted, not creeping. *Stalks* about half as long as the *fronds*, flaggy with coarse rusty hairs, such as cover both sides of the leafy part, especially at the edges. There is a vacant space, as in the last, between the *capules* and the margin of the leaf, well expressed by Plumier, and mentioned by Swartz.

A. hirtum. Great Hairy Acrostichum. Willd. n. 11. Swartz Syn. Fil. 419 and 194.—*Fronde* elliptic-lanceolate, pointed, scaly on both sides, like their stalks; the margin dotted, and somewhat crenate: fertile ones much narrower, covered to the edge with capules and convoluted scales.—Suggested by Swartz to be a native of Madeira, but we have always believed our fine specimens to have been gathered by the late Mr. Smeathman, in the West Indies. The *root* is thick and scaly, apparently somewhat creeping. *Fronde* a span long, on scaly stalks often exceeding that length; thickly besprinkled sometimes on both sides, but especially on the under one, which is the palest, with small, ovate or heart-shaped, pointed, petulate, close-pressed scales, of a pale shining brown. Many of the transverse veins terminate, near the margin, in depressed dots. The fertile *fronds* are much shorter and narrower, somewhat heart-shaped at the base, covered entirely at the back with shining rusty capules, intermixed with lanceolate, convoluted, tubular scales. We have one *frond*, two-thirds of which are barren and broadly elliptical, but the upper part is suddenly contracted into a lanceolate form, covered with capules and scales. The main rib is always very scaly beneath.

A. undulatum. Wavy Hairy Acrostichum. Willd. n. 14. (Lingua cervina villosa, major et rufescens; Plum. Fil. 110. t. 126.)—*Fronde* ovato-lanceolate, somewhat wavy, bristly on both sides, like their stalks; the margin slightly crenate and obscurely dotted: barren ones emarginate: fertile ones acute.—Found by Plumier on the trunks of old trees, in Martinico. Nearly related to the last, but distinct. The *fronds* are smaller and narrower, with much less evident marginal dots. The bristly hairs, scattered over both surfaces, and also clothing the stalks, in some degree indeed partake of the nature of scales, and are channelled, or slightly tubular, at their base; but they totally differ from the flat close scales of the foregoing. The end of each barren *frond* is more or less emarginate, with a little tuft, or bud, of scales in the fissure.

A. latifolium. Broad-thick-leaved Acrostichum. Willd. n. 15. Swartz Syn. Fil. 9. Ind. Occ. 1589. (A. n. 1; Browne Jam. 104. A. longifolium; Willd. n. 16. Jacq. Coll. v. 2. 105. Swartz Syn. Fil. 9. Lingua cervina rigida et glabra; Plum. Fil. 118. t. 135.)—*Fronde* oblong-lanceolate, bordered, contracted at each end, smooth on both sides, as well as the stalks: fertile ones of the same shape, with a smooth, narrow, membranous edge. Native of rocks, and old mossy trunks of trees, in Jamaica and Martinico. The *root* is thick and creeping, clothed at the extremity, and about the bottoms of the stalks, with large, brown, chaffy scales. *Fronde* scattered, from a span to twelve or eighteen inches long, erect, entire, rigid, with a narrow, thin, membranous, entire border, a stout reddish rib, and scarcely any traces of veins, both surfaces being peculiarly even and smooth. The stalks are smooth and naked, angular, sometimes as long as the fronds, but generally shorter. The fertile *fronds* agree with the barren ones in shape and size, as well as in their narrow, membranous, naked border, but the whole under side, except that border, is densely clothed with innumerable, minute, snuff-coloured capules, unaccompanied by any scales or hairs. Jacquin described his plant independent of Swartz,

but we cannot find the leaf pretence for distinguishing them, even as varieties, the revolute position of the feed-bearing frond, in Plumier's plate, being merely owing to its young state, as his description implies. The stalks, at an early period, may probably be somewhat scaly, though afterwards naked, even in the fertile fronds.

A. crinitum. Hairy Oval Acrostichum. Linn. Sp. Pl. 1523. Willd. n. 23. Ait. n. 2. Swartz Syn. Fil. 11. (Lingua cervina villosa, amplis foliis subtrotundis; Plum. Fil. 109. t. 125. Phyllitis crinita, latifolium folio; Petiv. Fil. n. 145. t. 13. f. 14. copied from Plumier.)—*Fronde* elliptical, obtuse at each end, hairy, densely fringed. Stalk and mid-rib hairy.—Gathered by Plumier in Martinico. Brought from the West Indies to Kew Garden, by Admiral Bligh, in 1793. A very fine and large species, specimens of which are rare. Each *frond* is about a foot long, and half as much in breadth, fleshy; of a somewhat yellowish-green on the upper side, besprinkled with slender bristly hairs, which, as well as the thick fringe, and the copious hairs on the stalks, are coal-black. The fructification of this plant has not been ascertained, for what Plumier noticed, on the very young leaves, were most probably the tumid or glandular bases of the hairs; nor was he at all confident on this subject. It may well, however, by analogy, be considered as an *Acrostichum*. The *root* is tufted and flaggy. We place this fern next to species with which it most nearly accords; the following one being incorrectly inserted before it by Willdenow.

A. citrifolium. Lemon-leaved Acrostichum. Linn. Sp. Pl. 1529. Willd. n. 22. Swartz Syn. Fil. 9. (A. n. 3; Linn. Amoen. Acad. v. 1. 269. Hemionitis parastica; Linn. Sp. Pl. 1535. H. n. 2; Browne Jam. 95, from the author. Lingua cervina scandens, citrei foliis, minor; Plum. Fil. 101. t. 116. Lonchitis vanillie folio; Petiv. Fil. n. 150. t. 15. f. 1.)—*Fronde* alternate, ovate, pointed; tapering at the base, on short stalks, smooth, reticulated with veins. Common stalk creeping, scaly.—Found on trees near rivulets in Martinico, and in the cooler, shady, inland woods of the mountainous parts of Jamaica. The common stem, or main root, creeps to a great extent, among mosses, or *Jungermannie*, up the old trunks of trees, attaching itself by numerous flaggy radicles. It is clothed with large, acute, reticulated, finely toothed, pelucid scales. The *fronds* are situated alternately, about one or two inches from each other, on short bordered stalks, spreading in two directions, and are ovate or elliptical, of a fine shining green, rather fleshy, very smooth, two or three inches long, and one or one and a half broad, obscurely crenate. There is only about half way up any decided mid-rib, but the principal veins, parallel at first, branch out into regular, very elegant reticulations. Some of the uppermost and youngest *fronds*, according to Plumier, are entirely covered at the back, with minute, densely crowded, bright clefnut, capules, except a central naked line, indicating a mid-rib. We have no specimen in fructification, but several capules accidentally sticking to one of the barren fronds, are remarkably small, very pale, with dark jointed rings. Linnæus originally adopted this fern, as an *Acrostichum*, from Plumier. When he received specimens of the same from Browne, as a *Hemionitis*, he did not discover that he had already classed the plant in his system; hence it occurs twice, even in his Sp. Pl.—*Hemionitis obtusa*, Willd. Sp. Pl. v. 5. 127, agrees very nearly with this *Acrostichum*, in size and texture of the *fronds*, and most precisely in their veiny reticulations; but its fructification is described as essentially different.

SECT. 2. *Frond simple, divided*. Four species.

ACROSTICHUM.

A. pelatum. Shield Acrostichum. Willd. n. 26. Swartz Syn. Fil. 11. Ind. Occ. 1593. (Ofmunda pelata; Swartz Prodr. 127. Lichen digitatus, geranii facie; Plum. Fil. 141. t. 50. f. A. Hepatica digitata fungoides; Pet. Fil. n. 188. l. 11. f. 3.)—Barren fronds in many forked, linear, radiating segments; fertile ones undivided, roundish-kidney-shaped, finely crenate.—Found on the mossy trunks of trees, in Jamaica and Hispaniola. This remarkable little fern has the habit of a *Trichomanes*; or of some very singular *Jungfermannie*, brought by Mr. Menzies from New Zealand. The trailing creeping root throws up several stalked, vertical, membranous, barren fronds, deeply divided into two principal lobes, and each of those irregularly into numerous, linear, single-ribbed segments, all spreading like a fan. The fertile fronds are about as tall, but smaller, not an inch broad, roundish, or somewhat kidney-shaped, horizontal; pale green and smooth above; covered beneath with small, brown, shining, annulated capules.

A. alicorne. Stag's-horn Acrostichum. Willd. n. 29. Swartz Syn. Fil. 12. 17. and 196. Brown n. 1. Ait. n. 3. ("A. Stenaria; Beauvois Fl. d'Oware, 2. t. 2." A. bifurcatum; Cavan. Leccion. 241. n. 587. Neuroplatyceros aethiopicus, nervosifoliis, cornu cervinum referentibus; Pluk. Amalth. 151. t. 429. f. 2. Cornu alcis Simbor dicta; Bont. Hist. Nat. 121, with a figure.)—Fronds somewhat tufted, forked, coriaceous, ribbed; downy at the back; from a peltate, leafy, spongy base.—Native of Guinea, Madagascar, Java, and New South Wales, growing on the trunks of trees. This is a very large and striking species, attached to the trees, or sometimes to rocks, by a peltate, dilated, somewhat membranous, irregular, veiny, lobed base, of a shining brown, a foot in diameter; thin at the edges; thick and spongy in the centre, where it is fixed by downy branching radicles, and from whence it throws up two or three erect, flat, irregularly forked fronds, a foot or two in height, rather dilated upwards, entire at the edges, from one to two inches broad in the different parts; tapering at the base into a stout, channelled, winged footstalk. The ultimate divisions are level-topped, linear, bluntish, near a finger's length, each bearing at its back, in the lower half, a broad, irregular, dense, naked mass of innumerable brown capules, so disposed, in close lines, that the whole mass appears striated. The whole frond is strongly ribbed; green and smooth above; whitish and downy beneath; the ribs forked, smooth, reddish. We cannot but think the singular dilated base of this fern is no other than one of its seminal leaves, or reputed cotyledons, greatly enlarged, and more permanent than usual. *Polypodium quercifolium* of Linnaeus, Willd. Sp. Pl. v. 5. 170, has something analogous in its barren fronds, which are only advanced a step nearer towards the proper habit of a fern. See Ger. Em. 1133.

Seçt. 3. *Frond ternate*. Two species.

A. quercifolium. Oak-leaved Acrostichum. Willd. n. 30. Swartz Syn. Fil. 12. Retz. Obf. fasc. 6. 39. "Schkuhr Crypt. 2. t. 3." (Ofmunda trifida; Jacq. Coll. v. 3. 281. t. 20. f. 3.)—Fronds ternate, bluntly lobed; fertile ones contracted, linear-oblong, somewhat cut.—Found on trees in Ceylon, by Koenig. A delicate slender fern, whose small, creeping, scaly root sends up several erect fronds, from six inches to a foot high, whose downy stalks are also scaly in their lower part. The terminal leaflet is much the largest, two or three inches long, and one broad, in the barren fronds, with downy ribs and edges, obtuse, slightly and variously sinuated; the lateral ones an inch long, rounded, somewhat lobed. The fertile

fronds have each a much taller smoother stalk, but their leaflets are, as usual, much smaller and narrower, their backs covered, except the ribs and margin, with minute, stalked, annulated capules.

A. auritum. Eared Acrostichum. Willd. n. 31. Swartz Syn. Fil. 13. and 198. (Filix florida; Rumph. Amboin. v. 6. 78. t. 35. f. 1.)—Fronds ternate, pinnatifid, cut; fertile ones doubly pinnate, with linear entire segments.—Native of Amboyna and Java, growing among coarse grasses, on the banks of rivers. *Rumphius, Thunberg*. Stalks from one to two feet high, slender, angular, smooth, black and shining. Fronds smooth, slightly veiny, of three principal leaves variously pinnatifid, lobed and cut, several inches long; the middle one largest: the fertile fronds are more compound, with extremely narrow linear leaflets or segments.

Seçt. 4. *Frond pinnatifid*. Three species.

A. ferrulatum. Finely-ferrated Acrostichum. Willd. n. 32. (Polypodium fuscum tenuissimum denticulis ferratum; Plum. Fil. 63. t. 81.)—Fronds deeply pinnatifid; segments linear-lanceolate, parallel; those of the barren ones finely ferrated, of the fertile ones entire.—Gathered by Plumier, in the forests of Hispaniola. The long, creeping, nearly smooth, blackish root sends up several fronds, twelve or eighteen inches high, on shortish smooth stalks. The outline of each is lanceolate, taper-pointed, composed of a great number of crowded parallel segments, divided almost to the mid-rib, each segment linear, acute, finely and sharply ferrated, smooth on both sides, thin and almost membranous, with a rib and many finely forked veins. From the very extremity of the root springs one frond, a little smaller than the rest, but of a similar structure, except that its segments are nearly all entire at the margins, and bear on their backs a dense assemblage of minute chestnut-coloured capules, some few of the upper segments only, with the point, being naked and ferrated. By the figure, this fern would be judged a *Blechnum*, and possibly it might, if examined in a young state, prove to be such, the capules extending over the leaf at an advanced period only, when the involucre is often reflexed, or obliterated; but as no botanist, besides Plumier, appears to have seen the plant, we must rely on his account of the matter, and he very precisely says the back of this fertile frond is at first, as it were, chagreen'd, and chestnut-coloured, being subsequently entirely covered with fine dust, of the same hue.

The others of this section are, *A. lepidopteris* of Langsdorff and Fischer, Ic. Fil. t. 2, from Brazil; and *A. brunneum* of Willdenow, from the Caraccas.

Seçt. 5. *Frond pinnate*. Fifteen species, besides one of Mr. Brown's.

A. bifurcatum. Slender Forked Acrostichum. Willd. n. 35. Swartz Syn. Fil. 12. "Schkuhr Crypt. t. 2. f. 3." (Ofmunda bifurcata; Jacq. Coll. v. 3. 282. t. 20. f. 4. Filicula corniculata infule Sanctæ Helenæ; Pluk. Mant. 83. Phyt. t. 350. f. 4.)—Fronds pinnate; leaflets linear, deeply divided, spreading: those of the fertile fronds rounded; the lower ones more or less ternate; upper solitary.—Native of St. Helena and the West Indies. A slender delicate fern, allied in habit to *A. quercifolium*, described in the third section, but much smaller, and with very different barren leaflets. Its height is about six inches; the stalks wiry, or almost capillary.

A. forbifolium. Service-leaved Acrostichum. Linn. Sp. Pl. 1526. Willd. n. 38. Ait. n. 4. (Onoclea forbifolia; Swartz Syn. Fil. 112. Filix scandens latifolia ferrata; Plum. Amer. 8. t. 12. Lingua cervina scandens, foliis laurinis

ACROSTICHUM.

laurinis ferratis; Plum. Fil. 102. t. 117. *Lonchitis calami-feris*, pinnis ferratis; Petiv. Fil. n. 153. t. 9. f. 8.)—Frons pointed, smooth; leaflets of the barren ones lanceolate, pinnate, ferratis; wedge-shaped at the base: of the fertile ones linear, entire. Common-stalk climbing, scaly.—This climbs up the stems of trees in various parts of the West Indies, the scaly common stalk being the thickness of a goose-quill. *Frons* alternate, somewhat stalked, a foot long, lanceolate; barren leaflets an inch and a half or two inches long, half an inch broad; fertile ones rather shorter, and very much narrower; their edges slightly inflexed when young; the mid-ribs hairy; all the rest of the under surface densely covered with *capsules*. Linnæus, long after he had published this species, confounded with it a very different plant, figured in Sloane's Jamaica, v. 1. t. 38, and in Pluk. Phyt. t. 287, (not 286.) f. 3, which is preserved in the Linnæan herbarium; but for want of knowing the fructification, we cannot determine its genus with any certainty. The main-stalk of each frond is slightly winged, and the habit of the whole like a *DANÆA*, (see that article,) except the leaflets being alternate.

A. aureum. Great Golden Acrostichum. Linn. Sp. Pl. 1525. Willd. n. 41. Swartz Syn. Fil. 13. Pursh n. 1. "Schkuhr Crypt. 2. t. 1." (Lingua cervina aurea; Plum. Fil. 87. t. 104. *Filix palustris aurea*, foliis linguæ cervinæ; Plum. Amer. 5. t. 7. *Phyllitis ramosa aurea*; Petiv. Fil. n. 142. t. 8. f. 5.)—Frons pinnate; leaflets alternate, uniform, coriaceous, oblong, bluntish, entire, smooth, with reticulated veins; wedge-shaped and unequal at the base: upper ones fertile, of the same size.—Native of bogs and wet places in the West Indies. Pursh found it in deep swamps near the sea-coast of Florida, in July. This is a noble fern, from five to nine feet high, conspicuous for its large broad leaflets, from a span to twelve inches in length, curiously marked with oblong veiny reticulations. About four or five of the uppermost, and perhaps the lower part of the next, are densely covered at the back with innumerable capsules, of a golden chestnut colour.

A. fraxinifolium. Great Ash-leaved Acrostichum. Br. n. 2.—"Frons pinnate, smooth; leaflets stalked, oblong-tongue-shaped, pointed, entire, reticulated: upper ones fertile, contracted."—Discovered by Mr. Brown, in the tropical part of New Holland. Very closely related to *A. aureum*, but differing in its acute and short-pointed leaflets.

A. punctatum. Dotted Acrostichum. Willd. n. 45. Swartz Syn. Fil. 13. (*A. punctatum*; Linn. Suppl. 444, but not Sp. Pl. 1524. *A. auriculatum*; Lamarck Dict. v. 1. 36.)—Frons pinnate; fertile leaflets lanceolate, acute, entire; dotted on the upper side; lowermost auricled; uppermost somewhat confluent.—Native of the isle of Bourbon. This species is known only from the Linnæan specimen, communicated by Thouin, which consists of one frond, about two feet high, entirely fertile, with a longish smooth stalk, and eight leaflets, each near three inches in length, and almost one in breadth, tapering at both ends, undulated or somewhat crenate; smooth and bright green, besprinkled with depressed dots, above; covered, nearly to the edge, with tawny capsules, beneath. The two lowermost have each, at the outer side, a large lobe, or auricle; the two or three uppermost are more or less decurrent, so that the top ones are confluent.

A. alienum. Various-lobed Acrostichum. Willd. n. 48. Swartz Syn. Fil. 13. Ind. Occ. 1595. (*Filix latifolia*, in pinnulis obtusis, et leviter crenatis, divisa; Plum. Fil. 10. t. 10. *Osmunda pulverulenta*, pinnis vix ferratis; Petiv. Fil. n. 154. t. 8. f. 1.)—Frons pinnate; leaflets pinnatifid; the upper ones confluent; lobes rounded, distant

toothed, smooth, reticulated with veins: fertile ones with narrower, less divided, leaflets.—Found by Plumier in Martinico; by Swartz on the mountains of Jamaica. Our specimens came from St. Kitt's. This is a fine species, the fronds crowded, three or four feet high, smooth and membranous, of a fine transparent green; the base of each common stalk tumid, permanent. The lower leaflets, a foot long, are deeply pinnatifid, and somewhat auricled; the middle ones roundly lobed; uppermost wavy, and strongly confluent. All the ribs are white and smooth. Fertile fronds entirely distinct, smaller and less divided or lobed in every part, but their segments are extremely various. The under side, except the ribs, is densely covered, to the very edges, with brown capsules. None of the stalks are scaly.

Sect. 6. *Frond doubly pinnatifid, or doubly pinnate*. Thirteen species, besides one of Mr. Brown's.

A. cervinum. Hart's-tongue Acrostichum. Willd. n. 50. Swartz Syn. Fil. 14 and 200. (*Osmunda cervina*; Linn. Sp. Pl. 1521. *O. linguæ cervinæ foliis*; Plum. Fil. 132. t. 154. *O. racemifera*, phyllitidis folio; Petiv. Fil. n. 162. t. 8. f. 13.)—Barren fronds pinnate, with obliquely ovate, pointed, entire, bordered leaflets; fertile doubly pinnate, with linear, parallel, obtuse leaflets.—Apparently, by Plumier's account, not uncommon in wet woods, or about the banks of rivers, in Martinico. Dr. Swartz seems to have met with the same in Jamaica, and we have it from St. Kitt's. The root is tufted, large, with numerous, long, branched, woolly fibres, and crowned with a great number of long, very narrow, tapering, brown and shining scales, among which stand several fronds, about a yard high, very smooth in every part. The barren ones are simply pinnate, with 18 or 20 stalked leaflets, a span long, and near two inches broad, entire, taper-pointed, with one rib, and many fine parallel transverse veins, not reticulated; the base of each obliquely, and very unequally, wedge-shaped. Fertile fronds fewer, doubly pinnate, consisting entirely of numerous small, sessile, parallel, but not crowded, leaflets, a quarter or one-third of an inch in length, covered at the back with light-brown stalked capsules.

A. Marantæ. Scaly European Acrostichum. Linn. Sp. Pl. 1527. Willd. n. 53. Swartz Syn. Fil. 14. Prodr. Fl. Græc. n. 2344. Fl. Græc. t. 964, unpubl. "Schkuhr Crypt. 4. t. 4." Sprengel Crypt. 89. t. 2. f. 18, not good. (*Lonchitis alpina Marantæ*; Camer. Epit. 666.)—Frons doubly pinnate, uniform; leaflets oblong, obtuse, entire, dilated or lobed at the base; the upper ones confluent; all clothed beneath with imbricated hair-pointed scales. Stalks shaggy.—We have already described this fern (see the article *NOTHOLENA*, n. 1); but a more careful examination has induced us, both here and in the Prodr. Fl. Græc., to retain it in *Acrostichum*, as well as the two following species; for the capsules appear to cover every part of the under side of its fronds, except their scaly mid-rib. With respect to *Notbolena trichomanoides*, we readily concur with Mr. Brown in keeping it distinct from *Pteris*; not having seen his *N. vellea* or *Pumilio*, we cannot form an opinion of those species.

A. velleum. Woolly European Acrostichum. Willd. n. 54. Swartz Syn. Fil. 14. Ait. n. 5. Prodr. Fl. Græc. n. 2345. Fl. Græc. t. 965, unpubl. (*A. lanuginosum*; Destomb. Atlant. v. 2. 400. t. 256. "Schkuhr Crypt. 8. t. 1. *Lonchitis mollior lanuginosa*, Ceterach facie; Barrel. Ic. t. 857, 858. *Filicula crispa*, lanugine hepatici coloris vestita, ex infulis fortunatis; Pluk. Almag. 150. Phyt. t. 281. f. 4.)—Frons doubly pinnate, elliptic-oblong, uniform; leaflets obtuse, ovate or heart-shaped, notched laterally, very shaggy on both sides, like the stalks.

—Native

—Native of Spain, Barbary, Madeira, and Zante, in the fissures of rocks. Rather smaller than the last, with shorter stalks and denser fronds, whole leaflets are short and rounded, hairy on both sides rather than scaly; their common stalks of a malagony colour, their pubescence hoary, without the golden, or bright copper, hue of *A. Marantæ*. The root is neither scaly, nor creeping.

A. difans. Distant-winged Acrostichum. (Notholæna difans; Brown Prodr. v. 1. 146.)—Fronds doubly pinnate, linear-lanceolate, uniform; branches opposite, distant, somewhat deltoid; leaflets oblong, obtuse; the lower ones pinnatifid. Stalks and ribs shaggy, with hair-pointed scales. (See NOTHOLÆNA n. 2.) The *capules* decidedly cover every part of the under side of each leaflet, except the scaly rib, in as broad and continuous patches, as in any other Acrostichum; at least when, like our specimen, they are arrived at maturity.

A. sulphureum. Sulphur-coloured Acrostichum. Willd. n. 56. Swartz Syn. Fil. 15. Ind. Occ. 1597. Schkuhr Crypt. 4. t. 4.—Fronds doubly pinnate; leaflets oblong-wedge-shaped, pinnatifid, cloven and notched; clothed with pale yellow powder at the back.—Native of shady rocks, in the southern part of Jamaica. Swartz. Linnæus had numerous specimens of this fern, which he left undetermined, or perhaps confounded with the following, from which they differ in the wedge-like shape, and more delicate texture, of their leaflets, as well as the pale sulphur colour of the powder that covers their under surface. The masses of *capules* are most dense about the middle of each leaflet, the tips being naked.

A. calomelanos. Mealy Acrostichum. Linn. Sp. Pl. 1529. Willd. n. 57. Hort. Berol. t. 41. Swartz Syn. Fil. 15. "Schkuhr Crypt. 4. t. 5." (Filix albisimo pulvere confersa; Plum. Fil. 30. t. 40. Pet. Fil. n. 156. t. 9. f. 11. F. non ramosa major, caule nigro, furculis raris, &c.; Sloane Jam. v. 1. 92. t. 30. f. 2. Adiantum, nigro simile, albisimo pulvere confersum; Plum. Amer. 30. t. 44. *A. calomelanos americanum*; Pluk. Phyt. t. 124. f. 3.)

β. A. ebeneum; Linn. Sp. Pl. 1528? (Filix non ramosa minima, caule nigro, furculis raris, &c.; Sloane Jam. v. 1. 92. t. 53. f. 1.)

Fronds doubly pinnate; leaflets elliptic-oblong, clothed with white powder beneath; lowermost cut or pinnatifid, with an auricle from the upper edge at the base; upper ones serrated; uppermost confluent.—Native of shady situations in the West Indies. The fronds are tufted, and, when full grown, 12 or 18 inches high, with black shining stalks; the leaflets smooth, and of a fine deep green above; tapering, or wedge-shaped, at their base; in the upper part of each frond decurrent. Those which bear *capules* are less white, and rather grey, beneath, besprinkled with white dots, the *capules* most crowded about the middle region of each. Willdenow, on the positive assertion of Swartz, makes *A. ebeneum* of Linnæus a variety, Swartz esteeming it the same plant in a young state, when the fronds are only simply pinnate. But Willdenow declares that he had 100 times raised *calomelanos* from seed, without ever seeing the young fronds as represented by Sloane, t. 53. f. 1; and that his own figure was taken from a plant of one year's growth. Still we are disposed to believe Sloane's plant belongs to *calomelanos*; though it is far otherwise with the Linnæan *ebeneum*, the original specimen of which is simply pinnate, with broad, sessile, transverse, partly pinnatifid, leaflets, white beneath; the masses of *capules* nearer the margin than the rib. The upper leaflets, indeed, are decurrent and confluent.

Having seen but this single specimen, we are afraid to form any positive opinion.

A. chrysophyllum. Golden Acrostichum. Willd. n. 58. Swartz Syn. Fil. 15. Ind. Occ. 1598. (Filix aurea, pinnulis rotundè incisitis divisa; Plum. Fil. 33. t. 44. Adiantum pulverulentum aureum; Petiv. Fil. n. 160. t. 9. f. 9.)—Fronds doubly pinnate; leaflets ovate-oblong, obtuse, striated, polished; clothed beneath with deep-yellow powder; lower ones pinnatifid; upper confluent and wavy.—Native of rather mountainous pastures, in various parts of the West Indies. We are indebted to J. V. Thompson, esq. for a specimen of this elegant plant, which is conspicuously distinguished by the copious deep lemon-coloured powder, entirely covering the back of its leaflets, among which the *capules* seem sparingly, but uniformly, dispersed and sunk.

A. albidulum. Whitish Round-leaved Acrostichum Willd. n. 61. Swartz Syn. Fil. 16 and 205. t. 1. f. 2.—Fronds doubly pinnate; leaflets rounded, obtuse; powdery and white beneath; lowermost three-lobed; uppermost simple and undivided. *Capules* densely crowded towards the margin.—Gathered by Louis Née, in South America. Swartz. A delicate little fern, three or four inches high, with a capillary stalk. The whole frond is oblong, once or twice compounded, in a ternate manner. Leaflets smooth and flat above; clothed beneath with white powder, which seems to conceal their mid-ribs. The *capules* are brown, each with a shining ring, and are very numerously crowded, in dense masses, over two-thirds of each lateral portion of the leaflet, from the edges, leaving a bare stripe in the middle. Hence this species should seem referable to Mr. Brown's genus NOTHOLÆNA, to which we have already alluded (see that article); but the *capules* compose much broader masses than in *N. trichomanoides*, and seem unattended by hairs.

A. pieroides. Bordered Acrostichum. Brown n. 3.—"Fronds doubly pinnate, smooth; leaflets linear, reflexed at the margin."—Gathered by Mr. Brown, in the tropical part of New Holland. This species seems to answer to the character of Willdenow's *Lomaria*. We have seen no specimen.

ACROTRICHE, so called by Mr. Brown, from *ακρο*, terminal, and *τριχη*, τριχες, a hair, in allusion to the bearded points of the corolla.—Brown Prodr. Nov. Holl. v. 1. 547.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Eparicideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of five erect, concave, obtuse, permanent leaves, with a pair of smaller ones at their base. *Cor.* of one petal, funnel-shaped, longer than the calyx; limb in five equal, spreading segments, each furnished, towards the point, with a tuft of hairs directed inwards. Nectary a cup-shaped gland, slightly lobed, surrounding the base of the germen. *Stam.* Filaments five, thread-shaped, equal, inserted into the tube of the corolla, and not projecting beyond the mouth; anthers roundish-oblong, incumbent. *Pist.* Germen superior, globose; style columnar, short; stigma simple. *Peric.* Drupa globular, depressed, slightly pumpey. *Nut* solitary, of five lobes and five cells, its surface minutely cellular. *Seeds* solitary.

Eff. Ch. Outer calyx of two leaves. Corolla five-cleft, funnel-shaped; segments with a deflexed beard at the extremity. Drupa nearly dry. Nut of five cells, its surface minutely cellular.

This genus, the produce of New Holland, consists of humble much-branched shrubs, their branches generally divaricated. Leaves scattered. Spikes short, lateral, or axillary. Flowers small, white. Drupa small, with but little

little thickness, or pulp. We have examined only one specimen of this fruit, but the above appears to be the true meaning of the author whom we follow, that the shell of the nut is covered with small external cells, like a minute irregular honey-comb, to which the pulp of the drupa, filling the interstices of the lobes of the nut only, is attached. This character Mr. Brown seems to consider as very peculiar.

1. *A. divaricata*. Spreading-leaved Acrotliche. Br. n. 1.—Leaves lanceolate, pointed, divaricated, flat, green on both sides. Spikes axillary.—Found by Mr. Brown, at Port Jackson, New South Wales. We are not certain of having met with this species, among the various specimens sent by Dr. White, though one of them answers nearly to the characters, as far as we are able to investigate them. This specimen greatly resembles *MONOTOCA scoparia* (see that article); but the leaves are more divaricated, or deflexed, and not glaucous at the back.

2. *A. aggregata*. Aggregate Acrotliche. Br. n. 2.—“Leaves oblong-lanceolate, rather concave; glaucous beneath; smooth at the edges.”—Observed by Mr. Brown, in the tropical region of New Holland.

3. *A. ramiflora*. Flowery-branched Acrotliche. Br. n. 3.—“Leaves linear-lanceolate, pointed, divaricated; ribbed, and discoloured, beneath; recurved at the edges. Spikes small, situated on the branches.”—Gathered by the same distinguished botanist, on the southern coast of New Holland.

4. *A. ferrulata*. Finely-ferrated Acrotliche. Br. n. 4.—Leaves linear-lanceolate, spinous-pointed, spreading, hairy or nearly smooth; their edges fringed. Spikes axillary.—Gathered by Mr. Brown in Van Diemen’s island, as well as on the fourth coast of New Holland. We have specimens collected by general Grose, communicated by A. B. Lambert, esq. A small dwarf shrub, with densely tufted, hairy branches. Leaves racemose, one-third or half an inch long, each tipped with a yellowish prickle; three-ribbed, and rather glaucous, beneath; more or less hairy on both sides; their edges fringed with minute stiff hairs, as if ferrated. Flowers in short, lateral, erect clusters. Drupa the size of hemp-seed, depressed, glaucous, or rather silky. Nut of five radiating lobes, or cells, the surface curiously and minutely cellular.

5. *A. patula*. Spreading-branched Acrotliche. Br. n. 5.—“Leaves ovato-lanceolate, spinous-pointed, flattish, divaricated as well as the branches. Spikes small, axillary.”—Native of the southern coast of New Holland. *Brown*.

6. *A. ovalifolia*. Oval-leaved Acrotliche. Br. n. 6.—“Leaves ovate or elliptical, obtuse, pointless, flat, smooth-edged. Spikes axillary. Drupa slightly cellular.”—Gathered by Mr. Brown in the same country as the last.

7. *A. cordata*. Heart-leaved Acrotliche. Br. n. 7. (*Styphelia cordata*; Labill. Nov. Holl. 46. t. 63.)—Leaves heart-shaped, flat; striated beneath. Flowers axillary, solitary or in pairs.—Found by Labillardiere, in Van Leuwin’s land. A span high, erect, with small, rigid, thick leaves. Drupa scarcely bigger than mustard-seed. Mr. Brown, not having seen this plant, is not absolutely certain of its genus; though Labillardiere’s description of the corolla answers to *Acrotliche*.

8. *A. depressa*. Prostrate Acrotliche. Br. n. 8.—“Leaves ovate, somewhat heart-shaped, pointed, divaricated; convex above; veiny beneath. Stem depressed. Spikes small, on the branches.”—Gathered by Mr. Brown, on the fourth coast of New Holland without flowers, and with unripe fruit.

ACT of Faith, l. 2, day which was held; and let the

whole article refer to past time. To the article subjoin, such were the horrors of the inquisition in the reign of Philip II. *Auto da Fe* have not been frequent in late times; and it is perhaps more than half a century since the last, in which criminals were burnt.

ACT of Honour, in Commerce, an instrument drawn by a notary, when a bill is accepted for the honour of another person.

ACTS, in Poetry, col. 2. l. ult., dance, are indeed divided; but to compensate for this retrenchment, the two concluding dances are spun, &c.

ACTÆA, in Botany, see our former article, (thus named, it is generally thought, from *ακτις*, the shore, as being a plant that inhabits the sea-coast, or the margins of waters. But this is not appropriate; and we should rather suppose Linnæus, the author of the name, had in his mind the resemblance of the plant, in some respects, to Elder, *ακτις* of the Greeks.) —De Cand. Syst. v. 1. 381. Linn. Gen. 261. Schreb. 349. Willd. Sp. Pl. v. 2. 1139. Mart. Mill. Dict. v. 1. Sm. Fl. Brit. 562. Prodr. Fl. Græc. Sibth. v. 1. 356. Ait. Hort. Kew. v. 3. 286. Pursh 366. Juss. 235. Lamarck Illustr. t. 448. Gærtn. t. 114. (Christophoriana; Tourn. t. 154. Cimicifuga; Linn. Syst. Veg. ed. 14. 505. Am. Acad. v. 8. 193. Schreb. 369. Willd. Sp. Pl. v. 2. 1244. Mart. Mill. Dict. v. 1. Ait. Hort. Kew. v. 3. 324. Pursh 372. Juss. 234. Lamarck Illustr. t. 487. Gærtn. t. 140.) —Class and order, *Polyandria Monogynia*, (or rather perhaps *Pentagynia*.) Nat. Ord. *Multiflorique*, Linn. *Ranunculaceæ*, Juss. *Spuria*, De Cand.

Eff. Ch. Calyx of four leaves. Petals four. Germens one or more, superior, ovate. Stigma nearly sessile. Pericarp of one cell, with many seeds.

Perennial herbs. Leaves stalked, simple, lobed, or variously cut, imitating compound leaves, according to De Candolle; (most of them are certainly compound.) Flowers racemose, white; calyx and corolla very fugacious; stamens generally longer than the petals. Number in the parts of the flower very variable. Stamens sometimes imperfect in one flower, pistils in another.

The roots are drastic purges, in some degree poisonous, and the herbage is not to be trusted.

Eight species are wild in bushy rocky ground, or cold woods, of the northern hemisphere; one in Europe; in Siberia or Japan two; in North America five.

This genus is very natural, notwithstanding a diversity of characters in the several species. In the *Cimicifuga*, (which approach *Xanthorrhiza* and *Pæonia*;) the germens are numerous, which, as in true *Ranunculaceæ*, become aggregate fruits, bursting at their inner angle. The second section, *Macrotys*, has a similar but solitary fruit, nor ought it to be separated from the *Cimicifuga*, any more than *Consolida* from *Delphinium*. *Alæa* of Linnæus, the third section, has likewise a solitary fruit, exactly similar as to internal structure, but fleshy; yet not more to be separated on that account, than the somewhat berried species of *Clematis* from the rest. From these considerations, and the hints of Michaux and Richard, I refer to the original opinion of Linnæus, and distribute *Alæa* as follows. De Candolle.

We would observe, in support of this decision of our learned friend, that the anomalies in the fruit of *Fumaria*, whence many genera have been formed, appear to us analogous to these of *Alæa*. We are always happy to concur in the definition and confirmation of natural genera, in preference to the endless splitting and subdividing of such into artificial ones; which last, being the easiest of all things, is most tempting to a beginner, especially as he thinks that, in pursuing it, he is exercising great sagacity, and refining on

on the wisdom of ages. We should however certainly keep *Aëta* and *Cimicifuga* separate, were it not for *Macrotys*, which evidently, and almost necessarily, combines them.

SECT. 1. *Cimicifuga*. Fruit aggregate, burbling. Species one to four.

SECT. 2. *Macrotys*. Fruit single, burbling. Species five and six.

SECT. 3. *Christophoriana*. Fruit single, not burbling. Species seven and eight.

SECT. 1. *Cimicifuga*. Linn.

Flowers with many styles. Fruit dry, burbling, aggregate.

1. *A. Cimicifuga*. Bug-wort Actæa. De Cand. n. 1. Linn. Sp. Pl. 722. (*Cimicifuga*; Gmel. Sib. v. 4. 181. t. 70. Linn. Am. Acad. v. 2. 354. C. foetida; Linn. Syst. Nat. ed. 12. v. 2. 659.)—Germens four, nearly sessile, very hairy. Clusters paniced. Leaves divided in a once or twice ternate manner; their segments ovato-lanceolate, deeply toothed.—Native of various parts of Siberia, and of the north-west coast of America. See our former article *CIMICIFUGA*.

2. *A. podocarpa*. Stalked Actæa. De Cand. n. 2. (*Cimicifuga americana*; Michaux Boreal.-Amer. v. 1. 316.)—Germens four or five, stalked, smooth. Clusters paniced. Leaves twice compound.—Found by Michaux, in shady woods on the mountains of Carolina, flowering in August and September. Herb two feet high, with the habit of *A. racemosa*. Calyx of five ovate, concave leaves. Capsules four or five, smooth, compressed, pointed with the styles, and each supported by a stalk half its own length. De Cand.

3. *A. cordifolia*. Heart-leaved Actæa. De Cand. n. 3. (*Cimicifuga cordifolia*; Pursh 373, excluding the synonym.)—Germens two or three, smooth, sessile. Clusters paniced. Leaves divided in a twice ternate manner; their segments five or seven lobed, ferrated, heart-shaped at the base.—In shady woods on high mountains of Carolina, flowering in July. Resembles *A. Cimicifuga* very much in general habit. Pursh. Like *A. racemosa* and *podocarpa*, differing from the former in having numerous capsules, from the latter in their being sessile. Leaves smooth, their broad segments, (we should say leaflets,) almost resembling vine-leaves. Clusters elongated, wand-like, paniced, smooth, with a little acute bractæa under each partial stalk, and two smaller lateral ones at its base. De Cand.

4. *A. palmata*. Palmate Actæa. De Cand. n. 4. (*Cimicifuga palmata*; Michaux Boreal.-Amer. v. 1. 316. Pursh 373. Hydrastis; Lamarck Illustr. t. 500, which therefore is to be struck out of our article *HYDRASTIS*. “H. canadensis; Poir. Suppl. to Lam. Dict. v. 3. 71, but not of Linnæus.”)—Germens twelve to fifteen, in a roundish head. Clusters somewhat paniced, forked. Leaves palmate.—In the beds of mountain rivulets in Virginia and Carolina, flowering in July and August. A very tall and handsome plant; the leaves very large, and the flowers in great abundance. Pursh. The whole plant is smooth. Stem erect, simple, hollow. Leaves two, alternate; the lower one with a broadish stalk, an inch and a half long; the upper nearly sessile; both wedge-shaped at the base, very broad, with from three to five oval lobes, rather acute, and cut or serrated in their upper part. Flowers terminal, corymbose; their stalks forked, minutely downy; single-flowered and naked at the extremity; bractæated below. Calyx of four orbicular leaves. Germens distinct, crowded into a head. De Cand.

SECT. 2. *Macrotys*. “Raf. Schmalz in Bot. Journ. v. 2. 170.”

Flowers with a single style. Fruit dry, burbling.

5. *A. racemosa*. Long-clustered Actæa, or Black Snake-

root. Linn. Sp. Pl. 722. De Cand. n. 5. Willd. n. 2. Ait. n. 2. See ACTÆA n. 2. (*Cimicifuga serpentaria*; Pursh 372. *Christophoriana americana procerior et longior spicata*; Dill. Elth. 79. t. 67.)—Pistil one. Clusters very long. Fruit dry, burbling. Leaves divided in a thrice-ternate manner, ferrated, and somewhat cut.—In shady stony woods, from Canada to Florida, flowering in July and August. Pursh. Herbage like *A. spicata*, but larger; flowers like *A. Cimicifuga*, but monogynous; fruit like *A. cordifolia*, but of a single capsule. It varies however occasionally with two pistils. Clusters downy, very long and dense. Flowers pale, fetid, with small, thick, gibbous, stalked petals, each tipped with a bristly point. Capsules of two valves. Seeds oblong. De Cand. This species is often cultivated in England, as a hardy perennial. The copious white flowers are ornamental, but intolerably fetid, like the scent, well known to furgeons, of a carious bone. The plant is often six or seven feet high.

6. *A. japonica*. Japanese Actæa. Thunb. Jap. 221. De Cand. n. 6. Willd. n. 3.—Pistil one. Spikes very long. Leaves in three heart-shaped, palmate divisions, with from three to seven lobes.—Gathered in Japan by Thunberg, who describes it thus. Herb entirely smooth. Leaves stalked, ternate; leaflets stalked, simple, heart-shaped, cut, with five or seven notched lobes, ferrated, a palm in length and breadth; pale underneath. General and partial footstalks striated, longer than the leaflets. Spike from a palm to a span in length. Calyx and corolla soon falling. Germen oblong, smooth. Style none. The author gives no account of the fruit, so that it is impossible to say whether this species belongs to the second or third section.

SECT. 3. *Christophoriana* of Tournefort.

Fruit single, pulpy, not burbling.

7. *A. spicata*. Black-berried Actæa, or Herb Christoph. Linn. Sp. Pl. 722. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 918. Bull. Fr. t. 83. Fl. Dan. t. 589. (*Christophoriana*; Clus. Hist. v. 2. 86. Ger. Em. 979. Lob. Ic. 682.)—Pistil one. Berry nearly globular. Petals as long as the stamens. Cluster ovate. Leaves divided in a twice or thrice ternate manner; segments ovato-lanceolate, ferrated and cut.—Native of moist and shady mountainous situations, in most countries of Europe; very rare in England, being confined to the north-west part of Yorkshire; flowering in May. Roots fibrous. Berries always black. See ACTÆA n. 1.

8. *A. brachypetala*. Red or White-berried Actæa. De Cand. n. 8. (*A. americana*; Pursh 366. *A. spicata* β et γ; Willd. n. 1. Ait. n. . *A. rubra*; Willd. Enum. 561. Bigelow Bot. 129. *Aconitum baccais niveis et rubris*; Cornut. Canad. 76. t. 77. Morif. sect. 1. t. 2. f. 7.)—Pistil one. Berry ovate-oblong. Petals shorter than the stamens. Cluster ovate. Leaves divided in a twice or thrice ternate manner; segments ovato-lanceolate, ferrated and cut.—In shady rocky woods, in rich vegetable mould, from Canada to Virginia, principally on the mountains, flowering in April and May. Known by the name of Red and White Cohosh, and considered by the natives as a valuable medicine. Pursh. Root more tuberous than in the last. De Cand. Berries bright red, or white; there is said to be a blue-berried variety also. A plant with smaller white berries, tipped with red, on large thickened stalks, is thought by Dr. Bigelow a distinct species. His specimen justifies this opinion, and differs also in the terminal leaflets being ovate, not three-lobed. This merits further enquiry.

ACTINEA, from ακτις, a ray; meaning merely a radiated flower; nor is there anything unusual or striking, relative to the part in question in the instance before

us.—Juff. in Ann. du Mus. v. 2. 425." Willd. Sp. Pl. v. 3. 2213.—Clafs and order, *Syngenefia Polygamia-fuperflua*. Nat. Ord. *Compoſite diſcoideæ*, Linn. *Corymbifereæ*, Juff.

Gen. Ch. *Common Calyx* nearly flat, of many ſpreading, lanceolate, ſomewhat imbricated, nearly equal, permanent leaves, ſhorter than the florets. *Cor.* compound, radiated; *ſlorets* of the diſk perfect, numerous, tubular, longer than the calyx, five-toothed; thoſe of the radius in a ſimple ſeries, ligulate, wedge-shaped, obtuſe, flat, three-cleft almoſt half way down, twice as long as the calyx. *Stam.* in the tubular florets, Filaments five, capillary, ſhort; anthers acute, united into a prominent tube. *Piſt.* in the ſame, Germen oblong, downy; ſtyle thread-shaped, nearly as long as the ſtamens; ſtigmas two, capitate, divaricated between the points of the anthers. In the ligulate florets, ſtyle very ſhort. *Peric.* none. *Seeds* in each floret ſolitary, oblong, hairy, crowned with ſeveral membranous long-awned ſcales. *Recept.* convex, naked.

Eff. Ch. Receptacle naked. Seed-down of ſeveral chaffy, pointed, awned ſcales. Calyx of many equal leaves.

1. *A. heterophylla*. Various-leaved Sun-wort. Willd. n. 1. Juff. as above, t. 61. f. 2.—Gathered by Commerſon at Monte Video. The *ſtem* is ſhrubby, angular, furrowed; the *branches* leafy, downy when young, ſingle-flowered. *Leaves* alternate, ſeſſile, linear-oblong, an inch or two in length, rather fleſhy, ſlightly downy on both ſides, blunt, with a ſmall point; the lower ones generally furniſhed with a ſtrong tooth at each ſide; the upper ſmaller, narrower and entire. *Flowers* ſolitary, on long, naked, downy ſtalks, at the end of each branch, erect, an inch in diameter. *Calyx* downy. *Radius* ſhort, yellow. *Diſk* broad, convex, darker coloured; the *ſlorets* numerous, externally hairy in their upper part. Awns of the *ſeed-down* reddiſh, as long as the *partial corolla*.

This plant appears to us very nearly related to HELENIUM, (ſee that article,) into which genus it might, without any violence to nature, have been introduced. Even the *calyx* ſcarcely betrays a difference, for that of *Helenium* can hardly be conſidered as of one leaf, any more than thoſe of *Helianthus*, *Rudbeckia*, &c. The ſtructure of the *radius*, downineſs of the *ſeeds* and of the tubular *ſlorets*, pointed chaffy *ſeed-crown*, all agree. We have not indeed ſeen the deſcription given by the learned author of this genus, nor will our ſpecimen admit of an inveſtigation of the more recondite parts of fructification, without injury to ſo great a rarity; but we ſhould not ſcruple to ſink *Actinea* in *Helenium*, according to our preſent means of judging.

ACTINELLA, a diminutive of ACTINEA, (ſee that article,) and therefore inadmiſſible, as being contrary to one of the foundeſt laws of nomenclature. Nor is this genus, probably, any more than *Actinea*, diſtinct from *Helenium*, next to which *Actinella* is placed by Purſh, Fl. Amer. Sept. 494. 560, who deſcribes it as follows, citing Perſ. Syn. v. 2. 469, and, as a ſynonym, *Actinea*, Juff. in Ann. du Muſ. v. 2. 425.—Clafs and order, *Syngenefia Polygamia-fuperflua*.

Eff. Ch. Receptacle naked. Seed-crown of from four to fix chaffy-awned ſcales. Calyx of many equal leaves.

1. *A. lanata*.—Clothed all over with woolly down. *Leaves* linear; pinnatifid upwards. *Stalks* elongated, ſingle-flowered. *Radiant florets* with two teeth. *Seeds* five-sided, ſmooth.—Found by Governor Lewis, on the high lands of the Kooſkoolky. Perennial, flowering in June and July. The whole *herb* is clothed with white woolly down. *Stem* branched, round. *Branches* alternate, ſubdivided in the upper part; their ultimate diviſions ſingle-flowered. *Leaves*

of the main ſtem alternate, linear, dilated and pinnatifid upwards, toothed; thoſe of the branches linear, undivided. *Flower-ſtalks* terminal, ſwelling towards the end. *Flowers* orange-coloured, the ſize of *Targetes erecta*. *Calyx* oblong, ſimple, of from twelve to fourteen linear-lanceolate acute leaves. *Florets* of the *radius* from twelve to fourteen, oblong, ribbed, each with two teeth; thoſe of the *diſk* tubular, of the ſame colour. *Down* of from four to fix whitith, acute, chaffy ſcales, occaſionally torn. *Seeds* oblong, prismatic, with five angles. It reſembles in habit Juffieu's *Actinea* in Ann. du Muſ. v. 2. t. 61. f. 2. *Purſh*.

We are entirely at a loſs to account for the change in the generic name, if the genera are ſuppoſed the ſame, and it ſeems fortunate that both are likely to be funk in *Helenium*.

ACTINOCARPUS, from *ακτις*, a ray, and *καρπος*, fruit, alluding to the radiating poſition and form of the capſules. Mr. Brown was obliged to invent this very expreſſive name for the *Damaſonium* of Juffieu, becauſe the latter appellation has been adopted for another genus, in the works of Schreber and Willdenow.—Brown Prodr. Nov. Holl. v. 1. 342. (Damaſonium; Juff. Gen. 46. Tourn. t. 132.)—Clafs and order, *Hexandria Hexagymia*. Nat. Ord. *Tripetaloideæ*, Linn. *Junci*, Juff. *Alifmaceæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of three ovate, concave, permanent leaves. *Cor.* Petals three, roundiſh, flat, ſpreading, larger than the calyx, deciduous. *Stam.* Filaments ſix, awl-shaped, ſhorter than the corolla; anthers roundiſh. *Piſt.* Germens fix or eight, erect, combined at the baſe; ſtyles ſhort, ſpreading; ſtigmas ſimple. *Peric.* Capſules as many, combined at the baſe, ſpreading in the form of a ſtar, compressed, pointed, of one cell, burſting at the upper edge. *Seeds* two, elliptical, ſtalked, one erect, inſerted into the bottom of the capſule, the other at its curve, horizontal.

Eff. Ch. Calyx of three leaves. Petals three. Capſules fix or eight, compressed, combined at the baſe, ſpreading ſtar-wiſe. *Seeds* two.

1. *A. Damaſonium*. Great Starry-plantain. (Alifma Damaſonium; Linn. Sp. Pl. 486. Willd. Sp. Pl. v. 2. 277. Sm. Fl. Brit. 401. Engl. Bot. t. 1615. Curt. Lond. fac. 5. t. 28. Ait. Hort. Kew. v. 2. 332. Damaſonium ſtellatum; Dalech. Hiſt. 1058. Tourn. Inſt. 257. Raii Syn. 272. Plantago aquatica minor ſtellata; Ger. Em. 417.)—Capſules fix, burſting lengthwiſe; without wings at the baſe.—Native of watery places on a gravelly ſoil, in England, near London, as well as in Shropſhire, Suffolk, and Suſſex. It grows alſo in France and Siberia; flowering in June and July. The *root* is perennial, of many long ſimple fibres, as uſual with aquatic herbs. *Leaves* all radical, floating, ſtalked, elliptic-oblong, ſmooth, two inches long, with a ſtrong mid-rib, and two ſiner ribs, at each ſide, near the margin. *Footſtalks* dilated and winged below. *Flower-ſtalks* one or two, radical, erect, taller than the leaves, round, ſimple, each bearing two or three umbels of whitith *flowers*, giving it a whorled appearance. The *capſules* reſemble thoſe of the *Illicium*, or Starry Aniſe, in ſize and general figure.

2. *A. minor*. Smaller Starry-plantain. Br. n. 1.—“Capſules eight, burſting tranſverſely; with eight permanent wings at the baſe. Leaves three-ribbed.”—Native of the neighbourhood of Port Jackson, New South Wales, where it was obſerved by Mr. Brown.

We have here admitted this genus, from deference to the authority of Mr. Brown, who eiteems it abundantly different from *Alifma*, in the definite number of the *capſules*, their ſtellate diſpoſition, their combination at the baſe, and their two *ſeeds*. In the habit of the plants there is no difference.

The Linnæan remark that "there is rarely a genus in which one or other part of the fructification does not prove less constant, or uniform, than the rest," *Phil. Bot. fœd.* 170; a rule too much neglected by founders of new genera in all ages and countries, should teach us caution in every instance, and in the present perhaps might justify keeping the Linnæan *ALISMA* entire. See that article.

ACTINOTUS, so named by M. Labillardiere, *Nov. Holl.* v. 1. 67, from *ἀκτινωτός*, radiated, alluding to the form of the involucre. See *ERIOCALIA*, which last name is retained by Professor Sprengel, in his *Prodr. Plant. Umbellif.* 27, who gives the following essential character of this very curious genus.

Fruit ovate, villous, with five slender ribs, and crowned by the calyx. Umbel capitate. Involucreum very long, woolly.

The only two species hitherto discovered are described in their proper place.

ACTON, second article, for 853 r. 885. Add, Also, a town of Vermont, in the county of Windham, containing 245 inhabitants.

ACWORTH, l. 3, in 1810, 1523 inhabitants.

ADAIR, in *Geography*, a county in the district of Kentucky, which, with the town of Columbia, has 6011 inhabitants, including 956 slaves.

ADAM, ROBERT. For Kirkaldy, in Fifeshire, r. Edinburgh; and for Edinburgh r. that city.

ADAMAH. For Nephtali r. Naphtali.

ADAMS, in *Geography*, l. 2, r. 1763. At the close, add—Also, a town of New Hampshire, in the county of Coos, containing 244 inhabitants.—Also, a county of Ohio, containing 9434 inhabitants.—Also, a township of Ohio, in the county of Washington, having 620 inhabitants.—Also, a county of Pennsylvania, containing 15,152 inhabitants, of whom 71 are slaves.

ADANSON, MICHAEL, in *Biography*, the article already given requires some correction. This celebrated botanist belonged to a Scottish family, attached to the fortunes of the Pretender. He died of *mollities ossium*, August 3d, 1806, and not before, aged 79 years and 4 months. M. Cuvier, in the *Memoires de l'Institut*, v. 7, has published an elaborate *éloge* of Adanson, in which great justice is done to his ardour and acuteness in the pursuit of botany, and to his patience and magnanimity under great sufferings and privations, incident to the political convulsions of his country. The writer of this knew him at Paris in 1786. He was evidently a man of an active and penetrating mind, but devoted to his own imaginations and hypotheses, always attacking, as might be expected, the botanical system of Linnæus, but betraying a weakness unworthy of his own talents, in contemptuously reprobating the whole principles and performances of the illustrious Swede. Yet we are possessed of two letters from Adanson to Linnæus, both amicable and complimentary in the highest degree. In the first, dated June 28, 1754, the writer offers to communicate his discoveries and remarks made at Senegal, speaks of Gum *Edellium* as the *Thus*, or Frankincense, of Europeans, used for fumigation in churches, and exhorts Linnæus to continue to illustrate botanical science. The second, dated October 2, 1758, acknowledges the receipt of a most welcome letter from Linnæus; laments the recent death of Anthony de Jussieu, and the illness of Bernard de Jussieu, which obliged Adanson to undertake the department of herborizing with the students. He subjoins an account of the African tree Baobab, which Bernard de Jussieu had named *Adanonia*, and gives its natural generic character at length, professedly in the Linnæan manner, with several articles of information which

Linnæus afterwards introduced into his account of *Adanonia*. This letter moreover contains some matters relating to Zoology; mentions the great want of accuracy in the characters of almost all the exotic genera of plants, described by travellers, which the writer had examined at Senegal, and concludes with most respectfully thanking Linnæus for his promise to make Adanson a member of the Upsal Academy of Sciences. This promise appears never to have been fulfilled. It might well be dispensed with when Adanson, in the following year, read before the *Academie des Sciences*, at Paris, that history of botany, which now makes a part of the preface of his work, entitled *Familles des Plantes*, published in 1763. In this the system of Tournefort is exalted above the natural as well as artificial methods of Linnæus, and the person whose correspondence he had been courting, and to whose "favour and friendship" he had so lately recommended himself, is depreciated in the most contemptuous manner, in almost every thing he had done for the science of botany. This has been attributed to the correspondence of Adanson being slighted by Linnæus; but there was hardly time for such a consequence. He rather appears to have found it expedient and popular to attack the fame of the great naturalist, to whose merit the French were then becoming sensible, and who threatened to eclipse the honours so long enjoyed by Tournefort. Notwithstanding Tournefort's merits, Adanson tells us, p. 154, that "he has reason to think his own *Familles* will be adopted, as containing the sum of all the knowledge acquired in the science of botany." An author seldom errs more than when he prophesies the success of his own works. Had Adanson foretold that his performances would never be refuted, he had been right, for they have slept in almost total neglect. We have given a sufficient account of his method and nomenclature, under the head of **NATURAL ORDERS**. We are aware that it is still popular at Paris to commend him, nor would we deprive him of any praise which he can enjoy, without injustice to his predecessors, or without his authority leading to scientific error, and historical mistake.

ADDISON, JOSEPH, l. 2, r. Ambrosbury for Abrosbury.

ADDISON, County, l. 5, contained, in 1810, 19,998 inhabitants, dispersed in 24 townships.

ADDISON, l. 4, for 401 r. 1100. Add—Also, a town of Washington county, in the district of Maine, containing 399 inhabitants.—Also, a township of Pennsylvania, in the county of Somerset, having 678 inhabitants.

ADENANTHOS, in *Botany*, so named by Labillardiere, from *ἀνθρα*, a gland, and *ανθος*, a flower, on account of the glands, in the form of scales, attached to the permanent base of the corolla.—Labill. *Nov. Holl.* v. 1. 28. Brown-Tr. of Linn. Soc. v. 10. 151. *Prodr. Nov. Holl.* v. 1. 367.—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juss. Brown.

Gen. Ch. *Cal.* Involucreum single-flowered, of from four to eight short, imbricated leaves. *Cor.* of one petal, inferior, tubular, cut round near the base, and from above that part deciduous; its limb in four deep, lanceolate, flat segments, turned to one side. Nectary four glands, united with the permanent base of the corolla at its inside. *Stam.* Filaments four, short, inserted into the disk of each segment of the corolla; anthers oblong, erect. *Pist.* Germen superior, roundish; style thread-shaped, longer than the corolla; stigma vertical, awl-shaped, rather thicker than the style. *Peric.* Nut tumid, of one cell, with a single seed.

Eff. Ch. Involucreum imbricated, single-flowered. Corolla four-cleft, splitting circularly near the base. Nectary of four glands, attached to the bottom of the corolla. Style longer

longer than the corolla. Stigma vertical, awl-shaped. Nut tumid.

A shrubby New Holland genus. *Leaves* scattered, various in the different species. *Flowers* axillary, solitary, reddish; rarely terminal, somewhat aggregate, and yellowish. *Brown*.

1. *A. obovata*. Obovate-leaved Adenanthos. Labill. Nov. Holl. v. 1. 29. t. 37. Brown n. 1.—Leaves obovate, entire, smooth.—Observed by M. Labillardiere, as well as by Mr. Brown, on fony hills in Lewin's land, on the south coast of New Holland. *Branches* round, thickly clothed with coriaceous *leaves*, near an inch long, broadly obovate, triple-ribbed, besprinkled with blackish glandular dots; their lateral ribs sending off veins towards the margin. *Flowers* axillary, solitary, twice as long as the leaves. *Involucrum* of six or eight smooth scales. Points of the *corolla* scarcely hairy on the inner side. *Style* hairy, except at the top and bottom. *Stigma* rather swelling. *Labill*.

2. *A. cuneata*. Wedge-leaved Adenanthos. Labill. Nov. Holl. v. 1. 28. t. 36. Brown n. 2.—Leaves wedge-shaped, silky; bluntly toothed at the extremity.—Gathered near the sea-coast at Lewin's land, by Brown and Labillardiere. We have a specimen from the latter. This *Shrub* is about the height of a man. *Leaves* hardly an inch long, erect, stalked, silky and silvery on both sides, with three principal ribs, sometimes combined at the lower part; their abrupt extremity unequally and bluntly notched. *Flowers* towards the tops of the branches, axillary, stalked. *Involucrum* fringed, silky, as well as the outside of the *corolla*, whose segments are densely bearded on the inside. *Style* swelling and hairy in the middle.

3. *A. sericea*. Silky-leaved Adenanthos. Labill. Nov. Holl. v. 1. 29. t. 38. Brown n. 3.—Leaves thread-shaped, twice-ternate, silky. *Flowers* axillary, solitary. *Style* smooth.—Native of the sandy sea-coast of Lewin's land, where it was found by the authors cited. Our specimens were gathered by Mr. Menzies, at King George's sound, on the west coast of New Holland. The *branches* are round and silky, the younger ones most densely leafy. *Leaves* about an inch and a half long, twice or thrice deeply three-cleft, in narrow blunt, thread-shaped segments, clothed with silky hairs. *Flowers* towards the tops of the branches, densely hairy, rather longer than the leaves. *Style* smooth in every part, rather swelling in the middle.

4. *A. terminalis*. Terminal-flowered Adenanthos. Brown n. 4.—Leaves thread-shaped, three-cleft; their lateral segments cleft; middle one undivided. *Flowers* terminal, solitary or three together. *Style* shaggy.—Gathered by Mr. Brown, at Flinder's land, on the south coast of New Holland, in low ground near the sea-coast.

ADENODUS, so called by Loureiro, from *adon*, a gland, because of the glands of the flower, which remain to accompany the fruit.—Loureir. Cochinch. 204.—Class and order, *Dodecandria Monogynia*.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, reflexed, deciduous leaves. *Cor.* Petals five, ovate, nearly erect, the length of the calyx, divided half way down into many thread-shaped segments. Nectary five large, depressed, permanent, two-lobed glands. *Stam.* Filaments fifteen, short, spreading, inserted into the receptacle; anthers oblong, quadrangular, erect, split and reflexed at the summit. *Pist.* Germen superior, elongated; style awl-shaped, the length of the stamens; stigma acute. *Peric.* Drupa obovate-oblong, small, smooth, single-seeded. *Sced.* Nut oblong, rugged.

Eff. Ch. Calyx five-leaved, inferior. Petals five, fringed.

Nectariferous glands two-lobed, permanent. Drupa with a single seed.

1. *A. sylvestris*. Cây Côm trắng, of the Cochinchinefc.—Native of woods in Cochinchina. A middle-sized tree, with spreading branches. *Leaves* alternate, ovato-lanceolate, serrated, smooth. *Spikes* nearly terminal. *Flowers* variegated with red and white. *Loureiro*.

De Theis, Gloffaire de Botanique, 6, has anticipated us in the remark, that this plant approaches the genus *ELÆOCARPUS*. (See that article.) Indeed we have scarcely a doubt of its being one of that genus, though, having seen no specimen, we cannot absolutely assert this point. Still less can we determine whether Loureiro's plant be any of the species already known.

ADENOSMA, a word composed of *adon*, a gland, and *osma*, a scent, which expresses the glandular and fragrant nature of the herbage.—Brown Prodr. Nov. Holl. v. 1. 442.—Class and order, *Didymia Angiosperma*. Nat. Ord. *Perfonate*, Linn. *Scrophularia*, Juss. *Scrophularine*, Brown.

Eff. Ch. Calyx in five deep segments; the upper one largest. Corolla ringent; upper lip undivided, lower in three equal lobes. Anthers approaching each other. Stigma dilated. Capsule ovate, beaked, separable into two parts. Receptacles united to the futures.

1. *A. cerulea*. Blue Adenosma. Br. n. 1.—Gathered by sir Joseph Banks, and Dr. Solander, in the tropical region of New Holland. Seen by Mr. Brown in a dry itate only. An annual downy herb, besprinkled with glands, and smelling like mint, turning black in drying. The spike is leafy; or the flowers may be termed axillary. Calyx rough with jointed hairs, and accompanied by a pair of bractes. Corolla blue. *Brown*.

This author remarks, that *Ruellia uliginosa* and *balsamea* constitute a genus nearly akin to the present, and that both are related to the order of *Acanthi*, or *Acanthaceae*, but especially *Adenosma*, on account of its beaked capsule.

ADENOSTEMMA, Forst. Gen. t. 45. See LAVENIA.

ADEODATUS, POPE, in *Biography*, denominated "Dieu donné," God's Gift, was by birth a Roman, and by profession a monk. He became pope in 672, and died in 676.

ADEPS. Subjoin, See CELLULAR Substance.

ADERME, in Commerce. See QUINTAL.

ADIANTUM, in Botany, an ancient Latin name, which by Pliny's account, book 22. chap. 21, appears to have belonged to the very species of fern, *Adiantum Capillus-Veneris*, to which it is still applied. But that account, like half his work, as we have it, is a manifest jumble of various ill-assorted materials. What he hints there, as well as in the beginning of the 17th chapter of his 21st book, relative to the permanency of the leaves, whether originally reported of the same plant, or of some other, is not contrary to truth, inasmuch as this fern is almost always verdant. His derivation of the name, from *ad*, without, or contrary to, and *diava*, to moisten, because water trickles off the leaves without wetting them, may satisfy us, for want of a better; but how much better would such an explanation suit any glaucous herb, like the cabbage.—Linn. Gen. 560. Schreb. 757. Willd. Sp. Pl. v. 5. 427. Mart. Mill. Dict. v. 1. Swartz Syn. Fl. 120. Sm. Fl. Brit. 1138. Prodr. Fl. Græc. Sibth. v. 2. 278. Brown Prodr. Nov. Holl. v. 1. 155. Ait. Hort. Kew. v. 5. 524. Pursh 670. Juss. 15. Tourn. t. 317. Lamarck Dict. v. 1. 40. Illustr. t. 870.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorsifere*, *annulata*.

ADIANTUM.

Eff. Ch. Masses of capsules oblong, or roundish, inserted into each marginal, reflexed, limited involucrem.

Such is the character of the original *Adiantum* of all authors, a numerous genus, from which Dr. Swartz has first distinguished his *CHEILANTHES*, to be treated of hereafter in its proper place, whose character is, that the masses of capsules are really placed on the margin of the leaf itself, each being covered only by its respective involucrem. The difference is nice, and escaped every previous observer, but we believe it to be a very found one, inasmuch as it is attended by a difference of habit, and the involucrem of *Cheilanthes* is not always necessarily interrupted, though the masses of capsules, *forti*, are distinct.

In our former article, (see *ADIANTUM*,) forty-six species are briefly enumerated, with a particular account of two, which need not here be repeated. As the genus now stands, Willdenow has fifty-four, (besides nineteen of *Cheilanthes*), disposed in sections, of which we shall give examples, with additions of new species.

SECT. 1. *Fronde simplici.* Three species in Willdenow.

1, *A. reniforme*, Linn. Sp. Pl. 1556; 2, *ajacifolium* of Willdenow, Lamarck f. 2; and 3, *philippense*, Linn. Sp. Pl. 1556. We have none to add. For *A. sagittatum*, see LINDSÆA.

SECT. 2. *Fronde ternate.*

4, *A. triphyllum* only. Sm. Plant. Ic. t. 74.

SECT. 3. *Fronde pinnate.* Twelve species in Willdenow.

5, *A. macrophyllum*, Swartz Ind. Occ. 1707; 6, *obliquum*, Willd.; 7, *lunulatum*, Willd. Phytog. t. 9. f. 1; 8, *arcuatum*, Sw.; 9, *pumilum*, Sw. Pluk. Phyt. t. 251. f. 4; 10, *caudatum*, Linn. Mant. 308; 11, *hirsutum*, Willd. from the island of Mauritius; 12, *rhizophorum*, Sw. Syn. 320, from the same country. We have two to add.

A. platyphyllum. Broad-leaved Maidenhair. Swartz in Stockh. Transf. for 1817. 74. t. 3. f. 6.—Fronde pinnate; leaflets flaked, ovate, taper-pointed, nearly entire; oblique, and dilated upwards, at the base; glaucous beneath. Dots oblong, contiguous along the whole margin.—Native of shady woods in Brasil. *Freyreis*. A foot high, or more, consisting of from three to six alternate leaflets, two inches long and one broad, with numerous divaricating veins; the barren ones very inconspicuously serrated. *Common stalk* smooth, of a shining black. The insertion of the capsules is by no means well explained, either in the figure or description.

A. paradoxum. Ambiguous Maidenhair. Br. n. 1.—“Fronde pinnate; leaflets heart-shaped, oblong-ovate, or lanceolate; their veins underneath obsolete. Dots linear, uninterrupted.”—Gathered by Mr. Brown, near Port Jackson, New South Wales.

SECT. 4. *Fronde partly bipinnate.* Five species.

13, *A. deltoideum*, Sw. Ind. Occ. 1705; 14, *denticulatum*, *ibid.* 1711; 15, *salcatum*, *ibid.* 1715; 16, *varium*, Willd., found by Humboldt and Bonpland, near Caripe, in South America; 17, *ferrulatum*, Linn. Sp. Pl. 1557.

SECT. 5. *Fronde three-branched, digitate, or pedate; the branches pinnate.* Seven species.

18, *A. ternatum*, Willd., found near Caripe, in South America, by Humboldt and Bonpland; 19, *radiatum*, Linn. Sp. Pl. 1556; 20, *pedatum*, *ibid.* 1557, see our former article; 21, *Lindlea*, Cavan. Leccion. 271, gathered by Louis Née, at Quito; 22, *patens*, Willd., found by Bredemeyer at the Caracas; 23, *pubescens*, Willd., which is *pedatum* of Forst. Prodr. 83; 24, *stellulatum*, Linn. Sp. Pl. 1557. This last is unquestionably *A. fuscum*, Retz. Obf. fasc. 2. 28. t. 5, the figure of which precisely answers to the Linnæan specimen of *stellulatum*,

except that the upper sides of the branches in the latter are clothed with fine short rusty down, like velvet, which might escape the notice of professor Retzius. The *common stalk*, except at the very top, is quite smooth and naked, as described by him.

SECT. 6. *Fronde twice, thrice, or four times, pinnate.* Thirty species.

25, *A. Lancaea*, Linn. Sp. Pl. 1557; 26, *striatum*, Sw. Ind. Occ. 1717. Jacq. Ic. Rar. t. 646; 27, *tetraphyllum*, Willd., found by Humboldt and Bonpland near Caripe; 28, *polium*, Willdenow, found by the same at Cumana; 29, *pyramidale*, Willd., which is *Polypodium pyramidale*, Linn. Sp. Pl. 1554. This is *Filix ramosa pyramidalis, pinnis parvis*, Petiv. Fil. n. 40. t. 4. f. 12, not f. 2. Linnæus adopted this species entirely from Petiver's figure, and was thus led to make it a *Polypodium*. But that figure is copied from *Lonchitis ramosa tenuis, pediculis spinosis*, Plum. Fil. 42. t. 54, where the characters and habit of an *Adiantum* are conspicuous; 30, *melanoleucum*, Willd., adopted by this author, without seeing a specimen, from *Adiantum lunulis albicantibus signatum*, Plum. Fil. 79. t. 96; 31, *eristatum*, Linn. Sp. Pl. 1558; 32, *nervosum*, Swartz Syn. 123. (see *bispidalum*, Br. n. 2, at the end of this section); 33, *bispidalum*, Swartz Syn. 124 and 321, suspected by Mr. Brown to be the same as n. 32; 34, *villosum*, Linn. Sp. Pl. 1558; 35, *monosporatum*, Willd., gathered at the Caracas by Bredemeyer; 36, *ferrato-dentatum*, Willd., found by Humboldt and Bonpland near Caripe, and in Brasil; 37, *crenatum*, Willd., taken up entirely from *Lonchitis ramosa, rotundè crenata*, Plum. Fil. 41. t. 53; 38, *pulverulentum*, Linn. Sp. Pl. 1559; 39, *umbrosum*, Willd., found by Bredemeyer, in shady situations at the Caracas; 40, *trapeziforme*, Linn. Sp. Pl. 1559, a West Indian fern, strangely supposed to grow in Scotland, because Sibbald's rude figure of a variety of *Asplenium marinum* was taken for it; see Sm. Fl. Brit. 1128; 41, *pentadactylon*, Langsdorff and Fischer, Ic. Fil. t. 25, found in Brasil; 42, *affine*, Willd., which is *trapeziforme* of Forst. Prodr. 84. “Schkuhr Crypt. t. 121. b;” 43, *Capillus Veneris*, Linn. Sp. Pl. 1558. Fl. Brit. 1138. Engl. Bot. t. 1564, see our former article; 44, *emarginatum*, Willd., found by Bory de St. Vincent, on rocky margins of torrents in the isle of Bourbon; 45, *cuneatum*, Langsdorff and Fischer, Ic. Fil. t. 26, found in Brasil; 46, *tenerum*, Swartz Ind. Occ. 1719; 47, *fragile*, *ibid.* 1721; 48, *concinnum*, Willd., which is *tenerum*, Schkuhr Crypt. t. 121, (but not of other authors,) gathered by Humboldt and Bonpland in the Caracas; 49, *sumarioides*, Willd., communicated by Flüggé, from the isle of Bourbon; 50, *ethiopicum*, Linn. Sp. Pl. 1560; 51, *trigonum*, Labill. Nov. Holl. v. 2. 99. t. 248. f. 2, considered by Mr. Brown as not different from the following; 52, *affinile*, Swartz Syn. 125 and 322. t. 3. f. 4; 53, *pallens*, Swartz Syn. 125 and 323, figured in Pluk. Phyt. t. 403. f. 2; 54, *polyphyllum*, Willd., found at the Caracas by Bredemeyer. We subjoin the following.

A. bispidalum. Roughish New Holland Maidenhair. Br. n. 2. Swartz Syn. 124? See n. 33, above. (*A. nervosum*; Swartz Syn. 123? See n. 33, above. *A. pedatum*; Forst. Prodr. 83, on the authority of his herbarium.)—Fronde doubly pinnate; lowest branches divided; leaflets ovate-rhomboid, toothed in front, striated, rather hairy, and rough. Involucrem nearly orbicular, hairy. *Common stalk* and ribs rough.—Gathered by Dr. White, as well as by Mr. Brown, in New South Wales, and by the latter in the tropical part of New Holland. A foot high, or more, with a strong tufted root, whose crown is scaly. *Stalks* purplish-black, harsh. *Leaflets* somewhat flaked,

stalked, numerous on each long partial *branch*, crowded, oblique, jagged, half an inch in length, of a fine green. *Involucrum* crowded most about the inner, or upper, angle of the base, brown, round or kidney-shaped, rough with fine bristly hairs; their under side covered with little brown crowded *capsules*, which are quite unconnected with the leaf.

A. formosum. Elegant New Holland Maidenhair. Br. n. 3.—“Frond repeatedly compound, deltoid; branches triply pinnate; leaflets rhomboid, obtuse, smooth; the lower ones cut. *Involucrum* kidney-shaped. Partial ribs downy. Common stalk rough.”—Discovered by Mr. Brown, near Port Jackson, New South Wales. We know not that we have ever seen a specimen.

A. affmile. Rounded New Holland Maidenhair. Br. n. 4. Swartz Syn. 125 and 322. t. 3. f. 4. (*A. trigonum*; Labill. Nov. Holl. v. 2. 99. t. 248. f. 2; see n. 51 and 52 above.)—Frond repeatedly compound, very smooth; leaflets roundish-rhomboid, deeply notched in front; the notches contracted, each bearing a smooth kidney-shaped *involucrum*. Common stalk and ribs perfectly smooth.—Gathered by Dr. White and Mr. Brown, in the neighbourhood of Port Jackson, and by the latter, as well as M. Labillardiere, on the fourth coast of New Holland, and in Van Diemen’s island. From one to two feet high, composed of numerous little, fan-like, stalked, ribbed, bright-green leaflets, between whose rounded marginal segments the smooth, light-brown *involucrum*s are stationed. These by age become reflexed, and turn up the numerous pale *capsules* which cover their under surface.

A. subcordatum. Heart-leaved Maidenhair. Swartz in Stockh. Transf. for 1817. 75.—“Frond triply pinnate; leaflets stalked, somewhat heart-shaped, pointed, slightly crenate, with radiating veins. *Involucrum*s at each margin, roundish-crescent-shaped.”—Gathered by Mr. Freyreis, in shady woods in Brasil. *Common stalk* round, dark purple, smooth and polished. *Frond* eighteen inches long, its outline ovate, or deltoid. Primary and secondary *branches* alternate, widely spreading, straight, round, smooth, the colour of the stalk. *Leaflets* alternate, rather distant, some regular, others oblique and dilated at the upper angle of the base, an inch in length, with a long point to each; smooth on both sides; streaked beneath with copious, forked, radiating veins, and slightly glaucous; the margin obscurely serrated. *Common rib* slightly zigzag, polished. *Dots* at the upper and under edges, not at the base or apex, roundish, distinct, covered by brown crescent-shaped *involucrum*s. Swartz. This mode of expression must not be taken literally, for then the plant would be a *Cheilanthes*. The author adds, that this species is very distinct in the shape of its leaflets; for so only can we understand “*forma pinnarum*,” as meaning *pinnularum*.

A. intermedium. Intermediate Maidenhair. Swartz in Stockh. Transf. for 1817. 76.—“Frond doubly pinnate; leaflets halved, wedge-shaped, oblong-rhomboid, obtuse, ribbed and striated; with a right angle at the upper side of the base; serrated and fructifying at the front and apex. Stalk and ribs rough and downy.”—Gathered by Mr. Freyreis in low woods, in the interior part of Brasil, in September. *Root* creeping. *Common stalks* a foot high, triangular, rigid, roughish, brownish-black, beset with rusty hair. *Fronds* half as long, deltoid: first divisions opposite, linear-lanceolate, curved upwards, of three pair of leaflets, half an inch in length, besides an odd one rather longer, all somewhat stalked, slightly falcate, obtuse, crowded, smooth on both sides, of a brownish-green.

Dots four or five, distinct, each with a semicircular, curved, brown *involucrum*. Intermediate, as it were, between *crifatum* of Linnaeus, and *neruofum* of Swartz, n. 31 and 32, but differing from the former in having the *common stalk* not rough with prominent points, nor the lower *branches* deeply divided; from the latter in having wedge-shaped leaflets, somewhat falcate in front, and other particulars. It is perhaps too nearly related to *A. acuminatum* of Deveaux. Swartz.

ADJUDISING. See BUNDELA and REWAH.

ADIPOCIRE, in *Chemistry*, is described at length in the Cyclopædia; but the curious fact that this substance forms a principal ingredient in some species of BILIARY Calculi has been omitted under both articles.

ADJUSTMENT, the settling of the averages or losses on policies of assurance. See AVERAGE.

ADONIS, in *Botany*, was so named in memory of the favourite of Venus, reported by the poets to have been changed, by that goddess, into a flower. But whether ours is the very plant, known by this name to the ancients, would be almost as difficult to prove as the original fact. Our former article requires correction, in consequence of the publication of De Candolle, by which we have profited so much in ACONITUM, ACTÆA, &c.—De Cand. Syst. v. 1. 220. Linn. Gen. 281. Schreb. 377. Willd. Sp. Pl. v. 2. 1303. Mart. Mill. Dict. v. 1. Sm. Fl. Brit. 586. Prodr. Fl. Græc. Sibth. v. 1. 379. Ait. Hort. Kew. v. 3. 350. Juss. 232. Lamarck Illustr. t. 498. Gært. t. 74.—Class and order, Polyandria Polygynia. Nat. Ord. Multiflorique, Lina. Ranunculaceæ, Juss. De Cand.

Gen. Ch. Cal. Perianth inferior, of five obtuse, concave, close-pressed, somewhat coloured, deciduous leaves, sometimes with a small spur at the base. Cor. Petals from five to fifteen, oblong, obtuse, polished, with simple naked claws. Stam. Filaments numerous, very short, awl-shaped, inserted into the base of the receptacle; anthers oblong, inflexed. Pist. Germens numerous, ovate, inserted into the oblong-conical receptacle, crowded, above the stamens, each pointed with a very short, partly decurrent, style; stigmas acute, reflexed. Peric. none. Recept. oblong, spiked. Seeds numerous, irregular, angular; gibbous at the base; reflexed at the point, rather prominent, without awn or wing.

Efl. Ch. Calyx of five leaves. Petals from five to fifteen, destitute of nectaries. Seeds naked.

Herbaceous plants, with leafy stems. Leaves deeply cut, in a pinnate manner, their lobes many-cleft, in very numerous, linear segments. *Involucrum* none. Flowers solitary, at the summits of the stem, or branches, yellow, scarlet or crimson, never blue.

All the ten species are found in Europe, or in the adjoining countries of northern Africa and Asia; those of the first section in cultivated plains; of the second in rugged mountainous spots.

The perennial kinds have acrid, bitterish, purgative roots, capable of supplying the place of Hellebore. The annual ones are almost inactive.

The genus is divisible into two sections, by the habit and duration, confirmed by differences in the flowers and fruit, as follows.

SECT. 1. *Adonia*. De Candolle.

Adonis of C. Bauh. Pin. 178.

Petals from five to ten, concave or flat. Stam. eighteen or twenty. Seeds collected into an ovate or cylindrical spike, always smooth, each beaked with a straight conical style. Roots pale, annual, tapering, but little divided. All these annual ones are so nearly akin, that they have been taken by several

ADONIS.

several authors, perhaps not improperly, for varieties of one species. The following synonyms therefore are equally applicable to all of them.

Adonis. Matth. Valgr. v. 2. 257.

Flos Adonis, alius Eranthemum. Bauh. Hist. v. 3. p. 1. 125, 126.

Adonis radice anna. Linn. Hort. Cliff. 231, not 321. Sauv. Monip. 253.

A. annua. Lamarck Dict. v. 1. 45. Brot. Lufit. v. 2. 376.

A. n. 1158. Hall. Hist. v. 2. 66.

The following plants may, in M. De Candolle's opinion, be esteemed, with equal propriety, either species or varieties. He therefore proposes them with hesitation, recommending them to the observation of practical botanists. Whatever difficulties may attend some of these, we are persuaded that they cannot all be united, even though the *autumnalis* and *æstivalis* should prove the only two that are permanently distinct, and the foundations of all the rest.

1. *A. autumnalis.* Coru Adonis, or Pheasant's-eye. Linn. Sp. Pl. 771. De Cand. n. 1. Willd. n. 2. Sm. Prodr. Fl. Græc. Sibth. n. 1263. Fl. Brit. n. 1. Engl. Bot. t. 308. Curt. Lond. fasc. 2. t. 37. (Flos Adonis; Cluf. Hist. v. 1. 336. Raii Syn. 251. Park. Parad. 293. f. 5. Ger. Em. 387. Lob. Ic. 283. Adonis; Camer. Epit. 647. A. hortenifis, flore minore atrorubente; Morif. sect. 6. t. 8. f. 1. Eranthemum flore rubro; Bess. Eyst. æstiv. ord. 5. t. 11. f. 2.)—Calyx smooth. Petals concave, converging, scarcely larger than the calyx. Seeds somewhat reticulated, collected into an ovate head. Stem branched.—Native of corn-fields in various parts of Europe, from Germany to Greece, flowering through the summer to the end of autumn; not frequent in England, except in gardens, where it is often cultivated amongst other hardy annuals, and as De Candolle observes, preserves itself unaltered from seed. The root is somewhat spindle-shaped. Stem branched, bushy, round, striated, occasionally downy. Leaves alternate, dark green, thrice compound, with innumerable, crowded, rather short segments. Calyx pale green; sometimes purplish. Corolla of that peculiar intense crimson, or blood-colour, which gave occasion to the name of Pheasant's-eye, and probably to the original application of the fable to this very plant, whose beauty well merits the compliment. Each petal has a violet-coloured base. Petals inversely heart-shaped, usually about eight. Fruit ovate-oblong, measuring hardly an inch. Calyx-leaves gibbous below their insertion. M. De Candolle remarks, that there is occasionally, though rarely, a paler variety. This seems, by Dr. Withering's specimens, to be what he found on Salisbury plain, and took for *æstivalis*. Its petals are rounded, and do not extend beyond the calyx.

2. *A. flava.* Yellow Field Adonis. Villars Cat. Strafb. 247. De Cand. n. 2. (A. flore pallido; Camer. Epit. 648. "A. sylvestris, flore citrino; Tabern. Ic. t. 790." A. sylvestris, flore luteo, foliis longioribus; Mill. Ic. t. 14. f. 2? De Cand.)—Calyx smooth, with short spurs. Petals flat, oblong, twice the length of the calyx. Seeds rarely smooth, collected into an oblong head. Stem scarcely branched.—Common in corn-fields and vineyards in every part of France, and apparently in Germany also, flowering in June and July. The stem is almost always quite simple. Flowers yellow, or lemon-coloured, rarely pale orange. Calyx-leaves elongated and unattached at the base, almost as in *Sedum* and *Myosurus*. Petals flat, nearly linear. The flowers generally almost rival the size of *A. vernalis*, but there is a variety only half as large; they run into each other. De Candolle.

3. *A. micrantha.* Small-flowered Adonis. De Cand,

n. 3.—Calyx smooth; not spurred at the base. Petals flat, oblong, rather longer than the calyx. Seeds somewhat reticulated, collected into an ovate head. Stem somewhat branched.—Found in the south of France, in fields about Toulouse, Avignon, &c., flowering in May and June. A doubtful species. Flower small, yellow, or flame-coloured. Germs few, from seven to ten, composing a very short head. Stem simple at the base, but often a little branched at the summit. De Candolle.

4. *A. microcarpa.* Small-fruited Adonis. De Cand. n. 4. (A. annua, flore minimo, spicâ tenui longissimâ; Morif. sect. 6. t. 9. f. 4.)—Calyx smooth. Petals flat, oblong, twice the length of the calyx. Seeds reticulated, collected into an oblong head. Stem nearly simple.—Native of corn-fields in Spain, near Tudela; Dufour: in the life of Ivica; Delarocbe: in Teneriffe; Broussonet. Perhaps not distinct from *flava*, n. 2. It appears to differ in the stem not being half so tall, with more crowded foliage. The calyx is scarcely, or not at all, spurred at the base. Seeds about half the size of *flava*, more numerous, and much more reticulated, in a head eight or nine lines long. The corolla is either a lemon-yellow, or somewhat flame-coloured. De Candolle. We take the liberty of introducing Morifon's synonym, which seems to answer best to this species, though applied by De Candolle to the seventh.

5. *A. citrina.* Lemon-coloured Adonis. Hoffm. Germ. v. 1. 251, under n. 1. De Cand. n. 5. (Ranunculus arvensis, foliis chamæmeli, flore minore luteo; Tourn. Inf. 291? De Cand.)—Calyx hairy at the base. Petals flat, oblong, longer than the calyx. Seeds collected into an ovate-oblong head. Stem nearly simple. Flower almost sessile among the leaves.—Native of corn-fields in France, Germany, Teneriffe, &c. A small plant, with an erect, mostly simple, stem, and little yellow solitary flowers. Base of the calyx rough with hairs. Perhaps the synonyms may rather belong to *microcarpa*, or to *micrantha*. De Candolle.

6. *A. flammea.* Flame-coloured Adonis. Jacq. Austr. t. 355. De Cand. n. 6. Willd. n. 3. Ait. n. 3. Hoff. Syn. 308. Hoffm. Germ. v. 1. 251. (Eranthemum flore flammeo; Bess. Eyst. æstiv. ord. 5. t. 11. f. 3?)—Calyx hairy at the base. Petals flat, oblong, somewhat acute, longer than the calyx. Seeds collected into a cylindrical head. Stem branched. Flowers stalked.—Native of corn-fields in Austria, flowering in summer; Jacquin. In Brunswick; Hoffmann. The stem is two feet or more in height, branched from the bottom all the way up, furrowed, smooth or hairy. Footstalks hairy. Leaves light-green, with lanceolate segments. Flowers large, on long stalks. Calyx acute, jagged, reddish. Petals eight or nine lines in length, somewhat obovate, but more or less acute, and frequently toothed; their colour orange-scarlet.

7. *A. æstivalis.* Tall Scarlet Adonis. Linn. Sp. Pl. 771. De Cand. n. 7. Sm. Fl. Brit. 587, note. Tour on the Continent ed. 2. v. 3. 16. Prodr. Fl. Græc. Sibth. n. 1262. (A. miniata; Jacq. Austr. t. 354. Hoffm. Germ. v. 1. 251. A. annua, flore majore phœniceo; Morif. sect. 6. t. 9. f. 3. A. sylvestris, flore phœniceo; Bauh. Pin. 178. Anemone tenuifolia; Cord. Annot. 151, good.)—Calyx hairy at the base. Petals flat, oblong, obtuse, twice the length of the calyx. Seeds reticulated, collected into a long cylindrical spike. Stem slightly branched. Abundant in corn-fields of the south of Europe, France, Italy, &c.; frequent in Greece, according to Dr. Sibthorp, who from that circumstance, and its coincidence with a figure in the famous old manuscript copy of Dioscorides, at Vienna, was led to consider this species as the *αγγιμαρον* of that ancient botanist.

This

This *Adonis* is one of the tallest, with a copiously-branched, furrowed stem; light-green leaves; and long-stalked flowers, which we cannot, with De Candolle, term small ones, being, as far as we have seen, of the full size of any annual species of its genus. The petals are usually numerous, of a moist vivid scarlet. Fruit long, but not interrupted, except by accident. We cannot but consider our friend M. De Candolle as having cited Morison, on the present occasion, with less accuracy than usual, and we have made an alteration herein; see species 4th.

8. *A. dentata*. Toothed-seeded *Adonis*. "Delile Egypt. 17. Defscr. t. 53. f. 1." De Cand. n. 8.—"Calyx hairy at the base. Petals flat, oval-oblong, rather longer than the calyx. Seeds reticulated; tuberculated and toothed at the base; disposed in a long uninterrupted spike."—Native of corn-fields and barren ground, in Egypt and Cyprus; as well as in Provence, between Digne and Colmars. The stem is angular and striated, firm, branched. Flowers on short stalks. In the Egyptian specimens, the petals are oval, yellow, with blackish claws; seeds furnished at the base with tooth-like prickles, finely corrugated, less crested at the back, and disposed in a slender spike. In the Provence variety, the petals are oblong, and flame-coloured; seeds less toothed or tuberculated at the base, more crowded, lying over each other with their crests, so as to form a continued spike an inch long. De Candolle.

SECT. 2. *Configio*. Matthioli, De Candolle.

Petals from eight to fifteen, always oblong, flat. Stamens from 25 to 30. Seeds, collected into an ovate head, each ovate, beaked with its hooked recurved style. Roots perennial, thick at the crown, blackish, with clustered fibres.

9. *A. vernalis*. Spring *Adonis*. Linn. Sp. Pl. 771. De Cand. n. 9. Willd. n. 4. Ait. n. 4. Curt. Mag. t. 134. Lamarck f. 3. (*A. apennina*; Jac. Austr. t. 44. *Elleborus niger* verus; Trag. Hist. 406, not 206. *Helleborium*; Cord. Annot. 93. *Helleborus niger* ferulaceus; Lob. Ic. 784. Park Parad. 291. f. 6. Ger. Em. 746.)

β. Mentzelii; De Cand. excluding the syn. of Linnæus. (*Helleborus niger* ferulaceus, caule geniculato, flore magno, tulipæ minoris intar; Mentz. Pugill. t. 3; copied in Morif. fœct. 6. t. 9. f. 2.)

γ. *Sibirica*, *Patrinii*; De Cand. (*A.* n. 43; Gmel. Sib. v. 4. 200.)

Root somewhat tuberous. Stem branched from the bottom. Petals ten, fifteen, or more, elliptic-lanceolate. Calyx downy. Seeds hairy.—Native of mountainous or alpine situations, or open hills, in the isle of Oeland, Germany, the fourth of France, Switzerland, and Italy. Frequent with us in gardens, flowering in the early spring. The tuberous crown of the black perennial root, lends down many long, simple, rather stout fibres. The stems are herbaceous, a foot high, striated, leafy, more or less branched from the lower part, in an alternate order, rarely besprinkled with a few loose scattered hairs. Leaves crowded, sessile, alternate, smooth, in many three-cleft, linear, acute, entire segments; channelled above. Flowers terminal, solitary, nearly sessile, large and handsome, an inch and a half or two inches broad, of a bright shining yellow. Calyx-leaves concave, ovate, downy, striated. Petals twice as long, sometimes above an inch, usually ten or twelve, but sometimes, even in a wild state, above twenty; purplish beneath; varying in breadth, but always somewhat elliptical, either obtuse or acute, a little erenate. Stamens numerous, capillary, short, with vertical quadrangular anthers. Germens numerous, ovate, compressed, more or less covered with short soft hairs, and hooked with the recurved styles, collected into a globular head, the

stalk much elongated as the fruit ripens. We readily follow De Candolle in thinking the plant of Mentzelius, (see β.) a very inconsiderable variety, differing only in having short and simple stems, with larger flowers: but Linnæus has surely committed a great error in referring this plant to his *apennina*. The γ of De Candolle is said to have likewise a large flower.

10. *A. apennina*. Apennine *Adonis*. Linn. Sp. Pl. ed. 1. 548, excluding Mentzelius's synonym, ed. 2. 772. Willd. n. 5.—Root somewhat tuberous. Stem branched at the top. Petals fifteen, obovate. Calyx smooth. Seeds fringed.—Native of Siberia and the Apennines, according to Linnæus, who cultivated this plant at Upsal, as appears by the original specimen in his herbarium. He always considered this species as very near the last, and has been unusually precise in marking their differences. The stem of the present is fifteen or eighteen inches high, with several branches about the upper part, not from the lower. Segments of the leaves more numerous, lanceolate, and shining. Calyx yellowish, smooth, flat, without veins. Petals obovate, imbricated, generally more numerous. Stamens much reflexed. The germens seem to be fringed only, not all over downy. Linnæus concludes by observing that the former is entirely a vernal plant, as we find it; but the present lasts far into the summer. Nevertheless our intelligent friend M. De Candolle, who never saw this species but in the Linnæan collection, was induced, probably by the synonymy of Mentzelius, which cannot be the same, to reduce it to *vernalis*. We find more difficulty in understanding the two following.

11. *A. wolgensis*. Wolga *Adonis*. De Cand. n. 9. *addend. 545. ("A. apennina; Pallas Nov. Act. Petrop. v. 10." Steven, who sent specimens to De Candolle.)—"Radical and lower stem-leaves reduced to slightly sheathing scales; middle and uppermost leaves sessile. Seeds somewhat downy. Calyx externally hairy. Petals ten or twelve, oblong."—Gathered by Mr. Steven, near the banks of the Wolga. Perennial. Intermediate between *vernalis* and *pyrenaica*, differing from the former in having a branched stem, more distant leaves, often wanting on the lower part of the branches, and much less downy seeds. From the latter it is distinguished by having its lower leaves abortive, like scales, and the seeds, at least while young, somewhat downy. From both it differs in the calyx being externally downy or finely hairy, not smooth. Mr. Steven met with *A. vernalis* likewise in Tauris. De Candolle. These remarks of our learned friend cause us no small perplexity. All our specimens of *A. vernalis*, from Switzerland and the fourth of France, as well as the authentic Linnæan specimen, and one from professor Jacquin, have a downy calyx, and most of them branched stems. The half-ripe seeds in Jacquin's plant are sparingly downy all over; the germens of those from Switzerland scarcely downy at all.

12. *A. pyrenaica*. Pyrenean *Adonis*. De Cand. n. 10. "Fl. Franc. v. 5. 635." (*A. apennina*; Gouan Illustr. 33.)—"Radical leaves on long stalks, ternate; leaflets in many deep segments: upper leaves sessile. Fruit smooth. Petals eight or ten, oblong-wedge-shaped, undivided."—Found by Gouan in the valley of Eynes, in the eastern Pyrenees, flowering in July. The other places of growth, mentioned by De Candolle, are all best omitted. He directs us in his *Addenda* to strike out the reference to Pallas, as belonging to *A. wolgensis*; and perhaps also that of Fischer, *A. charophylla*. To the latter alteration we heartily assent. Dr. Fischer's own specimen, seen in our hands by De

Candolle, has nothing but scales in the place of radical leaves, and certainly agrees in every respect with Jacquin's specimen of *vernalis* above-mentioned. The calyx is in the same manner hairy at the base only, a circumstance, indeed, on which, the more we enquire into it, the less we find reason to rely. Our specimen will not admit of an examination of the *germens*. M. De Candolle speaks of his *pyrenaica*, (a species entirely unknown to us,) as "akin to *vernalis*, but most certainly distinct. The stem is often above a foot high, and branched. Radical leaves on long three-cleft footstalks. Flower nearly sessile, at its first expansion among the uppermost leaves. Head of seeds raised on a greatly elongated stalk. Petals eight to ten, smaller and more obtuse than in *A. vernalis*. Fruit, even before it is ripe, smooth."

We do not presume to form any decisive opinion concerning the perennial species of *Adonis*, without the examination of sufficiently perfect specimens, in every state of growth; but it appears to us that they are by no means well determined at present, nor do we perceive that any characters hitherto suggested are sufficient for the purpose. The *vernalis* and *pyrenaica* are probably very distinct, for which we have the weighty opinion of De Candolle; but whether the latter may not be found in many other countries, and confounded by the generality of botanists with *vernalis*, is a point we cannot satisfactorily determine.

ADPRESSA FOLIA, Close-pressed Leaves, are such as have the upper surface closely applied to the stem, or branch, on which they grow. This is so complete in some plants, such as *Passerina bifluta*, that only the under surface of each leaf being exposed to the air and light, the latter part appears to perform the functions proper to the upper surface of most leaves, and, in the instance just mentioned, assumes the deep green hue, and polished cuticle, usual on the upper side of leaves in general. Such is likewise the case with *Xeranthemum prostratum* and *scamoides* of Linnæus, now referred to **ELICHRYSUM**. See **LEAF**.

ADRASTÆA, so named by professor De Candolle, from *Adrastæa* or *Adrastia*, a surname of the goddess Nemesis, who was a daughter of Oceanus; because the plant in question is a native of New Holland, which has been called by some persons *Oceania*.—De Cand. Syst. v. 1. 424.—Class and order, *Decandria Digynia*. Nat. Ord. *Magnolæ*, Juss. *Dilleniaceæ*, De Cand.

Eff. Ch. Calyx inferior, of five permanent pointed leaves. Petals five, oval, shorter than the calyx. Filaments flat. Anthers linear, of two cells bursting lengthwise. Germens two, globose. Styles straight, close together, awl-shaped; conical at the base. Capsules membranous, of one cell. Seeds solitary?

1. *A. falsifolia*. Willow-leaved *Adrastæa*.—Native of bogs in New South Wales. Described by De Candolle from a dried specimen in Mr. Lambert's collection. This is a small shrub, approaching **HIBBERTIA**, (see that article,) in general appearance. The branches are round, long and slender, reddish-brown; downy when very young, but casting their cuticle in long portions when old. Leaves linear, entire, except three or five callous teeth at the extremity, the point being callous; their base somewhat contracted; their upper surface smooth, without veins; the under hoary with short silky hairs; their length is an inch and a half; breadth three lines; and they resemble the leaves of *Salix alba*, or of the Olive. Flowers at the ends of the young branches, solitary or in pairs, sessile between three or four crowded leaves, which exceed them in length. Calyx-leaves keeled, covered with close silky hairs; their margin mem-

branous; their point tipped with a bristle. Stamens ten, half the length of the calyx. Germens smooth.

ADRIANOPE, col. 2, l. 3, r. 1453.

ADVICE, in *Commerce*, denotes the information given by letter of a bill drawn by one merchant upon another.

ADVOCATE, l. 24, r. passed A.U. 549. Col. 2, l. 8, r. revived.

ÆCIDIDIUM, in *Botany, from *αἰμα*, a wound or injury, because the parts of a plant to which this genus of parasitical fungi attaches itself, always, in consequence, become diseased, discoloured, and either tumid, or, as it were, blasted.—Perf. Obs. Mycol. fasc. 1. 97. Syn. Fung. 204.*

—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*. Eff. Ch. Head conspicuous, sessile, round, membranous, at length bursting, with a toothed orifice. Seeds mealy, naked.

This genus is always parasitical on the backs of the leaves, or on the stem, of certain plants. In addition to what is said of it already, we shall subjoin illustrations of a few species. Perfoun defines them, in two sections.

SECT. 1. *Aggregate*. Heads assembled in patches, forming blotches on various leaves. Fourteen species.

Ae. cornutum. Horned *Æcidium*. Perf. n. 1. Obs. Mycol. fasc. 2. 22. t. 4. f. 2, 3. Sowerb. Fung. t. 319. (Lycoperdon corniferum; Fl. Dan. t. 838. L. corniculatum; Ehrh. Crypt. 200.)—Base yellowish. Heads nearly cylindrical, very long, curved, greyish-olive.—Found in autumn, on the leaves of the Mountain Ash. On the upper side of the leaf is seen an orange-coloured spot; on the under a swelling, out of which proceed six or seven bristle-like beards, a line and a half in length; each rather tumid at the base; contracted at the point, where it bursts irregularly.

Ae. cancellatum. Reticulated *Æcidium*. Perf. n. 2. Sowerb. Fung. t. 410. (Lycoperdon cancellatum; Jacq. Anstr. v. 1. 13. t. 17. Fl. Dan. t. 704.)—Base tawny. Heads oblong, splitting into fibrous masses, cohering at the summit.—Not rare on the leaves of garden pear-trees. We first saw it on a baking pear at Sir A. Hume's, Wormleybury, many years ago, where it still frequently occurs, without injury to the tree or fruit. The heads are much thicker and shorter than the foregoing, and when ripe, discharge their powdery seeds between the tough, brownish, permanent fibres of the head, which last as long as the leaf, and actually seem an extension of its woody fibres. We cannot but conceive Mr. Sowerby's t. 409 to be a different plant, belonging to the genus **SPHERIA** (see that article); or rather perhaps **NEMASPORA**, to be hereafter described.

Ae. oxycantha. White-thorn *Æcidium*. Perf. n. 3. (Ae. laceratum; Sowerb. Fung. t. 318. Lycoperdon penicillatum; Fl. Dan. t. 839?)—Base unequal, rusty. Heads ash-coloured, cylindrical, splitting nearly from top to bottom, into numerous, fibrous, spreading segments.—Found on the leaves, or young buds, of Common Hawthorn. Perfoun describes his specimens as divided to the very base, and therefore presumes the plant of Fl. Dan., which appears not split half way down, may be another species; but Mr. Sowerby's seems intermediate between both, and we can scarcely doubt his being the same as Perfoun's.

Ae. sufflaginis. Colt's-foot *Æcidium*. Perf. n. 10. Relh. 546. Sowerb. Fung. t. 397. f. 1. (Lycoperdon ephippium; Linn. Sp. Pl. 1655. Fl. Suec. ed. 2. 459. With. v. 4. 383.)—Base tawny-purple. Heads sunk, level-topped, with a many-cleft, reflexed border.—On the under side of the leaves of Colt's-foot and Butterbur, extremely common, in the form of broad orange-coloured spots, besprinkled

sprinkled with the little starry whitish orifices of the heads, full of orange powder. *Lycoperdon epiphyllum* of Hudson and Lightfoot are different from this, and perhaps from each other. *Uredo tussilaginis* resembles our plant in general aspect, but on near examination will be found less distinct, in the form of an orange powder, intermixed with the cotton of the Colt's-foot leaf, without distinct white starry heads.

Ae. berberidis. Barberry Æcidium. Perf. n. 11. Sowerb. Fung. t. 397. f. 5. (*Lycoperdon pucilliforme*; Jacq. Coll. v. 1. 122. t. 4. f. 1.)—Base orbicular, scarcely convex. Heads cylindrical, somewhat elongated, yellow.—Found on leaves of the Barberry, in cold wet autumnal weather, sometimes in the spring, consisting of very conspicuous and prominent tawny spots, the heads projecting much. The orifice of each is neither dilated, nor conspicuously toothed or jagged. The whole turns brown, or black, in decay, and may be observed in that state on the fallen leaves during winter.

Seç. 2. *Simple. Heads scattered, not combined by any distinct crust, or base.* Six species.

Ae. euphorbiæ. Spurge Æcidium. Perf. n. 15. "Humb. Friberg. 128." ("Lycoperdon euphorbiæ; Schrank. Bavar. v. 2. 631." *Efula* degener; Rivin. Tetrap. Irr. t. 113. f. 2.)—Simple, crowded. Heads pale, cylindrical, reflexed at the margin. Powder orange-coloured.—Frequent in summer on the leaves of *Euphorbia Cyparissias*, in Germany, France, and Switzerland, causing the whole plant to assume a diseased appearance, and often to fail of producing flowers. We scarcely think Rivinus, as Persoon hints, meant to consider this diseased *Euphorbia* as a distinct species.

Ae. tragopogi. Goat's-beard Æcidium. Perf. n. 15. b. Sowerb. Fung. t. 397. f. 2.—Scattered. Heads somewhat elliptical, with an irregularly torn white margin. Powder yellow.—On the stem and leaves of *Tragopogon pratensis*. Conspicuous for its short white heads. *Persoon*. That author certainly means to describe this as a distinct species from the last, though by an error, which ought to have been corrected in printing, he has given the same number to both. Hence he has really twenty species in all, though apparently but nineteen.

Ae. anemones. Wood-Anemone Æcidium. Perf. n. 17. Ust. Annal. v. 20. 135. (*Lycoperdon anemones*; Pulten. Tr. of Linn. Soc. v. 2. 311.)—Simple, scattered. Heads cylindrical, rather prominent, pale, mostly toothed, filled entirely with white powder.—Found in the spring on leaves of *Anemone nemorosa*, rendering the plant sickly, and often barren. Dr. Pulteney observed that this fungus originates under the cuticle, and may be seen, in a young state, through that membrane. At length each individual assumes a nearly globular form, bursting with lacerated edges, the cavity being lined with white powdery seeds, intermixed with minute fibres. In fading, each turns yellowish, then brown, and finally "each fungus is resolved into a farinose particle, resembling the fructification of a Polypody." *Pulteney*. The *Æ. fuscum*, Relh. Cant. 546. Sowerb. Fung. t. 53, found on the leaves and petals of the same species of *Anemone*, without injuring the plant, is the *Puccinia anemones*, Perf. Syn. Fung. 226, a genus described as destitute of a head, or peridium. In this respect we find it difficult to draw a line between Mr. Sowerby's figure, and his various representations of *Æcidia*, t. 398, though we doubt not the specific difference of the above two plants. Which of them is the "Conjurer of Chalgrove's Fern," Dill. in Raü Syn. 24. t. 3. f. 1, may be doubted; but we rather suppose the *Puccinia*.

Ae. punctatum. Yellow-Anemone Æcidium. Perf. n. 18. Ust. Annal. v. 20. 135. (*Ae. anemones*; Hoffm. Germ. v. 2. t. 11. f. 1.)—"Simple, scattered. Heads partly sunk, their border nearly closed. Powder compact, brownish."—Found rarely on the leaves of *Anemone ranunculoides*, which it marks with brown dots. The border of the orifice is but slightly, if at all, toothed. *Seeds* chestnut-coloured. *Persoon*. We have not heard of this species in Britain.

Mr. Sowerby has represented several more species of this genus in his *English Fungi*, t. 397, 398, such as *Æ. corni*, *confluens*, *rubi*, *fragariæ*, *menthæ*, *salicis*, *cardui*, *rosæ*; but we do not see clearly how the generic difference between *Æcidium* and *Puccinia* is, in most of them, to be determined.

ÆGÆ, l. 4. r. M. Gebelin.

ÆGERITA, in Botany, so called from *αἰγίζος*, a Poplar, or rather Alder tree, because the first-discovered species of this minute genus grows on the wood of the Alder, and was thence called *Sclerotium Aegerita*, which last word, on the establishment of the present genus, was taken for its generic name.—Perf. Syn. Fung. 684.—Class and order, *Cryptogamia Fungi*. Nat. Ord. Fungi.

Eff. Ch. Sessile granulations solid, filled with a somewhat mealy powder.

1. *Ae. candida*. White Aegerita. Perf. Disp. Fung. 40. (*Sclerotium Aegerita*; Hoffm. Germ. v. 2. t. 9. f. 1.)—Crowded, smooth, pure white.—Found not unfrequently in autumn, on the dry rotten wood of Alder, in moist situations. This fungus consists of numerous little crowded granulations, the size of millet-seed, globular or elliptical, as white as sugar-plums, solid but friable, the internal substance appearing, when highly magnified, full of seed-like bodies. *Hoffmann*.

2. *Ae. pallida*. Pale Aegerita. Perf. *ibid.*—Scattered, pale, somewhat warty.—On the fallen branches of Oaks. Distinguished by the inequality of its surface. *Persoon*.

3. *Ae. ? cæsa*. Grey Doubtful Aegerita. Perf. n. 3.—Scattered, glaucous or whitish.—On the trunks of trees in winter. Resembles small pale dots, of a softish substance; disappearing when dried. *Persoon*.

ÆGIALITIS, *αἰγιαλίτις*, an inhabitant of the coast, alluding to its place of growth.—Brown Prodr. Nov. Holl. v. 1. 426.—Class and order, *Pentandria Pentagynia*. Nat. Ord. *Aggregate*, Linn. *Plumboginetæ*, Juss. *Plumbagineæ*, Brown.

Eff. Ch. Calyx of one leaf, coriaceous, five-toothed, with folded angles. Petals five, their claws combined at the base, bearing the stamens. Stigmas capitate. Pericarp prominent, angular, nearly cylindrical, coriaceous, without valves. Seed germinating, without albumen. Plumula conspicuous.

1. *Ae. annulata*. Gathered by Mr. Brown, in the tropical part of New Holland, growing among *Rhizophoræ*, near the sea-shore. A perfectly smooth *shrub*, of humble growth, having round, brittle branches, marked with annular scars, where the leaves have been. *Leaves* alternate, without stipulas, flat, coriaceous, ovate, entire; and their footstalks bordered, dilated and sheathing at the base. *Spikes* panicled. *Flowers* white, alternate, somewhat imbricated, with three bracteas. *Brown*.

Akin to STATICE. See that article, and TAXAN-
THEMA.

ÆGICERAS, so called from *αἴξ*, a goat, and *κερας*, a horn, in allusion to the horn-like shape of the curved seed-vessel, the following is to be substituted in the place of our original article.—Gært. v. 1. 216. t. 46. Schreb. Gen. 156. Willd. Sp. Pl. v. 1. 1183. Mart. Mill. Dict. v. 1.

König Ann. of Bot. v. 1. 132. t. 3. Brown Prodr. Nov. Holl. v. 1. 534.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Myrsinæ*, Brown.

Gen. Ch. reformed. *Cal.* Perianth inferior, of five roundish-oblong, concave, coriaceous, permanent leaves, thickest at the base, obliquely imbricated at the margin. *Cor.* of one petal, falver-shaped, somewhat coriaceous; tube the length of the calyx, nearly cylindrical, thickish, rounded at the base; limb the length of the tube, in five deep, ovate, pointed, equal, reflexed segments. *Stam.* Filaments five, prominent, awl-shaped, twice the length of the tube, united at the bottom into a ring, attached to the base of the corolla; anthers arrow-shaped, incumbent, versatile, of two lobes and two cells, bursting longitudinally. *Pist.* Germen superior, linear-oblong, compressed, dotted, with rudiments of several seeds; style erect, the length of the stamens, tapering, permanent; stigma simple. *Peric.* Follicle cylindrical, coriaceous, curved, pointed, of one cell. *Seed* solitary, oblong, nearly filling the pericarp, and germinating there, attached by a thin flat umbilical cord, of its own length, which is dilated into a hood-like, pointed, partial tunic, closely covering the minute cotyledons, and part of the radicle; albumen none; embryo erect; radicle very large.

Eff. Ch. Calyx in five deep imbricated segments. Corolla falver-shaped, five-cleft, reflexed. Filaments joined at the base. Stigma simple. Follicle coriaceous, cylindrical. Seed solitary, with a hooded tunic.

1. *Ae. fragrans*. Fragrant *Aegiceræ*. König as above. Br. n. 1. (*Ae. majus*; Gært. n. as above. Willd. n. 1. *Rhizophora corniculata*; Linn. Sp. Pl. 635. Burm. Ind. 108. Pou-Kandel; Rheed. Hort. Malab. v. 6. 65. t. 36. *Mangium fruticosum corniculatum*; Rumph. Amboin. v. 3. 117. t. 77).—Native of the maritime woods and thickets of the East Indies, as well as of the tropical and eastern coasts of New Holland. The stems are rather shrubby than arborescent, several from the same root, ten to fourteen feet high, three or four inches in diameter, with numerous slender spreading branches. Leaves alternate, or imperfectly opposite, stalked, obovate, or somewhat elliptical, emarginate, entire, coriaceous, smooth, single-ribbed, from one to four inches long. They are reported to have a briny taste; and Mr. Browne noticed a saline efflorescence, or excretion, on their upper surface. Flowers white, fragrant, about half an inch broad before their corolla is reflexed, collected into umbels at the ends of the short lateral, as well as principal, branches. Seed-vessel near an inch and a half long, pointed, curved, but not spiral, as the generic name would seem to imply.

This shrub, which Linnæus confounded with his *Rhizophora*, is the only known species of a very distinct genus; the *A. minus*, Gært. t. 46. having been shewn by Mr. König to be *Connarus santaloides* of Vahl, Symb. v. 3. 87. *Santaloides*, Linn. Zeyl. 192. n. 408, a totally different plant in genus and natural order, though Gærtner has quoted for a synonym, *Umbraculum maris*, Rumph. Amboin. v. 3. 124. t. 82. This last, as well as *Mangium floridum* of the same writer, v. 3. 125. t. 83, appear very nearly related to our *Aegiceræ fragrans*; inasmuch that, without specimens, no one can safely distinguish them from it, or from each other, for the difference of size in their respective flowers is of no avail in Rumphius's, always variously diminished, plates.

ÆGINETIA, a restored genus, first founded by Linnæus, subsequently reduced by himself to **OROBANCHE**, and originally named in honour of **PAUL ÆGINETA**. (See

those articles).—Linn. Gen. ed. 5. 280. Dryandr. in Roxb. Coromand. v. 1. 63. Willd. Sp. Pl. v. 3. 346.—Clafs and order, *Didynamia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Pedicularæ*, Juss.

Gen. Ch. *Cal.* Perianth sheath-like, inferior, of one leaf, ovate, concave, inflated, coloured, permanent. *Cor.* of one petal, tubular, longer than the calyx; tube globular at the base, bent horizontally towards the middle, swelling upwards; limb spreading, in five short, rounded, equal segments. *Stam.* Filaments four, incurved, two shorter than the rest; anthers oblong, simple, converging in pairs, slightly bent. *Pist.* Germen superior, ovate; style simple, curved, the length and position of the stamens; stigma capitate, large. *Peric.* Capsule ovate, pointed, of two valves? with many cells. *Seeds* numerous, minute. *Receptacles* several, convoluted, attached to the valves.

Eff. Ch. Calyx of one leaf, opening lengthwise. Corolla with five equal segments. Capsule of many cells. *Seeds* numerous.

1. *Ae. indica*. Indian *Aeginetia*. Linn. Sp. Pl. v. 1. 632. Roxb. Coromand. v. 1. 63. t. 91. Willd. n. 1. (*Orobanche Aeginetia*; Linn. Sp. Pl. ed. 2. 883. "Thiém-cumulu; Rheed. Hort. Malab. v. 11. 97. t. 47.")—Native of Malabar, in the hilly parts of the Circars, but rare. *Roxburgh*. Root of many simple fibres, probably parasitical and annual. Stems several, purplish, a span high, simple, single-flowered, and naked, except a lanceolate, brown, sheathing scale at the bottom of each. Calyx rusty-coloured, an inch long, turning green as it fades. Corolla half as long again as the calyx, and more slender, of a violet purple; the tube pale; deciduous. Style permanent as the fruit ripens, curved, projecting laterally out of the calyx. *Seeds* and *receptacles* tawny.

The generic distinctions between this plant and *Orobanche* are obvious enough; the single-leaved spathaceous calyx, regular corolla, undivided stigma, and many-celled capsule, whose internal structure Dr. Roxburgh says he could never well determine, but the numerous convoluted partitions, or receptacles, which he describes, are sufficiently different from *Orobanche*. As to habit, these genera nearly agree, both having a rusty pubescence, a purple hue, and, if we mistake not, parasitical roots; though the inflorescence, and the form of the calyx, differ in each. *Aeginetia* appears to want the nectariferous gland, found at the base of the germen, in front, in *Orobanche*; it wants also the bracteas, observable in every species of the last-named genus, except the *uniflora*.

ÆGISSUS. See **ÆGYPTUS**.

ÆGLE, in Botany, the name of one of the **HESPERIDES**, (see that article,) chosen by Mr. Correa de Serra for this genus, as Linnæus had already dedicated one to her sister *Arebusa*.—Correa Tr. of Linn. Soc. v. 5. 222. Ait. Hort. Kew. v. 3. 284.—Clafs and order, *Polyandria Monogynia*. Nat. Ord. *Aurantia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, with five shallow lobes, at length deciduous. *Cor.* Petals five, ovate, acute, spreading, many times longer than the calyx. *Stam.* Filaments numerous, short, awl-shaped, inserted into the external part of the elevated receptacle of the flower; anthers oblong, erect, heart-shaped at the base. *Pist.* Germen superior, ovate; style short, thick; stigma oval, obscurely furrowed. *Peric.* Berry coated, globular, smooth, almost woody when ripe, not burbling, of ten or twelve cells obliterated as the pulp arrives at maturity. *Seeds* ovate, compressed, numerous in each cell, in a simple row, each inserted by a short partial stalk into the central column; albumen none.

Eff.

Eff. Ch. Petals five. Calyx five-cleft, inferior. Berry coated, of numerous cells. Seeds many.

1. *Ae. Marmelos*. Thorny Aegle, or Bengal Quince. Correa as above, 223. Willd. n. 1. Roxb. Coromand. v. 2. 23. t. 143. (*Crataeva Marmelos*; Linn. Sp. Pl. 637. Willd. Sp. Pl. v. 2. 853. *Cydonia exotica*; Baub. Pin. 435. *Cucurbitifera trifolia* indica, fructus pulpâ Cydonii amula; Raii Hist. v. 2. 1665. Pluk. Phyt. t. 170. f. 5. Bâlacus; Rumph. Amboin. v. 1. 197. t. 81. Covalam; Rheede Hort. Mal. v. 1. 37. t. 37. *Mareduo* of the Telingas.)—Native of the mountainous parts of the coast of Malabar, sometimes of the low lands, flowering during the hot season. This is a rather large tree, whose trunk is nearly erect, clothed with ash-coloured bark. Branches scattered. Spines stipular, in pairs, awl-shaped, pungent, strong, an inch in length, sometimes wanting. Leaves irregularly scattered, on downy stalks, ternate; leaflets elliptic-oblong, with a blunt point, serrated, single-ribbed, veiny, smooth; tapering at the base; unequal in size; the odd one largest, about three inches long. Flowers of a dirty white, in short, aggregate, terminal and axillary, clusters. Fruit the size of a large orange, with a hard smooth greyish shell, from which the Dutch in Ceylon are said to prepare a perfume. Dr. Roxburgh speaks of this fruit as delicious to the taste, and exquisitely fragrant, of a laxative quality, which renders it particularly serviceable in habitual costiveness. A clear tenacious gum, enveloping the seeds, makes a good cement. The wood of the tree is hard and durable, of a light chocolate colour, variegated with dark veins, and serves for many purposes. Mr. Correa mentions another, likewise arboreous, species of *Aegle*, found in the East Indies, and preserved in Sir J. Banks's herbarium, but of this he has unfortunately neglected to give either a name or description, nor have we seen any specimens. See FERONIA for a genus next akin to the above.

AEGOPOGON, already mentioned and explained, in its proper place, as a synonym of the *Spiraea Utmaria*, or rather perhaps *S. Aruncus*, is now adopted for the generic appellation of a South American genus of grasses, by Willdenow, after Humboldt and Bonpland.—Willd. Sp. Pl. v. 4. 899. Palifot de Beauvois Agrost. 122. t. 22. f. 3, 4. Kunth Nov. Gen. et Sp. v. 1. 132.—Class and order, *Polygamia Monœcia*. (Rather *Triandria Digynia*.) Nat. Ord. *Gramina*.

Eff. Ch. Calyx of two valves, single-flowered; the valves cloven; with an intermediate awn. Corolla of two valves; the outer with three awns; inner with two. Seed solitary, unconnected with the glumes. One or two lateral male flowers.

1. *Ae. cenchrades*. Spreading Aegopogon. Willd. n. 1. Palif. de Beauv. as above, f. 3. Kunth n. 1. t. 42.—Cluster lax. Flowers all equally stalked.—Gathered by Humboldt and Bonpland, on the exposed summit of mount Avila, near the town of Caracas; also in Quito; flowering from January to April. Root perennial. Stems numerous, branched at the base, forming a tuft; those which do not flower, about as long as the finger; the rest a span in height, naked above, densely leafy below. Leaves linear; the lowermost an inch, or an inch and a half long; the upper ones shorter. Sheaths striated, smooth, slightly membranous at the edges. Stipula divided. Cluster simple, rather turned to one side, but spreading loosely. This grass has the aspect of *Cenchrus citraris*, or of *Lappago racemosa*. Willdenow. We know it only from this author's description, and the figures cited. From M. de Beauvois our knowledge of the following species is entirely derived.

2. *Ae. rufifolius*. Small Aegopogon. Palif. de Beauv. as above, f. 4.—Cluster dense, turned one way. Perfect flower sessile.—Native country not recorded. The perfect flowers of this species, whose cluster is represented about half the size of the foregoing, are sessile, their calyx apparently of two equal, awl-shaped, undivided glumes. The two lateral, or male, flowers are elevated on equal, slender, parallel stalks, twice their own length, though but half as long as the intermediate perfect flower. The inner valve of their calyx seems entire, though awned. Their corolla consists of two entire, not cloven, valves, one of which only is awned. We do not pretend, without the investigation of specimens, to reconcile these contradictions of the generic character, nor to judge how far M. de Beauvois is right in uniting with this genus Mr. Brown's **AMPHIPOGON**, hereafter to be noticed in its proper place.

3. *Ae. geminiflorus*. Twin-flowered Aegopogon. Kunth as above n. 2. t. 43.—Male flower solitary.—Gathered by Humboldt and Bonpland, on the banks of the river Orinoco, between Cerro Duida and Rio Tamatama, near Esmeraldam, flowering in May. Habit much like the first species, but the spikelets are considerably smaller, while the central awn of one valve of the perfect flower is remarkably long, stout, and rough. Each flower is supported by a short partial stalk, and there are only two to each spikelet, not three as in the two foregoing species.

ÆOLUS, in *Mechanics*, subjoin, see **VENTILATOR**.

ÆON, l. 4, add.—Homer *Il.* v. 453. Pindar *Olym. A.* v. 18. Hence by an easy figure it is used to denote the customs and manners of life. *Esper.* ii. 2.

AERIDES, in *Botany*, from *anæ*, air, air; because one of the principal plants of this genus has long been celebrated, under the name of *Flos aëris*, for living entirely, as was supposed, upon air. This plant, and several others agreeing with it in habit, though not all perhaps in generic character, have been sent from the East Indies to Europe, in baskets, without earth or any other apparent source of nutriment, and have not only survived, but blossomed during their voyage, as well as after their arrival. Their stout fibrous roots, always more than half naked as they run over the branches of trees, having entwined themselves among the sticks of the basket, might perhaps imbibe sustenance from the air in those circumstances, as readily as in their natural situation; just as a pea will germinate and grow in moist cotton.—Loureir. *Cochinch.* 525. Swartz in *Schrâd. Journ.* v. 2. 233. t. 2. f. 4. Eujud. *Neues Journ.* v. 1. 88. *Kon. Tracts* 195. t. 8. f. Y. Willd. *Sp. Pl.* v. 4. 130. *Ait. Hort. Kew.* v. 5. 213.—Class and order, *Gynandria Monogynia*. Nat. Ord. *Orchidææ*.

Gen. Ch. reformed. Cal. Perianth of three equal, spreading, coloured leaves, gradually dilated upwards, somewhat wavy, rather obtuse. Cor. Petals two, much like the calyx-leaves in colour, size, and figure. Nectary a lip without a spur, shorter than the petals, inserted into the base of the style, gibbous underneath like a bag, often reversed over the column. Stam. Anther a vertical, hemispherical, moveable, deciduous lid, of two or four cells; masses of pollen globular, stalked, in pairs. Pist. Germen inferior, oblong; style erect, semi-cylindrical, concave in front; stigma in front, near the anther. Peric. Capsule obovate-oblong, with three large and three intermediate angles, of one cell and three valves, separating between the angles. Seeds numerous, minute, each invested with a chaffy tunic.

Eff. Ch. Calyx and corolla spreading, nearly uniform. Lip pouch-like, without a spur. Anther a vertical moveable lid.

AERIDES.

The species of this rare oriental genus are not at all distinctly known. Willdenow enumerates seven, to which we have some additions.

1. *A. retufum*. Blunt-leaved Air-blossom. Swartz n. 1. Willd. n. 1. (*Epidendrum retufum*; Linn. Sp. Pl. 1351. *Limodorum retufum*; Swartz Nov. Act. Upf. v. 6. 80. Anfieli Maravara; Rheed Hort. Malab. v. 12. 1. t. 1. Raii Hist. v. 3. 588. *Orchis abortiva aizoides malabariensis*, flore odoratiffimo variegato, intus aviculum representante; Rudd. Elyf. v. 2. 220. f. 5.)—Leaves nearly radical, linear, with two equal terminal notches. Cluster many-flowered, twice the length of the leaves. Capsules obovate.—Native of trees in the East Indies, flowering at the beginning and end of the rainy season, that is, in April and October, and lasting long. The plant is three feet high, attached to the bark by thick inflexed downy-coated fibrous roots, of a musky smell. Leaves spreading in two ranks, linear, stout, rigid, channelled, smooth, abrupt as if bitten off at the end, which seems characteristic of the genus; in this species the two notches are represented in the figure, which is all our authority, as equal and uniform. The flowers are very numerous, about forty, in several stalked, terminal clusters, all expanded at once, whitish besprinkled with red, blue and dusky spots. The lip is said to be pure white on both sides, with a tongue-like appendage, brilliant with blue and red. Each flower is less than an inch in diameter.

2. *A. pæmorsum*. Jagged-leaved Air-blossom. Willd. n. 2. ("Bitim Maram Maravara; Rheed Hort. Malab. v. 12. 5. t. 2." Raii Hist. v. 3. 589. *Orchis abortiva aizoides malabariensis altera*, flore odorato sanguineo colore, intus aviculum purpureum referente; Rudd. Elyf. v. 2. 221. f. 6.)—Leaves radical, linear, variously and unequally notched at the end. Cluster many-flowered, twice the length of the leaves. Capsules cylindrical.—Found on trees in Malabar. Nearly akin to the preceding, the flowers being in like manner spotted with red and blue, and moreover with yellow and green. The column is purple. Rheed says this species acquires a poisonous property by growing on the *Cansjira*, a shrub or tree akin to *Daphne*; which, if correct, is very remarkable. Perhaps fragments of the bark of that tree, which may well be supposed highly virulent, may have been gathered with the roots of the parasitical plant.

3. *A. ? lasiopetalum*. Woolly-flowered Air-blossom. Willd. n. 3. (*Epidendrum Flos aëris*? Retz. Obf. fasc. 6. 64.)—Stem branched, creeping. Leaves ovate-oblong, each seated on a bulb. Calyx externally woolly, acute as well as the petals.—Found by König, on trees in the East Indies. There is nothing in König's description of the flower to convince us of this being an *Aerides*, while the account of its acute leaves, (not described as jagged or abrupt,) and their bulbous accompaniment, render it probable that Willdenow has here made a mistake. We retain this species and the next, merely as we find them in his work, for future enquiry.

4. *A. ? matuinum*. Morning Air-blossom. Willd. n. 4. (*Epidendrum Flos aëris*, vel Saaronicum; Retz. Obf. fasc. 6. 58.)—This having a spur to the *nectary*, according to König's description, cannot belong to the genus before us. We therefore decline attempting a specific character, or any necessary correction of Willdenow's.

5. *A. odoratum*. Fragrant Air-blossom. Willd. n. 5. Ait. n. 1. (*A. odorata*; Loureir. n. 1.)—Stem ascending. Leaves linear, emarginate, reflexed. Clusters axillary. Lip three-cleft; lateral segments obtuse.—Found on trees in

China and Cochinchina, sometimes pendulous. Root of numerous thick fibres, entangled together. Stem nearly erect, a foot high. Leaves large and thick. Clusters simple, long, drooping. Flowers pale, rather fleshy, sweet-scented. If this species be hung up in a house, it will continue to grow, and to flower for many successful years; which Loureiro says he had long experienced. Sir Joseph Banks is recorded to have introduced this *Aerides* into the stoves at Kew, in 1800, but it has never flowered. The late dukes of Portland received an air-plant, as it was called, from China or the East Indies, about twenty-five years ago, which we rather believe to have been the *Epidendrum tessellatum*, Roxb. Corom. v. 1. 34. t. 42. *Cymbidium* n. 34. Willd. Sp. Pl. v. 4. 102; or at least very near that species. It came in a basket, without earth, in perfect health, and afterwards blossomed in the stove at Bullstrode; whether it received any different treatment there we have no recollection.

6. *A. arachnites*. Great Japanese Air-blossom. Swartz n. 2. Willd. n. 6. (*Epidendrum Flos aëris*; Linn. Sp. Pl. 1348. E. n. 7; Linn. Act. Upf. ann. 1740. 37. *Limodorum Flos aëris*; Swartz Nov. Act. Upf. v. 6. 80. Amogure Katong-ging; Kämpf. Amœn. Exot. 868. t. 869. f. 1.)—Stem ascending. Leaves linear-lanceolate. Calyx-leaves and petals linear, revolute; dilated at the extremity. Lip cleft in front, with an internal cleft appendage.—Native of Japan, growing parasitically on trees, and much admired for the musky scent of its large handsome flowers. The leaves are said to be narrow, thick, and rusty. Flowers from seven to twelve together, in a loose simple cluster. Calyx-leaves and petals all nearly similar, each two inches long, linear; convex above; concave underneath; suddenly dilated at the end into a quadrangular form, all lemon-coloured, beautifully spotted with purple. *Nectary* much shorter than the petals, somewhat stalked, consisting of a hollow abrupt lip, smooth, cleft deeply in front, ending below in a short point, from whose cavity springs an erect, fleshy, divided lobe or appendage. Such is the *nectary* of the plant figured by Dr. Swartz, of which two specimens are preserved in the Linnæan herbarium; but Kämpfer's figure exhibits a very different appearance of the same part, like three hairy leaves surrounding the column, in a manner we have never witnessed in any one of the *Orchideæ*. We suspect two species may be confounded by authors.

7. *A. coriaceum*. Leathery-leaved Air-blossom. Swartz n. 4. tab. 2. f. 4, 5, 6. Willd. n. 7.—"Stem-leaves ovate, pointed, somewhat coriaceous, striated. Spikes panicled."—Found on trees in Madagascar. The flower as represented in Dr. Swartz's figure, which is all we know of this plant, is hardly an inch wide; the lip a deep pouch, bearing in front a small deflexed appendage. Column very short.

8. *A. Borassii*. Fan-palm Air-blossom. Buchanan MSS.—Leaves radical, linear-oblong, obtuse, obliquely emarginate. Cluster leafless, radical. Lip with a revolute undivided border.—Found by Dr. Buchanan growing on *Borassus flabellifer*, in the Myfore. The thick cracked or jointed fibres of the root have each a central tough thread. Stem none. Leaves equitant, about six, a span long and an inch wide; their points rounded, but unequally, one side extending further beyond the notch than the other. Cluster simple, scarcely stalked, twice the length of the foliage, deflexed, many-flowered, lax, with a few sheathing scales at the base. Flowers about an inch and a half in diameter. Calyx-leaves ovate-lanceolate, obtuse, somewhat revolute, near an inch long, pale buff with a purplish central stripe. Petals like them, but flat, and rather broader. *Nectary* half

AERIDES.

as long, red, ringent, its revolute border as long as the pouch.

9. *A. maculatum*. Spotted-stalked Air-blossom. Buch. MSS.—Stem creeping. Leaves elliptic-oblong, equally emarginate. Clusters lateral, stalked, corymbose. Lip the length of the petals; its border pointed, dilated at each side.—Gathered by Dr. Buchanan, on trees in the Myfore country. The stems tend out very long curling fibrous roots. Branches short, leafy. Leaves obtuse, emarginate, hardly two inches long; sheathing at the base. Flower-stalk lateral, opposite to the lowest leaf on the branch, and protruding through its split base, a span long, erect, copiously spotted with dark purple, furnished with a few scattered bractæ, and terminating in a dense corymbose cluster of six or eight yellow unspotted flowers, with a similar bractæ to each partial stalk. Calyx-leaves and petals obovate, about half an inch long, nearly uniform. Lip somewhat boat-shaped, with a deep keel, and prominent ascending point, accompanied at each side by a rounded dilatation of the margin. The back of the flower is tinged with greenish or purplish brown.

10. *A. dasyogon*. Densely-bearded Air-blossom.—Stem ascending. Leaves ovate, with a jagged point. Umbels dense. Border of the lip kidney-shaped, densely bearded.—Found by Dr. Buchanan, in Upper Nepal. Roots composed of long, white, entangled fibres, running over the mossy branches of trees. Stems solitary, short, recurved, leafy. Leaves alternate, sheathing, broadly ovate, about three inches long, fleshy; smooth above; minutely scaly beneath; somewhat revolute; with three crowded, unequal, sharp teeth at the point. Flower-stalks lateral, solitary, half the length of the leaves, each bearing a dense umbel of numerous, nearly sessile, very beautiful and singular, reversed flowers, each hardly an inch in diameter. Calyx-leaves and petals similar, obovate concave; dark red on the upper side; green on the under. Lip keeled, but not very deeply, globose, yellowish, spotted with red; its border as long as the petals, dilated, kidney-shaped, white; dotted on the smooth disk with crimson; fringed and thickly clothed towards each side with short, fibrous processes, resembling velvet. Capsule three inches long.

11. *A. calceolare*. Slipper Air-blossom. Buch. MSS.—Stem creeping. Leaves linear-oblong, falcate, unequally jagged at the point. Umbels spreading. Border of the lip hemispherical, densely bearded.—Gathered by Dr. Buchanan, on the mossy branches of trees, in Upper Nepal. Stem creeping, by means of very long, sinuple, stout fibres, thrown out from within the sheaths of former leaves; its upper part ascending, leafy, three or four inches long. Leaves two-ranked, spreading, ascending, a span long, hardly an inch broad; jagged, with two sharp teeth, at one side of the point only. Umbels opposite to several of the lower leaves, solitary, stalked, lax, each of about five flowers, which are rather smaller than those of the last species, but the pouch of the lip is considerably larger in proportion, prominent, yellow variegated with red, as well as the disk of its border, which last is densely bearded with white fibres like the foregoing. Calyx-leaves and petals uniform, obovate, incurved, yellow spotted with red.

12. *A. rigidum*. Rigid Air-blossom. Buch. MSS.—Stem creeping. Leaves oblong, obtuse, rounded, unequally at the point, four times as long as the corymbose clusters. Lip with an obovate smooth border, the size and shape of the petals.—Found by Dr. Buchanan, running over rocks and large stones in Upper Nepal. The stem is woody, a yard long, and as thick as the finger, creeping among mosses, and sending out here and there, through the bases of

the leaves, very thick radicles. Leaves two-ranked, alternate, a foot long, extremely thick and coriaceous, three-ribbed, oblique at the termination, one side being greatly extended, in a round lobe, beyond the rib, the other sloping off below it. The lower part of each leaf has a joint, where it finally separates, leaving the sheathing permanent base, or footstalk, as in *A. Borassi*, *maculatum*, and others of this genus and natural order. Flower-stalks opposite to the leaves, solitary, alternate, about three inches long, distantly racemose in the lower part, corymbose at the summit, each bearing from five to seven nearly or quite sessile flowers, yellow spotted with red, about the size of the last. Calyx-leaves and petals obovate, uniform, erect. Lip agreeing with them in colour and shape, except the small prominent pouch at its base, and the apex being a little reflexed.

13. *A. undulatum*. Wavy-flowered Air-blossom. (*Epidendrum præmorium*; Roxb. *Corom.* v. 1. 34. t. 43. *Cymbidium præmorium*; Swartz *Nov. Act. Upf.* v. 6. 75. *Schrad. Neues Journ.* v. 1. 75. *Willd. Sp. Pl.* v. 4. 103. *Thalia Maravara*; Rheede *Hort. Malab.* v. 12. 6. t. 4. Raii *Hist.* v. 3. 590. *Orchis abortiva*, floribus luteis minoribus, radiis rubris; *Rudb. Elyf.* v. 2. 222. f. 8.)—Stem ascending. Leaves linear, channelled, abrupt, acutely pointed, thrice as long as the corymbose clusters. Lip with an obovate flat border, the size and shape of the petals.—Native of trunks and branches of trees, in the hilly parts of Malabar and Coromandel, flowering in October. The roots consist of numerous long stout fibres. Stem ascending, leafy, four or five inches high. Leaves two-ranked, alternate, recurved, coriaceous, six inches long and one broad, concave, ending in a femicircular notch, whose two extremities are pointed, and nearly equal. Inflorescence like the last. Flowers rather smaller, fragrant. Calyx-leaves and petals obovate, equal, slightly wavy at the edges, yellow, marked with transverse, crimson, undulating lines. Lip the size and shape of the petals, white dotted with red, its pouch but slightly indicated in parts of Dr. Roxburgh's figure, and probably so little obvious in nature, as to have easily escaped the artist's notice. Notwithstanding this apparent exception to the generic character, the present plant, improperly confounded by Linnæus with his *Epidendrum furvum*, is so strikingly allied to the last, and consequently to the two immediately preceding, that we must presume it to be an *Aerides*. If, on examination, it should prove to want the pouch, a fresh investigation must be instituted, respecting the distinguishing characters of this genus and *Cymbidium*.

The habit of *Aerides* is peculiar, though not perhaps exclusively so, in the termination of its leaves, always more or less abrupt, unequal, or jagged. We have never seen a living specimen of any of the genus, but Dr. Buchanan's fine and scientific coloured figures, drawn from nature under his own inspection, are as precise and satisfactory as possible, and that excellent botanist has himself pointed out to us the characters and habit of *Aerides*, as a natural genus.

With regard to the name, it well expresses the quality of living upon air alone, for which several species have attracted notice. Linnæus, who included the whole, with various other things, in his genus of *EPIDENDRUM*, (see that article,) particularly applied the specific name of *Flos æris* to our sixth species, citing with a query in *Æt. Upf.* the 2d chapter verse 7th of the Wisdom of Solomon. This, in the English translation is, "Let no flower of the spring pass by us." In a Latin version before us this text is rendered "*ne prætereat nos juvenudo ær.*" Whence this ambiguity arose, or whether Linnæus had any where read *flos veris*, which he confounded with *flos æris*, we have not materials to determine. At any rate, the text in question has evidently

no reference to this, or to any other particular plant whatever.

AESTIVATIO, in *Botany and Vegetable Physiology*, a term used by Linnæus for the mode in which the petals, or the segments, of a *corolla* are arranged with respect to each other, particularly before they expand. (See **COROLLA**.) The word comes from *æstas*, summer, and *æstiva*, summer-quarters, summer being the usual flowering season, and the *corolla* the shelter or accompaniment of the organs of fecundation. So *Vernatio* expresses the arrangement of the leaves of plants in the bud, or, in other words, their vernal condition. *Æstivatio imbricata*, expresses the divisions of the *corolla* being imbricated, or folded over each other, either from left to right, that is, with the motion of the sun, as in *Cistus*; or the reverse, of which latter Linnæus has in his manuscripts mentioned *Phlox* as one example, and we would point out *Hypericum* as another. *Æstivatio valvata* is when the divisions of the *corolla* meet in the bud like valves, side by side, as in *Protea* and its allies. Of this *Periploca* is an instance, notwithstanding the obliquity observable in the segments of that flower after expansion. Linnæus, in the MSS. above cited, speaks of *Peonia* as having, like its near relation *Aconitum*, one petal exterior to all the rest, though the *corolla* is what would be termed regular in the first genus, and very irregular in the second. Such a diversity indeed is of small moment, for Mr. Correa has observed that every natural order, as far as he could examine, possesses irregular and regular flowers. In general the direction of the parts of a *corolla*, as to their æstivation (if we may use that word), are invariably alike in genera of the same natural order. But **HERMANNIA**, (see that article,) affords a remarkable exception, every one of its species that we have seen bearing two flowers on the same stalk, has the petals of one of those flowers rolled to the right, while those of the other are disposed in a contrary position. Mr. Brown, in his learned *Prodromus* of New Holland plants, has paid more attention to the æstivation, in defining his natural orders, than any other botanist, and the term *æstivatio valvata* is, if we mistake not, his own invention.

ÆTH, l. 4, insert after Brussels. It is the chief place of a canton, in the department of Jemappe, and district of Tournay. The place contains 7634, and the canton 14,828 inhabitants. The territory includes 115 kilometres, and 11 communes. See **ATH**.

AETHIONEMA, in *Botany*, so named by Mr. Brown, apparently in allusion to some tawny or sun-burnt tinge in the flaments, from *æthra*, to scorch, and *maxa*, a flamen. We perceive in our dried specimens an occasional purple hue in these parts. It may perhaps be more remarkable in the species we have not seen.—Brown in Ait. Hort. Kew. v. 4. 80.—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliculosæ*, Linn. *Cruciferae*, Juss.

Æth. Ch. Pouch with boat-like winged valves (sometimes not bursting). Longer filaments either combined, or finely toothed towards the top. Insertion of the calyx unequal. *Brown*.

1. *Ac. faxatila*. Rock Aethionema. Ait. n. 1.

(*Thlaspi faxatile*; Linn. Sp. Pl. 901. "Schkuhr Handb. v. 2. 223. t. 180." See **THLASPI**, n. 6.)—Longer filaments distinct. Leaves oblong, tapering at the base.—Native of the south of Europe. Cultivated by Miller in 1759.

2. *Ac. monospermum*. One-seeded Aethionema. Ait. n. 2.—"Pouch single-seeded, without valves. Leaves oval or obovate."—Native of Spain. Cultivated in 1778, by Lee and Kennedy, at Hammermith. A hardy biennial, flowering in July and August. We have seen no specimen of this species. Our doubts respecting the genus may be found under **THLASPI**.

AFER, **DOMITIUS**, col. 2, l. 11, for vanity r. variety.

AFFINITY, in *Chemistry*. The celebrated doctrine of Bergman is the last in order discussed under the article **AFFINITY** in the *Cyclopædia*: since that time, however, very important changes in opinion have taken place, among chemists, respecting the nature and cause of chemical affinity. Some of these are mentioned in subsequent parts of the *Cyclopædia*, especially in the articles *CHEMICAL PROPORTIONS*, *SIMPLE BODIES*, and *ATOMIC THEORY*; but it may not be deemed superfluous to give a summary and connected view of the whole in this place.

Bergman's doctrine of *elective affinity*, so amply explained in the article above referred to, was universally admitted among chemists till 1803, when Berthollet published his Dissertation on Affinity in the *Memoirs of the Institute*, and about the same time his *Chemical Statics*. Berthollet considered affinity as an *attraction* existing between combining bodies. This attraction he appeared to consider as similar in its nature to that which exists between the planets, or in short, the principle of gravitation. It consequently, in his opinion, increased with the *masses* of bodies. According to this doctrine, therefore, bodies which have an affinity or attraction for one another, have a tendency always to combine, in a greater or less degree, chiefly in proportion to their *masses*. Thus, though barytes appears to possess a stronger affinity for sulphuric acid than potash, yet if we present a great quantity of potash to a small quantity of sulphate of barytes, the potash will separate a portion of the acid.

According to Berthollet, therefore, affinity is not *elective*. A substance which has a stronger affinity is not capable of separating entirely those which have a weaker, unless some other cause than mere strength of affinity operates. Instead of separating entirely the weaker body, it divides with it the base to which that body was united, each combining with a part of such base in the compound proportion of the strength of its affinity and of its quantity.

But no facts in chemistry are better established than those in which the addition of a third body frequently separates two substances previously united, the third body taking the place of one of the constituents, which is thereby separated altogether. Thus, if sulphuric acid be dropped into a solution of nitrate of barytes, or potash into a solution of nitrate of lime, the sulphate of barytes and the lime will precipitate, leaving, in the first instance, the nitric acid in a free state, and in the second, the potash combined with the nitric acid instead of the lime. These and many other well-known facts appearing, at first sight, contrary to Berthollet's doctrine, it was necessary for him to reconcile them to it. For this purpose, he called in the aid of the different modes of existence of bodies. According to him, therefore, whenever decomposition takes place, it is owing either to the *insolubility* or the *elasticity* of the ingredient which separates. Sulphate of barytes being insoluble in water, while nitrate of barytes and nitric acid are soluble in that liquid, it must happen,

AFFINITY.

happen, when the substances are mixed, that the insoluble salt precipitates, on account of its insolubility. It is the insolubility of lime that causes it to precipitate when potash is dropped into nitrate of lime. Accordingly, when potash is dropped into nitrate of soda, no precipitation whatever takes place, because both the potash and the soda are very soluble in water; but if we concentrate the solution sufficiently by evaporation, crystals of nitrate of potash will be deposited, because that salt is much less soluble in water than nitrate of soda. So also, when nitric acid is poured upon carbonate of lime, the carbonic acid is disengaged, and flies off, because its elasticity induces it to separate from the solid, and assume the gaseous state as soon as the nitric acid weakens the attraction, by means of which it was attached to the lime.

“Thus,” says Dr. Thomson, to whom we have been particularly indebted in the compilation of the present article, “we have two doctrines respecting affinity opposite to each other. According to Bergman, affinity is *elective*. The body which has the stronger affinity displaces that which has a weaker, and the strength of affinity may be measured by decomposition. According to Berthollet, affinity is *not elective*. It never produces decompositions, but only combinations, and the decompositions which take place are owing to the agency of other causes. The strength of affinity is not an absolute quantity, but increases with the mass of the attracting body. Berthollet’s doctrines lead to the opinion, that bodies are capable of uniting together indefinitely in any proportion whatever: Bergman’s, that they unite only in determinate proportions, and that these proportions are independent of the relative quantities of the combining substances which are present.” See *Atomic Theory*.

A most important fact respecting the combination of bodies was ascertained by Richter. This was illustrated in an elaborate work, published at different times between 1792 and 1802, which contains the result of his researches on the decompositions and combinations of chemical bodies. He observed, that when two neutral salts, which mutually decompose each other, are mixed together, the two newly formed salts still retain the same neutral state as the two original ones, from which they were formed. He likewise observed, that the same proportions of bases that saturate a given weight of one acid, saturate all the other acids; and the same proportion of acids that saturate one base, saturate all the other bases; which law enabled him to explain why two neutral salts form, as above-mentioned, two new salts, likewise neutral. These experiments and observations of Richter likewise enabled Fischer to attach a set of numbers to the acids and bases, indicating the weight of each which will saturate the numbers attached to all the other acids and bases.

Mr. Dalton, without being aware of the law already discovered by Richter, turned his attention to the subject about two years afterwards, and was struck with the small number of proportions in which simple substances are capable of combining, and the constancy of these proportions. This led him to form the doctrine of definite proportions, or atoms, as it is usually termed, and which, as well as Gay Lussac’s modification of it, our readers will find fully explained in the article *Definite Proportions*.

About the same period, that is, in the year 1803, the grand law respecting the agency of the galvanic battery in the decomposition of bodies was discovered by Berzelius and Hisinger. This law is, that *oxygen and acids* are accumulated round the *positive pole*; while *hydrogen, alkalis,*

earths, and metals, are accumulated round the *negative pole*. From this general law Berzelius deduced the consequence, that the decompositions in such instances were owing to the attractions existing between the bodies and the respective electricities. This opinion was afterwards extended by Davy, and the opinion in its extended form subsequently adopted by Berzelius himself. According to these celebrated chemists, chemical affinity is identical with electrical attraction, and bodies which unite chemically possess different kinds of electrical attractions. Every body, in their opinion, possesses a permanent elective state, either resinous or vitreous. Two bodies in the same state of electricity have no affinity for each other. Those in opposite states have an affinity, and the strength of the affinity is proportional to the degree of intensity of the different electricities in the two bodies; and in order to make bodies separate from each other, we have only to bring them into the same electrical state, by making them both vitreous or both resinous. See *ELECTRICITY* and *GALVANISM*.

Such is a summary account of the revolutions in opinion which have taken place respecting the nature of chemical affinity, and the principal discoveries which have given origin to these changes since the time of Bergman. We shall conclude this article with a few general remarks upon the subject.

In the first place, the question whether the affinities of substances for one another be definite quantities capable of being represented by numbers, cannot, in the present state of chemical science, be satisfactorily determined. For though some substances always appear capable of separating others, as, for example, barytes, potash; yet the reason may be, that the salts of barytes are less soluble than the salts of potash. Again, iron, as is well known, separates oxygen from water at all temperatures; but, on the other hand, it has been equally well ascertained, that the oxyd of iron is reduced when heated in hydrogen gas: “hence,” says Dr. Thomson, “we have no data for determining whether iron or hydrogen have the greatest affinity for oxygen; each seeming capable of depriving the other of oxygen in the very same circumstances.”

In certain cases, also, of double decompositions, it is often equally difficult to distinguish on which side the strongest affinities lie. Thus, as is well known, carbonate of barytes and sulphate of potash, when digested together, decompose each other, and are converted into sulphate of barytes and carbonate of potash; but on the other hand, it has been equally satisfactorily shewn by Mr. Phillips, that carbonate of potash is capable of decomposing the sulphate of barytes.

Pfaff, however, has shewn, that the tartrate of lime and the oxalate of lead are completely decomposed by the addition of no more sulphuric acid than is necessary to form sulphate of lime and sulphate of lead; and hence he infers, that the affinity of sulphuric acid for lime and lead is actually superior to the affinities of tartaric and oxalic acids for the same bases respectively.

Berthollet has attempted to account for the first of the above experiments by the effect of *mass*; and the experiments of Pfaff he endeavours to explain by the solubility of tartrate of lime and oxalate of lead, and the insolubility of the sulphate of lime and sulphate of lead in acids. And this brings us,

In the second place, to make a few remarks upon the supposed effects of *mass*, and the *modes of existence* of bodies in modifying chemical decompositions. With respect

to the effects of *masf*, though at first sight there appear to be some circumstances favouring the opinions of Berthollet respecting its influence in chemical operations, yet we can by no means agree in supposing its influence to be great as represented by that eminent chemist. No quantity of water, for example, would decompose sulphate of magnesia, though the affinity of sulphuric acid for water is very great, and though the insoluble nature of magnesia would, according to Berthollet's views, favour the union of the water with the acid. *Mafs* here, therefore, either does not operate at all, or very feebly; and there are numerous analogous instances, well known to every chemist, to which the same remarks are equally applicable.

Again, it has been sufficiently established, that gases unite with reference to their volume, and cannot be made to unite in intermediate proportions, even although the result of their union be likewise a gas. Thus, for example, one volume of chlorine gas and one volume of hydrogen gas unite together, and form, without any condensation, or other apparent physical change, two volumes of muriatic acid gas, nor can they be made to unite in any other proportions. Here then is an example of chemical union, in which the effects of *masf* and *mode of existence* are quite out of the question.

From these, and particularly from many recently established facts, we think it proved beyond a doubt, that the power which determines bodies to combine in certain proportions is a property inherent in the original cause of their union, and consequently is a power totally different from that exerted by *masf* or other external circumstance, though it is not perhaps altogether independent of their influence. For further information, we refer our readers to sir Humphry Davy's Elements of Chemical Philosophy, where, besides an excellent account of the subject in general, they will find a masterly refutation of Berthollet's doctrines.

AFÖRE, l. 2, for item r. item; l. 4, ditto.

AFZELIA, in *Botany*, (see that article,) is *Gerardia caffoides*, Pursh 424. (G. Afzelia; Michaux Boreal-Amer. v. 2. 20. Anonymos caffoides; Walt. Carolin. 171.)—"Panicked, with wand-like branches. Leaves pinnatifid, with linear bristle-like segments."—In dry sandy woods of Carolina and Georgia. Annual, flowering in July and August. *Flowers* small, yellow. *Pursh*.

AFZELIA, Sm. Tr. of Linn. Soc. v. 4. 221, so named in honour of its discoverer, Adam Afzelius, M.D. Demonstrator of Botany at Upsal, author of several dissertations on Swedish Roses, and of other learned botanical treatises, is a very noble genus, of which we have long expected from Dr. Afzelius himself an illustration of the species. They are all natives of Sierra Leone.—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Eff. Ch. Calyx tubular; limb in four deciduous segments. Petals four, with claws; the uppermost very large. Two upper Stamens imperfect. Legume with many cells. Seeds with a tunic at the base.

This genus consists of trees with large, smooth, abruptly pinnate, alternate leaves. The flowers are racemose, crimson, with small bractæes. Legumes woody and ponderous, smooth, ovate, acute. Seeds near an inch long, parallel, ovate, black, the lower half of each invested with a fleshy tunic, of a brilliant permanent scarlet, and a rather waxy appearance. The native Africans remove this tunic, and use the seeds for beads.

AGASTACHYS, from *αγαστος*, remarkable, and *ακτις*, a spike, alluding to the abundance of its spiked flowers.—

Brown Tr. of Linn. Soc. v. 10. 158. Prodr. Nov. Holl. v. 1. 371.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juss.

Eff. Ch. Corolla regular, of four petals, cohering at the base, bearing the stamens in the middle. Filaments distinct. Nectary none. Germs sessile, triangular, single-seeded. Stigma unilateral.

1. A. odorata. Fragrant Agastachys. Br. n. 1.—Found in the southern part of Van Diemen's island, near Adventure bay, by Mr. David Nelson, and afterwards by Mr. George Caley. A shrub, perfectly smooth in every part. Leaves scattered, entire, flat. Spikes numerous, simple, terminal, as well as axillary from the upper leaves. Flowers alternate, sessile, with a solitary, hooded, permanent bractea to each. Corolla yellowish, deciduous. Pistil shorter than the stamens. The fruit has not yet been examined. *Brown*.

AGATE, col. 2, l. 15. They are conveyed from Germany in blocks; and cut by means of diamond powder into leaves for making caps for the pivots of mariners' needles, and other purposes.

AGATHARCHUS, in *Biography*, a painter of the life of Samos, who is said to have been instructed by Æschylus in the art of introducing perspective into the decorations of theatres, and to have been the first who wrote on this subject, and communicated the art to Democritus and Anaxagoras.

AGDESTIS, in *Botany*, a fanciful name, adopted by De Candolle, from the authors of an unpublished Mexican Flora, whom he cites as Moç. and Selsé. It is applied to a doubtful genus, related to *Menispermum*, and perhaps of a sort of *lusus nature*, having stamens and pistils in the same flower, which is almost unexampled in this tribe. The above denomination is that of a fabulous monster, said to have been male as well as female, and produced by Jupiter from the stone *Agdos*. This genus therefore being not clearly understood, and as yet very little known, may hereafter be abolished as well as its name.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Menispermæ*, Juss. *Menispermæ*, De Cand.

Eff. Ch. Calyx inferior, of four leaves. Petals none. Filaments thread-shaped. Anthers oblong, cloven at each end, incumbent. Germs and style with four furrows. Stigmas four, spreading. Capsules four, combined.

1. A. clematidea. Boverly Agdestis.—Native of New Spain. A smooth shrub, with a branched, twining, round, striated stem. Leaves alternate, distant, stalked, exactly heart-shaped, entire, pointed; their lobes very obtuse. Flowers reddish, corymbose, axillary and terminal; their stalks three-cleft. Fruit unknown. This plant appears very nearly akin to *Clematis*.

AGGREGATE, the title of the 48th order in Linnæus's fragments of a natural system, placed between the *Stellate* and *Compositæ*. (See AGGREGATE.) This is a very miscellaneous and ill-defined order, of which it is by no means easy to seize the idea, much less to give any definition, or distinctive character. Vaillant first laid the foundation of this order, in the *Memoires de l'Acad. des Sciences* for 1722. "The natural order of *Aggregate*," says Linnæus, *Prel. in Ord. Nat.* 528, "was first investigated by Vaillant, in the *Mem. de l'Acad. des Sciences*. They agree with the *Compositæ* in having generally a common calyx as well as receptacle, collecting together many sessile florets, each of which has always an inferior germ. But there is a total difference with respect to the remaining parts of fructification, nor can these two orders be, by any means, united. The calyx, as above said, is common to many flowers,

flowers, or florets. The *common receptacle* is either naked, villous, hairy, or scaly. In the place of a *partial calyx* is the *corolla*, generally monopetalous, either regular or irregular, four-cleft or five-cleft, rarely polypetalous. *Stamens* four, with separate *anthers*. *Germs* inferior (with respect to each floret). *Fruit* single-seeded. The *flower* is therefore complete in this tribe, except only *Valeriana*, whose *calyx* is scarcely apparent. The *leaves* are often opposite. *Stem* often shrubby."

The genera which compose this order at the end of *Gen. Pl.* are, Sect. *a*. *Statice* only. *b*. *Hartogia*, *Brunia*, *Protea*, *Globularia*, *Leucadendron*, *Hebenstretia*, *Selago*, *Cephalanthus*, *Dipfacus*, *Scabiosa*, *Knausia*, *Allonia*. But in his own copy Linnæus has drawn a line between *Selago* and *Cephalanthus*, removing the β to that place, and characterizing his section *a* "*alternifolia infera*," the remainder of the whole order beginning with *Cephalanthus*, being "*oppositifolia superæ*." γ . *Valeriana*, *Morina*, *Baerbaria*, *Circea*, to which *Mirabilis* is added in MSS. δ . *Lonicera*, *Chiocecca*, *Trifolium*, *Mitchella*, *Linnaea*, *Morinda*, *Conocarpus*, *Loranthus*, *Viscum*, to which *Lisianthus* and *Hillia* are added, certainly with no propriety.

This order in fact is not one of our great botanist's most finished or happy performances. It comprehends Jussieu's *Dipsacæ*, *Proteacæ*, *Caprifoliæ*, with various solitary genera from different orders. *Statice* was always a stumbling block with Linnæus, nor does it affiliate with any thing among the *Aggregate*, being itself, however natural a genus, and as we think improperly subdivided by Tournefort and others, composed of species whose inflorescence is essentially different among themselves.

In his manuscripts Linnæus has extended his first section as far as *Selago* inclusive, erasing *Hartogia*, and giving the characters of alternate leaves, and a superior germ to this section. To the second section, which begins with *Cephalanthus*, he attributes opposite leaves, and an inferior germ. He thought *Statice* akin to *Brunia*, and *Protea* the same genus as *Leucadendron*. To his third section he more happily adds *Mirabilis*; but to the fourth he very unfortunately introduces *Lisianthus* and *Hillia*.

The intelligent botanist will without difficulty trace the numerous errors of the above arrangement to various causes. Several natural orders, now well defined, had not entered into the conception of Linnæus, such as the very natural and distinct one of *Proteacæ*; and of the *Caprifoliæ*, sketched in his fourth section, he had evidently but an obscure perception. Of the differences of the *Proteaceous* genera he had scarcely any knowledge. That he should not have formed a right idea of *Hebenstretia* and *Selago*, whose affinities are still in some uncertainty, is not wonderful; but they are unquestionably much out of place here. See *DIPSACÆ* for further observations respecting some of the *Aggregate*.

AGLABITES, l. 5, add, and governor in Africa, Heg. 184, A.D. 800. This dynasty lasted till the year of the Hegira 296, A.D. 908, and possessed the country which extended from Egypt to Tunis.

AGLAIA, in *Botany*, *αγλαία*, splendour and beauty, alluding to the shining verdure of the leaves, and elegance of the whole plant.—Loureir. Cochinch. 173.—Class and order, *Pentandria Digynia*, Lour. (rather perhaps *Pentandria Monogynia*.) Nat. Ord. *Tribilata*, Linn. *Meliæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, with five notches, minute, permanent. *Cor.* Petals five, ovate, concave, fleshy, converging almost closely into the form of a globe. Nectary tubular, with five plates, rather shorter than the petals. *Stam.* Filaments none; anthers five, ovate, included in the folds of the nectary. *Pist.* Germen ovate,

superior; style none; stigmas two, oblong, erect. *Peric.* Berry ovate, smooth, watery, of one cell. *Seed* solitary, ovate, slightly compressed, with four furrows.

Eff. Ch. Calyx inferior, five-toothed. Petals five, converging in the form of a globe. Berry with one seed.

1. *A. odorata*. Fragrant Aglaia. *Cyè ngâu* of the Cochinchinese. (Camunium sinense; Rumph. Amboin. v. 5, 28. t. 18. f. 1.)—Native of Cochinchina and China. Commonly cultivated in the latter country, for the sake of its great beauty and agreeable scent. Rumphius says it was imported from thence to Amboyna, where it still retained the Chinese name of *Tzjulang*, and was continually in leaf and blossom; being easily propagated by cuttings of the larger branches, whose bark must be bruised slightly, and then covered for the space of a month with good earth and dung, till roots are thrown out, which are then to be cut off and transplanted. Loureiro describes this plant as a tree eight feet high, with a yellowish hard wood, thin brown bark, and spreading branches forming a very dense head. *Leaves* pinnate with an odd one, consisting of three or five oval, entire, smooth, shining leaflets, tapering at the base, on short foot-stalks. *Clusters* axillary, oblong. *Flowers* yellow, very minute, globose, odoriferous. *Berry* small, red.

Rumphius describes the *flowers* orange-coloured, never producing fruit in Amboyna.

We cannot find that this plant of Rumphius is taken up by any author, nor is his description sufficient to procure it a place in any systematic work. Loureiro, however, has furnished us with sufficient characters to enable us to judge of its natural order, and to determine that it is not, as he suspected, the same genus with Thunberg's *Bumalda*.

AGRIPHYLUM, in *Botany*, so called by Jussieu, from *αγρα*, the holly, and *φυλλον*, a leaf, because its sinuated prickly leaves resemble that shrub. Juss. Gen. 190. See BERCKHEYA hereafter.

AGUJARI, LUCRETIA. See FILER *un* Son.

AGUILLAS, CAPE. *Dele Cape NEEDLES*.

AGUILLAS Bank, a bank on the southern coast of Africa, stretching from Cape Point across the entrance of False bay to the mouth of Rio Infanta, or Great Fish River, and to the 37th parallel of Southern latitude. Mr. Barrow conjectures that this bank at one time formed a part of the continent.

AHM, in *Commerce*. See STUBGEN.

AHMEDABAD. For **AGMED'S** r. **AHMED'S**; l. 6, r. Sebermathy.

AHMEDNAGUR, l. 2, r. Dowlatabad.

AHOUS. Add—This was once a large and flourishing city, the capital of a province of the same name, and the winter residence of Artabanus, the last of the Parthian kings; but it is now a wretched town, containing 600 or 700 inhabitants, and situated on the banks of the river Karoon; 48 miles S. of Shuster.

AIDAN, col. 2, l. 18, for bishop r. king.

AIDERBEITZAN. At the close add—It is separated from Armenia by the river Araxes, and from Irak by the Kizilozoin, or Golden stream. This province, including Erivan with the Karabag and Karadag, is divided into twelve districts, *viz.* Urumea, Ardebil, Tabreez, Maraga Khoee, Kulkham, Serab, Gumrood, Sa Bulagh, Karadag, Erivan, Nuckhivan, and Miskeen, yielding a revenue of 89,405 tomanes. The most picturesque, and at the same time most

M m 2 flourishing

flourishing division of Aiderbeitzan, or Azerbaijan, lies along the N. and W. borders of the lake Urumea from Tabreez to the confines of Armenia, in which direction are the towns of Shebuter, Tafoui (in ruins), Selmaft, Khoea, and Urumea.

AIDIA, in *Botany*, a genus of Loureiro's, unknown to us but from his description, whose name, from *αἰδιος*, *eternal*, alludes to the indelible nature of the wood.—Loureiro. Cochinch. 143.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Caprifolia*, Juss.

Gen. Ch. *Cal.* Perianth superior, tubular, five-toothed, erect. *Cor.* of one petal, falver-shaped; mouth of the tube woolly; limb in five deep lanceolate segments. *Stam.* Filaments none; anthers five, linear, inserted into the corolla between its segments. *Pist.* Germen ovate, inferior; style on a level with the anthers; stigma ovate-oblong. *Peric.* Berry ovate, "calycine," (meaning crowned by, and confluent with, the calyx,) small, umbilicated, of one cell. *Seed* solitary, ovate.

Eff. Ch. Corolla falver-shaped, woolly in the throat. Anthers linear, sessile between the segments of the corolla. Berry calycine, single-seeded.

1. *A. cochinchinensis*. Everlasting-wood. *Cây Thai* of the Cochinchinese.—Native of Cochinchina. A large tree, with spreading branches. Leaves opposite, lanceolate, entire, smooth. Flowers white, in short, lax, axillary clusters. The wood is white, heavy, composed of thick fibres, and not handsome. Its chief use is for building the lower parts of houses, and foundations of bridges, being extremely durable, either under ground or in water. *Loureiro*.

AIMONTE. Add, See **AYEMONTE**.

AINSWORTH, ROBERT, l. 2, for *Woodyale r. Woodyate*.

AIR, col. 11, l. 44, insert elastic, and *r.* whatever elastic matter, &c.

AIR, *Atmospheric*, in *Chemistry*. The most recent experiments shew that atmospheric air is composed by bulk of about 21 *per cent.* of oxygen and 79 *per cent.* of azote; and this coincides so nearly with four volumes of azote and one of oxygen, that Dr. Prout has been induced to consider this proportion as the true composition of atmospheric air, and consequently that it is a real chemical compound composed of one atom oxygen and two of azote. Upon this supposition, and the supposition that the atom of oxygen be 10 and the atom of azote be 17.5, atmospheric air will be composed by weight of

$$\left. \begin{array}{l} \text{Oxygen } 22.22 \\ \text{Azote } 77.77 \end{array} \right\} \text{ and by bulk of } \left\{ \begin{array}{l} 20 \\ 80 \end{array} \right.$$

And the specific gravity of oxygen gas will be 1.1111 and of azote .9722, atmospheric air being 1.000. See **ATOMIC Theory**, *Addenda*.

The reasons upon which the above opinion is chiefly founded are, in the first place, the impossibility of accounting on any other than chemical principles for the remarkable uniformity observed in the composition of atmospheric air all over the world. This fact is universally admitted, and no one can adduce even the slightest argument why this uniformity should be explained on principles different from those which govern other definite compounds, as, for example, water.

Secondly, experiment coincides extremely near with the above supposition, perhaps as nearly as it has ever done in any similar example, even in those on which the doctrine of volumes itself was founded by M. Gay Lussac. Those versed in eudiometry, and who know the imperfections of all eudiometrical methods hitherto advanced, will feel little inclined to vouch

for the *perfect* accuracy of their results, and to deny the possibility of an error of one *per cent.* Besides, when we reflect how liable the atmosphere is to contaminations of every kind, the chance of such an error is still further increased.

About the same time (November 1815) that the above opinion was advanced by Dr. Prout, a similar opinion was published by Dobereiner, in a paper inserted in Schweigger's Journal. Thomson's Annals of Philosophy, vol. vi. p. 321.

AIR, in *Geography*, a township of Pennsylvania, in the county of Bedford, containing 1179 inhabitants.

AIRY. See **AERY**.

AITZEMA, l. 2, *r.* Dockum.

AKISKA, in *Geography*, one of the Turkish pachalics of Armenia, which lies near the limits of the Turkish empire, and has the Black sea to the W., Immeritia to the N., Kars and Erzeroom to the S., and Georgia to the E. It extends a considerable way along the banks of the Kur, and contains much arable land, with many cities and villages, and minerals in its mountainous parts. Akalziké (new Castle) or Akiska, which gives name to the province, is the capital: it is a populous and commercial city, without walls or fortifications, and only defended by a ruined citadel, standing in an open valley on the left bank of the Kur, and inhabited by Jews, Turks, Greeks, Armenians, and Georgians.

ALA, in *Botany, l. 4, for upwards *r.* downwards.*

ALANGIUM, so denominated by Lamarek, by a slight alteration of one of its Malabar names, *Alangi*; and if any barbarous generic appellations are to be tolerated, this certainly may.—Lamarck Dict. v. 1. 174. Juss. Gen. 323. Vahl Symb. v. 2. 61. Willd. Sp. Pl. v. 2. 1174. Ait. Hort. Kew. v. 3. 302.—Class and order, *Icosandria Monogynia*. Nat. Ord. *Hesperideæ*, Linn. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, short, permanent, with from six to ten small erect teeth. *Cor.* Petals from six to ten, linear, undivided, much longer than the calyx into which they are inserted, spiral in the bud, afterwards recurved. Nectary cup-shaped. *Stam.* Filaments ten or twelve, inserted into the calyx, erect, thread-shaped, hairy below, scarcely half the length of the petals; anthers terminal, vertical, linear, obtuse, rather broader and longer than the filaments, bursting at each side longitudinally. *Pist.* Germen turbinate, inferior; style cylindrical, erect, rather longer than the stamens; stigma capitate, lobed, very large. *Peric.* Berry globular, with a rather coriaceous coat, crowned with the calyx, internally fleshy, of one cell. *Seeds* from one to three, nearly lenticular.

Eff. Ch. Corolla superior, with from six to ten teeth. Petals from six to ten. Berry coated, of one cell, with few seeds.

Obf. We do not scruple to remove this genus from the class *Polyandria*, where Willdenow has placed it, but with which the insertion of the filaments does not agree, to *Icosandria*, where it ranges with its natural allies. **LEMNISCIA** (see

(See that article) answers in habit, and in several characters, to *Alangium*; but its fruit is not sufficiently known to allow of an absolute decision, nor do the anthers agree.

1. *A. decapetalum*. Sage-leaved Alangium. Lamarck n. 1. Willd. n. 1. Ait. n. 1. Vahl Symb. v. 2. 61. (*Crewia falsifolia*; Linn. Suppl. 409. Angolam; Rheede Hort. Malab. v. 4. 39. t. 17. Arbor indica baciferia, fructu umbilicato rotundo, cerasi magnitudine diococo; Raii Hist. v. 2. 1497.)—Flowers with ten petals. Branches becoming spinous.—Native of the East Indies. Koenig sent specimens to Linnæus, and in the year 1779 he also communicated seeds from Ceylon to Kew garden; but their progeny has not yet flowered, if it be still alive. Rheede describes this as a handsome tree, an hundred feet high, and twelve in circumference, with spreading branches, white hard wood, and a bitterish, acrid, aromatic bark. The root is fungous, reddish, fragrant and bitter, with a yellowish bark. The branches bear leaves and flowers together, and finally assume a sharp spinous termination. Leaves alternate, on short downy stalks, ovate-oblong, obtuse, entire, ribbed, veiny, four or five inches long, pliant, fragrant; smooth and shining above; paler, reticulated, and roughish, beneath. Flowers axillary, either solitary, or two or three together, on simple, short, downy stalks. Calyx downy. Petals rather silky externally; white within. Anthers bright red. Fruit the size of a large cherry; downy when young; purplish when ripe, full of sweet fragrant pulp, which is esteemed very delicious, and contains one, two, or three black seeds. The inhabitants of Malabar compare the flowers to an imperial diadem, and therefore consider this tree as an emblem of royalty. The expressed juice of the root is purgative, and used for expelling intestinal worms. Its powder is thought an antidote for the bites of serpents, and other venomous animals.

2. *A. hexapetalum*. Broad-leaved Alangium. Lamarck n. 2. Willd. n. 2. Vahl Symb. v. 2. 62. (Kara Angolam; Rheede Hort. Malab. v. 4. 55. t. 26. Arbor indica prunifera, fructu umbilicato corticose perlici simili; Raii Hist. v. 2. 1483.)—Flowers with six petals. Branches not spinous.—Native of the coast of Malabar, in stony, sandy, mountainous places, always in flower and leaf. Its trunk is of lofty stature, but inferior to the former. Leaves broader, more ovate, and pointed, smooth, bitter and acrid, but not aromatic; paler beneath. Flowers smaller, whitish, nearly sessile, with only six petals. Fruit globose, the size of a small apple, having a thick, downy, purple coat, and viscid acid pulp.

3. *A. tomentosum*. Downy Alangium. Lamarck n. 3.—“Branches scarcely spinous. Leaves oblong, blunthigh; their ribs downy beneath, like the footstalks.”—Found in the East Indies by Sonnerat. Allied to the first species in the form of its leaves, and to the second in the nature of its fruit. The flowers are unknown. The young shoots, stalks, calyx, and ribs of the leaves, are clothed with short cottony down. Lamarck.

AL-ARAF, l. 5, for Alcoran r. Koran.

ALASAN, in *Geography*, the *Ausan* of Strabo, a river of Georgia, which separates this province from Shirvan, and taking its rise near that of the Araxi, not far from the gates of Caucasus, pursues a S.E. course, until it meets the Kur or Cyrus at Douhizil. About 30 miles above this place it is joined by the Kabri or Yari, which fertilizes the greatest part of the province of Kaket.

ALBA LONGA, l. 8, for furrowed r. farrowed.

ALBANIA, col. 2, l. 5, add—Mr. Houbouff rates the population of Albania at about 1,200,000 souls.

ALBANS, Sr., a township of America, l. 3, for 256 r. 1669.

ALBANY. Add after Saratoga—It is now restricted to an area of 462 square miles, or 295,689 acres. By the census in 1810, its population consisted of 34,661 souls, its senatorial electors were 2971, and the number of slaves was 772.

ALBANY, l. 4. This city and suburbs in 1812 contained about 12,000 inhabitants, 1800 houses and stores, 10 houses for public worship, and several public buildings.

ALBANY, a township of the district of Maine, in the county of Oxford, with 165 inhabitants.

ALBEMARLE, a county of America, &c. contained, in 1810, 18,268 inhabitants, of whom 9226 were slaves.

ALBERT'S or Current Dollar, with $\frac{1}{2}$ and $\frac{1}{4}$ ditto, Dutch silver coins valued at 50, 25, and 12 $\frac{1}{2}$ stivers, each about 1 per cent.agio. Albert's dollar is also used as a money of account at Riga. See RIX-DOLLAR.

ALBUMEN, in *Chemistry*. Considerable additions have been made to our knowledge respecting this important animal principle since the first volume of the Cyclopædia was published. These we shall briefly notice here.

The first thing deserving to be mentioned is the distinction between *coagulation*, *gelatinization*, and *precipitation*, terms which had been always confounded till Dr. Boileau defined their difference. By *coagulation* is now understood the passing of a substance from a fluid to a solid state by the agency of heat only, or, in some instances, without the immediate co-operation of any external agent; as, for example, in the *coagulation* of the fibrin of the blood. *Gelatinization* is the property which a warm solution of jelly possesses of becoming concrete as it cools. *Precipitation* is the effect which different substances or re-agents produce by combining and forming solid compounds with the principles operated upon.

The next circumstances deserving of notice are the effects of galvanism upon albumen, as ascertained by Mr. Brande.

Mr. Brande found, that when albumen was exposed to the action of a galvanic battery, an apparent coagulation took place at the negative pole, as well as at the positive. The effects of this agent, however, were different, according to its intensity. Thus, with a comparatively high power, the coagulation went on rapidly at the negative pole, and slowly at the positive; whereas, with a very low power, the coagulation was comparatively rapid at the positive pole, while at the negative pole no coagulation took place, the final proportion of albumen being retained in solution by the alkali attracted thither. Dr. Murray, however, who saw these experiments repeated in a general manner by Mr. Ellis, thinks that Mr. Brande was deceived, and that the appearance of coagulation was produced only from the numerous aerial bubbles entangled in the viscid albumen.

The opinion entertained by chemists at present respecting the coagulation of albumen, does not differ much from that of Bucquet, who considered it as a sort of soap, the animal matter being retained in solution by the foda present. An opinion, closely resembling this, has been successively advanced by Dr. Thomson, Sir Humphry Davy, and Mr. Brande, who appear to consider this albumen as merely a solution of an animal matter in water and foda, and that all the agents known to coagulate or precipitate it, act by abstracting the foda and water.

The effects of acids and other re-agents upon albumen, although they have been mentioned in a general manner in the

the Cyclopædia, deserve to be more fully detailed here, as much additional light has been thrown on the subject within the last few years, from the labours of Berzelius and others.

Acids, as is well known, precipitate albumen immediately; at least this is the case with all the mineral acids when concentrated. Dilute phosphoric, fluoric, and acetic acids, however, do not precipitate albumen. Coagulated albumen, according to Berzelius, is charred by concentrated sulphuric acid; but when diluted with six or seven times its weight of water, and digested with it, the acid assumes a reddish colour, but dissolves scarcely any thing. The portion not dissolved he considers as a compound of albumen with excess of acid. On depriving it of this excess of acid, by washing it with pure water, a neutral combination is obtained, which is soluble in water. This solution reddens litmus paper, and yields a precipitate with acids as well as alkalies, the former being combinations of the albumen with the acid employed, and which may be again rendered soluble by washing in water, the latter being again soluble with a slight excess of alkali. Hence he considers sulphuric acid to be capable of combining with albumen in two proportions; one in which the acid is neutralized, and which is soluble in water; the other, in which the acid is in excess, and which is insoluble in water. In dilute muriatic acid scarcely any of the albumen is dissolved, even by boiling, neither does the acid liquor afford any precipitate with ammonia, or prussiate of potash. Evaporated to dryness, a brownish residue is obtained, from which potash disengages a little ammonia. Concentrated muriatic acid decomposes albumen by boiling, and produces a red or violet-coloured solution. The albumen that has been digested in weak muriatic acid, by washing repeatedly with water, is converted into a gelatinous mass, which is perfectly soluble in tepid water: this is to be considered as a neutral combination of albumen with the acid, while the former one contains an excess. The solution has the same properties nearly as that of sulphuric acid above-mentioned. Nitric acid of sp. gr. 1.25, digested with albumen, renders it yellow, and diminishes its cohesion. The fluid becomes yellow, and a small quantity of fatty matter is formed. During this process, azotic gas is given out in abundance. After twenty-four hours, the albumen is converted into a pulverulent mass of a pale citron colour, which is deposited at the bottom. This matter being separated and well washed acquires a deep orange colour, which Berzelius considers as the *acide jaune* of Fourcroy and Vauquelin, who obtained it by digesting muscular flesh with nitric acid. This is soluble in alkaline leys, and imparts to them an orange colour; and it is also soluble in acetate of potash and soda. Thus, according to Berzelius, albumen is capable of existing with the nitric acid, as well as with the other acids, in two distinct states of combination, the one having an excess of acid, and of a pale yellow colour, and the other neutral, and of an orange hue. Berzelius seems to consider the different nature of the compounds formed with nitric acid to depend upon the formation of the malic acid, by the action of the nitric acid upon the albumen, which at the same time combines with it. Hence, in his opinion, they are triple compounds of albumen, nitric and malic acids. Mr. Hatchett found, that if albumen, after being steeped in diluted nitric acid, be washed, and then boiled in water, it is dissolved, and forms a pale yellow liquid, which gelatinizes when properly concentrated, and has all the properties of gelatine. Perhaps this boiling deprives it of the malic acid above-mentioned, or perhaps the malic acid was not formed by the dilute nitric acid; for Berzelius, who seems not to have been acquainted with this fact, found also, that when

albumen was precipitated from its solution in acetic acid by the nitric acid, the yellow precipitate was rendered gelatinous by washing, and soluble in water, like the compounds of albumen with the other acids above-mentioned; all which compounds are probably similar to the above, and which was considered by Mr. Hatchett as gelatine. The acetic acid readily dissolves albumen by the assistance of heat, first converting it, if previously coagulated, into a tremulous jelly. The solution is colourless, and of a mawkish and slightly acid taste. When sufficiently evaporated, it again becomes gelatinous; and when completely exhausted is a transparent mass which reddens litmus, but is insoluble both in hot and cold water, without a fresh addition of acetic acid. Ammonia and prussiate of potash produce from this solution in acetic acid a whitish precipitate. Alkalies also produce a precipitate which is again dissolved on their being added in slight excess. Sulphuric, muriatic, and nitric acids produce precipitates, which are compounds of the albumen with the acid employed, the acid being in excess; hence, if they are washed in water, as before observed, they become neutral, and capable of solution in water, like gelatine.

Solutions of the different earths, and even some of their salts, as alum, sulphate of magnesia, and silicated potash, were found by Dr. Thomson to have no effect upon albumen when dissolved in water, in the proportion of one white of an egg to a pint of water. The case, however, was very different with the metallic salts and oxyds, most of which were found to have a powerful effect upon it, especially the sulphates, muriates, and nitrates of the metals, while the prussiates, and one or two others, had no effect. One of the most delicate tests of albumen, according to Dr. Boßtock, is a solution of oxyuriate of mercury: a single drop of this, let fall into water, containing only $\frac{1}{100000}$ parts of its weight of albumen, produces an evident milkiness, and a curdy precipitate falls. Heat renders the operation of this test more effectual. Perhaps the test of albumen least liable to ambiguity, is that recommended by Berzelius above-mentioned; namely, the addition of the prussiate of potash to a solution of albumen in acetic acid. Albumen is composed of hydrogen, carbon, oxygen, and nitrogen or azote, in the proportions, according to the experiments of Gay Lussac and Thenard, of

Hydrogen	-	-	7.540
Carbon	-	-	52.883
Oxygen	-	-	23.872
Azote	-	-	15.705

100.000

Albumen never exists in an absolutely pure state in animal bodies, but is always combined with other animal matters, and various salts. See BLOOD and Animal FLUIDS.

ALBURGH, in *Geography*, a town of America, in Vermont, and county of Grand Isle, containing 1106 inhabitants.

ALBUS, in *Commerce*, a small coin and money of account at Cassel, Cologne, and other places in Germany. The whole principality of Hesse keeps accounts in rix-dollars of 32 albus, subdivided into 9 pfennings, or 12 hellers current. A specie rix-dollar is worth $4\frac{2}{3}$ Hessian albus. Coins in silver are, pieces of 8, $5\frac{1}{2}$, 4, 2 $\frac{1}{2}$, and 1 $\frac{1}{2}$ albus; and in copper, pieces of 1 and 2 albus. Cologne keeps accounts in rix-dollars specie of 80 albus,

A L C

or six-dollars current of 78 albus; the albus being reckoned at 12 hellers: and albuses are silver coins.

ALCEDO *Capensis*, l. 2, for short-tailed *r.* long-tailed. *A. rudis*, l. 3, *r.* long-tailed.

ALCEDO. Add—Dr. Shaw has described some other species, and referred some of those above-mentioned to other titles under *Alcedo*, and to *Galbula*. The *A. gigantea* is the *fusca* above-noted; the *afra* is the *maxima*: the *amazona* is glossy-green, white beneath; the sides of the neck white; those of the body variegated with green, and the wing and tail feathers spotted with white; the amazonian K. of Latham, about the size of the belted K., or *A. alycon*: a native of Cayenne. *A. Malimbica*, sea-green or beryl K. with the throat and belly white; the wing-coverts and streak across the eyes black: is much allied to the *A. capensis* in the form of its belt and distribution of its colours; numerous in Malimba, about the sea-coasts, feeding on worms and fish. *A. javanica*, blue K., with sea-green back, yellowish-white head, neck, and body; the crown of the head streaked with black. (See *A. leucocephala*.) *A. canerophaga*, greenish-blue K., yellowish beneath, with black wing-coverts and eye-stripe, and ferruginous bill; crab-eating K. of Latham: native of Senegal, where it is called Crab-eater. (See *A. Senegalensis*.) *A. Coromanda*, pale-violaceous rose-coloured K., rufescent beneath, with the rump marked by a longitudinal blueish-white band, and white throat: a native of Coromandel, an elegant species. *A. collaris*, blue-green K., white beneath, with white collar; Latham's variety of *A. facra*: a native of the Philippine islands. *A. bicolor* of Gmelin, referred to *A. inda*. *A. capistrata*, white-collared K. of Latham. (See *A. cærulea* above.) *A. albicollis* referred to *GALBULA*. *A. cyanoccephala*, described under *A. cæruleocephala*. *A. tribrachys*, tridigitated K. of Nat. Misc., deep-blue K., ferruginous beneath, with blackish wings and three-toed feet; a native of New Holland: to this the azure K. of Latham is much allied.

ALCINA, in *Botany*, Cavan. Ic. v. 1. 10. t. 15, fo named by that author, in memory of Francis Ignatius Alcina, a learned Spanish Jesuit, who resided long in the Philippine islands, and devoting his leisure hours to natural history, left a folio MS., of which Cavanilles speaks as likely to be published. This supposed genus, however, is now sunk in *WEDELIA*; see that article.

ALCOHOL, in *Chemistry*. A new analysis of alcohol has been lately published by M. de Sauffure. He employed for his analysis alcohol of the sp. gr. .8302, at the temperature of 62.8, obtained by rectifying common spirits. This alcohol he considered as a compound of 13.8 water, and 86.2 of the Richter's absolute alcohol; and the water being subtracted from the products obtained, the residue gave the composition of the absolute alcohol of Richter. His method of analysis was to pass the vapour of alcohol through a red-hot porcelain tube, and along a glass tube surrounded by ice nearly six feet in length. The products were carefully collected and weighed. There was a little charcoal deposited in the porcelain tube, and a very little oil in the glass tube. The water obtained amounted to $\frac{14.0}{100}$ of the weak alcohol employed, which was 1256.7 grs., and it contained $\frac{3.7}{100}$ of its weight of absolute alcohol. The combustible gas weighed 912.3 grs., and there was a loss of 55.82 grs. The gas was proved to possess the properties of olefiant gas. Hence it follows that alcohol may be considered as composed of olefiant gas and water; and the result of the analysis was, that the absolute alcohol of Richter is composed of

A L E

Hydrogen - - -	13.70
Carbon - - -	51.98
Oxygen - - -	34.32
	100.00

Or the composition may be stated thus:

Olefiant gas - - -	61.63
Water - - -	38.37
	100.00

If, with Dr. Thomson, we suppose alcohol to be a compound of one volume of olefiant gas, and one volume of vapour of water, condensed into one volume, its specific gravity in a state of vapour will be just equal to that of these two elastic fluids added together. The specific gravity of these two bodies is,

Olefiant gas - - -	.974
Vapour of water - - -	.625
	1.599

And M. Gay Lussac determined by experiment the specific gravity of the vapour of alcohol to be 1.613, which very nearly coincides with the above. Hence there is every reason for presuming that the above is the true composition of alcohol, which, stated more correctly on this supposition, will be as follows:

3 atoms hydrogen - - -	3.75
2 atoms carbon - - -	15.
1 atom oxygen - - -	10.
	28.75

Or per cent. of

Hydrogen - - -	13.04
Carbon - - -	52.17
Oxygen - - -	34.79
	100.00

Or,

Olefiant gas - - -	60.86
Vapour of water - - -	39.14
	100.00

See FERMENTATION, *Addenda*.

ALCOHOL of Sulphur, now generally termed *sulphuret of carbon*, is a curious compound of sulphur and carbon, first described by Lampadius. See CARBON, and particularly SULPHUR, in the Cyclopædia; where the recent experiments of Berzelius and Dr. Marcet on this substance are detailed.

ALDRICH, col. 2, l. 5, *r.* ascribed to him, but, as some say, erroneously.

ALE, col. 2, l. 28, after parliament, add—The gross duty on ale, or strong beer, is 10s. per barrel, with an allowance of 10d., so that the nett duty is 9s. 2d. For table-beer not worth more than 24s. the gross duty is 2s. per barrel, with an allowance of 2d., so that the nett duty is 1s. 10d.

By 48 Geo. III. c. 143. the several duties imposed upon
ale-

ale-licences by former acts were repealed, and a new duty of 2*l.* 2*s.* imposed. All persons who shall sell ale or beer by retail, or shall sell cyder or perry, to be consumed in their houses or premises, shall first take out an excise-licence, within the limits of the chief office of excise in London, under the hands and seals of two or more of the commissioners of excise in England, or of such persons as they, or the major part of them, shall appoint for that purpose: and in other parts of England, the licences are to be granted under the hands and seals of the several collectors and supervisors of excise within their respective districts. The duration of such licences is limited to the 10th of October next ensuing the time of granting thereof. All licences granted at the general licensing day shall be made for one year only, to commence on the 29th day of September.

ALE-Houses, l. 4, after houses, add—under penalty of 3*l.* 6*s.* 8*d.* 5 & 6 Ed. VI. c. 25. 26 Geo. II. c. 31.

L. 9, after cofts, add—But no person shall be liable to the said penalty, for selling ale or beer in casks containing not less than five gallons, or in bottles, not less than two dozen quarts, not to be drank in his house, out-house, yard, garden, orchard, or other place. 38 Geo. III. c. 54. Penalties may be mitigated for the first offence; and all penalties shall be sued for and determined within six months after the offence committed.

L. 15, after only, add—The day and place for granting licences shall be appointed by two or more justices for the division, by warrant under their hands and seals, at least ten days before such meeting, directed to the high constables, requiring them to order their petty constables, or other peace officers, to give notice to the several inn-keepers and alehouse-keepers within their respective constablewicks, of the day and place of such meeting: and all licences granted at any other time and place shall be void. And no licence shall be granted to any person not licensed the year preceding, (except in cities or towns corporate,) unless he produce a certificate under the hands of the minister and the major part of the churchwardens and overseers, or else of three or four reputable and substantial householders of the place, setting forth that such person is of good fame and of sober life and conversation; and it shall be mentioned in such licence that such certificate was produced, otherwise the licence shall be void. No justice of the peace, being a common brewer of ale or beer, inn-keeper, or distiller, or a seller of and dealer in ale or spirituous liquors, or interested in any of the said trades, or being a victualler or maltster, shall be capable or have any power to grant licences for selling ale or beer, or any other liquors, but the same shall be void. All mayors, town-clerks, and other persons whom it may concern, shall make out ale-licences duly stamped before the recognizance be taken; on pain of 1*l.*, half to the king, and half to the prosecutor, with cofts. 6 Geo. c. 21. 1 Ann. stat. 2. c. 22.

L. 18, after tipping, &c. add—1 Jac. c. 9. 1 Ch. c. 4. By 21 Jac. c. 7. innkeepers who suffer tipping are disabled from keeping an ale-house for three years. By 30 Geo. II. c. 24. if any person licensed to sell any sorts of liquors, or who shall sell or suffer the same to be sold in his house, out-house, ground, or apartment thereto belonging, shall knowingly suffer any gaming with cards, dice, draughts, shuffle-boards, mississippi, or billiard-tables, skittles, nine-pins, or with any other implement of gaming in his house, out-house, ground, or apartment thereunto belonging, by any journeymen, labourers, servants, or apprentices, and shall be convicted thereof on confession, or

oath of one witness, before a justice, within six days after the offence committed; he shall forfeit for the first offence 4*0*s.** and for every other offence 1*0*l.** by distress by warrant of such justice; three-fourths of which shall be to the churchwardens for the use of the poor, and one-fourth to the informer.

And if any journeyman, labourer, or apprentice, or servant, shall game in any house, out-house, ground, or apartment thereto belonging, wherein any liquors shall be sold, and complaint thereof shall be made on oath before one justice where the offence shall be committed, he shall issue his warrant to the constable or other peace-officer of the place wherein the offence is charged to have been committed, or where the offender shall reside, to apprehend and carry the offender before some justice of the place where the offence shall be committed, or where the offender shall reside; and if such person shall be convicted thereof by the oath of one witness or confession, he shall forfeit not exceeding 2*0*s.** nor less than 5*s.* as the justice shall order, every time he shall so offend, and be convicted as aforesaid, one-fourth to the informer, and three-fourths to the overseers for the use of the poor; and if he shall not forthwith pay down the same, such justice shall commit him to the house of correction, or some other prison of the place where he shall be apprehended, to be kept to hard labour for any time not exceeding one month, or until he shall pay the forfeiture.

If any person (allowing for some excepted cafes under 1 J. c. 9.) shall continue drinking or tipping in any inn, victualling-house, or ale-house, he shall on conviction thereof before a mayor or justice of the peace on view, confession, or oath of one witness, forfeit for every offence 3*s.* 4*d.*, to be paid within one week next after the conviction to the churchwardens, who shall be accountable for the same to the use of the poor; and if he shall refuse or neglect to pay the same, it shall be levied by distress. And if he be not able to pay the forfeiture, then the mayor, justice, or court where the conviction shall be, may punish the offender, by setting him in the stocks for every offence by the space of four hours. 1 J. c. 9. 4 J. c. 5. f. 4. 21 J. c. 7. f. 2. 1 C. c. 4.

If any alehouse-keeper shall be convicted of the said offence, he shall moreover for the space of three years be disabled to keep any such ale-house. 7 J. c. 10. 21 J. c. 7. f. 4.

ALECTORIA, in *Botany*, seems to derive its name from *αλεκτωρ*, unmarried, because nothing has been made out respecting the male flowers. This is one of the tribe of filamentous Lichens, established as a genus by Acharius, (see LICHENES,) and we shall endeavour to explain its characters.—Achar. Syn. 291. Lichenogr. t. 13. f. 1.—4. Sm. Prodr. Fl. Græc. Sibth. v. 2. 323.—Class and order, *Cryptogamia Alga*. Nat. Ord. *Lichenes*.

Ef. Ch. Frond cartilaginous, branched; spongy within. Shields fleshy, thick, bordered, flatish, of the substance of the frond; their disk slightly coloured.

1. *A. jubata*. Wiry Alectoria, or Rock-hair. Achar. n. 1. Prodr. Fl. Græc. n. 1. (Parmelia jubata; Achar. Meth. 272. Lichen jubatus; Linn. Sp. Pl. 1622. Achar. Prodr. 219. Westring Lich. 183. t. 14. Engl. Bot. t. 1880. Schrad. Journ. v. 1. 83. t. 3. f. 4. Unea jubata nigricans; Dill. Musc. 64. t. 12. f. 7.)

2. Lichen chalybeiformis; Linn. Sp. Pl. 1623. Achar. Prodr. 220. (Unea rigida, horum-vorsum extensa; Dill. Musc. 66. t. 13. f. 10. Parmelia jubata ð; Achar. Meth. 273.)

Frond thread-shaped, smooth, very much branched, of a smoky-

a smoky-brown; branches capillary, compressed at their subdivisions. Shields sessile, blackish, with an entire margin; at length convex and rugged. Warts tumid, powdery, white.—Found on the trunks and branches of old trees, especially of the fir kind, throughout Europe, from Lapland to the Bithynian Olympus. β . On pales, rocks, and stones. The shields are extremely rare. The older specimens hang in long blackish tufts, like the mane of a horse, from aged trees in mountain forests; the variety β grows prostrate and entangled. There is no central fibre, the inside being hollow, or slightly spongy. White powdery warts are frequent and conspicuous on the pendulous variety, but these are not now considered by Acharius as having any share in the fructification. The matter has not been decided either way by sufficient experiments. The learned author, whom we have just named, reckons up four more varieties, by the names of *capillaris* (which is *Lichen fetiformis* of Ehrhart); *lanestris*; *cana* (figured by Westring above cited, at his t. 14. f. B.); and *setacea*. These we have not examined. The *cana*, which is hoary, with pale flesh-coloured shields, appears to have some claims to specific distinction.

2. *A. crinalis*. Mane Alecatoria. Achar. n. 2. *Lichenogr.* 594.—“Fronde slightly compressed, much branched, greyish, very brittle; branches thread-shaped, roundish towards the upper part. Shields? convex, brown.”—Found often mixed with other filamentous Lichens, on the trunks and branches of trees. *Acharius*.

3. *A. usneoides*. Flattened Alecatoria, Arabian Usnea. Achar. n. 3. (*Parmelia usneoides*; Achar. Meth. 270. *Lichen Usnea*; Linn. Mant. 131. Swartz Ind. Occ. 1912. *Usnea ceratoides candicans, glabra et odorata*; Dill. Musc. 71. t. 13. f. 14? and certainly t. 84. f. 10.)—Fronde compressed, flat, longitudinally striated, much branched, pale and whitish; the branches somewhat fibrous. Shields flat, entire, of the same colour.—On trees in warm countries, in Asia, Africa, and America. Generally pendulous, always spreading, from six to eighteen inches long, linear, flat, cream-coloured, very smooth to the touch; fragrant and musky when fresh; easily splitting when old and dry into two flat layers, exposing a pure white internal powder. The shields are very small. By age the whole becomes of a dirty-buff colour. The Arabian physicians used this moss as a cordial, and thought it also procured sleep. See our n. 6.

4. *A. farmentosa*. Trailing Alecatoria. Achar. n. 4. (*Parmelia farmentosa*; Achar. Meth. 271. *Lichen farmentosa*; Achar. Prodr. 180. New Stockh. Transf. v. 16. 212. t. 8. f. 2. Schrad. Journ. v. 1. 83. t. 3. f. 4. Engl. Bot. t. 2040. L. longifissum, ex cinereo candicans, rugosus et mollior, receptaculis florum rufescentibus; Michx. Gen. 77. t. 39. f. 2. *Usnea loris* dichotomis, extrematibus tenuioribus; Dill. Musc. 59. t. 11. f. 2. U. dichotoma; Hoffm. Pl. Lich. t. 72.)—Fronde roundish, somewhat angular and pitted, much branched, forked and divaricated, whitish; ultimate branches capillary and lax. Shields livid, rather concave, with a pale entire border.—Native of mountainous tracts in various parts of Europe, on trees or rocks. Mr. Borrer and Mr. Hooker met with it on the mountains of Inverness-shire in 1808. The fronds are of an ivory white, creeping, widely divaricated, sometimes powdery, hollow; their ultimate branches peculiarly fine and numerous. Shields, communicated by Dr. Acharius, small, with a greenish flesh-coloured hollow disk, finally becoming flattened and dilated.

5. *A. thrausta*. Brittle Alecatoria. Achar. n. 5. *Lichenogr.* 596.—“Fronde round, somewhat compressed, branched,

white; black at the base; branches unequal, zigzag, minutely fibrous and somewhat tendril-like.”—Native of France and Switzerland. *Acharius*.

6. *A. arabum*. Arabian Alecatoria. Achar. n. 6. *Lichenogr.* 596. (*Usnea ceratoides candicans, glabra et odorata*; Dill. Musc. 71. t. 13. f. 14.)—Fronde round, somewhat compressed, branched, white; branches forked; the ultimate ones pointed and curved.—Native of the East Indies, St. Helena, and Madagascar. Professor Acharius adopts this from Dillenius without examining a specimen, considering it a distinct species from his *usneoides*, n. 3, with which other botanists have confounded it. He relies also on Dillenius for the present plant being the true *Usnea* of the Arabians. But as Dillenius confounded the two, and had no authority for taking one more than the other for the Arabian *Usnea*, we cannot place any reliance on him in this respect. How far the two plants, so very similar in his figures, are specifically distinct, can only be known by an examination of the specimen of his t. 13. f. 14. at Oxford. The other is sufficiently well known, and was drawn by him from the herbarium of Mr. Charles Du Bois.

7. *A. canariensis*. Canary Alecatoria. Achar. n. 7. (*Usnea dichotoma compressa, fomentis capillaceis terribus*; Dill. Musc. 72. t. 13. f. 15. *Muscus arboreus aurantiacus, flaminibus tenuissimis, ex insulis Fortunatis*; Pluk. Almag. 254. Phyt. t. 309. f. 1.)—Fronde compressed, branched, orange-coloured; branches simply or triply forked; their ultimate segments round and capillary.—Native of the Canary islands. Acharius adopts this species entirely from Dillenius, who describes it from a span to a foot in length, compressed, undivided in the lower part, but in the upper copiously and repeatedly branched; the branches occasionally three together, and their summits very fine. The whole is neither very rigid, nor soft, smoothish, of a dull yellow inclining to red. It tinges the saliva with a reddish-orange colour, but has no particular smell.

ALEMERT, col. 4. l. 28, for Memoires r. Membres. ALEPYRUM, in *Botany*, *a. without, xeruous, a bark, fibell, or covering*, alluding to the want of corollaceous glumes, by which this genus is distinguished from *DEVAUXIA* of the same author, to be described in its proper place hereafter.—Brown Prodr. Nov. Holl. v. 1. 253.—Class and order, *Monandria Polygynia*. Nat. Ord. *Restiacae*, Brown.

Gen. Ch. *Cal.* Sheath of two concave, keeled, permanent valves, clasping each other at the base, containing one or more flowers. *Cor.* none. *Stam.* Filament one, capillary, drooping, about as long as the calyx; anther simple, oval. *Pyl.* Germens several, from six to eighteen, ovate-oblong, superior, inserted into one side of a central oblong receptacle, and all turned one way; styles as many, thread-shaped, combined at the bottom, spreading or deflexed at the upper part; stigmas linear, downy. *Peric.* Capsules as many as the germens, membranous, oval, of one valve and one cell, bursting longitudinally at one side. *Seed* solitary, obovate, pendulous.

Ess. Ch. Sheath of two valves. Corolla none. Anther simple. Germens unilateral. Capsules bursting longitudinally at one side. Seed solitary.

A genus of small herbaceous plants, nearly allied to the more numerous one of *Devauxia*, and, in Mr. Brown's own opinion, scarcely to be separated therefrom, the want of petals in *Alepyrum* being the only difference. The three species described by this author are all natives of the south coast of New Holland, where he gathered them himself; nor do they appear to have been met with by any other botanist or collector. The roots are fibrous. *Leaves* radi-

cal, simple, linear-lanceolate, or fetaceous. *Flower-stalks* radical, unbranched, single-flowered.

1. *A. polygonum*. Many-jointed Alepyrum.—Sheath single-flowered; the outer valve with a leafy point. Germans from fifteen to eighteen. Stalk twice or thrice the length of the leaves.

2. *A. pumilio*. Dwarf Alepyrum.—Sheath single-flowered; the outer valve with a leafy point. Germans from six to nine. Stalk the length of the leaves.

3. *A. muticum*. Pointless Alepyrum.—Sheath with a few flowers; the outer valve pointed.

ALEXANDER, in *Geography*, a township of Ohio, in the county of Athens, having 765 inhabitants.

ALEXANDRIA, col. 6, l. 24, for Anafatius r. Anatolius.

ALEXANDRIA, a town of New Russia, &c. add—Also, the principal Russian settlement in the Fox islands, and the residence of the governor on the island of Kodiak. (See KODIAK and Fox Islands.) The harbour is excellent, and sheltered by several small islands lying to the S.W. It consists of about 50 houses built of logs, the rooms of which are caulked with moss, and covered with grass. This is the principal depôt of the African company, where the furs are collected. This town is named St. Paul by captain Lilliansky. It has a church, a barrack for the Russian convicts, a school, and several store-houses belonging to the N.W. Company. Campbell's Voyage round the World, p. 108.

ALEXANDRIA, in Grafton county, &c. for 298 r. 409.

ALEXANDRIA, in Hunterdon county, &c. for 1503 r. 2271; and for 40 r. 46.

ALEXANDRIA, in Pennsylvania. Add, containing, in 1810, 156 inhabitants.

ALEXANDRIA, a town of the district of Columbia, having 7227 inhabitants, of whom 1488 are slaves. The county of the same name, exclusive of the town, has 1325 inhabitants, including 353 slaves.

ALFORD, l. 2, for 577 r. 322.

ALFORD, a town of America, in the district of Maine and York county, containing 1106 inhabitants.

ALFRED, l. 7, for tenth r. fourth.

ALFRED, of Beverley. Subjoin—See ALRED.

ALGEBRA, *Specious*, l. 4 from bottom, for four r. three. Col. 2, l. 22, for + r. —, or a + b — c — d. Line 35, for a + b r. a + c.

ALGOA BAY. Subjoin—By Barrow's chart, Cape Recif in this bay is in S. lat. 34° 10'. E. long. 25° 40'. Variation 26° 40'.

ALIEN. Subjoin—It is also continued by the parliament of 1818.

ALIENS Duty. Add—See BOOK of Rates.

ALKALI, *New fixed*, in *Chemistry*. See LITHION.

ALKALI, *New Compound from Opium*. See MORPHIA and OPIUM.

ALKALINE ACRIMONY, l. 3, for four r. four.

ALL SFUGITA r. ALLA *Sfugita*.

ALL SOULS, l. *ult.*, for Joxtin r. Jortin.

ALLALITE. See MINERALOGY, *Addenda*.

ALLANITE. See MINERALOGY, *Addenda*.

ALLANTODIA, in *Botany*, from $\alpha\lambda\lambda\alpha\iota$; $\alpha\lambda\lambda\alpha\iota\sigma$; a *sausage*, alluding to the tumid oblong figure of the *Sori*, or lines of capsules, wrapped in their membranous coverings.—Brown Prodr. Nov. Holl. v. 1. 149.—Clats and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

En. Ch. Fructification in scattered oblique lines, accompanying a vein. Involucrum vaulted, originating laterally

from the vein, and inserted into it by both margins; at length separating at the inner one.

The habit of this genus, says Mr. Brown, is between NEPHRODIUM and DIPLAZIUM. (See those articles.) *Polypodium umbrosum*, Hort. Kew. ed. 1, affords an example of it, and there are some unpublished species. The cylindrical *involucrum* prohibits its union with *Aspidium* or *Athyrium* of various authors, and that membrane, being inserted by both margins into the same vein, and truly bursting, differs from the *involucrum* of *Asplenium*, whose upper edge is not connected with the frond.

We select the examples indicated by the author, not being quite satisfied of the limits of this genus, which is reduced to *Aspidium* in the second edition of Hort. Kew. possibly not with Mr. Brown's concurrence, his most indubitable genus of WOODSIA (see that article) being likewise there rejected.

We are possessed of many, perhaps of all, the nondescript *Allantodia* of which he speaks. To these some other *Aspidia* of Hort. Kew. may be akin; but *A. emulum*, placed next to *umbrosum*, is not one of them, any more than a few of the neighbouring species, referred by the writer of this article to *Cyathea* in Fl. Brit. whose *involucrum* surely does not answer to the above character, their *sori* being orbicular.

A. umbrosa. Madeira Wood Sausage-fern. (*Polypodium umbrosum*; Ait. Hort. Kew. ed. 1. v. 3. 466. *Aspidium umbrosum*; ed. 2. v. 5. 513. Willd. Sp. Pl. v. 5. 283. *A. axillare*; Schkuhr Crypt. t. 61.)—Frond triply pinnate; ultimate segments lanceolate, decurrent, deeply ferrated; the lower ferratures cleft. Lines contiguous; finally confluent.—Gathered in shady woods in Madeira, by the late Mr. Masson, who sent roots to Kew, in 1779, and gave specimens to the younger Linnæus. An elegant finely divided fern, about three feet high, with roughish *stalks*. *Leaflets* two or three inches long, and nearly one broad, pointed, pinnatifid almost to the mid-rib; the segments numerous, parallel, oblong, obtuse, decurrent, veiny, smooth, of a fine green; most ferrated at their extremity and upper margin; one or two of the lower ferratures often cleft at the point. *Lines* most copious about the lower part of each leaflet. *Capsules* brown. *Involucrum* pale, variously torn and reflexed.

A. australe. Southern Sausage-fern. Br. n. 1.—Frond doubly pinnate, deltoid, membranous, flaccid. *Leaflets* pinnatifid, tapering at the point; lobes oblong, obtuse, deeply ferrated, many-flowered. *Involucrum* oblong.—Native of Van Diemen's island.

A. tenera. Tender Sausage-fern. Br. n. 2.—Frond doubly pinnate, membranous, flaccid. *Leaflets* pinnatifid; lobes oblong, obtuse, ferrated, flowering at the base. *Spots* linear.—Gathered by Mr. Brown, in the neighbourhood of Port Jackson, New South Wales.

The *Aspidium axillare*, Willd. Sp. Pl. v. 5. 278. Ait. ed. 2. v. 5. 512, should seem, if the specific character of Willdenow were right, to belong to the present genus. But we suspect that character to have been taken from something else. The *sori* are by no means *recti*, or straight; but remarkably recurved, much beyond kidney-shaped, finally assuming almost the peltate form of a real *Aspidium*. In an early state indeed they are straight; but the inner margin is loose, dilated, and fringed. In habit nothing can be more closely allied to *Allantodia umbrosa* than this *Aspidium axillare*.

ALLASIA, from $\alpha\lambda\lambda\alpha\iota$; a *sausage*, or *black-pudding*, in reference to the shape and colour of the fruit.—Lourei. Cochinch. 84.—Clats and order, *Tetrandria Monogynia*. Nat. Ord. *Cucurbitaceae*, Linn. Juss.

Gen. Ch. *Cal.* of one leaf, inferior; tube short; limb in five,

five, rather acute, hairy segments. *Cor.* superior, of four small, roundish, concave, very hairy petals. *Stam.* Filaments four, awl-shaped, thick, about the length of the calyx; anthers inverted, two-lobed, each lobe of two cells. *Pist.* *Germen* roundish, between the calyx and corolla; style awl-shaped, the length of the stamens; stigma acute. *Peric.* Berry large, oblong, obtuse, smooth, fleshy, pendulous, of one cell. *Seeds* numerous, ovate, tumid, somewhat compressed, imbedded in pulp.

Eff. Ch. Berry with numerous seeds. *Germen* between the five-cleft calyx, and corolla of four petals.

1. *A. payos.* Black-pudding tree. *Muringuringue* of the Africans.—Observed by Loureiro, at Mozambique, near the eastern coast of Africa. A large tree, with spreading branches, destitute of thorns. *Leaves* opposite, digitate, of five oval, entire, hairy leaflets. *Stalks* many-flowered, nearly terminal. *Fruit* reddish-brown. A cataplasm of the leaves, applied to the back, below the kidneys, is said to promote delivery. Loureiro compares his plant, as to the leaves and fruit, with the *Sarcocolla*, Pfl. Raf. 160. It is easy to trace the natural order of this *Alliaja*, and its relationship to *Carica*. Having seen no specimens, we cannot undertake to correct some apparent inaccuracies, nor to define the real character of the genus; neither is it necessary here to criticize, or to alter, the generic or specific name.

ALLEGANY, in *Geography*, a county of New York, containing 1942 inhabitants, of whom 21 are slaves.

ALLEGHANY, or ALLEGHANY County, l. 5, for 10,309 r. 25,317, and for 159 r. 24.

ALLEGHANY, in Maryland, l. 5, for 4809 r. 6909, and for 258 r. 620. Add—Also, a township of Pennsylvania, in Cambria county, having 610 inhabitants.—Also, a township of Pennsylvania, in the county of Armstrong, containing 820 inhabitants.—Also, a township of Pennsylvania, in Somerset county, having 271 inhabitants.—Also, a township of Pennsylvania, in the county of Venango, having 299 inhabitants.—Also, a township of Huntingdon county, in Pennsylvania, with 1159 inhabitants.

ALLEN, a township of Pennsylvania, in Cumberland county, having 1837 inhabitants.

ALLENSTOWN, l. 2, for 254 r. 346.

ALLEN-TOWN, for 90 houses r. 129 t inhabitants.

ALLIGATOR, after LACERTA infer, see LIZARD.

ALLIUM, in *Botany*, an ancient Latin name, of which many different etymologies have been proposed, but none has been thought perfectly satisfactory, is deduced by De Theis from the Celtic, *all*, signifying hot, pungent, or burning, than which nothing can be more suitable, whether we consider the various kinds of Garlic, Onions, &c. in common use, or the numerous wild ones. Several species require to be added to the fifty-seven enumerated by our predecessor, the late Dr. Woodville, in the first volume of this work. (See ALLIUM.) We shall indicate their respective places in each section, interpersing, in the same order, a few remarks concerning other species.

SECT. 1. *Stem leafy. Leaves flat. Umbel bearing capsules only.*

1. *A. Ampeloprasum.* Willd. Sp. Pl. v. 2. 63. n. 1. Engl. Bot. t. 1657. Fl. Græc. t. 312, unpubl. Curt. Mag. t. 1385.

β. Smaller, with sweet-smelling bright crimson flowers.—This variety is a native of the Cape of Good Hope, being the *A. Ampeloprasum* of Thunb. Prodr. 65. It must not be confounded with the β of Curt. Mag. 1385, Waldf. and Kitaib. Hung. v. 1. 84. t. 82, which Mr. Ker now thinks a variety of *arenarium*, deprived of its flower-bulbs. The fame botanist, so deeply skilled in the plants of this natural

order and their allies, has expressed, like Linnæus, an opinion of the real *Ampeloprasum* not being specifically distinct from the garden Leek, *A. Porrum*, n. 2. It seems to us that the simply sheathed biennial root of this latter is essentially different from the large, globose, aggregate, perennial bulbs of the other; and the keels of the petals in *Porrum* are certainly much less rough, if ever at all so, than those of *Ampeloprasum*. A good figure of *A. Porrum* is much wanted.

Between 2 and 3. *A. Discocoris.* Sibth. in Prodr. Fl. Græc. n. 764. (μῶνυ; Diof. book 3, chap. 4.)—Found in dense bushy shady situations, in Caria, Mytia, and Cyprus. “The stem, in a rich soil, sometimes attains the height of five or six feet. Umbel large. Flowers white, somewhat resembling those of *Peganum Harmala*, as Diofcorides observes in speaking of the latter plant, book 3, chap. 53.” Such is all the information afforded by Dr. Sibthorp’s MSS., for he has left no specimen nor drawing of this interesting plant, supposed by him to be the μῶνυ, or *Moly*, of Diofcorides. He has not afforded us any materials for a specific character. Can his plant be the *A. orientale latifolium*, flore magno lacteo; Tourn. Cor. 26? Of this a specimen may perhaps be found, in the collections at Paris or Oxford.

SECT. 2. *Stem leafy. Leaves flat. Umbel accompanied by bulbs.*

Here perhaps ought to have been inserted, on account of its near affinity to *rosulum*, our *ambiguum*, figured in Curt. Mag. t. 978, and destined to appear in Fl. Græc. t. 327. See Sect. 4.

SECT. 3. *Stem leafy. Leaves nearly cylindrical. Umbel bearing capsules only.*

20, 21. *A. margaritaceum.* Pearly Garlick. Sm. Prodr. Fl. Græc. Sibth. n. 770. Fl. Græc. t. 315, unpubl.—Stem bearing round leaves and an umbel of capsules. Leaves channelled. Stamens three-pointed, prominent. Petals obovate, obtuse.—Gathered by Dr. Sibthorp, about Prusa in Bithynia, as well as on mount Athos, and in the islands of Naxos, Cyprus, and Cimolis. The bulb is about the size of a filbert, coated with brown ribbed scales. *Stem* solitary, a foot high, erect, round, slender, leafy in its lower half. *Leaves* about four, spreading, tapering, as thick as a crow’s quill, rather glaucous, smooth, six inches long; channelled along the upper side; sheathing at the base; the two lowermost shorter and soon withering. *Umbel* erect, oval, obtuse, dense, attended at the base by several short, reflexed, jagged, white involucreal scales. *Flowers* on slender, ascending or upright, simple stalks, an inch long at most. *Petals* obovate, concave, not a quarter of an inch in length, converging, streaked with green, white at the edges, purple at the keel. *Stamens* white; three of them simple, awl-shaped; three linear, with two long, lateral, spreading, narrow segments. *Germen* turbinate, with six prominent angles.

26, 27. *A. caucasicum.* Crimfon Caucasian Garlick. Ker in Curt. Mag. at the end of p. 1143. (*A. paniculatum*; ibid. t. 973, but not t. 1432. *A. globosum*; Redout. Liliac. t. 179, not t. 96 !)—*Stem* bearing thread-shaped sheathing leaves, and an umbel of capsules. One valve of the sheath elongated and cylindrical. *Stamens* simple. *Petals* ovate, acute. *Germen* globose.—Native of mount Caucasus. Raised by Mr. Loddiges, from seeds imported from Russia. The cylindrical leaves, globose umbel, shorter involucreum, ovate, not obovate petals, and round, even, not oblong and channelled, *germen*, as well as the rose-coloured flowers, are sufficient marks of distinction between this plant and *A. paniculatum*, of which an imperfect figure, representing the leaves as cylindrical (contrary to nature and the description) is given in Curt. Mag. t. 1432.

A. montanum. Crimson Olympian Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 775. Fl. Græc. t. 319, unpubl. (*A. montanum*, radice oblongâ; Tournef. Inst. 384, according to Sibthorp.)—Stem bearing nearly cylindrical leaves, and an umbel of capsules. Sheath elongated, deflexed. Stamens simple. Flower-stalks uniform.—Found in the grassy pastures of the Bithynian Olympus, by Dr. Sibthorp. The *bulb* is ovate-oblong, red, with a ribbed angular coat, fibrous at the summit. *Stem* four or five inches high, smooth, round, bearing about two slender, smooth, grass-green leaves, a little channelled on their upper side, one of them rising above the *umbel*, which is rather lax. *Petals* obovate, pale rose-coloured with a crimson mid-rib. *Germen* ovate-oblong, with six deep furrows.

A. stictiforme. Thrift-like Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 776. Fl. Græc. t. 320, unpubl.—Stem bearing nearly cylindrical leaves, and an umbel of capsules. Stamens simple. *Germen* three-lobed. Umbel many-flowered, somewhat capitate.—Gathered by Dr. Sibthorp, in the ile of Cimolis. The *bulb* is globular, about the size of a hazel nut, with several lateral offsets. *Stem* a span high, reddish. *Leaves* about three, shorter than the stem, recurved, with striated reddish sheaths. *Umbel* dense, of about an inch and a half in diameter, rose-coloured. *Petals* obovate. *Germen*, as well as the *capsule*, turbinate, abrupt, of three rounded lobes.

A. pilosum. Hairy-leaved Crimson Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 777. Fl. Græc. t. 321, unpubl.—Stem bearing nearly cylindrical leaves, and an umbel of capsules. Stamens simple. Leaves and their sheaths very hairy.—Found by Dr. Sibthorp in the island of Cimolis, and we believe in the Peloponnesus also. *Bulb* globular, small, purplish. *Stem* a span high. *Leaves* about four, spreading, tapering, remarkably rough with spreading hairs, as are likewise their long, striated, purplish sheaths. *Umbel* lax, hemispherical, many-flowered, smooth, the *flowers* and their *stalks* of a pale purplish crimson. *Petals* elliptic-obovate, obtuse. *Germen* of three hemispherical lobes, not turbinate.

A. junceum. Rush-leaved Purple Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 778. Fl. Græc. t. 322, unpubl.—Stem bearing thread-shaped leaves, and an umbel of capsules. Three alternate stamens five-cleft. Umbel capitate.—Discovered in the island of Cyprus, by Dr. Sibthorp, who took it for *A. Schoenoprasum*, from which, however like at first sight, it differs essentially. Our plant is more allied to *A. ascalonicum*, but still distinct, and the stem is truly leafy. *Bulbs* aggregate, ovate, with dark-brown, striated, elongated coats. *Stem* a foot high, slender, erect, leafy about one-third of its height. *Leaves* two, nearly as tall as the stem, very slender, tubular, quite round, smooth, a little glaucous, somewhat spreading at the top. *Umbel* globular, dense, its *sheath* of two broad, ovate, acute, concave, close leaves, shorter than the flowers. *Flower-stalks* green, but half the length of the *petals*, which are elliptic-oblong, acute, purplish, with a darker mid-rib. *Stamens* white; three of them simple, awl-shaped, the intermediate ones flat, dilated upwards, terminating in two taper vertical teeth, on each side of a similar one bearing the *anther*. *Germen* elliptical, with three slight furrows.

SECT. 4. *Leaves radical. Common Flower-stalk naked.*

35. *A. inodorum*. Carolina Garlic. Ait. Hort. Kew. ed. 1. v. 1. 427. ed. 2. n. 25. Willd. n. 33. Curt. Mag. t. 1129. (*A. fragrans*; Venten. Hort. Cels. t. 26. Redout. Liliac. t. 68. Pursh n. 2.)—"Stalk naked, obscurely triangular. Leaves linear, flat; keeled at the back. Umbel level-topped, capsule-bearing. Stamens simple."—On the

mountains of Virginia and Carolina, flowering in June. Perennial. *Flowers* white, with red veins. *Pursh*, who had seen it living. It is marked in *Hort. Kew.* as a hardy perennial, flowering in March and April, and introduced by the late Duchesse Dowager of Portland, in 1776. We presume Dr. Solander to be the author of the above characters, given in *Hort. Kew.*, and that the plant of the Botanical Magazine and that of Redouté are the same, though in the former work the *petals* are obovate, and remarkably elongated at the base; in the latter ovate, without any such elongation. One or other is a great, and very material, error, but not having seen the plant, we know not where the fault lies. There are errors also in the detail of its history. *Redouté* t. 6 for 68; *Venten. Malmaif.* copied by Pursh from the Magazine, for *Venten. Hort. Cels.*, which proving that the work was not consulted by Pursh, takes away our confidence in that author, as to synonyms. The name *inodorum* is acknowledged to express the want of the Garlic factor in the herbage, while that of *fragrans* alludes to the sweet scent of the *flowers*. We retain the original appellation. Mr. Ker, at the end of the history of t. 1293, in Curt. Mag. declares his conviction that *A. gracile*, our n. 55, is the same plant. We cannot assert the contrary, but we do not feel convinced, and there has been such a diversity of opinion on the subject, that till we can compare living specimens, we must leave the question in doubt. It is remarkable that Willdenow says *A. inodorum* "is like *angulosum* of Linnæus, but twice as large, and differing in the specific character," which chiefly amounts to the *stalk* of the latter being two-edged, and the *leaves* channelled. He had both plants living. But *angulosum* is most excellently represented in Curt. Mag. t. 1149, and surely few of the genus can bear less resemblance to t. 1129! It is scarcely more like Redouté's figures, named *fragrans*. We proceed to notice the species most akin to *inodorum*; for so at least it must be presumed to be.

35, 36. *A. gracile*. Jamaica Garlic. (See our n. 55.) Dryander. in Ait. Hort. Kew. v. 1. 429. ed. 2. n. 38. Willd. n. 52. Andr. Repos. t. 107. Ker in Curt. Mag. at the end of p. 1293, var. 1. (*A. striatum*; Redout. Liliac. t. 50. Curt. Mag. t. 1035? and t. 1524.)—"Stalk naked, round, very long. Leaves linear, channelled. Stamens awl-shaped, connected at the base."—Native of Jamaica, from whence it was sent to Kew, by Hinton East, esq., and flowered in the stove, in February. *Aiton*. Leaves a foot long, resembling those of a Narcissus. *Stalk* three feet high, slender. *Petals* erect, white, with claws, which are united with the *stamens* below, into a green tube. Perhaps this plant may form a distinct genus. *Dryander* as above. The writer of the present article happened to be with Mr. Dryander, when the original specimens of this *Allium* were brought from Kew, and on being asked for a name suggested the above. He then obtained a specimen, which is now, along with others gathered at Kew in 1788, in his herbarium, as well as one more, undoubtedly the same species, procured from Mr. Vere's collection, in 1814, as a rare plant, by the name of *A. striatum*. He can therefore speak to the whole *herb* being destitute of the Garlic odour, and to the want of scent in the *flowers*, by day at least, though they may very probably be, as reported, fragrant at night. He can also vouch for the fidelity of Mr. Andrews's figure; nor does he hesitate concerning t. 50 of Redouté; whatever scruples a deference to Mr. Ker may suggest, as to the two figures named *striatum* in Curt. Mag. The suspicion of a generic difference between this plant and *Allium*, arose in Mr. Dryander's mind, from the combination of the *flamens*, and was strengthened by the want of the garlic flavour,

flavour. The leaves are certainly not remarkably striated at the back, as in the real *striatum*, of which we shall next speak.

A. striatum. Streaked-leaved Garlick. (See our n. 37.) Jacq. Coll. v. 5. 51. Ic. Rar. t. 366. Willd. n. 35. Ait. n. 27.—Stalk naked, slightly triangular. Leaves linear, somewhat channelled; convex, with many furrows, but no keel, beneath. Umbel level-topped. Petals oblong-lanceolate. Stamens simple.—Native of the Cape of Good Hope, flowering in the garden in September and October. Whole plant smooth, without much scent. *Bulb* the size of a hazel-nut, white, coated. *Leaves* about four, all radical, six inches or more in length, linear, bluntish, oblique, but little channelled; rather convex and striated at the back, but not triangular. A transverse section, under a magnifier, shews a single row of perpendicular tubes, each running behind one of the furrows; but the leaf is not itself hollow, or tubular. *Stalk* radical, obscurely triangular, slender, erect, as tall as the leaves, or taller. *Umbel* of seven flowers, more or less, the partial stalks an inch and a half long. *Sheath* of two erect, ovate, pointed, membranous valves. *Petals* long-lanceolate, rather acute, spreading, white with a green longitudinal line in the middle. *Filaments* awl-shaped, equal, shorter than the petals. *Antthers* oblong, incumbent, yellow. *Jacquin*.

This figure and description surely do not suit our *gracile*. But whether the *striatum* does really come from the Cape, or from Virginia and Carolina, we are quite in the dark. Pursh's *striatum* is our *ornithogaloides*, n. 57. Curt. Mag. t. 1524 answers better to his description than t. 1035, but we cannot prove them the same. We have endeavoured to unravel the original materials which concern these three species, but having had no means of comparing fresh specimens, nor having indeed seen any at all of Jacquin's plant, we are unable to attempt good specific characters, and therefore leave the whole for future examination, satisfied of one thing, at least, that these species are not at present well understood. To illustrate them, great attention to the outline of the petals, shape and insertion of the stamens, and form of the germens, circumstances not yet well observed in *Allium*, will be found of primary importance.

39. *A. pedemontanum*. Red Piedmontese Garlick. Willd. n. 37. (*A. nigrum*; Allion. Pedem. v. 2. 158. t. 25. f. 1. *A. roseum*; Linn. Sp. Pl. ed. 2. 432, but not Sp. Pl. v. 1. 296.)—Stalk obscurely quadrangular. Bulb cylindrical. Leaves linear, obtuse, keeled at the back. Umbel rather dense, of few flowers. Petals elliptical.—Native of mountainous situations in Piedmont. Specimens from Alhoni and Bellardi prove this species, as distinct from *nigrum* as from *roseum*, to have been confounded by Linnæus with the latter, which has a globose, very prolific bulb, a somewhat leafy stem, and far more numerous, brighter-coloured, flowers.

39, 40. *A. stellatum*. Missouri Garlick. Ker in Curt. Mag. t. 1576. Ait. Epit. 363. (*A. angulosum*; Pursh n. 4, excluding the synonyms.)—Stalks somewhat two-edged, recurved before flowering. Bulb ovate-oblong. Leaves linear, triangular, sharply keeled. Umbel many-flowered, lax, level-topped. Stamens combined at the base. Germen depressed, bluntly triangular.—Found on the banks of the Missouri, by governor Lewis and Mr. Nuttall, flowering in July, and imported by Mr. Frazer, in whose nursery it bloomed in June 1813. Pursh by mistake says the flowers are white. In the Botanical Magazine they are represented of a deep pink, and the herbage somewhat glaucous. The stalks are two or more. The sheath is of

only one valve; but Mr. Ker doubts the permanency of that character.

A. cernuum. Bowed-umbelled Garlick. "Roth. Nov. Pl. Spec. in Roem. Archiv. n. 3. 40. Catal. Bot. fasc. 2. 33. t. 2." Sims and Kon. Ann. of Bot. v. 2. 27. Ker in Curt. Mag. t. 1324. Ait. Epit. 363.—Stalk angular; recurved at the summit. Leaves linear, slightly channelled, pointed. Umbel drooping, many-flowered. Stamens simple, twice as long as the corolla; tumid at the base. Germen turbinate.—Native of mount Caucasus, according to Mr. Aiton, who says it was introduced into England in 1801. The bulbs are oblong, tapering, aggregate. *Stalk* eighteen inches high; roundish, compressed, and recurved, at the top. *Leaves* bright-green, narrow. *Flowers* white, with a delicate rose-coloured tinge. *Petals* ovate. *Stamens* unequal at first, but finally all about twice the length of the corolla. *Germens* three-horned. *Ker*.

A. rubellum. Reddish Iberian Garlick. Marsch. Taur.-Caucas. v. 1. 264.—"Stalk nearly naked, round. Leaves semi-cylindrical, channelled. Sheath short. Umbel convex, many-flowered. Stamens simple, half as long as the corolla."—Gathered by Mr. Steven in Georgia. *Bulb* the size of a filbert. *Stalk* with one or two leaves sheathing the base, on which account the author cited doubts whether this species and the following might not be referred to the third section; but there are many of the fourth whose foliage, when the bulb is deep, becomes in some degree cauline. *Leaves* a line broad, rather fleshy. *Flower-stalks* slender, much longer than the flowers, which are hardly so big as those of *A. Ampeloprasum*, of a pale purple, with acute petals.

A. saxatile. Stone Garlick. Marsch. Taur.-Caucas. v. 1. 264. Sims and Kon. Ann. of Bot. v. 2. 436, excluding the synonym of Gmelin.—"Stalk almost naked, round. Leaves semi-cylindrical. Sheath pointed, longer than the umbel. Stamens simple, longer than the corolla."—Frequent on the lime-stone rocks of Taurida, flowering in July and August. *Bulbs* aggregate, oblong, with dark brown coats. *Stalk* with a few sheathing leaves at the base, like the foregoing. *Petals* spreading. There is a variety with purplish flowers, on the eastern mountains of Caucasia. This species is very closely related to *A. Illerianum*, Willd. n. 49, see our n. 51; but differs in having a long awl-shaped sheath. *Marschall*.

A. bisulcum. Jonquil-leaved Garlick. Redout. Liliac. t. 286. Curt. Mag. t. 1381. Ait. Epit. 363.—Bulb cylindrical. Stalk round. Leaves two-ranked, semi-cylindrical, channelled, acute. Umbel dense, convex. *Petals* oval. Filaments awl-shaped, the length of the corolla; three of them broader at the base.—Native country not known. The plant is said to be quite hardy, and of easy culture, flowering in June and July. Mr. Ker remarks its great resemblance to *sensifens*, (see n. 32.) Curt. Mag. t. 1150, next to which perhaps it ought to be placed, though akin also to our last, from which the shortness of the sheath distinguishes the present plant. The narrow and thick leaves are very different from *sensifens*; and Redouté has observed that the inner ones are channelled on both sides; which may, as Mr. Ker thinks, be occasioned by pressure in an early state.

40, 41. *A. triflorum*. Three-flowered Garlick, or Mountain Leeks. Pursh n. 5.—"Stalk naked, round, shorter than the leaves, which are lanceolate and ribbed. Umbel of few flowers."—In shady woods, on the high mountains of Pennsylvania, flowering in May and June. Perennial. *Pursh*.

44, 45. *A. lacinum*. Milk-white Garlick. Sm. Prodr. Fl.

Fl. Græc. Sibth. n. 781. Fl. Græc. t. 325, unpubl. (A. album; Bivona Sic. cent. 1. 16. "Santi Viagg. al Montam. 352. t. 7. Bertol. Gen. 51. Savi Etrusc. v. 2. 210.)—Stalk naked, triangular. Leaves lanceolate, sessile. Petals obtuse.—Native of fields in Italy and Sicily, flowering in March. This is one of those plants, which, on account of their novelty, or rarity, Dr. Sibthorp admitted into his *Flora Græca*, having gathered them in the course of his travels, though perhaps not in Greece itself. *A. laetum* agrees with *iriquetrum*, n. 44, next to which it should be placed, in having an acutely triangular stalk; but differs in the lanceolate leaves, and shorter, broader, more obtuse, petals. The stigma moreover is simple, not three-lobed.

A. ambiguum. Bulbous Rose Garlic. Sm. Prodr. Fl. Græc. Sibth. n. 783. Fl. Græc. t. 327, unpubl. (A. roseum β; Ker in Curt. Mag. t. 978. Bivona Sic. cent. 1. 18. Savi Etrusc. v. 2. 210. "A. carneum; Targioni Tozzetti Ist. Bot. ed. 2. v. 2. 242. t. 6. Moly angustifolium campanulatum, flore roseo, nodosum; Cupani Pamph. v. 2. t. 219." Moly serpentinum vocatum; Lob. Ic. 160.)—Stalk naked. Leaves semi-cylindrical. Stamens simple, shorter than the corolla. Umbel bulbiferous.—Native of Italy and Sicily, flowering in May. Frequent about Pifa. Savi. On the hills of St. Martino near Palermo. *Bivona*. This *Allium*, which, with respect to the *Flora Græca*, stands in the same predicament as the last, is made by all authors a variety of *roseum*; for the difference between the species with bulbiferous, and those with seed-bearing, umbels, is acknowledged to be, in many instances, not infallible. In the plant before us, however, there is a great disagreement, as to the character of *roseum*, which is described with flat leaves and a leafy stem. But the dried specimens are very much alike, not discovering in either the semi-cylindrical and hollow structure of the leaves, shewn by Dr. Sibthorp's figure. As to

the stem being leafy or not, many species are in this respect ambiguous, and *roseum* is perhaps improperly considered as of the former denomination. Their roots are precisely alike. The flowers of *roseum* are far more numerous, and of a finer pink hue.

We cannot conclude our survey of *Allium* without a remark that the whole genus requires to be reformed, with regard to the arrangement of the species, and the specific characters of many of them. We are also aware of several that might be added to the above list, but of which we want sufficient specimens or information clearly to dispose of them, so as to elucidate rather than confound the subject.

ALLOCHROITE. See MINERALOGY, *Addenda*.

ALLOY, in *Chemistry*, a combination of two or more metals. In addition to what has been said on this subject in the Cyclopadia, we may add the following tabular views from Dr. Thomson, of the general properties of the different alloys, as far as they have been examined. The chemistry of alloys is at present but little understood, and, as Dr. Thomson justly remarks, these compounds in general appear to be much better known to artists and manufacturers than to chemists.

The first of the following tables comprehends the alloys of the malleable metals with each other; the second, the alloys of the brittle metals; and the third, the alloys of the malleable and brittle metals. In these tables, the letter M signifies malleable; B, brittle; S, submalleable, used when the alloy is malleable in certain proportions, but brittle in others. O is used when the metals do not unite. The sign + is used when the alloy occupies a greater bulk than the separate metals; the sign — when the alloy occupies a smaller bulk. The first indicates an expansion; the second, a condensation.

ALMANAC, col. 2, l. 15, ad, see STAMP.

ALMUDE, in *Commerce*, a liquid measure in Portugal, &c. (See Table XXXII. of MEASURES.) At Lisbon, wine and oil are sold by the pipe of 26 almudes; but the pipe of Lisbon wine sent to England contains about 31 almudes, and the standard gauge at the London Custom-house is 140 gallons; the Lisbon almude is therefore reckoned at $4\frac{1}{2}$ English gallons. At Oporto, the pipe is divided into 21 almudes, which almude and its subdivisions are $49\frac{1}{2}$ per cent. greater than those of Lisbon; so that the standard gauge of a pipe of port at the Custom-house of London is 138 gallons, so that the almude of Oporto is accordingly equal to six English gallons and five pints nearly.

ALNUS, in *Botany*, the Alder, an ancient Latin name, which De Theis derives from the Celtic, *al*, near, and *lan*, the brink of a river, the letters having become transposed for easy pronunciation. This is fuitable enough to the tree in question, which always grows near water, even on the loftiest mountains, nor have we met with a better etymology.—Willd. Sp. Pl. v. 4. 334. Sm. Compend. 133. Prodr. Fl. Græc. Sibth. v. 2. 232. Ait. Hort. Kew. v. 5. 258. Pursh. 622. Raii Syn. 442. Tourn. t. 359. Gært. t. 90. (Betula, as to the character; Linn. Gen. 485. Sm. Fl. Brit. 1011. Engl. Bot. 1508. Lamarck Illustr. t. 760. f. 3. See BETULA.)—Class and order, *Monocotyledonaria*. Nat. Ord. *Amentaceæ*, Linn. Juss.

Gen. Ch. Male, *Cal.* Catkin cylindrical, imbricated every way, lax, composed of wedge-shaped, three-flowered, abrupt, three-cleft scales. *Cor.* compound, of three equal; tubular, four-cleft florets, sessile on the disk of each scale; their segments deep, equal, ovate, obtuse, spreading. *Stam.* Filaments four, minute, inserted into the base of each segment, and not quite so long as the segment; anthers of two round lobes.

Female, on the same plant, *Cal.* Catkin elliptical, imbricated, close, consisting of two-flowered, rounded, pointed, obscurely three-cleft, concave scales. *Cor.* none. *Pist.* Germens two to each scale, ovate, minute, depressed; styles two to each germen, tapering, rather longer than the scale; stigmas simple. *Seed.* Nut naked, compressed, of two cells, with solitary kernels.

Eff. Ch. Male, Calyx the scale of a catkin, of one leaf, three-cleft, three-flowered. Corolla deeply four-cleft.

Female, Calyx the scale of a catkin, of one leaf, obscurely three-cleft, two-flowered. Styles two. Nut compressed.

The presence of a *corolla* in the male flowers, with a determinate number of *filaments* equal to that of its segments, are sufficient marks of generic distinction between this genus and *Betula*, which has no *corolla* in either flower, and whose *filaments* are numerous, and indefinite. The fertile *catkin* moreover is elliptical in *Alnus*, cylindrical in *Betula*. Gærtner finds differences in the *seed*, which, if the *germen* be attended to, appear to us less decisive. By an accidental oversight, *Alnus* was neglected to be separated from *Betula*, in our PLANTS OF BRITAIN; see that article.

1. *A. glutinosa*. Common Alder. Gært. v. 2. 54. Willd. n. 1. Ait. n. 1. Sm. Compend. n. 1. Pursh n. 1. (Alnus; Matth. Valgr. v. 1. 127. Camer. Epit. 68. Lob. Ic. v. 2. 191. Ger. Em. 1477. Loef. Prull. 10. t. 1. A. n. 1630; Hall. Hist. v. 2. 300.)

β , *incisa*; leaves roundish, notched. Willd.

γ , *laciniata*; leaves oblong, pinnatifid, with acute segments. Willd. Ait. β .

δ , *quercifolia*; leaves oblong, sinuated, with obtuse segments. Willd.

Leaves roundish-wedge-shaped, obtuse, wavy, glutinous; downy at the branching of the veins beneath.—Native of

swamps and the neighbourhood of rivers and pools, in low lands, as well as on mountains, throughout Europe, the north of Asia, and of Africa, as also in Canada and on the north-west coast of America, (*Pursh.*) flowering in March or April. In landscape this tree often supplies the want of the rich dark foliage of the Oak, where the latter will not thrive. The leaves are not fully expanded till the end of May, but they remain late in autumn. For the uses and further history of this tree, see BETULA, n. 6. Our γ is the only variety cultivated for ornament, or rather curiosity, in England.

2. *A. oblongata*. Turkey Alder. Willd. n. 2. Ait. n. 2. (A. folio oblongo viridi; Bauh. Pin. 428. Hort. Angl. 5. Betula oblongata; Ait. ed. 1. v. 3. 338.)—Leaves elliptical, bluntish, glutinous; the branching of the veins naked beneath.—Native of the south of Europe. Cultivated in England ever since the year 1730, at least, but not much in request. The leaves are smaller than the foregoing, obovate, or elliptic-oblong, sharply serrated. *Catkins* of *seeds* nearly globular.

3. *A. incana*. Hoary Alder. Willd. n. 3. Ait. n. 3. (Alnus; Linn. Fl. Lapp. ed. 1. 260. A. folio incano; Bauh. Pin. 428. A. hirsuta; Bauh. Matth. 133. A. altera; Clus. Hist. v. 1. 12. A. n. 1631; Hall. Hist. v. 2. 301. Betula incana; Linn. Suppl. 417. Ait. ed. 1. v. 3. 339. Ehrh. Arb. 116. Beitr. v. 3. 22. Willd. Arb. 45. B. Alnus β ; Linn. Sp. Pl. 1394.)

β , *angulata*; leaves green beneath, with green footstalks. Ait.

γ , *pinnata*; leaves pinnate, hairy beneath; young branches hairy. Willd.

(Betula pinnata; "Lundmark in Stockh. Transf. for 1790, 122. t. 5.")—Leaves elliptic-oblong, acute; downy beneath; the branching of the veins naked. *Stipulas* lanceolate.—Native of marshes and the banks of rivers throughout Lapland. *Linnaeus*. It occurs also in alpine situations, in Germany, Switzerland, &c. The variety γ , of which we have specimens from Dr. Swartz, has been met with in one part of Sweden only, Wærmöland, and is increased by root only. The leaves are small, pinnate, and jagged. The usual appearance of *A. incana*, except its hoariness, and the glaucous hue of the back of its leaves, is not very unlike *A. glutinosa*. The leaves however are more acute, and their footstalks are reddish. This last character, as well as the glaucous hue just mentioned, is wanting in variety β . The general pubescence of the under side of the leaves renders it difficult to say how far the veins differ at their origin from those of the Common Alder, but though downy, they certainly want the glandular roughness so remarkable in that species. See BETULA, n. 7, for a further account of this tree.

4. *A. undulata*. Curl-leaved Alder. Willd. n. 4. Ait. n. 4. (A. crispata; Pursh n. 2. Betula crispata; Ait. ed. 1. v. 3. 339. Michaux Borel.-Amer. v. 2. 181.)—"Leaves oblong, acute; rounded at the base; veins hairy beneath, like the footstalks, but naked at their origin. *Stipulas* ovate-oblong."—In Canada, and on the high mountains of Pennsylvania, in swamps overrun with Bog-moss, flowering in April. *A. frut.*, not above three or four feet high. Leaves doubly serrated. *Pursh.* See BETULA n. 13. Willd. denows seems to have unwarrantably changed the name of this species.

5. *A. ferrulata*. Hazel Alder. Willd. n. 5. Ait. n. 5. Pursh n. 3. (Betula ferrulata; Ait. ed. 1. v. 3. 338. Michaux Borel.-Amer. v. 1. 181. Willd. Arb. 45. Smith Inf. of Georgia v. 2. 183. t. 92. B. rugosa; Ehrh. Beitr. v. 3. 21. "Wangenh. Amer. 85. t. 29. f. 60.")—Leaves obovate,

obovate, finely ferrated; veins and their origin hairy beneath. Stipulas elliptical, obtuse.—Native of North America. Common every where in swamps, and by river sides, flowering in March. A *shrub*, from six to ten feet high, growing in close thickets. *Pursh*. See *BETULA* n. 12. The *leaves* do not appear to be glutinous, or at least not so much so as the Common Alder, from which also they differ in being regularly and finely ferrated, not notched, or jagged.

ALOEXYLUM, ἀλοξύλον, *Aloes-wood*, a name given to the tree which produces this precious wood; by Loureiro; Fl. Cochinch. 267. See **AGALLOCHUM**.—He refers it to the Clafs and Order, *Decandria Monogynia*, and its Natural Order seems to be *Lomentaceæ*, Linn. *Leguminosa*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of four acute, hairy, deciduous leaves; the lowermost falcate, incurved, nearly twice as long as the rest. *Cor.* Petals five, unequal, longer than the calyx. *Stam.* Filaments ten; anthers *Pist.* Germen superior, elongated, curved, compressed; style thread-shaped; stigma *Peric.* Legume woody, smooth, falcate. *Seed* solitary, oblong, curved, tunicated.

Eff. Ch. Calyx of four acute deciduous leaves; the lower one longest. Petals five, unequal. Legume curved. Seed solitary, tunicated.

1. *A. Agallochum*. Fragrant Aloes-wood.—Native of the loftiest mountains of Cochinchina, near the great river which runs between that kingdom and Laosos. A large lofty tree, with erect branches. Bark fibrous, brown, smooth, not thick. *Leaves* alternate, stalked, lanceolate, flat, entire, smooth, rather coriaceous, eight inches long. *Flower-stalks* terminal, many-flowered. *Loureiro*. This genus is manifestly different from *AQUILARIA*. (See that article.) Loureiro describes the wood as white and inodorous, becoming resinous and fragrant in consequence of some injury, till the tree dies. No part of this tree is milky, nor poisonous. He adds, that all the sorts of genuine aloes-wood are produced by this tree, even the most precious, termed *Calambac*, which is found no where but on the mountains of Cham-pave, belonging to Cochinchina, situated about the 13th degree of north latitude. The inferior species, or rather varieties, are obtained in various places, sometimes in pieces weighing thirty pounds or more. "There are," says Loureiro, "other fragrant woods, called by ignorant persons *Agallochum*, and *Lignum Aloe*, differing greatly from each other, and the produce of different plants." The common writing paper of Cochinchina is made of the bark of this tree. Yet the plant itself seems rare, Loureiro having long enquired in vain for the flowers, and having obtained them but once, in a bruised and mutilated condition.

Whether the *Agallochum*, or *Calambac*, Rumph. Amboin. v. 2. 29, of which that author gives no figure, be the plant of Loureiro, we cannot positively determine, though it seems likely. The *Agallochum secundarium*, or *Garo*, of the same volume, 34. t. 10, is certainly the *Aquilaria*. We have received from Dr. Roxburgh specimens of the wood itself; as well as of the fruit, agreeing exactly with Rumphius's figure, and evidently the *Gyrinops Walla* of Gartner, v. 2. 276. t. 140. In Tr. of Linn. Soc. v. 11. 230, the writer of this has hinted at the probable affinity of *Aquilaria* to the *Euphorbia*.

ALONSOA, a genus established by Ruiz and Pavon, Fl. Peruv. Syst. 150, and adopted in Ait. Hort. Kew. v. 4. 27, is founded on two species of **HEMIMERIS**, (see that article,) nor can we discover the least possible character to distinguish them from the latter; which having been much consulted in its history by Linnæus, was perhaps not understood by the authors of the *Flora Peruviana*. These species are our *H. urticifolia*, (*Alonsoa incusfolia*; Fl. Peruv.) and

H. linearis, (*A. linearis* of the same work.) Professor Willdenow, though he had never seen more than one *Hemimeris*, the montana, and that in a dried state, could not overlook the identity of these genera, nor can we account for its having escaped the learned editors of the Hortus Kewensis. But it is evident from their generic character of *Alonsoa* that they did not contrast the two genera; for these are proved the same by the character itself, which runs thus, and is equally suitable to both.

Calyx in five deep segments. Corolla nearly wheel-shaped, reverted, five-cleft; the uppermost segment largest. Stamens declining; with smooth filaments; and converging uniform anthers. Capsule of two cells.

Hemimeris, being a long-established Linnæan name, of appropriate and unexceptionable meaning, must, of course, be retained.

ALPINIA, the article already given requires reformation, in consequence of subsequent discoveries, chiefly owing to Mr. Rofcoe's investigations. (See **SCITAMINEÆ** and **ROSCOEÆ**.) Recurring to the original genus, founded by Plumier, and adopted by Linnæus, as the basis of the whole, we do not, in quoting various authors, who have followed these, consider as *Alpinia* all that they have included herein. We shall limit the characters after Mr. Rofcoe's principles, so as to exclude what does not belong to this very natural genus, and, on the other hand, to introduce what has, under other names, been improperly separated from it.—Linn. Gen. 3. Schreb. 4. Willd. Sp. Pl. v. 1. 11. Mart. Mill. Diët. v. 1. Ait. Hort. Kew. v. 1. 3. Rofcoe Tr. of Linn. Soc. v. 8. 343. t. 20. f. 7. Sm. Ex. Bot. v. 2. 93. Roxb. Afiat. Ref. v. 11. diff. 7. Juff. 63. Gært. n. 12. (*Alpinia*; Plum. Gen. 26. t. 11. Rencalmia; Linn. Suppl. 7. Schreb. 2. Willd. Sp. Pl. v. 1. 6. Mart. Mill. Diët. v. 4. Catimbium; Juff. 62. Zerubom; Wendl. Sert. Hannov. t. 19. Jacq. Fragm. Bot. 50. t. 68.)—Clafs and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Canna*, Juff.

Gen. Ch. *Cal.* Perianth superior, of one leaf, tubular, irregularly splitting into two or three teeth. *Cor.* of one petal, irregular, tubular at the base: limb double, unequal; the outermost two-lipped, in three deep segments, of which the upper one is usually broadest, and concave, the two lower equal and narrower; innermost of a single lip, straight, as long or longer than the outer limb, dilated, lobed, or jagged, at the extremity, furnished at the base with a pair of awl-shaped teeth. *Stam.* Filament one, opposite to the lip, short and stout, quite simple; anther terminal, erect, thick, simple, without any appendage, convex at the back, emarginate, divided in front into two parallel, close, oblong lobes, bursting longitudinally. *Pist.* Germen inferior, elliptic-oblong, with three furrows; style thread-shaped, erect, smooth, the length of the stamens, embraced by the lobes of the anther; stigma peltate, umbilicated, hairy. *Peric.* Capsule fleshy, oval, abrupt, umbilicated, with three furrows, three valves, and three cells. *Seeds* numerous, tunicated, ovate, angular, abrupt, inserted into a pulpy receptacle.

Eff. Ch. Anther two-lobed, terminal, embracing the style, without any appendage. Inner limb of the corolla a simple lip. Capsule fleshy.

Dr. Roxburgh, who had opportunities of studying the various species of this, and many other Scitamineous genera, in their native situations, speaks of *Alpinia* as a good natural genus, having, besides the proper characters in the fructification, certain peculiarly striking ones in the habit. The roots are perennial, tuberous, strong, thick, crooked, running nearly horizontally, a little below the surface of the ground, and

ALPINIA.

and strongly marked with annular scars where former leaves have been; these send down copious, long, thick, fibrous radicles. *Stems* either biennial or perennial, numerous, tufted, straight, erect, or more or less recurved at the summit, densely leafy, each terminating in a copious *cluster*, or *panicle*, of large gaudy flowers, "except *Cardamomum*," says Dr. Roxburgh; but that plant, which has a radical panicle, is now excluded from *Alpinia*, and called by Dr. Maton *Eleotaria* in Tr. of Linn. Soc. v. 10. 249; having sufficient marks of generic distinction in the *flamen*. We shall endeavour to collect under one view the numerous species of this fine genus, of which we can find any account, or have seen any figures or specimens.

1. *A. racemosa*. Simple-clustered *Alpinia*. Linn. Sp. Pl. 2. Willd. n. 1. Ait. n. 1. Rofc. Tr. of Linn. Soc. v. 8. 345. Swartz Obs. 5. (*Alpinia racemosa* alba, cananacori foliis; Plum. Ic. 11. t. 20. Zingiber sylvestre minus, fructu e caulium summitate exeunte; Sloane Jam. v. 1. 165. t. 105. f. 1.)—Cluster simple, erect. Outer bractæe lanceolate, longer than the flowers. Calyx bell-shaped, with three blunt equal segments. Germen smooth.—Native of rather mountainous shady woods in the West Indies. Notwithstanding Dr. Swartz's doubts, we have no scruple respecting Plumier's synonym. Root branching, fleshy, with the flavour of Ginger; used in Jamaica as a poultice for cancers and other sores, according to Sloane, with good success. Stem herbaceous, two or three feet high, round, smooth, slender, simple, leafy. Leaves alternate, elliptic-lanceolate, entire, smooth, pointed, a foot long, with narrow sheathing footstalks exceeding them in length. Cluster terminal, solitary, stalked, unbranched, smooth, many-flowered. Outer bractæe lanceolate, blood-red; the lowest an inch and a half long, the rest about an inch; inner bell-shaped, containing one or two flowers, shorter than the calyx, permanent. Calyx red, with broad and shallow teeth. Corolla white; tube slender, longer than the calyx; outer limb with three nearly equal, ovate, erect segments; inner somewhat heart-shaped, three-lobed, the middle lobe notched. Germen bluntly triangular, quite smooth, as well as the capsule. Seeds shining.

2. *A. Galanga*. Galangale *Alpinia*. Rofc. Tr. of Linn. Soc. v. 8. 345. Roxb. n. 1. Willd. n. 2. (*Maranta Galanga*; Linn. Sp. Pl. 3. Swartz Obs. 8. *Amomum Galanga*; Loureir. Cochinch. 5? *Galanga* major; Rumph. Amboin. v. 5. 143. t. 63. Dale Pharm. 276. Ger. Em. 33.)—Cluster compound, erect. Bractæe all lanceolate, shorter than the flowers. Calyx bell-shaped, with three rather pointed equal segments. Germen slightly downy.—Native of various parts of the Malay Archipelago, communicated by the late Dr. Roxburgh, from the Calcutta garden, where this plant flowered during the hot season, and ripened seed, though very rarely, in November. The root proved to be the real *Galanga* major of the shops. The stem is said to be seven or eight feet high. Leaves eighteen or twenty-four inches long, soft to the touch, though scarcely conspicuously downy. Cluster large, with very numerous, crowded, short, racemose branches, all downy. Bractæe uniform, lanceolate, downy; those at the base of each principal branch very small. Flowers white. Calyx besprinkled with minute resinous dots. Corolla elongated; lip externally downy, cleft at the extremity. "Capsule small, obovate, smooth, deep orange-red, not opening spontaneously. Seeds only two in each cell, even in the germen, bitter and nauseous, each three-fourths covered with a white tunic." Roxburgh. See GALANGAL.

3. *A. occidentalis*. Scaly-clustered *Alpinia*. Swartz Ind. Occ. 9. Rofc. Tr. of Linn. Soc. v. 8. 345. Willd.

n. 4. Ait. n. 2. (*Amomum minus*, scapo vestito, floribus spicatis; Browne Jam. 113, excluding Sloane's synonym. *Paco-feroca* minor multicaulis; Plum. MSS. cum icone.)—Cluster compound, erect, on a scaly leafless stem. Partial bractæe imbricated, sheathing, dilated, abrupt, hairy. Calyx turbinate, with three broad obtuse segments. Germen slightly downy.—Native of moist parts of the mountainous woods of Jamaica, flowering all the year, but especially in spring. Root knotty and fleshy. Barren stems six feet high, erect, herbaceous, simple, leafy. Leaves elliptic-lanceolate, acute, very smooth, attached by a short contraction to their sheathing footstalks, as in the other species. Flowering stems as tall as the others, round, smooth, erect, not leafy, but clothed from top to bottom with sheathing, oblong, obtuse scales, and terminating in a dense, erect, cylindrical, compound, many-flowered cluster, with hairy stalks. Flowers all turned upwards, crowded, their partial stalks concealed by concave, sheathing, abrupt, partial bractæe, while each common stalk, or branch of the cluster, has at its base a very different, lanceolate, acute bractæa, half its own length. Calyx coloured, hairy at the base; its segments smooth, rounded and obtuse. Corolla pale yellow; tube the length of the calyx; lip veiny, cleft at the end. "Capsule rather small, coriaceous and fleshy, of three valves, red when ripe, pulpy within. Seeds yellow, two or three in each cell." Swartz. We are indebted to Mr. Lambert for a drawing of this plant, copied from Plumier's sketches at Oxford.

The habit of this species may, at first sight, seem to invalidate the character of a leafy stem, with terminal inflorescence, attributed to this genus in our introductory remarks. We think however that the difference between this and the others is more apparent than real. The scales may be considered as abortive leaves, not perfected on the flowering stems, while those stems which luxuriate in foliage, do not also bear fructification. Perhaps the roots are more prolific than in other species.

4. *A. Alughas*. Ceylon *Alpinia*. Rofc. Tr. of Linn. Soc. v. 8. 346. Roxb. n. 2. Ait. n. 3. (*Hellenia Alughas*; Willd. Sp. Pl. v. 1. 4. Andr. Repet. t. 501. *Heritiera Alughas*; Retz. Obs. fasc. 6. 1. t. 1.)—Cluster panicled, erect. Calyx bell-shaped, two-lobed. Germen hairy. Lip two-lobed.—Native of the East Indies. Very common in Bengal, flowering throughout the rainy season, and ripening fruit in October and November. We received in 1786 a flower from Kenig's specimen of this plant, sent to professor David Van Royen by the name of *Grana Paradisi Zeylanica*. It appears without doubt to be the *Alughas* of Hermann, mentioned, but not ascertained systematically, in Linn. Zeyl. 207. n. 449, and it is said to be the *Mala-infibikwa*, Rheede Hort. Mal. v. 11. t. 14. The illustrious sir William Jones has described it, by the Sanscrit name of *Taraca*, in the Asiatic Researches, v. 4. 240. The stem is two feet high, simple, leafy. Leaves lanceolate, pointed, smooth, with long sheaths. Cluster, or rather panicle, variously subdivided, lax, many-flowered, with densely downy stalks. Bractæe smooth, for the most part very small, but those under the principal subdivisions of the inflorescence are sometimes elongated and lanceolate, and one or two of the lowermost occasionally become very large and leafy. Calyx downy, especially at the base, remarkable for having only two marginal acute segments. Segments of the outer limb of the corolla oblong, equal, coloured green by Mr. Andrews, crimson, like the lip, in Retzius's plate, but the latter is probably accidental, the author having had no living specimen. The lip is longer than those segments, and, like them, externally hairy; its two lobes appear to be sometimes cleft. Stamen long, with a large anther, reddish as well as the style. Fruit globose, purplish.

ALPINIA.

purplish-black, with numerous tunicated seeds. This species was raised from seed by A. B. Lambert, eq., at Boyton, in Wiltshire, where it flowered very finely; but it is said to have been previously sent by Mr. Peter Good to Kew, in 1796.

5. *A. alba*. White Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 346. (Hellenia alba; Willd. Sp. Pl. v. 1. 5. Heritiera alba; Retz. Obf. fasc. 6. 18. *Languas vulgare*; Koen. in Retz. Obf. fasc. 3. 64.)—Cluster panicled. Calyx bell-shaped, three-lobed. Lip two-lobed. Leaves callous and fringed at the margin.—Native of China; cultivated in the East Indies. Koenig terms this plant *Galanga alba*, and speaks of it as in much use among the Malays. The roots are white, thicker than the thumb. Stems taller than a man, tuberous at the bottom, a little drooping at the top. Leaves about eighteen inches long, and hardly three broad, two-ranked, smooth on both sides; their edges callous, whitish, and rather rough with hairs. Five or six of the lower sheaths are unaccompanied by leaves. Cluster oblong, with smooth stalks, except the partial ones, which are rather hairy. Bractees lanceolate, acute, rusty-coloured, deciduous. Calyx with snow-white segments. Outer limb of the corolla greenish-white; lip inversely heart-shaped, deeply two-lobed, jagged and crisped at the margin, white, with fine rose-coloured veins. Capsule scarlet, membranous, rather rigid, striated. Koenig's full and correct description of the flower, leaves no doubt as to the genus of this plant, though we have seen no specimens.

6. *A. chinensis*. Chinese Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 346. (Hellenia chinensis; Willd. Sp. Pl. v. 1. 5. Heritiera chinensis; Retz. Obf. fasc. 6. 18. *Languas chinensis*; Koen. in Retz. Obf. fasc. 3. 65.)—Cluster panicled. Calyx bell-shaped, three-toothed, obtuse. Lip emarginate, finely-toothed. Leaves recurved at the point; membranous, and fringed with scattered hairs, at the margin.—Native of China? where at least it is cultivated, for medical use, in gardens. Root aromatic, with an acrid burning flavour, white, as thick as the middle finger. Stems two or three feet high, a little drooping at the summit. Leaves a span long, and two inches or two inches and a half broad, with a white rib and margin. Cluster narrow, three or four inches long, its stalks more or less clothed with close-pressed hairs. Calyx green. Corolla yellowish; the lip marked with a broad orange-coloured longitudinal stripe, and transverse waves of the same colour, accompanied by four blood-red veins. Fruit a capsule. Koenig.

7. *A. aquatica*. Water Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 346. (Hellenia aquatica; Willd. Sp. Pl. v. 1. 5. Heritiera aquatica; Retz. Obf. fasc. 6. 18. *Languas aquaticum*, l. sylvestre; Koen. in Retz. Obf. fasc. 3. 67.)—Panicle somewhat drooping at the top, with forked branches. Calyx bell-shaped, three-toothed. Lip four-toothed, erect; its lateral teeth with an oblong gland at the base, on each side.—Found in marshy places, among bushes, by the sides of rivulets in the East Indies, but not very common. Roots numerous, thread-shaped, white, sending forth runners. Stem about four feet in height, leafy, as thick as the finger. Leaves oblong, acute, coriaceous, of a beautiful green; rather roughly striated on the upper side; smooth at the back; the margin beset with minute callous teeth. Panicle slender, with two deciduous bractees at the base; flower-stalks forked, two-flowered, divaricated, round, smooth, white, shorter than the flowers. Bractees two or three, attached to the lower flower-stalks, linear-lanceolate, concave, membranous, whitish, deciduous. Calyx smooth, pure white, sometimes split at the inner side. Corolla white. Lip small, brown on the inner side,

rose-coloured near its union with the filament. Anther reddish, crowned with a small, coloured, erect, semi-orbicular membrane. Berry oval, smooth, black. Seeds five or more, triangular. Koenig. The membrane crowning the anther forms a small exception to the generic character, but can hardly invalidate it, or require the establishment of a separate genus; unless the fructification, when examined according to our present advanced knowledge, should afford other distinctive marks.

8. *A. malaccensis*. Malacca Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 345. Roxb. n. 3. (Maranta? malaccensis; Willd. Sp. Pl. v. 1. 14. Burm. Ind. 2. Galanga malaccensis; Rumph. Amboin. v. 5. 176. t. 71. f. 1.)—Cluster simple, erect. Leaves villous beneath. Lip broader than long, toothed, concave, obscurely three-lobed; lateral lobes incurved.—Native of Chittagong, from whence it was brought to the botanic garden at Calcutta, and flowers there in April and May. "This," says Dr. Roxburgh, "is the most stately and most beautiful of our Scitamineous plants. The flowers are particularly large; the bractees, and exterior limb of the corolla, pure, smooth, lucid white; the large lip variegated with crimson and yellow." Stem from twelve to fifteen feet high, villous. Leaves eighteen or twenty inches long, the breadth of five or six fingers, silky or downy beneath. Flowers about twelve, alternate. Rumphius, Burmann. This has not yet found its way to England, where it would doubtless be a great acquisition, as, by the above description, it seems to excel the magnificence and beauty of the following.

9. *A. nutans*. Drooping Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 346. Sm. Exot. Bot. v. 2. 93. t. 106. Roxb. n. 4. Ait. n. 4. (Globba nutans; Linn. Mant. 2. 170. Willd. Sp. Pl. v. 1. 153. Redout. Liliac. t. 60. G. sylvestris; Rumph. Amboin. v. 6. 140. t. 62, 63. *Renalmia nutans*; Andr. Repof. t. 360. Edwards t. 1. Thort. Illustr. t. 15. *Zerumbet speciosum*; Wendl. Sert. Hannover. t. 19. Jacq. Fragm. Bot. t. 68.)—Cluster somewhat compound, drooping. Leaves smooth on both sides. Lip inflated, crisped. Calyx irregularly toothed, tumid, bursting at one side.—Native of the interior parts of Bengal. Roxburgh. Also of Amboyna, and other places. It was introduced into the English stoves, in 1792, by Sir Joseph Banks, and flowering a few years after, excited the admiration of all beholders. The number of figures of this plant which have been published, prove it a general favourite. The tuberous odorous root is sometimes, as Dr. Roxburgh asserts, brought to England for *Galanga major*; see n. 2. Stem from five to eight feet high in India, but with us twelve to eighteen, perennial, erect, as thick as the finger, leafy. Leaves a foot long or more, with long sheaths, each sheath crowned with a stipula which is externally silky. The flower-buds before they expand are of a shining white, tinged with rose-colour, and are enveloped in large, concave, toothed bractees of the same porcelain-like splendid whiteness, all together composing a dense pendulous cluster, like a bunch of oblong grapes. When the flowers open, they display the magnificent concave lip yellow at the margin, internally variegated and streaked with every shade of crimson. The stamens and its anther are short and thick. Germs hairy. Capsule spherical, opening at the sides. Seeds aromatic, as is likewise the young germs. Linnæus has greatly confounded the history of this plant, with which he had no acquaintance but from the work of Rumphius. Yet he subsequently cited the same synonym and figures under his *Renalmia exaltata*, which is indeed an *Alpinia*, as we shall presently shew, but a widely different species.

The real genus *Glossa* is totally distinct from both; see that article.

10. *A. mutica*. Pointless Narrow-leaved Alpinia. Roxb. n. 5.—Cluster erect, compound. Leaves shortly stalked, linear-lanceolate, polished. Lip three-lobed; without a spur at the base. Capsule pulpy. Seeds numerous, angular, with an evanescent tunic.—Found by Mr. W. Roxburgh, the son of our ever-lamented East Indian botanist, in the forests of Prince of Wales's island, from whence being brought to the Calcutta garden, it flowered, more or less, during the whole year, but chiefly in the hot season, March, April, and May. This is also an elegant species, and holds a middle rank between *nutans* and *calcarata*. Roxburgh.

11. *A. calcarata*. Spurred Narrow-leaved Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 347. Roxb. n. 6. Ait. n. 5. (*Renealmia calcarata*; Andr. Repof. t. 421. *Globba erecta*; Redout. Liliac. t. 174.)—Cluster erect, somewhat compound. Leaves linear-lanceolate, polished. Lip ovate-oblong, cloven at the point. Segments of the outer limb linear-oblong.—Native of China, from whence it was introduced into the Calcutta garden in 1799, according to Dr. Roxburgh, who communicated the plant to Mr. Lambert. The numerous stems are from three to five feet high. Leaves narrow, acute, smooth. Cluster three or four inches long, downy, rather dense, the stalks, though partly compound, some of them bearing two or three flowers, being so short that the whole cluster resembles a spike. Leaves twelve or fifteen inches long and one broad, pointed. Bractees elliptical, concave, hardly equal to the calyx, which is tubular, white, split half way down at one side, and on the other very slightly and bluntly notched. Outer limb of the corolla pure white, the length of the tube, in three deep, equal, obtuse, flat, rather narrow segments. Lip nearly twice as long, concave, but not so tumid or inflated as in *A. nutans*; its upper side crimson, beautifully streaked; the extremity flattish, slightly cloven, more or less notched or curled. The base of the lip being furnished, as in *A. nutans* and some other species, with two small spurs, or awl-shaped appendages on the upper side, which are wanting in the last, seems to have occasioned the specific name, which is rather calculated to mislead. Dr. Roxburgh had once an intention of changing it to *spicata*, which would not have been more correct, and the above being printed by Andrews, it was suffered to remain. *A. angustifolia* would have been preferable to either.

12. *A. maculata*. Spotted-leaved Alpinia. Rofc. Tr. of Linn. Soc. v. 8. 347.—“Leaves ovate, spotted.”—Cultivated in the botanic garden at Liverpool. It is thus mentioned by Mr. Roscoe, but with a mark of doubt, nor have we met with any further information respecting this species.

13. *A. spicata*. Small Spiked Alpinia. Roxb. n. 8.—“Spike oblong, compactly imbricated, with narrow-lanceolate acute bractees.”—Native of Sumatra. Brought by Mr. William Roxburgh, from Bencoolen to the Calcutta garden, in 1803. At the close of the rains of 1808, it blossomed for the first time, and was then only about two feet high, being the smallest of the genus ever seen by Dr. Roxburgh. This is all the account he has left us of the present species.

14. *A. Renealmia*. Surinam Alpinia. (*Renealmia exaltata*; Linn. Suppl. 79, excluding the synonym of Rumphius, and the account of the stem and leaves taken from that author. Willd. Sp. Pl. v. 1. 6. “*Neue Bot. Ann. v. 3. 136.*” Myrsina n. 64; Linn. Pl. Surinam. in A. Moen. Acad. v. 8. 251. n. 3, excluding the synonym of

Merian, t. 54.)—Cluster lateral, compound. Calyx tubular, irregularly toothed.—Native of Surinam. The history of this plant is so confused, that we think it necessary to lay before the reader all the original materials. The generic description, Linn. Suppl. 7, and the specific one, p. 79 of the same work, beginning at the word *Racemus*, appear to have been made, with sufficient accuracy and fidelity, from specimens of a cluster of the flowers, and a quantity of the fruit, with a leaf, sent in bottles of spirits to Linnæus. The former was taken out and dried by Linnæus himself, for his herbarium, where it now lies, marked by him *Heliconia*, he having taken this specimen for Merian's t. 54, *Heliconia Bihai*, which it somewhat resembles in general aspect. The flowers, however, when examined, prove these plants totally different; but this mistake of Linnæus accounts for his erroneous reference to Merian. The spirits in the bottle of the fruit being gone, the latter is also dried; but enough remains to shew it has been a fleshy, very fibrous, oval, capsule, above an inch long, of three valves, strongly umbilicated, and containing numerous, roundish-obovate seeds, now of a shining brown. Their flavour is lost. A Dutch manuscript, sent from Surinam with the collection to which the above belonged, contains the following information. “No. 64 is a sort of reed, and has upon each stalk four such leaves as are here to be seen; two uppermost next to each other, and then the other two a span under the uppermost, and a span between these two, downwards to the fruit. The fruit is at first red; black when ripe. The feed in the fruit tastes exactly like Cardamom. The stalk to which the fruit grows is two feet and a half long, beset with twenty-five to twenty-seven fruits.” Such is as literal a translation as we could obtain. It seems undubitably to ascertain the situation of the inflorescence to be lateral, and in this point agrees with the following account given by Willdenow, we know not on whose authority. “A tree twenty feet high. Leaves five or six feet long, lanceolate, waved at the margin. The cluster originates from the trunk, above the root.” *Neue Bot. Ann.* as above. If this last description really belongs to the Linnæan *Renealmia*, our ideas of the plant are very incomplete. The lateral inflorescence would form a strong presumptive argument against its being an *Alpinia*; but we can assert, from a careful examination of one of the flowers, immersed in hot water, and compared with a living flower of *A. nutans*, that their structure agrees exactly, without the least mark of a generic difference, especially the essential part of the anther. This indeed appears from Linnæus's remarks in the *Supplementum*, without which our history would be incomplete. We shall leave the reader to compare it with the descriptions of other species, only observing beforehand that Linnæus considers the flower as reversed, placing the nectary uppermost.

Suppl. p. 7. *RENEALMIA*. Eff. Ch. Corolla three-cleft. Nectary oblong. Calyx of one leaf. Anther sessile, opposite to the nectary. Berry fleshy.

Nat. Ch. Cal. Perianth superior, tubular, of one leaf, bursting at the top into two or three irregular teeth. Cor. of one petal. Tube straight, cylindrical. Limb three-cleft: two upper (properly under) segments oblong, rounded, equal: lower segment scarcely longer, channelled, oblong. Nectary united with the tube, ascending under the upper segments, straight, the length of the corolla, oblong, with a tooth at the base on each side, and a hollow behind; dilated, and bluntly three-lobed, at the extremity. Stam. Filament none. Anther solitary, inserted into the mouth of the tube, in the bosom of the lower (upper) segment of the corolla, opposite to the nectary, unconnected, straight, linear,

linear, emarginate, marked with a furrow on the inner side, its length and breadth equal to the segment of the corolla. *Pist.* Germen inferior, oblong, obscurely triangular, smooth. Style thread-shaped, very smooth, erect; the length of the corolla. Stigma peltate, a little flat head, abrupt on the side towards the nectary, an orifice running into the style. *Peric.* Berry oblong, round, with three furrows, smooth, fleshy, with an umbilicated termination; three-celled in the centre; the cells soft and membranous. *Seeds* numerous, oblong, abrupt, quadrangular, very smooth.

P. 79. R. *exaltata*. Cluster with alternate, lanceolate, channelled, smooth, ribbed, deciduous bracteas. *Flower-stalks* in the bosoms of the bracteas, solitary, incurved, depressed, downy, short, each terminating in a sheath of one leaf, which bursts at the top, like the calyx, into two or three segments, to allow the flowers to protrude. Within this sheath is a flower, as well as another two-flowered sheath, so that each stalk bears three flowers. The calyx is exactly similar to these sheaths, inasmuch that it would be a sheath, if not seated on the top of the germen. Scarcely any other of the *Scitamineæ* has an anther so unconnected, and with so much of the common appearance of that organ. The fruit forms a compound pendulous cluster, resembling the fruit of *Momordica Elaterium* in size and figure; its cortical part thick and fleshy, hot, reddish; the triangular central cell has soft, juicy, membranous partitions. *Seeds* small, very smooth, black, very like those of *Anomum Cardamomum*. The preserved fruit is esteemed by the inhabitants of Surinam.

The following three species are lately added to *Alpinia* by Mr. Roscoe, from the inspection of some Chinese drawings, in the possession of the right honourable lord Stanley, V.P.L.S.

15. *A. pennicellata*. Pencilled *Alpinia*. Rofc. Tr. of Linn. Soc. v. 11. 280.—Cluster terminal, pendulous. Segments of the outer limb short, pointed. Lip emarginate. Leaves lanceolate, simple at the margin.—Native of China. The lip or nectary is broad, simple, emarginate, bright yellow regularly streaked with crimson. Leaves regularly nerved. The unfolded blossoms have, like some other species, the appearance of fine China ware.

16. *A. diffusa*. Cloven *Alpinia*. Rofc. *ibid.*—Cluster inclining. Segments of the outer limb ovate. Lip flat, panduriform. Leaves lanceolate, glaucous beneath. Stamen deeply cloven to the base.—Native of China. The margin of the leaves is strongly nerved. Lip broad, bright yellow, with a central rib, from which diverge crimson streaks. The filament is deeply cloven, each portion bearing its proper anther, (or rather we should say, one lobe of the anther,) between which rises the style, perfectly free, and not inclosed in a double anther, as in the rest of the proper *Scitamineæ*. This circumstance is so peculiar, that Mr. Roscoe thinks it may possibly entitle the plant to rank as a new genus; but being in other respects truly an *Alpinia*, he prefers retaining it here.

17. *A. bracteata*. Braçatead *Alpinia*. Rofc. *ibid.* 281.—Panicle loose. Leaves downy. Lip in three, nearly equal lobes; spurred at the base.—From the same country. The stem is jointed, rather spiral. Footstalks of the upper leaves uniting with the bracteas. Calyx concave, ovate. Nectary broad, flat, nearly circular, deeply indented at each side, yellow, with purple rays diverging from its base. Anther ovate. "Habit rather of a *Costus* than an *Alpinia*, but the inflorescence is a loose panicle, not a bracteated spike, and the whole construction of the corolla seems decisive of the genus." Rofcoe.

A. Cardamomum, Roxb. n. 7, the valuable *Cardamom*

of the shops; *Anomum repens* of Sonnerat and other authors, Willd. Sp. Pl. v. 1. 9; is now properly, we believe, removed from *Alpinia*, and proposed by Dr. Maton, Tr. of Linn. Soc. v. 10. 249, as a new genus, distinguished by two transverse processes at the top of the filament, and called by him ELETTERIA, under which name we propose hereafter to treat of this plant.

ALQUIER. Add—The fanega, which is the 15th part of the moyo, is = 4 alquiers = 8 moyos = 16 quarters = 32 outavas = 64 mequias. The alquier measures 675 French, or 817 English cubic inches; so that 21 alquiers are nearly = 1 English quarter; or, more correctly, 50 alquiers = 19 English bushels.

ALSOPHILA, in Botany, so named, we presume, from $\alpha\lambda\sigma\sigma$, a grove, or forest, and $\phi\lambda\lambda\omega$, to love; alluding to the favourite situation of the beautiful tribe of Tree Ferns, to which this belongs.—Brown Prodr. Nov. Holl. v. 1. 158.—This genus is founded on our *Cyathea aspera*, *C. extensa* of Swartz, *Polypodium lunulatum* of Forster, and some other allied species; but we scarcely think the deeper segments of the bursting involucrem, or the situation of the *fori* at the division, instead of the side, of a vein, can authorize a separation of these from CYATHEA. See that article.

ALSTEAD, in Geography, a town of America, in New Hampshire, and county of Cheshire, having 1694 inhabitants.

ALSTONIA, in Botany, received that name from Mr. Brown, in memory of Dr. CHARLES ALSTON, formerly Professor of Botany at Edinburgh. (See that article.) The genus originally dedicated to this gentleman, in the Supplement of LINNÆUS, is now sunk in SYMLOCOS. (See that article, and ALSTONIA.)—Brown Tr. of the Werner. Soc. v. 1. 75.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contorta*, Linn. *Apocynæ*, Juss. Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, in five deep, rather blunt, segments, permanent. Cor. of one petal, falver-shaped; tube cylindrical, many times longer than the calyx, somewhat tumid near the top, pervious, destitute of scales in the throat or mouth; limb horizontal, in five deep segments, folding over each other at the base, mostly shorter than the tube. Nectary none. Stam. Filaments five, short, inserted into the tube, and not reaching to its summit; anthers lanceolate, unconnected with the stigma, bursting longitudinally, enclosed within the tube. Pist. Germens two, simple; style solitary, central, thread-shaped, swelling at the top; stigma nearly conical. Peric. Follicles two, cylindrical, long, each of one cell and one valve. Seeds oblong, peltate, fringed, bearded with long hairs at each end.

Ess. Ch. Corolla falver-shaped, pervious; limb in five deep oblique segments. Nectaries none. Anthers lanceolate, within the tube, bursting lengthwise, unconnected with the stigma. Follicles two, cylindrical. Seeds fringed, bearded at each end.

This genus consists of trees, often of great height, with milky juice. Leaves either whorled or opposite, ribbed, smooth. Cymes terminal, panicled. Flowers for the most part white. Follicles generally very long. They grow in the East Indies, the Malay Archipelago, and the Society islands. *Alstonia* has little affinity to ECHITES, (see that article,) with which Linnæus would probably not have confounded it, had he examined the fruit, or attended to the figure in the Hort. Malab., of which work indeed he had not a copy. Brown.

1. *A. scholaris*. Tablet *Alstonia*. Br. n. 1. (Echites scholaris; Linn. Mant. 53. Willd. Sp. Pl. v. 1. 1241. Lignum scholaræ; Rumph. Amboin. v. 2. 246. t. 82. Pala;

Pala; Rheede Hort. Malab. 81. t. 45, not 46).—Leaves several in each whorl, obovate-oblong, obtuse, ribbed, furrowed with a marginal vein. Cymes stalked. Limb of the corolla but partially bearded. Follicles very long and slender.—Native of Malabar and the Molucca islands, in sandy ground, flowering in January. A very tall and spreading tree, whose wood, Rumphius tells us, is used by school-boys in India, as slates are with us. The leaves are from five to seven in each whorl, stalked, with numerous, parallel, transverse veins, or ribs. Cymes many-flowered, compound, spreading, downy. Flowers small, about half an inch long, whitish, sweet-scented, but offensive to the head. Corolla downy on the inside and out, but not densely bearded, or shaggy, except around the mouth. Follicles eighteen inches long, not so thick as a wheaten straw. Seeds furnished at each end with a tuft of very long silky hairs.

2. *A. spectabilis*. Handsome Alstonia. Br. n. 2.—“Leaves four in a whorl, elliptic-oblong, ribbed, somewhat pointed, without any marginal vein. Cymes stalked, shorter than the leaves. Limb of the corolla bearded. Follicles very long.”—Observed by Mr. Brown, in April 1803, in the island of Timor, near Coepang, bearing flowers and fruit. Very nearly akin to the foregoing, but distinct; not ill-represented by Rumphius's plate, t. 82, but his description agrees best with *A. scholaris*. Brown. We would observe, that the number of the leaves in this figure agrees best with *scholaris*, and that the omission of the marginal nerve, so little conspicuous in nature, is rather to be attributed to inaccuracy of the engraver, if not of the draughtsman.

3. *A. venenata*. Poisonous Alstonia. Br. n. 3.—Leaves four in a whorl, lanceolate, pointed; tapering at the base. Cymes forked. Tube of the corolla swelling upwards. Limb beardless, shorter than the tube. Follicles tapering at each end, scarcely so long as the leaves.—Native of the East Indies. Dr. Roxburgh. We received a specimen from the Rev. Dr. Rottler, gathered at Nundydroog, March 17, 1806. The leaves are crowded towards the ends of the branches, stalked, very smooth, three inches or more in length. Flowers like those of a *Tabernemontana*, their limb an inch broad, with oblong, oblique, rather blunt than acute segments; tube an inch and a half long, inflated in the upper part, very smooth, as well as the limb. The calyx is a little downy, or fringed. Flower-stalks quite smooth. We have not seen the follicles.

4. *A. costata*. Ribbed Alstonia. Br. n. 4. (Echites costata; Forst. Prodr. 20, excluding the synonym. Willd. Sp. Pl. v. 1. 1240.)—“Leaves opposite, elliptic-oblong, pointed, ribbed. Cymes loose. Segments of the limb lanceolate, beardless, longer than the tube. Follicles very long.”—Native of the Society Isles. Forster. Gathered by Sir Joseph Banks in Otahaité and Ulaieta, between the summits of hills (called by the natives *Atahé*). Brown. We presume the plant, not the hills. A moderate-sized tree. The seeds are fringed, but, according to Mr. Brown, the silky hairs at each end are not so remarkably elongated as in other species. Kametti-Valli, Hort. Malab. v. 9. t. 14, is a climber, having short follicles, with winged naked seeds, and therefore cannot, as Forster thought, be synonymous with this.

ALTAI MOUNTAINS. See ALTAI.

ALTERNANTHERA, in Botany, so called by Forskall, from the stamens being, as he thought, alternately furnished with anthers, and without them.—Forsk. Egypt.-Arab. 28. Brown Prodr. Nov. Holl. v. 1. 416.—Class

and order, *Pentandria Monogynia*. Nat. Ord. *Holeracea*, Linn. *Amarantibi*, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, coloured, pointed, spreading, permanent, and finally hardened, segments. Cor. none. Stam. Filaments five, capillary, shorter than the calyx, inserted into a membranous ring, surrounding the base of the germen, with more or less remarkable intermediate teeth; anthers simple, oval, of one cell, generally wanting on two or three of the filaments alternately. Pist. Germen ovate, acute; style very short; stigma capitate. Peric. Capfule membranous, inversely kidney-shaped, compressed, of one valve and one cell, inflated, not bursting, enclosed in the cartilaginous calyx. Seed solitary, roundish, pointed.

Eff. Ch. Calyx in five deep segments, cartilaginous. Corolla none. Stamens partly imperfect, inserted into a membranous ring, with intermediate teeth. Anthers single-celled. Stigma capitate. Capfule kidney-shaped, of one cell, without valves. Seed solitary.

Obf. Mr. Brown properly retains the name of ILLECEBRUM, (see that article,) for *I. verticillatum* and its allies, from which we can scarcely separate *I. Paronychia*, &c. He would divide the present genus, which agrees very nearly in habit with *Illecebrum*, into two sections. These we shall here adopt, according to his suggestion, for the distribution of the species.

Sect. 1. Two of the filaments deprived of anthers. Intermediate teeth very short, or obsolete.

1. *A. affinis*. Sessile-flowered Alternanthera. Fork. Egypt.-Arab. 28. (Illecebrum sessile; Linn. Sp. Pl. 300. Mant. 345. Willd. Sp. Pl. v. 1. 1209. Ait. Hort. Kew. v. 2. 61. Vahl Symb. v. 1. 22. *Amaranthoides humile maderaspatanum*, capitulis candicantibus, folio molli; Pluk. Phyt. t. 133. f. 1. *Amaranthus humilis*, foliis oppositis, flosculis in alis conglomeratis; Burm. Zeyl. 17. t. 4. f. 2.)—Calyx smooth; segments ovate, pointed, almost twice the length of the capfule. Leaves elliptic-lanceolate, nearly entire, bearded at their insertion. Stem procumbent, hairy on two opposite sides.—Native of Arabia and the East Indies. A biennial, or perhaps annual herb, whose branching stems spread on the ground, in every direction, to the length of a foot or more, and are leafy, bluntly quadrangular; the opposite furrows densely hairy. Leaves opposite, stalked, spreading or reflexed, from one to two inches long, bluntnish, nearly or quite entire, single-ribbed, smooth, bright green, rather fleshy. Footstalks very short, bearded, and connected by intermediate stipuleaceous bristles. Heads of flowers sessile, axillary, solitary, obtuse, half an inch, or more or less, in length, white and shining, like everlasting flowers. Calyx single-ribbed, strongly keeled, pellucid. Capfule broadly heart-shaped, finely reticulated. The leaves occasionally vary to an obovate, or spatulate figure.

2. *A. demiculata*. Toothed Alternanthera. Br. n. 1.—Calyx smooth; segments ovate, pointed, almost twice the length of the capfule. Leaves narrow-lanceolate, finely toothed, smooth; bearded at their insertion. Stem procumbent, smooth.—Gathered by Mr. Brown in the tropical part of New Holland, as well as in New South Wales, and Van Diemen's island. We have seen no specimen.

3. *A. nodiflora*. Knotty-flowered Alternanthera. Br. n. 2.—Calyx smooth; segments narrow-lanceolate, pointed, thrice the length of the capfule. Leaves linear-lanceolate, finely toothed, smooth; bearded at their insertion. Stem diffuse, square, smooth; its ultimate branches only downy on two opposite sides.—Discovered by Mr. Brown, in the tropical district of New Holland. These three species appear to be all nearly allied.

4. A.

4. *A. angustifolia*. Narrow-leaved Alternanthera. Br. n. 3.—Calyx externally woolly; segments ovate, acute, the length of the capsule. Heads nearly globose. Leaves linear, very smooth. Stem erect, angular.—Found by Mr. Brown, in the tropical part of New Holland.

5. *A. nana*. Dwarf Alternanthera. Br. n. 4.—Calyx smooth; segments ovate, slightly pointed, twice the length of the capsule. Leaves obovate-oblong, hairy; tapering at the base. Stem diffuse, hairy.—Found in the same country as the two last, by Mr. Brown.

SECT. 2. *Five of the filaments with perfect anthers; five intermediate ones conspicuous, without any.*

6. *A. Achyrantha*. Creeping Alternanthera. (Illecebrum Achyrantha; Linn. Sp. Pl. 299. Willd. Sp. Pl. v. 1. 1208. Ait. Hort. Kew. v. 2. 61. Achyrantha repens, foliis bliti pallidi; Dill. Elth. 8. t. 7. f. 7.)—Stem creeping. Leaves ovate; densely downy when young. Calyx with somewhat spinous points.—Native of Buenos Ayres, from whence it was sent to Sherard, before the year 1732. We have specimens from the Paris garden. There is reason to doubt whether Linnæus ever saw this species.

The root is perennial. Stems prostrate, from one to two feet long, repeatedly forked, leafy, most hairy at opposite sides, creeping by means of fibrous radicles from their lower joints. Leaves stalked, from one to two inches long, entire; nearly smooth, and of a bright green, when full-grown; the young ones covered on both sides with dense, itarry, hoary hairs, such as compose the pubescence of the stems, and especially of the younger branches. Heads small, from the forks of the stem, partly stalked, round, of but few flowers. Calyx brownish-white; segments three-ribbed, unequal, strongly keeled, partly hairy, accompanied as it seems occasionally with smaller smoothiser scales.

7. *A. polygonoides*. Perficaria-leaved Alternanthera. (Illecebrum polygonoides; Linn. Sp. Pl. 300. Willd. Sp. Pl. v. 1. 1208. Ait. Hort. Kew. v. 1. 61. Herniaria hirsuta repens, ad nodos alteros florida; Browne Jam. 184. Amaranthoides humile curassavicum, foliis polygoni; Hern. Par. 17, with a figure. Sloane Jam. v. 1. 141. t. 86. f. 2. A. marina hirsuta, halimi folio; Plum. l. 12. t. 21. f. 2.)—Stem creeping, hairy. Leaves elliptic-lanceolate, tapering at the base, stalked, all smooth. Calyx ovate, single-ribbed, unarmed; hairy at the bottom.—Native of South America. A smaller plant than the preceding, except the flowers; with longer, much narrower, leaves smooth at every period of their growth, on long stalks. Calyx of a brilliant white; its segments ovate, pointed, but not spinous, the mid-rib less prominent than in the foregoing; the base only beset with conspicuous hairs. Plumier's plant scarcely requires to be called a variety. The stem indeed is represented more hairy than it appears in our gardens, but it is always more or less so, and the hairs are always simple, not flattened like those of *A. Achyrantha*.

8. *A. fœcida*. Ribbed Alternanthera. (Illecebrum fœcidum; Linn. Sp. Pl. 300. Willd. Sp. Pl. v. 1. 1208. Gomphrena fœcida; Linn. Sp. Pl. ed. i. 225. Jacq. Amer. 88. t. 60. f. 4?)—Stem creeping, smooth. Leaves ovate-lanceolate, tapering at the base, stalked. Calyx lanceolate, unarmed, three-ribbed, hairy at the back.—Native of South America. Cultivated by Linnæus at Upsal. Jacquin's figure more resembles the last, closely according with Browne's specimen, which indeed Dr. Solander, who sent it to Linnæus, marked *Gomphrena fœcida*; but the latter found it to be his own *Illecebrum polygonoides*. The plant before us, from the Upsal garden, is a truly distinct species, with broader leaves, an inch and a half or two inches long, roughish with callous points; a smooth stem; and very

different flowers. The segments of the calyx are much narrower, brown at the base, with three strong ribs, and clothed at the back, more than half way up, with prominent hairs; their points are tapering, but not spinous.

Mr. Brown speaks of some American nondescript species, referable to this section. Whether the following be among them we know not, but they appear to be nondescript.

9. *A. villosa*. Woolly-branched Alternanthera.—Stem decumbent, hairy; flaggy at the joints. Leaves obovate, stalked, nearly smooth. Calyx ovate, single-ribbed, smooth.—Sent to Linnæus by Thouin, from the Paris garden, without any mention of its native country. Stems above a foot long, with ascending very hairy branches, bent at each joint. Leaves an inch or more in length, bluntish, dotted, rarely besprinkled with a few long hairs. Footstalks accompanied, above their insertion, with very dense filipular tufts, of long flaggy hairs, jointed, like all those on the stem and foliage. Of the flowers we have seen only one small axillary head, apparently not come to perfection, but its glumes are evidently unlike all the preceding, broadly ovate, even and smooth, acute but not spinous, with a simple mid-rib.

10. *A. echinata*. Prickly-headed Alternanthera.—Stem prostrate, hairy. Leaves roundish-oval, smooth. Calyx spinous-pointed; outer segments lanceolate, elongated, partly three-ribbed, smooth; two inner shorter, gibbous, hairy at the back.—Gathered by Commerçon at Monte Video, and sent by Thouin to the younger Linnæus. This remarkable species is among the largest we have seen. The leaves indeed are not above an inch long, but they are nearly as much in breadth, tapering at the base, their surface dotted with little points, not hairy. Heads sessile, axillary, somewhat aggregate, globose or oblong, pale brown, shining, distinguished by the length and sharp thorns of their three outer calyx-segments, one of which is strongly three-ribbed, and by the tufted hairs of the two inner ones, projecting very conspicuously between them.

ALTMICKLIC, in Commerce, a Turkish silver coin = 60 paras.

ALTON, in America. Add—The town contains 1279 inhabitants.

ALTUN-KUPRI, or the Golden Bridge, a town of Persia, in the pachalic of Bagdad, about the size of Kupri, (which see,) situated on a fine plain, on the northern bank of the Little Zab, 32 furlongs from Mosul.

ALUMINA, in Chemistry, an earthy substance, described as elementary, but which Sir Humphrey Davy has rendered probable to be a compound of a metallic basis with oxygen. See ALUMINUM *infra*.

We have little to add to the description of alumina, except the curious fact observed by Saussure, that this substance does not give out the peculiar earthy smell which has been considered as characteristic of it, except it be mixed with oxyd of iron.

ALUMINA, Salts of, the compounds formed by the different acids with alumina. By some accident, the description of most of the salts of alumina has been omitted. We shall therefore take the opportunity of introducing them here.

Nitrate of Alumina. See NITRATE of Alumina.

Carbonate of Alumina. The existence of this salt has been usually admitted by chemists. Bergman, however, could not form it artificially, though he allows its existence, because when alum is mixed with an alkaline carbonate, part of the alumina remains in solution till the carbonic acid be driven off. Saussure has more recently shewn, that water saturated with carbonic acid is capable of dissolving alumina, but that this combination is destroyed by simple exposure to the air. Carbonate of alumina, therefore, cannot exist in a dry

dry itate. What had formerly been considered as dry carbonate of alumina is a triple compound of alumina, carbonic acid, and the alkali employed in precipitating the alumina.

Phosphate of Alumina. This salt may be formed by saturating phosphoric acid with alumina. According to Fourcroy, who is the only chemist that has examined it, the phosphate of alumina is a tasteless powder, infoluble in water. When diffused in excess of phosphoric acid, it yields a gritty powder and a gummy solution, which by heat is converted into a transparent glass.

Sulphate of Alumina. See ALUM and SULPHATE of Alumina. In addition to what has been said under these articles, we may add the following analysis of alum by Vauquelin, Thenard and Roard, and Berzelius.

	Vauquelin.	Thenard and Roard.	Berzelius.
Sulphuric acid	30.52	26.04	34.23
Alumina -	10.50	12.53	10.86
Potash -	10.40	10.02	9.81
Water -	48.58	51.41	45.00
	100.00	100.00	99.90

The analysis of Berzelius is probably most accurate, and is equivalent to

Sulphate of alumina - - -	36.85
Sulphate of potash - - -	18.15
Water - - - - -	45.00
	100.00

Which nearly coincides, according to Dr. Thomson, with three atoms of sulphate of alumina, one atom of sulphate of potash, and twenty-three atoms of water.

According to the experiments of Thenard and Roard, alum usually contains a little sulphate of iron, and the goodness of its qualities as a mordant in dyeing, according to these chemists, depends entirely upon the proportion of that salt present. The more free it is from it the better. The purest alum examined contained about $\frac{1}{2000}$ th part of its weight of sulphate of iron; the impurest about $\frac{1}{1000}$. When freed from sulphate of iron, every species of alum tried acts exactly in the same manner as a mordant.

Sulphite of Alumina. See SULPHITE of Alumina.

Borate of Alumina. This salt may be formed by mixing together the solutions of borate of soda and sulphate of alumina. It is said to be scarcely soluble in water.

Arsenate of Alumina. See ARSENATE of Alumina.

Tungstate of Alumina. A white powder infoluble in water.

Acetate of Alumina. See ACETATE of Alumina.

Benzoate of Alumina. This salt crystallizes, is soluble in water, and deliquesces on exposure to the air.

Succinate of Alumina. Wenzel states, that this salt crystallizes in prisms, and is easily decomposed by heat.

Camphorate of Alumina. This salt may be formed by heating together newly precipitated alumina and camphoric acid. It is a white powder, of an acid bitterish taste, and slightly refringent. Water dissolves about $\frac{1}{20}$ th part of its weight of this salt: it is not soluble in boiling water, but separates as the water cools. Cold alcohol dissolves very little of it; but by the assistance of heat that fluid takes up a considerable quantity, which separates on the cooling of the alcohol. This salt undergoes but little change from the action of the air. Exposed to heat the acid volatilizes; and when the salt is thrown on burning coals it takes fire, and burns with a blue flame.

Suberate of Alumina. This salt does not crystallize. It has a yellowish colour, and always contains an excess of acid. On exposure to the air it attracts moisture. When heated the acid is volatilized, and the alumina left in a state of purity.

Oxalate of Alumina. Oxalic acid readily dissolves alumina, and forms an uncrystallizable deliquescent salt, with excess of acid, of a yellowish colour, and sparingly soluble in alcohol. It is said to be composed of

Oxalic acid and water - -	56
Alumina - - - - -	44
	100

Mellate of Alumina. This salt exists in the form of a white flaky powder.

Tartrate of Alumina. See TARTRATES.

Tartrate of Potash and Alumina. This triple salt may be formed by saturating tartar with alumina. It nearly resembles the last salt. Neither the alkalies nor alkaline carbonates, according to Thenard, produce precipitates in this salt.

Saccharate of Alumina. A white powder, infoluble in water.

Urate of Alumina. A white powder, closely resembling in its appearance the uric acid.

Malate of Alumina. This salt is almost infoluble in water; hence Mr. Chenevix has proposed the malic acid as a means of separating alumina from magnesia.

Sorbate of Alumina. From the experiments of Mr. Donovan, the discoverer of sorbic acid, it appears that this salt has no existence.

Zumate of Alumina. A gummy mass, not altered by exposure to the air.

Gallate of Alumina. According to sir Humphrey Davy, a solution of galls, in which alumina has been diffused, deposits after some time transparent prismatic crystals, which are the super-gallate of alumina. The quantity of alumina they contain is so small as not to disguise the properties of the acid.

Dr. Thomson is disposed to consider the salts of alumina in general as composed of one atom of alumina and one atom of the respective acids, and if this be admitted their composition may be readily ascertained.

With respect to the uses of the salts of alumina, see ALUM, DYEING, MORDANT, TAWING, &c.

ALUMINITE. See MINERALOGY, *Addenda*.

ALUMINUM, in *Chemistry*, the metallic basis of alumina. Sir Humphrey Davy shewed, that when potassium is passed through alumina heated to whiteness, a considerable proportion of it is converted into potash, and grey metallic particles are perceived in the mass, which effervesce in water and air, and are converted into alumina. When a globe of iron is fused by galvanism in contact with moist alumina, it forms an alloy with aluminum, which effervesces slowly in water, and becomes covered with a white powder. These metallic particles Davy considered as the basis of alumina, and in conformity to this view denominated it *aluminum*. The above, however, is all we know at present respecting this metal.

ALYXIA, in *Botany*, (see ΓΥΝΟΡΟΝ,) which latter will probably give way, as in such a case it ought, being founded in error, to the former. Brown Prodr. Nov. Holl. v. 1. 469.

AMADAN. Add—The present town contains in 10,000 meanly-built houses more than 40,000 inhabitants. It is famous

famous for its manufacture of leather; and it is also a mart of commerce between Ispahan and Bagdad, and between Bagdad and Tekroun. N. lat. 35° 51'. E. long. 48°.

AMADIA. Add—This town does not contain above 600 houses; but the plain, at the foot of the hill, is covered with dependent villages. It is nominally dependent upon the pacha of Bagdad, but pays him no tribute.

AMANDA, a township of Ohio, in the county of Fairfield, having 836 inhabitants.

AMANTIA, in *Botany*, $\alpha\mu\alpha\tau\iota\alpha$, an old Greek name for *Fungi* in general, is used by Haller, after Dillenius, for the whole Linnaean genus of **AGARICUS**, (see that article,) or nearly so. Perfoon adopts it for such species only as are furnished with a *volva*, which, on that account, he considers generically distinct.—Perf. Syn. Fung. 246.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Efil. Ch. Stalk with a wrapper at the base. Head fleshy. Gills crowded, nearly undivided.

Obf. The *head* is generally warty, and the *stalk* elongated, either naked, or furnished with a ring. Perfoon describes seventeen species, partly wrong numbered, all which, being more or less remarkable, and some of them very much so, we shall in order enumerate, with the addition of one.

SECT. 1. *Stalk surrounded at the base with a distinct wrapper, but destitute of a ring at the top.*

1. *A. livida.* Livid Egg-Agaric. Perf. Disp. Meth. 66. (*Agaricus plumbeus*; Schæff. Fung. v. 4. 37. t. 85, 86. With. Bot. Arr. v. 4. 244. Fl. Dan. t. 1014. *A. vaginatus*; Bulliard t. 512. f. M, according to Perfoon.)—Head bossed, flatfish, striated, livid lead-coloured. Gills white, as well as the long stalk.—Not uncommon in autumn, after rain, about the skirts of woods, and borders of fields. The *wrapper* bursts irregularly. The *stalk* is hollow, and rather long in proportion, about twice the diameter of the *head*, which is protuberant and brownish in the middle, greyish-lead-coloured and striated at the margin. Some individuals are much thicker than others. Schæffer gives a good representation of the various states and forms of this species. The *head* is sometimes fluted with angular warts, at least when young, as represented by Battarra, *Leucomyces gemmatas*, Batt. Fung. Arim. 28. t. 6. f. B. commended highly in Withering; and by Micheli, t. 78. f. 2. These figures exhibit a state and habit of the plant, the reverse of what appears in the *Fl. Dan.* and especially in Bulliard. This is generally allowed to be a poisonous fungus. Some varieties are indicated by Perfoon, one with yellowish gills, Schæff. t. 244; and another with a browner *head*, and tapering *stalk*, found in fir woods, which seems to connect the present with the following species.

2. *A. spadicea.* Tawny-brown Egg-Agaric. Perf. Disp. Meth. 66. (*Agaricus badius*; Schæff. Fung. v. 4. 63. t. 245. With. v. 4. 227. *A. fulvus*; ib. t. 95. *A. vaginatus*; Bulliard t. 512, f. N?)—Head somewhat bell-shaped, bossed, striated, brittle, orange-brown. Gills white. Stalk pale brown, scaly.—Found in dry woods, about August, in various parts of England and Germany. Akin to the foregoing, but much more delicate in texture. We should scarcely think it more than a variety.

3. *A. incarnata.* Flesh-coloured Egg-Agaric. Perf. n. 3. (“*Agaricus incarnatus*; Batfeh. Elench. Fung. 51.” *Fungus magnus efulentus*; e volva erumpens, pileolo villosa albo, lamellis carneis, pediculo cylindrico glabro, pariter albo; Mich. Gen. 182. t. 76. f. 1; not f. 2 as Perfoon has it.)—Head hemispherical, white, hairy. Gills flesh-coloured. Stalk white, cylindrical.—Found by Micheli, on old half-decayed trees, in the woods of Viareggio near Florence, in

Vol. XXXIX.

June. No other botanist seems to have met with this fungus; at least not in the state described by Micheli. He represents it of very large dimensions, the *head* full six inches broad, while in its convex state, and covered with fine hairs. *Wrapper* much divided and jagged, tumid. *Stalk* six inches high, smooth, thick, and very straight.

Albertini and Schweiniz, in their very learned *Conspetus Fungorum*, 142, speak of what they deem a variety of this, whose *head* is smooth, scarcely bearing any minute fibres or scales, by no means hairy or shaggy. Every other part agrees with Micheli's account. The undivided *gills* are white, soon assuming a rosy flesh-colour from the seminal powder. *Head* never becoming quite flat; the border neither furrowed nor striated.

4. *A. virgata.* Striped Egg-Agaric. Perf. Disp. Meth. 18 and 66. (*Agaricus volvaceus*; Bulliard t. 262. Sowerb. Fung. t. 1. With. v. 4. 286. Relh. Cant. 507. *A. latus*; With. v. 4. 231?)—Aggregate. Head conical-bell-shaped, somewhat hairy, grey streaked with black. Gills reddish-cinnamon-coloured.—This occurs chiefly on the rotten tan of hot-beds, in summer. The *stalk* is often a foot high, slender in proportion, of a dirty white, bursting from a large pale-olive wrapper. *Head* about three inches broad, splitting into several unequal portions. Perfoon esteems Schæffer's *Agaricus bombycinus*, t. 98, as perhaps a mere variety of the above, with a yellowish *wrapper*, and a shaggy-coated *head*. Dr. Withering distinguishes between the plants of Bulliard and Sowerby. The latter is certainly Relhau's.

5. *A. pusilla.* Small Egg-Agaric. Perf. Obf. Mycol. v. 2. 36. t. 4. f. 4, 5. (*Agaricus volvaceus minor*; Bull. t. 330, not 330.)—Head hemispherical, bossed, pellucid, of a pearly white, somewhat cottony. Gills flesh-coloured. Stalk white, rather longer than the breadth of the *head*.—Native of gardens and woods in autumn, in a southern exposure. Bulliard. We have not heard of this species in Britain. Its appearance is elegant and delicate. *Head* an inch, or inch and a half, in diameter. *Wrapper* turbinate, much divided, permanent.

SECT. 2. *Stalk proceeding from a lax wrapper, and furnished at the upper part with a ring.*
