ÆHOITULLA, in *Zoology*. See **ÆHÆTULLA**.

ÆICHRYSON, in *Botany*, a name given to the **SEDUM majus**; called also *Æithales*.

ÆINAUTÆ, in *Antiquity*, senators of Miletus, who held their deliberations on board a ship, far from shore, and till matters were resolved upon, never returned to land. The greek word *αἰναυται* signifies *always mariners*. Plut. in *Quæst. Rom.*

ÆIZOON, *αἰζων*, from *αι* always, and *ζων* life, *sempervivum* is a name given to **SEDUM** of **HOUSELEEK**.

ÆLANA, or **ELANA**, in *Ancient Geography*, a city of Arabia Petræa on the Red Sea, at the north end of the Ælanitic gulf. It is now called *Ailat*.

ÆLANITIC, **ÆLANTIC**, or **ELANITIC gulf**, a bay of the Red Sea, verging towards the north-east, and belonging to Arabia; so called from the city Ælana, situated near it.

ÆLEA, a small place of Dardania, south-west of Sardica.

ÆLEN, **ELEN**, **ALA**, **AQUILEGIA** or **HALCYDES**, in *Geography*, a large market town in the canton of Bern in Switzerland, which was greatly damaged by an inundation in 1740. It gives name to one of the four mandements into which the government, lordship or county of Aelen is divided. This district, which was for some time subject to Savoy, was afterwards given to the landholders of the Valais, who in 1536 exchanged it with the city of Bern for another district called Gundis. This lordship itself, which is now managed by a governor residing in a seat on an eminence in the town of Aelen, consists of a tract of fertile hills and vales, producing fine fruits and excellent wines; and the richness of its pastures is manifested by its large breeds of cattle.

ÆLFRED, in *Biography*. See **ALFRED**.

ÆLFRIC, an eminent ecclesiastic of the tenth century, who was the son of an earl of Kent, and who, after some imperfect instructions, received from an ignorant secular priest, assumed the habit of the Benedictine order of monks in the monastery of Abingdon, over which Athelwold presided. When Athelwold was created bishop of Winchester in 963, Ælfric among other Abingdon monks was settled in his cathedral; and, in order to testify his gratitude, for the advantages which he had enjoyed under the tuition of Athelwold, he conformed to the wishes of his benefactor in communicating instruction to the youth of his diocese. With this view, he compiled his Latin Saxon vocabulary, and some Latin Colloquies. The former work was pub-

lished by Somner, under the title of a glossary, at Oxford in 1659. Ælfric also translated from the Latin into the Saxon language, most of the historical books of the Old Testament, part of which was printed at Oxford in 1698. At Winchester he also drew up his canons, a kind of charge to be delivered by the bishops to their clergy, which are preserved in the first volume of Spelman's Councils, and were composed, says his biographer, (*ubi infra*) between the years 980 and 987. Upon his removal about the year last-mentioned to Cerne Abbey, he translated from the Latin fathers, the first volume of his homilies. In 988 he was made abbot of St. Alban's, and composed a liturgy for the service of his abbey; and about the latter end of the year 991, when he was bishop of Wilton, he translated a second volume of Homilies. Here he also wrote his Latin-Saxon grammar, a supplement to his Homilies, a Tract dedicated to Sigward or Sigferth, containing two epistles on the Old and New Testaments, which his biographer supposes to have been written between the years 987 and 991. In 994 Ælfric was translated to the see of Canterbury, where, after exerting himself with laudable spirit and prudence for some years, in defending his diocese against the incursions of the Danes, he died Nov. 16th, in the year 1005. He was buried at Abingdon, but his remains were transferred to Canterbury in the reign of Canute. He is represented as the greatest prelate the Saxon church ever had since the days of St. Austin; and as our first reformer next to king Alfred, by introducing the knowledge of the scriptures among the laity. For the times, it must be allowed, he was a man of considerable learning; his morals were irreproachable, and his faith was free from many of the corruptions which have disgraced religion. There was another Ælfric surnamed *Bata*, who was pupil of the former in the school established by Athelwold at Winchester, who was made archbishop of York in 1023, and died in 1051. Another of the same name was abbot of Malmesbury in 974, was created bishop of Crediton in 977, and died in 981. There were several other persons of this name. The celebrated antiquary Leland has expressed his doubts, whether Ælfric, the author of the Latin-Saxon grammar, was the same with the translator of the Homilies, or with the abbot of St. Alban's, who drew up the liturgy, which continued to be used there till his own times. Bale and Pitts have ascribed these three works to three different persons. Whereas, archbishop Usher, by confounding Ælfric, archbishop of Canterbury, with Ælfric, archbishop of York, and with Ælfric, bishop of Crediton, has reduced into one person three men who were really distinct. See Edwardi-Rowei Morefi de Ælfrico, Dorobernensi Archiepiscopo, Commentarius; ed. per Dr. Thorkelin, 4to. 1789.

ÆLIA, an appellation derived from one of the names of Adrian, and applied to several towns.

ÆLIA adiana. See **ZAMA**.—*Augusta mercurialis*. See **TRËNA**.

ÆLIA Capitolina, a name given by the emperor Adrian, from Ælius that of his own family, and Capitolinus the epithet of Jupiter, to the new city which he caused to be built about A. D. 134, near the spot where the ancient Jerusalem stood; and which, on his visit to the eastern parts of the Roman empire, he found in ruins. Here he settled a Roman colony, and dedicated a temple to Jupiter Capitolinus in the room of that of Jerusalem. This profanation of the holy place irritated the passions, increased the rebellions, and aggravated the sufferings of the Jews during the reign of Adrian. The city was once more

taken by them and burnt. Adrian rebuilt it, re-established the colony, ordered the marble statue of a hog, which the Jews held in religious abhorrence, to be set up over the gate which opened towards Bethlehem, and published an edict, strictly forbidding any Jew on pain of death to enter the city, or even to look at it from a distance. He also fixed a vigilant garrison of a Roman cohort to enforce the execution of his orders. Christians, however, were permitted to remain; and they elected a bishop, who, being of the race of the Gentiles, formed a flourishing church of Gentile converts; and these abolished the Jewish observances which had prevailed among the Christians that had been profelyted from the Jews; and in consequence of this total renunciation of the Jewish law, they obtained a free admission into the colony of Adrian. In this state the city remained till the time of Constantine, the first Christian emperor, who greatly improved it and restored the name of Jerusalem, though that of *Ælia* continued to be occasionally used by Greek, Latin, and Mahometan authors. The Jews, however, were not permitted to reside there. Attempting in vain to get possession of their capital, Constantine caused their ears to be cut off, their bodies to be marked as rebels, and dispersed them over all the provinces of the empire, as fugitives and slaves. The coins of Adrian, Antoninus Pius, and Marcus Aurelius, are inscribed with the characters COL. AEL. CAP. i. e. *Colonia Ælia Capitolina*. Latin medals were struck at *Ælia* in honour of Adrian and other Roman emperors.

ÆLIA Riccina. See *RICCINA*.

ÆLIAN, *Claudius*, in *Biography*, was born at Præneste in Italy, about the year 80, and taught rhetoric at Rome, where he lived in the time of the emperors Nerva, Trajan, Adrian and Antoninus, according to the account of Vossius extracted from the Greek historians, but according to Perizonius, under the emperor Alexander Severus, who began his reign A. D. 222. Philostratus informs us, that he was a Roman citizen, and that his life was extended beyond sixty years. He was surnamed *Μελιγλωσσος* or *Μελιφθόγγος*, *honey-mouthed* and *honey-speeched*, on account of the peculiar sweetness of his style, both in his discourses and writings. Martial refers to this excellence, lib. xii. epigr. 24.

“O jucunda, Covine, solitudo,
Carrucæ magis, effedoque gratum
Facundi mihi munus Æliani.”

He was honoured with the appellation of Sophist, which was a title appropriate in that age to men of wisdom and learning; and with the office of pontifex, as Suidas informs us. He appears to have devoted himself with peculiar assiduity to literary pursuits, and to the study and practice of eloquence. As a writer he acquired a high degree of reputation, and as a person of sound principles and integrity he has been much extolled. *Ælian* greatly admired and diligently studied Plato, Aristotle, Isocrates and Plutarch, and particularly the poets Homer, Anacreon, Archilochus, &c. and he expresses himself in terms of peculiar commendation of Hipparchus, the son of Pisistratus, as the liberal patron of the poets. Such were his impartiality and candour, that though he was himself a Roman, he declares his preference of the Greek writers. His most celebrated works are his “*Variæ Historiæ*,” of which we have an excellent edition in Greek and Latin by Gronovius, in two vols. 4to.; to which are annexed the “*Fragments*” of *Ælian*, collected by Kuhnus, out of Suidas, Stobæus and Eustathius: and his 17 books “*De Natura Animalium*,” published by the same editor, two vols. 4to. with the animadversions of Gesner, Triller, and Gronovius.

The style of the latter is more elegant than that of the former, which does not seem to have had the last revival of the author. *Ælian* also wrote an accusation or invective against Heliogabalus, or, as some say, Domitian, under the fictitious name of *Gymnis Tyrannus*. He also composed a book against “*Atheists, or on Providence*,” which is much commended by Suidas, and another “*On Divine Appearances, or the Declinations of Providence*.” Some ascribe to him the work intitled “*Tactica*,” addressed to Adrian; but Perizonius is of opinion, that the author of this work was a native of Greece, of the same name, and that he lived about a century before *Ælian*. Those who wish to see more of the talents and writings of *Ælian*, the age in which he lived, and the various editions of his works, may consult Perizonius’s preface to the first volume of the *Variæ Historiæ*, by Gronovius.

ÆLIANUS Mœcius, lived in the time of the emperor Adrian. Galen mentions him with respect. He had great confidence in the Theriaca, as a preventative and cure of the plague.

ÆLI Pons, in *Ancient Geography*, one of the fortresses in or near the wall built by Adrian, now Portland in Northumberland, between Newcastle and Morpeth.

ÆLIUS Pons, now *Il ponte S. Angelo*, a stone bridge at Rome over the Tyber, leading to the Burgo and Vatican from the city, along the mole built by the emperor Adrian.

ÆLIUS Maurus, in *Biography*, was a writer in the reign of the emperor Caracalla, who was then very old, and had been a slave to Phlegon, the freedman of the emperor Adrian. This writer is cited by Spartian in his account of the death of Severus.

ÆLLO, in *Mythology*, one of the three HARPIES.

AELQUAPPE, in *Ichthyology*, the common name among the German nations of a fish of the mustela kind, the viviparous *LELPOUT*, called by Schonefeldt *mustela vivipara*, and in some places *acelpute*, *aelmoder* and *aelmutter*.

AELST, *EVERT VAN*, in *Biography*, a painter, was born at Delft in 1602, and died at the age of 56 in 1658. In painting dead game, fruit, armour, helmets with plumes of feathers, or vases of gold and silver, he exhibited a striking resemblance of nature, and gave an extraordinary lustre to the gold, silver and steel. Pilkington’s Dict.

AELST, *WILLIAM VAN*, the nephew and disciple of the former, was born at Delft in 1620, and died in 1679. He excelled his master in the exercise of his art. His pencil was so light and his touch so delicate, that the objects he painted seemed real. Before the year 1656, he exercised his profession in France and Italy, and afterwards settled at Amsterdam; where his works were much admired, and sold for a large price. The grand duke of Florence honoured him with a gold chain and medal, in acknowledgment of his merit. Pilkington.

AELT, in *Geography*, an abbey of Benedictines upon the river Iltz, below Wassenburg, in Bavaria.

ÆLUÆONES, in *Ancient Geography*, a people of Germany mentioned by Ptolemy, and called *Hilleviones* by Pliny, and *Hellusii* by Tacitus.

ÆLURI, a people placed by Suidas near the Alps, which separated them from the Gauls.

ÆLEUROPOLIS, formed of *αλουρος*, *a cat*, and *πολις* *city*, a town of Egypt, mentioned by Leunclavius.

ÆLURUS, in *Mythology*, the god of the cats: he is represented by the ancient Egyptians, sometimes as a cat, sometimes as a man with a cat’s head. Such was the veneration with which cats were regarded by the Egyptians, that if a person killed any of them, with or without design, he

he was punished with death; and it is reported, that, in time of a famine, which compelled the inhabitants to devour one another, no person was accused of having tasted any of these sacred animals. See Diodor. Sicul. l. i. tom. i. p. 94. Ed. Westeling.

ÆLURUS, in *Zoology*. See CIVET.

ÆLUS; in *Ancient Geography*, a borough of Arabia Felix, belonging, according to Ptolemy, to the Ælefar.

ÆM, AM, or AME, a liquid measure used in most parts of Germany; but different in different towns: the æm commonly contains 20 vertils, or 80 masses; that of Heidelberg is equal to 48 masses; and that of Wirtemberg to 160 masses. See AAM.

ÆMATHIA, or EMATHIA, in *Ancient Geography*, a district of Macedonia, which received its appellation from Æmathius, a prince of remote antiquity, and extended as far as the Sinus Thermaicus, or gulf of Salonichi to the east. It contained several considerable cities, particularly ÆGFA. This district formerly gave name to the whole country of Macedonia.

ÆMILIA, one of the 17 provinces of Italy in the later divisions of the Roman empire, bounded on the north by the Po, on the east by the Adriatic gulf, on the south by the Apennines, and extending to the south east as far as Ariminum.

ÆMILIAN way. See ROMAN WAYS.

ÆMILIANA, a town of Spain.

ÆMILIANI, JEROME, in *Biography*, was founder of the regular clerks of St. Maieul in the 16th century. See FATHERS of *Somasquo*.

ÆMILIANUS, ÆMILIUS, or C. JULIUS, a Moor of mean descent, who, having served from his youth in the Roman armies, raised himself to the first employments in the state, and became first consul, and afterward emperor. Under Gallus he was governor of Pannonia and Mæsia; and in this station he rallied the intimidated and dispersed forces of Rome, and by a signal victory routed the barbarians, who were spreading devastation through the Illyrian provinces, and terror as far as the gates of Rome itself. Having distributed as a donative the money collected for the tribute, he was proclaimed emperor on the field of battle by the acclamations of the soldiers. A. D. 253. Gallus, who was at this time heedless of the public welfare, and indulging himself in the pleasures of Italy, was roused out of his lethargy by information of the success, revolt and hostile approaches of his aspiring lieutenant, now the declared emperor. Æmilianus, by forced marches, hastened to Interamna, now Terni, about 32 miles from Rome; and here he was met by Gallus, and his son Volusianus, at the head of a considerable army. The troops of the latter, comparing the ignominious conduct of their sovereign with the glory of his rival, and seduced by the offer of a considerable increase of pay, deserted from the Imperial standard; and having murdered both Gallus and his son, united, with the followers of Æmilianus, in proclaiming him emperor. The senate added their legal sanction to the rights of conquest. To this assembly, the new emperor addressed assurances, that he should resign to their wisdom the civil administration, and reserving to himself the office of their general, that he would in a short time assert the glory of Rome, and deliver the empire from all the barbarians of the north and of the east. His pride was flattered by the applause of the senate; and medals are still extant, representing him with the names and attributes of Hercules the Victor, and Mars the Avenger. When Valerian, who was conducting a numerous and well disciplined body of troops to the assistance of Gallus, heard

at Rhætia that he was dead, he quickened his march, and determined to revenge his death. The army of Æmilianus, composed of traitors to their former sovereign, lay encamped on the plains of Spoleto, and awed by the character and forces of Valerian, he had no sooner arrived than they imbrued their hands in the blood of a prince who had been so lately the object of their partial choice. Thus Valerian obtained the possession of the throne, without wading to it through the blood of the Roman citizens. Æmilianus was killed at a bridge in the vicinity of Spoleto, which Victor the younger pretends was denominated, from this circumstance, the bloody bridge. He died in the 46th year of his age, after a short reign of three, or at most four months. Eusebius (l. vii. c. 10. p. 255) does not rank him among the emperors; and in the chronicle of Alexandria and that of Nicephorus, Valerian is placed immediately after Gallus. According to Aurelius Victor (in Æmil.) he died a natural death. Anc. Un. Hist. vol. 13. p. 482, 8vo. Gibbon's Hist. vol. i. p. 408. 410, 8vo.

ÆMILIUS, PAULUS, the son of Lucius Paulus, who was killed at the battle of Cannæ, was born about the year of Rome 530, ante Christ 224, and was twice consul. He lived, says Plutarch, in an age that abounded with great men, and took pains to be inferior to none of them. His first military command was in Spain, whither he went as prætor in the war with Antiochus, to quell a general revolt, in effecting which he succeeded. In his first consulate (ante Christ 182,) he triumphed over the Ligurians, and on his return lived privately, and superintended the education of his children; and in the second, (ante Christ 168) subdued Perseus, king of Macedonia, reduced that country to a Roman province, and established a new form of government, from which circumstance he obtained the name of *Macedonicus*. His behaviour, in consequence of his decisive victory, evinced him to be a man of strict justice; for, according to the rules of war, he gave the plunder of the camp to the infantry, and that of the adjacent territory to the horse. The cities he would not suffer to be touched: and as for the royal treasures he conveyed every part of them to Rome, though his integrity excited the ill-will of the army. In his progress through Greece, with a view of settling the division of the country, and establishing his new plan of government, he went to Epirus for the purpose of executing a decree of the Senate, which was so severe, that he could not read it without tears, though he could not demur in obeying it. This decree granted to the Roman army the pillage of the whole of the country which had adhered to Perseus. Æmilianus distributed his troops in small bodies through the town, under a pretence of securing their liberty; but when the ten chiefs of the state had brought into the camp, in pursuance of his orders, all the gold and silver they could find, he allowed the soldiers, on a certain day and hour, to make booty of the remaining property of the poor inhabitants; of whom 150,000 were made slaves, and sold for the benefit of the republic.

His conduct towards Perseus, the vanquished and degraded sovereign, manifested nobleness of mind. When the king's ambassadors approached, he said to those that were near him, "Mark the inconstancy of fortune; this man, who but the other day thought the ample kingdom of Macedonia nothing, whilst he was hindered from subduing the Dardanians and Illyrians, now confined in a narrow island, sends these poor men to ask favours." When Perseus entered his tent, and would have thrown himself at the feet of the consul, he rose hastily, gave him his hand, and would

would not suffer him to kneel; and afterwards treated him with civility and respect. When Æmilius returned to Rome, he obtained, after some hesitation, a triumph of three days, which was one of the most splendid spectacles Rome had ever beheld. The gold and silver carried in the show amounted to a sum which was sufficient to free the people from all taxes for 125 years. Perseus was at this time confined in a common gaol; and the consul's reply to his request, that he might not be made a spectacle in his triumph was not so honourable to his humanity as his former conduct. "This (says he) is entirely in your own power; you need not ask the favour of us;" intimating that the king might kill himself, and thus avoid the shame of being exposed. However, when the humiliating spectacle was finished, and the unfortunate Perseus confined, with circumstances of depression and cruelty, in the common gaol, Æmilius ordered him to be released, and treated with greater decency. The consul did not long survive his triumph. Having accepted the office of censor, and discharged it with honour, he fell into a lingering illness, of which he died, in the 64th year of his age, ante Christ 160. His funeral was conducted with great solemnity; and the natives of those countries which he had conquered, who were then at Rome, attended the procession, contended for the honour of carrying his bier, and paid the tribute of their tears and praises to his humanity and integrity. To his children he only left at his death the patrimony he had received from his ancestors, without having augmented it, says Plutarch, by a single drachina. One of his two sons, by his first marriage, was adopted into the family of the Scipios, and called *Africanus Minor*, and the other into another family: and of the two others by his second wife, who were the hopes of his family, one died five days before his triumph, and the other three days after it. "Fortune, says he, on this occasion, by placing my triumph between the funerals of my two children, as though she meant to divert herself with human events, overwhelms me indeed with trouble and sorrow, but ascertains a full security to my country, having emptied her whole quiver upon me. She has taken a pleasure in exposing the conqueror and the conquered alike, as a spectacle to all mankind; with this difference indeed, that the conquered Perseus has still his children, but those of the conqueror Paulus Æmilius are now no more. But the public happiness alleviates my grief for my domestic misfortunes." His character, says a judicious biographer (See Aikin's Gen. Biog.) was that of a genuine Roman, adorned with letters, and humanized by philosophy. As a military man he may be estimated by the maxim delivered by him to his son Scipio; "A good general never gives battle but when led to it by absolute necessity, or by a very favourable opportunity." He was twice married, first to Papiria, the daughter of Papirius Mafso; and being divorced from her, he took a second wife. In early life his reputation was such that he obtained the ædileship against twelve competitors, who afterwards became consuls. The office of augur he faithfully executed, with a rigid attention to the performance of every rite enjoined by the religion of his country; nor was he less observant of that military discipline by which Rome had become victorious. Plut. in Paul. Æmil. Oper. tom. i. p. 255, &c. edit. Xyland.

ÆMILIUS MACER, a poet of the Augustine age, wrote on the virtues of herbs. There are several editions of his works; but in general so altered and interpolated, Haller says, by the monks, that the genuine lines are scarcely to be distinguished. Many of his verses were inserted in the popular work called the *Schola Salernitana*.

ÆMILIUS PARTHENIANUS, one of the Latin historians, flourished under the emperor Marcus Aurelius. He composed a history of all those who attempted to usurp the sovereign power, and brought it down at least to the year 175, for he wrote the life of Avidius Cassius. He is quoted by Vulcatius Gallicanus, who lived under Diocletian. Voss. Hist. Lat. lib. iii.

ÆMILIUS, PAULUS, a celebrated historian, was a native of Verona, and gained such reputation in Italy, that he was invited into France by Louis XII, in order to write a Latin history of the kings of France, and had a canonry granted him in the cathedral of Paris. He was thirty years in writing this history, and yet it was not completed at his death. Erasmus says of him, that he resembled the painter Protogenes, who thought he had never finished his pieces: thus, says he, Paulus Æmilius is never satisfied with himself. It was his usual custom to revise and alter his own performances, that they would hardly be known to be the same; and this made him so slow, that elephants could bring forth sooner than he could produce a work. Lipsius speaks of his history and manner of writing in terms of high commendation. It is divided into ten books, and extends from Pharamond to the fifth year of Charles VIII. in 1488. The tenth book was left unfinished; but the history was continued in nine books to the close of the reign of Francis I. by Arnoldus Ferronius, and the continuation was published at Paris in 1650. Æmilius, as to his private life, was a man of exemplary conduct and irreproachable reputation. He died at Paris in 1529, and was buried in the cathedral. Biog. Dict.

ÆMILIUS PONS, one of the bridges of Rome, called also *Sublicius*, because it was built on piles.

ÆMINES *Portus*, were situated in a small island of Gaul, now called *Embiez*, between Taurocutum on the north-west and the promontory Citharistes.

ÆMINIUM, a town and river in Spain mentioned by Pliny (tom. i. p. 228.), now called *Agueda*. This town was situated in the province of Lusitania, near the northern bank of the Monda, a little to the south of Talabriga.

ÆMOBOLIUM, in *Antiquity*, the blood of a bull or ram, offered in the sacrifices, called taurobolia and criobolia; in which sense the word occurs in ancient inscriptions. Reinesius and Vandale take it for a corruption, and alter it to Ægobolium. M. de Boze defends the Æmobolium.

ÆMODÆ, or EMODÆ, in *Ancient Geography*, islands of the Ocean to the north of Great Britain.

ÆMONA, *Lanbach* or *Laybach*, a Roman colony and a fortified place in Italy to the east of the Julian Alps.

ÆMONIA, one of the ancient names given to Thessaly.

ÆN, or AIN, a village of Judæa, belonging to the tribe of Judah, and afterwards comprehended in that of Simeon, and assigned to the Levites of this tribe.

ÆNA, or AINA, a town of Arabia Felix; and also a town of Macedonia.

ÆNEIA. See ÆNIADÆ.

ÆNARIA, an island in the bay of Cumæ, or opposite to Cumæ in Italy. It derived its name, says Pliny (l. iii. c. 6. tom. i. p. 160.) from its being the station of the ships of Æneas. It is called Inarine by Virgil (*Æn.* ix. v. 716.), by Ovid (*Metam.* l. xiv. v. 89. t. ii. p. 939. Ed. Burm.), and by Silius Italicus (l. viii. v. 543. p. 436. Ed. Drakenb.), and it is now ISCHIA. It has not been improbably conjectured, that this island was, at some former period, violently separated from the continent by an earthquake. The evidences of such a disruption are calcined

rocks,

rocks, numerous caverns, and the nature of the soil, which yields a great quantity of alum. About the year 1459, Bartholomew Perdex, a Genoese merchant passing by this island, observed several aluminous rocks along the coast; some of which he calcined in a furnace, and thus obtained excellent alum. By this discovery he was enabled to revive the art of making alum, which had been neglected in Italy for many centuries, and which he brought from Rocea, in Syria, where he traded for many years.

About 163 years before this period, it is said that the most pleasant and fruitful part of this island was destroyed by a volcano, and that a small town was consumed by the flames which issued from it, and afterwards swallowed up. Grævii Thesaur. Antiq. et Hist. Italiæ, vol. ix. p. 3, p. 88. For other authorities to the same purpose, see Beckman's Hist. Invent. et Discov. vol. i. p. 303, &c.

ÆNARIUM, a grove of Achaia consecrated to Jupiter, where, as Strabo (tom. i. p. 593.) informs us, the Achæans held their public assemblies.

ÆNEA, or ÆNIA, a city of Mygdonia in Macedonia, at the southern entrance of the Thessalonian Gulf near the island Pallene, is said to have been founded by Æneas. On the promontory adjoining to this city there was a temple of Venus, according to Dion. Halicarn. the foundation of which is attributed to the same person. See Dion. Halicarn. l. i. t. i. p. 39. Ed. Oxon. Livy, l. xl. c. 4. t. v. p. 432. Ed. Drahenb. Stephan. de Urb. p. 44. Livy, (l. xlv. c. 10. t. v. p. 752.) places Ænia in a fruitful country, about fifteen miles from Thessalonica and opposite to Pydna; but this must be laxly interpreted, as Pydna was near the river Aliacmon, and Ænia was probably near the upper part of the Thermian bay. Ænia has been sometimes erroneously confounded with Ænus.

ÆNEAS, in *Entomology*, a species of PAPILIO, with black wings, a green spot on the upper part of the primores, and a sanguineous spot on the postici. It is found in India.

ÆNEAS, in *Fabulous History*, was a Trojan prince, the son of Venus and Anchises, who, at the destruction of Troy, is said, probably by poetical fiction, to have carried away his aged father and his household gods on his back. Hence, it is alledged, Virgil distinguishes him by the epithet *Pius*. See *Ælian*, Var. Hist. tom. i. p. 264. He also led his son Ascanius by the hand, and thus saved his father and son, &c. from the Greeks; but he lost his wife Creusa in the escape. Some say that he and Antenor betrayed the city of Troy. But Virgil, desirous of maintaining his resemblance to Ulysses in all his adventures, excuses him. After the siege of Troy he landed in Africa, and was kindly received by Dido; but quitting her coast, he arrived in Latium or Italy, where he married Lavinia, the daughter of king Latinus, who thus secured to him the throne of Latium. The story of the loves of Dido and Æneas, though an interesting part of the Æneid, is allowed to be a mere poetical ornament, introduced by a gross anachronism. Æneas, as a testimony of his gratitude to Latinus and affection for Lavinia, gave her name to the camp he had pitched, and, instead of Troy, called it Lavinium. The Trojans followed the example of their leader, and by marriages, forming alliances with the Latin families, became, in a short time, one and the same people with the Latins. In the mean time Turnus, who had been contracted to Lavinia, and who was disappointed in his expectations by her marriage with Æneas, went over to the Rutuli; and excited a battle between them and the Latins, in which both he and Latinus were killed. Thus Æneas, by the

death of his father-in-law, and of his rival, obtained the quiet possession of the kingdom of Latium, which he governed with great wisdom, and transmitted to his posterity. Æneas is said to have reigned three years, in which time he established the worship of the gods of his own country, and to the religion of the Latins added that of Troy. The two palladiums, which had been the protectors of that city, became the tutelary deities of Lavinium, and in succeeding ages, of the whole Roman empire. The worship of Vesta was likewise introduced by Æneas, and probably by his means Jupiter, Venus, and many other deities, who had been revered in Troy, became known to the Latins; from which circumstance some have supposed that the poets took occasion to represent him under the character of a *pious* hero. The Rutuli, in the mean while, entered into an alliance with Mezentius, king of the Tyrrhenians, and united with them in their attempts to drive out these new adventurers. Æneas engaged them in a battle, which lasted till night; when being driven to the banks of the Numicus that ran close by Lavinium, he was forced into the river, and was there drowned, in the year of the Julian period 3538, ante Christ 1176. The Trojans concealed his body; and pretending that he had suddenly vanished away, made his credulous subjects regard him as a deity; and they accordingly erected a temple to him under the title of Jupiter Indiges. Virgil has immortalized this prince, by making him the hero of his Æneid.

Æneas was succeeded by his son Ascanius, so called from a river of Phrygia of that name, and denominated Julus from Ilus, formed from Ilium or Troy, who founded *Alba longa* as the capital of his kingdom. See Dion. Halicarn. l. i. p. 34. 51. tom. i. Ed. Oxon. 1704. Livy, l. i. c. 2. and 2. tom. i. p. 18.—21. Ed. Drakenh.

ÆNEAS of *Gaza*, a sophist by profession, was originally a disciple of Hierocles, and a Platonic philosopher, but afterwards became a Christian, and flourished about the year 487. He himself assures us, that he saw the African confessors, whose tongues were cut out by Hunneric king of the Vandals, in 484, under the reign of the emperor Zeno; and that he heard them speak. This supernatural gift of the African confessors, who spoke without tongues, says Mr. Gibbon (*History of the Decline and Fall of the Roman Empire*, vol. vi. p. 295, 8vo.), will command the assent of those, and of those only, who already believe that their language was pure and orthodox. But the stubborn mind of an infidel is guarded by secret incurable suspicion; and the Arian, or Socinian, who has seriously rejected the doctrine of the Trinity, will not be shaken by the most plausible evidence of our Athanasian miracle. Æneas composed a dialogue, entitled "Theophrastus," on the immortality of the soul, and the resurrection of the body; besides twenty-five epistles, still extant. The dialogue was first translated into Latin, and published at Basil in 1516, in Greek and Latin, at Basil in 1560, with other pieces, at Leipzig in 1658, with a translation and notes by Barthius, in 4to. See *Biblioth. Patrum*, tom. viii. p. 664, 665. *Cave's Hist. Liter.* p. 297, and Fabricius, *Bibl. Græc.* tom. i. p. 427.

ÆNEAS, TACTICUS, one of the most ancient Greek authors who have written on the art of war. He lived about 300 years before the Christian æra. The age in which he lived is settled by Casaubon, who informs us, that Cineas, who was a disciple of Epicurus, and an ambassador from Pyrrhus to Rome in the 125th Olympiad, composed an epitome of the works of Æneas. His work was published by Casaubon, in Greek and Latin, with notes, and it is annexed to his edition of Polybius, printed

printed at Paris, fol. 1609. See also Fabr. Bibl. Græc. l. iii. c. 30. sec. 9.

ÆNIAS, SYLVIUS, PICCOLOMINI, was born on the 18th of October, 1405, at Corsigni, a small town in the territory of Sienna, the name of which he afterwards changed into *Pienza*. His mother, when she was pregnant with him, dreamed that she should be delivered of a mitred infant, and interpreting her dream by the mode of degrading clergymen, which at that time was crowning them with a paper mitre, she conceived her son would be a disgrace to her family. But the dream proved to be a preface of his future advancement. Having been well educated, though in low circumstances, at a grammar-school in his native town, he was enabled, by the assistance of friends, to go to the university of Sienna, in 1423, where he made great proficiency, and published several pieces in the Latin and Tuscan languages. In 1431, he attended Cardinal Capraica, surnamed *De Fermo*, to the Council of Basil, as his secretary. He occupied the same office under Cardinal Albergoti, who sent him to Scotland to mediate a peace between the English and Scots. Upon his return, he was appointed Secretary to the Council of Basil, which he defended against the authority of the Popes, both by his speeches and writings. This Council assigned to him other offices of importance; and he was employed in various embassies; in one of which, to Strasburg, he is said to have had an intrigue with a lady, by whom he had a son. For this adventure he has made an humorous apology, in a letter to his father, preserved in Wharton's Appendix to Cave's Hist. Liter. p. 114, anno 1458. In 1439, he was crowned by the Emperor Frederic III. with the poetic laurel; and, in 1442, appointed Secretary to the Empire, and advanced to the senatorial order. Having made his peace with Pope Eugenius III, he was honoured with the office of secretary to his Holiness, which he was allowed to retain without resigning his post under the emperor. Upon the decease of this pope, Æneas was chosen by the cardinals to preside in the conclave till another pope should be elected. Pope Nicholas conferred upon him the bishopric of Trieste, and he was at the same time appointed counsellor to the emperor, and superintendent of the most important concerns of the empire. He afterwards became archbishop of Sienna; and, in 1452, attended Frederic to Rome, when he went to receive the Imperial crown. Upon his return, he was named legate of Bohemia and Austria. In 1456, he was made a Cardinal; and, upon the decease of Calixtus III, in 1458, elected pope, by the name of Pius II. Upon his advancement to the papal chair, his views and sentiments, like those of others in similar circumstances, underwent a total revolution. He published a bull, retracting all he had written in defence of the Council of Basil, meanly apologized for his former conduct, and became a strenuous advocate of the papal prerogatives.

"We exhort and advise you in the Lord, (says he) not to pay any regard to those writings which injure in any manner the authority of the apostolic see, and assert opinions which the holy Roman church does not receive. If you find any thing contrary to this in our dialogues or letters, or in any other of our works, despise such notions, reject them, follow what we maintain now. Believe what I assert now I am in years, rather than what I said when I was young; regard a pope rather than a private man; in short, reject *Æneas Sylvius*, and revere *Pius II.*" On this occasion, he declared appeals from the pope to a council to be null, erroneous and detestable, and contrary to the sacred canons.

Although he declaimed, with all the powers of his eloquence against the Turkish war, when he was secretary to the emperor, and described, from his own experience, the repugnant state and spirit of Christendom; yet, when he was raised to the papal throne, he devoted his life to the prosecution of this war. With this view, he attended a convention of princes at Mantua; but when the pontiff appeared at Ancona, to embark in person with the troops, engagements vanished in excuses; a precise day was adjourned to an indefinite term; and his effective army consisted of some German pilgrims, whom he was obliged to disband with indulgences and alms. The French, who had incurred the pope's displeasure by appealing to a council in defence of the Pragmatic sanction, opposed this measure; but he seems to have been placated by the consent of Louis XI, in 1461, to abolish that edict, which the parliament of Paris had so lately and so vigorously supported. In the following year, 1462, he interposed in a dispute which took place between the Cordeliers and Dominicans, and issued a bull forbidding them to brand one another with the odious epithets of heretics. In the exercise of his high office, Pius exerted himself with spirit and activity in bringing many contentions to a peaceful termination, and in settling the claims of various princes. During his pontificate he received ambassadors from the Patriarchs of the east; who professed their unanimous agreement to submit to the pope as vicegerent of Jesus Christ. At Ancona, whither he repaired for the purpose of embarking in the prosecution of the Turkish war, he was seized with a fever, which terminated in his death, on the 14th of August, 1464, in the 59th year of his age.

Spondanus, in his ecclesiastical Annals, says, that he was inferior to none in learning, eloquence, dexterity, and prudence: and the cardinal of Pavia, in his speech to the conclave, concerning the choice of a successor, pronounces this eulogium on Pius II. that he was a pope who had all the virtues in his character; and that he had merited the utmost commendation by his zeal for religion, his integrity of manners, his solid judgment, and profound learning. Ambition, however, seems to have been his ruling principle; and his conduct furnishes an example, in addition to many others, of the versatility which a change of circumstances produces in persons that are influenced by this principle. The verse of Virgil's *Æneid*, (lib. i. v. 382) which begins — *Sum pius Æneas* — and the end of the following verse — *fama super Æthera notus*, have been applied to him.

A history of his life, supposed to have been written by himself, was published by his secretary, John Gobelin. It was printed at Rome in 4to. in 1584 and 1589, and at Frankfort, in folio, in 1614. We have an edition of Æneas Sylvius's works, printed at Basil, in folio, in 1551. His life is prefixed to the edition of his works, printed at Helmstadt, in folio, in 1700.

Some apophthegms of Æneas are recorded, of which the following are a specimen: As a covetous man is never satisfied with money, so a learned man should not be with knowledge.—Common men should esteem learning as silver, noblemen prize it as gold, and princes as jewels.—The laws have power over the commonalty, but are feeble to the greater ones.—A citizen should look upon his family as subject to the city, the city to his country, the country to the world, and the world to God.—The chief place with kings is slippery.—And as all rivers run into the sea, so do all vices into the court.—The tongue of a sycophant is a king's greatest plague.—A prince who would trust nobody

is good for nothing, and he who believed every body no better.—He who governs many should himself be ruled by many.—Those who go to law are the birds, the court the field, the judge the net, and the lawyers the fowlers.—Men ought to be presented to dignities, not dignities to men.—A covetous man never pleases any body, but by his death. To tell lies is a slavish vice.—Lust sullies and stains every age of man, but quite extinguishes old age.

ÆNEATORES, in *Antiquity*, the musicians in an army; including those who played trumpets, horns, litui, buccinae, &c. The word is formed from *Æneus*, on account of the brazen instruments used by them.

ÆNEID, in *Literary History*, the title of Virgil's celebrated epic poem. The subject of this poem is very happily chosen: as nothing could be more noble, so nothing could be more interesting to the Roman people, than Virgil's tracing the origin of their state to a hero of such celebrity as *Æneas*. Whilst the object was splendid in itself, the theme afforded the poet an opportunity of pursuing, by means of the traditionary history of his country, the future great exploits of the Romans, and of describing Italy and the territory of Rome itself, in its ancient and fabulous state. Dr. Blair thinks that there is no foundation for the opinion, advanced by some critics, that the *Æneid* is an allegorical poem, bearing constant reference to the character and reign of Augustus Caesar; or that Virgil's chief design in composing it was to reconcile the Romans to the government of that prince, who is pourtrayed under the character of *Æneas*. In this poem, unity of action is perfectly preserved; one main object being always kept in view, which was the settlement of *Æneas* in Italy, by order of the Gods. The episodes are likewise sufficiently connected with the main subject; and the nodus, or intrigue of the poem is, according to the plan of ancient machinery, happily formed. The wrath of Juno, who opposes the Trojan settlement in Italy, occasions all the difficulties which embarrass the undertaking of *Æneas*, and connects, throughout the whole work, the human with the celestial operations. Hence arise the tempest which throws *Æneas* on the African shore, the passion of Dido, who endeavours to detain him at Carthage, and the efforts of Turnus, who opposes him in war. At last, however, Juno's resentment is placated, upon a composition with Jupiter, that the Trojan name should be sunk in the Latin, and the hero becomes victorious. The poem, however, is not free from imperfections: one of which is, that there are scarce any characters marked in the *Æneid*. In this respect it is inferior to the *Iliad*, which abounds with characters and action. The character of *Æneas* himself is cold and tame, and not marked with any of those strokes that touch the heart. His behaviour to Dido manifests obduracy, which renders him unamiable. Dido's own character is well supported, and exhibits a figure more truly animated than any other which Virgil has chosen. Besides this defect of character in the *Æneid*, the distribution and management of the subject are, in some respects, exceptionable. Allowance indeed ought to be made for an incomplete work; for it is said, that the six last books did not receive the finishing hand of the author; on which account he ordered, by his will, the *Æneid* to be committed to the flames, which was happily prevented by Augustus. The wars with the Latins are inferior, in point of dignity, to the destruction of Troy, the intrigue with Dido, and the descent into hell; and in the conduct of these wars, the reader, as Voltaire observes, is tempted to take part with Turnus against *Æneas*. This defect might have

been remedied by the poet's making *Æneas*, instead of distressing Lavinia, by killing her lover and occasioning her mother's death, and embroiling her country in a war, deliver her from the persecution of some rival, who was odious to her and to the whole country. The distinguishing excellence of Virgil is tenderness. He was endowed by nature with exquisite sensibility; he felt every affecting circumstance in the scenes which he describes; and he knows how, by a single stroke, to reach the heart. This, in an epic poem, is the merit next to sublimity, and renders the composition interesting to every reader. The second book is one of the greatest master-pieces that was ever executed; and Virgil seems to have there exerted all the powers of his genius, as the subject afforded a variety of scenes, both of the awful and tender kind. The images of horror, presented by a city burning and sacked in the night, are finely mixed with pathetic and affecting incidents. The death of old Priam, and the family-pieces of *Æneas*, Anchises, and Creusa, are as tender as can be conceived. The fourth book, relating the unhappy passion and death of Dido, has been always most justly admired. The interview of *Æneas* with Andromache and Helenus in the third book; the episodes of Pallas and Evander, of Nisus and Euryalus, of Lausus and Mezentius, in the Italian wars, are striking instances of the poet's power of raising the tender emotions. The best and most finished books, upon the whole, are the first, the second, the fourth, the sixth, the seventh, the eighth, and the twelfth. Virgil's battles are, in point of fire and sublimity, inferior to those of Homer; but there is one important episode, the descent into hell, in which he has far exceeded Homer in his *Odyssey*. In all antiquity there is nothing equal, in its kind, to the sixth book of the *Æneid*. Through the whole description of the invisible world, there is displayed a certain philosophical sublime, which Virgil's platonic genius, and the enlarged ideas of the Augustan age, enabled him to support with a degree of majesty far beyond what the rude ideas of Homer's age allowed him to attain. It is needless to say any thing in praise of the sweetness and beauty of Virgil's numbers, which are universally acknowledged. Elegance and tenderness are the distinguishing excellencies of the *Æneid*. For the feeble passages of this poem, it ought to be admitted as an excuse that the *Æneid* was an unfinished work. Blair's Lectures, vol. iii. p. 248—258.

A late writer, viz. M. la Harpe, in his *Lycée*, or Lectures at the Lyceum, does not allow Virgil to be the inventor of a single incident, and scarcely of a verse, in his poem. He is not only accused of imitating Homer in his plan, his battles, and his principal events, as well as in his verses, but of plagiarisms from the old poets Ennius, Pacuvius, Accius, and Suetivus, and from his contemporaries Lucretius, Catullus, Tibullus, Varius, and Furius. It is confessed, however, that the 3d, 4th, and 6th books are great and admirable productions. The excellence of Virgil, in the estimation of this author, rests on the constant perfection of his style, to surpass which seems impossible. It is at once, he says, the delight and despair of all who wish to cultivate poetry; so that if he has not equalled Homer in invention, variety, or constant interest, he has surpassed him in the beauty of particular parts, and in the fine taste by which he has embellished his narratives.

ÆNESIPPA, in *Ancient Geography*, called by Strabo *Ænesipasta*, an island of the Mediterranean, on the coast of Lybia.

ÆNESISPHYRA, a promontory, according to Strabo, and a port, according to Ptolemy, at the extremity of the

Catabathmus magnus, terminating the Lybian nome, to the north-west, near the frontiers of Marmarica.

ÆNI, in *Ancient Geography*, an island of the Red Sea, placed by Ptolemy to the east of Hippos, and to the south of the Plautic gulf.

ÆNIA was a city of the Perræbi in Thessaly; and also the name of a small piece of Asia Minor, in the Tross, according to Strabo, about 50 stadia from Patacepsis. See ÆNEA.

ÆNIADÆ, the name of two cities; one in Acarnania, on the Ionian sea, near the mouth of the river Achelous, denominated by Strabo *Æniadæ*, and now called by modern travellers *Dragonislo*; and another, according to Stephanus, in Macedonia. See ÆNEA.

ÆNIANA, a fortified town of Asia, near the Caspian sea.

ÆNIANES, a people of the southern part of Thessaly, who dwelt to the east of mount Oeta, upon the Spercheus. Pliny reckons them among the Ætolians.

ÆNIGMA, a proposition put in obscure, ambiguous, and generally contradictory terms to puzzle, or exercise the wit, in finding out its meaning; or, an obscure discourse covering some common and well known thing, under remote and uncommon terms.

The word is formed of *αἰνέσθαι*, *obscurè inruere*, to hint a thing darkly; of *ἄνος*, an *obscure speech, discourse*.

The Latins sometimes call it *scirpus*, *sirpus*, or *serapus*. The populace with us name it *riddle*; from the Belgic *reiden*, or the Saxon *araethan*, to interpret.

Fra. Junius defines an ænigma to be an obscure parable, or allegory; and makes two kinds: the one *greater*, rendering the sentence more intricate and knotty, by a multitude of words; the other lesser, consisting of only one or two remote words, or allusions; as in Isaiah, ch. xi. 1. where Jesus Christ is called *נֵזֶר*, *firculus, rod, or branch*.

Fa. Bohours, in the memoirs of Trevoux, defines an ænigma, a discourse, or painting, including some hidden meaning, which is proposed to be guessed.

ÆNIGMAS, *painted*, are representations of the works of nature, or art, concealed under human figures, drawn from history or fable. Thus Jesus Christ, in the middle of the doctors, represents the Bible, &c.

A verbal ænigma is a witty, artful, and abstruse description of any thing.

The use of ænigmas was very great among the Egyptians. Gale thinks they might borrow their custom from the Hebrews, among whom, it is certain, ænigmas were not less in use. Witness Samson's riddle, Judges xiv. 12. 13. *I will now put forth a riddle to you, &c.* *וְיָרֶן*, i. e. according to Vatable, an *ænigmatical problem*: the LXX. render it, *πρόβλημα*. Solomon is said to have been particularly skilful in the solution of ænigmas. Joseph. Antiq. lib. v. cap. 2. Clemens assures us, that the Egyptians placed *sphinxes* before their temples; to intimate that the doctrines of God and religion were *ænigmatical* and obscure. See *HIEROGLYPHIC*.

Some represent the ænigma as the same with *gryphus*; but the more exact writers make a distinction; though wherein the difference lies is not agreed on. Some make it consist in this, that the ænigma properly imports something merry or jocose, and *gryphus* a subject more grave and profound. Others reduce the difference to this, that in the *gryphus* there is something captious, and capable of leading into a snare, which is not found in the ænigma.

The *REBUS* is also ranked by some in the number of ænigmas.

In a general sense, every dark saying, every difficult question, every parable may pass for an ænigma. Hence obscure laws are called *ænigmata juris*.

The alchemists are great dealers in the ænigmatical language, their processes for the philosopher's stone being generally wrapped up in riddles: e. g. *Fac ex mare et famina circulum, inde quadrangulum, hinc triangulum, fac circulum et habebis lapidem philosophorum*. Barchusen has published an explanation of the riddles of chemists, alchemists, physicians, &c.

Among the ænigmas of chemists, that called the sibylline ænigma is famous, of which we had a copy in a MS. of Stephanus Alexandrinus.

Ἐνία γράμματ' ἔχου, τετραδέκαστος εἶμι, νόμος.
 Αἱ τρεῖς αἱ πρῶται ἐνὸς γράμματ' ἔχου ἐλάττω,
 Ἡ λοιπὴ δὲ τὰ λοιπὰ, καὶ εἰς τὸ ἄρῃνα τὰ πρῶτα.
 Τὴ πρῶτὸς δ' ἀριθμῶς ἑκατοντάδης εἰς δις ἑπτά,
 Καὶ τρεῖς τρεῖς δεκάδης καὶ δις τρία. Ἦνᾶς δὲ τὰς εἶμι,
 Ὅσα ἀμύντος ἔσθ' τὴς παρ' ἐμὲ σφίσις.

Thus translated by M. Leibnitz.

*Literulis noscor quadrifyllabus ipse novemis:
 Syllaba habet binas, nisi quod tenet ultima ternas.
 Vocales quatuor, quibus non propria vox est.
 Bis septem vicibus numerum centuria totum
 Ingreditur, decadesque novem, tum bis tria. Si me
 Noveris, hinc aditus ad sacra nostra patent.*

Stephanus gives a mystical solution of this ænigma. Moret will have it signify the name Jehovah, which, according to him, comprehends the number 1696, abating one, the number contained in the ænigma. Brentius maintains that the whole sum amounts to 1711, and that it represents the word *σοφία*. The generality understand it of the word arsenic, or *ΑΡΣΕΝΙΚΟΝ*. M. Leibnitz gives a very artful solution of it in this sense, by only supposing the A to stand for a thousand, and I for unity, as we sometimes find them used by grammarians.

The operation of cupping, performed in ancient days by a machine of brass, is ingeniously represented by the following ænigma:

Ἄνδρ' εἶδον πυρὶ χαλκῶν ἐπ' ἀνέρι κληκίσσασθαι;
 "I saw a man, who, unprovok'd with ire,
 Stuck brass upon another's back by fire."
 Arist. Rhetor. l. iii. c. 2. t. 2. p. 586. Ed. Duval.

Aulus Gellius (xii. 6.) has preserved a Latin ænigma, which he also calls a *sirpus* or *sirpos*, debased (says Mr. Harris in his *Philological Inquiries*, p. 202.) with all the quibble of a barbarous age:

"Semel minusne, an bis minus, (non fat scio)
 An utrumque eorum (ut quondam audivi dicier)
 Jovi ipsi regi noluit concedere."

It is thus translated by Mr. Harris: "Was it *once minus*, or *twice minus*, (I am not enough informed), or was it not rather *the two taken together*, (as I have heard it said formerly) that would not give way to Jove himself, the sovereign." The *two taken together*, that is, *once minus*, and *twice minus*, make, when so taken, *thrice minus*; and *thrice minus* in Latin is *ter minus*; which, taken as a single word, is *terminus*, the god of boundaries. The meaning of the riddle coincides with the Pagan legend, which says, that, when in honour of Jove the capitol was founded, the other gods consented to retire, but the god *Terminus* refused. See Ovid's *Fasti*, l. iii.; 667, &c. t. iii. p. 137. Ed. Burn.

The moral of the fable is just and ingenious, viz. that boundaries are sacred, and never should be moved.

F. Menestrier has attempted to reduce the composition and resolution of enigmas to a kind of art, with fixed rules, and principles, which he calls the philosophy of ænigmatic images.

ÆNIGMA, *the subject of an*, should be something easily conceived, and generally known.

ÆNIGMAS, *the form of*, consists in the words, which, whether they be in prose or verse, contain either some description, a question, or a prosopœia. Those of the last kind are the most pleasing, inasmuch as they give life and action to things, which otherwise have them not. They are commonly involved either in a pun or metaphor, or sometimes in both. In such fancies, contrary to the principles of good metaphor, and good writing, perplexity is caused, not by accident, but by design, and the pleasure lies in being able to resolve it. To make an ænigma, therefore, two things are to be pitched on, which bear some resemblance to each other, as the sun, and a monarch; or a ship, and a houle; and on this resemblance is to be raised a superstructure of contrarieties to amuse and perplex. It is easier to find great subjects for ænigmas in figures than in words, inasmuch as painting attracts the eyes, and excites the attention to discover the sense. The subjects of ænigmas in painting are to be taken either from history or fable; the composition here is a kind of metamorphosis, wherein, e. g. human figures are changed into trees, and rivers into metals. This conversion, however, does not depend merely on caprice; there must be something of suitableness, and even erudition to authorise it. Thus the battle of Constantine against Maxentius may be taken for the subject of an ænigma, to represent the game of chess: the sign which appeared in the heavens with the words, *in hoc signo vinces*, may properly enough represent the secret of this game, which consists in saving the king. It is much easier to turn *mythology* into ænigmas, than *history*. Accordingly several have imagined, that the conquest of the golden fleece was no other than the transmutation of metals; and that the fable of Circe was the art of chemistry in ænigma. Ænigmas of pure invention are a kind of poetry, and more subtle than those drawn from mythology; since here the matter itself is to be created: instead of adopting some history or received fable, something probable is feigned, the chief action whereof is known, e. g. a shipwreck, a conflagration, an amphitheatre, or the like. It is essential to enigmas, that the history or fable under which they are presented, be known to every body; otherwise it will comprehend two enigmas instead of one; the first of the history or fable, the second of the sense in which it is to be taken. Another essential rule of the ænigma is, that it only admits of one sense. Every ænigma which is susceptible of different interpretations, all equally natural, is so far imperfect.

ÆNIGMAS, *the solution or explanation of*, forms a kind of exercise, that is as difficult as it is amusing, and that affords scope for invention and penetration. By the solution of an ænigma we are to understand the discovery of a motto corresponding to the action and persons represented in a picture, taken either from history or mythology. This motto must, either by itself or its attendant circumstances, divert the spectators, and furnish occasion for displaying wit, and introducing pieces of poetry to illustrate the subject and awaken the attention of the audience. Those enigmas which are expressed by figures, are more difficult of solution than such as consist of words, because images may have a greater variety of significations than words; so that to fix them to a particular

sense, we must apply every situation, symbol, &c. without omitting a circumstance belonging to them. As there are few persons in history or mythology that have not some particular character, this character must be regarded, in order to determine what the figure in any painting signifies, and to discover how it agrees with the subject of which we would explain it. Thus, if Proteus be represented in a picture, it may be taken to denote *inconstancy*, and applied either to a physical or moral subject, the character of which is mutability; e. g. an almanack which expresses the variable weather, seasons, heat, cold, storms, and the like. The *colours* of figures may also help to unriddle what they mean, e. g. *white* is an emblem of innocence, *red* of modesty, *green* of hope, *black* of sorrow, &c. When figures are accompanied with symbols, they are more determinate; these being, as it were, the soul of ænigmas, and the key that opens the mystery of them. Of all the symbols that occur in the writings of those who have treated of the subject, those only of Pythagoras are truly ænigmatical, which, under obscure proverbs, convey lessons of morality: as when he uses the phrase *stateram ne transilias* to signify, *do no injustice*. Some ænigmas are so complicated, that no rules will serve for the solution of them, and that they occasion great perplexity to those who endeavour to interpret them. Such is that ancient and celebrated ænigma, called *Ælia Lælia crispis*, which has puzzled many learned persons, who have directed their attention to subjects of this nature. There are two copies of it, each of which claims authenticity. The one, formerly engraven on marble and more lately cut in fresh characters, by order of Achilles Volta, is preserved by the family of Volta at Casaralta near Bologna, and is as follows:

D. M.

Ælia Lælia Crispis,

Nec vir, nec mulier, nec androgyna,

Nec puella, nec juvenis, nec anus.

Nec casta, nec meretrix, nec pudica,

Sed omnia.

Sublata

Neque fame, neque ferro, neque veneno,

Sed omnibus.

Nec cælo, nec aquis, nec terris,

Sed ubique jacet.

LUCIUS AGATHO PRISCUS

Nec maritus, nec amator, nec necessarius,

Neque mœrens, neque gaudens, neque flens,

Hanc

Nec molem, nec pyramidem, nec sepulchrum,

Sed omnia,

Scit et nescit cui posuerit."

Thus translated: *Ælia Lælia Crispis, who was neither male, female, nor hermaphrodite; neither a girl, nor a young woman, nor an old woman; neither chaste, nor a whore, nor a modest woman; but all these. She died neither by famine, nor sword, nor poison; but by all these. She lies neither in the air, nor in the water, nor in the earth; but every where. Lucius Agatho Priscus, neither husband, nor lover, nor relation, neither sorrowful, nor rejoicing, nor weeping, erected this, which is neither fabric, nor pyramid, nor tomb; but all these; but to whom, he knows, and does not know."*

The other copy of this ænigma was found written in Gothic letters in a MS. at Milan, introduced with A. M. P. P. D. instead of D. M. *diis manibus*, which an anonymous author (Act. Erud. Lips. Mens. Mart. 1732) interpreting the riddle of a monument erected by one of the Ælian family to his own soul, decyphers thus: *anima mee propria dico*: at the end is the following addition: viz.

"Hoc est sepulchrum intus cadaver non habens,
Hoc est cadaver sepulchrum extra non habens,
Sed cadaver idem est et sepulchrum sibi."

i. e. "Here is a sepulchre without a corpse; here is a corpse without a sepulchre: the corpse and sepulchre are one and the same."

Of this ænigma the solutions have been very numerous. On the four sides of the stone, on which it is inscribed, there are twelve different explanations, with the names of their sagacious authors. Mario Michael Angelo will have it to be rain; Licetus, the beginning and ending of friendship; Gevartius, love; Pontinus, the remains of three different persons: Turrius, the *materia prima*; Barnaud, an eunuch, or the philosopher's stone; Agathias Scholasticus, Niobe; R. Vossius, the rational soul, or the *idea Platonis*; Boxhornius, a shadow; Ovid Montalbanus, hemp; M. de Cicogne, pope Joan; Heumannus, Lot's wife; another anonymous person, the Christian church; Terronus, music; Vesmondus, a lawsuit; and, to add no more, Count Malvasia, in a treatise intitled *Ælia Lælia Crispis non nata resurgens*, interprets it of a daughter promised to a person in marriage, who died pregnant with a male child before the celebration of her nuptials. See Keyser's Travels, vol. iii. 264, &c. 8vo.

ÆNIGMATICAL, something that relates to, or partakes of the nature of ænigmas.

The philosophy of the DRUIDS was altogether ænigmatical.

The ancient sages in general affected an ænigmatical way of writing, to conceal their doctrines from the populace. The Romans in Nero's time were obliged to have recourse to the like method, though for different reasons. The ænigmatical characters of the Egyptians were a species of HIEROGLYPHICS, consisting of such as bore no natural resemblance to the things they represented. Such was the beetle, used to express the sun: the serpent, to represent the stars.

We read of an ænigmatical medal presented by the Huguenots to Henry III. Schott has published an explication of an ænigmatical coin of the emperor Augustus, concerning which antiquaries have been long divided.

ÆNIGMATOGRAPHER, or ÆNIGMATIST, a maker or explainer of ænigmas.

Hardouin, Vander Hardt, &c. are great ænigmatists.

ÆNIGMATOGRAPHY, ÆNIGMATOGRAPHIA, compounded of *αἰνίγμα* and *γραφειν*, to describe, the art of making and resolving, or collecting ÆNIGMAS.

Ænigmatography, otherwise called *ænigmatology*, may be divided into general and particular. The first gives rules concerning the nature, kinds, composition, and use of ænigmas; the second considers the ænigmas in particular sciences, or languages, Greek, Latin, Hebrew, philological, philosophical, theological, &c.

Nic. Reusæer has a treatise, under the title of *Ænigmatographia*.

ÆNIPPE, in *Entomology*, a species of PAPILIO, with roundish yellow wings, all of which are marked beneath with ocellated points; the fore wings with six, and the hinder with seven. It is found in China.

ÆNITTOLOGIUS, in *Poetry*, a kind of verse consisting of two *dactyls*, and three *trochæi*. Such is,

Prelia dira placent truci juvenæ.

ÆNIUM, in *Ancient Geography*, a promontory near Ænia, on the Thermaic gulf.

ÆNIUS, a small river of Dardania in Asia.

ÆNNUM, a small town of Egypt, mentioned by Pliny (t. i. p. 341.) called by others *Philoteræ*, and now *Susquent*.

ÆNOLA, in *Geography*, a market town of Naples, in

the province or jurisdiction of Terra di Lavoro. N. lat. 41° 15'. E. long. 13° 22'.

ÆNONA, in *Ancient Geography*, a city of Liburnia, called by Pliny (t. i. p. 178.) *Civitas Pafini*, now *Nona*. It lies on the Adriatic, by which it is almost surrounded, over against the island Gissa, and distant from it about four miles to the west. M. d'Anville places it to the south of Jadera in Dalmatia.

ÆNUS, a river of Vindelicæ, in Germany, which rises in the Rhetian Alps, and discharges itself into the Danube. It is now the INN. Near this river was the town called *Æni pons* of Antonine, from a bridge that connected Noricum with that part of Vindelicæ, inhabited by the Boii.

Ænus was also a river of the Cimbric Chersonesus.

Ænus was also a mountain of Cephalenia, one of the Greek islands, where was a temple of Jupiter.

Ænus, Ænos, or Ænuus, a town of Thrace, built, says Strabo, cited by Stephanus (de Urb. p. 45.) by the Cumæans, but according to Mela, who seems to mistake this town for Ænia, by the exile Æneas. If it was founded by the Trojans, it was enlarged by the Cumæans. It is situated on one of the two mouths of the Hebrus. It was a free town, says Pliny (t. i. p. 204) in which was the tomb of Polydorus; and was one of the towns, Maronea being the other, on the Ægean Sea, conquered by Philip, the father of Perseus, and upon the defeat of the latter by the Romans, promised to Eumenes, king of Pergamus; but afterwards declared by the senate free and independent. Livy, l. xxxi. c. 16. c. 31. t. iv. p. 534, 557. Ed. Drakenb. Polybius, p. 380, 854. Ed. Casaub. The epithet derived from it is *Ænius*. It was also called *Apfynthus*. Here, according to Plutarch, (t. i. p. 763. Ed. Xylandr.) the brother of Cato of Utica died, and was honoured with a monument of marble in the forum of the *Ænii*. This town is now *Exo*.

Stephanus mentions four other towns of this name; one built by Ænus, the brother of Guneus; another, a city of Thessaly; a third, of the country of the Locrians; and a fourth, between Thapsacus and the Euphrates. There is also an island of this name adjoining to Arabia Felix.

ÆOLIAN ISLANDS are seven islands, situate between Sicily and Italy, in the Tyrrhenian or Tuscan sea; so called according to Pliny, (t. i. p. 164. Ed. Hard.) because Æolus reigned there in the time of the Trojan war. They were denominated by the Greeks *Hephestiades*, and by the Romans *Vulcaniæ*, from their fiery eruptions. They were also called by Strabo, (t. i. p. 394.) *λιπαρῶν νήσοι*, *i. e. Liparensum insule*, from Lipara, the chief of them. Their names, according to Pliny, with whom Diodorus Siculus, (l. v. c. 7. t. i. p. 335. Ed. Weffeling.) agrees, are Lipara, Hiera, Strongyle, Didyme, Ericusa, Phœnicusa, and Euonymos. They are now called, *Isole di Lipari*. Ptolemy mentions fifteen of these islands; but he includes in the number several other little islands, which are too far distant to be properly included under the denomination of the Æolian islands.

ÆOLIC, in a general sense, denotes something belonging to ÆOLIS.

ÆOLIC, or ÆOLIAN, in *Grammar*, denotes one of the five dialects of the Greek tongue. It was first used in Bœotia; whence it passed into Æolia, and was that in which Sappho and Alcæus wrote. We find also a mixture of it in the writings of Theocritus, Pindar, Homer, and many others. The Æolic dialect generally throws out the aspirate or sharp spirit, as *ἡμέρα* for *ἡμέρα*, *day*; draws back

Ionians and Dorians, were Greek nations who migrated into Asia about 60 years after the taking of Troy, and 20 before the return of the Heraclidæ into Peloponnesus; that is about 1124 years before the Christian æra, according to the statement of Dr. Blair's Chronology. Others say this emigration was 140 years after the taking of Troy, and 60 years after the return of the Heraclidæ. The Æolic migration preceded the Ionic about 80 years; and that of the Dorians was posterior to the Ionic near 70 years. Strabo (*ubi supra*) says, that tradition referred the migration of the Æolians to an earlier period than that of the Ionians by four generations: that their colony was conducted by Cresus, that they were led into Thrace by his son and successor Penthilus, about 60 years after the destruction of Troy, at the time of the return of the Heraclidæ to Peloponnesus; that Archelaus, the son of Penthilus, conducted them towards Cyzicus; and that his son Graus advanced with them to the river Granicus, and took possession of Lesbos.

The Æolians were divided, after their settlement in Asia, into small states, or cantons, independent of each other, but united in one common confederacy. Their country, though more extensive than that of the Ionians, was inferior to it in all other respects. The Æolians, as well as the other Greek colonies in Asia, enjoyed their liberties, and lived according to their own laws, from the time of their migration to the reign of Croesus, king of Lydia, to whose power they were forced to submit. But as they were allowed to live unmolested under his mild government, they took occasion from this indulgence to oppose Cyrus, when he first invaded Lydia; but they were reduced to subjection by this victorious prince; and their state was more dependent under the Persian monarchs than it had ever been before. The Æolians and Dorians were not inferior to the European Greeks, till they were subdued by the Persians, but having lost their liberty they sunk into indolence, and became no less effeminate than the other Asiatics. Upon the conclusion of the peace between the Greeks and Persians, in the reign of Artaxerxes, one of the articles, sworn to by both parties, was, that all the Greek states of Asia should be made free, and allowed to live according to their own laws. Their condition was very various, and the Persian yoke, to which they were compelled to submit, was very oppressive, till they were rescued by Alexander, who restored all the Greeks in Asia to the enjoyment of their ancient rights and privileges. After the death of Alexander, they fell under the power of the kings of Syria, and continued subject to them till the Romans, after having delivered Greece from the oppression of Philip, king of Macedon, obliged Antiochus III. surnamed the Great, to grant the same liberty to the Greek colonies in Asia, which they had procured for the Greek states in Europe. They then entered into an alliance with the Romans, till they were subdued by Mithridates, king of Pontus, who compelled them to join with him against the Romans. Upon Sylla's arrival in Asia, they again declared for the Romans; but Sylla having completely subdued the lesser Asia, they were deprived of their liberty and burdened with taxes, which reduced them to beggary. They never afterwards were able to recover their ancient splendour, notwithstanding the favour shewn them by many of the emperors, under whose protection they enjoyed some share of liberty. Æolis is now a district of Anatolia; but is not remarkable in any respect, neither does it seem to enjoy any branch or article of trade.

Herod. l. i. p. 26—73, 141. l. ii. p. 90, &c. Diod. Sic. l. ii. p. 403, and l. xiv. p. 725. Ed. Wesseling. Thucyd. l. i. p. 62. Ed. Duker. Liv. l. xxxv. c. 16. tom. iv. p. 925. Ed. Drakenb.

ÆOLIUM, a city of the Thracian Cherfonesus. M. d'Anville places it at the entrance of the Hellespont to the north, and calls it, with Pliny; Elaus.

ÆOLUS, in *Entomology*, a species of PAPHILIO, with caudated azure wings, a black spot on the primores, and a white band, striated with black, under all of them; found in South America and India.

ÆOLUS, in *Mechanics*, denotes a portable machine, not long since invented by Mr. Tidd, for refreshing and changing the air in rooms.

This machine is adapted in its dimensions to supply the place of a square of glass in a sash window, and is executed in so small a compass, as to project but a little way from the sash, and in so neat a manner, says the inventor, as to be an elegant ornament to the place where it is fixed. It works without the least noise, requires no attendance, and occasions neither trouble nor expence to keep it in order. It throws in only such a quantity of air as is agreeable; and leaves off working, of its own accord, whenever the door or window is opened.

ÆOLUS, in *Heathen Mythology*, the god of the winds, painted with swollen cheeks, like one who with main force endeavours to blow a blast; also with two wings on his shoulders, and a high-coloured fiery countenance. He is said to have been the son of Jupiter by Acasta, or Sigesta, the daughter of Hippotus: or, according to others, the son of Hippotus by Menelea, daughter of Hillus, king of Lipara. He dwelt, as some say, in the island Strongyle now Strombolo, one of the ÆOLIAN islands; or, as others say, either at Rhegium in Italy, or in Lipara. The government of the winds is said to be under his direction and controul. Some mythologists explain the fables relating to Æolus by representing him as a wise and good prince, who was able in consequence of his skill in the sciences, by the flux and reflux of the tides, and the appearances of the volcano in the island Strongyle, to foretel storms and tempests. See Polybii Fragmenta, p. 988.

ÆOLUS'S *Harp*, in *Music*, an instrument so named, from its producing an agreeable harmony, merely by the action of the wind.—It is thus constructed.—Let a box be made of as thin deal as possible, (*Plate 1. Music, fig. 1.*) of the exact length answering to the width of the window in which it is intended to be placed; five or six inches deep and seven or eight inches wide. Let there be glued upon it at *aa*, two pieces of waincoat about half an inch high, and a quarter of an inch thick, to serve as bridges for the strings; and within side, at each end, under *bb*, glue two pieces of beech, about an inch square, of length equal to the width of the box, which are to sustain the pegs. Into these fix as many pins, such as are used in a harpichord, as there are to be strings in the instrument, half at one end, and half at the other, at equal distances. It now remains to string it with small catgut, or blue first fiddle-strings, fixing one end to a small brass pin, as at *ee*, (*fig. 2.*) and twisting the other round the opposite pin at *bb*.

When these strings are tuned unison, and the instrument placed with the strings outward, in the window to which it is fitted, it will, provided the air blows on that window, give a sound like a distant choir, increasing or decreasing, according to the strength of the wind.

The roses in the middle only represent sound-holes; the thinner the top is, the better will the instrument perform. Mr. Thompson, in a note to his celebrated Ode on this instrument, ascribes the invention of it to Mr. Oswald; whereas it was known to Kircher above a hundred years ago; and the method of constructing and using it is described by him in a book intitled *Magia Phonotactica & Phonurgia*.

An improved form of this instrument is represented in
fig.

Fig. 3. constructed by the late Rev. W. Jones. The strings, instead of being on the outside, are fixed to a sounding-board or belly within a wooden case, and the wind is admitted to them through an horizontal aperture. In this form the instrument is portable, and may be used any where in the open air.

Æolus's harp produces all the harmonies of a single string, divided in harmonical proportion. See HARMONICS. The tension of the strings must not be great; as the air, if gentle, has not sufficient power to make them vibrate; and, if it blows fresh, the instrument does not sing, but scream. Its crescendo and diminuendo, or the gradual advancing and retiring of its delicate tones, can only be described by the instrument itself.

Kircher has attempted to account for the phenomena of the Æolian harp, by supposing the current of air to strike on different portions of the string. But this is contrary to experience; for, if we suppose the Æolian note to be one-fifth above the original note of the string, that is, one third of the whole, then, according to Kircher, the remaining part would be at rest, which is not the fact; for an obstacle applied to any other point besides the quiescent points of division, will destroy the Æolian tone. The chords also that would arise on this theory are not such as really take place in nature; thus, where the chord consists of the notes F and A, the first note F is produced, according to Kircher, by the blasts striking on one fourth of the string: and in this case, the remaining part of the string must be at rest according to Kircher, which is contrary to experience; or, if it be agitated as one string, it must produce the note of three-fourths of the whole string, that is, a fourth above the bass note; whereas, the note really produced is the double octave to the third above the bass note.

Mr. Young, in order to ascertain the order of the notes in this instrument, took off all the strings but one; and, placing it in a proper situation, he was surprised to hear a great variety of notes, and frequently such as were not produced by any aliquot part of the string; and he often heard a chord of two or three notes from this single string. These complex and extraordinary phenomena at first perplexed him; and he almost despaired of being able to account for them on the principle of aliquot parts. On farther examination, however, he found that they all flowed naturally and easily from this principle. Having directed his attention to the effect of a current of air rushing against a stretched elastic string, he observed, that a blast against the middle point of the string moved the whole of it from its rectilinal position; and that the string by its elasticity, returned to its former position: so as thus to continue vibrating and exciting pulses in the air, which produced the tone of the entire string. If the current of air be too strong and rapid, when the string is bent, it will retain its curvature. But though the whole string cannot perform its vibrations in this case, the subordinate aliquot parts may; and these will be of different lengths according to the rapidity of the blast. Thus, when the velocity of the current increases so as to prevent the vibration of the whole string, those particles which strike against the middle points of the halves of the string agitate those halves, as in the case of sympathetic and secondary tones; and as these halves vibrate in half the time of the whole string, though the blast may be too rapid to admit of the vibration of the whole, yet it can have no more effect in preventing the motion of the halves than it would have on the whole string if its tension were quadruple: for the times of vibrations in strings of different lengths, and agreeing in other circumstances, are directly as the lengths; and in strings differing in tension, and agreeing in other circumstances, inversely as the square roots of

the tensions: and therefore, their vibrations may become strong enough to excite such pulses as will affect the drum of the ear: and the same may be said of other aliquot divisions of the string. Those particles which strike against such points of the string as are not in the middle of aliquot parts, will interrupt and counteract each other's vibrations, as in the case of sympathetic and secondary tones, and therefore will not produce a sensible effect. These principles are illustrated and applied by Mr. Young in his "Enquiry into the Principal Phenomena of Sound and Musical Strings," printed at London in 1784, 8vo.

ÆON, ΑΙΩΝ, *age*, literally signifies the duration of a thing. But the word has been used by Greek writers in different senses. It was first applied to the age of man, or the duration of human life. In succeeding times it was used by philosophers to express the duration of spiritual and invisible beings.

Χρονος was used to denote the measure of corporeal and changing objects; and αἰων or αἰων, for the measure of such as were immutable and eternal. And, as God is the chief of spiritual and immutable beings, his eternal duration was expressed by this term, and thus it is now commonly understood. It was afterwards attributed to other spiritual and invisible beings; and the oriental philosophers, who lived about the time of Christ's appearance, and made use of the Greek language, understood by it the duration of eternal and immutable things, the space or period of time in which they exist. By a metonymy, the term was employed to signify the beings themselves. Thus, the Supreme Being was called αἰων, or Æon; and the angels also distinguished by the title of Æons. Accordingly, the Gnostics, who had formed the notion of an invisible and spiritual world, composed of entities or virtues, proceeding from the Supreme Being, and succeeding each other at certain intervals of time, so as to constitute an eternal chain, of which our world was the terminating link, assigned to the beings that formed this chain a certain term of duration, and a certain sphere of action. These terms of duration were at first called αἰωνες, æons, and they themselves were afterwards metonymically distinguished by that title. Mosheim's Eccl. Hist. by MacLaine, vol. i. p. 89. 8vo.

Some have affixed another idea to the word *æon*; in order to which they have made use of the philosophy of Plato, giving reality to the ideas which that philosopher had imagined in God; and even personifying them, and feigning them distinct from God, and to have been produced by him; some male, others female. See PLATONISM.

These ideas they call æons; of an assemblage of which they compose their deity, calling it *πληρωμα*, a Greek word, signifying *fulness*.

Some say that Simon Magus was the first inventor of these æons, which seem, however, to have sprung from the oriental philosophy, and which were adopted by the Gnostics; afterwards brought to perfection by Valentinus; who, resigning on those who preceded him in this way, produced a long genealogy of æons, to the number of 30. The first, and most perfect, he particularly denominates Πρωτος, *Proton*, that is, *pre-existent*; beside other names, the most usual whereof was that of *Bythos*, Βυθος, *depth*.

This *Bythos*, he says, continued long alone with *Ενωσια*, *Enusia*, *Thought*; whom Valentinus also called *Χαρις*, *Grace*, and *Σιγη*, *Silence*. At length *Bythos*, with *Sige*, produced *Nous*, *Nes*, *Understanding*; and *Αληθεια*, *Truth*, her sister. *Nous* begat two æons; *Logos*, *Λογος*, *Word*; and *Zoe*, *Ζωη*, *Life*; which begat two others; *Ανθρωπος*, *Ανθρωπος*, *Man*; and *Εκκλησια*, *Church*. And these eight æons were the chief of all the rest.

The *Word*, *Λόγος*, and *Life*, *Ζωή*, beget ten other *æons*; *Man* and the *Church*, beget twelve more; among whom were, the *Paraclete*, *Faith*, *Hope*, *Charity*, the *Perfect*, *Τελειός*; and *Wisdom*, *Σοφία*. And thus were thirty *æons* made up; which, altogether, made the *Pleroma*, *Πλήρωμα*, or *spiritual and invisible plenitude*. See *Gnostics*, and *Valentinians*.

Æon likewise, in the *Pbianic Theology*, was the first created woman.

ÆORA, in the *Medical Writings of the Ancients*, is used for gestation; which sort of exercise was often prescribed by the physicians of those days. Other exercises consisted principally in the motion of the body; but in the *æora* the limbs were at rest, while the body was carried about and moved from place to place, in such a manner as the physician prescribed. It had therefore the advantages of exercise; without the fatigue of it.

This exercise was promoted several ways: sometimes the patient was laid in a sort of hammock, supported by ropes, and moved backward and forward; sometimes his bed run nimbly on its feet. And beside these, the several ways of travelling were accounted species of the *æora*, whether in the litter, in a boat or ship, or on even ground in a chariot.

Alepiades was the first who brought gestation into practice, which was used as a means to recover strength after a fever, &c.

ÆPEA, in *Ancient Geography*, a city of Laconica, according to Stephanus (de Urb. p. 46.), and of Messenia, according to Strabo (t. i. p. 553.), who calls it *Thuria*, and deduces its name from its situation on the top of a hill. It is one of the seven cities promised by Agamemnon to Achilles, and is mentioned by Homer, *Il.* ix. v. 152.

“Καλὴν τ’ Ἀπειραν καὶ Πήδασον ἀμπελοεισσαν.

Pulchramque *Æpeam*, Pedasumque vitiferam.”

Stephanus mentions another city of this name in Cyprus, built by Demophon, the son of Theseus, on mount *Clarius*, which was afterwards called *Solos* in honour of *Solon*; and another in *Crete*.

ÆPOLIUM, a place situated, according to Pliny, between the *Danube* and *Tyras*.

ÆPY, a city of *Messenia*, so called, says Stephanus, from its being fortified; but more probably from its elevated situation, to which *Stattius* refers (*Theb.* l. iv. p. 421. Ed. *Varior*).

“—Et fummis ingestum montibus *Æpy*.”

ÆQUABONA, a town of *Lusitania*, to the south of the *Tagus*, near its mouth, and in view of *Olisippo* or *Lisbon*.

ÆQUANA *juga*, mountains of *Picenum*, in *Naples*, now called *Montagna di Sorrento*, denominated from the town *Æqua*, which, being destroyed, was replaced by *Vicus*, now *Vico di Sorrento*, called also *Æquana*. Thus, *Silius Italicus*, *Punic.* l. v. p. 276. Ed. *Drakenb*.

“—Ac felicia *Baccho*

Æquana, et *Zephyro Surrentum molle salubri*.”

ÆQUATA Superficies, in *Botany*, denotes a surface devoid of all inequality; and differs from *planus* in not requiring the part to be level, or in a rectilinear direction, but often occurs in round bodies, as in the pedicles of *Isia*.

ÆQUI, *ÆVICOLI*, or *ÆVICULI*, in *Ancient History*, inhabitants of Italy, who were situated between the *Sabines* and *Latins*, and whose capital city was *Bola*. *M. d’Anville* places them on the banks of the *Anio*, with the *Samnites* to the north and the *Marrucini* to the east; but others apprehend that their territory extended farther south, so as to comprehend *Algidum*. They are mentioned under the different appellations above-stated, by the historians and poets; and are described as a hardy and valiant people, who were

much employed in agriculture, and also in military exercises. Thus *Virgil*, *Æn.* l. ix. v. 608.

“—*Juventus*

Aut raris terram domat, aut quatit oppida bello.”

And *Virgil*’s description seems to be borrowed by *Silius Italicus*, when speaking of these people, *Punic.* l. 8. 371, p. 419, he says—

“—*Rastrisque domant Æquicula rura*.”

The etymology of their name has been ascribed by *M. Gebelin* to the word *aqua*, or *æwa*, *water*, expressing their situation near the sources of the *Anio*, *Tolonus*, &c. which was more aquatic than any part of *Latium*. Others have supposed, that the *Equi*, who were distinguished by their love of justice, furnished the epithet *equus*, *just*. *Livy* discriminates them from the *Latins*, when he represents them (*l. ii. c. 30. t. 1. p. 369. Ed. Drakenb.*) as invading their territory. They had frequent wars with the *Romans*, as *Livy* has informed us (*l. 2—10.*) but were at length subdued by them. Their capital *Bola* was taken by *Camillus* in the year of *Rome* 369, and their country was soon after laid waste, in order to deprive them of the power to revolt. They still, however, retained their enmity against the *Romans*; and, when occasion offered, joined the other enemies of *Rome*. About the year *U. C.* 449, they united with the *Samnites*; but they were no more that formidable nation, which had often struck terror into the *Roman* legions; inaction had enervated them; and they were unable to maintain the field in their contest with the disciplined armies of *Rome*. At this time their country was overrun and laid waste. The conquerors took possession of forty-one towns in fifty days, most of which they razed or burnt, and thus they almost exterminated the whole nation of the *Æqui*. *Anc. Un. Hist.* vol. x. p. 304. The cities *Cliternum*, *Carseoli* or *Carfula*, *Valeria*, *Sublaqueum*, *Algidum*, *Vicovaro*, *Treba*, *Vitellia*, *Corbio*, and *Subiaco* belonged to the *Æqui*.

ÆQUIMÆLIUM, in *Roman Antiquity*, a name given to that part of the city of *Rome* on which stood the house of *Sp. Mælius*, who attempted to usurp the supreme power by bribing the people, and who, refusing to appear before the dictator *Cincinnatus*, was put to death by *Servilius Ahala*, master of the horse. His house was demolished, and the region of the city where it stood was called *Area Æquimælii*. *Livy*, t. i. p. 919. Ed. *Drakenb*.

ÆQUINOCTIUM, in *Ancient Geography*, a town of *Upper Pannonia*, which is placed by *M. d’Anville* on the *Danube*, south-east of *Vindobona*.

ÆQUUM, a *Roman* colony of *Dalmatia* in *Illyria*, placed by *M. d’Anville* north-east of *Scardona*.

ÆQUUS Tuticus, a place of Italy in the *Saturnium*, north-east of *Beneventum*: the term *Tuticus* in *Samnite* being synonymous with *magnus*. A *Roman* way, called *Æquotutican*, passed by this place towards *Canusium*. The ruins of it may be seen near *Buon-Albergo*.

ÆRA, in *Chronology*, a fixed point of time, from whence to begin a computation of the years ensuing.

The word is also sometimes written in ancient authors, *era*. Its origin is contested, though it is generally allowed to have had its rise in *Spain*. *Sepulveda* supposes it formed from *A. E. R. A.* the notes or abbreviations of the words, *annus erat Augusti*, occasioned by the Spaniards beginning their computation from the time their country came under the dominion of *Augustus*, or that of their receiving the *Roman* calendar. This opinion, however ingenious, is rejected by *Scaliger*, not only on account that in the ancient abbreviations *A* never stood for *annus*, unless when preceded by *V* for *visit*; and that it seems improbable they should

put ER for *erat*, and the letter A, without any discrimination, both for *annus* and *Augustus*. Vossius nevertheless favours the conjecture, and judges it at least as probable as either that of Isidore, who derives *era* from *es*, the tribute-money, wherewith Augustus taxed the world: or that of Scaliger himself, who deduces it likewise from *es*, though in a different manner. *Æs*, he observes, was used among the ancients for an *article*, or *item*, in an account; and hence it came also to stand for a sum or number itself. From the plural *era*, came by corruption *era*, *eram*, in the singular; much as *Ostia*, *Ostiam*, the name of a place, from *Ostia*, the mouths of the Tyber.

ÆRA amounts to the same with *EPOCHÆ*; though some authors make a difference between them; but wherein it consists they do not agree. A late critic assigns this difference, that in strictness of speech, *epocha* is that fixed point where an *æra* made use of commences. *Bibl. Germ.* tom. v. p. 172. Vallemont makes another difference, viz. that an *epocha* is a point fixed by chronologers, and an *æra* a like point, only fixed by the popular usage of a country, or nation. Perhaps it might not be amiss if chronologers would keep to this difference, but it is certain most of them hitherto use the two words promiscuously. The proper idea of an *æra*, as it is now generally understood, is that of a series of years, reckoned from a fixed point of time, called an epoch or *epocha*. Thus we say, that the Christian *æra* began at the epoch of the birth of Christ, and any particular year is such a year, according to the date of it, of the Christian *æra*. The particular *æras* are mentioned under *EPOCHÆ*. See also *CHRONOLOGY*.

ÆRA is also used, in some writers of the barbarous age, for any year.

In which sense, we meet with *entering down the æra*, the *eleven hundred and eighth æra*, &c.

ÆRÆ, in *Ancient Geography*, a town of Macedonia, and another of Ionia in Asia Minor, according to Stephan. Byzant. and a people of Asia towards Gedrosia or Germania according to Ptolemy.

ÆRARIUM, the public treasury of the Roman state.

The temple of Saturn at Rome, being the great treasury of the state, was first called *ærarium*; from *as*, *aris*, *copper*; that being the only money in use before the year of Rome 485, when the silver began to be coined.

It was first erected under Augustus, and maintained by a yearly voluntary contribution; but that proving insufficient, the twentieth part of all legacies and inheritances except of such as fell to the next of kin, or to the poor, were assigned to this treasury.

For the custody hereof, three of the emperor's life-guards were constituted *præfecti ærarii*.

ÆRARIUM differs from *fiscus*, as the first contained the public money, the second that of the prince. Yet the two are sometimes used indiscriminately for each other. *Calv. Lex. Jur.*

ÆRARIUM sanctius, was an appendage to the former, added on occasion of the growth of the Roman state, when there was not room enough for lodging all the public monies, and the public acts, which were deposited with it.

It was called *sanctius*, because placed in an inner and safer part of the temple; or because in it was lodged the *aurum vicismarium*, or twentieth, which was kept as a fund or reserve, for extreme necessity of the state. On which account it was also called *ærarium vicismarium*.

ÆRARIUM Ilithæ, or of *Juno Lucina*, was erected by Servius Tullius, sixth king of the Romans, and composed of money paid in by parents for the birth of each child. The

ærarium Veneris, called *Libitine*, was for the custody of money paid into it for those who *died*: and the *ærarium juvenutis* for the money deposited on account of those who arrived at the age of manhood. By these means he was able to ascertain the population and wealth of the country. *Dion. Hal. lib. iv. tom. i. p. 212. Ed. Oxon.*

ÆRARIUM privatum, or the privy purse, contained the money and effects which the prince was master of before his accession to the empire. This was under the care of the *COMES rerum privatarum*.—We meet also with other lesser treasuries, *æraria minora*, in the provinces.

ÆRARIUM Ecclesiæ, the *treasury* or *bank of the church*, was formed in the first century of the Christian *æra*, of free gifts, which were collected and preserved in churches, partly for the purpose of defraying the expence of divine service, and partly to relieve the poor. Such capitals, which were considered as ecclesiastical funds, were by Rudentius, (*Hymn. ii. in honorem Laurentii*) in the beginning of the fifth century, called *montes annonæ*, and *arca numinis*. Tertullian (*Apolog. c. 39. oper. p. 35. Ed. Rigaltii.*) calls them *deposita pietatis*; and hence were formed the *montes pietatis* of later times. See *MOUNTS of Piety*.

ÆRARIUS, in *Antiquity*, an officer instituted by Alexander Severus, for the distribution of the money given in largesses to the soldiery, or people. *Pitisc. Lex. Ant.*

ÆRARIUS was also used for a person whose name was struck out by the censors from the *album*, or list of his century, and was only considered as a citizen so far as to make him subject to pay taxes, *æra*, without being entitled to any privileges, or advantages, from the common-wealth.

Hence the phrases, *ærarium facere*, *inter ærarios referre*, *ærarius eximere*, &c.—Not only plebeians, to whom some have restrained it, but also knights and senators, were subject to this kind of degradation.

The *ærarii* were incapable of making a will, of inheriting, of voting in assemblies, of enjoying any post of honour or profit; in effect, were only subject to the burdens, without the benefits of society; yet they retained their freedom, and were not reduced to the condition of slaves. To be made an *ærarius* was a punishment inflicted for some offence, and reputed one degree more severe than to be expelled a tribe, *tribu moveri*. Concerning the precise meaning of these terms and the penalties denoted by them, which have been differently understood by critics, see a note to c. xviii. l. 24. *Livy, tom. iii. p. 859. Ed. Drakenb.*

ÆRARIUS is also used for a person employed in coining, or working brass.

These are sometimes called *ærarii fusores*: at other times *ærarius* is distinguished from *fusor*; the former answering to what we now call copper-smiths, the latter to founders.

ÆRARIUS is also applied to a soldier who receives pay.

ÆRATA aqua. See *ZIMENT water*.

AERATED water. See *PYRMONT water*.

AERATION of soils, in *Agriculture*, denotes the impregnation of them with air, by ploughing, harrowing, and other means of *PULVERIZATION*, which serve to release the air in the interstices of the soils, and to form various kinds of new combinations.

ÆRDING, or *ERDING*, in *Geography*, a small town of Lower Bavaria, seven leagues south of Landshut, on the river Sempt, in a district which produces the best grain of that country. It was set on fire by the Swedes in 1632, and in 1648 reduced by them to ashes.

ÆREA, in *Ancient Geography*, a town of Thrace upon the Propontis, south of a small gulf, and north-west of Perinthus. It is also a surname of Diana, taken from a mountain of Argolis, where she was worshipped.

ÆRE *collato*, or *conlato*, in *Roman Antiquity*, are terms found in inscriptions, which denote that the charges of erecting a tomb or monument were defrayed either by the friends of the deceased or by the people.

ÆRE diruti, a phrase applied to soldiers, who were punished by being deprived of their pay.

ÆRĒOLUS, answering to the Greek *χαλκος*, was a weight according to Diodorus and Suidas equal to $\frac{1}{4}$ th, and according to others equal to $\frac{1}{5}$ th of the **OBOLUS**, which was $\frac{1}{2}$ grain.

ÆRIA, in *Ancient Geography*, a town in that part of Gallia Narbonensis, which was inhabited by the Cavaiores. It was so called, says Strabo (t. i. p. 83.), because it was situated on an eminence. M. d'Anville places it south-east of Vasio, and north-east of Carpentoracte. This name was also given to one of the islands of Thrace, called *Thafus*. The Saly, and also Egypt, were anciently called *Æria*. Apollon. Rhod. l. i. v. 580. p. 58. l. iv. 267. p. 400. Ed. Hoelzlin. This name is also given by Helychius to Ethiopia.

ÆRIAL, something that consists of, or has relation to, air. The Esseni, the most refined and rational sect among the Jews, held, that the human soul consisted of an aerial substance: and the Rosicrucians, and other visionaries, fill the atmosphere with aerial inhabitants.

ÆRIAL Perspective is that which represents bodies weakened and diminished in proportion to their distance from the eye, and which judicious artists practise by diffusing a kind of thin vapour over them, that deceives the eye agreeably. Aerial perspective chiefly respects the colours of objects, whose force and lustre it takes off more or less, to make them appear as if more or less remote. It is founded on this, that the longer column of air an object is seen through, the more feebly do the visual rays emitted from it affect the eye. Objects seen in a camera obscura sensibly exhibit this effect.

ÆRIAL tribute, in *Antiquity*, was an annual gift of 120 thousand pounds, which the emperor Justinian accepted from his prætorian prefect; and the means of payment were abandoned to the discretion of that powerful magistrate.

ÆRIANS, in *Ecclesiastical History*, a religious sect denominated from Aërius, an Armenian priest of the fourth century. The Aërians had much the same sentiments in respect of the Trinity as the Arians: beside which, they condemned prayers and offerings for the dead, stated fasts and feasts, the celebration of Easter, and other rites of the same nature, in which the multitude think the life and soul of religion to consist; set fasts they considered as Jewish ordinances, and they conceived that to observe Easter was to give heed to Jewish fables (Titus, i. 14. 1 Tim. i. 4.). Though they sometimes fasted on the fourth day of the week, as others did, it was not from a regard to any religious obligation, but merely of their own free will. What Epiphanius says of their chusing to fast on the Lord's day must therefore be a calumny. They also held, that there is no difference between priests and bishops, but that the priesthood and episcopate are absolutely one and the same order, or dignity: an opinion, says Mosheim, which was agreeable to many good Christians, who were no longer able to bear the tyranny and arrogance of the bishops of that century, and which has been since strenuously asserted by many modern divines and others. Aërius built his doctrine chiefly on some passages in St. Paul's writings; and among others, on that in 1 Tim. iv. 14. where the apostle exhorts Timothy not to neglect "the gift he had received by the laying on of the hands of the presbytery." Here, observes Aërius, is no mention of bishops; but Timothy

evidently received his ordination from the presbyters or priests. Epiphanius zealously maintains the superiority of bishops against the Aërians. The word *presbytery*, used by St. Paul, he observes, includes both bishops and priests; the whole senate, or assembly, of the ecclesiastics of the place. Aërius, and his followers, whose great purpose seems to have been that of reducing Christianity to its primitive simplicity, met with great difficulties. They were excluded from churches, and cities, and villages; and being obliged to wander abroad, they suffered great hardships. Being thus generally and violently opposed, they could not increase to any great number, and in time they were reduced to nothing. Tillemont considers them as Calvinists; and it is certain, that their ideas of church government were formed very much upon the Presbyterian plan. Mosh. Eccl. Hist. vol. i. 387. Lardner's Works, vol. iv. p. 306, &c.

ÆRICA, or **ERICA**, in *Ichthyology*, a name given by Gaza and others to the common herring.

ÆRII montes, in *Ancient Geography*, mountains of Sicily, called also *Hærei*, and considered by some as a branch of Ætna, extending to the north-west.

ÆRIRUSA, the ancient name for the sky-coloured **JASPER**.

ÆRITES, in *Botany*, a name given to **ANAGALLIS**.

ÆERNEN, *Aragnum*, in *Geography*, a large walled town of the Valais in Switzerland, which is the court town of the tithing, and which has a council-house where its meetings are held. With this town is incorporated another small place on the Deusch-hill, otherwise called *Mons Dei*, at the foot of which hill is a lofty stone bridge over the Rhone. N. lat. 46° 19'. E. long. 8°.

ÆERVE, a small river of Bœotia, rising in mount Cithæron, and discharging itself into Ælopus.

ÆEROGRAPHY, from *αἴρ*, *air*, and *γράφω*, *I describe*, a description of the **AIR**, or **ATMOSPHERE**, its limits, dimensions, properties, &c.

This amounts to much the same with *aerology*, unless we suppose the latter to enter into the rational, and the former to confine itself to a description of the more obvious affections thereof.

ÆEROLOGY, from *αἴρ*, and *λόγος*, *discourse*; the doctrine or science of the air, and its phenomena, its properties, good and bad qualities, &c. See **AIR**.

ÆEROLOGY, called also the *aerologica*, makes a part of the regimen of health, or the branch of medicine called by some *diatœssica*, or the **NON-NATURALS**, which treats of air, its properties and use in the animal economy, and its efficacy in preserving and restoring health. See **AIR**.

ÆEROMANCY, **ÆEROMANTIA**, compounded of *αἴρ*, *air*, and *μαντεύω*, *divination*, an ancient species of divination performed by means of the air, and its phenomena. *Aeromancy* included the business of **AUGURY**, and *auspicia*; the rules of prediction from uncommon winds, storms, showers, and other prodigies. Modern authors speak of a more rational aeromancy, meaning by it the art of foretelling the changes and variations in the air and weather, winds, storms, and the like.

Morhof advances considerations for reducing aeromancy to a certainty, by means of a regular series of meteorological observations. But though many such have been instituted with great care in many parts, this art has hitherto made a very small progress. Of this kind is Huxham's book *De Aere*.

Barometers, thermometers, hygrometers, and anemometers, are of considerable use in this kind of aeromancy.

Mizoldus has published a body of rules for foretelling storms, &c. drawn partly from vulgar observations, and the

the experience of mariners, partly from astrological considerations; under the title of *AEROMANTIA*.

AEROMELI, a name given to honey, and also to *MANNA*. See *DRO OMELI*.

AEROMETRY, *AEROMETRIA*, compounded of *αἴρ*, *air*, and *μετρέω*, *to measure*, the art of measuring the *AIR*, its powers, and properties; and including the laws of the motion, gravitation, pressure, elasticity, refraction, condensation, &c. of the atmospheric fluid.

The word *aerometry* is but little used: in lieu hereof, we commonly call this branch of philosophy, *PNEUMATICS*. C. Wolsius, professor of mathematics at Hall, having reduced many of the affections of this fluid to geometrical demonstration, first published *Elements of Aerometry*, at Leipzig, 1709, in high Dutch, and afterwards more largely in Latin, which have been twice inserted in his *Curfus Mathematicus*, in eight volumes 4to.

AERONAUTICA, from *αἴρ*, and *ναυτικός*, derived from *ναύς*, *ship*, the art of sailing a vessel through the air, or atmosphere, sustained as a ship in the sea.

AEROPHOBIA, formed of *αἴρ*, *air*, and *φοβός*, *fear*, a term that has been sometimes used for the dread of fresh air. Dr. Franklin says, that he has been sometimes seized with this aerophobia, considering fresh air as an enemy, and excluding it from the rooms which he has occupied. But experience convinced him of his error, and taught him to regard fresh air as eminently conducive to health. Any air, he says, is preferable to that of a close chamber, which has been again and again respired without any change. The same sagacious philosopher has occasionally rallied those valetudinarians, who, wrapping themselves in close garments, hurry from the noxious air of a close chamber with as much of it as they can carry with them into as close a carriage, from which the external air is carefully excluded, and thus proceed to take the air for the benefit of their health.

AEROPHYLACEA, in *Natural History*, denote subterraneous receptacles of air or wind.

The word is compounded of *αἴρ*, *air*, and *φυλάκη*, *custodia*, *keeping*.—In which sense *aerophylacea* stands contradistinguished from *hydrophylacea*, *pyrophylacea*, &c.

Kircher speaks much of *aerophylacea*, or huge caverns, replete with air, disposed under ground, from whence, through numerous occult passages, that element is conveyed either to subterraneous receptacles of water, which are hereby raised into springs or rivers, or into the funds of subterraneous fire, which are thus fed and kept alive for the reparation of metals, minerals, and the like.

AEROPUS, in *Entomology*, a species of *PAPILIO*, having brown wings marked with a yellow band and a single ocellus at the base of the primores. It is found in India and South America.

AEROPUS, in *Ancient Geography*, a mountain of Macedonia.

AEROSIS, among the *Ancient Physicians*, denotes the act whereby the blood is attenuated and converted into an *aura* for the support of the vital spirits, and the maintenance of the flame of life.

AEROSTATICA, from *αἴρ*, and *στατικός*, from *ἵστημι*, *statio*, is used by some authors for the science called by others *AEROMETRY*. It is properly the doctrine of the weight, pressure and balance of the *AIR* and *ATMOSPHERE*.

AEROSTATION, formed of *αἴρ*, *air*, and *στάσις*, of *ἵστημι*, *I weigh*, the science of weights, in its primary and proper sense, denotes the science of weights, suspended in the air; but in the modern application of the term, it signifies the art of navigation through the air, both in the principles and the practice of it. Hence also the machines.

which are employed for this purpose, are called *aerostats*, or *aerostatic machines*; and, on account of their round figure, *air-balloons*. The *aeronaut*, formed of *αἴρ* and *ναυτικός*, *sailor*, is the person who navigates through the air by means of such machines.

AEROSTATION, principles of. The fundamental principles of this art have been long and generally known; although the application of them to practice seems to be altogether a modern discovery. They are particularly illustrated in this Dictionary under the articles *Weight of AIR*, *Elasticity of AIR*, and *Specific GRAVITY*.

It will be sufficient, therefore, to observe in this place, that any body, which is specifically, or bulk for bulk, lighter than the atmospheric air encompassing the earth, will be buoyed up by it, and ascend; but as the density of the *ATMOSPHERE* decreases, on account of the diminished pressure of the superincumbent air, and the elastic property which it possesses, at different elevations above the earth, this body can rise only to a height in which the surrounding air will be of the same specific gravity with itself. In this situation it will either float, or be driven in the direction of the wind or current of air, to which it is exposed. An air-balloon is a body of this kind, the whole mass of which, including its covering and contents, and the several weights annexed to it, is of less specific gravity than that of the air in which it rises.

Heat is well known to rarefy and expand, and consequently to lessen the specific gravity of the air to which it is applied; and the diminution of its weight is proportional to the heat. To the observations that occur under *Elasticity of AIR* to this purpose, we shall here add, that one degree of heat, according to the scale of Fahrenheit's thermometer, seems to expand the air about one four hundredth part; and about 400, or rather 435, degrees of heat, will just double the bulk of a quantity of air. If, therefore, the air inclosed in any kind of covering be heated, and consequently dilated, to such a degree, as that the excess of the weight of an equal bulk of common air above the weight of the heated air, is greater than the weight of the covering and its appendages, this whole mass will ascend in the atmosphere, till, by the cooling and condensation of the included air, or the diminished density of the surrounding air, it becomes of the same specific gravity with the air in which it floats; and without renewed heat, it will gradually descend.

If, instead of heating common air inclosed in any covering, and thus diminishing its weight, the covering be filled with an elastic fluid, lighter than atmospheric air; so that the excess of the weight of an equal bulk of the latter above that of the inclosed elastic fluid be greater than the weight of the covering and its appendages, the whole mass will in this case ascend in the atmosphere, and continue to rise till it attains a height at which the surrounding air is of the same specific gravity with itself. Inflammable air is a fluid of this kind. For the knowledge of many of its properties, we are indebted to Mr. Henry Cavendish; who discovered, that if common air is eight hundred times lighter than water, inflammable air is seven times lighter than common air; but if common air is eight hundred and fifty times lighter than water, then inflammable air is 10,8 times lighter than common air. See *Phil. Transf.* vol. lvi. art. 19. and *Inflammable AIR* or *HYDROGEN*.

The construction of air-balloons depends upon the principles above stated; and they are of two kinds, as one or the other of the preceding methods of preparing them is adopted.

AEROSTATION, history of. In the various schemes that

have been proposed for navigating through the air, some have had recourse to artificial wings; which, being constructed like those of birds, and annexed to the human body, might bear it up, and by their motion, produce either by mechanical springs, or muscular exertion, effect its progress in any direction at pleasure. This is one of the methods of artificial flying suggested by bishop Wilkins, in the seventh chapter of his *Dædalus, or Treatise on Mechanical Motions*; but the success of it is doubtful, and experiments made in this way have been few and unsatisfactory. Borelli (*De Motu Animalium*, cap. 22. prop. 193 and 204, p. 196 and 208, ed. 1710), having compared the power of the muscles which act on the wings of a bird with that of the muscles of the breast and arms of a man, finds the latter altogether insufficient to produce, by means of any wings, that motion against the air, which is necessary to raise a man in the atmosphere.

Others, with greater probability of success, have proposed to attach the human body to some mass, which being lighter than air, might raise itself and the annexed weight into the regions of that element. This method has actually succeeded; though Borelli (*ubi supra*), as well as Leibnitz, denied the possibility of a man's flying by any of the means with which they were acquainted.

It is needless to recite any of the accounts relating to this subject, which have been transmitted to us by the ancients. Most, if not all of them, are fabulous. An ingenious writer, in a work cited at the close of this article, has given us the result of his enquiries into the records of antiquity; and he informs us, that the earliest account of any thing relating to flying, which has the appearance of authenticity, is that of the wooden pigeon, constructed by Archytas in the fourth century, before the Christian æra, and of which Aulus Gellius (*Noctes Atticæ*, lib. x. cap. 12.) relates, that it could fly by means of mechanical powers, and by an inclosed spirit. This spirit, or aura, our author apprehends, was nothing more than a sort of animation, which the machine appeared to be possessed of, in consequence of its extraordinary mechanism. Aeroftation was, therefore, a subject either altogether unknown, or very imperfectly understood among the ancients; unless we suppose it to be one of those arts, of which the records are lost. In later times, the schemes which have been proposed by ingenious men seem to have terminated in speculation. The reader will find a brief account of some of them under the articles *ATMOSPHERE* and *Artificial FLYING*, and a more comprehensive history of the projects and achievements of different persons, in the work cited below. Upon the whole it appears, that the art of traversing the air is an invention of our own time; and the whole history of it is comprehended within a very short period.

Soon after Mr. Cavendish's discovery of the specific gravity of inflammable air, it occurred to the ingenious Dr. Black of Edinburgh, that if a bladder, sufficiently light and thin, were filled with this air, it would form a mass lighter than the same bulk of atmospheric air, and rise in it. This thought was suggested in his lectures in 1767 or 1768; and he proposed, by means of the allantois of a calf, to try the experiment. Other employments, however, prevented the execution of his design. The possibility of constructing a vessel, which, when filled with inflammable air, would ascend in the atmosphere, had occurred also to Mr. Cavallo about the same time; and to him belongs the honour of having first made experiments on this subject, in the beginning of the year 1782, of which an account was read to the Royal Society, on the 20th of

June in that year. He tried bladders; but the thinnest of these, however scraped and cleaned, were too heavy. In using China paper, he found that the inflammable air passed through its pores, like water through a sieve; and having failed of success by blowing this air into a thick solution of gum, thick varnishes, and oil paint, he was under a necessity of being satisfied with soap-balls, which, being inflated with inflammable air, by dipping the end of a small glass tube, connected with a bladder containing the air, into a thick solution of soap, and gently compressing the bladder, ascended rapidly in the atmosphere; and these were the first sort of inflammable air-balloons that were ever made.

For balloons formed on a larger scale, and on the principle of rarefied air, we must direct our attention to France; where the two brothers, Stephen and Joseph Montgolfier, paper-manufacturers at Annonay, about 36 miles from Lyons, distinguished themselves by exhibiting the first of those aerostatic machines, which have since excited so much attention and astonishment. The first idea of such a machine was suggested to them by the natural ascent of the smoke and clouds in the atmosphere; and the first experiment was made at Avignon by Stephen, the eldest of the two brothers, towards the middle of November, 1782. Having prepared a bag of fine silk, in the shape of a parallelepipedon, and in capacity about forty cubic feet, he applied to its aperture burning paper, which rarefied the air, and thus formed a kind of cloud in the bag; and when it became sufficiently expanded, it ascended rapidly to the ceiling. Soon afterwards the experiment was repeated by the two brothers at Annonay, in the open air, when the machine ascended to the height of about seventy feet. Encouraged by their success, they constructed a machine, the capacity of which was about 650 cubic feet; which, in the experiment, broke the ropes that confined it, and after ascending rapidly to the height of about 600 feet, fell on the adjoining ground. With another machine, 35 feet in diameter, they repeated the experiment in April, 1783; when breaking loose from its confinement, it rose to the height of above 1000 feet, and being carried by the wind, it fell at the distance of about three quarters of a mile from the place where it ascended. The capacity of this machine was equal to about 23,430 cubic feet; and when inflated, it measured 117 English feet in circumference. The covering of it was formed of linen, lined with paper; its shape was nearly spherical; and its aperture was fixed to a wooden frame about 16 feet in surface. When filled with vapour, which was conjectured to be about half as heavy as common air, it was capable of lifting up about 490 pounds, besides its own weight, which, together with that of the wooden frame, was equal to 500 pounds. With this machine the next experiment was performed at Annonay, on the 5th of June, 1783, before a great multitude of spectators. The flaccid bag was suspended on a pole 35 feet high; straw and chopped wool were burnt under the opening at the bottom; the vapour, or rather smoke, soon inflated the bag, so as to distend it in all its parts; and this immense mass ascended in the air with such a velocity, that in less than 10 minutes it reached the height of about 6000 feet. A breeze carried it in an horizontal direction to the distance of 7668 feet; and it then fell gently on the ground. Mr. Montgolfier attributed the ascent of the machine, not to the rarefaction of the heated air, which is the true cause, but to a certain gas or aeriform fluid, specifically lighter than common air, which was supposed to be disengaged from burning substances, and which

has been commonly called Montgolfier's gas, as balloons of this kind have been denominated *Montgolfiers*.

As soon as the news of this experiment reached Paris, the philosophers of the city, conceiving that a new sort of gas, half as heavy as common air, had been discovered by Messrs. Montgolfier, and knowing that the weight of inflammable air was not more than the eighth or tenth part of the weight of common air, justly concluded that inflammable air would answer the purpose of this experiment better than the gas of Montgolfier, and resolved to make trial of it. A subscription was opened by M. Faujas de St. Fond towards defraying the expence of the experiment. A sufficient sum of money having been soon raised, Messrs. Roberts were appointed to construct the machine; and M. Charles, professor of experimental philosophy, to superintend the work. After surmounting many difficulties in obtaining a sufficient quantity of inflammable air, and finding a substance light enough for the covering, they at length constructed a globe of lutestring, which was rendered impervious to the inclosed air by a varnish of elastic gum or $\kappa\alpha\upsilon\tau\epsilon\upsilon\omicron\upsilon\varsigma$, dissolved in some kind of spirit or essential oil. The diameter of this globe, which from its shape was denominated a balloon, was about thirteen feet, and it had only one aperture, like a bladder, to which a stop-cock was adapted: its weight, when empty, together with that of the stop-cock, was 25 pounds. On the 23d of August, 1783, they began to fill the globe with inflammable air; but this, being their first attempt, was attended with many hindrances and disappointments. At last, however, it was prepared for exhibition; and on the 27th it was carried to the Champ de Mars, where, being disengaged from the cords that held it down, it rose before a prodigious concourse of people, in less than two minutes, to the height of 3123 feet. It then entered a cloud, but soon appeared again; and at last it was lost among other clouds. This balloon, after having floated about three quarters of an hour, fell in a field about fifteen miles distant from the place of ascent; where, as we may naturally imagine, it occasioned much astonishment to the peasants. Its fall was owing to a rent, occasioned by the expansion of the inflammable air in that rare part of the atmosphere to which it ascended. When the balloon went up, its specific gravity was 35 pounds less than that of common air.

In consequence of this brilliant experiment, many balloons were made on a small scale; gold-beaters skin was used for the covering; and their size was from 9 to 18 inches in diameter.

Mr. Montgolfier repeated an experiment with a machine of his construction before the commissaries of the Academy of Sciences on the 11th and 12th of September. This machine was 74 feet high, and about 43 feet in diameter. When distended, it appeared spheroidal. It was made of canvas, covered with paper, both within and without; and it weighed 1000 pounds.

The operation of filling it with rarefied air, produced by means of the combustion of 50 pounds of dry straw, and 12 pounds of chopped wool, was performed in about nine minutes; and its force of ascension, when inflated, was so great that it raised eight men who held it some feet from the ground. This machine was so much damaged by the rain, that it was found necessary to prepare another for exhibition before the king and royal family on the 19th. This new machine consisted of cloth, made of linen and cotton thread, and was painted with water-colours both within and without. Its height was near 60 feet, and its diameter about 43 feet. Having made the necessary preparations for in-

flating it, the operation was begun about one o'clock on the 19th of September, before the king and queen, the court, and all the Parisians who could procure a conveyance to Versailles. In eleven minutes it was sufficiently distended, and the ropes being cut, it ascended, bearing up with it a wicker cage, in which were a sheep, a cock, and a duck. Its power of ascension, or the weight by which it was lighter than an equal bulk of common air, allowing for the cage and animals, was 696 pounds.

This balloon rose to the height of about 1440 feet; and being driven by the wind, it descended gradually and fell gently into a wood, at the distance of 10,200 feet from Versailles. After remaining in the atmosphere eight minutes, the animals in the cage were safely landed. The sheep was found feeding; the cock had received some hurt on one of his wings, probably from a kick of the sheep; the duck was perfectly well.

The success of this experiment induced M. Pilatre de Rozier, with a philosophical intrepidity which will be recorded with applause in the history of aërostation, to offer himself as the first adventurer in this aerial navigation. Mr. Montgolfier constructed a new machine for this purpose in a garden in the Fauxbourg St. Antoine. Its shape was oval; its diameter being about 48 feet, and its height about 74 feet. To the aperture at the bottom was annexed a wicker gallery about three feet broad, with a ballustrade about three feet high. From the middle of the aperture was suspended by chains, which came down from the sides of the machine, an iron grate or brazier, in which a fire was lighted for inflating the machine; and port-holes were opened in the gallery, towards the aperture, through which any person, who might venture to ascend, might feed the fire on the grate with fuel, and regulate the dilatation of the inclosed air of the machine at pleasure. The weight of this aërostat was upwards of 1600 pounds. On the 15th of October, the fire being lighted and the machine inflated, M. P. de Rozier placed himself in the gallery, and ascended, to the astonishment of a multitude of spectators, to the height of 84 feet from the ground, and there kept the machine afloat during 4' 25", by repeatedly throwing straw and wool upon the fire: the machine then descended gradually and gently, through a medium of increasing density, to the ground; and the intrepid adventurer assured the spectators that he had not experienced the least inconvenience in this aerial excursion. This experiment was repeated on the 17th, and on the 19th, when M. P. de Rozier, in his descent, and in order to avoid danger by reascending, evinced to a multitude of observers, that the machine may be made to ascend and descend at the pleasure of the aeronaut, by merely increasing or diminishing the fire in the grate. The balloon having been hauled down, M. Giraud de Villette placed himself in the gallery opposite to M. Rozier; and being suffered to ascend, it hovered for about nine minutes over Paris in the sight of all its inhabitants at the height of about 330 feet. In another experiment the marquis of Arlandes ascended with M. Rozier much in the same manner. In consequence of the report of the preceding experiment, signed by the commissaries of the Academy of Sciences, it was ordered that the annual prize of 600 livres should be given to Messrs. Montgolfier for the year 1783. In the experiments above recited the machine was secured by ropes: but they were soon succeeded by unconfined aerial navigation. Accordingly the balloon of 74 feet in height, above mentioned, was removed to La Muette, a royal palace in the Bois de Boulogne: and all things being ready, on the 21st of November M. P. de Rozier

Rover and the marquis d'Arlandes took their respective parts in the gallery, and at 54 minutes after one the machine was absolutely abandoned to the element, and ascended calmly and majestically in the atmosphere. The aeronauts, having reached the height of about 280 feet, waved their hats to the astonished multitude: but they soon rose too high to be distinguished, and are thought to have soared to an elevation of above 3000 feet. They were at first driven by a north-west wind horizontally over the river Seine and over Paris, taking care to clear the steeples and high buildings by increasing the fire; and in rising met with a current of air, which carried them southward. Having passed the Boulevard, and desisting from supplying the fire with fuel, they descended very gently in a field beyond the new Boulevard, about 9000 yards distant from the palace de la Maette. They were in the air about 25 minutes. The weight of the whole apparatus, including that of the two travellers, was between 1600 and 1700 pounds.

Notwithstanding the rapid progress of aërostation in France, we have no authentic account of any aërostatic experiments performed in other countries till about the close of the year 1783. The first experiment of this kind, publicly exhibited in our own country, was performed in London on the 27th of November, by count Zambecconi, an ingenious Italian, with a balloon of oil silk, 10 feet in diameter, and weighing 11 pounds. It was gilt, in order to render it more beautiful and more impermeable to the inflammable air. This balloon, three-fourths of which were filled with inflammable air, was launched from the Artillery-ground, in the presence of a vast concourse of spectators, at one o'clock in the afternoon, and at half past three was taken up near Petworth, in Sussex, 48 miles distant from London; so that it travelled at the rate of near 20 miles an hour. Its descent was occasioned by a rent, which must have been the effect of the rarefaction of the inflammable air, when the balloon ascended to the rarer part of the atmosphere.

The Parisian philosophers having concerted and executed the first aerial voyage with a balloon inflated by heated air, determined to attempt a similar voyage with a balloon filled with inflammable air, which seemed to be preferable to dilated air in every respect, the expence attending it excepted. A subscription was opened to defray the charges, which were estimated at about ten thousand livres; and the balloon was constructed by Messrs. Roberts, of gores of silk, varnished with a solution of elastic gum. Its form was spherical, and it measured $27\frac{1}{2}$ feet in diameter. The upper hemisphere was covered by a net, which was fastened to the hoop encircling its middle, and called its equator. To this equator was suspended by ropes a car or boat, covered with painted linen and beautifully ornamented, which swung a few feet below the balloon. In order to prevent the bursting of the machine by the expansion of the inflammable air in a rarefied medium, it was furnished with a valve, which might be opened by means of a string annexed to it, for the discharge of part of the internal air without admitting the external to enter. To this balloon was likewise annexed a long pipe through which it was filled. The apparatus for filling it consisted of several casks placed round a large tub of water, each of which had a long tin tube, terminating under a vessel or funnel, that was inverted into the water of the tub. A tube proceeding from this funnel, communicated with the balloon, which stood just over it. Iron filings and diluted vitriolic acid were put into the casks; and the inflammable air, produced from these materials, passed through the tin tubes, through the water of the tub, and through the funnel of the balloon. The car was ballasted with sand-bags; so that by letting

some of the air escape through the valve they might descend, and by discharging some of their ballast ascend. The specific gravity of the inflammable air, with which the balloon was filled, was to that of common air nearly as 1 to 5 $\frac{1}{2}$. and the balloon's power of ascension, when filled for the experiment and when actually ascending, was twenty pounds. The weight of the balloon and of its various appendages was 604 $\frac{1}{2}$ pounds, and therefore the weight sustained by the inflammable air was 624 $\frac{1}{2}$ pounds; and if from the weight of the common air displaced, which was found to be 771 $\frac{1}{2}$ pounds, the former be subtracted, there will remain 147 pounds for the real weight of the inflammable air contained in the balloon.

The 1st of December was fixed upon for the display of this grand experiment; and every precaution was made for conducting it with advantage. The garden of the Thuilleries was the scene of operation; and it was crowded and encompassed with an innumerable multitude of observers. Signals were given by the firing of cannon, waving of pendants, &c. A final *Montgolfier* was launched for shewing the direction of the wind, and for the amusement of the people, previously to the general display. At three quarters after one o'clock, M. Charles and one of the Roberts, having seated themselves in the boat attached to the balloon, and furnished with proper instruments, provisions, and cloathing, left the ground, and ascended with a moderately accelerated velocity to the height of about 600 yards; the surrounding multitude standing silent with fear and amazement. At this height the aerial navigators made signals of their safety. When they went up, the thermometer, according to Fahrenheit's scale, stood at 59°; and the barometer at 30, 18 inches. At the height to which they ascended the barometer stood at 27 inches, whence they deduced their elevation to be nearly 600 yards. During the rest of the voyage the quicksilver in the barometer was generally between 27 and 27, 65 inches, rising and falling as part of the ballast was thrown out or some of the inflammable air escaped from the balloon. The thermometer generally stood between 53 and 57°. Soon after their ascent, they remained stationary for some time: they then moved horizontally in the direction of N. N. W. and having crossed the Seine, and passed over several towns and villages, to the great astonishment of the inhabitants, they descended in a field about 27 miles distant from Paris at a quarter past three o'clock; so that they had travelled at the rate of about fifteen miles an hour, without feeling the least inconvenience. The balloon still containing a considerable quantity of inflammable air, M. Charles re-ascended alone. In ten minutes he thought himself at the elevation of about 1500 toises. The globe, being now in a rarefied medium, swelled considerably; but when some of the inflammable air was discharged, it rose still higher. The barometer, which at his departure stood at 28 inches four lines, had now fallen to 18 inches ten lines. The thermometer, from about 47° of Fahrenheit's scale, had sunk to 21°. From these data the elevation of the globe was estimated at 1524 toises, or about 3,100 yards. M. de Meunier supposes that he ascended to the height of at least 3500 yards. He continued in the air about 33 minutes, and by occasionally pulling the string of the upper valve, and thus letting out the gas, he descended about three miles from the place of his ascent. All the inconvenience he experienced in his elevation was a dry sharp cold, with a pain in one of his ears and a part of his face, which he ascribed to the dilatation of the internal air. The small balloon, launched by M. Montgolfier, was found to have moved in a direction opposite to that of the aeronauts; whence it is inferred, that

that there were two currents of air at different heights above the earth.

In the month of December of this year, several experiments with balloons were made at Philadelphia, in America, by Messrs. Rittenhouse and Hopkins. They contrived to connect several small balloons together, and thus they enabled a man to ascend to the height of 100 feet, and to float to a considerable distance. But fear induced him to cut open the balloons, and thus to descend. Small balloons were at this time very common, both in France and England.

In January 1784, Mr. J. Montgolfier, accompanied by six other persons, ascended at Lyons, with a large rarefied air-balloon, 131 feet high, and 104 feet diameter, to the height of about 1000 yards. This was the largest machine that had hitherto been made. It was formed of a double covering of linen, with three layers of paper between, and strengthened with strings and ribbons. It contained about 540,000 cubic feet of igneous gas; and its weight, including the gallery and passengers, was 1600 pounds. After remaining in the air about fifteen minutes, a rent in the machine occasioned its fall: and when it came within about 600 feet of the ground, it descended with a degree of celerity which very much alarmed the spectators; but they all landed without injury.

On the 22d of February an inflammable air-balloon about five feet in diameter, was launched from Sandwich in Kent, which, travelling at the rate of about 30 miles an hour, crossed the English Channel, and descended in a field about nine miles from Lisle, in French Flanders.

The first person in Italy, who was at the expence of constructing an aerostatic machine for making an aerial voyage, was the chevalier Paul Andreani of Milan: his machine was spherical, about 68 feet in diameter, and formed upon the principle of those of Montgolfier. The chevalier, and two brothers of the name of Gerli, who had assisted in the construction of it, ascended, on the 25th of February, to the height of about 1200 feet; and they remained in the atmosphere about twenty minutes.

From the calculations made respecting the capacity of this machine, it appears, that the included air was not rarefied above one-third, or that the included warm air was not less than two-thirds of that which would have filled the machine, when of the same temperature with the external air; and this is the utmost degree of rarefaction that can be reasonably expected in balloons of this kind.

The next aerial voyage was performed by M. Jean Pierre Blanchard, who had for several years been employed, though without success, in attempts of flying by mechanical contrivances. This voyage was performed in March 1784, with a balloon 27 feet in diameter, to which a boat was suspended, with two wings and a rudder annexed to the boat, and a large umbrella or parachute spread horizontally between the boat and the balloon, designed to check the fall provided that the balloon should burst. The greatest altitude to which Mr. Blanchard ascended from the Champ de Mars at Paris, is supposed to be 9591 feet; and it appears from his own acknowledgment that the wings and rudder of his boat had little, if any, power in guiding the balloon from the direction of the wind. He was in the air an hour and a quarter, and descended at Billancourt, near Seve, after having experienced heat, cold, hunger, and an excessive drowsiness.

Aerostatic experiments and aerial voyages became so frequent in the course of the year 1784, that the limits of this article will not allow our particularly recording them. We

shall, therefore, merely mention those which were attended with any peculiar circumstances. Messrs. de Morveau and Bertrud ascended from Dijon in April, to the height of about 13000 feet, with an inflammable air balloon; the thermometer was observed to stand at 25 degrees. They were in the air during one hour and 25 minutes, and went to the distance of about 18 miles. Their ears were affected in the manner described by Mr. Charles. The clouds floated beneath them, and secluded them from the earth: and they jointly repeated the motto inscribed on their aerostat:—
“*Surgit nunc gallus ad æthera.*”

In May, four ladies and two gentlemen ascended with a Montgolfier at Paris above the highest buildings; the machine was confined by ropes. It was 74 feet high, and 72 in diameter.

In a second voyage performed by Mr. Blanchard from Rouen, in May, it was observed, that his wings and oars could not carry him in any other direction than that of the wind. The mercury in the barometer descended as low as 20,57 inches; but on the earth, before he ascended, it stood at 30,16 inches.

At Lyons, on the 4th of June, M. Fleurant and Madame Thibet, the first lady that made an aerial voyage, ascended in the presence of Gustavus king of Sweden to the height of 8500 feet, and floated to the distance of about two miles in 45 minutes.

A balloon, 32½ feet in diameter, filled with inflammable air, extracted from zinc, was raised at Nantes on the 14th of June with two persons, *viz.* M. Coustard de Massi and M. Mouchet; which ascended to a great height, and in 58 minutes travelled to the distance of 27 miles.

On the 23d of June a large aerostat, on the principle of rarefied air, 91½ feet high and 79 feet in diameter, was elevated by Montgolfier at Versailles, in the presence of the royal family and the king of Sweden. M. Pilatre de Rozier and M. Pronit, ascended with it, and continued for 28 minutes at the height of 11732 feet and observed the clouds below them, that reflected to the region which they occupied the rays of the sun; the temperature of the air being 5° below the freezing point; and in three quarters of an hour they travelled to the distance of 36 miles. In consequence of this experiment the king granted to M. Rozier a pension of 2000 livres.

On the 15th of July the duke of Chartres, the two brothers Roberts, and another person, ascended with an inflammable air-balloon of an oblong form, 55½ feet long and 34 feet in diameter, from the Park of St. Cloud: the machine remained in the atmosphere about 45 minutes. This machine contained an interior small balloon, filled with common air, by which means it was proposed to make it ascend or descend without any loss of inflammable air or ballast. The boat was furnished with a helm and oars, intended for guiding it. At the place of departure the barometer stood at 30, 12 inches. Three minutes after ascending, the balloon was lost in the clouds and involved in a dense vapour. An agitation of the air, resembling a whirlwind, alarmed the aerial voyagers, and occasioned several shocks, which prevented their using any of the instruments and contrivances prepared for the direction of the balloon. Other circumstances concurred to increase their danger; and when the mercury, standing in the barometer at 24,36 inches, indicated their height to be about 5100 feet, they found it necessary to make holes in the bottom for discharging the inflammable air: and having made a rent of between seven and eight feet, they descended very rapidly, and at last came safely to the ground.

On the 18th of July M. Blanchard, accompanied by a
Mr.

Mr. Boby, made his third aerial voyage with the same inflammable air-balloon, at Rouen; and ascended so high as to make the mercury in the barometer fall 4, 76 inches, and the thermometer 40°. In two hours and a quarter they floated 45 miles, or at the rate of twenty miles an hour. In this voyage Mr. Blanchard conceived, that by agitating the wings of his boat he could not only ascend and descend, but move sideways against the wind; but subsequent trials do not seem to have established this fact. The machine retained its air during the night, and several ladies amused themselves the next day, by ascending with it to the height of 80 feet, the length of the ropes to which it was attached.

In the course of this summer two persons, one in Spain, and another in America, were in danger of losing their lives by ascending with rarefied air-machines. The former was scorched by the machine's taking fire, and so hurt by his fall, that his life was long despaired of; and the latter was wafted against the wall of a house, and so entangled, that he fell from the height of about twenty feet, and the machine took fire, and was consumed.

In the month of August the Abbe Carnus, professor of philosophy, and M. Louchet, professor of belles lettres, ascended at Rodez, a town of Guienne in France, with an aerostatic machine of 57 feet in diameter. The air was calm, and the machine did not travel farther than about 14900 yards in 46 minutes; and the height to which it ascended was 3920 yards above the level of the town. The thermometer was 34 degrees lower than it was at the earth when they ascended. On examining the air in one of two bottles, which they had filled at their highest elevation, they found that it contained a quarter less air than if it had been filled at about the level of the sea; and the air, tried by the test of nitrous air, was found more pure than that near the surface of the earth.

The first aerial voyage in England was performed in London, on the 15th of September, by Vincent Lunardi, a native of Italy. His balloon was made of oiled silk, painted in alternate stripes of blue and red. Its diameter was 33 feet. From a net which went over about two-thirds of the balloon, descended 45 cords to a hoop hanging below the balloon, and to which the gallery was attached. The balloon had no valve; and its neck, which terminated in the form of a pear, was the aperture through which the inflammable air was introduced, and through which it might be let out. The air for filling the balloon was produced from zinc by means of diluted vitriolic acid. Mr. Lunardi departed from the Artillery-ground at two o'clock; and with him were a dog, a cat, and a pigeon. After throwing out some sand to clear the houses, he ascended to a great height. The direction of his motion at first was north-west by west, but as the balloon rose higher, it fell into another current of air, which carried it nearly north. About half after three he descended very near the ground, and landed the cat, which was almost dead with cold: then rising, he prosecuted his voyage. He ascribes his descent to the action of an oar; but as he was under the necessity of throwing out ballast in order to re-ascend, his descent was more probably occasioned by the loss of inflammable air. At ten minutes past four he descended on a meadow near Ware in Hertfordshire. The only philosophical instrument which he carried with him was a thermometer, which in the course of his voyage stood as low as 29°, and he observed that the drops of water which collected round the balloon were frozen.

The longest and the most interesting voyage, which was performed about this time, was that of Messrs. Roberts and

M. Collin Hullin, at Paris, on the 19th of September. Their aerostat was filled with inflammable air. Its diameter was 27½ feet, and its length 46½ feet, and it was made to float with its longest part parallel to the horizon, with a boat of nearly 17 feet long attached to a net that went over it as far as its middle. To the boat were annexed wings or oars, in the form of an umbrella. At 12 o'clock they ascended with 450 pounds of ballast, and after various manœuvres descended at 40 minutes past six o'clock near Arras, in Artois, having still 200 pounds of their ballast remaining in the boat. Having risen about 1400 feet, they perceived stormy clouds which they endeavoured to avoid; but the current of air was uniform from the height of 600 to 4200 feet. The barometer on the coast of the sea was 29,61 inches, and sunk to 23,94 inches. They found that by working with their oars, they accelerated their course. In the prosecution of their voyage, which was 150 miles, they heard two claps of thunder; and the cold occasioned by the approach of stormy clouds made the thermometer fall from 77° to 59°, and condensed the inflammable air in the balloon, so as to make it descend very low. From some experiments they concluded, that they were able by the use of two oars to deviate from the direction of the wind about 22°. But this experiment requires repetition, in order to ascertain with accuracy the effect here ascribed to oars.

The second aerial voyage in England was performed by Mr. Blanchard and M. Sheldon, professor of anatomy to the Royal Academy, the first Englishman who ascended with an aerostatic machine. This experiment was performed at Chelsea on the 16th of October. The wings used on this occasion seemed to have produced no deviation in the machine's tracks from the direction of the wind. Mr. Blanchard, having landed his friend about the distance of 14 miles from Chelsea, proceeded alone with different currents; and ascended so high as to experience great difficulty of breathing: a pigeon also, which flew away from the boat, laboured for some time with its wings, in order to sustain itself in the rarefied air, and after wandering for a good while returned and rested on one side of the boat. Mr. Blanchard perceiving the sea before him descended near Rumley, about 75 miles from London, having travelled at the rate of nearly 20 miles an hour.

On the 12th of October, Mr. Sadler, of Oxford, made a voyage of 14 miles from that place in 17 minutes, with an inflammable air-balloon of his own contrivance and construction.

Mr. Blanchard's fifth aerial voyage was performed from London on the 30th of November, in company with Dr. J. Jefferies, a native of America. This voyage was about twenty-one miles. It does not appear that they derived any advantage from their oars in directing the course of the balloon.

On the 4th of January, 1785, Mr. Harper ascended with an inflammable air-balloon from Birmingham: he went to the distance of 50 miles in about an hour and a quarter, and found no inconveniences beside such as might be expected from the changes of wet and cold, and a temporary deafness. The thermometer descended from 40° to 28°.

On the 7th of January, Mr. Blanchard, accompanied by Dr. Jefferies, departed with the balloon, which had carried him five times through the air, from Dover-castle towards the French coast. In their passage they were under a necessity of throwing away every thing which they had with them in the boat, and to part even with their clothes, in order to prevent the balloon from falling into the sea: but

as they approached the land, it began to rise: and in two hours they reached the high grounds near Calais, and the balloon rising still higher over the land, they descended safely in the forest of Guinnes. In consequence of this voyage the king of France presented Mr. Blanchard with a gift of 12000 livres, and granted him a pension of 1200 livres a year. A bottle which was thrown out of the boat in the time of their danger, struck the water with such force, that the shock was heard at a considerable elevation, and sensibly felt on the ear and balloon.

On the 19th of January Mr. Crosbie ascended at Dublin with an inflammable air balloon to a great height, and rose so rapidly as to be out of sight in $3\frac{1}{2}$ minutes. By opening the valve he descended suddenly as he approached very near the sea. On the 23d of March Count Zambeccari and Admiral Sir Edward Vernon ascended at London, and sailed to Horsham in Sussex, at the distance of 35 miles, in less than an hour. At the height of about two miles, the barometer having fallen from 30.4 inches to 20.8 inches, an accident endangered them, and obliged them to descend. In their descent they passed through a dense cloud, which covered them with snow. They observed that the balloon revolved perpetually round its vertical axis, with such rapidity as to perform each revolution in four or five seconds; they also mention a kind of rustling noise, which they heard among the clouds, and that the balloon was greatly agitated in its descent. On the 5th of May, Mr. Sadler and Mr. Windham ascended at Moulsey Hurst; and were driven by a current of air towards the sea. They fortunately descended at the conflux of the Thames and Medway; but the cords of their machine being released, it instantly ascended and floated to a considerable distance, and was taken up by a trading vessel at sea, where it fell. On the 12th of May, Mr. Crosbie ascended at Dublin, but soon came down again with a velocity which alarmed the spectators. Upon his descent, Mr. McGuire, a college youth, sprung into the machine, and was carried off by the ascending balloon towards the Channel; he at length fell into the sea, and was taken up by a boat dispatched for his relief, just when his strength was exhausted with swimming, and thus his life was saved.

The fate of M. P. de Rozier, the first aerial navigator, and of his companion M. Romain, has been much lamented. They ascended at Boulogne on the 15th of June, with an intention of crossing the Channel to England. Their machine consisted of a spherical balloon 37 feet in diameter, filled with inflammable air; and under this balloon was suspended a small Montgolfier, or fire-balloon, ten feet in diameter. This Montgolfier was designed for rarefying the atmospheric air, and thus diminishing the specific gravity of the whole apparatus. For the first twenty minutes they seemed to pursue the proper course; but the balloon seemed to be much inflated, and the aeronauts appeared anxious to descend. Soon however, when they were at the height of about three quarters of a mile, the whole apparatus was in flames, and the unfortunate adventurers fell to the ground, and were killed on the spot.

On the 19th of July Mr. Crosbie ascended at Dublin, with a view of crossing the Channel to England. To a wicker basket of a circular form, which he had substituted for the boat, he had affixed a number of bladders, for the purpose of rendering his gallery buoyant, in case of a disaster at sea. The height to which he ascended at one time was such, that by the intense cold his ink was frozen, and the mercury sunk into the ball of the thermometer. He himself was sick, and he felt a strong impression on the tympanum of his ears. At his utmost elevation he thought

himself stationary; but on discharging some gas, he descended to a very rough current of air blowing to the north. He then entered a dense cloud, and experienced strong blasts of winds, with thunder and lightning, which brought him with rapidity towards the surface of the water. The water soon entered his ear; the force of the wind plunged him into the ocean; and it was with difficulty that he got on his cork jacket. The bladders which he had prepared were now found of great use. The water, added to his own weight, served as ballast; and the balloon maintaining its poise, answered the purpose of a sail, by means of which, and a snatch-block to his ear, he moved before the wind as regularly as a sailing vessel. He was at length overtaken by some vessels that were crowding sail after him, and conveyed to Dunleary, with the balloon towed after them. On the 22d of July, Major Money, who ascended at Norwich, was driven out to sea, and after having been blown about for about two hours, he dropped into the water. After much exertion for preserving his life, and when he was almost despairing of relief, he was taken up by a revenue cutter in a state of extreme weakness; having been struggling to keep himself above water for about seven hours. The longest voyage that had been hitherto made was performed by Mr. Blanchard towards the end of August. He ascended at Lisle, accompanied by the chevalier de L'Epinaud, and traversed a distance of 300 miles before they descended. On this, as well as on other occasions, Mr. Blanchard made trial of a parachute, in the form of a large umbrella, which he contrived for breaking the fall in case of any accident. With this machine he let down a dog, which came to the ground gently, and unhurt.

On the 8th of September Mr. Baldwin ascended from the city of Chester, and performed an aerial voyage of 25 miles in two hours and a quarter. His greatest elevation was about a mile and an half, and he supposes that the velocity of his motion was sometimes at the rate of 30 miles an hour. He has published a circumstantial account of his voyage, described the appearances of the clouds as he passed through them, and annexed a variety of observations relating to aërostation, which render his treatise valuable and interesting to those who wish to acquaint themselves with this subject. It would be tedious to recount the aerial expeditions that were performed in various parts of our own country, as well as on the continent, in the whole course of the year 1785; more especially as they have afforded us no experiment or discovery of any peculiar importance. The most persevering aerial navigator has been Mr. Blanchard. In August 1788, he ascended at Brunswick for the thirty-second time. Within two years from the first discovery of this art of navigating the atmosphere, more than forty different persons performed the experiment without any material injury; and it may be justly questioned, says Mr. Cavallo, whether the first forty persons, who trusted themselves to the sea in boats, escaped so safely. The catastrophe that befel Rozier, and the unpleasant circumstances that have happened to some of the aeronauts in our own country, have been owing not so much to the principle of the art, as to want of judgment, or imprudent management in the conduct of it.

We shall close this abstract of the history of aërostation with the observations of a very competent judge on the respective advantages and disadvantages of balloons made with inflammable air, and of those that are raised by means of hot air, to the former of which he gives the preference. The principal comparative advantages of the rarefied air-balloons are, their being filled with little or no expence; their not requiring to be made of so expensive materials; and the com-

balloons necessary to fill them being found almost every where, so that when the provision of fuel is exhausted, the aeronaut may descend and recruit his fuel, in order to proceed on his voyage. But they must be larger than balloons of the other sort, in order to take up the same weight; and the pressure of fire is a continual trouble and a continual danger. Experience has, in many instances, evinced the disastrous consequences that have attended them. On the other hand, the inflammable air balloon must be made of a substance impervious to the subtle gas: the gas itself cannot be produced without a considerable expense; and it is not easy to find the material and apparatus necessary for the production of it in every place. Improvements, however, daily occur in the preparation of the coverings of these balloons, so as to render them nearly impervious to the inflammable air: and it has been found that an inflammable air-balloon, 30 feet in diameter, may be so made as to sustain two persons and a considerable quantity of ballast in the air for more than 24 hours, when properly managed; and one man might possibly be supported by the same machine for three days.

Aerostation, practice of. The shape of the balloon is one of the first objects of consideration in the construction of this machine. As a sphere admits the greatest capacity under the least surface, the spherical figure, or that which approaches nearest to it, has been generally preferred. However, since bodies of this form oppose a greater surface to the air, and consequently a greater obstruction to the action of the oar or wings than those of some other form, and therefore cannot be so well guided in a calm, or in a course different from the direction of the wind, it has been proposed to construct balloons of a conical or oblong figure, and to make them proceed with their narrow end forward. Mr. Hoole, an ingenious writer, who is now publishing a translation of the works of Leeuwenhoek, in his *Thoughts on the farther Improvement of Aerostation*, suggests the shape of a fish as the most proper: the sharp head, under such a form, will serve to divide the resisting fluid, and open a passage, and the tail will serve as a rudder to steer its course. He also proposes to fix a seat for the traveller in the lower part of the body of the fish, or in the centre of gravity of the whole mass, so that the machine may be always horizontal, and that the impulse of any force used there may actuate the whole body. And he farther suggests, that the traveller should be furnished with instruments of sufficient surface to take hold of the air, and of sufficient strength to bear the whole exertion of his muscular force, analogous in their form and situation to the fins of fishes. But by adopting the oblong shape, the surface, and consequently the weight of the cover, must be augmented, in order to obtain the same lifting power with that of a sphere, both because its capacity will be less under the same surface, and because its capacity must be made greater in order to compensate for the augmentation of weight. Besides, an oblong machine cannot easily be kept with the smallest part forward in the atmosphere; and if it should turn sideways, as it probably might, the proposed advantage would thereby be lost: not to add, that accidental circumstances might occur which would endanger its overturning.

In order to expedite the calculations that relate to the construction of a balloon of a spherical form, it should be remembered, that the circumferences of spheres are as their diameters; their surfaces as the squares; and their solid contents as the cubes of the diameters. The proportion of the diameter to the circumference of a circle, *i. e.* 7 to 22, or 1 to $3\frac{1}{7}$, should be recollected; so

that if the diameter of a balloon be 35 feet, its circumference will be 110 feet. If the diameter be multiplied by the circumference, the product will be the surface of the sphere; *i. e.* $35 \times 110 = 3850$ square feet. If this surface be divided by the breadth (in feet) of the stuff of which the balloon is made, the quotient will be the number of feet in length necessary for contracting the balloon: thus, if the stuff be 3 feet wide, $\frac{3850}{3} = 1283\frac{1}{3}$ feet, or 428 yards nearly, which

is the quantity for a balloon of 35 feet in diameter. By knowing the weight of a given piece of the stuff, as of a square yard or square foot, it is easy to find the weight of the whole bag, by multiplying the surface in square feet or yards by the weight of a square foot or yard; *e. g.* if each square yard weigh 16 ounces, or one pound, the whole bag will weigh 428 pounds. Again, the capacity, or solid content of the sphere, may be found by multiplying $\frac{1}{6}$ of the surface by the diameter, or by taking $\frac{1}{4}$ of the cube of the diameter; thus, in the present instance, we shall have 22458 cubic feet for the capacity of the balloon, or the number of cubic feet of air which it will displace. From the content and surface of the balloon, we may deduce its power of ascension or levity in the following manner:—a cubic foot of air weighs, at an average, about $1\frac{1}{2}$ ounce, and adding to the number 22458, its fifth part, we shall have 26950 ounces, or 1684 pounds, for the weight of the common air displaced by the balloon. From this weight, deducting the weight of the bag, or 428 pounds, there will remain 1256 pounds expressing the levity of the balloon, independently of the contained air. If this be inflammable air, its weight varies from $\frac{1}{4}$ to $\frac{1}{7}$ the weight of common air; if it be taken at $\frac{1}{6}$ of the weight of common air, then $\frac{1684}{6} = 280$ pounds will denote the weight of the air filling the balloon; and taking this from 1256, *i. e.* $1256 - 280$, will leave 976 pounds, the power of ascension of the balloon, or the weight which it will carry up, consisting of the car, ropes, passengers, ballast, and other necessaries. If heated air be used, the density of this is diminished about one-third; and therefore, taking from 1684 one-third of itself, there will remain 1123 for the weight of the contained warm air, and this subtracted from 1256, leaves 133 pounds for the levity of the balloon; but as this is not sufficient for carrying up the car, passengers, &c. it is evident that a larger balloon, on Montgolfier's principle, is necessary for the same purpose that may be effected by a smaller one of inflammable air. To estimate the power of ascension corresponding to any given weight, *e. g.* 1000 pounds; since the levities are nearly as the cubes of the diameters, and consequently the diameters as the cube roots of the levities; and the levities being as 133 to 1000, *i. e.* nearly as 1 to 8, the cube-roots are as 1 to 2; consequently 1 : 2 :: 35 : 70 feet, the diameter of a Montgolfier, made of the same thickness of stuff as the former, and capable of lifting 1000 pounds. Pursuing the same kind of calculation, it is easy to estimate the size of a balloon, made of stuff of a given thickness, and filled with air of a given density, that will just float in air. From the weight of a cubic foot of common air, subtract that of a cubic foot of the lighter or contained air; then divide 6 times the weight of a square foot of the stuff by the remainder, and the quotient will be the diameter, in feet, of the balloon that will just float at the surface of the earth. Suppose the stuff to be 1 pound to the square yard, or $\frac{16}{9}$ ounces to the square foot, and this multiplied by 6 gives $\frac{32}{3}$; then the cubic foot of common air weighing $1\frac{1}{2}$ ounce, and of heated air $\frac{2}{3}$ of the same, the difference being $\frac{2}{9}$;

consequently $\frac{32}{3}$ divided by $\frac{2}{3}$, gives $26\frac{2}{3}$ feet, which is the diameter of a Montgolfier that will just float: but if inflammable air, $\frac{1}{5}$ the weight of common air, be used, the difference between $1\frac{1}{2}$ and $\frac{1}{5}$ of it is one; by which dividing $\frac{32}{3}$ or $10\frac{2}{3}$, the quotient $10\frac{2}{3}$ feet will be the diameter of an inflammable air-balloon that will just float. If the diameter, in either of these cases be increased, the respective balloons will ascend in the atmosphere.

In order to determine the height to which a given balloon will rise, when the diameter of the balloon, and the weight that exactly balances it are given, proceed in the following manner:—compute the contents of the globe in cubic feet, and divide its restraining weight in ounces by this content, and the quotient will be the difference in density or specific gravity of the atmosphere at the surface of the earth, and that at the height to which the balloon will rise; subtract this difference or quotient from $1\frac{1}{2}$ or 1, 2, the density at the earth, and the remainder will be the density at that height; then the height corresponding to that density will be found with sufficient exactness in the annexed Table.

e. g. Let the diameter of the balloon be 35 feet, its capacity 22458, and the levity of the first 976 pounds, or 15616 ounces; the quotient of the latter number divided by the former, *i. e.* $\frac{15616}{22458}$, is .695, which is the density at the utmost height, and to which in the Table corresponds somewhat less than $2\frac{1}{2}$ miles, and this is the height to which the balloon will ascend. When the same balloon was filled with heated air, its levity was equal to 133 pounds, or 2128 ounces, which divided by 22458, the capacity, gives the quotient, .095; and this subtracted from 1.200, leaves 1.105 for the density; to which, in the Table corresponds half a mile, or more nearly $\frac{2}{3}$ of a mile. Such are the heights to which these balloons would nearly ascend, if they retained their figure, and lost none of the contained air: or, more precisely, these are the heights at which they would settle; for their acquired velocity would at first carry them above these heights, till their motion would be destroyed; and then they would descend below these heights, though not so much as they had gone above them: after which they would reascend, and pass these heights again, but not so far as they had gone below them; thus vibrating alternately above and below these heights, but every-time less and less. These calculations for finding the height to which the balloon will ascend, are formed independently of the different states of the thermometer at the highest point and at the surface of the earth; but the allowances to be made on this account will appear from what is delivered under the article ATMOSPHERE.

Next to the shape, it is necessary to consider the stuff that is most proper for forming the envelope of the inflammable or rarefied air. Silk stuff, especially that which is called lutestring, properly varnished, has been most commonly used for inflammable air-balloons: and common linen, lined within and without with paper, varnished, for those of rarefied air. Varnished paper, or gold beater's skin, will answer the purpose for making small inflammable air-bal-

loons; and the small rarefied air-balloons may be made of paper without any varnish or other preparation.

The stuff for large balloons of both kinds require some previous preparation. The best mode of preparing the cloth for a machine upon Montgolfier's principle, is first to soak it in a solution of sal ammoniac and lize, using one pound of each to every gallon of water; and when the cloth is quite dry, to paint it over with some earthy colour, and strong lize or glue. It may be also varnished over, when perfectly dry, with some stiff oily varnish or simple drying linseed oil; which would dry before it penetrates quite through the cloth.

The varnish for the silk or linen of the inflammable air-balloons should be impermeable to the inflammable gas, pliable, and sufficiently dry to adhere firmly to the stuff. In France much has been said of the elastic gum varnish; but the composition of it is kept a secret. This gum is known to be soluble in divers essential oils, and also by vitriolic ether. The former solution forms a varnish which never perfectly dries: the latter dries readily, but the solution is too dear for common use. The following varnish has been recommended. To one pint of linseed oil, add two ounces of litharge, two ounces of white vitriol, and two ounces of gum sandarach; boil the whole for about an hour over a slow fire; then let it cool; separate it from the sediment, or strain it through a sieve, and dilute it with a sufficient quantity of spirits of turpentine. But the best varnish for an inflammable air-balloon is made with bird-lime. Mr. Cavallo directs to prepare it in the following manner, which, in his opinion, is preferable to that of M. Faujas de Saint Fond. In order to render linseed oil drying, boil it with two ounces of saccharum saturni and three ounces of litharge, for every pint of oil, till the oil hath dissolved them; then put a pound of bird-lime and half a pint of the drying oil into a pot of iron or copper, holding about a gallon; and let it boil gently over a slow charcoal fire till the bird-lime ceases to crackle: then pour upon it two pints and a half of drying oil, and boil it for about an hour longer, stirring it often with an iron or wooden spatula. As the varnish in boiling swells much, the pot should be removed from the fire and replaced when the varnish subsides. Whilst it is boiling, it should be occasionally examined, in order to determine whether it has boiled enough. For this purpose, take some of it upon the blade of a large knife, and after rubbing the blade of another knife upon it, separate the knives, and when on their separation the varnish begins to form threads between the two knives, it has boiled enough, and should be removed from the fire. When it is almost cold, add about an equal quantity of spirits of turpentine, mix both well together, and let the mass rest till the next day; then having warmed it a little, strain and bottle it. If it is too thick, add more spirits of turpentine. This varnish should be laid upon the stuff, when perfectly dry, in a luke-warm state; a thin coat of it upon one side, and about twelve hours after two other coats should be laid on, one on each side, and in twenty-four hours the silk may be used.

Mr. Blanchard's method of making elastic gum varnish for the silk of a balloon is as follows. Dissolve elastic gum, cut small, in five times its weight of spirits of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed oil for a few minutes, and strain it. Use it warm.

The pieces of which an inflammable air-balloon is to be formed, must be cut of a proper size, according to the proposed dimensions of it, when the varnish is sufficiently dry. The pieces that compose the surface of the balloon are like

Height in miles.	Density.

those gores that form the superficies of a globe: and the best method of cutting them is to describe a pattern of wood or stiff card-paper, and to cut the silk or stuff upon it. One of these pieces, that may serve as a pattern for others, is represented in *Plate I. Pneumatics, fig. 2.* In this figure, suppose A E and B C to be two right lines perpendicular to each other. Then find the circumference answering to the given diameter of the balloon in feet and decimals of a foot; and make A D and D E each equal to a quarter of the circumference, so that A E may be equal to half the circumference. Divide A D into 18 equal parts, and to the points of division apply the lines *fg, hi, kl, &c.* parallel to each other, and perpendicular to A D. Divide the whole circumference into twice the given number of pieces, and make D C and D B each equal to the quotient of this division; so that B C will be equal to the greatest breadth of one of those pieces. Multiply this quotient or D C by the decimals annexed to *fg*, viz. 0.99619, and the product expresses the length of *fg*; and multiply D C by the decimals annexed to *hi*, and the product expresses the length of *hi*, &c. Having thus found the lengths of all these lines, draw by hand a curve line, passing through their extremities, and this will be the edge of one quarter of the pattern. The other quarters A B D, E B D, E D C, may be easily described by applying to each of them a piece of paper equal to A D C. Suppose the diameter of the balloon to be 20 feet, and that it is to be made of 12 pieces. In order to draw the pattern, find the circumference of the balloon, which is 62,83 feet, and dividing it by 4, the quotient is 15,7 feet: consequently A D and D E will be each equal to 15,7 feet. Divide the circumference 62,83 by 24, or double the number of pieces that are to form the balloon; and the quotient 2,618 feet will be the length of D C or B D; therefore B C is equal to 5,236 feet. Then dividing A D into 18 equal parts, and drawing the parallel lines from the points of division, find the length of these lines by multiplying 2,618 by the decimals annexed to that line: thus, 2,618 multiplied by 0.99619 gives 2,608 feet for the length of *fg*; and multiplying 2,618 by 0,98481, we shall have 2,578 feet for the length of *hi*, &c. The pieces cut after such a pattern should be left about one half or three quarters of an inch all round larger than the pattern, in order to allow for the seams. They may be joined by laying about half an inch of the edge of one piece over the edge of the other, and sewing them with a double stitching. Mr. Blanchard joins them very expeditiously in the following manner. He lays about half an inch of the edge of one piece flat over the edge of the other, and passes a hot iron over it; in doing which, a piece of paper ought to be laid both under and over the silk. The joining may be rendered more secure, by running it with a silk thread, and sticking a ribband over it. The ribbands laid over seams may be stuck with common glue, provided the varnish of the silk is properly dried. When the glue is quite dry, the ribbands should be varnished over, to prevent their being unglued by the rain.

To the upper part of the balloon there must be adapted a valve, opening inward, to which is annexed a string passing through a hole made in a small round piece of wood which is fastened to the lowest part of the balloon opposite to the valve, to the boat below it; so that the aeronaut may open it as occasion requires, and let the inflammable air out of the balloon. To the lower part of the balloon are fixed two pipes of the same stuff with the covering, six inches in diameter for a balloon of thirty feet, and much larger for balloons of greater size, and long enough to reach the boat. These pipes are the apertures through which the inflammable air is introduced into the balloon.

The boat may be made of wicker-work, and covered with leather, well painted or varnished over. The best method of suspending it is by means of ropes, proceeding from the net which goes over the balloon. This net should be formed to the shape of the balloon, and fall down to the middle of it, and have various cords proceeding from it to the circumference of a circle, about two feet below the balloon; and from that circle other ropes should go to the edge of the boat. This circle may be made of wood, or of several pieces of slender cane bound together. The meshes of the net may be small at top, against which part of the balloon the inflammable air exerts the greatest force, and increase in size as they recede from the top. A hoop has been sometimes put round the middle of the balloon for fastening the net. This is not absolutely necessary; but when used, it is best made of pieces of cane bound together, and covered with leather. When the balloon and its appendages are constructed, the next object of importance is to procure proper materials for filling it. With respect to those inflated by heated air, nothing need be said till the method of filling them is described.

Inflammable air for balloons of the other kind may be obtained in several ways; but the best methods are by applying acids to certain metals; by exposing animal, vegetable, and some mineral substances, in a close vessel, to a strong fire; or by transmitting the vapour of certain fluids through red-hot tubes.

In the first of these methods, iron, zinc, and vitriolic acid, are the materials most commonly used. The vitriolic acid must be diluted with five or six parts of water. Iron may be expected to yield in the common way about 1700 times its own bulk of gas; or $4\frac{1}{2}$ ounces of iron, the like weight of oil of vitriol, and $22\frac{1}{2}$ ounces of water will produce one cubic foot of inflammable air: six ounces of zinc, an equal weight of oil of vitriol, and 30 ounces of water, are necessary for producing the same quantity. It is more proper to use the turnings or chippings of great pieces of iron, as of cannon, &c. than the filings of that metal: because the heat attending the effervescence will be diminished, and the diluted acid will pass more readily through the interstices of the turnings, when they are heaped together, than through the filings which stick closer to one another. The weight of the inflammable air, thus obtained by means of acid of vitriol, is, in the common way of procuring it, generally one-seventh part of the weight of common air; and with the necessary precautions for philosophical experiments, less than one-tenth of the weight of common air. The other elastic fluids, which are generated with the inflammable air, may be separated from it by passing the inflammable air through water, in which quick-lime has been dissolved; the water will absorb these fluids, cool the inflammable air, and prevent its overheating the balloon, when it is introduced into it. As white vitriol is sold much dearer than the vitriol of iron, it will be a saving to make the inflammable air by means of zinc and vitriolic acid, rather than of this acid and iron: because the sale of the white vitriol arising from the former will, in a degree, be a compensation for the expence of the materials.

Inflammable air may also be obtained at a much cheaper rate by the action of fire on various substances; but the gas thus obtained is not so light as that produced by the effervescence of acids and metals. The substances proper to be used for this purpose are pit-coal, asphaltum, amber, rock oil, and other minerals; wood, and especially oak, camphor oil, spirits of wine, æther, and animal substances, which yield air of different degrees and of various specific gravity. But pit-coal is the substance most proper to be used. A pound

of pit-coal, exposed to a red heat, yields about three cubic feet of inflammable air, which, whether it be passed through water or not, weighs about one-fourth of the weight of an equal bulk of common air.

Dr. Priestley observes, that animal or vegetable substances will yield six and even ten times more inflammable air, when the fire is suddenly increased than when it is gently raised, though it be afterwards made very strong. And Mr. Cavallo informs us, that the various substances above enumerated generally yield all their inflammable air in about an hour's time. The usual method is to inclose the substances in earthen or iron vessels, and thus to expose them to a strong fire sufficient to make the vessels red-hot; the inflammable air proceeding from the aperture of the vessel, is received into a tube or refrigeratory, and passing through the tube or worm, is at last collected in a balloon or other vessel. A gun-barrel has been often used for essays of this kind. The manner of conducting this process is particularly described by Mr. Cavallo, *ubi infra*.

The last method of obtaining inflammable air was lately discovered by Mr. Lavoisier, and also by Dr. Priestley. Mr. Lavoisier made the steam of boiling water pass through the barrel of a gun, kept red-hot by burning coals. Dr. Priestley uses, instead of the gun-barrel, a tube of red-hot brass, upon which the steam of water has no effect, and which he fills with the pieces of iron which are separated in the boring of cannon. By this method he obtains an inflammable air, the specific gravity of which is to that of common air as 1 to 13. In this method, a tube about three quarters of an inch in diameter, and about three feet long, is filled with iron turnings; then the neck of a retort or close boiler is luted to one of its ends, and the worm of a refrigeratory is adapted to its other extremity. The middle part of the tube is then surrounded with burning coals, so as to keep about one foot in length of it red-hot, and a fire is always made under the retort or boiler sufficient to make the water boil with vehemence. In this process a considerable quantity of inflammable air comes out of the worm of the refrigeratory. It is said that iron yields one half more air by this means, than by the action of vitriolic acid. See HYDROGEN.

Balloons of the smaller size, such as those of two or three feet in diameter, and also bladders, may be filled with inflammable air, after passing it through water, by means of the following simple apparatus. See *Plate I. Pneumatics, fig. 3*. A is the bottle that contains the ingredients which produce the gas: BCD is a tube in form of a syphon, fastened by one extremity into the neck of this bottle, and passing through a hole of the stopper of another bottle E, it extends so far as almost to touch the bottom of this bottle, which is nearly full of water. To another hole made in the cork of the bottle E is adapted another tube, to the outward extremity of which a bladder, or the aperture of the balloon is tied. The inflammable air, coming out of the aperture D of the tube, passes through the water of the bottle E, and then enters into the bladder or balloon. Two small casks might be used instead of the bottles A and E.

Another apparatus for producing hydrogen and conveying it into a balloon is exhibited in *fig. 4*. ABC is a vessel made of clay, or of iron, in the form of a Florence flask; and the substance yielding gas is introduced into it so as to occupy about thirds, or less, of its cavity. If the substance swell much by the action of the fire applied to it, a tube of brass, or first a brass and then a leaden tube must be luted to the neck C of the vessel, and the extremity D of the tube is made to pass through the water of a tub H I, and to terminate under an inverted vessel E F, to the upper aperture

of which the balloon, or a tube going to the balloon is adapted. When the part, A B, of the vessel is put into the fire, and made red-hot, the inflammable air that is generated will come out of the tube C D, and passing through the water of the tub, it will at last enter into the balloon G. As a considerable quantity of common air remains in the inverted vessel E F, before the operation is begun, it should have a stop-cock, K, through which it may be drawn out by suction, and then the water will ascend as high as the stop-cock. The aperture of the vessel, E F, should be at least one foot below the surface of the water in H I; and the fire should be at a sufficient distance from the tub H I, that the inflammable air, if any of it should escape, may not take fire and do injury.

The method of filling large aerostatic machines with rarefied air is as follows. A scaffold ABCD (*Plate II. fig. 5*.) the breadth of which is at least two-thirds of the diameter of the machine, is elevated about six or eight feet above the ground. From the middle of it descends a well E F, rising about two or three feet above it, and reaching to the ground, furnished with a door or two, through which the fire in the well is supplied with fuel. The well should be constructed of brick or of plastered wood; and its diameter should be somewhat less than that of the machine. On each side of the scaffold are erected two masts H I, K L, each of which has a pulley at the top, and rendered firm by means of ropes K G, K P, H P, H G. The machine to be filled is placed on the scaffold, with its neck round the aperture of the well. The rope passing over the pulleys of the two masts, serves, by pulling its two ends, to lift the balloon about fifteen feet or more above the scaffold: and the rest of the machine is represented by the dotted lines in the figure M N O. The machine is kept steady and held down, whilst filling, by ropes passing through loops or holes about its equator; and these ropes may be easily disengaged from the machine, by slipping them through the loops, when it is able to sustain itself. The proper combustibles to be lighted in the well are those which burn quick and clear, rather than such as produce much smoke; because it is hot air, and not smoke, that is required to be introduced into the machine. Small wood and straw have been found to be very fit for this purpose. Mr. Cavallo observes, as the result of many experiments with small machines, that spirits of wine are upon the whole the best combustible; but its price may prevent its being used for large machines. As the current of hot air ascends, the machine will soon dilate, and lift itself above the scaffold and gallery, which was covered by it. The passengers, fuel, instruments, &c. are then placed in the gallery. When the machine makes efforts to ascend, its aperture must be brought, by means of the ropes annexed to it, towards the side of the well, a little above the scaffold. The fire-place is then suspended in it; the fire lighted in the grate; and the lateral ropes being slipped off, the machine is abandoned to the air. It will appear in the atmosphere as it is represented in *fig. 6*. It has been determined by accurate experiments, that only one-third of the common air can be expelled from these large machines; and therefore, the ascending power of the rarefied air in them can be estimated as only equal to half an ounce avoirdupois for every cubic foot. The apparatus for filling an inflammable air balloon is represented in *fig. 7*. A, A are two tubs, about three feet in diameter, and nearly two feet deep, inverted in larger tubs, B, B, full of water. At the bottom of each of the inverted tubs there is a hole, to which is adapted a tin tube E, about seven inches in diameter, and seven or eight inches long. To these tubes the silken tubes of the balloon

balloon are tied. Each of the tubs, B, is surrounded by several strong casks, so regulated in number and capacity, as to be less than half full, when the materials are equally distributed. In the top of each of these casks are two holes; and to one of the holes is adapted a tin tube, formed so as to pass over the edge of the tub B, and through the water, and to terminate with its aperture under the inverted tub A. The other hole, which serves for supplying the cask with materials, is stopped with a wooden plug. These tin tubes may be about three inches and a half in diameter, and the other holes may be smaller. Two masts, with a rope, &c. are used for this machine, as well as for the former, although they are not absolutely necessary; because the balloon, by means of a narrow scaffold, or other contrivance, may be elevated five or six feet above the level of the tubs A A. When the balloon is to be filled, the net is put over it and suspended, as exhibited in C D F; and having expelled all the common air from it, its silk tubes are fastened round the tin tubes E E, and the materials in the casks are properly proportioned; the iron being first put in, then the water, and lastly the vitriolic acid. The balloon will soon be inflated by this inflammable air, and support itself without the aid of the rope G H. As the filling advances, the net is adjusted round it, the cords, proceeding from the net, are fastened to the hoop M N; the boat I K is suspended from the hoop M N, and every thing necessary for the voyage is deposited in the boat. When the balloon is a little more than three quarters full, the silken tubes are separated from the tin tubes, and their extremities being tied, they are placed in the boat. Finally, when the aeronauts are seated in the boat, the lateral ropes are slipped off, and the machine ascends in the air, appearing as in *fig.* 8. In order to produce such a bulk of inflammable air as is necessary for a balloon of 30 feet in diameter, whose capacity is 14137 cubic feet, there will be required about 3900 pounds of iron turnings, 3900 pounds of vitriolic acid, and 19500 pounds of water. The balloon will not be above three quarters full.

These proportions, stated by Mr. Cavallo, are too great with respect to the metal and acid, and too small with regard to the water. Mr. Lunardi, who had considerable experience in the practice of aërostation, filled his balloons at Edinburgh and Glasgow with about 2000 pounds of the chippings of cannon procured from Carron, the same quantity of vitriolic acid, and 12,000 pounds of water. The iron was placed in layers in his vessels, with straw between them, in order to enlarge the surface exposed to the action of the acid. He used only two large casks, which were sunk in the ground, and conveyed the gas into the balloon without passing through water; and he contrived to fill his balloon in less than half an hour, which operation had on former occasions required at least two hours.

The inflammable air with which they fill their balloons at the Aërostatic Institute, not long since established in France, is obtained by the following method, which is simple and not very expensive. Six cylinders, or tubes of iron, are fixed by masonry in a furnace of easy and expeditious construction, in such a manner that the two ends of each cylinder project out of the furnace; and these are furnished with strong covers or lids of iron. Into these cylinders are introduced tubes of metal, one of which serves to convey warm water into the red-hot cylinder, and the other to convey the air which is produced through a reservoir filled with caustic ley, into the balloon. The cylinders are partly filled with the chippings or turnings of iron that are procured from the boring of cannon. The excessive heat of the furnace, which is maintained by a supply of char-

coal during the operation, is communicated to the cylinders and their contents. In this state, boiling water is conveyed by one of the tubes to each cylinder; and as soon as it communicates with the inflamed iron, the water is decomposed: the one part, called the oxygen, attaches itself to the iron and calcines it; but the other part, or the hydrogen, is combined with a quantity of the igneous substance, called caloric, and becomes hydrogenous gas, or inflammable air, which remains in a permanent state of elastic fluidity, and weighs seven or eight times less than the atmospheric air. As the water contains a small quantity of carbon or fixed air, which would add weight to the air of the balloon, it is made to pass through water in which caustic alkali has been dissolved. This fluid attaches the carbon to itself, and thus the pure inflammable air is conveyed into the balloon. The cylinders, in this operation, are sometimes fused; for preventing which accident, a pyrometer is annexed to the extremity of the cylinder which projects from the furnace; and the fire is regulated by a scale connected with the pyrometer. The operation of filling a balloon, 30 feet in diameter, in this way will occupy about four hours.

In estimating the ascending power of these machines, that of the inflammable air should be considered as equal to one ounce avoirdupois for every cubic foot, which is one sixth of the weight of common air; and therefore, if the capacity of a balloon is 12000 cubic feet, and three-fourths of it are filled with inflammable air, obtained from iron and diluted vitriolic acid, the ascending power of that gas may be estimated at 9000 ounces, or 562½ pounds; from which the weight of the covering, boat, and other appendages, must be subtracted.

The conduct of balloons, when constructed, filled, and actually ascending in the atmosphere, is an object of great importance in the practice of aërostation. The method generally used for elevating or lowering the balloons with rarefied air, has been the increase or diminution of the fire; and this is entirely at the command of the aeronaut, as long as he has any fuel in the gallery. The inflammable air-balloons have been generally raised or lowered by diminishing the weight in the boat, or by letting out some of the gas through the valve. But the alternate escape of the air in descending, and discharge of the ballast for ascending, will by degrees render the machine incapable of floating; for in the air it is impossible to supply the loss of ballast, and very difficult to supply that of inflammable air. These balloons will also rise or fall by means of the rarefaction or condensation of the inclosed air, occasioned by heat and cold. It has been proposed to aid a balloon in its alternate motion of ascent and descent, by annexing to it a vessel of common air, which might be condensed by lowering the machine, and rarefied again, by expelling part of it, for raising the machine. But a vessel adapted to this purpose must be very strong, and, after all, the assistance afforded by it would not be very considerable. M. Meunier, in order to attain this end, proposes to inclose one balloon filled with common air in another filled with inflammable air: as the balloon ascends, the inflammable air is dilated, and of course compresses the internal balloon containing common air; and by diminishing its quantity, lessens its weight. If it should be necessary to supply this loss, he says it may be easily done by a pair of bellows fixed in the gallery. Others have proposed to annex a small machine with rarefied air to an inflammable air-balloon by ropes, at such a distance that the fire of the former might not affect the inflammable air of the latter: the whole apparatus, thus combined, of balloons formed on the two principles of heated and inflammable air,

might be raised or lowered by merely increasing or diminishing the fire in the lower balloon. Wings or oars seem to have contributed little to the effect of either raising or lowering balloons.

Many schemes have been proposed for directing the horizontal motion of balloons. Some have thought of annexing sails to a balloon, in order to give it the advantage of the wind; but to this proposal it has been objected, that as the aerostatic machines are at rest with respect to the air that surrounds them, they feel no wind, and consequently can derive no benefit from the sails. An ingenious writer observes, that the case of vessels at sea is quite different from that of balloons; because the former move with a velocity incomparably less than that of the wind impelling them, on account of the resistance of the water; and therefore, the difference between the velocity of the wind, and that of ships, occasions that stream of air which acts upon the sails. But a balloon, finding no resistance, acquires the same velocity with the surrounding air, and therefore can feel no wind. The same author adds, that the most rational projects for directing an aerostatic machine are those which propose to exert a force against the ambient air on one side of the machine, so as to move it in the opposite direction. Oars and wings are the only instruments that have been used for this purpose with any measure of success; but farther experiments are necessary to ascertain their effect. If wings or oars be used, the best method of moving them is by the immediate application of human power, as in the case of the oars of boats on the water. However they should be as large and light as possible; and they may be made of silk stretched between wires, tubes, or sticks. If they are flat they must be turned edgewise when they are moved in the direction of the balloon's course, and flat in the opposite direction. One of the wings, used by Mr. Blanchard, is represented in *fig. 9*. That used by Mr. Lunardi consisted of many silk shutters or valves ABC D, DE C F, &c. (*fig. 10*.) each of which opens only on one side, viz. A D B C upon the line A B, D E C F upon the line D C, &c; and by this construction, it becomes unnecessary to turn these oars edgewise. One of the wings, constructed by Zambeccari is exhibited in *fig. 11*, and is nothing more than a piece of silk stretched between two tin tubes set at an angle; and so contrived as to turn edgewise of themselves, when they go in one direction. *Fig. 12* represents one of the wings used by Messrs. Roberts, in the voyage of September 19th, 1784. The greatest effect produced by the wings of an aerostatic machine was that which occurred in this voyage. It is not difficult to determine what force is necessary to move a given machine in the air with any proposed velocity. Dr. Hutton found, from accurate experiments, that a globe of $6\frac{1}{8}$ inches in diameter, and moving with a velocity of 20 feet in a second, sustains a resistance from the air, which is equal to the weight or pressure of one ounce avoirdupois; and that with different surfaces and the same velocity, the resistances are directly proportional to the surfaces nearly; and also that, with different velocities, the resistances are proportional to the squares of the velocities nearly. By these data the resistance to move a given balloon with any velocity may be assigned. Let the balloon be 35 feet in diameter; then if it moved with the velocity of 20 feet per second, or almost 14 miles per hour, it would counteract a resistance equal to 271 pounds; with a motion of seven miles an hour, the resistance would be 68 pounds; and at three miles and an half in an hour, the resistance would be 17 pounds; and such is the force with which the aeronauts must act on the air in a contrary direction, in order to communicate such a degree

of motion to the machine. If the balloon move through a rarer part of the atmosphere than that at the surface of the earth, as $\frac{1}{3}$ d or $\frac{1}{4}$ th, &c. rarer, the resistance will be less in the same proportion; yet the force of the oars will be diminished as much; and therefore the same difficulty remains. It may be observed in general, that the aeronaut must strike the air, by means of his oars, with a force just equal to the resistance of the air or the balloon, and therefore he must strike that air with a velocity which must be greater as the surface of the oar is less than the resisted surface of the globe, but not in the same proportion, because the force is as the square of the velocity. Suppose that the aeronaut acts with an oar equal to 100 square feet of surface to move the balloon above-mentioned at the rate of 20 feet per second, or 14 miles an hour, then he must move this oar with the great velocity of 62 feet per second, or nearly 43 miles an hour; and so in proportion for other velocities of the balloon. Hence it is highly probable, that it will never be in the power of man to guide such machines with any tolerable degree of success, especially when any considerable wind blows, which is generally the case. A helm seems to have no particular power in directing the course of a balloon, for the same reason that has been alledged to evince the inefficacy of sails. We have not in air, as in water, says count de Mirabeau, in his Considerations on the Order of Cincinnatus, the resource of a fixed point of action upon a fluid, which has also much greater resistance than air. He adds, that as there are different currents of air, sometimes in opposite directions, and balloons are capable of ascending and descending in search of these currents, this circumstance may favour the hope of directing aerostatic machines. Perhaps, an attention to the means by which birds fly against the wind, added to observations of comparative anatomy upon fishes and birds, which surmount the currents of the two fluids that are common to us and them, may also suggest new ideas with respect to the direction of balloons. Time alone, and numerous experiments, can bring these reflections to maturity, and realize the expectations suggested by them.

Several of the foreign journals have lately announced an invention of professor Danzel for directing an air-balloon through the atmosphere. With this view he has constructed two cylinders, or axles, to the ends of which are fixed, in the form of a cross, four sails, or oars, moveable at the point of their insertion in the cylinder, in such a manner, that when made to move round by means of a handle, the eight oars, like the cogs of a water-mill wheel, present successively to the air sometimes their flat side and sometimes their edge. To cause each oar to turn back on itself about the fourth part of a circle, M. Danzel has not only left sufficient play at the point where the flick of each oar is inserted in the cylinder, but has placed the stick in such a manner that the air itself makes the oar fall back, at each turn, with the necessary velocity and precision. Each of the two cylinders, armed with its four oars or sails, is destined to occupy one side of the balloon, with its four oars on each side. For a farther account of this apparatus and of its effect, see Philosophical Magazine, vol. iv. p. 108.

As parachutes, in the form of umbrellas, have been proposed in order to guard against accidents, and to break the fall in cases of sudden descent, we shall here annex a method of eliminating the power of such defensive machines. A person, moving uniformly at the rate of ten feet per second, may descend with safety. For this uniform descent the resistance of the air must be equal to the whole descending weight. Suppose then that the weight of the aeronaut is 150 pounds, and that the parachute is flat and circular, and
made

made of such materials as that every square foot of it weighs two ounces, and that the weight be such in the proportion of the periphery of the circle to the circle diameter of the parachute, which will descend at the rate of ten feet per second, that be upwards of 70 feet; and if the parachute be extended on the lower side, its power will be rather greater, and its diameter may be less. In order to estimate the power of a flat circular parachute, or the resistance it meets with in a air of a near density, which descends with a given velocity, say as the number 283 to the square of the velocity in feet, so is the square of the diameter in feet to a fourth number, which will be the resistance in pounds. And if it be required to know, with what velocity a parachute will descend with a given weight, say as the given diameter is to the square root of the weight, so is the number 283 to a fourth, which will be the velocity in air of a mean density. Thus, if the diameter of a balloon be 50, and its weight, together with that of a man, be 530 pounds, the square root of which is 23; very nearly; then 50:23::283:13; and therefore the man and parachute will descend with the velocity of 13 feet per second, which, as it is equal to that acquired by leaping freely from a height of two feet two inches, may be very safely sustained.

AEROSTATION, uses of. The advantages of an art, so lately discovered, have not yet been sufficiently ascertained; but we may reasonably expect, considering the progress it has made in so short a space of time, that many benefits may result from the farther prosecution of it. To say the least, it is unphilosophical to discourage future trials and improvements, because the uses of this art do not immediately appear. With regard to philosophical observations, derived from aerostation, it is acknowledged that very few have yet been made. The novelty of the discovery, and of the prospect, says Mr. Cavallo, has generally distracted the attention; and besides, most of the aerial voyages have been made by persons who had pecuniary profit alone in view, or who were stimulated to ascend in the atmosphere for the sake of the prospect, or by the vanity of adding their names to the list of aerial adventurers. Aerial navigation, considered as a mode of travelling between distant places, independently of its furnishing means of conveyance to places otherwise inaccessible, is attended with many advantages and conveniences. The aeronaut has much less trouble with this machine than a sailor with a ship in the most favourable circumstances. With a moderate wind, aerial navigators have often gone at the rate of forty or fifty miles an hour, and very commonly at the rate of thirty miles without any agitation, or even feeling the wind, and without the danger of losing time by being often becalmed. Aerostatic machines may serve the purpose of escaping from ships that cannot safely land, from besieged places, and from other circumstances of danger. A small balloon six or seven feet in diameter, says an anonymous author in his proposal of various means for saving the crews of vessels shipwrecked near the coast, would answer this purpose, by carrying to the shore a string capable of drawing a cord, with which several ropes might be afterwards conveyed to the vessel. They also expedite the communication of important events by signals, and serve for exploring, from a great elevation, adjacent coasts or regions, fleets and armies. To the latter of these purposes they have been actually applied by the French, in the course of the last war; and to the elevation of a balloon, and the information obtained in consequence of thus reconnoitering the army of the enemy, they ascribe the signal victory obtained in the battle of Fleurus in 1794. The balloon employed on this occasion,

was called the *Entree-nant*, and it was under the direction of M. Conté, the captain of the aeronauts at Meudon, accompanied by an adjutant and a general. He ascended twice in the same day, to the height of 220 fathoms, for the purpose of observing the position and manœuvres of the enemy. He continued each time four hours in the air, and corresponded with General Jourdan, who commanded the French army, by means of pre-concerted signals. The enterprise was discovered by the enemy, and a battery opened its fire against the ascending aeronauts; but they soon gained an elevation which was beyond the reach of their fire. This balloon was prepared under the direction of the *Aerostatic INSTITUTE*, for the use of the army of the north; as were also another called *Celèste*, for the army of the Sambre and Meuse; and the *Hercule* and *Intrepide*, for the army of the Rhine and Moselle. Another, thirty feet in circumference, and weighing 160 pounds, was destined for the army of Italy. A new machine, invented by M. Conté, the director of the Aerostatic Institute, was designed to aid the aeronauts in communicating intelligence, and was denominated the *Aerostatic TELEGRAPH*. Balloons may likewise serve to explore the state of the atmosphere at different heights, and to furnish observations, which shall illustrate a variety of phenomena, depending on the density, temperature, and other qualities of the air. From one experiment that has been already made we learn, that the air of a high region, preserved and examined by means of nitrous air, was found to be purer than the air below. The application of these machines to electrical experiments, is a very obvious use of which they are capable. The first person who employed them in this way seems to have been the Abbé Bertholon, at Montpellier. He raised several air balloons, furnished with long and slender wires, having their lower ends fastened to a glass stick, or other insulating substance; and thereby obtained from the wires electric fluid sufficient to shew the attraction, repulsion, and even the sparks of electricity. The existence of a continual electricity, of the positive kind, in a clear atmosphere, known indeed before, has been farther ascertained by strings fastened to balloons floating in the atmosphere. Some have apprehended danger from the electricity of the atmosphere; and have thought that a stroke of lightning, or the smallest electrical spark, happening near a balloon, might set fire to the inflammable air, and destroy both the machine and the adventurers. Mr. Cavallo has suggested several considerations for diminishing apprehensions of this kind. Balloons have been already raised in every season of the year, and even when thunder has been heard, without injury. In case of danger, the aeronauts may either descend to the earth, or ascend above the region of the clouds and thunder storms. Besides, as balloons are formed of materials that are not conductors of electricity, they are not likely to receive strokes, especially as by being encompassed with air they stand insulated. Moreover, inflammable air by itself, or unmixed with a certain quantity of common air, will not burn; so that if an electric spark should happen to pass through the balloon, it would not set fire to the inflammable air, unless a hole was made in the covering.

For a variety of other important and useful particulars relating to the subject of aerostation, we must refer to Mr. Cavallo's curious and comprehensive work, entitled, the *History and Practice of Aerostation*, 8vo. 1785; which will afford the reader ample information concerning the principles of this art, and the history of its progress, the method of constructing and managing balloons, the nature and preparation of the materials of which they are formed, the observations and uses to which they are adapted,

adapted, and rules for estimating the heights to which they ascend.

AERSCHOT, or **ARSCHOT**, in *Geography*, a town of the Aultrian Netherlands in the duchy of Brabant, and capital of the district of the same name, which was raised to a marquifate in 1507, and to a duchy in 1533. The town is small, but fortified and well inhabited, seated on the river Demer, about ten miles east of Mechlin, and eight miles north of Louvain, and contains a collegiate church, two monasteries, and three nunneries. It belongs to the House of Arenberg. N. lat. 51°. E. long. 5° 44'.

AERTSEN, in *Biography*. See **AARSENS**.

ÆRVA, in *Botany*, a genus of the *monadelphia decan-dria* class and order. The characters of which are, that the flowers are polygamous; the calyx is five-leaved and patent; the stamina are five, and barren; the pistillum is a globulous ovary, having a filiform style terminated by a bifid stigma; the fruit is a capsule, which is oblong, single-seeded and encompassed by the calyx. There is one species, viz. *Æ. ægyptiaca* or *tomentosa*, which grows on sandy calcareous soil in Arabia. La Marek thinks it bears affinity to the **AMARANTUS**.

ÆRUGINOUS, something partaking of, or like to, the rust of copper.

Authors do not seem perfectly agreed about the colour to be expressed by this word, some expressing by it green, others brown.

ÆRUGO denotes **RUST**, especially that of copper.

Naturalists speak of two kinds of *æru-go*, one *native*, and the other *fañitious*: the *native*, is only the superficial particles of the metal dissolved; and intimately mixed with acid salt; in which form it is ordinarily found in copper-mines, and other moist places: and the *artificial*, commonly called **VERDIGRIFE**, or copper converted into a green calx by vinous acid.

One species of *natural æru-go* is a greenish marcasite, like the drops of iron; it is found in copper-mines, but is of no use. Dioscorides (lib. v. c. 91, 92.) and Pliny (lib. xxxiv. c. 11. 12.) say expressly, that a substance of the nature of these stones, which yielded copper when melted, was scraped off in the mines of Cyprus, much in the manner now practised in Hungary, where the outer coat of the copper ore is thus collected, and afterwards purified by being washed in water. Another species, according to the account of Dioscorides, was procured from the water of a grotto in the same island; and the most saleable natural verdigrife is still obtained in the same way in Hungary. The clear water which runs from old copper works is put into large vessels, and after some time the green earth falls to the bottom as a sediment. There is also, on some mountains in Moravia, a sort of green grains, like sand, that is of a grass green, when used in painting. It is called the *Hungarian mountain*, or *sea verdigrife*. See **mountain GREEN**.

ÆRUGO rasilis, or *as viride*, is a rust formed on copper, by hanging a plate of it over the strongest vinegar for some time, without suffering the one to touch the other. It was only used externally by Dioscorides and the ancient physicians for cleansing ulcers, and destroying excrescences; but it has been more lately employed externally with effeñce of myrrh and honey of roses in fistule and aphthæ, and also internally for malignant ulcers that have corroded the bones, and either with or without turbith mineral as a

remedy for men or beasts that have been bitten by mad dogs or wolves. The dose has been from three to six grains. Pills, formed of the *æru-go*, in a manner however that has been concealed, have been recommended for a cancer of the breasts; but their beneficial effect has been disputed. Gmelin's App. Med. vol. i. p. 346.

ÆRUGO salis, in *Natural History*, a name given by Pliny, and several other ancient authors, to a reddish slimy matter, separated from the Egyptian salt, called **NATRUM**, in purifying it. We find this matter remain in the filter, on dissolving and filtering the Egyptian nitre, at this time; it seems to be a mixture of bituminous matter, and a red earth, which had mixed themselves among the cakes of the salt, during the time of their concreting from the water.

ÆRUSCATORES, formed from *æruscari*, to beg, mump, &c. in *Antiquity*, a kind of sharpening strollers, who got their living by tricks, telling fortunes, and the like, much like modern gypsies. The term is also applied to oppressive tax-gatherers.

The *Galli*, or priests of Cybele, were called *æruscatores magnæ matris*, on account of their begging, or collecting alms in the streets. To which end they had little bells whereby to draw people's attention to them, much like some orders of mendicants abroad.

ÆERY, or **AIRY**, in speaking of hawks, eagles, or the like, answers to the **NEST** of other birds.

ÆS, in *Antiquity*, has various significations; but it properly denotes *brass* or *copper*. It was for a long time applied indiscriminately to either of these metals; and it was not till a late period that metallurgists, in order to distinguish them, gave the name *cuprum* to copper: as *copper* was the first metal used in coinage by the Romans, the word *æ* was used in their language to signify money in general. It likewise denoted a particular coin made of that metal.

Æs caldarium, or *cast brass*, otherwise called *as olarium*, or *pot brass*, is a species of *brass* mentioned by Pliny, which was not capable of being hammered. This is likewise a term used by the German *mineralists*, for a substance which sometimes occurs to those who work upon **CO-BALT**, and is used for making the fine blue colour called **SMALT**.

Æs candidum, among the *Ancients*, was different from that which we call white brass; it is a purer and whiter kind of metal found, it is said, under the veins of silver, somewhat analogous to Venetian **TALC**. They had probably a method of making **COPPER white** as well as *yellow*, equal, if not superior, to that now in use. The phrases of *orichalcum album* in Virgil (*Æn.* xii. v. 87.) and λευκον κραμμι among the Greeks, strictly signify *white BRASS*.

Æs Corinthium, a precious metallic composition, of a much finer colour than common brass, and for its beauty little inferior to gold. Pliny says, (*Hist.* tom. ii. p. 640. Ed. Hard.) that this was an accidental mixture of metals at the sack and conflagration of Corinth by L. Mummius, 146 years before Christ; when the gold, silver, and brass statues, and all metallic substances, melting and mingling together, formed this mass. He says, that there were three sorts of Corinthian brass, viz. the red, the white, and that which was of the colour of money, according to the different proportions of gold and silver that were in it. But some refiners, who have strictly examined this metal, find no gold in it; a circumstance which, if true, suggests one reason, among others, for concluding, that this account is fabulous. However, the fable has been interpreted by some to signify, that the art of making **COPPER** into **BRASS** was first discovered by the Corinthians, who found the **CALA-**

MINE stone on the plains of Peloponnesus, or at least that they brought this art to perfection.

Æs *coronarium*, is used by Pliny, (H. N. tom. ii. p. 659.) to denote brass wrought into thin plates, and which, he says, stained with the gall of bulls, furnished a sort of gold for the crowns of players. This was called *as ductil*, in contradistinction to the *as fissile*, or *as cædarium*. They were both brought from Cyprus.

Æs *Cyprum*, was a kind of copper produced in the island of Cyprus. This denomination was first given to copper in general; whence it was called *cyprum*, and at length *cuprum*. The superiority of the Cyprian copper gave occasion to this appellation.

Æs *flavum*, *yellow copper*. All the Roman authors have mentioned the method of making BRASS with *calamine* and *copper*; but their finest kind, which they called *oricbaleum*, or *auricbaleum*, they distinguished from the inferior sorts, which had only the name of *æs flavum*.

Æs *grave* denoted money among the Romans, which was paid by weight, and not by tale. In this sense it is used by Buddæus and Scaliger.

But others by *æs grave* understand large pieces of copper coined, containing, for instance, an *as*, or pound of that metal, such as we find current in Sweden. These they assert bore the title *æs grave*, till the time in which they were reduced to a smaller standard.—Gronovius, on the contrary, maintains, that the *as*, or pound weight, did not acquire the appellation, *æs grave*, till after their reduction. Philos. Trans. N^o. 19.

Kuster rejects all these opinions, and asserts, that the expression is used to denote any kind of copper-money compared with gold or silver; which, with regard to the bulk and size of the pieces, was much lighter, though of greater value.

But this system, however plausible, is rejected by several learned men, particularly Perizonius, and Mr. Ward. The former has a dissertation on the subject, wherein the opinion of Gronovius is farther examined and defended.

Æs *hepaticon* was of a silverish colour, and probably what the moderns call BRONZE; though some confound it with the *as Corinthium*.

Æs *pauperum* is a name given to *copper ore*, divested of its silver, when it contains any.

Æs *rude*, that unshaped, or not fashioned for any particular purpose.—Some will have this to be the same with *æs grave*.—The money, during the first ages of Rome, was all of this kind.

Others, by *æs rude*, understand metal unstamped; in opposition to *as signatum*, that stamped, or coined.

Æs *ustum*, called also *as Veneris*,—*as crematum*,—*crocus Veneris*, and *cinis eris*, is a term which, like many others among the old chemists, has been applied to two or three different substances; it is, therefore, on this account deservedly rejected from the reformed nomenclature. Kunkel (Labor. Chym. p. iii. c. 39.) employs it as a general denomination for a perfect oxyd of copper prepared by heat; the expression is, however, more commonly employed to denote a pharmaceutical preparation once much in vogue as an escharotic, but now fallen into disuse. This *æs ustum* essentially consists of copper and sulphur; and the different varieties originate from the relative proportions of the ingredients, and the different states of oxydation of the copper. It is usually prepared by stratifying in a crucible copper clippings and powdered sulphur, and heating the crucible by degrees till it ceases to emit any vapours; it must then be raised to a dull red heat for an hour; there results a brittle mass which

when pulverized and washed is the substance in question. Barchusen's method is still more simple, consisting merely in heating a slip of copper to whiteness, and rubbing it with a roll of brimstone; as soon as it is taken out of the fire, the copper combines eagerly with the sulphur, and the compound runs down in drops, and is received in a basin of water: this is then pulverized and washed. In both these cases the compound is a slightly oxydated copper, saturated with sulphur; of an iron brown colour. In addition to these processes Lemery goes on to heat the sulphurated oxyd in a reverberatory nine times successively, quenching it in linseed oil after each roasting. He thus obtains a product of a high red colour, which in fact is a simple oxyd of copper, the sulphur being burnt out. Some recommend a mixture of nitre or common salt with the sulphur, and the substance resulting from this, if not washed, is certainly a very powerful escharotic on account of the sulphurated alkali which is thus combined with the oxyd of copper. As to the sal ammoniac and vinegar, in which some previously steep the copper, it is wholly useless, all its effect being destroyed by the subsequent heating. Dict. Method. Art. Æs ustum.—New Dispensatory, 1765, p. 498.—Beaumé's Chymic. Experiment. vol. ii. p. 651.—Gren's Chemistry, vol. ii. p. 269.

Æs *ustum* is very drying and deterfive, and has been, on that account, mixed with plasters and unguents, for drying up fistulous ulcers, and imbibing acrimonious humours, or sanies. It is also commended for disorders of the eyes; and joined with cardomoms and honey-water, it has been prescribed internally to epileptics, with whom, according to Dioscorides, it operates as an emetic, and according to Aretæus, as a laxative. See Gmelin's App. Med. vol. i. p. 344. It is likewise used for colouring glass.

Æs *uxorium*, in *Antiquity*, a sum paid, by bachelors, as a penalty for living single to old age.

This tax for not marrying seems to have been first imposed in the year of Rome 350, under the censorship of M. Furius Camillus, and M. Poithumus.

At the *census*, or review of the people, each person was asked, *Et tu ex anima sententia uxorem habes liberum querendorum causa?* He who had no wife, was hereupon fined after a certain rate, called *æs uxorium*.

Æs; *flos Æris*, called by the Greeks, χρυσος ανθρος (sometimes confounded by moderns with *calcantium*), is prepared of COPPER melted, and removed into other furnaces, wherein being exposed to a farther and greater heat, and vehemently agitated by bellows, it deposits an infinite number of small scales, like millet grains, which being separated by lotion, make the *flos æris*. The cold water is poured on the copper, as it runs out of the furnace into the receiver.

Æs; *squama Æris* properly denotes flakes of that metal struck off by the hammer, in the operations of the forge, &c. These, from the Cyprian copper-works, are called *Helitæ*.

Æs; *per Æs & libram* was a *formula* in the Roman law, whereby purchases and sales were ratified.

Originally the phrase seems to have been only used in speaking of things sold by weight, or by the scales; but it afterwards was used on other occasions. Hence even in ADOPTIONS, as there was a kind of imaginary purchase, the formula thereof expressed, that the person adopted was bought *per æs & libram*.

ÆSA, in *Ancient Geography*, a town of Thrace, near Pallene. Steph. Byz.

ÆSALON, in *Ornithology*, a species of FALCON, called in English the MERLIN. *Æsalon carolinienfis*, is the name given

given by Brisson to the *accipiter minor* of Catesby, and the *FALCO sparverius* of Linnæus, which has a yellow cere, brown head, red vertex and abdomen, and bluish wings. The head of the female is encompassed by seven blackish spots.

ÆSANIS, in *Ancient Geography*, a town of Phrygia Major, according to Ptolemy.

ÆSAPUS, a river of Mysia, in Asia Minor, according to Strabo, which rose south-west of Scepsis, and discharged itself into the Propontis, west of Cyzicus.

ÆSAR, *Serchio*, a river of Etruria in Italy, which, says Strabo, joined the Arnus at Pisa, but its mouth is said to be ten miles north of that of this river.

ÆSAR, in *Mythology*, a deity of the Etruscans. It is said that the letter C being obliterated in the word *Cæsar*, annexed to a statue of Augustus, the augurs deduced from this accident on the part of the statuary, a sorrowful preface. As C was a numeral letter, denoting 100, they concluded that he had not 100 days to live: but as the word *Æsar* was the name of a deity, they thence inferred that he would be deified after his death.

ÆSARONENSII, in *Ancient Geography*, a people of the northern part of Sardinia.

ÆSARUS, *Evaro*, a small river of Brutium, which watered the town of Croton. Ovid (*Met.* l. 15. v. 23.) calls it *Æsaris*.

ÆSCH, in *Ichthyology*, a name by which some have called the GRAYLING, or tumbler, a fish of the truttaceous kind, called in Latin *thymallus*.

ÆSCHINES, in *Biography*, an Athenian philosopher of low extraction, said by some to be the son of Charinus, a sausage-maker, and by others, the son of Lyfania. He discovered an early desire of knowledge, and, though oppressed by poverty, was assiduous and persevering in the pursuit of it. With this view he placed himself under the tuition of Socrates, who was gratified by the respect which was paid to him by this young and studious, though mean disciple. Upon first offering himself to the notice of Socrates, he told the philosopher that the only thing which it was in his power to present him, in return for his kindness in giving him instruction, was *himself*. Socrates replied, that he accepted and esteemed the present, and hoped to render it more valuable by culture. He adhered to his master with unalterable fidelity and constancy, and enjoyed his particular friendship. Impelled by poverty, he determined to quit Athens; and after the example of Plato and others, to visit the court of Dionysius, the tyrant of Sicily, who was, at this time, either through vanity or jealousy, a general patron of philosophers. Upon his arrival in Syracuse, he was slighted by Plato on account of his poverty; but Aristippus introduced him to the prince, by whom he was liberally rewarded for his Socratic Dialogues. Plutarch, however, vindicates Plato from this charge, and says that when he was neglected at Syracuse, the philosopher recommended him to Dionysius, and engaged for him the protection and favour of the sovereign. See Plut. Commentarius de Adulatoris et Amici discriminatione apud Oper. tom. ii. p. 67. Ed. Xyland. Æschines remained in Sicily till the expulsion of the tyrant, and then returned to Athens. But fearing to become a rival of Plato or Aristippus, who were in high esteem, by any public exhibition, he taught philosophy in private, and maintained himself by the pecuniary recompence which he received for his instructions. Afterwards, in order to gain a more ample subsistence, he appeared as a public orator. Laertius says, that he wrote judicial orations for the vindication of the innocent. Besides orations and epistles, Æschines wrote seven Socratic

Dialogues in the true spirit of his master, on temperance, moderation, humanity, integrity, and other virtues: of which only three are extant, *viz.* one concerning Virtue, whether it can be taught; a second concerning Riches, whether they are good; and a third, concerning Death, whether it is to be feared; a fragment of a fourth, on the Duties of a State of Marriage, may be found in Cicero de Inventione Rhetorica, l. i. c. 31. They are published by Le Clerc, with notes and several dissertations, in the "Silvæ Philologicæ." Amstelod. 1711. Fabricius (*Bibl. Græc.* tom. i. p. 829.) Suidas (in *Λεξιμῆς*) and Lucian (de Parasito. Op. tom. ii. p. 860. Ed. Reitzii.) have given an account of them. Some have charged him with purloining the works of Antisthenes, and with publishing dialogues of Socrates, confided with him by Xantippe, as his own. This Æschines, who is a different person from Æschines the orator, is said by Diodorus Siculus (*Hist.* tom. ii. p. 62. Ed. Wesseling.) to have flourished about the 103d Olympiad.

ÆSCHINES, the *Orator*, was the son of Atromctus, a grammarian and schoolmaster, and Glaucothea, who is said to have been a timbrel-player. See Lucian (in *Somm.* tom. i. p. 17.) Philostratus (de vit. Sophist. ap. Oper. p. 506. Ed. Olearii.) He was distinguished, as Plutarch says (*X Orat. Vit.* ap. Oper. tom. ii. p. 840.) neither by his birth nor riches. In his youth, Æschines being of a robust constitution, devoted himself to the exercises of the gymnasium, and having a clear voice, he performed a part in the exhibition of tragedies. Some say that he attended the lectures of Isocrates and Plato; but according to others, he received instruction from Alcidas, the preceptor of Gorgias. His progress, however, was considerable, and he became a competitor with Demosthenes; and by his public conduct incurred his displeasure. When the Athenians negotiated a peace with Philip of Macedon, Æschines and Demosthenes were two of the ten ambassadors employed for this purpose. On this occasion, it is said that Æschines was bribed by Philip, and persuaded the Athenians, in opposition to the remonstrances of Demosthenes, to confide in the promises of the sovereign of Macedon. Thus deluded, they gave this prince an opportunity to possess himself of Thermopylæ, and to enter the territory of Phocis. Philip, aspiring to be a generalissimo of the Greeks, was anxious to be appointed to this office by the council of the Amphycions. With this view, he contrived, by intrigue and corruption, to engage the support of Æschines; who, in a studied oration, prevailed with the deputies of the Greek cities, assembled in the council of the Amphycions, to elect him for their general, and to invest him with full power to act as he should think proper. By this artifice Philip got possession of Elatæa, the chief city of Phocis, and thus established himself in a situation the most favourable for the execution of his farther designs. Demosthenes exerted all his powers of eloquence to rouse the Athenians, and to induce them to unite with the Thebans in disconcerting the machinations of Philip. His eloquence was effectual, and the two hostile armies encamped near Cheronea, a city of Bœotia. The wisdom and force of Philip prevailed, and Demosthenes, being less a warrior than a statesman, and being more capable of giving counsel in his harangues than of enforcing and supporting it by intrepid courage, threw down his arms, and fled with the other discomfited troops. The shock which Athens received at this time, the effect of which it was never able to recover, was ascribed to Demosthenes; and Æschines took the lead in criminating his rival: and he, accordingly, drew up an accusation against Ctesiphon, or rather against Demosthenes.

The conflict between these two orators excited very general attention, and the two orations that were delivered by them have been always considered as the master-pieces of antiquity, especially that of Demosthenes, which is more powerful and impressive than that of Æschines. The latter lost his cause, and was sentenced to banishment for his rash accusation, ante Christ. 330. Upon this, he settled at Rhodes, where he opened a school of eloquence, the reputation of which subsisted for many ages. He is said to have commenced his lectures with the two orations that had occasioned his banishment. That of Æschines himself was received with applause; but when the auditor heard that of Demosthenes, their plaudits were redoubled. On this occasion, Æschines declared, with a candour and liberality highly honourable to him as an enemy and rival, *What applauses would you not have bestow'd, if you had heard Demosthenes speak it himself!* Plutarch and Philostratus, *ubi supra*. When Æschines left Athens, in order to embark for Rhodes, Demosthenes ran after him and obliged him to accept a purse of money; upon which Æschines exclaimed, *How will it be possible for me not to regret a country, in which I leave an enemy more generous than I can hope to find friends in any other part of the world!* From Rhodes, Æschines removed to Samos, and there he died, at the age of 75 years. Some have said, that Æschines was the first who delivered extemporaneous orations, a practice which others have ascribed to Gorgias. Philostratus extols him for luminous perspicuity, decorous gravity, and distinguished energy; and he is denominated by Demosthenes *μεγαλοφρονέστατος*. Quinçilian, comparing him with Demosthenes, says of him, (*Inst. Orat. l. x. c. i. tom. ii. p. 901. Ed. Burman.*) *Plenior Æschines, et magis fufus, et grandiori similis, quo minus strictus est: carnis tamen plus habet, lacertorum minus*. Photius ascribes nine epistles (according to the number of the muses) to Æschines; but there are twelve, which were addressed to the Athenians when he was an exile at Rhodes, in Wolfius's edition of Demosthenes and Æschines, p. 205; and Taylor has added them to his edition. The ancients acknowledge only three genuine orations, viz. 1. *Adversus Timarchum* (Wolf. Ed. p. 259.) Timarchus was his accuser, and it is said that in consequence of the reproaches of Æschines he laid violent hands on himself. 2. *De falsa Legatione*, (Ib. p. 395.) This is an apology for himself against Demosthenes, who had accused him of perfidy in an embassy to Philip. 3. *Adversus Ctesiphontem*, (Ib. p. 425.) who decreed the golden crown to Demosthenes. Fabricius compares these orations to the three graces. Another oration, intitled *Δηλιακος νημος*, was formerly inscribed with the name of Æschines; but the ancients ascribe it to another person of the same name. See Plutarch and Philostratus, *ubi supra*. Demosthen. et Æschin. Opera, by Wolfius Francof. 1604. Fabricius. Bibl. Græc. tom. i. p. 412—928, &c. Laertius, (tom. i. p. 118. tom. ii. p. 107. Ed. Meib.) mentions several other persons, called Æschines; and this identity of name has occasioned no small confusion in the history of the persons, and particularly with regard to the Socratic philosopher and Athenian orator, who are the subjects of these articles.

ÆSCHNA, in *Entomology*, the name of a species of water-fly, of an ash-colour, with four wings, and a long body, hairy near the tail.

ÆSCHRION, in *Biography*, a fellow citizen, and one of the masters of Galen, by whom he is mentioned with respect. He had great faith in a medicine he invented against the effects of the bite of a mad dog. The following is the prescription, and it is, without doubt, as efficacious as the famous composition recommended by Dr. Mead. Take of the ashes

of lobsters, burnt alive in a copper vessel, ten parts; of gentian, in powder, five parts; of jucansa, one part; mix them, and let the patient take a spoonful in a glass of water every day, for forty days. There are some idle ceremonies directed to be observed in making the powder, which are here omitted.

ÆSCHY, in *Geography*, a town of Switzerland in the Canton of Bern; two leagues south-east of Spiek.

ÆSCHYLUS, in *Biography*, the famous tragic poet, was born at Athens, in the last year of the 63d Olympiad, or the 525th year before Christ, according to the Arundelian marbles, on which Stanley, in his notes on the life of this poet, relies. He was the son of Euphoriion, and distinguished by his military valour as well as by the exercise of those signal talents, which intitle him to the appellation of the *father of tragedy*.

At the battle of Marathon, his brother, Cynægryus, signalized himself; and, as Herodotus informs us (l. ii. p. 491. Ed. Wessell.) laid hold of the prow of one of the Persian ships with his hands, which were cut off by an axe, so that he died of his wounds; and his youngest brother Aminias, says Diodorus Siculus (l. xi. p. 426. Ed. Wessell.), who had the command of a squadron of ships, conducted himself with such skill and bravery, that he sunk the admiral of the Persian fleet, and gained distinguished honour. In these battles, as we learn from Pausanias (l. i. p. 35. Ed. Kulnii), as well as in those of Platæa and Artemisium, he was present; and we are assured that he acquitted himself with honour. But his principal attention was directed to the composition of tragedies and the improvement of the stage. Pausanias informs us (l. i. p. 49.) that he was admonished by Bacchus, when a boy and asleep in the field, to write tragedies; and that when he awoke he made a trial and succeeded.

His mind was naturally strong and ardent; and the austerity of his character was manifested by his silence and gravity. From his youth he had been accustomed to the lessons of those poets, who, living near to the heroic times, conceived ideas corresponding in sublimity to the illustrious deeds that were then achieved. In the history of these remote ages he beheld every where the impress of grandeur, and frequently that of ferocity. In order to bring scenes of this kind to view, and to exhibit, as it were, before the eyes of the spectator the time and place, and various circumstances of events, Æschylus employed all the resources of theatrical representation: and thus the illusion became a reality. Sufarion and Thepsis, and Phrynichus, the disciple of the latter, had proceeded but a little way. Thepsis indeed had introduced a single actor, and Phrynichus selected that kind of verse which is most suitable to the drama, and made some other changes; nevertheless tragedy was in its infancy before the time of Æschylus. In his first tragedies he introduced a second actor; and, afterwards, copying the example of Sophocles, who had just entered on his theatrical career, he admitted a third, and sometimes even a fourth. By thus multiplying persons, one of his actors became the hero of the piece, and possessed the principal interest; and as the chorus now held only a subaltern station, Æschylus abridged its part. He is censured for having admitted mute characters into his drama; but it has been suggested that the veil which covered them and the silent grief which they manifested, produced a more sensible effect than any lamentations and tears. What he has said of his hero Hippomedon (Sept. contr. Theb. v. 506.) may be applied to himself:

“ — Before him strides
Gigantic terror, tow'ring to the skies.”

And yet he knew how to fet bounds to the emotions which he earnestly laboured to excite, and constantly avoided polluting the stage with blood; for he wished to produce scenes that should be terrible but not horrible. He rarely excites pity or tears, either because he was naturally destitute of a very delicate sensibility, or because he did not wish to render his auditors effeminate. An ingenious author (See Anacharsis's Travels in Greece by the Abbé Barthelini, vol. vi. p. 10, &c.) has examined the manner in which Æschylus has acquitted himself in the different parts of tragedy, *viz.* in the fable, manners, sentiments, diction, decoration, and music. His plots, says this writer, are extremely simple; and he sometimes interests us merely by the recital of facts and the vivacity of the dialogue (in Sept. contr. Theb.); and at other times (in Suppl. and Eumen.) by the vigour of his style, and the terror of his scenes. In his estimation the unities of action and of time were essential, but that of place less necessary. His chorus makes a part of the whole. It is the comforter of the wretched, the counsellor of kings, the terror of tyrants, and the confident of all. Sometimes it participates in the action during its whole continuance, as in Suppl. and Eumen. The character and manners of his personages rarely fail in suitableness and consistency. He usually wrote his models from the heroic times, and sustains his characters at the elevation to which Homer had raised his heroes; and it should be recollected that he wrote in the time of the Persian war. As he inclines more to excite terror than pity, he seeks only to render his characters more furious, but without injury to the theatrical interest. See the character of Clytemnestra, in Agamemnon; and particularly v. 1571, 1445, 1494, 1411, 1398, 1506.

In his time no other style was known for heroic composition, but that of the epopeia and that of the dithyrambic. As they suited the elevation of his ideas and sentiments, Æschylus, without enfeebling them, referred them to tragedy. Hurried away by an enthusiasm, which he was unable to govern, he lavishes epithets, metaphors, every figurative expression of the emotions of the soul, and whatever may give weight, strength, and magnificence to language, or animate and render it impassioned. Beneath his vigorous pencil, narrative, sentiments, and maxims, are changed into images, which are striking for their beauty or singularity. Of a man of consummate prudence, he says, (Sept. contr. Theb. v. 599).—"He reaps those sage and generous resolutions, which spring in the deep furrows of his soul;" and he thus warns a free people early to watch over the conduct of a citizen dangerous from his abilities and his riches: "Beware how you nurse up a young lion, how you carest him while he yet fears you, or how you resist him when he is grown a stranger to fear." And yet these shining passages are sometimes accompanied by an obscurity, which arises not only from his extreme conciseness and the boldness of his figures, but also from new words with which he affected to enrich his style. The style of Æschylus is in general noble and sublime: in certain parts grand to excess, and pompous to inflation; but sometimes degraded and disgusting by ignoble comparisons, a puerile play on words, and other defects which are common to this author, with all those who possess more genius than taste. But notwithstanding his faults, he merits a distinguished rank among the most celebrated poets of Greece.

Æschylus adapted the dress of his characters, and the decorations of the theatre, to those impressions of grandeur which he wished to produce on the minds of the

auditors. As nature had given to heroes a lofty stature and impressed a majesty on their persons which commanded respect, Æschylus raised his actors on high stilts or buskins. He covered their features, which were often irregular and disagreeable, with a mask; he clothed them in flowing and magnificent robes, such as the priests of Ceres have not blushed to adopt. The inferior actors were also provided with masks and dresses suited to their parts. He also obtained a theatre, furnished with machines, and embellished with decorations. Here the sound of the trumpet was reverberated, the incense was seen to burn on the altars, the shades of the dead to arise from the tombs, and the furies to rush from the gulphs of Tartarus. At the sight of some of the dreadful spectres which he contrived, and the sound of their hideous howlings, it is said that terror seized on the whole assembly, women miscarried, and children expired with fear: and the magistrates were under a necessity of issuing orders, that the chorus should consist only of 15 actors instead of 50.

Æschylus paid particular attention to the performance of the actors, regulating their steps, and directing them to give additional force to the action, by appropriate and expressive gestures. He also instructed them more effectually by his example, as he performed with them in his pieces. Besides, he employed a person, called *Telestes*, who had brought the art of gesture to such perfection, that in the representation of the seven chiefs before Thebes, he performed with so much truth and expression, that his action might have supplied the place of words. See Athenæi Deipnosophist, l. i. p. 22. Ed. Casaub.

Æschylus also applied to tragedy the lofty modulations and impetuous rhythmus of certain airs calculated to excite courage, without adopting those innovations which began to disfigure the ancient music. His choral chant is full of grandeur and decorum, and constantly in the diatonic genus, which is the most simple and natural of all.

Quintilian (Inst. Orat. l. i. c. 1. tom. ii. p. 897) gives the following character of Æschylus, as a writer; "*Tragœdias primus in lucem Æschylus protulit, sublimis et gravis, & grandiloquus sæpe usque ad vitium, sed rudis in plerisque & incompositus, &c.*" Longinus (Ed. Pearce, p. 99.) says, that he had a noble boldness of expression, and that his imagination was elevated and heroic. Some have asserted that he never composed but when he had drunk freely; and by others he has been compared to Shakespeare for energy of sentiment and style, as well as for the expression of character and passion by the happy use of trivial circumstances. Horace describes the character of Æschylus in his *Ars Poet.* v. 282, &c.

"Post hunc personæ, pallæque repertor honestæ,
Æschylus, et modicis intravit pulpita tignis,
Et docuit magnæque loqui nitique cothurno."

Æschylus, says a modern author, exhibits both the beauties and the defects of an early original writer. He is bold, nervous, and animated; but very obscure and difficult to be understood; partly by reason of the incorrect state in which his works have been transmitted to us, and partly on account of the nature of his style, which is crowded with metaphors, often harsh and tumid. He abounds with martial ideas and descriptions. He has much fire and elevation; less of tenderness than force. He delights in the marvellous. The ghost of Darius in the *Perse*, the inspiration of Cassandra in *Agamemnon*, and the songs of the Furies in the *Eumenides*, are beautiful in their kind, and strongly expressive of his genius. Blair's *Lect.* vol. iii. p. 340.

Ælian informs us (Var. Hist. l. v. c. xviii. tom. i. p. 433. Ed.

Ed. Gronov.), that Æschylus was charged with impiety by the Athenians, and condemned to be stoned to death. The ground of the charge is not that which Herodotus and Pausanias have supposed, viz. Æschylus's adopting the theology of the Egyptians rather than that of the Greeks, and presuming to say that Diana was the daughter of Ceres and not of Latona; but more probably that which Clemens Alex. has stated (Strom. l. ii. oper. tom. i. p. 467. Ed. Potteri.) that Æschylus, being himself uninitiated, profaned the mysteries by exposing them in one of his dramas on the stage. However this be, the Athenians were preparing to execute the sentence that was pronounced against Æschylus, when his brother Aminias drew aside his cloak and presented his arm without a hand, which he had lost at the battle of Salamis, in defence of his country. This sight interested the compassion and honour of his judges, and induced them to revoke their decree and to pardon Æschylus.

Plutarch (in Cimon. op. tom. i. p. 483.) says, that Æschylus, being disgusted with the preference given to Sophocles in the contest for the prize of poetic merit, abandoned his country and went to reside in Sicily. There Hiero distinguished him with benefactions and honours; but he soon died, at the age of 69 years, ante Christ. 456. Pliny informs us, (H. N. l. x. c. iii. tom. i. p. 547.) that whilst he was walking in the field, in order to avoid a danger of which he was forewarned, with respect to the mode of his death, an eagle, hovering over him in the air, let fall a tortoise upon his head, for the purpose of breaking the shell, which instantly killed him. The following epitaph, composed by himself (for the original of which see Pausanias, p. 35. Ed. Kuhnii.) was engraved on his tomb:—"Here lies Æschylus, the son of Euphron, born in Attica. He died in the fertile country of Gela. The Persians and the woods of Marathon will for ever attest his valour." At the time when he wrote these lines, he was unquestionably disgusted with literary fame, and knew no glory more illustrious than that of arms.

The Athenians decreed honours to his memory; and authors who have intended to dedicate their talents to the theatre, have gone to offer libations, and to recite their works at his tomb. There are seven of his tragedies extant, of which the best edition is the folio of Thomas Stanley, published in 1663, with a Latin translation and learned Commentary. There have been many other editions, and also translations (See Fabric. Bibl. Græc. tom. i. l. ii. c. xvi. p. 600—618.) of these tragedies: Potter's translation, published in 4to. at London, 1777; and afterwards in 2 volumes, 8vo. deserves to be particularly mentioned. Stanley, in his Life of Æschylus, has mentioned several other persons of the same name.

ÆSCHYNOMENE, formed of *αἰσχνομαί*, to be ashamed, because it retreats from the touch; *bastard sensitive plant*, in Botany, a genus of the *diadelphia decandria* class and order; and of the natural order of *papilionaceæ* or *leguminosæ*: the characters of which are, that the calyx is a one-leaved, bell-shaped, subbilabiate with equal lips, upper bifid, and lower three-toothed perianthium; the corolla papilionaceous, with sub-cordate, scarcely gaping, large banner, subovate, obtuse wings, shorter than the banner, and lunate, acuminate keel of the length of the wings: the stamina have 10 filaments, single and nine-cleft, and small anthers: the pistillum is an oblong, villous, columnar germen, the style subulate and rising, the stigmas simple, rather obtuse: the pericarpium is a long, flat, jointed, rough, one-celled legume, opening at the truncate joints; the seeds are solitary, between the joints, and kidney-shaped. Martyn enumerates

twelve species, viz. the *grandiflora*, *arboræa*, *coccinea*, *aspera*, *americana*, *indica*, *sesban* or *Egyptian*, *pumila* or *dwarf*, *sensitiva*, *heterophylla*, *lugenaria*, and *cannabinæ*.

The 1st is a shrub, from 10 to 15 feet in height, a native of the East Indies, cultivated in Jamaica, and in England by Miller, in 1768. The seeds are agreeable to domestic birds.—The 2d grows to the height of six or seven feet, with a single stem, and bears large and copper-coloured flowers.—The 3d is a native of the East Indies, and of the islands Otaheite and Huaheine in the South Seas.—The 4th is a native of the East Indies.—The 5th is somewhat sensitive: during the night, and at the approach of rain, the leaves fold together. It is a native of Jamaica, and was cultivated in 1739 by Miller.—The 6th is a native of the East Indies.—The 7th is a native of Egypt, was cultivated in 1680, in the botanic garden of Oxford, and flowers in July and August.—The 8th is a native of the East Indies; and the 9th, of the West Indies.—The 10th and 11th are natives of Cochinchina.—And the 12th is a native of the East Indies, which may be treated as hemp and used for the same purposes. The first sort is with difficulty preserved through the winter in this country. The 2d, 3d, and 7th, may, like the first, be preserved through the winter in a warm stove, will flower early in the following summer, and their seeds will ripen in the autumn: they must be kept dry in winter, or else they are subject to rot. The 4th, 5th, 6th, and 8th species are annual, and must be brought forward early in the year, otherwise their seeds will not be perfected. All the sorts are propagated by seeds, which should be sown on a hot-bed early in the spring; and when the plants are strong enough to be removed, they should be put each into a separate small pot, filled with light earth, and plunged into a fresh hot-bed; and as they advance in growth, they should be shifted into larger pots; but care should be taken that the pots be not too large, which will prevent their thriving.

ÆSCHYNOMENOUS Plants, among *Botanists*, are those properly called *Sensitive plants*.

ÆSCULANUS, *Æres*, or *Æs*, in *Antiquity*, are different names given to the divinity who presided over the coinage of copper money. This Æsculanus, it is said, was the father of Argentinus, because copper was employed before silver; and Argentinus, the father of Aurinus, because gold money succeeded silver; and thus they had three divinities presiding over the coinage of the three principal metals. On some medals of the emperors there are found three god-defes, represented with balances, a cornucopiæ, and near them a piece of the different metals.

ÆSCULAPII *Anguis*, in *Zoology*, the name of a harmless species of serpent, common in Spain and Italy, called also *PARÆA*. The *coluber esculapii* of Linnæus has white and black bands, which are bisected by a white ring, and is found in both Indies.

ÆSCULAPIUS, in *Astronomy*, the ancient name for the constellation OPHIUCUS.

ÆSCULAPIUS, *Esculapius*, and as Pausanias calls him *Aselepius*, in *Mythology*, the god of medicine, was the son of Apollo, by the nymph Coronis, born at Epidaurus, and educated by Chiron, the preceptor of Achilles, who taught him to cure diseases of the most dangerous and desperate kind, and even to raise the dead. The history of Æsculapius, like that of other deified heroes of antiquity, is involved in great obscurity, and many absurd and incredible stories are related concerning him. If we regard the reports of the people of Epidaurus, which is said to be the place of his nativity, as Pausanias has represented them; (l. ii. c. 26. p. 170. Ed. Kuhnii.) a shepherd, having

lost his dog, and one of his she-goats, found them on a neighbouring mountain, near a child who shone with an extraordinary splendence, and whom the goat suckled, and the dog guarded. This child was Æsculapius. As he advanced in age and wisdom, he dedicated his days to the relief of the unhappy. The most dangerous wounds and maladies yielded to his operations, his remedies, his harmonious songs, and the magical words which he employed. The gods, it is said, pardoned him his success; but as he dared to call the dead to life, Pluto complained, and Jupiter struck him dead with a thunder-bolt. See Pindar. Pyth. l. iii. v. 10. 92. p. 196. 201. Ed. West and Welsted. Diod. Sicul. l. iv. tom. i. p. 315. Ed. Wessell. Plin. H. N. l. 29. tom. ii. p. 493.

It is added, that Æsculapius was the disciple of Chiron, and having been entrusted with the secrets of his master, he communicated them to his sons Machaon and Podalirius, who after his death reigned over a small city in Thessaly. During the siege of Troy, they signalled themselves by their courage in the field of battle, and by their skill in the treatment of wounds (Homer Il. l. ii. v. 730. l. iv. v. 219. l. ix. v. 832.), the only part of the medical art that was much known in those remote ages. The children of Machaon, who was killed under the walls of Troy, followed the profession of their father, and settled in the country. They raised altars to their grandfather, and merited the same honours themselves by the services which they rendered to the human race. See Pausanias, l. ii. c. 11. p. 136. c. 23. p. 163. c. 26. p. 171. and 172. Ed. Kuhnii.

The founder of so respectable a family soon became the object of public veneration, though his advancement to the rank of gods must have been posterior to the time of Homer, who only speaks of him as a simple individual. In process of time divine honours were every where paid to him. At Epidaurus he had a famous temple, in which his statue, made of gold and ivory, by Thrasymedes of Paros, was placed on a throne of the same materials. It was crowned with rays with a knotty stick in one hand, and stretching out the other arm over a serpent, which seemed to raise itself up in order to reach it; and a dog lay at his feet. The Epidaurians instituted festivals and games, which were at first annually, (Plat. in Ion. tom. i. p. 530. Ed. Serrani.) and afterwards once in five years celebrated in honour of him. From Epidaurus his worship passed to the other cities of Greece, and even to distant countries. In all his temples votive tablets were hung up, on which were recorded the diseases cured by his assistance. This god was brought to Rome, by order of Apollo, when a pestilence raged in that city, in the times of the republic, under the consulate of Posthumus Megellus and C. Junius Brutus. About the year of Rome 462, the Sibylline books were consulted, and an embassy was appointed to bring the god from Epidaurus to Rome, who is said to have stolen away from his old worshippers under the form of a serpent; and on his arrival, to the great joy of the people, the plague soon ceased. On this occasion altars were erected along the banks of the Tiber, and numerous sacrifices were offered to the new deity. The Romans designed to erect a temple in honour of him, within the walls of the city; but the god who resided in the vicinity of Epidaurus, and not within the city, is said to have chosen his abode in the midst of the Tiber, on an island formed in the infancy of the republic by straw, trees, sand, and the rubbish of the city. Thither the serpent retired, and from that time the island was called the island of Æsculapius, and a temple was erected in the form of a ship, to which, as to the temple of

the god of health, the common people frequently repaired. The sick were restored to health, and in token of gratitude offered a cock to Æsculapius. Of this temple there were some remains in the 16th century, near the church of St. Bartholomew, in the island of the Tiber. From this time Æsculapius was honoured at Rome as one of the chief of their made gods. On coins, &c. he is crowned with laurel, in token of his descent from Apollo, and he is represented with a mild aspect, and with hair and beard not unlike those of the mild Jupiter: his right arm is bare, in order to denote his readiness for any operation; his left holds a stick, with a serpent twisted round it. He is sometimes seen accompanied by his wife *Hygeia* or health, with their son *Telesphorus*, or convalescence, between them. The dog and cock have been reputed sacred to this deity on account of their vigilance; and the raven for his forecast. Statius, lib. iii. Sylv. iv. v. 25. Ovid. Met. l. xv. tom. ii. p. 1065. Ed. Burman. Sueton. in Claud. tom. i. p. 686. Ed. Pitisc. — Liv. Epitom. lib. xi. tom. iii. p. 197. Ed. Burman. — Plut. Quæst. Rom. tom. ii. p. 286. — Pausan. Corinth. l. ii. p. 171. Achaic. l. vii. p. 592, &c. Ed. Kuhnii. — Cicero, (de Nat. Deor. l. iii. c. 22. tom. ii. p. 635. Ed Olivet.) mentions three deities called Æsculapius; the first the son of Apollo, worshipped in Arcadia, who invented the probe and bandages for wounds; the second, the brother of the second Mercury, killed by lightning; and the third, the son of Arsippus and Arinoe, who first discovered the art of tooth-drawing and purging.

Those who trace the origin of medicine, as well as the other arts and sciences, to the Egyptians, ascribe the invention of it to Toforthrus or Seforthrus, a king of Memphis, and the second of the third dynasty of Manetho, who was called Æsculapius on account of his great skill in that art. This prince was much more ancient than the Grecian Æsculapius, and though Africanus places him some years after Athothis, the successor of Menes, supposed to be the same with Thoth, or the first Hermes, yet others make them contemporaries, as they must have been if this Æsculapius was the same with the son of Sydye and the brother of the Cabiri.—Anc. Un. Hist. v. i. p. 246. 8vo.

ÆSCULUS, *Horse-Chestnut*, in *Botany*, a genus of the *heptandria monogynia* class and order, of the natural order of *tribulate*, and the *acera* of Jussieu. It is the *hippocastanum* of Tournefort, and the *pavia* of Boerhaave. The name æsculus is derived from *esca*, food; and the old names of *hippocastanum* and *castanea equina*, from the similitude of the fruit to that of the chestnut, and from its being given to horses. Its characters are, that the calyx is a one-leaved, ventricose, small and five-toothed perianthium: the corolla consists of five roundish petals, plaited and waving about the edge, flat, spreading, with narrow claws, inserted into the calyx, and irregularly coloured; the stamina have subulate, declining filaments, of the length of the corolla, and ascending anthers: the pistillum is a roundish germ, ending in a subulate style; the stigma acuminate: the pericarpium is a leathery, roundish, three-celled, three-valved capsule: the seeds are two and sub-globular. Van Royen de Necker and Miller observed both hermaphrodite and male flowers in this genus. There are three species, viz. the *Æ. hippocastanum*, or common horse chestnut; the leaves of which are digitate, with seven entire leaflets, and prickly capsules; the *Æ. flava* or yellow-flowered horse-chestnut, with leaves digitate with five leaflets, the laminas of the corolla cordate roundish, and the claws twice the length of the calyx; and the *Æ. pavia*, or scarlet horse-chestnut, which has flowers with eight stamina, digitate leaves with five or six serrate leaflets, smooth capsules,

capsules, lamina of the corolla obovate, and claws of the length of the calyx; and the *Æ. parva*, with a long thick tube, and a short stalk.

The 1st species, or *common horse-chestnut*, was brought from the northern parts of Asia into Europe about the year 1552, and sent to Vienna about the year 1558. From Vienna it was conveyed to France and Italy; but it came to us from the latter. It is distinguished by the beautiful parabolic form of its branches, the disposition and structure of its digitate leaves, and by the pyramidal bunches of its white flowers, variegated near the centre with yellow or red. Although this tree is now less in esteem for avenues and walks than it formerly was, on account of the early decay of its leaves, it affords an excellent shade; and the spikes of flowers which appear in May, with the intermixture of large leaves, exhibit a noble appearance. The most eligible situation for these trees is in lawns and parks, where they may be planted singly, and where their fruit will be serviceable to the deer, who are fond of it. This tree is of quick growth; and in a few years it will afford a good shade in summer, and yield plenty of flowers. Trees, raised from nuts, have in 12 or 14 years become large enough to shade two or three chairs with their branches, which in the season are covered with flowers. But the trees are of short duration, and the wood is of little value. It serves, however, for water-pipes, turner's ware, and fuel: and for these uses it is worth the charge of planting, and should be sowed in November or December.

The *common horse-chestnut* is propagated by sowing the nuts, after preserving them in sand during the winter, in order to prevent their rotting early in the spring. In this case the plants, in a proper soil, will shoot near a foot the first summer; and they may be transplanted, either in the following autumn, or in February and March, into the nursery, and set in rows at the distance of three feet, and one foot asunder, where they are to remain two years; and they will then be fit for planting where they are to continue. The most favourable soil for them is a sandy loam, inclining to moisture. The whole shoot of this tree is completed in less than three weeks after the buds are opened; and as soon as the flowers are fallen, the buds for the succeeding year are formed, which continue swelling till autumn, when they are overspread with a thick tenacious juice, that defends the tender buds from the winter frost; and on the return of warmth, the juice melts and runs off, and the buds are left at liberty to extend themselves. Of this tree there are varieties, with gold and silver striped leaves, which are increased by layers, and by budding or grafting them upon stocks of the common sort.

In Turkey the nuts of this tree are ground and mixed with the provender for their horses, especially those which are troubled with coughs, or are broken-winded; in both which disorders they are reckoned very good. M. Raimont, of Anjou, gave them, mixed with other food, to his cows; and they increased the quantity of milk, without injuring its quality; and he apprehends that if they were blanched and rasped, or otherwise prepared, they might be given to hogs and poultry. *Memoirs of the Royal Society of Agriculture at Tours*, vol. i. p. 121.

Io. Jac. Zannichelli informs us, that after many trials he has found the bark to have the same effect as the Peruvian bark: and Dr. Fuchs, teacher of medicine at Iena, has prepared from the ripe fruit, divested of the husks, an extract, which, according to his experiments, may be used, perhaps, instead of the expensive *extractum chinæ*. Its good effects, as a febrifuge, have been confirmed by many writers.

The *horse-chestnut* has been employed in France and Switzerland for the purpose of bleaching yarn; and it is recommended in the *Mem. of the Society of Bern*, vol. ii. part 2, as capable of extensive use in whitening not only flax and hemp, but silk and wool. It contains an astringent saponaceous juice, which is obtained by peeling the nuts, and grinding or rasping them. They are then mixed with hot rain or running water, in the proportion of 20 nuts to 10 or 12 quarts of water. Wove caps and stockings were milled in this water, and took the dye extremely well; and successful trials were made of it in fulling stuffs and cloths. Linen washed in this water takes a pleasing light sky-blue colour; and the filaments of hemp, steeped in it some days, were easily separated. The Author of the memoir above referred to, imagines, that if the meal of the chestnuts could be made into cakes or balls, it would answer the purposes of soap, in washing and fulling. The sediment, after infusion, loses its bitter taste, and becomes good food for fowls when mixed with bran. The Edinburgh College have admitted the *horse-chestnut* into their Pharmacopœia of 1783, on the recommendation of Dr. Gardiner, who says, that three or four grains of the powder snuffed up the nostrils in the evening, operates next morning as an excellent sternutatory, and thereby proves very beneficial in obstinate inflammations of the eyes. A patent was granted in 1796, to Lord W. Murray, for his discovery of a method of extracting starch from horse-chestnuts. See STARCH.

The 2d species, or *yellow-flowered horse chestnut*, is a native of North Carolina, was cultivated with us in 1764, and flowers in May and June.

The 3d species, or *scarlet horse-chestnut*, rises to the height of 20 feet, without much extending its branches; its bark is smooth, and the leaves, which are opposite, on long red petioles, are of a light green. The flowers, which are produced from the ends of the branches upon long naked peduncles, are much smaller than the common sort and wholly red: they appear in June, and are sometimes succeeded by fruit in England; but the seeds rarely ripen here. It grows naturally in Brasil, Carolina, Florida, Japan, and several parts of the east; and was cultivated with us in 1712. This tree may be propagated by the nuts, which must be procured from the countries where it grows naturally. They must be sown in pots early in the spring, and the pots should be plunged into a moderate hot-bed, and towards the end of May into the ground in a south-east border; and in dry weather the plants should be watered, and secured from early frosts. In the following spring they should be planted at the distance of a foot from each other, in a sheltered situation, and in the succeeding winter sheltered from cold by some light covering. The common method practised by the nurserymen, who propagate this tree for sale, is to graft or bud it upon stocks of the common horse-chestnut; but as the stocks greatly outgrow the bud or graft, the trees make a bad appearance, nor do they last long. Martyn.

ÆSEPIUS, in *Ancient Geography*, a river of Myfia, which Strabo (l. 12. t. ii. p. 847) on the authority of Homer, makes the boundary between Myfia and Troba. See ÆSAPUS.

ÆSERNIA, in *Ancient Geography*, *Ifernina*, a town of the Samnites, which was a Roman colony belonging to the Caracini between Aufidena north, and Bovianum south-east. It was not far from the river Vulturno. Silius Italicus (l. viii. v. 56) refers to it; and the appellation *Efernini* of Pliny (l. iii. c. 12.) is derived from it.

ÆSHNA, in *Entomology*, a sub-division of the UNOGATA, or fifth class of insects, by Fabricius, comprehending several species of the LIBELLULA of Linnæus, characterized by equal

equal lacinie or fringes of the lip. The species are,
 1. *L.* or *Æ. minuta*, with a yellow abdomen, two black lines, hinder wings yellow, and two black spots, found in China.
 2. *Æ. clavata*, with a clavated abdomen, gibbous base, and body variegated with brown and green, found in China.
 3. *Æ. maculata* or *variegata*, with two yellow lines on each side of the thorax, and a black spot at the base of the wings, found in Terra del Fuego.
 4. *Æ. grandis*, with four yellow lines on the thorax and variegated body, found near the waters of Europe, and in the Sandwich islands.
 5. *Æ. forcipata*, with a black thorax, various yellowish marks, and unguiculated tail, found in Europe.

ÆSICA, in *Ancient Geography*, is supposed to have been the present village of Netterby in Cumberland.

ÆSIS, *Æsio*, *Fiumicino*, a small river of Italy, which separated the Senones from Picenum, and emptied itself into the Adriatic sea, near Ancona. See *Sil. Ital. lib. viii. v. 446*.

ÆSISIUM, a town of Italy, belonging to the Umbrians.

ÆSITÆ, a people of Arabia Deserta, placed by Ptolemy below the Cauchabeni.

ÆSIUM, called also *Æsis*, a town of Umbria in Italy, situate upon the western bank of the *Æsis*, which was the common boundary of Umbria and Picenum. In after-ages it received a Roman colony.

ÆSNECY, in *Lavo*, denotes priority of age among coparceners.

ÆSOLA, or *ÆSULA*, in *Ancient Geography*, a town of Italy, near the Tiber and not far from Penum. It was situated upon a hill between the Tiber and Prænestis; and according to Livy, who speaks of *Ars Æsulana* (l. xxvi. c. ix. t. iii. p. 1069. Ed. Burman.) it was a fortified place. It is mentioned by Horace (l. iii. od. 29.) and by Paterculus (l. i. c. 14.) as a colony; and Pliny also (l. iii. c. 9.) speaks of the *Æsolani* in his time, though no vestige of them now remains.

ÆSON, a town of Thessaly, founded by *Æson*, the father of Jason: and also a river of Thessaly towards Magnesia, near this town.

ÆSONA, or *Æsona*, a town of Spain, between the rivers Sicoris and Nuceria.

ÆSOP, in *Biography*, a native of Phrygia, who lived in the time of Solon, about the 51st or 52d olympiad, the first year of which coincides with the 572d before Christ, and during the reign of Cræsus the last king of Lydia. His condition was that of a slave, and his person was so deformed, that one of his masters found great difficulty in disposing of him, as every one who saw him was shocked at the unsightliness of his figure. He is also said to have been for a considerable time without the use of speech. His mental talents, however, compensated for his bodily defects, and commanded attention and respect notwithstanding the meanness of his condition. His first master was Demarchus, an Athenian, in whose service he is supposed to have acquired his purity in the Greek tongue. From him he was transferred to Xanthus, a Samian philosopher; and he was sold by Xanthus to Iadmon, who was likewise a Samian, and who granted him his freedom on account of his extraordinary abilities; others say that he became free by the favour of Rhodope, a celebrated courtizan. Having obtained his liberty, *Æsop* acquired very distinguished reputation, and was much esteemed by Cræsus, although in the first interview his deformity made an unfavourable impression on the mind of the king, who found the observation of *Æsop*, on another occasion, signally verified in his own case, *viz.* that we ought not to consider

the form of the vessel, but the quality of the liquor which it contains. Phædrus (l. i. fab. 2.) informs us that he made several voyages into Greece, either for his own pleasure, or upon the affairs of Cræsus: and being at Athens soon after Pisistratus had usurped the sovereignty and abolished the popular government, and observing the impatience of the Athenians under this new yoke, he repeated to them the fable of the frogs who demanded a king from Jupiter. In order to account for the miseries of human life, *Æsop* used to say, that when Prometheus formed man of clay, he tempered the materials with tears. As to the time of *Æsop*'s death, Eusebius and Suidas refer it to the 54th olympiad; but this date is not consistent with the occasion to which Phædrus ascribes the fable of the frogs; for Pisistratus assumed the sovereignty of Athens in the first year of the 55th olympiad. In Blair's Tables, his death is fixed to about the year before Christ, 561. The manner of his death is thus related by Plutarch, in his treatise *de his qui sero à numine puniuntur*, (apud Oper. tom. ii. p. 556. Ed. Xylandr.) Having gone to Delphos, by order of Cræsus, with a large quantity of gold and silver, to offer a costly sacrifice to Apollo, and to distribute a considerable sum amongst the inhabitants, a quarrel arose between him and the Delphians, which induced him to return the money, and to inform the king that the people were unworthy of the liberal benefaction which he intended for them. The inhabitants of Delphos, thus incensed, charged him with sacrilege, and having procured his condemnation, precipitated him from a rock and occasioned his death. Apollo punished them for this act of violence with pestilence and famine; and in order to avert these evils, it was proclaimed in all the assemblies of Greece, that if any one, for the honour of *Æsop*, would claim vengeance for his death, they would give him satisfaction. A relation of Iadmon, a former master of *Æsop*, presented himself, says Herodotus (l. ii. p. 168. Ed. Westfeling.) and obtained satisfaction; and thus the Delphians were rescued from the pestilence and famine by which they were distressed. The Athenians afterwards erected a noble statue, executed by Lysippus, to the honour of this ingenious and learned slave, in order to let all the people know, as Phædrus (lib. ii.) observes, that the path of honour was alike accessible to all mankind; and that it was not to birth, but merit, they rendered this distinguishing honour.

“*Æsopo ingentem statuam posuere Attici,
 Servumque collocarunt æterna in basi,
 Patre honoris seirent ut cunctis viam,
 Nec genere tribui, sed virtuti gloriam.*”

Æsop, it is said, composed his fables, in order to alleviate the hardships of servitude; and it has been generally supposed that he was the first author or inventor of this species of composition: and thus Phædrus (Prol. ad lib. i.) represents him:

“*Æsopus auctor quam materiam reperit,
 Hanc ego polivi versibus senariis.*

If any thoughts in these Iambics shine,
 Th' invention's *Æsop*'s, and the verse is mine.”

But Quinctilian (Inst. Orat. l. v. c. 11. tom. i. p. 441.) ascribes the honour of the invention to Hesiod, who is known to have lived 130 years before the time of *Æsop*: and he speaks of them as admirably adapted to delight and captivate the minds, particularly, of the vulgar and uninformed. *Æsop*, however, improved this kind of writing, and adopted a variety of images, which combine the agreeable with the instructive, and communicate practical precepts in a familiar and impressive manner. To this purpose

Æsop (Noël. Att. l. ii. c. 20.) observes, that Æsop, the fabulist, was deservedly esteemed wise, since he did not, after the manner of the philosophers, rigidly and imperiously detest such things as were proper subjects of counsel and persuasion, but by forming amusing and agreeable apologies he charms and commands attention, and thus insinuates into the mind subjects that deserve consideration. Many of Æsop's fables have been ascribed to Phauldes, who lived in the 14th century, and wrote a life of him, which abounds with unchronicled and incredible relations.

Plato (in Phædo. Oper. tom. i. p. 60. Ed. Sereni.) Plutarch (de Aud. Poet. Op. tom. ii. p. 16.) Suidas in *Æsop*, and others, inform us, that Socrates, a little before his death, translated some of Æsop's Fables into verse; and Plato (l. ii. de Republica. tom. ii. p. 37.) recommends it to nurses to instruct children in their behaviour, in order to form their manners, and to inspire them at an early age with the love of wisdom. Among many editions of Æsop's Fables, by Aldus, Rob. Stephens, Plantin, &c. we may mention Hudson's, Oxon. 1718, 8vo. which has been the foundation of several others.

Fabritius (Bibl. Græc. tom. i. p. 391.) has enumerated nine other persons under the name of Æsop. Of these, one was a Greek historian, who wrote a romantic history of Alexander the Great; but it is not known at what time he lived.

Another of them was,

Æsop (Clodius,) a celebrated tragic actor, who lived about the 670th year of Rome, and amassed great wealth by the exercise of his profession. Plutarch (in Cicero. Op. tom. i. p. 863.) informs us, that Cicero studied action under the instruction of Æsop, as well as that of Roscius, and in speaking of this performer, he says, that he entered into his part to such a degree as to be sometimes transported beyond the power of self-government. Accordingly, whilst he was representing the deliberation of Atreus, who wished to revenge himself on Thyestes, he snote one of the servants that happened to cross the stage, with his truncheon, and laid him dead at his feet. Æsop lived in the most luxurious and extravagant manner; and Pliny (N.H. l. x. c. 51. tom. i. p. 571. Ed. Hard.) says, that at one entertainment he had a dish, which cost 100 sesterces, or about 872 pounds sterling, and the dish consisted of singing and speaking birds, some of which cost six sesterces, or about 52*l.* each. At the dedication of Pompey's theatre, U. C. 698, Æsop, when he was attempting to amuse the spectators in his usual manner, was obliged to stop short in a sentence on account of the failure of his voice; so that he was, probably, then in the decline of life. The son of this Æsop was more luxurious than his father; for he is said, on a particular occasion, to have dissolved pearls for his guests to swallow. See Val. Max. l. ix. c. i. num. 2. Pliny N. H. l. ix. c. lix. tom. i. p. 524. Ed. Hard. Horacæ (Sat. iii. lib. ii. v. 239, &c.) speaks only of one pearl of great value, which he dissolved in vinegar and drank:

“Filius Æsopi detractam ex aure Metellæ,
Sellect ut decies solidum absorberet, aceto
Diluit insignem baccam: qui sanior, ac si
Illud idem in rapidum flumen, jaceretve cloacam?”

Æsop, notwithstanding his profusion, is said to have died worth above a hundred and sixty thousand pounds. Macrob. Saturn. l. ii. c. x.

ÆSOPUS, in *Entomology*, a species of PAVILIO, with the wings brown on the upper part, a white spot, and underneath white and unspotted; the *Papilio Thitys* of Drury; found in India.

ÆSPING, in *Zoology*, the *coluber chrysa* of Linnæus,

a species of viper, found in Sweden, resembling the *Aspis*, but smaller than that species. Linnæus questions whether it may not be the same. Its bite is venomous, and in some cases has proved fatal. Count de la Cèpede, in the second volume of his *Histoire Naturelle des Serpens*, &c. recommends the juice expressed from the leaves of the ash as a specific against it.

ÆSTII, in *Ancient Geography*, a people of Germany, near the borders of Prussia and Poland. They are represented by Tacitus (De Mor. German. apud Op. t. ii. p. 630. Ed. Gronov.) as resembling the Suevi in their customs and manners, and the Britons in their language.

ÆSTIMATIO *Capitis*, in our ancient law-books. See WERE, and WERELADE.

King Athelstan, in a great assembly held at Exeter, declared what mulcts were to be paid *pro effluatone capitis*, for offence committed against several persons according to their degrees: the *effluatone* of the king's head to be 3000 thrymsæ; of an archbishop, or satrapa, or prince, 15000; of a bishop, or a senator, 8000; of a priest, or a thane, 2000, &c.

ÆSTIVAL, or ESTIVAL, of or belonging to summer.

Thus, we say, the *æstival solstice*, &c. in opposition to *brumal*.

ÆSTIVAL *point* is that whereby the sun's ascent above the equator is determined.

ÆSTIVAL *signs* are those extended from the summer solstitial point, *i. e.* the sun's greatest declination northward, to the intersection of the ecliptic and equinoctial southward, including Cancer, Leo, Virgo.

ÆSTIVATION, in *Botany*, a term expressing the state of the bud in summer, and used by Linnæus to denote one of those circumstances which constitute the HABIT of plants.

ÆSTRIANS, in *Ancient Geography*, the inhabitants of a district of Macedonia, the chief city of which was formerly called *Æstrium*.

ÆSTUARIVM, a town of Spain, between Noega and Salia.

ÆSTUARY, ÆSTUARIUM, in *Geography*, an ARM of the SEA, running up a good way into the land.

Such is Bristol channel, many of the friths of Scotland, &c. See BAY.

ÆSTUARY is sometimes also used in *Pharmacy*, for a vapour bath, *balneum vaporosum*.

ÆSTUARY, in the *Ancient Baths*, was applied to the occult passages, or openings from the *hypocaustum*, or stove, penetrating into the chambers. Pitisc. Lex. Ant.

To such a passage in the house of Pompeia, Statius refers. (Sylv. lib. i. §. 5. v. 58.)

———“Ubi languidus ignis inerrat
Ædibus, et tenuem volvunt hypocausta vaporem.”

ÆSYMNETIC *monarchy*, among *Ancient Writers on Government*, denotes a limited elective monarchy. Arist. Pol. c. 10. The word is formed from *αἰσχρονομία*, *regno, I govern*.—An *asymnetic* state stands opposed to a barbaric, or hereditary one.

ÆSYMNIUM, in *Antiquity*, a monument erected to the memory of the deceased heroes, by Æsymnus the Megarean. Upon consulting the oracle at Delphos, how the country might prosper and enjoy the most auspicious government, he received for answer, that it would be most likely to prosper if it followed the counsel of the most numerous; and understanding the oracle to refer to the dead, he built this monument and encompassed it with a council-house; and thus the Megareans hoped to obtain wise and salutary counsel. See Pausania Attic. l. i. p. 104. Kuhnii.

ÆTÆEI,

ÆTÆEI, in *Ancient Geography*, a people, according to Ptolemy, of Arabia Felix.

ÆTARA, a town of Africa, placed by Ptolemy between the town of Tabraca and the river Anapfagus.

ÆTATE *probanda*, in *Laws*, a writ that lay to inquire whether the king's tenant, holding in chief by chivalry, were of full age to receive his lands into his own hands. It was directed to the escheator of the county; but is now difused, since wards and liverys are taken away by the statute Car. II. Reg. Orig. 294.

ÆTH, or **ATH**, in *Geography*, a strong little town of the county of Hainault, in the Austrian Netherlands, situate on the river Dender, about 20 miles south-west of Brussels. It had formerly an abbey of nuns, and some good linen manufactures.

ÆTHÆA, a town of Laconia.

ÆTHALÆ, in *Natural History*, a name given by some writers to the *calmia fornacum*, or **TUTTY**.

It had this name from its being the concreted foot, or vapour of the *lapis calaminaris*, and copper, melted together, in the making of brass.

ÆTHALIA, or **ILVA**, now *Elva*, in *Ancient Geography*, an island on the coast of Etruria, about 100 miles in compass, and abounding with iron. It was so called from *αιθαλι*, smoke, issuing from the shops of Vulcan.

ÆTHALIDÆ, a people of Attica, in the tribe of Leontides.

ÆTHALOEIS, a town of Mysia, east of mount Ida, and south of Scepsis.

ÆTHELING, in *British History*. See **ATHELING**.

ÆTHER, in *Physiology*, is usually understood of a thin, subtle matter, or medium, much finer and rarer than air; which, commencing from the limits of our atmosphere, possesses the whole heavenly space.

The word is supposed to be formed from the verb *αιθω*, to burn, to flame; some of the ancients, particularly Anaxagoras, supposing it of the nature of fire.

The philosophers cannot conceive that the largest part of the creation should be perfectly void; and therefore fill it with a species of matter under the denomination of æther. —But they vary extremely as to the nature and character of this æther. —Some conceive it is a body *sui generis*, appointed only to fill up the vacancies between the heavenly bodies; and therefore confined to the regions above our atmosphere. —Others suppose it of so subtle and penetrating a nature, as to pervade the air, and other bodies; and possess the pores and intervals thereof. —Others deny the existence of any such specific matter; and think the air itself, by that immense tenuity and expansion of which it is found capable, may diffuse itself through the interstellar spaces, and be the only matter found in them.

In effect, æther being no object of our sense, but the mere product of imagination, introduced only for the sake of hypothesis, or to solve some phenomenon, real or imaginary; authors take the liberty to modify it how they please. —Some suppose it of an elementary nature, like other bodies, and only distinguished by its tenuity, and the other affections resulting from it; which is the philosophical æther. —Others will have it of another species, and not elementary; but rather a sort of sixth element, of a pure, more refined, and spirituous nature than the substances about our earth; and void of the common properties of matter, as gravity, &c. —Such is the ancient idea of æther or ætherial matter.

The term æther being thus embarrassed with a variety of ideas, and arbitrarily applied to so many different things, the later philosophers choose to set it aside; and accord-

ingly, the Cartesians use the term *materia subtilis*, which is their æther; and Sir Isaac Newton sometimes a *subtile spirit*, as in the close of his *Principia*; (apud Oper. tom. iii. p. 174. Ed. Horfl.) and sometimes a *subtile* or *æthereal medium*; as in his *Optics*. *Queries* 18—24, apud Oper. tom. iv. p. 223—226. See also his letter to Mr. Boyle, apud Oper. tom. iv. p. 385, &c.

The truth is, there are numerous considerations, which seem to evince the existence of some matter in the air much finer than the air itself. There is an unknown something which remains behind when the air is taken away; as appears from certain effects which we see produced *in vacuo*. —Heat, Sir Isaac Newton observes, is communicated through a vacuum, almost as readily as through air; but such communication cannot be without some interjacent body, to act as a medium. And such body must be subtle enough to penetrate the pores of glass; and may be very well concluded to penetrate those of all other bodies, and consequently be diffused through all the parts of space; which answers to the full character of an æther. He supposes that it is rarer in the pores of bodies than in open spaces, and even rarer in small pores and dense bodies than in large pores and rare bodies; and also, that its density increases in receding from gross matter, so as to be greater, e. g. at the $\frac{1}{100}$ th of an inch from the surface of any body than at its surface; and so on.

The existence of such an ætherial medium being settled, that author proceeds to its properties; inferring it to be not only rarer and more fluid than air, but exceedingly more elastic and active: in virtue of which properties, he shews, that a great part of the phenomena of nature may be produced by it. The elastic force of this medium, in proportion to its density, according to his mode of estimating it, must be above 700000 × 700000 times greater than the elastic force of the air in proportion to its density. If, he says, any one should suppose that æther, like our air, may contain particles which endeavour to recede from one another, and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of its particles may contribute to the greatness of the force, by which those particles may recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and by consequence exceedingly less able to resist the motions of projectiles, and exceedingly more able to press upon gross bodies by endeavouring to expand itself. The resistance of this medium, he supposes, to be very inconsiderable. If this æther should be supposed 700000 times more elastic than our air, and above 700000 times more rare, its resistance would be above 600000000 times less than that of water; and a resistance so small would scarcely make any sensible alteration in the motions of the planets in 10,000 years.

To the action of this medium he ascribes the attractions of gravitation and cohesion, the attractions and repulsions of electrical bodies, the elastic force of the air, and of nervous fibres, and the emission, refraction, reflection, and other phenomena of light, the effects and communication of heat; as also sensation, muscular motion, &c. In fine, this same matter seems the *primum mobile*, the first source or spring, of physical action in the modern system.

The Cartesian æther is supposed not only to pervade, but adequately to fill all the vacancies of bodies; and thus to make an absolute *plenum* in the universe. See **MATERIA subtilis**.

But Sir Isaac Newton overturns this opinion, from divers considerations; by shewing that the celestial spaces are void of all sensible resistance: for, hence it follows, that

the matter contained in them must be immensely rare, because the resistance of bodies is chiefly as their density; so that if the heavens were thus adequately filled with a medium or matter, how subtle soever, they would resist the motion of the planets and comets much more than quicksilver or gold.

The existence of such a subtle fluid as æther has been almost universally allowed: and its importance and utility, in the general system of nature, have been very generally acknowledged. Dr. Reid, indeed, seems to have entertained doubts on this subject. He observes, that although Sir Isaac Newton had formed conjectures about this æther near 50 years before he died, and had it in contemplation as a subject of enquiry, during that long space; yet it does not appear that he ever found any convincing proof of its existence, but considered it to the last as a question, whether there be such an æther or not. Regarding, therefore, the authority of Newton himself, he is of opinion that we ought to hold the existence of such an æther as a matter not established by proof, but to be examined into by experiments; and he adds, "I have never heard that, since his time, any new evidence has been found of its existence." Dr. Hartley, however, whose system of the mind and its operations is founded on the reality of this æther, alleges, that if we suppose the existence of such a subtle medium, and of its properties, to be destitute of all direct evidence, yet, if it seems to account for a great variety of phenomena, it will have an indirect evidence in its favour by this means. To which mode of reasoning Dr. Reid replies, that there never was an hypothesis invented by an ingenious man which has not this evidence in its favour. The vortices of Des Cartes, the sylphs and gnomes of Mr. Pope, serve to account for a great variety of phenomena. Hartley's *Observations on Man*, p. 7. 4to. 1791. Reid's *Essay on the Intellectual Powers of Man*, p. 87. Some late writers have ascribed the phenomena of electricity and magnetism to a fluid of this kind, under the denominations of the electrical and magnetical fluid; and they have referred to its operation in different circumstances, many of those effects, which are inexplicable without such a fluid, diffused through every part of the material universe. See ELECTRICITY, *cause of GRAVITY, HEAT, LIGHT, MAGNETISM, REFLECTION, REFRACTION, SENSATION, SOUND, VIBRATION, &c.*

ÆTHER, in *Chemistry*. See ETHER.

ÆTHERIA, in *Ancient Geography*, is a name formerly given to Ethiopia, under which appellation, it is mentioned both by Pliny (l. vi. c. 30.) and Strabo, l. ii. p. 82.

ÆTHERIA *Herba*, is a name given to ERINGO.

ÆTHERIAL, ÆTHERIUS, something that belongs to or partakes of the nature of æther.

Thus, we say, the ætherial space, ætherial regions, &c. Some of the ancients divided the universe, with respect to the matter contained in it, into *elementary* and *ætherial*.

Under æther, or the ætherial world, was included all that space above the uppermost element, *viz.* fire.—This they supposed to be perfectly homogeneous, incorruptible, unchangeable, &c. See CORRUPTION.

The ancient Platonists and Pythagoreans suppose different bodies united with the human soul, *viz.* the gross, or material one; a finer aerial one; and, thirdly, the finest of all, which they call ætherial, celestial, luciform, &c.

This kind of body they conceived peculiarly belonging to such souls after death, as are purged and cleansed from corporeal affections, lusts, and passions. That this distinction of two interior vehicles, or tunicles of the soul, besides the outer vestment of the terrestrial body, was not a mere figment of the latter Platonists since christianity was introduced,

appears plainly from Virgil's description of the pure ætherial and fiery body, which he distinguishes from the spirituous or airy body, in which unpurged souls receive punishment after death. After describing this punishment, he proceeds in this manner:

"Donec longa dies, perfecto temporis orbe,
Concretam exemit labem, purumque reliquit
Ætherium sensum, atque aurai simplicis ignem."
Æn. l. vi. v. 745, &c. Tom. iii. p. 118.
Ed. Burnan.

The ground of this opinion seems to have been the notion which these philosophers entertained concerning the pre-existence of the human soul, which, according to their imagination, was invested with a lucid and ætherial body, either from eternity, or die from the first commencement of the habitable world; and which, being coeval with the soul itself, and also incorruptible, inseparably adhered to it, in its subsequent lapses and descents, first into an aerial, and then into a terrestrial body; this being, as it were, the bond of union betwixt the soul and them. The Pythagoreans and Platonists, however, were not all of this opinion; for some of them supposed, that, according to the moral disposition of the soul, it always finds or forms a suitable body, correspondently pure or impure; and consequently that, by moral virtue and philosophy, it might again recover that celestial body, which was lost by its fall and descent into the grosser body. See Cudworth's *Intell. System*, b. i. c. 5. vol. ii. p. 788,—793. Ed. Birch.

The Chaldees placed an ætherial world between the *empyrium* and the region of the fixed stars. Beside which, they sometimes also speak of a second ætherial world, meaning by it the stary orb: and a third ætherial world, by which is meant the planetary region. Stanley *Hist. Phil.* 1040.

ÆTHERIAL *phosphorus*, is a name generally given, by Bernouilli, to that otherwise called mercurial, or barometrical PHOSPHORUS.

ÆTHERIAL *oil*, is a fine, subtle, ESSENTIAL OIL, approaching nearly to the nature of a spirit.

Thus, the pure liquor rising next after the spirit, in the distillation of turpentine, is called the *ætherial oil of turpentine*.

Some chemists distinguish two principles in URINE; the one a volatile urinous salt, resembling spirit of nitre; the other, an ætherial oil, or sulphur, partaking of the nature of spirit of wine.

ÆTHERIAL *Heaven*. See HEAVEN.

ÆTHERIUS, in *Biography*, an architect, who lived in the beginning of the 6th century, during the reign of Anastasius I. emperor of the east, who made him a privy-counsellor. He built an edifice, named Chalcis, in the palace of Constantinople, and he is supposed to have constructed the strong wall which extends from the sea to Selimbria, for preventing the incursions of the Bulgarians and Scythians.

ÆTHICIA, in *Ancient Geography*, a country, according to Strabo, adjacent to Macedonia, Thessaly, and Pindus, inhabited by the *Æthices*.

ÆTHIOPE, a name formerly given to the island of LESBOS.

ÆTHIOPIA, in *Geography*. See ETHIOPIA.

ÆTHIOPIAN *crown*, in *Natural History*, the name of a shell-fish, of the genus of the *dolium*, or *concha globosa*. It is of a brown colour, but differs from the common shells of this genus in having the top or head dentated, so as to represent a crown.

ÆTHIOPIS, signifies *Ethiopian clary*. See also SALVIA.

ÆTHIOPS,

ÆTHIOPS, in *Pharmacy*, a name given to certain metallic preparations of a dark colour; and though the term is at present superseded, it is yet too familiar to chemists to be wholly omitted. There are four pharmaceutical articles of this name, æthiops antimoniæ, æthiops martialis, æthiops mercurii per se, and æthiops mineralis.

ÆTHIOPS antimoniæ, is a combination of the sulphurets of antimony and mercury; the old way of preparing it is, to mix together equal parts of common salt and crude antimony, and flux the mass in a crucible; when cold there will be found a dusky scoria, resting upon a metallic looking substance, which is the crude antimony nearly in the same state as at first. The scoria being separated, the antimony is to be ground with an equal weight of mercury till they are well united. The first part of this process seems wholly unnecessary, and accordingly the antimonial æthiops is generally made by trituration of crude antimony with an equal weight of mercury. A still more expeditious and equally efficacious way of preparing this medicine, is to fuse some crude antimony in an earthenware crucible, and when it is upon the point of fixing, to add to it an equal weight of hot mercury; the mixture immediately becomes more fluid, and after a while becomes solid: when cold it must be levigated in a mortar, and washed. Sometimes, instead of crude antimony, the golden sulphur of this metal is made use of.

The medical effects of antimonial æthiops are chiefly as a sudorific in small doses, and as a purgative and emetic in larger ones. It has been exhibited with effect in old inveterate cases of lues, scrophula, and glandular obstructions, but on account of the irregularity of its action, is now fallen much into disuse. The pilulæ æthiopicæ of the late Edinburgh pharmacopœia, were composed chiefly of mercury and golden sulphur of antimony, but in the last edition of this as well as of the London pharmacopœia the æthiops antimonii is wholly omitted. *New Dispensatory*, 1765. p. 545.—*Lewis's Mat. Med.* vol. i. p. 161.

ÆTHIOPS Martialis, *safran de Mars de Lemery*, is a pure magnetic oxyd of iron, and was first introduced into the materia medica by the younger Lemery; he directs it to be prepared in the following manner. Into a large glass basin put a few pounds of clean unruled iron filings, then add a sufficient quantity of water to cover them to the depth of five or six inches: this mixture is to be stirred up with an iron spatula, two or three times a day, and fresh water to be supplied in proportion to the evaporation; at the end of five or six months almost the whole of the iron will be converted into a black fine powder which remains suspended in the water for some seconds after agitation. The water thus rendered turbid is to be decanted into a cucurbit or retort, and allowed to repose till the whole of the iron is deposited; the supernatant clear liquor must then be poured off, and the remaining moisture evaporated by the heat of a sand-bath, care being taken to prevent the access of air to the powder while drying; if the process has been well conducted, the result is a pure black pulverulent magnetic oxyd of iron; as however by moisture and contact with the atmosphere, it soon passes into the state of yellow oxyd, it is necessary to keep it in a dry well closed vial. M. Lemery, the inventor of this preparation, as is usual in similar cases, strongly maintained its superiority over all the other medicinal forms of iron; the tediousness of the process, however, has prevented its use from being very general: it certainly possesses in a high degree the tonic properties which characterize the salts and other preparations of iron, but is superseded in both the British pharmacopœias

by the *rubigo ferri*. *Beaumé Chymic. Experim.* vol. ii. p. 547. *Beaumé Elements de Pharmacie*, p. 137. *Macquer's Chem. Dictionary*, Art. *Æthiops Martial*.

ÆTHIOPS Mercurii per se; *Æthiops albus*; by this name is distinguished in the German pharmacopœias an imperfect oxyd of mercury prepared by triturating the metal with gum arabic, or any other simple mucilage, or by long continued agitation in contact with atmospheric air. Even when all possible care has been taken, this is a very imperfect mercurial oxyd, and in common the metal is merely reduced to a fine state of division. *Loebecke* recommends it in a dose from half a scruple to half a dram, either alone or united with jalap, in buboes, gonorrhœa and other cutaneous affections of a venereal kind, and also in inflammations of the liver; and it has been successfully administered in intermittent fevers. *Gmelin's App. Med.* vol. ii. p. 145. vol. iii. p. 124.

ÆTHIOPS Mineralis.—*Æthiops mineral*.—*Hydrargyrum sulphuratus niger*.—*Edin. Pharmac.* *Hydrargyrum cum sulphure*.—*Lond. Pharmac.* This is directed by the London and Edinburgh Dispensatories to be prepared by triturating in a glass or marble mortar equal parts of sulphur and mercury, or one part of the former, and two of the latter, till they have united into an uniform black powder. Notwithstanding, however, the directions of the college, the æthiops is in fact generally made by stirring mercury into melted sulphur, and then pulverizing the mass; by which manipulation much time is saved: a method equally expeditious, and perhaps upon the whole preferable to this, is to mix a solution of sulphurated alkali with the mercury and sulphur, in which case the two combine very readily by simple trituration, and by subsequent washing, the alkali is easily got rid of. *Æthiops mineral* is, therefore, mercury at its *minimum* of oxydation, saturated with sulphur: it is one of the least active of the mercurial medicines, and is used in conjunction with tin filings as a vermifuge, and in some cutaneous diseases. If the combination of the mercury and sulphur is perfect, it will not whiten the surface of gold when rubbed upon it. *Lond. and Edin. Pharmacop.*—*Lewis's Mat. Med.* vol. i. p. 148.—*Beaumé Chymic. Experim.* vol. ii. p. 456.

Authors are not agreed as to the merits of æthiops mineral. *Cheyne*, and many more, commend it highly. It has been prescribed for the worms, and for crudities and acrimony of the humours: and by some persons it has been reputed infallible against the itch and other cutaneous diseases. *Gmelin's App. Med.* vol. ii. p. 129. *Boerhaave*, on the contrary, and some others, reject it as useless. He says that it cannot enter the absorbent vessels, the lacteals, or lymphatics, but passes directly through the intestinal tube, where it may happen to destroy worms, if it operates luckily. Those are deceived who expect any other effects from it. He adds, that it is unwarily given, in large quantities, to children and persons of tender constitutions, as being a foreign mass, unconquerable by the body, and the more to be suspected, as it continues there for a long time sluggish and inactive.

The æthiops, as it is now prepared, with a double proportion of mercury, is more likely to produce effect than the inactive preparation formerly used.

ÆTHIOPS vegetabilis, is formed by burning the seaweed, or sea-oak, the *rucus vesiculifus* of *Linnaeus*, in the open air, and then reducing it into a black powder. It is sometimes used to remove scrophulous swellings.

Dr. Russell recommends it as an useful assistant to seawater in the cure of disorders of the glands, when taken in the

the quantity of a dram; and he says, that, as an internal medicine, it is much superior to the olivital burnt sponge; that, used as a dentifrice, it is beneficial for correcting laxities of the gums; and that its detergent virtue appeared by its effect in cleansing the teeth. See Murray's App. Med. vol. v. p. 540.

ÆTHIOPS *Jovialis*, formed of equal parts of mercury, tin, and sulphur, is recommended in an occasional dose of half a dram, as an antidote to the tania. Gmelin's App. Med. vol. ii. p. 132.

ÆTHIOPS, is also a name given to several compositions, which are distinguished by epithets founded on the uses to which they are applied: as *Æ. antipthibificæ*, formed of mercury extinguished by balsam of Peru, of Canada or of Copaiva, and which is said by Astruc to afford relief in several species of phtisis: *Æ. antirheumaticæ*, consisting of mercury ground and uniformly mixed with gum guaiacum, which is recommended in the rheumatism and gout: *Æ. diureticæ*, composed of quicksilver well mixed with juniper gum or sal ammoniac, which promotes the excretion of urine as well as the insensible perspiration: and *Æ. purgans* formed with manna or jalap into an uniform powder, and recommended as a laxative, and for destroying intestine worms. Gmelin's App. Med. vol. i. p. 115.

ÆTHIOPS, in *Entomology*, a species of the CERAMBYX, black, with a spinose thorax, and with the two bands of the elytra, and the point of the apex yellow, and middle-sized antennæ, found at the Cape of Good Hope.

Æthiops is also a species of the CARABUS, wholly black, found at Berlin, and a species of the CIMEX, black, with a ridge on the middle of the thorax, and black spinose tibiæ, found at Cayenne. *Æthiops* is also a species of PABILIO, with black wings; the primores marked with three white bands, and cerulean spots on the upper part, and the posterior with two longitudinal pale furrows at the base, and a transverse ridge, with five cerulean points; found out of Europe. *Æthiops* is also a species of APIS, or the black bee, with the margin of the segments of the abdomen white; found in America. *Æthiops* is also the hairy black MUSCA, with black wings, white at the apex; two points, and a silvery anus; found in Italy.

ÆTHIOPS, in *Natural History*, a species of the TURBO, with the shell transversely furrowed and black; the first windings are nearly striated; the succeeding ones are of a silvery brightness, with the lip and limb brown; the aperture is dilated.

ÆTHIOPS *fulica*, in *Ornithology*, is the wholly black FULICA or COOT of Sparrow.

ÆTHIOPS *Simia*, in *Zoology*, the white eye-lid APE of Pennant, and MANGABEY of Buffon.

ÆTHOLICES, in *Physic*, derived from *αῖθω*, to inflame, is a name given to superficial pustules, or boils in the skin, occasioned by heat.

ÆTHON, in *Mythology*, formed of *αῖθω*, to burn, one of the four horses of the sun, which caused the fall of Phaeton, according to Ovid. Claudian calls one of the horses of Pluto's chariot by the same name, from *αῖθω*, black.

ÆTHIRA, in *Geography*, a river of Sweden, called also FALKENBERG.

ÆTHRIA, a name formerly given to the island of RHODES.

ÆTHUSA, *Ἀῖθουσα*, beggarly, in *Botany*, a genus of the pentandria digynia class and order; and belonging to the natural order of umbellatæ or umbellifera: the characters are, that the calyx is an universal spreading umbel, with the rays gradually shortening towards the middle, and the par-

tial is also spreading but small; having no universal involucre, and the partial one placed on the outside, and consisting only of three very long, linear, pendulous leaflets; and the proper perianthium scarce observable: the universal corolla is nearly uniform, with all the floscules fertile, and the partial has the petals bent in, heart-shaped and unequal: the stamina are simple filaments with roundish anthers: the pistillum is an inferior germ, and the styles are reflex with obtuse stigmas: it has no pericarpium, and the fruit is roundish, streaked and bipartite: the seeds are two, roundish, streaked, except on a third part of the surface, which is plane. There are four species, viz. 1. *Æ. cynapium*, common fool's parsley, or lesser hemlock, which is a common weed in fields and kitchen gardens, and in a slight degree poisonous. It is easily distinguished when in flower, or in July and August, from true parsley and chervil, by the three narrow pendent leaflets of the involucre, placed on the outer part only of the umbel, and by its being a much humbler plant than either of the others. The leaves also, in an earlier state, are of a different form and a darker hue, and when bruised emit in a slight degree a disagreeable venomous smell. The safest way to avoid doubt or danger is to cultivate the curled parsley. Most cattle eat it, but it is said to be noxious to geese. 2. *Æ. Bunius*, or *Montana*, coriander-leaved fool's parsley, which is a native of the Pyrenees. La Marek thinks this species should be joined to the SESELI. 3. *Æ. Meum*, Spignel, Meu, or *Baldmoney*, which grows wild in the mountains of Switzerland, Germany, Aultria, Carniola, Italy and Spain, and also in the high pastures of Wiltmoreland, Cumberland, Lancashire, and Merionethshire. This is the MEUM *athamaniticum* in Dr. Smith's arrangement of British plants, vol. i. p. 308. The roots and seeds are aromatic and acrid, and recommended as carminative and stomachic in asthmas and obstructions of the lungs, in the stone, stoppage of urine, and all uterine disorders: and the infusion both of the roots and the seeds is sometimes given to cure intermittent fevers both in England and amongst the inhabitants of the Alps. Spignel is also an ingredient in Theriaca and Mithridate, and appears to be of the same nature with lovage. The difference betwixt the roots is most considerable in the extracts by water, that of the spignel being unpleasantly bitterish, with little or nothing of the sweetness of that of the roots of lovage. The spirituous extract of Spignel, more aromatic than that of the lovage, is moderately warm, bitterish and pungent. Lewis's Mat. Med. Dioscorides and Galen tell us, that the too frequent use of this medicine, or too large doses of it, will occasion violent pains in the head. It may be given in substance from half a dram to two scruples, or from a dram to two drams in infusion. Geoffroy Mat. Med. vol. ii. p. 105. 4. *Æ. fatua*, fine-leaved fool's parsley, was introduced here in 1781, and flowers in August or September. Its native climate is not known. La Marek has joined to this genus the PHYLLANDRIUM *mutellina* of Linnæus. The first species is annual, and may easily be kept down in gardens, by not suffering it to seed; the second may be propagated by seeds, and flowers in July; the third and fourth are hardy perennial plants, and may be increased by parting the roots at Michaelmas, or sowing the seeds soon after they are ripe in July and August; and keeping the plants in a shady situation and moist soil. Martyn's Müller's Dict.

ÆTHUSA. See ÆCUSA.

ÆTHYIA, in *Ornithology*, a name by which the old authors have called one of the web-footed fowl, seeming to be the UTAMANIA of Crete, or the common AUK or RAZOR-BILL.

ÆTHYSSEIS,

ÆTHYSSEIS, a people of Lybia near Marmarica.

ÆTIANS, **ÆTIANI**, in *Church History*, a sect or branch of **ARIANS**, so called from their leader **ÆTIUS**, in the fourth century.

The *Ætians* were of the stricter kind of *Arians*, who held that the Son and Holy Ghost are in every respect dissimilar to the Father. Whence also they are called *Anomai* and *Heteroufiani*; sometimes *pure Arians*.

The profession of this doctrine was contrary to an established law of the emperor Constantian, who had decreed, "that no man should say, that the Son of God was of the same substance with God, or of a different substance, but that he was in all things like to him that begat him." By such nice distinctions were the consciences of mankind directed and guarded; and the freedom of religious inquiry restricted; and the slightest deviation from the prescribed rule exposed them to exile and other similar penalties.

ÆTINIUM, in *Ancient Geography*, a town, placed by Ptolemy, in Macedonia, and which, he says, belonged to the *Eliotes*, but as they inhabited Thessaly, its situation is not well ascertained.

ÆTIOLOGICAL, something that assigns the cause of an effect, or appearance.

ÆTIOLOGY, in *Medicine*, a *rationale*, or discourse of the cause of a disease, or it is that part of **PATHOLOGY**, which is employed in exploring the causes of diseases. The word is compounded of *αἰτία*, *cause*, and *λόγος*, *discourse*. In this sense, we say, the *ætiology* of the small pox, of the *hydropobia*, of the gout, the dropsy, &c.

ÆTIOLOGY is used for a figure in *Rhetoric*, whereby, in relating an event, we assign also the cause of it. In which sense, *ætiology* differs from *color*, as the former assigns the true cause, the latter only a feigned or specious one.

The sceptics were professed opponents of all *ætiology*, or argumentation from causes.

ÆTION, in *Biography*, an eminent painter, whose picture of Roxana and Alexander was exhibited at the Olympic games. It represents a magnificent chamber, in which Roxana is seated on a bed, with a modest and confused aspect, whilst Alexander is standing before her. Several Cupids are fluttering about her; some of whom hold up the curtain, others undress the lady, and others again present Alexander to his mistress, at whose feet he lays his crown, being accompanied by Ephestion with a torch in his hand, and leaning upon a youth who represents Hymen. Other Cupids appear in different attitudes and situations. This picture gained *Ætion* such a degree of reputation, that the president of the games gave him his daughter in marriage. *Ætion* is mentioned with distinguished respect by Cicero, *De claris orat. ap. op. tom. i. p. 395. ed. Olivet.*

ÆTITES, or *eagle-stone*, in *Natural History*, a stony or crustated stone, hollow within, and containing a *nucleus*, which, on shaking, rattles within. It was formerly in repute for several extraordinary *magical*, as well as *medical* powers; such as preventing abortion, discovering thieves, and other ridiculous properties.

The word is formed from *αἰτός*, *eagle*; and by the Italians this stone is called *pietra d'aquila*: the popular tradition being, that it is found in the eagle's nest, whither it is supposed to be carried while the female sits, to prevent her eggs from being rotten. Matthioli says, that birds of prey could never hatch their young without it, and that they go in search of it as far as the East Indies. Baufch has written a Latin treatise on the subject.

The *lapis ætites* is found in several parts: near Trevoux in France, one can scarce dig a few feet, without finding

considerable strata or beds, of the coarse or ferruginous kind.—They are originally soft, and of the colour of yellow ochre.

But the finest and most valued of all the eagle-stones, are accidental states of one or other of our common **FLINTS**. These are so far from being a peculiar species of fossil, though usually accounted such, that they are not determinately of any one species of pebble. That, however, which most usually furnishes them is the brown-centered pebble, with whitish, bluish, and brown crusts. The plain history of this remarkable fossil is this: the central nucleus of many species of pebbles, peculiarly of this, is coarser than the rest of the stone, that is, it is made up of more earth and less crystal: the natural consequence of which must be, that being of a more loose and rare texture, it is in drying more apt to shrink than such masses as are composed of a harder and purer matter. The central nucleus in this species is also surrounded with a whitish crust, of a more loose texture, and more subject to shrink in drying than even the nucleus itself; and being composed of more earth and less crystal, is also more friable and soft. The outer circles of this stone are of a much harder substance. Whenever the earthy matter in the nucleus, and first crust of this pebble, a little exceeds its just proportion, the consequence will be, that the stone will become an *ætites*: for the nucleus shrinking and contracting itself to a small size on the evaporation of its fluid matter, must separate itself from its first crust, and that also shrinking, must be drawn backward toward the other crusts; whence the cavity will become larger between that and the nucleus, and consequently, the nucleus will rattle in it when the stone is shaken. The pebble in this state having been afterwards rolled about by waters, the nucleus has by rolling broken to pieces all the inner crust, and is usually found in the hollow of the stone, buried in a large quantity of a whitish powder. These eagle-stones are not uncommon in our gravel-pits, but being by their hollowness rendered less strong than the solid pebbles, we frequently find them broken. Hill. The *Ætites* is classed by Chaptal (*Chem. v. ii. p. 340*) among the bog ores, or argillaceous ores of iron: and Kirwan (*Elem. Miner. vol. ii. p. 178*) describes it under the fourth variety of the first family of these ores; as, externally, yellowish brown, internally lighter, with a kernel, whose colour is mostly ochre yellow. The form is generally that of a rounded knob, or approaching more or less to the kidney form, seldom quadrangular; the surface is generally fouled with earth. The lustre of the external rind resembles that of silk or is somewhat less glossy, and metallic. The kernel, which is sometimes loose, has no lustre at all. The fracture of the former is even, or fine splintery; that of the interior fine earthy. Externally it presents one or more curved lamellar concentric concretions, the kernel none. Its hardness is between that which is one degree superior to that of chalk or yielding to the nail, and that which hardly yields to the knife; it is brittle and heavy. Its streak is light yellowish brown, commonly brighter.

The *ætites* is also known by the names *eucocium*, *echites*, *lapis aquile*, *erodialis*, *aguleius*, & *lapis pregnans*; some rank it under the class of precious stones, to which it has no title.

ÆTIUS, in *Biography*, one of the followers of Arius, was born at Antioch in Syria, and flourished, according to Cave (*Hist. Lit. tom. i. p. 218*) about the year 359, and died in, or soon after, the year 366. Having contended with difficulties in early life on account of the reduced condition of his parents, he applied with diligence and success

to the acquisition of literature at Alexandria in his mature years; and in this city he learned the art of physic, which he honourably practised for the benefit of those who needed his advice. From Alexandria he returned to Antioch, where he was ordained deacon, as some say, by Theodorus, bishop of that city; or, according to Epiphanius, by George, the Arminian, bishop of Alexandria. He seems to have been a man of sound understanding and considerable knowledge, though his acquaintance with the more ancient Christian writers was partial and imperfect. As he had adopted the sentiments of Arius, and had acquired the talents of an able and invincible disputant; whom, says Gibbon, (Hist. vol. iii. p. 340) it was impossible either to silence or to convince, he was banished by Constantius, who, amidst conference, says the historian (Id. p. 354) was alarmed by the impiety of Ætius, into a remote part of Pontus, *i. e.* says Gibbon, citing Philostorgius (*ubi supra* p. 376) to Amblala, a district inhabited by savages, and visited by war and pestilence; but he was restored by Julian, who honoured him with his patronage, and gave him an estate near Mitylene in Lesbos, where he sometimes resided; though he probably died at Constantinople, and was there buried by Eunomius and his other friends in a very respectful manner. The displeasure of the Catholics against Ætius was so great, that they stigmatized him with the odious appellation of Atheist. Epiphanius has preserved a small book of Ætius concerning the faith, consisting of 47 propositions or short chapters, which he has answered; and he also says, from report, that Ætius had composed 300 such chapters. He is said to have held a public disputation with Athonius, the Manichean, of Alexandria, and to have obtained so complete a victory over him, that he died of grief seven days after. He was the founder of a sect called ÆTIANS. Lardner's Works, vol. iii. p. 396. vol. iv. p. 122.

ÆTIUS, called *Amidenus*, from *Amida* in *Mesopotamia*, the place of his birth, flourished at Alexandria, about the end of the fifth century, as Friend clearly demonstrates, from several passages in his works, in which reference is made to St. Cyril, who died in 444; and to Petrus Archiator, who was physician to Theodoric. He left sixteen books divided into four *tetrabiblia*, on the practice of physic and surgery, principally collected from Galen and other earlier writers, but with some original observations. "We find many passages, Friend observes, in this author, to convince us how much the actual and potential cautery were then in use; particularly in a palsy. He says from Archigenes, that he should not at all hesitate to make an eschar either way, and this in several places; one in the nape, where the spinal marrow takes its rise; two on each side of it, &c. and if the ulcers continue running a good while, he should not doubt of a perfect recovery." The late Mr. Pott revived this practice in the palsy of the lower limbs, applying his caustics in those cases on each side of the spine, a little above the sacrum, induced to it we have no doubt, from reading this passage; and the practice is now general, and is frequently attended with complete success, so that it seems wonderful physicians do not use them in hemiplegia, and in other similar untractable diseases. Ætius is the earliest writer who ascribed medical efficacy to the external use of the magnet. But this he does upon report, and not from his own experience. "*Tradunt* (says he) *magnetem detentum manu chiragrorum ac podagricorum dolores ipsorum sedare. Æquè convulsis opitulatur.* It is reported that those who are afflicted with the gout in their hands or feet, or with convulsions, are relieved by holding a magnet in their hands." The works of Ætius were translated into

Latin by Janus Cornarius, a physician of Frankfort, and published, accompanied with the Greek, at Basle, 1542, in folio. Henry Stephens has inserted them in his edition of *Medici principes*, printed at Geneva, 1567. The last and best edition is that of Franz at Leipzig in 1777.

ÆTIUS, whose father was Gaudentius, an illustrious citizen of the province of Scythia, and master-general of the cavalry, and mother a rich and noble Italian, was one of the generals of Placidia, the mother of Valentinian III. who reigned 25 years in the name of her son.

Ætius served at first among the troops of the emperor's household, and after the battle of Polentia in 403, he was delivered as an hostage to Alaric, and afterwards to the Huns with whose chiefs he became intimately acquainted. His stature, which was tall and majestic, and his constitution, which was robust, fitted him for the duties and toils of a military life. He is also commended by the ancients for his prudence and address in the conduct of political business, as well as for his intrepidity and experience in war. His regard to justice was so strict, that no temptation could induce him to deviate from the exercise of it. On his return from the country of the Huns he married the daughter of Carpilio, the captain of the guards; and was employed in offices of high trust in the empire. When Marfeilles was attacked by Ataulphus, Ætius and Count Boniface were united in its defence; and these two great commanders are said to have deserved the distinguishing appellation of the last Romans. They were unhappily rivals, and their mutual jealousy and discord terminated in the loss of Africa and the death of Boniface. After the death of Honorius, the empire was usurped by John his chief secretary, and Ætius connected himself with the usurper, and was employed to procure the assistance of the Huns. John, however, was soon cut off; and Ætius within three days entered Italy with 60,000 Huns, who served to secure to him a reconciliation with Placidia, and who, by a grant of the province of Pannonia, were prevailed upon to return into their own country. Having induced Placidia to recal Boniface from his government of Africa, and at the same time advised him not to comply, he was the cause of the revolt of his rival, and the loss of Africa; and the discovery of this fraud produced a civil war between these two commanders, which terminated in the death of Boniface, and in the exile of Ætius to the court of Rugilas, king of the Huns, in Pannonia. He soon returned, however, to his own country; and he was indebted to their alliance for his safety and restoration. Instead of the suppliant language of a guilty exile, he solicited his pardon at the head of a large army of barbarians; and the empress Placidia was under a necessity of forgetting his rebellion and his treachery, and of delivering herself, her son Valentinian and the Western empire, into the hands of an insolent subject. The fortunate Ætius, who was immediately promoted to the rank of patrician, and thrice invested with the honours of the consullship, assumed, with the title of Master of the cavalry and infantry, the whole military power of the state; and he is sometimes styled, by cotemporary writers, the duke or general of the Romans of the West. The Gothic historian, Jornandes, ingenuously confesses, that Ætius was born for the salvation of the Roman republic; and in the eulogium which a cotemporary historian bestows upon him, he says that his mind and body were alike capable of the most laborious efforts; that he possessed the genuine courage, that can despise not only dangers but injuries, and that it was impossible either to corrupt, or deceive, or intimidate the firm integrity of his soul. But these lavish praises are not

very consistent with his conduct towards Boniface. Ælius assiduously cultivated the alliance of the Huns. Whilst he resided in their tents, as an hostage or an exile, he had familiarly conversed with Attila himself, and the two antagonists were connected by a personal and military friendship, which was afterwards confirmed by gifts and embassies. Thus a numerous army of Huns and Alani, whom Ætius had attached to his person, was employed in the defence of Gaul. He established a treaty with Genferic, which averted the Vandals from the plunder of Italy. He restored the authority of the empire in Spain and Gaul, and compelled the Franks and Suevi, after vanquishing them in the field, to become useful allies. He afterwards concluded a peace with Theodoric, king of the Visigoths, who inhabited the southern provinces of Gaul; after a signal defeat, in which 8000 Goths fell near the walls of Narbonne; and Ætius and Theodoric, in mutual alliance, gave battle to the innumerable host of Attila, encamped before Orleans, and compelled them to raise the siege. On the plains of Chalons, where the valiant Theodoric fell, Ætius, aided by the intrepid Torismond, obtained a victory over the Huns, and obliged Attila to retreat. When Attila invaded Italy, his prudence and courage served to harass and retard the march of the invader; nor did he ever appear more truly great, than at the time when his conduct was suspected by a timid and distrustful sovereign, and blamed by an ignorant and ungrateful people. At length the emperor jealous of his merit, and fearing his wealth, power, and popularity, put him to death in 454 with his own hand, under a pretence, encouraged by the malicious insinuations of Heraclius the eunuch, that he had permitted the invasion of the Huns, after Attila's defeat, and that he was aspiring to the empire; and thus plunged his sword in the breast of a general who had saved his empire. Thus fell the best general of his age, the terror of Attila, and the bulwark of the western provinces, says Sidonius, by the hand of the greatest coward in the whole empire. By this act he converted the public contempt into deep and universal abhorrence. Such sentiments, says Gibbon (Hist. vol. vi. p. 139), seldom pervade the walls of a palace; yet the emperor was confounded by the honest reply of a Roman, whose approbation he had not disdained to solicit: "I am ignorant, Sir, of your motives or provocations. I only know, that you have acted like a man who cuts off his right hand with his left." The memorable letter, entitled *the groans of the Britons*, was addressed to Ætius, A. D. 449, who was then consul the third time. "We know not, say they, even which way to flee: chased by the barbarians to the sea, and forced back by the sea upon the barbarians, we have only left us the choice of two deaths, either to perish by the sword, or to be swallowed up by the waves." Rome was then threatened by Attila, and the Britons received no assistance. Anc. Un. Hist. v. xiv. p. 417. Gibbon's Hist. vol. vi.

ÆTNA, in *Geography*, the highest mountain in Sicily. In the *Itinerary* it is called *Æthana*, and supposed to be derived from *æthra*, to burn. Bochart (Geog. Sac. l. i. c. xxviii. apud oper. tom. i. p. 526. Ed. Villem.) deduces the name from אֶתְנָא, *Æthna*, signifying either a furnace, or darkness; and he cites several authorities from the poets that favour both the one and the other of these etymologies. The inhabitants of the island call it *Monte Gibello*, or by contraction *Mongibello*, i. e. *Mount of Mounts*. This mountain, which has been famous for both its bulk and volcanic eruptions for many ages, is situated in the eastern part of Sicily, called *Val di Demoni*, or *Demonia*, from a notion that the numerous caverns of Ætna are inhabited by demons, and

other wicked and miserable beings. N. lat. 37° 40'. E. long. 15°.

The fire, which is continually burning in the bowels of this mountain, led the poets to place here the forges of the Cyclops, under the direction of Vulcan, and the prison of the giants who rebelled against Jupiter. Upon this supposition they erected a temple to Vulcan upon the hill, in which was kept, as we are informed by Ælian (de Animal. l. xi. c. iii. tom. ii. p. 608.), a perpetual fire, as in the temple of Vesta; this element being a symbol of that deity.

The *figure* of this mountain is a kind of obtuse, truncated cone, extended at the base, and terminating in a bifurcated vertex, which consists of two eminences at a considerable distance from each other.

With regard to the *formation* of Ætna, M. De Buffon is of opinion that, on account of its height and immense bulk, it ought to be considered as one of the primitive mountains, coeval with the earth itself; and that it vomited flames soon after the creation; but that, on the subsiding of the waters which covered the face of the earth, it ceased to burn, because there was not a sufficient quantity of fluid for producing an effervescence with its mineral contents. After a long lapse of ages, the Straits of Gibraltar were burst open, and the ocean mixed with the Mediterranean Sea; and a similar rupture of the Bosphorus furnished an additional supply of water, and thus it deluged the land between Sicily and Italy, and approached the basis of Ætna. In consequence of this event, the mountain began to emit flames anew, which at different intervals, and with various degrees of force, it has continued to do until the present time. From Homer's silence with respect to the eruption of this mountain, we may justly infer, that it did not burn in his days; and therefore the first known eruptions of Ætna must be dated after his age. Other writers, who have not adopted the whole of Buffon's hypothesis, maintain, that Ætna existed as a mountain before it became a volcano. Dolomieu, cited by Mr. Kirwan (Irish Transf. vol. vi. p. 306), found immense heaps of sea-shells in the north-east flanks of this mountain, at the height of near 2000 feet above the surface of the sea. Hence he concludes, that this volcano existed as a mountain before it was uncovered by the sea. He adds, that at the height of about 2400 feet, there are regular strata of grey clay filled with marine shells; and these strata must have been deposited while the mountain was progressively formed under the sea. He further affirms, that in some parts of this mountain, the calcareous strata exist under the lava. Count Borch also, in his Letters on Sicily and Malta, informs us, that the original stone of which Ætna consists, is granite mixed with jasper, neither of which is lava; and he says, that it abounds in mines of lead and copper, which are never found entire in lava. This geologist pretends, that Ætna is at least 8000 years old; and this high antiquity he infers from the layers of vegetable earth, which he discovered betwixt different beds of lava. Canon Recupero, who had been employed in writing the history of Mount Ætna, has also discovered a stratum of lava, which, in his opinion, flowed from the mountain in the time of the second Punic war, or about 2000 years ago. This stratum, he says, is not yet covered with soil sufficient for producing either corn or vines. It requires, then, about 2000 years to convert a stratum of lava into a fertile field. But in digging a pit near Jaci, in the neighbourhood of Ætna, he discovered seven distinct layers of lava, most of which were covered with a thick bed of rich earth; and as the eruption which formed the lowest of these lavas, flowed from the mountain at least 14000

years ago, he deduces from this circumstance a corresponding era for the formation of the mountain. Mr. Brydone, (See his *Tour through Sicily and Malta*, vol. i. p. 115, 132) informs us, that Recupero was much embarrassed by this discovery and the inference it afforded, because they contradicted the history of Moses. For the relief of the canon and the satisfaction of the traveller, we might alledge, that the Mosaic history contains nothing that is repugnant to the notions here suggested concerning the antiquity of the earth. Although man has not existed longer on the earth than the period assigned in this history, the earth itself might have existed, and probably did exist, in some other form and for other purposes, for ages before this period. Besides, we might ask, is the lava to which the canon directs our attention, the same which flowed from *Ætna* in the second Carthaginian war; and is not the time required for converting lavas into fertile fields very different, according to the different consistency of the lavas and their different situations with respect to elevation or depression, and to their being exposed to wind, rain, &c. just as the time, in which heaps of iron slag which resembles lava, are covered with verdure, is very different at different furnaces, according to the nature of the slag, and the situation of the furnace? But there is an argument deducible from fact, which invalidates and totally overthrows the canon's objection. *Ætna* and *Vesuvius* resemble each other with regard to the various circumstances that pertain to this subject; but the eruption of *Vesuvius*, which destroyed *Herulancum*, happened A. D. 79, or about 1700 years ago. The matter which overwhelmed this ancient town, is covered by the produce of six other subsequent eruptions: and these several strata of lava are separated by veins of good soil. See *Phil. Trans.* vol. lxi. p. 7. and *Bishop Watson's Apology for Christianity*, in sermons and tracts, p. 383, &c.

Further, *Dolomieu* (Ponce, 472.) informs us, that vegetable earth does not exist between beds of lava; and he observes, that if this were the case, no conclusion relative to their age could fairly be deduced from this circumstance, as some lavas become fertile much sooner than others. To this purpose, *Chevalier Gioeni*, in 1787, found lavas, that were projected in 1766, in a state of vegetation, while other lavas, much more ancient, remained barren. It is also well known, that beds of volcanic ashes and pumice vegetate sooner than any other. Mr. *Dolomieu* adds, that canon *Recupero* denied his ever having expressed any doubt with regard to the Mosaic history; and could not conceive why a late celebrated traveller should endeavour to render suspicious the orthodoxy of his belief. So far from having been persecuted on that account, he had a pension from the court of *Naples* to his death, with many testimonies of esteem. The abbé *Spallanzani* (See *Travels into the two Sicilies*, vol. i. p. 205, &c.) has stated and examined the argument of *Count Borch*, deduced from the decomposition and vegetation of different strata of lava, in proof of the antiquity of the world. A lava, says the Count, that was produced by an eruption in 1157, had a coating of earth in December, 1776, that was 12 inches thick; another which had flowed in 1329, had one of 8 inches; on that of 1669, was found more than one inch; whilst the most recent, that of 1766, was entirely destitute of such earth. The abbé allows that lavas, after a series of years, are invested with a stratum of earth proper for vegetation; and that the earth is originally produced by the decomposition of the lava and that of the plants which have taken root upon it. But lavas are very different in their consistency and other qualities; and these differences must render the argument of

Count Borch and such reasoners very inconclusive. The lava, which flowed in 1329, and which was examined by the Count 447 years after its eruption, was covered with eight inches of earth; and yet the lava of the *Arso* in *Hebra*, which rushed into the sea in 1302, appeared in 1788 to have preserved its hardness and sterility. Another current of lava, near *Catania*, which has been employed for 2000 years for the purpose of building, retains such a degree of hardness, that where the art and labour of cultivation have not been applied to it, it still continues altogether sterile. He concludes upon the whole, that all calculations on the greater or less quantity of earth which may cover lavas are very uncertain and fallacious.

But to return from this digression, with regard to the antiquity of *Ætna*, we observe, that naturalists have generally maintained, that *Ætna*, like other insulated mountains, is the gradual production of volcanic eruptions. It is certain, that every great eruption produces a new mountain; and that *Ætna* consists of a number of hills and declivities, more nearly or more remotely connected, which have been occasioned by the commotions and changes, to which it has been subject in the course of many past centuries. *Ætna* may therefore be regarded, not as a single volcano, but as an assemblage of volcanos, many of which are extinguished or burn with a gentle fire, and of which some few are still acting imperceptibly or visibly, with violence.

M. Houel, one of the latest and most accurate inspectors of this mountain, observes, (in his *Voyage Pittoresque*), that *Ætna* is entirely composed of substances that have been discharged from the volcano in its various eruptions. From the quantities of marine bodies that are deposited over its lower part, he infers, as others have done, that it must have been once covered by the sea, to at least one half of its present height; and he supposes that, in this state, the currents of the ocean would gradually accumulate upon it large masses, not only of its own productions, such as shells and bones of fishes, but of several other substances intermixed with the matters discharged from the focus of the burning mountain. These masses, he conceives, would, in process of time, so increase as to form those various mountains which now surround the volcano. The currents of the ocean would likewise convey some part of the discharged matter of the volcano to a greater distance; and thus form those mountains that are separated from it, and that are found farther removed. The base of this mountain, according to this ingenious author's observations, consists of alternate layers of lava and marine substances, successively deposited upon one another, and reaching to a considerable, but unknown depth. These must descend to the level of the stratum of lava, which was discharged by the volcano at its first origin. The last layer, deposited by the sea, is a range of calcareous eminences of considerable height, placed on a basis of lava. Beneath this, there is another stratum of sea-pebbles, rounded by their mutual attrition in the conflict of the waves. This, again, lies upon a yellowish rock, consisting of a species of indurated sand. The river *Sineto* flows over this rock; and the base of the river is much higher than that of *Ætna*, which is on a level with the sea: but the primary base of the volcano is unknown.

From the mountains of calcareous matter that are scattered over the lower part of *Ætna*, the inhabitants provide themselves with limestone, and they apply fragments of lava, instead of stones, of which they have none, to the purposes of building. The mountains that surround *Ætna*, and that are observed to great advantage from its summit, evidently indicate, by their conical figure and the cavity at their top, their

their being the productions of fire. They bear unequivocal marks of the effects of this destructive agent in an accumulation of lava, scorix and volcanic sand. Whether the origin of these mountains is to be traced to the expansive effort of the ignited matter contained within the great abyss of Ætna, and which, incapable of ascending to the upper crater, bursts forth at the sides; or whether they are to be ascribed to particular conflagrations and eruptions, which have no communication with the immense furnace within the crater, has been a subject of inquiry and discussion. The former alternative has been generally allowed; and it must be acknowledged that this is frequently the fact. Instances, however, may be cited, which afford strong reasons for believing that the production of the lateral mountains is owing to partial eruptions, which have no communication with the principal crater. Of this kind is *Monte Rosso*, of which an account will be given in the sequel of this article. Sir W. Hamilton reckons 44 mountains of this kind on the side of Catania, with their distinct craters, most of which are now in a state of fertility.

From the consideration of the constituent parts of Ætna, and the mode of its formation, we shall proceed to state its dimensions. These have not yet been satisfactorily ascertained. Its stupendous height and bulk were noticed so long ago as the time of Pindar, more than 435 years before Christ, in a passage which we shall cite in the progress of our account. He represents it not only as the eternal abode of snows, but as the pillar of heaven. The ancients in general, as well as the moderns, have been accustomed to consider Ætna as one of the highest mountains on the globe. There are many passages in their writings, says Mr. Brydone, that shew this; though, perhaps, none more strongly than their making Deucalion and Pyrrha take refuge on the top of this mountain, in order to save themselves from the universal deluge. These ideas, however, appear to be very erroneous; for Sir George Shuckburgh observes, (Phil. Trans. vol. lxxvii. p. 595.) that Vesuvius, placed upon Mount Ætna, would not be equal to the height of Mont Blanc. The accounts of those who have visited Ætna in later times have been very various. The following measures have been given by different authors.

Height above the surface of the sea, 10,036 feet.	} Faujas de S. Fond in his <i>Volcans du Vivarais</i> .	
Circumference at the base, 180 miles.		
Height, 4000 French toises.		} Kircher.
— 3 miles 264 paces.		
— 4 — 6 and 8 miles.		} Italian Mathematicians.
— 12000 feet — —		
— 2500 toises; circumference 183 miles.		} Brydone.
— 1950 toises; diameter 30 miles.		
— 2000 fathoms; circumference 60 leagues; and superficies 300 square leagues.		} Recupero.
— summit above the Mediterranean 10954 feet.		
— circumference of the visible horizon on the top of Mount Ætna, 6' being allowed for refraction, is 1093 English miles.	} Mentelle Geogr. Comp. Buffon's Nat. Hist. by Smellie, v. ix. 147.	
		} Sir George Shuckburgh, Phil. Trans. vol. lxxvii. p. 595.

Others make its height only 2000 toises, and its superficies 300 square miles. By the following heights of the thermometer and barometer, at different stations, extracted from Brydone's *Tour*, v. i. p. 211, their respective elevations

might be ascertained, if the altitudes by the instruments were accurately taken.

Height of Fahrenheit's Thermometer.

At Catania, May 26, at noon, - - -	76
Ditto, — 27, at 5 in the morning - -	72
At Nicolosi, 12 miles up the mountain, at noon	73
At the cave, called Spelonca del Capriolo, in the second region, where there was a considerable quantity of snow, at 7 at night - -	61
In the same cave, at half an hour past 11 - -	52
At the Torre del Filosofo, in the third region, at three in the morning - - -	34½
At the foot of the crater of Ætna - - -	33
About half way up the crater - - -	29
On the summit of Ætna, a little before sun-rise	27

Height of the Barometer in inches and lines.

At the sea-side at Catania - - -	29.8½
At the village of Piedmonti, in the first region of Ætna - - -	27.8
At Nicolosi, ditto - - -	27.1½
At the Castagno di Cento Cavalli, in the second region - - -	24.2
At the Torre del Filosofo, in the third region	20.5
At the foot of the crater - - -	20.4½
Within about 300 yards of the summit - -	19.6½
At the summit of Ætna, where the wind prevented an exact observation, supposed to be - -	19.4

M. Houel (*ubi supra*) states the circumference of the base at 40 miles; and though he had no opportunity of measuring the altitude, he observes, that it had been done by M. de Saussure, who found it to be 10,036 feet, or, as we learn from Senebier, 10,963 English feet. This was ascertained on the 5th of June, 1773, at 20' after seven in the morning. The height of the barometer, on the most elevated part, at the brink of the crater, was 18 inches 11¼ lines; which, by the necessary corrections, is reduced to 18 inches 10⅙ lines. At the same time, the mercury at Catania, placed only one foot above the level of the sea, stood at 28 inches 2⅞ lines, which must be reduced to 28 inches 1¼ line, on account of the requisite corrections for the thermometer.

Some have supposed, that volcanic mountains always increase in height by the products of successive eruptions, till they are extinguished. However, it is generally conceived that the height and bulk of Ætna are much the same now as they were in former times. The dilapidations, occasioned by the falling in, and absorption of the summit, have produced, for time immemorial, no sensible diminution; as the losses resulting from some eruptions are repaired by others which succeed. In proof of this, it is alledged, that if any considerable decrease of the mountain had taken place, ice and snow would not have continued, in a climate so mild, to envelope the top of the mountain, as they now do, even during the greatest heats of summer. On the contrary, it is a very old opinion (vide Seneca, *Epist.* 179, and *Ælian Var. Hist.* l. viii. c. xi. tom. i. p. 548.) and adopted by M. Houel, that Ætna is in a state of decay and diminution, so that it cannot be observed at so great a distance as formerly. It is full of excavations; and he considers the torrents of lava, which overspread its sides from time to time, as insufficient for repairing the waste occasioned by rains, rivulets, and torrents flowing down from the summit. Hence he concludes that, unless the eruptions become more frequent than they have been for some time past, the height of the mountain will be gradually reduced to that of the surrounding beds of lava. Over the sides of Ætna there are scattered

tered no fewer than 77 cities, towns, and villages; and allowing 1200 or 1500 persons to each of these, the whole number of the inhabitants of Mount Ætna, will be 92,400 or 115,500.

In our farther description of this mountain, and of its volcanic productions and appearances, we shall avail ourselves of the accounts that have been given by those who have visited it; selecting from each those circumstances that are most deserving of notice, and combining them together so as to form a connected and continued narrative. The writers to whose observations we shall principally refer are Borelli, Hist. Incend. Ætnæ, An. 1669; M. Jac. d'Orville's Sicula, Mr. Brydone's Tour through Sicily, vol. i. Sir William Hamilton's Campi phlegræi, and Phil. Trans. Riedesel's Travels in Sicily. Swinburne's Travels in the Two Sicilies, vol. iv. Abbé Spallanzani's Travels in the Two Sicilies; &c. vol. i. M. Dolomieu, and M. Houel, Voyage Pittoresque.

The ascent of Mount Ætna is tedious, difficult, and perilous; and few have had resolution to undertake it. From Catania, where the journey usually commences, to the summit, the distance is about 30 miles: and the traveller, in the progress of his journey, passes through three distinct climates, which might be justly denominated, on account of the variety of their temperature, the torrid, the temperate, and the frigid zones. Accordingly the whole mountain is divided into three distinct regions, called *La Regione Culta*, or *Piedmontese*, the fertile region; *Il Regione Sylvosa*, or *Nemorosa*, the woody region; and *Il Regione Deserta*, or *Scoperta*, the barren region. Count Borch has added a fourth, which he calls the region of snow; and he has subdivided these four regions into several districts.

The *first* or *lowest* region, extends through an interval of ascent from 12 to 18 miles, according to the statements of different writers. Its whole circumference is estimated by Recupero at 183 miles, and its surface is supposed by Buffon to exceed 220 square leagues. It is bounded by the sea to the south and south-east, and on all its other sides by the rivers Semetus and Alcantara, which almost run round it. The city of Catania and several villages are situated in this first zone; and it abounds in pastures, orchards, and various kinds of fruit trees. The fertility of this region has been recorded by Strabo, Fazello, Peter Bembo, and most of the travellers who have visited Ætna; and it is justly ascribed to the decomposition of the lava, and of those vegetables, which have been introduced by the arts of agriculture, and the exertions of human industry. In some parts, however, the lava appears in craggy eminences above the soil. Where the earth is shallow, the roots of trees, unable to penetrate the hard lava, extend themselves horizontally near the surface; but where there is a greater depth of earth, the soil is more fertile and productive. The first station in the ascent of the mountain is *Nicolosi*, (see Pl. 1. NAT. HIST. fig. 2. let. H.) which, according to Brydone's statement, is 12 miles up the mountain, and by Houel's account 2496 feet above the level of the sea. The road from Catania to this station lies over old lavas and the mouths of extinguished volcanos, which are now converted into corn fields, vineyards, and orchards. The figs of this region, and the fruit in general, are reckoned the finest in Sicily. When the harvest was finished at Catania and the heat extreme, Mr. Brydone found the corn green at *Nicolosi*, and the heat moderate. The lava of this region flows from a number of small mountains, which are dispersed over the immense declivity of Ætna. These mountains, which are of a conical or hemispherical figure, are formed by eruptions; and they are generally about two or three miles in

circuit, and about 300 or 400 feet high. They are covered with a rich verdure, and beautiful trees. Not far from *Nicolosi* is *Monte Rosso*, which was formerly a plain; but in 1669 a new vertex was opened in it, and discharged a dreadful torrent of lava, which flowed as far as the sea, and formed a kind of promontory (as Y.) It is surrounded to the extent of two miles with a black sand, which was thrown out in that eruption, and which then covered a space of 15 miles, to such a depth as to bury the vines and shrubs that were scattered over the soil. Some of the finer particles of it were wafted by the wind as far as *Catania*. The sand is very deep as you approach the mountain; and the mountain is forked at the vertex. By Borelli's account its circumference at the base does not exceed two miles, and its perpendicular height is not more than 150 paces; whereas, Sir William Hamilton estimates its height at a mile, and its circuit at three miles. Spallanzani prefers the former estimate. Amongst 100 or more mountains, which rear their heads on the sides of Mount Ætna, this is the only one with the history of the formation of which we are acquainted. The base of the lava of this mountain is horn-stone, of a grey colour, rough to the touch, and of a moderately fine grain. It gives sparks with steel, and sounds when it is struck. It serves as a matrix to a great number of felt-spathose or shoerlaceous crystallizations. The scorix, of which the mountain is principally composed, have the same kind of base, containing shoerls and felt-spars; but they are more light and friable than the lava, and have a kind of vitreous appearance. These and other differences are produced by the mutual collision and pulverization of these scorix. The number of detached shoerls that are found on and near *Monte Rosso* is very great. Dolomieu thought, that they first entered into the body of the lava, and that they were separated from it by means of the sulphur, which had scorified the lava, but had not produced the same effect on the shoerls, because of the small quantity of iron which they contain; and consequently they remained free and detached. Spallanzani rejects this hypothesis; as upon experiments with the magnetic needle he found that the martial principle was more abundant in the shoerls than in their base; and he therefore accounts for their separation from the lava in another way. The volcanic fire, which melted the lava, was incapable of melting these shoerls, which are not only refractory to the fire, but of a different specific gravity from the lava. When this was melted, elevated to a great height, and separated into small particles in the progress of the eruption, a number of shoerls were detached from it, and fell, isolated, partly within the crater, and partly around it. Accordingly he found, that the shoerls detached from the lava are infusible in the furnace; but those which are incorporated with the lava sustain a perfect fusion. These shoerls are not peculiar to the lava of *Monte Rosso*; but they are found in many other mountains of Ætna. Spallanzani analysed them, and from 100 docimastic pounds, he obtained the following result: *viz.*

	Pounds
Silex - - -	34,5
Lime - - -	18,7
Iron - - -	7,6

Magnesia - - -	11,
Sum -	84,2

The mountain derives its name *Monte Rosso*, or red mountain, from the tinge of this colour which some parts of

of it exhibit; though other parts are white, and others yellow, blue, and green, with different shades and mixtures. All these parts, says the Abbè, are found in a state more or less decomposed; and in general, they are only scorix; the colours are produced by iron, changed or modified by acids. Of these scorix, some have not been affected by acids; and they are covered with a thin pellucid coat of glass, just as if a sheet of water had been thrown over them, and suddenly frozen. This phenomenon is remarkable at Ætna, because we there meet with no vitrifications.

M. Houel went down into one of the openings of this mountain with torches, but could not reach the bottom, and was obliged soon to return on account of the extreme cold. The crater is of an oval form, and the opening through which he descended was in one extremity; but he inclined to think that the crater which rises above it had been formed of matter discharged by another mouth; or perhaps it might have had a more central opening, through which the stones, sand, &c. that form the crater, were discharged. This mountain is one of the mouths of Ætna, through which it discharges, from time to time, great quantities of lava, sand, ashes, &c. The sides of the craters are not all of the same height; those to the east and west are considerably higher than the intermediate summits, because the currents of the ashes passed alternately from east to west, and fell upon these sides in greater quantities than upon the others; which circumstance has given to this volcano the appearance of two summits.

St. *Niccolo dell' Arena*, in the neighbourhood of this mountain, is an agreeable resting-place for travellers who visit Ætna. This is an ancient edifice, founded on the lava, and was formerly the habitation of a number of Benedictine monks, who, about 200 years ago were obliged, on account of the devastations occasioned by the lava to abandon it, and retire to Catania. Here are many inscriptions, which record the ruinous earthquakes, torrents of lava, and showers of sand and ashes by which it has been damaged and even destroyed, together with the dates of their different repairs. The black lava, thrown up in 1669, is more easily changed into vegetable earth than the lava; and has for many years been planted with extensive vineyards: whilst there are many beds of ancient lava that remain in an unproductive state, and destitute of every kind of vegetable.

At a small distance there is another mountain, called *Montpelieri*, or *Monpileri* (see letter G.). This is of a spherical form, and its perpendicular height does not exceed 300 feet, and its circuit is about a mile. It is perfectly regular on every side, and richly overspread with fruits and flowers. Its crater is large in proportion to the mountain itself, and is as exactly hollowed out as the best made bowl. This mountain was formed by the first eruption that destroyed the ancient *HYBLA*, which was celebrated for its fertility, and particularly for its honey, and thence called *Mal Passi*; thus, in consequence of being reduced by several eruptions, and more particularly by that of 1669, to a state of wretched sterility, it obtained the contemptuous appellation of *Mal Passi*. The lava, however, in its course over this beautiful country, has left several little islands or hillocks, which exhibit a singular appearance, with all the bloom of the most luxuriant vegetation, encompassed and rendered almost inaccessible by large fields of black and rugged lava.

About three miles above *San Niccolo dell' Arena*, the lower region of Ætna terminates, and the middle region begins. This is called the *Regione Sylvosa*, the woody region, or the temperate zone; and extends from eight to ten miles in a direct line towards the top of the mountain. Its circumference is estimated by *Recupero* at 70 or 80 miles;

and it comprehends a surface of about 40 or 45 square leagues. It forms a zone of the brightest green all around the mountain; which exhibits a pleasing contrast to the white and hoary head of this venerable mountain, and it is called the woody region, because it abounds with oaks, beeches, firs, and pines. The soil is a vegetable earth, generated by the decomposition of the lava, and similar to that in the lower region. "As soon as we entered these delightful forests, says Mr. Brydone, we seemed to have got into another world. The air, which was before sultry and hot, was now cool and refreshing; and every breeze was loaded with a thousand perfumes; the whole ground being covered over with the richest aromatic plants. Many parts of this region are really the most heavenly spots upon earth; and if Ætna resembles hell within, it may with equal justice be said to resemble Paradise without. Here, he says, you gather the most delicious fruit, rising from what was lately a black and barren rock. Here the ground is covered with every flower, and we wander over these beauties and contemplate this wilderness of sweets, without considering that hell, with all its terrors, is immediately under our feet; and that a few yards separate us from lakes of liquid fire and brimstone." "These majestic forests of Ætna, says Mr. Houel, afford a singular spectacle, and bear no resemblance to those of other countries. Their verdure is more lively, and the trees of which they consist are of greater height." These advantages they owe to the soil on which they grow, which is peculiarly favourable to luxuriant vegetation. The Hawthorn trees are of an immense size. The beeches appear like so many ramified pillars, and the tufted branches of the oak, like close bushes, impenetrable to the rays of the sun. The appearance of the woods in general is exceedingly picturesque, not only on account of the number and variety of the trees, but from the inequality of the ground, which exhibits them like the ranges of an amphitheatre one above another. The east side of the woody region abounds with chestnut trees of an extraordinary size. These are cultivated by the inhabitants with particular attention; and as they are wrought into hoops for casks, they yield a profitable article of trade. But the most remarkable of these trees is the *Castagno di cento Cavalli*, or the chestnut tree of an hundred horse; so called, because it is supposed to be capable of sheltering an hundred horses under the canopy of its boughs. Fabulous report deduces its name from the following circumstance. Jean of Arragon, during her stay in Sicily, whilst she was travelling from Spain to Naples, visited Mount Ætna, and was attended by her principal nobility: but being overtaken by a storm, all of them found shelter under this tree. It stands upon a rising ground, and is surrounded by an open pasture, which is bounded by woods and vineyards. Its height has of late been much diminished by lopping its branches, partly under a notion of increasing its fruitfulness, but principally, perhaps, for obtaining a supply of fuel. Some have supposed that it was merely a bush or clump of several trees united. But *Recupero*, and *Swinnburne* inform us, that upon digging round it they found all the stems united in one root, or body, at a very small depth under ground. Of this trunk five divisions are formed, each of which sends forth enormous branches. The exterior surface of these divisions is covered with bark, but on the inside there is none; the subsistence and verdure of the tree depending upon the external bark. The intervals are of different extent: one of them is wide enough for two coaches to drive abreast. In the middle cavity, or the part that is denominated the hollow of the tree, a hut is built for the habitation and use of those who collect and preserve its fruit, and who dry the nuts in an oven, and

prepare preserves of them for sale. Mr. Swinburne says, that his whole caravan, men and animals, were accommodated at their ease in this extraordinary inclosure; and that after three accurate measurements, he found the outer circumference at one inch above the ground, to be 196 English feet. This tree formerly belonged to St. Agatha, but has lately been declared the property of the crown. There are other trees of a similar kind at a small distance, which are more worthy of admiration than this, as their trunk is entire. One of them, which was clear of branches to the height of 15 feet, and perfectly sound, measured, in the girth, at three feet above the ground, 57 feet. The forest of pines, as it is called, is almost inaccessible, on account of the rocks and precipices that surround it. It is chiefly worthy of notice, as it leads the traveller to the *snow grotto*. This cavity has been lately formed by the action of the waters under the beds of lava, and removing the stratum of pozzolana below them. It is situated on a mount named *Finochio*. This grotto has been repaired at the expence of the Knights of Malta, who have hired this and other caverns in the mountain for the purpose of holding snow, which is more wanted in their island than in Sicily, and which forms a very considerable article of commerce. The snow is thrown in at two openings above; and they have access to these as well as to the internal parts by flights of steps. A considerable extent of ground is enclosed by high walls above the grotto; so that when the wind drives down the snow from the higher parts of the mountain, it is stopped by the walls of this inclosure. It is then thrown into the grotto, where the thickness of the beds of lava, which cover it, prevents any injury from the summer heat. At the season of exportation, it is pressed close in large bags, and lumps of it are wrapped up in leaves, and conveyed to the shore on mules. Pieces of snow, preserved in this manner, have appeared like the most transparent crystal.

Spallanzani detracts from the commendation which has been given by other writers to the luxuriance of vegetation in this region. The oaks, he says, are low and stunted in their growth; and the beeches which grow only in the upper extremity of the zone, would appear mere pigmies, if they were placed beside those which rear their lofty heads on the Apennines and the Alps. This he attributes to the little depth of earth proper for vegetation.

The woods and verdure of the regions, now described, viz. the inferior and the middle, have been recorded by most of the ancient writers; and therefore the commencement of this vegetation must be lost in the obscurity of time. What is still more remarkable with respect to this woody region, is the circumstance, that the surface of it is so unequal, that it every where presents hills, or rather mountains; all of which have been produced by different eruptions from the summit of Ætna, and other craters below the summit, several of which have formerly laid waste this zone, which is now converted into luxuriant forests. Most of the travellers in this region have sought shelter on the night preceding their farther ascent, in the cave called *La Spelonca del Capriolo*, or *La Grotta delle Capre*, or the grotto of the goats, because these animals take refuge here in bad weather. This cave has been formed, from time immemorial, by the lava, when in a fluid state, and seems to have been enlarged by the torrents of water that have passed through it, and carried away some of the sand and stones of which it consists. The lava is of a horn-stone base; and though its texture is earthy and porous, it possesses a considerable degree of hardness. It contains some shoerls, and two kinds of felt-spars, some of which are of a flat figure, and brilliant appearance, and others irregular in their

form, with little lustre, and manifesting a degree of calcination without any fusion. There are some other stones interspersed, which are thought, from their hardness and green colour, to be chrysolites. This grotto is situated about 5054 feet above the level of the sea, according to the calculations of M. de Sauffure. It is surrounded by stately and majestic oaks, the dry leaves of which supply the travellers who shelter in it with beds, as the wood does with fuel. In the neighbourhood of this cave there are two beautiful mountains, the craters of which are larger than that of Vesuvius. They are now filled with oaks, and covered to a great depth with the richest soil.

The upper region of Ætna, called its *frigid zone*, or the *Regione Deserta*, is marked out by a circle of snow and ice, extending, as some state, to the distance of about eight miles; but according to Fazello, nearly twelve, and having the great crater in its centre. The surface of this zone is for the most part flat and even; and the approach to it is indicated by the decline of vegetation, by uncovered rocks of lava, and heaps of sand, by near views of an expanse of snow and ice, and of the torrents of smoke issuing from the crater of the mountain, and by the difficulty and danger of advancing amidst streams of melted snow, fleets of ice, and gusts of chilling wind. The curious traveller, however, thinks himself amply recompensed, upon gaining the summit, for the perils with which he has encountered. His fatigue is alleviated by the reflection that the emperor Adrian, and the philosopher Plato, underwent the same: for the purpose of exploring the summit of the mountain, and of gratifying themselves with a view of the rising sun from this eminence. Most of the travellers who have visited Ætna, have been anxious to reach its summit at the dawn of the morning, before the vapours that are raised by the sun obscure surrounding objects; and they all agree in describing the extent and beauty of the prospect. When Mr. Brydone and his companions ascended this eminence, elevated above the common region of vapour, in the night, they observed that the number of the stars seemed to be much increased, and that their light appeared brighter than usual. The lustre of the milky way was like a pure flame, that shot across the heavens; and with the naked eye they could observe clusters of stars which were totally invisible in the lower regions. Below them on the mountain they perceived a moving light among the forests, which might probably have been an ignis fatuus, and they took notice of several of those meteors that are called falling stars, which appeared to be as much above them, as when they were seen from the plain; and from this circumstance Mr. Brydone infers, that these meteors move in regions much more remote than the bounds which some philosophers have ascribed to our atmosphere. Before dawn they arrived at the ruins of an ancient structure, called *Il Torre del Filosofo*, which some suppose to have been built by Empedocles, for his convenience in observing the conflagrations, and studying the nature of Mount Ætna. By others it is supposed to be the ruins of a temple of Vulcan. Others again imagine it to be a watch-tower, built by the Normans, for the purpose of observing the motions of their enemies, and giving notice of them by signals, to the different bodies of troops scattered over the island. M. Houel thinks it is not very ancient; neither the materials of which it consists, nor the mode of architecture, bearing any resemblance to those of the Greeks or Romans. Some have asserted, that they have found in this ruin, fragments of brick and marble; but no such fragments now exist. The materials were examined by Spallanzani, who discovered that they consisted of a cement of lime, which by length of time is become carbonate

bonate of lime, and two kinds of lava, which exhaled an argillaceous odour in their fractures, and whose base was the horn-stone. These materials were collected upon the spot, and rendered compact and united by a cement of lime.

The prospect from the summit of Ætna has been described in very animated and glowing colours, by many writers. The gradations of the morning dawn appear with singular advantage from this elevated situation. At the rising of the sun, says M. Houel, the horizon was serene, without a single cloud. The coast of Calabria could not be distinguished from the adjoining sea: but a fiery radiance soon began to appear behind the Italian hills, which bounded the prospect to the east. The fleecy clouds, which usually appear in the morning, were tinged with purple; the atmosphere became strongly illuminated; and, reflecting the rays of the rising sun, glowed with a bright effulgence of flame. The immense elevation of the summit of Ætna caught the first rays of light, and yielded a dazzling, but animating splendour. The sea still retained its dark hue, nor did the fields and forests yet reflect the solar rays. As the sun gradually advanced above the horizon, his light was diffused over the hills which lie below the peak of Ætna. This huge mountain stood like an island in the midst of the ocean, presenting to view a multitude of luminous points, the number and lustre of which rapidly increased. The scene, says this author, was as if the universe had been observed suddenly springing from the night of non-existence. The tall forests, the lofty hills, and extensive plains of Ætna, now presented themselves to view. The base, the vast tracts of adjacent level ground, the cities of Sicily, its parched shores, with the dashing waves and wide expanse of the ocean gradually appeared, whilst some fleeting vapours, driven by the wind, occasionally interrupted part of this grand and magnificent prospect. In a little while the display was so distinct, that places before known were easily recognized. On the south were seen the hills of Camerata and Trapani; on the north, the mounts Pelegrino and Thermi, with the celebrated Enna, once crowned with the temples of Ceres and Proserpine. Among these mountains appeared many rivers, like lines of glittering silver, winding their course through rich and fertile fields, and washing the walls of twenty cities, while their banks were crowded with villages, hamlets, &c. that rise among the ruins of the most illustrious republics of antiquity. On the south and north were observed the rivers whose course bounds the immense base of Ætna; and at a much greater distance were seen the isles of Lipari, Alicudi, Felicocide, Parinacia and Stromboli.

On the sun's first rising, says Mr. Brydone, the shadow of the mountain extends across the whole island, and makes a large tract visible even in the sea and in the air. This shadow is gradually shortened, and, in a little time, is confined only to the neighbourhood of Ætna. Between the body of the sun, as it is seen rising from the ocean, and the spectator, immense tracts of sea and land intervene; the islands of Lipari, Paraci, Alicudi, Stromboli, and Volcano, with their smoky summits appear under your feet; and you look down on the whole of Sicily as on a map, and can trace every river through all its windings from its source to its mouth. The extent of the horizon is no less than 800 miles in diameter; and Massa, a Sicilian author, observes, that the African coast, as well as that of Naples, with many of its islands, have often been discovered from the top of Ætna. But the most beautiful parts of the scene, in the judgment of Mr. Brydone, are the mountain itself, the island of Sicily, and the numerous islands lying around it; all which seem as if they were brought close round the skirts

of Ætna, the distances appearing reduced to nothing. The same scene is described in similar language by Spallanzani. No elevated region in the whole globe, says this author, offers at one view so ample an extent of land and sea, as the summit of Ætna. The first of the sublime objects which it presents is the immense mass of its own colossal body. The first part, and that which is nearest the observer, is the *upper region*, commonly covered with snow and ice, and occasionally exhibiting rough and craggy cliffs, either piled on each other or separate, and rising perpendicularly, towards the middle of this zone; an assemblage of fugitive clouds, irradiated by the sun, and all in motion, increased the wild variety of the scene. Lower down appeared the *middle region*, with its numerous woods and multitude of mountains, originating from fiery eruptions; and beyond this the eye discerns, with admiration, the *lower region*, the most spacious of the three, adorned with elegant villas and castles, verdant hills and flowery fields, and terminated by the extensive coast, where, to the south, stands the beautiful city of Catania, to which the neighbouring sea serves as a mirror. The observer, at this elevation, discovers not only the entire massy body of Ætna itself, but the whole of the island of Sicily, with all its noble cities, lofty hills, extensive plains, and meandering rivers. Malta is also perceived at an indistinct distance; the eye commands the environs of Messina, and the greater part of Calabria; while Lipari and the Æolian isles appear so near as to be under the feet of the observer, and as if by stooping down he might touch them with his finger. The far stretching surface of the adjacent and surrounding sea presented an object no less majestic, and led the eye to an immense distance, bounded only by the heavens. "Seated," says Spallanzani, "in the midst of this theatre of the wonders of nature, I felt an indescribable pleasure from the multiplicity and beauty of the objects I surveyed; and a kind of internal satisfaction and exultation of heart. The sun was advancing to the meridian, unobscured by the smallest cloud, and Reaumur's thermometer stood at the 10th degree above the freezing point; I was therefore in that temperature which is most friendly to man, and the refined air I breathed, as if it had been entirely vital, communicated a vigour and agility to my limbs, and an activity and life to my ideas, which appeared to be of a celestial nature."

The access to the principal crater of Ætna is rendered both inconvenient and perilous, for a distance of near four miles, by a variety of circumstances which different travellers have described. The summit of the mountain is a plain covered with scorice, ashes, and sand, which have been thrown out of the volcano at its successive eruptions, and which are so loose as to endanger the traveller's being swallowed up at every step of his progress. It is also covered with snow and ice, and obscured with clouds, excepting at times when these clouds are low and range along the sides of the mountain, so as to present an object of terror. The winds, likewise, blow with such violence that persons can scarcely stand securely, nor endure the cold which benumbs their limbs. The south wind is, on the top of Ætna, the most prevalent, and the cold is so intense, that travellers have often found their clothes insufficient to protect them. But the most formidable impediments to the progress of the adventurers in this perilous journey are the streams of mephitic vapour which rise on the sides, and the thick clouds of sulphureous smoke which burst from the mouth of the volcano, even when it is not in a state of agitation. The fountains that issue from the crater are also singularly terrifying, and have discouraged some persons from approaching the spot whence they proceed. M. Houel compares them

to a discharge of cannon in the wide abyss, which being reflected from the various caverns produces reverberations of the most alarming kind. By means of these sounds, which in the open air would be considered as slight explosions, become more tremendous than the loudest thunder.

When Spallanzani visited this mountain, he observed, when he was at the distance of two miles and a half from the limit of his journey, two white columns of smoke, which arose from its summit; one, towards the north-east side of the mountain, and another towards the north-west; several other streams of smoke, which arose from inferior parts towards the west, pursued the direction of these two larger columns. As he proceeded, he met with a torrent of lava, which he was obliged to cross in order to arrive at the smoking summit. This torrent was covered with scoria, which projected in some places in a variety of prominent points, and in others sunk in hollows, which rendered his passage extremely difficult; and the lava itself, though the interval from its discharge was 11 months, was in many parts of it red-hot. His difficulties increased as he passed that tract, which may properly be called the cone of *Ætna*, and which, in a right line, is about a mile in length. Having arrived, after much labour and fatigue, within 150 paces from the vertex of the cone, he found himself enveloped by the vapours of the several streams of smoke that issued from the top and sides of the mountain; and his progress was rendered extremely hazardous by the effect which these noxious vapours produced on his respiration. He soon, however, recovered his strength and resolution, and arrived at the utmost summit of the mountain, where he began to discover the edges of the crater. Here he viewed with astonishment the configuration of the borders, the internal sides, the form of the immense cavern, its bottom, and an aperture which appeared in it, the melted matter which boiled within, and the smoke which ascended from it; and he has minutely described the several appearances from his own attentive and accurate observation. The upper edges of the crater, which are broken and indented in several places, are, as he judged by the eye, about a mile and a half in circuit, and form an oval, the longest diameter of which extends from east to west. Its internal sides, which are inclined at different angles in its several parts, form a kind of funnel of a conical figure, and abound with concretions, which he found to be the muriate of ammoniac. The bottom was nearly an horizontal plane, about two-thirds of a mile in circumference; in which plane was visible a circular aperture, about five poles in diameter, from which proceeded the largest of the two columns of smoke, observed before he arrived at the summit of *Ætna*. This column appeared at its origin to be about 20 feet in diameter, and whilst it remained within the crater, ascended in a perpendicular direction; but when it arose above the edges, it was made to incline towards the west by a light wind; and afterwards it dilated into an extended and rare volume. The smoke was of a white colour. Within the crater Spallanzani observed a liquid and ignited matter, which continually undulated and boiled, alternately rising and falling, without spreading over the bottom. This, he says, was the melted lava, which had arisen to that aperture from the bottom of the *Ætnean* gulf. Several large stones were thrown into the crater, some of which struck the liquid lava and produced a sound similar to that which would have been occasioned by their falling into a thick tenacious paste; but the stones which fell on the bottom rebounded, and their sound was different from that of the others. Hence our author infers, that the bottom must be thick and solid,

which, if this were not the case, would have been broken by heavy stones falling from so great a height.

The summit of *Ætna*, surrounded with large masses of lava, is exhibited in Plate 1. NAT. HIST. fig. 2. A. A. A. represents one edge of the lava of 1787, which issued from the upper crater. B. B. is the circumference of the crater, with its cleft. C. C. through which the internal part is discernible. D. is the flat bottom of the crater; and E. the aperture in the bottom, from which the larger column of smoke F. F. arose; which aperture, though it was at one side of the bottom, is, for the greater distinctness of view, represented in the middle. G. G. is that part of the edge of the crater from which its internal part is best seen, and where the design of it might be most conveniently taken. H. H. is the smaller column of smoke to the north-east.

Spallanzani informs us, that beside the eminence on which he stood, there is another to the north, a quarter of a mile higher, which renders the summit of *Ætna* properly bifurcated. The crater on this second pre-eminence, and from which the lesser column of smoke ascends, is about one half smaller than the other, and is separated from it by a partition of scoria and accumulated lava, which lies in a direction from east to west. The Abbè has compared his own observations with those of others who have described the crater of *Ætna* in the course of 20 years, or from the time when it was visited by Baron Riedesel in 1767, to that of his own journey in 1788. At the time of the Baron's observation, the crater was enlarged towards the east with an aperture which does not now exist; and as the stones which were then thrown in did not return the smallest found, the bottom of the crater could not be formed with the hard and flat surface which the Abbè has described. Within the gulf itself was heard a noise similar to that of the waves of the sea, when agitated by a tempest; and this must probably have proceeded from the lava within the bounds of the mountain, in a liquified and perturbed state. Sir William Hamilton arrived at the summit of *Ætna* on the 26th of October, 1769; but was prevented from distinctly viewing the lower parts of the crater by the smoke that issued from it. From what he was able to observe he concludes, that its figure resembled that of a funnel, diminishing till it ended in a point, and that this funnel was crusted over with salt and sulphur. The crater was then two miles and a half in circumference; and must have undergone great changes in the interval that elapsed between these observations and those of Riedesel, in whose time there must have been an abyss as well as a funnel; nor does the point in which the funnel terminated admit of the flat bottom described by Spallanzani. The dimensions of the crater, stated by Sir William Hamilton, the Abbè accounts for by supposing, that the partition which now separates the great crater into two parts has been produced since the time of his observation; for the sum of the two circumferences which the Abbè has noticed would not much differ from the other measure. Mr. Brydone, who observed the crater on the 29th of May 1770, says, that it was then a circle of about three miles and a half in circumference, that it shelved down on each side, and that it formed a regular hollow, like a vast amphitheatre, and that a great mouth opened near the center. Count Borch arrived at the mountain on the 16th of October 1776, and merely observes, that the crater is formed like a funnel, and that the summit is bifurcated; a circumstance unnoticed by Sir W. Hamilton, who affirms, on the contrary, that the summit is single; and the Abbè therefore concludes, that one of these summits has been produced since the journey of Brydone in 1770. M.

D'Orville, who ascended Ætna in 1727, remarked two craters, one larger than the other, and in circumference somewhat more than four miles, from which issued clouds of smoke and reddish flames. On looking into this crater, he and his companions were unable to discern the bottom on account of the flames and smoke. They only observed that a conical hill, formed of lava, rose in the middle of the crater, the top of which they estimated to be 60 feet below them; and as they were probably able to see about 60 feet lower, they conjectured that the circuit of this hill might be from 600 to 800 feet.

M. Houel, whose account of this mountain was published in 1782, and who made a drawing of the crater, represents its environs as consisting of three eminences, forming an equilateral triangle, though when viewed at a distance, only two of them can be seen; for which reason the Sicilians have denominated the mountain *bicorne*, or double horned. The situation of the principal mouth is in the midst of these three eminences. Its diameter was only about 60 feet; but it was so filled with smoke that nothing remarkable could be discovered. This author observes, that the cone is not exactly in the middle of the plain, but that it lies somewhat more to the north than the south. Every observation, therefore, tends to evince the inconstancy of the internal configuration and dimensions of this volcano. Beside the changes which have taken place on the summit of Ætna, with respect to the number, form and size of its craters, Fazello and Borelli describe another alteration occasioned by the falling in and absorption of the extreme summit of the mountain within its crater. The former author relates, that in his time there arose in the mouth of the crater a little hill, isolated on every side, which formed the vertex of the mountain, and which, in a terrible eruption, fell into the gulf, and thus enlarged the crater and diminished the height of the mountain. The hill itself had been produced by a former eruption in 1444. Borelli likewise informs us, that in the conflagration of 1669 the summit of Ætna which rose, like a tower, to a great height above the part which is level, was swallowed up in the deep gulf. Strabo (tom. i. p. 420, &c.) relying on the account of those who had visited Ætna in his time, describes the summit as a level plain, about 20 stadia in circumference, surrounded by a brow, or ridge, of the height of a wall; and he adds, that in the middle of the plain arose a smoky hill, the smoke of which ascended in a direct line to the height of 20 feet. Solinus (cap. 11) informs us, that there were two craters, from which the vapours issued. Cardinal Bembo likewise found two craters, one higher than the other, and about as far distant as a stone might be thrown from a sling. The extreme violence of the wind and the exhaled fumes prevented his approaching the upper crater; but he describes it from the information of others, as situated on the highest part of the summit of Ætna, about three miles in circumference, formed like a funnel, and having in its middle a spacious cavity. In the time of Fazello, who visited Ætna after Bembo, there was only one crater about four miles in circumference. Its form was that of a funnel; it emitted fire and thick smoke; and a subterraneous noise was heard, which resembled the boiling of an immense caldron on a very fierce fire.

As for the difference that occurred with regard to the appearance of the smoke, noticed by different writers, some of whom represent it as rolling down the sides of the mountain, and others, as ascending perpendicularly to a great height, and afterwards falling, like white flowers on the top of the mountain; it was owing, without doubt, not only to the different density of the air on Ætna at different times, but also to the diversity of the smoke, which would sometimes be lighter and sometimes heavier than the air itself.

according to the qualities of the substances from which it is produced.

The effects of the air at the summit of Ætna, recited by different writers, have also been very different. Some have complained of the difficulty of respiration which they experienced, whilst others felt no such difficulty, and assert that respiration is performed with equal ease on the top of the mountain, as in the country below. It appears from the observations of M. Saussure in his travels on the Alps, that, although at the height of Mount Blanc, about 2450 poles above the level of the sea, a considerable difficulty of respiration was occasioned by the rarefaction of the air, no such inconvenience was experienced at the less elevation of 1900 poles. The height of Ætna being less than the last measure, it is natural to infer that the respiration of many persons would not be incommoded, whilst the contrary happens to others, according to the different strength and habit of body of different individuals. The observed difference of the barometer indicated in these various circumstances a considerable difference in the weight and rarity of the air.

Spallanzani observes, that Ætna has at all times been very deficient in springs; and when he visited this mountain, water was so extremely scarce, that a single drop of rain had not fallen for nine months. As the rain water which the peasants, who inhabit different parts of it, had collected in cisterns was exhausted, they were obliged to go in search of it to those parts of the mountain at considerable distances, where a scanty spring might still be found. This author has observed a similar scarcity of springs in the Æolian or Lipari islands; and he apprehends, that other volcanic countries are subject to the same inconvenience. The rains, he says, which descend on mountains of this kind, fall on tufas or scoriz, in which they sink deep and do not again appear, because they meet with no argillaceous or stony strata capable of detaining them; whereas such strata are frequent in other mountains, and produce numerous springs, as we find to be the case in the Alps and Apennines. When the rains fall on compact and solid lavas, they do not sink into them, but run down their declivities, forming rivers and torrents in the rainy season, and not true springs. In several parts of Ætna, and especially near the *Grotta delle Capre*, he observed large furrows hollowed in the lavas, by the action of the rain water. Other writers, however, have given a very different account. They state, that Ætna abounds with fountains and with rivers of considerable magnitude. See *ACIS* and *ALCANTARA*. Mr. Brydone informs us, that there are several periodical springs on Ætna, that flow during the day and stop at night, which he attributes to the alternate melting and freezing of the snow. There are also poisonous springs, which emit a very noxious vapour; and others which afford fine salt; and others again, whose water serves for dyeing particular colours. On the north side of the snowy region, there are several small lakes which never freeze. M. Houel estimates the quantity of water which flows down the sides of the mountain to be such, that if it were collected it would fill the channel of a river 36 feet broad and six feet deep; and he adds, that streams of water are seen to issue at all different degrees of height from the base to the summit of the mountain; and that these continue to flow even during the drought of summer. The supply of these streams, he thinks, cannot be accounted for by the water deposited by the clouds, nor by the melting of the snow; but the source of it must be more regular and permanent. This he conceives to be the evaporation of those aqueous particles that arise from the constant ebullition at the bottom of the volcanic focus, and which, in his opinion, are necessary to the subsistence of volcanoes. These vapours, issuing from the

great crater, and from innumerable fissures in the sides of the mountain, are condensed by the cold of that elevated region of the atmosphere, and percolating through the earth, furnish the numerous streams of Ætna with water.

The numerous caverns that are met with in different parts of Ætna deserve notice. The grotto of the goats, the snow grotto, and those of mount Rosso, have been already mentioned. Kircher speaks of one, which he saw, capable of containing 30,000 persons. One of these caverns still retains the name of Proserpine, from its being supposed by the ancients, that it was by this entry Pluto conveyed her into his dominions; on which occasion Ovid describes Ceres as searching for her daughter with two trees, which she had plucked from the mountain, for serving the purpose of torches. These trees he calls *Tæda*; and they produce great quantities of a kind of rosin, called Catalana, and esteemed a cure for sores. Ovid. *Fast.* l. iv. tom. iii. p. 271. Ed. Burm. *Diod. Sic.* tom. i. p. 333. Ed. Wellfing.

Ætna produces a great variety of plants and flowers, as well as trees of a larger size, such as the chestnut, oak and cork tree, &c. Mr. Brydone enumerates the cinnamon, sassaaparilla, sassafras, rhubarb and palma Christi: and he adds, that it was celebrated by the ancients for its odoriferous productions. See *Diod. Sic.* tom. i. p. 322. Plutarch and Aristotle intimate that the smell of the plants was so strong on many parts of the mountain, that it was impossible to hunt. There was formerly a great variety of wild beasts in the woody region of Ætna; but the number of them is now much reduced. There are still wild boars, roebucks and wild goats; but the race of stags is thought to be extinct. The horses and cattle of mount Ætna were once esteemed the best in Sicily. The cattle are still of a large size, but the horses have degenerated. Spallanzani informs us, that partridges (*Tetrao rufus*, Linn.) were shot at the upper extremity of the middle region, and in this region he met with several birds of the titmouse species (*Parus œruleus*, Linn.) a kite (*Falco milvus*), three jays (*corvus glandularius*), two thrushes (*Turdus viscivorus*), and several ravens and crows (*corvus corax*; *corvus corone*.) But in the middle of the higher region he saw no other animals, except some lion-ants (*Myrmecleon formicarum*, Linn.) which made their pitfalls in the dust of the lavas.

We shall close this article, already extended to a considerable length, and comprising every kind of information which we have met with concerning Ætna, with an account of its principal eruptions. The first symptom of an approaching eruption is an increase of the smoke, in fair weather; and after some time, a puff of black smoke is seen to shoot up to a considerable height in the midst of the white. These puffs are attended with considerable explosions; and the ascending column of black smoke is followed by a reddish flame. The smoke appears black in the day, and in the night resembles flame. Showers of ashes precede; earthquakes frequently accompany them; and red hot stones are projected to a great height in the air. The crater and smoke, at the time of an eruption, are so highly electrical, that they throw off spontaneous flashes into the air; and the smoke has sometimes extended, says Mr. Brydone, for upwards of 100 miles, and produced dreadful effects, killing shepherds and flocks on the mountains, blasting trees, and setting fire to houses which occupied an elevated situation. From the column of ascending smoke continual flashes of forked or zig-zag lightning proceed, and this is sometimes attended with thunder. When these appearances have continued for three or four months, the lava, or stream of melted mineral matter, boils over the top of the crater, or bursts through some weak place in the side. Upon the appearance of the lava, the violent eruptions of the moun-

tain generally, though not always, cease; but without a vent for the lava, the commotion is very much increased. In the night this lava appears like a stream of fire, and flows to a great distance; but in the day its progress is marked by a white smoke. It has been a subject of discussion among philosophers, whether the eruptions of volcanoes are now less frequent than they were formerly. This is probably the case, as the matter in the volcanic focus was then greater in quantity than it is at present; and the cavities being smaller were sooner filled with vapour, and the center of the focus was nearer the surface than it is now, in consequence of repeated eruptions and discharges. The whole number of the eruptions of this mountain, of which we have any record, says Spallanzani, before and after the Christian era, is 31; and 10 only, according to Gioeni, have issued immediately from the highest crater; but it is not easy to make an exact estimate, as the same eruption has continued with or without intermissions, for some time; and has been taken singly by some writers, whilst others have reckoned every renewal of it separately. The eruptions of Ætna have been reported and described by several of the ancient poets. The first of these, by whom they are mentioned, is Pindar, in the following passage, the fifth decade of an ode which was composed in the 78th olympiad, about four or five years after the second eruption mentioned by Thucydides.

Κίον,
 Δ'εραίνια συνίχθεις
 Νιφόσσο' Ἄγωνα, πάρεστις
 Νινοῦ; ὄξεις; τιθνην; &c.

Pythia. Od. i. v. 36. &c. p. 168.
 Ed. West and Wellsted.

Now under sulph'rous Cuma's sea-bound coast,
 And vast Sicilia lies his shaggy breast;
 By snowy Ætna, nurse of endless frost,
 The pillar'd prop of Heav'n, for ever press'd:
 Forth from whose nitrous caverns issuing rise
 Pure liquid fountains of tempestuous fire,
 And veil in ruddy mists the noon-day skies,
 While wrapt in smoke the eddying flames aspire;
 Or gleaming thro' the night with hideous roar,
 Far o'er the red'ning main huge rocky fragments pour.

G. West's translation, Odes of Pindar, vol. i. p. 56.
 12mo. &c.

They are also described by Virgil, in consequence of the eruption which happened, according to Mr. Oldenburg (*ubi infra*) at the time of the expedition of Æneas, who, being terrified with the fire of this burning mountain, left Sicily.

Horrificis juxta tonat Ætna ruinis,
 Interdumque atram prorumpit ad Æthera nubem,
 Turbine fumantem piceo et candente favilla;
 Adtollitque globos flammaram, et Sidera lambit;
 Interdum scopulos avolsaque viscera montis
 Erigit cructans, liquefacta saxa sub auras
 Cum gemitu glomerat, fundoque exæfluat imo.
 Æncid. l. iii. v. 571, &c. tom. ii. p. 433, &c.
 Ed. Burman.

The philosophical poet, Lucretius, has also mentioned the eruptions of Ætna.

Per fauces montis ut Ætnæ
 Exspirent ignes interdum turbine tanto,
 Expediam: neque enim mediocri clade co'orta
 Flammæ tempeilas, Siculûm dominata per agros
 Finitumis ad se convertit gentibus ora;
 Fumida quom cœli scintillare omnia templa

Cernentes,

Cermentes, pavida complebant pectora curâ,
Quid moliretur rerum natura novarum.

Lib. vi. v. 639, &c.

Vol. iii. p. 309, &c. Ed. Wakefield.

For Silius Italicus's description of Ætna, see Punic. lib. xiv. v. 55. 69. p. 697. Ed. Drakenb.

Mr. Oldenburg has enumerated several eruptions which happened before his time in the Phil. Trans. No. 48. Abridgm. vol. ii. p. 386. The first he mentions is that to which we have already referred; but the first eruption of which we have any positive historical record is that mentioned by Diodorus Siculus (l. 5. tom. i. p. 335. Ed. Wessel.), though he does not specify the precise period when it happened. This event, however, compelled the Sicani to abandon the eastern parts of Sicily, and to settle in the southern parts. This territory was afterwards occupied by the Sicilians, who migrated thither from Italy. The *second* eruption is the first of three that are recited by Thucydides (Hist. l. iii. c. 116. p. 237. Ed. Duker.) without mentioning the exact date of any one of them. He says, that from the arrival of the first Greek colonies that settled in Sicily, viz. in the third year of the 11th olympiad, corresponding to the year 733 before the Christian æra (vid. Annales Thucyd. p. 12), to the third year of the 88th olympiad, Ant. Christ. 425, Ætna, at three different times, discharged torrents of fire. This second eruption happened according to Eusebius (Chronicon. MDXC.) Ant. Christ. 565. The *third* eruption, or the second mentioned by Thucydides, happened, as he says, in the 50th year before the last; or as it is stated (vid. Annales Thucyd. p. 31. Ed. Wessel.) Ante Christ. 475. Olymp. 76½, when Phædo was archon at Athens. But the Oxford marble refers it to the 1st year of the 75th olympiad, Ant. Christ. 477, when Xantippus was archon at Athens. In the second year of this Olympiad, it is said the Athenians gained their boasted victory over Xerxes's general, Mardonius, near Plataea. Both the eruption of the volcano and the victory of the Athenians are commemorated in an ancient inscription on the marble table above-mentioned. It was at this eruption, as we are told, that two rich brothers, named Amphinomus and Anapis, disregarding their effects, rushed into the flames and carried off their aged parents on their backs. It is said that the fire spared these youths, whilst others who took the same road were consumed. The citizens of Catania recompensed this act of filial piety with a temple and divine honours. The heroic deed is represented on an ancient medal, and it is recorded by several ancient authors, as Strabo, (tom. i. p. 412.) Silius Italicus, (l. xiv. vers. cxvii. p. 703.) Valerius Maximus (l. v. c. 4) Pausanias (Phocica. l. x. p. 867. Ed. Kuhnii) Ælian (Fragmenta. Var. Hist. tom. ii. 1054) Seneca, Aristotle, Claudian, Solinus, &c. The *fourth* eruption, or the third mentioned by Thucydides, occurred, as we have already hinted, in the 88th olympiad, Ant. Christ. 425. and laid waste the territory of Catania. The *fifth* is dated by Orosius, in the consulship of Sergius Fulvius Flaccus, and Quintus Calpurnius Piso, about 133 years before Christ. Livy (l. liv. c. 12. tom. v. p. 1043. Ed. Drakenb.) mentions an eruption in the consulship of C. Lælius and Q. Servilius, Ante Christ. 140. The *sixth* happened in the 125th year before the Christian æra, and Orosius says, that a number of fishes were destroyed by it, and that the inhabitants of Lipari suffered exceedingly by eating them. The *seventh* eruption, which occurred in the 121st year before Christ, desolated Catania to such a degree, that the inhabitants were excused by the Romans from paying taxes for 10 years, in order to enable them to repair the damage which they had sustained.

This is mentioned by Livy (l. lxi. c. 41. tom. vi. p. 11). An *eighth* eruption happened in the 43d year before Christ, not long before the death of Cæsar, and was afterwards regarded as an omen of this event. The *ninth* eruption is mentioned by Suetonius, in his life of Caligula (tom. i. p. 608. Ed. Pitisc.) It happened A. D. 40, and terrified the emperor so as to make him fly precipitately from Messina. This is reckoned the 13th eruption by Cluverius in his Sicil. l. 8. §. 2. Carrera mentions two eruptions, one in the year 253 and another in 420. The eruption which happened in the reign of Charlemagne, A. D. 812, is recorded by Geoffroy of Viterbo in his chronicle. In 1169, Sicily was disturbed by a violent earthquake, which extended to Reggio on the opposite side of the strait. Catania was destroyed by it, and 15,000 persons perished. On this occasion old rivers disappeared, and new ones burst out; and the ridge of Ætna fell on the side near Taormina. The spring of Arethusa became muddy and brackish; and the fountain of Ajo ceased to flow for two hours, and then gushed forth more abundantly than before. The sea at Messina retired far within its usual limits, and then overflowed its ordinary banks, and swallowed up a number of persons, who had fled to the shore for safety. Corn and trees of all sorts were destroyed, and the fields were covered with stones so as to become unfit for cultivation. From the year 1160, or as some say 1157, to 1169, Sicily repeatedly suffered from earthquakes and eruptions. This was followed by another eruption in 1181 or 1184, when streams of fire ran down the declivity of the mountain: and in 1329 the inhabitants of the mountain and of the whole island were alarmed by the commotions and noises of Ætna, and by the flames and stones, and other attendants of an eruption, which succeeded them. On this occasion a new crater was opened, and the flaming materials that were disgorged from it overspread the adjacent fields, destroyed their buildings, and occasioned the death of birds and quadrupeds, and of the fishes of the rivers and contiguous parts of the sea. A spectator says, that he could not think Babylon or Sodom was destroyed with such awful severity. The ashes were carried by the wind as far as Malta, and many persons are said to have died of terror. In 1333, Ætna made another terrible explosion, which was succeeded by that of 1381, which extended its ravages to the confines of Catania, and burnt up the olive-yards in the neighbourhood of the city, and again by another in 1444, when the mountain shook and discharged a quantity of lava, and large rocks were broken off from its summit and precipitated into the sea. Slight eruptions occurred in 1446 and 1447; but the eruption of 1536, after a cessation of near 100 years, was very dreadful in its appearance and effects, and lasted for a considerable time. A thick cloud, tinged with red in the middle, hovered over the summit of the mountain, which was attended by a strong west wind, and succeeded by the discharge of a large quantity of burning materials, that rushed with the noise and rapidity of a torrent down the eastern side of the mountain, and destroyed buildings and animals that lay in its way. A similar stream of liquid fire held its course towards the west, and did great damage. Several chasms were opened on the sides of the mountain, from which streams of ignited matter were thrown up to a great height into the air; and a learned physician whose curiosity, and desire of information led him to examine the eruption, was burnt to ashes by a volley of burning stones. This continued with little intermission for a whole year, and terminated by causing the river Simetus suddenly to overflow its banks, and carry off those who lived near it with their cattle and other property. The country near Paterno

suffered much; and the neighbouring castles, and more than 500 houses were destroyed by the ravages of the river, and trees were torn up by violent blasts of wind. Ætna was convulsed and rent in several places, and poured forth torrents of lava, which destroyed the vineyards and gardens at the monastery of St. *Nicholas d' Arena*, and proceeded onwards to *Nicolosi*, burnt *Morpellieri* and *Fallica*, and did great injury wherever it spread. The commotions of Ætna were so great, that the summit fell in with a tremendous noise, and the shocks of the earthquake that attended them were felt through the whole island. The inhabitants were so much alarmed and distressed, that they appeared in mourning, and continued in this state for a considerable part of the year. In 1567 and 1579, the ravages of Ætna were renewed; and from 1603 to 1636 its eruptions were occasionally repeated, and torrents of lava flowed from it, which destroyed the woods and vineyards in those parts to which they reached. In 1650, as Oldenburg informs us, from Kircher's *Mundus Subterraneus*, the mountain burnt on the north side, and produced great devastation. Carrera was witness of a dreadful conflagration in 1663, which lasted till the end of May 1678. But the eruption of 1669 was the most formidable and most destructive. Borelli, who was an eye witness of this catastrophe, and some English merchants who were also upon the spot and who examined its effects, of whose report we have a detailed account, in the *Phil. Trans.* (No. 51. abr. vol. ii. p. 387.) have minutely described the access, and progress, and ruinous consequences of this eruption. It was preceded, for eighteen days, with a dark sky, thunder and lightning, and frequent concussions of the earth, which destroyed many houses in the village of *Nicolosi*, and dispersed its inhabitants. The old crater on the summit of Ætna raged for two or three months before this event, in an unusual manner; and this was also the case with Volcano and Stromboli, two burning islands to the west of it. In the evening of the 11th of March, at the distance of about twenty miles from the old mouth, and ten miles from Catania, a chasm was opened in the east side of the mountain; which is said to have been several miles (Borelli says twelve) in length, and five or six feet wide. This was not far from the place where *Monte Rosso* afterwards arose, and extended in the direction of the grand crater of Ætna. See Pl. i. Nat. Hist. fig. 2. V. V. V. On the night following, in the place where this mountain now stands, another large cleft opened, and several other chasms were formed in different parts of the mountain; and there issued from all of them huge volumes of smoke, accompanied with the usual phenomena of thunder and earthquake. From the principal chasm there issued the same night a stream of lava, which directed its course to a lake, called *la Hardia*, about six miles from *Morpellieri*, and in its way destroyed many dwelling-houses and other buildings in the adjacent villages. The next day it moved towards a tract of country called *Mal Passo*, inhabited by about 800 people, which, in the space of twenty hours, was entirely depopulated and laid waste; the lava then changed its direction, and destroyed some other villages. *Morpellieri*, and its inhabitants, were also destroyed. On the 23d of March the stream of lava was in some places two miles broad, and extended itself to the village of *Mazzalucia*. On this day a new gulf was opened, from which were discharged sand and ashes, which formed a hill with two summits, two miles in circumference, and 150 paces high; these consisted of stones of different colours. The new mountain of *Nicolosi* continued to discharge ashes for three months, in such quantity as to cover the adjoining tract of country for 15 miles. Some of

these ashes were conveyed by the winds as far as Messina and Calabria; and others spread over the southern country, about Agolta, Lentini, and remoter parts. On the 25th of March the whole mountain, even to its highest summit, was agitated by a very violent earthquake. The highest crater, or its loftiest eminence, then sunk into the volcanic focus, and the spot which it had occupied became a deep gulf, more than a mile in extent, from which were thrown up enormous masses of smoke, ashes, and stones. At this time it is said, the famous block of lava on mount Frumento was discharged from the volcanic focus. The torrent of lava, which still continued to flow, directed its course towards Catania; it first passed under its walls for a considerable distance into the sea, but afterwards accumulated and passed over them in several places. The gardens and grounds belonging to the convent of the Benedictines were overwhelmed by it; and by its taking this direction many buildings in the town escaped. From hence it divided into separate channels or streams, and flowed chiefly into the sea. The English merchants say, that it had overwhelmed in the upland country, 14 towns and villages, some of which contained 3 or 4000 inhabitants, and stood in a fruitful country, where the fire had not before this time made any devastation; and they add, "there is not now so much as any sign where these towns stood, except the church and steeple of one of them, which was situated on an eminence." The Earl of Winchelsea, who at this time happened to be there on his way home from an embassy to Constantinople, in his account of this tremendous catastrophe, informs us, that the inundation of fire, cinders, and burning stones, advanced into the sea 600 yards, and a mile in breadth: that it destroyed in 40 days the habitations of 27,000 persons; and of 20,000 persons, who inhabited Catania, 3000 only remained. He adds, that the fiery deluge, in its progress, met with a lake four miles in compass, and not only filled it up, though it was four fathoms deep, but raised it into a mountain. He observes, according to an extract, cited by Sir William Hamilton, that he could see at ten miles distance the fire begin to run from the mountain in a direct line, and the flame to ascend in bulk and height equal to those of the loftiest steeple in this kingdom, and to throw up large stones into the air. He discerned also the river of fire descending the mountain, exhibiting a terrible fiery or red colour, and bearing stones, which swam upon it, as big as an ordinary table. This fire was observed to move in several other places, emitting flames and smoke resembling those of a furnace of melted iron, and occasioning a loud noise especially by means of the great pieces that fell into the sea. He adds, upon the information of a cavalier of Malta, that the river was as liquid, when it issued from the mountain, as water, and came out like a torrent with great violence; and that it was five or six fathoms both in depth and breadth, and that no stones could sink in it. Borelli observes, that when they threw stones into the chasm of the mountain, they could not hear them strike the bottom. Burning rocks, he says, 60 palms in length, were thrown to the distance of a mile, and stones of a lesser size were carried upwards of three miles, and the thunder and lightning from the smoke were not less terrible than the noise of the mountain. After the most violent struggles, and shaking of the whole island, when the lava got vent it sprang up into the air to the height of 60 palms; the sun, for many weeks, did not appear, and the day seemed to be changed into night; and it was not till four months from the time when it began to discharge its contents, that these dreadful symptoms abated. This deluge of fire, after destroying the finest country in Sicily, and sweeping away churches, villages, and

convents before it, burst over the lofty walls of Catania, and covered five of its bastions, with the intervening curtains; and from thence pouring down on the city, it laid waste every object it met with, overwhelming and burying all in one promiscuous ruin. He regrets the destruction of many remains of antiquity; particularly an amphitheatre, which he calls *Coliseo*, the *Circus Maximus*, the *Naumachia*, and several temples. Borelli has calculated, that the matter discharged at this eruption was sufficient to fill a space of 93,838,750 cubic paces.

The English merchants, to whose account we have already referred, describe the lava as a mass consisting of metals and minerals, which being rendered liquid by the fierceness of the fire in the bowels of the earth, boiled up and gushed forth as the water does at the head of some great river; and having run in a full body for a stone's cast or more, the extremity of it became crustified, and formed those hard stones which the people call *sciari*, and which resembled huge cakes of sea-coal strongly ignited. The lava thus proceeded to the sea, when the conflict between the two elements occasioned a noise more dreadful than the loudest thunder, which was heard to a great distance; the water retired before it, the fish on the coast were destroyed, the transparency of the waters was lost for several months; and the clouds or vapours that ascended from it darkened the sun. The fire, say these gentlemen, spread about three miles in breadth, and 17 miles in length. When they attempted to go up to the mouth, whence the lava issued, they could not advance nearer to it than a furlong, but they should be overwhelmed by a pillar of ashes, which seemed to them to exceed twice the bulk of the steeple of St. Paul's church in London, and to ascend into the air to a much greater height. From the mouth proceeded a loud noise, like the beating of billows against rocks, or distant thunder, which was at intervals so violent as to be heard 60 or even 100 miles off; and so far were the ashes carried. The hole whence the lava issued was about ten feet in diameter. Sir William Hamilton informs us, that the lava, on which there were no signs of vegetation in 1769, is 14 miles in length, and in many parts six in breadth, and that after destroying many hundred monuments in Catania it ran far into the sea, forming a safe harbour, which was soon after filled up by a fresh torrent of the same inflamed matter.

The eruption of 1682 produced a burning gulf on the top of the mountain, and its lava was diffused over the hill of *Mazzarra*. In 1686 a quantity of this ignited matter was thrown off from the summit of the mountain, and after consuming woods, vineyards, and crops of grain through the extent of four leagues, its course was stopped in a valley near the castle of *Majoli*. Several people, whose curiosity led them to watch the progress of the lava on a hill between the wood of Catania and the confines of *Cirita* were buried under the hill which suddenly sunk inwards.

After a long interval of rest, the eruptions of *Ætna* were renewed in 1755, when a prodigious torrent of boiling water issued from the great crater. The discharge of water was preceded by smoke and flames, subterraneous noise and convulsions of the earth, the usual signs of an approaching eruption; at length the torrent burst forth, and formed tremendous cataracts in descending from one chain of rocks to another, till it reached the cultivated plains, which it overspread for many miles; and after separating into several deep and rapid rivers, it discharged itself into the sea. The ravages of this inundation, on account of both the quantity and the heat of the water, were very extensively injurious; and though the mountain continued to throw up water only for half an

hour, it produced not only alarm but very considerable damage wherever it flowed. When the discharge of water ceased, the noise, smoke, and convulsions were continued; and there appeared two new chasms, from which two torrents of lava issued, and pursued their course through the snow, which covered the summit of the mountain. The discharge of water was followed in five days by an explosion of small stones and sand, some of which were carried as far as the hills of *Mascali*; and the black sand was driven to *Messina*, and even over the strait to *Reggio* in Calabria. Some of the sand was conveyed, by the shifting of the wind, to the plains of *Agolla*. In two days the mountain opened again, and discharged a torrent of lava which moved towards the plain, at the rate of a mile a day, and continued for six days.

Recupero examined the course of the torrent of water above mentioned. He found that it proceeded from the bowels of the mountain, and pursuing a channel which it formed from the summit to the sea, it gained accession from the melted snow; and in its progress destroyed a large forest of trees, which were torn up by the violence of the current, though some of them were not less than two and two and a half feet in diameter. The main torrent divided into four principal streams, and these again separated into smaller currents; but afterwards reuniting, they formed islands, and larger rivers, about 900 feet wide, and of a depth which could not be easily ascertained. The channel of the waters, in their farther descent, was alternately contracted and dilated; and in some places it was not less than 1500 feet. Fragments of lava, and huge rocks, were removed by the current, and valleys were filled up by the sand which the waters deposited. When Recupero visited the mountain, after an interval of ten years from the eruption, the whole side of the hill bore the marks of the deluge. In 1763 there was an eruption, which continued with intermissions for three months. From the crater, opened on this occasion, a pyramid of fire issued; which ascended to a great height in the air, and exhibited an artificial fire-work, attended with the explosion of a formidable battery, which shook the earth under those who were spectators of the scene. The lava that flowed from the crater yielded a very brilliant light, retained its heat, and exhaled its smoke for two years; nor did any snow appear on the summit of *Ætna* for five years. In 1764, a new crater was opened at a considerable distance from *Ætna*; and in 1766 another was opened at the grotto of *Paterno*, which formed a mountain that after an interval of four years discharged great quantities of smoke, with loud explosions. In this interval the lava was not cooled, nor was the fire extinguished. Its fury was spent on a beautiful forest, which it laid waste, to the extent of many miles. In 1780, the convulsions of the mountain were often renewed, and several new craters were formed; and from these flowed streams of lava, which moved with different velocities, and in various directions. The most considerable of these flowed from a crater on Mount *Frumento* on the summit of *Ætna*; and flowing in a stream about 200 paces in breadth, at the rate of about a mile in a day, spread through the valley of *Landunza*. From another crater red hot stones were projected, and a current of lava was discharged, which flowed over a tract of country two miles in extent.

The next eruption of *Ætna* happened in July, 1787, and has been accurately described by *Gioeni*, in an account of it printed at Catania in the same year, of which we have a French translation, by *M. Dolomieu*, at the close of his *Catalogue Raisonné*. It was preceded by the usual signs of an approaching eruption for several days, *i. e.* from the 1st

to the 17th of July, when the lava flowed from the hinder part of one of the two mountains that form the double head of Ætna. On the next day, after renewed shocks and the appearance of a thick smoke, a shower of fine black brilliant sand descended: on the east side there was a fall of stones; and at the foot of the mountain a deluge of flashes of fire, scorix, and lava. In the evening conical flames appeared alternately to rise and fall from the volcano; at three the next morning the mountain seemed to be cleft, and the summit was a burning mass. Two of the conical flames, viz. one on the north and another on the south, were of an immense extent; where these separated, another cone of flame, composed of many smaller ones, appeared to ascend above the mountain over a base of about a mile and a half in diameter to a height supposed to be about two miles. This cone was covered with a thick smoke, in which were seen very brilliant flashes of lightning; a phenomenon which had not been observed in other eruptions. Sounds resembling the explosions of a large cannon were also occasionally heard. From the cone, as from a fountain, there was perceived a jet of many flaming volcanic matters, which were thrown to the distance of six or seven miles; and from the base of the cone there issued a thick smoke, which darkened parts of the flame, at the time when the rivers of lava were discharged. This beautiful appearance continued for three quarters of an hour. It began the next night with greater force, but lasted only for half an hour. In the intervals Ætna continued to throw out flames, smoke, ignited stones, and showers of sand. From the 20th to the 22d, the appearances gradually ceased. The stream of lava flowed towards Bronte and the plain of Lago. After the eruption, the western side of the top of the mountain was covered with hardened lava, scorix, and stones. The travellers were annoyed by smoke, showers of sand, mephitic vapours, and excessive heat. The lava that proceeded from the western point was observed to separate into two branches, one of which was directed towards Libeccio, and the other, already mentioned, towards the plain of Lago.

The lava on the western head of the mountain had been evidently in a state of fusion; and from one of the spiracula, the odour was that of liver of sulphur. The thermometer in descending was at 40° of Fahrenheit's scale; but near the lava, on the plain of Lago, it was 140°. The lava extended two miles; its breadth was from 13½ to 21 feet, and its depth 13½ feet. There was another eruption in October, 1787; the effects of which are described by the Abbè Spallanzani. The stream of lava that issued on this occasion, from the great crater, was three miles in length; its breadth was in some places about a quarter of a mile, and in others one third, and in other parts still greater: its greatest depth was about 18 feet, and the least six. Its course was along the west side of the mountain; and the effervescence that produced it was, like that of July, extremely violent. The scorix were like that of the torrent in July of a black colour; but differed from them in their adhesion to the lava, in their external vitreous appearance, their greater weight, and their hardness, which was such as to yield sparks with steel, almost as plentifully as flints. These differences are ascribed to accidental combinations of the same substance; the constituent principles of both these scorix being the same. Both contained the same felspar lamellæ. For other particulars, relating to the causes and products of volcanic eruptions, see **BASALTES**, **LAVA**, **POZZOLANO**, and **VOLCANO**. For the places adjacent to Ætna, see **CATANIA**, **CYCLOPS**, **HYBLA**, and **TRIZZA**.

ÆTNA, a name given to a city of Sicily, founded by Hiero of Syracuse, in the 1st year of the 76th Olympiad,

on the ruins of Catania; which was dispossessed of its primitive inhabitants. After the death of Hiero, the Catanians returned, expelled the new occupiers, and destroyed the sepulchre of the Syracusan monarch. The Ætneans retired to *Imessa*, or *Enessa*, which was the name given to mount Ætna, and which was distant about 80 stadia from Catania, called it Ætna, and announced Hiero to be its founder. Diodorus says, that Dionysius of Syracuse persuaded the inhabitants of Catania to remove to Ætna, because it was a fortified town. Authors are now hardly agreed about the situation of Ætna. Strabo, tom. i. p. 412. Diod. Sic. l. ii. c. 76. tom. i. p. 461. l. xiv. p. 644, &c. Thucyd. Annales. p. 31. Ed. Weffeling.

ÆTNA salt, *sal Ætne*, a name given by some authors to the *sal ammoniac*, which is found on the surface and sides of the openings of Ætna, and other burning mountains after their eruptions; and sometimes on the surface of the ferruginous matter which they throw out. This salt makes a very various appearance in many cases; it is sometimes found in large and thick cakes, sometimes only in form of a thin powder, scattered over the surface of the earth and stones. Some of this salt is yellow, some white, and some greenish.

This salt is a concrete of nitre, sulphur, and vitriol, burnt and sublimed together. Borelli found once a vast quantity of this salt on mount Ætna, and tried many experiments on it; from whence he concluded, that this salt is so far from occasioning the explosions of the mountain, as some have supposed, that it does not exist in it, but is formed during the burning. Phil. Trans. N° 100.

ÆTOLIA, in *Ancient Geography*, a province of Greece, which formerly comprehended the country now called the *Despotat*, or *little Greece*, was parted on the east by the river Evenus, now the Fidari, from the Locrenses Ozolæ, and on the west from Acamania by the Achelous; and on the north it bordered upon the country of the Dorians and part of Epirus, and on the south extended to the bay of Corinth. Its utmost extent from north to south was about 48 miles; and from east to west its greatest breadth was somewhat above 20 miles. According to Strabo (l. x. tom. ii. p. 691) it was customary to divide Ætolia into two districts, the one called the ancient Ætolia, which lay between the rivers Achelous and Calydon on the Evenus, and which was a level and fruitful country, and the other denominated *επικτητος* or the acquired, which was contiguous to the Locrians, towards Naupactus and Eupalium, and extended northwards towards the mountain Oeta, and which was more craggy and barren. He also informs us (tom. i. p. 548, tom. ii. p. 711.) that it derived its name from Ætolus, the son of Endymion, who being compelled to leave Elis, removed to this country, and founded several cities in it; of which the principal were Thermus, Calydon, and Pleuron. Their only sea-port was Oenias on the Corinthian bay. Of their kings, who succeeded Ætolus, little more is known than their names. It does not appear by whom it was inhabited before Ætolus took possession of it; and its subsequent history for several ages is very obscure and doubtful. Thucydides (l. i. p. 5. Ed. Duker.) Plutarch, (in Theseo) Strabo, and other ancient writers represent the Ætolians, as the greatest robbers in Greece, and as continuing such for many centuries, after Hercules, Theseus, and other heroes, had extirpated those banditti every where else; to them Strabo ascribes the invention of the sling. Livy (l. xxxvi. tom. iv. p. 1040.) describes them as a proud, arrogant, and ungrateful people, but as good warriors; and they are said to have fought with one shoe, whence the epithet *μονοσχοπιδης* has been

been applied to them. Polybius (Megal. Hist. l. iv. passim p. 270, &c. Ed. Casaubon.) speaks of them as a turbulent people; seldom at peace among themselves, and generally at war with their neighbours; utter strangers to all sense of friendship, or principles of honour; ready to betray their friends whenever they had the least prospect of deriving any advantage from their treachery; and, in short, as persons who were regarded by the other states of Greece as outlaws and public robbers. In war, however, they were bold and enterprising; inured to hardship and labour; and jealous of their liberties, in defence of which they were ready to sacrifice their lives.

The constitution of the Ætolian republic was formed in imitation of that of the Achæans, and with a view of counteracting their growing power. It was governed by a general assembly, a prætor, and other magistrates of inferior rank and authority. The general assembly usually met once a year, and on extraordinary occasions it was summoned by the prætor more frequently; and this national council possessed the whole power of enacting laws, declaring war, making peace, and concluding alliances with other states. Each city of the Ætolian alliance deputed members, composing a council which was called the Apocleti, and which consisted of the most eminent men of the nation, whose office resembled that of the demurgi among the Achæans. Their chief magistrates, in subordination to the prætor, were the general of the horse, the public secretary, and the ephori. The republic of Ætolia, thus formed and governed, distinguished itself above all the other nations of Greece, in opposing the ambitious designs of the Macedonian princes. Having kindled the Cleomenic war, and that of the allies, called the Social war, in the heart of Peloponnesus, with a view of humbling their antagonists the Achæans, they resisted for three years, with the assistance of the Eleans and Lacedæmonians, the united forces of Achæa and Macedon; but they were at last obliged to purchase a peace by surrendering to Philip the whole of Acarnania. But as they gave it up with reluctance, they were anxious to seize the first favourable opportunity that occurred for regaining it. With this view they concluded an alliance with the Romans, Ante Christ. 211; which was ratified two years after it was formed, by both nations. The articles of which it consisted were ordered by the senate to be deposited in the capitol, as a lasting monument of their first alliance with the Greek nation. Hostilities, however, immediately commenced, as soon as the treaty was concluded. Whilst the forces of Philip were employed in Macedon, the Ætolians entered Acarnania; where they found a very determined and vigorous opposition. Notwithstanding the assistance which they were likely to derive from Lævinus, the Roman General, who had projected the alliance with them, they were intimidated by the resolution of the Acarnanians, and returned home without attempting to provoke a people who had declared their purpose either to conquer or die. Diverted from prosecuting their first design, they turned their arms against Anticyra, a city of the Loeri, and aided by the Romans, compelled it to surrender. This success encouraged them to march into Achaia, and to oppose the forces of Philip. The hostile armies met near Lamia, a city of Phthiotis, where the Ætolians were twice defeated. After this victory Philip was prevailed upon by an embassy from Ptolemy Philopater, king of Egypt, and by deputies from the islands of Chios and Rhodes, and the city of Athens, to grant the Ætolians a truce of thirty days, and to enter into a negotiation for peace. Polybius has preserved (l. xi. c. 4. p. 626) one of the speeches which was delivered on this occasion, and

which may be considered as a master-piece of the kind. The negotiation, however, proved unsuccessful; and the war was renewed with considerable, though temporary, advantage on the part of the Ætolians and their confederates. During the absence of Philip, they possessed themselves of several cities: but upon his return, being abandoned by the Romans, they were under a necessity of concluding a peace upon very unfavourable terms, Ante Christ. 204. This peace was of short duration. An extraordinary diet was held at Naupactus, in which the friendship and alliance of the Ætolians were solicited by Philip, and also by the two powerful republics of Athens and Rome. The Romans, however, prevailed (Ante Christ. 201), and the Ætolians, after some previous conquests, entered Thessaly, where they were met by Philip, and, after a considerable slaughter, totally routed. Next year they rallied again, and re-entered Thessaly, plundering and destroying wherever they came, and either putting the inhabitants to the sword, or selling them for slaves to the best bidder. The Ætolians maintained their attachment to the Romans during the course of the war, and were favoured by the Roman commanders above the other nations of Greece; but after the battle of Cynocephalæ, in which Philip was entirely defeated, their mutual affection abated. The Ætolians arrogated to themselves the glory of this victory; and Flaminius, the Roman general, mortified their vanity and excited their resentment, by granting a truce to the deputies of Philip without consulting them. When a negotiation for peace between Philip and the Romans commenced, the Ætolians obstructed it; and it was concluded Ante Christ. 196, without their concurrence. Dissatisfied with the conduct of the Romans on this occasion, they meditated revenge, and exerted themselves in raising new enemies against their former allies. They made their first attempt in the assembly of the Amphyctons, but failing here, they had recourse to Antiochus king of Syria, Nabis tyrant of Lacedæmon, and even to Philip king of Macedon. They were immediately joined by Nabis; and having concerted a plan for seizing on three cities, which were reckoned the bulwarks of Greece, viz. Chalcis in Eubœa, Demetrias in Thessaly, and Lacedæmon in the center of Peloponnesus, they proceeded to the execution of it. Having succeeded by stratagem in gaining possession of Demetrias, Antiochus, who had declared in their favour, determined to land in this place; and in the year (Ante Christ. 192) he arrived in Greece; and in a diet held at Lamia, he was honoured with the title of generalissimo, or commander in chief of all the Greek armies against Rome. The king of Syria having gained possession of Chalcis, was joined by several of the Greek states, who renounced their alliance with Rome: but Chalcis in the event proved no less fatal to Antiochus than Capua had been to Hannibal. During his residence in this city he formed a connection with the daughter of Cleoptoïemus, one of the chief citizens, and married her. Such was the ardour of his attachment to the new queen, that he seemed to forget Rome, Greece and Syria. The king spent the winter in feasting and rejoicings; his example infected the officers of his army; the soldiers abandoned themselves to idleness and debauchery; and mutiny and disorder universally prevailed. The Romans availed themselves of these circumstances; and in the year Ante Christ. 191, declared war against him, and dispatched a powerful army into Greece. The Ætolians could afford him little assistance; nor was he able to stay the progress of the Roman army, till they compelled him to take refuge first in Chalcis, and afterwards to set sail for Asia and retire to Ephesus. The Ætolians were strongly fortified

fortified at Heraclea; although their number amounted only to 2000, they held out 40 days against the incessant attacks of the whole consular army under the victorious Aëlius. The town was at length taken by stratagem, and delivered up to be pillaged by the soldiers. Lamia, which had been for some time unsuccessfully besieged by Philip, surrendered to the Romans. After the lots of these two cities, the Ætolians sent ambassadors to the Roman consul, who sued for a peace; but they could merely obtain a truce of 10 days. When this truce was near expiring, the Ætolian ambassadors at Rome were admitted to an audience of the senate; and were told, that they must either submit to the will of the senate, or pay the republic a thousand talents, and make neither war nor peace with any other power, without the consent and approbation of Rome. The ambassadors hesitated in complying with these terms, and were ordered to leave Rome that day, and Italy in a fortnight. The Ætolians upon a second application obtained a truce of six months; and the consular army was withdrawn from Greece. But during the interval of negotiation they invaded the territories of Philip, and reduced several provinces, which they solicited the permission of the Romans to retain. Their ambassadors enforced their application by a false report, that the two Scipios had been made prisoners by Antiochus, and that the Roman army was entirely defeated. The senate, incensed by this artifice, dismissed the ambassadors, and forbade their return without the express consent of the generals whom the republic were about to send for carrying on the war in their country. In the year, Ante Christ. 189, the Romans began their hostile operations with the siege of Ambracia, which was feebly succoured by the Ætolians, and which they vigorously defended. The contending armies having formed two mines near the wall of the city, fought for some time under ground, first with pickaxes and spades, and then with swords and spears; and each party secured itself by making a kind of rampart with the loose earth. The Ætolians on this occasion invented a singular kind of machine, in order to drive the enemy out of the mine: this was a hollow vessel, with an iron bottom, bored with holes and armed with spikes for preventing the approach of the enemy. They filled this vessel with feathers, and having brought it to the place where the two mines met, they set the feathers on fire; and by driving with bellows the smoke on the besiegers obliged them to quit the mine; and by this stratagem they gained time for repairing the foundations of the walls. The siege, however, was continued, and Ambracia was under a necessity of capitulating. After this event, the Ætolians sent ambassadors to Rome; and their application being enforced by the concurrence of the Rhodians and Athenians, and also of Valerius, who was brother to the consul Fulvius, and the son of Lævinus, who formed the first treaty of alliance between Rome and Ætolia, a peace was concluded on the following terms.—1. The majesty of the Roman people shall be revered in all Ætolia. 2. Ætolia shall not suffer the armies of those who are at war with Rome to pass through her territories, and the enemies of Rome shall likewise be enemies of Ætolia. 3. She shall in 100 days deliver to the magistrates of Corcyra all prisoners and deserters, both of the Romans and their allies, except those who have been taken twice, or during her alliance with Rome. 4. The Ætolians shall pay to the Roman general in Ætolia 200 Euboic talents, of the same value with that of the Athenian talents, and engage to pay 50 talents more within six years. 5. They shall deliver to the consul 40 hostages of his choice, none of whom shall

be under 12 or above 40 years of age; the prætor, general of the horse, and those who had been already hostages at Rome, excepted. 6. Ætolia shall renounce all pretensions to the cities and territories which the Romans have conquered since the consulate of Flaminius, though they had formerly belonged to the Ætolians. 7. The city of Oenias and its districts, shall continue subject to the Acarnanians. 8. Cephallenia shall not be included in this treaty. Severe as these terms were, the Ætolian republic was reduced to a much worse condition after the conquest of Macedonia by Paulus Æmilius; for those who had openly declared for Perseus, and others who had secretly favoured him, were sent to Rome, and there detained, so that they were never allowed to return to their native country. Five hundred and fifty of the chief persons of the nation were barbarously assassinated by the partisans of Rome under a suspicion of wishing well to Perseus; and though the Ætolians appeared in mourning habits before Paulus Æmilius, and complained of this inhuman treatment, they obtained no redress. From this time none were advanced to stations of honour or office in Ætolia, but those who were known to prefer the interest of Rome to that of their own country. In this state of humiliating subjection did the Ætolians continue till the destruction of Corinth, and the dissolution of the Achæan league, when Ætolia, with the other free states of Greece, was reduced to a Roman province, commonly called the province of Achaia. Nevertheless, each state and city were governed by their own laws, under the superintendency of the prætor, who was sent annually from Rome into Achaia. The whole nation paid a stipulated tribute, and the rich were prohibited from possessing lands any where except in their own country. Livy, l. 26.—27.—31.—32.—33.—35.—36.—37.—38.—39. tom. iii. iv. v. Ed. Drakenb. Polybius Hist. l. 2. 4.—9.—10.—11.—17. pp. 91.—272.—560.—596.—626.—743. Excerpt. Legat. pp. 788.—796.—802.—806.—825.—828. Ed. Casaub. Pausanias in Achaic. p. 521, &c. Ed. Kuhnii.

In this state, with little alteration, Ætolia continued under the emperors, till the reign of Constantine the Great, who, in his new partition of the provinces of the empire, divided the Western parts of Greece from the rest, calling them new Epirus, and subjecting the whole country to the *præfectus prætorii* of Illyricum. Under the successors of Constantine, Greece was divided into several principalities, especially after the taking of Constantinople by the western princes. At that time, Theodorus Angelus, a noble Grecian, of the Imperial family, seized on Ætolia and Epirus. The former he left to Michael his son, who maintained it against Michael Paleologus, the first emperor of the Greeks, after the expulsion of the Latins. Charles, the last prince of this family, dying in 1430, without lawful issue, bequeathed Ætolia to his brother's son, named also Charles, and ACARNANIA to his natural sons, Memnon, Turnus, and Hercules. But great disputes arising about this division, Amurath II. after the reduction of Theflalonica, seized so favourable an opportunity, and expelled them all in 1432. The Mahometans were afterwards dispossessed of this country by the famous prince of Epirus, George Castriot, commonly called Scanderbeg, who, with a small army, opposed the whole power of the Ottoman empire, having defeated those barbarians in 22 pitched battles. This hero, at his death, left great part of Ætolia to the Venetians; but they not being able to oppose such a formidable power, the whole country was soon reduced by Mahomed II, whose successors still possess it. Anc. Un. Hist. vol. vi. 155—205. 8vo.

ÆTOLIA, an ancient town of the Peloponnesus, placed by Steph. Byzant. in Laconia.

ÆTORCHECUM, a promontory of Bithynia.

ÆTUATES, a people of Helvetia, upon the frontiers of Rhætia, towards the sources of the Rhine.

ÆTULANA, a country of Armenia Minor.

ÆTYMANDRI, a people of Asia.

ÆVSKAIA, in *Geography*, a town of Siberia, situated on the Irtilh; 20 leagues north-west of Tara.

ÆX, the name of one of the nurses of Jupiter, who was placed among the stars.

ÆXONA, a borough of Attica, dependent upon the tribe of Cæropides. The inhabitants were so much addicted to calumny, that *αἰξωνοειδης* was used proverbially for speaking evil of another.

ÆXONIA, was also the name of a city of Magnesia in Thessaly. Stephan. Byz.

ÆZALA, a town of the greater Armenia in Asia.

ÆZANIS, a town of the greater Phrygia in Asia.

ÆZARI, an ancient people of Africa, who gave name to a canton of Marmarica.

ÆZICA, a country of Thrace.

AFDELLES, in *Ichthyology*, a name given by the Cretans to the fish called at Rome, *donzellina* and *zigurella*. See **JULIS**.

AFER, *Constantinus*, in *Biography*. See **CONSTANTINUS**.

AFER, *Domitius*, a celebrated orator, was born at Nîsnes, in Gaul, in the year before Christ 15 or 16, and lived under Tiberius, and the three succeeding emperors. After his advancement to the office of prætor, his ambition led him to aspire after higher honours; and with this view, preferring fame to virtue, he exercised his talents as an accuser. Claudia Pulchra, the cousin of Agrippina, was the first object of his attack; and by charging her with adultery, witchcraft and magical operations against the emperor, he recommended himself to Tiberius, who had conceived an invincible detestation of Agrippina. Agrippina, however, much as she must have resented his conduct, treated him with the contempt he deserved; for when she accidentally met with him after the impeachment of Claudia, and he was endeavouring to avoid her, the pertinently applied to him the passage in Homer (Il. *æ.* 335.)

Οὐκ ἔμεν ἐμῶν ἐπιπέποι, ἀλλ' Ἀγαμέμνων.

"It is not of you, it is of Agamemnon I complain:"

Thus intimating her disdain of him, who was the mere minister of an injustice that proceeded from a higher power. Afer next year directed his accusation against Quintilius Varus, the son of Claudia; in which he was aided by P. Dolabella, who was a man of birth and the relation of Varus. Finding this practice to be a source of wealth and honours, at the degenerate period in which he lived, he adhered to it through life, and incurred the contempt even of his admirers, by persisting in it when his faculties were impaired by age, and the decay of his powers eclipsed the fame of his former eloquence. His advancement at this period depended on his talents for flattery, as well as on those by which he was distinguished as a public speaker. Having erected a statue to Caligula, he introduced into the inscription a record, which he undoubtedly designed as an expression of respect, that the emperor was a second time consul at the age of 27 years. Caligula interpreted the compliment as a censure upon him for violating the law, and as a reproach of his youth; and pronounced a vehement oration against him in the senate. Afer, instead of making any reply in his own vindication, professed the highest admiration of the emperor's eloquence, and re-

peated the greatest part of his speech in strains of rapture. By this seasonable artifice he not only obtained a pardon, but induced the emperor to dispossess the consuls of their office, and by this act of injustice to make way for the advancement of Afer.

This orator died in the reign of Nero, A. D. 59, in consequence, as it is said, of eating to excess. Quinctilian assiduously cultivated the friendship of Afer, and was in his youth a constant attendant on his pleadings. Of his eloquence he speaks in terms of high commendation, as distinguished by art and vanity, intiling him to rank among the first orators of Rome. According to his account, Afer often introduced pleasant stories and strokes of wit in his pleadings; and collections were made of his jests. He discouraged and condemned the prevailing practice of vociferous applause; and being repeatedly interrupted whilst he was pleading slowly and gravely before the Centumviri, he paused, and addressing the judges, observed, "Gentlemen, our profession is ruined." Afer, however, exposed himself to ridicule, by continuing to plead under the infirmities and decays of advanced life: some, says Quinctilian, laughed, others were ashamed; and he observes that Afer incurred the reproach, "*Malle eum desicere, quam desinere;*" or, "that he had rather fail than finish:" and he grounds on his conduct a recommendation to orators to withdraw, when age incapacitates them for maintaining their former reputation. The orator, he says, in order to prevent falling into these snares of old age, should find a retreat, and come into port with a sound vessel. Tacitus, Annal. l. iv. c. 66. tom. i. p. 517. l. xiv. c. 19. tom. i. p. 935. Ed. Gronov. Dion Cassius, Hist. Rom. tom. ii. p. 922. Ed. Reimar. Quinctilian, Inst. l. v. c. 7. tom. i. p. 378. l. vi. c. 3. p. 535. l. x. c. 1. p. 918. l. xii. c. 11. tom. ii. p. 1107. Ed. Burman. Pliny, Epist. li. p. 14.

AFFA, a weight used on the gold coast of Guinea. It is equal to an ounce, and the half of it is called *eggeba*. Most of the blacks on the gold coast give these names to those weights.

AFFACUS, in *Geography*, a town on the Barbary shore, eight leagues south-east from **AFRICA**.

AFFANG, a town of the archduchy of Austria, three leagues west of Steyr.

AFFAR, a town of Arabia Felix; 14 German miles east of Loheia.

AFFATOMIA, in *Ancient Law*, a kind of donation made by thrusting a wand into the person's bosom, to whom it was made. Du-Cange.

AFFECTED, in *Algebra*. See **ADFFECTED**.

AFFECTIO bovina, is a disease incident to cattle, occasioned by a little worm, bred between the flesh and the skin; which works its way over all parts of the body.

AFFECTION, in a general sense, denotes an **ATTRIBUTE** peculiar to some subject, and arising from the very idea or essence of it.

The word is formed from *afficere*, to *affect*; the **SUBJECT** being here supposed in some measure *affected*, or acted on, by the thing attributed to it.

In this sense, *affection* is synonymous with *property*, or with what the schoolmen call *proprium quarto modo*.

Philosophers are divided as to the doctrine and division of affections: according to Aristotle, they are either *subordinating*, or *subordinated*; under the first of which comes only *mode*; and under the second, *limiteness*, *place*, and *time*. The generality of Peripatetics divide affections into *internal*, as motion and limiteness; and *external*, as place and time. According to Sperslingius, affections are better divided into *simple* or *united*, and *disjunct* or *separate*: under the first he comprehends

comprehends *quantity, quality, place, and time*; under the second, *motion, and rest*.

Affections are also distinguished into those of *body*, and those of *mind*.

Affections of *body*, are certain modifications of it; occasioned or induced by motion; in virtue of which, a body comes to be so and so disposed.

The affections of *body* are sometimes subdivided into *primary* and *secondary*.

Affections, *primary*, are those which arise either from the idea of matter, as quantity and figure; or from that of form, as quality and power; or both together, as motion, place, and time.

Affections, *secondary, or derivative*, are those which arise from some of the primary; *e. gr.* from quantity, as divisibility, continuity, contiguity, finity, impenetrability; from *figure*, as regularity and irregularity; from *quality*, as health, strength, &c.

The epithet *mechanical* is applied to those affections that are properties of matter, resulting from its figure, bulk or motion.

Affections of *mind*, are what we more usually call *PASSIONS*.

Dr. Cogan, in his Philosophical Treatise on the Passions, very properly distinguishes between affection and passion; and he accurately discriminates between both these terms, and that feeling, which is usually denominated *EMOTION*. The term affection, he says, has a different signification from either of the other two, and represents a less violent, and generally a more durable influence, which things have upon the mind. It is applicable to the manner in which we are affected by them for a continuance; and supposes a more deliberate predilection and aversion, in consequence of the permanent influence of some prevailing quality. This distinguishes it from the transient impulse of passion; nor is it so intimately connected with any external signs, which distinguishes it from *emotions*. The affections sometimes succeed to passions and emotions, because these may have been excited by something that becomes permanently interesting; or they may be gradually inspired, by a deliberate attention to the good or bad qualities of their objects. In this philosophic sense of the word, affection is applicable to an unpleasant as well as pleasant state of the mind, when impressed by any object or quality; it may be produced by any thing that torments or corrodes the heart, as well as by that which charms and delights it. Custom, however, chiefly appropriates the term to the kindly and benevolent affections.

In the same manner Dr. Reid (Essays, p. 143. 167.) has applied the general name of affections to those various principles of action in man, which have persons for their immediate object, and which imply, in their very nature, our being well or ill-affected to some person, or at least, to some animated being: and whether they dispose us to do good or hurt to others. He observes, however, that the word affection seems, by custom, to be limited to good affections. Accordingly, when we speak of having affection for any person, it is always understood to be a benevolent affection. In the extensive sense above stated, our affections are very naturally divided into benevolent and malevolent, as they respectively imply our being well or ill affected towards their object. The characters of love and hatred, resulting from the infinitely various situations and circumstances upon which their development and operations depend, entitle them to the denomination of *primary or cardinal affections*.

Our benevolent affections, whilst they differ in the feel-

ing, or sensation, which is a common ingredient in all of them, and in the objects to which they are directed, agree in these two respects, *viz.* that the feeling which accompanies them is agreeable, and that they imply a desire of happiness to their object. The first of these affections is that of parents and children, and other near relations, commonly called *natural affections*: the second, is *GRATITUDE* to benefactors: the third, is *PIETY* and *COMPASSION* towards the distressed: a fourth is *ESTEEM* of the wise and good: the fifth is *FRIENDSHIP*: the sixth, is *LOVE* between the sexes: and the last, is *PATRIOTISM* or public spirit; that is, an affection to any community to which we belong.

The *malevolent affections*, commonly called *PASSIONS*, in the arrangement of Dr. Reid, are *EMULATION* and *RESENTMENT*. For the difference between affection and disposition; See *DISPOSITION*.

Affection, in *Geometry*, is synonymous with property.

Affection, in *Medicine*, denotes a morbid, or preternatural state of the body, or some of its parts. Thus we say, an *HYPOCHONDRIACAL*, an *HYSTERICAL* affection; and, in like manner, such a part of the body is affected, *i. e.* indisposed, or seized with a *DISEASE*.

AFFEERORS, AFFERATORES, in *Law*, persons appointed in court-leets, and courts-baron, upon oath, to settle and moderate the *FINES* of such as have committed faults arbitrarily punishable, or which have no express penalty set down by statute. See stat. 25 Edw. III. c. 7.

The word is formed, according to Cowel, of the French *affier, to affirm*; by reason those appointed to this office do affirm, upon their oaths, what penalty they think, in conscience, the offender hath deserved. Others better derive it from *affeurer*, a word in the customary of Normandy, rendered by the Latin interpreters, *taxare, to set the price of a thing*; as *affimare, indicare, &c.*—Kitchin joins the three words as *synonyma*; *affidati, amerciatores, afferores*.

AFFENTHAL, in *Geography*, a valley of Suabia in the Ortenaw, near Straßburg, famous for its excellent wines.

AFFERI, in *Law*. See *AVERIA*.

AFFETTUOSO, or *Con AFFETTO*, in the *Italian Music*, is used to denote that kind of music, which must be performed in a very tender, moving, and affecting manner; and for that reason rather slow than fast. This term, placed at the beginning of a musical air, implies, in point of time, a movement between *andante* and *largo*; and requires a sweet and affecting expression of the melody.

AFFIANCE, in *Law*, the plighting of troth between a man and woman, upon an agreement in marriage to be had between them.

AFFIDATIO Dominorum, signifies an oath taken by the lords in parliament: thus called in the Rot. Parl. Hen. VI.

AFFIDATUS, or *AFFIDIATUS*, in our *Law Books*, denotes a tenant by *FEALTY*.

Affidati are not properly vassals, but *quasi* vassals, or persons who vow fealty to, and put themselves under the protection of, another.

In this sense they amount to the same with what are otherwise called *commendati*, and *recommendoti*.

AFFIDAVIT, an *OATH* in writing, sworn before some person who hath authority to take such oath; and, made use of, and read in court, upon motions; though not allowed upon trials.

In the court of Chancery is an *Affidavit-office*, under the direction of a *Master of CHANCERY*.

AFFILA, in *Ancient Geography*, a district of Italy belonging to the *Hernici*.

AFFILIANUS

AFFILIANUS *mons*, a mountain of Italy, near the Tiber. The colony *Æsula* was at the foot of this mountain.

AFFILIATION, *ADFIATIO*, in *Middle Age Writers*, the same with **ADOPTION**. See also **ADFIATION**.

Among the ancient Gauls, affiliation was a sort of adoption only practised among the great.—It was performed with military ceremonies: the father presented a battle-axe to the person he was to adopt for his son, as an intimation that he was to preferre the effects he thus called him to succeed to, by arms.

AFFINAGE is sometimes used, in *Ancient Law Books*, for the refining of metals.

AFFINITY properly imports a relation contracted between one of two parties married, and the kindred of the other party.

The word is originally Latin, compounded of *ad, to*, and *finis, boundary, limit*; by reason, as the lawyers say, that one of the families here approaches to the bounds of the other. *Quod due cognationes per nuptias copulantur, & altera ad alterius cognationes finem accedit*. Or, as another expresses it, *Quod utriusque cognationis fines in unum locum conferuntur*.

In which sense the word stands contradistinguished from *consanguinity*, which is a relation by blood.

Affinity does not found any real kinship; it is no more than a kind of fiction, introduced on account of the close relation between husband and wife. It is even said to cease, when the cause of it ceases. Hence a woman who is not capable of being a witness for her husband's brother, during his life-time, is allowed for a witness, when a widow, by reason the affinity is dissolved. Yet, with regard to the contracting marriage, affinity is not dissolved by death, though it be in every thing else.

In the Mosaic law there are several degrees of affinity, wherein **MARRIAGE** is expressly prohibited, which yet seem not at all prohibited by the law of nature.

Thus (see Lev. xviii. 7, &c.) a son could not marry his mother, nor his father's second wife: a brother could not marry his sister, either by the father only or by the mother only, much less if related to him both by father and mother; a grandfather could not marry his grand-daughter; no one could marry the daughter of his father's wife, nor the sister of his father or mother; nor the uncle his niece, nor the aunt her nephew; nor the nephew the wife of his uncle by the father's side: a father-in-law could not marry his daughter-in-law; nor a brother the wife of his brother, while living, nor after the death of that brother, if he left children; if he left no children, the living brother was to raise up children to his deceased brother, by marrying his widow: it was forbidden to marry a mother and her daughter at one time, or the daughter of the mother's son, or the daughter of her daughter, or two sisters together. The patriarchs, indeed, before the law, sometimes married their half-sisters, as Abraham married Sarah, his father's daughter by another mother; or two sisters together, as Jacob married Rachel and Leah; but these cases are not examples, because they might then plead necessity or custom, and the prohibitory law as not existing. If other instances occur before or since the law, the Scripture expressly disapproves of them, as Reuben's incest with Bilhah, his father's concubine, and the connection of Ammon with his sister Tamar; and that of Herod Antipas with Herodias, his sister-in-law, or his brother Philip's wife, while her husband was living, and that which St. Paul reproves among the Corinthians, 2 Cor. v. Calmet.

The *Canonists* distinguish three species of affinity.—The first, that contracted between the husband and the relations

by blood of his wife; and between the wife and the relations by blood of her husband.

The second, between the husband and those related to his wife by marriage; and the wife, and those so related to her husband.

The third, between the husband and the relations of his wife's relations; and the wife, and the relations of her husband's relations.

By the fourth council of Lateran, held in 1213, it was decreed, that none but the first kind was any real affinity; the rest being mere refinements, which ought to be set aside.

The degrees are reckoned after the same manner in affinity as in **CONSANGUINITY**; and therefore differently in the *Canon Law* from what they are in the *Civil Law*.

Whatever line or degree of consanguinity the kindred of one of the parties married are in, they are in the same line and degree of affinity to the other. And again, in whatever line or degree of affinity persons are, in the first kind, they are in the same in the second and third kinds of affinity. Hence arise what we may call a direct and collateral, an ascending and a descending line of affinity.

The Romanists talk of a *spiritual* affinity, contracted by the sacrament of baptism and confirmation. In that church, a god-father may not marry with his god-daughter, without a dispensation.

The degrees and terms of affinity are chiefly, father-in-law, *i. e.* husband's or wife's father, in Latin, *soer*; step-father, *i. e.* mother's husband, *vitricus*; mother-in-law, *i. e.* husband's or wife's mother, *soera*; step-mother, *i. e.* father's wife, *noverca*; son-in-law, *gener*; daughter-in-law, *nurus*; step-daughter, *i. e.* husband's or wife's daughter by another marriage, *privigna*; step-son, *i. e.* husband's or wife's son by a former marriage, *privignus*; which two last, considered in relation to each other, are called *comprivigni*; son-in-law, *i. e.* daughter's husband; brother-in-law, *i. e.* husband's brother, or sister's husband, *levir*; wife's brother, brother's wife; sister-in-law, *i. e.* husband's or wife's sister. Calv. Lex. Jur.

AFFINITY, in the *Civil Law*, is divided into *civil*, that between free persons; and *servile*, that between slaves.

AFFINITY, *legitimate*, is that contracted by a proper and legal *matrimony*; or, between slaves, by *contubernium*.

AFFINITY, *illegitimate*, that contracted out of legal marriage.

Affinity may be contracted by an unlawful commerce: thus a person who has impregnated two sisters, is prohibited marrying either of them; thus an affinity may commence between husband and wife, by his lying with her sister.

AFFINITY, *true*, is that subsisting while the marriage between the two parties subsists.

AFFINITY, *quasi*, that subsisting either after the dissolution of the marriage, as between a husband and his wife's daughter, begot by another after her being divorced from him; or before the marriage is solemnized, as that between a father and a daughter, only espoused, or betrothed to his son.

AFFINITY is also used figuratively, for a conformity, or agreement, between one thing and another.

In which sense the word stands opposed to diversity, variety, opposition, &c.

Bishop Wilkins gives tables, wherein things are classed according to their affinities. Vide *Real Charact.* p. ii. p. 22.

Henckelius has a treatise on the affinity between *vegetables* and *minerals*.

AFFINITY is more particularly used in speaking of the relation or similitude between LANGUAGES, occasioned by their being derived from the same source.

We use also affinity of words, sounds, &c.

AFFINITY, *Affinité*, Fr. *Verwandtschaft*, Germ. *Franföslap*, Swed. *Attraction of composition*—*Elective attraction* of Bergman.

This term, which in its proper and original sense signifies a proximity of relationship, has been adopted by modern philosophers as the expression of a force purely chemical, by which substances of different natures are made to combine with each other. This particular metaphorical use of the word is not, however, of very old standing. Barchusen is probably the first who introduced it; speaking of the difficulty of obtaining chemical elements perfectly pure, he accounts for it in the following way, “*Arctam enim atque reciprocam inter se habent affinitatem.*” Boerhaave, however, contributed more than any other to bring the word into common use; thus we find in his *Elementa Chemiæ*; “*Particulæ solventes et solutæ se affinitate suæ naturæ, colligunt in corpora homogenea.*” Bergman has preferred the term *attraction*, as more conformable to the precision of scientific language; since, however, all bodies in nature attract each other, while chemical affinity exists only between particular substances, it seems upon the whole more convenient to appropriate a term to the expression of this particular force, without, however, rigorously excluding the synonymous phrase *elective attraction*, which the high authority of Bergman has introduced into the chemical nomenclature.

In treating of so important a subject as chemical affinity, it will be necessary, for the sake of clearness to divide it into six sections.

The first will contain a sketch of the progress of discoveries in affinity.

In the second the cause of affinity will be discussed.

The third will treat of single and compound affinity, and the construction of tables and schemes,

In the fourth the several methods of estimating numerically the force of affinity will be considered.

The fifth will contain the laws of affinity.

The sixth will be appropriated to the consideration of certain anomalies.

§ I. *History of Affinity.*

The general fact that all substances have not the same relative degree of affinity for each other, must have been observed as soon as the smallest attention began to be paid to chemical phenomena, and in the first rude attempts to explain the cause of this difference of force, recourse was had to the maxim of Hippocrates, *ὁμοίον ἐκχέλει πρὸς τὸ ὁμοίον, simile venit ad simile.* This doctrine of the old school we still find in Beccher, who supposed that there was a hidden principle of similitude in all substances capable of mutual chemical combination. Another sect, at the head of whom was Lemery, endeavoured to explain chemical agency by considering solvents as composed of a multitude of fine points, and thus mechanically predisposed to enter the pores and separate the particles of substances exposed to their action.

Stahl, however, rejecting the hypothesis of mere mechanical forces, attributed the power of menstrua to the attraction of contact or intimate cohesion; for, to use his own language, “*combinationes quæcumque non aliter fieri quam per arctam appositionem.*”——“*Non per modum canei, neque per modum incurfus in unam particulam separandum, sed potius per modum apprehensionis seu arctæ ap-*

plicationis.” This eminent chemist also deduced from his experiments a variety of facts and observations, tending to prove that an union once formed could not be dissolved without a more intimate union of one of its constituent parts with another substance.

It is to Geoffroy, the elder, that chemistry is indebted for the happy idea of collecting these scattered facts, and sketching the outlines of the general rules of analysis and composition. In the year 1718, he presented to the Royal Academy of Sciences at Paris the first table of affinity, or as he calls it, “*Des différens rapports observés en chymie entre différentes substances,*” (some of the different relations observed in chemistry between different substances). This table, which merits preservation, as a curious historical memorial, and the pattern of all that have appeared since, consisted of only seventeen columns very imperfectly filled, and presented rules, which for the most part have been changed or considerably modified. With all its errors, however, it is justly to be considered as the basis and guide to all our chemical knowledge: it has been enlarged and improved, but still retains its original form and essence, and as the great fabric of experimental science advances towards perfection, so will this, which is its epitome and model.

No very material improvement appears to have been made on Geoffroy's table till Cellert, the celebrated professor of Freyburg, published, in 1750, his *Chymia Metallurgica*; in this work was contained a new table of affinity extended to 28 columns, and at the bottom of each was a list of substances which he had found not to be acted on by the body placed at the head of the column. Rudiger, in 1756, inserted in his system of Chemistry a table of affinity reduced to 15 columns, in which the fixed alkalies and lime are placed parallel with each other, and before ammonia in the column of acids: he also added, in a small supplementary table, those bodies which refused to combine without the intervention of a third.

In consequence of a prize offered by the Academy of Rouen, in 1758, a very important addition was made to the table of affinities by M. Limbourg; he extended the number of columns to 33; he ascertained that zinc should be placed at the head of the metals in the column of acids, and that it precipitated them all, even by the dry way; he maintained, that lime and the fixed alkalies acted by means of affinity on animal matter; and pointed out several cases in which the order of affinities was changed by the influence of temperature or the volatility of one of the ingredients.

From this period, the importance of the subject being fully established, tables were multiplied and the general system of affinity was investigated by some of the ablest chemists of the age, among whom the names of Erxleben and Weigleb stand eminently distinguished. At length, in 1775, the illustrious Bergman published his dissertation on elective attractions, in the transactions of the Royal Society of Upsal, and successive editions of his tables made their appearance in 1779 and 1783. These tables may justly be considered as a masterpiece of skill and industry; the affinities of no less than 59 substances are ascertained with great exactness, and the distinction between those that take place in the moist and dry way is precisely stated: the method of regiltering cases of compound affinity is perfected, and 64 of the most important are added to the general stock of chemical science. Since the death of Bergman, successive impressions of his tables have appeared with little or no alteration, till Dr. Pearson's in 1799. In this, the nomenclature is changed, and in part reformed according to the French system, a few articles to be found in Bergman.

Bergman are expunged on the authority of later investigations, and the number of columns is increased to 62.

It is not, however, to the construction of tables, important as they are, that the researches of chemists on the subject of affinity have been confined. Since the discovery of the great law of attraction, by Newton, it has been the uniform endeavour of the ablest philosophers to show that the cause of chemical phenomena is only a branch or modification of this universal property of matter, and the names of Buffon, Macquer, Limbourg, and Morveau, stand conspicuous for their endeavours in this department: it is to Kirwan that we owe the able attempt to reduce the force of contending affinities to numerical calculation; and the sagacious Berthollet, in his "*Recherches sur les lois de l'affinité*," has just now opened a new field of enquiry on this most important subject.

§ II. Cause of Chemical Affinity.

There have been only two ways of accounting for chemical affinity; the one is by having recourse to a gratuitous and inexplicable principle of sympathy, and which therefore is merely the substitution of one metaphor for another; and the other is an endeavour, by the help of experiment and calculation, to shew the identity of affinity and the Newtonian attraction. The first of these, as it does not profess to be supported by any external evidence, may be passed by; the other requires a particular examination.

It was the opinion of Newton, and a very natural one in his situation, that the force of attraction which he had demonstrated to be the efficient cause of the planetary motions, of the alternation of the tides, of the descent of heavy bodies, and of the oscillation of the pendulum, was an essential property of matter, and, as such, the cause of chemical phenomena: perceiving acids to be some of the most powerful agents in the production of these effects, he hence defined them as bodies that attract strongly, and are strongly attracted ("*acidum dicimus quod multum attrahit et attrahitur*"). This however is to be considered merely as a conjecture of that great man, since no attempt was made by him to submit to calculation any cases of affinity, or even to obviate the weighty objections that might be brought against the theory. The essential foundations of the Newtonian attraction are, that the force of gravitation is in a direct ratio to the mass or quantity of ponderable matter; and that the increase of the force is in an inverse ratio to the square of the distance, or, to make this plainer by an example: If the lead of a plumb-line is suspended two yards from the side of a mountain, the attractive force exercised upon it will be four times less than if the distance between the lead and the mountain was only one yard; for

$$2 \times 2 : 1 \times 1 :: 4 : 1.$$

Although, however, the justness of this law be rigorously demonstrated in all cases where the distance is capable of being measured, how does it apply to those instances in which bodies are supposed to touch each other? How can the apparent uniformity of attraction be made to explain the infinite variety of chemical affinity? To this fundamental and obvious objection Buffon has given the following reply. The distances between the several heavenly bodies are so considerable, that they may be looked upon with regard to their action on each other as so many gravitating points, the slight differences in their figure being of little or no account. If the moon and the earth, instead of being spherical, were each in the form of a short cylinder, whose transverse axis should be equal to their present diameters,

the law of their reciprocal action would not be materially altered by such a change, because the relative distance of each particle of the moon from the earth would, notwithstanding, be nearly the same as before; but if these globes were drawn out into very long cylinders, and brought within a short distance of each other, the law of their reciprocal action would seem very different, on account of the prodigious change in the situation of their particles relatively to each other, and to the whole; thus in proportion as figure enters as an element into the calculation of distance, the law would appear to vary, though remaining fundamentally the same.

Whatever stress be laid upon this proposition (which appears to have been acquiesced in by Bergman and Macquer), that in attractions between bodies that are nearly in contact with each other, the force is modified by the figure of the molecule, it must be confessed that not a single case of affinity has yet been resolved by the application of the law of the square of the distance, modified by the figure; and several eminent mathematicians, at the same time that they admit chemical affinity to be only an effect of attraction, maintain it to follow in these cases a different law from that which Newton demonstrated, which yet remains to be investigated.

Morveau, in his elaborate treatise of affinity in the *Dictionnaire Methodique*, has endeavoured to support the theory of Buffon, by certain analogical arguments, the scope of which is, that in the attractions of adhesion and cohesion, in capillary attraction and crystallization, all of which are generally admitted to depend upon the same law as the attraction of gravitation, there are cases equally difficult to be reconciled with the rule of the square of the distance, as those in chemical affinity: he also brings to his aid an ingenious argument of Macquer, to this effect: Since we are ignorant of the density of the elementary particles of bodies, it is impossible to ascertain the density of the aggregates formed by their union; it may therefore happen, that a body, whose primitive particles have little density, should, notwithstanding, be an aggregate of great density, provided these particles are of such a figure as to adhere intimately to each other by all their surfaces: for the same reason, a compound may have but little density, though its constituent particles have individually a great deal, if their form is such as to allow of but few points of contact. Thus, although copper in mass has less density than silver, it is possible that its ultimate particles should be superior in this respect to those of silver; or, allowing it to be of inferior density, it may still be capable, on account of the figure of its component particles, to enter into such intimate contact with those of a third body, as shall more than make up for its inferior density: hence the superior affinity which copper has for nitric acid, over that which silver possesses, may be owing to a superior attraction, on account of the greater density of its primitive particles, or their better aptitude for contact.

It is obvious, however, that all these arguments are merely hypothetical, and at best, only enable us to conceive the possibility of the phenomena of chemical attraction being equally reconcilable to the laws of general attraction as those cases of adhesion, capillary attraction, &c. which have not yet, by the ablest mathematicians, been reduced to calculation. If a single case of affinity had been demonstrated by the rule of the square of the distance, modified by even the supposed figure of the molecule, it might be admitted as a strong presumption, that affinity depended on the same laws as gravitation; but as long as this remains a desideratum,

we must be content to acquiesce in our total ignorance of the primary cause of chemical phenomena.

§ III. Of different kinds of Affinity, and the Construction of Tables and Schemes.

Whether the attractions of gravitation, of adhesion, of cohesion, and of composition, be or be not considered as essentially the same, there is yet difference enough between them to allow of a very accurate definition of each, and this is the more necessary to be done, as there are certain complicated cases of chemical affinity, in which the agency of all these forces may be distinctly perceived.

Gravitation then is an attraction between two bodies at an ascertainable distance from each other, whose force is directly as the mass, and inversely as the square of the distance.

Adhesion is an attraction that takes place at the plane of contact, whose force is peculiar for each substance in nature, and in a direct ratio to the surface of contact.

Cohesion, or aggregation, is an attraction between molecules of the same nature, whose force is peculiar for each substance, and in an inverse ratio to the quantity of caloric, interposed between the particles.

Affinity, or the attraction of composition, is that which, uniting together different homogeneous substances, whether simple or compound, produces an uniform whole, incapable of being resolved by mechanical force, and whose characteristic properties are often different, and sometimes contrary to those of its constituent parts. Thus, if running mercury is added to melted sulphur, a compound is produced, which has neither the colour, the splendour, the inflammability, the volatility, nor the specific gravity, of either of its constituent parts.

It is this affinity of composition which is the great agent in all the operations of nature and art, that are referable to the science of chemistry; not only as an instrument of synthesis, as might be supposed from the primary meaning of the term, but also as the sole means of analysis; there being no way of resolving a chemical compound, but by exposing its elements to the action of stronger affinities than those which retain them in union.

All the known instances of affinity may be arranged under three classes, according to the number of elementary substances, acting on each other at the same time, and the number of new compounds thus produced.—Where only two are concerned, it may be called a case of *concurrent affinity*, or affinity of composition, in which, if the force of their mutual affinity is ever so little superior to the sum of their respective degrees of cohesion, combination will take place. Thus, if a piece of quicklime is put into muriatic acid, the sum of their cohesions being less than the force of their mutual affinity, the two substances will unite together, and there will result a homogeneous compound muriatic of lime, possessing the properties neither of the earth nor of the acid. Those instances also, in which more than two bodies unite together into one compound, come equally under this rule; as, when sulphuric acid, alumine and potash are mixed together; the result is common alum, a salt possessing peculiar properties, which could never have been inferred from those of its elements. All the cases belonging to this first class are those of concurrent affinities, where two or more substances by virtue of their attraction for each other, unite into one homogeneous body. Hence it appears, that though every substance has different degrees of affinity for other substances yet the strongest does not necessarily act to the exclusion of the rest.

It is not, however, always, nor indeed generally, the case, where more than two substances are concerned, that their respective affinities concur to produce one new substance; for it usually happens that their difference of force produces one binary compound, to the exclusion of the third element, on account of the weakness of its attraction for the new compound. Thus, if muriatic and sulphuric acid are mixed together, and an aqueous solution of pure barytes is then added, an instant combination will take place between the sulphuric acid and the barytes, to the exclusion of the muriatic acid; and this last, having also no affinity with the sulphat of barytes thus formed, or at least not sufficiently strong to overcome the sum of their several forces of cohesion, remains permanently excluded. In this instance, therefore, we see how two bodies, whose mutual affinity is very considerable, may unite together to the total exclusion of a third substance. To make this plainer, let A B, be two substances, whose several affinity for C, is equal respectively to 4 and 7: it is obvious then, that B, will unite to C, with a force $= 7 - 4 = 3$; the first effect, therefore, of mixing these substances will be the production of B C, to the exclusion of A: and if the affinity of A, for B C, should be inferior to the cohesive attraction of the several particles of B C, for each other, it is clear that A, must be permanently excluded, notwithstanding its original affinity for C. This exclusion of the weaker by the stronger affinity takes place, not only when the two forces commence their action at the same time, but even when the weaker affinity has been previously allowed to exert its whole action on the base; thus, if muriatic acid and barytes are brought into contact, they combine and form muriat of barytes, which compound is held together by the force of affinity between the two; but when to this compound we present sulphuric acid, whose affinity for the earthy base is stronger than that of muriatic acid, an immediate change takes place, the whole of the muriatic acid is dislodged, and the sulphuric acid combines with the barytes with a force equal to their mutual affinity, minus that of the muriatic acid: or, to recur to our former illustration; if A C, are held together by a force $= 4$, upon the addition of B, whose force is $= 7$, the attraction of A, to C, will be counterbalanced by $\frac{3}{4}$ of B's affinity for A, and the remainder of B's force will produce the combination B C, $= \frac{3}{4}$ of the original attraction between B and C. This, and similar cases are naturally illustrated by supposing C, to have a *disposition* to unite with A and B, A, being at first the only one present, the combination A C, is produced; afterwards, when B, offers itself, C, having a *preferable attachment* to B, quits A, and forms the combination or *partnership* B, C. It is this metaphorical explanation which induced Bergman to call all those instances where a compound already formed is separated by the action of superior affinities, cases of *elective attraction*; and because in the above example only three substances are concerned, one new compound being formed, and the element of weakest affinity being excluded, it is properly distinguished as a case of *single elective affinity*, which forms the second class, ranking immediately after that of concurrent affinity.

From the consideration of single elective affinity, the progress is easy to that of double, or, more properly speaking, compound elective affinity. Suppose the affinity between sulphuric acid and potash, the constituent parts of sulphat of potash, to be $= 12$, and the affinity of nitrous acid for potash $= 9$, and that of oxyd of mercury for sulphuric acid $= 8$, it is evidently impossible to decompose sulphat

fulphat of potash by either nitrous acid or mercurial oxyd, acting separately: if, however, their action be combined, so as that the metallic oxyd shall exert its affinity on the sulphuric acid, while the nitrous acid is doing the same with respect to the potash, then, as $9 + 8$ is greater than 12 , so will the affinities of nitrat of potash and fulphat of mercury be superior to that of fulphat of potash: but nitrous acid and mercury, the two agents in this decomposition, have also a strong attraction for each other, tending to unite them into the compound salt nitrat of Mercury, let this force be $= 4$; it is evident then, that, upon the addition of nitrated mercury to fulphat of potash, there are four distinct affinities acting two by two against each other. The *quiescent* affinities, or those which resist decomposition, are the attraction between sulphuric acid and potash $= 12$, and that between nitrous acid and mercury $= 4$, the sum of which is $= 16$. The *divellent* affinities, or those which tend to break the original combinations, are those of nitrous acid and potash $= 9$, and of sulphuric acid and mercury $= 8$, which together are $= 17$. Now as 17 is to 16 , so is the sum of the divellent, to that of the quiescent affinities. On the addition, therefore, of nitrat of mercury to fulphat of potash, there will be a decomposition of both salts, and the formation of two new ones, nitrat of potash and fulphat of mercury. This is an example of *compound elective affinity*; which may therefore be defined

as the resolution of a compound by means of the united affinities of its elements for those of another compound. It is obviously impossible, by means of double elective attraction, to obtain either of the elementary parts of a body in a separate uncombined state; but although in this respect it is inferior to single elective affinity, it is nevertheless infinitely superior in the vast variety of its application, and in its rendering not merely possible but even easy, a number of decompositions, which are absolutely impracticable by single elective attraction. Almost all the substances in nature are compounds, and the changes that we see continually operating around us, are brought about by very complicated affinities; so it is in nearly every process of art in which chemistry is concerned, a thorough knowledge, therefore, of the general principles of compound affinity is absolutely necessary to be acquired at the very threshold of the science.

From what has been already said, it is obvious that every chemical fact arranges itself under one or other of the three species of chemical affinity; and hence may be conceived the obligation that science is under to Geoffroy, for his ingenious method of arranging cases of single elective attraction, so as to enable the enquirer to discover in an instant any particular fact that he is looking for, or to compare, at a single glance, the results of numerous and complicated experiments.

Of these Tables, the first is a transcript of the original one, published by Geoffroy, and which merits preservation as an historical memorial of an important æra in chemical science. The second and third are, with a few alterations, copies of Dr. Pearson's enlarged edition of Bergman's tables.

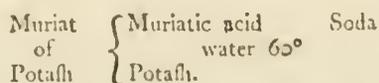

Table II. contains the elective affinities, as far as they have been ascertained, of sixty of the most important chemical substances. All these take place through the medium of water, in which one or both the substances are dissolved, the temperature therefore, in all the cases here mentioned, cannot exceed 212° Fahrenheit. At the head of each column, in larger characters than the rest, and divided from them by a horizontal line, is the name of the substance whose affinities are the subject of the rest of the column; and these are arranged in the order of their intensity, so as that the substance of strongest affinity with that which is at the head of the column, stands the nearest to it. Thus in the column of lime, N° 8, the substances from oxalic acid downwards, present a decreasing series of the affinities of lime: hence the combination of lime with any substance in the column, may be decomposed by any of the bodies that precede this substance, but is not broken by those which succeed it. The use and application of this table is obvious. If, for example, it is required to decompose an aqueous solution of muriat of soda (common salt) by single affinity; the first inquiry is, which of the two component parts is to be set at liberty: suppose it to be the acid, I am then to find a substance whose affinity with soda is greater than that of muriatic acid, for this purpose I turn to the column of soda N° 11, and find that by the addition of either sulphuric or nitric acid, I shall be able to decompose the salt in question, so as to obtain its acid in a disengaged state: if, on the other hand, the alkaline base is wanted, I find, upon inspecting the column of muriatic acid, N° 18, that the affinity of potash for muriatic acid is greater than that of soda; and therefore, by this means, I obtain muriat of potash and free soda. Again, if citrat of lime is to be decomposed, I find, by referring to citric acid, column 30, that it is impossible to do it so as to set at liberty the lime,

because this stands the first in the column of citric acid; but from the column of lime N° 8, it appears that no less than thirteen acids will each of them separate the lime, so as to leave the citric acid disengaged. If the decomposition of sulphat of Barytes is required, it is plain from the column of Barytes, N° 6, that it cannot be decomposed so as to set the sulphuric acid at liberty; it is also equally obvious from the column of sulphuric acid, N° 14, that the Barytes cannot be separated, sulphat of Barytes therefore is undecomposable in water by single affinity.

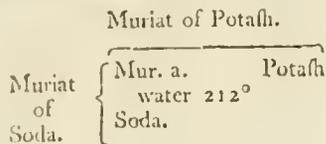

In Table III. the affinities of forty-three substances, without the medium of water, and at a temperature equal to the fusion of at least one of the substances in each instance, are registered: the application and construction of this table is precisely the same as of the former; to enlarge more upon it is therefore unnecessary: it is curious, however, to observe how the order of affinities is modified by temperature; for we find that sulphat of Barytes which is undecomposable by single affinity in water, may at a high heat be decomposed with separation of the Barytes, by potash or soda; and with separation of the acid by the phosphoric, boracic or arsenic acids.

The construction of Geoffroy's tables, although admirably well suited to express the general results of single affinity, is deficient as a method of registering the conclusions from single and unconnected experiments; on which account the *sehemes* of Bergman, either invented or at least first brought into general use by him, have been universally adopted for this purpose. The register of an experiment in affinity ought not to be considered as complete, except it expresses clearly, 1. the *result*, i. e. whether or not any change is effected; 2d, the *menstruum*, whether water, alcohol, &c. is the fluid in which the substances are dissolved: 3dly, the *temperature* of the substances at the time of experiment. 4thly, the *state* of the new substances, whether they are precipitated from the menstruum, or remain dissolved, or are sublimed. Now all these circumstances are expressed clearly and concisely in the following *sehemes*. Suppose the experiment is made to decompose muriat of potash in water at the common temperature, by soda, it will be found that no change

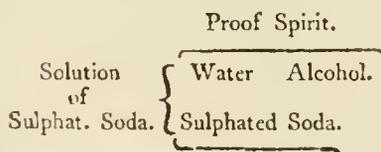

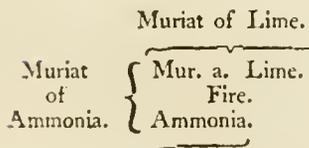

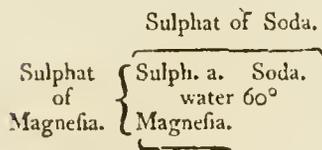

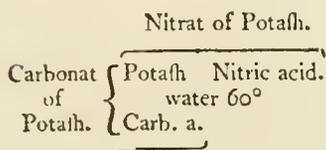

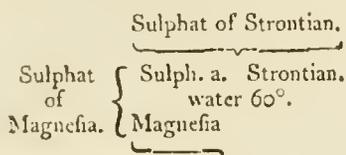

change takes place, this is expressed by the following diagram, or scheme.

The substance to be decomposed is placed on the left hand, and is immediately followed by a bracket whose point is turned towards the compound; within the bracket are the names of the two simple substances of which the compound is formed, and parallel to one of them is the substance by whose affinity a decomposition was expected: no change however taking place, the scheme is left thus imperfect; in the centre is the name of the menstruum and the temperature in degrees of Fahrenheit's thermometer.

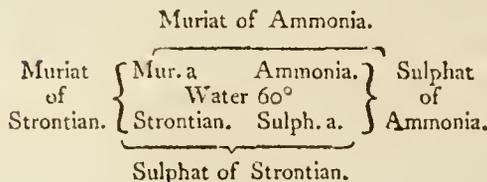

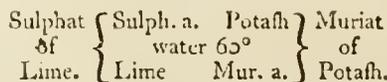

This scheme expresses, that if to a boiling hot solution of muriat of soda in water, potash be added, a decomposition takes place; muriat of potash being formed, and the soda being set at liberty: the straight line under the soda, and the pointless bracket under muriat of potash, express that both substances remain in solution.

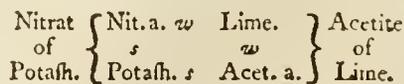

of simple affinity: in the first, we see that strontian added to sulphated magnesia dissolved in water, at the ordinary temperature, decomposes it, and produces sulphat of strontian, and magnesia, both of which are precipitated. In the second, the addition of nitric acid, to a solution of carbonated potash, produces nitrat of potash remaining in solution, while the carbonic acid is volatilized. In the third, sulphated magnesia with soda, produces sulphat of soda remaining in solution, and the magnesia is precipitated. In the fourth, dry muriat of ammonia and lime, heated together, produce ammonia which is volatilized in the form of gas, and muriat of lime remains behind. In the fifth, a solution of sulphated soda being added to alcohol, the water and alcohol unite together, while the sulphat of soda is precipitated.

It is impossible to arrange the results of experiments in compound affinity in a tabular form; accordingly, schemes framed on the same principles as those for single affinity, have been adopted for the convenient registering of all the known facts on this subject. For example, the facts that sulphat of lime and muriat of potash do not decompose each other; and that muriat of strontian, and sulphat of ammonia do decompose each other, together with the circumstances of such experiments are expressed in the two following schemes.

§ IV. *Methods of estimating numerically the force of elective Affinities.*

Notwithstanding the vast importance of Geoffroy's tables, and of all later ones constructed on the same plan, it is obvious that we can only learn from them the greater or less degree of affinity which different substances have for the same body, according to the order in which they are arranged; and though this is sufficient for foretelling the result in cases of single elective affinity, yet in more complicated cases, where the mutual attractions of four or more substances are concerned, the want of a numerical expression for the force of affinity, in order to infer with any probability the result of an untried experiment, must have forcibly impressed the mind of every chemist. Thus, if the result of a mixture of nitrat of potash with acetite of lime is required, all that can be learnt from the inspection of the tables is, that the affinity of nitric acid for potash is stronger than for lime, and that the affinity of lime for acetic acid is weaker than that for potash, or, to express it in a tabular form,

hence we have,
 Quietcent affinities = $s + w$.
 Divellent affinities = $s + w$.

The above five schemes illustrate all the remaining cases

And it is impossible hence to conclude whether or not any chemical change will take place: but if we find the affinity of nitrous acid for potash = 12, of the same for lime = 7; of acetous acid for potash = 14, of the same for lime = 6,

$$\text{Nitrat of Potash.} \left\{ \begin{array}{l} \text{Nit. a. } 6 \\ \text{Potash } 12 \\ \text{Acet. a. } 14 \end{array} \right. \begin{array}{l} \text{Lime} \\ + \\ \text{Acet. a.} \end{array} \left. \begin{array}{l} \\ \\ \end{array} \right\} \begin{array}{l} \text{Acetite} \\ \text{of} \\ \text{Lime.} \end{array}$$

$$\frac{20}{20}$$

we shall then have

$$\text{Quiescent affinities} = \frac{12 + 7}{20} = 19$$

$$\text{Divellent affinities} = 6 + 14 = 20$$

and hence we may with certainty infer that a double decomposition will take place, with a force equal to the excess of 20 over 19.

Chemical philosophers have not, however, by any means agreed on the method to be followed for the attainment of this desirable object; some with M. Wenzel, consider the time requisite for effecting solution as the expression of the force of the affinity between a substance and its menstruum; others with Fourcroy, believe the intensity of this to be more accurately measured by its resistance to decomposition, than by its rapidity in uniting bodies: according to Macquer the force of affinity is expressed by the facility with which bodies unite, compounded with the force by which they continue united. Kirwan, on the other hand, has estimated the affinity of acids for their bases by the different proportions of them that they require for saturation. And from this very diversity of opinions may be inferred the great difficulty of the subject.

According to M. Wenzel, the disposition to chemical union between bodies varies with the figure of their constituent parts; and, regarding the action of menstrua upon them as a mere mechanical impulse, subject to calculation upon the principles of statics, he concludes, that the rapidity of solution is an exponent of the force of affinity; and therefore, that *the affinity of different bodies with any common menstruum, is in an inverse ratio of the time required for their solution.* To prove this, he procured equal cylinders of silver, copper, lead, and other metals in a state of purity, having weighed them, he covered them with varnish so as to leave only one end exposed to the action of the solvent: they were then separately suspended in equal quantities of nitric acid, and left to its action for an hour; being then taken out and freed from their varnish, they were weighed, and the quantity dissolved of each was found to correspond with the order of their respective affinities for the acid. This large conclusion of M. Wenzel's from so partial an experiment, is however, most strikingly contradicted by facts: the cylinders of silver and lead will be scarce perceptibly acted on in muriatic and sulphuric acids, whereas these will precipitate a nitrous solution of either metal with the greatest ease; a multitude of similar obvious contradictions to the rule might be mentioned, if need were, besides that M. Wenzel's method, if ever so accurate, is capable only of being applied in cases where one of the substances is a solid.

The resistance which the parts of a compound offer to any force that is employed to separate them, offers a probable method of estimating the degree of their mutual affinity: since however the union is chemical, it is plain that mechanical means of separation cannot be used for this purpose, and there are very few chemical agents that can be

made the subject of calculation. The only method proposed by Fourcroy, and one that he himself allows, is inapplicable to the greatest number of cases, is to ascertain the thermometrical temperature necessary to effect a separation. It is certain that the application of high degrees of heat in many cases opposes the action of chemical affinity: the force of affinity for caloric (heat) is also probably different in every natural substance, we know in many cases, as in the burning of lime, the reduction of mercurial oxyds, &c. that mere caloric is capable of separating carbonic acid from lime, oxygen from mercury, &c. it is not therefore *a priori* improbable, that the affinity of any acid for the different alkaline, earthy, and metallic bases should be truly expressed by the various quantities of caloric, as indicated by the degrees of the thermometer and pyrometer, required for the decomposition of the different salts. But although this rule certainly holds good in some cases, yet the greater number of compound salts are incapable of being decomposed by the greatest quantity of mere caloric that we are able to apply, and almost all the cases of chemical affinity through the medium of water, are also incommensurate with the scale proposed.

In consequence of these difficulties both Fourcroy and Morveau have agreed in proposing an arbitrary number as the basis of their respective numerical series, all the other terms of which are brought by approximation and comparison with the results of known experiments, to bear certain proportions to the standard term, and to each other.

It is plain, therefore, that a table, constructed on these principles, can never be any thing more than an approach towards the truth; and even this can only be effected by repeated corrections according to the results of a vast multitude of experiments; and in all untried cases it is reduced merely to an argument from analogy. In order to verify the numbers in the following short table of Morveau, no less than 490 experiments would be necessary, and probably more than half these would require separate adjustments of all the numbers in the table; it may be conceived therefore how many centuries of incessant labour would be required to tabulate in this manner with any accuracy, even the binary combinations of the present chemical substances.

How far this Table, which has already undergone repeated

	Sulphuric acid.	Nitric acid.	Muriatic acid.	Acetous acid.	Carbonic acid.
Barytes	66	62	36	28	14
Potash	62	58	32	26	9
Soda	58	50	31	25	8
Lime	54	44	24	19	12
Ammonia	46	38	21	20	4
Magnesia	50	40	22	17	6
Alumine	40	36	18	15	2

corrections by its able author is to be depended upon, a few examples will show.

If acetite of barytes be added to sulphat of soda, a decomposition will take place, and there will be produced sulphat of barytes and acetite of soda: now according to the Table, the sum of the

Quiescent affinities = $28 + 58 = 86$
Divellent affinities

= $66 + 25 = 91$.
this case, therefore, is resolved truly by the Table.

Nitrat of Potash and acetite of lime mutually

mutually decompose each other, forming nitrat of lime and acetate of potash, but by the Table

$$\text{Quiescent affinities} = 58 + 19 = 77$$

$$\text{Divellent affinities} = 44 + 26 = 70$$

The Table, therefore, in this instance, is erroneous.

Nitrat of soda and muriat of ammonia mutually decompose each other; but by the Table,

$$\text{Quiescent affinities} = 50 + 21 = 71$$

$$\text{Divellent affinities} = 38 + 31 = 69$$

Nitrat of potash and sulphat of ammonia mutually decompose each other; but by the Table,

$$\text{Quiescent affinities} = 58 + 46 = 104$$

$$\text{Divellent affinities} = 38 + 62 = 100$$

Hence is obvious the great probability of error in all calculations and reasonings founded on this Table.

Mr. Kirwan's numerical system of affinities is founded on the proportion of base necessary to saturate a given quantity of acid; and as no one has treated this important subject with such unwearied ability and profound investigation as the learned president of the Royal Irish Academy, it will be necessary to enter somewhat minutely into an examination of the fundamental parts of his system.

The first object with Mr. Kirwan was to ascertain exactly the quantity of *real acid* in each of the three mineral acids, at a determinate specific gravity (by *real acid* is to be understood acid free from all water, except such as is necessary to its very constitution). For this purpose, assuming that muriatic acid, in the form of gas, is free from all mixture with water, he procured 100 cubic inches of this acid gas, and found its weight to be = 60 grains, the barometer standing at 29.6, and the thermometer at 57°. The barometrical pressure remaining the same, and the temperature being = 49°, he found that 10 grains of water absorbed an equal weight of muriatic acid gas, and the liquid acid thus formed occupied the space of 13.3 grains of water; hence the specific gravity of this acid was equal to about 1.5, and that of a muriatic acid equal in purity to the acid gas, and of the same degree of condensation as the *real acid* contained in the above mentioned liquid acid, would be equal to 3.03. Taking this, therefore, as the specific gravity of *real muriatic acid*, he next established the proportion of this contained in muriatic acids of different specific gravity. Not being able to obtain nitric or sulphuric acids in a state of gas, he calculated the proportion of *real acid* contained in these liquors, upon the supposition that equal quantities of the three acids, reduced to the state of *real acid*, required equal weights of potash for their saturation: the results of these calculations being found to accord with the actual specific gravities of these acids, diluted with different known quantities of water, he hence inferred the truth of the principle that he had assumed. Proceeding from these data he next ascertained the quantity of *real acid*, and *real base*, in all the salts formed by the three acids, with alkaline and earthy bases, and comparing these results with the known order of affinity of the bases for the acids, he drew the general conclusions, "That the quantity of *real acid* necessary to saturate a given weight of any of the bases, is "in an inverse ratio to the affinity of the bases with the "acid; and that the quantity of any of the bases necessary "to saturate a given quantity of any acid, is in the direct "ratio of the affinity of the same acid with the base." Or in other words, that, of two bases, which has the strongest affinity for any given acid, requires the least quantity of acid for its saturation; and a given quantity of acid will

take up a greater quantity of one base than of another, in proportion to the force of its affinity for the base.

If these deductions are legitimate, the following Table, containing the quantities of base required to saturate 100 parts of *real acid*, is also a true expression of their respective forces of chemical affinity.

	Potash.	Soda.	Lime.	Ammonia.	Magnes.	Alumine.
Sulphuric acid.	215	165	110	90	80	75
Nitric acid.	215	165	96	87	75	65
Muriatic acid.	215	158	89	79	71	55

Mr. Kirwan's method has, however, been examined with much care, by two of the ablest chemical philosophers that the age can boast of, M. M. Morveau and Berthollet; and a number of very serious objections have been brought against it. These may be divided into those which call in question the essential principle of the force of affinity being in direct ratio to the quantity of base, and those which only relate to the accuracy of particular experiments.

The essential objections are contained in the following experiments of Morveau. A quantity of sulphuric acid containing, according to the table of Kirwan, 100 grains of *real acid*, required, for saturation, 201 grains of crystallized carbonat of potash. A quantity of nitric acid, containing also, according to Kirwan, 100 grains of *real acid* required 302 grains of the same salt for saturation. A quantity of muriatic acid, containing 100 grains of *real acid*, required 905 grains of the same salt. Hence it appears either that Mr. Kirwan's fundamental calculations are erroneous, or that the very principle of his whole system is false: for not only do equal quantities of *real acids* require for their saturation different quantities of the potash, but the quantity of base required is in an inverse ratio to the force of affinity, being exactly the reverse of the principle that Kirwan lays down.

Again, according to Kirwan's corrected tables,

Sulphat of potash consists of	{ Acid 100
	{ Potash 108.7
Sulphat of lime - - -	{ Acid 100
	{ Lime 80.6
Nitrat of potash - - -	{ Acid 100
	{ Potash 83.33
Nitrat of lime - - -	{ Acid 100
	{ Lime 34.4

Now, if a solution be made in water of such a quantity of sulphat of potash as contains 100 grains of *real acid*, and to this a sufficient quantity of nitrat of lime be added to convert the whole of the sulphuric acid into sulphat of lime, it is evident that 80.6 grains of lime will be required, and 234.4 grains of nitric acid will be set at liberty; but this quantity of nitric acid would require for saturation 195.32 grains of potash, whereas the decomposed sulphat of potash will furnish only 108.7 grains; there should remain therefore 64.87 grains of nitric acid in excess, or uncombined.

with any base. If, however, we put this calculation to the test of experiment, we shall find whether the liquor be diluted, or concentrated, or even brought to crystallization, that there is not the smallest trace to be found of any disengaged acid.

Besides the above, there are several other important objections to Mr. Kirwan's theory, especially to that part of it in which he supposes equal quantities of real sulphuric, nitric, and muriatic acids, to require for their saturation the same proportion of potash. The force of these objections has been acknowledged by Mr. Kirwan in his treatise "on the strength of acids and the composition of neutral salts;" he has, in consequence, deduced the proportion of real acid, in

100 parts.	Potash.	Soda.	Ammon.	Barytes.	Strontian.	Lime.	Magnesia.
Sulphuric	121.48	78.32	26.05	200.	138.	70.	57.92
Nitric	117.7	73.43	40.35	178.12	116.86	55.7	47.64
Muriatic	177.6	136.2	58.48	314.46	216.21	118.3	89.8
Carbonic	95.1	149.6		354.5	231 +	122.	50.

§ V. Laws of Affinity.

Before the subject of affinity was so well understood as it is at present, or rather while chemists were not yet aware of the extreme difficulty and uncertainty of their researches, all the known facts were collected and classified, and from them was deduced a number of general laws of affinity, most of which have been since overturned, or essentially modified by later more accurate investigations. The enumeration of these laws, with such restrictions as have been induced by modern discoveries, will form the subject of this section.

1. *Chemical affinity takes place only between bodies of different natures.*

This necessarily follows from the definition given in the third section, by which chemical affinity was distinguished from the attraction of aggregation or cohesion, by this very circumstance.

2. *Affinity takes place only between the ultimate particles of bodies.*

Where two simple substances enter into combination, this may be allowed to be the case, but certainly does not happen when compound bodies unite with each other: thus when oxygen and hydrogen combine together into water, and oxygen and sulphur into sulphuric acid, there is probably an affinity between the ultimate particles of oxygen with those of hydrogen in one case, and those of sulphur in the other; but when water and sulphuric acid combine together, the affinity takes place between particles of water and of acid, each of which is resolvable into its chemical elements, and is, therefore, not in a state of ultimate division.

3. *The affinity which any one body has for a series of others, is not equal in force towards each individual of that series.*

It is probable that no two substances can be found, whose separate affinity for a third is perfectly equal in similar circumstances; that such instances, if they ever occur, are at least very rare, is obvious from all that has been said concerning single and compound elective affinity; the whole of which essentially depends upon this law, and is at the same time a demonstration of its truth.

4. *Chemical affinity may act upon more than two substances at the same time, and unite them into one compound.*

A considerable number of triple salts has lately been discovered which seem to countenance this law; perhaps,

nitrous and sulphuric acids, from other less exceptionable data; so that his numerical table of the strength of affinities is now by far the most correct of any that has yet been constructed; and his fundamental principle, that the quantity of base required to saturate a given quantity of real acid, is a true expression of the force of affinity between the acid and the base, seems to receive additional confirmation in proportion to the advance of chemical knowledge.

The following corrected table of the quantity of base taken up by 100 parts of sulphuric, nitric, muriatic, and carbonic acids, is copied from Mr. Kirwan's essay on the analysis of mineral waters.

however, it is scarcely yet established beyond the reach of controversy. In one sense, indeed, almost all the salts may be said to be compounds of more than two substances, thus, sulphat of iron consists of sulphur, iron, and oxygen; carbonat of ammonia, of carbon, hydrogen, azot, and oxygen: but in these and similar cases, it is universally allowed that the affinity of a binary compound is totally different from that of its elements: so, the neutral salt, carbonat of ammonia, is not held together by the concurrent affinities of its four primary elements, but by those of its two immediate compound parts, carbonic acid and ammonia. Common alum is usually considered as a proper triple salt, in which the separate affinities of sulphuric acid, alumine, and potash, are acting on each other at the same time; of this, however, there appears not the least evidence, for though the salt in question may be made by adding together sulphuric acid, alumine, and potash, yet the same result is obtained by combining acidulous sulphat of alumine with sulphat of potash. Similar observations may be made on the ammoniacomagnesian and other triple salts, as they are called.

5. *Chemical action will not take place between two bodies except one of them, at least, is in a fluid state.*

This, though more accurate than the ancient maxim, "corpora non agunt nisi sint soluta," is obviously borrowed from it. There are two kinds of fluidity, the elastic and non-elastic, and these require to be carefully distinguished from each other: the first, or the gaseous, is for the most part very unfavourable to chemical combination, while the second, or the liquid, (including both fusion and solution) is one of the most indispensable circumstances in all cases of affinity.

6. *Chemical affinity is in an inverse ratio to the attraction of aggregation.*

This would seem to be a necessary deduction from the preceding law; it is not, however, to be admitted without many limitations. The aggregation of bodies may be destroyed by mere mechanical means to a certain degree; such is the effect of the operations of cutting, rasping, pounding, &c. Now in all these, and similar cases, the above law holds strictly true; the ease and rapidity with which bodies are decomposed, or enter into new combinations being directly as the quantity of surface that they present, or inversely as their masses. Thus fluat of lime (fluor spar) in entire crystals, is wholly unaffected by sulphuric acid, but in

proportion as its surfaces are multiplied by grinding it down to powder, so is its attraction of aggregation diminished; and the action of the sulphuric acid on the lime, to the exclusion of the fluoric acid, becomes more energetic. It would be more correct to say, that the *efficiency* of chemical affinity is inversely as the attraction of aggregation; because its absolute force remains constantly the same, and it only appears to increase on account of the diminution of its antagonistic attraction. Thus, let the chemical affinity of lime and fluoric acid be = 10, and the force of its cohesive attraction, when crystallized = 6, the sum of its quiescent affinities will be = 16. Let the affinity of sulphuric acid for lime, or the divellent affinity be = 13; it is obvious that no decomposition can take place, although the chemical divellent affinity is superior to the quiescent one; but, these continuing the same, let the attraction of aggregation be reduced by mechanical triture to be only = 2, then the strongest chemical affinity will become efficacious, and a decomposition will take place.

The aggregation of bodies is, however, more frequently overcome by the action of solution by water, or fusion by fire, and these menstrua are so commonly made use of that the habit is insensibly acquired of considering solutions of substances in water or fire, as equally simple with the same bodies when in a concrete state. It is from this oversight that all the apparent exceptions to this law have originated. "If, says Morveau, we apply heat to a mixture of acid and water, or of alcohol and water, which are real chemical combinations, we only augment the degree of their rarefaction; but instead of thus promoting their union we separate them; the same is the case with those metallic oxyds that are decomposable by mere heat, and of all those compound salts, one of the principles of which is more fixed than the other." It, however, caloric is capable of being exhibited in an uncombined state, and of being distinguished from all other substances by peculiar sensible properties, if these are modified and changed by combination with different bodies, if caloric may be transferred from one body to another, according to an ascertained order of chemical affinity; and finally, if it may be separated from its combination, and again exhibited with all the original properties that were at first characteristic of it, what reason is there to deny that it is so far a material substance, as to be capable of chemical combination? To recur, therefore, to the examples adduced by Morveau: if to the compound of alcohol and water a certain quantity of caloric be added, it will be divided between the two ingredients, according to their respective affinities, and in proportion to the addition of this new substance will the original affinities of the water and alcohol be weakened: the alcohol being the soonest saturated with caloric, will assume a gaseous form, and being assisted by the attraction of gravitation, will separate from the water. In all this there is nothing inconsistent with the general order of chemical agency; whereas the reasoning of Morveau involves a contradiction in terms: for if the force of chemical affinity is capable of being overcome by rarefaction, and if rarefaction is nothing but the greatest possible resolution of an aggregate, it follows that the absolute force of chemical affinity may be overcome by the negation of the attraction of aggregation.

7. *When two or more substances unite to form a chemical compound, they lose their own peculiar properties, and those of the new compound are not to be inferred from the properties of its elements.*

It is not meant by this, that the properties of a com-

ound are always, and in every particular different from those of its constituent parts, only that they are by no means intermediate between them. The reverse of this was maintained by the earlier chemists, and accordingly Stahl taught that salts were composed of earth and water, because he fancied their properties to be a medium between those of these two substances. It will probably be thought at present that the very instance which Stahl has selected to prove his maxim is rather conclusive on the contrary side; but numberless other more unexceptionable examples occur in every department of chemistry. Tin and iron are both of them very ductile, but if equal parts of the two are melted together, the result is a brittle alloy. Magnesia is tasteless, sulphuric acid is intensely sour, combine them, and we obtain a bitter salt. Alkali is colourless, syrup of violets is purple, the product upon mixture is green; carbonic acid and ammonia, when separate, are gaseous, mix them, and they become solid. Amalgam of lead, and of bismuth are solid, by combination they form a liquid.

8. *The capacity for caloric is always changed by chemical combination.*

This law is, in fact, only an offset from the preceding; and for the explanation of it, see CALORIC.

§ VI. Anomalies.

All those cases of chemical affinity, which either really or apparently contradict the general laws that have just been cited, may be reduced to two classes; *viz.* those depending on the variable force of affinity itself, and those occasioned by the action of other antagonistic attractions.

1. The whole system of Bergman depends on the absolute uniformity of elective attraction, on its being a constant force, so that if (the temperature and menstruum remaining the same) the combination A B is decomposed by C, to the exclusion of B, the new substance A C, cannot be again separated by B, so as to reproduce A B, and leave C at liberty. With still more rigour does this apply to all the methods of estimating numerically the excess of one affinity over another, independently of the relative quantities of the substances employed. It appears, nevertheless, from Berthollet's treatise on this subject, that in almost all cases of change produced by elective affinity, there is not a total transfer of the base, but a partition of it between the two opposite attracting substances in a compound ratio of the relative force of affinity and quantity of each. That in many cases the excess of quantity may supply the deficiency of force, and therefore that the mass must be carefully taken into consideration, together with the specific force in the construction of tables of affinity. Barytes is properly placed by Bergman at the head of the column of the affinities of sulphuric acid, in water; not however because it is impossible for sulphat of barytes to be decomposed by any other substance, but because, if equal quantities are taken of all the substances that combine with sulphuric acid, barytes will be found to decompose the greatest proportion of any other sulphat; and of the sulphat of barytes the largest part will remain undecomposed by a quantity of any body equal in weight to the barytic part of the salt in question. Thus, if equal parts of pure potash and sulphat of barytes are boiled together to dryness in a small quantity of water, it will be found that the sulphuric acid has been divided between the two bases in the compound ratio of their mass and their force of affinity; the greater part of the barytic sulphat will be found undecomposed, a small quantity of barytes will be found at liberty, most of the potash

potash will also be uncombined, but a certain proportion will be united with the sulphuric acid which the barytes has loil, in the form of fulphat of potash. To make this matter plainer, let us examine the results of the decomposition of fulphat of barytes by potash, and of fulphat of potash by barytes, as calculated from Mr. Kirwan's data. Sulphat of barytes contains 3.33 parts of sulphuric acid and 6.66 of barytes: if therefore we take ten parts of this salt and an equal quantity of potash we have,

3.33 sulph. a.
6.66 barytes
10. potash.

and the affinity of equal parts of barytes and potash for sulphuric acid being : 2 : 1.21 the acid, if shared between them in the compound ratio of their mass and their affinity, will be 13.32 to barytes, and 12.1 to potash: now the composition of fulphat of barytes being as already stated, and that of fulphat of potash being 54 of alkali to 45 of acid, there will remain undecomposed 5.22 parts of barytic fulphat; 5.18 of barytes will be set at liberty; 3.47 of fulphated potash will be produced, and 8.11 of potash will continue uncombined. If, on the other hand, we mix equal parts of fulphat of potash and barytes we shall have

5.48 potash
4.52 sulph. a.
10. barytes

and the acid being divided between the bases in the compound ratio of their masses and force of affinity, will give 6.63 parts to the potash and 20. to the barytes: there will then be 2.48 parts sulphat of potash remaining undecomposed, and 3.24 barytes uncombined; 4.12 parts potash will be set at liberty, and 10.14 fulphat of barytes will be produced.

It is not merely in a few instances that this partition of one body between two others, according to their respective masses and affinities, takes place, there being scarcely any example to the contrary. Lime has a weaker affinity than potash for sulphuric acid; yet lime, when acting on an equal weight of fulphat of potash, is capable of partly decomposing it: the same happens with phosphat of lime and potash, with fulphat of potash and soda, &c.

From these and similar experiments it follows, that when a compound of two substances is acted on by any third body, that part of the compound which is the subject of combination, is shared between the two remaining elements, not only in the proportion of their respective degrees of affinity, but also according to their quantity; these two substances therefore must be considered as opposite forces, dividing between them the subject of combination, according to the ratio of their intensity, and this intensity depends, not only on the energy of affinity, but also on the quantity, so that by varying this in either, the effect produced will be proportionably modified.

Another consequence is, that the action of a substance in opposition to any particular combination decreases, as it advances towards saturation; and as the force of this is continually diminishing, so the power of the substance eliminated is enlarging according to its increased quantity, and this effect takes place till the antagonist forces exactly counterpoise each other.

A third inference is, that in cases of precipitation the precipitate necessarily retains a portion of the substance with which it had before been combined; for during the instant of this action, a partition is made of the subject of combination in proportion to the affinities and masses of the substances employed.

2. The variable ratio of the force of affinity between the two elements of particular compounds, is another ano-

maly and occasional source of error. Thus the black oxyd of manganese readily parts with a portion of its oxygen, by the action of such a portion of caloric as will just raise it to ignition; but after it has parted with this excess of oxygen, the affinity which unites it to the remainder, follows a much higher ratio, so that the utmost possible accumulation of caloric is unable to produce any further decomposition: hence the affinity of metallic manganese for oxygen is very high, and the affinity of the white oxyd of manganese for oxygen is much lower than it ought to be, provided the affinity of these two substances was in an uniform ratio, according to their relative proportions. So again, the acidulous fulphat of barytes is decomposed by an equal quantity of water into the common barytic fulphat and sulphuric acid, yet no addition of water can produce any further decomposition of this earthy salt; the general fact, therefore, of mass compensating for inferiority of attractive force does not here hold good. Another striking example of the same is the decomposition of tartrite of potash by acetous acid, into acidulous tartrite of potash and acetite of potash; and the resistance made by the acidulous tartrite to all further decomposition by any quantity of acetous acid. The same may be said of the affinity of muriatic acid to oxygen, and of its base for the same substance.

3. The order of chemical affinities is often modified by the attraction of saline vegetation, a power belonging to all but the deliquescent salts, which causes them to separate from the water that holds them in solution, and rise in the form of vegetations up the sides of the vessel in which they are contained; the efflorescent salts are more particularly subject to this attraction, and consequently their affinities are the most frequently disturbed by this force. Muriat of soda is scarcely, if at all, decomposed by carbonated lime in water; but if, according to Scheele's process, lime and muriat of soda are mixed with only so much water as will make the mass into a paste, and this is exposed to carbonic acid gas, a saline efflorescence will shortly make its appearance, possessing all the properties of carbonated soda, and the muriat of lime in a deliquescent state will be found at the bottom of the vessel: but if the carbonat of soda is dissolved and added to the muriat of lime, an immediate decomposition will take place, and carbonated lime and muriat of soda will be produced. A similar effect happens when iron is moistened with muriat of soda and exposed to carbonic acid gas.

4. The last cause of anomaly that need be mentioned, arises from the affinity of water with substances dissolved in it, and this is a very important circumstance to be aware of, as it accounts for the otherwise inexplicable phenomenon of what are called *incompatible salts* in certain mineral waters. Bergman, Kirwan, Cavendish, and other eminent chemists, have discovered in mineral waters the co-existence of small quantities of various salts, which, in common circumstances, decompose each other; thus the waters of Rathbone-place, according to Cavendish, contain in the pint 0.9 of a grain carbonated ammonia, and 1.2 grains of fulphat of lime. A gallon of Harrowgate water contains 13 grains muriated lime, and 5 grains fulphated magnesia. But in both these cases, on account of the small quantity of salt compared to that of the water, the affinity of this salt, aided by its mass, is capable of overcoming the excess of the divellent, over the quietest affinities of the salts that it holds in solution; and is obviously the true reason of the fact, for if, by evaporation, a considerable proportion of the water is taken away, the divellent affinities of the two salts become efficacious, and decomposition takes place.

For other subjects in some measure connected with the important

important subject of chemical affinity, see ADHESION, CRYSTALLIZATION, SATURATION, SOLUTION.

AFFION, is a name given by the Arabians to opium; and also to an electary, in which opium is an ingredient.

AFFIRMATION, *affirmatio*, in *Logic*, a positive proposition, alledging the truth or reality of something.

Affirmation is defined, by the *Logicians*, an act whereby we attribute one idea to another; as supposing it to belong, or agree to it.—As when, conceiving perfection to agree to the Deity, we say, *God is perfect*.

This, on other occasions, is called ENUNCIATION, PROPOSITION, COMPOSITION, and JUDGING.

AFFIRMATION, in *Law*, signifies the ratifying or confirming a former law, or judgment.

We say, to *affirm* a judgment: the house of lords, on an appeal, *affirmed* the decree of the Lord Chancellor, or of the lords of session in Scotland.

Affirmance is used in the same sense. 8 Hen. vi. c. 12.

AFFIRMATION is also used in *Grammar*, by some reclus upon that art, for what is usually called a VERB; because the office of that part of speech is to express what we affirm or attribute to any subject.

AFFIRMATION is also used for a solemn form of attesting the truth, allowed to be used by the QUAKERS, instead of an oath, which they hold absolutely unlawful to take. See the form of the affirmation, &c. under the article QUAKER.

AFFIRMATION is of divers kinds, tacit, by words, by a nod, or gesture, &c.

In a civil law sense, affirmation may be divided into *simple*, which is that from which no obligation arises; and *qualified*, which infers an obligation.

The requisites of this latter are, that it be, 1. deliberate and free; 2. sincere; 3. certain and specific; 4. clear and perspicuous.

AFFIRMATIVE, in *Logic*. See AFFIRMATION.

There are universal *affirmative* propositions; and such, usually, are the first of SYLLOGISMS.

In *Algebra* we have also *affirmative* or positive QUANTITIES, which have their appropriated CHARACTERS. The term *affirmative* was introduced by Vieta.

AFFIRMATIVE sign, or character. See CHARACTER.

AFFIRMATIVE, in *Grammar*. Authors distinguish *affirmative* particles; such is, *yes*.

The term *affirmative* is sometimes also used *substantively*. Thus we say, the *affirmative* is the more probable side of the question: there were so many votes, or voices, for the *affirmative*.

AFFIRMATIVE is particularly applied, in the Roman INQUISITION, to such heretics as own the errors and opinions with which they are charged; and maintain them in their examination with firmness and resolution.

AFFIX, *affixus*, compounded of *ad* and *figo*, I fix, in *Grammar*, a particle added at the close of a word, either to diversify its form, or alter its signification. In which sense, *affix* is the same with *suffix*; though *affix* is sometimes, but less properly, applied more generally so as to include prefix particles.

We meet with affixes in the Saxon, the German, and

other northern languages; but more especially in the Hebrew and other oriental tongues.

The Hebrew affixes are single syllables, frequently single letters, subjoined to nouns and verbs; and contribute not a little to the brevity of that language. The affixes of nouns may be called *possessive affixes*, as they denote the possessive pronouns; and those of verbs, *verbal affixes*. In feminine nouns, ending in ה, the ה is changed into ת, before the affixes, and י is inserted after the plural feminine termination ות, probably for softening the sound; e. g. תורתִי, *my law*, and תורתֵינוּ, *our laws*. The ם of the plural masculine termination is expelled by the affixes, and when י, *my*, is affixed to the plural, after ם is expelled, the י of the plural coalesces with the affix; and they are distinguishable only by the sense, or by other words in the sentence; e. g. ספרי, *my books*, ספרינו, *our books*. Plural affixes are not unfrequently subjoined to singular nouns, and *vice versa*; e. g. רברך (1 Kings viii. 26) for רברוך *thy sword*; and אבותם (Exod. iv. 5) for אב תיהם, *their fathers*. As the possessive pronouns are subjoined to nouns, the personal pronouns are subjoined to verbs in the same manner. In this case the ה of the third person singular feminine is changed into ת, and the ת of the second person singular feminine assumes י, before the affixes; e. g. אהבתהו (1 Sam. xviii. 28) *he loved him*, ונתתהו ונתתהו אהבהו ונתתהו (Ezek. xvi. 19). for ונתתהו, *and thou gavest him*. In the second person plural, masculine and feminine of Kal, the ם and ך final are ejected, and their place is supplied by ך, inserted before the affixes; e. g. מסרתהו, for מסרתהו and מסרתנו, *ye delivered him*. Sometimes the ך is wanting, and thus this person is not easily distinguished from the third, second and first person singular; as צינהני (Zech. vii. 5). for צינתוני, *did ye fast unto me?* Affixes are sometimes subjoined to the infinitives of passive verbs, in which case these infinitives assume the rank of substantive nouns; as, ביום הנראם (Gen. v. 2). *In the day when they were created, or of their creation*. When affixes are thus joined to infinitives, they may be taken either actively or passively, or expressed by the nominative or accusative case, according to the sense of the passage; e. g. ביום מסרו, may be understood to signify either, *In the day in which he himself delivered, or in which he delivered him*. Some adverbs, and all prepositions assume affixes; but as the affixes of verbs are generally rendered by the accusative, and those of nouns by the genitive, the affixes of adverbs are expressed by the nominative, and those of prepositions by the case which the preposition governs. Wilson's Elements of Heb. Gram. p. 108. 174. Mafeseh, Heb. Gr. vol. i. p. 65, 171, 189.

The oriental languages are much the same as to the RADICALS; and differ chiefly from each other as to *affixes* and *PREFIXES*. Mem. Acad. Inscip. tom. ix. p. 334.

AFFLATUS, formed from *ad* and *flare*, to blow, literally denotes a blast of wind, breath, or vapour, striking with force against another body.

Naturalists sometimes speak of the *afflatus* of serpents.

Tully uses the word *figuratively*, for a divine INSPIRATION. In which sense, he ascribes all great and eminent accomplishments to a divine *afflatus*. See PYTHIA.

AFFLENK, in *Geography*, a town of Stiria, in Germany; two leagues north of Pruck.

AFFLICTION is not itself, in propriety of medical speech, a disease, but it produces many, for whatever excites envy, anger, or hatred, produces diseases from tense fibres; as whatever excites fear, grief, joy, or delight, begets diseases from relaxation.

Many

Many chronical diseases, particularly the *phthifia*, spring from affliction. For a very remarkable history of the effect of affliction, see Hist. de l'Acad. Roy. des Scienc. an. 1732.

AFFLUX, in *Electricity*, is opposed to *efflux*; and both terms were used by the Abbé Nollet, and also by Dr. Watson, previously to the discovery of positive and negative electrics. They apprehended, that in all electrical operations, there was both an afflux of electrical matter to the globe and the conductor, and likewise an efflux of the same matter from them. Dr. Watson soon corrected this mistaken opinion; but the Abbé Nollet was more tenacious; and he was confirmed in his attachment to this favourite theory by observing, that bodies not insulated, plunged in electric atmospheres, shewed signs of electricity; not perceiving, that the electricity of such bodies was in its nature and effects different from, and directly opposite to that of the electrified body, in the atmosphere of which they were involved. See **ELECTRICITY**.

AFFORAGE, in the French *Customs*, a duty paid to the lord of a district, for permission to sell wine, or other liquors within his seignory.

Afforage is also used for the rate or price of provisions laid and fixed by the provost, or sheriffs, of Paris.

AFFORARE, to *affear*, in *Law*, is to set a value on any thing: and *afforatus* denotes appraised or valued, as things vendible in a fair or market. Du-Cange. See **AFFEERORS**.

AFFORCEMENT, *afforciamentum*, derived from the barbarous Latin *afforciare*, to *strengthen*, *confirm*, in some ancient charters, denotes a **FORTRESS**, or work of **FORTIFICATION** and **DEFENCE**.

AFFORESTING, *afforestatio*, the turning ground into **FOREST**. In this sense, the word stands opposite to **DEAFFORESTING**.

The Conqueror, and his successors, continued afforesting the lands of the subject for many reigns; till the grievance became so notorious, that the people of all degrees and denominations were brought to sue for relief; which was at length obtained, and commissions were granted to survey and perambulate the forest, and separate all the new afforested lands, and re-convert them to the uses of their proprietors, under the name and quality of **PURLIEU**, or *pouralle land*.

AFFRANCHISEMENT. See **MANUMISSION**.

AFFRAY, in *Law*, is derived from the French word *affrayer*, to *affright*, and it formerly meant no more; as when persons appeared with armour or weapons, not usually worn, to the terror of others. Stat. 2 Edw. III. cap. 3. But it now implies a skirmish or fighting between two or more, in some public place, to the terror of his majesty's subjects; and there must be a stroke given or offered, or a weapon drawn, otherwise it is not an affray; but if the fighting be in private it is no affray, but an assault. 3 Inst. 158. It is inquirable in the court leet, and punishable by justices of peace in their sessions, by fine and imprisonment; and it differs from **ASSAULT**, in that it is a wrong to the public; whereas assault is of a private nature. Lamb. lib. ii. Affrays may be suppressed by any private person present, who is justifiable in endeavouring to part the combatants, whatever consequences may ensue. But a constable, or other similar officer, may break open doors to suppress an affray, or apprehend the affrayers; and he may either take them before a justice, or imprison them by his own authority, for a convenient time, till the heat is over; and may then, perhaps, also make them find sureties for the peace. 3 Inst. 158. 1 Hawkins P. c. 134, 136, 138. The offence of affray admits of several degrees of aggravation.

This is the case when two persons deliberately engage in a **DUEL**, though no mischief has actually ensued. Another aggravation is, when the officers of justice are disturbed by an affray, in the due execution of their office, or where it occurs in the king's court and such places. All affrays in a church or church-yard are deemed heinous offences; and therefore it is enacted, by Stat. 5 and 6 Edw. VI. c. 4. that if any person shall, by words only, quarrel, chide or brawl, in a church or church-yard, the ordinary shall suspend him, if a layman, *ab ingressu ecclesie*; and, if a clerk in orders, from the ministration of his office, during pleasure. And, if any person in such church or church-yard proceeds to smite or lay violent hands upon another, he shall be excommunicated, *ipso facto*; or if he strikes him with a weapon, or draws any weapon with intent to strike, he shall, besides excommunication, (being convicted by a jury) have one of his ears cut off; or, having no ears, be branded with the letter F in his cheek. Blackst. Com. vol. iv. p. 146.

AFFREIGHTMENT, or **AFFRETAMENT**, **AFFRETAMENTUM**, in *Law*, signifies the **FREIGHT** of a ship.

The word is formed from the French *fret*, which expresses the same thing.

AFFRONTE, French, compounded of *ad*, to, and *fronte*, forehead, in *Heraldry*, is understood of animals borne in an **ESCUTCHEON** as facing, or with their heads turned towards each other. This is otherwise called *confrontè*; and stands opposed to *adoffè*. When a savage's head is full-faced, it is said to be *affrontè*. The word often occurs in the same sense with *gardant*.

AFFUERA, in *Geography*, one of the islands of Juan Fernandes, on the South-sea coast, in the kingdom of Chili. Its longitude, from the meridian of Callao, is 30° 20', and it is about 400 leagues to the north of Cape Horn. This coast swarms with sea lions and wolves.

AFFUIAGE, *affuiagium*, derived from *affoer*, q. d. *affoerare*, to make a fire, of *ad* and *focus*, in *Ancient Customs*, a right of cutting fuel-wood in a forest, or the like, for maintaining family-fire. Du-Cange.

AFFUSION, the act of pouring some fluid substance on another body. Dr. Grew gives several experiments of the luteation arising from the affusion of divers menstruums on all sorts of bodies. Divines and church historians speak of **BAPTISM** by *affusion*; which amounts to much the same with what we now call sprinkling.

AFGHANS, in *Geography* and *History*, comprehend generally the several tribes of Mahometans, who inhabit the northern parts of India; some of whom are spread over the whole of India, and known by the name of *Pattans*: they are esteemed the best soldiers in the country. In a more restricted sense, they are the indigenous possessors of a tract of country, which stretches from the mountains of Tartary to certain parts of the gulf of Cambay and Persia, and from the Indus to the confines of Persia; and their principal settlements have been the mountainous districts bordering on Kandahar, Cabul, Gazna, Pehaweer or Peshor, and Hazaret, &c. The Afghans are represented as a rude unlettered people, without a written character, says Mr. Forster (Journey from Bengal to England, through the northern parts of India, &c.), and speaking a language, called *Pushto*, peculiar to themselves. They are a robust hardy race of men, and being generally addicted to a state of predatory warfare, their manners largely partake of a barbarous insolence, and they avow a fixed contempt for the occupations of civil life. The territory which they chiefly inhabit is denominated by Mr. Forster *Afghanistan*, and he observes that, though the natives are denominated Tartars in some histories of Asia, they bear no resemblance to those people,

people, in their persons, manners, or language. They have been sometimes subject to the Moguls, and sometimes to the Persians, but more frequently independent. During the weak reign of Shah Sultan Hossain, and the tyranny of the eunuchs, by whom he was governed, they suffered many severe oppressions; and under the direction of Mir i. e. Amir, Weis, or Vaez, one of their chiefs, a man of a bold and enterprising spirit, they determined to revolt, and to throw off the Persian yoke. Having ineffectually petitioned for redress, and their deputies to the Persian court being dismissed as the agents of a seditious and turbulent people, their leader, Mir Weis, was seized and sent as a prisoner to Ispahan. He contrived, however, by his presents and his eloquence, so to ingratiate himself with the king's ministers, and with the king himself, that he was not only released, but acquitted and favoured with the royal protection. This visit afforded him an opportunity of observing the weakness of the Persian monarchy, and of concerting measures for the success of the enterprise which he had projected. With a view of uniting the Afghans in his interest, he obtained leave to make the pilgrimage to Mecca; and here he obtained a dispensation for effecting the revolt which he had meditated. After the successful execution of several preparatory measures, and the murder of the Khan of Kandahar, and his Persian and Georgian adherents, he marched forward to the city, which he surprised and took. He was then joined by the Afghans, who, after several alternate defeats and victories, obtained peaceable possession of the whole kingdom of Kandahar, A. D. 1713. Mir Weis, however, who had for some time assumed the title of king, with other ensigns of sovereignty, died in his new kingdom in the year 1715, and was succeeded on the throne by his brother, Mir Abdollah. This prince was destitute of talents, ambition, and courage; and therefore formed a design of restoring Kandahar to the crown of Persia. Whilst he was negotiating the surrender, he was killed by his nephew Mir Mahmud, a prince of the age of 18, who was proclaimed king of Kandahar, within six months after the death of his father.

In 1717, the *Abdoltees*, another tribe of Afghans, who resided in the province of Herat, and who had submitted to Persia, on condition of not being subject to foreign governors, resolved to follow the example of the Afghans of Kandahar, and to emancipate themselves from the Persian yoke. They succeeded in their attempt, and Herat became an independent republic. Mir Mahmud, availing himself of the revolt of the Abdoltees, and of other concurring circumstances, which contributed to enfeeble the Persian government, proceeded to the execution of the design which his father had conceived of subduing the whole of Persia, and engaged the Afghans, the Abdoltees, and the other inhabitants of adjacent states, to co-operate with him. Accordingly he began his march in January 1722; and having advanced within three leagues of Ispahan, the capital, he pitched his camp and prepared for battle. The Persian army, after suffering a great slaughter, whilst the loss of the Afghans was very inconsiderable, was betrayed by one of its own generals, and reduced to the greatest distress. Mahmud having gained the suburbs, invested the city; but several unfavourable circumstances occurred during the siege, and the Afghans must have withdrawn if Shah Hossain had not been deserted and betrayed by those in whom he placed his chief confidence. After enduring the horrors of famine for two months to such a degree that the besieged were under the necessity of consuming every kind of brute animal they could find, and of appeasing their hunger by eating the bodies of those who died, and even murdering their fellow-citizens and children, the city capitulated on condition

of Hossain's resigning the empire, together with his person and principal officers of the court, into the hands of the conqueror. "Such," said the vanquished and distressed monarch, addressing the Afghan prince, "is the instability of human grandeur: God disposes of empires as he pleases, and takes them from one nation to give them to another; but I promise to consider you always as my own father; and I will undertake nothing for the future without your advice." As soon as these words were uttered four thousand Afghans were ordered to take possession of the royal palace, and the gates of the city. Thus, when Hossain had reigned 28 years, the dynasty of the Sefis, or Satis, ended in the person of this prince, the 10th successor of Ismael, its founder, after having lasted 223 years. For the manner in which Mahmud closed his life and reign, see the article MAHMUD. He was succeeded by Ashruff, the son of Abdollah, whom the Afghans raised to the throne of Persia, A. D. 1725. The Afghans at this juncture were masters of Khorasan, Kerman and Pars in Persia; and under the conduct of Ashruff, they obtained some successes against the Turks; but in 1727, they concluded a peace with them, and Ashruff acknowledged the Ottoman emperor lawful sovereign of Persia. About this time, especially in 1729, Nadir Shah, otherwise called Kuli Khan, began to distinguish himself. Having totally routed the Abdoltee Afghans, of whom 5000 were made prisoners, and near 15,000 killed and wounded, and having taken possession of Herat, he proceeded to meet Ashruff, who was marching towards Khorasan at the head of an army of 30,000 men. The Afghans were terrified by the prospect of encountering the victorious general of the Persians, and wished to avoid an action. They were, however, compelled to engage, and the event was a complete victory on the part of the Persians. The loss sustained by the Afghans was about 12,000 men: and that of the Persians amounted to the number of 4000. Ashruff retreated towards Ispahan, and was pursued by Kuli Khan. On his approach the Afghans quitted their several garrisons and fled towards the capital, where they deposited ample stores of provisions, with the purpose of defending themselves to the last extremity. But Ashruff determined to try the event of a battle before he submitted to a siege. Accordingly he marched out to a convenient situation about 30 miles from the city, and waited Kuli Khan's arrival. In the mean while he exercised the most wanton cruelty on the Persians, ordering all the principal men to be cut off, and afterwards all they could find in the streets; so that, for the space of 20 days, there was not a Persian to be seen abroad, none appearing but women, who came out to buy the common necessaries of life. At last Kuli Khan arrived and obtained a complete victory. Ashruff having lost 7000 men, retired to Ispahan, and issued an order, that all the inhabitants should be slaughtered, and the palace and other houses set on fire. As they were about to execute this barbarous order, the Persian army approached the city; upon which Ashruff and his men, having loaded their beasts with money, hastened to save themselves by flight; and in a few hours there was scarce an Afghan to be seen in the city. The Afghans took up their winter-quarters at Shiraz; but they were pursued by Kuli Khan, Jan. 1730; and after an obstinate resistance, compelled to fly, and to leave behind them a great part of their treasure, and most of their women and children. Ashruff, with about 1500 of his men, marched directly towards Kandahar; but most of them deserted him; and the rest were surprised by a body of the Balluches, and after a gallant defence, he and most of his party were cut to pieces. Thus ended the usurpation of the Afghans in Persia.

After Nadir Shah was proclaimed emperor of Persia in

1736, he proceeded with his army towards Kandahar, in order to reduce to subjection the Afghans, who were the only enemies of the Persian empire whom he had not subdued. Having secured Kandahar and Cabul, and advancing in his march towards Peishor, he was much accommodated by these hardy mountaineers, and in several skirmishes with them lost many men, who were either killed or wounded. The Afghans had fortified themselves so strongly on the tops of the hills, that this victorious general found it impossible to force their passes without much bloodshed; and he therefore sent them offers of accommodation, which they accepted the more readily, as they had not received for four or five years the usual allowance from court for their services in defending the passes of the mountains. Nadir Shah, upon paying them a certain sum of money, was allowed to march forward without molestation: several of the Afghans enlisted in his army; and others joined him in his further progress. The mountainous residences of the Afghans were included in the territories to the westward of the river Attek, formally ceded to Nadir Shah by Mahommed Shah, in the year 1739. A body of Afghans, in the service of Nadir Shah, was commanded by Ahmed Khan, who, after the assassination of this barbarous conqueror in 1747, took possession of Cabul, and with the resources furnished by the treasure which he thus obtained, laid the foundation of an independent government, including Afghanistan Gour, Multan, Sind, and Cashmir. Ahmed was succeeded in 1773, by his son Timur Shah, who, besides his Afghan and Indian dominions, possessed a large division of Khorasan. His successor, who now fills the throne, carried his arms in 1796 as far as Lahor, when he was recalled by intestine commotions. Hanway's Hist. Acc. of the British Trade, &c. vol. iii. p. 27, &c. &c. Hanway's Trav. vol. iii. p. 148, &c. Frazer's Hist. Nadir Shah, p. 91. Raynal's Revol. vol. ii. p. 68.

In the 2d volume of the Asiatic Researches, we have some curious particulars relating to the Afghans: they call themselves the posterity of MELIC TALUT, or king Saul. In a war, they say, which raged between the children of Israel and the Amalekites, the latter, being victorious, plundered the Jews, and obtained possession of the ark of the covenant. Considering this as the God of the Jews, they threw it into the fire, which did not injure it; and having ineffectually endeavoured by other methods to destroy it, they placed it in their temple, and all the idols bowed to it. At length they fallened it upon a cow, which they turned loose in the wilderness. They are said to have applied to Samuel, after their defeat by the Amalekites, for a king; and at this time the angel Gabriel descended, and delivered a wand, with instruction, that the person, whose stature corresponded with that wand, should be king of Israel. Melic Talut was then a herdsman of inferior condition: and having lost a cow, he applied to Samuel for assistance to satisfy the owner. Samuel, perceiving his lofty stature, asked his name: He answered Talut. Upon which, having measured him with the wand, he said to the children of Israel, "God has raised Talut to be your king." How shall we know, said they, that he shall be our king? Samuel replied, they should know, that God had constituted Talut their king, by his restoring the ark of the covenant. He accordingly restored it, and they acknowledged him their sovereign. After Talut obtained the kingdom, he seized part of the territories of Jalut, or Goliath, who assembled a large army, but was killed by David. Talut afterwards died a martyr in the war against the infidels; and God constituted David king of the Jews. Melic Talut, they say, had two sons, one called Berkia and the other Irmia,

who served David and were beloved by him. The son of Berkia was called Afghan, and the son of Irmia was named Usbec. The latter was eminent for his learning; and the former for his corporeal strength, which struck terror into Demons and Genii. Afghan made frequent excursions to the mountains; where his progeny, after his death, established themselves, lived in a state of independence, built forts, and exterminated the infidels. The late Henry Vanfittart, Esq. informs us, that a very particular account of the Afghans has been written by the late *Hefiz Rahmet Khan*, a chief of the Rohillas, from which the curious reader may derive much information. They are Mussulmans, partly of the SOXNITE, and partly of the SHITE persuasion. They boast much of the antiquity of their origin, and the reputation of their tribe; but other Mussulmans reject their claim, and consider them of modern, and even base extraction. From history however, we learn, that they have distinguished themselves by their courage, both singly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been regarded as the chief strength of the army, in which they have served. As they have been applauded for their virtues, they have also been reproached for vices; having sometimes been guilty of treachery, and even acted the base part of assassins. They consist of four classes, viz. *pure Afghans*, whose fathers and mothers were Afghans; those whose fathers were Afghans, but their mothers of another nation; such as had Afghan mothers, and fathers of another nation; and the children of women, whose mothers were Afghans, and fathers or husbands of a different nation.

The above account is extracted from the Persian Abridgment of a book, called *The Secrets of the Afghans*, written in the Pushto language, a specimen of which is added. The work was communicated by Henry Vanfittart, Esq. to the late Sir William Jones, who was then president of the Asiatic society. Although their claim to a descent from Saul seems to resemble some of the fictions borrowed by Mahomet from the later Jewish Rabbins, Sir William Jones has no doubt that the Afghans are descendants of Israel. "We learn, says he, from *ESDRAS*, that the ten tribes, after a wandering journey, came to a country called Arfaxeth; where, we may suppose, they settled. Now the Afghans are said by the best Persian historians to be descended from the Jews; they have among themselves traditions of such a descent; and it is even asserted, that their families are distinguished by the names of Jewish tribes; although, since their conversion to the *Islam*, they studiously conceal their origin: the Pushto language, of which I have seen a dictionary, has a manifest resemblance to the Chaldaic; and a considerable district under their dominion is called *Hazàreh*, or *Hazàret*, which might easily have been changed into the word used by *ESDRAS*. I strongly recommend an enquiry into the literature and history of the Afghans."

AFLOAT, in *Sea language*, denotes the state of a ship when she is buoyed up by the water from the ground.

AFFOBA, in *Botany*, a name given by the natives of Guinea, to a kind of plant, of the genus of the phascolus, or kidney bean. They use it pounded and mixed with oil, to cure the itch, and other cutaneous foulnesses. It is more hairy than the common kinds, and its leaves are very small. Phil. Trans. N^o 232.

AFORE, signifies that part of a ship which lies forward, or near the stern. It also means *farther forward*, as the manger stands afore the fore-mast, or nearer to the stern.

AFRA, in *Geography*, a strong castle on the frontiers of Quara in Africa, built by Cherif Mahomed, king of Sur, N. lat. 2° 25'. E. long. 23° 15'.

AFRA, in *Entomology*, a species of PAPILO, with brown wings, six ocelli, and the hinder wings marked with cinereous veins; found in the southern deserts of Russia.

AFRANIUS, L. in *Biography*, a Latin comic poet, who flourished about the year U. C. 654, or a century before Christ. Cicero (de Clar. Orat. apud Oper. t. i. p. 434, Ed. Olivet.) says, that he imitated C. Titus, and commends him for the acuteness of his genius and the fluency of his style. Horace (Epill. l. iii. ep. 1. v. 57.) represents him as resembling Menander. Quincilian, (l. x. c. 1. t. ii. p. 913) whilst he celebrates his talents for comedy, expresses a wish that he had not sullied his performances by impure and unnatural love-adventures, which were declaratory of his own manners. Suetonius in his life of Nero, (apud Oper. t. ii. p. 743. Ed. Pitisc.) mentions a comedy of Afranius, intitled *Incendium* or *Conflagration*, on the exhibitions of which the house that was burned was devoted to be pillaged by the actors. Some fragments of this poet's works are preserved in Mattaire's *Corpus Poetarum*, Lond. 1713, fol.

AFRICA, in *Geography* and *History*, was anciently one of the three parts of the known world, which was divided into Europe, Asia, and Africa, and called by the Greeks *ἡτρωπία*, continents; and is now one of the four quarters of the globe. Bochart (Geog. Sac. apud op. tom. i. col. 488.) after enumerating several etymologies of the name Africa, which he disapproves, deduces it from a Punic word *feric*, signifying an ear of corn, and referring to the fertility of this country. Dr. Hyde supposes it to be derived from the Phœnician or Punic *Havarca*, or *Avreca*; i. e. the *Barca*, or country of Barca, which was one of the most remarkable parts of this continent. Servius in Virgil (*Æn.* v. v. 128. tom. ii. p. 618. Ed. Burm.) deduces it from *αφρησ*, *sine frigore*, and the appellation expresses the heat of the climate. Africa, called by the ancients *Libya*, was divided by them into Africa *propria*, and Africa *interior*. Africa *propria*, or the territory of CARTHAGE, has had various limits assigned to it by the ancient geographers. Mela (l. i. c. 7.) and Ptolemy (l. iv. c. 3.) comprehend under this appellation all the countries situated between the river Amphaga and the borders of Cyrenaica, which, according to Pliny (H. N. l. v. c. 4.) were inhabited by twenty-six different nations: and thus they would include Numidia and the Regio Syrtica, which are countries distinct from the proper territory of Carthage. Its true limits seem to have been (See Cellar. Ant. Geog. tom. ii. p. 85.) the river Tufca, or boundary of Numidia, on the west; the Mediterranean, or African Sea on the north; the frontiers of the Garamantes and deserts of Libya interior on the south; and the Mediterranean, with the Lesser Syrtis, on the east. It comprehended two provinces, *viz.* the *Regio ZEUGITANA* and *BYZACIUM*, with which the kingdom of TUNIS, as it is divided by Dr. Shaw (Travels, p. 73.) into the summer and winter circuits, nearly corresponds. The chief lakes of this region, noticed by the ancients, are *Hipponitis*, the *Palus Sifara*, the *Palus Tritonis*, the *Palus Pallus*, and the *Palus Libya*: the most famous river was the BAGRADA; and the principal islands on the coast of Africa *propria* were the COSSYRA, the TARICHIÆ, LOPADUSA, ÆGUSA, the LARUNESIÆ, DRACONTIA, GALATA, and ÆGIMURUS.

Africa was first peopled, principally by Ham and his descendants. Mizraim peopled Egypt. (See Gen. x. 6. 13.) The Pathrusim, the Naphtalim, the Casuhim, and the Ludim took possession of other parts: though their respective situa-

tions are not precisely known. Some have supposed that the Lehabim settled in Libya, and Phut between Nubia and Libya, along the Mediterranean, and that many of the Canaanites, when they were driven out of their country by Joshua, retired into Africa. At a later period, the inhabitants of this country were the Aules, whose chief city was AVZA, the Maxyes and Machlyes both Libyan nations, the Zaucees, and the Zygantes, who cultivated bees, and made honey. All these were, probably, a mixture of old Libyans and Phœnicians, and in several respects resembled both these nations.

Africa *interior* comprehended those remoter and more southern countries of Africa, most of which were little known to the Greeks and Romans otherwise than by uncertain and fabulous report. The western part of this division was called *Libya interior*, and it was chiefly inhabited by the *Gætuli*, *Garamantes*, *Nigritæ*, and *Hesperium Æthiopiæ*. The eastern part was denominated by Ptolemy *Æthiopia sub Ægypto*. See ABYSSINIA, EGYPT, and ETHIOPIA. The Romans do not seem to have extended their conquests and intercourse beyond the tropic of Cancer. The kingdoms with which they were more immediately connected were Numidia, Mauritania, and Gætulia. As for the inhabitants of the more retired and southerly parts, they were ignorant even of their names, and much more of their character and manners. Some account will be given of the notions that prevailed respecting them in their proper places, under the real or fabulous appellations by which they were distinguished, as *Astacuri*, *Blemmyes*, *Cadupi*, *Dolopes*, *Elephantopagi*, *Ichthyophagi*, *Lotophagi*, &c. &c.

The ignorance of the ancients, concerning the extent of Africa, appears from their disagreement in ascertaining its just limits; whilst some, as Sallust, (Jugurth. Bell. c. 20. tom. i. p. 26. Ed. Haverc.) Mela, (l. i. c. 8.) Pliny (l. iii. c. 1. tom. i. p. 135. Ed. Hard.) Dionysius, (Perieg. v. 18.) Hirtius, (De Alex. Bell. c. 14.) Polybius, (Hist. l. iii. p. 191. Ed. Casaub.) and Solinus, have preferred for this purpose the western branch of the Nile, or even the great Catabathmus or desert; which last would assign to Asia, not only Egypt, but part of Libya: others, as Ptolemy, (l. iv. c. 5.) and Strabo, (l. i. tom. i. p. 61.) with the modern geographers, fix the isthmus of Suez, and the Arabian gulf, as the boundaries of Asia and Africa. This, says Strabo, is a more natural limit than the Nile; and thus, says Ptolemy, the whole of Egypt is included in Africa. But the knowledge both of Ptolemy and Strabo comprehended only a small part of Africa. Strabo was only acquainted with that part of it which the Romans had reduced under their power, and this was scarcely a tenth part of it, and he seems not to have known any thing with certainty concerning the form and state of the southern parts of Africa (l. xvi. t. ii. p. 1180.); and though Ptolemy was acquainted with some other parts, which were not known to the Romans, yet by the division which he hath made of it into twelve regions, we may conceive that nearly one half of it was unknown to him. This inquisitive and learned geographer appears to have been unacquainted with any part of Africa, situated a few degrees beyond the equinoctial line; for he supposes that this great continent was not surrounded by the sea, but that it stretched, without interruption, and increasing in its breadth, towards the south. Geog. l. 4. c. 9. Leo Africanus, who was an eminent African geographer, after all his studies, travels, and researches, appears to have been imperfectly acquainted with this country; for by dividing it merely into four parts, *viz.* Barbary, Numidia or Biledulgerid, Libya, and Nigritia or Negroland, he excludes from it the whole kingdom of Egypt

Egypt, and the two Ethiopias. It was not known for many ages, that Africa was a peninsula, every where surrounded by the sea, excepting at the isthmus of Suez, which joins it to Asia. The knowledge of the Romans was restricted to those provinces which stretch along the Mediterranean sea, from Egypt westward to the straits of Gades. The Phœnicians, however, at an earlier period, seem to have been acquainted with both the south-east and western coasts of Africa. A Phœnician fleet, as Herodotus informs us, (l. iv. c. 42. p. 298. Ed. Wesseling.) fitted out by Necho, king of Egypt, took its departure about 604 years before the Christian æra, from a port in the Red sea, doubled the southern promontory of Africa, and, after a voyage of three years, returned by the straits of Gades, to the mouth of the Nile. Eudoxus of Cyzicus, is said to have held the same course, and to have accomplished the same arduous undertaking. Plin. H. N. l. ii. c. 67. tom. i. p. 106. Strabo, (l. ii. tom. i. p. 155.) mentions this voyage of Eudoxus, and treats it as a fabulous tale. Dr. Vincent, in his *Periplus of the Erythrean sea*, published in 1800, argues with great ingenuity against the possibility of an African circumnavigation previously to that of the Portuguese; and he asserts, that there is no evidence of a farther progress to the south, on the western coast of Africa, than that of Hanno; nor on the eastern, than that of the *Periplus*. An anonymous writer is disposed to credit the voyage, related by Herodotus, till it can be proved that the circumnavigation, in such vessels as the Phœnicians then possessed, was physically impossible; and in support of this opinion, he alleges the simplicity of the narrative, unblended with miraculous adventures—the discovery of two important truths, *viz.* the falling of the shadow to the south, and the peninsular form of the African continent; one of which could be ascertained by no other means, and the former of which was disbelieved by the writer who relates it; and the consideration, that the navigators only put to sea when circumstances were favourable; and though the attempt was hazardous, and success improbable, still no insurmountable impediment to its completion exists. Month. Rev. New Series. vol. xxxiv. p. 122. The Carthaginians also, imbibing the spirit, and following the example of the Phœnicians, extended their intercourse with this country. Whilst they made considerable progress, by land, into the interior provinces of Africa, trading with some of them, and subjecting others to their empire; they sailed along the western coast of this great continent, almost to the tropic of Cancer, and planted several colonies, in order to civilize the natives, and accustom them to commerce. In the prosperous age of the Carthaginian republic, Hanno, with a fleet equipped by authority of the senate, and at the public expence, was directed to steer towards the south, and seems to have advanced much nearer the equinoctial line than any former navigator. Major Rennell supposes his navigation to have terminated at Sherbro' river, or found, which was also the limit of the knowledge of Ptolemy. Plin. H. N. l. v. c. 1. t. i. p. 241. *Hannonis Periplus apud Geograph. minores* ed. Hudson, vol. i. p. 1. The authenticity of this work has been questioned by Mr. Dodwell (*ubi supra*), and vindicated by M. de Montesquieu (Sp. of Laws, b. xxi. c. 8. v. ii. p. 44.) and M. de Bougainville, in a Dissertation published in tom. xxvi. of the *Mem. de l'Acad. des Inscriptions*, &c. The voyage, it is said, was performed in small vessels, which kept near the coast; and the observations made on the appearance and state of the countries on the coast of Africa have been confirmed by the relations of modern navigators. Nevertheless, Polybius, (Hist. l. iii. p. 192. Ed. Casaub.) long after the period assigned to

these voyages, affirms, that it was not known in his time, whether Africa was a continued continent, stretching to the south, or whether it was encompassed by the sea; and Pliny (H. N. l. ii. c. 68. t. i. p. 107.) asserts, that there can be no communication between the southern and northern temperate zones. In order to obviate these difficulties, Dr. Robertson observes, (Hist. Amer. vol. i. p. 15. 8vo.) that the Phœnicians and Carthaginians concealed any knowledge they acquired concerning the remote regions of the earth, with a mercantile jealousy. Many of their discoveries seem to have been scarcely known beyond the precincts of their own states. The navigation round Africa is recorded by the Greek and Roman writers, rather as a strange amusing tale, than as a real transaction. As neither the progress of the Phœnician and Carthaginian discoveries, nor the extent of their navigation, were communicated to the rest of mankind, all memorials of their skill in naval affairs seem, in a great measure, to have perished, when the maritime power of the former was annihilated by Alexander's conquest of Tyre, and the empire of the latter was overturned by the Roman arms. It was not till a century after the invention of the mariner's compass in 1302, that navigation began to advance beyond the state to which it had attained before the downfall of the Roman empire. The first regular plan for discovering unknown countries was formed in Portugal by John I. surnamed the bastard, after he had obtained secure possession of the crown, by the peace concluded with Castile, A. D. 1411. Whilst an armament was equipping, in order to attack the Moors who were settled on the coast of Barbary, a fleet, consisting of a few vessels, was destined in 1412 to sail along the western shore of Africa, and to discover the countries that were situated on that coast. This fleet doubled Cape Non, which had been the formidable boundary of the Portuguese navigation before this period, and proceeded 160 miles beyond it to Cape Bojador. The rocky cliffs, adjacent to this cape, deterred any farther progress. In 1418, a new attempt was made for doubling this cape, but though the attempt proved unsuccessful, it terminated in the discovery of Porto Santo; and another expedition, in 1419, was recompensed by the discovery of Madeira. The Portuguese, by their voyage to this island, were accustomed to quit the coast, and venture into the open sea. By pursuing this course they succeeded, A. D. 1433, in doubling cape Bojador, and in advancing within the tropics; so that in a few years they discovered the river Senegal, and the whole coast extending from Cape Blanco to Cape de Verd. As far as the river Senegal they found the African coast inhabited by people resembling the Moors of Barbary; but to the south of that river, they beheld men with skins black as ebony, with short curled hair, flat noses, thick lips, and all those peculiar features which are now known to distinguish the race of Negroes. The search for unknown countries became now an object of general attention; and it was encouraged first by the discovery of the Cape de Verd islands; and soon after, *viz.* in 1449, by that of the Azores. So slow and gradual, however, was the progress of discovery, that the Portuguese, during the life of prince Henry, who had projected and patronised undertakings of this kind, and who died in 1463, did not advance nearer to the equinoctial line than five degrees; and after their continued exertions for half a century, they had not discovered more than 1500 miles of the African coast. From Cape Non to the Senegal, the country along the coast was found to be a sandy, barren tract, thinly inhabited by a wretched people, professing the Mahometan religion, and subject to the extensive empire of Morocco. But to the

South of that river, the power and religion of the Mahometans were unknown; the country was divided into small independent principalities, the population was considerable, the soil fertile; and the Portuguese soon discovered that it produced ivory, rich gums, gold, and other valuable commodities, which afforded the prospect of a lucrative commerce, as well as the gratification of curiosity. Having ventured to cross the line in 1471, they found that region of the torrid zone, which was supposed to be scorched with intolerable heat, to be not only habitable, but populous and fertile. In 1482, a powerful fleet was fitted out, which, after discovering the kingdoms of Benin and Congo, advanced above 1500 miles beyond the line; and in order to secure the possession of the countries which they discovered, and to derive commercial advantages from them, forts were erected on the coast of Guinea, colonies were settled, and by various measures of policy, the Portuguese power and commerce in Africa were established upon a solid foundation. By constant intercourse with the Africans, the Portuguese gained increasing knowledge of the country; they found, that contrary to the doctrine of Ptolemy, the continent inclined towards the east; and they began to indulge a hope, founded on the report of the ancient Phœnician voyages round Africa, of proceeding by the same route to the East Indies, and of engrossing that commerce, which has been the source of wealth and power to every nation by which it has been possessed. In 1486, a voyage of discovery was projected, and the conduct of it was committed to Bartholomew Diaz, an experienced and brave officer, who stretched farther towards the south than any of his predecessors, and discovered near 1000 miles of a new country. After encountering many difficulties and hazards, in an unknown and tempestuous ocean, he at length descried that lofty promontory which bounds Africa to the south; but having made the discovery, he was compelled, by the shattered state of his ships, and the turbulent disposition of his crew, to return home. This promontory he called *Cabo Tormentoso*, or the stormy cape; but the king, his master, extending his views by this course to India, gave it a name of better omen, which it has ever since retained,—the *Cape of Good Hope*. In 1497, a squadron was equipped for prosecuting the scheme of opening a passage to the East Indies by this cape; and the command of it was entrusted with Vasco de Gama, a man of noble birth, and possessed of talents adapted to the enterprise. Ignorant of the course of the winds in the Atlantic ocean, he set sail in July, an improper season of the year; and bearing towards the south, he struggled with contrary winds for four months, before he reached the cape. During an interval of calm weather, he doubled this formidable promontory, and pursued his voyage towards the north-east, along the African coast. After touching at several ports and various adventures, he came to anchor before the city of Melinda. From hence he proceeded to Calcut, where he arrived May 22, 1498; but as he had neither force sufficient to attempt a settlement, nor commodities proper for carrying on any commerce, he hastened back to Portugal, with an account of his success in performing a voyage the longest, as well as the most difficult, that had ever been made since the first invention of navigation. He landed at Lisbon, Sept. 14, 1499, two years, two months, and five days from the time he left that port. To this voyage we are indebted for the discovery of the southern and western boundaries of the African continent; and from the Portuguese we also derive our earliest knowledge of many of its interior parts, and of the most considerable kingdoms and empires of which it consists, particularly those of Habesh or *ABYSSINIA*, *MONOMOTAPA*, *MONOMUCI*, the eastern

kingdoms of *CONGO*, *ANGOLA*, *METAMBA*, *LOANGO*, and others on the western side; those of *SOFALA*, *MOZAMBIQUE*, *QUILOA*, *MOMBASA*, and *MELINDA*, on the eastern coast. Their missionaries collected and recorded many particulars with respect to their various religions, governments, laws, customs, products, and commerce, at a time when the means of information concerning the interior of Africa were very scanty and imperfect.

Africa, at a former distant period, contained several kingdoms and states, eminent for the liberal arts, for wealth and power, and for the most extensive commerce. Almost all the northern parts of this continent were full of people, from the Red Sea to the Atlantic Ocean. The kingdoms of *EGYPT* and *ETHIOPIA* were much celebrated, and the rich and powerful state of *CARTHAGE* extended her commerce to every region of the then known world; and even the British shores were visited by her fleets. At length the Romans, after a contest which lasted for more than 100 years, totally subdued this famous republic and destroyed their city, and then reduced under their power other kingdoms and states of Africa. See *NUMIDIA*, *MAURITANIA*, *GÆTULIA*, &c. The Roman empire retained its possessions in this country for several ages, and found them an ample source of revenue, as well as necessary supply.

The 10,000 Euboic, or Phœnician talents, amounting to about four millions sterling, which vanquished Carthage was condemned to pay within the term of fifty years, as Polybius informs us, (*Hist. l. xv. c. 2. p. 706.*) were a slight acknowledgment of the superiority of Rome, and bear a very small proportion to the taxes afterwards raised both on the lands and on the persons of the inhabitants, after the fertile coast of Africa was reduced into a province. It would be tedious to recite the oppressions which the Africans suffered from the rapacity of the Roman governors, and the distractions which were the consequences of their religious disputes, after the introduction of Christianity, and which were rather augmented than appeased under the unseasonable interference of the civil power. Of the latter, some account will be given under the articles *CIRCUMCELLIONES* and *DONATISTS*; and with respect to the former it will be sufficient to select a single instance.

About the year of our Lord 366, Count Romanus possessed the military command of Africa. At this time the three flourishing cities of Oea, Leptis, and Sabrata, which, under the name of Tripoli, had long constituted a federal union, were invaded and pillaged by the barbarians of Gætulia; and several of their most honourable citizens were surpris'd and massacred. In this state of distress they applied to Romanus for succour; but the price of his assistance was so enormous, that they were incapable of purchasing it. Their application by two deputies to the emperor Valentinian was equally unavailing; for though he deputed Palladius to examine the state of Africa, and the conduct of Romanus, he behaved in such a manner that, for concealing his own guilt, he was under a necessity of attesting the innocence and merit of the Count. The charge of the Tripolitans was declared to be false and frivolous; the citizens of Leptis were compelled to contradict the truth of their own decrees, and to censure the behaviour of their own deputies; the president of Tripoli, who had presumed to pity the distress of the province, was publicly executed at Utica; four distinguished citizens were put to death, as accomplices of the imaginary fraud, and the tongues of two others were cut out, by the express order of the savage emperor. Romanus was continued in the command, till the Africans were provoked, by his avarice, to join the rebellious standard

of Firmus the Moor, A. D. 372. Firmus was the son of one of the richest and most powerful of the Moorish princes, who acknowledged the supremacy of Rome; and having slain his brother in a domestic quarrel, he became obnoxious to the displeasure of Romanus. Unable to conciliate him, he appealed against the tyrant, who was an object of universal contempt and hatred, to the sword and to the people. Having established his power in the provinces of Mauritania and Numidia, and whilst he was hesitating whether he should assume the diadem of a Moorish king, or the purple of a Roman emperor, Theodosius the famous Roman general, with a small band of veterans, unexpectedly arrived on the African coast, and quelled the rebellion by his prudence and activity; and Firmus, deprived of all hopes of escape, disappointed the insulting triumph of the Romans, by strangling himself in the night. Romanus, who was the original cause of this rebellion, escaped with impunity, by fraud and forgery; and Theodosius, the restorer of Britain and of Africa, on a vague suspicion that his name and services were superior to the rank of a subject, was ignominiously beheld at Carthage. Gibbon's Hist. vol. iv. 301—308, 8vo.

The Romans, however, did not long retain their dominion in Africa. It was lost in consequence of a quarrel between BONIFACE and ÆTIUS, two Roman generals, who were rivals in reputation and power. The former was supreme governor of the Roman territories in this country; but in the year 427, he was induced to revolt, by the treachery of the latter: and in order to avenge his quarrel and maintain his authority, in opposition to his rival, he sought the assistance of Genseric, a warlike prince of the Vandals, who left the kingdom of Galicia, where he had succeeded his brother Gonderic, and sailing over the straits of Gades, landed on the coasts of Barbary, A. D. 429. The army, which he commanded, amounted at first only to 50,000 effective men; but his own dexterity, and the discontents of Africa, soon fortified the Vandal powers, by the accession of numerous and active allies. The wandering Moors of Mauritania precipitated themselves into an alliance with the enemies of Rome; and a crowd of naked savages rushed from the woods and vallies of Mount Atlas, to satiate their revenge on the polished tyrants, who had injuriously expelled them from the native sovereignty of the land. The persecutions of the DONATISTS favoured the design of Genseric, who avowed himself an enemy of the orthodox communion, and who led them to expect a repeal of the odious and oppressive edicts of the Roman emperors. The conquest of Africa was facilitated by the active zeal, or the secret favour, of a domestic faction; and the intolerant spirit, which disgraced the triumph of Christianity, contributed to the loss of the most important province of the west.

Boniface having vindicated his innocence at the imperial court, and regained the favour of the empress Placidia, repented of the application which he had made to Genseric, and attempted, by various conciliatory means, to induce him and his adventurers to return to Spain. But all his efforts for this purpose were ineffectual. Although Carthage, and the Roman garrisons, returned with their general to the allegiance of Valentinian, the rest of Africa was distracted with war and faction; and the inexorable king of the Vandals disdained all terms of accommodation, Boniface and his veterans, with the hasty levies of provincial troops, were defeated with considerable loss; the victorious barbarians insulted the open country; and Carthage, Cirta, and Hippo Regius were the only cities that still adhered to the declining interest of Rome. The long

and narrow tract of the African coast to which the Roman power extended was fertile and populous; and besides the supply which it afforded to the inhabitants, the annual exportation, particularly of wheat, was so regular and plentiful that Africa deserved the name of the common granary of Rome and of mankind; and it was called by an ancient writer the soul of the commonwealth. On a sudden, the seven fruitful provinces, from Tangier to Tripoli, were overwhelmed by the invasion of the Vandals; and where they found resistance, such were their dispositions and habits, they seldom gave quarter. Boniface, distressed beyond measure by the view of the ruin which he had occasioned, and by his inability to stay its progress, retired into Hippo Regius, which was immediately besieged. By the skill of this distinguished commander, the siege was protracted above 14 months; and thus Boniface was recruited by a powerful armament from Constantinople. As soon as he obtained this help he marched out against the Vandals; and the loss of a second battle irretrievably decided the fate of Africa; upon which he embarked for Italy with the precipitation of despair, and soon after, A. D. 432, fell in a rencounter with his rival ÆTIUS. In the year 439 Carthage was reduced, 585 years after the destruction of the city and republic by the younger Scipio: the licentious troops of the victor were permitted to satiate their rage and avarice, and all persons were enjoined by an edict, and under the threatened penalty of death and torture, to deliver their gold, silver, jewels and valuable furniture or apparel, to the royal officers. The lands that formed the immediate district of Carthage were divided among the barbarians; and Genseric reserved for his own domain the fertile territory of Byzacium and the adjacent parts of Numidia and Gætulia. Genseric was no less arbitrary and intolerant in the government of the church than of the state. He would not allow the Africans, who fled before him in the field, to dispute his will in synods and churches; and therefore, as he himself had renounced the orthodox communion, he oppressed his catholic subjects by severe laws and punishments. His son Hunneric, who succeeded him, A. D. 477, inherited his vices, and tormented the catholics with the same unrelenting fury. The throne of Africa was successively filled by the two nephews of Hunneric, by Gundamund, A. D. 484, and by Thrasimund, A. D. 496; both of whom emulated the cruelty of their uncle, and the last of whom even exceeded it: for in the hour of death he exacted from his successor a solemn oath, that he would never tolerate the sectaries of Athanasius. Hilderic, the gentle son of the savage Hunneric, ascended the throne A. D. 523, and his accession was distinguished by the restoration of peace and universal freedom. In 530, the government was wrested from him by his cousin Gelimer; but the Vandal kingdom, before he could enjoy or abuse his power, was subverted by the arms of Belisarius; and the orthodox party retaliated the injuries which they had suffered. The recovery of Africa was intrusted by Justinian with Belisarius; and in 533 he landed on the coast with an army, well chosen and properly equipped for the important service to which they were destined. As the Romans approached Carthage, the mind of Gelimer was filled with anxiety and terror. The battle that ensued terminated in the defeat of the Vandals, who, accustomed only to a Moorish enemy, were incapable of withstanding the arms and discipline of the Romans. Gelimer fled towards the deserts of Numidia; and Belisarius pitched his camp on the field of victory at the distance of ten miles from Carthage. When he drew near the city, he found it blazing with torches, as signals of the public joy; the gates were thrown open; and the inhabitants, with acclamations of gratitude, hailed and welcomed their Roman

deliverers. When the Imperial fleet arrived, the mariners were immediately landed to unite with the military in the triumph of their conquest; and they were directed by Belisarius to remember, in their march through the city, that the Vandals had been the tyrants, but that they were the deliverers of the Africans, who must now be respected as the voluntary and affectionate subjects of their common sovereign. "The voice of menace and complaint was silent; the trade of Carthage was not interrupted; while Africa changed her master and her government, the shops continued open and busy; and the soldiers, after sufficient guards had been posted, modestly departed to the houses which were allotted for their reception. Belisarius fixed his residence in the palace; seated himself on the throne of Genferic; accepted and distributed the barbaric spoil; granted their lives to the suppliant Vandals; and laboured to repair the damage which the suburb of Mandracium had sustained in the preceding night. At supper he entertained his principal officers with the form and magnificence of a royal banquet."

Gelimer, who endeavoured to rally his scattered forces, encamped within four days' journey of Carthage, and was joined by his brother Zano, who returned to him, at his earnest request, from the conquest of Sardinia. In their march towards Carthage, their army increased, and surpassed, in a tenfold proportion, that of the Romans, commanded by Belisarius. After a severe engagement, Zano fell; and the pusillanimous flight of Gelimer exposed the vanity of his recent declaration, that, to the vanquished, death was a relief, life a burthen, and infamy the only object of terror. The Vandals, deserted by their king, hastily dispersed; and the Romans entered the camp without resistance, and disgraced themselves by the massacre and plunder which followed their victory. Belisarius, with the dawn of the next morning, recalled them to order and obedience; and he extended his protection to the suppliant Vandals, exercising a proper vigilance, that they might neither disturb the public peace, nor become the victims of popular revenge. Gelimer had fled to the inaccessible country of the Moors, and Belisarius, desisting from the pursuit, resolved to fix his winter-quarters at Carthage. From thence he conveyed information to the emperor, that, in the space of three months, he had achieved the conquest of Africa. The emperor received the news with devout gratitude; and proceeded, without delay, to the full establishment of the catholic church. "Her jurisdiction, wealth, and immunities," says Mr. Gibbon, "perhaps the most essential part of episcopal religion, were restored and amplified with a liberal hand: the Arian worship was suppressed; the Donatist meetings were proscribed; and the synod of Carthage, by the voice of 217 bishops, applauded the just measure of pious retaliation." Gelimer was traced to the mountain of Papua, in the inland country of Numidia, where he had struggled with the hardship and mortification of the most abject condition, and brought captive to Carthage. When the royal captive accosted his conqueror, he is said to have burst into a fit of laughter. Some might have inferred from this singular circumstance, that he had been deprived of his senses by extreme grief; but to more intelligent observers, this unseasonable mirth insinuated, that the vain and transitory scenes of human greatness are unworthy of a serious thought. Belisarius returned, A. D. 534, to Constantinople, and obtained a very signal and splendid triumph. Gelimer advanced slowly in the train of attendants on this occasion; and maintained the majesty of a king. Not a tear nor a sigh escaped him; but he repeatedly pronounced the words of Solomon, VANITY! VANITY! ALL IS VANITY! The departure of Belisarius

from Africa was followed by new troubles, which continued for several years, and accelerated the ruin of its most flourishing provinces. The taxes were multiplied by arbitrary assessments; the crown lands were resumed, and the Roman soldiers, who had married the widows and daughters of the Vandals, claimed the estates which Genferic had assigned to the victorious troops. The dissatisfaction and mutiny increased; and they were aggravated by soldiers, who had imbibed the doctrines, and were infligated by the clergy of the Arian sect. A conspiracy was formed at Carthage, against the life of Solomon, the successor of Belisarius; and a furious sedition was kindled in the Circus which desolated Africa above ten years. The head of the insurgents was a private soldier, whose name was Stozza. When he fell, another person, called Gontharis, promised to divide Africa with the Moors, and aspired to the throne of Carthage. His reign, however, lasted only 30 days. The rebellion of the Moors continued for some time; but their insolence was checked by a battle, in which 17 of their princes were slain, and the submission of their tribes was celebrated with lavish applause by the people of Constantinople. Such, it has been observed, was the desolation of Africa in the reign of Justinian, that, in many parts, a stranger might wander whole days without seeing the face either of a friend or an enemy. The nation of the Vandals, amounting to 160,000 warriors, exclusively of children, women, and slaves, had disappeared. Their number was much exceeded by that of the Moorish families, extirpated in a relentless war; and the same destruction was retaliated on the Romans and their allies, who perished by the climate, their mutual quarrels, and the rage of the barbarians. Procopius confidently affirms, that five millions of Africans were consumed by the wars and government of the emperor Justinian. The conquest of Africa, by the Saracens, was first attempted by the arms of the caliph Othman, A. D. 647; and the conduct of the war was entrusted to Abdallah, his foster-brother. After some partial successes and very considerable losses, in a campaign of 15 months, the Saracens retreated to the confines of Egypt, with the captives and the wealth of their African expedition. Their western conquests were suspended near 20 years. At length the fearless Akbah plunged into the heart of the country, traversed the wilderness, in which his successors erected the splendid capitals of Fez and Morocco, and penetrated farther to the verge of the Atlantic and the Great Desert. The career of Akbah was restrained by the prospect of a boundless ocean. Spurring his horse into the waves, and raising his eyes to heaven, he exclaimed with the tone of a fanatic—"Great God! if my course were not stopped by this sea, I would still go on, to the unknown kingdoms of the west, preaching the unity of thy holy name, and putting to the sword the rebellious nations who worship any other gods than thee." But this ardent conqueror was recalled from the shores of the Atlantic by the defection of the Africans; and overpowered by a multitude of insurgents, he had only left the resource of an honourable death. His fate was avenged by his successor Zuheir, who vanquished the natives in many battles, and was himself overcome by a powerful army, sent from Constantinople to the relief of Carthage. The conquest of Africa was resumed by the caliph Abdalmalek; and after some progress, his farther advances were obstructed by the forces of the eastern empire, under the præfect and patrician John, a general of experience and renown. But in the ensuing spring, he was compelled to evacuate the fortifications of Carthage; and after a second battle in the neighbourhood of Utica, the Greeks and Goths were again defeated,

and compelled to embark, and make their escape. The conquest of Africa was finally completed between the years 698 and 709. To the progress and establishment of the Saracens, we may ascribe the decline and extinction of Christianity, on the northern coast of Africa. Gibbon's Hist. of the Decline and Fall of the Roman empire, vol. iv. 301. vol. vi. 11, &c. vol. vii. 168.—186.—349. vol. ix. 449, &c.

When the Saracen empire was divided into seven kingdoms in 936, the African states retained their independence long after the others were subdued by the Turks; but in the beginning of the 16th century, being afraid of falling under the yoke of Spain, they invited the Turks to their assistance; who first protected, and then enslaved them. They are still dependent on the Ottoman empire; not as subjects of the Grand Seignior, but as acknowledging his protection by an annual tribute. On the coasts piracy prevails to such a degree, that some of the chief princes in Europe have been glad to procure liberty to trade in the Mediterranean without molestation, by a pecuniary compensation.

Africa, as it is described by modern geographers, is a large peninsula, connected with Asia by the isthmus of Suez; bounded on the north by the Mediterranean, which separates it from Europe; on the east by the above-named isthmus, the Red Sea, and the Indian Ocean, which divides it from Asia; on the south by the Southern Ocean; and on the west by the Atlantic, which separates it from America; and extending from Cape Bona in the Mediterranean, $37^{\circ} 10'$ N. lat. to the Cape of Good Hope, $34^{\circ} 29'$ S. lat. or about 4980 miles, and from Cape Verd $17^{\circ} 33'$ W. long. to Cape Guardafui, near the straits of Babelmandel, $51^{\circ} 20'$ E. long. or about 4790 miles. Its figure is that of a triangle or pyramid, whose base is the northern part, reaching along the Mediterranean from the mouth of the Nile to the straits of Gibraltar, and vertex the Cape of Good Hope; but the sides, extending along the Atlantic to the west, and the Red Sea or Indian Ocean to the east, are very irregular. As the equator passes nearly through the middle of the country, the greatest part of it lies within the tropics; and therefore the heat, augmented by the reflection of the sandy soil of the interior parts, is hardly tolerable to any besides the natives. Those parts, however, that lie near the coasts or in vallies, and on the banks of the rivers, are very fertile and productive; and the country in general is capable of great improvement by cultivation. Its situation for commerce is preferable to that of any other quarter of the globe; as it has a more easy communication with Europe, Asia and America, than either of these has with the rest. Its coast is opposite to that of Europe, for almost 1000 miles from east to west, and the distance of one from the other is no where 100 leagues, and in some places not more than 20 leagues. It is separated from Asia only by the Red Sea for a considerable interval from north to south, and their distance is from 5 leagues to 50: it also fronts the southern coast of Asia, though at a greater distance, and it is adapted for commerce by the interposition of islands from Madagascar to Malabar, and by the alternation of the trade winds. Its coast for 2000 miles lies opposite to America, and the western islands, at a distance of 500 to 700 leagues. Besides, it has many large and navigable rivers, which intersect the country in various directions, and form a communication between the internal parts and the surrounding ocean; and its harbours are very numerous and commodious, and capable of being rendered secure by fortifications. The principal rivers of Africa, which we shall more particularly describe under their several names, are the NILE, NIGER, MOROCCO, GAMBIA,

SENEGAL, SIERRA LEONA, BENIN, CONGO, ZAIRE, WANZA, BRAVAHUL, RIO DEL SPIRITO SANTO, KUNENI, MACUMBO, LORENZO, SABLE, KUAMA or ZAMBESE, COAVO, ZEBEE, and MAGADONA. There are many other rivers which will be mentioned in the detail of the several countries to which they belong. On the banks of several of these rivers there are villages and towns, which carry on a considerable traffic, and exchange their valuable commodities, as gums, elephant's teeth, slaves, civet, bezoar and gold dust for European trinkets, glass beads, bugles, or, at best, some brass or iron tools, and frequently for brandy and other spirituous liquors, of which the inhabitants are so fond that they will part even with their children in order to obtain them. Another source of commerce is found in the mines with which the mountains abound. The mountains of Africa are the ATLAS, the *mountains of the MOON*, the *mountains of SIERRA LEONA*; the mountains of Crystal near the lake of Zafan, so called from their mines of that beautiful mineral, and those of sakt-petre, stretching eastward from the kingdom of Congo, the Pico-franco running through the middle of Caffraria, and part of the country of the Hottentots, the Table mountain at the Cape of Good Hope, so called from its square figure, and other mountains of ABYSSINIA. From the discoveries of Mr. Park, a late traveller in Africa, we learn, that a belt of mountains, extending from west to east, occupies the parallels between 10 and 11 degrees of N. lat. This great ridge of mountains is very productive in gold, and more particularly in the parts opposite to MANDING and BAMBOUK on the west, and to WANGARA on the east. See ТОМБУСТОО.—Most of the countries bordering on the mountains share in their wealth by means of the rivulets that flow from them. There is no country in the world, says Leo Africanus, richer in gold and silver than some kingdoms in Africa; as those of Mandingo, Ethiopia, Congo, Angola, Butua, Quiticui, Monomotapa, Cafati and Mocnemugi. Father Labat also minutely specifies a great variety of rich mines, of which the negroes have not been able to avail themselves sufficiently, on account of their ignorance of the operations of mining. Copper is a valuable ore found in this part of the globe; and in such abundance, that an opinion prevails, that the mountains called Atlas are all copper. On the northern coasts, the fields, though imperfectly cultivated, produce very large crops of grain: and it is very reasonably supposed, from the qualities of the soil and climate in different parts of the country, that the richest articles of the East and West-India commerce might be obtained from Africa. The spices of Banda, Ternate and Amboyna, might be produced on the rich and fruitful shores of Melinda on the east side, or on those of the slave coast on the west side of the country. The cinnamon of Ceylon, the tea of China and Japan, and the coffee of Mocha, might be produced on the same coast; and it has been affirmed, that the sugars of Barbadoes and Jamaica, and also the ginger, cotton, rice, pepper or pimento, with the cocoa, the indigo, and every other plant which is now obtained from these islands, would be as easily produced in Africa, and that the crops would be equally profitable, if they were cultivated with the same skill and industry as in America. Notwithstanding the capability of cultivation and the advantages for commerce which Africa possesses, it is lamentable to reflect, that a country which has near 10,000 miles of sea-coast, many large rivers and good harbours, a productive soil and extensive population, should remain destitute of the benefits which arts and industry, and commerce, might afford them. It is a reproach to neighbouring nations, that such a country should be so long neglected;

people; and that the principal advantage derived from it should be of that kind, which entails war and wretchedness on the Africans themselves, which perpetuates the degradation and misery of so great a part of the human species, and which reflects indelible disgrace on those enlightened and christian empires of the globe, that, amidst all the improvements of modern times and various laudable attempts for ameliorating the condition of mankind, have not, at the commencement of the nineteenth century of the CHRISTIAN era, abolished a traffic, long known and long lamented, under the denomination of the *SLAVE-trade*. Of the nature of this trade, and of the efforts that have been made for restraining, regulating and abolishing it, an account will be given under that article. The principal branches of the African trade are slaves, gold and ivory, which is carried on with the GUINEA or western coast, by the exchange of woollen and linen manufactures, hard-ware and spirituous liquors. The Dutch and French, as well as the English, have their different settlements for this purpose. See *African Company*;—GOLD, GRAIN, IVORY and SLAVE *trade*, and SIERRA LEONA. The Portuguese are in possession of the east and west coasts of Africa, from the tropic of Capricorn to the Equator; which immense tract they became masters of by their successive voyages and fortunate discovery of the Cape of Good Hope. From the coast of Zanguebar, on the eastern side, they trade not only for the articles above-mentioned, but likewise for several others, as *Senal*, *adocs*, civet, ambergris and frankincense. The Dutch have had also settlements towards the southern parts of the continent, in the country called Caffraria, or the land of the Hottentots; and they were long in possession of the Cape Town, which is well settled and fortified, till it was captured by the English in 1797, but restored and made a free port by the peace of 1801; and here their ships bound for India were accustomed to put in, and trade with the natives for their cattle, in exchange for which they gave them spirituous liquors. Some laudable attempts have been lately made for establishing colonies on the western coast of Africa, with a view of civilizing the inhabitants, introducing commerce among them, and gradually abolishing the slave-trade. M. Wadstrom in his Essay on Colonization, published in two parts in 1794 and 1795, has given a particular account of these attempts; but we are sorry to observe that their permanent utility is very doubtful and precarious. See AQUAPIM, BULAM, SIERRA LEONA, and SLAVE-trade.—With respect to the inland parts of Africa, they seem in all ages of the world to have been in the same barbarous and uncivilized state in which we find them at present. To account for this fact an ingenious writer observes, that there are in Africa none of those great inlets, such as the Baltic and Adriatic seas in Europe, the Mediterranean and Euxine seas in both Europe and Asia, and the Gulphs of Arabia, Persia, India, Bengal, and Siam, in Asia, for carrying maritime commerce into the interior parts of that great continent; and the great rivers of Africa are at too great a distance from one another to give occasion to any considerable inland navigation. Besides the commerce which any nation can carry on by means of a river, which does not break itself into any great number of branches or canals, and which runs into another territory before it reaches the sea, can never be very considerable; because it is always in the power of the nations who possess that other territory to obstruct the communication between the upper country and the sea. Smith's Wealth of Nations, vol. i. p. 32. The chief capes on the African coast are BON, BLANCO, CANTIN, GEER, NON, BOJADOR, BARBAS, VERD, MONTE, PALMAS, *Three POINTS*, COAST, FOR-

MESSA, LOFFZ, NIGRO, GOOD HOPE, FUMOS, COPIENTES, SEBASTIAN, DELGADO, and GUARDAFUI. There is but one strait in Africa, which is called BABEL-MANDEL. Modern geographers are not agreed about the division of Africa. Some have divided it into two general parts, under the denominations of the country of the whites and that of the blacks. The former comprehends Egypt, Barbary containing six subdivisions, viz. Barca, Tunis, in which is Tripoli; Tremecen, in which is Algiers; Fez, Morocco; Dara, Biledulgerid, and Zaara or the Desert. The country of the blacks contains the following provinces on the sea-coast, viz. Nigritia, Guinea, Congo, Caffraria, Sofala, Abex, Ajan and Zanguebar; and in the interior parts, Nubia, Ethiopia or Abyssinia, Moenomugi and Monomotapa. The following general distribution will direct the reader to those articles in this dictionary, where he may find a further account of the several kingdoms and states of which it consists, viz. 1. EGYPT. 2. *Upper* Ethiopia, comprehending NUBIA, ABYSSINIA and ABEX. 3. ZANGUEBAR, with ANIAN or Ajan, which lie on the east of Africa. 4. *Lower* ETHIOPIA, in the interior part, MOENOMUGI, MONOMOTAPA and CAFFRARIA, called by some the land of the HOTTENTOTS, which lie on the south. 5. GUINEA, upper and lower, on the south-west. 6. NIGRITIA or NEGROLAND, in the middle of Africa, extending almost quite through the country, from east to west, on both sides of the river Niger. 7. SAHARA or ZAARA, or the Desert, to the northward of Nigritia. 8. BILEDULGERID, to the northward of Sahara. 9. The empire of FEZ and MOROCCO, containing the north-west part of Africa. 10. The coast of BARBARY, on the north, containing the countries of ALGIERS, TUNIS, TRIPOLI and BARCA. Major Rennell in his Geographical Illustrations of Mr Park's journey, represents north Africa as composed of *three* distinct parts. The *first* and smallest is a fertile region along the Mediterranean, commonly distinguished by the name of *Barbary*; and which, on the supposition that the Mediterranean was once dry land, with the exception of a lake for the surrounding rivers, might be regarded as a part of Europe; because it possesses more of the European than of the African character. The *second* part is what may be deemed the body of north Africa, comprised between Cape Verd and the Red Sea, on the west and east; and having the Great Desert or Sahara and its members, on the north; the Ethiopic ocean and south Africa on the opposite side. The prominent feature of this immense region is a vast belt of elevated land, generally running from west to east about the tenth degree of latitude, and extending from Cape Verd, its western extremity, to the mountains of Abyssinia, the eastern extremity; which has on the north side a lofty tract, that turns the Nile to the northward beyond Abyssinia, and on the south a multitude of rivers, some of them very large, that descend from that side, and join the Atlantic and Ethiopic seas, from the Rio Grande on the west to Cape Lopez on the east. A similar ridge stretches to the south, through the middle of south Africa, and forms an impenetrable barrier between the two coasts; on this account the Portuguese in Congo and Angola have never been able to penetrate to the coast of the Indian Ocean. From Mr Bruce (Travels, vol. iii. p. 668.) we also learn, that a high chain of mountains from 6° runs southwards through the middle of Africa; and he supposes the gold of Sofala to be drawn from these mountains. Major Rennell supposes, that the surface of the Sahara has a general dip to the southward, whilst it declines also to the eastward; and that the rivers receive all their supplies from the south, no streams of any bulk being col-

lected in the Desert. Hence he infers, that there must be a large hollow in the interior of Africa, between the high land of Nubia on the east, and Munding on the west, and of which the mountains and Desert form the other two sides; similar to the cavity in Asia, to whose waters the Caspian and Aral serve as recipients. The *third*, part of north Africa, in the distribution of Mr. Rennell, is the Great Desert or Sahara, and its members, consisting of the lesser deserts of Bornou, Bilma, Barea, Sort, &c. For the description of this part, see SAHARA.

Many laudable attempts have been lately made, under the encouragement afforded by the *AFRICAN Association*, for discovering the interior, and hitherto very much unknown, parts of Africa. Mr. Park, a very intelligent and intrepid, and it may be justly added, a very successful adventurer in this mission, has made several important discoveries. Having left PISANIA, N. lat. 13°. 35'. about 200 miles from the mouth of the Gambia, Dec. 2, 1795, he returned thither after an absence of eighteen months. In this long interval of time, he explored the interior of Africa to the distance of 1200 miles, in a direct line from Cape Verd; proceeding in a tract bounded by the 15th and returning by the 12th parallel of latitude. His first station was MEDINA, the capital of the kingdom of WOOLLI, whence he pursued his journey by KOLOR, to KOOJAR, the frontier towns of this country. Here he refreshed himself with a liquor made from corn previously malted, with bitter roots instead of hops. After passing a wilderness of two days journey, he reached TALLIKA, the frontier town of BONDOU, and at FATTECONDA, the capital, he was introduced to the king Almami. From Bondou Mr. Park proceeded to the kingdom of KAJAAGA, and having been ill treated at JOAG, the frontier town, he prosecuted his journey to the kingdom of KASSON, and passing TESSEF, the frontier town, arrived at KOONIAKARY, the capital. Here he was treated kindly by the king; and having remained here for some time, he resumed his journey, and arrived at KENMOO, the capital of KAARTA. Following the route which Daifi, the king of this country, prescribed, through the kingdom of LUDAMAR to that of BAMBARRA, he passed MARINA, on his way to SIMBING, the frontier town of LUDAMAR.

Having left JARRA, the frontier town of this country, he pursued his journey and reached SAMPAGA. He was afterwards seized by a party of Moors, and conducted back to BENOWM, the residence of Ali, king of Ludamar, where he was treated with great severity by the bigotted and malicious Moors, and escaped death only by a pistol's twice missing fire. At length he fortunately escaped, and reached a negro town called WAWRA, belonging to Mansong, king of Bambarra; and passing through several towns of this kingdom, he arrived at SEGO, on the banks of the Niger, which he found to be as broad as the Thames at Westminster, and flowing slowly to the *eastward*. Pursuing his course in this direction along the banks of the river, he passed through the towns of KABBA, MODIBOO and KEA, and reached MOORZAN. Here he crossed the Niger to SILLA, which was the termination of his journey to the east. In his return westward on the northern bank of the river, he arrived at BAMMAKOO, the frontier of the kingdom of Bambarra, and quitting the Niger at this place, he proceeded to SIBIDOOLOO, the frontier town of the kingdom of MANDING. Hence he pursued his journey to KAMALIA, where he remained seven months. In his progress from Kamalia he traversed the JALONKO wilderness, by an interval of 100 miles, and having crossed the Black River, a principal branch of the Senegal, he arrived at MALACOTTA; and after a journey of 500 miles reached

Medina, the capital of the king of Woolli's dominions, on the 4th of June 1797, which he had left in December 1795. From hence he proceeded to Pisania, and afterwards returned to England.

All the inhabitants of the African continent, though distinguished under a variety of denominations, according to their different situations, origin, tribes and governments, are commonly included under the twofold distinction of Africans and Arabs, or Whites and Blacks. The white Africans, according to Leo Africanus, (l. i. c. 9.) and Marmol, (l. i. c. 24.) are divided into five nations or tribes, *viz.* the ZANHAGIANS, MUSMUDANS, ZENETÆ, GUMERANIANS, and FLOARES; and to these 600 capital families of BERBERS, and the most considerable ones in Africa, owe their origin. They first settled in Barbary, and from thence gradually dispersed themselves over the greatest part of Africa. For an account of the black Africans, see BLACKS and NEGROES.

The Ancients and Moderns have concurred in giving a very unfavourable representation of the disposition and character of the native Africans. Lucan (l. iv.) Virgil (*Æn. viii. cum not. Servii*) and many others, describe them as proud, indolent, thievish, revengeful, addicted to all kinds of lust, cruel, inconstant, superstitious and cowardly. So general has been the unfavourable opinion entertained concerning these people, that it has given occasion to a common proverb, that all the inhabitants of the globe have some good as well as ill qualities, except the Africans. But this degeneracy of character is owing more to their bad education, their tyrannical governments, and their unsettled state, than to their country; for this has produced several distinguished persons, among whom we might enumerate St. Cyprian, Augustin, and Tertullian, in the class of divines; Hanno, Hannibal and Afrubal, in the list of heroes; Terence among the poets, and many others. We might also appeal to the industry with which they have formerly cultivated their lands, and applied to commerce and the useful arts. If they are now, too generally, ignorant and depraved, idle, dishonest or superstitious, we are to seek the cause of the evil in the nature of their governments, and the inattention and neglect with which they have been treated. The religion of the native Africans has been the grossest kind of idolatry, blended with the magical and superstitious rites of the ancient Egyptians. Nevertheless we discover many relics of Judaism not only in ABySSINIA, but in many other parts of Africa; where many Jews, driven there at a very early period, or by the dispersion after the destruction of Jerusalem, or by the persecutions of later times, have settled and maintained their religious worship and ceremonies. Christianity was also introduced at an early age of the Christian era into this country, and has subsisted, under one form or other, and amidst great dissensions and corruptions, in various districts of Africa to the present day. The interior parts of Africa remain still in the darkness of Paganism, as they have been in a great degree inaccessible to the most adventurous of the Europeans. Indeed, in the maritime provinces of this great peninsula, and especially where the Portuguese have their settlements, there are several districts in which the religion of Rome has prevailed over the savage superstitious of that barbarous region. But the ingenuous historians, even of the Roman Catholic persuasion, who have given accounts of the African colonies, acknowledge, that of the profelytes made to the faith of the gospel few deserve the denomination of Christians; as most of them retain the abominable superstitious of their ancestors, and the best among them dishonour their profession by various practices of a most vicious and corrupt nature. The missions in Africa have been much neglected by the Portuguese; and the few missionaries

missionaries that were sent thither were men void of learning, and destitute almost of every qualification that was necessary towards carrying on such an important undertaking. What may be the result of Protestant missions, more lately undertaken and prosecuted with a considerable degree of zeal, time alone must discover. Those who liberally patronize and encourage them, augur from circumstances that have already occurred increasing success. But the most prevalent religion in Africa (if we except Paganism) is that of Mahomet, which is blended and intermixed with tenets and practices, that are more or less of Pagan, Jewish and Christian original. See MARABOUTS. Of the habits and manners of the Africans, an account will occur under the appellation of ARABS, under the different denominations by which they are distinguished, as MOORS, NEGROES, &c. and in the description of the different countries in which they reside.

The interior parts of Africa are inhabited, according to Mr. Park's report, by three distinct races of men; *viz.* the MANDINGOES or proper negroes, native children of Nigritia; the FOULAHs, or white Æthiopians of Ptolemy and Pliny, who have neither the crisped hair, the thick lips, nor jetty blackness of the Mandingoes; and the MOORS, natives of Arabia, who, in their persons and complexions, exactly resemble the MULATTOES of our West Indies, and who are devoted followers of Mahomet, and the most intolerant, perfidious and sanguinary of the human race. Though these three nations are frequently intermixed, yet the negroes, whether Mandingoes or Foulahs, generally inhabit to the south of the moors. The negroes are for the most part husbandmen: the moors, like their Arabian ancestors, are roving shepherds, or wandering merchants; who seem, from the earliest times, to have overspread the habitable parts of the great African Desert, and the Oases or fertile islands, thinly scattered through that sandy ocean. Hence they extended their arms southwards, and made themselves masters of several of the negroe kingdoms on the Niger; so that their dominions form a narrow belt running from west to east on the skirts of the Desert, from the Atlantic coast to the mountains of Abyssinia. The common boundary of the moors and negroes forms a striking feature in the moral, as well as in the political and physical geography of Africa. Herodotus (compare Euterpe, c. 32, and Melpomene, c. 197—pp. 117 and 368. Ed. Wessell.) fixed the boundary of the Libyans and Æthiopians, *i. e.* of the moors and negroes, near the banks of the Niger; and in this respect circumstances do not seem to have been materially altered since his time.

Mr. Park observes, that the population in the countries which he visited was not very great, considering the extent and fertility of the soil, and the ease with which lands were obtained. He found many extensive and beautiful districts entirely destitute of inhabitants; and, in general, the borders of the different kingdoms were either very thinly peopled, or entirely deserted. Many places, such as the banks of the Gambia, the Senegal, and other rivers towards the coast, were unhealthy, and on this account unfavourable to population. To this circumstance, it is chiefly owing, that the interior countries abound more with inhabitants than the maritime districts; for the negro nations, observed by this traveller, though divided into a number of petty independent states, subsist chiefly by the same means, live nearly in the same temperature, and possess a wonderful similarity of disposition. Perhaps the circumstance of the slave-trade may suggest another cause of the poverty of native inhabitants towards the sea-coast. Our traveller concurs with others in representing the disposition of the women as uniformly benevolent; in proof of this

the following incident is related. When Mr. Park was prohibited by the king of Bambarra from crossing the Niger, and ordered to pass the night in a distant village, none of the inhabitants would receive him into their houses, and he was preparing to lodge in the branches of a tree. In this state, exhausted with hunger and fatigue, and unprotected from a storm, he was relieved by a woman who was returning from the labours of the field. To her hut he was kindly invited; and his distress was alleviated by the tender attention which he experienced. The female part of the family, says Mr. Park, lightened their labour by songs, one of which was composed extempore; for I was myself the subject of it. It was sung by one of the young women, the rest joining in a sort of chorus. The air was sweet and plaintive; and the words, literally translated, were these: "The winds roared, and the rains fell.—The poor white man, faint and weary, came and sat under our tree. He has no mother to bring him milk; no wife to grind his corn.—*Chorus.* Let us pity the white man; no mother has he, &c. &c." These words have been since formed into verse by the Dukes of Devonshire, and set to music by Ferrari; and the song is as follows:

I.

The loud wind roar'd, the rain fell fast;
The white man yielded to the blast:
He sat him down, beneath our tree;
For weary, sad, and faint was he:
And ah! no wife or mother's care,
For him, the milk or corn prepare:

CHORUS.

*The white man shall our pity share:
Alas! no wife or mother's care,
For him the milk or corn prepare.*

II.

The storm is o'er; the tempest past;
And mercy's voice has hush'd the blast:
The wind is heard in whispers low,
The white man far away must go:—
But ever in his heart will bear
Remembrance of the negro's care.

CHORUS.

*Go, white man, go;—but with thee bear
The negro's wish, the negro's prayer:
Remembrance of the negro's care.*

From Mr. Park we further learn, that with respect to the property in the soil, the lands in native woods were considered as belonging to the king, or, where the government was not monarchical, to the state. When any individual of free condition had the means of cultivating more land than he actually possessed, he applied to the chief man of the district, who allowed him an extension of territory, on condition of forfeiture, if the lands were not brought into cultivation by a given period. The condition being fulfilled, the soil became vested in the possessor; and, for aught he knew, descended to the heirs. The Africans appear to have no astronomical knowledge; and the little geography to which they pretend is erroneous; for they suppose, that the earth is an extended plain beyond which is the sea, or river of salt-water; and on the farther shores of which are situated two countries, called Tobando doo, and Jong sang doo, "the land of the white people;" and "the land where slaves are sold." Park's Travels in the interior districts of Africa in 1795, 1796, 1797. *passim.*

AFRICA, the name of a sea-port of Tunis on the coast of Barbary,

Barbary, 30 leagues south-east from Tunis, N. lat. 35° 36'. E. long. 11° 10'. The fortifications were demolished by Charles V.

AFRICA, in *Antiquity*, is represented on medals by the head of a woman, dressed in the skin of an elephant, with the trunk projecting forward in front. This kind of attire is peculiar to some queens of Egypt. Near the figure of Africa we frequently see a scorpion, serpent, or lion, animals belonging to this part of the world, and mountains alluding to the seven mountains of Mauritania Tingitana.

AFRICAN Association was formed in 1788, with a view of promoting the discovery of the interior parts of Africa. Out of 95 members, of which this society appears to have consisted, a committee of five gentlemen was elected, for directing its funds, conducting its correspondence, and the choice of the persons to whom the geographic mission was to be assigned. These gentlemen were Lord Rawdon, the Bishop of Landaff, (Dr. Watson) Sir Joseph Banks, H. Beaufoy, Esq. and Mr. Stuart. The two first persons that were appointed for accomplishing the laudable object of the society were Mr. Ledyard and Mr. Lucas. The former undertook, at his own desire, the perilous task of travelling from east to west in the latitude attributed to the Niger, the widest part of the continent of Africa. With this view he arrived at Cairo in August 1788; but death disappointed the hopes that were formed from his projected journey. For a short account of the singular adventures of this extraordinary man, see LEDYARD. Mr. Lucas embarked for Tripoli in October 1788, with instructions to proceed over the desert of Zaara to Fezzan, to collect, and to transmit by way of Tripoli, whatever intelligence he could obtain respecting the interior of the continent, and to return by way of Gambia, or the coast of Guinea. The peregrinations of this traveller terminated at Mefurata, in Feb. 7, 1789; and he was able to transmit to the society only the result of his conferences with persons who were travelling with him to Fezzan. See FEZZAN, BORNOU, and CASHNA. The object of Mr. Park's mission was to ascertain the course, and, if possible, the rise and termination of the Niger, and to use his utmost exertions for visiting the principal towns in its neighbourhood, particularly TOMBOCTOO and HOUSSA; and of the result of it some account is given in the preceding article, and will be farther found under the several heads to which we have referred.

AFRICAN Company. See COMPANY.

AFRICAN Islands are distributed into those which lie in the Eastern or Indian Ocean, and those of the Western or Atlantic Ocean. The former are ZOCOTRA or SOCOTORA, BABELMANDEL, COMORRA islands, MAURITIUS, MADAGASCAR and BOURBON. The latter are ST. HELENA, ASCENSION, ST. MATTHEW, ST. THOMAS, ANNABOA, PRINCE'S island, FERNANDO PO, GOREE, CAPE VERD islands, ARGUIN island, CANARY islands, MADEIRA, PORTO SANTO, and the AZORES.

AFRICANUS, JULIUS, in *Biography*, an eminent christian writer and chronologer, who flourished in the beginning of the third century. It is not certain, whether he was a native of Palestine, or of Africa; but as he was employed in an embassy to the emperor Heliogabalus, between the years 218 and 222, for the restoration of Emmaus, which was afterwards called Nicopolis, and as he attended the lectures of Heraclius, at Alexandria, some time before the year 231, there can be no doubt concerning the time in which he lived. Suidas says he was of Africa; but his more constant residence seems to have been in Palestine, where he was probably born. The works ascribed to this author by Eusebius and Photius

are "the Cesti," a collection of passages from various authors, chiefly on physical topics, of which only a few fragments remain; "Chronology," in five books, containing a recital of events from the creation to the year of Christ 221; and two letters, "one to Origen," concerning the history of Sufanna, annexed to the book of Daniel, which he considers to be a forgery, and "another to Aristides," for reconciling the disagreement between Matthew and Luke, on the genealogy of Christ. The Cesti is ascribed by Valerius, J. Scaliger and Du Pin, to another person called Sextus, who was an African and a Gentile philosopher. Jerom does not include it in the list of the works of Africanus; but Vossius and Wetstein believe it to have been written by him. Julius Africanus was undoubtedly a christian, nor does antiquity justify the opinion that he was originally a heathen. The chronology is much commended by Photius, as concise and yet comprehending every thing necessary to be related. Some fragments of it are preserved; and have been freely used both by Eusebius in his chronicle and by other historians. Of the letter to Aristides, there is a large fragment in Eusebius's Ecclesiastical History, and the entire letter to Origen is extant, which is learned and critical, and does great honour to its author. Africanus affords a valuable attestation to the two Gospels of St. Matthew and St. Luke; and we have sufficient reason to believe, that this great and learned man received as scripture the books generally received by Christians in his time. "We may glory," says the excellent Dr. Lardner, "in Africanus as a christian. For it cannot but be a pleasure to observe, that in those early days there were some within the inclosure of the church of Christ, whose shining abilities rendered them the ornament of the age in which they lived; when they appear also to have been men of unspotted characters, and give evident proofs of honesty and integrity." Lardner's works, vol. ii. p. 431

—441.

AFRICANUS, LEO. See LEO Africanus.

AFRICANUS, SCIPIO. See SCIPIO.

AFRICERONES, a people, according to Ptolemy, of Libya, a province of Africa.

AFRICTA denotes a kind of wafers, which the ancients used in their sacrifices. Arnob. lib. vii.

AFRIQUE, in *Geography*, a small town of France, in the department of Aveyron, six miles east of Vabres.

AFRIQUE, a mountain of France in Burgundy, extending between Dijon and the small town of Chagni about ten leagues. At the foot of these mountains the vines are found which yield the Burgundy wine.

AFSHAR, the denomination of a Turcoman tribe, which is divided into two or three clans, of one of which the father of Kuli Khan was chief.

AFSLAGERS, persons appointed by the burgo-masters of Amsterdam, to preside over the public sales made in that city. They must always have a clerk of the secretary's office with them, to take an account of the sale. They correspond to OUR BROKERS, or AUCTIONEERS.

AFT, the hinder part of the ship, or that nearest the stern. See ABAFT.

AFTER, is a term applied to any object in the hinder part of the ship, as after-hatchway, after-sails, &c.

AFTER-BIRTH, in *Midwifery*. See PLACENTA.

AFTER-grass, or **AFTER-math**, in *Agriculture*, denotes the second crop, or grass which springs up after mowing; or grass-math that is cut after some kinds of corn.

AFTER-noon, the latter half of the artificial day, or that space between noon and night.

The ancient Romans dedicated their afternoons to diversion,

sion, as their forenoons to business; and their usual diversions were the game called *pila*, and other exercises of the body, especially walking or riding. These lasted till the eighth or ninth hour, answering to our three o'clock, which was the time for the baths. After bathing, they anointed and perfumed themselves; and, about the tenth hour, went to *cena*, *supper*, about three hours before sun-set; which done, the day was ended at the public spectacles, theatrical or amphitheatrical sports; with music, singing, and the like.

AFTER-fails usually comprehend all those which are attended on the mizen-mast, and on the stays, between the mizen and main-masts.

AFTER-throvs, or *pains*, *enixus posteriori*, *dolores post partum*, in *Midwifery*, are pains resembling labour pains, though ordinarily less violent, which occur after the expulsion of the fœtus and placenta. They are occasioned by the contraction of the uterus to expel congealed blood, parts of the membranes, or other foreign bodies from its cavity, as well as to reduce the capacity of the blood vessels, which during pregnancy acquire a considerable magnitude, to the size they had prior to conception. They are more or less severe in different women, but are found very rarely to occur after first labours. They are more frequent, severe, and lasting, after the birth of large, than of small or middling sized children, or after labours that have terminated in an unusually quick and rapid manner, particularly if the placenta has been extracted almost immediately after the birth of the child. Mr. White, of Manchester, to whom we are indebted for many valuable practical observations, on the manner of conducting labour, is of opinion, that after-pains are almost entirely occasioned by extracting the shoulders and body of the child, immediately after the birth of the head, instead of waiting and suffering them to be expelled by the pains; and says, that by pursuing a different course, and leaving the whole of the process to nature, in ordinary cases, he had been so fortunate, that, in the course of several years, he had neither been under the necessity of introducing his hand into the uterus to extract the placenta, nor to give opiates or other medicines to quiet after-pains, except in a single instance, "the after-pains having been so trifling, under his management, both with regard to violence and duration, as not to deserve notice." *Treatment on the management of pregnant and lying-in women*, p. 111. See more on this subject, under the word *LABOUR*. After-pains, even when most severe, are still unattended with danger. They are best relieved by the application of warm cloths, with gentle friction to the abdomen, by giving internally twenty-five or thirty drops of the tincture of opium, or by assiduously rubbing upon the region of the uterus, a mixture composed of four parts volatile liniment, and one of the tincture of opium, by administering frequent draughts of warm gruel, and giving castor oil, or some other gentle purge on the following day. See *LABOUR*.

AFTER-swarms, in speaking of bees, are secondary or posterior swarms, frequently found to quit the hives within a fortnight after the first.

Butler tells us, that the after-swarms differ from the prime, in that the latter are directed by the vulgar, or crowd of bees, whose only rule is the fulness of the hive; whereas the former are appointed by the ruling bees, and indicated by a noise or call, which these make for the space of two or three days, as it were to give warning to the common herd to prepare for a march. Within eight or ten days after the prime swarm is gone, if the princefs next in order find a competent number fledged and ready, she begins to tune her

treble voice, in a mournful and begging note, as if she prayed the queen-mother to let them go; to which voice, if the vouchsafe a reply, by tuning her base to the other's treble, it marks her consent; in consequence of which, within a day or two after, if the weather allow, the new swarm appears. If the *prime* swarm be broken, the *after* will both call and swarm the sooner, perhaps the next day; in which a third, sometimes a fourth, succeeds in the same season: but all usually within a fortnight after the prime swarm. See *SWARM*.

AFTO, in *Botany*, a name given by the natives of Guinea, to a plant of the *crisimum* kind, which they grind to powder, and take as snuff, to cure the head-ach. Petiver has called this plant the woody and wooly *erysimum*, or hedge-mustard, of the coasts of Guinea. Phil. Trans. N° 232.

AFUERA, in *Geography*. See *AFFUERA*.

AFWESTAD, a large copper-work, belonging to the crown of Sweden, situate on the river Dal-Elbe, in the province Thalland or Dalecarlia. It resembles a town in its extent, and has its own church. Copper-plates are manufactured, and the small copper money is coined in this place; which has also a royal post-house.

AFZELIA, in *Botany*, a genus of the *didynamia angiospermia* class and order; the characters of which are, that the calyx is quinque-partite, the corolla campanulated, and the capsule rotundated, acuminate, double-celled, gaping at the apex and polyspermous; with hemispheric receptacles. There is one species, *viz.* the *Afzelia Cassioides*. This is the *Afzelia* of Gmelin, which Dr. Smith says is too uncertain to be honoured by such a name, after that of Adam Afzelius, professor of botany in the academy of Upsal; and therefore he has appropriated it to a new species of the *decandria monogynia* class and order, near the *Hymenaea*, and of the natural order of *leguminosæ*: the essential characters of which are, that the calyx is tubulose with a limb quadridid, deciduous; the petals are four, unguiculated, with a very large head; the filaments are two, superior, sterile; the legumen many-celled; the seeds arillated at the base. It is found in Africa, near the equinoctial. Linnæan Transf. vol. 4. p. 221.

AGA, in the language of the Moguls, &c. signifies a great man, lord, or commander.

In this last sense, the term is also used among the Turks: thus, the *Ag* of the Janizaries is their colonel; and is the only person who is allowed to appear before the Grand Seigneur, without his arms across his breast, in the posture of a slave. The *capî aga*, is the captain of the gate of the seraglio.

The title *aga* is also given, by way of courtesy, to several persons of distinction, though not in any office, or command, to entitle them to it; as to the eunuchs of the seraglio.

The chief officers under the *KHAN* of Tartary are called by this name. And among the Algerines, we read of *agas* chosen from among the *boluck bashis* (the first rank of military officers), and sent to govern in chief the towns and garrisons of that state. See *ALGIERS*.

On some occasions, in lieu of *aga*, they say *agasi*, or *agassi*. Thus the *aga*, or governor of the pages, is called *capî agassi*; and the *aga* or general of the horse, *spabilar agassi*.

AGA, or *ADJA*, in *Geography*, a village about half a mile from Anamaboa, on the *GOLD coast* of Africa, where the Dutch formerly had a fort; and where, it is said, they have now one factor. Its situation is by no means favourable to commerce, as the landing is difficult and dangerous; but the adjacent country produces several valuable commodities, and among others a very fine cotton.

AGA Cretensium, in *Botany*, signifies the Spanish milk-thistle.

AGA. See AGAR.

AGAAZI, or AGAGI, in *Geography*, a denomination given in Abyssinia to a class of those SHEPHERDS, who are said to have been employed by the descendants of Cush, the first inhabitants of the country, in dispersing the produce of Arabia and the eastern coast of Africa over the Continent, and who thus acquired wealth and influence. The noblest and most warlike of all the shepherds were those that inhabited the mountains of Habab, a considerable ridge reaching along the Red Sea, from the neighbourhood of Masuah to Suakem, and who by degrees extended themselves through the whole province of Tigré. *Ag-ag*, says Mr. Bruce, denoted the nobles and chiefs of the armed shepherds, whence came their title, *king of kings*; and the plural of this is *Agagi*, or, as it is written in the Ethiopic, *Agaazi*. The king of Amalek, mentioned 1 Samuel, ch. xv. and slain by Samuel, was, according to this writer, an Arab shepherd. Bruce's Trav. v. i. 387. Of this appellation, Ludolf (Hist. Æthiop. b. i. c. 1.) gives a different etymology. The Agaazi assumed this denomination, and called their country *Geez*, either on account of the liberty they enjoyed, or because they transported themselves from one place to another: the radical word *Geeza* admitting both these significations. Their language is *Geez*; they have always had letters among them; and they are all circumcised, both men and women. This right they profess to have derived from the family of Ishmael and his descendants, with whom they were connected at an early period in their trading voyages.

AGABENI. See AGUBENI.

AGABUS, in *Scripture history*, a prophet, and as the Greeks say, one of the 70 disciples of our Saviour (Acts xi. 28) A. D. 43. He predicted a great famine, which, as St. Luke informs us, occurred in the 4th year of Claudius, A. D. 44. It is also mentioned by profane historians, Sueton. in Claud. c. xviii. t. i. p. 668 ed. Pitisc. Josephus, ant. l. xx. c. ii. Oper. t. i. p. 960. ed. Haverc. On this occasion the Christians at Antioch sent their contribution by Paul and Barnabas to Jerusalem, for the relief of their distressed brethren. Helena, queen of Adiabene, also assisted the Jews with corn and other provisions from Egypt and Cyprus, as Josephus (*ubi supra*) informs us. Several years after this period (*viz.* A. D. 58) Agabus had an interview with St. Paul, at Cæsarea, and foretold the sufferings that awaited him at Jerusalem, whither he was determined to proceed, Acts xxi. 10. From the Greeks we learn, that Agabus suffered martyrdom at Antioch, and they observe his festival, March 8. The Latins, since the 9th century, have kept it, Feb. 9.

AGABRA or ÆGABRA, in *Ancient Geography*, a town of Boetia, in Spain.

AGADEK, one of the Fox islands in the Northern Pacific Ocean.

AGADEZ, in *Geography*, a kingdom of Africa, placed by Leo Africanus and Marmol, directly east of Yguida, and by De Lisle, south and south-east of it. On the east it has the kingdom of Bornou; on the north-north-east, the desert of Lempta, and Yguida; on the south, Cano; and on the west, the provinces Zapara and Guber, and a lake north of the Niger. This province is divided into two districts, the northern, called on account of its sterility, the Desert, and the southern, fertile in grass, corn and cattle. De Lisle mentions three considerable towns in the latter division, *viz.* *Agad*, the capital of the whole province, Deyhir and Secmana, little inferior in wealth and population to the metropolis. He adds, that *sena* is produced here in great abundance, and that the principal trade of the natives consists in this article and manna. The southern inhabitants feed

cattle, live in the open country, and resemble in their manners the wandering Arabs. Agad, the capital, called also by the Arabs Audegall, is situated in a valley between two high mountains, and at the spring of a considerable river that waters the southern country and discharges itself into the Niger. According to La Croix's account, the inhabitants are chiefly merchants, and strangers, who have settled there, enclosed the town with walls, and built their houses in the Moreseo fashion. The sovereign is said to be tributary to the king of Tombucto, and yet to preserve the state of a powerful, independent and despotic prince. Mod. Un. Hist. vol. xiv. p. 260. 8vo. The province of Agadez is placed by Major Rennell, in his map of North Africa, in the eastern division of the Great Desert, or Sahara, and the capital in N. lat. 20° 15'. E. long. 13° 14'. In the proceedings of the African association, Agadez is made a province of the Cashua empire, and the inhabitants are said to load their immense caravans with the salt of Bornou, and to engross the profits of this invaluable trade. The only acknowledgment they make for it is the trifling price which they pay in brass and copper (the currency of Bornou) to the neighbouring peasants.

AGADNA, a small town in the island of Guam.

AGAG, or AGAGA, a kingdom of Africa, which depends on the empire of Monomotapa. It is bounded on the east by the country of the Negroes, and on the north by the kingdom of Tacua. The capital is of the same name.

AGAGEER, a name given in Abyssinia to those whose business it is to hunt and kill elephants. Their appellation is formed from the word Agar, which signifies to hough or hamstring with a sharp weapon. These persons dwell constantly in the woods, and live entirely upon the flesh of the beasts which they kill, chiefly on that of the elephant and rhinoceros. They are light and agile, both on horseback and on foot; of a swarthy complexion; and have European features. None of them are woolly-headed. The manner in which they kill the elephant is as follows: two men, altogether naked, mount the same horse; the foremost manages the horse, and the hindmost has a broad sword, such as the Selavonians use, and procured from Trieste; the handle of which he grasps with his left hand, whilst with his right he takes hold of a part of the blade, round which whip-cord is twisted. The edges of the sword are as sharp as a razor, and yet he thus carries it without a scabbard. When the elephant is found feeding, the horseman runs before him, and when he flies, crosses him in all directions, using at the same time a variety of expressions and exclamations, which he is foolish enough to believe the elephant understands. The animal incensed by this noise, attempts to seize the horse and rider with his trunk, or proboscis; and for this purpose he turns himself about in every direction, instead of making his escape. The horseman after some evolutions of this kind, rides up to the side of the elephant and drops his companion on the off-side; and whilst the rider engages the attention of the animal, the other person gives him a stroke above the heel, in that part which in the human subject is called the tendon of Achilles. At this moment the horseman turns round and takes up his companion; and runs with full speed after the rest of the herd; and sometimes an expert Agageer will kill three out of one herd. The blow commonly separates the tendon, or at least wounds it to such a degree that the weight of the animal breaks it. In this state the horseman, and his companions, speedily dispatch the animal with their javelins and lances; when he is slain, the flesh is cut off the bones into strings, and these are hung on the branches of trees to dry, without salt; and are then laid by for their stock of provision in the season of the rains.

The elephant sometimes reaches the most dextrous riders with his proboscis; and having dashed the horse to the ground sets his feet upon him, and soon tears him limb from limb. Bruce's Travels, vol. iv. 297. &c. See ELEPHANT.

AGAI. See AGIO.

ΑΓΑΙ, in *Geography*, a small port of Provence, about two leagues from Frejus.

AGALACTIA, in *Physic*, signifies a deficiency of milk in a mother, who is therefore called by Hippocrates *αλακτος*.

AGALLEGA. See GALLEGA.

AGALLOCHUM, a medicinal wood imported from the East Indies, usually in small bits, of a very fragrant scent. The word is derived from the verb *αλλομαι*, I boast, in allusion to the excellency of its odour. This wood is otherwise called *lignum aloes*, and *xyloaloe*, q. d. *aloe-wood*, not that it is produced from the common aloe-plant, which yields the inspissated juice of that name. It is the produce of a tree of a very different kind, growing in the East Indies, particularly Sumatra and Cochinchina, or the EXÆCARIA *Agallocha* of Linnæus. Some call it likewise *lignum paradisi*. It yields a concrete oil. See its chemical history in Neumann's Works, p. 420.

It is of a bluish purple colour, marked with veins and spots, very heavy and bitter; when burnt it yields drops of an astringent liquor, and a sweet aromatic fume. It is hot and drying, and esteemed a great strengthener of the nerves in general, but particularly of the head and stomach.

The various names and accounts given of the agallochum are so very different, as well as the specimens of it common in our shops, that it does not seem to be properly known amongst us.

Bauhin and the Moderns distinguish three sorts of agallochum, which differ either as to the excellence of their quality, or to the country that produces them; accordingly they call the *first* CALAMBAC, which is the most excellent agallochum, denominated also calambac Indorum, kanam Cochinchinum, and fokio. The *second* is the agallochum of the shops, denominated *lignum aloes*. The *third* is also called CALAMBAC, agallochum sylvestre, and lignum aloes Mexicanum.

M. de Loureiro, whose long residence in Cochinchina, whence the real and most esteemed agallochum is exported to all the Asiatic markets, led him to an acquaintance with this substance, has described the tree which produces it, and gives a history of its formation. To the genus of plants, of which this is a species, he gives the name of ALOEXYLUM, and the particular species he calls *aloexylum verum*. The resinous concretion which is found in these trees, when in a decayed state, is the true agallochum, the history of which is satisfactorily detailed in a Memoir, on its true nature and origin, in vol. i. of the Memoirs of the Royal Academy of Sciences, at Lisbon.

AGALMATA, in *Antiquity*, originally denoted the ornaments of temples and statues; but came afterwards to be popularly used for the statues and temples themselves, and for the impressions and images on a seal.

AGAMA, in *Zoology*, a species of LACERTA, with a long round tail, the upper part of the neck and under part of the head aculeated, with reverse scales. There is a variety of this called *iguana salamandrina*, with the tail imbricated by large scales, as the former is denominated *iguana cordylina*. It is found in America.

AGAMASKA or VINERS, in *Geography*, an island in James's bay, in North America.

AGAMEDA, in *Ancient Geography*, a place in the isle of

Lesbos, near Pyrrha. Here was a fountain of the same name, which had been also that of a woman, who was distinguished by her skill in preparing poisons.

AGAMEMNON, in *Classical Biography*, one of the heroes engaged in the Trojan war, was the son according to Homer, and according to Herodotus, the grandson of Atreus, whom he succeeded in the government of Argos and Mycenæ. Homer calls him and his brother Menelaus Atrides, the sons of Atreus; but Hesiod and others say, they were the sons of Phisthenes, the brother of Atreus. Agamemnon, having engaged the succour of Tyndarus, king of Sparta, drove Thyestes, his uncle, from Argos; killed his son Tantalus, and married Clytemnestra, his wife, by whom he had four daughters, but according to Euripides only two, viz. Iphigenia and Electra, and one son, the famous Orestes. To him was entrusted the command of the confederate army against Troy, which expedition commenced, according to the chronology of Blair, 1193 years before Christ. At Aulis, where the fleet was detained by contrary winds, Calchas, the soothsayer, enjoined the sacrifice of Iphigenia, the daughter of Agamemnon, as a propitiatory offering to Diana; but his compliance with this superstitious and cruel order, produced a fatal hatred between him and his wife Clytemnestra. In the Trojan war, he distinguished himself as a prince and general; though his unjust treatment of Achilles, from whom he took Briseis, occasioned many evils to the Greeks. Upon his return he brought with him, as a concubine, Cassandra, the daughter of Priam, and was insidiously received by Clytemnestra, who had formed a criminal connection with Egisthus, and who assisted that prince in assassinating him. His son Orestes afterwards took revenge on the murderers; and the calamitous events that marked the history of this family have been favourite subjects of the tragic muse of ancient Greece, and of its imitators in modern times. The death of Agamemnon is the subject of a tragedy of Æschylus and of Seneca.

AGAMEMNON, in *Entomology*, a species of *Papilio*, with black wings, spotted with green, and the hinder ones having on the under part a lunated ocellus and red spots. It is found in Asia.

AGAMEMNON'S fountains were situated in Ionia, about 5000 paces from Smyrna.

AGAMENTICUS, in *Geography*, a high mountain of America, in the district of Maine, distant about six miles from Bald-head and eight from York harbour, which is a noted mark for seamen, particularly in the entry of Pascataqua harbour. It is covered with wood and shrubs, and affords pasture to its summit, whence the prospect is enchanting. N. lat. 43° 16'. W. long. 70° 39'.

AGAMENTICUS is also a river in the center of York county and district of Maine. It receives its waters from the ocean through the bay of Pascataqua, and has only a scanty supply from streams of fresh water. Its mouth is about four miles south from Cape Neddick river, and admits small vessels.

AGAMI, in *Ornithology*, a name given by the French at Cayenne, and applied by Buffon to the *Psophia crepitans* of Linnæus, the *grus psophia* of Pallas, the *Phasianus Antillarum* of Brisson, and the *gold-breasted trumpeter* of Latham; the specific character of which is, that its head and breast are smooth and shining green. This bird is 22 inches long, with a short tail concealed by the upper coverts and not projecting beyond the wings, and legs five inches high, covered with small scales, reaching two inches above the knee, which are not feathered. Its head, throat, and superior half of the neck, are covered with a short, close and soft down; the fore-

fore-part of the lower surface of the neck and breast are covered with a beautiful gorget of brilliant colours, varying between green, gold green, blue and violet: the upper part of its back and adjacent portion of the neck black, and the plumage of the hinder part of the back changes into a tawny-rufous; but the under-side of the body, and also the wings and tail are black, the great feathers which extend on the rump and tail are light ash-coloured; and the legs are greenish. The most characteristic property of these birds is the singular noise, called trumpeting, which they make, as some have commonly supposed by the anus, but as others have ascertained, by means of their lungs and the capacity of their membranous cells. The wind-pipe, before its entrance into the breast, is about the thickness of a swan's quill, bony and cylindrical. In the breast it is more slender and cartilaginous, and divides into two semicircular canals, formed of membranes, and capable of extension. The air-bag on the right side descends to the pelvis, and within the breast is divided into three or four cells, by transverse membranous diaphragms. That on the left side is much narrower, and terminates in the loins. The common food of these birds is grain; but they also eat small fish, flesh and bread. In their natural state, they inhabit the forests in the warm climates of America, and associate in large flocks on the mountains; and they escape, when surprised in their haunts, by the swiftness of their feet rather than by the use of their wings, as they never rise higher than a few feet. They form a bed for their eggs, of which they lay from 10 to 16, by scraping the earth at the roots of large trees, but construct no nest. In their domestic state, they manifest a wonderful attachment to their benefactors, and are no less fond and faithful than dogs. By their intercourse with men, their instincts are moulded like those of dogs; and it is said that they may be trained to tend a flock of sheep. They are jealous of rivals; fight with dogs, cats and birds of prey, and keep the poultry in great subjection. They follow persons through the streets and out of town, and it is difficult to get rid of them. Of all the feathered tribes the agami is the most attached to the society of man, and indeed is the only bird that has a social turn. In this respect it is as eminently distinguished above other birds, as the dog is above quadrupeds. Buffon's Birds, vol. iv. p. 390, &c. Eng. Transl.

AGAMI is also a species of ARDEA, in the Linnæan system by Gmelin, found in Cayenne, about 31 inches long, and having long feathers in the tail. These feathers are of a deep blue; the under side of the body is rufous; the neck is of the same colour before, but bluish below, and dark blue above. The head is black, the occiput bluish and crested, the temples and the portion above the eyes white.

AGAMIA, in *Ancient Geography*, a promontory and port of Asia Minor, near Troy. Steph. Byz.

AGAMINA, or AGAMANA, *Kabem*, a borough of Mesopotamia, situate, according to Ptolemy, on the Euphrates, towards 33° 55' lat.

AGAMIUS, a town of Asia Minor, near Heraclea.

AGAMIUM, a borough of Italy, belonging to the Infubres.

AGAN, in *Geography*, one of the Ladrone islands. Here Magellan, the famous navigator, was assassinated in 1521.

AGANAGRA, in *Ancient Geography*, a town of India beyond the Ganges, according to Ptolemy.

AGANGINÆ, a people of Ethiopia.

AGANIPPE, a fountain of Helicon, sacred to the Muses, whence they derived the appellation of *Aganippides*. Ovid (*Fast.* l. v. v. 7.) makes *Hippocrene* and *Aganippe* the same; but Solinus, and others, distinguish them and ascribe their being united to poetic licence. The water

of this fountain was, to those who drank it, the test of the furor poeticus.

AGANLY *river*, a branch of Kuban river, which falls into the sea of Afoph from the south.

AGANZAVA, a town of Asia, in the interior part of Media, situate, according to Ptolemy, in long. 89° and lat. 39° 30'.

AGAPÆ, or AGAPIS, formed of the Greek ἀγάπη, *love*, in *Church History*, a kind of religious festival, celebrated, in the ancient church, to keep up a harmony and concord among its members. To these *agapai*, we have a reference by St. Jude, v. 12. and also by St. Peter (2d Epistle c. ii. v. 13.) if with the Alexandrian copy, vulgar Latin and Arabic versions, we read ἀγαπᾶς for ἀγαπᾶν. Tertullian is the first author who has particularly described these feasts. Apolog. c. xxxix. Oper. p. 35. Ed. Rigalt. Having taken notice of some luxurious suppers among the Heathens, he adds, "the nature of our supper is indicated by its name; it is called by a word, which, in the Greek language, signifies love. We are not anxious about the expence of the entertainment; since we regard that as gain which is expended with a pious purpose, in the relief and refreshment of all among us that are indigent.—The occasion of our entertainment being so honourable, you may judge of the manner of its being conducted; it consists in the discharge of religious duties; it admits nothing vile, nothing immodest. Before we sit down, prayer is made to God. The hungry eat as much as they desire, and every one drinks as much as can be useful to sober men. We so feast, as men, who have their minds impressed with the idea of spending the night in the worship of God; we so converse, as men, who are conscious that the Lord heareth them.—Prayer also concludes the feast; and every one departs to his own concerns, &c." Pliny also (*Ep.* xvii. cited by Tertullian, Apolog. c. ii. *ubi supra* p. 3.) evidently refers to these feasts, when he informs Trajan, that the whole fault or error of the Christians was this, that it was their custom, on a stated day, to hold their assemblies before the morning-light, and to bind themselves by a sacrament (or oath) to do no wickedness, &c.; which things being performed they departed, and came again to partake of a common and innocent meal; from which however they desisted, after I published my edict against clubs or assemblies. Lucian (*de Morte Peregrini* § xii. Oper. t. iii. p. 335. Ed. Reitzii) says, that when Peregrinus, a Christian, was in prison, various suppers were brought in and their sacred discourses were delivered. These suppers seem to have been the agapæ of the ancient Christians. It appears, therefore, that they were of early original, and had been long in use; but they were not considered as an institution of the Gospel, or observed in obedience to a divine command. If this had been the case, they would not have been discontinued in consequence of the edict of a Heathen magistrate, or disused in future times. They were conducted with decorum, and afforded opportunities for the exercise of devotion and charity; and therefore do not warrant the reproach insinuated by a celebrated historian, who, in his usual sarcastic manner, says (*Gibb. Hist.* vol. ii. p. 346. Svo.) that "the feasts of love or agapæ, constituted a very pleasing part of the public worship." The ingenious Mr. Hallett in his discourse on the agapæ (*Notes on several texts of scripture, &c.* vol. iii. p. 235, &c.) maintains, in opposition to some other writers, that these agapæ, being suppers, were not concomitants, or appendages of the eucharist. They were entirely distinct and independent things, celebrated about twelve hours after the eucharist, which was celebrated in the morning. To which may be added the testimony of Justin Martyr, who, in his account of the public worship of the church, and particularly

larly of the eucharist, does not say one word of the *αγαπα*, or love-feasts, as connected with it either before or after. They continued in the church during the four full centuries; but the council of Laodicea, about the middle of the fourth century, banished them from the churches, and still allowed them in private houses. The third council of Carthage, A. D. 397, ordains by a canon, which is repeated by the African council, in the beginning of the fifth century, that they should not be held in churches, except in cases of peculiar necessity: with which the decree of the council of Auxerre, in the beginning of the seventh century agrees. Photius, about the middle of the ninth century, and Arsenius, in the middle of the thirteenth century, represent the matter accordingly; or that the *αγαπα* were prohibited in churches, but allowed and encouraged in private houses. When they were totally abolished, we have no account. When they were occasionally charged with impunity by the Heathens, they were restrained and regulated.

The kiss of charity, with which the ceremony used to end, was no longer given between different sexes; and it was expressly forbidden to have any beds, or couches for the convenience of those who should be disposed to eat more at their ease. Notwithstanding these precautions, it was found necessary to discontinue them; for as they were introduced when Christians had all things common, or with the community of goods, which under wise restrictions their first circumstances required, they remained long after the disuse of the custom, which was the original occasion of them. See *ABYSSINIA*.

Some authors imagine the *αγαπα* to have been, not a commemoration of our Saviour, but a custom borrowed from the Heathens: *Mos vero ille, ut referunt, says Sedulius, on the xith chapter of the Epistle to the Corinth. de Gentili adhibe superstitione veniebat.* And Faustus, the Manichee, is represented, by St. Augustine, as reproaching the Christians with converting the Heathen sacrifices into *αγαπα*: to which he replies, we do not borrow our love-feasts from the sacrifices of the Gentiles; our love-feasts feed the poor. Cont. Faust. Manich. l. xx. c. 20. Some have thought that St. Paul speaks of the *αγαπα*, when he reproves the Corinthians for their disorderly practice. 1 Cor. xi. 17, &c. These *αγαπα*, as Chryostom, Theophylact, Pelagius, Oecumenius, &c. imagined, immediately succeeded the eucharist; and at these feasts the disorders happened. Mr. Hallett (*ubi supra*) contends, that they occurred in celebrating the eucharist itself. It may be observed, that the Christians did not consider the *αγαπα* as religious or divine institutions, like the Lord's supper. If they had, their councils would no more have banished them out of the churches than the eucharist itself.

AGAPANTHUS, (*quasi αγαπηθος ωθος, pleasant flower*) in Botany, a genus of the *hexandria monogynia* class and order, of the natural order of *Liliacea*, the *Spathaceæ* of Linnæus, and the *Narcissi* of Jussieu. Its characters are, that the calyx is a Spathe common gaping at the side; the corolla is one-petalled, funnel-shaped and regular; tube cornered, as if composed of six claws, the border six-parted, with the parts oblong and spreading; the stamina are six filaments inserted into the throat, shorter than the corolla, declinate; the anthers kidney-shaped and incumbent; the pistillum is a superior germ, oblong, three-cornered: the style filiform, of the length of the stamens and declinate; the stigma simple or trifid; the pericarpium is an oblong capsule, three-sided, three-celled, three-valved: valves navicular, with contrary dissepiment; the seeds numerous, oblong, compressed and enlarged with a membrane. There is one species, viz. *αγαπανthus umbellatus*, the *CRINUM Africanum* of Linnæus, or

African blue lily. This is the African tuberoso hyacinth, with a blue umbellated flower.

The root of this plant is composed of thick fleshy fibres; from the same head arises a cluster of leaves, which are thick and succulent, and of a dark green colour. Between these issues the flower stalk, supporting an umbel of blue flowers in a sheath, and each flower standing on a pedicle, about an inch long. The umbel being large, the flowers numerous, and of a light blue colour, make a fine appearance. They come out at the end of August or beginning of September, and frequently continue in beauty till spring. The flowers are those of the *hemerocallis*, but this genus is distinct from it in its spathe. It is a native of the Cape of Good Hope, from whence it was brought to Holland, and in 1692 it was cultivated at Hampton Court.

This plant is propagated by offsets, taken off at the latter end of June, planted in separate pots, with light kitchen-garden earth, and placed in a shady situation. In five weeks the offsets will put off new roots; and the pots should then be removed to a more sunny situation, and have more water. In September they will put out their flower stalks, and toward the end of the month the flowers will begin to open, and should be removed under shelter in bad weather, but in good weather exposed to the free air. Toward the end of October they should be removed to the green-house and have the benefit of free air, and be occasionally watered during winter in mild weather, but in frost they should be kept dry. It requires only protection from frost and moisture; and should not therefore have any artificial warmth in winter, and in summer it should be placed in the open air. Martyn's Miller's Dict.

AGAPE, in *Antiquity*, signifies an afternoon, or evening's meal.

AGAPETÆ, in *Ecclesiastical History*, a name given to certain virgins and widows, who, in the ancient church, associated themselves with, and attended on ecclesiastics, out of a motive of piety and charity.

In the primitive days there were women instituted *DEACONESSES*; who, devoting themselves to the service of the church, took up their abode with the ministers, and assisted them in their functions.

In the fervour of the primitive piety, there was nothing scandalous in these societies; but they afterwards degenerated into libertinism: inasmuch, that St. Jerom asks, with indignation, *unde agapetarum pestis in ecclesias introitit?* This gave occasion to councils to suppress them.—St. Athanasius mentions a priest, named Leontius, who, to remove all occasion of suspicion, offered to mutilate himself to preserve his beloved companion.

AGAPETUS, in *Biography*, a deacon of the church of Constantinople in the 6th century, who addressed a letter, called *σχολη βασιλικη, Scheda Regia*, to the emperor Justinian, on the duties of a prince, and thus obtained rank among the most judicious writers of the century. This letter was printed at Basil by Frobenius in 1521, 8vo., and at Cologne in 1604. It is included in the *Bibliotheca patrum*. Molheim, *Eccel. Hist.* v. ii. p. 120. Fabric. *Bibl. Græc.* t. vi. p. 570.

AGAPETUS, Pope, was a native Roman, and raised to the papal see by the interest of Theodotus, king of Italy, in 535. This pope resisted the interference of the emperor Justinian, in ecclesiastical concerns, asserted the supremacy of the papal authority in the church, and maintained its independence on the civil power. He was firm and resolute, notwithstanding the threats of the emperor in opposing a measure which he disapproved, and boldly said, "when I came to Justinian, I hoped to meet a Christian prince, but I have found a Dioclesian." He died at Constantinople in 536,

and was enrolled among the saints; and the Roman see was at this time so poor, that in order to defray the expences of his journey thither, he was obliged to pawn the sacred vessels of the church of St. Peter. Bower and Dupin.

AGAPETUS II. Pope, a Roman by birth, obtained the papacy in 946, and held it till the year 956. He exerted himself in terminating the dissensions of Italy, and sent for the emperor Otho to oppose Berenger II. who assumed the regal power in this country. He was reputed a man of extraordinary sanctity. Dupin. Fabric. Bibl. Græc. t. vi. p. 570.

AGAPHONOVA, in *Geography*, a river of Siberia, which runs into the Frozen Ocean.

AGAPIS lapis, in *Natural History*, a name given by ancient writers, to a stone of a dusky yellow, or the colour of a lion's skin; it was held in great esteem in many nations, on account of its supposed virtues, as an anodyne and vulnerary.

AGAPIUS, in *Biography*, a Manichæan writer, mentioned by Photius, who is supposed to have lived about the middle of the 4th century. Some say, that he was a disciple of Manes towards the close of the third century, that he opposed the sentiments of Eunomius concerning the Trinity, and that he wrote three books in defence of the Manichæan principles; one a work of twenty-three books, another consisting of 102 chapters, inscribed to a woman of the same sect, named Urania; and a third, intitled Heptalogus, preserved in the Anathemas against the Manichæes, or form of abjuring Manichæism, by Fabricius, Cotelerius and Tullius. His work, says Photius, was so absurd and impious, that it could only shame and confound those who followed him and the Manichæan doctrines; and he is denominated by the same writer, a detestable and impious man, and distinguished as one of the twelve disciples of Manes. Gen. Dict. Lardner's works, vol. iii. p. 306. Fabricius (Bibl. Græc. t. x. p. 383) has mentioned several other persons of this name; such as a monk of mount Athos, who lived about the year 1640, and published a book entitled *αμαρτωλων σωτηρια*, the salvation of sinners; Agapius, a bishop of Cæsarea, the predecessor of Eusebius; Agapius, an Athenian philosopher, a disciple of Proclus, and supposed to be the same with the eminent physician and rhetorician of Alexandria and Constantinople, whose distinguished talents are noticed by Suidas.

AGAR, in *Ancient Geography*, a town of Byzacium, described by Hirtius, a few miles westward of Lempta or Leptis parva, and sixteen miles from Thapsus. It was one of Cæsar's stations; the village which now occupies the rocky situation in which it stood is called by the Arabs Boohadjar, *i. e.* the father of a stone, or the stony city. Shaw's Trav. p. 109.

AGARA, a town of the Phylliatics, in India, on this side of the Ganges, according to Ptolemy.

AGARAFFO, or AXARAFFE, a small, pleasant and fertile country of Andalusia, in Spain. Its principal town is San-Lucar-la-Major, erected into a duchy by Philip IV. in favour of Count d'Olivarez.

AGARD, ARTHUR, in *Biography*, a learned antiquary of this country, was born at Toston, in Derbyshire, A. D. 1540; and having been educated for the law, was appointed deputy-chamberlain of the Exchequer in 1570, which office he held 45 years. By means of this office he was enabled to pursue those curious researches, of which he produced several valuable publications. Having directed his particular attention to the Dooms-day book, he wrote a learned treatise on the use and true meaning of the obscure words that occur in it; he also compiled a book, containing "a catalogue of the records preserved in his Majesty's four treasuries," and

"an account of all leagues, treaties of peace, intercourses and marriages with foreign nations." This work, with eleven other treatises in MS. relating to matters of the Exchequer, he ordered by his will to be delivered to the office. His other collections, amounting to twenty volumes, were bequeathed to Sir Robert Cotton, and deposited in his library. His essays read to the Antiquarian Society were published by Mr. Hearne, in his "collection of curious discourses by eminent antiquaries," and are as follow, *viz.* "Opinion touching the Antiquity, &c. of Parliament," the genuineness of which is doubted:—"The Antiquity of English Shires:—"On the Dimensions of the Land of England:—"Of the Authority, &c. of Heralds in England:—"Of the Antiquity and Privileges of the Inns of Court and of Chancery:—"Of the Diversity of Names of this Island." By his established reputation for the knowledge of antiquities he was one of the most conspicuous members of a *Society of ANTIQUARIES*, which subsisted from 1572 to 1604. He died in 1615, and was buried in the cloister of Westminster Abbey. Mr. Camden denominates him a most excellent antiquary. Biog. Brit.

AGAREN1, or AGAREN1ANS, a name given by some to the followers of the religion of Mahomet.

The word is derived from Agar, or Hagar, handmaid of Abraham, and mother of Ishmael; and properly denotes the Arabs, called also Ishmaelites, and more lately Saracens.

AGARENUM, the capital of the Agarenians, in Arabia; it was attacked by Trajan, but without success.

AGARIC, AGARICUS, called *Amanita* by *Dillenius*, in *Botany*, a genus of the order of *fungi*, and class of *cryptogamia*; the characters of which are, that the pileus or cap has gills underneath; that the gills differ in substance from the rest of the plant, being composed of two lamina; and that the seeds are in the gills. Gmelin, in the 13th edition of the Linnæan system, 1791, enumerates 390 different species; and Dr. Withering, in the third edition of his arrangement of British plants, 1796, (vol. iv. p. 154, &c.) ascertains and describes 282 British species, besides several varieties. He distributes them into three general classes, comprehending those which have central stems, those with lateral stems, and those which have no stems; and he again subdivides the two former classes into such as have solid, and such as have hollow stems, with decurrent, fixed and loose gills respectively. Under these heads he arranges the species, by the colour of the gills, into those whose gills are white, brown, red, buff, yellow, grey, green, and purple. As this ingenious author has formed a system, that serves to facilitate the investigation and description of the several species of agarics, we shall here give a brief sketch of the principles upon which it is founded. Agarics are composed of a cap or pileus, with gills underneath, and are either with or without stems. The stems are either central or lateral. They have also a root, which is more or less apparent, and some of them, in their unfolded state, wholly enclosed in a membranaceous or leather-like case, called a *wrapper*. Some of them have also a *curtain*, or thin membrane, extending from the stem to the edge of the pileus, which is rent as the pileus expands, and soon vanishes; but the part attached to the stem often remains, and forms round it a *ring*, which is more or less permanent, as its substance is more or less tender. These parts are seen in Plate V. BOTANY, *fig.* F, which exhibits the vertical section of an agaric in its egg-state. The wrapper is seen at m, m, m, m, m; the pileus at n, n; the gill at o, o; p is the stem before it shoots up; and q, q, the curtain. On the section of a stem at B, may be seen the remains of a curtain,

curtain, then called a ring. The curtain, ring and wrapper are of little use in the discrimination of the species. The two former are common to all the secondary subdivisions of agarics with central stems; but the latter is confined to plants with solid stems, nor does it pertain to those whose gills are decurrent. The stem of an agaric is either solid or hollow: the former is represented at A; the latter at B. In examining an agaric, it will immediately appear whether the stem be solid or hollow, by cutting it across about the middle with a sharp knife. Next to the gills, the stem of an agaric is the part least liable to variation. The gills are the flat, thin substances, found underneath the pileus, and attached to it, and are of a different texture from that of the stem or pileus. They assume different colours in different species, and vary much in their respective lengths. Each gill consists of two membranes, between which the seeds are formed. The gills are always attached to the pileus, and sometimes to that only, as at *fig. E. c. c.* They often shoulder up against the stem, and are fixed to it, as at *fig. A. b;* and they are also extended along it downwards, as at *a.* This is called a *decurrent* gill. The *fixed* and *decurrent* gills are attached to the stem only by their ends, which are next to the center of the pileus, and not by their edges, as is sometimes the case in agarics, whose pilei are nearly cylindrical. The gills, as they contain the fructification of these plants, are peculiarly important. They vary in length, always extending to the edge of the pileus, but seldom reaching to the stem; and they are sometimes forked or divided, and sometimes connected or anastomosing with one another. These circumstances are illustrated by *fig. C.* and *fig. G.* The gills are uniform at *d;* and below it they are connected at the edge of the pileus; at *e* they appear in pairs, at *f* there are four, and at *g* eight in a set; at *h* they are seen irregular, or without any determinate number; at *i* they are branching, and at *k* branching and anastomosing. *Fig. C* exhibits the gills loose from the stem, with the inner end fixed to a collar which surrounds the top of the stem, though not in contact with it. These several circumstances are subject to such variation, that they do not serve to distinguish the different species. The colour of the gills, however, is obvious and permanent; and as the colour is principally, if not solely, caused by that of the seeds within them, this affords the most fixed and certain characteristic, on which to found the distinctions of the species; and together with the structure, the colour, particularly of the flat sides of the gills, will be at all times sufficient to furnish permanent specific distinctions. The stem is a less variable part than the pileus; its shape, the proportions of its length to its breadth, and of both to the pileus, afford tolerable distinctive marks; and its colours, though more changeable than those of the gills, are perhaps rather more fixed than those of the pileus. The pileus, or cap, is the part of an agaric, that is the least certain. Its shape is either conical (as at *E.*), convex (as at *D.*), flat, or hollowed at the top like a funnel, and is constantly varying in the same plant, though it is much the same in the same species, when the plant is in perfection, or when it is fully or almost fully expanded. Its colour is uncertain; and so is also the viscosity or clamminess on the surface of the pileus and stem, which has sometimes characterised agarics. The lactescence of some agarics, or their property of yielding a milky juice, which in some species is mild, and in others acrid, is very precarious and inconstant. Such as we have briefly recited, are the principles upon which Dr. Withering's system is founded; and it seems well adapted for extending our acquaintance with the va-

rious species of agaric that occur, and rendering the knowledge already acquired more accurate. Withering's Arrangement, vol. i. p. 375—380. See CRYPTOGAMIA, FUNGUS, and MUSHROOM.

Of all the species of agaric, one only has been selected for cultivation in our gardens, *viz.* the *A. campestris*, or *common mushroom*, or *champignon*. The gills of this species are loose, pinky red, changing to a liver-colour, in contact with the stem, but not united to it; very thick set, irregularly disposed, some forked next the stem, some next the edge of the pileus, some at both ends, and in that case generally excluding the intermediate smaller gills. The pileus is white, changing to brown when old, and becoming scurfy; regularly convex, fleshy, flatter with age, from two to four inches, and sometimes nine inches in diameter, and liquefying in decay; the flesh white. The stem is solid, white, cylindrical, from two to three inches high, half an inch in diameter; the curtain white and delicate. When this mushroom first makes its appearance, it is smooth and almost globular; and in this state it is called a button. This species is esteemed the best and most savoury of the genus, and is much in request for the table in England. It is eaten fresh, either stewed or boiled, and preserved either as a pickle or in powder; and it furnishes the sauce called KETCHUP. The field plants are better for eating than those raised on artificial beds, their flesh being more tender; and those who are accustomed to them can distinguish them by their smell. But the cultivated ones are more lightly, may be more easily collected in the proper state for eating, and are firmer and better for pickling. The wild mushrooms are found in parks and other pastures, where the turf has not been ploughed up for many years; and the best time for gathering them is August and September. Dr. Withering mentions four varieties. The *A. Georgii* of Linnæus resembles the former, but is much inferior to it in flavour. Its gills are yellowish white; the pileus yellow, convex, hollow in the center; the stem yellow thickish and smooth; the juice yellow, which flows plentifully from it when wounded. It is gathered in September in woods and pastures. A variety of this is found on the sea coast of Cornwall, of a large size, with the button as big as a potatoe; the expanded pileus 18 inches over, the stem as thick as a man's wrist, the gills very pale, the curtain tough, and thick as leather, and the juice yellowish. A plant of this kind, as Dr. Withering informs us, was gathered on an old hot-bed in a garden in Birmingham, which weighed 14 pounds. The *A. procerus*, or tall mushroom, is not uncommon on hedge banks and dry pastures, and is sometimes exposed to sale in Covent-garden market. It may be distinguished from the genuine sort by the sponginess of its flesh, and from others by its fine and large horizontal ring. The gills are white, uniform, and fixed to a collar; the pileus is a broad cone, bossed, white brown, and scaly; the stem is scaly, and the ring loose. This plant, when preserved in pickle, is very apt to run into the vinous fermentation. Dr. Withering enumerates four varieties of this species, one of which is the *A. excoriatus* of Schæffer and Hay, which is a beautiful plant, approaching in structure to the former, but of a smaller size. It is gathered in September. *A. serampelinus* is the most splendid of all the agarics. Its gills are fixed, bright golden yellow, and nearly orange under the edge of the pileus, regularly disposed four in a set; fleshy, brittle, and serrated at the edge with a paler cottony matter: the pileus is a fine lake red, changing with age to a rich orange and buff, and every intermediate shade

of these colours, which render it very beautiful; convex, center bossed, edge turned down, three to four inches diameter, cloth to the touch; flesh pale buff; stem solid, nearly cylindrical, but gradually tapering upwards, rich buff, fringed with fine rose red, three to five inches high, half inch in diameter; flesh pale, buffy, spongy and elastic. This is common in Italy, and brought to the markets for sale. The ancient Romans esteemed it one of the greatest luxuries for the table. It was made the vehicle for poison to Claudius Cæsar by his wife Agrippina, and has therefore been celebrated by Juvenal and Martial. Schæffer and Clusius have recited several curious circumstances respecting it. Dr. Withering apprehends that these authors have mistaken the species, and that their account should be transferred to the *A. deliciosus*. The *A. serampelinus* is eatable, but its taste is not at all agreeable. It is the *A. cæsaræus* of Schæffer, and first found by Dr. Withering's daughter, on the red rock plantations at Edgballon, July 6th 1791; and afterwards in Sept. 1793; and in July 1792, amongst moss in the fir plantations at Tettenhall, Staffordshire. Dr. W. enumerates five varieties.

A. deliciosus has gills decurrent, flame-coloured, narrow, regularly branched; pileus rich red brown; flesh nearly flat, but somewhat hollowed at the centre and the edge turned in, from one and a half to three inches over; orange-colour; stem orange, solid, tapering downwards, from one to two inches high, and a quarter to three-eighths inch diameter; hollow with age. The juice is rich yellow, which soon turns green. It is found in the fir-plantations of Scotland, and in those of the barren hills at Barr, in Staffordshire. Dr. Smith also found it at Hillingdon, Middlesex, under some fir-trees, and it also grows near Guildford. It is much esteemed in Italy, and exposed in the markets, and supposed to have been the *A. cæsaræus* mentioned by the authors cited under the preceding article. Dr. Withering enumerates three varieties, one of which affords, from every part of it when wounded, a copious discharge of yellow acrid juice. They are gathered in woods and dry pastures in Sept. and Oct.

A. cinnamomeus has gills, four in a set, broad about the middle, deep tawny red, and fixed by claws; pileus convex but bossed, of a rich cinnamon colour, from one and a half to three and a half inches diameter; the stem hollow, cylindrical, silky, shining, two inches high, thick as a goose quill, of a fine full yellow colour. This is a species that is readily distinguished by its cinnamon-colour. It is found in woods in September and October; and has a good flavour. It is the *A. cinnamomeus* of Bolton. The *A. cyathiformis* of Schæffer is a variety of this.

A. bulbosus has white, loose, irregular gills; pileus convex, white, smooth, sometimes fringed at the edge, four or five inches over; flesh white, spongy and very thick; stem solid, cylindrical, smooth, white, four inches high, and half inch or more in diameter: ring permanent, broad, and white. This species possesses all the parts belonging to the genus, and is well adapted to instruct the learner in understanding them. It is found from spring to the end of autumn in rich soil, and also in gardens, on the sides and at the base of hot-beds. Dr. Withering enumerates four varieties, found in woods about the roots of trees, and in pastures: and he refers the *A. bulbosus* of the Fl. angl. to the *A. glaucopus* of Schæffer, with brown gills, from four to eight in a set, chestnut and semi-globular pileus, thick stem of a white or pinky colour, and curtain resembling a cobweb, white flesh with a pinky tinge, solid whitish stem, and very large bulbous root. The *A. bulbosus* of Hudson and Ray is referred by this author to *A. violaceus* of Linnæus; which has fixed purple gills, numerous, eight in a set; long gills sometimes cloven, and a few of them

decurrent; purple pileus, soft, smooth, firm, convex, but centrally depressed with age, and cracking at the edge, which is somewhat turned down, from half inch to five inches over: stem solid, cylindrical, purple, bulbous at the base, from one to four inches high, and from a quarter to one inch in diameter; and curtain like a cobweb. In maturity, it plentifully emits a powder of the colour of Spanish snuff. It is not uncommon from October to December, in Edgballon and Barr plantations, in the woods near Bath, and at Powick near Worcester. With much broiling and duly seasoned, it is esteemed delicious as an oyster. *A. candidus* of Linnæus is small and white, with an hemispherical pileus having its margin turned inwards and flexile gills, and stem cylindrical and flexuous. Dr. Withering refers the *A. candidus* of Hudson to the *MERULIUS umbelliferus*. *A. nitens* has gills decurrent, white, few, short and in pairs; pileus white; boss yellowish, at first conical, then flat, and lastly inverted, two inches in diameter; stem solid, whitish buff, bending, three inches high, and a quarter of an inch in diameter. The whole plant is very viscid, but dries when gathered. Dr. W. suspects it to be an unusually large plant of the *A. eburneus*. It is found in autumn in Packington Park, Warwickshire. *A. mutabilis* of Schæffer has loose, yellow brown gills, four in a set; brown orange pileus, convex and bossed; stem hollow, cylindrical, red brown and scaly below, and whitish above the ring; curtain thready; ring permanent and imperfect. It is common in August, on decaying and rotten wood. The *A. mutabilis* of Hudson, Ray, &c. is referred by Dr. W. to the *A. velutipes* of Curtis, with pale yellow gills, eight in a set; pileus brown orange, nearly flat; stem yellow above, velvety and dark brown below. It is not uncommon in April and October, grows in clusters, and is generally attached to rotten wood. *A. crassipes* has gills white, brownish at the edges, fleshy, distant, four in a set; pileus reddish brown, boiled and cracking; stem tapering downwards and ribbed. It grows in clusters, at the base of decaying trees. The *A. crassipes* of Schæffer is made by Dr. W. a variety of the *A. elasticus* with white gills, four in a set; pileus chestnut and semi-globular; stem buffy, white and tapering. This agaric is tough and strong, with a considerable elasticity, and found under oak trees in August, September and October. *A. varius* has white gills, not numerous, two or four in a set; pileus conical and scored; stem cylindrical, glossy, stiff, and about the size of a crow-quill. Of this species Dr. W. has enumerated eight varieties, most of which are found at the roots of silver birch trees. The *A. varius* of Schæffer is in Dr. W.'s arrangement a variety of the *A. glaucopus*, and that of Bolton a variety of the *A. fimi-putris* of Bulliard, which has gills dark brown to black, four or eight in a set; pileus pale brown, conical, blunt, with polished apex, and white stem. It is found in October, in gardens. A variety of it, with four gills in a set, and a pileus grey to black, is found among rotten leaves in grass-land. Another variety, which is the *A. varius* of Bolton, is found on grass-plats and new mown fields in July. It has chocolate gills from brown to black, mottled, and in pairs; pileus mouse-colour, conical and pointed; stem of the same colour, cylindrical and firm. This, though a common, is a very beautiful species. In a summer morning it is covered with a bloom like that of a plumb, having often a glittering spangled appearance; its form is regular, and the fringe of the curtain peculiarly delicate. Another variety, with the stem of a dark mulberry colour, is found in wet gravel where no grass grows, and sometimes on cow-dung, in which case the stem, under the shelter of long grass, is covered with a white hoariness, which is easily rubbed off.

A. integer of Linæus has gills white, mostly uniform; pileus of various tints, crimson, pink, lilac, or tawny brown, changing to dirty yellow or to lead colour; stem solid, cylindrical and white. It is very common and beautiful; found in woods and pastures, under trees, and snails are very fond of it. Dr. Withering enumerates nine varieties. *A. orcadæ* has loose gills, with the part attached to the pileus jutting up very close to the stem, so as to give them almost the appearance of being fixed, watery brownish white, two or four in a set, the small ones very minute, and the large ones sometimes splitting at the outer end; not numerous, rather broad for the size of the plant; frequently connected to the pileus by ligaments; pileus pale buffy brown, convex, irregular, with a sudden depression of the border at some distance from the center, often giving the appearance of a large rounded boss in the middle; central colour generally deeper; from one to one and three quarters inch over; and the edge turning up with age: stem solid, white, changing to watery brown, cylindrical, but thicker and flattened just under the pileus, very tough, mostly crooked, twisted when dry, rarely central, one and half inch high and thick as a crow-quill. This is the 27th fungus of Ray's synopsis, ed. 3. p. 6. *A. pratensis* of Hudson, and *coriarius* of Lightfoot. There are two varieties; one with cream-coloured gills, buff pileus, and mealy stem, and another with yellow brown, more fleshy and more regularly convex pileus, found in groves. Mr. Woodward says, that this species has a much higher flavour than the common mushroom, but he suggests, that from its leathery nature it is indigestible, except in the form of powder, in which it is admirable. Dr. Withering, however, observes, that he has seen the pileus and gills of this agaric very brittle and tender, when fully saturated with moisture in rainy seasons, and in that state it is sufficiently digestible. Professor Martyn informs us, that he has eaten these mushrooms for 40 years without injury, and without perceiving that toughness like leather, of which others have complained, except in very dry weather, or when they are in too advanced a state. They should be gathered young and early in a morning, and properly dressed. They are found in hedge banks, upland pastures, and sheep commons, particularly in those patches called FAIRY RINGS. Those that are found in woods and hedges are of inferior flavour to such as are gathered in dry pastures, which have a very pleasant smell and luscious flavour, either when stewed alone, or in ragouts, &c. This sort makes excellent ketchup, and is much valued in the form of powder. It is in season during September and October, but may be dried so as to be in use for table all the winter. Mr. Lightfoot supposes that this species is the *moucron* of the French, who use it in ragouts, instead of that, and acknowledge it to be equal in flavour, but more tough. The *moucron*, however, has a very thick and fleshy pileus, its gills are very narrow and numerous, and fixed to the stem, and the stem is thick and short. Dr. Withering has carefully distinguished several other species from this *jairy* agaric, or *Scotch bonnets*, as it is called by Mr. Ray. *A. chantarelles* of Linæus, is the *MERULIUS cantharellus* of Dr. Withering, and may be eaten with safety; but it is more tough and less highly flavoured than either the *A. orcadæ* or *A. campestris*. Ailione enumerates the following species as edible, viz. *A. candidus*—*bulbosus*—*chantarellus*—*nitens*—*deliciosus*—*mutabilis*—*brunneus*—*escoriatus*—*georgii*—*crispipes*—*varius*—*violaceus*—*syboticus*. But he has omitted *A. campestris*. In many parts of Europe several other sorts are eaten, which are thought with us to be poisonous. Of this number we may reckon the *A. piperatus*, which, though it be the most acrid and suspicious of all the agarics,

is eaten in great quantity by the Russians. They fill large vessels with these mushrooms in the autumn, season or pickle them with salt, and eat them in the ensuing Lent. The *A. piperatus* of Linæus has gills, pale pinky red, numerous, in pairs; pileus dirty yellow white, woolly, depressed in the centre; and stem pale yellow. This is the *A. torminzus* of Schæffer. The *A. piperatus* of Bolton, and *A. lactifusus acris* of Bulliard is referred by Dr. W. to the *A. Lejleri*, which has gills whitish, numerous and narrow; pileus smooth, irregular, flattish, depressed in the center; stem white, eccentric; and juice like milk. Lister first found it in England. This plant, with its varieties, is met with in plantations of wood. It is much eaten by insects and snails. *A. clypeatus* is described by Dr. W. as having gills fixed slightly to the stem, greyish watery brown, four or eight in a set: pileus brown, convex, bossed, border scored, very viscid, so that flies lighting upon it cannot escape; paler in colour when divested of this viscid matter, one to one inch and half over; stem hollow, white, viscid, tender, easily broken, splitting, three or four inches high, and thick as a crow quill. This species is found in woodland pastures in September. Dr. Percival, in the last vol. of his Essays, p. 267, relates the case of a man, who was poisoned by eating a mushroom, which Mr. Hudson thinks was one of this species. *A. muscarius*, or reddish mushroom, has a large pileus, varying much in colour, white, red or crimson, convex, sprinkled with downy warts, which are raised, compact and angular, or thin, flat, and ragged, turning up with age, from two to seven inches over; flesh white, reddish in decay: gills fixed, white, yellowish with age, mostly uniform, but a shorter one sometimes intervening; the shorter gills varying much in length, but rarely less than one third the length of the long ones: the stem solid and cylindrical, but the internal substance shrivelling with age, leaves irregular hollows; scaly, bulbous at the base, from three to five inches high, and from three quarters to one and a half inch in diameter; ring, broad, permanent, and turned down upon the stem. This plant rises out of the ground inclosed within its brown fluted wrapper. It is found in pastures. The juice rubbed on the walls and bed-posts destroys bugs; and in the north of Europe the inhabitants infuse it in milk, and set it in their windows, in order to poison the flies who taste it. This is the *moucho-more* of the Russians, Kamtschadales, and Koriars, who use it for intoxication. They sometimes eat it dry, and sometimes immerse it in a liquor made with the epilobium; and when they drink this liquor, they are seized with convulsions in all their limbs, followed with that kind of raving which attends a burning fever. They personify this mushroom; and if they are urged by its effects to suicide, or any dreadful crime, they pretend to obey its commands. To fit themselves for premeditated assassination, they recur to the use of the *moucho-more*. A powder of the root, or of that part of the stem which is covered by the earth, is recommended in epileptic cases, and externally applied for dissipating hard globular swellings, and for healing ulcers. The dose is from half a scruple to one, taken thrice a day in water; and a dram administered once a day in vinegar, has been thought more efficacious. Murray, App. Med. vol. v. p. 560. Dr. Withering enumerates ten varieties of this species.

The agarics, with lateral stems, and those without stems, are chiefly found on rotten wood, or stumps and fragments of decayed trees. Of the latter sort we shall mention only the *A. quercinus*, or agaric of the oak: the gills are brown, very much branched and anastomosing, thick, forming oblong angular, and nearly circular cavities, especially towards the edges; the pileus brown, woody, nearly semicircular,

or of no regular shape, marked with circular tiled ridges, as well as with different shades of colour, soft to the touch like buff leather or fine cork, from one to five inches over, or more. This species, of which Dr. W. enumerates two varieties, seems to connect the agarics with the BOLETI. For a further account of the dietetical and medical qualities of agarics, and for the method of cultivating and propagating those which are chiefly used, see MUSHROOM.

AGARIC, in *Pharmacy*, a kind of fungous excrescence, growing on the trunks and large branches of several trees; but, chiefly on the larch-trees and upon some kinds of oak, when old and decayed. Three-fourths of it consist of a resinous substance, and the remainder is a slimy mucilaginous earthy matter, so tenacious, as scarcely, by any method, to be dissolved by water. It comes forth on the tree in the beginning of the spring, and continues to increase till autumn. The best is easily cut with a knife, friable between the fingers, and has no hard, or gritty, or coloured veins. It has no pedicle, and is internally of a simple uniform structure throughout its whole substance. Agaric is brought from different places; the best comes from the Levant; that which comes from Savoy and Dauphiny being less esteemed. Holland also supplies some, but that is reckoned the worst; because it is grated, and whitened at top with chalk. By a chemical solution it passes almost wholly into oil; it yields no volatile salt, but abounds with a sort of flaky earth, and acid phlegm; as to texture, it seems much to resemble COLOCYNTH. Agaric is an ingredient in the *theriacal Andromachi*, where it is admitted in quality of a cordial: though its cardiac virtue is excepted to as much as its purgative. Agaric was a purge in much esteem among the ancients, but has deservedly fallen into disrepute of later years, as it occasions unsupportable nausea; and as no preparations of it appear to be equal to the more common and experienced cathartics. The druggists consider only that which grows upon the larch-tree to be the right sort. For its chemical history, see Neumann's Works, p. 349. The *Agaric of the oak*, so denominated, because the best is supposed to be produced on the oak, sometimes also called false or bastard Agaric, is the BOLETUS *Igniarius* of Linnaeus. This fungus has been specifically named *Igniarius*, and also touch-wood or spunk, from its readily catching fire, and from its being used in some places as tinder. For this purpose the Germans boil it in strong ley, dry it, and boil it again in a solution of salt-petre. It is externally of an ash-colour, and internally dusky-coloured, soft and tough. In Franconia pieces of the inner substance are beaten so as to resemble leather, and sewed together for making garments: this agaric has been much used by surgeons as an external styptic. The mode of preparing this substance is as follows: Take a piece of fresh agaric, which has been removed from the oak or larch-tree in autumn, and pare off its exterior rind; the coat underneath, being of a compact texture, is then to be separated from the porous part, and well beaten with a hammer until it becomes extremely pliable. The outer hard part, and the inner loose surface, are of very little use; but the middle portion, thus prepared, must be kept dry in slices of a convenient size. A small piece is to be laid exactly over the bleeding artery, and over that a second, or even a third, somewhat larger; and lastly a compress, to retain the whole in its place. Its application to this purpose was derived from the French, and it was successively recommended, first by Brossard in 1750, afterwards by Morand, Bouquot, Faget, Rochard, and De Mey, who employed it not only to restrain the bleeding of wounds, but to prevent hæmorrhages after amputations, which it is reported to have done as effectually as the ligature. Several English surgeons have also published

cases in which the agaric was successfully used, as Sharp, Warner, Gooch and others. Some have remarked that, where it seemed to succeed, the subjects were brought so low before the operation, that little danger was to be apprehended from the hæmorrhage, though no other application had been made than that of dry lint and flour. Neale's Obs. on the use of agaric, &c. It has now lost its reputation both in France and England; nor does it appear, from its sensible qualities, to be possessed of any truly styptic power, at least to any considerable degree. This fungus probably acts no otherwise than as a pliable soft substance, adhering to the orifices of the vessels, till they have contracted spontaneously. Some other fungi have been employed with the same intention; such as the lycoperdon, or dusty mushroom, and the fungus vinosus, found on the casks and walls of wine-vaults. Lewis's Mat. Med. Woodville Med. Bot. vol. iv. p. 160. Since it possesses no efficacy without a firm compress, we believe the LIGATURE will be generally preferred, as more secure, and less troublesome to the patient. See HÆMORRHAGE.

AGARIC, *Female*. See BOLETUS.

AGARIC MINERAL, *Bergmilch*, *Bergmehl* Germ. *Creta farinacea*.—This mineral substance is always found in a loose or semi-indurated state in the fissures of rocks or at the bottom of lakes; it almost floats on water, is entirely soluble in nitric acid with effervescence, and probably consists wholly of carbonat of lime: it is not applied to any particular use. There are two varieties of this species, of which the following are the essential characters.

Var. I. *Bergmilch* of Werner.

Dusty—colour whitish red or yellow; very friable; of a dry feel, does not adhere to the tongue, and gives no gloss to the skin when rubbed on it.

Var. II. Colour white, composed of scaly particles, very friable; of a greasy feel, and communicates a gloss to the skin; falls to pieces in water, and adheres to the tongue. Mr. Kirwan (*Elem. Miner.* vol. i. p. 76) mentions a third variety, of a silvery white colour, resembling mica in its structure, of a soft feel and somewhat unctuous like tale, almost entirely soluble in nitrous acid; and the solution has all the properties of a solution of calcareous earth. This substance was formerly used internally against hæmorrhages, strangury, gravel, and especially in dysenteries; and externally to dry and heal old ulcers, stop defluxions of the eyes, &c. See *Silvery CHALK*.

AGARICITES, in *Natural History*, a species of *Madrepora*, stemless, and furrowed, with carinated furrows and concatenated stars. It is found in the sea, between the islands of AMERICA.

AGARICUM, a species of *Acyonium*, with a filiform stem, and a kidney-shaped case. This is the kidney-shaped purple *Sea-PEN* of Ellis, found in the sea that washes the coast of South Carolina. Its body is about an inch long, and half an inch across the narrowest part, with a small roundish tail, an inch in length, proceeding from the middle of the body, full of rings from one end to the other, like an earth-worm, with a small groove running along the middle of the upper and under part, from one end to the other. The upper part of the body is convex, and near a quarter of an inch thick; the whole surface is covered with minute yellow starry openings, through which are protruded little suckers, like polypes, each furnished with six tentacles or filaments, which seem to be the proper mouths of the animal. The under part of the body is flat, and the surface is full of the ramifications of fleshy fibres, which, proceeding from the insertion of the tail, as their common centre, branch out so as to communicate with the starry openings on the exterior edge and upper surface of the animal. See

Plate I. *Cerallines*, &c. fig. v. Phil. Transf. vol. Lii. P. 427.

AGARICUS *Sinus*, in *Ancient Geography*, a gulph of India, on this side the Ganges, according to Ptolemy.

AGARON, in *Natural History*, a name given by Adanson to a species of *Volva*; the *ispidula* of Gmelin's edition of the *Linnæan System*.

AGARRA, in *Ancient Geography*, a town of Susana, in Asia; placed by Ptolemy in long. 83° 40'; and lat. 33° 20'.

AGARUM, a promontory of Asiatic Sarmatia, near the river *Agarus*, which ran from north to south, and discharged itself into the *Pelus Maotis*. According to Ptolemy, it was situated in long. 63°, and lat. 49° 40'. Ovid (Pont. iv. 10.) calls the river, *Sagaris*; and it is now *Sagor*.

AGASUS, a port mentioned by Pliny, situate between the promontory of Garganus and the river Cerbalus; and supposed to be the same with *Porto Græco*. Agafus, or Agassa, was also a town of Macedonia in Europe.

AGASYLLIS, in the *Materia Medica*, a name given by some of the ancient Greek writers to gum ammoniac; and by Dioscorides, to the tree which produces that gum. By their description of this medicine, it appears not to have been the same which we know by this name.

AGATA, in *Ancient Geography*, a small town and bishop's see of Naples in the Principato Ultra.

AGATE, *Αχατες*, *Achates*, of Theophrastus and Pliny; *Agath*, Fr. *Achat*, Germ. *Agater*, Swed. This word is used by modern mineralogists not as denominating any particular species of stone, but a siliceous mixture of quartz, hornstone, flint, calcedony, amethyst, jasper, carnelian, or heliotrope, aggregated into binary or more complex combinations. It has nevertheless several peculiar characters by which it may readily be distinguished from other minerals. Although it consists of parts differing in colour and transparency, yet these possess a certain uniformity of arrangement, and slide into each other by such nice gradations as show them to have been all of simultaneous formation; and hence it differs from *siliceous Breccia*, in which angular fragments of siliceous pebbles are cemented by a siliceous paste: for in all these the cement, whether quartz, calcedony, or flint, is wholly distinct from the fragments that it invests, and the arrangement of the whole is merely casual. As it differs in the colour of its constituent parts, so it does in their transparency; it is never wholly opaque like jasper, nor transparent as quartz crystal: it takes a very high polish, and its opaquer parts usually present the appearance of dots, eyes, veins, zones, bands, or ramifications. Its colours are yellowish, reddish, bluish, or milk white, honey-orange, or ochre yellow, flesh blood, or brick red, reddish brown, violet blue, and brownish green. Specific gravity from 2.55 to 2.7. It gives fire with steel very plentifully.

It is found in the form of irregular rounded nodules, from the size of a pin's head, to more than a foot in diameter; or in strata, and sometimes, though rarely, stalactitic. Several varieties of agate are distinguished by the lapidaries: the finer semi-transparent kinds, consisting principally of calcedony, are called oriental: in the banded agates the colours are disposed in strict parallel lines or bands; while in the fortification agate, the most beautiful of all the varieties, they are arranged in waved and angular concentric zones: the landscape agate, by the name alone, sufficiently declares its irregular appearance: the moss agate, or Mochoa stone, is filled with dendritical crystallizations of iron ore, so nearly resembling some kinds of moss, as to have been actually mistaken for real vegetables by Daubenton.

Agates are found, for the most part, in argillaceous porphyry, occasionally in gypsum, near the river Wolga they

occur between the strata of secondary limestone, and certain rocky tracts in Siberia consist almost entirely of a puddingstone, of which agates and calcedony form an essential constituent part. The argillaceous porphyry being a rock that is easily disintegrated by the action of the air and moisture, the agates and other siliceous pebbles that it contains fall out and are washed by the rains into the beds of rivers; here, by friction upon each other, the asperities on their surface are worn off, and in this state they are generally found on the sea-shore and in gravel beds. The most beautiful agates that this island produces, are commonly known by the name of *Scotch pebbles*; these are met with in various parts of Scotland, but principally in the vicinity of Dunbar. The agates of Germany are the largest, especially those from Kunersdorf in Saxony. The Dutchy of Deuxponts, the Palatinate, Hesse, Thuringia, Wirtemberg, Bavaria, Bohemia, and Silesia also furnish them in great abundance. The river Achates in Sicily was of old celebrated for these pebbles, and hence they have acquired their name: the other parts of Europe, where they are found, are principally Tuscany, Candia, and Iceland. Some exquisitely fine specimens have been brought from Siberia, and the island of Ceylon; and they have lately been discovered in great plenty in the bed of a river at the eastern extremity of the settlement at the Cape of Good Hope.

The uses of agate are principally for ornamental works; the engraved gems, those precious remains of ancient art are principally agate, and much ingenuity has been shewn in the accommodation of the natural veins and marks to the figures engraven upon them; it is also much esteemed by modern lapidaries for seals. Small mortars are made of agate, and are used by the enameller, and in the laboratory for grinding substances that are too hard to be triturated any other way.

A dark stain approaching to red, or red purple, may be communicated to agate, by heating it in warm ashes, and then moistening its surface with nitro-muriat of gold, or nitrat of silver; when the stone is become dry, it must be set for a day or two in a dark moist place, and then exposed to the full sun: by this method the most delicate zones and ramifications, which are not visible in the natural state of the stone, are made to appear in a very beautiful manner; this tinge is, however, destroyed by nitrous acid, or a moderate heat: and thus artificial stains may be distinguished from the native colours. A deep black is given to agate by soaking it when heated, in boiling nitrat of copper, and then heating it nearly to redness in a covered crucible. Mochoa stones are imitated by spreading a solution of nitrated copper over the surface of a plain agate, and then setting a small iron nail on its head in the middle; the nitrous acid unites with the iron, and deposits the copper in beautiful arborescent radiations from the centre; the nail must then be removed, and the surface carefully washed, by dipping the stone in warm water; afterwards on the application of a moderate heat, the copper becomes black.— This deposition, however, being merely superficial, requires to be covered with a plate of polished crystal, in the manner of a doublet. If the ramifications are required to be very fine, the agate should be moistened with a dilute nitrat of silver superaturated with the metal, or a solution of lunar caustic in water, a small piece of zinc is to be placed in the middle till the ramifications are sufficiently far advanced; the stone must then be washed carefully in warm water, and afterwards exposed to sulphurated hydrogen gas, till the silver is become black.

Agate is said to be imitated very successfully in glass; and Neri, in his "*Art de la Verrerie*," gives three different receipts for this purpose: of these the following is recommended

mended both by the author and by Kunkel, as producing a composition for splendour and vividness of colour often superior to real agate. Take seven ounces of granulated silver, and five ounces of mercury, four drams of minium, one ounce of verdegris, and scales of copper, crude antimony, and black manganese, of each half an ounce; dissolve the silver by itself in nitrous acid, and having ground the rest of the materials together, add first two pounds of nitrous acid, and then the nitrated silver, mixing both liquors evenly and intimately with the other substances; then dissolve two drams of gold in nitro-muriatic acid, and grind together the following ingredients; *viz.* cinnabar, twelve drams; sulphurated oxyd of copper, twenty drams, sulphurated oxyd of iron, four drams, and white oxyd of tin, oxyd of iron, iron scales, zaffre, orpiment, and white arsenic, of each half an ounce; mix the solution of gold with this compound powder, and then add thrice its weight of nitro-muriatic acid: digest in separate glass vessels for twenty-four hours in a sand-bath the above nitrous and nitro-muriatic mixtures, then add them together, and distil to dryness; there will remain a powder of a reddish green colour. Also take twenty pounds of clear flint glass, and reduce it to a fine powder, in a clean steel mortar, add to this two ounces and a half of the above colouring composition, and flux them together; when the whole is in clear fusion, stir it up from the bottom and let it continue melted for twenty-four hours, then stir it again, and allow it to cool very gradually; its colour will then be a middle tint between yellow and blue. Place the crucible again in the furnace, and when the glass is melted, add, at five or six different times, the following mixture; calcined tartar, eight ounces, vitrified wood foot, two ounces, and half an ounce of perfect oxyd of iron: this will make the glass swell considerably, and therefore requires much care to prevent it from flowing over: when all is quiet, heat it well for twenty-four hours longer without touching it, and it will then be fit for use. Kirwan Mineralog.—Kirwan Geolog. Ess.—Lametherie Theorie de la Terre.—Lewis's Commerce of Arts.—Neri sur la Verrerie.

Some writers have distributed agates, with regard to the objects that are represented upon them, into arborescent, as *DENDRACHATES* and *DENDRITES*; horned or *CERACHATES*; aphrodisian, a term given by Velschius to an agate in his custody, of a flesh colour, with a half moon on one side represented by a milky semicircle, and on the other, the phases of Vesper, or the evening-star; corioid, with human hair; arithmetical, with the numbers 4191, 191 (Settala. Mus. 81.); astronomical, with the hemisphere and its several orbs, and the earth in the middle; anthropomorphous, with the figures of men or women, one of which, mentioned by Kircher, represents a heroine armed; and another, in the library of Francfort, exhibiting the heart, lungs, and part of the veins of a man; but the most celebrated of this kind is that of Pyrrhus, representing the nine Muses with their attributes, and Apollo in the middle, playing upon the harp (see Plin. l. xxxvii. c. 3. Hard. Not.); leucophthalmous, bearing the figures of eyes, as of birds, fishes, and wolves, called by Cardan and others lycophthalmi, of goats denominated ægophthalmi, of oxen boophthalmi, &c.; the Tiberian agate in the treasury of the French king's chapel, representing the apotheosis of Augustus, and the series and portraits of the family of Tiberius and Julia, with divers foreign nations subdued in war, concerning which, many different conjectures and explications have been advanced by the learned; and the Isaac agate, a curious antique at Rome, so called, because it represents the head of Isis, and distinguished by the epithet *annularis*, as being set in a ring. However, in this kind of

distribution, and in the denominations to which it has given occasion, the imagination has often missed the judgment.

Beccaria observes, that the electric sparks will not be conducted by the surface of polished agates; and M. Bose has shewn, that the agate was very early known to possess electrical powers.

AGATE, among *Antiquaries*, denotes a stone of this kind, engraven by art.

In which sense agates make a species of antique gems; in the workmanship whereof, we find eminent proofs of the greatest skill and dexterity of the ancient sculptors. Several agates of exquisite beauty are preserved in the cabinets of the curious. The facts, or histories, represented in antique agates, with how much address soever conducted, are become, at this distance of time, many of them obscure and dubious, and their explication difficult enough; whence divers mistakes have been committed, and numerous conjectures and disputes raised. Hist. Acad. R. Inscr. tom. i.

AGATE, is also the name of an instrument used by gold-wire drawers; so called from the agate in the middle of it, which forms its principal part.

AGATHA. See *ACHATES*.

AGATHA, *St.* in *Geography*, a small town of Naples, in the farther principality, on the confines of Terra di Labora, between Capua and Beneventum, eight leagues, north-east of Naples. N. lat. 40° 55'. E. long. 14° 22'.

AGATHA, in *Ancient Geography*, a city of Gallia Narbonensis, built by the Massylians, mentioned by Pliny, (lib. iii. c. 4.) and by Strabo, (tom. i. p. 272. 276.) See *AGDE*.

AGATHA, in *Natural History*, a species of the *PAPILIO Nymphalis*, with dentated wings, the upper part yellow, the under grey; and the posterior wings have one black spot above, and three spots beneath. It is found in India.

AGATHARCHIDES, or *AGATHARCHUS* of Chnidus, in *Biography*, a Greek historian, grammarian and rhetorician, mentioned by Josephus, (antiq. l. xii. c. 1. tom. i. p. 585. Cont. Appion. l. i. tom. ii. p. 457. Ed. Hard.) Diodorus Siculus, (Bibl. Hist. tom. i. p. 50. p. 181. Ed. Wessel.) Strabo, (tom. ii. p. 969. p. 1125. Ed. Casaub.) Lucian, (tom. iii. p. 222. Ed. Reitz.) and other ancient writers, was contemporary with Eratosthenes, though younger than him, and flourished under Ptolemy Philometor, about 177 years before Christ. He was reader to Heraclida, and president of the Alexandrian Library, and wrote several historical treatises; of which Photius mentions 49 books, concerning the affairs of Europe, 10 of Asia, five of the Red Sea, and an epitome of what had been written on this subject in one book. Some fragments of his writings may be found in Josephus (*ubi supra*), and Photius in his Bibliotheca, 213. 250. Fabric. Bib. Græc. tom. ii. p. 207. The testimony of Agatharchides is alledged by a learned writer to prove, that in the reign of Ptolemy Philometor, 146 years after the death of Alexander, the Greek sovereigns of Egypt had not yet traded directly to India, but imported the commodities of India from SABA, the capital of Yemen. This ancient writer's description of the western coast of the Red Sea closes at Ptolemais, as if there were no regular commerce beyond that point. See Vincent's Periplus of the Erythrean Sea, part i. p. 31.

AGATHEMER Orthobis, a geographer, who lived, as some say, near the time of Septimius Severus, and according to others, in the 15th century. He wrote in Greek two books of a compendium of Geography for the use of his pupil Philo, which is commended by J. Vossius, L. Holstenius and G. Wendelinus, and which was first published in 8vo. with a translation and notes, by Tennulius, at Amsterdam, in 1671; afterwards by Gronovius in 4to. at Leyden, 1697; and

and by Hudson in the 2d vol. of the *Geographi Minores* Oxon. 1703. Fabr. Bib. Græc. tom. iii. p. 40.

AGATHIAS, one of the Byzantine historians, was born at Myrina, a city of *Æolis*; and having studied the law at Alexandria, exercised the profession of an advocate at Smyrna, and acquired the appellation of *Scholasticus*, from the schools in which lawyers were instructed. Although in the introduction to his history, he speaks favourably of the Christians, it does not appear that he himself was of this number; Vossius and others believe that he was a Pagan; Pagi and Fabricius maintain, that he was a Christian. It is certain that no invectives against Christianity have escaped either him or Procopius. He was undoubtedly a man of candour and moderation. In speaking of the Germans, who had a multitude of deities, and offered cruel sacrifices, he says, they who are in error are rather objects of commiseration, than of contempt and hatred; for all men aim at truth: if they are in error, it is not the fault of their will but of their judgment, as they are attached to opinions once embraced by them. He also laments, in the introduction to his history, that wars and battles are so much the subjects of poems and histories; which, as he says, he cannot ascribe to the stars, nor to fate, as some do: for if the world were governed by fate, there would be an end of choice; and there would be no longer virtue among men, nor any room for instruction or improvement in arts and sciences. Nor are wars and contentions, he adds, agreeable to the mind of God, who is supremely good: they must therefore be ascribed to the avarice and ambition of men. His history was written after the year 565, when Justinian died, and published after the year 593. It was undertaken at the desire of Eutychianus, secretary of state, who is supposed to have furnished materials; commences with the 26th year of the emperor's reign, A. D. 553, where Procopius ends, and closes with the slaughter of the Huns in 559. He investigates the causes of the events which he records, and often gives his opinion of them without disguise. His style is easy and florid, though Sigonius has represented him as a low and unpolished writer. He also wrote 80 Epigrams, which are preserved in the *Anthologia*; and, as Suidas informs us, other pieces, partly in prose and partly in verse, intitled, "Daphniaca." Agathias's history was published by Vulcanius, with a translation and notes, at Leyden, in 4to. A. D. 1594; and elegantly reprinted at Paris in fol. in 1660. Fabr. Bib. Græc. tom. vi. p. 260. Lardner's Works, vol. ix. p. 85.

AGATHIAS, a very famous Grecian statuary, born at Ephesus. According to some accounts, this was the sculptor who executed the celebrated Apollo Belvidere; and the Gladiator Repellens: but other accounts, more to be relied upon, state, that the artists who produced those works are certainly unknown.

AGATHO, the *Athenian*, a tragic and comic poet, was the disciple of Prodicus and Socrates, applauded by Plato, in his Protagoras, (*Oper. tom. i. p. 315. Ed. Seriani*) for his beauty and virtue, and described by Aristophanes in his comedy of the Frogs, (p. 124. *Ed. Kusteri*) as a good poet and the darling of his friends; but severely censured for his morals in the comedy, intitled *Thegnophorizusæ*, (p. 483.) He is represented as the favourite of Euripides, and also of Pausanias the Ceramian, whom he accompanied, as *Ælian* informs us (*Var. Hist. l. ii. c. 21. tom. i. p. 120. Ed. Gronov.*), to the court of Archelaus, king of Macedonia, where he continued till his death. *Ælian* says, that he often quarrelled with Pausanias for the sake of enjoying the exquisite pleasure which a reconciliation afforded him. His first tragedy obtained the prize; and he was crowned in the presence of 30,000 persons, in the 4th year

of the 90th olympiad, B. C. 417. There is nothing now extant of Agatho, except a few quotations preserved by Aristotle, Athenæus, *Ælian* and others. His compositions abounded so much with antitheses, as to give him occasion for saying to a person, who wished him to expunge them, "you do not consider that you would rend Agatho from himself." See *Ælian* (*Var. Hist. l. xiv. c. 13. tom. ii. p. 947.*) Athenæus (*Deipnosophist. l. v. p. 211. Ed. Casaub.*) cites the following antithesis: "If I tell you the truth, I shall not please you; and if I please you, I shall not tell you the truth." The antitheses recorded by Aristotle, (*Eudemiorum. l. v. c. 2. and c. 4. tom. ii. p. 243, 244. and Rhetor. l. ii. c. 24. tom. ii. p. 581. Ed. Du Val.*) are the three following: "The only thing impossible to God, is to cause that not to be made that has been made:" "fortune loves art, and art loves fortune:" "it is probable, that a great many improbable things may happen to mortals."

AGATHO, *Pope*, a native of Palermo, who was advanced from a monastery to the papal see, in 679. At this time the controversy occasioned by the *Monothelites* agitated the Christian church, and the first exercise of Agatho's pontifical authority was that of convening synods in the western provinces, to decide concerning their doctrine. These synods having declared the *Monothelite* doctrine to be heretical, Agatho sent legates on behalf of the western church to the general council held at Constantinople in 680. At this council the *Monothelites* were solemnly condemned. Thus Agatho, by his legates, renounced a doctrine which had been confirmed by the edict of a former council, and sanctioned by the approbation of his predecessor, Pope Honorius; and he concurred in the condemnation of Honorius, and enforced by penal laws the sentence of the council. In this instance the infallibility of Honorius, and that of Agatho and the sixth council, are in direct opposition. It is observed, likewise, as a fact worthy of notice in the history of the papal power, that this council was summoned by the emperor; that no appeal was made to the decision of former popes; and that no peculiar deference was manifested to the authority of the bishop of Rome. After the dissolution of this council, Agatho directed his attention to the temporal interest of his see, and particularly to the remission of the fine paid to the emperors on the election of a new pope. He died, A. D. 682. His sanctity was held in such veneration that, if we credit the account of Platina, his kiss was an instant cure for the leprosy. His letters against the *Monothelites*, addressed to the emperors Constantine, Heraclius, and Tiberius, Gr. and Lat.; and to Ethelred, king of the Mercians, and Theodore, archbishop of Canterbury, Lat.; and the abbot Sexulphus, which last is said to be supposititious and written by some English monk, are preserved in the records of the sixth council, A. D. 680. *Harduin's Concilia. tom. iii.* Another letter, granting peculiar privileges to the monastery of Weremouth, may be seen in *Dugdale's Monasticon Anglicanum. Dupin's Hist. Seventh Century, vol. iii. p. 37. Bower.*

AGATHOCLES, king, or tyrant of Sicily, was the son of Carinus, a potter, of Rhegium, and born at Thermæ in Sicily. In consequence of strange dreams of his mother, whilst she was pregnant, to which the father paid a superstitious regard, the infant was exposed in the fields, as soon as it was born, and committed to the care of a person who was to watch it till it died. The mother, hearing of his condition, took the child and entrusted it with her brother Heraclides, and called it, after her father's name, Agathocles. At the age of seven years, he was introduced to the father, and the secret of his preservation was communicated to him by the mother. The distress occasioned by self-reproach in the recollection of his conduct, was soon succeeded

by the joy of having a son, who was singularly beautiful, restored to him. Soon after the discovery, Carinus, with his family, removed to Syracuse, and brought up his son to his own trade. Having joined Timoleon, who had routed the Carthaginians, both the father and son were enrolled among the Syracusan citizens. Upon the death of Carinus, Agathocles was recommended to Demas, a rich citizen, by whose favour and interest he was liberally supplied, and, in due time, advanced to the dignity of a chiliarch, an office which gave him the command of a thousand men. Agathocles, having distinguished himself by his military talents, married the widow of his patron, Demas, and thus became the most wealthy citizen of Syracuse. When the supreme power in this city was usurped by Sosistratus, Agathocles retired to Italy; but aspiring to the sovereignty, first of Crotona, and afterwards of Tarentum, he became an object of general hatred and terror; and being expelled from these cities, and finding no admission into any other, he assembled a band of exiles and robbers, and plundered the country. At Rhegium, he unexpectedly attacked Sosistratus, and compelled him to abandon his enterprise. When this usurper was forced to abdicate the sovereignty of Syracuse, and to quit the city, he and the exiles who accompanied him, had recourse to the Carthaginians, who espoused their cause. The Syracusians recalled Agathocles, and appointed him to the chief command of the forces that were raised for repelling the attack of Sosistratus and the Carthaginians. Having successfully discharged the trust that was reposed in him, he assumed a sovereign power, and by the measure he pursued convinced his fellow-citizens that he was aspiring to the monarchy. The Syracusians, in these circumstances of alarm and danger, applied to the Corinthians for a commander; and they deputed Acestorides to this office. Agathocles saved his life by a stratagem; and having made his escape, he proceeded to raise troops in different parts of Sicily, and was soon in a condition to approach the city at the head of a considerable army. The Syracusians, dreading a civil war, sent ambassadors to treat with Agathocles, who disbanded his forces; and being conducted by the citizens to the temple of Ceres, took a solemn oath, according to the established custom, that he would do nothing to the prejudice of the democracy. Being again restored to the chief command of the army, he indulged his ambitious views without regarding his oath, courted the favour of the populace, and massacred the nobles and chief citizens, so that in a few hours, more than 4000 of them were killed, and the streets were covered with dead bodies. Although he pretended to resign the command and to retire, he conducted his artifice with so much skill and success, that he was unanimously proclaimed king, and appointed to govern with an absolute and uncontrolled power. In order to render himself popular, the first law he enacted was, that all former debts should be cancelled, and the lands equally divided among the rich and the poor; and such was his behaviour, that he gained the attachment and confidence of his subjects. With their cordial concurrence he reduced, in two years, the whole island; a few cities held by the Carthaginians excepted. His progress alarmed the Carthaginians, and they deputed Hamilcar, with a powerful fleet and army, to restrain it. The first encounter, near the river Himera, terminated in favour of Agathocles; but the loss which Hamilcar had sustained by a storm in his voyage, and by the first engagement, being repaired by a powerful reinforcement, the attack on the part of the Carthaginians was renewed, and Agathocles was compelled to save himself, first in Gela, and afterwards within the walls of his metropolis, to which they laid close siege; proposing by the reduction of this city to gain possession of the whole island. Thus pressed

by the Carthaginians, and abandoned, on account of his former cruelties, by all his allies in Sicily, Agathocles formed the bold design of transferring the war into Africa, and besieging Carthage, when he himself was besieged in the metropolis, which was the only city of Sicily in his possession. Without communicating his design to any confidential person, he informed the Syracusians in general terms, that he had conceived a plan which would be effectual for their rescue: and collecting together the most intrepid of the soldiers and citizens, and incorporating the slaves, whom he emancipated, among his troops, he embarked all his forces on board 60 gallees, sailed directly for Africa, and landed on the coast, in the third year of the 117th olympiad, B. C. 310. Here he disclosed his views to the army, and animated them to vigorous efforts by assurances of success. The soldiers received his address with loud acclamations. He then determined to burn all his ships, except one or two, which he reserved for carrying dispatches. When he communicated this daring resolution to the army, he told them, that when they left Syracuse and were pursued by the enemy, he applied in the moment of danger to Ceres and Proserpine, the tutelary goddesses of Sicily, and promised to burn all the vessels of his fleet, if they delivered his men from the enemy, and enabled them to land safe in Africa. "Aid me, therefore, O fellow soldiers!" said he, "to discharge this vow; for the goddesses can easily make us amends for this sacrifice." When these words were uttered, he allowed no time for deliberation; but taking a torch in his hand, he set fire to his own ship; the officers imitated his example, and were cheerfully followed by the soldiers. He then led them against an important place, called the Great City, that was subject to Carthage, which they took by storm; they then proceeded to Tunis and took it. Having enriched themselves with the plunder, he caused both cities to be levelled with the ground, that there might be no place of retreat, and no hope of safety but in victory; and encamped in the open fields. He next proceeded towards Carthage; and charging the Carthaginian army with incredible vigour, killed Hanno, one of their chief generals; and at last, by the treachery of Bomilear, another general, obtained a complete victory. When the news of this victory was conveyed to Syracuse, Hamilcar raised the siege, and was afterwards taken by the Syracusians, who made an unexpected sally and routed his army, consisting of 120,000 men, and put to a cruel death. His head was sent to Africa, as an acceptable present to Agathocles. Whilst Agathocles was preparing for the siege of Carthage, he was joined by Ophellas, prince of the Cyreneans, who had been one of Alexander's captains; but the deluded prince was perfidiously murdered. The savage tyrant, being now at the head of a numerous army, assumed the title of the king of Africa; and invested Carthage, with a view of reducing it by famine. During this interval, he passed over into Sicily with a detachment of 2000 men, in order to reduce those inhabitants of the cities, who had taken up arms and associated in defence of their liberties. His purpose was speedily accomplished; and he hastened his return to Africa. He found his army in great distress; and in an attempt for obtaining relief, he was defeated, and then deserted by the Africans, so that he was under a necessity of leaving the country. Upon his return to Sicily, he perpetrated the most horrid acts of cruelty. He first marched against the Egestines, who had revolted in his absence, and having taken their town by storm, he put all the inhabitants to death, without distinction of age or sex, and with circumstances of the most savage barbarity. He also ordered all those to be massacred who were related to the Syracusians, who attended him in the Carthaginian expedition,

rebellion, or to any of the African army, from the greatness of their to the sucking child. Diodorus, however, whom he had banished, gained some temporary advantages; but he was at length subdued; and being of a similar disposition with Agathocles himself, admitted into his intimate friendship and confidence. Having totally reduced the island, except those cities which, by a treaty, he had restored to the Carthaginians, he passed over into Italy and subdued the Brutii. From Italy he crossed over to the Lipari islands, and obtained a tribute of 100 talents of gold: he also stripped the temples, and set sail for Syracuse with 11 ships laden with the gold and spoils, which were all lost in a storm, that excepted in which he himself escaped. He was reserved for a more miserable end; for, at the instigation of his grandson Archagathus, he was poisoned by means of an envenomed tooth-pick, prepared by one Moenon; and, as history reports, if it may be credited, hurried away to the funeral pile, and burnt whilst alive, in the 28th year of his reign, and 72d, according to Diodorus Siculus, and according to others, 95th of his age.

Agathocles was distinguished by his intrepidity and valour, and by a certain greatness of mind, which forbade his being ashamed of his mean extraction, and which induced him, at public entertainments, to use earthen-ware, whilst his guests were served in gold and silver plate; alledging, that though he wore a diadem, yet he was still a potter. Polybius (l. xv. p. 720. Ed. Casaub.) deduces from the meanness of his condition an argument to prove his capacity and talents; and when Scipio Africanus was asked, who were the most prudent in the conduct of their affairs, and most judiciously bold in the execution of their designs, replied—Agathocles, and Dionysius the elder. Nevertheless, his acts of cruelty were so numerous and so atrocious, that they obscure the lustre of his talents and exploits; and whilst we admire his conduct on many occasions, we cannot forbear execrating his memory. Diod. Sicul. l. xix. t. 2. p. 317, &c. l. xx. t. ii. p. 408, &c. p. 492. Ed. Wessell. Justin. l. xxii. Anc. Univ. Hist. vol. vi. p. 455. 470.

AGATHOCLIS *insula*, in *Ancient Geography*, two small islands of the Red Sea, placed by M. d'Anville, at a small distance to the west of Dioscorides, or Socotra; and north-east of the cape Aromata.

AGATHODÆMON, in *Mythology*, a beneficent GENIUS, or DEMON. The word is compounded of *αγαθος*, good, and *δαίμων*, demon. This name was given to the divinity, which the Egyptians called Cneph, by the Greek writers who travelled into Egypt; and Vulcan was the emblem under which the Greeks represented Cneph in their temples. The Egyptians gave also the same name to the Nile and to its symbols.

Among ancient writers, *agathodæmon* is a denomination given to a kind of serpents, bred up and revered by the Egyptians, from an opinion of some sanctity residing in them.

They are also called dragons, *Dracones*, or *dracunculi*, and fabulously described as having wings.—They appear to be the same with those otherwise called SIRENES. Laniprid. in Heliog. cap. xxviii. Casaub. Not. in Suet. ed. 2. Bochart. Hiero. p. ii. lib. iii. cap. 14. We find upon the abraxas and some medals of Adrian the representation of a serpent, bearing the head of Serapis instead of its own: which is an evident allusion to the Serapis of the Nile, or divinity of Canopus, and a second emblem of that river which was first represented by Agathodæmon. The head of the Agathodæmon is often covered with rays on the abraxas. The appendages to the head of the agathodæmons remind us of the *anguis cerastes* of Linnæus.

AGATHODÆMON, in *Biography*, an artist of Alexandria, prepared a series of maps for the illustration of Ptolemy's

Geography, in which the position of all the places mentioned by this eminent geographer, with their latitude and longitude, is laid down precisely according to his ideas. Fabr. Bib. Græc. tom. ii. p. 412.

AGATHONIS *insula*, in *Ancient Geography*, an island of Africa, in the Arabian gulf; according to Ptolemy, in long. 65° 15', and lat. 23° 20'.

AGATHONISI, a small island of the Grecian Archipelago, about a league south of Samos.

AGATHOS-DEMON, was a name given by Ptolemy to the left branch of the Nile, which extended from the upper part of the Delta where was the town of Cereefura, to the canopic mouth, situate to the east of the town of Canopus. This is also the name given by Steph. Byz. to an island in the Indian sea.

AGATHOPHYLLUM, in *Botany*, a name given by Professor Martyn to the RAVENSARA of the Linnæan system.

AGATHOPOLIS, in *Geography*, an episcopal city of Thrace, under the archbishopric of Adrianopolis.

AGATHYRNUM, or AGATHYRSUM, in *Ancient Geography*, a town of Sicily, built, according to Diodorus. (tom. i. p. 337.) by Agathyrnus, the son of Æolus, in the time of the Trojan war. It is supposed to have stood near the place now called *San-Marco*, at a small distance from the promontory, called by the Sicilians *Capo d'Orlando*.

AGATHYRSIANS, in *Ancient History*, the inhabitants of a district of Scythia, or European Sarmatia, mentioned by Herodotus (lib. iv. c. 104. p. 328. Ed. Wesseling.) who were very rich, and who had their women in common, for the sake of binding the men more intimately to one another, and preventing jealousies and other ill effects of matrimony. In other respects they conformed to the customs of the Thracians. From Virgil (*Æneid*. iv. v. 146.) who calls them “—*piciti Agathyrsi*,” it appears, that they had the common practice of painting their bodies. They also are said to have used gold in their ornaments. They pretended to be descended from Agathyrsis, the son of Hercules the Libyan.

AGATTON, in *Geography*, a town of the kingdom of Beain, in Africa, situate on a small eminence, forming an island, at the entrance of the river Formosa, near the sea. It is more healthy than any other part of the country, and surrounded with fruit trees. It has several circumjacent villages, whose inhabitants resort to it at every principal market, which is held for five days. It was formerly very considerable, but has suffered much from wars. N. lat. 6° 30'. E. long. 5° 44'.

AGATU, one of the Fox islands, in the Northern Pacific Ocean.

AGATY, the name of a Malabar tree, bearing a fruit in taste and shape like the kidney-bean. Ray's Hist.

AGAU, or AGAW, in *Geography*, a small kingdom of Africa, dependent upon Abyssinia. It lies between the lake Dembea and the Nile.

AGAVA, in *Ancient Geography*, a town of Africa, placed by Ptolemy in the Pentapolis, or Syrtis.

AGAVE, formed from *αγαυος*, admirable, in *Botany*, a genus of the *hexandria monogynia* class and order, of the natural order of *coronarieæ*, and of the *bromeliæ* of *Jussieu*. Its characters are, that it has no calyx; that the corolla is one-petalled, and funnel-shaped, with a six-parted equal border, and lanceolate erect parts; the stamina are filiform, erect filaments, longer than the corolla; the anthers linear, shorter than the filaments and versatile; the pistillum is an oblong germen, growing thinner towards both ends, inferior; the style filiform, of the length of the stamina, and three-cornered; the stigma headed and three-cornered; the pericarpium is an oblong, three-cornered, three-celled, three-valved capsule; and the seeds are numerous. The species enumerated

enumerated by Martyn are six, and in the Linnæan system by Gmelin seven. The first is the *A. Americana*, or Great American aloe, whose stems, when vigorous, rise upwards of twenty feet high, (one in the king of Prussia's garden rose to 40 feet), and branch out on every side, so as to form a kind of pyramid, composed of greenish yellow flowers, which stand erect and come out in thick clusters at every joint. The seeds do not come to maturity in England. When this plant flowers, it makes a beautiful appearance; and if it be protected from the cold in autumn, a succession of new flowers will be produced for near three months, in favourable seasons. It has been a common error, that this plant does not flower till it is 100 years old: the truth is, that the flowering depends on its growth; so that in hot countries it will flower in a few years; but in colder climates the growth is slower, and it will be much longer before it shoots up a stem. The first European who possessed an American aloe, is said to have been Cortufus, who had one in 1561; and Parkinson reports that it was first brought into Spain. The first that flowered in England is said to have been Mr. Cowell's, at Hoxton, in 1729, but they have occurred so often since that time, that they are now scarcely considered as rarities. Few of the variety with yellow-edged leaves have yet blossomed. There are hedges of the common agave in Spain, Portugal, Sicily and Calabria; it flourishes also about Naples, and in other parts of Italy. The juice of the leaves, strained, and reduced to a thick consistence by being exposed to the sun, may be made up into balls, by means of lye-ashes. It will lather with salt-water as well as fresh. The leaves, instead of passing between the rollers of a mill, may be pounded in a wooden mortar, and the juice brought to a consistence by the sun or by boiling. A gallon of juice will yield about a pound of soft extract. The leaves are also used for scouring pewter, or other kitchen utensils, and floors. In Algarvia, where pasture is scarce, they are cut in thin transverse slices, and given to cattle. The inward substance of the decayed stalk will serve for tinder. The fibres of the leaves, separated by bruising and steeping in water, and afterwards beating them, will make a thread for common uses. The process for this purpose at Loule, in Portugal is as follows: Having plucked the largest and best leaves, one of them is laid on a square board which a person presses obliquely between his breast and the ground, and he scrapes it with a square iron bar held in both hands; thus all the juices and pulp are pressed out, and the nerves of the leaf only remain, which may then be divided into very fine threads. These are hung over a thin cord to dry. This thread is not strong, and easily rots in water, but it consists of straight fibres, and is applicable to many purposes. Link's Travels in Portugal by Hinckley, p. 445. Varieties of the common American agave, with gold and silver striped leaves, are not now uncommon in the English gardens. The Karatto agave is a variety brought from St. Christopher's, and the name is given to other species of this genus, and has leaves from 2½ feet to 3 long, and about 3 inches broad, ending in a black spine, and more erect than those of the others. This sort has not flowered in England. 2. *A. vivipara*, or *childing* agave or aloe, stemless, with toothed leaves, never grows to a large size; as it produces no suckers from the root, it cannot be increased till it flowers. This plant grows in St. Domingo and Jamaica, and its resinous juice forms a part of the caballine aloes of the shops. It was first cultivated by Mr. Miller, in 1731. 3. *A. virginica* resembles the first so much as not to be distinguishable from it, except by good judges. The leaves are narrower and of a paler colour; the stems are not so high, nor do they branch in the same manner; but the flowers are collected into a close head at the top. It

was introduced in 1755, into the Kew garden, by Mr. J. Cree. 4. *A. lurida* has two varieties, viz. the *Vera-Cruz* agave, which resembles the first, with thinner leaves, indentures at the edges much closer and not so deep, and blacker spines; and the *rigid* or *narrow-leaved* agave, with long, narrow, stiff leaves, entire and terminated by a stiff black spine. It was cultivated in 1731, by Mr. Miller. 5. *A. tuberosa*, or tuberos-rooted agave, has the leaves indented at their edges, and each indenture terminates in a spine; the root is thick, and swells close above the surface of the ground; in other respects it agrees with the stiff species; it has two varieties, viz. the *single-thorned* and *double-thorned* agave. It grows in the Antilles, and has been cultivated at Paris under the name of *A. angustifolia*. 6. *A. foetida* has long, narrow, stiff leaves, of a pale green colour, waved on their edges, those on the side spread open, and those in the centre closely folded over each other, and encompassing the bud. The juice of the leaves has a bad smell. It is seldom more than 3 feet high, but the flower stem rises near 20, and branches out in the manner of the first, but more horizontally, and the flowers are smaller and of a greener colour. This species grows in the woods of St. Domingo. A plant of this species, which flowered in 1755, and then died, was cultivated in 1690 in the Royal garden at Hampton Court. Of the leaves are formed ropes and various kinds of cloth, which serve for garments and other purposes. 7. *A. cubensis* has ciliato-spinose leaves and a hexapetalous corolla. M. La Marek makes this a variety of the *A. mexicana*, the Metl, or Magueli of the Mexicans; it grows in Mexico and the island of Cuba. The mucilaginous juice is used as soap for washing, and the leaves are formed into a thread, which serves them for ropes, cloth, and other uses.

The first and third species are hardy. Those of the former sort will bear the open air in mild seasons; but require being sheltered in the winter. They are propagated by off sets. The third species generally puts out suckers enough for propagation. They should be planted in pots filled with light sandy earth, housed in winter, and have little wet. In the summer they may be exposed to the open air, and remain thus till October. The Vera-Cruz agave should be longer in the house, as it is more tender. The second, fourth and sixth, never produce off-sets or suckers from the root; but when they flower, there will be abundance of them; but they may be propagated by taking off some of the larger roots, when the plants are shifted. The second, fifth and sixth, with the Karatto and rigid agaves, are more tender than the others, and cannot be preserved in winter, unless they are placed in a warm stove, nor will they thrive if set abroad in the summer. They require a light sandy earth, and should have little wet in winter; but in summer they may be gently watered twice a week. They must be shifted every summer into fresh pots; but the pots should be small, that their roots may be confined; otherwise the plants will not thrive. Linnæus has separated this genus from the *Aloe*, because the stamina and style are extended much longer than the corolla, and the corolla rests upon the germ. Besides, all the agaves have their central leaves, closely folding over each other, and embracing the flower-stem in the centre; so that these never flower till all the leaves are expanded, and when the flower is past, the plants die. Whereas the flower-stem of the aloe is produced on one side of the centre, annually from the same plant, and the leaves are more expanded than in this genus. Martyn's Miller's Dict.

AGAVE, in *Mythology*, the name of one of the 50 Nereïds.

AGAVE, in *Natural History*, a species of *PAPILIO Menanous*, with roundish yellow wings; the anterior black above and brown below. It is found in Cayenne.

AGAVI, in *Ancient Geography*, a people of Mæsia, or of Thrace.

AGAUNA, now St. Maurice, a burgh of the Vallais, in the valley of Pennin, celebrated on account of the martyrs of the Theban legion, who suffered decimation rather than renounce Christianity. Sigismund, king of Burgundy, erected a monastery here in 515.

AGAÜPE, in *Botany*, a name used by some authors for the common white water-Lily.

AGAZZIRI, in *Geography*, an ancient people near the mouth of the Vistula.

AGBIENSUM *municipium*, *Beiffons*, a municipal town of Africa, built upon a hill, about half a league from Thuca. Here are found the ruins of ancient temples.

AGDAMI, a town of Arabia Felix, placed by Ptolemy in long. 73° 30'. and lat. 21° 20'.

AGDE, anciently ΑΓΑΘΑ, a small but populous city in the department of Hérault, and late province of Languedoc in France, in a diocese of the same name, situate on the river Hérault, at the distance of about half a league from the sea. The diocese is one of the richest districts of the country; it is within the province of Narbonne, and contains 18 parishes. The ancient Agathia was a small island; but the accumulation of sand at the mouth of the Hérault has now joined it to the continent. It produces fine wool, wine, oil, corn, and silk. The town has a harbour for small vessels, defended by a little fort at the mouth of the river. Most of the inhabitants are tradesmen or seamen. The houses are mean, the cathedral small, and the bishop's palace an old building. The bishop is lord of the city, and styled Count of Agde. The chapel of Notre Dame de Grace, in the vicinity of the town, attracts a great number of pilgrims and devotees. The Capuchin convent is also much resorted to on account of the image of the Virgin Mary, which is placed in a distinct chapel adjoining it: the convent has apartments for the accommodation of the pilgrims, who repair hither to perform their nine days' devotion. The vicinity of Agde abounds with extinguished volcanoes. Cap d'Agde is one of them; and the rock of Agde is nothing but a hard lava, so that the town is built and paved with this lava, which is very black. Buffon's Nat. Hist. by Smellie, v. ix. p. 201. N. lat. 43° 18' 57". E. long. 3° 28' 11".

AGDENAS *Bay*, is a part of that of DRONTHEIM, in Norway: in the neighbourhood the soil produces plenty of grain.

AGDENITES, a name given to a people of Carmania.

AGDERUINE, a small town in the island of Minorca, situate near a mountain south-east of Cape Bajoles. N. lat. 40° 15'. E. long. 4° 14'.

AGDISTIS, a mountain of Asia Minor, near the town of Pessinus.

AGDU, a rock on the frontiers of Asia Minor, famous in ancient mythology.

AGE, in *Antiquity*, a word which was proclaimed by a public crier whilst the Roman magistrates were taking the auspices, or whilst they were sacrificing, in order to command the attention of the people. The word was also an order to the priest or other person, for immolating a victim, as *age*, or *hoc age*, in reply to his question, *agon? or agone? shall I strike? Thus Ovid Fast. i. 321. tom. iii. p. 33. Ed. Burm.*

“ Qui calido strictus tincturus sanguine cultros
Semper agone? rogas; nec nisi iustus agis.”

See AGON.

AGE, in the most general sense of the term, denotes the

duration of any substance, animate or inanimate; and is applied either to the whole period of its existence, or to that portion of it which precedes the time to which the description of it refers. In this sense it is used to signify either the whole natural duration of the LIFE of man, or any interval of it that has elapsed before the period to which we refer. The ordinary age of mankind has been observed to vary in such a manner as to afford an instructive and pleasing display of the wisdom of divine Providence. When age is understood of a certain portion of the life of man, its whole duration is divided into four different ages, viz. infancy, youth, manhood, and old age: the first extending to the 14th year; the second, denominated youth, adolescence, or the age of puberty, commencing at 14, and terminating at about 25; manhood, or the virile age, concluding at 50; and the last ending at the close of life. Some divide the first period into infancy and childhood, and the last likewise into two stages, calling that which succeeds the age of 75, decrepit old age. Shakespeare has admirably described these different stages in his comedy of “As you like it.”

———“His acts being seven ages. At first, the infant,

Mewling and puking in the nurse's arms:

And then, the whining school-boy, with his satchel,

And shining morning face, creeping like snail

Unwillingly to school: And then, the lover;

Sighing like furnace, with a woful ballad

Made to his Mistress' eyebrow: Then, a soldier;

Full of strange oaths, and bearded like the pard,

Jealous in honour, sudden and quick in quarrel,

Seeking the bubble reputation

Even in the cannon's mouth: And then, the justice;

In fair round belly, with good capon lin'd,

With eyes severe, and beard of formal cut,

Full of wise saws and modern instances,

And so he plays his part: The sixth age shifts

Into the lean and slipper'd pantaloon;

With spectacles on nose, and pouch on side;

His youthful hose well-sav'd, a world too wide

For his shrunk shank; and his big manly voice,

Turning again toward childish treble, pipes

And whistles in his sound: Last scene of all,

That ends this strange eventful history,

Is second childishness, and mere oblivion;

Sans teeth, sans eyes, sans taste, sans every thing.

See LONGEVITY.

Age is applicable to the duration of things inanimate or factitious; and in this use of the term we speak of the age of a house, of a country, of a state or kingdom, &c. It is likewise used in reference to vegetable substances, as of roots, leaves, corn, wine, &c. Trees are said, after a certain age, to waste and decay. An oak, at 100 years old, ceases to grow. The usual rule for judging of the age of wood, is by the number of circles which appear in the substance of a trunk or stock cut perpendicularly, each circle being supposed to be the growth of a year; though some reject this method as precarious, alledging, that a simple circle is sometimes the produce of several years: besides that, after a certain age, no new circles are formed. Phil. Trans. N° 43. Act. Erud. Lipf. 1713.

AGE, in *Chronology*, is used for a CENTURY, or a period of 100 years: in which sense it is the same with *seculum*, and differs from GENERATION. It is also used in speaking of the time past since the creation of the world.

The several ages of the world may be reduced to three grand epochas, viz. the age of the law of nature, called by the Jews the void age, from Adam to Moses.—The age of

the Jewish law, from Moses to Christ, called by the Jews the present age.—And the age of grace, from Christ to the present year. The Jews call the third age, the age to come, or future age; denoting by it the time from the advent of the Messiah to the end of the world. See INCARNATION and ΕΡΟΧΑ.

The Romans distinguished the time that preceded them into three ages: the obscure or uncertain age, which reached down as low as Ogyges king of Attica; in whose reign the deluge happened in Greece.—The fabulous, or heroic age, which ended at the first olympiad; and the historical age, which commenced at the building of Rome. Varro calls the period preceding the deluge, an age entirely unknown. The second he calls fabulous, on account of the numerous fables, with which the accounts of it, that have been transmitted to posterity, are interwoven. Diodorus Siculus, (tom. i. p. 8.) extends the fabulous age no farther than the Trojan war; from which time the mist which had overcast the preceding periods begins to clear up, and some rays of truth to break out. The commencement of the historical age is usually referred to the first olympiad, in the year of the world 3228, and still continues. This division, it is to be observed, only holds good with regard to the Greeks and Romans, who had no histories earlier than the first olympiad. The Jews, Egyptians, Phœnicians, and Chaldees, not to add the Indians and Chinese, pretend to much higher antiquity.

Among the poets, the four ages of the world are, the golden, the silver, the brazen, and the iron age. See the Metamorphosis of Ovid, lib. i. or rather Hesiod, in his poem, *Εργα και ημεραι*, *Opera et Dies*, ver. 108, &c. He is the first that has described these four ages.

During the golden age Saturn reigned, and universal harmony and plenty prevailed. See SATURN. The silver age commenced when men began to deviate from the paths of virtue, and their lives became less happy. The brazen and iron ages denote periods of greater degeneracy. A late author, however, inverts the order of the poets; and thinks the first, which was a period of ignorance and barbarism, might be more properly denominated an *iron* than a *golden* age; when cities and states were founded, the silver age commenced; and since arts and sciences, navigation and commerce, have been cultivated, the golden age has taken place.

Bochart (*Geog. Sac. l. iv. c. 12. t. i. col. 226. Ed. Villem.*) has described these four ages of the poets in the following manner. The first, or golden age, lasted under the government of Saturn, or Noah, 100 years from the flood to Phaleg, in which period there was no division of the land. Thus Tibullus represents it, (lib. i. eleg. iii.)

—“ Non fixus in agris,
Qui regeret certis finibus arva, lapis.”

And Virgil (*Georg. i. v. 126.*)

“ Nec signare quidem aut partiri limite campum
Fas erat.”

In the silver age, the lands were divided and cultivated, houses were built, and the tower of Babylon was erected.

“ Tum primum subierc domos, &c.”

The third, or brazen age, was marked by the insurrection of Nimrod, the Bæchus of the ancients, first a hunter and afterwards a warrior, who transferred his power from wild beasts to men, and established a tyrannical government. Thus described by Virgil, (*ubi supra. v. 139.*)

“ Tum laqueis captare feras, et fallere vifeo,
Inventum: et magnos canibus circumdare faltus.”

And by Ovid: *Metam. lib. i. v. 125.*

“ Tertia post illas successit æneæ proles,
Sævior ingenis, et ad horrida promptior arma.”

And also by Hesiod, (*Op. and Dies. v. 143. p. 134. Ed. Robinf.*) thus translated:

“ Tertia deinde ætas fummi Jovis edita nutu,
Vilior argento, de duro constitit ære.
Fraxinea et vehemens robuſtaque, Martis amore
In pugnas et bella ruens.”

This was succeeded by the iron age in which we live.

On some ancient northern monuments we find the rocky or stony age, which corresponds to the brazen age of Hesiod, and the Greeks; being called rocky, on account of Noah's ark, which rested on mount Ararat. The northern poets also denominate the fourth age the ashen age, from a Gothic king, Madenis or Mannus, who, on account of his great strength, was said to be made of ash; or because in his time people began to make use of weapons made of that wood. *Phil. Transf. N° 301.*

Age is sometimes used among the ancient poets in the same sense with GENERATION, for a period of 30 years. Thus Nestor is said to have lived three ages, when he was 90 years old.

The East Indians also reckon four ages since the beginning.—The first, which they represent as a sort of golden age, lasted according to them, 1728000 years: in this the god Brahma was born, and the men were all giants; their manners were innocent: they were exempt from diseases, and lived 400 years.—In the second age, which lasted 1296000 years, their rajas were born: vice now crept into the world; mens lives were fallen to 300 years, and their size retrenched proportionally.—Under the third age, which lasted 8064000 years, vice being more increased, men only attained to 200 years.—The last age is that wherein we now live, of which 4027213 years are already gone; and the life of man sunk to one fourth of its original duration.

The period preceding the birth of Jesus Christ has been generally divided into six ages. The first extends from the creation to the deluge, and comprehends 1656 years. The second age, from the deluge to Abraham's entering the land of Promise, A. M. 2082, comprehends 426 years. The third age, from Abraham's entrance into the promised land to the Exodus A. M. 2512, includes 430 years. The fourth age, from the Exodus to the building of the temple by Solomon, A. M. 2992, contains 480 years. The fifth age, from the foundation of Solomon's temple to the Babylonish captivity, A. M. 3416, comprehends 424 years. The sixth age, from the Babylonish captivity to the birth of Jesus Christ, A. M. 4000, the fourth year before the vulgar æra, includes 584 years. Those who follow the Septuagint, or Greek version, divide this period into seven ages, *viz.*

1. From the creation to the deluge, 2262 years.
2. From the deluge to the confusion of tongues, 738 years.
3. From this confusion to the calling of Abraham, 460 years.
4. From this period to Jacob's descent into Egypt, 215 years; and from this event to the Exodus, 430 years, making the whole 645 years.
5. From the Exodus to Saul, 774 years.
6. From Saul to Cyrus, 583 years.
7. From Cyrus to the vulgar æra of Christians, 538 years; the whole period from the creation to this period, containing 6000 years. See CHRONOLOGY.

The Sibylline oracles divide the duration of the world into

ten ages; and, according to Josephus, each age contained 600 years; and it appears by Virgil's 4th eclogue, and by other testimonies, that the age of Augustus was reputed the end of those ten ages; and, consequently, as the period of the world's duration. The age of Augustus was appropriated by the senators in a peculiar manner to the time in which this emperor lived.

Other historians reckon from the creation to the taking of Troy, 2830 years; and to the foundation of Rome, 3250; from the conquest of Carthage, by Scipio, to Jesus Christ, 200; from Jesus Christ to Constantine, 312; and to the re-establishment of the empire of the West, 808 years.

The denomination of *middle age* is applied by some to the space of time, which commenced from Constantine, and ended with the taking of Constantinople by the Turks, in the 15th century; or, to the interval that elapsed between the fall of the western or Latin empire, near the close of the fourth century, and that of the eastern or Grecian about the middle of the fifteenth, comprehending near 1000 years. Others date the *middle age* from the division of the empire by Theodosius, at the close of the fourth century, and extend it to the time of the emperor Maximilian I. at the beginning of the 16th century, when the empire was first divided into circles. But this seems more accommodated to the state of Germany in particular, than to that of Europe in general. The *middle* is by some denominated the *barbarous age*, and the latter part of it the *lowest age*. Some divide it into the *non-academical* and *academical*. The former comprehends the interval from the 6th to the 9th century, during which schools or academies were lost in Europe. The latter denotes the period from the 9th century, when schools were restored, and universities established, chiefly by the care of Charlemagne.

AGE, in the *History of Literature and the Arts*, is applied to a period peculiarly distinguished by the cultivation of learning, and the extraordinary productions of genius. Accordingly learned men have marked out four of these happy ages. The first is the *Grecian age*, which commenced near the time of the Peloponnesian war, and extended till the time of Alexander the Great; within which period we have Herodotus, Thucydides, Xenophon, Socrates, Plato, Aristotle, Demosthenes, Æschines, Lyfias, Isocrates, Pindar, Æschylus, Euripides, Sophocles, Aristophanes, Menander, Anacreon, Theocritus, Lyfippus, Apelles, Phidias, Praxiteles. The second is the *Roman age*, included nearly within the days of Julius Cæsar and Augustus; affording us, Catullus, Lucretius, Terence, Virgil, Horace, Tibullus, Propertius, Ovid, Phædrus, Cæsar, Cicero, Livy, Sallust, Strabo, Dionysius of Halicarnassus, Varro, and Vitruvius. This period, or at least a considerable portion of it, has been denominated by way of eminence the *Augustan age*, or the *age of Augustus*, which has been regarded as the age of genius, elegance and politeness. The *third age* is that which followed the taking of Constantinople by Mahomet II., or that of the restoration of learning, under the popes Julius II. and Leo X., which produced the following eminent characters, *viz.* Aristotle, Tasso, Sannazarius, Vida, Machiavel, Guicciardini, Davila, Erasmus, Paul Jovius, Michael Angelo, Raphael, Titian. The *fourth age* comprehends that of Louis XIV. and Queen Anne, when France was distinguished by Corneille, Racine, De Retz, Moliere, Boileau, Fontaine, Rousseau, Bossuet, Feneion, Bourdaloue, Pascal, Malebranche, Massillon, Brayere, Bayle, Fontenelle, Vertot; and when England exhibited Dryden, Pope, Addison, Prior, Swift, Parnell, Arbuthnot, Congreve, Otway, Young, Rowe, Atterbury, Shaftsbury, Bolingbroke, Tillot-

son, Temple, Boyle, Locke, Newton, Clarke. Those who lived in the two first of these periods are generally distinguished by the appellation of the antients, when a comparison is instituted between the antients and the moderns, including also under the first class one or two who lived in a more early age, as Homer in particular; and the moderns comprehend those who flourished in the two last of the ages above-mentioned, including also the eminent writers down to our own times. Voltaire's *Age of Louis XIV.* vol. i. p. 1, &c. Blair's *Lectures on Rhetoric and Belles Lettres*, vol. iii. p. 4.

There are other periods, which, on account of the extreme ignorance that prevailed, have been denominated *ages of ignorance*. Such are the 9th, 10th, and 11th centuries, in the modern history of Europe; when few kings and nobles, much less the common people, were able to write or read. These were ages of slavery, civil and religious, as well as ignorance.

AGE of *Medals*. See MEDAL.

AGE, in *Horsefanship*, forms a very important branch of knowledge, and consists in being enabled to judge of the progress of a horse's years from correspondent alterations in his body. The teeth are usually examined for this purpose, as they exhibit in almost all horses the same changes in appearance and form at stated periods. This becomes necessary, as there are but few whose knowledge is sufficiently extensive to enable them to judge of the age by any other means; but where it can be done it is more useful than by this ordinary mode; for in this country, where horses are ridden very hard, and consequently early ruined, it is not uncommon to find a horse at six years old, feeble, debilitated, and exhibiting all the marks of old age, except in his mouth; on the contrary, when the animal falls into other hands, at 10 or 12 he has all the vigour of youth, and his teeth are the only parts that present an indication of age: it is therefore more useful to examine the general appearance of the animal, than to be guided altogether by the marks in the teeth; for, provided the horse has not been too early worked, nor too hard rode, and has no natural nor accidental defects, his nominal age should be but a secondary consideration. It is the custom of some excellent horsemen never to hunt their horses, till they are eight or nine years old, a period at which other horses are usually refused as aged, and unfit for fatigue.—Horses, when aged, usually become hollow above the eyes, the hoofs become rugged, the under lip falls, and if grey, they become white. La Fosse, the younger, recapitulates the appearances of the teeth nearly in the following manner.—The horse is foaled with six molar or grinding teeth in each jaw; the tenth or twelfth day after the two front nippers appear above and below, and in fourteen or fifteen days from this, the two intermediate are pushed out; the corner ones are not cut till three months after. At ten months the incisive or nippers are on a level with each other, the front less than the middle, and these again less than the corners; they at this time have a very sensible cavity. At twelve months this cavity becomes smaller, and the animal appears with four molar teeth on each side, above and below, three of the temporaneous or colts, and one permanent or horse tooth; at eighteen the cavity in the nippers is filled up, and there are five grinders, two of the horse, and three temporaneous; at two years, the first of the colts molar teeth in each jaw, above and below, are displaced. At two years and a half, or three years, the front nippers fall and give place to the permanent ones; at three and a half the middle nippers are likewise removed, at which period the second milk-molar falls; at four years the horse is found with six molar teeth, five of his new set, and one of his last; at four years and a half the corner nippers of the colt fall and give place

place to the permanent set, and the last temporaneous grinder disappears. At five years old the tushes in the horse usually appear; at five and a half they are completely out, and the internal wall of the corner nippers, which before was incompletely formed, is now on a level with the rest; at this period the incisive or nippers have all of them a cavity formed in the substance between the inner and outer walls, and it is the disappearance of this that marks the age. At six years those in the front nippers below are filled up, the tushes are likewise slightly blunted; at seven years the mark or cavity in the middle nippers is filled up, and the tushes a little more worn. At eight years old the corner nippers are likewise plain, and the tushes are round and shortened. At this period the horse is said to be aged, and to have lost his mark; but among good judges the teeth still exhibit sufficient indications. At nine the groove in the tushes is worn away nearly, and the nippers become rather rounded; at ten these appearances are still stronger; at twelve the tushes only exhibit a rounded stump, the nippers push forward, become yellow; and as the age advances, appear triangular and usually uneven.

Monsieur St. Bel, the late professor of the English Veterinary College, used to assert, that after eight years the cavities in the anterior or upper incisive teeth filled up with equal regularity; thus from eight to ten the front ones were filled up, from ten to twelve the two middle, and from twelve to fourteen those of the corner; but though some pains have been taken to ascertain this, it does not appear that the disappearance of the cavities in these teeth is attended with sufficient regularity to warrant confidence. It is a custom with dishonest dealers to draw the colts nippers, particularly the corner ones, by which means the permanent set which are underneath, immediately appear, and the horse is considered much older than he is; but if the other appearances detailed here are attended to, this may be readily detected. See Plate where the age from the appearance of the teeth is accurately represented. See also **TEETH**, and **ANATOMY** of the *Horse*.

AGE, in *Hunting*, is an article of consequence.—Deer, and other beasts of game, have different denominations according to their age.

The age of a hart, &c. is chiefly judged of by the furniture of his head, which is annually enlarged both in height and thickness, from the second to the eighth year, and then continues nearly in equal beauty during the vigour of life. But, when he grows old, *i. e.* from eight years forward, his horns decline.

The first **HEAD**, called, in fallow deer, *broches*, and, in red deer, *pricks*, does not come till the second year of their age: the next year, they bear four or six small branches; the fourth year, eight or ten; the fifth, ten or twelve; the sixth, fourteen or sixteen; the seventh year they bear their heads beamed, branched and fumed, as much as ever they will be. The number of antlers or palms is by no means constant, when the animal is in the highest degree of vigour and perfection; for it varies according to the quantity of nourishment and repose the animal has enjoyed, and the size of the horns depends upon the same cause. The huntsmen have several other marks, whereby to know an old hart without seeing him; as, the slot, entries, abatures, soils, fewmets, gate, and fraying posts. See **SLot**, &c.

The age of other beasts that are chased, is estimated by their appearance: as a fox and a hare by their colour. In birds of the game kind, it is usually distinguished by the colour of the legs and wing-feathers.

AGE of neat cattle, *viz.* the *ox*, *cow*, and *bull*, is known

by their teeth and horns; but from long habit and the greater convenience, the horns are more usually studied; but in that breed without horns, the teeth must be nearly the sole criterion. The ox has no upper incisive teeth, but a few days after calving eight nippers appear in the lower jaw, which remain till ten months, when the second dentition commences by the displacement of the two front teeth, to which succeed two permanent ones, larger but not so white.—At 12 months, the grinders are some of them changed; at 15 or 16 months, the incisive on each side next the front is changed; at two years the third incisive on each side; and at three years the corners are replaced by the permanent, which complete the set. These are for the first years of the animal's life, even, long, and white; but in advanced age become yellow, or black, and uneven: between these periods all the grinders are changed.

The horns are likewise a permanent, and a temporaneous pair. The temporaneous pair are changed at the end of three years, and the permanent pair appear small, smooth, and terminated at the end with a small tubercle or button. In the following year this button grows from the head, and the line of growth is marked by a horny circle; the horns continue growing through life, and every succeeding year adds a circle, so that the age may be readily gained by counting three years for the first button, and an additional one for every remaining circle.

AGE of *Sheep* is learned likewise from the horns in those which have them, in others from the teeth. M. Buffon says they have, in the third year, four broad teeth before, in the fourth year six broad teeth, and in their fifth year eight of the same kind: but our farmers reckon, that when a sheep is one shear, or year, it has two broad teeth before, when two shear, it will have four; when three shear, six; and when four shear, or years, it will have eight. The age of the horned sheep is most conveniently learned by the horns, which shew themselves in the first year, soon after birth, and are not changed, but continue to protrude a ring or circle annually, as long as they live, so that as many circles as their horns present, so many years are they old. In goats, the teeth and horns follow the same laws; and therefore their age may be learned in the same way.

AGE of the *moon*, in *Astronomy*, is understood of the number of days elapsed since the last conjunction, or new moon; called also her **QUARTER**. The method for discovering her age is mentioned under the article **MOON**.

AGE, in *Law*, is particularly understood of a certain state or time in life, wherein a person is qualified for certain offices of civil society, of which before, for want of years and discretion, he was incapable.

By the Roman law we find different ages ascertained for different purposes; as, *consular age*, or that wherein a person might regularly hold the consulship, which was the 43d year, so that he might sue for it in the 42d. Where it is to be observed, that it was not necessary either of those years should be expired, but only begun: besides, that men of extraordinary merit towards the republic, were in this matter exempt from the ordinary laws. Hence Corvinus was consul at 23 years. Scipio Æmilianus at 36, and Pompey at 35: others broke through the laws by violence, as Caius Marius the younger, and Octavius Cæsar, who procured themselves to be made **CONSULS**, before 20 years of age. Machiav. Disc. in Liv. lib. i. c. 60. p. 210.

Judiciary age, or that wherein a person was capable of sitting as judge, was not always the same; for by the

Lex Servilia Glaucia, none were allowed to be chosen under 30 years of age, or above 60. By some other laws that age seems to have been limited to 35, but reduced afterwards by Augustus to 30; though Pitiseus supposes a mistake here in the text; and that, instead of 35 and 30, it ought to be read 25 and 20. *Lex. Ant. tom. i. Military age*, or that wherein the Romans were obliged to enter themselves in the army, was at 17 years; at 45 they might demand their dismissal. *Aquin. Lex. Milit. tom. i.* This age was subject to considerable variation. The ancient practice, as Vegetius informs us, was to arm young men when they attained the age of puberty: and this subsisted before and under the first kings. Servius Tullius (about the year of Rome 178) fixed the period of military service from 17 to 46 years: those who had not reached this last term were called *juniores*, and those who had passed it *seniores*. Manlius, however, who saved the capitol, had served from the age of 16 years. Adrian commenced his military service at the age of 15 years; and instances occur, in the Roman history, of persons who were called forth to military service within the age of 50 years. But the age established by Servius Tullius was confirmed by Caius Gracchus, A. U. C. 632. The Gauls and Germans served from the age of puberty to extreme old age. The Persians fixed the period of military service from 20 to 50 years. The Scythians and Lacedæmonians extended it from the age of puberty to 60 years. The Athenians commenced at 18 years to guard the city and frontiers, and at 20 they engaged in foreign service, and continued to the age of 40 years. Aristotle fixed the military age at 17 years; (*Polit. lib. viii.*), and Plato in his *Republica* determines it from 20 to 60 years. Among the Lombards, the age of entry was between 18 and 19; among the Saxons at 13.

The *age for holding offices in the city*, as *quæstor*, *ædile*, *tribune of the people*, &c. is not determined by the annual laws of Villius, but appears to have been the 27: a year. For it was necessary that the person who claimed any urban employment, had first served ten years without interruption in the army, commencing from the 17th year. Though some think the *quæstorship* might have been held at 25 years. *Polyb. lib. vi. cap. 17.* The *prætorian age*, or that wherein a person might solicit for the *prætorship*, was at 40; two years earlier than the age required for *consul*. But M. Brutus was *prætor* with Cassius, two years before his death; *i. e.* at the age of 35 years; and Dion (*lib. p. 477*) fixes this age at 30 years. *Legitimate age*, denotes the age of 25; so called, as some imagine, because youth were then by law allowed to take the direction of their affairs into their own hands. *Briss. Select. Ant. ex Jur. Civ. lib. iii. c. 2.* *Dispensation of age, ætatis venia*, is a right which a person obtained from the prince, or sovereign, of setting aside a tutor or curator, and taking the administration of his affairs into his own hands, before the legitimate age. *Calv. Lex. Jur.* The *adoptive age*; called also *plena pubertas*, requires the adopter to be eighteen years older than the person adopted, that there may appear a probability of his being a natural child. *Pitisc. Lex. Ant.* See ADOPTION.

By the common law, there are two principal ages in a man: at 14, he is at the *age of discretion*; at 21 years, at *full age*.

With respect to a woman, there were anciently six ages observed: at seven years, her father might distrain the tenants of his manor for aid to marry her; for at those years she may consent to matrimony.—At nine years old she is

dowable; for then, or within half a year after, she is said to be able *promereri dotem*, & *virum suscipere*.—At twelve years, she is able finally to ratify and confirm, or annul her former consent to matrimony; and, if proved to have sufficient discretion, may bequeath her personal estate.—At 14, she may take her lands into her own hands; and should be out of ward, if she were at this age at her ancestor's death: at this period she is at years of legal discretion, and may choose a guardian.—At 16, she should be out of ward, though at the death of her ancestor she was under 14: the reason is, that then she might take a husband able to perform knight's service: she may be executrix, at 17.—At 21 years, she may dispose of herself and alienate lands and tenements.

As for a man: the age of 12 years binds to appearance before the sheriff and coroner for inquiry after robberies, and impowers taking the oath of allegiance; 52 Hen. III. 14. At the age of 14, he may chuse his own guardian, and claim his lands held in feoffage; though Bracton limits this to 15 years; with whom Glanville agrees.—At 14, a man may consent or disagree to marriage.—At that age, likewise, he may dispose of personal estate by will, if his discretion be actually proved, though not of lands until 21: at 14 also, persons may be witnesses, though in some cases they have been admitted much younger. 2 Hawk. 434. Persons under 14 are not, in general, punishable for crimes; but they must answer for any trespass. 1 Inst. 247.—At 15, he ought to be sworn to the peace, an. 24 Edw. I. stat. 3.—At 17, he may be an executor.—At the age of 21, a man was obliged to be a knight, if he had 20 pounds land per annum fee, or for term of life, anno. 1 Ed. II. stat. 1. But this statute is repealed, 16 Car. I. cap. 20. The same age also enables him to make contracts and manage his own estate; which, till that time, he cannot do with security to those who deal with him; so that at this age he is at his own disposal, and may claim his lands, goods and chattels. Full age, in male or female, is 21 years; and this age is completed on the day preceding the anniversary of a person's birth (*Salk. 44. 625. Lord Raym. 480.*) who, till that time, is an INFANT, and so stiled in law. Among the antient Greeks and Romans women were never of age, but subject to perpetual guardianship, unless when married; and when that perpetual tutelage wore away in process of time, we find, that, in females as well as males, full age was not till 25 years. By the constitution of different kingdoms, this period is fixed at different times. Scotland agrees with England in this point; but in Naples they are of full age at 18; in Holland at 25; and formerly in France, with regard to marriage, not till 30.

With regard to capital crimes, the age of 12 years was established, by the ancient Saxon law, for the age of possible discretion; and from thence till the offender was 14, it was *ætas pubertati proxima*, in which he might, or might not be guilty of a crime, according to his natural capacity or incapacity. Under 12 it was held, that he could not be guilty in will, neither after 14 could he be supposed innocent of any capital crime which he committed. But by the law, as it now stands, and has stood, at least ever since the time of Edw. III., the capacity of doing ill, or contracting guilt, is not so much estimated by age, as by the delinquent's maturity of understanding, so that *malitia supplet ætatem*. Under seven years of age, an infant cannot be guilty of felony; but at eight years old he may be guilty. Under 14, though an infant shall be *prima facie* adjudged to be *doli incapax*, yet, if it appear to the court and jury, that

that he was *doli capax*, and could discern between good and evil, he may be convicted and suffer death. Thus, a girl of 13 has been burnt for killing her mistress; and one boy of ten, and another of nine years of age, who had killed their companions, have been sentenced to death, and the boy of ten years of age was actually hanged; because it appeared upon their trial, that the one hid himself, and the other hid the body of the person he had killed. An instance occurred in the 17th century of a boy eight years old, who was tried for firing two barns; and it appearing that he had malice and cunning, he was found guilty, condemned and hanged. In later times a boy, ten years old, was convicted on his own confession of murdering his bed-fellow, and by the unanimous opinion of all the judges capitally punished. In such cases, however, the evidence of that malice, which is to supply age, ought to be clear and strong beyond all doubt and contradiction.

The age of 24 years enabled a man to enter into an order of religion, without consent of parents, anno 4 Hen. IV. cap. 17. At 24, he may be ordained a priest; and at 30, he may be a bishop. No person can be a member of parliament under the age of 21 years. Though the age of 21 is the full age of either man or woman, yet they may under that age contract for necessaries suitable to their quality and proper instruction, and the contract shall bind them. An infant, who has an advowson, may present to the benefice when it becomes void. He may also purchase lands, though the purchase be incomplete; and when he is of age, he may agree or disagree to it, without assigning any reason; and so may his heirs after him, if he should die before the completion of the agreement. In some cases, he may bind himself apprentice, by indenture, for seven years. 5 Eliz. c. 4.—43 Eliz. c. 2. and he may, by deed or will, appoint a guardian to his children, if he has any. 12 Car. II. c. 24. If either man or woman do any act before the time prescribed by law, they may retract it when they come to the proper age; but if they do not, they are supposed to ratify it, and it shall be deemed valid. Thus, if a man marry before fourteen, or a woman before twelve, they may either agree or disagree to the marriage, when they attain those respective ages. See MARRIAGE. But the age of marriage has undergone divers modifications: in princes, it is allowed earlier than in private persons; in some countries than in others. In Persia, girls are married at nine, boys only at thirteen: in Holland, males are not allowed to marry without consent of parents or curators, before twenty-five; girls not before twenty: the Romans chose to marry their wives young, for the advantage of having them innocent and tractable. Others declaim against premature marriages. Some have pretended to limit the other extreme of marriageable age to forty-five; but this too will be variable in different constitutions. We meet with instances of generation from 60 to 104, or even 121 years of age. Plott. Nat. Hist. Staff. chap. viii. § 3.

Various methods have been in use for determining this age. One sect of ancient Roman lawyers, called Cassiani, fixed it by the state of the body, which Justinian and others after him, suppose to have been done by search, or inspection of the genital parts, at least in the male sex; for as to the female, it is pretended the twelfth year was the only guide, though others alledge that the eruption of the menses served instead of it. The Proculiani, on the contrary, determined the puberty of males by the expiration of the fourteenth year. Javolenus took a middle course, and made use of both methods.

The *Canon* or *Ecclesiastical Law* also denotes divers ages,

viz. of baptism; of ordination to priesthood, and confirmation to episcopacy.

The *Civil Law* distinguished the age of minors, or those under 25 years old, into three stages: *infantia*, from the birth till seven years of age; *pueritia*, from seven to 14; and *pubertas*, from fourteen upwards. The period of *pueritia*, was again subdivided into *etas infantia proxima*, from seven years to 10½, and *etas pubertati proxima*, from 10½ to 14 years. During the first stage of infancy, and the next half stage of childhood, *infantia proxima*, they were not punishable for any crime. During the other half stage of childhood, approaching to puberty, from 10½ to 14, they were indeed punishable, if found to be *doli capaces*, or capable of mischief; but with many mitigations, and not with the utmost rigour of the law. During the last stage (at the age of puberty, and upwards) minors were liable to be punished, as well capitally, as otherwise. Blackst. Com. vol. i. 463. vol. iv. 22.

AGE prier, atatem precari, a petition, or motion made in court, by one in his minority, having an action brought against him for lands coming to him by descent; requesting that the action may rest till he come to full age.—This the court, in most cases, ought to grant.—But minors, as purchasers, shall not have it: nor intent of assise, dower, or partition; though they may in debt. Hob. 342. D. Alr. 259.

It is otherwise in the *Civil Law*, which obliges children in their minority to answer to their TUTORs or CURATORS. See PAROL DEMURRER.

AGEA, in *Geography*, a town of Irak, in Persia, 35 leagues east of Ispahan.

AGED of the mountain, is a title, or denomination, given to the chief, or prince, of the people called ASSASSINS.

AGEDA, in *Geography*, the name of a plain about 30 leagues from Buda in Hungary, on which was held a general assembly of the Jewish Rabbies, A. D. 1650, in order to examine and debate the question, whether the Messiah was come. Three hundred Rabbies, with a great multitude of other Jews, from different nations, were collected together on this occasion; and R. Zachariah, of the tribe of Levi, was chosen their president and speaker. The negative of the question was carried by a majority of voices, and it was agreed that the advent of the Messiah was delayed on account of their sins and impenitence. They also agreed, after some debate, in the circumstances that would attend his appearance: and they were of opinion, that he would appear as a great conqueror, and deliver them from every foreign yoke—that he would alter nothing in the Mosaic religion—and that he was to be born of a virgin; and that his miraculous birth was to be a characteristic, by which he should be known to those who were strangers to the covenant. Some ecclesiasties, deputed from Rome, attended this meeting; and when they began to extol the worship, ceremonies and authority of their church, they excited a tumultuous outcry of “no Christ! no God-man! no intercession of Saints! no worship of images! no prayers to the Virgin!” accompanied with loud clamours, rending of clothes, &c. and thus the conference of that day terminated. On the 8th day, they agreed to hold another council, three years after this, in Syria. Some of the Jewish doctors are said to have hesitated in their opinion, and expressed a desire of conversing with protestant divines; but the interference of so many monks deterred them, and made them fear some tragical conclusion to their assembly. Brett's Narrative in the Phoenix, tom. ii. p. 554.

AGEDAMA, a small island on the coast of Carmania.

AGEDINCUM, *Sens*, a town of Gaul, the capital of the Senones. See AGENDICUM.

AGEEG, a small island on the coast of the Red Sea, N. lat. 18° 5'. E. long. 38° 30', which gives name to a nation inhabiting the adjoining district of the country.

AGELASTA, in *Antiquity*, formed of *a priv.* and *ἄλας*, to *laugh*, and denoting *sorrowful*, a famous stone in Attica, near the well called Callichoras, upon which Ceres reited, when she was fatigued in the search for her daughter. Here, according to Pausanias, (Attic. p. 93) they commended the Eleutianian feasts.

AGELNOTH, or *ÆGELNOTH*, *Achelnotus*, in *Biography*, succeeded Livingus, in the see of Canterbury, in the reign of Canute the Great, A. D. 1020; he was the son of earl Agilmer, and obtained the appellation of *good*, for his acts of piety and benevolence. By his interest and influence with Canute, he restrained some of his excesses, and induced him to bestow large sums of money for the support of the foreign churches. In his way to Rome, for receiving his pall from pope Benedict VIII. he purchased at Pavia, with a large sum, a relic, which was the arm of St. Augulin, and transmitted it to England as a present to Leofric, earl of Coventry. By other more important services he is said to have given lustre to the Archiepiscopal see. Upon Canute's death, he refused to crown his son Harold; alledging a promise which he made to the late king, that he would place the crown only upon one of the issue of queen Emma. Neither threats nor promises could prevail with him to violate his engagement; and he laid the crown upon the altar, with an imprecation against those bishops who should dare to perform the ceremony. He died in the year 1038. His writings were "a Panegyric on the Blessed Virgin Mary,"—"a Letter to earl Leofric, concerning St. Augustin,"—and "Letters to several persons." *Biog. Brit.*

AGEM, in *Botany*, is a name given to the Persian LILAC.

AGEMA, in the *Ancient Military Art*, a kind of soldiery, chiefly in the Macedonian armies.

The word is Greek, and literally denotes vehemence; to express the strength and eagerness of this corps; or it may be derived from *αγω*, to lead; because it consisted of elephants, horse and foot, which preceded the king, and formed, as it were, the royal guard.

Some will rather have *agema* to have denoted a certain number of picked men, answering to a legion among the Romans, which is authorized by a passage in Livy, (l. xlii. c. 51. e. 58. tom. v. p. 673. 682. Ed. Drakenh. Not.); Arrian (De Exped. Alex. l. vii. p. 287. Ed. Gronov.) on the contrary, speaks of the *agema* as a wing of horse; but the term is also applied to foot. This body of troops is also mentioned by Q. Curtius, (l. iv. c. 13. tom. i. p. 271. Ed. Drakenh.) and by Polybius, (l. v. p. 372. 408. Ed. Casaub.) *vid. Suidas* in *voc.*

AGEMOGLANS, or AZAMOGLANS, children of tribute, raised every third year by the Grand Seigneur, among the Christians whom he tolerates in his dominions.

The word, in its original, signifies a barbarian's child; that is, a child not a Turk.—It is compounded of two Arabic words, 1. *اگم*, *agem*, which among the Turks signifies as much as barbarous among the Greeks; the former people dividing the world into Arabs or Turks, and *agem*; as the latter divided it into Grecians and barbarians. 2. *אגל*, *child*.

The commissioners appointed for this levy take them by force even out of the houses of Christians; always claiming one in three, and pitching upon such as seem the handsomest, and promise to be the most serviceable.

These are immediately conveyed to Gallipoli, or Constan-

tinople; where they are first circumcised, then instructed in the Mahometan faith, taught the Turkish language, and the exercises of war, till such time as they become of age to bear arms: and out of these the order of JANIZARIES is formed.

Such as are not judged proper for the army, they employ in the lowest and most servile offices of the seraglio; as in the kitchen, stables, &c.

The *agemoglan*s only differ from the *ichoglan*s, as the former are bred up for the lower, and the latter reserved for the higher offices of the empire. Their pay does not amount to more than seven aspers and a half, or threepence halfpenny, a day.

AGEN, in *Geography*, an ancient large and well inhabited, but ill built, city of France, the capital of Agenois, in the late province of Guienne, and new department of the Lot and Garonne, and the episcopal see of the department of Aveyron. Its situation in a fertile country on the banks of the Garonne, is favourable for trade; but the indolence of its inhabitants deprives them in a degree of the advantage of it. Prunes are a considerable article of commerce; and the hemp which grows in the neighbourhood is manufactured into table linen, and sent from hence to Cadiz, and afterwards exported to the Spanish islands. Here are also manufactories of camblets, serges, and sail-cloth. The gates and old walls, which remain, mark the antiquity and extent of this town. The palace, which was formerly the castle of Montravel, and where the sessions is held, is situated without the walls of the old city; and there is another castle, called La Sagne, of which the ruins only exist. Agen is 108 miles south-east of Bourdeaux. N. lat. 44° 12' 7". E. long. 0° 35' 49".

AGENABAT, a town of Transylvania, ten miles north-east of Hermanstadt, N. lat. 46° 32'. E. long. 24° 50'.

AGENDA, in a general sense, denotes things to be done or performed, in consequence of a man's duty.

The word is Latin, formed from *agere*, to do; and divines speak of the agenda of a Christian, meaning the things to be practised, by way of contradistinction from *credenda*, or the things to be believed; the former imports the articles of obedience, the latter of faith.

AGENDA is also used for a book containing notes or memorandums of things necessary to be done; in which sense agenda amounts to much the same with table-book, &c. An anonymous French author has published the agenda of a man of the world, containing maxims, or rules, proper for the conduct of life. *Tablettes de l'Homme de Cosmop.* 1715.

AGENDA is more particularly used, among *Ecclesiastical Writers*, for the service or office of the church. We meet with *agenda matutina* & *vespertina*, morning and evening prayers; *agenda diei*, the office of the day, whether feast or fast day; *agenda mortuorum*, called also simply *agenda*, the service for the dead.

AGENDA is also applied to certain church-books, compiled by public authority, prescribing the order and manner to be observed by the ministers and people, in the principal ceremonies and devotions of the church.

In which sense agenda amounts to the same with what is otherwise called *ritual*, *liturgy*, *acalouthia*, *missal*, *formulary*, *directory*, &c.

AGENDICUM, in *Ancient Geography*, the chief city of the Senones beyond the Alps, thus written by Cæsar, but called *Agedicum* by Ptolemy, and by others *Agradicum*. See SENS.

AGENFRIDA, in *Ancient Customs*, denotes own lord, or one who has the absolute property and dominion of a thing.

The word is also written *agenfriga*, and *agenfric*. It is derived from the Saxon *agen*, *own*, and *fræa*, *lord*.

AGENHINE, in our *Old Writers*, signifies a guest that has lodged at an inn for three nights, after which time he is accounted one of the family; and if he offended the king's peace, his host was answerable for him. It is also written *bogenhine* and *bogenhyne*.

AGENOIS, in *Geography*, a country of France, in the late province of Guienne, (now department of the Lot and Garonne) comprehending about 120 square leagues. It is a very fertile and healthy country, and was formerly inhabited by the Nitriobriges, mentioned by Cæsar. It formed a part of the kingdom of Aquitania, and was afterwards possessed by the counts of Toulouse, and successively by the English and French. See *AGEN*.

AGENOR, in *Fabulous History*, was the son of Neptune and Lybia, and the father of Cadmus. He reigned in Phœnicia and married Thelepasta, by whom he had three sons, Cadmus, Phœnix and Cilix, and a daughter called Europa. Jupiter carried away the daughter, and Agenor ordered his three sons to seek for her, forbidding them to return to his court without her. Their search was fruitless, and they were banished, and settled in different countries.

AGENOR, in *Natural History*, a species of *PAPILIO Eques*, with black wings, sanguineous at their base; the posterior having a white disc with black spots. It is found in China.

AGENORIA, formed of *αἰνος*, *strong*, in *Mythology*, the goddess of industry and courage, as *Vacuna* was of indolence.

AGENT, AGENS, in *Physics*, that whereby a thing is done, or effected; or that which has a power whereby it acts on another; or by its action induces some change in it. The word *agent* is used promiscuously with *EFFICIENT*, and in contradistinction to *PATIENT*.

The schools divide agents into *natural* and *free*.

AGENTS, *natural* or *physical*, are those immediately determined by the Author of nature, to produce one sort of effect; with an incapacity to produce the contrary.

AGENTS, *natural*, are again subdivided into *univocal*, which are such as produce effects of the same kind and denomination with the *agents* themselves; and *equivocal*, whose effects are of a different kind, &c. from the *agents*.

The schoolmen reckon the following circumstances necessary to the being of an *agent*; *viz.* that it be contiguous to the object, distinct from it, have a power over it, a sphere of activity, and a proportion or rate of acting.

AGENT, *free* or *voluntary*, is that which may equally do any thing, or its opposite; as acting not from any pre-determination, but from choice.—Such is the mind supposed to be, which has a spontaneous power of chusing or refusing.

It is a celebrated question among *philosophers* and *divines*, whether man be a free, or a necessary agent? It may be thus stated: man is a necessary agent, if all his actions are so determined by the cause preceding each action, that no one past action could possibly not have come to pass, or have been otherwise than it was; nor one future action can possibly not come to pass, or be otherwise than it shall be. On the contrary, man is a free agent, if he be able at any time, in certain circumstances, to do different things; or, in other words, if he is not ever unavoidably determined in every point of time, by the circumstances he is in, to do that one thing he does, and not possibly to do any other.

Which of these two definitions agrees to man, is a question of fact to be determined by what we experience in ourselves, with regard to the operations of our own minds. See *LIBERTY*, *NECESSITY*, and *WILL*.

The term agent evidently implies a power of self-determination; and the epithet *necessary*, applied to agent, forms a solecism both in sense and language. Price's Review, &c. p. 315, &c.

AGENT is more particularly used for the minister of a prince, or state, at another court.

In which sense, agents are commonly reputed a species of public ministers, or *AMBASSADORS*: but they differ essentially, as agents are not invested with any representative character, although entrusted with the affairs and interests of their princes. See *ENVOY*.

AGENT is also used for a person intrusted with the management of affairs, either of a corporation, or private person. In which sense the word coincides with *deputy*, *procurator*, *syndic*, *factor*, &c.

Among the officers in the *EXCHEQUER*, there are four agents for taxes.

AGENTS of *bank and exchange*, are public officers, established in the trading cities of France, to negotiate matters between merchants relating to bills of exchange, and the buying and selling of goods: the same with those who, among us, are called *EXCHANGE-BROKERS*.

AGENTS of the *victualling office*, are officers under the commissioners, appointed to buy and contract for provisions, &c. Some of these are settled in the ports, where they have much the same office and authority as the commissioners in London.

AGENT-victualler, is used in the same sense.

AGENT and *patient*, in *Common Law*, is where a person does, or gives, something to himself; so that he is at the same time both the doer and giver, and the receiver or party it is done to.—Such is a woman, when she endows herself with part of her husband's inheritance.

AGENT, in *Chemistry*. According to the ancient chemists, substances were composed of active and passive principles; the latter of which received impressions from and were modified by the former, without exerting any reciprocal action. Spirit, oil and salt, were considered as the active, and earth and water, as the passive principles. This distinction evidently arose from the phenomena of solution, and the apparent energy which acids and other fluids exhibit in their combination with metals and solids in general. It is now however universally allowed, and indeed necessarily follows from the doctrine of affinity, that whenever two substances combine together, it is in consequence of a mutual attraction, which belongs as much to one element as to the other of a compound; this definition therefore of chemical agent is no longer adhered to, and though we still continue to use the expression of one body having a powerful action on another, it is by no means intended to deny the equal reciprocity of chemical attraction.

The general term agent signifies, therefore, in strictness, any substance capable of producing chemical action; and when, in explaining a process, the quality of agent is attributed to a body, it is only used as a designation of the substance whose presence determines the combination or decomposition. In which sense it is sometimes attributed to menstrua, or such bodies as in mixture have the greatest share of activity and motion; and it is sometimes also used for what we more usually call *instrument*. Thus fire, water, air, earth, and menstrua, are chemical agents.

That internal agent in man, whereby all the vital motions necessary to the preservation and restoration of the body are managed, is by some called *nature*; by others *archæus*, *callidum innatum*, animal soul, vital spirit, or principle, &c.

AGENTE, in *Music*, a term which, in the infancy of counterpoint, was given, by the Italians, to the note of percussion,

that occasions and accompanies a prepared discord upon a binding note; which note was termed the *patient*.

In the preceding example, C is the *patient*, E prepares the discord, D is the moving note or *agent*, and B its *resolution*.

AGENTES in rebus, one of the ranks of officers, in the court of the Constantinopolitan emperors, whose business was to collect and convey the corn, both for the army and household; carry letters and messages from court to all parts of the empire; regulate couriers, and their vehicles; to make frequent journeys and expeditions through the provinces; inspect any motions, disturbances, machinations tending that way, and give early notice thereof to the emperor. Aquin. Lex. Mil. tom. i. Pitifc. Lex. Ant. tom. i. Calv. Lex. Jur.

The *agentes* in rebus, are by some made synonymous with our post-masters, but their function was of great extent. They correspond to what the Greeks call *πυρφοροί*, and the Latins *veredarii*.

There were divers orders or degrees of *agentes* in rebus, as *tribuni*, *primicerii*, *senatores*, *ducenarii*, *biarchi*, *circitores*, *equites*, *tyrones*, &c. through all which they rose *gradatim*. Their chief was denominated *princeps*, which was a post of great dignity, being reckoned on a level with that of provincial.

The *princeps agentium in rebus* resided at Constantinople, others of them were settled in every part of the empire; and are also said to have served as interpreters.

AGEOMETRIA, a defect in point of **GEOMETRY**, or a deviation from the strict principles and conclusions of that science.

This is otherwise called *ageometresia*.

Some have complained of the *ageometria* of the Scriptures, in respect of the proportions of the *brazen sea*, *ark*, &c.

AGER *vestigialis privatus*, in *Roman Antiquity*, that whose property was granted to private persons on the reserve of a certain rent, or tribute.

AGER *vestigialis publicus*, that whose property was reserved to the public, and being let out to farm, the rents or profits accrued to the public treasury.

AGER is also used for a certain portion or measure of land, antiently allowed in the division of grounds to each citizen.

In the early days of the Roman state, the *ager* was only two *jugera*, amounting to $1\frac{1}{4}$ English acre. After the expulsion of the kings, seven *jugera* were allowed a plebeian.—Under the tribunate of C. Licinius Stolo, in the year of Rome 379, a law was made to limit estates to 500 *jugera*, or 330 English acres, and to decree the distribution of the surplus in the possession of any individual amongst those who had no land. Under Julius Cæsar another *AGRARIAN* law was published, by which those who enlarged their pittance of land were to pay 50 *aurei* to the public.

AGER is also used in *Middle Age Writers*, for what we now call an *acre*.

AGER, or **AGUER**, in *Geography*, a small town of Catalonia, in Spain, near the river Segra, north of Lerida, and 25 leagues west of Barcelona. N. lat. 41° 55'. E. long. 0° 34'.

AGER, a river of Austria, which runs into the Traun, about a league north from Schwannastatt.

AGER is also a district in a fief of **AGGERHUUS**, in Norway, called *Aggers-Herred*.

AGER *Picenus*. See **PICENUM**.

AGERATUM, compounded of the privative α and $\gamma\epsilon\gamma\epsilon\iota$, *old age*, and denoting *never-old* or *ever-green*, in *Botany*, a genus of plants, of the *Syngenesia polygamia equalis* class and order, of the natural order of *composita discoides*, and *corymbiferæ* of Jussieu; the characters of which are, that the common calyx is oblong, with many, lanceolate, sub-equal scales: the compound corolla is uniform, corollets hermaphrodite, tubulous, numerous, equal, scarcely longer than the calyx; proper monopetalous, funnel-shaped, border quadrifid and spreading; the stamina are capillary filaments, very short, the anther cylindric and tubular; the pistillum is an oblong germ, style filiform, of the length of the stamina, the stigmas are two, very slender and erect; no pericarpium, calyx unchanged; the seed solitary, oblong, angular, crowned with a chaffy, five-leaved, upright awned calycle; the receptacle naked, convex, and very small. It differs from **EUPATORIUM** in the crown of the seeds; and from **BIDENS** in the nakedness of the receptacle. Martyn enumerates two species, *viz.* 1. *A. conyzoides*, hairy *ageratum*, with ovate leaves and hairy stem, which flowers in July and August, and is a native of Africa, the islands of America, and the isle of Tanna, in the South Seas. This species is propagated by sowing the seeds on a hot bed in the Spring; and when the plants are strong enough to bear removing, transplanting them into another moderate hot-bed; where they should be watered, and shaded till they have taken root. In June they should be inured to the open air, and transplanted towards the middle of the month into the open ground, where they will continue flowering from July till the frosts in Autumn destroy them. The seeds ripen in September and October. 2. *A. ciliare*, with leaves ovate, crenate, obtuse, and smooth stem, which is a native of the East Indies, and of China, near Canton. The *A. Houssonianum* of Miller, found wild at La Vera Cruz, by Dr. Housfoun, does not differ from the first sort. In Gmelin's edition of Linnæus, we have a third species, *viz.* *A. Guianense*, with cordated, serrated, and petiolated leaves. See **ACHILLEA**, **ATHANASIA**, **CONYZA**, **ERINUS**, **EUPATORIUM** and **SENECIO**.

AGERATUM, in the *Materia Medica*, is a species of *Achillea*, with numerous, small, oblong, narrow leaves, called in English *sweet milfoil* and *maullin*. It bears a near resemblance to the costmary, and is denominated *balsamita fœmina*, as that is called *balsamita mas*. It is also called *eupatorium mesfues*, on account of its supposed virtue in diseases and obstructions of the liver. It is a native of Italy, the South of France, and of Spain; and is found by the road sides, where it flowers from August to October. As it is seldom used with us for medicinal purposes, it is not cultivated in the gardens for sale. There are two varieties of it, one having longer and more compact corymbs, the other with broader leaves and smaller flowers. It is sweet to the smell, and of a bitter taste, and aromatic. Linnæus reckons it obsolete and superfluous. Allione, on the contrary, thinks it an efficacious plant, and recommends it in all disorders arising from a debility of the nerves. Dr. Lewis says of this and the costmary, that these herbs have been used as mild corroborants and aperients, in weaknesses of the stomach, obstructions of the viscera, and cachectic dispositions; and though at present disregarded, they promise, from their sensible qualities, to be medicines of some utility. Riverius recommends *ageratum*, on account of its astringent quality, as an antidote to incontinence of urine; and Gesner has discovered a brisk purgative quality in its roots.

AGERATUS lapis, in the *Materia Medica* of the *Antients*,

cients, the name of a stone mentioned by Galen and other writers; and said to be of the nature of the Phrygian stone, but more astringent; and as that was used in dying, this was in dressing of leather. We have no account of its external appearance, but probably it contained vitriol, and perhaps alun.

The great use of vitriol or copperas in the management of leather is well known; and the stones which contain it, or pyrites, are every where common. The method used also in the preparation of the *Phrygius lapis*, which was the wetting and slightly calcining it, must be very proper to make the vitriol contained in this appear, and exert itself in the working with it. This stone is used by shoemakers to polish women's shoes.

AGERIUM. See AGISTMENT.

AGERSOE, in *Geography*, a small island of Denmark, in the Greater Belt; two leagues south of Corfoer.

AGES, signifies the palm or hollow of the hand.

AGESANDER, in *Biography*, one of the three sculptors, who jointly executed the famous antique group of LAOCOON, was born at Rhodes, and flourished about the 88th olympiad. His name stands first upon the plinth of the group.

AGESILAUS, in *Ancient History*, one of the most illustrious kings of Sparta, succeeded his brother Agis against the competition of his nephew Leotychides, to whom by the laws the crown would have regularly descended. As he was a younger son of Archidamus II. he could have no view to the kingdom; and he was therefore educated in all the rigour of the Spartan discipline, and in the habits of self-denial, labour and obedience, from which those who were heirs to the throne were exempted. He thus acquired a degree of popularity, which, notwithstanding his low stature, and his being lame in one leg, secured his succession; more especially as he was patronized and supported by Lyfander, whose influence in the state was very considerable, and his rival was suspected of being the son of Alcibiades, who was said to have corrupted the queen of Agis, by a present of a thousand daries. His disposition and manners, which combined resolution and activity, with condescension and gentleness, more than counterbalanced his natural defects; and though the oracle had warned the Spartans against a *lame reign*, Lyfander contrived to interpret the warning as a caution against the illegitimacy of Leotychides, and thus to facilitate the establishment of Agesilaus. By his subsequent conduct he ingratiated himself with persons of all ranks and parties to such a degree, that the Ephori are said to have checked his ambition by imposing a fine upon him, because he attached the affections of the citizens to himself alone, and thus alienated them from the republic to which they rightfully belonged. Such, however, were the attention and deference which he manifested towards the Ephori and the senate, that he obtained their entire confidence; and his authority was superior to that of any other king of Sparta. Soon after he ascended the throne, ante Christ. 396, the king of Persia fitted out a powerful fleet, in order to deprive the Lacedæmonians of their empire at sea. Agesilaus, at the instigation of Lyfander, was appointed general of the forces that were destined to an expedition against Artaxerxes; and he accepted the office on condition, that a council of 30 Spartan commanders should accompany him, and that Lyfander should be the chief of this council. During his delay at Aulis, he had a quarrel with the Bœotians about a sacrifice, which occasioned a war, that terminated in the subversion of the Spartan dominion. When he arrived at Ephesus, a message was addressed to him by Tissaphernes, the lieutenant of the Persian king, demanding his reason for

coming into Asia with an armed force; to which he replied, that his purpose was to aid the Greeks, who inhabited there, in recovering their ancient liberty. Tissaphernes, in order to gain time, promised in behalf of his master to grant liberty to the Grecian cities of Asia. Agesilaus acquiesced, and a truce was settled between them. In the mean while the Persian general, regardless of his oath, took advantage of the delay, assembled troops and prepared for war. Agesilaus, though apprized of his treachery, adhered to his engagement; and this religious observation of a solemn treaty gained him, as Xenophon informs us, the universal esteem of the cities, whilst Tissaphernes, by a different conduct, entirely lost their favour. This interval afforded the Lacedæmonian general an opportunity for acquiring an accurate knowledge of the state of the country and of the disposition of the inhabitants. In the course of his enquiry he found that Lyfander arrogated a degree of power, which encroached on his authority and obstructed his influence. Agesilaus did not dissemble his disgust. Having given the most considerable commands and best governments to private officers, he appointed Lyfander commissary of the stores and distributor of provisions, and for the purpose of further mortifying him and deriding the Ionians, he directed them "to consult their master-butcher." Lyfander, afterwards returning to Greece, projected a variety of schemes for overturning the constitution of Sparta, but his death prevented their accomplishment.

When Tissaphernes had collected his forces, he commanded Agesilaus to retire from Asia, and upon his refusal declared war against him. The subordinate officers of the Spartan general were alarmed, but Agesilaus himself was composed and cheerful; and having transmitted his thanks to Tissaphernes "for having made the Gods, by his perjury, the enemies of Persia, and the friends of Greece," he made a feint of marching his army into Caria, the residence of the Persian lieutenant, but actually overran Phrygia, where he took many towns and amassed immense treasures, which he distributed among his officers and soldiers. Having wintered at Ephesus, he devoted the ensuing spring to the exercise and discipline of his army, which he encouraged by the distribution of prizes; and at the same time he inspired his soldiers with a contempt of their enemies, by stripping the prisoners and exposing them and their garments to sale. The latter were eagerly purchased; but the prisoners themselves were so delicate and feeble, that they were deemed of no service or value: "see there," says Agesilaus to his soldiers, "the persons against whom you fight;" and pointing to their rich spoils, "behold there for what you fight." As the season advanced, the Lacedæmonian army marched into Lydia, defeated the Persians near Sardis, and ravaged the whole country. This success terminated in the death of Tissaphernes; his command devolved on Tithraustes, who attempted to conciliate Agesilaus by rich presents, and to induce him to withdraw his troops and to return into Greece by the promise of liberty to the cities of Asia, upon their payment of the customary tribute. The Spartan king, however, deferred the proposed accommodation till he had submitted it to the consideration of the state, and received orders for this purpose. In the mean while he marched into Phrygia, which was the province of Pharnabazus, and the expense of his expedition thither was defrayed by Tithraustes. During his progress he received new powers from home, by which he was constituted sole commander both by sea and land; an honour which Sparta had never before conferred on any of its generals. From Phrygia, where he amassed large sums of money, he advanced as far as Paphlagonia, and formed an alliance with Cotys, the prince of that

country. Phrygia was at this time laid waste by Spithridates who had revolted from Pharnabafus and joined Agefilaus. In these circumstances Pharnabafus demanded an interview with the Spartan king, whom he found fitting upon the grass; whilst the Persians spread rich carpets of various colours and magnificent cushions for the accommodation of their master. Overcome by the simplicity and modesty of Agefilaus, Pharnabafus sat down by his side upon the grass. At the close of this conference, they parted with mutual tokens of friendship and respect; to the exultations of Pharnabafus, which the Spartans heard with downcast eyes and profound silence, Agefilaus replied, that war often arms the best friends against each other for the defence of their country. "But," says he, "if you prefer the appellation of the friend and ally of the Greeks to that of the king of Persia's slave, you may reckon that all the troops you see before you, our arms, our ships, our persons, to the last man of us, are only here to defend your possessions, and secure your liberty, which of all blessings is the most precious and desirable." Pharnabafus pledged himself not to depart from the faith he had sworn to him, nor to quit his service; and Agefilaus taking him by the hand, and rising with him, replied, "that it was the pleasure of the Gods, that with such noble sentiments you should be rather our friend than our enemy;" and he promised to withdraw from his government, and never to return to it, whilst he could subsist any where else.

During the two years of Agefilaus's command in Asia, he exhibited all the talents of a warrior and statesman, and all the virtues of a Lacedæmonian. The remotest provinces trembled at his name, and resounded with the fame of his wisdom, disinterestedness, moderation, intrepid valour in the most pressing dangers, and invincible patience and firmness in enduring toil and fatigue. Such was the respect which his conduct and character commanded, that deputies were sent from all parts in order to form alliances with him; and his army increased continually by the accession of Barbarians that enlisted under his standard. Whilst he allowed his soldiers the advantage of pillage, he himself was not chargeable with any act of cruelty or injustice. His prudence and authority were so much esteemed, that he restored order and tranquillity to all the cities of Asia, and reinstated them in the possession of their liberty, not only without shedding of blood, but without even banishing a single person. Ambitious of extending the glory of his country, and of Greece in general, he had formed the design of attacking the king of Persia in the heart of his dominions, and of so occupying his time and attention, that he might have no leisure for directing his hostile views and schemes to distant provinces. But before he could execute his purpose, he was recalled by the Ephori to the defence of his own country. As soon as he received the order for returning, he instantly obeyed; alleging, that he received the command not for himself, but for his country and its allies. "I know, says he, that a general does not deserve, or possess, that name really, but as he submits to the laws and the Ephori, and obeys the magistrates." On his departure, however, he said, "that 30,000 of the king's archers drove him out of Asia;" alluding in these words to a species of Persian coin, which had on one side the figure of an archer, 30,000 of which pieces of money had been dispersed in Greece to corrupt the orators and persons of greatest power in the cities.

Agefilaus, when he quitted Asia, was accompanied by Xenophon; and at Ephesus he committed half the gold he had brought with him from his expedition into Persia with Cyrus to the custody of Megabyzus, the guardian of Diana's temple, with an order, in case of his death, to conse-

crate it to the goddess. On his return through Thrace, he only demanded, "whether he should pass as a friend or an enemy;" and when the king of Macedon replied, "that he would consider of it:" "Let him consider, says Agefilaus, in the mean time we will march." Before he arrived at Sparta, he received an order from the Ephori to invade Bœotia, with which he complied, though the measure was not such as he approved. On the plains of Chæronea, a very severe engagement took place, in which Agefilaus received several wounds, and his life was exposed to great danger. Some of the enemy had taken refuge in a temple of Minerva, near the field of battle; and these Agefilaus ordered to be dismissed, and appointed a guard to escort them in safety wherever they chose to go. After this battle he returned to Sparta, and was received with admiration and joy. Uncorrupted by the customs and manners of foreign countries, as other generals had been, he made no alteration in his diet, furniture, or equipage. His enterprise against Corinth did not succeed; but his expedition against the Acarnanians compelled them to sue for peace. In the year before Christ, 387, the sovereignty of Greece was guaranteed to Sparta by the peace with the Persian king, negotiated by Antalcidas, on the dishonourable condition of abandoning the Greek cities of Asia to the Persians. After this event, the Spartans treated some of the smaller states in a tyrannical manner, and unjustly seized the citadel of Thebes, in which act Agefilaus disgracefully concurred. Sparta was thus involved in a new war with Athens, in which the Thebans, under the illustrious Epaminondas, became formidable to their oppressors: and it was alleged against Agefilaus, that he had taught them the art of war, by his expeditions against them, so that they were able to encounter the Lacedæmonians in the field, as was the case in the battle of Leuctra, when Archidamus, the son of Agefilaus, and Cleombrotus, the other Spartan king, were defeated with great loss, and Cleombrotus left dead on the spot. In consequence of this disaster, Agefilaus was invested with a dictatorial power, for the purpose of saving the fugitives from the severity of the Spartan laws, without prejudice to the state: and on this occasion he decreed:—"let the laws sleep to-day, but to-morrow let them resume their full vigour." After this battle, Agefilaus exerted himself in levying a new army, in defending Sparta from the hostile attacks of Epaminondas, and in suppressing a conspiracy which took place among the Spartans themselves. In the year before Christ 362, some new commotions broke out in Peloponnesus; and Agefilaus was defeated, at the head of the Spartans and their allies, in the battle of Mantinea, by Epaminondas, who died in the moment of victory. When a general peace was established, the Lacedæmonians were excepted, by the culpable obstinacy of Agefilaus, who refused to concur, because the Messenians were comprehended in it as a separate state.

Agefilaus, in the decline of life, accepted the command of a band of mercenary troops in the service of Tachos, who aspired to the throne of Egypt. This commission reflected no great honour on the character of this illustrious Spartan, who, at the age of 80 years, degraded himself by receiving the pay of an Egyptian, and serving a barbarian, who had revolted against his master. The Egyptians resorted in great multitudes to see a man, whose name and character had been so long and so generally applauded; but connecting splendour and magnificence with their ideas, they were disappointed when they saw an old man, of a mean aspect and low stature: they applied to him the fable of the mountain in labour, and could scarce refrain from laughter and ridicule. His conduct, however, soon produced a change of opinion.

opinion. When he found that Tachos did not assign him the command of the whole army, but restricted his authority merely to the foreign troops, he was surprized and mortified; and he was the more incensed by the contempt with which his counsel was received, and by various instances of neglect which he experienced. Thus provoked, he joined those Egyptians who took part with Nectanebis, the other competitor for the crown, and assisted them in establishing the rival of Tachos on the throne. Agefilaus pleaded public utility as an apology for his versatile conduct in this instance: Xenophon attempts to palliate it; but Plutarch charges it with the infamy of perfidy and treason. The following winter, in the year before Christ 361, he embarked to return to Lacedæmon; but was driven by a storm upon the coast of Africa, into a place called the Port of Menelaus; where he fell sick and died, at the age of 84 years, after a reign of 41 years, during 30 of which he maintained the most distinguished reputation. His latter years, after the battle of Leuctra, were less honourable: and Xenophon, in his eulogium of this prince, has been thought too much to exaggerate his virtues, and to extenuate his faults. His body was carried to Sparta, and embalmed with wax instead of honey, which was usually employed for this purpose. His son Archidamus succeeded to the throne, which continued in his house to Agis, who was the fifth king of the line of Agefilaus. His life and actions have been recorded, not only by Xenophon, his intimate friend and panegyrist, but by Diodorus Siculus, Plutarch, and Nepos. Many anecdotes are related concerning him, which sufficiently mark his character, and evince the high estimation in which he was held by his contemporaries. Hearing the great king, an appellation assumed by the kings of Persia, spoken of in terms of extraordinary commendation; he is reported to have said—"I cannot conceive wherein he is greater than I, unless he be more just." His regard to justice, however, was sometimes sacrificed to his attachment to his country, and to the bias of private friendship and affection. In recommending a friend to a judge, he says—"If Nicias be not guilty, acquit him for his innocence; if he be, acquit him for my sake; but, however it be, acquit him." His contempt of unmerited praise, and his superiority to ostentation and vain-glory were prominent features in his character. Accordingly, he would never permit, during his life, that his picture should be drawn; and at his death, he expressly forbid any image to be made of him, either in colours or relieve. "Let my actions," he would say, "if deserving, be my monument." The following anecdote furnishes a pleasing evidence of his domestic affections. When a friend found him riding upon a stick with his children, "Tell nobody what you have seen (said Agefilaus) till you are yourself a father." Xenophon *Hist. Græc.* Plutarch in Agefil. Corn. Nepos. in Agefil. *Univ. Hist.* vol. v. p. 460. Diodorus Siculus. *Rolin's Ant. Hist.* vol. iii. p. 369—400. vol. iv. p. 137—196.

AGESILAUS, in *Mythology*, the surname of Pluto, which was given to him, because he conducted all mankind into his empire; *παρά τὸ ἄγειν τὰς ψυχάς.*

AGESINATES, in *Ancient Geography*, a people of Gaul, placed by M. d'Anville in the territory of the Pictones or Pictavi.

AGESSUS, a town of Thrace, called by Pliny (*l. iii. c. 11.*) *Agafus*, and by Livy, (*l. xlv. c. 7.*) *Agassa*, but assigned to Macedonia in the confines of Thrace. Stephan. *Byz.* Hardouin mentions imperial Greek medals belonging to this city.

AGETORIA, in *Antiquity*, feasts mentioned by Hesy-

chius, which were probably instituted in honour of Apollo, and the same that were observed by the Lacedæmonians, under the appellation of *CARNIA*. Venus was also honoured at these feasts, as we may conclude from the name of *αγντας*, which was given in the island of Cyprus to the priest of this goddess.

AGEUSTIA, or AGHEUSTIA, formed of *α privat.* and *γευσται, to taste*, in *Medicine*, a defect in the sense of taste. This disease may arise from an organic affection, or an atonic state, of the organs. The taste may be depraved or diminished by fur, mucus, *ΑΡΤΗΤΗΞ*, ulcers, &c. on the tongue; or by a diseased secretion of saliva. It may be entirely abolished by injuries done to the nerves of the tongue and palate.

This constitutes one of the genera of diseases in the arrangement of Dr. Cullen; and he divides it into *A. organica*, arising from a disease in the membrane of the tongue, keeping off from the nerves those substances which ought to produce taste; and *A. atonica*, which occurs without any evident disease of the tongue.

Cure.—When the taste is diminished or depraved by fur or mucus, as usually happens in *FEVERS*, it is rarely possible to restore it by any other means than those which subdue the fever. The tongue, teeth, and fauces, should be washed with detergent gargles, of which the aqua ammoniacæ, or common sal volatile, properly diluted with water, is the most effectual in dissolving the mucus. The tongue may be gently scraped when moist, and the teeth brushed. When the taste is depraved by a diseased secretion of saliva, the cure depends on restoring the natural secretion. If bile, or any *SABURRA* in the stomach, disorder the natural taste, recourse must be had to emetics or the proper correctors of the offending cause: acidity is removed by alkalies, chalk, magnesia, and even by other acids.

AGGADA, in *Jewish Antiquity*, an ingenious tale or story; of which kind there are many in the Talmud.

There are several books extant among the Jews under this title. R. San Israel Ben Juda has published *Novellas Aggadarum*, or new explanations of the stories and relations in the *TALMUD*, discovering the hidden meanings thereof.

AGGAS, ROBERT, in *Biography*, commonly called *AUCUS*, a good English landscape painter, who was also skilled in architecture, lived in the reign of Charles II. He painted both in oil and distemper, but few of his pictures are extant. The best is a landscape presented to the company of paper-stainers, and preserved in their hall. He died in London, in 1679, at the age of about 60 years. *Biog. Dict.*

AGGAS, RALPH, an engraver, published the plan of Oxford and Cambridge, in 1578, and a map of Dunwich in 1589. He engraved, on wooden blocks, the plan of London, afterwards engraved on copper by Vertue. Strutt.

AGGER, in *Ancient Writers*, denotes the middle part of a military road, raised into a ridge, with a gentle slope on either side, to make a drain for the water, and keep the way dry. The appellation is also used for the whole road, or military way.

Where high-ways were to be made in low grounds, as between two hills, the Romans used to raise them above the adjacent land, so as to make them on a level with the hills. These banks they called *aggeres*. Bergier mentions several in the *Gallia Belgica*, which were thus raised, ten, fifteen, or twenty feet above ground, and five or six leagues long.

They are sometimes also called *aggeres calceati*, and now generally known by the name *CHAUSSEES*, or *CAUSEWAYS*.

AGGER also denotes a work of fortification, used both for the

the defence and attack of towns, camps, &c. In which sense it is the same with what was otherwise called *vallum*, and in later times *aggerstum*, and among the moderns *lines*; sometimes *cavaliers*, *terrasses*, &c.

The agger was usually a bank, or elevation of earth, or other matter, bound and supported with timber; having sometimes turrets on the top, wherein the workmen, engineers, and soldiery were placed. It was also accompanied with a ditch, which served as its chief defence.

The usual materials of which it was made, were earth, boughs, fascines, flakes, and even trunks of trees, ropes, &c. variously crossed, and interwoven somewhat in the figure of stars; whence they were called *stellati axes*. See Lucan iii. 455, 501. Silius Ital. xiii. 109. Where these were wanting, stones, bricks, tiles, supplied the office: on some occasions, arms, utensils, pack-saddles, were thrown in to fill up. What is more, we read of aggers formed of the carcases of the slain; sometimes of dead bones mixed with lime, and even with the heads of slaughtered citizens. For want of due binding, or solid materials, aggers have sometimes tumbled down, with infinite mischief to the men.

The besiegers used to carry on a work of this kind nearer and nearer towards the place, till at length they even reached the wall. The methods taken, on the other side, to defeat them, were by fire, especially if the agger were of wood; by sapping and undermining, if of earth; and, in some cases, by erecting a counter agger. Thus the inhabitants of Gaza defended themselves against Alexander. Q. Curtius iv. b. xxi.

The height of the agger was frequently equal to that of the wall of the place. Cæsar tells us of one he made, which was 30 feet high, and 330 feet broad. Besides the use of aggers before towns, the generals used to fortify their camps with such works; for want of this precaution divers armies have been surpris'd and ruined.

There were vast aggers made in towns and places on the sea-side, fortified with towers, castles, &c. Those made by Cæsar and Pompey at Brundisium, are famous. Sometimes aggers were even built across arms of the sea, lakes, and morasses; as was done by Alexander before Tyre, and by M. Antony and Cassius.

The wall of *Severus*, in the north of England, may be considered as a grand agger, to which belong several lesser ones. Besides the principal agger or *vallum*, on the brink of the ditch, Mr. Horsley describes another agger on the south side of the former, about five paces distant from it, which he calls the south agger; and another larger agger on the north side of the ditch, called the north agger. This latter he conjectures to have served as a military way; the former, probably, was made for an inner defence, in case the enemy should beat them from any part of the principal *vallum*, or to protect the soldiers against any sudden attack from the provincial Britons.

AGGER *Tarquiniæ*, *Tarquin's agger*, was a famous fence built by Tarquinius Superbus, on the east side of Rome, to stop the incursions of the Latins, and other enemies, whereby the city might be infested. See Plin. iii. 5. Criminals were thrown down from the top of this rampart. Juv. Sat. vi. 288. Sueton. in Cal. c. 27. n. 3.

AGGER is also used for the earth dug out of a trench, and thrown upon the brink of it.

In which sense, the chevalier Folard thinks the word to be understood, when used in the plural number, since we can hardly suppose they would raise a number of cavaliers, or terrasses.

AGGER is also used for a bank, or wall, erected against the sea, or some great river, to confine or keep it within bounds.

In which sense, agger amounts to the same with what the ancients call *tumulus* and *moles*; the Dutch, *dylke*; we, *dam*, *sea-wall*.

AGGER also denotes a heap of earth, raised over the graves of the ancients.

In which sense, it amounts to the same with *tumulus*; and is sometimes also called *aggerstum*.

AGGER, in *Geography*, a river of the circle of Westphalia, which waters the county of Marck and the duchy of Berg, and falls into the Rhine.

AGGERHUUS, or CHRISTIANIA, the largest diocese or general government in the south part of Norway; and the richest, as well as most considerable, in the whole kingdom. It was formerly called *Hammerstift*, and afterwards known by the name of *Opsele*. Aggerhuus is also the name of a fortress in this diocese, on the west side of the bay, near which lies the city of CHRISTIANIA. It is not known when it was built. It has been repeatedly besieged by the Swedes, viz. in 1310, in 1567, and in 1717, by Charles XII. without success. The governor of Aggerhuus is the chief governor of Norway: he presides in the high court of justice, called *Overhofstet*, which judges in the last resort, all civil causes above a certain value. In all causes surpassing that value, an appeal lies to the supreme court at Copenhagen. N. lat. 59° 6'. E. long. 10° 20'. The oldest church in this diocese, said to have been built about 700 years ago, and called *Aggers*, is situated about a quarter of a Norway mile north of the castle. The population of this diocese is estimated at 215,043 persons.

AGGERS-HERRED, a shief of Aggerhuus, which comprises three districts, with as many courts of judicature, viz. *Afcher*, East and West *Barum*, and *Ager*. CHRISTIANA is situated in this district.

AGGEROUT, or AGGEROUD, supposed to be the ancient ARSINOË, is situated at the extremity of the Red Sea, about two leagues from the port of Suez. Here terminated the famous canal, begun by Necos and finished by Ptolemy Philadelphus, for joining the Nile to the Red Sea. Between the time of Ptolemy and our days, the Red Sea has retired two leagues, which is the distance of Aggeroud from Suez.

AGGI, a river of Persia, which runs into the Aras, near Chambe, in the province of Aiderbeitzan.

AGGILE, a town of Prussia; 13 leagues east-north-east of Konigsberg.

AGGLESTONE, otherwise called *Stone-Barrow*, and vulgarly the *Devil's Night Cap*, is a remarkable monument of antiquity situated in the north-east extremity of the isle of Purbeck. Its dimensions are 60 feet in circumference at the bottom, in the middle 80, and at or near the top 90; and it is computed to contain 407 tons of stone. The name seems to have been derived from the Saxon *halig*, or *halig, holy*, and *stan, stone*, which expresses its ancient use: as it was probably a rock idol in the British age.

AGGLUTINANTS, in *Pharmacy*, a species of strengthening medicines, whose office and effect are to adhere to the solid parts of the body, and thus recruit and supply the place of what is worn off, and wasted, in the animal actions.

Agglutinants are most of them of the glutinous kind, or such as easily form themselves into jellies, and gummy consistences; whence the name *agglutinant*, which is formed of *ad, to*, and *gluten, glue*.

For the operation and use of agglutinants, see STRENGTHENERS.

The principal simples which come under this class, found in the shops, are, isinglass, olibanum, gum arabic, dragon's blood,

blood, cassia, sago, vermicelli, pulse, comfrey, plantain, &c. If the term, says Dr. Cullen, has any foundation at all, it must have the same meaning with that of nutrient; and there is no propriety in using a doubtful theoretical term. Nor is the term less improperly applied to medicines that are suited to cement and reunite parts preternaturally separated, and therefore employed in wounds and ulcers. British surgeons neither know nor employ any such medicines: the business is the work of nature; and their concern is to remove impediments to its operation. Cullen's *Mat. Med.* vol. i. 163.

AGGLUTINATIO Pilorum, a healing or reducing the hairs of the eye-lids, that grow inwards, to their natural order and situation. This may be done by mastic applied with a probe, which bends the hairs back into their proper order. Bitumen, the slime of a snail taken off with a needle, the juice of hawks-weed, the liquor of agglutinants, or ammoniac, produce the same effect.

AGGLUTINATION, literally denotes the act of joining or cementing two bodies together, by means of a proper **GLUE OR CEMENT**.

In *Medicine*, the term is peculiarly used for the apposition or adherence of a new substance; or the giving a greater consistence to the animal fluids, to fit them the more for nourishment.

Some assign a difference between agglutination and *assimilation*: in that species of leprosy called *λεπροση*, there is an adhesion, or agglutination of the nutriment, but no *assimilation*. In the anasarcaous dropsy, on the contrary, there is an *adjunction*, without any agglutination; i. e. there is an afflux of new matter, or nourishment, but this is so thin, and watery, that it wants the due stiffness and tenacity to make it bind.

Some will have agglutination to be effected by a *ferment*: others assert, that by reason of the glutinous quality of the chyle, a mere contact suffices to make it adhere to the parts.

AGGLUTINATION is used by some astronomers to denote the meeting of two or more stars in the same part of the **ZODIAC**.

AGGLUTINATION is more peculiarly understood of the seeming condition of several stars, so as to form a **NEBULOUS STAR**.

AGGLUTINATION, in *Surgery*, the same as **ADHESION**. The reunion of wounds was formerly supposed to be effected by means of certain applications, named **AGGLUTINANTS**; but these remedies are now known to act only by keeping the separated parts in exact apposition. The doctrine of adhesion is treated at large in the first volume of Mr. John Bell's "*Principles of Surgery*." See the article **WOUNDS**.

A preternatural agglutination of the eyelids constitutes the disease named **ANCHYLOEOPHARON**.

AGGRAVATION, compounded of *ad, to,* and *gravis,* heavy, the act of augmenting a **CRIME**, or **PUNISHMENT** thereof.

Aggravation, in the *Romish Canon Law*, is particularly used for an ecclesiastical censure, threatening an **EXCOMMUNICATION**, after three admonitions used in vain.

From aggravation they proceed to re-aggravation; which is the last **EXCOMMUNICATION**.

AGGREGATÆ glandulae, the small glands in the cellular, which is next to the villous coat of the intestines, are so called; but as these glands are not visible in an uninjected gut, many anatomists suspect them to be only little bits of separated wax.

AGGREGATÆ Terra, in the Linnæan system of *Mineralogy*, denote the seventh order of earths, compre-

hending those that are formed of the aggregate earths of the preceding orders. To this order belong the six following genera, viz. *Granites, Gneissum, Porphyrias, Amygdalites, Breccia,* and *Arenarius*.

AGGREGATE, is formed of *ad, to,* and *greg, gregis,* a flock, the sum, or result of several things, *aggregated,* or added together.

Natural bodies are *aggregates*, or assemblages of particles, or corpuscles, bound together by the principles of attraction. Bodies politic are likewise said to be aggregate; such as mayor and commonality, dean and chapter, &c. in contradistinction to corporation *sole*; such as the king, a bishop, &c.

AGGREGATE, in general, signifies a body resulting from the union of others of the same kind which are smaller, the whole sum of which combined is called the aggregate. The minutest parts into which an aggregate can be imagined to be divided without decomposition, are called ingredient parts; but the parts into which it is divided by decomposition are called component parts or principles. It is particularly used by some chemists and naturalists, for a numerous collection of atoms, or minute corpuscles, whether homogeneous or heterogeneous, joined together by contiguity, without regard to the quality of such atoms. In which sense aggregate differs from **MIXT**, as the former supposes no particular situation, or position, of the corpuscles, other than what arises from their proportion, and the relation they bear to the ambient bodies, among which the coalition is formed.

Aggregate also differs from mixt, as the latter is formed immediately out of the principles of matter, so firmly united, as that it was very difficult, if not impossible, to separate them.

Aggregate again differs from compound, as the latter is formed out of mixts, and is easily dissolvable.

Aggregates then, are the ultimate compounds, or the last effects of composition; they resolve into compounds as their next ingredients, these into mixts, and mixts into simples, or principles; though in strictness, aggregates may resolve also into mixts, and mixts into simples, inasmuch as they consist of heterogeneous parts.

This doctrine and distinction of aggregates, mixts, and compounds, is the foundation of the *chemical theory* of Becher and Stahl; the last of whom has traced it with great exactness. Hence has arisen a new doctrine of earths, metals, &c. which has since been illustrated and extended by the best modern chemists.

AGGREGATE, in *Botany*, is a term used to express those flowers, which are composed of parts or florets, so united or *incorporated* by means either of the receptacle or calyx, that no one of them can be taken away without destroying the form of the whole. They are opposed to simple flowers, which have no such common part, which is either the receptacle or the calyx, and are usually divided into seven kinds, viz. the *aggregate*, properly so called, whose receptacle is dilated, and whose florets are supported by foot-stalks; such are the blue daisy, thrift, or sea-pink, &c.: the *compound*, which consist of several florets, that are placed, without partial peduncles, on a common dilated receptacle, and within a common perianthium; and where each floret hath its proper calyx, it is also a perianthium: *Umbellate*, when the flower consists of many florets placed on fastigate peduncles, proceeding from the same stem or receptacle; and which, though of different lengths, rise to such a height as to form a regular head or **UMBEL**, flat, convex, or concave: *Cymous*, when several fastigate peduncles proceed from the same centre, like the umbel, and rise to nearly an even height; but unlike the umbel, the secondary

ary or partial peduncles proceed without any regular order, as in sambucus, viburnum, &c.: *Amentaceous*, which have a long common receptacle, along which are disposed squamæ or scales, which form that sort of calyx called the *AMENTUM*: *Glumose*, which proceed from a common husky calyx belonging to grasses, called *GLUMA*, many of which flowers are placed on a common receptacle called *racis*, collecting the florets into the spike, as triticum, hordeum, lolium, &c.: and *Spadiceous*, which have a common receptacle, protruded from within a common calyx, called *SPATHA*, along which are disposed several florets. Such a receptacle is called a **PADIX*, and is either branched, as in phoenix; or simple, as in narcissus, &c. In this last case, the florets may be disposed all around it, as in calla, dracontium, &c.; on the lower part of it, as in arum, &c.; or on one side, as in zosteria, &c. These flowers have generally no partial calyx.

AGGREGATE, in the *Linnean System of Botany*, is one of the natural methods of classing plants, and comprehending those which have **AGGREGATE** flowers.

AGGREGATE fund. See **FUND.**

AGGREGATE corporation. See **CORPORATION.**

AGGREGATION, in *Physics*, a species of **UNION**, whereby several things, which have no natural dependence or connection with one another, are collected together, so as in some sense to constitute one. Thus, a heap of sand, or a mass of ruins, are bodies by aggregation.

AGGREGATION, in *Chemistry*, denotes the adhesion of parts of the same kind. Thus, a number of pieces of brimstone united by fusion, form an aggregate. For the difference between aggregation, mixture, and combination, or composition, see these articles.

AGGREGATION is also used *figuratively*, for **ASSOCIATION**. We say, to be of a company, or community, by aggregation.—An aggregation of several doctors to the faculty of laws.—In Italy, aggregations are frequently made of houses, or families; by virtue whereof, they all bear the same name and arms.

AGGRESSOR, in *Law*, is the person of two contending parties, who makes the assault or attack; or who began the quarrel, encounter, or difference.

In criminal matters, it is always first inquired who was the aggressor.

AGGSPACH, in *Geography*, a market town in the circle above the Manharts-berg, in Austria, seated on the Danube; 12 leagues west of Vienna.

AGGYA, in *Ancient Geography*, a town of Africa, mentioned by St. Augustin.

AGHADOE, a village of Ireland, anciently a bishop's see, now united with Ardferit.

AGHENISH, an island of Ireland, in the river Shannon; 16 miles below Limerick.

AGHER, or **AUGHER**, a town of Ireland, in the south of Ulster, not far from Clogher.

AGHEUSTIA, in *Medicine*. See **AGEUSTIA**.

AGHRIM, in *Geography*, a town of Ireland, in the county of Wicklow and province of Leinster, about 31 miles south-west of Wicklow.

AGHRIM, a village in the county of Galway, worthy of being recorded on account of a decisive battle fought there and at Kilcommodon hill, July 12th, 1691, between general Ginkle and M. St. Ruth, the two commanders under William III. and James II. when St. Ruth, with 7000 of his men, were slain, and of the English only 600.

AGHRIS Point, a cape on the west coast of Ireland, and north coast of the county of Sligo; 11 miles west of Sligo. N. lat. 54° 17'. W. long. 9° 22'.

AGHUNALASHKA, or **UNALASKA**, one of the Fox islands in the northern Archipelago.

AGIA, a river on the north of Pensacola, the capital of West Florida, which, running east-north-east, falls into the bay of Santa Maria Galves.

AGIA Laura, a town of European Turkey, in the province of Macedonia; 19 miles south-east of Saloniki.

AGIADES, a kind of Turkish soldiery, employed in fortifying of camps, smoothing of roads, and the like offices. **Du-Cange**.

AGIAHALID, the name of an Egyptian tree, called also *lycio* and *lycium*; it resembles the wild pear.

AGIASMA, from *αγιος*, *holy*, among *Ancient Writers*, is sometimes used for the whole church, sometimes for the more sacred part, or *beina*, wherein mass was said. **Du-Cange**.

AGIASOLUK, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 31 miles south-south-east of Smyrna.

AGIDES, denoting *jugglers*, in *Antiquity*, a name given to the priests of Cybele.

AGIDUM, or **NAGIDUM**, in *Ancient Geography*, a town of Cyprus, situated between *Aphrodisium* and *Lapathus*.

AGIGENSALON, a town of Asiatic Turkey, about a day's journey from Tocat, in the road to Ispahan from Constantinople.

AGILD, or **AGILDE**, from the privative *a*, and the Saxon *gildon*, *to pay*, in our *Ancient Customs*, a person so vile, that whoever killed him was to pay no mulct for his death.

AGILITY, a light and active habitude, or disposition of the members and parts of the body designed for motion. Some define agility, the art or habit of directing our strength, *i. e.* of exerting, or remitting it to advantage.

The improving of agility was one of the chief objects of the institutions of games and exercises. The *athletæ* made particular profession of the science of cultivating and improving agility.

AGILLARIUS, in *Ancient Law-books*, a heyward, or keeper of a herd of cattle in a common field.

The *agillarius*, or *heyward of a town, or village*, was to supervise the greater cattle, or common herd of beasts, and keep them within their due bounds; and was otherwise called *bubulus*, *q. d. cow-ward*, (whence the reproachful term *coward*.)—If he were a cottager, or other servile tenant, he was exempted from the customary service, as being presumed to be always attending on his herd, as a shepherd on his flock, who had therefore the like privilege.

The *agillarius of the lord of a manor, or a religious house*, was an officer appointed to take care of the tillage and harvest-work, to pay the labourers, and see there were no encroachments made, or trespasses committed: the same in effect with what has been otherwise called *fieldsteward*, and *titling-man*; and among us **BAILIFF**.

AGILUS, in *Ancient Geography*, a village of Peloponnesus, near mount Ira, in Messenia, where, according to Pausanias, (l. iv. Messen. c. xix.) Aristomenes was rescued from custody by the aid of a young woman, who afforded him the means of killing five guards, who conducted him to Sparta.

AGIMERE, in *Geography*, a country of Hindostan, bounded on the east by Agra, on the north by Delhi, on the south by Guzerat, and on the west by the sandy deserts towards the Indus. Its extent is considerable, and it comprehends many smaller states, as Agimere proper, Rampour, the

Foodpour, Rantampour, Ioinagur, Banfwalch, Nagore, and Bickaneer. The capital of this subah, of the same name, is situated in a pleasant valley, and on all sides surrounded by mountains. Its circumference is six miles, and it is guarded by walls, towers, and a strong fortress; 170 miles west-south-west from Agra, and 178 miles west from Delhi. N. lat. 26° 24'. E. long. 75° 20'.

AGIMYTHA, a town of Asia in India, on the other side the Ganges. According to Ptolemy, it was situated in long. 170° 40'. and lat. 18° 40'.

AGINCOURT, in *Geography and History*, a village of the French Netherlands, situated in the county of St. Pol, ex-department of the Straits of Calais; N. lat. 50° 35' and E. long. 2° 10'; remarkable for a glorious victory which the English, commanded by king Henry V. obtained over the French, Oct. 25th, in 1415. The army of Henry was reduced by sickness and various accidents to 10,000 men; and the French had collected a force consisting of 100,000, or, as some say, of 140,000 men, to intercept the march of the English from Harfleur towards Calais. The king had recourse to all the means in his power for encouraging the progress of his small army, amidst the difficulties and inconveniences of their route; and on the evening of October 24, they arrived at Agincourt, within sight of the French, and prepared for a battle, which it was impossible to avoid. Whilst the English soldiers were exhorting one another to fight bravely in the approaching action, the king overhearing some of his nobles expressing a wish, that the many brave men who were idle in England were present to assist them, exclaimed—"No! I would not have one man more; if we are defeated, we are too many; if it shall please God to give us the victory, as I trust he will, the smaller our number, the greater our glory." Henry, with the advantage of moon-light, reconnoitred the ground, and pitched upon a field of battle, admirably adapted for preserving a small army from being surrounded by a great one. It was a gentle declivity, from the village of Agincourt, of sufficient extent for his small army, defended on each side by hedges, trees, and brush-wood. Having determined upon the place of action, the king and his army betook themselves to rest; except those who, considering this as the last night of their lives, spent it in devotion. The French, exulting in their numbers, confident of victory, and supplied with abundance of provisions, spent the night in riotous festivity, and in forming schemes for the disposal of their prisoners and booty. It was, in general, resolved to put all the English to the sword, except the king and the chief nobility, who were to be made prisoners for the sake of their ransom. On the next morning the hostile armies were ranged in order of battle; each of them forming three lines, with bodies of cavalry on each wing. The constable d'Albert, who commanded the French army, lost the advantage of his superior number by drawing up his troops in a narrow plain, between two woods; and this was observed to be the chief cause of all the disasters that followed. The king of England employed various arts to supply his defect of numbers. His first line consisted wholly of archers, four in file; each of whom, besides his bow and arrows, had a battle-axe, a sword, and a stake pointed with iron at both ends, which he fixed before him in the ground, with the point inclining outwards, to protect him from the cavalry. This was a new invention, and had a happy effect. He dismissed all his prisoners on their word of honour to surrender themselves at Calais, if he gained the victory; and lodged all his baggage in the village of Agincourt, in his rear, under a slender guard. The first line was commanded by Edward duke of York; the second by the king himself; and the third by the duke of Exeter, the king's uncle. When the lines

were formed, the king, in shining armour, with a crown of gold, adorned with precious stones, on his helmet, mounted on a fine white horse, rode along them, and addressed each corps with a cheerful countenance and animating speeches. To inflame their resentment against their enemies, he told them that the French had determined to cut off three fingers of the right hand of every prisoner; and to rouse their love of honour, he declared, that every soldier who behaved well, should from that time be deemed a gentleman, and entitled to bear coat-armour. The English thus incited to exertion, stripped themselves almost naked, that they might deal their blows with the greater rapidity and vigour. The two armies, prepared for action, stood for a considerable time gazing at each other in solemn silence. At 10 o'clock, however, Henry, fearing that the French would discover the danger of their situation, and decline a battle, commanded the charge to be sounded. Upon this the English kneeled down and kissed the ground, and then rising suddenly, discharged a flight of arrows, which did great execution among the crowded ranks of the French. This onset was succeeded by the attack of a body of archers, who had been placed in ambush, and who discharged their arrows on the flank of the French line, and threw it into disorder. The battle now became general, and raged with uncommon fury. When the English archers had expended all their arrows, they threw away their bows, and, rushing forward, made dreadful havoc with their swords and battle-axes; the first line of the enemy was thus defeated; and its leaders either killed or taken prisoners. The second line, commanded by the duke d'Alençon, who had vowed either to kill the king or take him prisoner, or to perish in the attempt, advanced to the charge, and was encountered by the second line of the English, conducted by the king. The conflict was very furious. The duke d'Alençon forced his way to the king, and assaulted him with great violence; but the king brought him to the ground, and he was instantly dispatched. Discouraged by this disaster, the second line made no farther resistance; and the third fled without striking a blow; and thus the English, after a violent struggle of three hours, obtained a complete and signal victory. Although the king did not permit his men to pursue the fugitives to any great distance, the number of his captives exceeded that of his soldiers; and many of these prisoners were persons of rank and fortune, who, encumbered with their heavy armour, could not make their escape. The French left dead on the field of battle, the constable d'Albert, three dukes, the archbishop of Sens, one marshal, 13 earls, 92 barons, 1500 knights, and a far greater number of gentlemen, besides several thousands of common soldiers. The French historians acknowledge, that the loss of the English was inconsiderable; and those of our own contemporary writers who make it the greatest, affirm that it did not exceed 100; and that the duke of York and the earl of Suffolk were the only great men who fell on that side in this memorable action. To the gross error committed by the constable d'Albert, as much as to the wife measures of Henry, and the heroic valour of the English, the disgrace and ruin of the French army may be imputed. Henry, after this battle, pursued his march to Calais, with his spoils and prisoners; embarked for England, Nov. 16, and arrived that evening at Dover, where he was received with transports of joy, many of the people plunging into the sea to meet his barge. At his triumphant entry into London, Nov. 23, the shows and pageants exhibited by the citizens were so numerous that it would have required a volume to describe them. Henry's Hist. vol. ix. p. 46—54. 8vo.

AGINIS, a burgh or village of Asia in Susiana, situate on the east bank of the Tigris, towards lat. 30° 15'.

AGINNA, one of the towns of Iberia, mentioned by Ptolemy, at the boundary of Colchis, and placed in long. 75° and lat. 46° 30'.

AGINNATA, a people of India, on the other side of the Ganges.

AGINNUM, a city of the Nitiobriges, in Gallia Aquitania, now *Angoulême*, or *Agen*.

AGINSKA, a river of Siberia, which runs into the Uda. N. lat. 52° 25'. E. long. 98° 14'.

AGIO, in *Commerce*, an Italian word, signifying *aid*, is a term used chiefly in Holland, and at Venice, for the difference between the value of bank money, and current money. So that if a merchant who sells his merchandise, stipulated to be paid either 100 livres bank money, or 105 cash, or current money, in such case the agio is said to be 5 *per cent*.

The bank agio varies in almost every place, and is greater or smaller, according as the currency is supposed to be more or less degraded below the standard of the state. At Amsterdam it used to be generally about 5 *per cent*.; and by a resolution adopted not long before the late period of confusion, the bank sold bank-money for currency, at 5 *per cent*. agio, and bought it again at 4 *per cent*. agio. In consequence of this resolution, the agio could never either rise above 5, or sink below 4 *per cent*.; and the proportion between the market price of bank, and that of current money, was kept at all times very near to the proportion between their intrinsic values. One part of the profit of the bank accrued from selling bank-money at 5 *per cent*. agio, and buying it in at four. At Venice, the agio was 20 *per cent*. fixed: at Genoa, from 15 to 16 *per cent*. The agio of the bank of Hamburg, which is said to be commonly about 14 *per cent*. is the supposed difference between the good standard money of the state, and the clipped, worn, and diminished currency poured into it from all the neighbouring states. See **BANK** and **EXCHANGE**.

AGIO is also used for the profit arising from discounting a note, bill, or the like.

AGIO is also used, though with some impropriety, for the rate of exchange of a sum negotiated, whether to profit or loss. It is also sometimes called **AGAI**.

AGIO of assurance is used, by some, for what we more usually call *policy of ASSURANCE*.

AGIOI Sarania, in *Geography*, a town of the island of Candy; 16 miles south from Setia.

AGIOSYMANDRUM, compounded of *αγιος*, *holy*, and *συναγωγη*, *I signify*; a wooden instrument used by the Greek and other churches, under the dominion of the Turks, to call together assemblies of the people.

The agiosymandrum was introduced in the place of bells, which the Turks prohibited their Christian subjects the use of, lest they should make them subservient to sedition.

AGIRIA, in *Ancient Geography*, a district of Spain, south-east of Bilbilis, belonging to the Celtiberians.

AGIRIUM. See **AGURIUM**.

AGIRU, in *Geography*, the western part of the island of Corsu, comprehending 20 villages, and about 8000 inhabitants: the only remarkable place in it is Castle St. Angelo, which lies on the south cape called Palacrum; and beneath it stands a stately castle called Paleo Castrizza.

AGIS IV. in *Ancient History*, king of Sparta, was the son of Endamidas, and the 16th descendant from Agesilaus, who made an expedition into Persia. This prince was eminently distinguished by his virtue in a corrupt period of the Spartan state, and by his laudable efforts for the reformation of his country. Sparta was sunk by the influx of wealth into luxury and indolence; and the discipline esta-

lished by the wisdom of Lycurgus, was neglected and contemned. Agis, though brought up in affluence and indulgence by his mother Agefilrate, and his grandmother Archidamia, who, as Plutarch informs us, possessed more gold and silver than all the other Lacedæmonians, lamented the degeneracy of his country; and at the age of 20 years, exhibited a signal example of self-denial and abstinence in his own conduct, and nobly attempted to restore the ancient discipline of Sparta. With this view he aspired to the royal power, and explicitly declared, "that he should not value being king, if it were not for the hopes of reviving the ancient laws and discipline of Sparta." A new law had been introduced, at the instigation of Epitades, one of the Ephori, in order to avenge himself on one of his sons, who had displeased him, for the alienation of hereditary estates. The consequence of this law was, that all patrimonial possessions were soon engrossed by a few persons; general poverty, and indolence prevailed; the inferior classes of the people envied their superiors; and those who were destitute of revenues, and excluded from a participation of honour and wealth, were indifferent and reluctant in their efforts against a common enemy, and constantly waiting for an opportunity to ameliorate their abject and depressed condition. In these circumstances of aggrandizement, on the one hand, and oppression and dissatisfaction on the other, Agis determined upon reformation. By the influence of Agesilaus, his maternal uncle, who with sinister views embarked in the design, he engaged the co-operation of his mother and grandmother. The young men generally concurred; but those in more advanced life, and also the women of rank and wealth, trembled at the name of Lycurgus and reformation; and induced Leonidas, the other king, to oppose the projects of Agis. Agis, however, succeeded in obtaining a decree for cancelling all debts, and for the equal division of all the lands. For this purpose, he made an offer to the community of his own large estate, with 600 talents in money; and he procured, by the interposition and assistance of Lysander, the deposition and banishment of Leonidas, and the concurrence of Cleombrotus, his successor. The first measure that was adopted was the cancelling of debts; and in the execution of this, Agesilaus, who being much in debt, was likely to be greatly benefited by it, was very active. Accordingly, all bonds were brought to the market-place, and burned in one pile, which Agesilaus called "a glorious flame." But he contrived to defer the accomplishment of the other part of the equalizing plan; and, as Agis was under a necessity of marching to the succour of the Achæans, Agesilaus, by his tyrannical conduct, induced a conspiracy for restoring Leonidas, which proved successful, and Cleombrotus was sent into exile. Agis, upon his return, was obliged to recur for sanctuary to a temple; and being betrayed by some false friends, who were bribed for this purpose, he was arrested in the name of the Ephori, and hurried to prison. Leonidas with a band of mercenaries, surrounded the prison, and the Ephori, and members of the senate who were in his interest, went in to interrogate Agis concerning the motives of his proceedings. The king averred, that it was his purpose to restore the institutions of Lycurgus; and that he would adhere to this purpose, even in the prospect of an immature death. His enemies then proceeded to pass sentence of death upon him, and the officers were ordered to remove him into a room where malefactors were strangled. But they, and even the mercenary soldiers, were restrained by their respect for his character from doing him any injury. When it was known that he was in custody, his mother and grandmother, and a multitude of people, assembled round the prison, and requested that he might have a fair trial. This applica-

tion in his favour, merely served to hasten his fate. As he was led to execution, he said to an officer whom he observed in tears—"Weep not for me, my friend, for as I am thus suffering contrary to all law and justice, I am much happier, and more to be envied, than those who have condemned me." He then offered his neck to the executioner, without the least sign of reluctance. The grandmother of Agis was next seized and executed; and last of all his mother was ordered to enter the dismal dungeon, where she beheld her son lying dead on the ground, and her aged parent at a little distance, with the fatal cord about her neck. Having laid the corpse by that of her son, and decently covered it with linen, she cast herself on the body of Agis, and tenderly saluting his cold lips, exclaimed—"O my son, the excess of thy humanity and moderation has been fatal, both to us and thee." Upon which, Amphares, one of the senators, whose cruelty had been signally displayed in this tragic scene, addressed her with a savage aspect—"Since you knew and approved the designs of your son, you shall share his recompence." She instantly rose, and rushed to the fatal cord, crying out—"May this, at least, be useful to Sparta."

Leonidas completed this tragedy, by forcing Agiatiss, the consort of Agis, who was very rich, and distinguished by her wisdom and virtue, as well as her beauty, to marry his son Cleomenes, to whom she conducted herself with as much attention as was consistent with the tender regard she entertained for the memory of Agis, and who is said to have profited by the account she gave him of the designs which the murdered sovereign had formed for the regulation of the government. Plut. in Agid. apud oper. tom. i. p. 795. Rollin's Anc. Hist. vol. v. p. 425—442.

AGIST, in *Law*, signifies to take in and feed the cattle of strangers in the king's forest, and to gather up the money due for the same. Chart. de Foresta, 9 Henry III. cap. 9. The officers appointed for this purpose are called *agisters*, or *gistakers*, and are made by the king's letters patent: there are four of them in every forest, wherein the king hath any pannage. Manw. For. Laws, 8vo.

The time for this is fifteen days before Michaelmas, and as many after, when the running of the cattle cannot prejudice the game.

AGISTMENT, is supposed to be formed of the French *giste*, a bed, or lying place: though Kennet excepts to this etymon, and chooses rather to derive it from *ager*, the field, or feeding-place for cattle; imagining agistment to have originally been the same with *agrarium*, *agerium*, or *agroticum*, the profit of feeding cattle on such a piece of ground. The term is applied to taking other men's cattle into any ground, at a certain rate per week. It is so called, because the cattle are suffered *agister*, that is, to be *levant* and *couchant* there; and many great farms are employed to this purpose. 2 Inst. 643. Our graziers call cattle, which they thus take in to keep, *gifestments*; and to *giste*, or *juice*, the ground, is when the occupier thereof feeds it not with his own flock, but takes in the cattle of others, to *agist* or pasture it. Agistment is likewise the profit of such feeding in a ground or field: and extends to the depasturing of barren cattle of the owner, for which tythes shall be paid to the parson.

Agistment is also used metaphorically for a charge, or burden on any thing.

In this sense we meet with *terra ad custodiam maris agistata*, i. e. *charged with a tribute to keep out the sea*.—So *terre agistate*, are lands whose owners are bound to keep up the sea-banks.

Agistment denotes likewise the duty or levy for repairing the banks and walls in Romney-marsh, which was particularly called *agistamentum*; and the act of laying such a pro-

portion of this duty on the several estates, was called *agistate*. Spelman.

AGISTOR, or AGISTATOR. See AGIST and AGISTMENT.

AGISYMBBA, in *Ancient Geography*, now Zanguebar, a district of Libya interior, situated, according to Agathemerus, to the south and east of the Æthiopes Anthropophagi. The parallel passing through this country 16° south of the equator, bounded the knowledge of the ancients to the south.

AGISYMBBA, in *Modern Geography*, a town of Africa, in the kingdom of Congo.

AGITA, or AGUTI, in *Ancient Geography*, a small island between Sicily and Africa.

AGITATION, AGITATIO, properly signifies *shaking*; or reciprocal MOTION of a body.

The prophets, quakers, Pythian priestesses, &c. were subject to violent *agitations* of body. See INSPIRATION.

Among physiologists, the term is sometimes appropriated to that species of earthquake, called *tremor*, or *arictatio*.

Among the philosophers, it is chiefly used for an intestine commotion of the parts of any natural body.

Thus, fire is said to agitate the minute particles of bodies.—Fermentation and effervescence are attended with a brisk agitation of the particles.

Heat is supposed by some to consist in the agitation of the parts of the hot body; and sound is produced by a tremulous agitation, excited first in the sonorous body, and communicated thence to the ambient air.

AGITATION is likewise used for a violent hurry or perturbation of spirits, occasioned by some predominant passion.

AGITATION is also used, in *Medicine*, for a species of exercise, popularly called *swinging*; and, in general, for any exercise which shakes the body.

Bartholine mentions fits of the tooth-ach, deafness, &c. removed by vehement agitations of the body; and they have been found of especial use for preventing and dissolving concretions.

Dr. Sydenham attributes the great benefits of riding to agitation, which is very efficacious in removing obstructions of the *viscera*. See ÆORA.

Sanguification is in great measure effected by the agitation of the parts of the blood and chyle, in their continual circulation. DIGESTION itself is only supposed by some to be an insensible kind of agitation.

AGITATION of *beasts in the forest*, anciently signified the DRIFT of beasts in the forest.

AGITATIVE, something having power to agitate or shake another.

AGITATIVE force of a *pendulum*, is that which produces motion in it.

The *agitative force* of the pendulum arises from three things: 1. The power of gravity. 2. The weight fastened at the end of the rod. 3. The distance of that weight from the point of suspension; or, which amounts to the same thing, the length of the rod, or *pendulum*. Hist. Acad. Scien. 1714.

AGITATO, in *Musie*, a term which implies not only a quick movement but a character of expression arising from passion and perturbation. Piccini's air, "Se il ciel mi divide," in the Alessandro of Metastasio, furnishes an admirable example of this kind of movement.

AGITATOR, in *Antiquity*, a *charioteer*; or he who drove or directed a chariot, or horses, in a race.

In which sense agitator amounts to the same with what the Romans called *auriga*; and we, a coachman, driver, &c.

AGITATOR was more peculiarly used for him who drove in the public *currule* games in the *circus*.

The agitators were distinguished by their habits, into

ruffati, albati, prasini, and veneti, which gave rise and denomination to so many factions. Besides which, they had other marks or ensigns of their family, corresponding to what we call arms.

The conquerors, besides the ordinary rewards, *bravie*, as crowns, &c. had statues erected to them in the circus; on the bases whereof, their titles, achievements, &c. were inscribed; several of which are still found among ancient inscriptions, drawn in the following formulae: *Vicit sejnge, septenage, bigas, trigas, uno anno, alieno principio, duobus utrojnque, &c.*

It has been disputed, whether the *agitators* were on the footing of mimes and pantomimes, and by law held infamous? Briffon. Select. ex Jur. Civ. Ant. lib. i. cap. 10.

AGITATORS, miliarior, agitatores miliarii, were those who drove in the forum at Constantinople, a place adorned with statues, &c. after the manner of the circus at Rome, having a *milium*, or *miliarium*, in the middle.

AGITATORS, in English History, were certain officers, created by the army in 1647, to take care of its interests. Each troop or company furnished two private men or inferior officers, under this title, who represented the army; whilst a council of the principal officers was appointed after the model of the house of peers; and thus a military parliament was formed in opposition to the parliament at Westminster. Cromwell leagued himself with the agitators, whom he found to have greater interest than the council of war; and who undertook to make proposals relating to the reformation of religion, and the state.

The agitators as well as the council of officers were altogether moved by his direction, and conveyed his wish to the whole army. By means of these instruments he overawed the parliament, and reduced it to submission; and having gained possession of the king's person, to whom for some time he and his officers paid attention and respect, he contrived to terrify him by the menaces of the agitators, and thus induced him to make his escape from Hampton Court, and to take refuge at Carisbroke Castle, in the Isle of Wight. Cromwell, being entirely master of the parliament, and free from all anxiety with regard to the custody of the king's person, applied himself seriously to quell those disorders in the army, which he himself had artfully raised and successfully employed, against both king and parliament. With this view, besides other measures which he adopted, he issued orders for discontinuing the meetings of the agitators; and he pretended to pay entire obedience to the parliament, whom, being now fully reduced to subjection, he proposed to make, for the future, the instruments of his authority. But the *Levellers*, for so that party was called, because they wished to abolish royalty and nobility, to level all ranks of men, to introduce an universal equality both of property and of power, and who maintained that the meanest sentinel, if enlightened by the spirit, was entitled to equal regard with the greatest commander, having tasted the sweets of dominion, would not easily be deprived of it. They secretly continued their meetings; they asserted, that their officers, as much as any part of the church or state, needed reformation; and several regiments joined in seditious remonstrances and petitions. Separate rendezvous were concerted; and every thing tended to anarchy and confusion. But this distemper was soon cured by the rough, but dextrous hand of Cromwell. He chose the opportunity of a review, that he might display the greater boldness, and spread the terror the more widely. He seized the ring-leaders before their companions; held in the field a council of war; shot one mutineer instantly, and struck such dread into the rest, that they presently threw down the symbols of sedition, which they had displayed, and thenceforth returned to their discipline and obedience. Hume's Hist. vol. vii. p. 109. 8vo.

AGLA, formed of the initial letters of the four following Hebrew words *אתה גבר לעולם אדני* g. d. *thou art strong in the eternal God*, was a name given by the superstitious Jews in the Middle Age, to the Deity; and which they disposed of in the three angles, and in the middle of two triangles laid one over the other. This figure they called the shield of David, and pretended, that it was a security against wounds, would extinguish fire, and was able to perform other wonders. Fabr. Cod. Apocr. V. T. tom. ii. p. 1006. tom. iii. p. 143.

AGLA, or *AGUILA*, in *Geography*, a town of Africa, in the kingdom of Fez, near the river Guarga.

AGLA Minor, a district of Spain, assigned by Pliny to the Bactitani.

AGLABITES, in *History*, one of the Arabian independent dynasties, which subsisted in Africa in the ninth century, and which derived its name and power from Ibrahim, son of Aglab, the lieutenant of the famous Harun al Rashid.

AGLAIA, in *Mythology*, the name of the youngest of the three Graces, espoused to Vulcan.

AGLAIA, in *Natural History*, a species of *PAPILIO Nymphalis*, with dentated yellow wings, spotted with black; the under part having silvery spots. It is found on the violet in Europe. The larva is solitary, spinose and black, with ferruginous spots disposed on the sides of a square; the pupa is brown.

AGLAOPHAME, one of the *SIRENS*.

AGLAOPHOTIS, in *Botany*, a name used, by some, for *PIONY*.

AGLASOUN, in *Geography*, a town of Asiatic Turkey; eight miles south west from Iſbarteſh.

AGLAURA, or *AGRAULA*, in *Mythology*, the daughter of Cecrops, founder and king of Athens. She had two sisters, Herſa and Pandroſa. Minerva having concealed Erichthonius, after his birth, in a basket, committed him to the custody of theſe three princeſſes, forbidding them to open the basket. Herſa and Pandroſa obſerved the order; but Aglaura, unable to reſtrain her curioſity, opened the basket and found the infant with feet like thoſe of a ſerpent. Minerva puniſhed her by means of Envy, who made her jealous of Herſa, the favourite of Mercury. When he attempted to prevent the acceſs of this deity to his miſtreſs, he ſtruck her with his caduceus, and converted her into a rock. Nevertheless ſhe was honoured after her death in a temple at Salamina, with a yearly ſacrifice of a human victim, which Deſphalus, king of Cyprus, in the time of Seleucus, changed into an ox. See *AGRAULIA*.

AGLECTS, *AGLEETS*, or *AGLEEDS*, among *Florists*, the *APICES*, or pendants hanging on the tip-ends of *CHIVES*, or *STAMINA*; as in tulips, roſes, ſpike-graſs, &c.

AGLIA, in *Geography*, a ſmall town of Italy, in the marquiſate of Jvrea, and principality of Piedmont, to which belongs a diſtrict and earldom; ſeven miles ſouth from Jvrea.

AGLIA, among *Ancient Surgeons*, a whitish cicatrix, or ſpot in the eye, formed by a congeſtion of humours.

AGLIBOLUS. The Palmyrenes worſhipped the ſun under this title.

AGLIONBY, JOHN, in *Biography*, an English divine, was born in Cumberland, and admitted a ſtudent at Oxford in 1583. He was diſtinguiſhed as a polite and learned preacher. After his return from his travels, he was made chaplain in ordinary to queen Elizabeth, to which office he was alſo appointed by king James I.; and he is ſaid to have had a concern in the tranſlation of the New Teſtament, ordered by that king in 1604. He died at Iſlip near Oxford, where he was rector, Feb. 6th, 1609-10, at the age of 43. He was eminently accompliſhed in various kinds of learning,

well

well acquainted with the fathers and school divinity, and a great critic in the languages. Gen. Diſt.

AGLONE, in *Geography*, a river of Prussia, which runs into the Minnie, near Proeculus.

AGMANISPHE or ATMANISPHE, in *Ancient Geography*, a village of Arabia Felix, assigned by Ptolemy to the Homerites.

AGME, in *Surgery*, signifies a fracture.

AGMEN, in *Antiquity*, properly denotes a Roman army in march. In which sense, it stands contradistinguished from *acies*, which denoted the army in battle array; though, on some occasions, we find the two words used indifferently for each other.

The Roman armies, in their marches, were divided into *primum agmen*, answering to our vanguard; *medium agmen*, our main-battle; and *postremum agmen*, the rear-guard.

The order of their march was thus: after the first signal with the trumpets, &c. the tents were taken down, and the baggage packed up; at the second signal, the baggage was to be loaded on the horses and carriages; and at the third signal, they were to begin their march. First came the *extraordinarii*; then the auxiliaries of the first wing with their baggage; these were followed by the legions. The cavalry marched either on each side, or behind.

AGMEN *pilatum*, that disposed in a narrow oblong form, or column; being also close and compact; thus called, as resembling the figure of a *pila*, or *pier*. Vegetius compares it to that of a broach, or spit. This form was chiefly used in marching without their baggage, through bad ways and close countries.

AGMEN *quadratum*, that ranged somewhat in a square form, being the method ordinarily observed in the Roman armies. This was also called *agmen grave*, by the Greeks *τετραγωνος ταξις*. The three lines, or columns, in which the army usually marched, were considerably more in length or breadth, than in depth; but as the baggage marched somewhat in the same order, the whole approached to the figure of a square.

AGMEN is also used for any number of persons, or even animals, moving or advancing in some regular order.

AGMET, or AGMAT, in *Geography*, was formerly the capital of Morocco, in Africa, situated on a declivity of a hill, which is part of Mount Atlas, and near a river of the same name; six leagues south from Morocco. It is at present reduced and inhabited by poor people. N. lat. 30° 56'. W. long. 7° 15'.

AGMONDESHAM, or AMERSHAM, an ancient town of Buckinghamshire, situated betwixt hills that are covered with woods; about 26 miles north-west from London. It has a town-hall and free-school, sends two members to parliament, and has a market on Tuesday. The manufacture of this town is black lace: and a cotton manufactory was lately established in it, which employs many of the lower class, though the business is performed by machinery. The number of houses in this borough is 267; but the right of voting is restricted to about a fourth part of this number, which consists of those who pay scot and lot. This parish, together with the adjoining hamlet of Colehill, contains 403 houses, 859 male and 1171 female inhabitants. The mansion of T. D. T. Drake, Esq. called Shardloes, to which family the borough belongs, is situated about 1½ mile from the town.

AGNA, in *Ancient Geography*, a river of Mauritania.

AGNACAT, *Scaligeri pyri species*. In a country of America, beyond the Terra de Labrador, toward the isthmus of Darien, there is a tree of the figure and size of a pear-tree, always covered with leaves, and of an extraordinary greenness and lustre. It bears a fruit also like a pear, but green

even when it is ripe; the pulp is of the same colour, sweet, fat, and tastes like butter. It is a powerful promoter of venereal vigour. Ray's Hist.

AGNADELLO, in *Geography*, a small town of Italy, on a canal between the rivers Adda and Serio, in the duchy of Milan and territory of Cremona. It is famous for a victory gained here by the French over the Venetians in 1509, and for a battle fought between prince Eugene and the duke of Vendome in 1705. See CASSANO. N. lat. 45° 25'. E. long. 9° 26'.

AGNAN, *St.* a town of the late province of Berry, and department of Loire and Cher, in France, situate on the river Cher, containing a castle, with one collegiate church and two convents. N. lat. 46° 27'. E. long. 1° 26'.

AGNANIA, or ANAGNI, a small very ancient town of Italy, in the Campagna of Rome. It is situated upon a mountain; and has a cathedral and five convents. N. lat. 41° 45'. E. long. 12° 55'.

AGNANO, *lake of*, a circular lake, nearly two miles in circumference, in the vicinity of Naples, near Pozzuolo, which has all the appearances of a volcanic crater. Its shape is that of an inverted funnel; and its sides and bottom are formed of tufa, interspersed with fragments of lava and pumice-stone. Numerous flocks of ducks swim on its surface, and its waters contain great quantities of tenches and frogs. The frogs in their tadpole state, having tails resembling the hinder part of a fish with a round body and legs like a frog, furnished occasion for the vulgar to conclude that they were monstrous animals, half fish and half frogs. Vallisneri discovered the cause of this vulgar error. The tenches and eels of this lake are, in winter, of a very good flavour; but in summer they are not eatable, on account of the great quantities of flax and hemp which are brought hither from all the neighbouring parts to be mellowed in the water. The water sometimes boils up to the height of two inches, but without any sensible heat. Keyſler's Trav. vol. iii. p. 113. Spallanzani's Trav. vol. i. p. 125.

AGNANTHUS, formed of *αγνος*, chaste, and *ανθος*, a flower, in *Botany*, the name given by Vaillant to a genus of plants, called afterwards CORNUZIA by Plumier and Linnaeus.

AGNATI, in the *Roman Law*, the male descendants from the same father; and in the *Scots law*, *agnates* are understood to be those who are nearest related by the father, though females intervene.

AGNATION, formed from *ad*, to, and *nasci*, to be born, in the *Civil Law*, the kinship, or relation between the descendants of the same father, being males, and issued only from males.

Agnation differs from *cognition*, as the latter is an universal name, under which the whole family, and even the *agnati* themselves are contained; and agnation, a particular branch of cognition, which only includes the descendants in the male line. Again, agnation is properly only a civil name, as that of *gens*, or family; cognition, a natural name, or derived from blood.

By the law of the *Twelve Tables*, males and females succeed one another, according to the order of proximity, and without any regard to the sex: but the laws were afterwards changed in this respect, by the *Lex Voconia*; and women were excluded from the privileges of agnation, excepting such as were within the degree of consanguinity; *i. e.* excepting the sisters of him who died abintestate; and it was hence that the difference between *agnati* and *cognati* first took its rise.

But this difference was again abolished by Justinian (Inst. 3. 10.), and the females were reinstated in the right of agnation; and all the descendants on the father's side, whether

male or female, were appointed to succeed each other in order of age, according to the order of proximity.

If new cognation came to take in all the relations of the mother as well as father, and agnation to be restrained to those of the father alone.

Adoptive children enjoy the privileges of agnation; which was called *simil* in their respect, in opposition to the other which was *na wal*.

AGNEL, an ancient French gold coin, first struck under the reign of St. Louis, worth about twelve sols six deniers. The agnel is also called sometimes *mouton d'or*, and *agnel d'or*. The denomination is supposed to have arisen from the figure of a lamb, or sheep, struck on one side. After the reign of St. Louis, they bore on the reverse the words, "Christus regnat, vincit, imperat."

AGNELËT, an ancient French silver coin, first struck under Philip le Bel, worth about twenty sols.

AGNELLI, FREDERIC, in *Biography*, was an engraver of Milan in the beginning of the 17th century. His chief employment seems to have been portraits, though he sometimes engraved architecture and emblematical subjects. The dome of Milan was engraved by him. Strutt.

AGNEREINS, in *Geography*, a small place, which was once the residence of a Castellany, in the former principality of Dombes, and present department of Ain, in France.

AGNES, in *Natural History*, a name given by Cramer to a species of *PAPILIO Danaus*, the ZANGIS of Gmelin's edition of the Linnæan system.

AGNES, *St.*, in *Geography*, one of the SCILLY islands, which, though of small extent, is well cultivated, and fertile in corn and grass. The inhabitants, who are poor, form about 50 households, and yield the proprietor 40l. a year. The church is small and neat, and was built by the Godolphin family. But the principal ornament and support of this island is the light-house, whence St. Agnes is called the *Light-house* island. This stands on the most elevated ground, and is built with stone from the foundation to the lantern, which is 51 feet high; the gallery 4, the sash-lights 11½ feet high, 3 feet 2 inches wide, and 16 in number. The floor of the lantern is brick, upon which is placed a square iron grate, barred on every side, with one great chimney in the canopy roof, and several lesser ones, to let out the smoke; and a large pair of smith's bellows is so fixed as to be used with ease when it is wanted. This noble structure is plastered white, and serves as a day mark to ships coming from the South. The keeper of this light-house has a salary of 40l. a year from the Trinity-house, with a dwelling-house and ground for a garden. His assistant is allowed 20l. a year. The light-house is annually supplied with coals, and the carriage of these from the sea-side to the building is a benefit to the poor inhabitants. The true latitude of the light-house is E. 49° 56'. long. 6° 46'. W.

AGNES, *St.*, is also the name of a Cape on the coast of Patagonia, in South America. S. lat. 53° 55'. W. long. 66° 35'.

AGNETSIN or AGNETEIN, two contiguous towns of Transylvania, on the river Hopesch, four leagues north of Hermanstadt. N. lat. 46° 45'. E. long. 25° 26'.

AGNI-CORNU, *Αγνικουρνος*, a promontory of Egypt, to the north-east of the Bolbitine gulph.

AGNIERS, the denomination of a tribe or canton of Iroquois Indians, who vigorously and repeatedly resisted the French in their attempts to settle in Canada. They appeared for a long time among the most determined enemies to the pious missionaries, who made various efforts for their conversion; however, in 1668, many of them were converted to the Catholic faith, more perhaps from a regard to convenience and interest than by conviction. These converts, amongst whom were some distinguished females, removed to the Huron settlement

of Lorette, where they were encouraged to reside, in hopes of their forming a barrier against the incursions of their savage countrymen. But no influence or address was sufficient to keep them steady in their attachment to the French nation. Frontenac, who, in 1689, was declared governor of Canada, though his previous conduct had been extremely offensive and irritating, planned an expedition against the Agniers, and resolved utterly to extinguish them. For this purpose he employed a large army of regulars, and of such Canadians and Indians as were attached to his interest; which entered into the country of the Agniers, destroyed three villages, and massacred most of the inhabitants. See CANADA and IROQUOIS.

AGNIFER is an appellation applied, by some *Ecclesiastical Writers*, to John the Baptist, and used in the same sense with *precursor*, or *forerunner*.

AGNINA *membrana*, in *Anatomy*, the same as the AMNIOS.

AGNINA *lactuca*, see LACTUCA.

AGNO, in *Geography*, a district of Lavis, in Switzerland, containing 41 parishes or villages, and bordering on a part of the *Lugano* lake, which is called the *lago d'Agno*, and receives into it a river of the same name.

AGNO, a river of Naples, which rises in the mountainous parts of Terra di Lavoro, washes the town of Acerra, and, passing between Capua and Averfa, falls into the Mediterranean, about seven miles north of Puzzuoli.

AGNODICE, in *Biography*, an Athenian lady, who in the disguise of a man, attended the lessons of Herophilus, and acquired so much knowledge of the treatment of diseases, as to be in great request among her own sex, to whom she discovered her contrivance. She was particularly expert in the practice of midwifery. At length the physicians, jealous of her success, it is said, and ignorant of her sex, accused her of introducing herself to the women under the pretence of assisting them in their labours and complaints, but in reality from views of incontinence. Being cited to the areopagus, she made herself known; and her judges were so well satisfied with her conduct, and perhaps with the women for patronizing her, that they repealed a law then existing, prohibiting women to practise any branch of medicine, and decreed that women of the rank of citizens might be allowed that liberty. A physician, M. Heeque, Eloy says, published a volume in the year 1747, intitled, *De L'indépendance aux Hommes, d'accoucher des Femmes*, written with much ingenuity; in which he attributes the looseness in the morals of the present age, to the custom of admitting men to the general practice of midwifery, for in particular cases he acknowledges their assistance to be necessary. His book has given birth to others in this country, written with the same view of endeavouring to excite a prejudice in the women against employing men, particularly by the late Mr. Philip Thicknes. But the virulence, and the indelicacy of his writings on the subject, must have defeated his end; as it would argue a greater degree of indelicacy to have been supposed capable of reading his book, than to permit the practice he pretends to censure. The strongest argument against admitting men into the general practice is, that in all ordinary cases, women are perfectly competent; but as cases do, and must for ever occur, in which a kind of assistance is required that women are incapable of giving, if the men were not to attend in ordinary cases, they would not acquire the expertness that is necessary to enable them to deliver in difficult and extraordinary cases.

AGNOETÆ, of *ἀγνοεω*, to be ignorant of, in *Church History*, a sect of Eutychians, whose founder is said to have been Themistius, a deacon of Alexandria, in the 6th century, who maintained that Christ, considered as to his human nature,

was ignorant of certain things, and particularly of the time of the day of judgment.

Eulogius, patriarch of Alexandria, ascribes this doctrine to certain solitaries in the neighbourhood of Jerusalem, who, in defence hereof, alledged divers texts of the New Testament, and, among others, this of St. Mark, chap. xiii. ver. 32. "Of that day and hour knoweth no man; no not the angels who are in heaven, neither the Son, but the Father only."

The ancient Arians, and the modern Unitarians, urge this and similar passages as arguments against the deity of Christ. To which it has been replied, by means of a distinction to which the others object, that Christ, as a man, did not know the day of judgment; or, that he was not commissioned to gratify the curiosity of his disciples in this respect, by revealing it to them. Accordingly Dr. Macknight (*Harmony*, p. 520.) observes, that the word *οιδει* (Mark xiii. 32.) has the force of the Hebrew conjugation Hiphil; and *οιδει*, in the sense of this conjugation, signifies to *make another to know*, or to *declare*. And he reads the text, "But of that day, and hour, none maketh you to know;" *i. e.* none hath power to make you know it. Neither man, nor angel, nor even the Son himself can reveal the day and hour of the destruction of Jerusalem to you; because the Father hath determined that it should not be revealed.

AGNOIA, a word used by *Physicians*, when a person in a fever does not know his acquaintance. When a rigor accompanies this symptom, Hippocrates says it is dangerous.

AGNOMEN, in *Antiquity*, an epithet given to a person, either by way of praise, or dispraise, or from some remarkable event, which became, as it were, an additional name, but peculiar to the person, and not descendible to his issue. Thus, one of the Scipios was named *Africanus*, and the other *Asiaticus*, from the brave achievements which the one performed in Africa, and the other in Asia.

The agnomen was the third in order of the three Roman names.—Thus in Marcus Tullius Cicero, Marcus is the *prænomen*, Tullius the *nomen*, and Cicero the *agnomen*.

Others think the agnomen to have been the fourth or honorary name, superadded on account of some extraordinary action or virtue. Thus, in the case of Lucius Cornelius Scipio Asiaticus, Lucius was the *prænomen*, Cornelius the *nomen*, Scipio the surname or cognomen, and Asiaticus the agnomen. But many of the ancient authors, as Livy, Cicero, and Valerius Maximus, call the fourth name cognomen. Some imagine agnomen and cognomen to have been the same, as they generally are, except in cases of ADOPTION.

It was a custom among the Romans, for a person, when adopted into another family to lay aside all his other names, and only retain his family-name, to which he added the *prænomen*, *nomen*, and *cognomen* of the adopter.

Thus P. Cornelius Scipio, being adopted by Q. Cæcilius Metellus, laid aside his *prænomen* PUBLIUS, and *nomen* CORNELIUS, and was called Q. Cæcilius Metellus Scipio.

AGNON, in *Ancient Geography*, a fountain of Greece, in Arcadia, which derived its name from the nymph Agno, who had been the nurse of Jupiter. It is said that the water of this fountain rose in a cloud and then descended in rain.

AGNONE, or ANGLONA, in *Geography*, a town of Naples, in the Abruzzo citra; nine miles south south-east of Cività Borella.

AGNONIA, a town of Thrace, near Amphipolis, founded by Agnon the Athenian, who conducted hither a colony. Steph. Byz.

AGNOS, a borough of Attica, belonging, says Steph. Byz. to the tribe of Demetriades, but according to Suidas to

the tribe of Acamantides, and assigned by others to the tribe of Attalides.

AGNOS, in *Ichthyology*, a name given by Athenæus, and many of the other Greek writers, to that fish called *callyonymus* or *uranoscopus*.

AGNOTES, in *Ancient Geography*, a people of Gaul, whose situation is not precisely known. M. d'Anville places them in Brittany, north-west of the Ostinii: and he says that the western part of the diocese of Leon has still preserved in one of the districts of the diocese the name of *Ack*.

AGNUS *Castus*, the *chaste tree*, in *Botany*, a species of VITEX. This is a native of Sicily, where it affects humid and shady places; but has been so long ago as 1570, introduced into the gardens of this country, where it bears the cold of winter in the open ground. This plant was famous among the ancients as a specific for the preservation of chastity, and the preventing of all venereal desires, pollutions, &c.

The Greeks call it *αφο*, *chaste*; to which has since been added the reduplicative *castus*, *v. d.* *chaste*, *chaste*.

The Athenian ladies, who made profession of chastity, lay upon leaves of *agnus castus*, during the feast of Ceres. Pliny Hist. N. lib. xxiv. c. 9. See CEREALIA. The seeds, which have long been medicinally used, and were formerly admitted as an article of the *Materia Medica*, are of a round figure and about the size of pepper; they have a pungent acrid taste, and an unpleasant aromatic smell; from the days of Dioscorides they have been much celebrated for their efficacy in subduing the inclination natural between the sexes; and from their usefulness to those that lead a monastic life, they have been called *monk's pepper*. These seeds, so far from possessing an antiaphrodisiac virtue, have had an opposite quality ascribed to them by modern writers. Their aromatic pungency favours this opinion, which is confirmed by the statement of Bergius, who says that they are carminative and emmenagogue. In this island they do not promise much medical advantage.

The shrub is also called *agnon*, *vitex*, sometimes *eleagnon*, *lygon*, and *lygus*.

AGNUS *Dei*, in the *Romish Church*, denotes a cake of wax stamped with the figure of a lamb, supporting the banner of the cross, consecrated in the due form by the pope, to be distributed in presents among the people, and supposed to have great virtues annexed to it.

The name literally signifies *Lamb of God*: this being supposed an image or representation of the Lamb of God, who took away the sins of the world.

They cover it up with a piece of stuff, cut in form of a heart, and carry it very devoutly in their processions.—The Romish priests, and religious, derive considerable pecuniary advantage from selling these *Agnus Dei's* to some, and presenting them to others. The pope provides a regular supply, by consecrating once in seven years: they are distributed by the master of the wardrobe; and received by the cardinals, and other prelates, with great reverence, in their caps and mitres.—This ceremony they pretend to derive from an ancient custom of the church, wherein part of the paschal taper, consecrated on Holy Thursday, was distributed among the people, to perfume their houses, fields, &c. in order to drive away devils, and to preserve them from storms and tempests.

Other imaginary virtues are likewise attributed to them. See concerning the origin of *Agnus Dei's*, Jour. des Scav. tom. xxxi. p. 252. Mem. de Trev. ann. 1722. p. 2010. Their virtues, Act. Erud. Lips. Supp. tom. iv. p. 224. Their mythic meanings, Du Pin. Bibl. Ececl. tom. xviii. p. 68. The order of consecrating them, Magri. Notiz. de Vocab. Ececl. in voc.

Some authors also speak of a kind of metalline *Agnus Dei*, hung to chaplets, or pater-nollers.

The *Agnus Dei* is forbidden to be brought into England, under the pain of incurring a *præmunire*. 13 Eliz. cap. 2.

Agnus Dei is also a name popularly given to that part of the mass, wherein the priest, striking his breast three times, recharms, with a loud voice, a prayer beginning with the words *Agnus Dei*. It is said to have been first brought into the island by pope Sergius I.

Agnus Scythicus, in *Natural History*, a kind of *zophyte*, or plant-animal, said to grow in Tartary, resembling the figure and structure of a lamb.

The Scythian lamb is also called *agnus vegetabilis*, *agnus Tartaricus*, and by the people of the country, *borometz*, *boramet*, or *boranetz*.

The usual account given of this extraordinary production is, that the Tartars sow in their ground a seed resembling that of melon, but less oblong; from whence arises a plant called by them *borometz*, i. e. *lamb*, growing almost to the height of three feet, and having feet, hoofs, ears, and the whole head, excepting horns, resembling that animal. In lieu of horns, it has a peculiar sort of hair, not unlike horns; it is covered with a fine thin skin, which being pulled off, is worn by the natives as a cover for the head. The pulp within resembles that of the *gammarus*; and when wounded, a liquor oozes out like blood. It lives as long as there is grass and herbage around it: but when these are consumed, it wastes and dies. They add, that wolves are fond of it, while no other beasts will feed on it.

Deusingius seems to have been the first who suspected this account to be fabulous: and Kæmpfer, when in the country, made diligent inquiry concerning it, but could hear of nothing like it.

As to the plants shewn under this denomination, in some repositories of rarities, they appear to be originally the roots, or stalks, of certain vegetables, probably of the capillary or fern kind, and supposed by some to be the *polypodium aureum*, covered with a woolly moss, which naturally bearing resemblance to the figure of a lamb, have been helped out and brought near to it by art, and the addition of new parts.

Sir Hans Sloane, and Breynius, give us the figures and descriptions of such *borometzes* in their collections. It is from these plants that the Indian moss is gathered, famous for its use in staunching blood. Breynius and Libavius have written expressly on the *Agnus Scythicus*. Phil. Trans. N^o 287. and N^o 390. Abr. vol. ii. p. 646. vol. vi. pt. 2. p. 317. See Botany, pl. vi. fig. 7.

AGOAS *Bellas*, in *Geography*, a town of Portugal, in the province of Estramadura; three and a half leagues north-east from Thomar.

AGOAS *de Moura*, a town in the same kingdom and province; four and a half leagues north-east of Setuval.

AGOAS *Oventas*, a town in the same province of Portugal, seven leagues east-north-east from Abrantes.

AGOBARD, in *Biography*, archbishop of Lyons, was one of the most learned and celebrated prelates of the 9th century. He was born in the year 779, removed from Spain into France in 782, ordained priest in 804, and, having been nine years coadjutor to Leidrade, archbishop of Lyons, was appointed his successor in 816, upon his retiring to a monastery, with the consent of the emperor and the whole synod of the French bishops. From this see he was expelled by Lewis the Debonnaire, because he espoused the party of his son Lotharius, and was one of the chief instruments in deposing him in the assembly of bishops at Compiègne in 833. But the sons of Lewis, having made their peace with him, restored Agobard to the favour of

the emperor, and also to his see, in the possession of which he continued till his death in 840. As a scholar and a divine, Agobard was much more distinguished than as a politician. He zealously opposed the worship and use of images in a treatise "de Picturis et Imaginibus;" he wrote another treatise to prove that Christ was not merely the adopted, but the true and natural son of God; and a tract on the Priesthood, recommending attention to the character of those who were appointed to this office, asserting their privileges and inculcating their duty. His work concerning hail and thunder, was a direct attack upon superstition, and designed to expose a prevailing error, that it was in the power of sorcerers to raise tempests. During an epidemic disease, which occasioned large donations to the church, in hopes of preventing the infection, he wrote a tract to expose the avarice of the clergy, who, in a season of public calamity, took advantage of the fears and credulity of the people. He also opposed the practice of duelling, and wrote to the emperor soliciting the repeal of the law of Gondebaud, which allowed the decision of disputes by single combat, or by the ordeal of fire and water. He also wrote several tracts against the Jews. His manner of writing was simple and easy; his reasoning was commonly just; and he manifests an extensive acquaintance with the doctrines of the fathers and the discipline of the church; so that considering the period in which he lived, he deserves to be regarded as a man of talents and learning. His works, after having been long buried in obscurity, were published by Masso in 1605; and a more correct edition of them by Baluzze at Paris in 1666, in two volumes, 8vo. This edition has been reprinted in tom. xiv. of the Bibliotheca Patrum. Gen. Dict. Dupin. Cave's Hist. Liter. tom. ii. p. 11. Ed. Oxon.

AGOBEL, in *Geography*, a town of Africa, in the kingdom of Tremecen; four leagues from Oran. There is another town of the same name in the province of Hea, and empire of Morocco.

AGOGA, αγωγη, *ductus*, of αγω, *duco*, I draw, in *Natural History*, a ditch or drain for carrying off the water from a mine.

AGOGA, in *Geography*, a town of Africa on the slave coast.

AGOGE, αγωγή, in the *Ancient Music*, a species of modulation, wherein the sounds or notes proceed by continuous degrees of the scale, both rising and falling. As when we sing re, mi, fa, sol, la: la, sol, fa, mi, re.

Agoge answers to what the Latins call *ductus*, and the Italians *conducimento*, and *di grado*: it stands contradistinguished from *place*, *petitea*, &c.

Agoge makes the first part of the *melopœia*, or art of modulating.

There are three species and cases of this modulation; first, when the sounds follow each other from grave to acute, i. e. rising as in singing, BCDE. This the Latins call *ductus rectus*, and the Italians *conducimento retto*.

The second, when they go from acute to grave, i. e. falling, as in the notes EDCB, called by the ancients *ductus revertens*, and by the modern Italians *conducimento ritornante*.

The third, when they rise by flats and fall by sharps, as in D, E, F, sharp, G, or, *vice versa*, as in G, F, natural, E flat, D. This the ancients call *ductus circumcurrens*, and the Italians *conducimento circumcorrente*. Euclid. Introd. Harm. p. 22. Aristid. Quintil. de Melop. lib. i. Mem. Acad. Infer. tom. vii. Malcolm on Mus. chap. xiv. sec. 4. In the ancient Greek music, agoge is of similar import with the Italian word *movimento*, *motivo*, and the English, *movement*; of which, in compositions of two parts, there are three kinds; viz. *moto retto*, *moto contrario*, and *moto obliquo*, i. e. equal, contrary and oblique.

AGOGLIASTRO, or **AGUILASTRO**, in *Geography*, a small island in the Mediterranean; three miles north from cape Barbarossa in Sardinia.

AGOL, a town of Africa, in the upper Ethiopia.

AGOMISO, an island in James's bay, near its western coast, north north-east from Albany fort.

AGOMPHIASIS, or **GOMPHIASIS**, a dilemper of the teeth. It confits in their being loose in their sockets.

AGON, in *Antiquity*, a dispute or contest for the mastery, either in some exercise of the body or of the mind.

There were agones on certain days, in most of the ancient feasts, and other ceremonies in honour of the gods, or heroes.

There were also agones established expressly, and not attached to any other solemnity.—Such was the *agon gymnicus*, at Athens; the *agon Nemaus*, instituted by the Argians in the 53d Olympiad; the *agon Olympius*, instituted by Hercules, 430 years before the first Olympiad; the *agon Adrianalus*, instituted at Athens, by the emperor Adrian, called Παναθηναϊα, Παναθηναϊα, and Ολυμπια Αδριανα.

The Romans had also agones instituted after the example of the Greeks: the emperor Aurelian established the *agon solis*, *agon of the sun*; and Dioclesian, the *agon capitolinus*, which was held every fourth year, after the manner of the Olympic games.—Hence the years, instead of *lustra*, are sometimes numbered by agones. The *agon ischylicus*, instituted at Puzzuoli by the emperor Antoninus Pius, and held every fifth year, was a sacred combat, and the victors at it were called *hieronice*: they were to be received into the city, through a breach in the wall, made on purpose. The *agon musicus* was that wherein either poets, or musicians, disputed for the prize; such was that dedicated by Ptolemy to Apollo and the Muses, with rewards assigned to the writers who gained the victory. Of this kind were also found some in the Pythian, Nemean, and Isthmian games; also in the Olympic games, after Nero's time, who first introduced a musical *agon* here; others were founded by the emperor Domitian, and others at Rome, Naples, Alba, &c. The *agon Neronianus* was a quinquennial combat, called also *Neronian*, from the name of its institutor, who here bore away the prize for playing on the harp, *cithara*.

AGON is also used for a place near the Tyber, otherwise called *circus Flaminius*, wherein curule games and combats were celebrated.

AGON is also used by *Physicians* for the struggle of death.

AGON was also a minister of sacrifice, whose business was to strike the victim. The name is supposed to have been derived hence, that standing ready to give the stroke, he asked *agon*, or *agone*, *shall I strike?*

The *agon* was also called *papa*, *cultrarius*, and *victimarius*.

AGON, in *Geography*, an island in the north part of Hallingland, one of the provinces of Sweden, which has a good harbour and skilful mariners. It is in that part of the Baltic, called the Bothnia Gulph. N. lat. 61° 20'. E. long. 18° 10'.

AGONALES, in *Antiquity*, an epithet given to the **SALII**, consecrated by Numa Pompilius to the god Mars, surnamed *Gradivus*.

They were also called *Quirinales*, from the *Mons Quirinalis*, where they officiated. Rosinus calls them *Agonenfes Salii*.

AGONALIA, in *Antiquity*, feasts celebrated by the Romans, in honour of Janus; or, as some would have it, in honour of the god *Agonius*, whom the Romans used to

invoke upon their undertaking any business of importance. They appear to have been instituted by Numa, and held thrice in the year, viz. on the fifth of the ides of January, on the twelfth of the calends of June, and the third of the ides of December. Struv. Ant. Rom. c. 8.

AGONALIS CIRCUS, now the *Piazza Navona*, is one of the most magnificent areas in Rome, near 80 common paces in breadth, and about 380 in length, adorned with three stately fountains, which serve to keep the air fresh and cool, and with noble statues, viz. Neptune by Bernini, the Triton and Dolphin by Michael Angelo, the Danube by Claude, the Ganges by Baretta, the Nile by Pancelli, and Rio de la Plata by Raggi; all of which are of white marble, and also the obelisk of Caracalla of Egyptian marble, and covered with hieroglyphics, which was erected here by Innocent X. in 1651. The reason of annexing the epithet *Agonalis* to this *Circus* is not ascertained. Ovid seems to derive it from the *Agones*, or solemn games, supposed to have been the *ludi Apollinares*, or *Actiaci*, instituted by Augustus, from which circumstance the *Circus* was called *Apollinaris*, and it was also denominated *Alexandrianus*, from Alexander Severus, who either enclosed or repaired it.

AGONATA, in *Entomology*, the fourth class of insects in the system of Fabricius; comprehending the cancer, the pagurus, the hippa, the scyllarus, the asiacus, the squilla, and the gammarus. Linnæus has included the insects of this class under the genus of **CANCER**.

AGONE. See **HENBANE**.

AGONES, in *Ancient Geography*, a people who, according to Mela, inhabited that district of the Milanese, now called *la val de Gogna*. Polybius (l. ii. p. 103.) places them in the Celtic Gaul, near Sens. Acaunum was their capital.

AGONES. an island near the mouth of the Anas.

AGONIUS, in *Mythology*, a name given to Mercury, because he presided over the Agonalian games, of which he is said by some to have been the inventor. See **AGONALIA**.

AGONISMA, in *Antiquity*, the palm or prize given to the victor in a game or combat.

AGONISTARCHA, of *αγων*, *combat*, and *αρχος*, *chief*, in *Antiquity*, seems to have been much the same with *agonotheta*; though some suggest a difference, making it the office of the former to preside at, and direct the private exercises of the *athleta*, which they went through by way of practice, before they made their appearance on the public theatres or amphitheatres.

AGONISTIC, *agonistica*, the science of what relates to the combats or *agones* of the ancients.

In which sense, *agonistic* amounts to much the same with *athletic*, and makes a branch of *gymnastics*.

AGONISTIC, *αγωνιστικον*, is also used among *Ancient Physicians*, for cold spring-water.

The reason of the denomination is taken from the plentiful use of that element in the state of an acute erysipelaceous fever, wherein water was supposed to combat and struggle with the febrile heat.

AGONISTICI, in *Ecclesiastical History*, a name given by Donatus to those of his sect, whom he sent into the neighbouring places, fairs, markets, &c. to preach his doctrine; for which reason they were also called *circitores*, *celliones*, *catropeite*, *coropita*, and, at Rome, *montenses*.

They were called *agonistici*, from *αγων*, *combat*; because they were sent, as it were, to fight, and subdue the people to their opinion.

AGONIUM, in *Roman Antiquity*, was used for the day whereon the *rex sacrorum* sacrificed a victim. The same name was also given to the place wherein the games were anciently celebrated.

AGONNA, in *Geography*, a kingdom of Africa, on the Gold Coast, extends from the Devil's Mount, which separates it from *Aron*, and stretches along the sea coast to the village Anonfa, on the frontiers of *Aquamboe*, through a space of sixteen miles, bounded on the North by Songuay, and on the South by the ocean. It abounds in towns and villages along the sea, the chief of which are Dajon, Polder, Mango, Winiba, and Simpa, besides several others. It is said to be rich in gold mines, the gold of which the Negroes gather in the sand after a heavy fall of rain; but the natives have opposed opening the mines for fear of being dispossessed of their territory by the Europeans. Agonna surpasses Aeron in extent and population, and is equal to it in fertility and beauty. It has the advantage of a large fresh-water river, well stocked with fish and oysters. The English have built a fort in the middle of Agonna, at a village called Simpa or Winiba, but the fort is not of any great strength. The village is populous, and the inhabitants industrious in fishing and in agriculture; for they breed a great number of cattle, which they sell to their neighbours. At a small distance is Barku, a village once frequented by the French, where the language that is uniform along the Gold Coast changes into a different dialect, and a little farther it becomes altogether new.

This, according to Barbot, is the chief town in the kingdom of Agonna; and he says, that the surrounding country is fertile, pleasant, and well adapted for the establishment of a factory. The English had formerly great influence here; but the Dutch have gained advantage, and built a triangular fort at Barku, mounted with 12 pieces of cannon. When Bosman wrote, Agonna was governed by a queen, who was distinguished by extraordinary talents. But though she did not chuse to share her power with a husband, she was no stranger to the softer passions; and contrived means of indulging them, by a succession of slaves, and as some say, by a number of lovers at a time. N. lat. 5° 6'. W. long. 1°. Mod. Un. Hist. vol. xiii. p. 445.

AGONOTHETA, compounded of *ἀγων*, *combat*, and *θετης*, *he who disposes*, in *Antiquity*, a magistrate chosen among the Greeks, to preside, and to be the superintendant of the sacred games, or combats: and whose province it was to register the name and country of each champion, to defray the expences of the games, and to adjudge the prizes to the conquerors.

Among the Romans, the like officer was denominated *designator*, and *munerarius*.

Middle-age writers usually confound *agonistæ*, the combatants at the games, with the *agonothetæ*, or presidents of them.

The *agonothetæ* had also the immediate charge of the discipline and morals of the *athletæ*. They examined, and admitted them into the society or order, or expelled them from it. During the combats, the *agonothetæ* were clothed in purple, and rode in a triumphant manner through the circus, holding in their hands an ivory sceptre with an eagle on it. Juvenal. Sat. xi. 192.

Van Dale has an express dissertation on the *agonothetæ*.

The name *agonotheta* is still retained in schools and academies, for him who defrays the charge of the prizes distributed. The founders of prizes are perpetual *agonothetæ*.

AGONOS, in *Physic*, a Greek word signifying *barren*. Hippocrates applies it to women who have no children, though they might have them, if the impediment were removed.

AGONUS, in *Ichthyology*, a name used by authors, for

the fish called by some *sarachus*, by others *chalcis*, and by others *pardella*.

It is in many particulars very like the *alaufa*, or shad, called the mother of herrings, but smaller, never arriving at more than a foot in length: and is always lean and lank in spring, and fat in autumn. But the distinctions between it and the *alaufa*, if real, are so very small, that Mr. Ray, and many of the most accurate naturalists, have suspected it the same fish, only in a different state.

AGONY, **AGONIA**, denotes the extremity of pain, or a disease, when nature makes her last effort, or struggle, to throw off the evil that oppresses her.

The word is formed from the Greek *ἀγων*, *certamen*, *combat*; this being a kind of strife between life and death.

Much of the terror of death consists in the pangs and convulsions wherewith the agony seems attended; though we have reason to believe, that the pain in such cases is, ordinarily, not extremely acute; a course of pain and sickness having usually stupified, and indisposed the nerves for any quick sensations. However, various means have been thought of for mitigating the agony of death. Lord Bacon considers this as part of the province of the physician, and that not only when such a mitigation may tend to a recovery, but also when there being no farther hopes of a recovery, it can only tend to make the passage out of life more calm and easy. Accordingly, he ranks *euthanasia*, or the art of dying easily, among the *desiderata* of science: and does not even seem to disapprove of the course Epicurus took for that end.—“*Hinc itygius ebrius hausit aquas.*” De Augm. Sc. lib. iv. c. 4.

Opium has been applied for this purpose, with the applause of some, but the condemnation of more.

Baglivi promised a treatise express, *De Medicina Agonizantium*, or the method of treating persons in the *agonies* of death. But perhaps one of the best receipts for this end, is that of Mr. Patin, *viz. abstinence from all medicines*.

Our Saviour's agony in the garden has perplexed several commentators; and some learned persons seem studiously to have avoided the term *agony* in their translations, as Beza, Le Clerc, and Lenfant; and in the translations of the Syriac version by Tremellius, Trostius and others, we have *timor*, or fear, for agony. Dr. Lardner (vol. xi. p. 86) suggests that *γεννησιμος εν αγωνια*, (Luke xxii. 44) might be translated *being under great concern*. The effect of this agony has been differently explained. Many expositors have thought with M. Le Clerc, that the expression *οι δρας αυτης εστιν σφοδρα αιμασος*, only implies, that the drops of sweat were large and clammy, like clots of gore. Grotius understands the expression metaphorically, as denoting excessive sweat; but Dr. Whitby (in loc.) observes, that Aristotle (Hist. Anim. lib. iii. c. 19. Oper. tom. i. p. 809. De part. An. lib. iii. c. 5. Oper. tom. i. p. 1008) and Diodorus Siculus (lib. xvii. Oper. tom. ii. p. 230) mention bloody sweats, as attending some extraordinary agony of mind. Leti also, in his life of pope Sixtus V. p. 200, and Sir John Chardin, in his History of Persia, vol. i. p. 126, mention a similar phenomenon; to which Dr. Jackson (Works, vol. ii. p. 819) adds another from Thuanus, lib. x. p. 221. See Doddridge's Family Expofitor, vol. ii. p. 517.

Bartholinus (de Cruce, p. 184. 193) produces examples of sweats that have been actually mixed with blood. So does Maldonat in Matt. xxvi. 37. The possibility of this circumstance is ascertained by a fact well known in history, *viz.* that Charles IX. of France died of a malady, in which his blood gushed out of all the pores of his body. Voltaire (Univ. Hist. chap. 142) describes it thus; “Charles IX. died

in his 25th year.—The malady of which he died was very extraordinary; the blood gushed out of all his pores.' This accident, of which there are some instances, was owing either to excessive fear, to violent passion, or to a warm and melancholy constitution.

AGONYCLITÆ, or **AGONYCLITES**, compounded of the privative *α*, *γ*ου, *knee*, and *κλινω*, *to bend*, in *Ecclesiastical History*, a sect, in the seventh century, whose distinguishing principle it was never to kneel, but to pray standing. See **GENUFLEXION**.

AGORÆUS, formed of *αγορα*, *market*, in *Antiquity*, an appellation given to those deities who had statues in the public market-places, or *fora*. Mercury, whose statue was erected in almost every public place, was distinguished by this appellation.

AGORÆUS was also the name of a subordinate magistrate, in the cities of Asia, whose business it was to administer justice to artificers and the people.

AGORAH, *Malagra*, in *Ancient Geography*, a city of the Thracian Chersonesus, which stood on the gulph of Melas.

AGORAH, an ancient money of Egypt and Asia. See **GERAH**.

AGORANIS, in *Ancient Geography*, a river of India, mentioned by Arrian, *Indic. cap. 4.* which flowed into the Ganges.

AGORANOMUS, compounded of *αγορα*, *market*, and *νομος*, *law*, in *Antiquity*, a magistrate of Athens, established for the maintenance of good order and policy in the markets, settling the prices of provisions, excepting corn, and deciding disputes relating to buying and selling, inspecting the weights, measures, and the like.

The agoranomus, among the Greeks, was much the same with the *curule ÆDILE* among the Romans.

Aristotle distinguishes two kinds of magistrates, the *agoranomi*, who had the superintendance of the markets; and the *astynomi*, who inspected the buildings of the *(αἰσα) cities*. The *agoranomi*, at Athens, were ten in number, five belonging to the city, and as many to the Piræus: though others make them fifteen in all, of whom they assign ten to the city. To these a certain toll or tribute was paid, by all who brought any thing to sell in the market.

AGORITÆ, in *Ancient Geography*, a people of Asiatic Sarmatia.

AGORO, in *Geography*, a town of Italy, situate on the river Cordevol, on the frontiers of the Tyrolese; 21 miles west north-west from Belluno.

AGOSTA, a town of Sicily on the east end of the island, to the south of Catania, with an excellent harbour. The greatest part of it was destroyed by an earthquake in 1693; but has been since rebuilt. N. lat. 37° 20'. E. long. 15° 15'.

AGOSTA island, in the Gulph of Venice, is nearly south from the west end of Carzola and Lessina islands, and west of Augustina shoals and rocks. It affords a good road for ships, in N. lat. 42° 40'. E. long. 18° 52'.

AGOSTINO, **PAULO**, **DA VALERONA**, in *Biography*, an eminent musical composer, was born in 1593, educated in the Roman school of music, under Bernardo Nanini, and succeeded Soriano, as master of the pontifical chapel at St. Peter's. He is represented as one of the most scientific and inventive composers of his time in every species of music; and his productions for four, six, or eight choirs or chorusses were the admiration of all Rome. Padre Martinj has preserved an *agnus dei*, in eight parts, of this composer, which is a very extraordinary performance. He died in 1629, at the age of 36 years. *Burney Hist. Music, vol. iii.* *Hawkins Music, vol. iv.*

AGOSTUS, *αγοστος*, in *Anatomy*, signifies the part of the arm from the fingers to the elbow; also the palm or hollow of the hand.

AGOUT, in *Geography*, a river of France, which rises in the Cevennes, and runs into the Tarn, near Montauban.

AGOUTI, in *Zoology*. See **AGUTI**.

AGOWS, in *Geography*, the inhabitants of a province of Abyssinia, which is bounded by the mountains of Amid Amid on the east; by Bure and Umbarma, and the country of the Gongas, on the west; by Damot and Gafat on the south; and by Dingleber on the north. Of the Agows there are two nations; the one near the fountains of the Nile, called the Agows of Damot, from their vicinity to that province; the other near the head of the Tacazze, in the province of Lasta, called the Teheratz Agows, from Tehera, a principal town, tribe and district, near Lasta and Begemder. The country of Agows lies in a very elevated situation, and forms a kind of amphitheatre of lofty mountains; and the climate of course is temperate and wholesome. In the shade, or in a house, the air is cool, as there is a constant breeze which mitigates the scorching heat of the sun, even at noon-day, though the latitude is not much greater than 10°. But notwithstanding the moderate temperature of the climate, the Agows do not live to any great age, which is probably owing to the oppression they suffer. Their country abounds with all the necessaries of life; and yet their taxes, tributes and services are so numerous, and their dependent condition so distressing, that they are only the manufacturers of the commodities they sell, in order to satisfy the exorbitant demands of their oppressors; and are constrained to live in a state of penury and misery, that is scarcely conceivable. Mr. Bruce informs us, that he saw a number of women, wrinkled and sun-burnt so as hardly to appear human, wandering about under a burning sun, each of whom had one and sometimes two children upon their back, and gathering the seeds of bent grass to make a kind of bread. The Agows, in whose country the Nile rises, are one of the most considerable nations, with respect both to power and wealth, in Abyssinia. When their whole force is raised, they can bring into the field 4000 horse, and a great number of foot; but their power has been much reduced by the incursions of the Gallas. Their riches, however, are still greater than their power; for though their province is hardly 60 miles long, and 30 miles broad, yet Gondar and the whole neighbouring country depend for the necessaries of life, cattle, honey, butter, wheat, hides, wax, and a number of such articles, upon the Agows, who frequent the capital to the amount of a 1000 and 1500 at a time, in order to dispose of these commodities. The Abyssinian princes have therefore compounded with them for an increase of tribute, in lieu of military service; but when they have deviated from this prudent practice, the Agows have been great sufferers. The butter, which they carry to a great distance in this hot climate, is prevented from putrefaction by a root called *moe-moco*, resembling a carrot; which they bruise and mix with it, and thus they preserve it fresh for a considerable time. This root answers the purpose more certainly than salt, which could not be conveniently appropriated to this use, as it serves for money, and is used instead of silver coin as change for gold. Brides paint their feet, the palms of their hands, and their nails, with this drug. Mr. Bruce brought a considerable quantity of the seed, resembling that of coriander, into Europe. The Agows dispose of their commodities, not only at the market of Gondar, but to the neighbouring black Savages, the woolly-headed Shangalla, and receive in exchange elephants' teeth, horns of the rhinoceros, gold and fine cotton. This trade, which might be materially beneficial, is very

much interrupted by the barbarity and fraud of both nations. Besides what they sell, and what they pay to the governor of Damot, the Agows present a tribute to the king of 1000 dabra of honey, each dabra containing about 60lb. weight; 1500 oxen, and 1000 ounces of gold. The clothing of the Agows consists of hides, which they soften and manufacture in a manner peculiar to themselves. Of these they form a kind of skirt, which reaches down to their feet, and is girded with a belt about their middle. The lower part resembles a large double petticoat, one fold of which they turn back over their shoulders, fastening it with a skewer across their breast before, and the married women carry their children in it behind. The younger sort are generally naked. The women are commonly thin, and, like the men, below the middle size. Barrenness is unknown among them. They are marriageable at nine years of age; at 11 they actually marry and bear children; and continue child-bearing to the age of 30, and in some instances beyond that period.

With regard to religion the Agows are grossly idolatrous and superstitious. The Nile, or the spirit residing in that river, is the object of their worship; whom they address under the titles of "the everlasting God, light of the world, eye of the world, God of peace, their Saviour, and Father of the Universe." To this Deity they present their supplications for seasonable rain, plenty of grafs, and the preservation of a particular kind of serpents; at the same time deprecating thunder; and their prayers are pronounced very pathetically with a kind of tone or song. The shum or priest of the river, with whom Mr. Bruce conversed, pretended to have intercourse with a spirit, which occasionally appeared to him, and revealed to him future events. This spirit, he said, was of the river, God, the father of mankind. Thunder was deprecated, as the priest informed him, because it was hurtful to the bees, and their chief revenue was honey and wax. They prayed for serpents, because they taught the approach of good or evil. Serpents are kept in some of their houses; and they are fed with butter and milk before they undertake a journey, or any affair of consequence; and if they do not eat, this is considered as a bad omen. Before an invasion of the Gallas, they say these serpents disappear, and are no where to be found. Fasil, a sagacious governor of the country, who was addicted to this species of divination, would never mount his horse, or go from home, if an animal of this kind, which he had in his custody, refused to eat. Once a year, on the first appearance of the dog-star, or, as others say, 11 days after, their devotion is attended with circumstances of peculiar solemnity; on which occasion they sacrifice a black heifer, distribute parts of it to several clans, eat the carcase raw, and drink the water of the Nile. The bones are then burnt to ashes; and the head is carried into a cavern, which they say reaches below the fountains of the river, and there they perform their secret worship, which no one is allowed to divulge. The Agows of Damot worship the Nile; and those of Lasta pay nearly the same worship to the Siris or Tacazzé. These last have a separate language, and are Troglodytes, who live in caverns. Mr. Bruce apprehends that Agow is a compound of two words, *Ag-aha*, *q. d.* the Shepherds of the river; and that the species of idolatry introduced by them is a proof that they originally came from Canaan, where they imbibed materialism instead of the pure Sabæan worship of the Shepherds of AGAAZI, which was at an early period, the only religion of this part of Africa. The mountains in all the districts or clans of Agows are perforated in caves of a very large size, which some suppose were their ancient habitations, when they were Tro-

glodytes, or places of retreat when they were alarmed by the approach of their most formidable enemies, the Gallas. Others think it not improbable, that these caverns were used for religious purposes; that of GEESEH, in particular, was without a doubt a place of secret worship paid to the river, as it is still appropriated to that use, not only by the inhabitants of the village, but by the assembly of the clans in general, who retire for the celebration of those rites, to which none but the heads of families in the Agows country are ever admitted. Bruce's Trav. vol. i. 401, vol. iii. p. 527.

AGRA, a kind of sweet-scented wood, found in the island of Hainan, on the coast of China.

AGRA *Caramba*, is another sweet-scented wood, which also comes from the island of Hainan.

AGRA, in *Ancient Geography*, the name of a district of Attica, near the source of the Ilissus, where Diana hunted for the first time. Pausanias (*Attic. lib. i. p. 45.*) says, that she had a temple in this place, dedicated to Diana Agrestis.

AGRA, was also a town of Sufiana —another of Arabia; —and another, an episcopal see of Numidia in Africa.

AGRA, called *Agara* by Ptolemy, in *Geography*, the capital of a Subah, or province of the same name, in Hindostan. It stands on the river Jemna, about 50 miles above its confluence with the Tehamu, and 300 miles north-east of Surat; and from being an inconsiderable town with a small castle of earth, it became not only the capital of the province, but the first city in India for magnificence and commerce, during the long reign of the emperor Akbar, and of his son; and it even now exhibits more numerous monuments of former splendour than any city of Hindostan. Akbar, pleased with its situation, very much enlarged and adorned it, and in 1566 made it the seat of his court and empire: and hence it has been often called *Akbarabad*, or Akbar's habitation. The city is very long but not broad, in the form of a crescent; and surrounded by a wall of red stone, and a ditch 100 feet wide. The streets, with the exception of a few, are narrow and ill arranged; the houses are generally low and mean buildings; and the space within the wall is laid out in gardens and palaces, so that it is less populous than might be imagined, considering its extent. The castle and palace are structures of astonishing size and magnificence. The walls of the former consist of stone and brick, terraced in several places, and 20 cubits high. Between this and the river is a large space, designed for the exercise of the troops and other diversions in the emperor's view. The palace, which is within the castle, contains three courts, encompassed with porticos and galleries, all painted and gilt; and some pieces are said to have been plated with gold. Under the galleries of the first court are the lodgings for the imperial guards; those for the officers are in the second court; and the third contains the stately apartments of the emperor and his ladies. The completion of the palace occupied above 1000 labourers for 12 years, and cost nearly three millions of rupees. The emperor, for the execution of his plan, collected together, by the promise of ample rewards, the most skilful architects and the most celebrated artists in every branch, both of external ornament and domestic decoration. Besides the royal palace, there are several others ranged in a line, which belong to the princes and great lords of the court; and before it there is a very large square, and there are also 12 other squares in different parts of the city. The Caravanserais are more than 60 in number, and some of them have six large courts with their porticos. There are at Agra above 800 public baths, and a great number of mosques, with very magnificent sepulchres. Among the latter is the mausoleum of Akbar him-

self, and another erected by the emperor Shah-jehan for his empress Mahd-Asia, at the expense of 60 lacks of rupees, or 750,000*l.* N. lat. 26° 43'. E. long. 76° 44'.

Between this city and Lahore in the Panjab, which are distant from each other 500 miles, there is planted on each side of the road a continued row of shady trees, forming an avenue, to which, whether we consider its extent, its beauty, or its utility in a hot climate, there is nothing similar in any country. Rennell's Memoir. p. 69. Frazer's Hist. Nadir Shah, p. 25.

The province, or Subah of Agra, is bounded on the north by the province of Delhi, on the east by Oude, on the south by Malwa, and on the west by Agimere, and is about 175 miles long and as many broad. According to the divisions of the emperor Akbar, it contains 13 circars or counties, which are divided into 203 pergunnahs or hundreds. The amount of the revenue is 16,156,257 Sicca rupees; and the number of the forces are 50,600 cavalry, 577,570 infantry, and 221 elephants. It is, after many revolutions, says Mr. Maurice, in vol. i. of his Indian Antiquities, published in 1793, at present possessed by Madajee Sindia, one of the most formidable of the self-created sovereigns of the Hindostan. The indigo of this province is deemed the most valuable in the East Indies. Its productions are also rice and cotton, oranges and lemons; and its manufactures are white cloth, silken stuffs, silver and gold lace, &c.

AGRA, or EGRA, is the name given by Pliny (Nat. Hist. tom. i. p. 339. Ed. Hard.) to the town of HEJAZ, in Arabia Felix, now called Hejr, or Al-Hheg'r; situated, in N. lat. 28° 30'. amidst a ridge of rocky mountains, denominated 'Al-Athaleb, *i. e.* the fragments of stones; out of which many houses have been cut, as some say, by the Amalekites, or by their ancestors the Adites, Iramites, and Thamudites. The Thamudeni of the ancients are represented by Pliny as neighbours to this city.

AGRADO *Ilbea*, a town of Africa, in Lower Guinea.

AGRÆ, a city of Arcadia, mentioned by Pliny, tom. i. p. 195.

AGRÆA, a country of Greece, which extended itself into Ætolia and Acarnania.

AGRÆI, a people of Arabia Felix, who, according to Pliny, were good warriors: and also a people of Ætolia in Greece, near the Achelous.

AGRAGA, an episcopal city of Spain.

AGRAGAS. See AGRIGENTUM. This was also a river of Sicily, which joined the Hypsa, below Agrigentum.

AGRAN, *Agrie*, and *Agriani*, a people of Pæonia, between Hæmus and Rhodope.

AGRAKOVA, a town of Russia, in the government of Archangel, on the west of the White Sea; 17 German miles west of Archangel.

AGRAM. See ZAGRAB.

GRAMONT, a small town of Catalonia in Spain, between Lerida and Solsona, on the river Segre, but the capital of a jurisdiction. N. lat. 41° 50'. E. long. 58'.

AGRANE, a borough of Babylon, ruined by the Persians.

AGRARIÆ *stationes*, in the *Ancient Military Art*, corps of guards posted in the fields, and in the open air.

AGRARIÆ *naves*, was used for vessels placed to keep watch, or guard.

AGRARIAN, *agrarius*, formed of *ager*, a field, in a general sense, something relating to fields or lands.

AGRARIAN, in the Roman *Jurisprudence*, a denomination given to such laws as relate to the partition or distribution of lands.

There are 15 or 20 *agrarian* laws; whereof the principal are, the *Lex Cassia*, in the year of Rome 268; the *Lex Licinia*, in 386; the *Lex Flaminia*, in 525; two Sempromian laws, in the year 620; the *Lex Apuleia*, in the year 653; the *Lex Bæbia*; the *Lex Cornelia*, in 673; the *Lex Servilia*, in 690; the *Lex Flavia*; the *Lex Julia*, in the year 691; the *Lex Ælia Licinia*, the *Lex Livina*, the *Lex Marcia*, the *Lex Roscia*, made after the taking of Carthage; the *Lex Floria*, and the *Lex Titia*. See AGER.

AGRARIAN *Law*, *Lex AGRARIA*, absolutely, and by way of eminence, so called, was a celebrated law, published by Spurius Cassius, about the year 268, B. C. 486, for an equal division of the conquered lands among all the citizens, and for limiting the quantity of ground possessed by each person to a certain number of acres. Those other two in the Digest, the one published by Cæsar, and the other by Nerva, only relate to the limits or boundaries of grounds; and have no relation to that of Spurius Cassius. The Roman lands were of divers kinds, some conquered from the enemies, and not yet brought to the public account: others brought indeed to the public, but clandestinely usurped by private great men: lastly, others purchased with the public money, in order to be divided. Agrarian laws, either for dividing lands taken from the enemy, or the public lands, or those purchased with the public money, were easily passed without disturbance; but those whereby private rich men were to be out of their lands, and the common people put in possession of what had been held by the nobility, were never attempted without great disturbances. This is the first time the Agrarian law was mentioned; and the measure originated in the ambitious views of Cassius, who thus intrigued for gaining the favour of the people, and for attaining absolute power. The law had the appearance of equity, and could not less than be agreeable to the people, whose misery it relieved. But as the lands, which Cassius wished to have distributed among the poorer citizens had been unjustly usurped by the rich, the proposal alarmed the Senators, partly because they were personally interested in it, and partly because they apprehended its dangerous consequences. The people were at first pleased; but when they understood that the Latins were to partake with them of the advantage, they were disgusted. To conciliate the Latins, and to engage their concurrence in his favour, were the objects which Cassius had in view; but the jealousy and dissatisfaction of the Roman people disappointed his hopes, and terminated in his death. As soon as he was found guilty of aspiring to the sovereignty, and sentence was passed upon him, he was carried by the Questors to the Tarpeian rock, which fronted the Forum, and thrown down from the top to the bottom in the presence of the people; such was the customary punishment of this crime amongst the Romans. His house was also demolished and his estate sold by auction. With the money arising from it a statue of brass was erected to Ceres. The Plebeians, when they afterwards found that the decree of the Senate for the distribution of lands was not executed, nor any measures adopted for this purpose, reproached themselves with the condemnation of Cassius, as an act of imprudence, and even of injustice. In the year of Rome 299, the subject of the agrarian laws, which had been suspended for 30 years, was revived by the Tribunes; and the people demanded, that as they shared with the Patricians in the labours and dangers of the commonwealth; they might also share with them in the benefits accruing from them. But a new partition would have been attended with great difficulties; and it seemed impossible to proceed in this business, without manifest injustice to many persons in actual possession of the lands to be distributed, who had really

really bought them, and without occasioning great and universal commotions in the commonwealth. For these reasons the Senate firmly opposed the establishment of the agrarian laws. About the year 377, C. Licinius Stolo, a rich plebeian, and tribune of the people, attempted to restrain the overgrown power and wealth of the patricians, by proposing a law, which should restrict every Roman citizen to the possession of 500 acres, and oblige him to surrender the overplus, in order to be divided among the poorer citizens. His motion, though enforced by the influence of his colleague in the tribuneship, L. Sextius, was over-ruled; and new commotions occasioned by the approach of the Gauls, having engaged the public attention, the business of the agrarian law was deferred for nine years; and about the end of that time it was again revived, and the law was established: this was called the Licinian law; and the mover of it was soon afterwards condemned by his own law. Having been found to possess more than 1000 acres, 500 of them were distributed among the poor citizens, and he was compelled to pay the fine, which he had annexed to the violation of the law. In consequence of this abuse, the law itself was abolished. In process of time, however, the great and rich possessed themselves of almost all the lands that belonged originally to the state, either by purchase, or by paying a greater quit-rent, or by violence. Several regulations had been proposed for restraining these usurpations. At length other measures having been found ineffectual, (A. U. C. 620. Ante. Christ. 134.) Tiberius Gracchus, urged by his mother Cornelia, proposed the revival of the Licinian law; and that the rich should quit the lands which they held contrary to the laws, after having received from the public the value of them; and that the citizens, whose circumstances required relief, should take possession of them. Many objections were urged against this mild and humane regulation, as Plutarch calls it: and the prosecution of it brought the commonwealth to the brink of destruction, and cost the two illustrious brothers, the Gracchi, their lives. Their efforts were of little avail, as the laws they laboured to introduce were gradually abolished after their death. Cicero, in speaking of the partition of lands and the remittance of debts, says (Offic. l. 2. n. 78.) "that to undertake to discharge debtors by the authority of the magistrate, or to pass the law so often proposed for the distribution of lands, is to sap the two principal foundations of the commonwealth; of which the one is peace between the citizens, which could not subsist, if creditors were to lose their fortunes by the discharging of debtors; and the other justice, which is entirely subverted, from the instant no one can assure himself of continuing peaceable possessor of his right." The agrarian law of the tribune Saturninus, which was carried with violence A. U. C. 652. was of very short duration; and that of Rullus in the year 689, which was more exorbitant than any other, and gave up to a small number of citizens, under the pretext of relieving the poor, almost all the revenues of the commonwealth, afforded Cicero an admirable opportunity of displaying his eloquence in exposing it, and inducing the people to resist it. The exordium of his oration on this occasion has been much admired. Cic. II. in Rull. The agrarian law of Cæsar was presented to the Senate in the beginning of his consulship, A. U. 693; and he urged in its favour, that a distribution of lands among the poor citizens was altogether useful, were necessary to deliver the city from a multitude of people with which it was overburdened, and often gave rise to seditions; to repeople and cultivate several parts of Italy, which were abandoned; to recompense the soldiers who had served the commonwealth, and to give

subsistence to many citizens who wanted it. He proposed the execution of it in the mildest and most moderate manner; and that 20 commissioners should preside at the distribution of the lands, excepting himself out of the number. Notwithstanding these specious pleas, Cato inveighed loudly against the project of Cæsar, alledging that he did not so much apprehend the division of the lands, as the wages that would be required of the people by those who sought to inveigle them by this present. Cato was imprisoned for his opposition; and when another senator was asked by Cæsar why he departed before the Senate broke up, he replied, "because I had rather be with Cato in a prison, than with you in the Senate." Cæsar appealed to the people; and having engaged the concurrence of Pompey and Crassus, the resistance of Bibulus, Cæsar's colleague in the consulship, and the vehement opposition of Cato were ineffectual. The law was authorized by the suffrages of the people. Cicero acquiesced in this measure, by observing a kind of neutrality; and argues to this purpose: "Let us remain neuter, as if buried in a house in the country. Cæsar hopes that I will second him and invites me to it. See the advantages I shall gain by taking this party; the friendship of Pompey, and even that of Cæsar, if I desired it; a reconciliation with my enemies; the peace of the multitude; and the assurance of quiet in my old age: but after the conduct I have maintained in my consulship, and the principles which I have maintained in my writings, ought not my rule to be this maxim of Homer (Il. M. 243), the best of all counsels is to defend one's country?" Cicero ad Attic. ii. 3. In persuading Cato to give up his resistance to this measure, he conjures him to consider, "that if Cato has no need of Rome, Rome has need of Cato." Cic. pro Sext. p. 61.

Several have pleaded for the necessity of agrarian laws among us. William Sprigge, or, as some say, Fr. Osborne, has written expressly on this subject. See also the Supplement to Dr. Price's Observations on Reverfionary Payments, &c. p. 381.

But the author who seems to have entered most deeply into the nature and use of agrarian laws, is Harrington; he shews that the balance of property in a state cannot be fixed but by laws, and the laws whereby such a provision is made are agrarian laws. Now these are necessary to the stability of government, because governments will, according to the diverse balance of property, be of diverse or contrary natures, that is, monarchical or popular. Thus monarchy requires of the standard of property, that it be vast or great; and of agrarian laws, that they hinder recess or diminution, at least in so much as is thereby entailed upon honour. But popular government requires, that the standard be moderate, and that its agrarian laws prevent accumulation.

This author thinks, that in a territory not exceeding England in revenue, if the balance be in more hands than 300, it is declining from monarchy; and if it be in fewer than 5000 hands, it is swerving from a commonwealth.

The same writer defines an equal agrarian, a perpetual law, establishing and preserving the balance of dominion by such a distribution that no one man, or number of men, within the compass of the few, or aristocracy, can come to overpower the whole people by their possessions in lands.

He also observes, that the people of Rome, by striving for an agrarian, strove to save their liberty; and that commonwealth, through want of such a law, or the non-observance of it, came to ruin.

In the Grecian cities, the defect of an agrarian was supplied by *ostracism*.

In Venice, the council of ten, and the officers of pomp, restrain those who might be too powerful; and these two orders in a commonwealth, where the gentry have but small estates in land, are as much as needs be in lieu of an agrarian.

Some German republics have no more to supply the place of this law than that estates descending are divided among the children.—And the same law would establish an agrarian in England.

Agrarian laws may be framed different ways, as by entailing the lands upon certain families, without power of alienation in any case, as in Israel and Lacedæmon: or, except with leave of the magistrate, as in Spain. But this, by making some families too secure, as those in possession, and others too despairing, as those not in possession, may render the whole people less industrious.

Therefore Harrington prefers a law regulating estates, so that no man shall have above two thousand pounds a year in land; and that the estates of those who exceed this proportion shall be divided in descending to their children, till the greatest share do not exceed 2000*l. per annum*. This is the rule he lays down for his commonwealth of Oceana, by which he means his scheme for the government of England.

By this law, Harrington intended that the property of land in England should never fall into fewer hands than 5000; as he computes the rents of this country to be ten millions. But if these rents, as is probable, amount now to twenty millions, it would follow that, by our author's rule, the land could never be in less than 10,000 hands, which, according to his system, must effectually secure the liberties of the people.

It would exceed the limits of our design, to enter into the full detail of all the reasonings of this ingenious author on the subject of agrarian laws; we therefore refer to his works: Toland's Edition, 4to. 1771. See also GOVERNMENT, PROPERTY, &c.

AGRARIUM. See AGISTMENT.

AGREDA, in *Geography*, a town of Spain, in Old Castile, at the foot of Mount Cayo, where the ancient *Gracchuris* stood; three leagues south-west from Tarazona. N. lat. 41° 53'. W. long. 2°.

AGREDA, is also the name of a town in the kingdom of Popayan, in South America; forty miles north from Quito.

AGREDA, MARY of, in *Biography*, a deluded fanatic, or a bold impostor, was born at Agreda, in Spain, in 1602, took the veil in 1620, in a convent founded by her father and mother, was elected superior in 1627, and died in 1665. In 1637, she began to write the life of the Holy Virgin, in consequence, as she pretended, of orders received from God and the Virgin; and when it was finished, she annexed to it an attestation, that its contents had been communicated to her by divine revelation. This fanciful work was translated, by Father Crozet, and formally condemned by the doctors of the Sorbonne. The translation, in three volumes, 4to. was published at Brussels, in 1717. Gen. Dict.

AGREEMENT, AGREEMENTUM, in *Law*, a joining, or putting together, of two or more minds in any thing done or to be done.

Of this there may be three sorts.—The first, an agreement executed at the beginning, mentioned in the statute of 25 Edw. III. cap. 3. which says, "That the goods bought by forestallers, being thereof attainted, shall be forfeited to the king; if the buyer thereof have made *gree* with the seller:" where the word *gree* otherwise called *agreement executed*, signifies payment for the things, or satisfaction.

The second is an *agreement after an act*, that is, where one does an act, and another agrees and assents thereto afterwards.—The third is an *agreement executory*, which is, when both parties at one time are *agreed* that such a thing shall be done in time to come. It is called executory, because the thing is to be done afterwards.

Agreements are to be in writing, by stat. 29 Car. II. cap. 3. of *frauds and perjuries*.

AGRESSES, or OGRESSES, in *Heraldry*, the same as **PELLETS**.

AGRESTA, in the *Materia Medica*, an unripe grape; otherwise called *ombax*, and *uva acerba*, by the French *verjus*.

Agrestæ are held cooling, detensive, and astringent; they temper the acrimony of the bile, and cheer the heart. Eaten plentifully, they have been found to destroy worms. The term is sometimes also applied to the juices of this fruit, more properly called *omphacium*.

AGRESTI, LIVIO, DA FURLI, was a painter of history, who died in 1580. He was a disciple of Picirino del Vaga, and is commended by Vasari, for the richness of his invention, the goodness of his colouring, and the correctness of his design. Pilkington.

AGREVE, in *Geography*, a small town of France, in Vivarais, at the foot of the mountains.

AGRI, in *Ancient Geography*, a people placed by Ptolemy, in European Sarmatia.

AGRIA, a name given to **HOLLY**; and also to a malignant pustule, of which there are two sorts. The one is small, with a roughness, redness, and slight corrosion of the skin; it is of a round figure, its centre is smooth, and it spreads slowly. It is cured by rubbing it with falling spittle. The other sort ulcerates with a violent redness and corrosion, so as to make the hair fall off; it is of an unequal form, and turns leprous. It is cured by poultices of **PELLITORY of the wall**.

AGRIA, or RGER, in *Geography*. See **ERLACE**.

AGRIAMPELOS, formed of *αγριος*, *wild*; and *αμπελος*, *a vine*; the *wild VINE*; and, according to Gerard, the **black BRIONY**.

AGRIANA, in *Ancient Geography*, a town of Capadocia.

AGRIANES, a small river of Thrace, which rose north of Heraclea, and discharged itself into the Hebrus. This was also the name of a people near mount Pagæus, in Thrace.

AGRIANIA. See **AGRIONIA**.

AGRICOLA, CNÆUS JULIUS, in *Biography*, an illustrious Roman, was born on the 13th of June, in the second consulship of Caius Cæsar, A. D. 38. Tacitus dates his birth, in the third consulship of Caius; but as he died in his 56th year, by the same historian's account, he must have been born sooner. He was a descendant of the colony of Forojulii or Frejus, in Provence, the place of his nativity; and his grandfathers, on both sides, were of the equestrian rank. His father, Julius Græcinus, was of the order of senators, and distinguished by his wisdom and eloquence. His character is mentioned with respect by Seneca, (*de Benef. lib. ii.*) and he is cited as a writer by Pliny, tom. i. p. 710. Vid. Index Auctorum, tom. i. p. 61. Ed. Hard. Caligula wished him to accuse Silanus; and because he refused, caused him to be put to death. Agricola being thus deprived, at an early age, of the instruction which his father was so capable of giving him, the care of his education devolved upon Julia Procilla, his mother. By her he was removed, when a child, to Marfeilles, which was then deemed the Athens of Gaul; where the politeness of Greece was happily blended with the provincial simplicity of

of manners. Here he manifested the vigour of his mind, by an assiduous application to the study of philosophy; but his mother, conceiving this kind of science to be inconsistent with the active life to which he was destined, moderated the ardour with which he pursued it. The scene of the first military service in which he engaged was Britain; and the General, to whose immediate care he was entrusted, was Suetonius Paulinus, who was then employed in the arduous business of recovering the provinces that had revolted from their subjection to the Roman power. His conduct secured the esteem and patronage of this distinguished commander; and the office of tribune of a legion, to which he was appointed, afforded him an opportunity of gaining that knowledge of his profession, and that acquaintance with the country, which laid the foundation of his future celebrity. On his return to Rome, in pursuit of the honours that belonged to his rank, he married Domitia Decidiana, a lady eminently distinguished by her virtues, as well as by her noble birth; and this domestic connection was a source of uninterrupted felicity. Having discharged the office of quaestor, in the rich province of Asia, under Salvius Titianus, brother to Otho, who was afterwards emperor, with a probity which no temptation could corrupt, he spent several years in that state of inactivity, which was most secure and most eligible under a prince so suspicious and cruel as Nero. In the mean while, he performed the duties of praetor and tribune of the people, with a degree of prudence, which led him to avoid both the extremes of parsimony and prodigality.

On the accession of Galba, Agricola was charged with a commission to take an account of the property belonging to the temples, which Nero had purloined; and in the execution of this business he recovered what was attainable, and prevented farther depredations. In the commotions that succeeded the death of Galba, he seems to have taken no part. At this time (A. D. 69), he was much distressed by the news of his mother's death, who had been murdered at Intemelii, in Liguria, by the troops belonging to the emperor Otho's fleet, and whose estates they had plundered. Whilst he was preparing to pay the last tribute of respect to an honoured parent, and to redress the injury which his patrimony had sustained, he received information that Vespasian had assumed the empire, and immediately determined to attach himself to his cause. From Liguria, he probably hastened to Rome; and he was appointed, by Mucianus, to the command of the 20th legion in Britain, which had manifested some signs of disaffection and mutiny. Having, by his wife and moderate conduct, secured the obedience of the legion, he continued for some time in the country, under the government, first of Vectius Bolanus, and afterwards of Petilius Cerialis. Under the former governor, who was meek and peaceable, he suppressed his martial ardour, and renounced what was specious for that which was really useful; and under the latter, who was active and enterprising, he was prompt in executing the orders he received, and yet modest in relating his successes; so that he thus acquired fame without envy. When he returned to Rome, Vespasian created him a patrician, and invested him with the government of Aquitania, in Gaul, which then comprehended the whole country between the river Loire, and the Pyrenean mountains. Here he performed the duties of a civil governor for three years, in a manner which commanded universal esteem. He was recalled by Vespasian, A. D. 77, and made consul with Domitian. During the year of his consulship, he contracted his daughter to Tacitus, the historian, who has furnished the memoirs of his life; and at

the expiration of his office, he was admitted into the college of pontiffs, and appointed governor of Britain, whither he repaired, in order to compose the tumults of this distracted province. Julius Frontinus, his predecessor, was a man of abilities, and had conquered the warlike nation of the Silures.

On the arrival of Agricola, he found the Ordovices, or inhabitants of North Wales, in a state of insurrection. At a late season of the year, and in opposition to the timid counsel of some of his principal officers, he marched against them, by a signal defeat almost extirpated the nation, and then reduced Mona, or the isle of Anglesey. His next object was to correct those abuses which had occasioned the hostilities of the Britons, and to conciliate their attachment by equitable and humane measures. He also softened their manners by inducing them to cultivate the arts of peace, by providing for the liberal education of the sons of their chieftains, and by promoting the use of the Roman habit and language. In return for their liberty, of which they were deprived, he endeavoured to establish amongst them tranquillity. Luxury, says Tacitus, soon followed; and the Britons called those qualities politeness and good breeding, which were, in fact, the shackle and badge of their servitude.

Agricola, having secured the southern part of the island, prepared, in the third year of his government, to extend his arms northwards; and having spread the ravages of war as far as the Frith of Tay, he proceeded to secure his conquests by a chain of fortresses, in the arrangement of which his military skill was eminently displayed. This chain extended from the Clyde to the Frith of Forth; and he thus separated the conquered part of the island from the fierce and unsubdued tribes of the north. His fifth campaign was devoted to the conquest and security of those parts of Scotland which lie over against Ireland, to which island he directed his views, and which, after his return to Rome, he avowed his purpose of subduing and retaining. The operations of the sixth campaign were principally directed against those who inhabit the eastern parts beyond the Frith of Forth; and in these, the army was accompanied by the fleet, which explored the inlets and harbours, and enclosed the natives on all sides. Agricola was the first Roman general that ever employed a fleet against the Britons, who had always looked upon the sea as their last resource, if ever they should be conquered by land. That resource was now taken from them; and they no longer knew what defence to make against an enemy, who was master of both elements. However, the Caledonians assembled in great numbers, and made a fierce attack on one of the Roman camps; but after a temporary success, they were repulsed with great loss. But they determined to persevere, and thought of nothing but renewing the war. Accordingly, they closed this campaign with arming their youth, providing places of safety for their wives and children, and forming alliances for their future succour. For the seventh campaign, Agricola, as well as the Caledonians, made great preparation. The Grampian hills were the scene of a decisive engagement. Here the natives, forming an army of more than 30,000 men, under the command of Galgacus, made their stand; and here also Agricola, having disposed his troops in the most advantageous position, waited the descent of the enemy from the hills.

Each General addressed his army previously to the battle, and their speeches, which are recorded by Tacitus, were re-echoed with shouts of applause. For a long time the victory was disputed, but at last the Romans prevailed, and

with

with a small comparative loss of 340 men, killed 10,000 of the Caledonians, and dispersed the rest. Agricola, after receiving hostages from some of the tribes, withdrew his army slowly within the Roman limits, and ordered the commander of his fleet to circumnavigate the island. Whilst Agricola was extending his conquests in a distant province, Domitian succeeded to the empire, and became jealous of his reputation and power. He ordered, however, the insignia of triumph to be decreed him by the senate, together with a statue, and all the honour which a private man could receive under the emperors, in lieu of the triumph itself, to which no one but the prince was now entitled. At the same time the emperor recalled Agricola, and under a pretence of favour, propagated a rumour that he intended to appoint him to the government of Syria. Agricola peaceably surrendered the province to his successor; and when he arrived at Rome, he entered the palace by night, in order to avoid tumult, and to prevent any occasion of offence to the jealous Domitian, where he was received by the emperor with a cold salutation, and then suffered to mingle with the crowd of courtiers, and afterwards to retire, unnoticed and unrecompensed, into private life. His popularity was dangerous to him in this tyrannical reign; but his prudence and moderation enabled him to escape uninjured. In this private manner did he pass nine years of his life. At length the year arrived in which the proconsulships of Asia and Africa were to be drawn by lots; and one or other of them must, in due course, have fallen to him. The emperor, dreading the union of such influence as this station would give, with his extraordinary talents and reputation, contrived by his emissaries to induce him to request being excused from the office, and to plead as an apology, his love of retirement and ease. The artifice succeeded, and the emperor acted his part in granting the request of Agricola, with his usual haughtiness and arrogance: nor did Domitian give him the present which was usually bestowed on these occasions. Soon after this event, Agricola was seized with the disorder which terminated in his death. Common rumour attributed it to poison; and the officious inquiries of Domitian, during its progress, increased the suspicion, though it was probably unfounded. He died, when Collega and Priscus were consuls, August 23, A. D. 93, in the 56th year of his age, leaving a widow and one daughter, who was the wife of Tacitus. He lost a son, at a very early age, while he was in Britain. His death was universally lamented. The portrait which Tacitus has drawn of his father-in-law, with his pen, excels (says Crevier) all that the pencil of the greatest painters, or chizel of the ablest sculptors, could have achieved to perpetuate the memory of Agricola. He was unwilling to let posterity be ignorant even of his form and person: he tells us, that he was well made, though not tall; that his countenance was rather mild than stern; that candour and probity were pictured in his face; that none could see him without loving him; and that all were delighted to find the *great* and the *honest* man united in him. He was not ambitious of possessing a large fortune; but he enjoyed such an one as was sufficient for a noble and generous mind. He had tasted all the satisfactions which result from the consciousness of having acted suitably to the obligations of his superior stations; and he had been vested with all the ornaments and titles, which, however misplaced in others, were in him the rewards of real merit. He might be styled an happy man, as Tacitus observes, since he escaped the miseries in which the Roman empire was soon after involved; and died while his wife and daughter were living, in the possession of his dignity, in the height of his fame, and with all his relations and friends safe and prosperous. His death was pathetically

lamented by Tacitus, in an elegant apostrophe to Agricola himself, of which no translation can do justice to the energy and conciseness of the original. "What aggravates mine and your daughter's sorrow," says Tacitus, "besides the loss of you, is, that we had not the opportunity of sitting by you in your sickness, supporting you in your faintings, and enjoying the satisfaction of your last looks and embraces. Then we should have received from you those commands and counsels, which would have been perpetually fixed on our memory. This is a great cause of our regret: you were lost to us by four years' absence from us. It is certain that you, best of fathers, wanted nothing suitable to your character and circumstances, since your tender wife was present with you; but you should have been lamented with other tears besides her's; and in your last moments your eyes were bereaved of the sight of some who were very dear to you. If there be any residence for the manes of the virtuous; if, as philosophers think, the souls of the great are not extinguished with their bodies; may you rest in peace, and recall us your family from too weak and womanish lamentations for your death, to the contemplation of your virtues, which it is very unreasonable to regret. Let us rather honour you with a just admiration. This is the true honour, and the best instance of piety, which we your nearest relations can shew you. This is what I shall represent to your daughter and your wife, that the former would revere the memory of her father, and the latter that of her husband, by revolving all his actions and words in their minds, and reflect more upon the character and idea of his soul than those of his body. Not that I would, in the least, oppose erecting to you images of marble or brass; but as the bodies of men are perishing and mortal, so likewise are their statues: but the form of the mind is eternal, and can never be preserved or expressed by any foreign materials or art, but only by the real character and behaviour of the person who imitates it. Whatever we loved and admired in Agricola still remains, and will for ever remain in the minds of men, and in the everlasting fame that attends noble actions. Many of the ancients will be sunk in oblivion, without the least remain of fame or reputation; but Agricola will be transmitted to posterity, and survive in immortal honour." Taciti Vita Agric. apud Op. tom. ii. p. 465. Ed. Ernesti. Crevier's Rom. Emp. vol. vi. p. 346—388. Gen. Dict.

AGRICOLA, CHRISTOPHER LUDWIG, a landscape and portrait painter, was born at Ratibon, in 1667, and died there in 1719. He engraved a landscape, in which is represented the fable of Diana and Actæon. Strutt.

AGRICOLA, GEORGE, was born at Glauchen, in Misnia, (Meissen) in Upper Saxony, the 24th March, 1494, and received the principal part of his education in Italy, where he applied himself diligently to his studies, particularly to the study of medicine. Returning to Germany, he settled at Joachimstedt, in Misnia, and practised physic there, with considerable reputation and success. He then removed to Chemnitz, that he might be near the rich mines in Saxony, the scene of his future greatness; as from the perfect acquaintance he there acquired of the nature of metals, proceeded those rich stores of knowledge which are scattered in profusion over his numerous works on mineralogy. He is said to have told the Dukes of Saxony, that their subterraneous treasure far exceeded in value all they possessed on the surface of the earth. He was very little, however, assisted by their bounty, furnishing nearly the whole of the expences of his labours and his experiments from his own fortune. The treatises he wrote on the subjects of metals and mineralogy, are composed in an elegant Latin style: they abound in curious information, and were, for a long time, considered as standard works. He maintained his

attachment to the old religion, though he lived among Lutherans. He died at Chemnitz, November 21, 1555, and was buried at Zeitz; the bigotry of his townsmen not allowing him a grave among them. G. Fabricius, his intimate friend, composed the following epigram on his works;

“Viderat Agricola, Phæbo monstrante, libellos,
Jupiter, et tales edidit ore sonos.
Ex ipso hic terre thesauros eruet orco,
Et fratris pandet tertia regna mei.”

His works on mines, published originally in parts, were collected and printed together, at Basil, 1546, in folio. They are chiefly comprehended under the following titles: “De ortu et causis subterraneorum;” “De Natura eorum quæ effluunt ex terra;” “De Natura Fossilium;” “De Medicatis Fontibus;” “De Subterraneis Animantibus;” and “De veteribus et novis Metallis.” His great work, “De re Metallica,” was printed at the same place, 1561, also in folio; “De Mensuris et Ponderibus, Romanorum et Græcorum,” with additions referring to modern times, 1550, folio; “De Peste Libri tres,” Basil, 1554, 8vo; “Opus de Fossilibus, cum Annotationibus Georgii Fabricii,” 1657. He also wrote other treatises on political and theological subjects.

AGRICOLA, JOHN, a Saxon divine, was born at Eilenben, in Germany, April 20th, 1492. Mosheim describes him as an eminent doctor of the Lutheran church, though chargeable with vanity, presumption, and artifice. He was minister, and principal of a college in his own country; and attended the elector of Saxony to the diet of Spire, in 1526; and to that of Augsburg, in 1530. Urged by ambition, he quitted his own country in 1536, and went to Wittenberg, where he settled as a professor and minister. Although he wrote against Melancthon, in 1527, he was not much noticed before the year 1538, when he took occasion, from the doctrine of Luther, concerning the ground of man's acceptance and salvation, to declaim against the *læw*; maintaining, that it was neither fit to be proposed to the people as a rule of manners, nor to be used in the church as a means of instruction; and that the *gospel* alone was to be inculcated and explained, both in the churches and in the schools of learning; and he thus became the founder of the sect of ANTI-NOMIANS. Luther, who had been before his friend, attacked him with great severity; and his accusations were supported by the divines of Wittenberg. At length, by the interposition of the electors of Saxony and of Brandenburg, Agricola was induced to publish a recantation of his errors, and to retract the injurious reproaches which he had cast upon Luther. Mosheim says, this recantation does not seem to have been sincere; as he returned to his errors, when his fears were dispelled by the death of Luther, and gained proselytes to his extravagant doctrine. Agricola was employed by Charles V., in 1548, in conjunction with other persons, and liberally rewarded, in composing the INTERIM. It is said, that he wanted to restore the use of holy oil in the case of the sick; and that he attributed a supernatural efficacy to it. Some have said, that he was a Papist; and others charge him with being a man of pleasure, and with maintaining all religions to be in themselves really indifferent. When he left Saxony, he was patronized at the court of Brandenburg, by the elector Joachim II. whose favour he enjoyed till his death, which happened at Berlin, in 1566. His “Explication of German Proverbs,” and his “Commentaries upon St. Luke,” are the principal of his works, Gen. Dict. Mosh. Eccl. Hist. vol. iv. p. 321, &c.

AGRICOLA, MARTIN, a theoretic and practical musician,

who was chanter of Magdeburg, and flourished about the middle of the 16th century. He died, June 10th, 1556. His works are two treatises on music, written in German verse, and published at Wittenberg, in 1528 and 1529; the latter of which, viz. “Musica Instrumentalis,” was republished, with large additions, in 1545; and contains an explanation of the fundamentals of music, together with a description of the instruments used in his time, and the method of playing upon them; and an account of the division of the monochord, and of a temperature for the organ and harpsichord: a tract “on Figurate Music,” and a brief treatise “De Proportionibus:” a treatise, intitled, “Scholia in Musicam planam Wenceslai Philomatis ex variis Musicorum scriptis per Magdeb. Schola collectis:” a larger work, intitled, “Melodiæ Scholasticæ sub horarum intervallis decantandæ,” published at Magdeburg in 1682; and a posthumous work, intitled “Duo Libri Musices continentes compendium Artis, et illustria Exempla, &c.” published in 1561. His several treatises were designed for the instruction of beginners in the study of music. Hawkins's Hist. Music. vol. iii. p. 83.

AGRICOLA, MICHAEL, a Lutheran minister at Abo, in Finland, was the first who translated the New Testament into the language of the country, and thus contributed to the propagation of Lutheranism. It was printed in 1548. He died in 1556. Gen. Dict.

AGRICOLA, RODOLPHUS, was born in the village of Basson, near Groningen, in Friesland, in the year 1442; and distinguished by his love and pursuit of literature. Having finished his education at Louvain, where he maintained an exemplary character for sobriety and application, he declined the professor's chair, which was offered him, and visited France and Italy for farther improvement. At Ferrara, he studied Greek, and availed himself of the lectures of philosophy that were read by Theodore Gaza; and at the same time taught Latin, which he was able to write with so much purity and elegance as to rival Guarini, in prose; and the Strozzi, celebrated writers at that period, in verse. After a residence of two years in Ferrara, he returned to the Netherlands, about the year 1477; and, at Daventer, had an interview with Erasmus, whose future celebrity, though he was then a boy of ten years old, he had the sagacity to predict. His love of independence, and his solicitude for securing leisure to indulge his literary taste, induced him to forego several offices of honour and profit, which he might have obtained by the favour of the emperor Maximilian I. At length, in 1482, he settled in the Palatinate, residing sometimes at Heidelberg, and sometimes at Worms, and delivering occasional lectures in polite literature. The Elector Palatine was his auditor; and in compliance with his request, Agricola composed, “An Abridgment of Ancient History.” He was also much respected by John d'Alburgh, bishop of Worms, whom he had instructed in the Greek language. About the 40th year of his age he directed his thoughts to the study of divinity; and by the assistance of a Jew, made considerable progress in the Hebrew language; but death put a stop to his literary pursuits, at Heidelberg, in 1485. Although his natural temper, which was characterized by a fondness for ease and leisure, was altogether inconsistent with the active exertions of a reformer, he seems, however, to have deplored the darkness of the church, and to have had some glimpse of the light which illuminated it in the next century. The indolence of his disposition prevented his entering into the married state, though he professed an attachment to the female sex; and took pleasure in amusing them with elegant verses, and with musical performances, both vocal and instrumental, in which he excelled. To

Agricola

Agricola belongs the praise of having restored the Greek learning to Germany, and of having contributed, in an eminent degree, to the revival of literature and classical taste, in an age which required his exertions, and when they were highly useful. Erasmus, in his *Adagies*, calls him "a man truly divine." Bayle says, that Italy, which at that time treated every thing as barbarous that was on this side the Alps, produced no genius comparable to what Friesland could boast of in her *Agricola*." A learned Venetian, in an epitaph, ranks Agricola with the most celebrated names of Greece and Rome. His works, of which the principal is his treatise intitled, "*De Inventione Dialectica*," were collected by Alard, in two volumes, 4to, and printed at Louvain, in 1516; and by Oeco, at Cologne, in 1539. Gen. Dict.

AGRICULTURE, the science which explains the art or means of cultivating and improving the earth or soil, so as to render it fertile and productive. The term seems to be formed from the Latin words *ager*, *field*, and *cultura*, *culture*, or *tillage*, from *colere* to *till*.

The art of agriculture, in this view, comprehends the nature of *climate* and *soil*, the methods of performing the different operations that are requisite in the cultivation and improvement of arable and grass lands, as *inclosing*, the making of fences, as *hedges*, *ditches*, *walls*, *railings*, *pailings*, *gates*, *draining*, *paring*, and *burning*, *watering*, *swarping*, *fallowing*, *ploughing*, *manuring*, *sowing*, *harroving*, *weeding*, *hoing*; the growing and preserving of different sorts of crops, as *wheat*, *rye*, *barley*, *oats*, *beans*, *peas*, *potatoes*, *turnips*, *carrots*, *cabbages*, *hops*, *hemp*, *flax*, *woad*, *madder*, &c.; and the raising of various kinds of seeds, as *rape*, *mustard*, &c.; *rotation of crops*, *reaping*, *mowing*, *stacking*, *thrashing*; the management of artificial and natural grasses, as *clover*, *lucern*, *sainfoin*, *tares*, *vetches*, &c.; the converting of arable lands to grass, *meadows*, *pastures*, *hay-making*; the cultivating and preserving of fruits, as *apples*, *pears*, *cherries*, &c.; and the preparation of fruit liquors, as *cyder*, *perry*, &c.; *orchards*; the planting of timber-trees, *woods*, *copplices*, *plantations*, &c.; the inventing of implements, as *ploughs*, *harrows*, *rollers*, *hoes*, *drills*, *waggons*, *carts*, *mills*, *kilns*, &c.; the construction of farm-buildings, as *houses*, *offices*, *steds*, *cottages*; the nature of *farms*, *tithes*, *leases*, &c.

In a more extensive sense it also includes the breeding, rearing, feeding, and general management of all sorts of live stock, as *cattle*, *horses*, *sheep*, *lambs*, *hogs*, *rabbits*, *poultry*, *pigeons*, *bees*, &c.; the conducting of the various processes and preparations which have a relation to the different products obtained from them, as *milk*, *butter*, *cheese*, or what are generally termed *cow-keeping* and *dairying*; and lastly, as connected with political economy, the construction of *roads* and *canals*, the forming of *embankments*, and the nature of *weights* and *measures*. Full accounts and explanations of these will be given in the course of this work, under their respective heads.

Gardening may likewise be considered as an *improved* branch of agriculture.

Among the Ancients the business of husbandry was frequently understood by the term *Georgica*.

This useful and important art, though less splendid than many others, appears to have attracted the notice of mankind in the earliest periods of the world; and this is not indeed very extraordinary, when it is considered that the excellence and prosperity of them at such periods must almost have solely depended upon it. In the earliest stage of society, men, as hunters, must have found, from experience, that the mode of procuring subsistence by the bow or the chase was attended with infinite toil as well as hazard, and precarious in the event; and therefore, not by any means

calculated to supply the wants or increase the comforts of social life. In the pastoral state also, which may be regarded as the second step in the advancement of society, men must soon have discovered, that though more certain of subsistence, and less exposed to danger and hardships, their herds and flocks were liable to innumerable accidents, and that they might at once be reduced to all the miseries of famine.—Under such circumstances and apprehensions, it was therefore natural for them to think of some means by which they might, with more certainty, procure the necessaries of life. For this purpose they would naturally turn their attention towards the earth, and discover that from it might be drawn whatever could render life comfortable. Experience would likewise inform them, that, by due cultivation of the soil, fruits, and grain of various kinds, fit for nourishment, might be procured in abundance; but that, by neglecting this art, the natural fertility of the soil, the warmth of the sun, and the regular revolutions of the seasons, would be in a great measure unavailing.

What may be termed the art of husbandry having commenced in this way, it is easy to perceive that it must have been extremely simple in these early ages, and its advances towards perfection slow and almost imperceptible. By most of the eastern nations agriculture seems to have been particularly attended to and encouraged from the most early periods. That the Japanese were extremely interested in its promotion is evinced by the great care taken in collecting and preserving all sorts of manures; and among the Chinese it has constantly received the distinguished regard and protection of their princes and nobility, and been considered as the most honourable and important of all employments. The use of the drill, which has but lately been introduced and adopted in European countries, is said to have been long known and employed by them.

The Chaldeans are found to have carried this valuable art to a considerable degree of advancement; as they cultivated their lands with great assiduity, and enjoyed the pleasing satisfaction of receiving from their fields plentiful harvests. The Egyptians also, who, from the fertility of their country, caused by the annual overflowings of the Nile, raised prodigious quantities of corn, were so sensible of the blessings resulting from agriculture, that they ascribed the invention of it to Osiris, and even carried their superstitious gratitude so far, as to worship those animals that laboured in tilling the ground. The Phœnicians were also famous for their skill in agriculture; but finding themselves too much confined in their native country, by the conquests of neighbouring nations, they spread themselves through the greater part of the islands of the Mediterranean, and carried with them their knowledge in husbandry. The Carthaginians following the taste of their ancestors, are said to have applied themselves assiduously to the study of agriculture. Mago, their famous general, wrote no less than twenty-eight books on that subject, which Columella tells us were translated into Latin by an express decree of the Roman senate; and Servius adds, that Virgil used these books as a model when he wrote his *Georgics*. The art of sowing corn, and the tillage of land, were probably invented in Sicily; as that island was very fruitful in corn, and agriculture was there esteemed so honourable an employment, that even their kings did not disdain to practise it with their own hands. The Athenians, who were the first people that received any tincture of politeness, taught the use of corn to the rest of the Greeks; they also taught them the manner of cultivating the ground, and preparing it for seed. The Greeks soon perceived that bread was more wholesome, and its taste more delicate than acorns, and accordingly thanked the gods for such an unexpected

and beneficial present. After this, the Athenian kings thinking it more glorious to govern a small state wisely, than to aggrandize themselves by foreign conquests, withdrew their subjects from war, and employed them solely in cultivating the earth. This constant application carried agriculture to a considerable degree of advancement, and reduced it into a more perfect art.

Hesiod, who is generally thought to have been contemporary with Homer, was the first among the Greeks who wrote on this subject. He called his poem "Weeks and Days," because agriculture requires an exact observance of times and seasons. The other eminent Greek writers upon agriculture are Democritus of Abdera, Socraticus, Xenophon, Paretinus, Architas, Aristotle, and Theophrastus, from whom the art received considerable improvements, as also from Hieron, Epicharmus, Philometer, and Attalus.

The ancient Romans esteemed agriculture such an honourable employment, that, in the earliest times of the republic, the highest praise that could be given to a man, was to say of him, that he cultivated well his own spot of ground. The most illustrious senators applied themselves to this profession; nor had they either splendour or majesty, but when they appeared in public. And their greatest generals, at their return from the toils of war, from taking of cities, and subduing of nations, were impatient till they were again employed in cultivating their lands; and thought it no disgrace to follow the plough, though they were at the same time prepared to serve the wants of the republic, attend her councils, or put themselves at the head of her armies. It must indeed be allowed, that when the Romans became tainted with the luxury of Asia, they gradually lost the noble simplicity of their ancestors, and employed their slaves in the severer labours of a country life. But though they did not themselves hold the plough, yet even men of consular dignity looked upon it as a reward for their public services, when they obtained leave to retire into the country; and were equally respected when overlooking their farms, as when seated in the chair of magistracy. M. Cato, the censor, that illustrious Roman general, orator, politician, and lawyer, after having governed provinces, and subdued nations, did not think it below his station to write a large treatise on agriculture.

This work, according to Servius, was dedicated to his own son, and was the first Latin treatise on that subject. It has been handed down to us, it is said, in all its purity, and in the same manner that Cato wrote it. Varro composed a treatise on the same subject, but on a more regular plan. This work is embellished with all the Greek and Latin erudition of that learned author. Agriculture also received great improvements from the two Sallustians, and likewise from Scorsia, Tremellius, and M. Terentius. Virgil has adorned it with the language of the muses, and given it majesty by his verse. He has finely embellished those precepts of husbandry which were left by Hesiod and Mago.

Columella, who flourished in the reign of the emperor Claudius, wrote twelve books on husbandry, which contain a variety of interesting facts and observations. He was a native of Boetia, in Spain, and had devoted much time to the study of rural affairs.

From this period till the reign of Constantine IV. husbandry appears to have been in a declining state, when that wise emperor caused a large collection of the most useful precepts relating to the art to be extracted from the best writers, and published under the title of Geoponics. Some say he made this collection with his own hand. Nor is this at all improbable, as it is well known that, after he had conquered the Saracens and Arabians, he not only practised,

but studied the arts of peace, fixing his chief attention on the advancement of agriculture.

But from the time of Constantine IV. till about the year 1478, it lay in a kind of dormant and neglected state, when Crescenzio, an Italian, revived it by publishing an excellent performance on the subject at Florence. He was soon followed by several of his countrymen, among whom Tatti, Stefano, Augustino Gallo, Santovino, Lauro and Tarello, deserve to be particularly noticed.

In the mean time, in our own country, Fitz Herbert, judge of the Common Pleas, shone with unrivalled lustre in the practical parts of husbandry. He published two treatises on this subject; the first, which was entitled "The Book of Husbandry," appeared in 1534; and the second, called, "The Book of Surveying and Improvements," in 1539. As the observations and instructions contained in these works were the result of much experience, they excited great attention to the subject, and soon raised a spirit of emulation in his countrymen, in consequence of which many treatises of the same kind successively appeared; but time has deprived us of many of these writings, or at least they are become so very scarce, as only to be found in the libraries of the curious.

About the year 1600, France made considerable efforts to retrieve husbandry, as appears from several large works, particularly *Les Moyens de devenir riche*, and the *Cosmopolite*, by Barnard de Palissy, an indigent potter; *Le Théâtre d'Agriculture*, by de Serres; *L'Agriculture et Maison Rustique*, by Messrs. Etienne and Liebault, and lately *Le Cours Complet d'Agriculture*, by M. L'Abbe Rosier, &c.—The Flemings, about the same period, were more attentive to the practice of husbandry than the publishing of books on the subject; their attention being doubtless to carry on a private lucrative trade, without instructing their neighbours in their modes of cultivation; hence it happened, that whoever was desirous of copying their method of agriculture, was obliged to travel into their country, and make his remarks upon the spot. Their principal idea of husbandry, which was indeed just enough, consisted in making a farm resemble a garden as much as possible. The adoption of such an excellent principle at first setting out, led them of course to undertake the culture of small estates only, which they kept perfectly free from weeds, by continually hoeing and turning the ground, and rendering it rich and productive, by manuring it plentifully and in the most judicious manner. When by this means they had brought the soil to a proper degree of cleanliness, health and vigour, they ventured chiefly upon the culture of the more delicate grasses, as the surest mode of acquiring wealth in husbandry upon a small estate, without the expence of keeping many draught horses or servants; and the experience of a few years was abundantly sufficient to convince them, that ten acres of the best vegetables for feeding cattle, properly cultivated, would maintain a larger stock of grazing animals than forty acres of common farm grass. They also found that the best vegetables for this purpose were lucern, saintfoin, trefoil of most denominations, sweet fenugreek, buck, and cow-wheat, field turnips and spurrey. The political secret of their husbandry, therefore, consisted in letting farms on improvement. They also discovered eight or ten new sorts of manure. They were the first among the moderns who ploughed in living or green crops, for the purpose of fertilising the earth, and confined their sheep at night in large sheds built on purpose, whose floors were covered with sand or virgin earth, &c. which the shepherd carted away every morning to the compost dunghill. This useful and judicious practice has, since that period, been too little attended to by the practical farmer.

Our fatal domestic wars, during the reign of Charles I. changed the instruments of husbandry into martial weapons; but after the death of that unfortunate monarch, artful and avaricious men crept into the confiscated estates of the nobility, gentry, and clergy; and as many of these new encroachers had risen from the plough, so they returned with pleasure to their old profession, being chiefly animated by a love of gain. Plattes, Hartlib, Blythe, and others, seized this favourable disposition of the common people, and encouraged it by writings, which have since had few to equal them; nor was Cromwell wanting in leading his assistance in this important business. Sir Hugh Platt was one of the most ingenious husbandmen of the age in which he lived; and so great was his modesty, that all his works, except his *Paradise of Flora*, seem to be posthumous. He held a correspondence with all the lovers and promoters of agriculture and gardening in England; and such was the justice and honesty of his temper, that he always named the author of every discovery that was communicated to him. Perhaps no man, in any period in the history of the art, discovered, or at least brought into use, so many new sorts of manure, as his account of the compost and covered dunghill, and his observations on the fertilising qualities, contained in salt, street dirt, and the sullage of streets in great cities, clay, fuller's-earth, moorish earth, dunghills made in layers, fern, hair, burned vegetables, malt-dust, willow-tree earth, soap boiler's ashes, marle, and broken pilchards, sufficiently demonstrate.

Gabriel Plattes may likewise be esteemed an original genius in promoting the improvement of agriculture. He began his valuable observations in the time of queen Elizabeth, and continued them through the reigns of James I. Charles I. and during the first three or four years of the commonwealth. But notwithstanding the great merit displayed in his writings, the public shamefully suffered him to starve and perish in the streets of London, not having a shirt upon his back when he died.

Samuel Hartlib, a celebrated writer on husbandry, was highly beloved and esteemed by Milton, and other ingenious men of that time. In his preface to a work commonly called his *Legacy*, first published in the year 1650, he laments that no public director of husbandry was established in England by authority; and that we had not adopted the Flemish method of letting farms upon improvement. These observations of Hartlib procured him a pension of one hundred pounds a year from Cromwell, who was a great favourer of agricultural improvements, and the writer afterwards, the better to fulfil the intentions of his benefactor, procured Dr. Beati's excellent annotations on the *Legacy*, with several other valuable pieces from his numerous correspondents. The period in which this author flourished appears to have been an æra when English husbandry rose to great perfection; for the preceding wars had made the country gentry poor, and, in consequence, more industrious. They found the cultivation of their own lands to be the most profitable post they could occupy. But a few years afterwards, when the Restoration took place, all this industry and knowledge became useless, from the new system that was acted upon, and were exchanged for heedlessness and dissipation; from which husbandry passed almost entirely into the hands of common farmers. But the famous work usually attributed to Hartlib, and called the *Legacy*, was only drawn up at his request; and, after passing through his correction and revision, published by him. The real author of the treatise, which consists of one general answer to the following question: "What are the actual defects and omissions, as also the possible improvements, in English husbandry?" was a person of the name of R. Child, who seems to have been acquainted with many

ingenious improvers of agriculture at that period. Several other pieces succeeded the publication of the *Legacy*, which greatly improved and augmented the means of cultivation.

Grew, by the publication of the *Anatomy of Plants*, and shewing, in some measure, the economy of the vegetable system, contributed to enlarge the views and extend the enquiries concerning the nature of vegetation and the food of plants. But a principal writer who inspired his countrymen, with a desire of reviving the study of agriculture after the Restoration, was Evelyn; who being followed by Duckett, Ray, Dugdale, and several other authors, the art of cultivation was greatly recovered, and some new improvements introduced; and the establishment of the Royal Society which took place a few years afterwards, contributed still more fully to the advancement of it, by serving as a focus for collecting and recording valuable materials on the nature of vegetation and the principles of agriculture, as well as other subjects. About the year 1706, many additions and improvements were made in this useful art.—Mortimer, by his explanations of various practical modes of management; Bradley, by reducing the facts on vegetation into a more systematic order; Hales, by his valuable statical experiments and investigations; and Miller, by the publication of his dictionary, and other works, contributed very materially. But agriculture is probably still more indebted to the exertions of Tull, notwithstanding the evident utility of many of his positions, as by shewing the utility and importance of drilling, and frequent hoeing or stirring the ground about the roots of plants, and thereby keeping them clean and free from weeds, farmers have been induced to adopt more clean and sure methods of cultivating their arable lands. The introduction of this system of management, therefore, in some degree, forms an æra in the history of English husbandry.

In Ireland about the middle of the last century, the art of husbandry began to make considerable progress; that country having had very strong prejudices in behalf of a very wretched method of agriculture, until about that period, when Blythe opened the eyes of the people by his incomparable writings; since which a spirit of improvement has, more or less, been promoted and carried on with zeal and constancy by the nobility, clergy, and gentry of the kingdom. In proof of which it may be sufficient to observe, that a society for the encouragement of agriculture has been established, the transactions of which are highly respectable and important. In many respects, however, Irish husbandry is still much behind that of Britain.

At the conclusion of the peace of Aix-la-Chapelle, almost all the nations of Europe, by a sort of tacit consent, applied themselves to the study of agriculture; and continued to do so, more or less, amidst the universal confusion that soon succeeded. The French found, by repeated experience, that they could never maintain a long war, or procure a tolerable peace, unless they raised corn enough to support themselves in such a manner as that they should not be obliged to submit to harsh terms on one hand, or perish by famine on the other. Their king, therefore, thought proper to give public encouragement to agriculture, and was even present at the making of several experiments. The rich and great, of various ranks and stations, followed this noble example, and the ladies even put in for their share of fame in the laudable undertaking. Even during the hurry and distresses of the last war, some attention was paid to agriculture. Prize questions were then proposed annually in rural academies, particularly at the two academies of Lyons and Bourdeaux, and many alterations were made by the

society for improving agriculture in Brittany ; and after the conclusion of peace, matters were carried on with greater vigour.

The university of Amiens has made various proposals to the public for the advancement of husbandry ; while the Marquis de Tourbilly, a writer, proceeding chiefly on experience, undertook the principal direction of the Geographical Society, established at Tours, and the society of Rouen was also usefully employed on the same subject.

It may be added, that many societies were afterwards established by royal approbation, for the promoting of agriculture, and rendering the knowledge of it more general, and extended.

The convulsive shock of the Revolution, which has overturned many useful establishments, and retarded the advancement of many improvements, has not by any means prevented the progress of agriculture, as is evinced by the appearance of numerous papers on the subject in the transactions of different societies. Indeed, it would seem probable, that from the crippled state of commerce in that country, unusual attention has been paid to the art of cultivation.

The science of agriculture is publicly taught in the Swedish, Danish, and German universities. Nor has Italy been inactive. The Neapolitans of the present age have condescended to return back to the first rudiments of revived husbandry, and began to study afresh the agriculture of Crescenzo, first published in the year 1478. The people of Bergamo have pursued the same track, and given the world a new edition of the Ricardo d'Agricoltura di Tarcello, which was originally published at Mantua, in 1577.

The duchy of Tuscany has imbibed the same spirit. A private gentleman left his whole fortune to endow an academy of agriculture. Even Ferrara, a small territory in the papal dominions, has contributed its just contingent, and made some laudable attempts in this art. Animated with a desire that the people under his government should excel in husbandry, his Sardinian Majesty sent subjects to learn the practice of foreign countries, and made several attempts to establish a better method of agriculture among his subjects. In Poland, where a natural fertility of soil seems in some measure to dispense with the necessity of calling in improvements, M. de Bieleulki, formerly grand marshal of the crown, made many successful attempts to introduce the new or drill husbandry among his countrymen, and procured the best instruments from France, England, and other parts of Europe.

The Hollanders seem to have given the least attention to agriculture, if we except a few collateral instances, such as the draining of fens and morasses, and the making of canals and embankments ; and even these have probably proceeded more from the motives of self-preservation, than any particular turn towards husbandry.

In the year 1759, a society established itself at Berne, in Switzerland, for the advancement of agriculture and rural economy. That society consisted of many ingenious private persons, and also of some of great weight and influence in the republic ; most of them men of a true cast for the improvement of husbandry, being enabled to join the practice with the theory. They have published several useful papers on different matters connected with the subject. We must not omit to mention here, that Linnaeus and his disciples performed much in the north of Europe, particularly in discovering new, profitable, and well suited food for cattle. At the same time Sweden has bestowed successful labours on a soil, which was before looked upon as cold, barren, and incapable of melioration ; of this the memoirs published at

Stockholm will be a lasting monument. Denmark, as well as many courts in Germany have followed a similar example. His Danish Majesty encourages, in particular, the woollen manufactory ; and the late king sent three persons into Arabia Felix, to make remarks, and bring over such plants and trees as might be useful in husbandry, building, &c. Nor has the duchy of Wirtemberg, a country by no means particularly favourable to corn and pasturage, failed to contribute its assistance towards the improvement of agriculture, having some time ago communicated to the public its economical labours from the press at Stutgard. The learned of Leipzig, and Hanover, have not been inattentive to the art of supporting human kind ; for amidst the rage and devastations of war, the Journal d'Agriculture, printed at Leipzig, and the Recueils d'Hanovre, printed at that city, have been brought out.

Even Spain, naturally inactive on these occasions, in spite of all the prejudices of a bigoted religion, invited Linnæus, with the offer of a large pension, to superintend a college, founded for the sake of making new inquiries into the history of nature, and the art of agriculture.

But it is probably in our own country that agriculture has been most attended to, and received the greatest improvement ; from his Majesty having long, with a patriotic zeal and personal attention, worthy of the elevated situation which he holds, directed his views to the introduction of new and better modes of cultivation and rural improvement, as well as economy and convenience in the management of every department of agricultural business, connected with his varied and extensive farms, an example and encouragement has not only been held out, but an attention excited to the art, which could not possibly have been produced by any other less distinguished means ; so that there is reason to hope, from the spirit that now animates a great number of the nobility and gentry, that this useful art may, in a few years, be carried to a much greater degree of perfection than it has yet reached in any age or nation. In this view, the respectable society established at London, for the encouragement of arts, have already done much, and there is reason to hope, from their increased resources, that they may do much more. A vast variety of different machines for facilitating the practice of agriculture have been invented and presented to the public, in consequence of the large premiums and bounties which have been offered. The institution of societies in many different parts of the kingdom for the improvement of agriculture, and the endowment of a professorship at Edinburgh for the same laudable purpose, cannot but promote the study, and enlarge the boundaries of the science.

About the year 1767, Mr. Young commenced his valuable and well directed labours, which, by attracting the attention of practical agriculturists on those improved means of cultivation that are made use of in parts of the country, very remote from each other, and shewing the great utility of experimental inquiries on the subject, and by promoting and diffusing a taste for the science, from the easy and popular language of his writings, have rendered the most essential advantages to the agriculture of the nation. Doctor George Fordyce has likewise contributed in no small degree to the advancement of the science, by the publication of his Elements of Agriculture and Vegetation, a work in which the chemical principles of the various substances that enter into the composition of soils and manures are well explained.

Mr. Marshall too, by registering the local customs and practices of different districts, has afforded considerable service to the farmer, by bringing him acquainted with a variety of modes of rural management, which he could not otherwise have known.

The indefatigable exertions of Dr. Anderson in promoting the improvement of the more practical branches of the art, by his various detached writings, have likewise contributed much to its advancement; and Mr. Bakewell, by drawing the attention of the breeder and grazier to the most advantageous modes of breeding, rearing, and feeding, as well as the general management of different kinds of live stock, has greatly promoted the improvement of that intricate, though important branch of husbandry, which has since been brought still nearer perfection by the vast and well directed exertions of his Grace the Duke of Bedford, and other noblemen, equally zealous in forwarding the advancement of this difficult department of the art.

But neither the distinguished example of the Sovereign, the endeavours of provincial societies, nor the exertions of private individuals, with whatever zeal and attention they may be directed, are probably sufficient to extend the knowledge of husbandry to that degree which is necessary for its complete and radical improvement. This could only be fully accomplished by the powerful influence and expensive exertions of a national establishment instituted for the purpose. Such an institution has at last been brought forward and established by the intelligent and persevering efforts of Sir John Sinclair; to the honour of the country, the age, and the individual who suggested it. The institution of a Board of Agriculture and internal improvement has already contributed materially to the extension and advancement of the knowledge of rural affairs. The state of the art in the greatest part of the kingdom has been ascertained, a great variety of new and interesting facts and practices have been brought to view, and improvements in the instrumental and other departments suggested. Among these the elucidation of the principles and practice of draining or removing the injurious wetness of land, arising from springs and other causes, as laid down and explained by Mr. Elkington, is of great importance and deserving of notice, not only as the basis or foundation of many improvements in the art, but as leading to the convenient and easy application of water for irrigation and various other purposes. See BOARD OF AGRICULTURE.

In addition to this great source of improvement, the science of agriculture has lately derived essential advantages from the judicious application of the principles of other sciences.

In this respect the modern discoveries in chemistry and vegetation have been particularly important, as is evident from the works of Tillet and Hassenfratz, on the Continent, and of Priestley, Anderson, Kirwan, Dundonald, Darwin, and many others in our own country. By these our knowledge of the principles of vegetation, and the operations of different substances upon each other, has been much enlarged; and our acquaintance with the nature, formation, and modes of applying manures, or the food of plants, rendered more clear and satisfactory.

AGRIELÆA, in *Botany*, the wild OLIVE.

AGRIFOLIUM, or **AQUIFOLIUM**, in *Botany*. See ILEX and HOLLY.

AGRIGAN, or isle of St. Francis Xavier, in *Geography*, one of the Ladrones or Marianne islands, which is mountainous and large, being about 50 miles in circumference, and remarkable for its volcano. N. lat. 19° 4'. E. long. 146°.

AGRIGENTUM, or **AGRAGAS**, in *Ancient Geography*, a very famous city on the south coast of Sicily, near the spot which is now occupied by GIRGENTI. The principal part of the ancient city, as Mr. Swinburne and M. Houelle inform us, lay in the vale; and the present town of Girgenti is situated on the mountain, where was the citadel of Cocalus, and probably the ancient city. Agrigentum de-

rived its name from Agragas, the original name of the city, and also of a neighbouring stream, both which according to Polybius, were so called from the country, denominated *αγραγενία*, *acrage*, on account of its fertility. Some authors, ascending to fabulous antiquity, relate, that Dædalus fled to this spot for protection against Minos, and built many wonderful edifices for Cocalus, king of the island. Polybius (lib. ix. p. 560. Ed. Casaub.) says, that it was founded by a colony of Rhodians; that it was situated on a rock; and guarded by a fortress to which there was only one way of access; and that in the citadel there was a temple of Minerva, and also of Jupiter Atabyrius, who was worshipped under this appellation, in the isle of Rhodes. Thucydides (Hist. lib. iv. p. 380. and Annal. p. 23. Ed. Duker) informs us, that Agragas was founded by a colony from Gela, under the command of Arilthonus and Pythilus, in the 50th olympiad, or 579 years before Christ. It stood between the rivers Agragas and Hypsa, the former of which is now called Fiume di Gergenti, and Fiume di San Biaggio, and the latter Fiume Drago. The situation of Agrigentum was admirably adapted to the purposes of defence, commerce, and pleasure. It was guarded by a barrier of rocks, which were strongly fortified; sheltered by pleasant hills; and enjoyed the view of a spacious plain, watered by the Agragas, and a convenient port or emporium at the mouth of the river. Its free government and commercial spirit raised it to a degree of wealth and power, exceeded only by those of Syracuse. Its buildings of every kind were in a singular degree magnificent and splendid. Besides the temples already mentioned, that of Jupiter Olympius deserves particular notice. According to the account of Diodorus Siculus (lib. xiii. tom. i. p. 607. Ed. Weffeling,) it was 340 feet long, 60 broad, and 120 feet high. This historian extols the beauty of the columns, which supported the building, the admirable structure of the porticoes, and the exquisite taste with which the bas-reliefs and paintings were executed; but he adds, that the stately edifice was never finished. On the eastern side was exhibited the battle of the Giants, and on the west the capture of Troy, with the figures of the heroes in their appropriate habits. Cicero, against Verres, speaks of the magnificence of the statues which he carried away. Mr. Swinburne informs us, (*Travels*, vol. iv. p. 24.) that it has not now remaining one stone upon another; and that it is barely possible, with the liberal aid of conjecture, to discover the traces of its plan and dimensions. He adds, that the cathedral of Rome exceeds this celebrated Agrigentine temple more than doubly in every dimension; being 215 feet higher, 334 longer, and 433 wider. The other ruins which this writer surveyed, and which he has cursorily described, are those of the temple dedicated to Ceres and Proserpine, the peculiar patronesses of Sicily, the temple of Juno, the doric temple of Concord, which has all its columns, entablature, pediments, and walls entire, with part of the roof wanting, and which is now converted into a church, consecrated to St. Gregory, bishop of Girgenti; the temple of Hercules, the tomb of Thero, the temple of Esculapius, and the temple of Castor and Pollux. Near this is a large lake or fish pond, described by Diodorus at seven stadia in circuit and 20 cubits deep. It was cut in the solid rock, and water was conveyed to it from the hills; a great quantity of fish was bred in it for the public entertainments; swans and other wild fowl swam along its surface for the amusement of the citizens, and the depth of water prevented an enemy from surprising the town on that side. It is now dry, and used as a garden.

The inhabitants of Agrigentum, with all their advantages, were corrupted and enfeebled by their addictedness to luxury

luxury and pleasure; and fell a sacrifice to the power of their enemies. Empedocles attempted their reformation; and, as Diogenes Laertius informs us (l. 8. segm. 63. tom. i. p. 532. Ed. Meibom.), reproached them with devoting themselves every day to pleasure, as if they were to die on the morrow, and with building their houses, as if they were to live for ever. They are commended, however, for their hospitality, for which they were no less distinguished than for their magnificence and luxury. Gellias, a rich citizen, placed porters at his gate, to invite strangers to take their repast and rest in his house; and he is said to have once entertained 500 horsemen with meat, drink, and clothes. Phalaris, whose name is familiar to most readers, on account of his cruelty, and the brazen bull in which he tortured his enemies, usurped the sovereignty of Agrigentum, in the second year of the 52d olympiad, B. C. 571; but having possessed it for about 16 years, he shared the common fate of tyrants, and is said by some, to have been put to death in his own bull. After his death, the Agrigentines enjoyed their liberty about 50 years; at the end of which period, Thero assumed the sovereign authority. Under his government, which was just and moderate, Agrigentum was tranquil and secure; and in consequence of his union with his son-in-law, Gelo, king of Syracuse, in a war against the Carthaginians, Sicily was, for a time, delivered from her African oppressors. He was succeeded by his son, Thralidæus, who was deprived of the royal authority; and Agrigentum was restored to her old democratical government. Its tranquillity was interrupted by Ducetius, a chief of the mountaineer descendants of the Siculi; but restored by the co-operation of the Syracusans. The union of the Agrigentines and Syracusans did not long continue; and the former, after an unsuccessful contest, were obliged to submit to humiliating terms of peace. The enemies with whom they next had to contend were the Carthaginians; who routed their armies, took their city, and almost extirpated their race. The situation of Agrigentum, on that coast of Sicily which faced Africa, and its prodigious wealth, induced Hannibal to open his campaign with the siege of this city; and the event was peculiarly distressing to the inhabitants. Those who were able to remove, during the progress of the siege, which lasted 8 months, went to Gela; those who were left behind were committed to the sword, by the orders of Imilcon; and the riches of a city, which had contained 200,000 inhabitants, and which had never before been plundered, were rifled by the conquerors. The city itself was reduced to ruins. This calamitous event happened in the 92d olympiad, or about the year B. C. 410. Agrigentum remained for 50 years buried under its own ruins, till Timoleon, after vanquishing the Carthaginians, and restoring liberty to Sicily, collected the descendants of the Agrigentines, and sent them to re-establish the habitations of their ancestors. Such were the vigour and success of their exertions, that Agrigentum was soon in a condition to arrogate supremacy over all the Sicilian republics. At length, they and their leader Xenodocus, after some favourable operations against Agathocles, who was supported by the Carthaginians in his usurpation of the sovereignty of Syracuse, were reduced to the necessity of humbly suing to him for peace. This commonwealth afterwards took a strong part with Pyrrhus, king of Epirus, in his attempt upon Italy; and when he left Sicily to the mercy of her enemies, threw itself into the arms of Carthage. During the first Punic war, Agrigentum was the head-quarters of the Carthaginians; it was defended by a numerous garrison, under the command of Hanno; and, after resisting a blockade of seven or eight months, was at

last surrendered to the Consul Lævinus, in consequence of the treachery of Mutines, about the year before Christ, 198. This officer being deprived of his commission by Hanno, because he envied and dreaded his increasing reputation, meditated revenge; and conspiring with the Numidians, who were attached to him, against Hanno, he placed himself at their head, and having seized one of the gates, put the Romans in possession of it. Hanno, and a few officers, made their escape; but the rest of the army were murdered by the guards, which Lævinus had posted in all the avenues to intercept their flight. The chiefs of the Agrigentines were, by the consul's order, first scourged with rods, and then beheaded. The common people were made slaves, and sold to the best bidder. The spoils of the pillaged city were put up to sale, and the money returned to the public treasury. Livy, hb. xxvi. c. xl. tom. iii. p. 1138. Ed. Drakenb. Polybius, lib. i. p. 15—19. After this period, Agrigentum is seldom mentioned in history; nor is it easy to ascertain the precise time of the destruction of the old city, and the building of the new one. See **GIRGENTI**.

The Agrigentines had a port to the east of the mouth of the small river, Agragas; called *Emporium Agrigentunorum*.

AGRIGINTINE salt, in *Natural History*, a kind of eatable salt, famous among the ancients for its not crackling in the fire as common salt does. It might probably owe this quality to the fineness of the powder, in form of which it was generally used.

AGRII, in *Ancient Geography*, a people of Ethiopia, called by the Greeks *Cynanogii*.

AGRILIA, a town of Gaul on the river *Liger*.

AGRILIUM, a town of Asia Minor, in Bithynia, to the south-east of Nicæa.

AGRIMONIA, **AGRIMONY**, in *Botany*, a genus of the *dodecandria digynia* class and order, of the natural order of *Senticosæ*, and of the *Rosuceæ* of Jussieu. Its characters are, that the calyx is a one-leaved, five-cleft, acute, small, superior, permanent perianthium, fenced with an outer calyx; the corolla has five, flat, emarginate petals, with the claws narrow, inserted into the calyx; the stamina are capillary filaments, shorter than the corolla, inserted into the calyx; the anthers small, twin and compressed; the pistillum is a germ inferior; the styles simple, of the length of the stamina; the stigmas obtuse; no pericarpium; the calyx contracted at the neck, and hardened; the feeds are two and roundish. N. B. The number of stamina is very uncertain, 12, 10, 7. The agrimonia of Tournefort has the outer calyx growing to the inner; two feeds; stamina 12 to 20; fruit fenced with bristles. The agrimonoides T. has the outer calyx detached; one seed; stamina about seven. Of this genus there are five species; viz. 1. *A. eupatoria*, common agrimony, with stem leaves pinnate; the end-lobe petiolate; the fruits hispid. Of this species there are two varieties; *A. minor*, or white agrimony, and *A. odorata*, or sweet-scented agrimony. 2. *A. reptans*, creeping agrimony, with stem-leaves pinnate or winged; the end-lobe sessile; the fruits hispid. 3. *A. decumbens*, with leaves pinnate hispid; stem procumbent; fruits every way hispid-hooked. 4. *A. agrimonoides*, three-leaved agrimony, with stem-leaves ternate, and fruits smooth. 5. *A. parviflora*, small-flowered agrimony, with stem-leaves pinnate, leaflets many and lanceolate, petals half as long again as the calyx, and fruits hispid. The first species has a cylindrical, roughish, hairy stem, from one to three feet high; hairy leaves, covered with rising dots, and segments ending in small reddish glands, interruptedly pinnate; composed of six or seven pairs of leaflets,

leaves, the smallest pair being entire, the others deeply serrated: the fruit stalks are surrounded at the top with a sort of outer calyx, which is cloven into five spear-shaped irregular segments, hairy at the edges and on the outside: within this the fruit-stalk is covered with white upright bristles, above which is a circle of numerous green awns hooked at the end, and within these the proper calyx of five leaves, spear-shaped, glandular without, marked within with three green lines, terminating with a reddish point: the petals are egg-shaped, concave, slightly notched at the end, twice as long as the cup: the stamina from 5 to 12: the germen crowned with the calyx, and a yellowish fleshy receptacle; the flowers yellow, in a long thin spike; and one seed is frequently abortive. This grows in the borders of corn fields, shady places and hedges in Great Britain and most parts of Europe: it is perennial, and flowers in June and July. The root in spring is sweet-scented; an infusion of it is used by the Canadians with great success, in burning fevers; and Dr. Hill says, that an infusion of six ounces of the crown of the root in a quart of boiling water, sweetened with honey, and drank, to the quantity of half a pint, three times a day, is an effectual cure for the jaundice. He recommends to begin with a vomit, to keep the bowels soluble, and to persist in the use of the medicine as long as any symptoms of the disease remain. The leaves have a slightly bitterish roughish taste, accompanied with an agreeable, though weak, aromatic flavour: the flowers have a stronger and more agreeable smell, resembling, when fresh gathered, that of apricots. They readily give out their virtues to water and rectified spirit: and in distillation with water, the leaves afford a yellowish essential oil, with the odour of the herb. This plant has been principally regarded as a mild astringent and corroborant, and many recommend it as a deobstruent, especially in hepatic and other visceral obstructions. Instances occur of its successful use in cases where the liver was much enlarged and indurated. It has been used with advantage in hæmorrhages, and for giving tone to a lax and weak state of the solids. In cutaneous disorders, particularly the scabies, it is said to have great efficacy: for which purpose it was given infused with liquorice in the form of tea: but, according to Alston, it should be always exhibited in the state of powder. The country people sometimes apply the leaves by way of cataplasm in contusions and fresh wounds. When the plant comes into flower, it will dye wool of a good bright full nankeen colour; and if gathered in September, it yields a darker yellow: and for the purposes of the dyers, it deserves further trial. In the Berlin acts, it is recommended for dressing leather. Sheep and goats eat it: Cows, horses and swine refuse it.

The white agrimony is smaller than the common sort, and grows naturally in Italy. The sweet-scented agrimony grows near four feet high; its leaves have more wings than the former; they are longer and narrower, and have sharper serratures; when handled they emit an agreeable odour. The infusion of the leaves is an agreeable cooling tea to persons in a fever. This is a native of Italy, and was cultivated here in 1640.

Marty's Miller's Dict. Lewis Mat. Med. p. 28. Murray Mat. Med. vol. iii. p. 148. Withering's Bot. Arr. vol. ii. p. 443. Woodville's Med. Bot. vol. iv. p. 125. Dr. Cullen (Mat. Med. vol. ii. p. 31.) after observing, that agrimony is now omitted by the London and Edinburgh colleges, adds, that it still has more attention given to it than it deserves. It has some astringent powers; but they are very feeble. Dr. Cullen expresses his surprize on finding Dr. Haller and Prof. Murray repeating after an author of so little credit as Chomel, that he had cured a scirrhus liver by

means of agrimony; and it seems equally frivolous in Spielmann to tell us, that Forrelius had by agrimony broke down a stone in the bladder, and brought it away in pieces by the urine.

The second species is of humble growth; has longer and narrower pinna than the former, and the spikes of flowers are very short and thick. It multiplies faster than the common sort, and the seeds are much larger and tougher. It has been furnished from the botanic garden at Paris, whither it was sent by Mr. Tournefort; and cultivated here by Mr. Miller, in 1739. The third species is a native of the Cape of Good Hope, and is usually monogynous. The fourth species is a native of Italy and Caraiola, in moist woods and among bushes; and was cultivated in 1739, by Miller. The fifth species is a native of North America; and cultivated in 1766, by Mr. James Gordon.

These plants are hardy and perennial, and will thrive almost in any soil or situation, and require no other care than keeping them clear from weeds. They may be propagated, by parting their roots in autumn, and planting them at a distance of at least two feet; or by seeds sown in autumn.

AGRIMONIA *Molucca*, is a variety of *BIDENS pilosa*.

AGRIMONOIDES, in *Botany*, a species of AGRIMONY.

AGRIMONTE, or AGROMONTE, in *Geography*, a small ruined town in the Basilicata, in the kingdom of Naples. E. long. 22° 34'. N. lat. 40° 25'.

AGRIMONY, in *Botany*. See AGRIMONIA.

AGRIMONY, *hemp*, in *Botany*. See EUPATORIUM.

AGRIMONY, *bastard-hemp*. See AGERATUM.

AGRIMONY, *water-hemp*, in *Botany*. See BIDENS.

AGRINAGARA, in *Ancient Geography*, a town of India, on this side the Ganges; placed by Ptolemy in long. 118° 15', and lat. 22° 30'.

AGRINIUM, a town placed by Polybius in Ætolia. It was on the left of the river Achelous, and north-east of Thermus.

AGRIOCARDAMUM. See CARDAMINE.

AGRIOCASTANUM, the same as EARTH-NUT, popularly called *pig-nut*, and *arnot*.

AGRIOCINARA, in *Botany*, a name used by some authors for that species of wild ARTICHOAK, the root of which is used instead of the *costus nigra*.

AGRIOCOCCIMELA, or *prunus sylvestris*. See PLUM-tree.

AGRIOMELA, a name for the *crab APPLE*.

AGRIOMELANZANION, in the *Botanical Writers of the Ancients*, a word that has perplexed many of the later writers. The Arabian writers, Avicenna and Serapion, used the word *bedengian* for the fruit of the *pomum amoris*, a kind of esculent nightshade, or *solanum*, called by the old Greek writers, as Theophrastus, &c. *strychnus*, and only distinguished from the other *strychni*, or nightshades, by its being described as wholesome, not poisonous. From this Arabic word *bedengian*, the Italians formed their word *melanzana*, and the late Greek writers their *melanzanion*, which they used as the name of the same fruit. This, when the plant was cultivated in gardens, was probably larger and fairer than when it grew wild; but in this latter state was not less used, but was distinguished by the term *agriomelanzanion*. If the Greeks, who use this word, or the *melanzanion*, would have appropriated them to the *pomum amoris*, and distinguished these from the other nightshades, they would have done service to the world.

AGRION signifies the PEUCEDANUM, called also *agriophyllum*.

AGRION, in *Entomology*, a division of the **UNOCATA** class of insects in the system of Fabricius, comprehending five species, and many varieties, which are referred to the genus of **LIBELLULA** in the Linnæan system, by Gmelin. They are characterized by having their wings erect when quiescent, eyes remote, and the exterior lacinie of the lip bilid.

AGRIONIA, **AGRANIA** or **AGRANIA**, in *Antiquity*, feasts instituted at Argos, in honour of a daughter of Proetus. Plutarch, in describing this feast, says, that the women searched here for Bacchus, and not finding him, they relinquished their pursuit, saying, that he was gone to the muses. They supped together, and after their repast proposed to one another ænigmas. These mysteries signified, that learning and the muses ought to accompany good cheer; and that a veil is thrown over excess on such occasions by the muses. This feast was celebrated in the night, and those who attended it were decorated with a garland of ground-ivy. It was probably the same that was celebrated at Thbes, in honour of the dead. At Orchemenes, no women, who belonged to a family, become odious on account of any barbarous action, were allowed to attend this feast.

AGRIOPHAGI, compounded of *αγριος* wild, and *φαγω*, I eat, in *Antiquity*, a name given to those who fed on wild beasts. Pliny places them in Ethiopia. Ptolemy refers them to India, on this side the Ganges, and ascribes the appellation to the people whom he calls *Pulinds*.

AGRIORIGANUM, in *Botany*, wild marjoram.

AGRIOSELINUM, signifies wild PARSLEY.

AGRIPALMA, a name given to MOTHER-WORT.

AGRIPENNE, in *Ornithology*, a name given by Buffon to the *EMBERIZA oryzivora*, of the Linnæan system.

AGRIPO, in *Geography*, a peninsula, commonly called **NEGROPONT**.

AGRIPPA, a name applied, among the ancients, to children born in an unusual or irregular manner; particularly such as come with the feet foremost, instead of the head.

They were called *agrippæ*, according to Pliny, on account of their being (*agre parti*) born with difficulty. Salmastius derives it from the Greek *αγριος*, *venari*, and *ἵππος*, *equus*, q. d. a hunter of horses.

Daventer has a particular chapter of *agrippas*, or infants coming with their feet foremost, which, according to him, is one of the most convenient and safe ways for a mature birth.

Agrippa gives the denomination to an unguent, described in the *Antidotarium Nicolai*, and in several other dispensatories, supposed, by some, to have been invented by Agrippa, king of Judæa, but, as others suspect, by Julius Agrippa, a Roman physician.

AGRIPPA, in *Biography*, an astronomer of Bithynia, lived towards the close of the first century. Ptolemy in his *Almagest* informs us, that Agrippa observed a conjunction of the moon with the Pleiades on the 29th of November, in the fourth year of the 217th olympiad, or A. D. 92.

AGRIPPA, *Henry Cornelius*, a physician, philosopher and divine, of various and great attainments, but of an eccentric disposition, which exposed him to as great vicissitudes of fortune, was born at Cologne, September 14th, A. D. 1486, of a noble family, which had been long in the service of the house of Austria. In early life, he was secretary to the emperor Maximilian, and continued his military service in the army for seven years. As a soldier he dis-

tinguished himself by his valour, and obtained the honour of knighthood: nor was he less distinguished by his application to literature and science. Of eight languages, which he acquired in his youth, six were so familiar to him, that he could even use them fluently in public discourse. Soon after he forsook the military profession, he obtained the united academic honours of doctor in law and physic. The philosopher's stone, as it was called, or the art of transmuting baser metals into gold, engaged his attention; and in the pursuit of it, he had no doubt of commanding the admiration of the multitude, and the patronage of princes. With these romantic views he commenced his travels; and in 1507, being then in the 21st year of his age, he visited France, and in the following year spent some time in Spain. Upon his return to France, he resided at the college of Dole in Burgundy, and read public lectures in divinity; in consequence of which he was appointed regent with a salary. Notwithstanding his popularity, as a public lecturer, the freedom and novelty of some things which he advanced alarmed the monks, and rendered it necessary for him to surrender his office at Dole. In 1510 he passed over from France into England, and during his stay in London, published a treatise on the epistles of St. Paul. His next remove was to his native city, where for some short time he read lectures in scholastic theology: he afterwards resumed his military station in the emperor's army in Italy; but he was soon induced by Cardinal de St. Croix to abandon this connexion, and to attend as a theologian at the council of Pisa. After the dissolution of this assembly, he read lectures in divinity, sometimes at Turin, and sometimes at Pavia. But he was constrained by the difficulty of procuring decent subsistence for his wife and son, to whom he was affectionately attached, to leave Pavia, and to try what his friends at Cologne could do for him. In 1518, their interference availed in procuring for him the office of syndic, advocate, and orator of the city of Mentz. Here he provoked the enmity of the monks, partly by maintaining the dangerous error, that St. Anne, the mother of the Virgin Mary, had only one husband, whereas it was the popular opinion that she had three; and partly, by exerting himself in the vindication of a poor woman, who had been accused to the inquisition of witchcraft. In 1520, he left Mentz, and returned to Cologne, where he lost his wife in 1521. Restless in his temper, he removed to Geneva; and here, in 1522, married a second wife, whom he supported by the practice of physic, as long as he continued in this city; but in 1523, he exercised his profession at Friburg in Switzerland, and in 1524, settled at Lyons, as physician to the mother of Francis I. This lady, apprehending that he could, by his Astrological talents, predict future events, desired to be informed concerning the affairs of France. Agrippa was disgusted by the application: the princess, displeased by his refusing to satisfy her curiosity, discontinued his pension, and this circumstance involved him in new difficulties. His next settlement was at Antwerp, where his singular talents attracted general notice, and procured for him various offers of distinguished patronage. In 1529, he was honoured with invitations from Henry VIII. of England, the chancellor of the emperor, an Italian marquis, and Margaret of Austria, mistress of the Netherlands. He accepted the proposal of the latter, and became historiographer to the emperor Charles V. Agrippa's eccentric genius would not allow him to enjoy at ease the honour and emolument to which he was entitled. In 1530, he published "a Treatise on the vanity of the Sciences," which was a severe satire on the monks, theologians, preach-

ers, and members of the universities: but Erasmus, in speaking of this work, says, "that on every occasion he lashes vice and commends virtue; but there are persons who can bear nothing but praise." On this occasion, the emperor, probably incited by his sister, whom the monks had prejudiced against Agrippa, withdrew his pension, and suffered him to be imprisoned for debt at Brussels, in 1531. After the death of Margaret, Agrippa was released from prison; but he published another treatise at Antwerp, "on Occult Philosophy," which revived the animosity of his enemies. The design of this work was to explain, on the principles of the emanative system, the harmony of the elementary, celestial, and intellectual worlds. But the clergy discovered or suspected error and heresy; and succeeded in delaying the publication of a third edition. But in 1533 it was published at Cologne; and another edition appeared in 1542, which is the most complete, and the most scarce. This publication was accompanied with an "Apology for himself to the Senate of Cologne," which excited violent resentment, and obliged him to withdraw to Bonn; where he is said to have divorced his third wife, whom he had married after the death of his second in 1529, by whom he had five sons. The peculiarity of his temper, and the narrowness of his circumstances, impelled him once more to try his fortune in France; and accordingly he returned to Lyons in the year 1535. Here his reception was very different from what he expected: he was imprisoned on account of some satirical papers which he had published against the mother of Francis I. Having obtained a release, he retired to Grenoble in the same year, 1535, and there he died, either in the hospital of the city, or in the house of a friend.

As Agrippa was an adept in chemistry, and professed to be an astrologer, he was reputed to be a magician, and supposed to be accompanied by a genius, or devil, in the shape of a black dog. That he was not possessed of the grand art of alchemy is plain, from the poor circumstances in which he lived and died. He possessed wonderful talents for acquiring the knowledge of languages, and a versatility of genius, which enabled him to assume and exercise a variety of professions. He was a soldier and a philosopher; a municipal officer and a lecturer; a lawyer and a physician; an astrologer and a divine. Nevertheless, he was always embarrassed and distressed; and though one flattering prospect after another presented itself, he could not so avail himself of them as to procure a permanent competence. Such was the liberality of his mind, and the extent of his knowledge, that he might have been eminently useful in instructing and reforming the age in which he lived, if he had not been fickle and selfish. Whilst he applauded Luther, he continued in the communion of the church of Rome, and obtained the commendation of the pope for his fidelity. "If he had any decided principles, they were those of that mystical system of philosophy, which finds a sublime and spiritual meaning in all the operations of nature, and leads the soul, (according to his own language, in his Epistles) to a mysterious intercourse, and an essential and immediate union with God. The most valuable service which he performed to society was that of chastising the follies of ignorance and the vices of priestcraft, in his satirical writings, which entitle him, in the scale of letters, to a place, though of inferior distinction, with Erasmus. In fine, Agrippa, though an extraordinary, and on the whole a splendid character, was rather a dazzling meteor than a steady and useful luminary."

His principal writings, besides those we have mentioned, and several other pieces, were, "A Dissertation on Original

Sin," designed to prove that the fall of our first parents was the consequence of inchoate love: "A Declamation on the excellence of Women," written to gratify Margaret of Austria: "A Commentary on the Art of Raymond Lully," which is as unintelligible and ridiculous as the original. A mutilated edition of his works was printed at Lyons, in 8vo, in 1586. They were published in French at Paris, in 1726. His "Vanity of the Sciences" was printed in 4to, at Antwerp, in 1530, 1532, 1539; and the last edition has a head of the author. It was printed at Paris, in 8vo, in 1531; and has been translated into Italian and French. Gen. Dict.

AGRIPPA, surnamed CASTOR, flourished under the Emperor Adrian, about the year 132. Eusebius (Ecc. Hist. lib. iv. c. 7. p. 120. Ed. Vales.) represents him as an excellent writer, who had ably confuted the errors of Basilides; but his works are lost, and no considerable fragment of them remains.

AGRIPPA I., HEROD, was the son of Aristobulus, by Berenice, the daughter of Herod the Great. He was brought up at Rome, with Drusus, the son of Tiberius; but having been reduced to penury by his liberality and profusion, he was under a necessity, upon the death of Drusus, of retiring to Judaea, where he immured himself in a castle of Idumea, and determined to starve himself to death. His wife, Cyprus, the daughter of Phasael, and the granddaughter of Herod the Great, diverted his purpose, by procuring for him some present relief. He also obtained temporary assistance from Herod, the husband of Herodias, who made him a magistrate of Tiberias; but afterwards upbraiding him at a banquet with his kindness, Agrippa was offended, and withdrew to Flaccus, governor of Syria, and afterwards to Rome. Here he attached himself to Caius Cæsar; and having incensed Tiberius, by some expressions that signified a wish for his death, and which were reported to the emperor, he was thrown into prison and loaded with chains. Upon the death of Tiberius, and the accession of Caius Caligula, he was immediately released and distinguished by tokens of favour. The new emperor arrayed him in purple; exchanged his iron chain for one of gold of the same weight; put a diadem on his head, conferred on him the title of king, and granted him the tetrarchy of his late uncle Philip, and that of Abylene, in Syria, which had formerly belonged to Lyfania, A. D. 37. After continuing a year at Rome, he obtained leave to visit his new dominions; and embarking at Puteoli, he sailed over to Alexandria, where his magnificent entry provoked the inhabitants, and exposed him to insult and indignity. The conduct of Flaccus, the Roman governor, who refused him the redress which he demanded, and who was a violent persecutor of the Jews in this city, was reported by Agrippa to the emperor; and by him he was ordered to be recalled, stripped of his wealth, and banished into an island of the Archipelago, where, at length, he was put to death. Herod Antipas, who had, on a former occasion, treated Agrippa with contempt, beheld his elevation with jealousy and envy; and accompanied by his wife, Agrippa's sister, he took a journey to Rome, in order to obtain similar honours; but Agrippa, in the mean while, accused Herod to the emperor, as having been concerned in the conspiracy of Sejanus, and thus procured his disgrace and banishment to Lyons, in France. Caius conferred the treasures of Herod, and also the tetrarchy which he had possessed 43 years, on Agrippa. A circumstance, however, occurred at this time, A. D. 39, which was a very severe test of Caligula's attachment to Agrippa. The emperor had ordered his statue to be erected and worshipped in the sanc-
tuary

ture of the Jewish temple at Jerusalem. The Jews resisted the execution of the order; and Petronius, the governor, delayed it. Whilst the emperor was reading Petronius's letter, in which he excused his delay, and requested further instructions, Agrippa presented himself as an intercessor in behalf of the Jews; but so great were his agitation and distress, that he fainted away, and was carried off to his own palace. As soon as he recovered, he wrote a pathetic letter to the emperor, preserved in the works of Philo (tom. ii. p. 586. Ed. Mangey), in which he declares, that, for his own part, he should not out-live the profanation of the sacred temple, and that it would undoubtedly complete the ruin of the Jewish nation. Cains relented; and after some further artifices on the part of Agrippa, the order was countermanded. The attempt, however, was afterwards renewed; but the assassination of the emperor, A. D. 41, prevented the dreadful consequences which the execution of it must have produced.

Agrippa, who was now at Rome, contributed to the accession of Claudius; and was remunerated by the confirmation of all Caligula's grants; by the addition of Judæa, Samaria, and the Southern parts of Idumæa; and by several edicts in favour of the Jews. He was, likewise, honoured with the consular insignia, and indulged with the privilege of paying his compliments to the emperor in Greek; a ceremony which was usually performed in the Latin language. At his request, the kingdom of Chalcis, in Syria, was bestowed on his brother and son-in-law, Herod. All these grants were engraved on copper, and set up in the capitol; and Agrippa was thus possessed of territories, which extended to the farthest limits of the dominions of his grandfather, Herod the Great. Agrippa, soon after the establishment of Claudius, returned to his kingdom, where he manifested a zealous attachment to the religion of his country; and caused the golden chain, which Cains had given him, to be hung up in one of the most conspicuous parts of the temple, as a monument to posterity of the instability of human affairs. He deposed and appointed several high-priests in a short time. His government was conducted, according to Josephus, with a great degree of moderation and clemency; but Dion Cassius, (lib. lix. tom. ii. p. 928. Ed. Reimari) says, that Agrippa was reckoned one of Caligula's advisers in his cruel and tyrannical measures. If he had been less anxious to please the Jews, he would not probably have disgraced his reign by the persecution of the Christians, who seemed to have been very quiet at Jerusalem ever since St. Paul's conversion. The martyrdom of James the Less, the brother of John, and the imprisonment of Peter, are justly ascribed to him. But with his zeal for the Jewish rites and practices, he blended Heathen observances, which gave offence; and, in conformity to the Roman taste, he exhibited shows of gladiators and public games. At Cæsarea, whither he went with a splendid and numerous retinue, for the purpose of celebrating some games in honour of Claudius Cæsar, he appeared in a brilliant garb on the theatre, and addressed an elegant speech to the deputies of Tyre and Sidon, who appeared before him to make an apology for some offence, and to solicit his future favour. These ambassadors, and other attendants on the occasion, expressed their adulation in the most extravagant terms; exclaiming, that his voice was that of a god, and not a man, and practising some attitudes that approached to those of adoration. The king, so far from restraining these expressions of flattery and homage, manifested his approbation of them; he was immediately seized with a violent disorder in his bowels, probably similar to that of Herod, his grandfather, and attended

with the same circumstances, which, after a torture of five days, terminated in his death, A. D. 44. in the 54th year of his age, and the 7th of his reign. He left a son of the same name, and three daughters, viz. Berenice, who was married to Herod, her father's brother; and Mariamne and Drusilla, both unmarried, but contracted; the former to Julius Archelaus, the son of Chalcias, or Elebias, probably of the Herodian family; and the latter to Epiphanes, the son of Antiochus, king of Comagene, but afterwards married to Azizus, king of Emesa. Mariamne abandoned Archelaus, her husband, to marry Demetrius, a noble and rich Jew of Alexandria, and one of the chief magistrates; by whom she had a son, named Agrippinus. Drusilla left her husband, and renounced the Jewish religion to marry Felix, governor of Judæa: by him she had a son, called Agrippa, who perished with his mother, in the conflagration occasioned by mount Vesuvius, under the emperor Titus. His death was celebrated at Cæsarea with tumultuous rejoicings, and his memory insulted with the vilest outrages. Joseph. Antiq. Philos. Legat. Ant. Un. Hist. vol. iii. p. 272—279. 8vo.

AGRIPPA II. HEROD, was the son of Agrippa I.; educated at Rome, and at the death of his father was 17 years old; and therefore thought too young for succeeding in the kingdom. Judæa, on this occasion, became a Roman province, and was committed to the care of Cuspius Fadus, who received instructions to punish those who had insulted the memory of the late king. When Herod, the uncle of Agrippa, died, the superintendency of the temple and sacred treasury, the privilege of nominating the high-priest, and the kingdom of Chalcis, were conferred upon him. He resided chiefly at Jerusalem, where, with his sister Berenice, he heard Paul's defence before Festus, the Roman governor, (recorded Acts, xxv. xxvi.) and owned himself almost convinced by it. Agrippa displeased the Jews by building a palace, which overlooked the temple, and exposed their service to the view of Festus and the Romans; but to prevent this intrusion, they erected a partition wall, which the king ordered to be demolished. On application to the emperor, and by the intercession of Poppæa, the wall was allowed to remain. At the commencement of that revolt, which terminated in the destruction of the Jewish nation, Agrippa, attempting to appease the Jews, was so insulted by them that he was obliged to secure himself from their violence, by leaving Jerusalem. He afterwards joined Cestius, the Roman governor; and when Vespasian arrived in the province, he met him with a considerable reinforcement, and accompanied him to Rome, when he took possession of the empire. During the siege of Jerusalem, he was very serviceable to Titus; and after its reduction, he and Berenice (with whom he was suspected to have had an incestuous intercourse) retired to Rome. His kingdom is said to have been enlarged by the influence of Titus, who was passionately attached to his sister Berenice; and who would have married her, if the Romans had not resisted his design, partly because she was a Jewess, and partly because she was royally descended. He was, therefore, obliged to send her away. As for Agrippa, he was the last of the Herodian race that bore the royal title, and is supposed to have died at Rome, as some say, A. D. 90; according to others, A. D. 94; and as others say, A. D. 100. Joseph. Ant. Bell. Jud. Ant. Un. Hist. vol. iii. Gen. Diët.

AGRIPPA, *Marcus-Vipsanius*, was a person of obscure origin at Rome, educated with Octavianus, afterwards Augustus, distinguished as his companion and friend, confided as his favourite general, in all the vicissitudes of his life, and lamented by him at his death. Although his family

mily is not known, he must have risen into early notice, as his first wife was Attica, the daughter of Pomponius Atticus. When the war broke out between Marc Antony and Octavianus, Agrippa rescued Salvidienus, the general of the latter, in circumstances of imminent danger; and concurring with him, drove Lucius, Antony's brother, into the city of Perugia, and invested the place before he had time to reflect on his own perilous situation. Being afterwards appointed commander of the fleet of Octavianus, he took Hiera, one of the Eolian islands, and afterwards obtained, by his skill and valour, a complete victory over the whole fleet of Pompey, for which he was honoured with a standard and a rostral crown. On another occasion, when Antony had assembled his fleet at Actium, Agrippa interrupted his convoys; and having made several descents on the coast of Greece, which harassed the enemy, and dispersed a squadron that was advancing to join Antony, he directed the famous naval engagement that ensued, and by which Octavianus secured the empire. Octavianus, having thus acquired the supreme power, consulted his two friends Agrippa and Mecænas, whether he should retain his superiority or surrender it to the senate. Agrippa advised the restoration of the Roman liberty; but Mecænas's advice to retain his power was more agreeable to the views of Octavianus, and was therefore followed; and yet Agrippa still retained his master's favour. In the year before Christ 28, they were colleagues in the consulate, which was the second time of Agrippa's bearing that office; and the coalition was renewed in the following year.

Agrippa by marrying Marcella, the emperor's niece, was received into the imperial family; and in their command of the army, Octavianus and Agrippa possessed equal authority and distinction. His munificence was signally displayed in the buildings which he erected at Rome; the most remarkable of which were his portico for the use of popular assemblies, and the famous temple called the PANTHEON. When Octavianus was dangerously ill in the year before Christ 23, he committed to him his ring, which being considered as a preference of Agrippa for his successor, offended Marcellus, and rendered it necessary on the recovery of Augustus, to remove him from court by an honourable exile to the rich government of Syria. Upon the death of Marcellus, Agrippa was recalled to Rome, where he was married to Julia, the daughter of Augustus and Marcellus's widow, and contributed to restore the tranquillity of the city. The next service he performed was to oppose the Germans, who had made an incursion into Gaul, and to drive them back beyond the Rhine. The Cantabrians, who were vigorously combating for liberty, demanded greater exertions; but they were at last completely reduced. A triumph, which he declined, was decreed to him by the senate on this occasion; but in recompence of his service, Augustus associated him with himself in the tribunitian power, which was conferred on him for five years; he was also appointed joint Censor, and concurred with Augustus in that reduction of senators, which was called a Reform of the Order. His two children by Julia were also adopted by the emperor in the year before Christ 17. After three years he was sent to appease the dissensions that had occurred in the east. As he was passing through Ionia with Herod the Great, the Jews complained to him, that they were hindered in sending their tribute to the temple at Jerusalem; that they were obliged to serve in the army; and had other hardships imposed upon them inconsistent with the privileges granted them by the Romans. Agrippa gave them and their adversaries a solemn hearing, and in court confirmed to them their privileges; and gave orders, that no one should molest them in the observation of

their peculiar rites and customs. Having also appeased some troubles which had arisen in the Cimmerian Bosphorus, he returned home, and a triumph was again decreed him, which he refused. After this period no person that was not of the imperial family ever obtained a triumph in Rome. The tribunitian power having been renewed to him for five years more, he was next sent to Pannonia, and having quieted the disturbances in that country, he returned to Italy, where he was attacked in Campania, with a fever that soon terminated in his death, A. U. C. 742. B. C. 12. in the 51st year of his age. Augustus, as soon as he heard of his illness, left the sports which were then exhibited by his two grandsons in honour of Minerva, and hastened to visit his dying friend; but he had expired a few minutes before his arrival. The news greatly afflicted him, and he lamented the loss of the greatest general of his age, the wisest minister, and the most faithful and disinterested friend. His body was conveyed to Rome, and buried in Augustus's own mausoleum, near Marcellus; the emperor pronounced his funeral oration, and declared, that he would not be separated, even after his death, from two persons, whom he so tenderly loved in his life. By his will he bequeathed the fine gardens and bath, which were called by his name, to the Roman people; but his principal heir was Augustus. His surviving children were one daughter by his first wife Cæcilia Attica, named Agrippina, and married to Tiberius; and three sons and two daughters by his third wife Julia. Two of the sons died in their youth; and the other, Posthumus Agrippa, was sacrificed to the jealousy of Tiberius soon after his accession; one of the daughters, viz. Julia, was married to Lucius Paulus; and the other Agrippina, to the celebrated Germanicus. Agrippa's fame sufficiently established by his great actions, has derived an accession from the immortal records of poetry. Virgil, in his anticipation of the battle of Actium, gives the following dignified sketch of this commander:

“Parte alia ventis et dis Agrippa secundis,
Arduus, agmen agens: cui, belli insigne superbum,
Tempora navali fulgent rostrata corona.”

Æn. viii. 682.

“Agrippa seconds him with prosp'rous gales,
And with propitious gods, his foes assails:
A naval crown, that binds his manly brows,
The happy fortune of the fight foreshows.”

DRYDEN.

Horace also addresses to him an ode (Od. vi. lib. 1.) in which he confesses his own inability to celebrate worthily his great exploits, a task fitter for the Homeric pen of Varius. Sueton. in Aug. Op. tom. i. p. 157, &c. Ed. Pitife. Dion. Cass. Op. lib. 45-54. tom. ii. p. 419, &c. Ed. Reimari. Ant. Univ. Hist. vol. xii. p. 96-172. 8vo. Crevier's Hist. Rom. Emp. vol. iii. Gen. Biog.

AGRIPPA, *Mænenius*, was consul of Rome, A. U. C. 251. Ante Christ. 503. He obtained the honours of a triumph for a complete victory, which he and his colleague P. Posthumus gained over the Sabines. When the people resisted the tyranny of the Patricians, in the consulate of Virginius and Veturius, he was deputed to effect a reconciliation; and it is said that, on this occasion, he pronounced the famous apologue of the stomach and members, by which, with promises of a redress of grievances, he gained his purpose. In their demand of magistracies of their own (who were the tribunes) to protect their rights, he acquiesced; and he advised the senate to comply. He died, at an advanced age, with a character highly esteemed for wisdom and integrity; but so poor, that his relations intended to bury him in a private manner. The people, how-

ever, assented themselves at two ounces of brass each, in order to procure for him a magnificent funeral; and when the senate, unwilling to sanction this mode of raising money, decreed a sum for the purpose out of the treasury, the people refused to receive back their money, but ordered it to be paid to the children of the deceased. Livy, lib. ii. c. 16. 32. 33. p. 308-381-389. Ed. Drakenb. Dionys. Halicarn. tom. i. p. 390. 340. Ed. Oxon.

AGRIPPA, in *Ancient Geography*, a colony of Bithynia in Asia, formed by the *Agrippenses*.

AGRIPPADES, a name given by Herod to ANTHEDON.

AGRIPPINA, the elder, in *Biography and History*, was the daughter of Marcus Agrippa, and wife of Germanicus Cæsar. When the German Legions revolted in the beginning of the reign of Tiberius, she attended her husband in the camp; and though she had the charge of an infant son and was pregnant with a second child, it was with difficulty that she was persuaded to retire from the danger that threatened them; and the commiseration which her situation excited induced the revolters to return to their allegiance. On another occasion, when the victorious Germans were on their march to make an irruption into Gaul, and it was proposed to demolish the bridge on the Rhine, near Treves, in order to stop their progress, Agrippina prevented it, and thus secured a retreat for Cecina and his legions. When they arrived, she met them at the head of the bridge, returned them thanks for their valour, and distributed among them clothes and medicines. The jealous spirit of Tiberius took offence at this conduct, which merited commendation, and aggravated the dislike with which she was regarded at court, in consequence of her disagreement with Livia, the mother of the emperor. She afterwards attended her husband in his difficult and perilous expedition to the Eastern provinces of the empire, and was the sorrowful witness of his last conflict, which happened at Antioch, A. D. 19. The dying prince conjured her by the memory of a husband once dear to her, and by their children, the product of mutual love, to restrain her great spirit, yield to her hostile fortune, and take care at her return to Rome not to irritate those in power by an ill-judged rivalry. Agrippina gathered the ashes of her deceased husband, and braving the dangers of the sea in the worst season of the year, hastened home, and landed at Brundisium, carrying the sepulchral urn, and accompanied by two of her children. The mournful spectacle produced an universal groan amidst the multitude, who waited her landing; nor were the lamentations of relations to be distinguished, as Tacitus has described the scene, from those of strangers, nor of men from those of women. Agrippina's spirit was unshaken; after her return to Rome, she forgot the dying charge of her husband, and fell a sacrifice to the wicked arts of Sejanus. By his agents he persuaded her, that it was the intention of the emperor to poison her; and she had the imprudence to disclose her suspicion to the reigning tyrant. This circumstance induced him to determine upon her ruin; and immediately after the death of his mother, Livia, he sent to the senate letters of accusation against her and her son Nero. The senate hesitated; but Sejanus furnished the evidence that was necessary for their condemnation. She was banished to the isle of Pandataria, now Santa Maria, lying off the coast of Terracina; and her son Nero was banished to the neighbouring isle of Pontia, where he soon died. Drusus, her second son, was confined in the lower apartments of the palace, and there famished. Agrippina survived about four years; and her death, which happened through want of food, either voluntarily or by compulsion, A. D. 33, was announced by Tiberius to the senate; and the savage tyrant accepted the

thanks of this body, for not ordering her to be strangled, and her body to be exposed like that of a common malefactor. This pretended clemency was more than counterbalanced by a charge against her of adultery with Asiatic Gallus, whose death, he said, had been the cause of hers. Her known character for chastity repelled this infamous charge; and Tacitus sums it up in a few words, by observing, that "impatient of equality and greedy of domination, she had banished female frailties by her masculine ambition." Her remains were brought in great pomp from Pandataria, by her son Caligula, soon after his accession, and deposited in the mausoleum of Augustus, and all sorts of honours were paid to her memory—"an instance, says an excellent biographer, of filial piety, which is one of the best things recorded of that imperial monster!" Tacit. Annal. lib. i. ii. iii. iv. Crevier's Hist. of the Emperors, vol. ii. iii.

AGRIPPINA, the younger, was the daughter of Germanicus, by the preceding Agrippina, and the mother of Nero. In the year 28 she was married by Tiberius to Cn. Domitius, belonging to the imperial family, but faithless, ferocious, and debauched; and as Agrippina was no less profligate than her husband, Domitius might well observe, as Suetonius informs us, (in Nero c. 6. tom. ii. p. 374. Ed. Pitisc.) when he was congratulated on the birth of a son, that from him and that princess nothing could be born but some monster, fatal to the human species; and his declaration was too exactly verified by the crimes and cruelties of Nero. Agrippina was distinguished with honours by her brother Caligula, at his accession; but lost her husband before the end of that reign. Before his death, however, she had an intrigue with M. Lepidus, who was the companion of Caligula in his debaucheries, and who aspired to the empire; and was concerned with him in his conspiracy against her brother. For this crime she and her sister Julia were deprived of the honours, which were conferred upon them at the commencement of this reign; their possessions were forfeited and sold by an auction in Gaul, at which Caligula presided; and they were banished to the isle of Pontus. Agrippina was compelled to carry in her arms the urn that held Lepidus's ashes all the way from Gaul to Rome; and at the same time Tigellinus, under the charge of adultery with her, was exiled. In the reign of Claudius, Agrippina was recalled from banishment, and married to a second husband, whose name was Crispus Passianus, a celebrated orator, who had been twice consul, and who was very rich; and whom his wife poisoned in order to obtain possession of his wealth, which he had bequeathed to her by his will. After the death of Messalina, the third wife of Claudius, this emperor was induced A. D. 48, by the persuasions of Pallas, to marry his niece Agrippina, who exercised the new powers she thus acquired with a degree of haughtiness, injustice and cruelty, that might have been reasonably expected from her well-known character. She did not blush, says Tacitus, to prostitute herself to Pallas, in order to secure her son's elevation, and to gratify her own insatiable thirst for gold; and because Lollia Paulina had been her rival for the imperial dignity, she was banished and put to death; and Dion Cassius (lib. lx. tom. ii. p. 970. Ed. Reimari.) says, that her head was brought to Agrippina, who opened and examined the teeth, in which there was some particular mark, that she might thus identify her person. She manifested her wisdom, however, in using her influence for recalling Seneca from banishment, and placing her son Nero under his tuition; but regardless of every principle of justice, she engaged the interest of Pallas, and prevailed with the weak emperor to adopt her son Domitius, then (*viz.* A. D. 50.) called Nero Claudius Cæsar, though he had a son of his own, Britannicus, to whom he was affectionately

fectionately attached, and to give him the prerogative of an elder brother. On this occasion Agrippina herself received an additional honour in the surname of Augusta. Britannicus was deprived of every opportunity of recommending himself to his father, and reduced by the arts of the empress to the most depressed condition. Agrippina ostentatiously exercised her authority in establishing a colony at the capital of the Ubii, where she was born, and in giving it the name of *Colonia Agrippina*, or *Agrippinensis*; but it has been for many ages called Cologne, and the name of Agrippina has been suppressed. Her vanity also led her to obtain leave to enter the capital in a car, like those in which the priests were carried, and on which all sacred things were deposited. In order to gratify her avarice, as well as her pride, she caused Statilius Taurus to be accused, and provoked him by false charges to suicide, that she might get possession of his fine gardens. At length, Claudius began to be sensible of the crimes of Agrippina; and after drinking freely he happened to drop an expression, which alarmed her, *viz.* that it was his fate first to bear the wickedness of his wives, and then to punish them. She had also a rival in Domitia Lepida, Nero's aunt, a woman no less unprincipled and debauched than herself; and she contrived, by accusing her of sorcery and magic and other crimes, to destroy her. She then directed the efforts of her malice against Narcissus, who was the declared friend of Britannicus and a powerful freedman; and succeeded first in driving him from court, and at length in procuring his death, as well as that of Julius Silanus, who was of high rank, and a descendant of Augustus. In the mean while, having removed Narcissus, the vigilant guardian of Claudius's life, she determined to sacrifice the emperor himself. His attachment to Britannicus was undissimulated; and he resolved upon soon giving him the toga virilis, "that Rome, as he said, may at last have a true Cæsar." Agrippina's fears accelerated her purpose; and she applied to Locuita, who had been lately condemned for administering poison after she had been long spared as the useful instrument of tyranny, to prepare the poison by which she designed to get rid of the emperor. The poison was mixed with mushrooms, a favourite dish of Claudius, and very speedily produced effect. Having dispatched the emperor, A. D. 54, she pretended sorrow on the occasion; and affecting tenderness for Britannicus, whom she kept in a state of retirement, she caused Nero, accompanied by Burrhus, to appear before the soldiers, and to be acknowledged as emperor.

The enormities with which Nero's reign commenced were sanctioned by her example, and encouraged by her authority. To her Nero paid great respect and deference, calling her "the best of mothers;" and the senate granted her the privilege of being preceded by two lictors, and the dignity of priestesses of Claudius, whom she had poisoned. These tokens of respect served only to inflame the ambition of Agrippina, whose design it was to reign under her son's name. Accordingly she privately and by concealment attended the debates of the senate, and at a public audience of ambassadors, she attempted to ascend the throne with her son; but was reasonably restrained by the suggestion of Seneca, that he should descend and meet her. But she soon perceived that her power began to decline, and this was a mortification, which her proud and violent spirit could not well bear. To divert the evil, she at one time raved and menaced, and at another resorted to every complying and soothing measure. The disgrace of Pallas was very hostile to her influence; and her son's respect diminished in proportion to the degree in which his independent power was established by the removal and death of Britannicus, and his consequent rescue from the

danger of a rival. When she attempted to pay court to the soldiers and nobles, Nero deprived her of her guards and honours, excluded her from the palace, and obliged her to retire, solitary and neglected, to her own palace. Nevertheless, she was again restored to favour, which she endeavoured to secure by various artifices; and, as it is said, by some compliances, which are the most odious and reproachful that can be conceived of in the relation of a mother and son. Poppæa's influence over Nero soon became paramount to every other; nor was it restrained even by the guilt of parricide, to which she stimulated him. But how to perpetrate this horrid deed, without exposing himself to public detestation, was a subject of serious deliberation. At length a galley was prepared by Anicetus, commander of his fleet, which might easily admit water, and founder; and Agrippina was enticed on board in the Baian bay. The stratagem, however, did not succeed; for though Acronia, the companion of Agrippina, lost her life, Agrippina herself got safe to shore. The crime could no longer be concealed; and it became necessary to complete what had been begun. Accordingly Anicetus, with a body of mariners, surrounded the house where she had taken refuge; and entering her chamber, dispatched her with many wounds, A. D. 59. To the assassins, it is said, she presented her womb, and bade them strike that part which had harboured such a monster. She was buried the same night without any ceremony, and had no tomb whilst Nero lived; but after his death some of her surviving servants erected a mean monument over her remains, near the high road from Rome to Misenum. Nero affected contrition after the event; but afterwards wrote a letter to the senate, or rather procured one to be written by Seneca, for which he has been much blamed, accusing her of many crimes, and charging her with a conspiracy, which rendered her death a fortunate event to the Roman people. The senate fervently decreed thanks to the gods for his escape, and the day on which Agrippina was born to be marked in the calendar as an inauspicious day. Her crimes were of the most atrocious kind, and her memory has been execrable. Nevertheless she is said to have been a princess of some learning, and to have written memoirs of her life, referred to by Tacitus and the elder Pliny. Suetonius in *Calig. Claud. and Nero. Tacit. Annual. lib. xii. 14. Crevier's Hist. Rom. Emp. vol. iii. and iv. Vofs. de Hist. Lat.*

AGRIPPINIANS, in *Church History*, the followers of Agrippinus, bishop of Carthage, in the third century, who first introduced and defended the practice of *rebaptization*. *Arnd. Lex. Ant. Eccl. p. 465.*

AGRIS, or *Agrisa*, in *Ancient Geography*, the name of a town of Carmania, between the mouth of the Sarus and the strait that leads to the Persian gulph. Long. 96° 30'; and lat. 23°, according to Ptolemy.

AGRIUS, in *Entomology*, a species of the SPHINX *Zygæna*, which is black, with wings pointed with green; the primores black, and the posterior blue; found in Surinam.

AGRIZALA, a town of Asia Minor, belonging to the Tectosagi of Galatia. Long. 2°. Lat. 41° 30', according to Ptolemy.

AGRIUM, in the *Materia Medica of the Ancients*, a name given to an impure sort of *natrum*. The purer sort of this salt they call *kalmyrhaga*, and the coarser and dirtier kind *agrium*. The former of these they had from Media, the latter from Thrace.

AGROIRA, a name which some have given to *Attalea* of Lydia.

AGROCA Road, in *Geography*, lies to the west of the *Bastimentos*, near *Portobello*, on the Spanish main, and is well

well secured for eight or nine ships; where they are landlocked by several islands, which appear at sea like part of the main. Malham's Naval Gazette.

AGROM, a disease frequent in Bengal, and other parts of the Indies, wherein the tongue chaps and cleaves in several places, being also extremely rough, and sometimes covered with white spots. The Indians are very fearful of this disease, which they attribute to extreme heat of the stomach.

Their remedy is, to chew the black-seeded basilica, drink some chalybeated liquor, or the juice of large mint.

AGRÒPOLI, in *Geography*, a town of the Principato Citra of Naples, on the gulph of Salerno; 26 miles west-fourth-west of Cangianno; and 22 miles south-south-east of Salerno. E. lon. 14° 54'. N. lat. 40° 22'.

AGROSPI, in *Ancient Geography*, a town of Ethiopia, situated, according to Ptolemy, on the banks of the Nile.

AGROSTEMMA, *Άγρου στεμμα*, the *garland of the field*, in *Botany*, a genus of the *decandria pentagynia* class and order, and natural order of *caryophyllei*. Its characters are, that the calyx is a one-leaved, coriaceous, or leather-like, tubulous, five-toothed, permanent perianthium; the corolla has five petals, with claws of the length of the tube of the calyx, and border spreading, obtuse and undivided; the stamina are ten awl-shaped filaments, five alternately later than the other five, inserted into each claw of the petals, the anthers simple; the pistillum an ovate germ, with filiform, erect styles, of the length of the stamina, and simple stigmas; the pericarpium an oblong-ovate, covered, one-celled, five-valved capsule; the seeds very numerous, kidney-shaped, and dotted; the receptacles free, as many as seeds; the interior ones gradually longer. *N.B.* The *A. githago* has not a crowned corolla, or blossom, as the others have. Dr. Smith (*Flor. Brit. vol. ii. p. 493.*), observes, that this genus is scarcely distinct from the *Lycniss*. There are four species, viz. 1. *A. githago*, corn campion or cockle, which is hirsute or hairy, with calyx longer than the corolla, petals entire, or slightly emarginate, and naked. 2. *A. coronaria*, rose campion, tomentose, with leaves ovate-lanceolate, petals slightly emarginate, crowned and ferrate. 3. *A. flos Jovis*, umbellate rose campion, tomentose, with emarginate petals and flowers in a corymb or kind of spike. 4. *A. cali rosa*, smooth campion, with leaves linear-lanceolate, emarginate petals, crowned. The *first* species is a common annual weed, in corn-fields, and flowers in June or July; the seeds are black, with a surface like shagreen, and appear in the microscope like a hedge-hog rolled up. The *second* species is biennial, a native of Italy, the Valais, and Siberia; but so long an inhabitant of English gardens, that it is become a kind of weed. Of this plant there are three varieties, one with deep red, another with flesh-coloured, and a third with white flowers; but they are not much esteemed, as the double rose-campion, which is a line flower, has excluded the others from most good gardens. The single rose campions are sufficiently propagated by their self-sown seeds. The variety with double-flowers, having no seeds, is propagated by parting the roots in autumn, and planting them in a border of fresh undunged earth, at the distance of about six inches; they should be watered gently till they have taken root: afterwards wet, as well as dung, is injurious to them. In spring they should be removed into the borders of the flower-garden, where they will be very ornamental, whilst they flower in July and August. The *third* species grows naturally on the Swiss and Piedmontese mountains, and in the Palatinate, and was cultivated in 1739, by Mr. Miller. It flowers in July, and the seeds ripen in September. It

will thrive best in a moist soil and shady situation. The *fourth* species is annual. It is a native of Italy, Sicily, and the Levant; but being a plant of little beauty, it is preserved in botanic gardens merely for variety. It was cultivated in 1739, by Mr. Miller.

AGROSTIS, formed from *αγρος*, a *field*, *bent-grass*, in *Botany*, a genus of the *triandria digynia* class and order, and of the natural order of *gramina* or grasses. Its characters are, that the calyx is a one-flowered, bivalve, acuminate glume, or husk tapering to a point; the corolla, bivalve and acuminate, with one valve larger than the other; the stamina have three filaments longer than the corolla, with forked anthers; the pistillum is a roundish germ with two reflex villous styles, and stigmas longitudinally hispid, or as Dr. Smith says, plumose: the pericarpium is a corolla growing to the seed, not gaping; the seed is roundish, pointed at both ends, with the corolla adhering closely to it. Professor Martyn enumerates 35 species, and Gmelin 42 species. They are distributed into two classes; the *aristate* or those with awns, and the *mutica* or naked, without awns. To the first class belong the following. 1. *A. spica venti*, silky bent-grass, with entire petals, the outer petal having a stiff, straight and very long awn, and the panicle spreading. 2. *A. interrupta*, interrupted-spike B. with bifid petals, the outer awned, the panicle attenuated, contracted and interrupted. 3. *A. miliacea*, millet B. with the outer petal terminating in a stiff straight awn of a moderate length. 4. *A. bromoides*, with a simple narrowed panicle, pubescent corolla, and awn straight, longer than the calyx. 5. *A. australis*, southern B. with the panicle approaching to a spike, the seed ovate and pubescent, and awn of the length of the calyx. 6. *A. arundinea*, reedy B. with oblong panicle, outer petal, villous at the base, and furnished with a writhed awn, longer than the calyx. 7. *A. calamagrostis*, branching B. with thickened panicle, the whole of the outer petal woolly, awned at the tip, and branching culm. 8. *A. serotina*, late B. with oblong mucronate floscules, and culm covered with very short leaves. 9. *A. rubra*, red B. with the flowering part of the panicle very spreading, outer petal smooth, awn terminal, spiral and recurved. 10. *A. spiciformis*, spiky B. with the panicle resembling a spike, two-awned flowers, one awn inserted into the receptacle, jointed and longer than the other, which is straight, and inserted below the tip of the corolla, which is rough. 11. *A. hirsuta*, hairy B. with the panicle approaching to a spike, culm and leaves hirsute, glumes of the corolla awned on the back, and bifid at the tip. 12. *A. matrella*, with the flowers in racemes, outer valve of the calyx bent in, and the tip of the keel only gaping. 13. *A. canina*, brown B. with ovate coloured calyx, naked corolla, an incurved awn on the back of the petals, and prostrate culms a little branching. To the class of awned agrostis, Gmelin refers the following species, viz. *A. vinealis* and *A. cinna*, of Martyn, *A. alpina*, with setaceous leaves, compact panicle, rough and coloured calyx, and exterior petal with a jointed awn in its back. *A. laevis*, with elongated calyxes, awn of the petals recurved at the back, and prostrate culms with four branches. *A. gigantea*, with the upper part of the panicle first flowering very wide, rough calyxes, the exterior petal smooth, the back slightly awned above, and an erect culm. *A. dubia*, with equal smooth calyxes, corolla mucronated below the apex, and setaceous leaves. *A. filucoides*, with setaceous leaves, spreading panicle, and petals with awn bent in at the base twice as long as the calyxes. *A. filiformis*, with filiform leaves and culms, approximate panicle, and smooth floscules awned at the base.

To the *second* class of Agrostis without awns are referred the

the following species, viz. 14. *A. stolonifera*, creeping B. or black squitch, with branches of the panicle spreading, naked, creeping culm, and equal calyces. Dr. Smith describes this species as having a compact panicle, ramose creeping culm, congested flowers, and calyces equal, lanceolate and pubescent. 15. *A. capillaris*, fine B. with panicle capillary, spreading, flexuose, and calyces equal, subulate smooth (slightly roughish, Gmel.) coloured. 16. *A. sylvatica*, wood B. with panicle contracted, calyces equal, those of the barren flowers shorter than the corolla, and those of the fertile ones twice as long. 17. *A. alba*, white B. with panicle loose, calyces equal, and culm creeping. 18. *A. pumila*, dwarf B. with panicle on one side, culms erect in bunches. 19. *A. minima*, least B. with panicle filiform, flowers, elliptic, retuse and awnless, and villous corolla. 20. *A. tenaciflora*, tough B. with panicle contracted, filiform; flowers linear, and valves parallel. 21. *A. virginica*, virginian B. with panicle contracted; leaves rolled inwards, subulate, rigid, standing out. 22. *A. mexicanu*, Mexican B. with panicle oblong heaped; calyces and corolla acuminate and nearly equal. 23. *A. purpurascens*, purple B. with panicle contracted, elongate, branches pressed close upright, and florets unequal and acuminate. 24. *A. indica*, Indian B. with panicle contracted, racemes lateral, erect, alternate. 25. *A. ciliata*, ciliate B. with glumes of the calyx angular and ciliate. 26. *A. panicca*, bearded B. with panicle subspiked; branches and branchlets fasciated; valves of the calyx and one of the corolla awned, that of the corolla very short. 27. *A. lenta*, forked B. with spikes subtern, umbellate, floscules awnless, oblong, acute, calycine valves subequal, leaves and sheaths smooth. 28. *A. complanata*, flat-stalked B. with spikes umbelled, smooth; outer calycine valves awned; flattened leaves and smooth sheaths. 29. *A. pungens*, prickly B. with panicle contracted, leaves involute, stiff, pungent, the upper ones obliquely opposite, and branching culm. 30. *A. vinealis*, short-awned B. with culms ascending, calyx coloured, awn nearly straight, from below the middle of the back, about as long as the calyx. 31. *A. ovata*, ovate-panicked B. with outer petal awned below the tip; panicle ovate, contracted and spikeform. 32. *A. odorata*, sweet B. having spikes, with the florets pointing one way, heaped together, awnless. 33. *A. plicata*, plaited-leaved B. with leaves plaited, and spike linear, awnless. 34. *A. cinna*, with panicle contracted, awnless, flowers acuminate, with one, two or three stamens, and leaves flat, scabrous. 35. *A. diandra*, with panicle elongate, contracted; flowers subulate, awnless, diandrous or two-staminate; and convolute leaves. Gmelin has omitted some of the preceding awnless species, and added the following, viz. *A. verticillata*, with straight panicle, interrupted by radiated rigid verticilli or whorls. *A. stricta*, with stiff panicle, having flowers, and an erect culm. *A. linearis*, with subquatern digitated spikes, and adpressed alternate, unilateral floscules. *A. procera*, with the foot-stalks of the panicle, racemose and somewhat erect, and the flowers hairy and lanceolate. *A. coronandiano*, with the panicle ovate, patent, the foot-stalks simple; second flowers, and equal, acute, glossy calyces. *A. aspera*, with contracted panicle; lateral, alternate, stiff racemes, and rough leaves. *A. avenacea*, with an erect, very slender panicle; and the awns twice longer than the calyx. *A. glomerata*, with bifid, glomerate, terminal spikes, and clawed plumose bractæ. *A. lateralis*, with bifid, lateral, solitary spikes, and clawed plumose bractæ. Dr. Stokes has observed that this is an artificial genus, and that the species which are chiefly distinguished by the presence or absence of the awn in the corolla, and which is inconstant, are not precisely ascertained. He therefore recommends particular attention to the open or closed

state in which the valves of the calyx are found, immediately after the shedding of the pollen and the ripening of the seed, and likewise to the flowers, whether they are scattered or clustered.

The first species, which is annual, is common in sandy corn-fields, and flowers in June and July. It is liable to be smutted. Horses and goats eat it; but sheep refuse it. The second is, according to Haller, a variety of the former: it is annual, and a native of France, Italy, Switzerland, Carniola, and Germany. The third is a native of Montpellier, Spain, and Siberia, was introduced by M. Thouin, in 1778, and resembles the first. The fourth is perennial, and grows wild about Montpellier. The fifth is a native of Portugal. The sixth is a native of many parts of Europe, and is perennial. Haller and Scopoli rank it amongst the *arundines*. The Kalmuc Tartars weave mats of it, and thatch their houses with it. Goats will almost die of hunger rather than eat it. The seventh resembles the former: is perennial; and a native of Germany and Switzerland and about Verona; these two species are referred by Gmelin to the genus *CALAMOSTRIS*, and are the *C. arvensis* and *C. arundinacea*. The eighth species was observed by Seguier, near Verona. The ninth is common in Sweden, and is found in Scotland, in low pastures. The tenth and eleventh were found in the Island of Teneriffe, by Masson. The twelfth is found in the sandy lands of Malabar. There are two varieties of the thirteenth, the rough and the smooth, which Dr. Stokes in Withering's arrangement, makes a distinct species under the name of *A. alpina*, and so classed by Gmelin: this is found plentiful in the higher downs in Dorsetshire and the higher parts in the new forest of Hants, and flowers in May and June. But Dr. Smith (Flor. Brit. vol. i. p. 78.) refers the *A. canina*, (α) of Hudson to the species of *A. canina*, and also the *A. vinealis* of Withering; and says it is perennial, flowering in July, and found in meadows and moist pastures: and the *A. canina* (β and γ) of Hudson, and *A. alpina* of Withering, above described, to a distinct species, viz. *A. setacea*, bristly B. with lanceolate calyces and corolla awned at the base; the awn geniculated and the radical leaves setaceous. It is perennial, flowering in July and August, and found on dry heaths, frequently in the west of England, and on the sea-coast near Weymouth. The fourteenth is perennial, a native of most parts of Europe, and found in moist meadows and pastures, and also in stiff cold arable lands, where it is very troublesome; for when such lands are broken up and fallowed, the roots are separated with difficulty from the adhesive soil. It flowers in July and August. Hudson joins this species with the capillaris, pumila, alba, and sylvatica, under the name of polymorpha; and Gmelin queries whether these and also the virginica are not varieties of the same species, owing their difference merely to the soil; some have supposed that this is the famous ORCHESTON GRASS. The fifteenth is very common, but chiefly grows on poor, dry and sandy land, and is disliked by cattle, as are the bents in general; it flowers in May and July. Gmelin queries whether it be not a species of alopecurus. Some have supposed that the *A. capillaris* of Linnæus, is the same with the *A. vulgaris*, which has a spreading panicle, branches bare at the base; florets numerous, calyx inner valve smooth, outer ferrulated upwards; blossom inner valve, but half the size of the outer; deciduous. Linnæus confounded these two plants; but the error was discovered by Dr. Smith. In general habit, says Withering, the plants are very much alike; but the real *A. capillaris* has the stem, leaves and husks of the calyx quite smooth, as well as every other part of the plant, whilst in the *A. vulgaris* the stem-leaves are rough, and the husks of the calyx are ferrulated on the

keel, as they are in every other British species of agrostis, except the *minima*. Again, in the *capillaris*, the valves of the blossoms are equal, but in the *A. vulgaris* the inner valve is only half the size of the other. Dr. Smith (Flor. Brit. vol. i. p. 79.) characterizes the *A. vulgaris*, or fine B. as having a spreading panicle, small branches divaricated and capillary, equal calyces, interior petal twice as short as the other: and to this species he refers the *A. vulgaris* of Withering; the *A. capillaris* of others, and the *A. polymorpha* (α) of Hudson, and as varieties, the *A. canina* of Withering, the *A. panicula* of Linnæus, and the third variety of Withering's *A. vulgaris*. It is perennial, flowers in July, and is found in meadows, pastures and ploughed fields. The sixteenth species is perennial, and grows in moist woods, as Bishop's-wood, Hamblead, and also in Hornsey wood, near London. It flowers in June and August. The seventeenth is perennial, and grows in ditches, marshes, and moist meadows. Withering mentions four varieties; one with panicle branches, crowded with florets at the base, which flowers in June and July, and is found in wet ditches, bogs, and marshes; a second, with calyx, both valves ferrulated, supposed to be the preceding plant, when growing in a drier situation, and found amongst wheat, in light sandy loam, flowering from July to September; a third, with the inner valve of the calyx only ferrulated upward, found in loamy soil, amongst wheat, and in very light sandy soil under the Norfolk course of turnip husbandry, and also elsewhere amongst potatoes; flowering from July to September; the fourth has both valves of the calyx ferrulated, the inner only on the upper half: it is found amongst wheat, in light land; flowering from July to September. The three last varieties constitute the greatest part of what is called squitch, in light arable lands; which are called white squitch, to distinguish it from *A. nigra* and *A. stolonifera*, which are called black squitch, or couch. Dr. Smith enumerates only two varieties, viz. the *A. alba*, and *A. sylvatica*, i. e. marsh and wood B. which he refers to this same species. The eighteenth is a native of Iceland, Sweden, Germany, Switzerland, England in dry places, Wales and Scotland; found in poor barren soil, e. g. heaths near Harrowgate, perennial, and flowering in July. The nineteenth is a native of France and Germany, and has been discovered by Mr. Stillingfleet, in Wales; it is common in sandy pastures on the south-west coast of Anglesea: By some it is denominated spring-plant, and said to flower early in March and April, and ripen its seed in May. Dr. Stokes refers this species to the *POA*. The twentieth is perennial, and a native of the East Indies. The twenty-first is an elegant little plant, and called by Browne crab-grass. The twenty-second is a native of South America, flowering the second year, having the appearance of cinna, and introduced in 1780, by Mr. G. Alexander. The twenty-third is a native of Jamaica; the twenty-fourth is a native of India, introduced in 1773, by the Earl of Bute; the twenty-fifth a native of Japan. The twenty-sixth comprehends the *panicus* and *monspeliensis* *ALOPECURUS* in the Linnæan system; the first grows in marshes and wet pastures, and the second in a dry soil, to which the difference is probably owing. The twenty-seventh is a native of the East Indies, found there by Dr. Koenig, and introduced in 1778 by Sir Joseph Banks. It is annual, and flowers in July and August. The twenty-eighth is a native of Jamaica; introduced in 1779; perennial, and flowers in July and August. The twenty-ninth is a native of Arabia and Barbary, used by the Arabs in the hæmorrhoids; perennial, and found in dry places off the coast in the country of Nice. The thirtieth is a native of Switzerland and the north of England; found on heaths, meadows and moist pastures, which have been long in turf.

Some parts of Hounslow heath abound with it. Dr. Smith (Flor. Brit. vol. i. p. 78) refers the *A. vinealis* of Withering to the *A. canina*. The thirty-first is a native of New Zealand: the thirty-second of Cochinchina, near the coast, where it is dried and used for perfuming their clothes; the thirty-third a native of the suburbs of Canton. The thirty-fourth and thirty-fifth have been referred by some to *CINNA*. Dr. Withering mentions some other species, viz. *A. palustris*, with the husks of the calyx equal, and the outer valve of the blossom twice the length and breadth of the inner; awn straight, much shorter than the blossom, fixed a little beneath its point; some consider this as an awned variety of the *A. alba palustris* of Hudson, but Dr. W. regards it as a distinct species. It is found in swamps and moist ditches; perennial, and flowering in June and July. *A. pallida*, with the valves of the calyx unequal; the inner valve of the blossom hair like, very short, awn somewhat longer than the blossom, fixed below its middle; it is sufficiently distinct from both the *A. alba* and *A. capillaris*; found in the New Forest, Hants, and flowering in May and June. *A. littoralis*, with panicle somewhat spike-like, the husks of the calyx awned; first found on the Norfolk coast by Sir Joseph Banks, perennial, flowering in June. The *A. littoralis*, sea-side B. according to Dr. Smith (*ubi supra*) has linear-lanceolate awned calyces, naked corolla; awn sub-terminal straight, and decumbent culms. It is perennial, flowers in August, and is found in clayey sea-shores; in salt-marshes near Cley, Norfolk. *A. nigra*, with scattered panicle, branches bare at the base, florets few; inner valve of the calyx smooth, and creeping root; it is different from the *A. stolonifera* of Linnæus, to which some have referred it; found in marley, clayey, and other cold wet soil, both in grass and under tillage; perennial, flowering from July to October. *A. maritima*, with large, rather spreading panicle; longer branches naked, shorter ones crowded with florets at the base; inner valve of the calyx smooth, outer ferrulated upwards; gathered by Dr. Pulteney in the sand on our southern sea-coasts; perennial, flowering in June and July. The *A. vulgaris* has been already mentioned. Martyn's Miller's Dict. Withering's Bot. Arr. vol. ii. p. 124-134.

For the propagation and culture of several of the above species; see GRASS. For other species, to which the name has been applied, see AIRA, ALOPECURUS, CALAMAGROSTIS, CENCHRUS, MELICA, MILIUM and SCHÆNUS.

AGROSTOGRAPHIA, compounded of *αγρως*, grass, and *γραφω*, description, in *Physiology*, the history, or description of grasses, or plants of the grassy kind.

AGROSTOGRAPHIA is also the title of a learned and laborious work of John Scheuchzer, containing an exact description of about 400 species of grass; particularly dog's-tooth, cyperus, cyperoides, rushes, &c. all disposed in a new method; yet the history is far from being complete.

AGROTIRI, in *Ancient Geography*, the most southern promontory of the island of Cyprus, east of Linafol. It is a small peninsula, connected with the continent by a very narrow tongue of land, and is now called cape De Gatti, on account of the great number of cats kept by the monks, who, in the 4th century, obtained permission to establish themselves there, as well as on mount Olympus, on condition of keeping a great many of those animals for hunting snakes, which had multiplied to an alarming degree; and which, it is said, have no greater enemies than cats. Sonini's travels in Greece and Turkey, p. 56.

A-GROUND, in *Sea-language*, expresses the situation of a ship whose bottom, or any part of it, rests upon the ground.

AGRYLA, in *Ancient Geography*, a city of the island

of Sardinia, founded, according to Steph. Byz. by a colony of Athenians.

AGRYPNIA, *αγρυπνια*, a privation of sleep; otherwise called watching, waking, *vigilia*, *pervigilium*, &c. Among physicians, this is a troublesome symptom in fevers and other disorders. In the Greek church, it is used for the vigil of any of the greater feast-days, observed by the monks and clergy. Du-Cange.

AGUA, in *Geography*. See OEGWA.

AGUA, *Fort Harbour*, is situate about a league north-north-east from Ferosa harbour, on the east coast of Newfoundland.

AGUA de Pao, a small town in the island of St. Michael, one of the Azores. It is situated in a fertile territory, which produces abundance of corn and excellent fruit. W. long. 25° 40'. N. lat. 38° 10'.

AGUA, *Rio del*, a river which falls into Bonaventura bay, on the coast of Popayan, in the South Sea; in about W. long. 77° and N. lat. 3° 30'. It affords good anchorage.

AGUA, *Reves*, a small place in the province of 'Traz-os montes, in Portugal.

AGUADA, a river which runs into Snienda bay, near cape Roque, on the coast of Brazil, about W. long. 34° 30' and S. lat. 5°.

AGUADA de Saldana, a gulph on the coast of Africa, 15 leagues north from Table bay.

AGUADIR-Toma, a town of Africa, in the empire of Morocco, in the province of Ius, 13 leagues south of Santa Cruz.

AGUADORE, a river in the island of Cuba, on the south side, and nearly north from the east end of Jamaica. Its mouth is in W. long. 75° 35' and N. lat. 20°.

AGUAGUIN, in *Botany*, the name of a shrub among the Africans, who esteem it greatly as a balsamic and vulnerary. The leaves of this shrub resemble those of our common lilac; they grow alternately, and stand upon foot-stalks of half an inch long; and when held up to the light, they shew a fine texture of the smaller veins. Philof. Transf. N° 232.

AGUAPECACA, in *Ornithology*, the name of a Brazilian bird of the moor-hen kind. It is of the size of a pigeon, very long-legged, and has a beak like that of the gallinaceous kind; its back, and the upper part of its wings, are brown, and in each wing they have a sharp horn, or prickle, serving for their defence. Marcgrave.

This is the jacana-peca of Buffon, the jacana annata of Brisson, the Brazilian jacana of Latham, and the *PARRA Brasiliensis* of Gmelin's Linnæan system, characterised by having the hinder claws very long, and the body greenish-black. At Guiana, where it is common, it is called kapouz, and also kinkin, from its shrill note: these birds are gregarious, and are found in flocks in the ditches, and among the rushes on the sides of the lakes; and they live on fish and water-insects.

AGUARA-QUIYA, in *Botany*, a Brasil plant, thought to be the *solanum vulgare*, or common nightshade, by Ray.

AGUARA-PONDA, a plant, otherwise called *viola spicata Brasiliensis*. It grows to the height of a foot and an half, or more, with a smooth, round, green, and jointed stalk; at each joint come forth four, five, or more, narrow, serrated, pointed, green, and unequal leaves; the top of the stalk bears an ear a foot long, smooth, and covered with flowers of a fine violet azure, or the colour of our *viola martia*, consisting of five roundish leaves. The whole flower is not unlike the *viola martia*, and has somewhat of its smell; the root is straight, of a moderate thickness, and shoots out into abundance of lesser ones, and these again into filaments.

There is another kind, distinguished by the wideness of its ear of flowers, which represents a helmet of a green colour. It is marked with cubic pits, from whence proceed azure flowers. Ray.

AGUAS, in *Geography*, a people of South America, on the banks of the river of the Amazons. They are said to be less polished than any other of the Indian nations.

AGUAS Bellas, a small place in the province of Estremadura, in Portugal.

AGUATULCO, AQUATULCO, or GUATULCO, a town and port of Mexico. Its harbour is large and much frequented. It is situated in the South Sea. W. long. 96° 40'. S. lat. 15° 10'.

AGUBENI, in *Ancient Geography*, a people placed by Ptolemy upon the frontiers of Arabia Deserta, very near Arabia Felix.

AGUCCHIA GIOVANNA, in *Biography*, was an engraver of the 16th century. He engraved the large design for the dome and cathedral of Milan. Strutt.

AGUE, in *Medicine*, a periodical disease of the fever-kind, consisting of a cold shivering fit, preceded by a hot one, and going off in a diaphoresis or sweating. If the coldness and shivering be inconsiderable, and only the hot fit felt, the disease is called an intermitting fever. According to the periods or times of the returns of the fit, the disease is either a QUOTIDIAN, TERTIAN, or QUARTAN ague, or fever. The cause of Agues, as well as of the REMITTENTS of hot climates, is now believed to be the miasmata or effluvia arising from putrid animal and vegetable substances mixed, or from the latter alone. See Dr. Jackson, &c. on Fever.

Sir John Pringle accounts for them by means of the principle of putrefaction. The heat of the body, he observes, varies little; and therefore the corruption produced in any of the humours must happen in a determinate time. If we suppose, that in the paroxysm, the more corrupted particles of the blood do not at all pass off through the skin with the sweat, but that some part of them is discharged with the bile; their particles coming into the intestines, and being from thence taken up by the lacteals, and carried into the blood, may there act as a new ferment, and occasion a return of the fit. Thus the corruption of the bile may be the cause of the first fit as well as of those that follow. He farther adds, that though all moist countries are subject to agues of some kind or other; yet if the moisture is pure, and the summers are not close and hot, they will mostly be regular tertian agues, and admit an easy cure. But if the moisture arises from long stagnating water, in which plants, fishes, and insects die and rot, then the damps, being of a putrid nature, occasion not only more frequent, but more dangerous fevers, which more commonly appear in the form of quotidians, and double tertians, than that of single ones. Accordingly they are found to vary with the season, on which the degree of putrefaction in a great measure depends.

These opinions of Sir John Pringle, as far as they rest on putrefactive particles, or ferments in the living body, are entertained only by a few pupils of the Boerhaavian school. The theories of fever in most general estimation at present, are contained in Dr. Darwin's Zoonomia, and Dr. Cullen's first lines.

The symptoms are, heaviness and reaching; a weak slow pulse; coldness and shivering felt first in the joints, thence creeping over the whole body; pain in the loins, and an involuntary motion of the under jaw.

This cold stage varies in its duration and severity with the kind of ague. It is shortest in the *quotidian*, and most distressing in the *tertian*.

The cold stage is succeeded by a full strong pulse, distressing

treffing febrile heat and flushing, indicating a free circulation of the blood through the extreme arteries on the surface of the body, which had been suspended or impeded during the preceding stage.

The diaphoresis, or sweating stage, which soon succeeds, may be considered as the CRISIS of that PAROXYSM; and generally of the disease, if proper means be employed to prevent its recurrence.

A venal ague is easily cured; but an autumnal one is more obstinate, especially in aged and cachectical persons; and, particularly, if complicated with a dropsy, peripneumony, &c.

When an ague proves fatal, it is usually in the cold fit. The cure is usually begun with an emetic of *ipecauanha*, an hour before the access, and completed with the *cortex Peruvianus*, administered in the interval between two fits; and continued, at times, to prevent a relapse.

We meet with divers other methods of curing agues, besides that by the *cortex*; as by means of 20 grains of Dover's powder; or ten grains of James's powder, with one of opium; or a quart of any hot tea, taken before the accession of the fit, in order to prevent, or greatly diminish the severity of the cold stage: by willow bark; by arsenic; by sul-ammoniac; and by *sul-volatile*, &c. which may act by attenuating the blood: in the island of Timor, by an infusion of flowers of little centaury. See Phil. Trans. N^o 145.

From the great variety of the means by which the ague has been, or appeared to be cured; we may conclude that any thing which can make a strong impression either upon the body or mind, a little while before the paroxysm, will cure the generality of agues. Etmuller gives divers instances of agues cured by putting the patient in a fit of passion. Others have been effected by a fright, a fit of drunkenness, &c. 'Do we not often see agues cured by amulets and *pericarpia*? I myself, says Mr. Boyle, was cured of a violent quotidian by applying to my wrists a paste made of bay-salt, new hops, and blue currants, which has also relieved many others both of quotidian and tertians.' Philos. Works abr. tom. i. p. 80.

Lord Bacon says, 'It is often tried, that juices of stock-gilly-flowers, rose-campion, garlick, and other things, applied to the wrists, and renewed, have cured long agues.' He likewise recommends in the heats of agues, to hold eggs of alabaster, and balls of crystal, in the hands.

Agues, it is said, have not been unfrequently cured by electricity. The most effectual and sure mode of applying this powerful stimulant, has been to draw sparks through flannel or the clothes, for about 10 or 15 minutes, either at the time of the fit, or a little before it is expected. In vol. iii. of the Memoirs of the Medical Society of London, we are told, that an obstinate quartan ague of five months' continuance was cured by this means. On the accession of the fit the patient was ordered to receive ten or more smart strokes through her arms and thorax, from a ten ounce vial, till she was seized with fear, and began to sweat, and then to go immediately into a warm bed and promote the sudorific effect for some hours, by taking frequent draughts of tepid small wine whey. By repeating this operation a few hours, says Dr. Flower, she was cured.

AGUE-cake, the popular name for a hard tumor on the left side of the belly, lower than the false ribs, said to be the effect of intermitting fevers.

AGUE-drops. See ARSENIC.

AGUE-tree. See LAURUS.

AGUE-free is a name given by some to SASSAFRAS, on account of its febrifuge virtue.

AGUEDA, in *Geography*, a town of Portugal, in the province of Beira, upon a branch of the river Vouga, six leagues north of Coimbra. W. long. 8° 26'. N. lat. 40° 36'.

AGUEDA, a river of Leon, which passes by Ciudad-Rodrigo.

AGUELAON, one of the LACCADIVE islands, in the Indian sea. E. long. 73° 25'. N. lat. 11°.

AGUEPERSE, or AIGUEPERSE, a town of France, in the department of Puy-de-Dome, seven leagues north-north-east of Riom.

AGUER, a sea-port town of Africa, situated at the foot of Mount Atlas, in the kingdom of Morocco. This town was built by the Portuguese, near a remarkable cape, on the north-west of the mouth of the river Sus, now called *Cape GEER*. It was taken by Diego Lopez de Segueria, who afterwards made a voyage to the East-Indies. As the town had a convenient harbour, and was famous for its fishery, this adventurer erected a strong fort to defend it. He sold it to Emanuel, king of Portugal, who added other fortifications, and a strong garrison. But after a vigorous defence, in which the enemy lost 16000 men, it was surrendered, A. D. 1536, to Mohammed, who became emperor of Morocco and Fez; and in revenge for his loss, he put the whole garrison to the sword, except the brave governor Mont Roy, whom he spared and favoured for the sake of his daughter, Donna Mercia, who consented to marry him, on condition of being allowed the free exercise of her religion, and of being regarded as his lawful wife.

AGUESSEAU, HENRY FRANCIS D', in *Biography*, a chancellor of France, was born at Limoges in 1668, of an ancient family of Saintonge. He owed the first rudiments of that literature to which he was devoted, to the instruction of his father, and his distinguishing taste for poetry to the society of Boileau, Racine and other eminent writers of that class. After having held the office of advocate-general of Paris for ten years, he was appointed procureur-general in 1700; and in this situation he distinguished himself by introducing several regulations, which contributed to the improvement of jurisprudence. He also directed a particular attention to the hospitals, and to the hardships occasioned by the scarcity in 1709, which indicated the amiable philanthropy of his temper, and in which he was singularly useful. He also approved himself the strenuous defender of the liberties of the Gallican church, in opposition both to Lewis XIV. and the chancellor Voisin, who solicited his concurrence in favour of the bull *Unigenitus*. After the death of Voisin, and in the regency of the duke of Orleans, he was made chancellor; and performed the duties of this office with that eminent wisdom and firmness, which the circumstances of the times demanded. In his resistance of the financial project of Law, he was for some time successful; but when the regent determined to adopt it, he was constrained in 1718 to retire to his country-seat at Fresnes; but in 1720 he was recalled and reinstated in his office. He was again deprived of it in 1722, recalled by Cardinal Fleury in 1727, and reinvested with the seals in 1737, which he held till his death. From the year 1729 to 1749 he was sedulously employed in reforming the laws, and remedying many notorious abuses that disgraced and obstructed the administration of them. His object was to supply their defects, and to facilitate the execution of them, without changing their fundamental principles; but in this extensive and laborious employment his progress was slow; and he met with difficulties, from his extensive views and from a regard to the profits of the legal profession, which produced indecision in his own judgment, and served to retard his dispatch of business. For the slowness of some of his determinations, he makes this very reasonable apology: "when I recollect (said he) that

the decree of a chancellor is a law, I think myself permitted to take a long time for consideration." His life, though assiduously occupied, was prolonged by his temperance and equanimity; but in the year 1750 his increasing infirmities admonished him of the necessity of withdrawing from public employments; and in 1751 he closed his life at the advanced age of 83 years.

Voltaire calls him the most learned magistrate ever possessed by France. Besides the languages of antiquity, he was acquainted with all the principal modern ones; and to his knowledge of the history of all ages and nations, he added that of jurisprudence in its most extensive sense. During his exclusion from office, he made no attempts for being restored; but always manifested a disposition superior to the honours which his talents and merit claimed, and a desire to be useful rather than to aspire after power and to accumulate wealth. Of his frugality, and of the various emoluments annexed to the dignities he possessed, the only fruit that remained was his library, in the improvement of which he limited himself to a certain annual expence. In the periods of his retirement, which he called "the fairest days of his life," he devoted himself to the maturity of his plan of legislation, to the education of his children, and to a variety of literary pursuits, among which were mathematics and the belles lettres; and these, together with agriculture, he deemed his recreations in the intervals of his severer occupations. However, when the public demanded his services, he surrendered the satisfactions of retirement and the pleasures of domestic life. Having in 1694 married Anne le Febure d'Ormesson, it was said on this occasion, that virtue and the graces were now first seen in alliance; but he had the misfortune to lose her in 1735. His grief corresponded to the affection that subsisted between them. Nevertheless he hastened to devote himself to the functions of his office; alledging, "that his services were due to the public, and it is not just (said he) that it should suffer by my domestic affliction." We are informed, that he never passed a day from his childhood, without reading some parts of the scriptures; and he was heard to say, that this was the balm of his life. Of his works nine volumes 4to. have been published. In these, he is said to have thought like a philosopher, and spoken as an orator. His eloquence has the force of logic and the order of geometry, united to the riches of erudition and the charms of persuasion. His style is chaste and harmonious, but deficient in warmth. When he once consulted his father in a discourse which he had taken pains to compose, and which he wished farther to improve, his father gave his opinion: "the fault of your discourse is its being too elegant; it will certainly be less so if you touch it again." *Nouv. Dict. Hist. Biog. Dict.*

AGUGA, *Cape*, lies southward of Puirá, on the coast of Peru, in South America. S. lat. 60°. W. long. 82°.

AGUIAS, a small town of Portugal, in Alentejo, to the west of Elvas, and to the east of Lisbon. The territory about it produces grain and oranges. W. long. 6° 41'. N. lat. 38° 30'

AGUGLIA. See **OBELISK**.

AGUGLIA is also the name given by the Italian fishermen to the *acus* of Oppian, called in English the *GAR-FISH*.

AGUIGUAN, or the island of the Holy Angel, in *Geography*, one of the Ladrões or Marianne islands, lies in the Southern Sea, in lat. 14° 43'; about 40 miles from Zarpaa; and about a league south-west of Tinian. It is a small island, about nine miles in compass, mountainous, but pleasant, and formerly well inhabited.

AGUILA, AUGELA, or OUGUELA, a town of Africa, in the kingdom of Fez, situate on the river Aguila or Erguela, and giving name to a district, which is for the most part sandy and barren, but in some places so well watered

as to afford plenty of dates; and it is separated from Barva by a mountain called Meys, which affords excellent pasture.

AGUILAR, a town of Spain, in Navarre, four leagues south-west of Ellella. E. long. 2° 30'. N. lat. 42° 35'.

AGUILAR *del Campo*, a town of Spain, in Old Castile, situate on the Alhama; three leagues from Calahorra.

AGUILLANEUF, or AUGILLANEUF, compounded of the French, *a, to, gui, misleto*, and *Pan neuf*, i. e. *the new year*; a form of rejoicing used among the ancient Franks on the first day of the year.

Its origin is traced from a druid ceremony: the priests used to go yearly in December, which with them was reputed a sacred month, to gather misleto off the oak in great solemnity. The prophets marched in the front, singing hymns in honour of their deities; after these came a herald with a *caduceus* in his hand; these were followed by three druids a-breast, bearing the things necessary for sacrifice. Last of all came the chief, or arch-druid, accompanied with the train of people.

The chief druid climbing the oak, cut off the misleto with a golden sickle, and the other druids received it in a white cloth. On the first day of the year it was distributed among the people, after having blessed and consecrated it by crying *au gui Pan neuf*, to proclaim the new year.

Of later times the name *aguillaneuf* was also given to a sort of begging, practised in some dioceses, for church tapers, on a new year's day, by a troop of young people of both sexes, having a chief, &c. It was attended with divers ridiculous ceremonies, as dancing in the church, &c. which occasioned the synods to suppress it.

AGUILLAS, *Cape*, in *Geography*, lies to the east of the Cape of Good Hope. See *Cape NEEDLES*.

AGUILLES, or AUGUILLES, cotton cloth, manufactured at Aleppo.

AGUILLON, FRANCIS, in *Biography*, a jesuit of Brussels, was professor of philosophy at Doway, and of theology at Antwerp. He was distinguished by his knowledge of mathematics, and is said to have first introduced studies of this kind into Flanders. He wrote a book of optics, intitled, "Opticorum, lib. vi. Philosophicis juxta ac Mathematicis utiles," which was printed at Antwerp, in 1613, fol. He was employed in finishing his "Catoptics and Dioptries" at the time of his death, which happened at Antwerp, in 1617, in the 50th year of his age. He is also said to have written a treatise of "Projections of the Sphere." He understood several languages; his judgment was accurate; his learning extensive; and his patience and fortitude under severe trials were very signal. Under the paroxysms of the asthma, to which he was subject, and which were very trying, just before his death, he repeatedly said: "Let God's will be done—I submit to it—I am willing to form myself absolutely upon the divine pleasure—I have now the torments which I often wished for, and desired of God." *Gen. Dict.*

AGUILLON *Point*, in *Geography*, a long narrow point, in a curvilinear form, north-east of the isle of Rhe, on the coast of France, and about three leagues north-west of Rochelle. To the east of Aguillon the bay contracts and terminates.

AGUIRRA, JOSEPH SAENZ *De*, in *Biography*, a learned Benedictine of the 17th century, was born in 1630, at Logroño, in Spain, and read lectures in theology at the university of Salamanca, where he took his degree of doctor of divinity. He was also censor and secretary of the supreme council of inquisition, and was honoured with a cardinal's hat by pope Innocent XI. in 1686. He died at Rome, in 1699. His life was exemplary; and his writings numerous. He is said to have retracted the doctrine of probability, which he had maintained, as soon as he found that it was inconsistent with the strictness and purity of the Christian morals. His publications,

publications were very various. Besides his works in theology, which amount to several volumes; a commentary on Aristotle's Ethics, and three folio volumes of philosophy, he published, "a Collection of the Councils of Spain," with an historical Introduction, of which extracts are given in the *Acta Erudit.* for Feb. 1688; but as several of his dissertations are written in defence of the spurious decretals of the first popes, Dupin has objected to them in his *Biblioth. des Auteurs Eccles.* tom. xviii. p. 248. Ed. Amst. 1711. Gen. Dict.

AGUL, in *Botany*, a small shrub very prickly; its leaves are longish, and resemble those of the knot-grass; it abounds with flowers of a reddish colour; these are succeeded by red husks; its root is long, and of a purple colour.

This plant is otherwise called *alhagi maurorum*, by Raulwolf: it grows in Arabia, Persia, and Mesopotamia. See HEDYSARUM.

AGUL, in *Geography*, a river of Russian Siberia, which runs into the Kan. E. long. 95° 24'. N. lat. 55° 16'.

AGUNA, a town of Africa, in the kingdom of Benin.

AGUNTUM, in *Ancient Geography*, now *Inniken*, a town of Rhætia, placed by Ptolemy in Norica, and by M. d'Anville to the north of the Carnic Alps, and north-west of *Julium Carnicum*.

AGURAH, in *Jewish Antiquity*, the twentieth part of an ancient silver SHEKEL. It was otherwise called *gerah* and *kesitah*. The Seventy render it *οβολος*.

AGURIUM, AGYRIUM, AGIRIUM, or AGYRENA, now S. Philippo d'Argyrone, in *Ancient Geography*, a town in the interior part of Sicily, placed by M. d'Anville in the road from Enna to Catania.

AGUSADURA, in *Ancient Customs*, a fee due from vassals to their lord, for sharpening their plowing tackle.

Anciently the tenants in some manors were not allowed to have their rural implements sharpened by any but those whom the lord appointed; for which an acknowledgment was to be paid, called *agufadura*, in some places *agufage*, which some take to be the same with what was otherwise called *reillage*, from the ancient French *reille*, a *plough-share*. Du-Cangé.

AGUSTINE, in *Mineralogy*, a barbarous term, compounded of Greek and Latin, meaning *without taste, insipid*, by which professor Trommsdorff has distinguished a supposed new earth, discovered by him in the year 1800.

The mines of Johan-Georgenstadt contain a mineral, which hitherto has been taken for the beryl: this being analysed for the purpose of ascertaining whether glycine was one of its constituent parts, yielded unexpectedly a new earth, which, from its forming insipid salts with acids, has been called by its inventor, *Agustine*.

This earth, when pure, has a great resemblance to alumine, adheres very feebly to carbonic acid, hardens by exposure to fire, and is insoluble in water. It differs, however, from pure clay, in the following particulars: 1. It is absolutely insoluble in any of the three alkalies, whether caustic or carbonated, in the moist or the dry way. 2. With acids it combines, readily forming nearly insipid salts. 3. It is equally soluble after induration by fire, as before. 4. Sulphuric acid forms with it a salt of difficult solution, and perfectly insipid, but which by a slight excess of acid, becomes soluble and crystallizes in stars. 5. Its acidulous phosphat is also very soluble. 6. But the acetite of *Agustine* is scarcely at all so.

These are all the facts that are as yet known concerning this substance: it rests entirely upon the authority of Trommsdorff, and as neither he nor any other chemist have since made the smallest mention of it, even this slight notice might here seem superfluous. *Annales de Chimie*, vol. xxxiv. p. 133.

AGUTI, the *CAVIA aguti* of Linnæus, in *Zoology*, has a very short tail; the upper parts of the body are of a brown colour, mixed with red and black, the rump of a bright orange, and the belly yellowish. Authors mention three varieties, *viz.* The lesser aguti, or *cavia aguti cunicularis*, with a very short tail, four toes before and three behind, and a yellowish belly. This is the *cuniculus agouti* of Brisson and Gronovius, the larger mouse of Brown, the American wild mouse of Ray, with the hair and voice of a pig; the aguti or acuti of Maregrave, &c. the long-nosed cavy of Pennant, and the agouti of Buffon. It is about the size of a rabbit, and inhabits Brasil, Guiana, Cayenne, and other parts of South America and the West India islands. 2. The larger agouti, or *cavia A. leporina*, with a very short tail; the upper parts of the body reddish, and the under white. This is the hare-like mouse of Linnæus, having four toes on the fore, and three on the hinder feet; the Javan coney of Brisson; the Java hare of Catesby; and the Java cavy of Pennant. It is of the size of a hare, and inhabits Surinam and the hotter parts of South America.

3. The American agouti, *cavia A. Americana* of Gmelin, and the American coney of Brisson and Seba; has a very short tail, and is clothed with coarse reddish fur. These three varieties inhabit South America, and some of the West India islands, particularly the Antilles. The first has a long nose, the upper lip divided; short, broad, rounded ears; black eyes; slender, and almost naked legs, of a black colour. The second has a small slender head, with prominent naked ears, rounded at the extremity. The hinder parts in both are larger than the fore parts, and the legs are long. The third variety is little known. These animals inhabit hollow trees, and burrow in the ground. They live on vegetables, which they collect in the day, and carry to their dwellings; they sit on their hind legs, and feed themselves with their paws; and when satiated with food, conceal the remainder; they grunt like pigs: when hunted with dogs, they run fast, with a kind of hopping or leaping pace, like that of a rabbit or hare, and take shelter in their holes or hollow trees; when irritated, the hair rises on the back, and they strike the ground with their hind feet; when young, they are easily tamed; and will of their own accord, go out and return again. They are very voracious, and grow fat; and their flesh is white and savoury, and eaten in South America. The female brings forth at all times of the year, and produces three, four, and sometimes five at a time.

AGUTI TREVA *insule Marignanae*, in *Botany*, a plant mentioned by de Laet. It has the leaves of the orange-tree, only thinner, a dewy flower, a large fruit, with a greenish rind, which contains kernels like those of the pomegranate, thin, sweet, and not ill-tasted.

AGUTIGUEPA *obi Brasiliensibus*, in *Medicine*, the name given by many authors to the ARROW-root, or *sagittaria alexipharmica* of the West Indies.

AGYEI, in *Antiquity*, a kind of obelisks consecrated to Apollo, and placed in the vestibules of houses, for their security.

The ayei were no other than huge stones, or perhaps sometimes timber, having either a circular or square basis, and terminating in a point at the top, sacred to Apollo, or, as some say, to Bacchus, as protector of the high-ways. Others will have them to have been erected to both those deities. Suidas and Pitiscus. They had sometimes the head of Apollo, Bacchus, or Mercury; and Steph. Byz. says, that they served like our direction-posts, to shew the way to any place.

AGYLLA, (*Cervateri*), in *Ancient Geography*, a town of Etruria, near the sea, so called by the Pelasgi, who came thither

thither from Theffaly. It was afterwards called *Cære*, as Strabo (Geog. tom. i. p. 337.) informs us, from this circumstance, that the Lydians, hearing the inhabitants frequently repeating to them the Greek expression *χαίρει*, i. e. *rejoice*, took this to be the name of the city, which it afterwards retained. Others, thinking this etymology more fanciful than just, deduce Agylla from *gillab*, *water*, as they had fountains in the neighbourhood; and Cære might be formed from *cari* or *cariab*, a *town*, in the language of the Lydians. The sons of Tarquin were banished to this town; and thither the vestals retired when, in the year 363, the Gauls laid siege to Rome. The laws and police of this city are much commended. History informs us that it united with the adherents of Tarquin against Rome; and that it afterwards demanded and obtained a truce of 100 years. It was one of the first cities which became municipal. Strabo says, that in his time, there remained only the ruins of this famous city; and it was known only by its baths.

AGYLLÆI, in *Ancient History*, a denomination given to the Pelasgi in Etruria. Insulated, as it were, in this country, they preserved, with little alteration, the manners and religion of the ancient inhabitants of Greece; they furnished considerable fleets, and aided the Carthaginians with 60 vessels in their war with the Phœcians, who had established themselves in the island of Sardinia; and though they were vanquished, they made many prisoners, whom, according to Herodotus (lib. i. 167. p. 79.) they put to death. They amassed a treasure at Delphi, by transmitting thither a tenth of their maritime profits; and by their commerce, and their piracies on the coast of Italy, and amidst the islands of the Ægean sea, they acquired a degree of power, which rendered them important allies or formidable enemies to their neighbours. Herodotus says, that their power was considerable in his time; and that, in consequence of an oracle, they had instituted funeral sacrifices and annual games, which they then celebrated. These people, who were sometimes called Tyrrhenians, sent succour to the Athenians in the Sicilian war, not long before the ruin of Veii by the Romans. They formed an alliance with the Romans, which gave them all the advantages belonging to Roman citizens, without the charges attending them; and they formed, under the name of Cærites, the third order of the republic. The Cærites bore arms in the Roman army, and were almost always united to the Romans, as Livy, (lib. vii. c. xx.), informs us; and they were considered, not merely as allies, but as a part of the nation. At length, deserted by the Roman marine, which found more spacious and convenient ports, and losing its commerce, Cære declined, and the inhabitants, who were Romans, were indiscriminately blended with the other citizens.

AGYNEIA, formed of *a priv.* and *γυν*, a *wife*, in *Botany*, a genus of the *monoecia monadelphica* class and order, according to Martyn; but in Gmelin's Linnæus, of the *triandria monogynia*, of the natural order of *triccocæ*, and the *Euphorbia* of Jussieu. Its generic characters are, that the male flowers are below the female; the calyx is six-leaved; the leaflets oblong, obtuse, equal, and permanent; no corolla; in the male, instead of filaments, a column shorter than the calyx; three or four anthers, oblong, growing to the column below the top: in the female flowers, the germ of the size of the calyx, sub-ovate, obtuse, perforated at top with a six-notched hole: neither style nor stigma: the pericarpium supposed to be a tricoccos capsule. There are two species, *viz.* 1. *A. impubes*, with leaves smooth on both sides. 2. *A. pubera*, with leaves downy underneath: both species are natives of China.

AGYNIANI, in *Church History*, a sect who condemned all use of flesh, and marriage, as not instituted by God, but introduced at the instigation of the devil.

The word is compounded of the privative *a*, and *γυν*, *woman*. They are sometimes also called *Agynneses* and *Agynii*; and are said to have appeared about the year 694.

AGYRTÆ, in *Antiquity*, a kind of strolling impostors running about the country, to pick up money by telling fortunes at rich men's doors, pretending to cure diseases by charms, sacrifices, and other religious mysteries; also to expiate the crimes of their deceased ancestors by virtue of certain odours and fumigations; to torment their enemies by the use of magical verses, and the like. The word is formed of the verb *αγυρτα*, *I congregate*; alluding to the practice of quacks, who gathered a crowd about them. See *ÆRUSCASTORES*.

AGYRTUS, in *Entomology*, a name given by Cramer to the *PAPILIO PHERECLUS* of Gmelin's Linnæus.

AHA, or AHU, in *Zoology*, a name given by the Persians to the *CERVUS pygargus* of the Linnæan system, or the *tail-less ROE* of Pennant, which has no tail, and three-forked horns. It inhabits the lofty mountains of Hircania, and of Russia and Siberia, beyond the Volga; and at the approach of winter descends into the plains and becomes hoary: it is called by the Russians *dikeja roza*, and by the Tartars *saiga*. This animal resembles the roe, but is much larger, being of the same deep red colour, with a large bed of white on the rump and buttocks, extending up the back; the fur is thick, in spring rough and erect, on the limbs and belly yellowish; the sides of the under lip and the space about the nose are black; but the point of the lip is white; the hairs of the eye-lids and round the orbits are long and black; the horns are very rugged at the bases, and full of knobs; the ears are covered on the inside with a very thick white fur. Gmelin's Linn.

AHAB, in *Scripture Biography*, one of the kings of Israel, was chiefly distinguished by his impieties. He succeeded his father, A. M. 3086; married Jezebel, the daughter of Ethbaal, king of the Sidonians, or rather the Tyrians; and at her instigation introduced the idolatrous worship of Baal among the Israelites. In his wicked reign there was a drought of three years continuance, probably the same with that mentioned by Josephus, (Ant. lib. viii. c. xv. § 2.) which happened, A. M. 3096. With a small force he obtained a signal victory over Benhadad, king of Syria, who had besieged Samaria. In a subsequent war, he endeavoured to elude the enemy by a change of clothes, but was accidentally killed by an arrow, about the year 897 before Christ. The despotic character of this prince, and the savage cruelty of his wife Jezebel, are strongly marked in the anecdote related concerning Naboth's vineyard. 1 Kings xvi. 29—33. xx. xxi. xxii. Gen. Dict.

AHÆTULLA, in *Zoology*, a species of *COLUMBER*, in the order of Serpents. It is found in Asia and America, about three feet 14 inches long, of a greenish-gold colour, with the skin, sometimes visible between the scales, black. Its head is elongated and narrow, with a black band over the eyes, and a tetrahedrous tail. By some authors it is called the long green Borneo snake, and the bonguatrora of Amboyna. Gmelin.

AHALOTH, in the *Materia Medica*, the Hebrew name used by some writers for the *lignum-aloes*, or *aloes wood*.

AHANIGER, in *Ichthyology*, a name given by Albertus and others, to the fish called by authors *ACUS vulgaris*, and by us the *GAR-FISH*.

AHAUSZ. See *AAHUS*.

AHASUERUS, in *Scripture History*, was the king of Persia,

Perſia, who advanced Eſther to be queen, and at her requeſt delivered the Jews from the deſtruction plotted for them by Haman. Archbiſhop Uther (Vide Annal. Vet. T. R. an. Jul. per. 4193), is of opinion, that this Ahaſuerus was Darius Hyſtaſpis; and that Atoſſa was the Vaſhti, and Artypſona the Eſther of the ſcriptures. But, according to Herodotus (lib. iii. and lib. vii.), the latter was the daughter of Cyrus, and therefore could not be Eſther; and the former had four ſons by Darius, beſides daughters, born to him after he was king; and therefore ſhe could not be the queen Vaſhti, divorced from her husband in the third year of his reign (Eſther i. 3.), nor be the Ahaſuerus who divorced her. Beſides, Atoſſa retained her influence over Darius to his death, and obtained the ſucceſſion of the crown for his ſon, Xerxes; whereas Vaſhti was removed from the preſence of Ahaſuerus by an irrevocable decree, (Eſther i. 19.) Joſ. Scaliger (de Emendatione, lib. 6.) maintains, that Xerxes was the Ahaſuerus, and Hameltris, his queen, the Eſther of ſcripture. This opinion is founded on the ſimilitude of names, but contradicted by the diſſimilitude of the characters of Hameltris and Eſther. Beſides, Herodotus (lib. ix.) ſays, that Xerxes had a ſon by Hameltris, that was marriageable in the 7th year of his reign; and therefore ſhe could not be Eſther. The Ahaſuerus of ſcripture, according to Dr. Prideaux, was Artaxerxes Longimanus. Joſephus poſitively ſays, (Ant. lib. xi. ch. vi.) that this was the perſon. The Septuagint, through the whole book of Eſther, uſe Artaxerxes for the Hebrew Ahaſuerus, wherever the appellation occurs; and the apocryphal additions to that book every where call the husband of Eſther Artaxerxes; and he could be no other than Artaxerxes Longimanus. The extraordinary favour ſhewn to the Jews by this king, firſt in ſending Ezra, and afterwards Nehemiah, to relieve this people, and reſtore them to their ancient proſperity, affords ſtrong preſumptive evidence, that they had near his perſon and high in his regard ſuch an advocate as Eſther. Prid. Conn. vol. i. p. 361, &c. 8vo. Ahaſuerus is alſo a name given in ſcripture (Ezra iv. 6.), to Cambyſes, the ſon of Cyrus; and to Aſtyages, king of the Medes. Dan. ix. 1.

AHAZ, ſucceeded his father Jotham, as king of Iſrael, at the age of 20 years, reigned till the year before Chriſt, 726, and addicted himſelf to the practice of idolatry. After the cuſtoms of the heathens he made his children to paſs through the fire; he ſhut up the temple, and deſtroyed its veſſels. He became tributary to Tiglath-pileſer, whoſe aſſiſtance he ſuppliated againſt the kings of Syria and Iſrael. Such was his impiety, that he was not allowed burial in the ſepulchres of the kings of Iſrael. 2 Kings xvi. 2 Chron. xxviii.

AHAZIAH, the ſon and ſucceſſor of Ahab, reigned two years, and continued the impieties of his father. 1 Kings xxii. 31.

AHAZIAH, was alſo the name of an idolatrous king of Judah, who ſucceeded Jehoram, and reigned one year. By his alliance with the houſe of Ahab, and the counſel of his mother Athaliah, he purſued evil practices; and he was ſlain by Jehu, in the year before Chriſt, 884. 2 Kings viii. 2 Chron. xxiii.

A-HEAD, in *Sea-language*, refers to any object that lies immediately before a ſhip, or towards that point of the compaſs to which her ſtem is directed: uſed in oppoſition to A-ſTERN.

AHEEN, in *Geography*, a tribe of the RAGPOUTI, in India.

AHER, a town of Perſia, in the province of Aider-beitzan; 30 miles north-weſt of Ardevil.

AHIJAH, in *Scripture Hiſtory*, a propheet of Shiloh; who is ſuppoſed to have delivered two meſſages from God to Solomon, one encouraging, whilt he was building the temple (1 Kings vi. 11.), and another threatening, expreſſive of diſpleaſure, on account of his miſconduct, (1 Kings xi. 6). He is one of thoſe who wrote the annals of this prince, 2 Chron. ix. 29. He alſo predicted the uſurpation of Jeroboam, declared the calamities that would befall his houſe on account of his idolatry, and alſo foretold the death of his ſon Abijah, 1 Kings xiv. He lived to an advanced age; but the time and manner of his death are not recorded.

AHIIMAAZ, ſon of Zadok the high prieſt, ſucceeded his father about A. M. 3000, under Solomon. During the rebellion of Abſalom, he informed David of the reſolution adopted in his council; and he and Jonathan eſcaped their purſuers by being concealed at Baharim. Ahimaaz was the firſt who gave intelligence to David of Abſalom's death. He was ſucceeded in the prieſthood by Azariah. 2 Sam. xv. 17. xvii. 17. 1 Sam. xxiii. 18-20. 1 Chron. vi. 9.

AHITHOPHEL, a native of Giloh, who, after having been David's counſellor, joined in the rebellion of Abſalom, and aſſiſted him with his advice. Huſhai, the friend of David, was employed to counteract the counſels of Ahithophel, and to deprive Abſalom, under a pretence of ſerving him, of the advantage that was likely to reſult from the meaſures which he propoſed. One of theſe meaſures was calculated to render David irreconcilable, and was immediately adopted; and the other to ſecure, or to ſlay him. Before the laſt counſel was followed, Huſhai's advice was deſired; and he recommended their aſſembling together the whole force of Iſrael, putting Abſalom at their head, and overwhelming David by their number. The treacherous counſel of Huſhai was preferred to that of Ahithophel; with which he was diſguiled and haſtened to his houſe at Giloh, where he put an end to his life. He probably foreſaw Abſalom's defeat, and dreaded the puniſhment which would be inflicted on himſelf as a traitor, when David was re-ſettled on the throne. A. M. 2981. Ante Chriſt. 1023. 2 Sam. xv.-xvii.

AHLDEN, in *Geography*, a bailiwick of the principality of Luneburg-Zell, in Germany, lying on both ſides of the Aller, which in this bailiwick receives the Leine and Bohme. It is one German mile and a half in length, and as much broad; and conſiſts of champaign, heaths, and ſandy grounds; and, to the ſouth of the Aller, has good marſh lands and paſtorage. Its woods are chiefly oak; and great quantities of timber are conveyed in ſtoats to Bremen. The inhabitants carry on a conſiderable trade in horſes, cattle, wool, honey, and wax.

Ahlden is alſo the name of a town ſituate on the old Leine, near the Aller, from the courſe of which it derives its name. Sophia-Dorothea, conſort to king George I., after her ſeparation, reſided in the palace of this town, from 1694 to 1726.

AHLEM, a vogtey, or diſtrict of the principality of Calenberg, in Germany, containing ſeven villages; the chief of which is Limmer.

AHLEN, a ſmall town of Munſter, in Weſtphalia, ſituate on the Werſe, which is ſummoned to the-land-diets, contains a collegiate church, two nunneries of Auguſtines, and a princely and rural court. See AALEN.

AHLWARDT, PETER, in *Biography*, profeſſor of logic and metaphyſics at Griefswalde, was born of mean parentage, in that city, February 14, 1710. Having made

made considerable proficiency in the Greek and Latin classics, he became a student of theology in 1727; but applied chiefly to mathematics and philosophy. In three years he removed to the university of Jena; and in 1732, returned to Griefswalde, where he read a course of lectures on mathematics and philosophy. In 1743, he became an adjunct of the philosophical faculty in that place, and nine years after was chosen professor: he also preached often with great approbation. He largely contributed to the critical researches of the society at Griefswalde, of which he was a member. He founded also the order of the Abelites, and wrote a treatise on the occasion, entitled, "The Abelite." His other principal works are, "Considerations on the Confession of Augsburg;" "Thoughts on the Powers of the Human Understanding;" "An Introduction to Philosophy;" "A Treatise on the Immortality of the Soul;" and "Brontotheologia, or Thoughts on thunder and lightning." He is said to have been so accurate in his composition, that he never corrected what he had once written. He died March 1st, 1791. Gen. Biog.

AHMED *Khan*, one of the race of Jenghis or Zingis, was the son of Hulaku, and brother of Abaka khan, whom he succeeded as emperor of the Moguls, in 1282. He assumed the name Ahmed, on his embracing Mohammedism; and on this occasion, he offered protection to all Mussulmans, in a letter to the Sultan of Egypt and Syria. This change of religion offended the princes of his family to such a degree, that he could never regain their affection. His nephew Argun raised an army against him, but he was soon defeated and taken prisoner. He was afterwards released by some conspirators, and having killed the emperor's principal officers, he pursued and overtook him; and delivered him up to his mother-in-law, who, in revenge for the loss of her own sons whom Ahmed had caused to be slain, put him to death, after a reign of two years and two months. A. D. 1284. Mod. Un. Hist. vol. iv. 390. &c.

AHMEDABAD, or AGMED'S *City*, in *Geography*, the capital of the province of Guzerat in India, so called from Sidtan Ahmed, who was king of that province, and kept his court in that city. It is 224 measured coss distant from Delhi, and 86 coss from Sarat. The city is situated in a delightful plain, watered by the little river Sabremelli. The walls are built with brick and stone, flanked at certain distances with large round towers and battlements. It has 12 gates; and, including the suburbs, is about four and a half miles in length. On the west side is the castle, walled with freestone, and as spacious as a little city: the caravanfary is on the south of the king's square, which is 700 paces long and 400 broad, planted round with trees, and is its chief ornament. Near this square is the king's palace with apartments richly ornamented; and in the midst of the city is the English factory. The Hindoos have in this place, which, from an eminence, appears like a wood being full of gardens, an hospital for sick birds, and another for sick beasts. For magnitude and wealth, this city is little inferior to the best in Europe; and the revenue which it yields, is generally reckoned to be ten times as much as that of Surat. Frazer's Kuli Khan. p. 29. Mod. Un. Hist. vol. v. p. 293.

AHMEDNAGUR, a city in the province of Dowlatabad in India, distant from Delhi 280 measured coss. Auringzebe died in this city. Frazer's Kuli Khan, p. 35.

AHMELLA, in *Botany*. See ACNELLA.

AHOLIBAH and AHOLAH, in *Scripture History*, are two feigned names, used by Ezekiel (ch. xxiii. 4.) to denote

the two kingdoms of Judah and Samaria. They are represented as fillers of Egyptian extraction: Ahola being Samaria; and Aholibah, Judah. They both prostituted themselves to the Egyptians and Assyrians, by imitating their idolatrous and wicked practices; and for that reason they were made captives and reduced to the most ignominious and cruel servitude.

AHONI, in *Geography*, a sea-port town of Africa, on the coast of Benin.

AHOUI, in *Botany*, the name of a genus of plants, called by Linnæus CERBERA.

AHOVAS, AHWAS, or AHVAZ, in *Geography*, a town of Persia in the province of Chusistan; about 240 miles west-south-west of Ispahan.

AHR. See AHER.

AHRABAN, a town of Asia in the province of Diarbekir, 30 leagues south of Diarbekir.

AHRENSBECK, a town of Germany, in the duchy of Holstein; 12 miles north-north-west of Lubeck; and also a bailiwick.

AHRENSDORF, a town of Germany, in the middle mark of Brandenburg; six miles south-south-east of Potsdam.

AHRIMAN. See ARIMANIUS.

AHRWEILER, a small town of Germany, in the electorate of Cologne, seated on the river Ahr, and furnishing good wine. It is eight leagues north-west of Coblenz. E. long. 6° 43'. N. lat. 50° 35'.

AHSA or AHASA. See AHOVAS.

AHU, in *Zoology*, the ibex capensis of Kolben, the kevel of Buffon, the flat-horned ANTELOPE of Pennant, and the ANTELOPE *Kevella* of Gmelin's Linnæus.

AHUCYATLI, the name of an American serpent, approaching to the nature of the hæmorrhus and rattlesnake, but larger than the former, and wanting the rattle of the latter; it is as fatal in the effect of its poison as any known species of serpent. Ray.

A-HULL, in *Sea-language*, denotes the situation of a ship, when all her sails are furled, on account of the violence of a storm, and when, having lashed her helm to the lee-side, she lies nearly with her side to the wind and sea, her head being somewhat inclined to the direction of the wind.

AHUN, in *Geography*, a town of France, in the department of the Creuse, and district of Gucret; three leagues south-east of Gucret. E. long. 1° 52'. N. lat. 49° 5'.

AHUYS, a town of Gothland, in Sweden, in the province of Schonon; about two leagues south-south-east of Christianstadt, near the Baltic sea. This is, as it were, the warehouse where the goods designed for Christianstadt are deposited. It has a good harbour, and was formerly a strong town, but is now decayed. E. long. 14° 10'. N. lat. 56° 20'.

AI, called by the LXX GAI, by Josephus AINA, and by others AJAH, in *Scripture Geography*, a town of Palestine, situate west of Bethel, and at a small distance north-west of Jericho. The 3000 men, first sent by Joshua to reduce this city, were repulsed, on account of Achan's sin, who had violated the anathema pronounced against the city of Jericho, by appropriating some of the spoil. A. M. 2553. After the expiation of this offence, the whole army of Israel marched against Ai, with orders to treat this city as Jericho had been treated, with this difference, that the plunder was to be given to the army. Joshua, having appointed an ambush of 30,000 men, marched against the city, and, by a feigned retreat, drew out the king of Ai with his troops; and upon a signal

given, by elevating his shield on the top of a pike, the men in ambush entered the city and set fire to it; and thus the soldiers of Ai, placed between two divisions of Joshua's army, were all destroyed; the king alone being preserved for a more ignominious death on a gibbet, where he continued till sun-set. The spoil of the place was afterwards divided among the Israelites. The men appointed for ambush are, in one place, said to be 30,000, and in another 5000. For reconciling this apparent contradiction, most commentators have generally supposed, that there were two bodies placed in ambuscade between Bethel and Ai, one of 25,000 and the other of 5000 men; the latter being probably a detachment from the 30,000 first sent, and ordered to lie as near to the city as possible. Masius allows only 5000 men for the ambuscade, and 25,000 for the attack. As for the signal, used by Joshua on this occasion, the Rabbins suppose that the shield was too small for this purpose, and that it must have been the staff belonging to one of their colours, in which opinion Chevalier Folard acquiesces; adding, that the whole colours were used on this occasion, the part being substituted, agreeably to the figurative language of the east, for the whole. It has been suggested, that this was one of the fire-pots, which are employed as ensigns by the eastern caravans, whose smoke would ascend to a great height, be easily seen, and signify the fate intended for the city; and as the frame and staff of this instrument were of iron, it answers to the translation of the LXX and Aquila. Joshua viii. Patrick, in *loc.* Calmet.

AI, in *Zoology*, the *BRADYPUS tridactylus* of Linnæus, or SLOTH, with three-toed feet and short tail.

ALA, or ALLIA, in *Ancient Geography*, a river of Italy which discharged itself into the Tiber, about 19 miles above Rome. On the banks of this river, 200 Fabians were destroyed in their engagement with the Veii, and the Romans were defeated by the Senones of Gaul, conducted by Brennus.

AJABIRE, or AJAVIRA, in *Geography*, a town of South America, in Peru; 35 leagues south of Cusco.

AJAH, אַיָּה, a Hebrew term, which St. Jerome translates vulture. Bochart supposes that it denotes the merlin; the Syriac renders it raven, and the Arabic owl. Our translation (Job xxvii. 7.) renders it vulture; but (Lev. xi. 14. Deut. xiv. 13.) kite. It is evidently a species of unclean bird, and most probably the vulture or kite, so called from its gluttony, or from its note. *Aim* (Jer. l. 39.) may perhaps be the plural of Ajah, and signify flights of vultures, which in some countries are very numerous; though Bochart conceives them to be jackals. Calmet. Bochart Op. tom. iii. p. 193. &c. Ed. Villem.

AIAIA, in *Ornithology*, the name of a Brazilian bird, of the PLATALEA, or SPOONBILL-kind, called by the Portuguese *colborado*. Its specific character is, that its body is blood-coloured. It is exactly of the same shape, but somewhat smaller than the European species, and its beak is in the very same manner broad at the end, with a furrow parallel to the margin, and of a cinerous-white colour. It differs from the European species, by the rose or carnation which paints the white ground of its plumage on the neck, the back, and the sides; the wings are more strongly coloured, and the red tint turns into a crimson on the shoulders and the covers of the tail, of which the quills are rufous; the shaft of those of the wing is marked with fine carmine; the head and throat are naked and whitish; the legs grey; and the claws blackish. These beautiful colours, says Buffon, are found only in the adult.

This species is the *platea rosea* of Brisson, the *p. incarnata*

of Sloane and Ray, the Brazilian spoonbill, called *ajaja*, of Maregrave and Willughby, the *roseate spoonbill* of Latham, and the *spatule couleur de rose* of Buffon. There is a variety, called *TLAVHQUECHUL*, which Buffon supposes to be the same bird in its adult state. This rose-coloured spoonbill is common about the shores of rivers, feeds on small fish, and is, says Maregrave, of an agreeable taste. It is diffused in the new continent from north to south, from the coasts of Mexico and Florida to Guiana and Brasil. It is also found in Jamaica, and probably in the adjacent islands; but the species is no where numerous. In the morning and evening the spoonbills are seen on the sea-shore, or settling on trunks that float near the beach; but about the middle of the day in very sultry weather they enter the creeks, and perch high on the aquatic trees. However, they are not very wild; as they pass at sea very near the canoes, and on land they will allow a person to approach them within gun-shot. Buffon's Birds. vol. vii. p. 437. Eng. Ed.

AJALON, in *Scripture Geography*, a name given to four different cities, viz. one in the tribe of Dan, between Timnah and Beth-sheMesh, assigned to the Levites; probably that referred to by Joshua chap. x. 12:—another, in the tribe of Benjamin, between Bethel to the north, and Jerusalem to the south:—a third, in the tribe of Ephraim, about two miles from Shechem:—and a fourth, in the tribe of Zebulun, whose precise situation is not known.

AJAN, or AXAS, in *Geography*, a country extending along the eastern coast of Africa, from Magadoxo to Cape Guardafui, comprehending about 10 degrees of latitude. This maritime tract contains several petty kingdoms and states; the principal of which are the kingdoms of ADEL or Zeila, and MAGADOXO or Madagoxo, on the coasts, and some others inland, hardly known even by their names. The eastern coast of Ajan is sandy and barren, the habitation merely of wild beasts, and therefore called the desert coast: but farther towards the north the country is fertile, producing all sorts of provision, and furnishing means of commerce, and particularly an excellent breed of horses, which foreign merchants take in exchange for silks, cottons and other cloths. The inhabitants along the coast are generally white with long hair; but towards the south they become more tawny, and even black. The negroes intermarry with the Bedowin Arabs, and carry on a great commerce with them in gold, slaves, horses and ivory, which they commonly bring from Abyssinia, whither they occasionally repair for the sake of plunder. As they are all either zealous Mohammedans or Bedowins, they are enemies to the Abyssinians, who are Christians; and their irruptions into Abyssinia accustom them to war. Those of them, and especially of the Bedowins, who live near the trading coasts, are arrant thieves. Mod. Un. Hist. vol. xii. p. 304., &c.

AJANDUM, a town of Asiatic Turkey, in the province of Natolia; eight leagues west-south-west of Sinope.

AJAR, in *Natural History*, the name given by Adamson to the *CHAMA antiquata* of the Linnæan system.

AJARAFE, in *Geography*, a fertile district of Spain, in the kingdom of Seville; in which there is a little town situated on the Guadianar, called Ciudad of St. Lucar la Mayor.

AJAS mons, a mountain of Marmarica, in Africa, according to Ptolemy.

AJAS, a small town of Asia, in Natolia, famous for its mineral waters; called also *Therma*.

AJAS is also a small town of Arabia Felix, situated in a valley, and about two days journey from Aden.

AJASALUCK, a name given by the Turks to the ancient **EPHESUS**. The name denotes the temple of the moon, and is derived from the magnificent structure formerly dedicated to Diana.

The ruins of this famous city serve now merely as a place of accommodation and shelter for the shepherds and their flocks, and is the occasional habitation of birds and beasts of prey. The glorious pomp, says Dr. Chandler, (*Travels*, p. 131) of its heathen worship is no longer remembered; and Christianity, which was there nursed by apostles, and fostered by general councils, until it increased to fulness of stature, barely lingers on in an existence hardly visible. By this writer it is described as exhibiting a very gloomy and melancholy appearance, though not absolutely without people. The fires which were lighted in the night among the bushes, and round which the villagers collected, afforded a dim prospect of ruin and desolation. A shrill owl, called *Cucavaia* from its note, with a night-hawk, flitted near them; and a jackall cried mournfully, as if forsaken by his companions on the mountain. The biblical critic may possibly consider this description as a lively comment on the language of the prophet. *Zeph. ii. 7, &c.*

AJATOCHTLI, in *Zoology*, a name given by Hernandez to the *DASYPUS octocinctus*, or *eight-banded ARMADILLO*.

AJAX OILIADES, in *Classical Biography*, one of the leaders of the Greeks, in the expedition against Troy, was the son of Oileus, a powerful chief of the Locrians. Homer (*Iliad lib. xiv. v. 520*) ascribes to him agility, and a promptitude in executing whatever he undertook, and he is said to have excelled in the use of the bow and javelin, and in swiftness of foot. Horace is by some commentators supposed to refer to him, *Od. xv. l. 1. v. 19*. Such was his daring resolution, that even the Gods could not awe and subdue him. Homer *Odyss. lib. iv. v. 502*.

“ Impious he roar’d defiance to the Gods,
To his own prowess all the glory gave.”

POPE.

The offence which is reported to have incurred the displeasure of the Gods, was his violation of Cassandra, the daughter of Priam, in the sanctuary of Minerva, where she had taken refuge. Ajax however denied the fact, and imputed the charge to the artifice of Agamemnon, who wished to keep Cassandra for himself. In his return home, he and his whole fleet were wrecked by the vengeance of Minerva. Some say that he escaped; and that in the moment of danger he impiously exclaimed: “ In spite of the Gods, I will escape.”—Homer *ubi supra. v. 504*.

“ The power defrauding who vouchsafed to save.”

POPE. Gen. Dict.

AJAX Telamonius, was the son of Telamon, prince of Salamis, and one of the principal heroes of the *Iliad*, whom Homer represents as inferior only to Achilles in strength and valour, and as the chief bulwark of the Greeks, after the secession of that warrior. “ His character,” says a much approved biographer, “ seems to be intended as the model of that steady, agreeable courage which is ever at hand, when its exertions are wanted, and requires no aid of circumstances to excite its energy. He is the only hero, who neither asks nor receives the assistance of a deity:”—and his character is exhibited as a striking instance of impiety and irreligion. It is said, that when he was going to the army, his father recommended to him always to join the assistance of God to his own per-

sonal courage. Ajax replied, that even cowards themselves were very often victorious by such aid; but for his part he should have no regard to it, and that he was free of being able to conquer without it. Thus Sophocles, in *Ajace*, represents the matter. Homer, however, partly vindicates him from the charge of total irreligion: for though he did not pray to Jupiter himself, when he prepared to engage the valiant Hector, he desired others to pray for him, either with a low voice, lest the Trojans should hear, or louder if they pleased; “ for,” says he, “ I fear no person in the world.” *Iliad lib. vii. v. 194*. When the arms of Achilles were adjudged by the Greek chieftains to his rival Ulysses, Ajax was bereaved of his understanding; and first venting his rage against a flock of sheep, taking them to be Greeks, he then turned his sword against himself. Fable reports, that the flower called hyacinth sprung from his blood. The Greeks erected a noble monument to him on the promontory of Rhoeteum. Pausanias says, (*lib. i.*) that one of their tribes bore the name of Ajax, and that the people of Salamis built a temple to him. Herodotus (*lib. viii. c. 64. c. 121.*) informs us, that the whole country of Greece invoked him a little before the battle of Salamis, and dedicated to him, as part of the first fruits due to the Gods, one of the ships which they had taken from the Persians in that battle. Pausanias relates, amongst other wonderful tales, that the waves cast the arms of Achilles upon the tomb of Ajax, after the shipwreck of Ulysses. The fate of Ajax was the subject of several eminent tragedies. Gen. Dict.

In his last martial exploit, when he was endeavouring to preserve and rescue the dead body of Patroclus, and when he was overwhelmed with a mist or darkness, which intercepted his view of the Grecian host, he made the following address to Jupiter, which has been much admired for its moral sublimity:

“ Lord of earth and air,
Oh king! oh father! hear my humble pray’r:
Dispel this cloud, the light of heaven restore:
Give me to see, and Ajax asks no more:
If Greece must perish, we thy will obey,
But let us perish in the face of day.”

Iliad lib. xvii. v. 645, &c. POPE.

An ingenious writer has justly appreciated the character of this hero. After a concise abstract of his history, and a detail of his principal exploits, he adds, “ Such is the Ajax of the *Iliad*:—a hero (as far as so rude an age admits of heroism) *in grain*; tried and proved by every difficulty and danger; not the meteor of a day, but shining with equal lustre through the whole period of action; always in his place; resorted to on every emergency, and never in vain; not hurried along by idle bravado or enthusiastic ardour, but making utility the guide of his actions; finally, never yielding but when mortal assistance was unavailable, and when a heaven-born champion, with celestial aid, was necessary to turn the tide of fortune. He may then stand in the number of *able and useful men*, whose value is superior to their fame:—a class of which there are members in every profession and rank of life, and to whose assistance, the first-rate characters owe great part of their celebrity and success.”

“ Such was the Antipater of Philip of Macedon:”—
“ Such was the Labienus of Cæsar, the Agrippa of Augustus, the Sully of Henry IV., the Cecil of Elizabeth, the Ireton of Cromwell. Such appear to be the generality of those officers in the British navy, under whose

conduct the empire of the ocean has been maintained for their country every where, against all foes, by dint of equal valour and unvarying skill. In science, in the arts, in the common business of life, such men might be pointed out. In general, they are those whom the leaders in important affairs would chuse for their seconds, to supply their places on occasion, act according to their plans, and take the management of separate and dependent parts. Their essential qualifications are, a perfect fitness for their posts, and a constant readiness to bring all their powers into full exertion:—firmness, vigilance, order, and the habit of fixing the attention upon particular objects." See Aikin's Letters to his Son. vol. ii.

AJAX, in *Antiquity*, a furious kind of dance, in use among the Grecians; intended to represent the madness of that hero, after his defeat by Ulysses, to whom the Greeks had given the preference in his contest for Achilles's arms.

Lucian, in his treatise of dancing, speaks of dancing the Ajax. There was also an annual feast, called *Ajantia*, *Αϊαντία*, consecrated to that prince, and observed with great solemnity in the island of Salamis, as well as in Attica; where, in memory of the valour of Ajax, a bier was exposed, set out with a complete suit of armour. Potter, *Archæol.*

ΑΪΑΧ, in *Entomology*, a species of the *PAPILIO eques*, with wings obtusely caudated and brown colour, yellowish bands and tawny anus. It is the papilio marcellus of Cramer, and found in North America.

AJAX, in *Conchology*, is a variety of the *MUREX lampas* of Gmelin's Linnæan system; called also *Rubeta*.

AJAZZO, in *Geography*, a sea-port town of Natolia, on a gulf of the same name, in the province of Caramania, anciently Cilicia, at the north-east extremity of the Mediterranean sea, 30 miles north of Antioch, and 50 west of Aleppo; where the city of Iffus antiently stood. It is situated near the gulf of Scanderoon. Here Alexander the Great defeated Darius a second time, and took his family prisoners. In the time of the crusades, this belonged successively to Christians, Saracens, and Turks, who now possess it. E. long. 33° 10'. N. lat. 37°.

AJAZZO or **AJACCIO**, is a sea-port town, in a bay of the same name, in the south-west part of the island of Corsica, with a bishop's see under the archbishopric of Pisa. It is situated in a fertile territory, abounding with excellent wines. It is guarded by a small citadel; the streets are straight and large; the houses well built; the adjacent walks agreeable; and the number of inhabitants about 4000, many of whom are Greeks. Its commerce is supplied by a fishery of black, red and white coral, and by its timber. The bay, though incommoded by rocks, affords secure anchorage for ships of considerable burden. The ancient town was situated about a league from the present, which was built in 1435; and many ruins of it are still remaining. A colony of Greeks was established in the vicinity of Ajazzo in the year 1677; but the protection of the Genoese could not prevent its being dispersed and partly destroyed by the Corsicans. E. long. 8° 50'. N. lat. 41° 50'.

AIBAN-KESRA, an old castle of ancient Babylonia, situate on the banks of the Tigris, in the government of Bagdad, and supposed to have been the residence of Cosroes, and other Persian kings.

AIBLING, a town of Germany in Upper Bavaria, near the river Manguald, and not far from its junction with the Inn. Long. 55°. lat. 34°.

AICHA, a small town of Upper Bavaria, situated on

the Paar; four leagues east-north-east of Augsborg. It was taken by the Swedes in 1633, and in 1634 laid in ashes by them. E. long. 30° 40'. N. lat. 48° 30'.

AICHBURG, a town of Germany in Stiria; four miles south-south-east of Fridberg. There is also a town of the same name in the archduchy of Austria; eight miles north-west of Efferding.

AICKIRCHEN, a town of Germany in the archduchy of Austria; seven miles west-north-west of Schwannastat.

AICHLBERG, a town of Germany in Carinthia; four leagues west-south-west of Villach.

AICHMALOTARCHA. See *ÆCHMALOTARCHA*.

AICHOSTADT, a city of Germany, the capital of a foreign bishopric of the same name in Franconia, situated in a fertile valley on the river Altmuhl, and founded in the year 748, by St. Boniface archbishop of Mentz. The diocese is 18 leagues long and 7 broad; and its inhabitants generally profess the catholic religion. The place of the bishop in the general diet of the empire is between the bishops of Worms and Spire, and he is the suffragan of the archbishopric of Mayence. The bishop has for his guard three companies of infantry, a company of cuirassiers, and a company of dragoons. At the cathedral of this city, the eucharist is exhibited in a vessel of gold, denominated the sun, of the weight of 40 mares, enriched with an incredible quantity of diamonds, pearls, and rubies. They reckon 350 diamonds, 1400 pearls, and 250 rubies, with many other precious stones. It was presented to the cathedral by the bishop of the diocese in 1611. But it is doubtful, whether some of the precious stones have not been exchanged, in some period of public distress, or by some artifice, for others of less value, that equally answer the purpose.

Aichstadt is four leagues north of Neuburg, five north-west of Ingolstadt, and 15 south of Nuremberg. E. long. 11°. N. lat. 49°.

AICHOSTADT ober, is a town on the Altmuhl, one league west of the former.

AID, or **ΑΥΔΕ**, **AUXILIUM**, literally denotes the help, succour, or assistance, which any person lends another, when too weak to do, or avoid, something.

The word is French; formed, according to M. Menage, from the Italian *aitare*; and that from the Latin *adjutare*, to help or assist.

AID, or **ΑΥΔΕ**, in *Law*, is when a petition is made in court, for the calling in of help from another person interested in the matter in question; who, it is probable, may not only strengthen the party's cause who thus prays for aid, but also prevent a prejudice arising to his own right. Thus in real actions, the tenant may pray in aid, and call for assistance of another to help him to plead, because of the feebleness of his own estate. A tenant for life may also pray in aid of him that hath the inheritance in remainder or reversion; and an incumbent may pray in aid of the patron or ordinary: that is, that they shall be joined in the action, and help to defend the title.—This is called *aid prier*; but this course of proceeding is now much disused.

A city, or corporation, holding a fee-farm of the king, may pray in aid of him, if any thing be demanded of them relating thereto.

The *aid prier* is sometimes also used, in the king's behalf, to prevent any proceedings against him till his counsel be called, and heard what they have to say for avoiding the king's prejudice, or loss. Jeak. Cent. 64. Termes de Ley, 35. Stat. 4 Edw. I. and 14 Edw. III.

AID de camp, an officer in the army, whose business is to attend

attend the general officers, and receive and carry their orders, as occasion requires.

When the king is in the field, he usually appoints young volunteers of quality to carry his orders, who are called the king's aids de camp.

Aid major, or adjutant, is an officer whose business is to ease the MAJOR of part of his duty; and to perform it all in his absence.

Some majors have several aid majors.—Each troop of guards has but one major, who has two aid majors under him, or more, according as the business requires.

Every regiment of foot has as many aid majors as it contains battalions.—When the battalion is drawn up, the aid major's post is on the left, beyond all the captains, and behind the lieutenant-colonel.

AID, AUXILIUM, in our *Ancient Customs*, denotes a subsidy or sum of money due to the lord, from his tenants, on certain occasions.

It differed from a *tax*, which is imposed at any time when wanted; whereas the *aid* could only be levied where it was customary, and where the particular occasion fell out.

Such was the *aid de relief*, due from the tenants in fee, upon the death of the lord mesn, to his heir, towards the charge of a relief of the fee, of the superior lord. This was abolished by king John's magna charta.

Such also was the *aid chevel*, or *capital aid*, due by vassals, to the chief lord, or the king, of whom they held *in capite*. Of this there are three kinds.

The first, of chivalry; or, as they call it, *par faire fitz chevalier*, toward making his eldest son a knight, when arrived at the age of fifteen years; the second of marriage, or *par fille marier*, towards marrying his eldest daughter.—Both these, with all charges incident thereto, are taken away by stat. 12 Car. II. See *TENURE, SERVICE, &c.*—Some will have them to have been first established in England by William the Conqueror, and afterwards transferred to Normandy; but the more common opinion is, that the Conqueror brought them with him.—The third was of a RANSOM, due when the lord was taken prisoner by the enemy.

It appears from Bracton (lib. ii. c. 16. §. 8) that, in the time of Henry III. these aids, which were allowed by the charter of king John, were supposed to be paid by the vassals, rather as tokens of good will and affection to their lords, than as proper concomitants of the service they owed. Glanville, on the contrary, considered them as due by their tenures. But, both by that author, and in the charter, it is said, that they ought to be taken in reasonable proportions. Glanville questions, whether the feudal lord could demand an aid of his tenants for the support of his war? And replies by saying, that he could not distrain for such aid; but they might give it, as a *benevolence*, and out of affection to their lord; whereas he considers the *aid de relief*, as a due, for which the lord, in virtue of his fief, had a legal right to distrain. Lyttelton's Hist. Henry II. vol. iii. p. 108. 8vo.

In some provinces there was a fourth kind of aid; due whenever the lord should undertake an expedition to the Holy Land.

We also read of aids paid the lord, when he was disposed to purchase any new land, or tenement. These were only granted once in his life.—Also aids for the repairing and fortifying of castles, seats, &c. and also aids to pay the lord's debts. To prevent this abuse, king John's magna charta ordained, that no aids be taken by the king without consent of parliament, nor in any wise by inferior lords, except only the three ancient ones above-mentioned, *viz.* for making the lord's eldest son a knight, for marrying his

eldest daughter, and for ransoming the lord's person, if taken prisoner. But this provision was omitted in Henry III's charter; and the same oppressions were continued till the 25 Edw. I. when the statute called *confirmatio chartarum* was enacted; which in this respect revived king John's charter, by ordaining that none but the ancient aids should be taken. But though the species of aids was thus restrained, yet the quantity of each aid remained arbitrary and uncertain. King John's charter, indeed, ordered that all aids taken by inferior lords should be reasonable; and that the aids taken by the king of his tenants *in capite* should be settled by parliament. But they were never completely ascertained and adjusted till the statute Westm. 1. 3 Edw. I. c. 36, which fixed the aids of inferior lords at twenty shillings, or the supposed twentieth part of the annual value of every knight's fee, for making the eldest son a knight, or marrying the eldest daughter; and the same was done with regard to the king's tenants *in capite*, by stat. 25 Edw. III. c. 11. The other aid, for ransom of the lord's person, being not in its nature capable of any certainty, was therefore never ascertained. Blackst. Com. lib. ii. c. 5. vol. ii. p. 64. 8vo.

By the stat. 34 Edw. I. it is ordained, that the king shall levy no aid or tax without his parliament.

Aids seem to have been first established with a view to the clients and freedmen of ancient Rome, who made presents to their patron towards his daughters fortune, as also on his birth-day, and on other solemn occasions.—Accordingly, Bouteiller relates, that in his time these aids depended on the courtesy and good will of the vassals; for which reason they were called, *droits de complaisance*.

The bishops also received aids from their ecclesiastics, called *synodals*, and *pentecostals*. They were to be paid at the time of their consecration; or when they had a king to entertain; or when called by the pope to his court, or to a council; as also when they went to receive the *pallium*.

Add, that the archdeacons also exacted aids from the clergy of their jurisdiction. See *PROCURATION*.

A kind of feudal aids are still levied in Germany, &c. under the title of *collekte*.

AIDS are also used in matters of polity, for any extraordinary taxes, or impositions, occasionally levied by the king and parliament, upon the subjects, to support the charges of the government, when the ordinary revenue is deficient.

AID, royal, is a name frequently given to the land-tax.

AID, in *Theology*; the aids or assistances of divine favour, which are offered to man, have been the subject of much dispute betwixt the Jansenists and Jesuits; for the composing whereof, a celebrated congregation was erected at Rome under the title of congregation of *aids*, *congregatio de auxiliis*.

Some divines, after St. Augustine, distinguish two kinds of aids, *viz.* *sine quo*, and *quo*.

Auxilium sine quo, that which the mind is at liberty either to use or refuse; such is supposed to have been the aid ministered to man in the state of innocence, while his mind and will were sound and upright.

Auxilium quo amounts to what is otherwise called efficacious grace, which surmounts and subdues the will; such, according to the Calvinists and Jansenists, is supposed to be the aid ministered by grace, in the present fallen state of human nature.

AIDS, in the *Manege*, are helps or assistances by which the horseman contributes towards the motion or action required of the horse, by a judicious use of his body, or the appointments of the horse.

Aids are of the greatest service in the manege, and form the only true language between the master and the horse; by these he is encouraged to act with propriety and energy, and the necessity of correction is prevented; consequently it must be evident that a great mixture of gentleness and spirit are requisite in their exhibition.

The principal aid is derived from the bridle; indeed the different management of this appointment forms several distinct aids, each of which is so useful and necessary that it might constitute a distinct lesson. The cavesson forms at once an aid and a correction of the most powerful kind, and in no way is the obedience of a horse so well secured as by this means. The spur is of this number likewise; when made use of as an aid, it is by gently closing the heels and applying the points only to the skin; but the calves of the legs are perhaps the best aids of this kind.

The whip is used as an aid to keep the attention of the horse alive, by elevating the hand and striking the aid, or gently patting the animal in different parts; judiciously managed to a well dressed horse, it forms a very lively and animating aid. The voice is likewise made use of as an aid. The motions of the thighs, knees, and the calves of the legs, form separate aids; that of the calves is the most important and useful, without a proper knowledge of which, both horse and rider must be defective. The calves are used together, or separate; when one calf alone is employed, it is usually accompanied with the hand, to alter the position of the body, or change the leg, by which any action is led. The elevation of the body in the stirrups forms another aid.

The aids made use of to make a horse go in airs, are either different in themselves, or differently applied, to those made use of on the ground. The general application of these aids on the road is a branch of riding in which English horsemen are by foreign masters deemed defective. The inner heel, inner leg, and inner rein, are called inner aids. The outer heel, outer leg, &c. are outer aids. See Berenger's Art of Horsemanship, vol. ii. p. 92, &c.

AIDS, in the *French Law*, denote a duty paid on all goods sold and transported either out of, or into the kingdom. In this sense aids answer to what the Latins call *vectigalia*, *vehendis mercibus*, and are paid by all kinds of persons, privileged, or non-privileged; by which they differ from *tailles*, *taxes*, which are only paid by the peasants, being a sort of capitation, answering to what the Latins call *tributum*.

AIDS, *court of*, in France, a court erected for the cognizance of matters relating to the taxes. Appeals come to this from the court of elections, where matters relating to the *taille* are first heard. The *court of aids*, of a province, is sometimes separated from the parliament of the province, and fixed in another city, as at Montpellier, Montauban, &c. There are twelve courts of aids, of which the principal is that at Paris.

AIDAN, in *Biography*, a British bishop of the 7th century, was employed in instructing the inhabitants of the Northern parts of England in the Christian religion. He was a monk in the monastery of Hii, or Jona, one of the Hebrides, which was subject to Britain, but given to the Picts, who inhabited those parts of Britain, in recompence of the zeal with which they had preached to them the faith of Christ. The kingdom of Northumberland, though it had received the Christian doctrine from Paulinus, archbishop of York, relapsed into idolatry. When Oswald, in 634, became king of Northumberland, he sent to Scotland for a missionary, qualified for instructing his subjects in the doctrines and duties of christianity. It happened that a

very improper person, an ecclesiastic named Corman, of severe disposition and rugged manners, was first deputed for this purpose; but it soon appeared that Aidan, who was mild and prudent, was much fitter for the office; accordingly he was consecrated a bishop and sent to the court of Oswald. At his solicitation the episcopal see was removed from York to Lindisfarne, a peninsula adjoining the Northumbrian coast by a narrow isthmus, called also Holy Island, because it was chiefly inhabited by monks. Here Aidan exercised an extensive jurisdiction, and preached the gospel with great success; deriving encouragement and assistance in his labour, from the condescending services of the king himself. After the death of Oswald he continued to preside in the church of Northumberland, and died in the year 651. We have an extraordinary instance of this bishop's liberality to the poor. Having received a present from king Oswin of a fine horse and rich housings, he met with a beggar, and dismounting, gave him the horse thus caparisoned. When the bishop expressed some displeasure at this singular act of humanity, and the slight put upon his favour, Aidan quietly but forcibly asked, "which do you value most, the son of a mare or a son of God?" the king was so affected that he fell upon his knees and intreated the bishop's forgiveness. Bede describes the character of Aidan in terms of high commendation, and ascribes to him miracles, which the credulity of the times in which he lived would be disposed to admit. To the report of one of his miracles we are inclined to give our assent. When the bishop gave the priest, who was to conduct the betrothed wife of Oswin by sea to Northumberland, a phial of holy oil, instructing him, in case of a storm, to pour it into the sea, and assuring him that it would soon become calm, it is possible he might not be unacquainted with the efficacy of oil thus applied, which has been long known, and is now sufficiently established by observation and experiment. Biog. Brit.

AIDERBEITZAN, ABERBIJAN, or, as the Persians call it, AZERBEYAN, in *Geography*, a province of Persia, borders to the east on the province of Ghilan, the Caspian Sea and Tabrislan, to the south on Irac, Ajemi, to the west and north-west upon Curdistan and Upper Armenia, and to the north on Schirwan and Georgia. The etymology of the name given by the Persians to this province imports a country of fire, so called on account of the temple erected in it for keeping their sacred fire. The soil is fruitful, and the climate healthy, though cold. The most considerable cities in it are Tauris, Ardevil and Sultania. The province extends from about 48° to 54° E. long. and from 36° to 39° N. lat.

AIDHAB, or GAIDHAB, or ARDAH, a town of Africa, and sea-port of Nubia, on the coast of the Red Sea. E. long. 35° 59'. N. lat. 22° 12'.

AIDONA, a town of Sicily, in the valley of Noto; four miles north-east of Piazza.

AIELLO, a small town and dukedom of Naples, in the Abruzzo Ultra, belonging by marriage to the hereditary prince of Modena.

AIELLO is also a town of Naples, in the district of Calabria Citra, with the title of a principality; nine miles south-south-west of Cosenza.

AIEREBA, in *Ichthyology*, the name of a fish of the *pastinaca marina* kind, but differing from all the others, in that the form of its body is regularly round, or oval, and its head placed far within the verge of its thin part. It is common in the Western Ocean; but it is not much esteemed for the table, being more loose and flabby in its flesh than the other kinds. Marcgrave.

AIGEN, in *Geography*, a town of Germany in the arch-dutchy

duchy of Austria, on the confines of Bohemia; 55 miles west of Vienna. E. long. $13^{\circ} 52'$. N. lat. $48^{\circ} 33'$.

AIGHENDALE, a liquid measure in Lancashire, containing seven quarts.

AIGITHALUS, *αιγιθαλος*, in *Ornithology*, a name by which Aristotle, and some of the old authors call the *PARUS*, or *TITMOUSE*.

AIGLANDE, in *Geography*, a town of France, in the department of the channel, and principal place of a canton, in the district of St. Lo; four leagues north-east of Coutances.

AIGLE (L'), *AQUILA*, a small well-built town of France, and capital of a district situate on the Rille, in the department of Orne; $10\frac{1}{2}$ leagues north-east of Alençon. Its principal commerce is corn, hard-wares and pins. It contains three parish churches, two convents, and a hospital; is surrounded with walls, and has six gates. E. long. $1^{\circ} 31'$. N. lat. $48^{\circ} 46'$.

AIGLE, a town of Switzerland, in a part of the Lower Valais, which belongs to the feignory of Berne, and forms part of a canton. It is situated on a small river, which runs into the Rhone, about a league below it; 12 leagues east-north-east of Geneva. The country about it has rich pastures, and good wines and fruit; but it often suffers from the inundations occasioned by the high mountains that bound it towards the north. The salt that is collected from the saline waters in its vicinity is refined at Aigle. E. long. $6^{\circ} 51'$. N. lat. $26^{\circ} 22'$.

AIGLE, a river of France, which waters part of the government of Orleanois, rises near Mée in Beauvais, and discharges itself into the Loir, between Chateaudun and Cloye.

AIGLETTE, in *Heraldry*. See *EAGLET*.

AIGN, in *Geography*, a town of Germany, in the circle of Bavaria, and archbishopric of Saltzburg, near which is a medicinal spring; two miles south-east of Saltzburg.

AIGNAN, a town of France, in the department of Gers and district of Nogaro; seven leagues west of Auch.

AIGNEY-LE-DUC, a town of France, in the department of the Cote d'Or, a district of Chatillon; $4\frac{1}{2}$ leagues south-south-east of Chatillon. It is situated on a small mountain, at the foot of which runs a stream of the same name. Its chief subsistence is derived from bleaching and the commerce of linen cloth.

AIGRE, a town of France, in the department of the Charente and district of Ruffec; $5\frac{1}{2}$ leagues north of Angouleme.

AIGREFEUILLE, a town of France, in the department of the Lower Loire and district of Clifton; $3\frac{1}{2}$ leagues south of Nantes.

AIGREMONTE, a small town of Burgundy in France, in the generality of Dijon.

AIGRETTE, in *Ornithology*, a name given by Buffon to different species of *ARDEA*, or the *EGRETS* of other authors.

AIGRETTE, in *Zoology*, a name given by Buffon to the *SIMIA AYGULA*.

AIGUE MARINE, in *Natural History*. See *AQUA MARINA*.

AIGUEBELLE, in *Geography*, a small town of Savoy, on the river Arc, surrounded by high mountains; five leagues east from Chambery. The manufacture of this place is silk.

AIGUEBELLE is also a small town of France, in the department of the Drome; two leagues south-east of Montelimart.

AIGUE-PERSE, a small town of France, in the de-

partment of Puy-de-Dome, and late province of Auvergne; 18 miles north of Clermont and 261 south of Paris. The cold water of a fountain near it has the appearance of boiling, and is said to be fatal to the animals that drink it. E. long. $3^{\circ} 20'$. N. lat. $45^{\circ} 50'$.

AIGUES, a river of France, which runs into the Rhone, near Orange.

AIGUESCAUDES, is situated in the valley of Ossau, in the principality of Bearn, in France; and is famous for a spring of water, soapy and sulphurous, and smelling like a rotten egg, which is deemed salutary in many inward and outward disorders.

AIGUES-MORTES, a town of France, in the department of the Gard and district of Nimes; $4\frac{1}{2}$ leagues south of Montpellier. The soil in the neighbourhood is sandy, and the air unwholesome on account of the stagnant waters that surround it. It formerly stood on the sea and had a harbour; but it is now above two leagues up the country, and the harbour is filled up. This place is famous for an interview which took place in 1538, between Charles V. and Francis I. after 20 years of open hostility or secret enmity; on which occasion they vied with each other in expressions of respect and friendship. E. long. $5^{\circ} 8'$. N. lat. $43^{\circ} 34'$.

AIGUES-VIVES, a town of France, in the department of the Gard and district of Sommieres, five leagues north-east of Montpellier.

AIGUILLON, a town of France, in the department of the Lot and Garonne, and district of Tonneins; six leagues north-west of Agen. This town carries on a considerable trade in wines, brandy and hemp. E. long. $0^{\circ} 22'$. N. lat. $44^{\circ} 25'$.

AIGUINES, a town of France, in the department of the Var and district of Barjols; $5\frac{1}{2}$ leagues north-east of Barjols.

AIGUISCE', AIGUISSE', or EGUISE', in *Heraldry*, a term applied to a *CROSS*, when its four ends are sharpened, but so as to terminate in obtuse angles.

The cross *aiguisee* differs from the cross *FITCHEE*, in that the latter goes tapering by degrees to a sharp point; whereas only the ends of the former are tapered.

Crosses were so formed by the Christians in their pilgrimages for the convenience of fixing them in the ground at their devotion. In the English blazon this kind of cross is called a *cross arde*.

AIGURANDE, or AGURANDE, in *Geography*, a town of France, in the department of the Indre, late province of Berry, and district of La Chatre; $8\frac{1}{2}$ leagues south of Chateauroux. The country round it furnishes fat cattle. E. long. $1^{\circ} 44'$. N. lat. $46^{\circ} 27'$.

AII, a people of India, placed by Ptolemy on this side the Ganges.

AIKES, a town of Transylvania, six leagues north-east of Klausenburg.

AIKMAN, WILLIAM, in *Biography*, a painter of considerable eminence, the son of William Aikman, Esq. of Cairney in Scotland, was born October 24th, 1682, and intended by his father, who was an advocate at the Scots bar, for his own profession; but the son declined the study of the law, and devoted himself to the fine arts, and particularly to that of painting. Having prosecuted his studies for some time in Britain, he removed to Italy in 1707, and resided for three years at Rome. He then travelled to Constantinople and Smyrna, and in 1712 returned from Rome to his own country; and in 1723 he settled in London, and followed the profession of painting under the patronage of the Duke of Argyle, the Earl of Burlington, Sir Godfrey Kneller, and some other encouragers of the arts of that period.

penod. For the Earl of Burlington he painted a large picture of the royal family, which his death prevented his finishing. It is now in the possession of the Duke of Devonshire. Towards the close of his life he painted many other portraits of persons of the first rank in England; and there are several portraits painted by him in Scotland, which are now in the possession of the Duke of Argyle, the Duke of Hamilton and others. This ingenious artist died in London, June 5th, 1751; and having lost his son about six months before, at the age of 17, their remains were removed to Edinburgh, and interred on the same day in the Greyfriars church-yard. Amongst his intimate friends we may reckon Mr. W. Somerville, the well-known author of the *Chace*, &c. Mr. Mallet, Mr. Allan Ramfay, and Mr. Thomson, each of whom paid an elegiac tribute to his memory. The following epitaph by Mr. Mallet, was engraven on his tomb.

“ Dear to the good and wise, disprais’d by none,
Here sleep, in peace, the father and the son;
By virtue, as by nature, close ally’d,
The painter’s genius, but without the pride:
Worth unambitious, wit afraid to shine;
Honour’s clear light, and friendship’s warmth divine:
The son fair rising, knew too short a date;
But, oh! how more severe the father’s fate!
He saw him torn untimely from his side,
Felt all a father’s anguish—wept, and dy’d.”

Mr. Thomson’s poem on the death of Mr. Aikman, closes with the following lines:

“ A friend, when dead, is but remov’d from sight,
Sunk in the lustre of eternal light;
And when the parting storms of life are o’er,
May yet rejoice us on a happier shore.
As those we love decay, we die in part;
String after string is sever’d from the heart,
Till loosen’d life, at last, but breathing clay,
Without one pang is glad to fall away.
Unhappy he, who latest feels the blow,
Whose eyes have wept o’er every friend laid low;
Dragg’d ling’ring on from partial death to death,
Till dying, all he can resign is breath.”

For the eight last lines, see Thomson’s Works, vol. ii.

p. 283.

In his style of painting Mr. Aikman seems to have aimed at imitating nature in her pleasing simplicity; his lights are soft, his shades mellow, and his colouring mild and harmonious. His touches have neither the force nor harshness of Rubens; nor does he seem, like Reynolds, ever to have aimed at adorning his portraits with the elegance of adventitious graces. His mind, tranquil and serene, delighted rather to wander with Thomson in the enchanting fields of Tempe, than to burst, with Michael Angelo, into the ruder scenes of the terrible and the sublime. His compositions are distinguished by a placid tranquillity of ease rather than a striking brilliancy of effect; and his portraits may be more readily mistaken for those of Kneller than any other eminent artist; not only because of the general resemblance in the dresses, which were those of the times, as they were contemporaries, but also for the manner of working, and the familiarity and bland mellowness of their tints. Biog. Di&.

AILAH, formerly *ÆLANA* and *ELATH* of Scripture, a ruined town of Arabia Petræa, on the north-west coast of the gulf of Akaba or Ailaha; about 140 miles south-east of Suez. E. long. 35° 0′. N. lat. 29° 20′.

ALLAN, a river of Siberia, which runs into the Penzinskaia gulf near Okiank.

AILANTHUS, formed of the Ambojna name *Aylanto*, which denotes the tree of heaven, so called on account of its lofty growth, in *Botany*, a genus of plants, the class and order of which are not ascertained. Prof. Martyn refers it to the *polygamia monoecia*, Schreber to the *diocia decandria*, and Gmelin to the *decandria trigynia*. Its characters are, that it has male, female and hermaphrodite flowers. The calyx of the male is a one-leafed, five-parted, very small perianthium; the corolla has five petals, lanceolate, acute, convolute at the base and spreading; the lamina have ten filaments, compressed, of the length of the corolla; the anthers are oblong and versatile. The calyx of the female is like that of the male, permanent; the corolla the same; the pistillum has from three to five germs, curved inwards; the styles are lateral and the stigmas capitate; the pericarpium has as many capsules as there are germs, compressed, membranaceous, sabre-shaped, acute, on one of the edges emarginate; the seeds are solitary, lens-shaped, bony, close to the emarginature. The calyx of the hermaphrodite is the same with that of the male and female; the corolla the same as in the male; the stamina have two or three filaments, as in the male; the pistillum, pericarpium and seed as in the female. There is one species, *viz.* *A. glandulosa*, or *tall ailanthus*, which is a tree with a straight trunk, 40 or 50 feet high, a native of China, and first raised in England about the year 1751. It grows fast in our climate, and as it rises to a considerable height, it is proper for ornamental plantations. A resinous juice, which soon hardens, flows from the wounded bark. The wood is hard, heavy, glossy like fatten, and susceptible of a very fine polish. This is the *Rhus Sinense*, &c. of Ellis. See Phil. Trans. vol. xxxix. p. 870, and vol. l. p. 446. Martyn’s Miller.

AILE, or AIEL, formed of Fr. *aieul*, *avus*, *grandfather*, in *Law*, a writ which lies where the grand-father, or great-grandfather, called *besaile*, was seized of lands or tenements in fee-simple, on the day he died; and a stranger abates or enters the same day, and dispossesseth the heir or grand-child. See ABATEMENT.

AILERONS, a diminutive of the French *aile*, *wing*, in *Natural History*, petty wings, a French term expressing two small shelly substances, resembling parts of wings, or young and just growing wings, and found in the two-winged flies, situated at the root of the larger wings. Reaumur.

AILES *virtées*, in *Natural History*, a French term used to express the wings of a series of insects, which seem of a middle nature, between the fly and the butterfly kind, and are therefore called *PAPILION mouches* by these writers. The wings of these insects are in part covered with dust, or scales, and in part free from it, and transparent. In these free parts they look glassy; whence their name, signifying *glassy wings*.

AILES BURY, in *Geography*. See AYLESBURY.

AILLANT-SUR-THOLON, a town of France, in the department of the Yonne, and district of Ivigny: 3½ leagues north-west of Auxerre.

AILLAS, a village of France, in the department of the Gironde, and district of Bazas; two leagues north-east of Bazas.

AILLY, a village of France, in the department of the Somme, and district of Abbeville; five leagues west-north-west of Amiens.

This is also the name of a town of France, in the same department, and district of Montdidier; three leagues south-south-east of Amiens.

AILLY, PETER D’, in *Biography*, bishop of Cambrai, and a bigoted ecclesiastic, was born of an obscure family at Compeigne in 1350. He finished his studies at Paris, and gave

gave proofs of a superior understanding even at college by his treatise "On Logic," "On the Nature of the Soul," and "On Meteors." In 1384 he was appointed grand-maître of the college of Navarre, where he had been educated. His zeal for the Catholic faith contributed to his advancement as much as his learning. Having pleaded in 1387, in favour of the miraculous conception, before the pope, he was appointed confessor to Charles VI. and chancellor of the University, and in 1391 bishop of Cambrai. He distinguished himself on various occasions as an advocate for the doctrines and ceremonies of the church; and at the general council of Constance, which lasted from the year 1414 to the year 1418, he was principal agent in the proceedings, which convicted Wickliff and Hus of heresy, and at last brought the latter to the stake, upon whom he pronounced the sentence of death. Notwithstanding his zeal against heresy, he is said to have been a friend to reformation, and that he wrote a book "On the Reformation of the Church," which, however, is not found among his works. His ideas of reformation must have been very partial and restricted, as he took pains to obtain a general council for terminating schism, and was attached to the absurdities of judicial astrology. On this subject he wrote a treatise, in which he maintained, that Noah's flood, the birth of Christ, and other such miraculous events, might have been predicted by astrology. He died in 1425, as some say, and according to others in 1419 or 1420, with the character of "the Eagle of France, and the indefatigable Mallet of Heretics." The epitaph on his tomb is as follows:

"Mors rapuit Petrum; petram subiit putre corpus:
Sed petram Christum spiritus ipse petit."

i. e. "Death seizes Peter, and under this stone,
His body decays; his spirit is flown
To Jesus his rock."

Of his numerous works several treatises and sermons were printed at Strasburg in 1490; his "Quæstiones in Sphæram Mundi" was printed at Paris in 1498, and at Venice in 1508; his "Treatise of Meteors" appeared at Paris in 1504, and his "Life of Cælestin V." in 1539. Cave Hist. Lit. vol. ii. Append. p. 84. Gen. Dict.

AILRED, ÆTHELRED, or EALRED, abbot of Revesby, in Lincolnshire, was born in 1109, and educated in Scotland, with Henry, son of David. He declined ecclesiastical preferment, and lived in studious retirement. His "History of the War of the Standard in the reign of Stephen;" "Genealogy of the English Kings;" "History of the Life and Miracles of Edward the Confessor;" and "History of the Nun of Watthun," written in Latin, are extant in the *Decem Scriptores*, published by Twysden, in London, 1652. His "Sermons," "Mirror of Charity," treatise "On the Child Jesus," and another "On Spiritual Friendship," were published at Douay, in 1631, and may be found in the *Bibliotheca Patrum*, tom. xxiii. He died in 1166. Cave Hist. Lit. vol. ii. p. 227. Biog. Brit.

AILSA, in *Geography*, an insulated rock near the isle of Bute, in Scotland, about two miles in circumference and 900 feet high, accessible on the north-east side, and the habitation of goats and rabbits, and sea-fowl, particularly the Solan geese, some of which are taken for food, and others for their feathers. The banks about it are well-stocked with cod and other fish.

AIMAKAN, a river of Siberia, which runs into the sea of Ochotskoi. E. long. 139° 14'. N. lat. 54° 44'.

AIMARGUES, or AYMARGUES, a town of France, with the title of a barony, in the department of the Gard, and diocese of Nîmes, situated in a marshy country on the

river Vidre; 5 leagues west of Arles, and 3½ south Nîmes. E. long. 3° 4'. N. lat. 44° 5'.

AIME, AIMO, or AXIMA, a small town of Savoy, on the river Here; six leagues east-north-east of Montlier.

AIMEER, one of the Soobahs, or grand divisions of Hindostan, according to the Ayeen-Akbery, or distribution of the emperor Akbar, is entirely in the possession of Sindiah and the Marattahs, and contains seven circars or counties, and 197 pergunnahs or hundreds. Its revenue is 22,841,507 daams, 320 daams being equal to a pound sterling. It has 86,500 cavalry, and 347,000 infantry.

AIMON, in *Biography*, a Benedictine Monk, wrote about the year 840, and is chiefly known as the author of a "History of France."

AIMONTE, in *Geography*, lies on the east side of the river Gaudiana near its mouth, which is the boundary from Portugal on the west, and is one of the best havens on the whole coast. W. long. 7° 15'. N. lat. 37° 5'.

AIMOUTIER, a town of France, in the department of Upper Vienna, and district of St. Leonard; seven leagues south-east of Limoges.

AIN, אֵין, signifying *fountain*, is an initial word prefixed to several Hebrew and Arabic appellations of places.

AIN, a river of France, whence one of the departments derives its name. It rises in Mount Jura, near Nozeroy, and after traversing a course from North to South of about 35 leagues, discharges itself into the Rhone, about five leagues above Lyons. The department of the Ain is one of the four departments, which are composed of the *ci-devant* Bresse, Bugey and Valromey, and the principality of Dombes; and into which the former province of Bourgogne is divided. It is bounded on the north by the department of Jura; on the east, by those of Lemans and Mont Blanc; on the south, by the river Rhone, which separates it from that of Here; and on the west, by the department of the Rhone. Its surface is about 1,077,432 square acres, or 549,905 hectares; its population amounts to about 288,700 persons; and it is divided into four communal districts. Its chief town is Bourg.

AIN, a town of Asia, in the Arabian Irak; 30 leagues west of Bassorah.

AINAD, a town of Arabia, in the province of Hadramaut.

AINAY-LE-CHATEAU, a town of France, in the department of Allier and district of Cerilly; eight leagues north-west of Moulins.

AINCREVILLE, a town of France, in the department of the Meuse, and district of Steuay; one league south-west of Dun.

AINEB-GUL, a town of Asiatic Turkey, in Natolia; 40 miles north-west of Degnizlu.

AIN-EL-CALU, a town of Africa, in the province of Tremecen, and kingdom of Fez.

AIN GEBEL, a town of Asia, in the province of Diarbekir; 16 leagues south-west of Mosul.

AINLING, a market town of Germany, in Upper Bavaria; ten miles north-west of Augsburg.

AINOD, a town of Germany, in the duchy of Stiria; eight miles north of Cilley.

AINSA, a small town of Spain, in the kingdom of Aragon, on the river Ara; six leagues north of Balbastro.

AINSWORTH, HENRY, in *Biography*, an eminent Nonconformist divine and Biblical commentator, flourished at the close of the 16th and commencement of the 17th century. About the year 1590, he united with the Brownists; and after struggling for some years with the dangers and troubles to which persons of this description were exposed by the indiscreet zeal of the bishops and the intolerance

of queen Elizabeth, he retired with many others of similar sentiments to Holland. At Amsterdam, Ainsworth and one of his brethren in exile, whose name was Johnson, established a church; and in 1602 published a confession of faith of the people called Brownists. But trivial points of discipline occasioned dissensions in the church, and these two leaders, with their respective parties, though they had fled from persecution at home, could not tolerate each other, nor live harmoniously in the same city. Johnson with his adherents removed to Embden, where he soon died, and his congregation was dissolved. Ainsworth withdrew to Ireland; and after some time returned to his friends at Amsterdam, and continued with them till his death, which was sudden, and not without suspicion of violence. The circumstance that is said to have occasioned it was somewhat extraordinary and deserves to be mentioned. Having found a diamond of great value in the streets of Amsterdam, he advertised it; and when the owner, who was a Jew, came to demand it, he offered him any acknowledgment which he would desire. Ainsworth, though poor, would accept of no remuneration but a conference with some of the Jewish rabbies, upon the prophecies of the Old Testament relating to the Messiah, which the Jew promised; but not having interest sufficient to obtain it, some have supposed that through shame or vexation, or from some other motive, he poisoned Ainsworth. This event happened about the year 1629. Mr. Ainsworth's distinguished talents and biblical learning were universally acknowledged. To these Bishop Hall paid a tribute of respect, even whilst he was writing against the party to which he belonged; and his annotations on the scriptures, though less regarded in England than they deserved, were much sought after and commended by persons of various sects in other countries. These "Annotations" appeared at different times; but in 1627 they were printed in one volume in folio, and another edition appeared in 1639, which is now become very scarce. To this work, it is said, the learned Lightfoot was much indebted. Of the other pieces of Ainsworth, we shall only mention his "Arrow against Idolatry." Neal's Hist. of the Puritans, vol. i. p. 386. 437. 4to. Biog. Brit.

AINSWORTH, ROBERT, a learned grammarian, was born at Woodyale, near Manchester, in Lancashire, in the year 1660, and was educated at Bolton, in the same county, where he afterwards kept a school. From Bolton he removed to Bethnal Green, near London, and he there continued the profession of school-master. At this period he published his "Short Treatise of Grammatical Institution." After pursuing in different places the labour of tuition till he had acquired a decent competency, he retired from business; and amused himself by searching the shops of brokers for old coins and other valuable curiosities, which he purchased at a small expence. He died at London in 1743, and was buried at Poplar. The following monumental inscription was written by himself:

"Rob. Ainsworth et uxor ejus, admodum senes,
Dormituri, vestem detritam hic exuerunt,
Novam, primo mane surgentes, induturi.
Dum fas, mortalis, sapias, et respice finem,
Hoc suadent manes, hoc canit Amramides."

Thus imitated—"Here Robert Ainsworth and his wife
Put off the worn-out vest of life;
Hoping the morn will soon appear,
When they a brighter robe shall wear.
To thy reflection, mortal friend,
Th' advice of Moses I commend,
Be wise, and meditate thy end."

To Ainsworth's judgment, industry, and perseverance in compiling a dictionary for the use of schools, great commendation is due. This useful work was undertaken by him in 1714; and after many interruptions and delays was completed in 1736, and dedicated to Dr. Mead. It has been since improved by Patrick, Ward, Young, and other learned men; and in 1773 there appeared a new edition, farther enlarged and improved by Morell. We have an useful abridgment of this dictionary by Mr. Thomas, in two large 8vo. volumes. Patrick's Pref. to the second edition of Ainsworth's Thesaurus, Biog. Brit.

AIN-ZAMIEL, in *Geography*, a town of Africa, in the province of Tremecen and kingdom of Fez.

AIOMAMA, or AIOMANO, a town of European Turkey, on a gulf of the same name, in the province of Romania; 14 leagues south-east of Saloniki. Cape Paillaios is the south-east limit of the gulf, and Cape Drapano its north-east extremity. The south point is about E. long. 24° 40'. and N. lat. 39° 50'.

AJOVEA, in *Botany*, a genus of the *hexandria monogynia* class and order; the characters of which are, that the calyx is single-leaved and tridentated, the corolla has three petals, the filaments are terminated with two glandules, the antheræ are doubly excavated, the stigma is divided in six segments, and the fruit is a roundish, single-celled, monofpermous berry. There is one species, *viz.* *A. guianensis*; which grows in the forests of Guiana.

AIOTOCHTLI, in *Zoology*; the Mexican name of the ARMADILLO.

AIPIMIXIRA, in *Ichthyology*, the name of an American fish, more usually known by the name of PUDIANO. It is a small fish, of the shape of the perch, with a purple back, and yellow sides and belly. Maregrave.

AIR, in *Physics*, a thin, fluid, elastic, transparent, ponderous, compressible, and dilatable body; surrounding the terraqueous globe to a considerable height.

Air was considered by some of the ancients as an element; but then, by element, they understood a different thing from what we do. See ELEMENTS.

It is certain, that air, taken in the popular sense, is far from the simplicity of an elementary substance; though some of its properties and uses in a state of combination with various substances, from which it has been extricated by modern analysis, may entitle it to this appellation. Hence air may be distinguished into *proper* or *elementary*, and *vulgar* or *heterogeneous*.

AIR, *elementary*, or AIR *properly so called*, is a subtil, homogeneous, elastic fluid: the basis, or fundamental ingredient of the atmospherical air, and that which gives it the denomination.

In this sense, it likewise enters into the composition of most, or perhaps all bodies, existing in them under a solid form, deprived of its elasticity and most of its distinguishing properties, and serving as their cement, and the universal bond of nature; but capable, by certain processes, of being disengaged from them, recovering its elasticity, and resembling the air of our atmosphere. See Hales's Vegetable Statics, chap. vi.

The peculiar nature of this aerial matter we know but little of; what authors have advanced concerning it being chiefly conjectural. We have no way of altogether separating it from the other matters with which in its purest state it is more or less combined, and consequently no way of ascertaining, with satisfactory evidence, its peculiar properties, abstractedly from those of other bodies.

Dr. Hook, and some others, maintain, that it is the same

same with their *æther*, or that fine, fluid, active matter, diffused through the whole expanse of the celestial regions; which coincides with Sir I. Newton's *subtile medium*, or spirit. In this view it is supposed to be a body *sui generis*, ingenerable, incorruptible, immutable, present in all places, and in all bodies.

Others, considering only its property of elasticity, which they account its essential and constituent character, suppose it to be mechanically producible; and to be no other than the matter of other bodies, so modified and altered, as to become permanently elastic. Sir Isaac Newton observes, that the particles of dense, compact, and fixed substances, cohering by a strong attractive force, are not separable without a vehement heat, or perhaps not without fermentation; and such bodies being at length rarefied by such heat or fermentation, become true *permanent air*; and distinguishable from vapour, which is only *apparent*, or *transient air*, as is evident from the experiment with the æolipile. Optics, Qu. 31, p. 371, 372. ed. 3. See AIR, *atmosphærical*.

Air, *vulgar* or *heterogeneous*, is a coalition of corpuscles of various kinds, constituting together one fluid mass, in which we live and move, and which we are continually receiving and expelling by respiration. The whole assemblage of this makes what we call the atmosphere; where this air, or atmosphere, terminates, there *æther* is supposed to commence; which is distinguished from air by its not making any sensible refraction of the rays of light, as air does.

Air, in this popular and extensive meaning of the term, is acknowledged by Mr. Boyle to be the most heterogeneous body in the universe. Boerhaave shews it to be an universal chaos, or colluvies, of all kinds of created bodies. Besides the matter of light or fire, which continually flows into it from the heavenly bodies, and probably the magnetic effluvia of the earth; whatever fire can volatilize is found in the air.

Hence, for instance, 1. The whole fossile kingdom must necessarily be found in it; for all of that tribe, as salts, sulphurs, stones, metals, &c. are convertible into fume, and thus capable of being rendered part of the air. Gold itself, the most fixed of all natural bodies, is found to adhere close to the sulphur in mines; and thus to be raised along with it. Mr. Boyle observes, that beside the saline effluvia of the common sort, such as the nitrous, vitriolic, marine, &c. there may be many compounded kinds of salts in the air, which we have not on earth, arising from different saline spirits, fortuitously meeting and mixing together. Thus, the glass windows of ancient buildings are sometimes observed to be corroded, as if they had been worm-eaten; though none of the simple salts above-mentioned have the faculty of corroding glass.

Sulphurs too must make a considerable ingredient of the air, on account of those many volcanos, grottos, caverns, and other spiracles chiefly affording that mineral, dispersed through the globe.

2. All the parts of the animal kingdom must also be in the air: for besides the copious effluvia continually emitted from their bodies, by the vital heat, in the ordinary process of perspiration; by means of which an animal, in the course of its duration, impregnates the air with many times the quantity of its own body; we find that any animal when dead, being exposed to the air, is in a certain time wholly incorporated with it.

3. As to vegetables, none of that class can be supposed wanting; since we know that all vegetables, by putrefaction, become volatile.

The associations, separations, attritions, dissolutions, and other operations of one sort of matter upon another, may likewise be considered as sources of numerous other neutral, or anonymous bodies, unknown to us.

4. Water is also diffused through the air in great abundance. Many familiar instances might be alledged to this purpose. A bottle of wine, when taken out of the cellar in the driest and hottest day of summer, will soon be covered with a dense vapour, which is water deposited by the air. The same appearance is observed on the outside of any metallic vessel, which, in warm weather, contains water cooled by ice or the solution of salt, or even spring water, which is some degrees colder than the air. For other facts of similar kind, see WATER.

Air, in this general sense, is one of the most considerable and universal agents in all nature; being concerned in the preservation of life, and the production of most of the phenomena relating to our world. Its properties and effects, including a great part of the researches and discoveries of the modern philosophers, have in a considerable degree been reduced to precise laws and demonstrations, in which form they make a very extensive and important branch of the mixed mathematics, called PNEUMATICS.

Air, *mechanical properties and effects of*. The most considerable of these are its *fluidity*, *weight*, and *elasticity*.

1. *Fluidity*. That the air is a fluid, is evident from the easy passage it affords to bodies through it; as in the propagation of smells, and other effluvia, and the easy conveyance it affords to sounds: for these and similar effects prove it to be a body, whose parts give way to any force impressed, and, in yielding, are easily moved among themselves; which is the definition of a fluid. Besides, it is certain, that no condensation by pressure, nor any degree of cold that has ever yet been produced, natural or artificial, have been sufficient to deprive it of its fluidity. It is true, indeed, that real permanent air may be extracted from solid bodies, and may be also absorbed by them; and in this state it must be very much condensed: but under what form it exists in those bodies, or how its particles are combined together, the researches of philosophy and chemistry have not yet been able to explore.

They who, with the Cartesians, make fluidity to consist in a perpetual intestine motion of the parts, find that air answers also to that character: thus, in a darkened room, where the species of external objects are brought in by a single ray, they appear in a continual fluctuation; and thus even the more accurate thermometers are observed never to remain a moment at rest.

The cause of this fluidity of air is attributed by some later philosophers to the fire intermixed with it; without which, they imagine, the atmosphere would harden into a solid impenetrable mass. And hence, the greater the degree of fire, the more fluid, moveable, and pervious is the air: and thus, as the degree of fire is continually varying, according to the circumstances and position of the heavenly bodies, the air is kept in a continual reciprocation. See Buffon's Hist. Nat. Supp. vol. i. Hence, in a great measure, it is said, that on the tops of the higher mountains, the senses of smelling, hearing, &c. are found very feeble. The increased rarity of the air at a considerable height may account for this effect; but the above hypothesis is contradicted by the more sensible experience of cold: the air, near the surface of the earth, deriving greater heat from the reflected than from the direct rays of the sun. See MOUNTAINS.

II. *Weight or gravity.* Of this property of air the ancients were not altogether unapprised; though their sentiments on the subject were confused and unsatisfactory. Aristotle (de Cælo, lib. iv. c. 1. op. tom. i. p. 485.) observes, that all the elements, fire excepted, have weight; and he adds, that a bladder inflated with air, weighs more than when it is quite empty. Plutarch (de Placitis, lib. i. c. 12. tom. ii. p. 883.) and Stobæus (Eclog. Phys. lib. i. c. 17. p. 32. Ed. 1609.) quote Aristotle as teaching, that the weight of air is between that of fire and earth; and he himself, treating of respiration, (cap. vii. oper. tom. i. p. 722.) reports the opinion of Empedocles, who ascribes the cause of it to the weight of the air, which by its pressure insinuates itself with force into the lungs. Plutarch (de Placit. lib. iv. c. xxii. tom. ii. p. 903.) expresses, in similar terms, the opinion of Aselepiades on this subject; and represents him as saying, that the external air, by its weight, opened its way with force into the breast. Heron of Alexandria, in his treatise intitled *Spiritualia*, constantly applies the *elasticity* of the air to produce such effects as are sufficient to convince us that he well understood that property of it: and Ctesibius, admitting the principle of the air's elasticity, invented wind-guns, which have been considered as a modern contrivance. Philo of Byzantium (in Veter. Mathem. p. 77. Ed. Paris.) describes these curious machines, constructed upon the principle of the air's being capable of condensation. Seneca also (Quæst. Nat. lib. v. c. v. and vi.) was acquainted with the weight and elastic force of the air; for he describes the constant effort by which it expands itself when it is compressed, and affirms, that it has the property of condensing itself, and forcing its way through all obstacles that oppose its passage. See Dutens's Inquiry into the origin of the Discoveries attributed to the Moderns, p. 186. 1769. The followers of Aristotle, however, abandoned the sentiments of their master on this subject; and for many ages maintained a contrary doctrine. The effects which are now known to result from the weight and elasticity of the air, were for a long time attributed to the imaginary principle, called *fuga vacui*, or nature's abhorrence of a vacuum; and Galileo himself admitted the principle, though he assigned a limit to it, corresponding to the weight of a column of water 34 feet high. This distinguished philosopher, however, was well apprised of the weight of the air as a body; and, in his Dialogues, he points out two methods of demonstrating it, by weighing it in bottles. But the pressure of the air was discovered by his disciple, Torricelli. In the year 1643, it occurred to him, that whatever might be the cause by which a column of water, 34 feet high, is sustained above its level, the same force would sustain a column of any other fluid, which weighed as much as that column of water, on the same base; and hence he concluded, that quicksilver, being about 14 times as heavy as water, would not be sustained at a greater height than that of 29 or 30 inches. He then made the experiment, called after his name; and inferred from it, that the weight of the air incumbent on the surface of the external quicksilver, counterbalanced the fluid contained in the tube. By this experiment he not only proved, as Galileo had before done, that the air had weight, but that its weight was the cause of the suspension of water and quicksilver in pumps and tubes, and that the weight of the whole column of it was equal to that of a like column of quicksilver, 30 inches high, or of water 34 or 35 feet high; but he did not ascertain the weight of any particular quantity of it, as a gallon, or a cubic foot; nor its specific gravity to water, which had been done, though inaccurately, by Galileo. Torricelli's experiment was published at Warsaw, in Poland, by Valerianus

Magnus, as his own discovery; but from the letters of Robert Boyle, it appears, that Torricelli's claim to priority is indisputable; and that neither Valerianus, nor Honoratus Fabri, to whom it has been ascribed so early as the year 1641, can justly dispute it with him. The first discovery of the weight and elasticity of the air has been lately ascribed to Jean Rey, who wrote in 1629, before Galileo, Torricelli, Des Cartes, and Pascal. His fourth and tenth essays have been cited in favour of his claims; but though he was apprized that compression augmented the weight of the air, and he seems to have believed, with Aristotle and others at a very ancient period, that air was heavy, yet the proofs which he alleges were not sufficient to convince the incredulity of the peripatetics. The Torricellian experiment, by which the fact was established, and which father Merfenne received an account of in 1644, was immediately communicated to the philosophers of France, and repeated in various ways by Messrs. Pascal and Petit; and this gave occasion to the ingenious treatise published by Pascal, at 23 years of age, intitled, "Experiences Nouvelles touchant la Vuide." Having, after some hesitation, adopted Torricelli's idea, and abandoned the principle of a *fuga vacui*, he devised several experiments for confirming it. One of these was to make a vacuum above the reservoir of quicksilver, in which case he found that it sunk to the common level: and he then engaged M. Perrier, his brother-in-law, to execute the famous experiment of Puy-de-Domme, who found that the height of the quicksilver half way up the mountain was less by some inches than at the foot of it; and that it was still less at the top. These facts incontrovertibly proved, that it was the weight of the atmosphere which counterpoised the quicksilver. Des Cartes had also just notions of the power of the air for sustaining fluids above their level, as appears by some letters about this time, and some years before; and in one of these he lays claim to the idea of the Puy-de-Domme experiment. See Cartesii opera. tom. ii. p. 243, 246.

The experiment of Pascal was repeated in various parts of the world; and particularly in 1653, by Dr. Power, in England; and in 1661, by Mr. Sinclair, professor of philosophy at Glasgow, in Scotland.

That the air is heavy, follows from its being a body; weight being an essential property of matter. And that it is a body, is evident from its excluding all other bodies out of the space it possesses: for if a glass jar be inverted into a vessel of water, the air, of which it is full, will allow but little water to enter into it. But we have many arguments to the same purpose from sense and experiment: thus, the hand, applied on the orifice of a vessel empty of air, soon feels the load of the incumbent atmosphere. Thus, glass vessels, exhausted of their air, are easily crushed to pieces by the weight of the air without. So, two small hollow segments of a sphere, four inches in diameter, exactly fitting each other, being emptied of air, are pressed together with a force equal to 188 pounds, by the weight of the ambient air; and that they are kept together by the pressure of the air is evident, by suspending them in an exhausted receiver, where they will separate of themselves. Farther, if a tube, close at one end, be filled with mercury, and the other end immersed in a basin of the same fluid, and thus erected, the mercury in the tube will be suspended at the height of about 30 inches above the surface of that in the basin. The reason of which suspension is, that the mercury in the tube cannot fall lower without raising that in the basin; which being pressed down by the weight of the incumbent atmosphere cannot give way, unless the weight of the mercury in the tube exceeds that of the air out of it.

it. That this is the case, is evident; because, if the whole apparatus be included in the receiver of an air pump, the mercury will fall in proportion as the air is exhausted; and on gradually letting in the air again, the mercury re-ascends to its former height. This makes what is usually called the *TORRICELLIAN experiment*.

To say no more, we can actually weigh air; for a vessel, full even of common air, is found, by a very nice balance, to weigh more than when the air is exhausted; a quart of air weighing about 17 grains; and the effect is proportionably more sensible, if the same vessel be weighed full of condensed air, and more especially in a receiver void of air.

The weight of air is continually varying, according to the different degree of heat and cold, and the concurrence of other causes. Pafchal observed it in France; and Des Cartes in Sweden, in 1650. Mr. Boyle, and others, observed it in England, in 1656. Some observers noticed, that it was generally greatest in the night and in winter; and that its variations were most considerable during winter, and in the northern regions. Hence arose the application of the *BAROMETER* to the uses of a *WEATHER-GLASS*. Ricciolus estimates the weight of air to that of water, to be as 1 to 1000; Merfennus as 1 to 1300, or 1 to 1356; Lana, as 1 to 640; Galileo only makes it as 1 to 400. Mr. Boyle, by a more accurate experiment, found it about London, as 1 to 938; and thinks, all things considered, the proportion of 1 to 1000 may be taken as a medium; for there is no fixing any precise ratio, since not only the air, but the water itself, is continually varying. Besides, experiments made in different places necessarily vary, on account of the different heights of the places, the seasons of making the experiment, and the different densities of air corresponding to these circumstances. It must be added, however, that by experiments made since, before the Royal Society, the proportion of air to water was, first, found as 1 to 840; then, as 1 to 852; and a third time, as 1 to 860. *Phil. Transf. N^o 181.* And lastly, by a very simple and accurate experiment of Mr. Hawksbee, the proportion was settled, as 1 to 885. *Phys. Mechan. Exper.* But these experiments being all made in the summer months, when the barometer was 29 $\frac{3}{4}$ inches high, Dr. Jurin thinks, that at a medium between heat and cold, when the barometer is 30 inches high, the proportion between the two fluids may be taken as 1 to 800; which agrees with the observation of the honourable Mr. Cavendish, the thermometer being at 50°, and the barometer at 29 $\frac{3}{4}$ inches. *Phil. Transf. vol. lvi. p. 152.*

Sir George Shuckburgh, (*Phil. Transf. vol. lxvii. p. 560.*) by a very accurate experiment, found it as 1 to 836; the barometer being at 29,27 inches, and the thermometer at 53°; and the comparative gravity of quicksilver to air, as 1136 $\frac{4}{6}$ to 1. The medium of all these is about one to 832 or 833, when reduced to the pressure of 30 inches of the barometer, and the mean temperature 55° of the thermometer. Upon the whole, it may be concluded, that when the barometer is at 30 inches, and the thermometer at the mean temperature of 55°, the density or gravity of water is to that of air as 833 $\frac{2}{3}$ to 1; that is, as $\frac{2500}{3}$ to 1, or as 2500 to 3; and for any changes in the height of the barometer, the ratio varies proportionally; and also that the density of the air is altered by the $\frac{1}{440}$ th part, for every degree of the thermometer above or below temperate. This number, which is a very good medium, having the fraction $\frac{2}{3}$, gives exactly 1 $\frac{2}{3}$ th of an ounce for the mean weight of a cubic foot of air; the weight of the cubic foot of water

being just 1000 ounces avoirdupois, and that of quicksilver equal to 13600 ounces.

Air, then, being heavy and fluid, the laws of its gravitation, or pressure, may be inferred to be the same as those of other fluids; and consequently its pressure must be proportional to its perpendicular altitude. This is also confirmed by experiment. For removing the Torricellian tube to a more elevated place, where the incumbent column of air is shorter, a proportionably shorter column of mercury is sustained; and that nearly at the rate of 100 feet for $\frac{1}{12}$ th of an inch of quicksilver. On this principle depend the structure and office of the *BAROMETER*.

From hence, also, it follows, that the air, like all other fluids, must press equally every way. This is confirmed by observing, that soft bodies sustain this pressure without any change of figure, and brittle bodies without breaking; though the pressure upon them be equal to that of a column of mercury thirty inches high, or a column of water of thirty-two or somewhat more feet. It is obvious, that no other cause can preserve such bodies unchanged, but the equal pressure on all sides, which resists as much as it is resisted. And hence, upon removing or diminishing the pressure on one side only, the effect of the pressure is soon perceived on the other. For the quantity and effect of this pressure of the atmosphere on the human body, and on the surface of the earth, and the laws of different heights, see *ATMOSPHERE*.

From the *gravity* of the air, considered in connection with its *fluidity*, several of its uses and effects may be easily deduced.

1. By means of its weight, &c. it closely invests the earth, with all the bodies upon it; and constringes and binds them down with a force amounting, according to the computation of M. Pafchal, to 2232 pounds weight upon every square foot, or upwards of 15 pounds upon every square inch. Hence it prevents, *e. gr.* the arterial vessels of plants and animals from being too much distended by the impetus of the circulating juices, or by the elastic force of the air, so plentifully contained in the blood.—Thus we see, in the operation of cupping, that, upon a diminution of the pressure of the air, the parts of the body grow tumid; which necessarily alters the manner of the circulation through the capillaries, &c.

The same cause hinders the juices from issuing and escaping through the pores of their containing vessels: this is experienced by such as travel up high mountains, who, in proportion as they ascend, find themselves more and more relaxed; and at length become subject to a spitting of blood, and other hæmorrhages; because the air doth not sufficiently constringe the vessels of the lungs. Similar effects are observed in animals that are enclosed under the receiver of the air-pump, who, as the air is taken from them, pant, swell, vomit, and discharge their urine and excrements. See *VACUUM*.

2. The weight of the air promotes the mixture of contiguous fluid bodies. Hence many liquids, as oils and salts, which readily and spontaneously mix in air, remain, on the removal of it, in a state of separation.

3. This gravity of air does in some cases determine the action of one body above another.

4. To the same principle are chiefly owing our winds, which are only air put in motion by some alteration in its equilibrium. It is the weight of the air that causes the clouds and vapours to float in it.

III. *Elasticity*—or a power of yielding to an impression by contracting its dimensions; and upon removing or diminishing the impressing cause, of returning to its former space or figure, is another quality of air. This elastic force

force has been long accounted the distinguishing property of air; the other properties hitherto enumerated being common to it with other fluids; though, from late experiments, it appears more than probable, that the capacity of being compressed and expanded is not peculiar to air. See WATER and COMPRESSION.

This property of air has been long known, and was ascertained by some experiments of lord Bacon, who, upon this principle, constructed his *vitrum calendare*, the first thermometer. Bacon. Nov. Organ. lib. ii. aph. 13.

Of this power we have numerous proofs.—Thus, a blown bladder being squeezed in the hand, we find the included air sensibly resist; so that upon ceasing to compress, the cavities or impressions, made in its surface, are readily expanded again, and filled up.

On this property of elasticity, the structure and office of the AIR-PUMP depend.

Every particle of air always exerts this visus, or endeavour to expand, and thus strives against an equal endeavour of the ambient particles, whose resistance happening by any means to be weakened, it immediately diffuses itself into an immense extent. Hence it is, that thin glass bubbles, or bladders filled with air, and exactly closed, being included in the exhausted receiver of an air-pump, burst by the force of the included air. So a bladder quite flaccid, containing only the smallest quantity of air, swells in the receiver, and appears quite full. The same effect is also found by carrying the flaccid bladder to the top of a high mountain. This experiment shews, that the elasticity of air is different from that of solid bodies: after these have been compressed, they only resume the figure which they had lost; whereas air, when the compressing force is removed, not only dilates, but occupies a much greater space than it did before; nor is it easy to assign the limits of its expansion. From some experiments of Col. Roy (Phil. Transf. vol. 67. p. 708.) it would seem, that the particles of air may be so far removed from one another, by the diminution of pressure, as to lose a very great part of their elastic force. It also appears that the elastic force of common air is greater than when its density is considerably augmented or diminished by an addition to, or subtraction from the weight with which it is usually loaded; a fact which contradicts the experience of Boyle, Mariotte, and others. These experiments also shew, that the elastic force of moist air is greatly superior to that of dry air; in some cases the total expansion of the former was more than four times that of the latter.

It has been questioned among philosophers, whether this elastic power of the air is capable of being destroyed or diminished. Mr. Boyle made several experiments, with a view to discover, how long air, brought to the greatest degree of expansion to which he could reduce it in his air-pump, would retain its spring; and could never observe any sensible diminution. De-faguliers found that air, after having been enclosed for half a year in a wind-gun, had lost none of its elasticity; and Roberval, after preserving it in the same manner for sixteen years, observed, that its expansive projectile force was the same as if it had been recently condensed. Nevertheless, Mr. Hauksbee concludes, from a later experiment, that the spring of the air may be so disturbed by a violent pressure, as to require some time to return to its natural tone. Dr. Hales inferred, from a number of experiments, that the elasticity of the air is capable of being impaired and diminished by a variety of causes, and of being actually destroyed, so that it is reduced to a fixed state. Hence he also concludes, that elasticity is not an essential immutable property of the particles of air; and that the atmosphere is a chaos, consisting not only of elastic, but also of unelastic air-

particles, which copiously float in it. Statical Essays, vol. i. p. 316.

The weight or pressure of the air, it is obvious, has no dependence on its elasticity; but would be the same, whether the air has such a property or not. But the air, being elastic, is necessarily affected by the pressure, which reduces it into such a space, as that the elasticity which re-acts against the compressing weight, is equal to that weight. Indeed, the law of this elasticity is, that it increases as the density of the air increases; and the density increases as the force increases by which it is pressed. Now, there must necessarily be a balance between the action and re-action; *i. e.* the gravity of the air, which tends to compress it, and the elasticity of the air, which endeavours to expand it, must be equal. And the elasticity of the air not very different from its natural state, being as the density, will of course be inversely as the space which it occupies.

Hence the elasticity increasing, or diminishing, universally, as the density increases or diminishes, *i. e.* as the distance between the particles diminishes, or increases, it is no matter whether the air be compressed and retained in such space, by the weight of the atmosphere, or by any other means; it must endeavour, in either case, to expand with the same force. And hence if air near the earth be pent up in a vessel, so as to cut off all communication with the external air, the pressure of the inclosed air will be equal to the weight of the atmosphere. Accordingly, we find mercury sustained to the same height, by the elastic force of air inclosed in a glass vessel, as by the whole atmospherical pressure.

On the same principle air may be artificially condensed; and hence the structure of the AIR-GUN.

Although it may be admitted as a general principle, that the density of the air is proportional to the force by which it is compressed, as the experiments of Mr. Boyle and Mr. Mariotte have evinced; yet in the case of condensed air, the rule will not be strictly applicable. When air is very forcibly compressed, so as to be reduced to $\frac{1}{4}$ th of its ordinary bulk, it makes a greater resistance, and requires a stronger force to compress it than the above principle allows. Hence it appears probable, that the particles of air cannot, by any possible pressure, be brought into perfect contact, or form a solid mass; and therefore that the degree of condensation has its limit. Thus also in very high degrees of rarefaction, the elasticity is decreased rather more than in an exact proportion to the weight or density of the air; whence it may be concluded, that there is a limit to its rarefaction or expansion, so that it cannot be expanded to infinity. Nevertheless, the utmost limits to which air of the density which it possesses at the surface of the earth, is capable of being compressed, have not been ascertained. Mr. Boyle reduced it at one time to the 14th part, and at another to the 40th part of its natural space. (Works. vol. iii. p. 507.) Dr. Halley says, that he has seen it compressed so as to be 60 times denser than in its natural state, which is farther confirmed by Mr. Papin, and M. Huygens. Dr. Hales (Stat. Exp. vol. ii. p. 343, &c.) by means of a press, condensed it 38 times; and by freezing water in an iron ball or globe, into 1522 times less space than it naturally occupies: in which state its density or specific gravity must be nearly double that of water; and as water is very slightly compressible, the particles of air must be in their nature different from those of water; since it would otherwise be impossible to reduce air to a bulk 800 times less than that which it occupies in its natural state.

However, Dr. Halley has asserted, in the Philosophical Transactions, (Abr. vol. ii. p. 17.) that from the experi-

ments made at London, and by the Academy del Cimento at Florence, it might be safely concluded, that no force whatever is able to reduce air into 800 times less space than that which it naturally possesses on the surface of our earth. In answer to which, M. Amontons, in the Memoirs of the French Academy, maintains, that there is no affixing any bounds to its condensation; that greater and greater weights will still reduce it into less and less compass; that it is only elastic in virtue of the fire which it contains; and that as it is impossible ever absolutely to drive all the fire out of it, it is impossible ever to make the utmost condensation.

The elasticity of the air exerts its force equally in all directions; and when released from the force that compresses it, it assumes a spherical figure in the interstices of the bodies that contain it. By exhausting the air from liquors placed under the receiver of an air-pump, the bubbles that gradually arise and are enlarged in size, retain their round figure. Such are also the bubbles that discharge themselves from a plate of metal immersed in a fluid in the same circumstances. On this account large glass globes are always formed of a spherical shape by blowing air through an iron tube into a piece of melted glass at the end of the tube.

The dilatation of the air by virtue of its elastic force, is found to be very surprising; and yet Dr. Wallis suggests, that we are far from knowing the utmost of which it is capable. In several experiments made by Mr. Boyle, it dilated first into 9 times its former space; then into 31 times; then into 60; and then into 150. Afterwards, it was brought to dilate into 8000 times its first space; then into 10,000, and even at last into 13,679 times its space; and this altogether by its own expansive force, without the help of fire. Boyle's Works by Birch, vol. i. p. 21, 22. vol. iii. p. 498, 499.

On this depend the structure and use of the MANOMETER. Hence it appears, that the air we breathe near the surface of the earth is compressed by the weight of the superincumbent column into at least the 13679th part of the space it would possess *in vacuo*. But if the same air be condensed by art, the space it will take up when most dilated, to that it possesses when condensed, will be, according to the same author's experiments, as 550,000 to 1.

We hence see how wild and erroneous the observation of Aristotle was, that air, rendered ten times rarer than before, changes its nature, and becomes fire.

It has generally been supposed, that air expands $\frac{1}{360}$ with each degree of the thermometer, commencing from the mean temperature 55°; and upon this principle tables have been computed by astronomers for correcting their mean refractions; but Sir George Shuckburgh allows at this temperature an expansion of $\frac{1}{347}$ for 1°. Phil. Trans. v. 67. p. 564. Mr. Hauksbee observed, that a portion of air, included in a glass tube, when the temperature was at the freezing point, formed a volume which was to that of the same quantity of air in the greatest heat of summer in England as 6 to 7. Moist air has been expanded into more than 12 times the space occupied by it in its freezing state; and Mercennus by means of the *æolipile* expanded it into more than 70 times its natural bulk. Muschenb. Introd. ad. Phil. Nat. tom. ii. p. 884. 4to.

M. Amontons, and others, we have already observed, attribute the rarefaction of the air wholly to the fire contained in it; and therefore, by increasing the degree of heat, the degree of rarefaction may be carried still farther than its spontaneous dilatation. Air is expanded $\frac{1}{3}$ of its bulk by boiling water. Hist. Acad. Sc. 1699.

Dr. Hales found that the air in a retort, when the bottom of the vessel was just beginning to be red hot, was expanded

through twice its former space, and in a white, or almost melting heat, it occupied thrice its former space; but Mr. Robins found, (New Principles of Gunnery, ch. 1. prop. 5. p. 12.) that air was expanded by the heat of iron, just beginning to be white, to four times its former bulk. Thus we account for the apparent inflation of a flaccid bladder, when it is warmed by the fire, and on this principle depend the structure and office of the THERMOMETER, and also the formation and ascent of air-balloons. See AEROSTATION.

M. Amontons first discovered that air will expand, in proportion to its density, with the same degree of heat. On this foundation, the ingenious author has a discourse, to prove, 'that the spring and weight of the air, with a moderate degree of warmth, may enable it to produce even 'earthquakes, and other of the most vehement commotions 'of nature.'

According to the experiments of this author, and M. de la Hire, a column of air on the surface of the earth, 36 fathoms high, is equal in weight to three lines depth of mercury; and it is found, that equal quantities of air possess spaces reciprocally proportioned to the weights with which they are pressed; the weight of the air, therefore, which would fill the whole space possessed by the terrestrial globe, would be equal to a cylinder of mercury, whose base is equal to the surface of the earth, and its height containing as many times three lines, as the atmospherical space contains orbs equal in weight to 36 fathoms of that wherein the experiment was made.—Hence, taking the denseness of all bodies, *e. gr.* gold, whose gravity is about 14,630 times greater than that of air in our orb, it is easy to compute, that this air would be reduced to the same density as gold, by the pressure of a column of mercury 14,630 times 28 inches high, *i. e.* 409,640 inches, since the bulks of air, in that case, would be in the reciprocal ratio of the weights by which they are pressed. These 409,640 inches, therefore, express the height at which the barometer must stand, where the air would be as heavy as gold, and the number $2\frac{5}{7}\frac{1}{3}\frac{2}{3}$ lines, the thickness to which our column of 36 fathoms of air would be reduced in the same place.

Now, we know, that 43,528 fathoms, which is the depth, where the above pressure, and consequent reduction take place, are only the 74th part of the semidiameter of the earth; and, therefore, beyond that depth, whatever matter exists, it must be heavier than gold. It is not improbable, therefore, that the remaining sphere of 6,451,538 fathoms diameter may be full of dense air, heavier by many degrees than the heaviest bodies which we know. Hence, again, as it is proved, the more air is compressed the more does the same degree of fire increase the force of its spring, and render it capable of a proportionably greater effect; we may infer, that a degree of heat, which in our orb can only produce a moderate effect, may have a very violent one in such lower orb; and that, as there may be many degrees of heat in nature, beyond that of boiling water, it is probable there may be some, whose violence, thus assisted by the weight of the air, may be sufficient to tear asunder the solid globe. Mem. de l'Acad. an. 1703. See EARTHQUAKES.

This elastic property of air is supposed by many philosophers to depend on the figure of its corpuscles, which they apprehend to be ramous; some maintain that they are so many minute *floculi*, resembling fleeces of wool; others conceive them rolled up like hoops, and curled like wires, or shavings of wood, or coiled like the springs of watches, and endeavouring to restore themselves in virtue of their texture: so that to produce air, must be to produce such a figure and disposition of parts; and those bodies only are proper

proper subject, which are susceptible of such disposition; which fluids, from the smoothness, roundness, and slipperiness of their parts, are not.

But Sir Isaac Newton (Optics, p. 371.) explains the matter otherwise; such a texture, he thinks, by no means sufficient to account for that vast power of elasticity observed in air, which is capable of diffusing itself into above a million of times more space than it before possessed.—But, as all bodies are shown to have an attractive and repelling power; and as both these are stronger in bodies, the denser, more compact, and solid they are; hence it follows, that when by heat, or any other powerful agent, the attractive force is surmounted, and the particles of the body separated so far as to be out of the sphere of attraction; the repelling power which then commences makes them recede from each other with a strong force proportionable to that with which they before cohered; and thus they become permanent air. And he has proved, that particles, endeavouring to recede from each other with forces reciprocally proportional to the distance between their centres, will compose an elastic fluid, whose density shall be proportional to its compression. Hence, says the same author, it is, that as the particles of permanent air are grosser, and rise from denser bodies, than those of transient air, or vapour, true air is more ponderous than vapour; and a moist atmosphere is lighter than a dry one.

The elastic power of the air above illustrated and evinced, is the second great source of the effects of this important fluid. By this property, it insinuates itself into the pores of bodies, and by possessing this prodigious faculty of expanding, which is so easily excited, it must necessarily put the particles of bodies into which it insinuates itself into perpetual oscillations. Indeed, the degree of heat, and the air's gravity and density, and consequently its elasticity and expansion, never remaining the same for the least space of time, there must be an incessant vibration, or dilatation and contraction of all bodies.

We observe this reciprocation in several instances, particularly in plants, the tracheæ, or air-vessels of which perform the office of lungs; for the contained air alternately expanding and contracting, as the heat increases or is diminished, by turns compresses the vessels, and eases them again: and thus promotes a circulation of their juices. See AIR-VESSELS.

Hence, we find, that no vegetation nor germination will proceed *in vacuo*. Indeed beans have been observed to grow a little tumid therein; and this has led some to attribute that to vegetation, which was really owing to no other cause than the dilatation of the air within them.

The air is very instrumental in the production and growth of vegetables, not only by invigorating their several juices, while in an elastic active state, but also by greatly contributing in a fixed state to the union and firm connection of their several constituent parts, and by supplying them with that food or palulum, which contributes to their growth.

From the same cause it is, that the air contained in bubbles of ice, by its continual action, bursts the ice; and thus also, as well as by the expansion of freezing fluids, glasses and other vessels frequently crack, when their contained liquors are frozen. Thus also, entire columns of marble sometimes cleave in the winter time, from some little bubble of included air's acquiring an increased elasticity: and to this it is owing, that few stones will bear to be heated by the fire without cracking by the expansive force of the air confined within their pores. From the same principle arise *putrefaction* and *fermentation*; neither of which will proceed, even in the best disposed subjects, *in vacuo*.

Since we find such great quantities of elastic air, generated in the solution of animal and vegetable substances, a good deal must constantly arise from the dissolution of these elements in the stomach and bowels, which is much promoted by it: and respiration, and even animal life, depend in a great measure upon the air.

In reality, all natural corruption and alteration seem to depend on air; and metals, particularly gold, only seem to be durable and incorruptible, in virtue of their not being pervious to air.

AIR, *effects of the different ingredients of.* Air not only acts by its common properties of gravity and elasticity, but there are numerous other effects, arising from the peculiar ingredients of which it consists.

Thus, 1. It not only dissolves and attenuates bodies by its pressure and attrition, but as a *chaos* containing all kinds of menstrua, and consequently possessing powers for dissolving all bodies. It is known that iron and copper readily dissolve, and become rusty in air, unless well defended with oil. Boerhaave assures us, that he has seen pillars of iron so reduced by air, that they might be crumbled to dust between the fingers; and as for copper, it is converted by the air into a substance much like the verdigrise produced by vinegar.

Mr. Boyle relates, that in the southern English colonies the great guns rust so fast, that after lying in the air for a few years, large cakes of *crocus martis* may be separated from them. Acosta adds, that in Peru the air dissolves lead, and considerably increases its weight. Yet gold is generally esteemed indissoluble by air; being never found to contract rust, though exposed to it ever so long. In the laboratories of chemists, however, where *aqua regia* is prepared, the air becoming impregnated with an unusual quantity of this menstruum, gold contracts a rust like other bodies.

Stones also undergo the changes incident to metals.—Thus, Purbeck stone, of which Salisbury cathedral consists, is observed gradually to become softer, and to moulder away in the air; and Mr. Boyle gives the same account of Blackington stone. He adds, that air may have a considerable operation on vitriol, even when a strong fire could act no further upon it. And he has found, that the fumes of a corrosive liquor work more suddenly and manifestly on a certain metal, when sustained in the air, than the menstruum itself did, which emitted fumes on those parts of the metal which it covered; referring to the effects of the effluvia of vinegar on COPPER.

The dissolving power of air is increased by heat, and by other causes. It combines with water; and, by access of cold, deposits part of the matter which was kept dissolved in it, by a greater degree of heat. Hence the water, by being deposited and condensed upon any cold body, such as glass, &c. in windows, forms fogs, and becomes visible. Air, likewise, has been supposed, by means of its dissolving power, to accelerate EVAPORATION and DISTILLATION. 2. Air volatilizes fixed bodies. Thus, sea-salt, being first calcined, then fused by the fire, and when fused, exposed to the air to liquify; when liquified set to dry, and then fused again, repeating the operation, will, by degrees, be almost wholly evaporated; nothing but a little earth remaining. Helmont mentions it as an arcanum in chemistry, to render fixed salt of tartar volatile; but this is easily effected by air alone: for, if some of this salt be exposed to the air, in a place replete with acid vapours, the salt draws the acid to itself, and when saturated with it, is volatile.

3. Air also fixes volatile bodies. Thus, though spirit

of nitre, or aquafortis, readily evaporates by the fire: yet if there be any putrefied urine near the place, the volatile spirit will be fixed, and fall down in form of *AQUA SECUNDA*.

4. Air brings many quiescent bodies into action; *i. e.* excites their latent powers. Thus, if an acid vapour be diffused through the air, all the bodies of which that is the proper menstruum, being dissolved by it, are brought into a state proper for action.

In the various operations of chemistry, air is a very necessary and important agent, the result of particular processes depending on its presence or absence, on its being open or enclosed. Thus the parts of animals and vegetables can only be calcined in open air; in close vessels they never become any other than black coals. And these operations are effected by the changes to which the air is liable. Many instances might be alledged to this purpose. Let it suffice to observe, that it is very difficult to procure oil of sulphur, *per campanam*, in a clear dry atmosphere; but in thick moist air it may be obtained with greater ease, and in larger quantities. So pure well-fermented wine, if it be carried to a place where the air is replenished with the fumes of new wine, then fermenting, will begin to ferment afresh.

The changes in the air arise from various causes, and are observable not only in its mechanical properties, such as gravity, density, &c. but in the ingredients that compose it. Thus, at Fahlun, in Sweden, noted for copper-mines, the mineral exhalations affect the air in such a manner, as to discolour the silver coin in purses; and the same effluvia change the colour of brass. In Carniola, Campania, &c. where are mines of sulphur, the air sometimes becomes very unwholesome, which occasions frequent epidemic diseases, &c.

The effluvia of animals also have their effect in varying the air, as is evident in contagious diseases, plagues, murrains, and other mortalities, which are spread by an infected air.

The sudden and fatal effect of noxious vapours has generally been supposed to be principally, if not wholly, owing to the loss and waste of the *vivifying spirit of air*. But Dr. Hales attributes this effect to the loss of a considerable part of the *air's elasticity*, and to the grossness and density of the vapours with which the air is charged. He found, by an experiment made on himself, that the lungs will not rise and dilate as usual, when they draw in such noxious air, the elasticity of which has been considerably diminished. For having made a bladder very supple by wetting it, and then cutting off so much of the neck as would make a hole wide enough to admit the biggest end of a large fossel, to which the bladder was bound; and then having blown the bladder, he put the small end of the fossel into his mouth, and, at the same time, pinched his nostrils so close, that no air might pass that way, and he could only breathe to and fro the air contained in the bladder, which, with the fossel, contained seventy-four cubic inches. In less than half a minute, he found a considerable difficulty in breathing; and at the end of a minute, the bladder was become so flaccid, that he could not blow it above half full, with the greatest expiration which he could make; and at the same time, he could plainly perceive that his lungs were much fallen, in the same manner as when we breathe out of them all the air we can at once. Hence he concluded, that a considerable quantity of the elasticity of the air was destroyed; and that when the suffocating quality of the air was the greatest, it was with much difficulty that he could dilate his lungs in a very small degree. From this, and several other experiments, he inferred, that the life of animals is preserved rather by the

elastic force of the air acting on their lungs than by its vivifying spirit; and that candles and matches cease to burn, after having been confined in a small quantity of air, not because they have rendered the air effete by consuming it; vivifying spirit, but because they have discharged a great quantity of acid fuliginous vapours, which partly destroy its elasticity, and retard the elastic motion of the remainder. He likewise found, that air, which passed through cloths dipped in vinegar, could be breathed to and fro as long again as the like quantity of air, which was not thus purified; so that sprinkling the decks of ships with vinegar may refresh the air; and this is confirmed by experience. But where the corruption of the air is much greater, as in close prisons, &c. nothing can be an adequate and effectual remedy but a *VENTILATOR*. He observed, likewise, that air is not disqualified for respiration merely by the additional moisture which it receives, but by some bad quality in that moisture. See his *Statistical Essays*, vol. i. p. 250. vol. ii. p. 320, &c.

Dr. Priestley observes, that, when animals die upon being put into air, in which other animals have died, after breathing in it as long as they could, it is plain that the cause of their death is not the want of any *pabulum vite*, which has been supposed to be contained in the air; but because the air is impregnated with something stimulating to their lungs; for they almost always die in convulsions, and are sometimes affected so suddenly, that they are irrecoverable after a single inspiration. And he has found the same effect from many other kinds of noxious air. He concludes, from subsequent experiments, that the air becomes phlogisticated in its passage through the lungs, by means of the blood. *Experiments and Observations on Air*, vol. i. p. 71. vol. ii. p. 31. vol. iii. p. 55. See *AZOT, BLOOD, and RESPIRATION*.

Vegetables likewise produce a change in the state of the air. Thus when a great part of the clove trees, which grow so plentifully in the island of Ternate, was felled at the solicitation of the Dutch, in order to heighten the value of that fruit, such a change ensued in the air, as shewed the salutary effects of the effluvia, or rather of the vegetation of the clove-trees, and their blossoms; the whole island soon after they were cut down, being exceeding sickly. See *AZOT*.

The air is also liable to alterations from the season of the year. Thus few subterraneous effluvia are emitted in the winter, because the pores are locked up by the frost, or covered by snow; the subterraneous heat being at work, and preparing a heat to be discharged in the ensuing spring. Again, from the winter solstice to the summer solstice, the sun's rays become more and more perpendicular, and consequently their impulse on the earth's surface more powerful; so that the globe, or soil, is more and more relaxed, softened, and putrefied, till he arrives at the tropic; where, with the force of a chemical agent, he resolves the superficial parts of the earth into their constituent principles, water, oil, salt, &c. which are all swept away into the atmosphere.

The height and depth of the air produce a farther alteration; the exhalations not rising high enough in any great quantity, to ascend above the tops of high mountains.

From some experiments with air-balloons, it has been proved, that the air of the higher regions is more impure than that at the surface of the earth; which is reasonably ascribed to the oxygen supplied by vegetation to the lower and contiguous stratum of air.

Nor must drought and moisture be denied their share, in varying the state of the atmosphere; in Guinea, the heat, with the moisture, conduces so much to putrefaction, that the purest white sugars are often full of maggots; and their

drugs soon lose their virtue; and many of them grow venomous: it is added, that in the island of St. Jago, they are obliged to expose their sweet-meats daily to the sun, in order to exhale the moisture contracted in the night, which would otherwise occasion them to putrefy.

On this principle depend the structure and use of the

HYGROMETER.

For the refracting power of air; see REFRACTION.

After all, some of our more curious and penetrating naturalists have observed certain effects of air, which do not appear to follow from any of the properties, or material, above recited. In this view, Mr. Boyle has composed a treatise of suspicions about some unknown properties of the air. The phenomena of fire and flame *in vacuo* seem, according to him, to argue some unknown vital substance diffused through the air, on account of which that fluid becomes so necessary to the subsistence of flame. Buffon supposes that air is necessary to the subsistence of fire, because it is most adapted to acquire that expansive motion, which is the principal property of fire. On this account fire combines with air; in preference to any other substance, and in a more intimate manner, as being of a nature most nearly approaching to its own; and therefore air is the proper aliment and most powerful assistant of fire. Hist. Nat. Supp. vol. i.

According to Dr. Priestley, the air is a menstruum for the phlogiston emitted by burning bodies; which must cease to burn when that menstruum is saturated with it. And he accounts in the same manner for the suffocation of animals in a confined space. When the phlogiston, emitted by burning bodies and breathing animals, can no longer be absorbed by the ambient air, both life and flame are extinguished. Exp. and Obs. &c. vol. i.

For the modern hypothesis, with regard to this subject, see COMBUSTION and PHLOGISTON.

Thus we find, that many causes combine to produce very considerable alterations in the state of the air, whereby it becomes less fit for respiration, and other purposes of nature; and if there were no provision for restoring its salubrity, it must, in time, become universally injurious and fatal. Dr. Priestley, in the course of his inquiries on this subject, has discovered the great restoratives, which are provided for this purpose. One of these is vegetation. In order to ascertain this fact, he put a sprig of mint, in a vigorous state, under a glass jar, inverted in water; and he found, contrary to his expectation, that this plant not only continued to live, though in a languishing way, for two months; but that the confined air was so little corrupted by the effluvia of the mint, that it would neither extinguish a candle, nor kill a small animal, which he conveyed into it. He found, likewise, that air, vitiated by a candle left in it till it was burnt out, was perfectly restored to its quality of supporting flame, after another sprig of mint had vegetated in it for some time. And, in order to shew that the aromatic flavour of the plant had no share in producing this effect, he observed, in a variety of other experiments, that vegetables of an offensive smell, and even such as had scarce any smell at all, but were of a quick growth, proved the best for this purpose. Nay, more, the virtue of growing vegetables was found to be an antidote to the baneful quality of air, corrupted by animal respiration and putrefaction; and he infers from a number of similar facts, that the injury, which is continually done to the atmosphere, by the respiration of so many animals, and the putrefaction of such masses of both vegetable and animal matter, is, in part at least, repaired by the vegetable creation; and notwithstanding the prodigious mass of air that is corrupted daily by the

above mentioned causes; yet, if we consider the immense profusion of vegetables upon the face of the earth, growing in places suited to their nature, and consequently at full liberty to exert all their powers, both inhaling and exhaling, it can hardly be thought, that the remedy is not adequate to the evil. Dr. Franklin, in a reflection on this discovery, expresses his hope, that it will give some check to the rage of destroying trees that grow near houses, which has accompanied our late improvements in gardening, from an opinion of their being unwholesome; adding, from long observation, that there is nothing unhealthy in the air of woods, "since the Americans have their country habitations in the midst of woods, and no people on earth enjoy better health, or are more prolific." Dr. Priestley has since discovered that light is necessary to enable plants to purify air: however, pure air is not produced by light or plants, but only by the purification of the impure air to which the plants have access. Obs. and Exp. on Air, vol. v. p. 18, 24, &c.

The sea, and other large bodies of water, are the second resource, which nature has provided for restoring the salubrity of corrupted air. Dr. Priestley found, that all kinds of noxious air were restored by continued agitation in a trough of water; the noxious effluvia being first imbibed by the water, and thereby transmitted to the common atmosphere. And he hence concludes, that the agitation of the sea, and of large lakes and rivers, must be highly useful for the purification of the atmosphere; the putrid matter being absorbed by the water, and imbibed by marine, and other aquatic plants, or applied to purposes yet unknown. Exp. and Obs. vol. i. sect. 2. and 4.

This ingenious philosopher apprehends, that the agitation of water, and the vegetation of plants, purify noxious air, by absorbing part of the phlogiston with which it is loaded; and that this phlogistic matter is the most essential part of the food and support of both vegetable and animal bodies. Ib. vol. i. p. 138, 139.

Dr. Priestley, improving upon the experiments and investigations of Boyle, Hales, Brownrigg, Black, Macbride, Cavendish, and others, has discovered many species of air, extracted by various processes from different kinds of substances; of which a summary account will be given in the course of this work. See also his curious and valuable Experiments and Observations on different Kinds of Air, in five volumes. And for a compendium of the history of discoveries on this subject, Lavoisier's Essays Physical and Chemical, vol. i.

For the resistance of the air, see RESISTANCE.

AIR, undulation of. See SOUND and UNDULATION.

AIR, in Chemistry. See GAS.

AIR, Atmospheric, common air, Gas atmosferique, Fr. Atmospheric air does not appear to have been the subject of chemical investigation before the time of Boyle; for though Aristotle, Pliny, and Paracelsus, have written largely concerning this fluid, they have confined themselves to the imperfect examination of some of its physical properties, to the mention of a few obvious facts, and to the invention of hypotheses, which, as they do not profess to be founded on experiment, may, in the present state of knowledge, be safely neglected.

It was, indeed, natural, that the great improver of Otto Guericke's original air-pump, fond as he was of chemical pursuits, should exercise his talents in researches on the properties of the atmosphere, more especially as, from the number of substances continually assuming the form of vapour, it was not improbable that common air should prove a very heterogeneous and easily decomposable mixture. The difficulty,

difficulty, however, of separating, by the only method then known, a portion of air from the rest of the atmosphere, and the necessary uncertainty of the first rude attempts to operate upon an invisible elastic substance, occasioned the progress of discovery in this department of chemical science to be unusually slow. The following facts, however, were ascertained by Boyle, which, when we consider the numerous obstacles from bad and imperfect apparatus that he had to contend with, are highly creditable to his industry and sagacity. He proved, that the presence of air was necessary to combustion and to animal life, by shewing, that in the exhausted receiver flame was almost immediately extinguished, and various small animals, and even fish, while in water, were in a short time killed: that the same phenomena take place, but more gradually, in a confined portion of atmospheric air; and that the death of animals, in this situation, was not owing to the heated exhalations from their bodies, as was then supposed, since the same effects took place when the apparatus was put into a frigorific mixture: he also ascertained, that animals live longer, *ceteris paribus*, in a given bulk of condensed than of rarefied air. On account of the imperfection of his apparatus, he was induced to believe, that no absorption of air took place in respiration; and he appears to have had no suspicion that pure atmospheric air was a compound substance.

Immediately after Boyle, succeeded Mayow, unquestionably the greatest chemical genius of that age, but whose works, by a singular fatality, excited little or no interest among his contemporaries, and were soon totally forgotten. In this state of unmerited neglect they remained for more than a century; and it is only within a very few years, that the public attention has been directed to the writings of a philosopher, who nearly anticipated those discoveries of Priestley, Lavoisier, and Cavendish, upon which are based almost all the modern improvements in chemistry. The first great improvement of Mayow in the analysis of atmospheric air, was the invention of a proper apparatus; for this purpose, rejecting the use of the air-pump, he made choice of glass jars, inverted in water, as the best method of confining the gasses upon which he experimented. Setting out from the facts discovered by Boyle, he argues, that since a lighted candle is extinguished much sooner in an exhausted receiver than in the same when filled with air, there must be something contained in the atmosphere necessary to the continuance of flame; and that a candle, in confined air, is not suffocated by its own fuliginous exhalations, but dies away for want of an aerial pabulum. The necessity of air to combustion is also proved, says he, from the impossibility of kindling a combustible body in vacuo by the concentrated solar rays, or by any other method. Having established this first position, he proceeds to infer, that it is not the whole air but only its more active particles, that are capable of supporting flame, because a candle goes out in confined air, while yet the greatest part of the elastic fluid remains unconsumed. Also, since sulphur, when mixed with nitre becomes capable of inflammation in vacuo, or even under water, it follows that nitre and atmospherical air contain some substance in common, which he calls *fire-air* particles (*particule igneo-aerea*.) He next determined the analogy between flame and animal life; and shewed, that each depended for their continuance on a supply of fire-air particles: that there was an actual consumption of air in combustion and respiration he proved, by the rise of water in the jars in which a live animal or a lighted candle was inclosed; and that the loss of bulk was owing to the abstraction of fire-air, appeared from the inability of the residue to support animal life. He also inferred, that the fire-air

particles were the heaviest part of atmospheric air, because, if two mice or two candles were confined in a tall cylindrical jar, inverted in water, so as that one should be near the upper part of the vessel, and the other at the bottom, the upper one, whether a candle or animal, would be extinguished some time before the lower one. With regard to the proportion of fire-air in the atmosphere, he only observed, that air rendered unfit for combustion by the breathing of an animal, lost about one fourteenth of its bulk; at the same time remarking, that there was probably only a part of the fire-air consumed: he afterwards, indeed, found, that the solution of iron in aquafortis occasioned a diminution of about 25 *per cent.* in atmospheric air; but though, in this case, he produced nitrous gas, and thus abstracted the oxygen of the atmosphere, yet, as he himself draws no conclusions from it, we should rather consider this as an accident than a discovery. Mayow never obtained the fire-air of the atmosphere in a separate state, and therefore was unable to confirm his analysis of atmospherical air by the synthetic proof; nevertheless, he was warranted by a very high probability in affirming that the atmosphere consisted of two kinds of air, of which the igneo-aerial was in the proportion of at least one to 13; that it exceeded the other part in its specific gravity, and was absolutely essential to the continuance of flame and animal life. The influence, however, of the prevalent hypothesis was at that time too strong to be shaken by sober experiment; and the labours and very name of Mayow, shortly sunk into oblivion: the atmosphere was still supposed to be an undecomposable element, and its effect on chemical processes was very generally overlooked.

In 1774, exactly a century after the publication of Mayow's work, the important discovery of dephlogisticated air, by Dr. Priestley, took place. This philosopher having inclosed some *mercurial precipitate per se*, in a jar filled with mercury, and inverted over the same, procured from it, by means of heat, a quantity of gas, in which a candle burnt with an enlarged flame, and increased light: the coincidence of this, with the effect produced by dephlogisticated nitrous gas in the same circumstances, as had been already observed by Dr. Priestley, induced him to believe that there was some common principle in nitrous acid and atmospherical air; and this suspicion was still further confirmed by the discovery, that common *red precipitate*, which is prepared by means of nitrous acid, yielded dephlogisticated air in the same manner as the precipitate *per se*. Hence, too, he concluded, that pure atmospherical air was not an element, and that dephlogisticated air was that one of its component parts to which the continuance of flame and animal life was entirely owing. Thus we find, both Mayow and Priestley arriving at the same general conclusions, through the medium of entirely different experiments; the fire-air of the one, and the dephlogisticated air of the other, being only two words for the same substance: the experiments of the latter possess, however, this capital superiority, that they exhibit in a separate uncombined state, that vital part of the atmosphere, the existence of which was only to be inferred from those of the former. There yet remained, however, for the complete proof of the composition of the atmosphere, that a part of it should be actually decomposed, so as to shew its elements separated; and then, by their union, to recompose atmospherical air. This deficiency was supplied by Lavoisier. He confined a few ounces of mercury and a certain portion of atmospherical air in a proper glass apparatus, and exposed the mercury for 12 days to a heat nearly equal to that of ebullition; during this period a part of the mercury was converted into a red oxyd, a certain portion of

the fire disappeared, the remainder was incapable of supporting flame, and the weight of the red oxyd exactly corresponded with the loss sustained by the mercury and the air; this red oxyd, being then heated in a small retort, was decomposed into running mercury and a gas which exhibited all the properties of dephlogisticated air; finally, this air, being mingled with the unrespirable residue, recomposed atmospherical air. From these and various other similar experiments, it appeared, that the lower part of the atmosphere consists of 27 parts OXYGEN *gas*; and 73 of a mephitic air, which upon a further analysis, yielded about 72 parts of AZOTIC *gas*; and one of CARBONIC *acid*. These experiments will be further detailed under the term EUDOMETRY.

From the slight adherence of these gasses with each other in the air, it is probable that they are not so much in a state of combination as of intimate mixture; and hence there are scarcely any chemical actions produced by the atmosphere, which are not more properly referable to some one or other of its constituent parts.

Atmospherical air, as such, is soluble in water; from which it may be separated by the action of the air-pump, or by long boiling or distillation; hence fish, confined in fresh distilled water, soon die for want of air; if, however, the water has been previously exposed to the atmosphere, a sufficient portion is absorbed to supply the demands of these animals. In like manner water is soluble in air, but the proportion of this must necessarily vary according to the differences in temperature and barometrical pressure. Boyle's works, vol. ii. Mayow, Tractatus, &c. Priestley on Air. Lavoisier's Elements.

AIR, *factitious*. While pneumatic chemistry was in its infancy, all those elastic fluids produced in chemical experiments, were distinguished by this appellation from the air of the atmosphere; since, however, these factitious airs have acquired peculiar names, the term has fallen into disuse.

For an account of Dr. Priestley's numerous experiments and observations on these several species of air, the reader is referred to the excellent work already cited.

AIR, *innate*, in *Anatomy*, is a fine aerial substance, supposed, by some anatomists, to be enclosed in the labyrinth of the inner EAR, and to minister to the due conveyance of sounds to the sensory.

But the existence of such innate air, has been called in question, and rendered very improbable. See EAR.

AIR, in *Geography*. See AYR.

AIR, a mountain of Arabia Felix, to the north of Medina, and near it. It abounds with trees that yield frankincense.

AIR, *atmospherical*, in *Medicine*, when combined with moisture, disiere it degrees of heat, electricity, and various effluvia and miasmata, constitutes the ATMOSPHERE; and forms one of those six external circumstances so celebrated in the schools, called NON-NATURALS. Simple atmospherical air is no further an object of medicine or physiology than as it forms the medium of RESPIRATION. See the preceding and subsequent articles.

AIR, in *Music*, signifies the MELODY, or treble part of a musical composition.

The word is also used for a tune, or song itself, that is, for a series of sounds whose movement is regular and graceful. Rhyme is as necessary in a musical air, whether vocal or instrumental, as in the words of a song. Each bar of an air should be well accented, and the periods well phrased.

The rules for harmony are mechanical, and neither difficult to learn nor teach, as may easily be conjectured from the innumerable treatises in all languages for combining sounds in composition. Aristotle, Horace, Boileau, and Pope, have told us how good poems are constructed; but who shall tell us how to think, how to invent, to ferment ideas? Among all the receipts for constructing harmony, we have none that are intelligible for melody: we are told what *may* be done, by what *has* been already successfully achieved; but this is only telling us what we may imitate, and whom we may plunder. There are no magic wands to point out, or vapours hovering over springs of invention; no indications where the golden mine of new conceptions lies hidden. So that from age to age, memory and compilation supply common minds, and satisfy common hearers. It has been said:

“ Sometimes a hero in an age appears;
 But scarce a Purcell in a thousand years.”

Handel was our magnus Apollo during the last century, and Rameau that of France. At present, Haydn and Mozart “are the gods of our idolatry,” and those of all Europe. But it is only such gifted men as these who furnish the rest of mankind with ideas.

The origin and progress of melody, derived from harmony, and phrased and formed into *Air*, have been fully detailed in the Gen. Hist. of Music, in tracing the progress of the musical drama or OPERA. National music every country, not wholly savage, has had from time immemorial. In Europe, Sicily, Spain, Provence, Venice, Scotland, Ireland, and Wales, have characteristic melodies or tunes, of great antiquity. But the first pleasing *Airs*, in cultivated music, that I have been able to find *harmonized*, and in regular modulation, were printed in three and four parts in separate books at Naples, in 1565. Of these the measures are airy, the intervals pleasing, and the counterpoint simple: all the parts generally moving together. They are printed without bars. The modulation borders a little on that of the ecclesiastical modes, but it begins and ends in the same key, which does not often happen in national tunes.

Air, in music, has various applications: in the melodrama, or opera, it distinguishes measured melody from recitative.

A bal-

A ballad, tune, or short instrumental air, consists of two strains or parts.

No very satisfactory etymology has been found for the word *Air*. Saumaise believes that it comes from *ara*, Lat.; but Menage disputes this derivation, in his Etymological Dictionary, without furnishing a better. The term *Aria* in Italian, is of no high antiquity: the first instance of its use in the Crusca Dictionary is from Redi, who died in 1698. We know, however, that the word became of general use about the middle of the 17th century.

Though Air sometimes implies the words of a song, as well as the melody in general; nice discrimination requires, that we should confine its import to melody, a tune, alone, and *song* to the words. A fine or pleasing air has nothing to do with the poetry, which may be fine, though ill set. And the air may be beautiful, even to non-sensical words.

Measured air, in an opera, is opposed to recitative, where no regular time is observed. This musical declamation, which needs only two kinds of notes, crotchets and quavers, with pauses at the end of a verse, approaches nearer to what we conceive to have been the vocal music of the ancients, confined to longs and shorts, than any of our Airs, except such as are very simple, can do. Chanting, in the Cathedral service, is more rapid than recitative; but resembles it by the absence of regular measure, more than Air, which must be arranged in some one of the divisions of common or triple time.

In accompanied recitative, short passages or fragments of Air occur in the instrumental parts, in measured melody, which is often called symphony; but the Italians, with more propriety, style these fragments Ritornelli; which see. Sometimes indeed the instruments accompany the reciter in regular time, which obliges the singer to pronounce the recitative in measure, (which likewise see). Of this the performers are informed by the words *a tempo*, in time.

A vocal air is only the melody of a single part or voice. If another part is added to it, in different intervals, it is styled a *Duo*, or *Duet*; in three parts, a *Trio*; in four, a *Quatuor*, or *Quartet*, &c.

The Ancients had Airs, both vocal and instrumental, called *Nomes*. The words of lyric measures, which we should call songs, were styled *Scolia*, (which see under their several articles).

In the work of Philodemus on music, which has been recovered from the cinders of Herculaneum, the best and only musical information it contains, after being so long expected, and with such difficulty deciphered, is the solution of the miraculous powers ascribed by the poets to Amphion, of building cities by music. We find in this tract, (which is but a fragment, and neither a treatise nor an eulogium on music, but a severe satire) that every trade, occupation, and profession, had its nomes or peculiar and appropriate Airs, which were played to the workmen; so that towns were not built *by* music, but *to* music, ΦΙΛΟΔΗΜΟΥ ΠΕΡΙ ΜΟΥΣΙΚΗΣ. We see in *Bassi-relievi* and ancient sculpture, that there was a musician at the stern of every vessel, to regulate and animate the rowers. Orpheus, civilising the world, and introducing religion and order among mankind, implied only that religious rites were accompanied by music. See PHILODEMUS.

The derivation and progress of air in dramatic music will be found under the article opera, in which lyric poetry became subordinate to music. We fear the word *subordinate* will offend the poets, and such as love poetry better than music. "The words (says Franklin) are only an excuse for

singing." And Stillingsfleet asks "who reads the *words* of a song but the author?" In a musical drama, the business is all transacted in recitative, or declamation: which business, at the end of a scene, is illustrated by a simile, or a few passionate lines, set to measured music, in florid counterpoint; and these are calculated to display the talents of a singer, and the genius and abilities of a composer. Were this not the case, and if the poetry would be better felt and understood by the mere articulation and impassioned enunciation of common speech, why disguise and involve it in a tune, accompanied and incumbered by different melodies?

"A song, or the words of an air for a great composer to set, and a capital singer to execute, should consist only of *one subject or passion*, expressed in as few and *soft words as possible*." Metastasio has furnished the best models of words for airs in the Italian opera. And with respect to English dramas for music, on the Italian plan in all things, except the dialogue being declaimed in common speech, instead of the musical tones of *recitative*, we shall venture to quote on the subject of song-writing, opinions which we thought just 30 years ago, and which, during that period, we have seen no reason to retract.

"Since the refinement of melody, and the exclusion of *recitative*, a song, which usually recapitulates, illustrates, or closes a scene, is not the place for epigrammatic points, or for a number of heterogeneous thoughts and clashing metaphors; if the writer has the least pity for the composer, or love for music, or wishes to afford the least opportunity for symmetry in the air, the thought should be *one*, and the numbers as smooth, and the expression as *easy and laconic as possible*. What sublime ecclesiastical music has Handel composed on the single words *Allhujah*, and *Amen!* But, in general, every new line in our songs, introduces a new thought; so that if the composer is more tender of the poet's reputation than his own, he must, at every line, change his subject, or be at strife with the bard; and in either case, the alternative is injurious to the general interest of the music, poetry, and audience.

"In an air, it is by reiterated strokes that passion is impressed; and the most passionate of all strains, is, perhaps, that in which a beautiful passage is repeated and varied, and when the singer, by a few appropriate notes of taste, feeling, or spirit, returns to the first subject, while it still vibrates on the ear, and is recent in the memory; this licence, no doubt, may be, and often is, abused; but not by men of true genius and taste." *Present state of Music in France and Italy*.

Alessandro Scarlatti, Vinci, and Pergolesi, were the first who refined, phrased, and polished vocal melody, and settled the form and cantilena of dramatic airs. But these elegant strains composed for great singers, and a polite audience, are totally different from national melodies, which are traditional, and were invented long before either the gammut or modulation was settled: as may be discovered by innumerable old tunes of different nations, that begin in one key, and end in another. Indeed the ancient chants of the Romish church did the same. See CHANT and CANTO FERMO.

The Gluckists, in France, censure all airs that they are unable to sing, or that are likely to draw the attention of the audience from the poet to the musician. M. Suard, in a long and well written article of the new *Encyclopedie Methodique*, has analysed several of the most exquisite and renowned Italian opera airs that have ever been sung on the stage, with a severity that borders on insensibility. All the charms,

charms, illusion, and extatic pleasure, arising to ears disposed to be pleased by vocal enchantment, is reasoned away. It would be more for the advantage of real lovers of music, if they would reason less and listen more, at musical performances. Music is an object of *sense*, not of intellect. Does the composition please by its ingenuity, grace, and variety? Does the voice or tone of the instrument by which it is executed, delight and charm you, by its intrinsic sweetness and accurate execution?—You then may venture to pronounce to yourself, that the composition and performance are perfect, without asking supercilious, and often superficial critics, what you are to say.

In spite of our reverence for poetry, and partiality to the dramas of Metastasio, we are inclined to think that airs, on the best models of Italy, may be introduced in a musical drama, without injuring the poet or the interest of the piece. No one is more delighted with the poetry of Milton, Dryden, or Pope, than the author of this article, when he reads, or hears it read; but he never wishes it to be sung. Lyric poetry is a distinct species of verse, and varied versification, which is to delight by other means than ratiocination, logic, or philosophy. As painting is a refinement of the ocular sense, music purifies and augments the power of the auricular organ. We can exist without either painting or music; both are innocent luxuries: in the one, we have objects in nature to copy and judge by; but in music, wholly a work of art and imagination, of which we have no type in nature; every arrangement and combination of sounds that is grateful, graceful, and pleasing, which has not been rendered uncouth by time, or vulgar by common use, is in the storehouse of a composer; whose business it is to select, adjust, and introduce it to the ear, as propriety and occasion may require.

To give a specimen of every species of air, vocal and instrumental, which cultivated genius has produced, would occupy many volumes of our work. All we can do is to give the *nomenclature* of those movements that are, and have been, in most general use, with their definitions: such as *prelude, allemande, courant, minuet, jig, saraband, siciliana, polonese, rondeau, hornpipe, country dance*; and in Italy, *barcarolla, aria alla napoletana, alla calabrese, veneziana, &c. &c.* all which see under their several heads.

Recitatives and airs for a single voice, succeeded madrigals of three, four, and more voices; as sonatas and concertos did Fantasias for instruments. (See these terms in their several places.)

In dramatic music, there are three several kinds of *air*: *Aria di cantabile*, a pathetic song; *aria di bravura*, a song of execution; and *aria parlante*, a speaking air; besides the *andante, rondeau, cavatina, &c.* These and the several movements in the dances of an opera, are varied to infinity. But the scale, as it is now divided and extended, offers ample materials for them all. If we but consider that the number of changes in eight bells, where there is no modulation or change of key, amounts to 40,320; that the twelve semi-tones of the octave, every one of which made a key-note, major and minor, generates as many transitions as the key of C; that the melodies found in these 12 scales may be still varied by the different lengths of notes, and may be truly said to be incalculable; and lastly, if we recollect what variety may be given to an air or melody arising warrantably from the fundamental base of each key, by different accompaniments, inversions, and double counterpoint, we shall be lost in the maze of infinite divisibility! The changes upon 12 bells, (suppose from G in alt, 5th space in the treble, to C 6th line in the bass) amounting to 479001600; would employ, to ring them all, 12 men,

night and day, for 75 years, ten months, one week, and three days, according to the proportion of ringing 720 changes in an hour of an astronomical day of 24 hours, 365 of which complete the year! See BELLS, CARILLONS, and CHANGES.

Since *da capos* have been abandoned in the opera *airs*, which occasioned many dramatic absurdities, the *cavalina*, or single strain, without a second part, prevailed; but that not furnishing an opportunity for fingers of great abilities; to manifest all their powers of execution, taste, and expression, in the same air; of late, every air for a great singer is a *due caratteri*, of two characters, consisting of two distinct movements, usually an *andante* and an *allegro di bravura*. It is often difficult from the sense of the words, to assign any other reason for these sudden gusts of passion, after a soothing and pathetic movement, but that of convincing the audience of a singer's marvellous agility of throat, and powers of exciting surprise by *des tours de force*. If such airs were composed purposely for a concert, at which a performer, from the multiplicity of his or her engagements, could only stay to sing *one* song, and that connected with nothing else, airs of two characters might encrease the singer's fame, and the pleasure of the audience, without absurdity; but in a serious drama, where character, connexion, and propriety should be supported, after labouring through a slow movement in a melancholy drag, as every singer does, if not gifted with powers of new and appropriate embellishments, the setting off full speed without a word appearing in the *libretto*, or opera book, for the necessity of taking slight in such an outrageous manner, we pity the poet and ourselves for being thus defrauded of all dramatic interest. In the course even of *two* acts, to which an opera is now cut down, opportunities for displaying all the powers of a singer, however extraordinary and various, may be found in every principal part, without violating the dignity of character, and rules of common sense. See MELODY, SONG, TUNE, and OPERA.

AIR, in *Mythology*, was adored by the heathens under the names of Jupiter and Juno; the former representing the superior and finer parts of the *atmosphère*, and the latter the inferior and grosser parts. The augurs also drew prefaces from the clouds, thunder, lightning, &c.

AIR, in *Painting*, &c. denotes the manner and very life of action; or it is that which describes such of those refined expressions, that do not arise from the motion of the features of the face, which are to be considered as the more immediate agents expressing the passions of the soul (see PASSIONS); but from the turn of the body, and especially of the head and neck. This term *air* is more particularly synonymous with GESTURE, or GRACEFUL ACTION or ATTITUDE. Painters are in danger of falling into affectation, while they attempt to give an air of elegance above vulgar ideas. Corregio and Guido have excelled in the airs of the heads, as well as of the whole figures they painted; but, perhaps, in some instances, even they may have exceeded the due bounds of nature.

AIR, in *Painting*, is also a great subject of consideration, as the interposing medium which tends to diminish the force or strength of objects and colours. See the article PERSPECTIVE AERIAL.

AIR, in *Surgery*. The application of gaseous matters to the purposes of surgery, has not been sufficiently attended to. There is reason to believe that several aeriform substances might be employed locally, as well as internally, to considerable advantage; but it would exceed the bounds we have prescribed to this department of our work, were we to adduce all the facts that might be brought forward to

illustrate the medicinal powers of air, in its different combinations. The application of fixed air, or carbonic acid gas, by means of the fermenting cataplasin, is pretty generally known, in cases of fetid and gangrenous sores. It has been advantageously used also in malignant ulcers of the nose, tongue, and mouth, as well as in caries of the bones.

Fixed air is plentifully obtained from a mixture of alkaline or chalky substances with vitriolic acid; and during the effervescence, applying the gas which is extricated immediately to the morbid part; or by impregnating water with it, compresses may be soaked in the water, and laid frequently over the seat of the disease. Mr. Loeffler, a German surgeon, has recommended a particular apparatus for this purpose, which may be easily constructed, and which he employs for saturating water with fixed air, by the mixture of chalk and vitriolic acid, or during the process of fermentation.

When we wish to apply the air to a cancerous breast, for example, we are to fill a bladder with the air as it rises from the above mixture. Then introduce a tube, fixed to its orifice, into another bladder, which is to be cut round in such a manner that it can be applied like an open bag around the breast, and held close to it with the hands. When it is fastened below, it must be untied, so that the fixed air may pass out of the first into the second bladder, and find access to the ulcerated part. In order to facilitate this process, a gentle degree of pressure is to be applied to the bladder; and, as one bladder will not be sufficient, a number of them should be provided in readiness, and filled for immediate use in succession. This operation is to be continued half an hour or longer each time, and repeated twice or thrice a day.

Mr. Witstock, who has written a German treatise on this subject, and with extraordinary success, recommends us to apply the carbonic acid gas, by means of a receiver or air-bell, connected with a flexible tube or pipe, sufficiently airtight; but as the vitriolic acid produces too strong a commotion, the gas is extricated for such purposes from a mixture of fixed alkali and vegetable acid.

The medicinal use of facitious airs is a subject which has been diligently considered by Dr. Beddoes, Dr. Thornton, Mr. Hill, Mr. Davy, and some other gentlemen in England; but the enquiry is still in its infancy, and has not been productive of so much public benefit as its zealous friends anticipated. Perhaps the attention of medical men to the local and external influence of gaseous matters, would better repay them for their trouble. Surgeons are not exactly agreed, whether the atmospheric air be hurtful to wounds and internal cavities, merely as air, or as it may be cold, hot, moist, dry, or variously modified. We hope these superficial hints will serve to excite the attention of professional gentlemen to this branch of the healing art. It likewise deserves further enquiry, whether the injection of fluids into the urinary bladder, impregnated with fixed air, &c. &c. be so efficacious, in calculous cases, as some persons have pretended.

From observations on bleeding in rheumatisms, and after taking cold, it is evident, the air can enter with all its qualities, and vitiate the whole texture of the blood, and other juices.

From the palsies, vertigoes, and other nervous affections caused by damps, mines, &c. it is evident, that air thus qualified can relax and obstruct the whole nervous system. And from the colics, fluxes, coughs, and consumptions produced by damp, moist, and nitrous air, it is evident it

can corrupt and spoil the noble organs, &c. See ATMOSPHERE, and preceding articles.

Air-bag, in *Botany*, a distended bladder-like seed-vessel, opening on one side, as in the periwinkle, or bladder-sena. It signifies also other kinds of distended air-vessels. See FOLLICULUS.

Air-balloons, a name lately given to those aerostatic machines that have been employed in aerial navigation. See AEROSTATION.

Air-bladder, in *Ichthyology*, a kind of vesicula, containing elastic air, found in the bodies of fish, by means whereof they are enabled to sustain themselves in any depth of water, and either to rise or sink at pleasure.

The air-bladder is the same with what is otherwise called the swim, or swimming-bladder. This membranous bag lies close to the back-bone, and is furnished with a strong muscular coat, by which it has the power of contraction and dilatation. It is connected with a glandular substance, which contains a quantity of red blood; and some have supposed that the air contained in the swimming-bladder, is derived from this substance. Two processes or appendices issue from its anterior part, and terminate in the fauces; and it is supposed by some writers to be that part which is called the *found*.

The discovery of the use of the air-bladder took its rise from observing, that a bubble of air in rising from the bottom of a fluid, continually dilates till it reaches the top, by reason of the continual diminution of the weight, or pressure, of the incumbent water. For the air, in the bladder, is like the bubble, more or less compressed, according to the depth the fish swims at, and takes up less or more space; and consequently the body of the fish, part of whose bulk this bladder is, is greater or less according to the several depths, though it retains the same weight. The rule of hydrostatics is, that a body heavier than so much water as is equal in quantity to the bulk of it, will sink; a body lighter, will swim; a body of equal weight will rest in any part of the water. By which rule, if the fish in the middle region of the water be of equal weight with an equal bulk of the water, the fish will rest there, without any tendency either upwards or downwards; and if the fish be deeper in the water, its bulk becoming less by the compression of the bladder, and yet retaining the same weight; it will sink and rest at the bottom: on the other side, if the fish be higher than the middle region, the air dilating itself, and the bulk of the fish consequently increasing, without any increase of the weight, the fish will rise and rest at the top of the water.

Perhaps the fish by some action can emit air out of the bladder, and afterwards out of its body; and also when there is not enough taken in more air, and convey it to this bladder; in which case it will be no wonder, that there should be always a fit proportion of air in the bodies of all fishes, to serve their use, according to the depth of water they live in: perhaps also, by some muscle, the fish can contract this bladder beyond the pressure of the weight of water; and perhaps it can by its sides, or some other defence, keep off the pressure of the water, and give the air leave to dilate itself. In these cases, the fish will be helped in all intermediate distances, and may rise or sink from any region without moving a fin.

If the air-bladder of a fish be pricked or broken, the fish presently sinks to the bottom, unable either to support or raise itself up again. Flat fishes, as soles, plaice, &c. which always lie groveling at the bottom, have no air-bladder.

Dead fishes are found swimming on the surface of the water, because the muscles of the membrane cease to act: and their bellies are uppermost, as the back-bone cannot yield, and the distended sac is protruded into the abdomen, and the back becomes consequently heaviest at its upper part.

In most fishes there is a manifest channel, leading from the gullet or upper orifice of the stomach to the air-bladder, which doubtless serves for conveying air into it. In a surgeon Mr. Willughby observed, that upon pressing the bladder the stomach presently swelled; so in that fish it seems the air passes freely both ways. Possibly the fish while alive may have a power to raise up this valve, and let out air on occasion.

In a variety of other fishes there are communications with some parts of the alimentary canal, particularly the oesophagus and stomach. The salmon has an opening from the fore-end of the air-bladder into the oesophagus, which is surrounded by a kind of muscular fibres. The herring has a sort of funnel, connecting the bottom of the stomach with the air-bag; by which the air probably comes out from it.

All the fishes of the cartilaginous kind want air-bladders: by what means it is they ascend and descend in water is yet unknown. The cetaceous kind, or sea-beasts, are also without the air-bladder: indeed, as these differ little from quadrupeds, but in the want of feet, the air which they receive into their lungs in inspiration, may serve to render their bodies equiponderant to water; and the constriction or dilatation of it, by the help of the diaphragm and muscles of respiration, may possibly assist them to descend, or ascend, in the water, by a light impulse thereof with their fins. Most of the eel-kind have bladders, yet they can hardly raise themselves in the water, by reason of the length and weight of their tails; the air-bladder being near their heads, may help them to lift up their heads and fore part. Ray's *Wisd. of God*, &c. part i. p. 26. Phil. Trans. N^o 114, Abridgment, vol. ii. p. 845.

There is great diversity in air-bladders, in respect of figure, substance, situation, and connection, in different fish. In some, the air-bladder, is divided into two, *e. gr.* in *carps*; and in others, into three. Needham maintains, that all fish which have teeth in their jaws have only a single air-bladder; whereas those without teeth have a double one; or, which amounts to the same, the air-bladder of these last is divided into two cells. Sig. Redi refutes this distinction; giving instances of fish with teeth, whose air-bladder is double; and of others without teeth, which have only a single air-bladder.

Dr. Priestley conjectures that the air, enclosed in the air-bladder of fishes, serves some farther purpose in their economy besides that of enabling them to rise or sink in water. Some fish have no air-bladder, and yet rise or sink without difficulty. That fishes cannot live without air is a well-known fact, established long ago by the experiments of Mr. Hauksbee. The fishes he employed were gudgeons, which are lively in the water, and which subsist for a considerable time when taken out of it. Having put three of these into a vessel of water, which had no communication with the external air, and which was designed to resemble a frozen pond, and other three into a vessel of water exhausted of its air; he observed, that in about half an hour the latter manifested signs of uneasiness by an unusual motion of their mouth and gills; and the former frequently ascended to the top of the vessel in which they were confined and then sunk down again, without any sensible alteration. After five hours the gudgeons in the vessel exhausted of its air, became less active; and in about three hours more those in the confined air lay at the

bottom of the vessel with their bellies upwards, without moving their fins or tail, but indicating life by a motion with their mouths. On uncovering the vessel, they revived in two or three hours, and were perfectly well next morning; at which time those in the vessel purged of its air were also recovered. When this last vessel was put under the receiver of an air-pump, and the air was exhausted, they all died. When the air was exhausted, they remained at the top, but on its readmission, they sunk to the bottom. It is not easy to explain the manner in which fishes are supplied with air, nor the benefit they derive from it; nor are the nature and qualities of the air, contained in their air-bladder, satisfactorily ascertained. Dr. Priestley (*Exp. and Obs. relating to Nat. Philos.* vol. ii. p. 138), confined minnows, and other small fishes in water without any access of common air, till they died, and upon examining this water, he found that it was somewhat worse than air in which a candle just goes out. Hence he infers, that air contained in water, in an unelastic state, is as necessary to the life of fishes, as air in an elastic state is to that of land-animals. Upon putting fishes into water impregnated with phlogisticated air, he found that it was not only injurious, but in process of time fatal to them; although he observes, that fishes, like insects and some other exsanguious animals, can live a considerable time without any thing equivalent to respiration. In mentioning some experiments on the state of the air, which is contained in the air-bladder of fishes, he remarks, that when these are taken out of the fish, the air cannot be discharged from them by pressure through any existing aperture, but he was always obliged to cut or burst them. The air itself, obtained from many of them, was not affected by nitrous air; but that of some, particularly of roaches, exhibited slight indications of the effect of this test. Upon the whole it thus appears, that he seldom met with oxygen, and with that only in a small quantity. Fourcroy made experiments on the air contained in the air-vessel of the carp, and found that for the most part it was perfectly pure azotic gas, though it sometimes contained a small quantity of carbonic acid gas. From the nature of the fluid he infers, that the air in the bladders of fishes is produced in the stomach. *Ann. de Chem.* i. 47. Dr. Monro, in his lectures, led his auditors to conclude, that it was fixed air. But Dr. Brodbelt of Jamaica, collecting about a quart of the air from the bladder of a large sword-fish, which, he says, consisted of innumerable cells that had no communication with one another, found to his surprize that it was oxygen. A flame was brightened and an ignited stick was rekindled by it; and it was so strong and pure, that the common experiment of a piece of steel-wire, heated and put into it, succeeded well, and threw out a most vivid light when melting. This pure air, he supposes, is adapted to serve the purposes of life, when the fish is far below the surface of the water. *Duncan's Ann. of Med.* for 1796, p. 393.

The water-snake, in lieu of a bladder, has a large membranous air-bag on its back, which empties and fills with air at pleasure, by an aperture, which it can shut very close, from without inwards, by means of a sort of valve, so that the least globule of water cannot enter without its consent. By this artifice it can enlarge or lessen the bulk of its body, and inhabit all depths of the water; though a conjecture has been advanced by Mr. Ray, that it is by the help of water which they take in and let out by two holes in the lower part of their abdomen, near to the ventricle. They sink in the water, by letting in some of it at these holes; the orifices whereof are opened and shut at pleasure, by means of proper muscles. The water being thus received

into the cavity of their abdomen, serves to make them preponderate the water, and descend; when they would ascend again, a compression is made by the muscles of their abdomen, and the water forced out again, at least so much as suffices to give the degree of levity wanted. Ray's *Wisd. of God*, part ii. p. 346.

Air-bladders, or *Air-bags*, in *Ornithology*, are cells or receptacles of air in the bodies of birds, which communicate with the lungs, and which are lodged both among the fleshy parts, and in the hollow bones of these animals. Mr. John Hunter, F. R. S. (*Philos. Transf.* vol. lxiv. part 1. p. 205, &c.) has published some curious observations on this subject, leading to a more particular inquiry into the final cause of this peculiarity in the structure of birds, which had not been sufficiently noticed and examined by anatomists and natural historians. He informs us, that the air-cells, which are found in the soft parts of birds, have no communication with the cavity of the common cellular membrane of the body; some of them communicate immediately with one another; and all of them may be said to have a communication together, by means of the lungs as a common centre. Some of them are placed in larger cavities, such as the abdomen; others are so lodged in the interstices of parts, that they would, at first, appear to be the common connecting membrane, as about the breast, axilla, &c. The bones which receive air are of two kinds; some, as the sternum, ribs, and vertebræ, have their internal substance divided into innumerable cells; whilst others, as the os humeri and the os femoris, are hollowed out into one large canal. These bones may be distinguished from those that do not receive air by their less specific gravity; by being less vascular, and consequently whiter, than others; by containing little or no oil; by having no marrow nor bloody pulpy substance, even in their cells; by not being, in general, so hard and firm as other bones; and by the ease with which the passage that conveys the air into the bones may be perceived.

The mechanism by which the lungs are adapted for communicating air to the above-mentioned parts consists principally in the attachment of the lungs to the diaphragm and their connection with the ribs and sides of the vertebræ. These adhesions are peculiar to this tribe of animals. For the communication of the air from the lungs to the other parts the diaphragm is perforated with large holes, which open a free passage between the cells of the lungs and the abdomen: and to each of these perforations is annexed a distinct membranous bag, which is very thin and transparent, and these bags, which receive the air, are extended over the whole abdomen. The lungs open at their anterior part, or towards the sternum, into membranous cells, which lie upon the sides of the pericardium, and communicate with the cells of the sternum. The superior part of the lungs opens into large cells of a loose net-work, through which the trachea, oesophagus, and large vessels, in their way from and to the heart pass. When these cells are distended with air, the size of the part where they lie is enlarged, and this distension indicates passion, as appears in the turkey-cock, pouting-pigeon, &c. and in the breast of a goose, when it cackles. These cells communicate with others in the axilla, under the large pectoral muscle, &c.; and those again with the cavity of the os humeri by small openings in the hollow surface, near the head of that bone. The posterior edges of the lungs, which lie on the sides of the spine, and project backwards between the ribs, open into the cells of the bodies of the vertebræ, ribs, canal of the medulla spinalis, sacrum, and other bones of the pelvis; and thus the air finds a passage to the cavity of the thigh-bone. This supply of the bones with air is not wholly by means of the lungs; for

the cells of the bones of the head, in some birds, are filled with it, as in the case of the owl, which has the diploe between the two plates of the scull cellular, and capable of admitting a considerable quantity of air from the Eustachian tube. Mr. Hunter, in his conjectures concerning the use of these cavities, concluded at last that they were to be considered as appendages to the lungs; and that they answer the same purpose with the two bags that form the lungs of amphibious animals which are continued down through the belly, the upper part of which performs the office of respiration, and the remainder of which is a reservoir of air. In consequence of this conformation these animals can breathe less frequently than others; and birds are thus aided in their flight, which must render frequency of respiration difficult, and a reservoir of air singularly useful. He farther suggests that this construction of the respiratory organs may assist birds in singing; and that the long continuance of the song of a canary-bird between its breathings may be owing to this cause. Dr. Latham (*Linneæan Transactions*, vol. iv. p. 94.) queries, whether this construction may not enable some birds to dive and stay for a considerable time under water. These air vesicles, according to Dr. Monro, are of considerable use in two respects. They serve, by distending the lungs with air, to render the bodies of birds specifically light, and also to straiten the trachea arteria, and thus return the air; and moreover to supply the place of a muscular diaphragm and strong abdominal muscles, and thus to aid the exclusion of the eggs and fæces.

Air-chamber, is a name given by Dr. Henshaw to a room contrived for obtaining the benefit of change of air, without going out of the house. According to his whimsical proposal, it is to be twelve feet square, and air-tight, furnished with a very large pair of organ bellows, to or from which air is to be conveyed through the wall by a copper pipe, with valves for opening inwardly and outwardly as occasion shall require. With these bellows, the air in the room is either to be condensed and made heavier, by forcing air in, or lighter and rarer by conveying air out of the room. See his *Aero-Chalinos*, or *Phil. Transf.* N° 133. See *VENTILATOR* and *Blowing-WHEEL*.

Air-gun, or *Wind-gun*, a machine which serves to explode bullets, and other shot, with great violence, by the expansive force of the air. This sort of implement, charged with air, has an effect scarcely inferior to that of a common fire-arm charged with gun-powder; but it discharges itself with a much less report; and it is this which probably gave occasion to the fable of white gun-powder. The first account of an air-gun, that has been noticed, is found in the *Elements d'Artillerie* of David Rivaut, who was preceptor to Louis XIII. of France. He ascribes the invention to one Marin, a burgher of Lisieux, who presented one to Henry IV.

The common air-gun (*Pneumatics*, Plate iii. fig. 14.) is made of brass, and has two barrels: the inside barrel K A of a small bore, from which the bullets are shot, and a larger barrel E C D R on the outside of it. In the stock of the gun there is a syringe, S M N P, whose rod M draws out to take in air, and piston S N drives the air before it through the valve E P into the cavity between the two barrels. The ball K is put down into its place in the small barrel with the rammer, as in another gun. There is another valve at S L, which, being opened by the trigger O, permits the air to come behind the bullet, so as to drive it out with great force. If this valve be opened and shut suddenly, one charge of condensed air may make several discharges of bullets; because only part of the injected air will go out at a time; and a new bullet may be put into the place K; but if the whole air be discharged on a single bullet, the

ball will be expelled more forcibly. This discharge is effected by means of a lock *kl* (*fig. 15.*) placed here as in other guns; for the trigger being pulled, the cock *k* will go down, and drive a lever *o*, that will open the valve, and let in the air upon the bullet *K*.

An air-gun of the most modern and approved construction is represented in *fig. 16.* *A* is the iron gun-barrel, with the lock, stock, ram-rod, &c. of about the size and weight of a common fowling-piece. Under the lock at *b* is a round steel-tube, with a small moveable pin in the inside, which is pushed out by the spring of the lock, when the trigger *a* is pulled. To this tube, *b*, is screwed a hollow copper-ball, *c*, containing a spring-valve at its aperture; and perfectly air-tight. Each gun has usually two of these balls, which are fully charged with condensed air by means of the condensing syringe *B*, *fig. 17.* Having rammed down the leaden bullet into the barrel, and screwed the copper ball home to the lock at *b*, let the trigger, *a*, be pulled, and the pin at *b* will be forcibly and instantly driven out against the valve in the ball, and will thus liberate a portion of the condensed air; which, rushing up through an aperture in the lock into the barrel immediately before the ball, will impel it to the distance of, at least, 60 or 70 yards. By recocking the piece, another discharge may be immediately made, and thus repeated 15 or 16 times, with a very small hissing noise, which at a distance is not audible. The condensed air is forced into the ball by the following apparatus. The ball, *c*, is screwed to the brass syringe *B* (*fig. 17.*) quite close. In this syringe is adapted a moveable piston and iron rod, *a*, at the end of which is a strong ring, into which is placed a stout iron rod, *kk*: upon this rod the feet are firmly placed, and the hands are applied to the wooden handles, *ii*, fixed to the syringe. By steadily moving the barrel *B*, up and down on the rod *a*, the ball, *c*, will become charged with condensed air; and it is easily known when it is filled to the utmost by the irresistible action which the air makes against the piston, when you are working the syringe. At the end of the rod *k*, is usually an eight-square hole, which serves as a key to make the ball fast on the screw, *l*, of the gun, and on the syringe. The piston-rod works air-tight by a collar of leathers on it, in the barrel, *B*; and therefore, when the barrel is pulled up, fresh air will rush in at the hole *b*; when the barrel is pushed down, the air in it can only pass into the ball at top; the barrel being drawn upwards, the operation is repeated, until the condensation is so strong as to resist the action of the piston.

Dr. Macbride (*Exper. Ess. p. 81.*) mentions an improvement of the air-gun by Dr. Ellis, in which the chamber for containing the condensed air is not in the stock, which makes the machine heavy and unwieldy, but has five or six hollow spheres belonging to it, of about three inches diameter, fitted to screw on the lock of the gun. These spheres are contrived with valves for confining the air, which is forced into their cavities, so that a servant can carry them ready-charged with condensed air; and thus the gun of this construction is rendered as light and portable as one of the smallest fowling-pieces.

The magazine air-gun is an improvement of the common air-gun, invented by an ingenious artist called L. Colbe. By his contrivance ten bullets are so lodged in a cavity, near the place of discharge, that they may be drawn into the shooting barrel, and successively shot so quickly, as to be nearly of the same use with so many different guns; the only motion required, when the air has been previously injected, being that of shutting and opening the hammer, and cocking and pulling the trigger. In *fig. 18*, is exhibited a section of the gun, as large in every part as the gun

itself; and so much of its length is shewn as is necessary to give a complete idea of the whole. *AEE* is part of the stock; *G* is the end of the injection syringe, with its valve, *H*, opening into the cavity, *FFFF*, between the barrels. *KK* is the small or shooting barrel, which receives the bullets, one at a time, from the magazine, *ED*, which is a serpentine cavity, wherein the bullets, *b, l*, &c. are lodged, and closed at the end *D*. The circular part, *SI&MI*, is the key of a cock, having a cylindrical hole, *IK*, through it, equal to the bore of the small barrel, and forming a part of it in the present situation. When the lock is taken off, the several parts, *Q, R, T, S, W*, &c. come into view, by means of which the discharge is made, by pushing up the pin, *Pp*, which raises and opens a valve, *V*, to let in the air against the bullet, *I*, from the cavity, *FFF*; which valve is immediately shut down again by means of a long spring of brass, *NN*. This valve, *V*, being a conical piece of brass, ground very true in the part which receives it, will of itself be sufficient to confine the air. To make a discharge, pull the trigger, *ZZ*, which throws up the sear, *yx*, and disengages it from the notch, *x*; upon which the strong spring, *WW*, moves the tumbler, *T*, to which the cock is fixed. The end, *u*, of this tumbler bears down the end *v*, of the tumbling lever, *R*, which, by its other end, *m*, raises the flat end, *l*, of the horizontal lever, *Q*, by which means the pin, *Pp*, is pushed up, and opening the valve, *V*, discharges the bullet; all which is evident from a bare view of the figure.

To bring another bullet instantly to succeed *I*, there is a part *H*, called the hammer, represented in *fig. 19.* and *fig. 20.* which by a square hole goes upon the square end of the key of the cock, and turns it about so as to place the cylindrical bore of the key *IK*, in any situation required.

Thus, when the bullet is in the gun, the bore of the key coincides with that of the barrel *KK*; but when it is discharged, the hammer *H* is instantly brought down to shut the pan of the gun; by which motion the bore of the key is turned into the situation *ik*, so as to coincide with the orifice of the magazine; and upon lifting the gun upright, the ball next the key tumbles into its cavity, and falling behind two small springs, *ss*, *fig. 18.* is by them detained. Then opening the hammer again, the ball is brought into its proper place, near the discharging valve, and the bore of the key again coincides with that of the shooting barrel. It appears how expeditious a method this is of charging and discharging a gun; and if the force of condensed air was as great as that of gunpowder, such an air-gun would actually answer the end of many guns, and prove the best defence against highwaymen or robbers; because, when there is reason to suspect them, they might then make five or six discharges before the robber can come within pistol-shot.

From the experiments of Mr. Robins, in his *New Principles of Gunnery*, (*See Mathem. Tracts of Robins, by Wilfon, vol. i. p. 73.*) it appears, that the force of gunpowder, at the moment of its explosion, is 1000 times greater than that of the elasticity of common air; and, therefore, that the latter may produce the same effect with the former, its condensation must be 1000 times greater than that of its natural state. But as the velocities with which equal balls are impelled are directly proportional to the square roots of the forces, the velocity with which an air-gun, containing air condensed only ten times, will project a ball, will be $\frac{1}{\sqrt{10}}$ th of that arising from gunpowder; and if the air were condensed 20 times, it would communicate a velocity of $\frac{1}{\sqrt{20}}$ th of that of gunpowder. In the air-gun, however, the reservoir of condensed air is commonly very large, in proportion to the tube which

contains the ball, and its density will be very little altered by expanding through that narrow tube; consequently the ball will be urged by nearly the same uniform force with that of the first instant: whereas the elastic fluid of inflamed gun-powder, bears a small proportion to the barrel of the gun, and by dilating from the small portion of it near the but-end into a comparatively large space, its elastic force will be proportionally weakened, and its action on the ball in the barrel will become gradually less and less. Hence it appears, that the air-gun will project its ball with a much greater proportional degree of velocity than that which is above stated; insomuch that air condensed ten times will produce a velocity not much inferior to that arising from the gun-powder.

However, in this kind of gun, and in all cases which require a very considerable condensation of air, it will be requisite to have the syringe of a small bore, *viz.* not exceeding half an inch in diameter; because the pressure against every square inch is about 15 pounds, and against every circular inch about 12 pounds. If, therefore, the syringe be one inch in diameter, when one atmosphere is injected, there will be a resistance of 12 pounds against the piston; when two, of 24 pounds; and when ten are injected, there will be a force of 120 pounds to overcome; whereas ten atmospheres act against the circular half inch piston, whose area is but one-fourth part so big, with a force but one-fourth as great, *viz.* 30 pounds; or 40 atmospheres may be injected with such a syringe as well as ten with the other. Defaguliers's Exp. Phil. vol. ii. p. 398, &c. Martin's Phil. Brit. vol. ii. p. 189, &c. Adams's Lect. on Nat. and Exp. Phil. by Jones, vol. i. p. 133.

Air-jacket, a jacket of leather, furnished with bags or bladders of the same material, inflated with air, and serving to buoy up the person who wears it, and to prevent his sinking in water, without any effort of swimming. These bags communicate with each other, and are filled with air by means of a leathern pipe, having at the end of it a stop-cock, accurately ground, so as to admit the injected air, and, when closed, to prevent its escape. The jacket must be well moistened with water before the bags are filled: otherwise the air will escape through the pores of the leather.

Air-lamp, a pneumatic machine, formed by the combination of inflammable air and electricity, which, by turning a stop-cock, produces a flame that may be restrained or continued at pleasure. The contrivance of machines of this sort was suggested by the experiments of Mr. Volta, Dr. Ingenhouz, &c. The air-lamp is now constructed in the following manner. A, (*Plate iii. Pneumatics, fig. 21.*) is a glass jar for containing the inflammable air; B, an open glass urn, that contains water, by the pressure of which the air is forced out of the jar A, through the brass-pipe *a*; C, is the stop-cock, so perforated, that the water may descend from B into A, and the air pass out through the pipe *a*. By turning the bar of the stop-cock to an horizontal position, the communication between the two vessels is closed, and the passage of the air obstructed; and by turning it into a vertical position, the communication is opened. The lower jar, A, is supplied with inflammable air by means of the bladder, (*fig. 22*); and two bladders of this kind accompany each lamp. It is used in the following manner: Take off the cover D, from the lamp, and turn the stop-cock upwards; then pour as much clear water into it as will fill the vessel, A, up to the pipe *a*; unscrew this pipe, and in its stead screw the small brass piece (*fig. 23.*) and to this screw one of the stop-cocks and bladder, (*fig. 22.*) With the bladder under one arm, one hand

to the cock at C, and the other to that of the bladder, open the apertures and press the bladder at the same time; and thus the air will be forced upon the water in A, and driven up the glass pipe through the tube into B, with a bubbling noise. When the vessel, A, is thus charged with air, the stop-cocks are to be turned, so as to cut off the communication with the external air. Care must be taken that the common atmospheric air does not mix with the inflammable; for if a mixture of these airs were fired, the explosion would be great and dangerous.

The apparatus for lighting this lamp is of the electrical kind; and it is as follows. The mahogany basis, E F, is a sort of box, about 12 inches square, and 5 inches deep; and in this is placed an electrophorus, consisting of a resinous cake *c*, and metallic plate *d*, which by a hinge at its back, admits of being pulled upwards and let down by the silken string *b*, connected both with it and with the stop-cock C. When this cake is once excited, its electrical effect upon the metal plate will be continued for a long time. A metallic chain, G, communicates with a wire and ball *e*, passing through a glass tube below, in the box over the plate, and above with a fine wire passing through a glass tube. This upper wire is bent to about $\frac{1}{4}$ th of an inch distance from the flame-pipe. It is evident that when the electrophorus in the box is previously excited, and the stop-cock, C, turned, the silken string, *b*, will raise the metallic plate; and this will give an electric spark to the ball and wire above, which will convey it instantly to the flame-pipe, and inflame the air issuing out of the pipe, in consequence of the pressure of the water in its descent into the vessel A. The cock, C, being turned back, the flame ceases; and turned again, appears; and will serve to light a candle, match, &c. whenever it may be thought proper. The number of times in which light may be produced will be very great, and will depend on the quantity of the inflammable air in the vessel A. If the cock is not turned back, the flame will continue till the whole of the inflammable air is consumed. The light thus produced will be sufficient for reading a large print in the night, or seeing the hour by a watch. When the electrophorus is to be excited, the silken string, *b*, is unhooked from the plate, and the apparatus taken out of the box; and the metallic plate is lifted up, whilst, with a silken or dry cat-skin rubber, you briskly rub the surface of the resinous cake. About 20 revolutions in rubbing will be sufficient, so that the plate will give a spark to the knuckle about the distance of an inch; and by the strength of the spark the degree of excitation is to be estimated. The silken string and small glass tubes, through which the wire, G, passes, should always be very dry, that the passage of the electrical spark may be quite perfect. The whole length of this apparatus is about 22 inches; but it may be made of any dimensions. Dr. Ingenhouz used a small apparatus, constructed upon a similar principle, in obtaining light for domestic purposes, both when at home and on his travels. Adams's Lectures by Jones, vol. ii. p. 99, &c.

Air-pipes, a contrivance invented by Mr. Sutton, a brewer of London, for clearing the holds of ships and other close places of their foul air. The principle upon which this contrivance is founded is well known. It is no other than the rarefying power of heat, which, by causing a diminution of the density of the air in one place, allows that which is in contact with it to rush in, and to be succeeded by a constant supply from remoter parts, till the air becomes every where equally elastic. If a tube, then, be laid in the well, hold, or any other part of a ship, and the upper part of this tube be sufficiently

heated to rarefy the impending column of air, the equilibrium will be maintained by the putrid air from the bottom of the tube, which being thus drawn out, will be succeeded by a supply of fresh air from the other parts of the ship; and by continuing the operation, the air will be changed in all parts of the ship. Upon this principle, Mr. Sutton proposed to purify the bad air of a ship, by means of the fire used for the coppers, or boiling places, with which every ship is provided. Under every such copper or boiler there are two holes separated by a grate, one for the fire and the other for the ashes; and there is also a flue, communicating with the fire-place, for the discharge of the smoke. The fire, after it is lighted, is preserved by the constant draught of air through these two holes and the flue; and if the two holes are closed, the fire is extinguished. But when these are closed, if another hole, communicating with any other airy place, and also with the fire, be opened, the fire will of course continue to burn. In order to clear the holds of the ships of the bad air, Mr. Sutton proposed to close the two holes above mentioned, *viz.* the fire-place and ash-place, with substantial iron doors, and to lay a copper or leaden pipe of sufficient size from the hold into the ash-place, and thus to supply a draught of air for feeding the fire; a constant discharge of air from the hold will be thus obtained, and fresh air will be supplied down the hatches, and by such other communications as are open into the hold. If other pipes are connected with this principal pipe, communicating either with the wells or lower decks, the air that serves to feed the fire will be drawn from such places.

In large ships, there is not only a copper, but a fire-grate, like those used in kitchens; behind this grate an iron tube might be fixed, and inserted quite through the brick-work and through the deck, so that one end of it might stand about a foot, or somewhat more, in the chimney above the brick-work, and the other made to enter into the hold or any other part of the ship. When the upper end of this tube is heated, the draught of air will be supplied from below, as in the other case. Mr. Sutton's practicable and useful contrivance was much opposed at its first proposal; and though his pipes were recommended by Dr. Mead and Mr. W. Watson, after several trials of their effect, they were very slowly introduced, and in process of time very much neglected. Mr. Sutton, after considerable delay, and with no small difficulty, obtained a patent for his invention.

Mr. Watson recommends the use of these pipes for the circulation of fresh air in houses, prisons, hospitals, wells, &c. And they have undoubtedly this obvious advantage, that by causing the putrid and noxious air to pass into the fire, they not only dissipate but destroy it. *Phil. Transf. abr. vol. viii. p. 628. 630. Mead's Works, p. 397—437.*

AIR-pump, a machine, by means of which the air may be exhausted out of proper vessels.

The use and effect of the air-pump is to make what we popularly call a *vacuum*; but this, in reality, is only a degree of rarefaction sufficient to suspend the ordinary effects of the atmosphere.

By this machine, therefore, we learn in some measure, what our earth would be without an atmosphere; and how much all vital, generative, nutritive, and alterative-powers, depend upon it.

The principle on which the air-pump is constructed, is the elasticity of the air; as that on which the common, or water-pump is founded, is the gravity of the same air.

The structure of the air-pump is, in itself, more simple even than that of the water-pump.—The latter supposes two principles, gravity and elasticity likewise; so that the water-pump must first be an air-pump, *i. e.* it must rarefy the air before it can raise the water.—In effect, water being a dormant unelastic fluid, needs some external agent to make it ascend; whereas air ascends in virtue of its own elastic activity: its natural tendency is to separate and leave a vacuum; and all that remains for art is to prevent the ambient air from supplying the place of that which thus spontaneously escapes. To make water ascend, the force wherewith it is pressed downwards is either to be diminished or increased in one part more than another; like a balance *in equilibrio*, one of whose scales may be made to rise, either by diminishing its own weight, or increasing that of the other; the water, therefore, recedes from the common centre of gravity by the very power with which it tends towards it indirectly or secondarily applied; because, two similar centripetal forces being made to act contrary to each other, what in the one over-balances the other must have the effect of a centrifugal force—Whereas, the principle whereby air is rarefied or diminished, does not respect the centre of the earth, but the centres of its own particles; being no other than a certain implanted power, whereby they immediately tend to recede from each other.

The invention of this noble instrument, to which the present age is indebted for so many fine discoveries, is ascribed to Otto de Guericke, the celebrated consul of Magdeburg, who exhibited his first public experiments with it, before the emperor and the states of Germany, at the breaking up of the imperial diet at Ratibon, in the year 1654: but his description of the instrument, and of the experiments performed with it, is contained in his "*Experimenta nova Magdeburgica de Vacuo Spatio*," and was not published before the year 1672, at Amsterdam.

Dr. Hooke and M. Duhamel, indeed, ascribe the invention of it to Mr. Boyle; but that ingenious author frankly confesses de Guericke to have been beforehand with him. In a letter which he wrote to his nephew, Lord Dungarvan, at Paris, about two years after Schottus's book was published, he introduces the acknowledgment of his obligation, for the discovery of this useful machine, to what he had heard of it, though he had not then perused it, by that well-applied passage of Pliny, *benignum est et plenum ingenii pudoris fateri per quos profeceris*. Some attempts, he assures us, he had made upon the same foundation, before he knew any thing of what had been done abroad: but the information he afterwards received from Schottus's *Mechanica Hydraulico Pneumatica*, published in 1657, wherein was an account of de Guericke's experiments, first enabled him to bring his design to any thing of maturity. From hence, with the assistance of Dr. Hooke, after two or three unsuccessful trials, arose a new air-pump more easy and manageable than the German one; and hence, or rather from the great variety of experiments that illustrious author applied it to, the engine came to be denominated *machina Boyliana*, and the vacuum produced by it, *vacuum Boylianum*.

AIR-pump, structure and use of the. The basis or essential part in the air-pump, is a metalline tube, answering to the barrel of a common pump, or syringe; having a valve at the bottom, opening upwards; and a moveable piston or embolus, answering to the sucker of a pump, furnished likewise with a valve opening upwards. The whole must be duly fitted to a vessel as a recipient or receiver.

The rest, being only circumstances chiefly respecting conveniency, have been diversified and improved from time

to time, according to the several views and address of the makers.

In our further account of the air-pump, we shall trace the various alterations it has undergone from the rude and inconvenient construction of Otto de Guericke to its present improved state. Guericke's machine is exhibited in *Plate iv. Pneumatics, fig. 24.* It consists of an iron three-legged frame, *a b c d f*, supporting a round iron plate, *b c*, in the middle of which is inserted a brass syringe, *g h*. The upper part of this syringe is furnished with a rim of lead, *y*, (*fig. A.*); and it is fastened below by means of an iron ring, *k k*, and three iron arms, *o o o*, to the legs of the frame. Within the rim *y*, there is a brass plate *m n*, (*fig. B.*) encompassed by a ring of leather, and fixed by three screws which terminates upwards in a small tube *n*, into which the pipe connected with the vessel to be exhausted is inserted, as occasion requires, and to which, on the lower side, is adapted a valve of leather, through which the air passes into the syringe. In this plate there is also another small valve at *z*, opening upwards, through which it escapes. This plate is covered by a copper vessel, *x x*, intended for containing water. The piston of the syringe *s b*, (*fig. 24.* and *fig. C.*) is connected by a joint at *t*, with the iron rod *t u*, which is fastened to the handle, *w u u*; and this moves round the pin at *w*, by which it is connected with one of the legs of the frame. In order to prevent air from entering into the syringe, a copper vessel of water is suspended by hooks to the arms, *o, o, o*, so that the lower part of the syringe at *k k*, and the piston, may be always covered with water, when the machine is at work. The receiver, *L*, is a glass sphere, adapted to a brass cap, *P P*, which has a pipe with a stop-cock, *q r*; and this pipe is fitted to the tube, *n*, above mentioned. From this brief description of the machine, its operation will be easily understood. When the piston, *s b*, is depressed, the air will be expanded in the syringe, *g h*, and that of the receiver will descend into it through the valve in the lower surface of the plate, *m n*; but when the piston is elevated, and the air is compressed, this valve shutting upwards will close the passage to the receiver, and make its escape through the valve *z*, which opens upwards. In order to render the exhaustion more complete, a small exhausting syringe is adapted to the plate, which is represented at *m*. See Guericke's *Exper. Nov. Magdeb. Amst. 1672. lib. iii. c. iv. and v. p. 77.*

This machine, though it might be deemed an excellent contrivance at the time of its invention, when the doctrine of the elasticity and expansion of the air was new, had many defects which it is hardly necessary now to mention. The force necessary for working it was very great, and the progress of its operation very slow. Besides, it was to be wrought under water, and it allowed of little change of subjects for experiments. Mr. Boyle, whose ideas of this machine, first suggested to him by Schottus's report of Guericke's construction, were executed by Dr. Hooke, whom he then employed as his operator, removed some of these inconveniences and diminished others.

The form of Mr. Boyle's air-pump appears in *Plate iv. Pneumatics, fig. 25.* It consisted of a spherical receiver, *A*, with a round hole at the top, whose diameter, *B C*, was about four inches; this was covered with a plate, having a brass rim, *D E*, which was firmly cemented to the ring of glass that surrounded the hole; and to the tapering orifice of the brass rim was adapted a brass stopple, *F G*, ground so exactly as to exclude as much as possible the admission of air. In the centre of the cover was a hole, *H I*, of about half an inch in diameter, provided with a socket, to which

the brass stopple, *K*, was so fitted as to prevent the entrance of air; and the lower part of this stopple was perforated with a hole, through which passed the string, *8, 9, 10*, for the convenience of moving to and fro the subjects of experiments. To the neck of the receiver a stop-cock, *N*, was fastened; and to the shank of the cock, *X*, a tin-plate, *M T U W*, was so cemented as to preclude the admission of air. The lower part of this machine consisted of a wooden frame with three legs, *1 1 1*, and a transverse board, *2 2 2*, on which the pump rested. The cylinder of this pump was cast brass; and it was fitted with a sucker, *4 4, 5 5*; of which one part, *4 4*, was covered with shoe-leather, so as exactly to fill the cavity of the cylinder; and to this was fastened the other part, which was a thick and narrow plate of iron, *5 5*, somewhat longer than the cylinder, indented on one edge with narrow teeth, so as to admit the corresponding teeth of a small iron nut, fastened by two staples to the under side of the transverse board *2, 2, 2*, on which the cylinder rests; and this is turned to and fro by the handle, *7*. The last part of this cylinder is the valve, *R*, consisting of a hole bored through at the top of the cylinder, somewhat tapering towards the cavity; into which hole is ground a tapering peg of brass, to be thrust in and taken out at pleasure. In order to prevent more effectually the admission of air, and to prepare the sucker of the pump for motion, a quantity of salad oil was poured in at the top of the receiver and also into the cylinder. The operator, having fixed the lower shank, *O*, of the stop-cock into the upper orifice of the cylinder, turns the handle, and thus forces the sucker to the top of it, so that no air may be left in its upper part. Then shutting the valve with the plug, and turning the handle the other way, he draws down the sucker to the bottom of the cylinder, and thus its cavity, into which no air is admitted, will be in an exhausted state. By turning the stop-cock, and opening a passage between the cylinder and the receiver, the air contained in the one will descend into the other; and this air being prevented from returning, by turning back the key of the stop-cock, will be made to open the valve and to escape into the external air by forcing the sucker to the top of the cylinder; by alternately moving the sucker upward and downward, turning the key and stopping the valve, as occasion requires, the exhaustion may be continued. See Boyle's Works, by Birch, vol. i. p. 7—10.

Mr. Boyle has described a second air-pump in the first continuation of his Physico-mechanical experiments. See his works, vol. iii. p. 180. This, like the former, had only one barrel, by which the receiver was exhausted; but it was so contrived as to be every where surrounded with water, that the ingress of air might be more effectually prevented. Besides, the receivers, which were of several forms and sizes, were fastened to an iron plate by means of a soft cement, so that they could be removed and changed at pleasure. The interposition of a moistened leather for fixing them, does not seem at this time to have occurred to him.

Notwithstanding all the precautions of Mr. Boyle, and his contrivances for excluding air by oil and leather, he found that the working of his pump by a single barrel was laborious, on account of the pressure of the atmosphere, a great part of which was to be removed at every elevation of the piston, when the exhaustion was nearly completed: and he himself candidly acknowledges, that it was rarely and with great difficulty, that he was able to produce any great degree of rarefaction. This useful machine was gradually improved by Papin, Mersenne, Mariotte, and others; but the introduction of a second barrel and piston was the principal

Principal improvement which it received about this period. To whom this was owing, it is not easy to decide: some ascribe it to Dr. Hooke, others to Papin, and others again to Hauksbee. An engine of this kind, with a double tube, is described by Mr. Boyle, in the second continuation of *Physico-mechanical Experiments*, (works, vol. iv. p. 510.); but the manner of working it, by means of a pulley and of iron stirrups or treads, upon which the operator stood, must have been extremely inconvenient. However, by the use of a second barrel and piston, contrived to rise and fall alternately with the other, and by the introduction of valves, which in this third air-pump of Mr. Boyle supplied the place of the plug and stop-cock which he had before used, as well as by the subsequent improvements of Hauksbee, the pressure of the atmosphere on the descending piston always nearly balanced that of the ascending one; so that the winch which worked them up and down was easily moved by a gentle force with one hand; and the exhaustion was also made in much less time. See Hauksbee's *Physico-Mechanical Experiments*, p. 1, &c. Mr. Vream, a pneumatic operator, employed by Defaguliers, made an improvement in Hauksbee's air-pump, by reducing the alternate motion of the hand and winch to a circular one. In his method the winch is turned quite round, and yet the pistons are alternately raised and depressed; by which the trouble of shifting the hand backwards and forwards, as well as the loss of time, and the shaking of the pump, are prevented. See Defaguliers's *Course of Exp. Philos.* vol. ii. p. 378. For a brief account of the progressive improvements of the air pump, see Cotes's *Hydrostatical and Pneumatical Lectures*, lect. xii. p. 156, &c.

The structure of the air-pump, thus improved, is represented in *Plate v. Pneumatics*, fig. 33. It consists of two brass barrels or cylinders, *aa, aa*, which communicate with each other by the cistern, *dd*, and with the receiver, *oooo*, which is ground level at the bottom, and set over a hole in the plate, by means of the bent pipe, *bb*. In these barrels the pistons, which are fastened so tight that no air can get between them and the barrels, are worked by a toothed wheel, turned by the handle, *bb*; and thus the racks, *cc*, with their pistons, are worked alternately up and down. The gage tube, *ll*, is immersed in a basin of quicksilver, *m*, at the bottom, and communicates with the receiver at the top; from which it may be occasionally disengaged by turning a cock; and *n* is another cock, by turning of which the air is again let into the exhausted receiver, passing into it with a hissing noise. The action of the toothed wheel and pistons is represented in fig. 34.

As the handle is turned backwards, it raises the piston *de*, in the barrel B K, by means of the wheel E, and rack D *d*: and as no air can get between the piston and barrel, all the air above *d* is lifted up towards B, and a vacuum is made in the barrel from *e* to *b*; upon which part of the air in the receiver by its spring rushes through the hole in the brass plate of the pump along the pipe G G, communicating with both barrels by the hollow trunk I H K, and pushing up the valve *b*, enters into the vacant part *be*, of the barrel B K. Then, as the handle F, is turned forward, the piston *de*, will be depressed in the barrel; and the air which had got into the barrel, finding no way of escape through the closed valve *b*, will ascend through a hole in the piston, and make its way into the external air through a valve at *d*; and it will be prevented by that valve from returning into the barrel, when the piston is again raised. At the next elevation of the piston, a vacuum is again made in the same manner as before, between *b* and *e*; upon which

more of the air that was left in the receiver will get out by its spring, and flow into the barrel, B K, through the valve *b*. The other piston and barrel act in the same manner; and as the handle, F, is turned backwards and forwards, it alternately raises and depresses the pistons in their barrels; one being raised whilst the other is depressed. By thus repeating the operation again and again, the air in the receiver is at length rarefied to such a degree, that its density does not exceed the thin air remaining in the barrel when the piston is raised: which done, the effect of the air-pump is at an end; the valve cannot now be opened, or if it could, no air would pass it; there being a just equilibrium between the air on each side.

To judge of the degree of exhaustion, there is added the gage-tube, *ll*, open at both ends, and about 34 inches long (fig. 33.), affixed to a wooden ruler, which is divided into inches and parts of an inch, from the bottom where it is even with the quicksilver in the basin, *m*, and continued to the top, a little below the plate of the air-pump, to 30 or 31 inches. Hence the air in the tube rarefying as fast as that in the receiver, in proportion as the exhaustion advances, the mercury will be raised by the pressure of the column of external air, prevailing over that of the column of air included; till the column of air, and mercury together, become a balance to that of the external air. When the mercury is thus risen to the same height as it stands in the barometer, which is indicated by the scale of inches added to the gage, the instrument is a just Torricellian tube; and the vacuum may be concluded to be as perfect as that in the upper end of the barometer. When the cock, *n*, is turned, so as to make a communication with the external air; this rushes in, and the mercury in the gage immediately subsides into the basin. See GAGE.

In estimating the gradual ascent of the quicksilver in the gage, it is evident that, as we continue to pump, the mercury continues to ascend; and that it approaches always more and more to the standard altitude, or about 29½ inches, more or less according to the variety of seasons. And it is easy to prove, that the defect of the height of the quicksilver in the gage from the standard altitude is always proportionable to the quantity of air which remains in the receiver; that the altitude itself of the quicksilver in the gage is proportionable to the quantity of air which has been exhausted from the receiver; and that the ascent of the quicksilver, upon every turn of the pump, is proportionable to the quantity evacuated by each turn. Let it be considered, that the whole pressure of the atmosphere upon the cistern of the gage is equal to, and may be balanced by, a column of quicksilver of the standard altitude; consequently, when the quicksilver in the gage has not yet arrived to the standard altitude, the defect must be supplied by some other equal force, and that force is the elastic power of the air remaining in the receiver; which communicating with the upper part of the gage, hinders the quicksilver from ascending, as it would otherwise do, to the standard altitude. The elasticity of the air in the receiver is then equivalent to the weight of the deficient quicksilver; but the weight of this is proportionable to the space it should possess, or to the defect of the height of the quicksilver in the gage from the standard height; therefore the elasticity of the remaining air is also proportionable to the same defect. But the density of any portion of air is proportionable to its elasticity, and the quantity in this case is proportionable to the density; and therefore the quantity of air remaining in the receiver is proportionable to the defect of the quicksilver in the gage from its standard altitude.

Hence

Hence it follows, that the quantity of air which was at first in the receiver before you began to pump, is proportionable to the whole standard altitude; and consequently the difference of this air, which was at first in the receiver, and that which remains after any certain number of turns, that is, the quantity of air exhausted, is proportionable to the difference of the standard altitude and the before-mentioned defect, that is, to the altitude of the quicksilver in the gage after that number of turns. Hence again it appears, that the quantity of air exhausted at every turn of the pump is proportionable to the ascent of the quicksilver upon each turn. See Cotes's *Hydrost. and Pneum. Lectures*, lect. 13. See GAGE.

There are several inconveniences attending air-pumps of the common form, though much improved from what they used to be formerly, and many attempts have been made to remedy them. It is a well-known fact, that pumps merely serve to rarefy the air to a considerable degree, and that none of them can produce a complete exhaustion; as the mercury in the gage is not raised by any of them to the height which it occupies in the Torricellian tube, when well purged of air. Few pumps will bring it within $\frac{1}{10}$ th of an inch. Hawksbee's, fitted up according to his own instructions, will seldom bring it within $\frac{1}{2}$ th; pumps with cocks of the best construction, and in the most favourable circumstances, will bring it within $\frac{1}{4}$ th; but none with valves fitted up with wet leather, or to any part of which water or any volatile fluids have access, will bring it nearer than $\frac{1}{2}$ th. Before we proceed to give an abridged account of the improvements that have been made in air-pumps, we observe, that the air-pumps most commonly used are made either with brass stop-cocks, or with valves of oil-skin or of leather, for preventing the return of the air into the receiver, out of which it had been exhausted. Pumps with stop-cocks, when well made and newly put together, are generally found to rarefy the air to a greater degree than those which are made with valves; but after having been used for some time, they become less accurate than those with valves. But the valves are also imperfect; as the external air, pressing upon that in the piston, prevents its rising, when the elastic force of the air in the receiver, under exhaustion, is much diminished. Attempts have been made, particularly by the abbé Nollet and Mr. Gravefande, to perfect the construction of cocks. In Gravefande's double-barrelled pump, the cocks at the bottom of the pistons are turned by an apparatus that is moved by the handle of the pump: the piston has no valve, and the rod is connected with it by a stirrup, as in a common pump. This rod has a cylindrical part, which passes through the stirrup, and moves freely in it through the space of about half an inch, between a shoulder above and a nut below. The stirrup supports a round plate, which has a short square tube, that fits tight into the hole of a piece of cork, and which has also a square shank, that goes into the square tube. Between the plate and the cork is put a piece of thin leather, soaked in oil, and another is placed between the cork and the plate which forms the sole of the stirrup. When the winch is turned to raise the piston from the bottom of the barrel, the friction of the piston against the barrel keeps it in its place, and the rod is drawn up through the stirrup. The wheel has thus liberty to turn about an inch; and this is sufficient to turn the cock, so as to cut off the communication with the external air, and to open that with the receiver. When this is done, the continued motion serves to raise up the piston to the top of the barrel. When the winch is turned in the opposite direction, the piston remains fixed till the cock is

turned, so as to shut the communication with the receiver; and open that with the external air. The cock has one perforation diametrically through it, and another in a perpendicular direction to this; and after reaching the centre, it passes along the axis of the cock, and communicates with the open air. By this communication, when it is opened, the air rushes in, and balances the pressure on the upper side of the piston in this barrel, so that the pressure on the other must be counteracted by the person who works the pump. In order to obviate this inconvenience, Gravefande put a valve on the orifice of the cock, by tying over it a slip of wet bladder or oiled leather; and by means of this the piston is pressed down, as long as the air in the barrel is rarer than the outward air, just as if the valve was in the piston itself. Gravefande, and also Muschenbroek, extol the operation of this pump, as exceeding that of pumps with valves. But it is evident that no precise estimate of its performance can be obtained, whilst the pistons, valves, and leathers of the pump are prepared by steeping them in oil, and afterwards in a mixture of water and spirits of wine. With this preparation the gage could not be brought within $\frac{1}{4}$ th of an inch of the barometer. Besides, a considerable space is left between the piston and cock, from which the air is never expelled; and if this be made very small, the pump must be worked very slowly; otherwise the air will not have time to diffuse itself from the receiver into the barrel, especially when the expelling force or the elasticity of the air, towards the close of the operation, is very small. The rarefaction will likewise be retarded by the valve, which will not open till the air below the piston is considerably denser than the external air. The cocks in pumps of this kind are subject to become loose by use, and to admit air: an inconvenience which might, indeed, be prevented by placing the barrels in a dish filled with oil. For a figure and description of Gravefande's pump, see Gravefande's *Mathem. Elem. of Natural Philosophy*, by Desaguliers, vol. ii. p. 14. &c. These pumps, if they were ever used in England, have been long superseded by the cheaper and more simple contrivance of valves, formed by tying a strip of bladder over a small hole, through which the air is allowed to pass in one direction only.

In the year 1750, the ingenious Mr. Smeaton directed his attention to the improvement of valve pumps. In considering the structure of these pumps, he observed, that the principal causes of their imperfection are, partly, the difficulty of opening the valves at the bottom of the barrels, and, partly, the piston's not fitting exactly, when put down to the bottom, which leaves a lodgment of air that is of bad effect. The first of these imperfections is owing to the smallness of the common valves, which are made of a piece of thin bladder stretched over a hole generally much less than $\frac{1}{10}$ th of an inch in diameter, and to the adhesion of the bladder to the plate upon which it is spread, by reason of the oil or water with which it is moistened: as the rarefaction of the air in the receiver is continued by the operation of the pump, its spring becomes so weak, that it is not able to overcome the cohesion of the bladder to the plate, the weight of the bladder, and the resistance occasioned by its being stretched. The larger the hole is, over which the bladder is laid, a proportionably greater force is exerted upon it by the included air in order to lift it up; and yet the aperture of the hole cannot be made very large, because the pressure of the incumbent air would either burst the valve, or so far force it down into the cavity as to prevent its lying flat and close upon the plate. In order to avoid these inconveniences, instead of one hole, Mr. Smeaton makes use of seven, all of equal size

size and shape, one being in the centre, and the other six round it, so that the valve is supported at proper distances by a kind of grating, formed by the solid parts between these holes, and resembling a honeycomb; and that the points of contact between the bladder and grating may be as few as possible, the holes are hexagonal, and the partitions are filed almost to an edge. The breadth of these hexagons is $\frac{7}{16}$ ths of an inch, and consequently the surface nine times larger than common; and as the circumference is three times greater than that of the common valve, and the cohesion to be overcome is, in the first moment of the air's exerting its force, proportional to the circumference of the hole, the valve over any of these holes will be raised with three times more ease. Besides, the raising of the valve over the centre-hole is aided on all sides by those that are placed round it; and as they all contribute as much to raise the bladder over the centre hole, as the air immediately acting under it, the valve will be raised with double the ease already supposed, or with a sixth part of the force commonly necessary. After the bladder begins to rise, it will expose a greater surface to the air underneath, which will cause it to move more easily.

The other defect in the common construction would still hinder the rarefaction from being carried on beyond a certain degree. For as the piston does not fit so closely to the bottom of the barrel, as totally to exclude the air, this air, as the piston rises, will expand itself; and pressing upon the valves in proportion to its density, hinder the air within the receiver from coming out. Hence, if the vacancy were equal to the 150th part of the capacity of the whole barrel, no air could pass out of the receiver, when expanded 150 times, though the piston were constantly drawn to the top; because the air in the receiver would be in *equilibrium* with that in the barrel, when in its most expanded state. In order to obviate this inconvenience, Mr. Smeaton shut up the top of the barrel with a plate, having in the middle a collar of leathers, through which the cylindrical rod works that carries the piston. The external air is thus prevented from pressing upon the piston; but for the discharge of the air that passes from below through the valve of the piston, there is a valve applied to the plate at the top, which opens upwards. By this construction, when the piston is put down to the bottom of the cylinder, the air under it will evacuate itself so much the more, as the valve of the piston opens more easily, when pressed by the rarefied air above it, than when pressed by the whole weight of the atmosphere; and as the piston may be made to fit as nearly to the top of the cylinder as it can to the bottom, the air may be rarefied as much above the piston, as it could before have been in the receiver. Hence it follows, that the air may now be rarefied in the receiver in duplicate proportion of what it could be upon the common principle. By this construction, the pump, consisting of a single barrel, may be worked with more ease than the common pump with two barrels, because the pressure of the outward air is taken off by the upper plate; and when a considerable degree of rarefaction is desired, it will produce it more speedily.

Mr. Smeaton has also contrived a new gage, which measures the expansion with certainty, to much less than the 1000th part of the whole. It consists of a bulb of glass, in shape resembling a pear, and sufficient to hold about half a pound of quicksilver. It is open at one end, and the other is a tube hermetically sealed at top. A scale divided into parts of about $\frac{1}{16}$ th of an inch each, and answering to a 1000th part of the whole capacity, is annexed to it. This gage, during the exhaustion of the receiver, is suspended in it by a slip-wire. When the pump is worked as much as is thought necessary, the gage is pushed down, till the open

end is immersed in a cistern of quicksilver placed underneath. The air being then let in, the quicksilver will be driven into the gage, till the air remaining in it becomes of the same density with the external; and as the air always takes the highest place, the tube being uppermost, the expansion will be determined by the number of divisions occupied by the air at the top. See GAGE.

This ingenious artist has succeeded so well in his construction of the air-pump, as to be able to rarefy air about 1000 times: whereas the best of the common air-pumps, esteemed good in their kind, and in complete order, never rarefied it above 140 times. Mr. Smeaton's air-pump acts also as a condensing engine, by the very simple apparatus of turning a cock; see CONDENSER. This air-pump is thus easily made an universal engine, for shewing any effect arising from an alteration in the density or spring of the air; and with a little addition may be made to shew the experiments of the *AIR-FOUNTAIN*, *AIR-gun*, &c. Phil. Trans. vol. xlvii. p. 415—423.

A perspective view of the principal parts of this pump is exhibited in *Plate vi. Pneumatics, fig. 45.* A is the barrel, B the cistern, in which is included the cock, with several joints, which are covered with water to keep them air-tight; and a little cock to let the water out of the cistern is marked G. C c c is the triangular handle of the key of the cock, which, by the marks on its arms, shews how it must be turned, that the pump may produce the effect desired. D H is the pipe of communication between the cock and the receiver. E is the pipe that communicates between the cock and the valve, on the upper plate of the barrel. F is the upper plate of the pump which contains the collar of leathers *d*, and V is the valve, which is covered by the piece *f*. G I is the syphon-gage, which is screwed on and off, and adapted to common purposes. It consists of a glass-tube hermetically sealed at *e*, and furnished with quicksilver in each leg, which, before the pump begins to work, lies level in the line *a b*; the space *b c* being filled with air of the common density. When the pump exhausts, the air in *b c* expands, and the quicksilver in the opposite leg rises, till it becomes a counterbalance to it. Its rise is shewn upon the scale I *e*, by which the expansion of the air in the receiver may be nearly estimated. When the pump condenses, the quicksilver rises in the other leg, and the degree may be nearly judged of by the contraction of the air in *b c*; marks being placed at $\frac{2}{3}$ and $\frac{1}{3}$ of the length of *b c* from *e*, which shew when the receiver contains double or treble its common quantity. K L is a screw-frame to hold down the receiver in condensing experiments, which takes off at pleasure, and is sufficient to hold down a receiver, the diameter of whose base is seven inches, when charged with a treble atmosphere; in which case it acts with a force of about 1200 pounds against the screw-frame. M is a screw that fastens a bolt, which slides up and down in that leg, by means of which the machine is made to stand fast on uneven ground. The structure, connection, and relative uses of the several parts of this pump will be further perceived in the following account of Smeaton's air-pump, constructed and improved by Mr. Nairne.

A perspective view of it appears in *Plate vi. Pneumatics, fig. 46.* A, A, are the two barrels of a simple double-barrelled air-pump; the tube *g g* conveys the air from the receiver placed in the pump-plate T, and the cock Q serves to cut off the communication between the receiver and the barrels A, A, when the exhaustion is completed. In the front of the pedestal Z is a screw, serving to admit air into the barrels, that the valves may not be pressed after the cock Q is turned; the button *i* readmits air into the receiver;

receiver; the syphon-gage *y* is made in the usual manner; but the cisterns *x, x*, prevent the gages from being dirtied by the oil, on the readmission of the air. The large barrel *C* has a solid plunger, worked by the rod *R*, which passes through the collar of leathers *u*; for the construction of which, as well as the internal structure of the barrel *C*, see *fig. 47*.

This is a vertical section of the barrel, &c.; the top or cup *U* screws on to the screw *u*, and the cavity *b* is made conical; the holes *e, e*, are made just large enough to let the piston rod pass freely; the cavity *b* is filled with circular greased leathers, through the center of which a hole is made, that barely admits the piston rod to pass; these leathers are crowded into *b*, and three or four thicknesses of them are left above the surface, *f*; and consequently, when the cup *U* is screwed down, these leathers are forced into the smaller part of the conical hollow *b*; and therefore they bind as much or as little as is requisite on the piston rod. The head *a* is screwed with eight screws on the upper flaunch or part of the barrel *C*; the bottom *B* screws on the lower flaunch or lower end of *C*; the plug *D* is accurately ground into a conical hole in the bottom *B* and has the lever *L* standing at right angles. As the whole nicety of the exhaustion of this air-pump depends upon this part, it should be very particularly described. The lever *L* is represented as standing to the left hand; and the hole *z* with its valve *1* is seen in connection with the pipe *P*, and consequently with the receiver; see the horizontal section *L D P*. But if the lever *L* is brought towards the word "CLOSED," the hole *z* with its valve *1* has moved onwards towards *D*; no hole is opposite to the hole of *P*, and consequently all communication between the receiver and the inside of the barrel *C* is cut off; but upon moving the lever *L* more towards the right hand, the hole *3* having "NO VALVE" will be in connection with *P*, and consequently there will be a direct or uninterrupted passage between the receiver and the inside of the barrel *C*. Upon attentively inspecting the section, it will be perceived by the directions in which the valves open and close, and the position of the passages which are drilled through the thickness of the barrel, that the ascent or descent of the solid plunger *N* equally exhausts the pipe *P*, and consequently the receiver. It must be remarked, that the valves exhibited in the section are drawn like lids of boxes, with joints for the purpose of shewing in what direction they open; but in reality the valves are made of oiled silk; and as on the nice construction of these the good action of the pump much depends, the best mode of making them will be illustrated in the section, *fig. A A*, which shews the plug *D*, on which the valve is to be fixed. In the first place, a groove must be turned, of a convenient size, so as to leave a cylindrical knob *F*, whose diameter may be four or five eighths, or more, of an inch; the hole which the oiled silk valve is intended to cover, is made through the axis or center of this knob, as is shewn by the dotted lines *H*; the ring *G* is to fit nicely into the groove, and to be flush with the general surface of the brass; the surface of the knob *F* must be turned away about double the thickness of the oiled silk for the purpose of preserving the oiled silk from injury by the piston's striking it; a slip of oiled silk about the width of four times the diameter of the hole, which it is to cover, must be laid over the hole in the center of the knob *F*, and the ring *G* carefully put in its place and there fixed by two or three screws. *Fig. B B* shews the construction of the reservoir *x x*, (*fig. 46*.), for the purpose of keeping the gages clean. The end of the gage *G*, for instance, passes through the bottom of the reservoir *x*, and reaches nearly to the top; and a piece of metal, flat

or like an inverted tea-faucet, is fixed to the top of *x*, *fig. B B*. The oil which comes from the pump through *m* is thrown on the back of the faucet, and running to its edges drops into the bottom part of the reservoir, and thus prevents any filth from getting into the tube *G*, *fig. 46*.

Having described the particular parts of this pump, we shall next explain the mode of working it, so as to obtain the greatest degree of exhaustion. A receiver well ground and made dry, with oil put upon its edge, is to be placed on the pump plate *T*, (*fig. 46*.), over the aperture of the pipe *P*; and the lever *L* is to be moved so as to stand under the word "VALVE." By working the piston of the cylinder *C* up and down, from the top to the bottom, the receiver becomes partly exhausted, and the mercury will rise from the cistern *M* up into the tube of the barometer gage *G*; the exhaustion must be continued till it will rise no higher; and turning the lever *L* under the word "CLOSED," the piston must be moved two or three times up and down; let it then be left at the bottom of the barrel *C*; move the lever *L* under the words "NO VALVE," and gently raise the piston to the top of the barrel. As there is now a direct communication between the receiver and the barrel *C*, without the intervention of a valve, the air will expand itself freely into the barrel, and the mercury of the gage will rise; keeping the piston at the top of the barrel, turn the lever again under the word "CLOSED," and repeat the operation as before; unscrew the receptacle for dirty oil *O*, and screw in its place the complete small exhausting syringe *S*; work this a few times, and repeat the operation with the barrel and the lever *L* as before, till the mercury will rise no higher in the gage.

By the process now described, the exhaustion has been made so perfect, that when an open cistern barometer, suspended in the room, has been on the rise, the mercury in the gage *G* has risen within $\frac{1}{100}$ th of an inch as high.

The double-barrelled air-pump *A A* being placed on the same stand, and having a communication with the pump plate *T*, as well as the improved pump *C*, is intended for exhausting large receivers very expeditiously; as both pumps may be worked at the same time; and more especially for preventing the improved pump from being used for trifling experiments, or those where water is made use of. In the pump plate *T* are two holes, situated near each other, one communicating with the double-barrelled, and the other with the improved pump, and serving the purpose of cutting off the communication of either with the receiver at pleasure. Indeed, when the double-barrelled pump is only used, the hole of the pipe *P*, leading to the barrel *C*, should always be carefully stoppered to prevent moisture of any kind from getting into it.

Since the time of Mr. Smeaton the air-pump has received very material improvements; for which we are indebted to the Rev. Mr. Prince, of Salem, in North-America; and to Mr. Cuthbertson, late of Amsterdam, and since settled in London.

Mr. Smeaton's success in facilitating the opening of the valves, at the bottom of the barrel and in the piston, led Mr. Prince to conceive, that if these valves were entirely removed, and the remaining air in the barrel could be more perfectly expelled, the rarefaction might be carried still farther. Upon this plan he constructed his air-pump. He removed the lower valve, and opened the bottom of the barrel into a cistern on which it was placed, and which had a free communication with the receiver; for the valve on the upper plate, at the top of the barrel, constructed like Mr. Smeaton's, made it unnecessary that there should be any at the bottom, in order to rarefy the air in the receiver. The cistern was made deep enough to admit of the piston's descending into it below the bottom of the barrel. If the piston be solid, that is, without a valve, when it enters the

barrel and rises to the top-plate, which is made air-tight with a collar of leathers, like Smeaton's, it forces out all the air above it; and as the air cannot return into the barrel on account of the valve in the top-plate, when the piston descends, there will be a vacuum between it and the plate; every thing being supposed perfect. But in working the pump, the piston is not allowed to descend entirely into the cistern so far as to leave the bottom of the barrel open; but it descends below a hole in the side of the barrel near the bottom, which opens a free communication between the barrel, cistern and receiver. Through this hole the air rushes from the cistern into the exhausted barrel, when the piston has dropped below it; and by its next ascent this air is forced out as the other was before. If the capacity of the receiver, cistern, pipes, &c. below the bottom of the barrel, taken together, be equal to the capacity of the barrel, half the remaining air will be expelled by every stroke. But as the working of this pump with a solid piston would be laborious, on account of the resistance it would meet with in its descent from the air beneath, though it would be lessened by every stroke as the air became more rarefied, Mr. Prince pierced three holes in the piston at equal distances from each other, and by a circular piece of bladder, tied over the top of the piston, formed a kind of valves over the holes, which opened with sufficient ease to prevent any labour in working the pump, by allowing the air to pass through the piston in its descent. The escape of the air does not, however, depend upon a passage through the piston into the barrel; for when the air, weakened by rarefaction, cannot open this valve, it will still get into the barrel when the communication is opened by the hole at the bottom. This piston will therefore descend as easily as any other, nor will the valves impede the rarefaction. By this construction the valves, made to open with more ease by Mr. Smeaton, are rendered unnecessary for rarefying the air; and that at the bottom of the barrel is entirely removed; the valve on the top-plate being the only one necessary in rarefying the air.

Having set aside the valves, which partly prevented the air from entering the barrel above the piston, Mr. Prince's next attempt was to expel the air more perfectly out of the barrel than Mr. Smeaton had done, by making a better vacuum between the piston and the top plate, so that more of the air might be allowed to expand itself into the barrel from the receiver. Mr. Prince also contrived to connect the valves on the top plate with the receiver occasionally by means of a pipe and cock, by the turning of which the machine might be made to exhaust or condense at pleasure. In order to remove the pressure of the atmosphere from the valve on the top plate, so that this valve might open as easily as the piston valve, he connected with the duct on the bottom piece, which conveys the air from the valves to the cock, a small pump of the same construction as the large one; having the barrel opening into the cistern, the piston rod, which is solid, moving through a collar of leathers, and a valve near the top, through which the air is forced into the atmosphere. This pump with one barrel is called the valve-pump; its chief use being to rarefy the air above the valves, or to remove the weight of the atmosphere from them. When this valve pump is used, the passage through the cock is shut up; and, therefore, instead of placing three ducts at equal distances round the cock in the manner of Mr. Smeaton's, Mr. Prince divided the whole into five equal parts, leaving the distance of one-fifth part between the ducts leading from the cistern and the valves to the cock, and two-fifths between each of these and the one leading from the cock to the receiver. By this adjustment, when the communication is open between the receiver and the

valves for condensation, the other hole through the cock opens the cisterns to the atmosphere; but when the communication is made between the cisterns and the receiver for exhaustion, a solid part of the key comes against the duct leading to the valve, and shuts it up, and the air which is forced out of the barrel passes through the atmosphere into the valve-pump; for the valve of the small pump may be kept open while the great one is worked.

Upon this construction, the pump with two barrels may be made like the common pump, which cannot be conveniently done where the lower valve is retained. In this pump the pistons do not move the whole length of the barrels; an horizontal section being made in them a little more than half way from the bottom, where the top-plates are inserted. The pump is thus made more convenient and simple, as the head of it is brought down upon the top of the barrels in the same manner as in the common air-pump. The barrels also stand upon the same plane with the receiver plate, and this plane is raised high enough to admit the common gage of 32 or 33 inches to stand under it without inconvenience in working the pump: as the winch moves through a less portion of an arch at each stroke than it would do if the pistons moved through the whole length of the barrels.

A gage for measuring the degree of condensation having a free communication with the valves, cock, &c. is placed between the barrels in this pump; and the gage is so constructed that it will also serve to measure the rarefaction above the valves when the air is worked off by the valve-pump. It consists of a pedestal, the die of which is made of glass, which forms a cistern for the mercury, a hollow brass pillar, and glass tube hermetically sealed at one end, which moves up and down in the pillar through a collar of leathers. When the pump is used as a condenser, the degree of condensation is shewn by a scale marked on one edge of the pillar; when it is used as an exhauster, the degree of rarefaction of the air above the valves is shewn by a scale on the other edge of the pillar. This gage will also shew, when the valves have done playing, either with the weight of the atmosphere on them or taken off, in the manner which the author has described. The degree of condensation may be also measured by the number of strokes of the winch. For the purposes of great condensation, Mr. Prince has fitted a condenser of a smaller bore than the barrel of the great pump to the cistern of the valve-pump, to be screwed on occasionally. Or, without this condenser, the valve-pump may be adapted to the purpose by being made a little larger, and by having a plate made to screw into the bottom of the cylinder, with a valve on it opening into the cistern; a hole must be made to be opened on the same occasion near the top of the cylinder, to let air in below the piston when this is drawn up above it.

The common gage, which is generally placed under the receiver-plate, is placed in the front of this pump, that it may be seen by the person who works it, and that the plate may be left free for other uses. The plate is so fixed to the pipe leading to the cock, that it may be taken off at pleasure, and used as a transferrer; and it may also serve for other purposes.

The head of this pump is made whole, except a small piece on the back, where the wheel is let in; and the wheel is freed from the piston-rods by pushing it into the back part of the head, and it is kept in its place by a button screwed into the socket of the axis behind. By this apparatus the piston-rods are dislodged from the wheel, and let down into the cisterns, when the pump is not used; and in these cisterns they may also have the advantage of being covered with oil. The principal joints of this pump are sunk into sockets, that the

the leathers; which close them may be covered with oil to prevent leaking. The lower part of the pump is fitted with drawers to contain the necessary apparatus.

A perspective view of a double-barrelled pump, made by Mr. Jones, according to the construction of Mr. Prince, may be seen in *Plate vii. Pneumatics, fig. 48.* A, A, are two brass barrels in which the pistons move; the barrels communicate with the receiver placed on the pump by means of the pipe B C, and canal D E; the rods of the pistons are seen at F, G; each of these is connected with a rack or piece having teeth on one side. At I there is a wheel, whose teeth are laid hold of by those of the rack; so that by turning the handle H the pistons are alternately raised or depressed, and the air is exhausted out of the receiver K L, the tube B C, and the canal D E, which communicate with one another. At the top of each barrel is a plate, on which is a box *m n*, containing a collar of leathers; through this the cylindrical part of the piston rod moves, air-tight; *o o* is the place of the valve on the top plate, into which a pipe is folded that conveys the air from the valves to the duct, passing under the valve-pump P, which is designed for preventing the pressure of the atmosphere from acting on the valve of the top plate. Q is the piston rod of this pump, and R the handle by which it is worked. Y is a cock to cut off occasionally the communication between the receiver and the working parts of the pump. At S is a screw, which closes the orifice of the canal D E, by unscrewing which the air may be admitted when required. Z is an oil-vessel for receiving the oil driven over by the action of the pump; and there should be always a small quantity of oil in the cups of the boxes *m, n*, that hold the collar of leathers through which the piston rods move; *abc* is the barometer-gage; *de* the box or cistern containing the mercury; and there is a divided box-scale affixed to the tube, for ascertaining the rise or fall of the mercury; a small ivory tube encompasses the lower end of the glass tube, and floats upon the quicksilver in the cistern; the upper end of this is always to be brought to coincide with the lower division of the box scale, by means of the screw under the cistern; and when it thus coincides, the divisions on the scale give the true distance from the surface of the mercury in the basin. The key *f* serves for tightening or loosening the screws of the pump. When either piston is down, in the operation of this pump, there is a free communication from the receiver through the tubes and the canal to the part of the barrel above the piston; when the piston rises, it forces out the air above it through the valve in the top plate; and as this valve prevents the air from returning into the barrel, when the piston descends, a vacuum is formed between it and the under surface of the top plate; as soon, therefore, as the piston has descended below the holes communicating, by the tubes and pipe, with the receiver, the air rushes into the exhausted barrel; on the next ascent of the piston, this air is forced out as before. To prevent the piston from meeting any resistance in its descent, there is a valve in it through which the air passes as the piston descends; but the air does not necessarily depend upon a passage through the piston in order to get into the barrel. By these means the piston descends as easily as in any other construction, while the valve in it does not impede the rarefaction. The valve pump P is, as we have observed, used for taking off the pressure of the atmosphere from the valve on the top plate of the pump, and for forming a more perfect vacuum between this plate and the piston, that nothing may prevent this instrument from exhausting as far as its expansive power will admit. The barometer gage *abc*, serving to measure the exhaustion of the receiver, consists of a tube, divided by an annexed scale

of inches and fractional parts of an inch, whose higher orifice communicates with the receiver, and the lower is immersed in a cistern of mercury. Before any exhaustion has taken place the mercury in the tube and cistern is upon the same level; and after any number of turns of the handle of the pump, the air in the tube and receiver is equally rarefied, and the mercury will ascend in the tube till the weight of the column above the surface of that in the cistern, and elasticity of the air in the receiver, taken together, be equivalent to the weight of the atmosphere; and if the altitude of the column is equal to the standard altitude, the vacuum in the receiver, and that above the mercury in the barometer, are the same. For an account of the syphon-gage, occasionally substituted for the barometer gage, and the pear gage; see *GAGE*.

In a contrivance, suggested by an ingenious workman of the late Mr. Adams, and annexed to the pumps constructed by Mr. Jones, one of the lower flexible oil-leans, or leather valves in the two barrels, is attached to a brass ring, which is allowed an interval of motion of $\frac{1}{4}$ th of an inch; a long wire is fixed to a bar over the diameter of the ring, which wire passes along the body of the piston and rod through a collar of leathers in the piston. By the friction of these leathers upon the rod, as they move up and down, the lower valve is occasionally raised and depressed; and thus a communication is opened with the barrel and receiver, and of course the exhaust is carried to as great a degree as the nature of the air itself appears to admit. By a comparison of the height of the mercury in a good barometer tube, Mr. Jones did not observe the $\frac{1}{2}$ th of an inch difference between this and that of the barometer gage to the pump; and consequently the rarefaction was about 1200 times; and hence he concludes that it was equal in power to that of Mr. Cuthbertson or any pump whatever.

We shall now describe more minutely the parts of which Mr. Prince's improved air-pump consists. *Fig. 49. Plate vii.* represents a perpendicular section of one of the barrels, the two cisterns, condensing gage, &c.; where A B is the barrel, C D is the cistern on which it stands, *aaaa* the leathered joint, sunk into a socket, and buried in oil; E F is the piston, with the cylindrical rod passing through a collar of leathers, G H, in the box H I. K shows the place of the valve on the top plate K, covered by the cross piece M M, into which is folded the pipe O O, that conveys the air from the valves to the duct going under the valve pump, as may be seen in *fig. 51.* *o* is part of the said duct; *p* is the joint sunk into a socket in the cross piece P P, which connects the cisterns, and has a duct through it leading to them. Into this duct open the ducts *q* and *r*, the first leading to the gage in front of the pump, and the other to the cock and receiver. The other barrel is left out of the figure, except Q, which is the top of it brought down out of its place for the purpose of shewing the top plate that shuts up the barrel, separated from the box, which contains the collar of leathers. S is one of the holes in the plate over which the valve lies, and which is covered by R in the cross piece. V V is the piston shewing the valve open on the top, which is to prevent labour when the pump condenses. W X is the cistern, in which is more distinctly seen the shoulder for the leather, which closes the point between this and the barrel, and also the socket in which the oil lies over the leather. Y Z is the condensing gage, with the orifice of the tube raised above the surface of the quicksilver; *ee* is the collar of leathers, through which the glass tube moves; and *i* is a small pipe coming up through the quicksilver to form a communication between the valves and the gage. In *fig. 50.* is seen the upper surface of the top

plate which closes the barrel, being foldered into it, shewing the place of the valves over the three small holes. *Fig. 51*, is a perpendicular section of the bottom piece, pipes, valve-pump, cock, &c. at right angles with the other section. *fig. 49*. The button *o* is screwed here into the top instead of the gage. *C D* is the valve-pump and cistern, *e* the place of the valve under the cup; *E F* the coek, shewing the duct through it leading to the atmosphere; *G H* the pipe leading from it to the stem of the receiver plate, in which is the cock *I*, to shut up the duct when the plate is used as a transferrer. *K K* is the plate; *L* a piece to shut up the hole, into which tubes, &c. are occasionally screwed to perform experiments without removing the plate. The dotted line at *O* shews the place of the screw which presses the plate against the pipe; *P Q* the pipe and common gage standing in front of the pump. *Fig. 52*, is a horizontal section of the cock, and pieces containing the ducts leading from it to the receiver, the cisterns and the valves on the top of the barrels; *A B* the duct, connecting the cisterns together; *C D* the duct leading from the cisterns to the cock; *G H* the duct leading from the cock through the pipe *A B* (*fig. 51*.) to the valves; *D E* the duct through the cock, which occasionally connects the two last mentioned ducts with the duct *E F*, leading from the cock to the receiver; *I* the duct in the cock leading to the atmosphere, which, when connected with the duct at *D*, lets the air into the cisterns and barrels for condensation; the other duct through the cock at the same time connecting *H* and *E*. This duct also, when connected with *E*, restores the equilibrium in the receiver. *K L* is part of the duct leading from the cisterns to the gage. The dotted circles shew the places of the pipe and valve-pump on the piece, and *r* the place where the air enters the valve-pump from the duct *G H*, and is thrown into the atmosphere when the pump exhaults. *Fig. 53*, shews the under surface of the boxes which contain the collars of leathers with the cross piece which connects them together, having a duct through it, as represented by the dotted line, through which the air passes from the valves into the pipe. This figure is chiefly designed to shew the places in which the valves play, as at *I*. American Transactions, vol. i. Boston, 1785. Nicholson's Journal, vol. i. p. 121-128. Adams's Lectures on Nat. and Exp. Philos. by Jones, vol. i. p. 51-54, p. 153.

The air-pump of Mr. Cuthbertson is so excellent in its structure, and so powerful in its effect, that it claims particular notice and description. A perspective view of it appears in *Plate viii. Pneumatics, fig. 56*. Its two principal gages are screwed into their places; but these need not be used together, except in cases where the utmost exactness is required. In common experiments, either of them may be taken away, and a stop-screw put into its place. When the pear-gage is used, a small round plate, large enough for the receiver to stand upon, must first be screwed into a hole at *A*; but when this gage is not used, this hole must be closed with a stop-screw. When all these gages are used, and the receiver is exhaulted, the stop-screw *B*, at the bottom of the pump, must be unscrewed, to admit the air into the receiver; but when the gages are not all used, the stop-screw at *A*, or either of the other two which are in the place of the gages, may be unscrewed for this purpose. In *fig. 57*, *C D* represents one of the barrels of the pump, *F* the collar of leathers, *G* a hollow cylindrical vessel to contain oil; *R* is also an oil-vessel, which receives the oil that is driven with the air through the hole *aa*, when the piston is drawn upwards; and when this is full, the oil is carried over with the air along the tube *T*, into the oil vessel *G*; *cc* is a wire which is driven upwards from the hole *aa*, by

the passage of the air: and as soon as this has escaped, falls down again by its own weight, shuts up the hole, and prevents any air from returning by that way into the barrel; at *dd* are fixed two pieces of brass, to keep the wire *cc* in such a direction as may preserve the hole air-tight. *H* is a cylindrical wire, which carries the piston *I*, and is made hollow to receive a long wire, *qq*, that opens and closes the hole *L*, which forms the communication with the receiver standing on the plate; *m* is part of a pipe, one end of which is screwed into the wire *qq*, that opens and shuts the hole *L*; and upon the other end, *O*, is screwed a nut, which, stopping in the smaller part of the hole, prevents the wire from being lifted too high. This wire and screw are more clearly seen in *fig. 58*, and *fig. 62*: they slide through a collar of leathers, *rr*, *fig. 58*, and *fig. 61*, in the middle piece of the piston. *Figures 60* and *61*, are the two main parts which compose the piston; and when the pieces in *figures 59* and *62* are added to it, the whole is represented by *fig. 58*. *Fig. 61*, is a piece of brass, turned in a conical form, with a shoulder or ledge at the bottom; a long female-screw is cut into it, about two-thirds of its length; and the remaining part of the hole, in which there is no screw, is about the same diameter as the screw part, except a thin plate at the end, which is of a breadth exactly equal to the thickness of *qq*. That part of the inside of the conical piece of brass, in which no thread is cut, is filled with oiled leathers with holes in them, through which *qq* can slide air-tight; there is also a male-screw with a hole in it, which is fitted to *qq*, and serves to press down the leathers *rr*. In *fig. 60*, *aaaa* is the outside of the piston, the inside of which is turned exactly to fit the outside of *fig. 61*; *bb* are round leathers, about 60 in number; *cc* is a circular plate of brass, of the size of the leathers; and *dd* is a screw, which serves to press them down as tight as is necessary. The male screw, at the end of *fig. 59*, is made to fit the female screw in *fig. 61*. If *fig. 62*, be pushed into *fig. 61*, this into *fig. 60*, and *fig. 59* screwed into the end of *fig. 61*, these will compose the whole piston, as represented by *fig. 58*. *H*, in *fig. 57*, represents the same part as *H* in *fig. 58*, and is that to which the rack is fixed. If this, therefore, be drawn upwards, it will make *fig. 61* shut close into *fig. 60*, and drive out the air above it; and when it is pushed downwards, it will open as far as the shoulders *aa*, (*fig. 60*.) will allow, and suffer the air to pass through. *AA* (*fig. 63*.) is the receiver plate; *BB* is a long square piece of glass, screwed to the undermost side of the plate, through which a hole is drilled, corresponding with that in the centre of the receiver plate, and with the three female screws *bb*.

In order to conceive how the rarefaction of the air is effected, suppose the piston to be at the bottom of the barrel, and a receiver to stand upon the plate, the inside of the barrel, from the top of the piston to *a*, is full of air, and the piston shut: when drawn upwards, by the hollow cylindrical wire *H*, it will drive the air before it, through the hole *aa*, into the oil-vessel *R*, and out into the atmosphere by the tube *T*. The piston will then be at the top of the barrel at *a*, and the wire *qq* will stand nearly as it is represented in the figure, just raised from the nut *o*. While the piston is moved upwards, the air will expand in the receiver, and be driven along the bent tube *m*, into the inside of the barrel. Thus the barrel will be filled with air, which, as the piston rises, will be rarefied in proportion as the capacity of the receiver, pipes, and barrel, is to the capacity of the barrel alone. When the piston is moved downwards again by *H*, it will force the conical part, *fig. 61*, out of the hollow part, *fig. 60*, as far as the shoulders *aa*; *fig. 58*, will

will rest upon *aa*, *fig. 60*, which will then be so far open as to permit the air to pass freely through it, while at the same time the end of *qq* is forced against the top of the hole, and closes it in order to prevent any air from returning into the receiver. Thus the piston, while moved downwards, suffers the air to pass out between the sides of *fig. 60*. and *fig. 61*, and when it is at the bottom of the barrel, will have the column of the air above it; and, consequently, when drawn upward, it will shut and drive out this air, and by opening the hole *L*, give a free passage to more air from the receiver. This process being continued, the air will be exhausted out of the receiver as far as its expansive power will permit: for in this machine there are no valves, as in the common air-pumps, to be forced open by the air in the receiver, which, when its elasticity is diminished, it becomes unable to affect; nor is there any thing to prevent the air from expanding to the greatest degree.

In using this machine for exhaustion, no directions are necessary besides those which relate to common pumps, nor is any peculiar care required to keep it in order, except that the oil-vessel, *G*, be always kept about half full of oil. When it has stood for a considerable time without being used, it will be proper to draw a table-spoonful or two of oil through it, by pouring it into the hole in the middle of the receiver plate, when the piston is at the bottom of the barrel; then, by moving the winch backward and forward to raise and depress the piston, the oil will be drawn through all the parts of the machine; and the superfluous part will be forced out through the tube *T*, into the oil-vessel *G*. Near the top of the cylindrical wire *H*, is a square hole, which is intended to let in some of the oil from the vessel *G*, that the oiled leathers, through which the wire *qq* slides, may always be duly supplied with it.

When the pump is required to condense, either at the time when it exhausts, or separately, the piece which contains the bent tube *T*, must be taken away, and *fig. 64*. put into its place, and fastened by the same screws. In the plate, *fig. 64*, is drawn as it is made for a double-barrelled pump; but for a single barrel, one piece is used, represented by *baa*, the double piece being cut off at the dotted line *aa*. In this piece is a female screw, for receiving the end of a long brass tube; to which a bladder, if sufficient for the experiment, must be tied; or else a glass, properly confined for this purpose, must be screwed to it. Then the air, which is exhausted out of a receiver standing on the plate, will be forced into the bladder or glass connected with the brass tube. But if the pump be double-barrelled, the apparatus, as represented by *fig. 64*, must be used, and the long brass tube screwed into the female screw at *C*.

The two gages are represented in *fig. 65*. and *fig. 66*; the one is the syphon-gage, and the other the barometer or long gage. When these are used, *fig. 65*. must be screwed into the female screw, *cb*, or into that at the other end *c*, *fig. 63*.; and *fig. 66* into the female screw *ab*, *fig. 63*.

If it be used as a single air-pump, either to exhaust or condense, the screw *K*, which fastens the rack to the cylindrical wire *H*, must be taken out; then turning the winch till this wire is depressed as low as possible, the machine will be rendered fit to exhaust as a single air-pump; and if it be required to condense, the directions already given with regard to the bent tube *T*, and *fig. 68*, must be observed.

Mr. Cuthbertson has, by a variety of experiments with this air-pump, shewn its great powers of exhaustion. With the double syphon gage, and also with the long gage, compared with an attached barometer, in which the mercury had been repeatedly boiled, the difference between the heights

of the mercurial column proved to be no more than $\frac{1}{50}$ th of an inch, the barometer standing at 30 inches, which gives an exhaustion of 1200 times. On some occasions, when the air was in a very dry state, he observed the difference to be as low as $\frac{1}{50}$ th of an inch, which indicates more than double the rarefaction. See Description of an improved Air-pump, by John Cuthbertson, 8vo. London: for an abstract, Nicholson's Journal, vol. i. p. 128—130.

We shall close our account of the two pumps of Prince and Cuthbertson with the following judicious remarks of Mr. Nicholson (in his Journal, vol. i. p. 131.) on their respective merits and imperfections. "There is no provision to open the upper fixed valve of Prince's greater barrel, except the difference between the pressures of the elastic fluid on each side of the strip of bladder; and this may reasonably be inferred to limit the power of his small pump. In Cuthbertson's pump, the same valve is exposed to the action of the atmosphere, together with that of a column of oil in the oil-vessel. The mischief in either instrument is probably trifling; but in both, the valve might have been opened mechanically. If this were done, the small pump of Prince might perhaps be unnecessary in most states of the atmosphere. With regard to the lower valves, Cuthbertson, by an admirable display of talents as a workman, has insured their action. Prince, on the other hand, has, by the process of reasoning, so far improved the instrument, that no valves are wanted. In this respect, he has the advantage of simplicity and cheapness, with equal effect. The mechanical combination of Cuthbertson's pump reduces the operation to one simple act of the handle: but Prince's engine requires some manipulation with regard to the play of the small pump; though this might have been remedied by a more skilful disposition of the first mover."

"The most perfect scheme for an air-pump, taking advantage of the labours of these judicious operators, seems to be that in which two pistons of the construction of Prince should work in one barrel; one piston being fixed at the lower end of the rod, and the other at the middle. The lower piston must come clear out of the barrel when down, and work air-tight through a diaphragm at an equal distance from the effective ends of the barrel. In the diaphragm must be a metallic valve, of the form of Cuthbertson's lower-valve, but with a short tail beneath, that it may be mechanically opened when the piston comes up. Above the diaphragm must work the other piston, similar to the first; but as it cannot quit the barrel when down, a small portion of the barrel must be enlarged, just above the diaphragm, so that the leathers may be clear in that position. Lastly, the top of the barrel must be closed and fitted with a valve and oil-vessel, according to the excellent contrivance of Cuthbertson."

"If we suppose the workmanship of such a pump to leave the space between the diaphragm and lower piston, when up, equal to one-thousandth part of the space passed through by the stroke of that piston, the rarefaction produced by this part of the engine will in theory bear the same proportion to that of the external air; and the same supposition applied to the upper piston, would increase the effect one thousand times more: whence the rarefaction would be one million times. How far the practical effect might fall short of this from the imperfections of workmanship, or the nature of the air, which in high rarefactions, may not diffuse itself equally through the containing spaces, or from other yet unobserved circumstances, cannot be deduced from mere reasoning without experiment."

It is observed in the Encyclopædia Britannica, (vol. xv. p. 107.) that a construction of the air-pump, similar to that

of Mr. Cuthbertson, was invented, and, in fact, executed, before the end of 1779, by Dr. Daniel Rutherford, afterwards professor of botany in the university of Edinburgh. He made a drawing of a pump, having a conical metal valve in the bottom, furnished with a long slender wire, sliding in the inside of the piston rod with a gentle friction, sufficient for lifting the valve, and secured against all chance of failure by a spring at the top, which took hold of a notch in the inside of the piston-rod, about a quarter of an inch from the lower end, so as certainly to lift the valve during the last quarter of an inch of the piston's motion. He had executed a valve on this principle; but his thoughts were diverted from the further prosecution of the business.

In Phil. Transf. (vol. lxxiii. p. 435,) we have a description by Mr. Cavallo, of an air-pump contrived and executed by Messrs. Haas and Hurter, instrument-makers in London, in the construction of which these artists have revived Guericke's method of opening the barrel-valve during the last strokes of the pump, by an external force; of this pump Mr. Cavallo says, that when it had been long used, it had, in the course of some experiments, rarefied 600 times.

The drawing and description of a new air-pump, acting by means of a quantity of oil in the barrel, and invented by James Sadler, Esq. have been published by Mr. Nicholson, in his Journal, vol. i. p. 441, &c. He says, that it possesses the desirable requisites of simplicity, cheapness, and power; though at the same time he very properly suggests, that the oil, in process of time, may become changed by the circulation, and less fit for the purpose, and probably carry with it bubbles of air. He does not mention its practical effects.

A new air-pump, similar in its principle to those of Mr. Smeaton and Mr. Cuthbertson, has lately been constructed by the Rev. Mr. Little, of the county of Mayo in Ireland. The principal parts of this machine are one barrel and piston, one stop-cock, one valve, and two pipes of communication. It is of a portable size, and so contrived as to be confined in a very small space. The barrel is placed horizontally, and the rack by which the piston is moved underneath the barrel, so that the machine may be packed in a box two feet long, 18 inches wide, and seven in depth. It is adapted to the purposes of a condensing as well as of an exhausting engine. As to the effects of this pump, the author informs us, that in several trials of exhaustion, in the months of July, August, and September, 1795, the air being generally very dry, the rarefaction produced, as shewn by the pear-gage, was, five times, between 3000 and 4000: the mercury in the barometer gage standing at the same times always above $\frac{1}{10}$ th part of an inch higher than it stood in a standard barometer of a wider bore, which was filled with mercury made very hot and poured into a hot tube, and the mercury in the reduced barometer-gage sunk below the level of the surrounding mercury. In the other nine trials, the rarefaction, as shewn by the pear-gage, was from 9000 to 26000; when the barometer-gage stood at $\frac{2}{3}$ ths of an inch higher than that in the standard barometer, and sunk in the reduced barometer still lower than before beneath the stagnant mercury. For a particular description and drawing of this instrument, and a minute detail of its practical effects; see Transactions of the Royal Irish Academy, vol. vi. p. 319—391.

The portable or table air-pump differs principally in size and the structure of the gage from the common air-pump described at the beginning of this article. It has two brass barrels, which are firmly retained in a perpendicular situation to the square wooden table on which they rest by a transverse beam, which is pressed upon them by screws at

the top of two pillars. From the hole in the center of the pump-plate, there is a perforation or canal in a brass piece, to the fore part of the frame of the pump; and from this canal there is a perforation right-angular to the former, passing to the center of the brass of each barrel. At each of these centers a valve is placed opening upwards to admit the air into the barrels. To each barrel a piston is so fitted that the air cannot pass between it and the sides of the barrel. Each piston has a valve opening upwards, that the air in the lower part of the barrel may escape through them into the common air. They are also connected with a rack, and are raised or depressed by a handle, the lower part of which is fixed to the axis of a cog-wheel, whose teeth lay hold of the rack. One piston is raised and the other is depressed, by the same turn of the handle. The operation of exhausting is the same as in the common pump. Two barrels are advantageous, because they perform the work more speedily, and also because the weight of the atmosphere, pressing upon the rising piston, is counterbalanced by the same weight pressing upon the other piston descending.

Behind the large receiver upon the pump-plate, there is a small plate for sustaining a small receiver. From the hole at the center of this plate there is a canal communicating with that which passes from the large receiver to the barrels. Under the receiver is a small bottle containing mercury, a small tube filled with mercury and freed from air, and inverted with the open end in the mercury; this is called the short barometer-gage. As the air is taken out of the receiver on this small plate, it is taken at the same time from the larger one; and the descent of the mercury in the tube will point out the degree of rarefaction in the receiver. The mercury, however, does not begin to descend in this tube till near three-fourths of the air have been exhausted; and the air is said to be as many times rarer than the atmosphere, as the column of mercury sustained in this tube is less than the height at which the mercury stands, at that time, in a common barometer. The syphon-gage, which is sometimes used, is a glass tube, bent in the form of a syphon, hermetically sealed at one end and open at the other. The longest leg is four inches, each of which is divided on an adjoining scale, into two equal parts. After considerable exhaustion the gage begins to act; and whilst the mercury falls in one leg, it rises in the other; and the quantity of air remaining will be determined by the difference of the height, at which it stands in both tubes. This gage is placed in the same situation with the short barometer gage. See GAGE.

The small single-barrelled pump has two plates, one for receivers, and the other for a short barometer-gage. Its principle is the same with that of the air-pump just described; excepting that it has only one barrel, and that its piston is merely worked by the hand. In general the single-barrelled pump is made only with one receiver-plate and a mahogany basis, to save expences, and with its small apparatus, to be packed in a portable mahogany case.

AIR-PUMP, laws of rarefaction in the receiver of it.—
1. For the proportion of air remaining at any time in the receiver, (supposing no vapour from moisture, &c.) we have the following general theorem.—“In a vessel exhausted by the air-pump, the primitive or natural air contained therein, is to the air remaining, as the aggregate of the capacity of the vessel and of the pump, (*i. e.* the cylinder left vacant in an elevation of the piston, with the pipe and other parts between the cylinder and the receiver) raised to a power whose exponent is equal to the number of strokes of the piston, to the capacity of the vessel alone raised to the same power.” M. Varignon gives an algebraical demonstration

stration of this theorem, in the Memoires de l'Acad. Roy. an. 1693, p. 233, seq. Id. an. 1705, p. 397, seq.; but it may be also demonstrated pneumatically, thus:—Calling the air remaining after the first stroke, the *first residual*; that after the second, the *second residual*, &c. and remembering that the air in the receiver is of the same density as that in the cylinder, when the piston is raised; it is evident, that the quantity of air in the receiver, is to the quantity of air in the cylinder, pipe, &c. as the capacity of the receiver to that of the cylinder, and consequently, the aggregate of the air in the receiver and the cylinder, *i. e.* the whole primitive air, is to the air in the vessel alone, *i. e.* to the first residual air, as the aggregate of the capacity of the receiver and the cylinder, to the capacity of the receiver alone. After the same manner it may be proved, that the quantity of the first residual air, is to the second residual, as the aggregate of the capacity of the receiver and cylinder to the capacity of the vessel alone. And the same proportion does the second residual bear to the third, and so of the rest.

This may be illustrated by an example. Suppose the capacity of the receiver to be twice as great as the capacity of the cylinder or barrel, then will the capacity of the barrel be to that of the barrel and receiver together as one to three; and the quantity of air exhausted at each turn of the pump is to the quantity of air which was in the receiver immediately before that turn, in the same proportion. So that by the first stroke of the pump, a third part of the air in the receiver is taken away; by the second stroke a third part of the remaining air is taken away; by the third stroke a third part of the next remainder is exhausted; and so on continually; the quantity of air evacuated at each stroke decreasing in the same proportion with the quantity of air remaining in the receiver immediately before that stroke; for it is very evident that the third part, or any other determinate part of any quantity must be diminished in the same proportion with the whole quantity itself. And as the quantity of air in the receiver is by each stroke of the pump diminished in the proportion of the capacity of the receiver to the capacity of the barrel and receiver taken together; each remainder will therefore be always less than the preceding remainder in the same given ratio; or, in other words, these remainders will be in a geometrical progression continually decreasing. To recur to the preceding example; the quantity exhausted at the first turn was a third part of the air in the receiver, and therefore the remaining air will be two-thirds of the same; and for the like reason, the remainder after the second turn will be two-thirds of the foregoing remainder; and so on continually; the decrease being always made, in the same proportion of two to three; consequently the decreasing quantities themselves are in a geometrical progression. And as the quantities exhausted at every turn decrease in the same proportion with these remainders; therefore the quantities exhausted at every turn are also in a geometrical progression. Thus it appears, that the evacuations and the remainders do both decrease in the same geometrical progression. If the remainders decrease in a geometrical progression, it is plain that, by continuing the agitations of the pump, you may render them as small as you please; that is, you may approach as near as you please to a perfect vacuum; but you can never entirely take away the remainder.

From the above reasoning it appears, that the product of the primitive air into the first, second, third, fourth, &c. residuals, is to the product of the first residual into the second, third, fourth, &c. as the product of the capacity of the receiver and cylinder together, multiplied as

often into itself as the number of strokes of the piston contains units, is to the factum arising from the capacity of the receiver alone, multiplied so often by itself; that is, as the power of the aggregate of the capacity of the receiver and cylinder together, whose exponent is the number of strokes of the piston, to the capacity of the vessel alone, raised to the same power. Consequently, the primitive air is to the last residual, in the ratio of those powers.

2. The number of strokes of the piston, together with the capacity of the receiver and cylinder with the wire, &c. being given; to find the ratio of the primitive air to the air remaining.

Subtract the logarithm of the capacity of the receiver, from that of the sum of the capacity of the receiver and the cylinder; then, the remainder being multiplied by the number of strokes of the piston, the product will be a logarithm, whose natural number shews how often the primitive air contains the remainder required.

Thus, if the capacity of the receiver be 460, that of the cylinder 580, and the number of strokes of the piston 6; the primitive air will be found to the remaining air as 1335 to 1, or 1335 to 10.

For, suppose the capacity of the vessel = v , that of the cylinder and vessel together = a , the number of strokes of the piston = n , and the remaining air = 1. Since the primitive is to the remaining air as a^n to v^n , the primitive air will also be to the remaining air, as $a^n \div v^n$ to 1. Consequently, if the remaining air be 1, the logarithm of the primitive air is $\log. a - \log. v \times n$.

3. The capacity of the receiver and the barrel being given; to find the number of strokes of the piston required to rarefy the air to a given degree.

Subtract the logarithm of the remaining air from the logarithm of the primitive air; and the logarithm of the capacity of the receiver, from that of the aggregate of the capacity of the receiver and cylinder; then, dividing the former difference by the latter, the quotient is the number of strokes required.

Let the primitive air be p , the remaining air r , and the other quantities as before: and we shall have $p : r :: a^n : v^n$; and the $\log. p - \log. r = n \times \log. a - \log. v$; and $n = \log. p - \log. r \div \log. a - \log. v$.

Thus, if the capacity of the cylinder be supposed 580, that of the receiver 460, and the primitive air to the remaining air, as 1335 to 10: the number of strokes required will be found to be 6.

4. The proportion of the primitive air to the remaining air, together with the capacity of the receiver and the number of strokes of the piston, being given; to find the capacity of the barrel.

Let the first-mentioned proportion be that of p to r ; the capacity of the receiver, v , that of the barrel, x , and the number of strokes of the piston, n ; then $p : r :: (v+x)^n : v^n$; and $\log. p - \log. r = n \times \log. \frac{v+x}{v} - n \times \log. v$: consequently, $\log. v + \frac{\log. p - \log. r}{n} = \log. v + x$. Hence,

find the logarithm of the capacity of the receiver and barrel, and from this the capacity itself, and subtracting that of the receiver, the capacity of the barrel will be known. For $p : r :: 1335 : 10$, $v = 460$, and $n = 6$: consequently,

$$\log. v + x = 2.6627578 + \left(\frac{3.1256530 - 1.0000000}{6} \right) =$$

$.3542755 = 3.0170333$, the log. of 1040. Consequently, $x = 1040 - 460 = 580$. See Wolf. Elem. Math. tom. ii. p. 289, &c. Cotes's Hyd. and Pneum. Lectures, lect. 13.

To the air-pump belongs a large apparatus of other vessels, accommodated to various kinds of experiments.

Besides the effects, and the phenomena of the air-pump, recounted under the articles VACUUM, AIR, &c. we may add some others; which, related at large, make the substance of Mr. Boyle's Physico-Mech. Exper.—As, that the flame of a candle *in vacuo* usually goes out in a minute, though it sometimes lasts two, but the wick thereof continues ignited after; and even emits a smoke, which ascends upwards.—That a kindled charcoal is totally extinguished in about five minutes, though in open air it remain alive half an hour; that it goes out by degrees, beginning from the top and the outsides.—That red-hot iron is not affected by the absence of the air; and yet that sulphur or gun-powder will not be lighted thereby, but only fused.—That a match, after lying seemingly extinct *in vacuo* a long time, revives again upon the re-admission of the air.—That a flint and steel strike sparks of fire as copiously *in vacuo* as out of it; and that the sparks move in all directions, upwards, downwards, &c. here as in the air.—That magnets and magnetic needles, are the same *in vacuo* as in air.—That smoke in an exhausted receiver, the luminary being extinct, gradually settles to the bottom in a darkish body, leaving the upper part clear and transparent; and that inclining the vessel sometimes on one side, and sometimes another, the smoke keeps its surface horizontal, after the nature of other fluids.—That the syphon does not run *in vacuo*.—That water freezes *in vacuo*.—That heat may be produced by attrition in the exhausted receiver.—That camphor will not take fire *in vacuo*; and that gun-powder, though some grains of a heap be kindled by a burning-glass *in vacuo*, will not give fire to the contiguous grains.—That glow-worms lose their light in proportion as the air is exhausted, and at length become totally obscure; but upon the re-admission of air, presently recover it all.—That electricity appears like the Aurora borealis.—That vipers and frogs swell much *in vacuo*, but will live an hour and half, or two hours; and though seemingly quite dead in that time, come to life again after being some hours in the air.—That snails survive ten hours; and efts or slow-worms, two or three days; leeches five or six.—That fishes will rise up to the top of water, placed under an exhausted receiver, because the air-bladder is expanded, and they are thus made specifically lighter than water; but if the bladder breaks, they sink down to the bottom and rise no more.—That animals who live in water will not die by exhausting the air out of the receiver, unless they are kept for a considerable time *in vacuo*.—That oysters will remain alive *in vacuo* 24 hours without harm.—That the heart of an eel taken out of the body, continues to beat *in vacuo*, more nimbly than in air; and this for a good part of an hour.—That warm blood, milk, gall, &c. undergo a considerable intumescence and ebullition *in vacuo*.—That a mouse, or other animal, may be brought, by degrees, to survive longer in rarefied air, than naturally it does.—That air may retain its usual pressure, after it is become unfit for respiration.—And that silk-worms' eggs will hatch *in vacuo*.

Besides the above-mentioned phenomena, many others are recited by different writers on this subject, and they may be found in the Philosophical Transaction of various Academies and Societies, and in the works of Torricelli, Pascal, Merfenne, Guericke, Schottus, Boyle, Hooke, Hauksbee, Duhamel, Mariotte, Hales, Muschenbroek, Gravefande, Defaguliers, Franklin, Cotes, Helsham, Martin, Ferguson, Adams, &c. &c. We shall subjoin for the exercise and amusement of our readers some farther experiments, arranged under distinct heads. For experiments that require peculiar

accuracy, the receiver should not be placed upon leather, either oiled or soaked in water; but the plate of the pump should be made very dry, and the inside of the receiver should be dried and rubbed with a warm cloth. The receiver may then be set upon the plate, and hog's lard, either alone or mixed with oil, be smeared round its outward edge. After performing any experiments, the pump should be cleared of any vapour that has been generated, by exhausting a large receiver to as great a degree as possible; and the vapour that remained in the barrel and pipes will be dissipated through the receiver; and if this be large, one exhaustion will be sufficient for clearing the pump. With small receivers the operation should be repeated two or three times. In some of the best pumps, the plate and edges of the receiver are ground so accurately as not to require any leathers; but as the plate is liable to be scratched by setting the receivers upon it, hog's lard or tallow spread upon their edges will be useful. This will prevent the edges from damaging the plate, and will not admit any vapour. When leathers are used for connecting the receiver with a pump plate and for making the junction air-tight, they are previously soaked in water, oil, or a mixture of melted bees' wax and hog's lard. When experiments are performed that require the use of mercury, a small pipe should be screwed into the hole of the pump plate, in order to prevent any of it, that may be accidentally spilt, from passing into the air-pipe and barrels; which would loosen the solder and corrode the brass.

I. Experiments for shewing the weight and pressure of the air.

1. Exhaust of its air a copper ball, such as C (*Plate v. Pneumatics, fig. 26.*) the neck of which is furnished with a stop-cock and a screw by means of which it may be fixed to the plate of an air-pump; suspend it, when exhausted, on the end B of one arm of a balance, A B, and lay upon it the small weight *p*, which must be counterpoised by a weight P in the opposite scale of the balance. Turn the cock of the ball, and the air will rush in and render it so much heavier, that the weight *p* must be removed in order to restore the equilibrium. If the ball holds a gallon, it will thus be found that a gallon of air weighs about the sixth part of an ounce. See WEIGHT of the AIR.

2. Place the small receiver O (*fig. 35.*) over the hole of the pump plate, and upon exhausting the air, the receiver will be fixed down to the plate by the pressure on its outside; and this pressure will be equal to as many times 15 pounds as there are square inches in that part of the plate, which the receiver covers. By turning the cock of the pump and readmitting the air, the receiver will become loose. In order to prove that the receiver O is held down by the pressure of the air, suspend it on the hook of the wire P P passing through the collar of leathers at the top of the receiver M, by which it is covered, and thus let it down on the plate of the pump; and when the air is exhausted from both receivers, the large receiver M will be fixed to the plate by the pressure of the external air; but the small one O will be loose and may be easily removed; on letting in the air, the lesser O will be fixed down upon the plate and the other will be released.

3. Place a small brass or glass vessel A B (*fig. 27.*) which is open at both ends over the hole of the pump plate, and cover the top of it with the hand; which, when the air is exhausted, will be pressed down by the weight of the external air, so that it cannot be released without difficulty till the air is readmitted.

4. Tie a piece of wet bladder, as *b* (*fig. 28.*) over the open top of the glass A; when it is dry, set the open end

A over the hole of the pump plate, and as you exhaust the air, the bladder will be pressed down and allume within the glass a concave figure, and at length it will break with a loud report. If a piece of flat glass be laid upon the top of this receiver, and joined to it by a rim of wet leather, the pressure of the outward air will break the glass, when the internal air is exhausted.

5. Immerse the neck *cd* of the hollow glass ball *eb* (*fig.* 29.) in the water of the phial *aa*; place it on the plate of the pump, and cover it and the hole of the plate with the receiver *A*; exhaust this receiver, and the air will escape by its spring from the ball *eb*, through the neck *dc*, rise in bubbles through the water, and pass off into the external air. When it has done bubbling, turn the cock of the pump, and the air that is admitted will by its pressure on the surface of the water force it up in a jet into the ball *eb*, and almost fill it; the small quantity of remaining air, which occupied the whole ball, and which is now reduced to a small space of condensation, preventing the water from filling the whole cavity of the ball. This experiment may be varied by screwing the end *A* of the brass pipe *ABF* (*fig.* 30.) into the hole of the pump plate, and placing, by means of wet leather, upon the plate *cd* a tall receiver *G H* close at the top, exhausting the receiver of its air and stopping the pipe by the cock *e*; when this is done remove the apparatus from the pump, set its end *A* in a basin of water, and open the pipe by turning the cock *e*; and the pressure of the air on the water will force it up through the pipe, so that it will ascend in a jet to the top of the receiver. See FOUNTAIN.

6. Set the jar *D* (*fig.* 31.) containing quicksilver, near the hole of the pump plate, and cover both with the tall open receiver *AB*. Into the plate *C*, placed upon the upper end of this receiver, introduce the open glass tube *gf*, immersed at its lower extremity in the quicksilver of the jar *D*, and serewed by a brass top annexed to it at *b* to the syringe *H*, which is itself serewed to the plate *C*. By the ring *I* draw up the piston of the syringe, and thus exhaust the tube of its air; and the quicksilver in the basin pressed by the undilated air of the receiver *AB* will ascend in the tube. That this ascent is owing to the pressure of the air, and not to what some have called suction, may be evinced by exhausting the receiver of its air, which will cause the quicksilver to descend into the jar, and by readmitting the air, which will raise it again in the tube, although the piston of the syringe be not moved. If the tube be about 32 or 33 inches high, the quicksilver will rise nearly as high in the tube as it stands at that time in the barometer. If the syringe has a small hole at *m*, and the piston be drawn up above that hole, the air will pass through it into the syringe and tube, and the quicksilver will immediately fall down into the jar.

7. Place the jar *A* (*fig.* 32.) with quicksilver in it on the pump plate, cover it with the receiver *B*, and push the open end of the glass tube *de* through the collar of leathers in the brass neck *C*, almost down to the quicksilver in the jar. Exhaust the receiver *B* of its air, and the tube *de*, which is close at the top *f*, will at the same time be exhausted. When the receiver has been well exhausted, push the open end of the tube into the quicksilver of the jar; and though the tube be exhausted of its air, the quicksilver will not rise in it, because there is no pressure on the surface of that in the jar. But upon admitting the air into the receiver, the quicksilver will immediately rise and stand as high as it did in consequence of the action of the syringe in the preceding experiment.

VOL. I.

These two last experiments not only exhibit the weight and pressure of the air, but they also shew that these are increased or diminished in proportion to the increase or decrease of the air's depth. See BAROMETER and TORRICELLIAN Experiment.

8. Join the two brass hemispheres *A* and *B* together (*fig.* 36.) by the interposition of a wet leather, with a hole in the middle of it; then serew the end *D* into the plate of the pump, and turn the cock *E* of the pipe, *CD*, communicating with the hemispheres; and having exhausted the air, turn the cock so as to stop the pipe. Having removed it from the pump, serew at the end *D*, the piece *Fb*; and two strong men pulling at the handles *g* and *h* will find it difficult to separate the hemispheres; for if the diameter be four inches, they will cohere together with a force equal to 188 pounds, the area being equal to the square of the diameter multiplied by 7854, and the pressure on every square inch being 15 pounds; *i. e.* $16 \times 7854 \times 15 = 188,496$ pounds. If they be suspended by either of the rings on the hook *P* of the receiver *M* (*fig.* 35.), and the receiver be exhausted of its air, they will separate of themselves.

9. Set the square phial *A* (*fig.* 37.) upon the pump plate, and cover it with the wire cage *B*; then placing it under a close receiver, exhaust the receiver and the phial which has a small hole under a valve at *b* of their air; and the air upon its readmission into the receiver, being prevented from passing into the phial by the valve *b*, will break it into a number of pieces by its pressure. Quicksilver may be also forced into wood, and made to pass through it by the pressure of the air.

II. Experiments for shewing the elasticity or spring of the air.

1. Place a bladder, containing a small quantity of air and well tied up, under a receiver; and when the receiver is exhausted, the air will expand and fill the bladder so that it will appear as if it were blown with common air. Upon letting in the air, the bladder pressed by it will be reduced to its original flaccid state. This bladder put into a box under a weight of 20 or 30 pounds, and covered with a receiver, will, upon the exhaustion of the receiver, raise the weight by means of the spring of the internal air.

2. Take the glass ball (*fig.* 29.) which was filled with water, a small bubble of air at the top of it excepted, and having placed it with its neck downward into the empty jar *aa*, and covered it with a close receiver, exhaust the receiver of its air, and the air-bubble will expand itself, and by its elastic force protrude the water out of the ball into the jar. Or, serew the pipe *AB* (*fig.* 30.) into the pump plate, and place the tall receiver *G H* upon the plate *cd*; exhaust the receiver, and then remove the apparatus and serew it into the copper vessel *CC* (*fig.* 38.) half filled with water. Then turning the cock *e* (*fig.* 30.) and the air confined in this vessel will by its spring force the water through the pipe *AB*, and cause it to form a jet into the exhausted receiver, equal to that which was produced by the pressure of the air in a former experiment; other circumstances being alike.

3. Let the balls annexed to the heads of the hollow glass images (*fig.* 39.) contain water sufficient to render them specifically heavier than water. Place them under a receiver and exhaust it; and the air in the balls will dilate, force part of the water out, and render the images lighter than water, so that they will ascend. On re-admitting the air, they will descend. Small apertures made in the feet of these images will vary the experiment, and answer the same purpose.

3. Animals that die in an exhausted receiver are evidently oppressed at first as with a great weight, then convulsed, and at last expire in apparent agony. Instead of repeating experiments of this kind, the effect of exhaustion is ascertained by what is usually, though improperly, called the lungs-glass. This consists of a bladder tied round a small tube which passes into a bottle, and sealed so tight, that the air cannot escape any way but through the tube. When this machine is put under a receiver and the air begins to be exhausted, the spring of that, which is contained in the bottle, and which cannot escape, compresses the bladder; and when air is again let in, the bladder expands; and these alternate motions of compression and dilatation have been supposed analogous to those of the lungs. See *fig. 40.*

4. Pour quicksilver into the bottle A (*fig. 41.*) and screw the brass collar *c*, of the tube B C, into the brass neck *b* of the bottle, and let the lower end of the tube be immersed into the quicksilver, so that the air above the quicksilver may be confined there. Cover this tube, which is open at the top, with the receiver G and large tube E F, fixed by brass collars to the receiver and close at the top. Exhaust the receiver and its tube; and the air will be thus exhausted out of the inner tube B C through its open top C; and then the air confined in the bottle A will, by its spring, force the quicksilver in the inner tube as it was raised in a former experiment by the pressure of the atmosphere; and thus it appears that the elasticity of the air is equivalent to its weight.

5. Screw the end C of the pipe C D (*fig. 42.*) into the hole of the pump plate, and open the communication between the three pipes E, F, and D C, and the hollow trunk A B, by turning the three cocks *d*, G and H. Cover the plates *g* and *b* with wet leathers, having holes in their middle, so as to communicate with the pipes; place the close receiver I upon the plate *g*; shut the pipe F, by turning the cock H; and exhaust the air out of the receiver I. Shut out the air by turning the cock *d*; remove the machine from the pump; screw it to the wooden stand L; and put the receiver K upon the plate *b*, on which it will be loose whilst it is full of air; but upon turning the cock H, and opening the communication between the pipes F and E, through the trunk A B, the air in K will, by its spring, pass from K to I, till it becomes of equal density in both receivers; and then they will be held down with equal force upon their respective plates by the pressure of the atmosphere, and the force with which K was held down will be divided between K and I. Thus it appears, that a force equal to half the elastic force of common air will act within the receivers against the whole pressure of the common air on their outsides. This instrument is called a double transferrer, and it serves to transfer the air from one vessel into another.

6. Fasten a cork in the square phial A (*fig. 37.*) with wax or cement; put it upon the pump plate, cover it with the wire cage B, and place a close receiver over the cage. Upon exhausting the receiver of its air, that which was enclosed within the phial will dilate itself, and having no counter pressure on the outside, will break the phial outwards by the force of its spring.

7. Place a shrivelled apple under a receiver, and as it is exhausted, the spring of the air within the apple will plump it out and cause the wrinkles to disappear; but upon readmitting the air, it will return to its shrivelled state.

8. Put a fresh egg, from the small end of which a little of the shell and film is removed, under the receiver; and when the air is pumped out, the small bubble of air contained between the shell and film at the larger end, will dilate

itself, and protrude the contents of the egg into the receiver. If the egg be placed in a jar of water under the receiver, its surface will be covered with bubbles of air in the progress of exhaustion.

9. Warm beer put under a receiver, exhausted of its air, will discharge bubbles, which will rise to the surface, and at length give it the appearance of boiling.

10. A piece of dry waincot or other wood, being put into warm water and covered with a receiver, will discharge air, as the receiver is exhausted, and exhibit bubbles of air, especially about its ends, because the pores lie lengthwise. A cubic inch of dry waincot has so much air in it, that it will continue bubbling for half an hour together.

If a piece of wood be made to pass through a plate covering the top of a receiver, with one part exposed to the air and the other immersed in a jar of water under the receiver, and the thumb be put on the top of the wood whilst the pump is working, the air contained in the pores of the wood will rush in bubbles through the water; but if the thumb be taken off, a stream of air will flow in through the wood; and thus by alternately taking off the thumb and placing it on the wood, the influx of the air will be alternately admitted and interrupted. See AIR and ELASTICITY of the Air.

III. Experiments for shewing the resistance of the air.

1. The machine (*fig. 43.*) consists of two mills, *a* and *b*, of equal weight, and moving independently and freely on their axes. Each mill has four thin vanes or sails, fixed in the axis; those of the mill *a* having their planes perpendicular to the axis, and those of the mill *b* having their planes parallel to it. When the mill *a* turns round in common air, it will suffer little resistance, because its sails cut the air with their thin edges; but the mill *b* is much resisted, because the broad sides of its sails move against the air, when it turns round. Each axle has a pin near the middle of the frame, which passes through the axle and projects a little on each side of it; upon these pins the slider *d* may be made to bear, and thus hinder the mills from going, when the strong spring *e* is set on bend against the opposite ends of the pins. Having set the machine upon the pump plate, draw up the slider *d* to the pins on one side, and set the spring *e* at bend upon the opposite ends of the pins; then push down the slider *d*, and the spring acting with equal strength on each mill will set them at work with equal forces and velocities; but the mill *a* will run much longer than *b*, because it meets with much less resistance. Draw up the slider again, and set the spring upon the pins as before; then cover the machine with the receiver M (*fig. 35.*) upon the pump plate; and having exhausted it, push down the wire P P, through the collar of leathers in the neck *q*, upon the slider, which disengaging it from the pins will allow the mills to turn round by the impulse of the spring; and as there is no air in the receiver that yields any sensible resistance, they will move for a longer time than in the open air, and when one stops, the other will stop also. Hence it appears, that the air resists moving bodies, and that equal bodies meet with different degrees of resistance, according as they present greater or less surfaces to the air, in the planes of their motions.

2. Put the guinea *a* and feather *b* (*fig. 44.*) upon the brass flap *c*; turn up the flap, and shut it into the notch *d*. Then putting a wet leather over the top of the tall receiver A B, which is open at both ends, cover it with the plate C, so that the tongs *e d* may hang within the receiver. Then having exhausted the receiver, draw up the wire *f*, and the tongs *e d* will be opened by a piece at its end, and the flap *c* falling

c falling down, the guinea and feather will be observed to descend with equal velocities, and by looking steadily to the bottom of the receiver, to fall to the pump plate at the same instant. When air is in the receiver, the guinea will fall in an instant, and the feather will descend gently and by an indirect motion. This apparatus is sometimes so constructed as to let three guineas with their feathers fall separately at three different times, without taking it off or exhausting the air afresh. See *RESISTANCE of the Air*.

IV. Miscellaneous Experiments.

1. Screw the syringe H (*fig. 31.*) to a piece of lead, weighing at least one pound; pull up the piston, which will cause a vacuum in the syringe, and the air by its pressure will drive back the lead upon it; raising it and counteracting its natural weight. But if the syringe and annexed weight be placed in an exhausted receiver, they will fall upon the piston by their natural gravity, and upon readmitting the air, they will be drove upward again, so that the piston will be at the bottom of the syringe.

2. To a balance A B, *Plate vii. Pneumatics, fig. 54.* suspend a weight of lead, and let it be in equilibrio with a piece of cork. Place this apparatus under a receiver and exhaust the air, and the cork will preponderate; but let the air be admitted, and the equilibrium will be restored. As the air is a fluid, all bodies lose as much of their weight in it as is equal to the weight of an equal bulk of the fluid; and as the cork is largest, it loses more of its absolute weight than the lead, and of course must be heavier in order to compensate this greater loss; but when the air is removed, all bodies gravitate according to their quantities of matter, and therefore the cork, which balanced the lead in air, will appear to be heavier *in vacuo*. A more elegant apparatus for this experiment, consisting of a light glass ball A, and a brass weight B, is exhibited in *fig. 55.*

3. Set a clean receiver upon the plate of a pump, and when you begin to exhaust it, hold a candle to the side of the receiver opposite to your eye, and several colours, resembling a halo, will appear about the candle, which are occasioned by the vapours that arise from the wet leathers and their refraction of the light.

4. Place a lighted candle under a tall receiver, and if it holds about a gallon, the candle will continue to burn about a minute; and its light will gradually decay and at length be extinguished. The smoke of the candle will ascend and form a kind of cloud at the top of the receiver; but upon exhausting it, the smoke will fall down to the bottom; thus shewing, that smoke does not ascend because it is positively light, but because it is lighter than air.

5. Let the pipe represented in *Plate viii. Pneumatics, fig. 68.* be annexed to the top of an open receiver, and the air be exhausted; then place one end of the pipe in the middle of a charcoal fire, and open the cock; and the noxious air of the charcoal will pass through the pipe into the receiver; remove the pipe from it, and let down a small lighted wax taper into the receiver, and it will be immediately extinguished. A mouse or bird let down into the receiver will be killed by the air which it contains. If a candle be let down gently, it will purify the air as it descends.

6. By connecting the wire that passes through the collar of leathers of a receiver with the trigger of a pistol lock, placed under it, exhausting the air, and then drawing the trigger, the flint will strike the steel and produce sparks of fire, which will not be visible as in the open air. Or, if two iron bullets be made red-hot, and one of them be under an exhausted receiver, it will not appear luminous, like the other which remains in the open air.

7. Set a bell upon a cushion under a receiver on the pump plate; and shake the pump so as to make the clapper strike against the bell, and the sound will be distinctly heard; but exhaust the receiver, and if the clapper be made to strike with great force against the bell, it will make no audible sound; hence it is inferred, that air is necessary for the propagation of sound.

AIR-SHAFTS, among *Miners*, denote holes or shafts let down from the open air to meet the adits, and furnish fresh air. The damp, want, and impurity of air, which occur, when adits are wrought 30 or 40 fathoms long, make it necessary to let down air-shafts, in order to give the air liberty to play through the whole work, and thus discharge bad vapours, and furnish good air for respiration: the expense of which shafts, in regard of their vast depths, hardness of the rock, drawing of water, &c. sometimes equals, nay exceeds, the ordinary charge of the whole ADIT.

Sir Robert Murray describes a method, used in the coal-mines at Liege, of working mines without air-shafts. *Phil. Transf. N^o 5.*

When the miners at Mendip have sunk a groove, they will not be at the charge of an air-shaft, till they come at ore; and for the supply of air have boxes of elm exactly closed, of about six inches in the clear, by which they carry it down about twenty fathoms. They cut a trench at a little distance from the top of the groove, covering it with turf and rods disposed to receive the pipe, which they contrive to come in side-ways to their groove, four feet from the top; which carries down the air to a great depth. When they come at ore, and need an air-shaft, they sink it four or five fathoms distant, according to the convenience of the breadth, and of the same fashion with the groove, to draw as well ore as air. *Phil. Transf. N^o 39.* See *MINING*.

AIR-THREADS of spiders. See *THREADS*.

AIR-TRUNK, a simple contrivance by Dr. Hales, for preventing the stagnation of putrid effluvia, and purifying the air in jails and close rooms; which consists of a square trunk open at both ends, one of which is fixed in the ceiling and the other is extended to a considerable height above the roof. The noxious effluvia, ascending to the top of the room, escape by this trunk. Some of these have been nine and others six inches in the clear; but whatever be their diameter, their length should be proportionable, in order to promote the ascent of the vapour. As the pressure of fluids, and consequently of the air, corresponds to their perpendicular altitude, the longer these trunks are, so much the greater will be the difference between columns of air pressing at the bottom and at the top; and of course so much the greater will be their effect. See *VENTILATOR*.

AIR-VESSEL, in *Hydraulics*, is a name given to those metalline cylinders, which are placed between the two forcing-pumps in the improved *FIRE-engines*. The water is injected by the action of the pistons through two pipes, with valves, into this vessel; the air previously contained in it will be compressed by the water, in proportion to the quantity admitted, and by its spring force the water into a pipe, which will discharge a constant and equal stream; whereas in the common squirting engine, the stream is discontinued between the several strokes. Other water-engines are furnished with vessels of this kind.

AIR-vessels, in *Botany*, are certain canals, or ducts, where-by a kind of absorption and respiration is effected in vegetable bodies.

Air-vessels have been distinguished from *SAP-vessels*; the former being supposed to correspond to the trachea, and

larges of animals; the latter to their lacteals and blood-vessels.

Dr. Grew, in an enquiry into the motion and cause of the air in vegetables, shews, that it enters them various ways, not only by the trunk, leaves, and other parts above ground, but at the root. For the reception, as well as expulsion of air, the pores are so very large in the trunks of some plants, as in the better sort of thick walking canes, that they are visible to a good eye without a glass; but with a glass, the cane seems as if it were stuck full of large pin-holes resembling the pores of the skin in the ends of the fingers, and ball of the hand. In the leaves of the pine, through a glass, they make an elegant show, standing almost exactly in rank and file throughout the length of the leaves.

But though the air enters in partly at the trunk and also at other parts, especially in some plants, yet its chief admission is at the root: much as in animals, some part of the air may continually pass into the body and blood by the pores of the skin; but the chief draught is at the mouth. If the chief entrance of the air were at the trunk, before it could be mixed with the sap in the root, it must descend; and so move not only contrary to its own nature, but in a contrary course to the sap: whereas by its reception at the root, and its transition from thence, it has a more natural and easy motion of ascent. See CIRCULATION of sap.

The same fact is farther deduced, from the fineness and smallness of the diametral apertures in the trunk, in comparison of those in the root; which nature has plainly designed for the separation of the air from the sap, after they are both together received into them. Grew, Anat. of Root, chap. iii. p. 127.

Air-vessels are found in the leaves of all plants, and are even discoverable in many without the help of glasses; for upon breaking the stalk or chief fibres of a leaf, the likeness of a fine wholly substance, or rather of curious small cob-webs, may be seen to hang at both the broken ends. This is taken notice of only in some few plants, as in *scabious*, where it is more visible: but may also be seen more or less in most others, if the leaves be very tenderly broken. This wool is really a skein of air-vessels, or rather of the fibres of the air-vessels, loosed from their spiral position, and so drawn out in length. Id. *ibid.* chap. iv. p. 155.

That air is inspired by vegetables, has been fully proved by Dr. Hales, in his Statical Essays, (vol. i. p. 155, &c.) and he has in many instances shewn, that air freely enters the vessels of trees, and that it is in great abundance wrought into their substance. But as to particular air-vessels in plants, he seems to speak doubtfully. He says, by way of question, may not the use of those spiral wreaths, that are coiled round the insides of those vessels, which are supposed to be air-vessels, and which are manifestly to be seen in several trees, and also in the leaves of the vine and *scabious*, may not these be designed by nature to promote the quicker ascent of air, by being in some measure conformed to its elastic contortions? For such spiral wreaths seem to be altogether useless, for promoting the ascent of any liquor, as the sap, which ascends most freely through innumerable other capillary vessels, having no such spiral coils in them: not that we are to suppose the air in its elastic state actually to touch, and thereby to be determined in the course of these spirals, as any liquor would be. But as the rays of light, when they are reflected from a solid body, are found to be reflected, without actually touching the reflecting body in the point of reflection; so it is not unreasonable to

suppose, that elastic air may, like light, be diverted from one course, and so be determined to another, by the solid bodies it approaches, without touching them, but rebounding like light from those solid bodies near the point of contact.

Dr. Hales has observed, that these spirals are coiled in a course opposite to the course of the sun, that is, from west to east. Vide Static. Ess. vol. ii. p. 265, 266.

Dr. Darwin, in his Phytologia, observes, that the vessels which Malpighi, Grew, and many others, have denominated bronchia, and erroneously thought to be air-vessels, and to serve the purpose of respiratory organs, are absorbent vessels, destined to imbibe the nutriment of plants, and that they are the genuine lungs of vegetables. These absorbent vessels, he says, which resemble the lacteals of animal bodies, are found in the roots of plants for imbibing nourishment from the moist earth, on the external surfaces of the bark and leaves, for absorbing the humidity of the atmosphere, and also in the internal surfaces of the cells and cavities of the vegetable system, where they absorb the secreted fluids, after they have performed the offices to which they are adapted. The existence of the first sort of absorbents, is evinced by the growth of plants, whilst moisture is applied to their roots, and by their withering when it is withdrawn. Those of the second sort are manifested by plucking off a leaf and laying it in water, which is found not to wither so soon as if it were left exposed to the dry air. The third class of vessels of this kind will be perceived to perform its office by moistening the alburnum or sap-wood, and the inner surface of the bark of a branch severed from a tree, which are thus preserved, whilst the same parts left unmoistened in the dry air are observed to wither. Besides, if vegetables be inserted in glass-tubes or narrow vessels, filled with water, the surface of the water will be seen to subside much sooner than by evaporation alone in similar circumstances. Dr. Darwin also contrived to evince these absorbent vessels to the eye, by clipping twigs of a fig-tree in a decoction of madder and of logwood, which after some time, upon cutting off about an inch of the stalk near the bottom, exhibited a circle of red points, believed by him to be the coloured ends of the absorbents, that existed in the newly formed alburnum. This ingenious writer expresses his astonishment that any person should have conceived these vessels, that are found in the alburnum, and which consist of a spiral line, to be air-vessels or tubes. He farther observes, that the absorbent vessels of trees, in passing down their trunks, consist of long hollow cylinders, of a spiral form, and of such large diameters in some vegetables, *e. g.* in cane, as to be visible, when dry and empty, to the naked eye. Through these air will pass rapidly upward and downward; and hence Dr. Hales has been led to coincide with Grew and others in opinion, that they are air-vessels or lungs, designed for respiration, and receiving atmospherical air in their natural state. But to their use as air-vessels he objects, because they have no communication with the horizontal air-vessels of plants, and they exist in the roots as well as in the trunks of plants, where, not being exposed to the atmosphere, they cannot serve the purpose of respiration. Air, however, in its combined state, or dissolved in water, may be absorbed by these vessels; and may appear when the pressure of the atmosphere is removed in the exhausted receiver, or when it is expanded by heat, as is the case in the froth observed at one end of a green stick, when the other is burning in the fire. Dr. Darwin apprehends, that the structure of those large vegetable absorbents, which have been erroneously called air-vessels, consists of a spiral line,

line, and not of a vessel interrupted with valves; and in this respect it differs from that of animal lymphatics.

According to this writer, the proper air-vessels are horizontal vessels of large diameter, which pass through the bark of trees to the albuminum. Malpighi has given a figure of these vessels, and Duhamel mentions fine horizontal perforations through the bark of trees, which he believes to be perspiratory or excretory organs; and besides these, he takes notice of others, that are larger, standing prominent in the birch-tree, and piercing the exterior bark; which probably contain air during the living state of the tree. Dr. Darwin supposes, that the horizontal vessels first mentioned contain air, enclosed in a thin moist membrane, which may serve the purpose of oxygenating the fluid in the extremities of some fine arteries of the embryo buds, in a manner similar to that by which the air at the broad end of the egg is thought to oxygenate the fluids in the termination of the placental vessels of the embryo chick.

AIRA, *Aiz* of Hippocrates and Theophrastus, *hair-grass*, in *Botany*, a genus of the *triandria digynia* class and order, and of the natural order of *gramina* or grasses. Its characters are, that the calyx is a two-flowered, two-valved glume; the valves ovate-lanceolate, acute and equal; the corolla bivalve, the valves like the former; nectary two-leaved, leaflets acute, gibbous at the base; the stamina have capillary filaments, of the length of the flower, with oblong anthers, forked at each end; the pistillum is an ovate germ, the styles setaceous spreading, with pubescent stigmas; no pericarpium; the seed sabovate, crowned with the corolla. It differs from *MELICA*, in having no rudiment of a third between each pair of floscules, the number of which varies. Martyn enumerates 14, and Gmelin, in his edition of Linnæus, 25 species; some of which are naked or awnless, and others awned.

Of the former, Martyn specifies, 1. *A. arundinacea*, or reedy hair-grass, with oblong panicle, on one side imbricate, and flat leaves, found in the Levant and in Cochinchina. 2. *A. minuta*, with loose panicle, almost level-topped, and very branching; an annual grass found in Spain. 3. *A. aquatica*, water hair-grass, with panicle spreading, flowers smooth, longer than the calyx, and leaves flat. This grass generally grows in the margins of pools and watery places, running in the water to a considerable distance, and is known by the purple or bluish colour of the panicles, and sweet taste of the flowers: perennial, flowering in May and June. This, says the author of the Farmer's Dictionary, is the grass which contributes chiefly to the sweetness of Cottenham cheese, and the fineness of Cambridge butter. There is a variety of this which grows in dry soils, with the calyces five-flowered, and the flowers very remote from each other. It occurs in sandy lands near Exmouth, about Northfleet in Kent, in Lancashire, and Yorkshire. In Dr. Withering's arrangement it is the *poa diffusans*; and Dr. Stokes suspects the *poa retrofracta* of Mr. Curtis to be the same with this. Gmelin adds to the class of the naked *aire*; 4. *A. capensis*, with a ramose culm, racemous flowers, and hairy corolla. 5. *A. kernigii*, with dense panicle, smooth calyces, and ascending culm; the *poa biflora* of some authors. 6. *A. bengalensis*, with erect panicle, three-flowered pedicles, and petals woolly within; the *arundo bengalensis* of other writers. 7. *A. miliacea*, with very numerous panicles, with floscules in three's, obtuse and distinct, and smooth striated leaves. 8. *A. agilopsoides*, with flowers turned to one side, with one valve of the corolla ovated and acuminate, and the other columnar and obtuse. Dr. Smith (Flor. Brit. vol. i. p. 83.) adds, *A. cristata*, with panicle spicated, calyces longer than the peduncle,

petals acuminate and unequal. It grows in high barren pastures and walls; perennial; flowering in July and August.

The awned *aire* enumerated by Martyn are as follow: 9. *A. subspicata*, with leaves flat, panicle spiked, flowers awned on the middle; awn reflex and loose; found on the mountains of Switzerland, Savoy, Denmark, and Lapland; perennial. 10. *A. cespitosa* or turfy hair-grass, with leaves flat, panicle spreading, petals villous, and awned at the base; awn straight and short; growing in moist meadows and woods, perennial, flowering in June and July, sometimes trailing on the ground to the length of several feet, and the panicle exhibiting a beautiful purple silky appearance. Dr. Withering mentions a variety of this with panicle viviparous, flowering in October, and found on Highland mountains. This is apt to grow in tufts, and occasion irregularities in the surface of meadows. Cows, goats, and swine eat it; but horses are not fond of it. It is the roughest and coarsest grass that grows in pastures or meadows; and cattle will not touch it, unless compelled by hunger. It is called by the vulgar haslocks, rough-caps, and bull's faces. To get rid of it, the land should first be drained, and the tufts of this noxious weed pared off and burnt; and the ashes they yield will be a good manure. 11. *A. flexuosa*, or waved mountain hair-grass, with leaves setaceous, culms almost naked, panicle spreading trichotomous, peduncles flexuose, and awns geniculated; perennial; flowering in July, and growing in heaths, woods, and barren pastures; eaten by horses, kine, and sheep. Dr. Withering suggests, that this is a variety of the *A. montana*, or rather the same in a more mature state. This is a principal grass on Bantlead Down, Mendip, &c. and is equally fine and nutritive with sheep's fescue. It is of difficult cultivation. Dr. Smith (Fl. Br. vol. i. p. 85.) mentions two varieties; one with a panicle, less spreading, and peduncles scarcely flexuose. This is the *A. montana* of Hudson, Withering, Relhan, and Leers, but not of Linnæus. The *A. setacea* of Hudson does not differ from this; but the *A. montana* of Linnæus is a very different grass, and has not yet been found in Britain. The other has a culm more leafy, a white panicle, scarcely flexuose, and grows in shady places. 12. *A. montana*, with leaves setaceous, panicle narrowed, flowers hairy at the base and awned, awn twisted and very long; supposed to be a variety of the former; perennial, in July and August; a native of high heaths and sandy pastures; eaten with avidity by sheep. A variety, called *setacea*, with awns twice the length of the florets, is mentioned by Hudson. 13. *A. alpina*, with leaves subulate, panicle dense, flowers hairy at the base and awned, awn short; growing on the mountains of Germany, Savoy, and Lapland. 14. *A. villosa*, with leaves subulate, panicle long and narrow, flowers subspherical, shaggy, awned; awn straight and short; found by Thunberg at the Cape of Good Hope. 15. *A. canescens*, grey hair-grass, with leaves setaceous, culm leafy, the upper one involving the panicle at bottom, like a spathe; awns clavated at the apex, shorter than the calyx; a native of sandy shores, on the coasts of Norfolk and Suffolk, the walls of Basil, and the sandy fields of Germany and Piedmont; perennial, flowering in July; the *avena canescens* of Wiggers. 16. *A. precox*, early hair-grass, with leaves setaceous, sheaths angled, flowers panicle-spiked, floscules sessile, naked at the base and awned on the back; found on dry commons, in ditches, on banks of streams, and in wet meadows; perennial, flowering in May and June, ripening its seeds in June; and called by Wiggers, *avena pusilla*. It has a sweet taste; cows are very fond of it; and it is eaten by horses and sheep. 17. *A. caryophylla*, silver hair-grass, with leaves setaceous, panicle divaricated, trichotomous, floscules

florescence sessile, dorsal awn geniculated; a native of sandy pastures, and heaths of England, France, Switzerland, Piedmont, Germany, and Denmark; annual, flowering in July. 18. *A. antarctica*, south-sea hair-grass, with leaves flat, panicle compound, spreading, calyces three-flowered, florescence awned in the middle, awn elongated straightish; a native of New Zealand. 19. *A. involucreta*, with panicle spreading, involucre with bristles at the base; florescence awnless; a native of Spain, on barren hills near Madrid; annual, and flowering in June and July. To these Gmelin adds, 20. *A. palustris*, with flat leaves, patent panicle, florescence hairy at the base, and the awn short and bent inwards. 21. *A. festucoides*, with filiform leaves, erect panicle, leaves coloured, and awned beyond the middle. 22. *A. juncea*, with leaves subulate, panicle patent, very obtuse, awn from the base of the length of the calyx. 23. *A. sinensis*, with fetaceous leaves, erect panicle, and villous florescence. 24. *A. media*, with fetaceous leaves, narrow panicle, florescence hairy at the base, awn subterminal, shorter. 25. *A. purpurea*, with leaves subulate-fetaceous, panicle scattered, one valve of the corolla entire, plumose, and culm erect. For the propagation and culture of Airs; See GRASS. Gmelin's Linneus. Martyn's Miller. Withering's Botanical Arrang. vol. ii. p. 135, &c.

AIRA Varia. See CYNOSURUS.

AIRANI, in Church History, a sect of Arians, in the fourth century, who denied the consubstantiality of the Holy Ghost with the Father and the Son.

They are otherwise called *Airaniste*, and are said to have taken their name from one Airas, who distinguished himself at the head of this party, in the reign of Valentinian and Gratian.

AIRANO, in Geography, a town of Italy in the Milanese, 10 leagues south-east of Como.

AIRAULT, PETER, in Latin *Ærodius*, in Biography, lieutenant-criminal in the presidial of Angiers, was born there in the year 1536, and executed the office in a manner that obtained for him the title of the "Rock of the Accused." He died in 1601, and left several treatises. His eldest son was educated by the Jesuits, and retained in their society, notwithstanding all the remonstrances and efforts of his father. Biog. Dict.

AIRAY, HENRY, an English divine, was born in Westmoreland, educated under the care of Bernard Gilpin, and sent to St. Edmund's Hall, Oxford, in 1579, at the age of nineteen years. He was afterwards removed to Queen's college, where he was successively servitor, fellow, and master. In 1598, he was chosen provost, and in 1606, vice-chancellor of the university. He was a constant and zealous preacher, and a zealous calvinist. He was much esteemed for his learning, gravity, and piety, and for his industry in discharging the duties of his office; and died in 1616. The following treatises, written by him, were published after his death, viz. "Lectures on the Epistle to the Philippians, 4to. 1618." "A Treatise against Bowing at the Name of Jesus." And, "A just and necessary Apology respecting a Suit at Law." Biog. Brit.

AIRE, in Geography, a town of France, in the department of Landes, formerly Gascony, and in the district of St. Sever, situate on the Adour, 155 leagues from Paris, and 5 leagues south-east of Mont-de-Marsan. It is a very ancient town, and the see of the suffragan bishop of Auch, containing 241 parishes. Its ancient name was *Vicus-Julii*, having been taken by the Romans, under the command of Julius

Cæsar. The Visigoths afterwards took possession of it; and Alaric, one of their kings, adorned it and fortified it with a castle. It has often since changed masters, and suffered much during the religious wars in France. N. lat. 43° 31'. E. long. 5° 26'.

AIRE, a town of France, in the department of Pas-de-Calais, formerly Artois; situate on the Lys, fortified by a castle, and communicating with St. Omer by a canal; and also with the fort St. Francois. It was taken by the allies in 1710, and restored to France by the peace of Utrecht. It is 9 leagues from St. Omer, 9 from Dunkirk, and 51 north of Paris. N. lat. 50° 30'. E. long. 2° 17'.

AIRE, a river of England, issuing into the Humber, and navigable to Leeds in Yorkshire.

AIRING, in the general sense of taking, or going into the fresh air, is too well known to need any explanation. See AEROPHOBIA.

The word is particularly used for exercising horses in the open air, which is of the greatest advantage to these animals. Many of the diseases to which horses are liable, are brought on by neglecting to exercise them.

AIRING a horse, should be distinguished from that species of exercise used in training horses for racing, as this is conducted at regular periods, and has in view not only the general health, but particularly the acquirement of wind and speed. Airing a horse, in a general way, may be done at any part of the day, but when the heat of the sun is too intense, as by this means he perspires too much, and is rendered irritable from the stings and bites of insects. It is better to give a horse a moderate airing twice a day, than a longer one at one time. It should be avoided immediately after a full meal; at those times the chest has not room to expand, therefore the wind is endangered; the food is likewise hurried, by the pressure of the abdominal muscles, too soon through the stomach to be digested, and too soon through the intestines, to be properly absorbed by the lacteals. In an airing the horse should first be walked, then trotted, and lastly moderately galloped; it is usually practised in a snaffle bridle, the propriety of which depends on the horse's mouth, and the hand of the rider; if the groom is not perfectly acquainted with the art of riding with a fine hand, which few of them are, a large bitted snaffle should be used. An airing should be continued long enough to give a horse an appetite, but not so long as to weaken his stomach. When horses are very fat it should be continued longer, that the absorbents may be stimulated to take up more of the adeps of the body. In foul, gross, greasy horses, the airings should be gentle, but continued for some time; in farcy this should be particularly observed. And in all diseases where there appears a defect in the absorbents, the exercise should be gentle, continued long, and frequently repeated. The numerous cautions made use of to air such particular horses, at particular times, have their foundation in whims and caprice: reason and science point out, that any time between the meals, when the sun is not in its full lustre, is proper for airing them. See EXERCISE.

AIROLA, in Geography, a town of the canton of Uri, in Switzerland, six leagues north of Altorf.

AIRON, a river of France which runs into the Loire near Decise.

AIRS, in Horsemanship, denote the artificial or practised motions of a managed horse.

Such are the demi-volt, curvet, capriole, croupade, balotade, step, and leap; also, advancing, yerking, and bounding. Some authors take airs in a more extensive sense; and divide them into low and high.

The low airs include the natural paces, as walking, trotting,

ting, galloping, and terra-a-terra. To which may be added, prancing, sidling, stopping, and turning.

The high, or raised airs, are all such motions as rise higher than the terra-a-terra; as the demi-volt, curvet, &c.

AIRVAULT, in *Geography*, a town of France, in the department of the two Sevrès, in the district of Thouars, four leagues north-north-east of Partenay.

AIRY triplicity, among *Astrologists*, the signs of Gemini, Libra, and Aquarius. See **TRIPPLICITY**.

AISA, in *Geography*, a town of Spain, in the kingdom of Arragon, two leagues and an half north of Jaca.

AISCH, a river of Germany, in Franconia, which rises near Iseheim, and discharges itself into the Regnitz, between Bamberg and Forcheim.

AISE, a river of France, which runs into the Orne, three leagues above Caen.

AISEAU, a town of Germany, in the circle of Westphalia, three miles east-south-east of Chastelet.

AJSEDABAD, a town of Persia, in the province of Irak Agemi, 22 leagues north-north-east of Amadan.

AISÉREY, a town of France, in the department of the Cote d'Or, in the district of St. Jean de Losne, three leagues south-south-east of Dijon.

AISEY-LE-DUC, a town of France, in the department of the Cote d'Or, in the district of Chatillon, 2½ leagues south of Chatillon.

AISIAMENTA, in *Law*. See **EASEMENT**.

AISNE, in *Geography*, a river of France, which rises in Champagne, runs by Soissons, and falls into the Oise above Compiègne. It gives name to a department which is one of the six formed of the *ci-devant* Soissonnois, le Beauvoisis, and le Vexin François; and it is one of the five into which the ancient Isle de France is divided. It is bounded on the north by the department of the North; on the east, by that of the Ardennes, and part of that of Marne; on the south, by part of Marne, and the department of Seine and Marne; and on the west, by the departments of the Oise and Somme. The extent is about 1,467,881 square acres, or 749,183 hectares; its population about 408,172 individuals; and it is divided into five communal districts. Its chief town is Laon.

AISTULPH, or **ASTULPHUS**, in *Biography and History*, king of the Lombards, was chosen to succeed his brother Rachis, who resigned the crown, A. D. 751; and by his gallantry in the field and wisdom in council advanced the kingdom to a pitch of grandeur, which occasioned its total ruin. Having ratified a peace with pope Stephen, and extended the term of it for 40 years, he seized the opportunity, which was afforded him by a war with the Saracens and Bulgarians, that engaged the attention of the eastern emperor Constantine Copronymus, to invade the exarchate of Ravenna, which he subdued, with all its dependencies, and added to the kingdom of the Lombards. Thus terminated the exarchate, which was reduced by the Lombards to a dukedom. Aistulphus proceeded to invade the Roman dukedom, and marching towards Rome, threatened to plunder the city and massacre the inhabitants, unless they acknowledged his sovereignty and paid him a yearly tribute. Pope Stephen was alarmed, and applied to the emperor for succour; but deriving no effectual assistance from the emperor, he recurred to Pepin, king of France, who marched an army into Italy, and after routing Aistulphus and his army invested Pavia, where he had taken refuge. The Lombard king was glad to purchase peace by restoring all the places he had taken, and even the exarchate, which was surrendered by Pepin to the see of Rome. But as soon as Pepin had departed, the Lombard king, in violation of his

engagements, and regardless of his hostages, approached Rome with his army and closely besieged it. Stephen renewed his application to his protector, and by the suppliant style of the letters which he addressed to him engaged him again to have recourse to arms. Aistulphus threw himself a second time into Pavia, whither he was pursued by Pepin, who closely invested the city. The siege was pressed with vigour, and Aistulphus reduced to such distress, that he was under a necessity of suing again for peace, which he obtained upon a promise to perform immediately the treaty that had been made the year before, and as an additional security to deliver up to the pope the city of Commachio, which was a place of great importance. Upon this Pepin renewed his donation to the pope; yielding to St. Peter and his successors the exarchate, Æmilia now Romagna, and Pentapolis now Marca d'Ancona, with all their cities, to be held by him for ever. See **EXARCHATE**. Aistulphus, lamenting the humbled state to which he was reduced, began again to prepare for recovering by force what he had been obliged to resign; but in the midst of his hostile preparations, he was killed whilst he was hunting, A. D. 756, and left no male issue. The code of laws which he published in the 5th year of his reign is still extant. *Anc. Un. Hist.* vol. xviii. p. 482, &c. Aistulphus and his queen are made the subject of a curious tale, of the free kind, to be found in *La Fontaine* and other *Novellists*. *Gen. Biog.*

AITHALIA, in *Geography*. See **ÆTHALIA** and **ELBA**.

AITOCZU, a considerable river of Lesser Asia, which rises in Mount Taurus, and falls into the south part of the Euxine sea.

AITON, **WILLIAM**, in *Biography*, an eminent botanist and gardener, was born in 1731 at a small village near Hamilton, in Lanarkshire, in Scotland. Having been trained betimes in the science and practice of horticulture, he came into England in 1754, and was engaged as an assistant by Mr. Philip Miller, well known as the author of the *Gardener's Dictionary*, who was then superintendent of the physic-garden at Chelsea. In this situation he soon attracted notice, and in 1759 he was recommended to the Princess Dowager of Wales, as a fit person to manage the botanical garden at Kew. In this office to which he was then appointed he continued during life; and here he laid the foundation both of his fame and fortune. As the garden at Kew was destined to be the repository of all the curious plants, that could be collected from the various quarters of the globe, Mr. Aiton had the most favourable opportunity for indulging his taste, and employing his care and skill in their cultivation; and in so doing he acquired distinguished reputation amongst the lovers of this science, and the particular esteem of his royal patrons. Under his superintendance Kew gardens became the principal scene of botanical culture in the kingdom. In 1783 Mr. Aiton was promoted to the more lucrative office of managing the pleasure and kitchen gardens at Kew, which he was allowed to retain in connection with the botanical department which he had before occupied. In 1789 he published his "*Hortus Kewensis*, or Catalogue of the Plants cultivated in the Royal Botanic garden at Kew," in three vols. 8vo. with 13 plates; a work, which had been the labour of many years, and which justly entitles him to respectful commemoration among the promoters of science. The number of species, contained in this Catalogue, is between 5 and 6000. A new and curious article in it relates to the first introduction of particular exotics into the English gardens. The system of arrangement is that of Linnæus, with such improvements as the advanced state of botanical science required. To Sir Joseph Banks, Dr. Solander, and Mr. Dryander, Mr. Aiton respectfully

spectfully acknowledges his obligations for assistance in compiling this celebrated work. The "Hortus Kewensis" was much valued by the best judges, and a large impression of it found a rapid sale. Notwithstanding the temperance and activity of Mr. Aiton, he laboured under the incurable malady of a scirrhous liver, which occasioned his death in 1793, in his 62d year. His eldest son, devoted to the same pursuits, and distinguished by his talents, was appointed, by the king's own nomination, to all his father's employments. The private character of Mr. Aiton was highly estimable for mildness, benevolence, piety, and every domestic and social virtue. He was interred in the church-yard of Kew, amidst a most respectable concourse of friends. Gen. Biog.

AITONA, in *Geography*, a small town of Spain in Catalonia, the capital of a marquisate.

AITONIA, in *Botany*, so called from Mr. W. Aiton, his Majesty's late gardener at Kew, a genus of the *monadelphica oelandria* class and order, and of the natural order of *columiferae*. Its characters are, that the calyx is a one-leafed, erect, four-parted, short perianthium, divided into four ovate, sharp segments; the corolla has four erect, equal, broadly-ovate, concave, very obtuse petals; the stamina have filaments, joined as far as the middle, divided above into eight, awl-shaped, furrowed, standing out of the corolla, and having ovate, furrowed anthers; the pistillum has a germ superior, ovate, smooth, subangular, style one, filiform, of the same length with the stamina, stigma obtuse, undivided; the pericarpium is an ovate dry, membranaceous, four-cornered, one-celled, brittle berry, the corners are produced and sharp; the seeds many, fixed to a column, globular and smooth. It varies with five-cleft, ten-stamened flowers. There is one species, *viz.* *A. capensis*, found at the Cape by Thunberg, and introduced here in 1774 by Mr. F. Masson. It has a shrubby stalk, six feet high, and a fruit resembling that of the winter-cherry. With us it is of slow growth and seldom exceeds three feet in height. At a sufficient age it produced flowers and fruit through the greatest part of the year. It is raised only from seeds, and must be kept in the green-house or cape-stove. Martyn.

AITTERBACH, in *Geography*, a river of Austria, which runs into the Traun, near Wels.

AITZEMA, LEO, in *Biography*, an eminent historian and diplomatist, was born at Doecum, in Friesland, in the year 1600. He was counsellor of the Hans Towns, and their resident at the Hague for 40 years; where he died in 1669, with the reputation of an excellent linguist, an able politician, and amiable manners. His "History of the United Provinces," written in Dutch, contains a large collection of treaties of peace, memoirs of ambassadors, letters, capitulations and other public acts, which is very valuable. The history is more faithful than elegant, and as far as it concerns religion, it is written with impartiality. The work was published in 15 volumes 4to. and was succeeded by another edition of seven volumes in folio. The period which the history comprehends begins with the year 1621 and terminates with 1668, and it has been continued to 1692. Gen. Dict.

AJUBATIPITA BRASILIENSIS, in *Botany*, the name of a shrub that bears a black fruit like an almond, which yields much oil.

AJUGA, *Bugula* of Jussieu, Tournefort and Miller, *bugle*, a genus of the *didynamia gymnospermia* class and order, and of the natural order of *verticillatae* or *labiate*. Its characters are, that the calyx is a one-leafed, short perianthium, cut half-way into five clefts, with the segments nearly equal;

the corolla is monopetalous and ringent; tube cylindric and bent in, the upper lip, very small, erect, bifid, obtuse, lower large, spreading, trifid, obtuse, middle division very large and obcordate, side ones small; the stamina have subulate, erect filaments, longer than the upper lip, anthers twin; the pistillum has a four-parted germ, style filiform, and with respect to situation and length as in the stamina, stigmas two, slender, the lowest shorter; no pericarpium, the calyx, which is converging, fosters the seeds, which are somewhat oblong. There are six species, *viz.* 1. *A. orientalis*, eastern bugle, with flowers inverted; first brought into Europe from the Levant by Tournefort, since observed by Thunberg in Japan, and by Loureiro in Cochinchina; cultivated in 1732. Of this there are two or three varieties, differing only in the colours of their flowers. 2. *A. pyramidalis*, pyramidal bugle, of which the spike is a quadrangular villous pyramid, the leaves approximating, the root-leaves very large, the bractæe nearly entire; biennial, flowering in April, or with us later; a native of Italy, France, Germany, Switzerland, Sweden, Denmark, Wales, and Scotland. 3.

A. alpina, alpine or mountain bugle, with stem simple, leaves smooth, unequally dentated, subuniform, the remoter verticilli bearing many flowers; growing naturally on the Alps, and in mountainous places in Carnarvonshire, Durham, and on the summit of a mountain near Castleton, Derbyshire; admitted into gardens for variety, and propagated by its trailing stalks; requiring a moist shady situation; perennial, and flowering in July. This is the *A. pyramidalis* of Hudson, and the *A. genevensis* of Withering. 4. *A. genevensis*, Geneva bugle, with leaves downy, streaked with lines, lowermost narrower, calyces shaggy, bractæe or floral leaves generally three-lobed; growing wild about Geneva, and in many of the southern countries of Europe; cultivated in 1759, by Miller. 5. *A. reptans*, common bugle, smooth, with solitary stem, and creeping by runners; perennial, flowering in May; growing in moist meadows, pastures, and woods in most parts of England; becoming somewhat hairy in high and dry situations, with a rounder stem and shorter creepers. Prof. Martyn mentions two varieties, one with a white and the other with a pale purple flower, which grow in several parts of Westmoreland; but they differ only in the colour of their flowers from the blue sort. The common bugle, called by officinal writers, *consolida media*, or middle confound, is recommended as a vulnerary herb, both internally and externally. For this purpose, infusions of the leaves, or the expressed juice, have been administered; and also as mild astringents and corroborants in fluxes and other disorders. Decoctions of them have been commended by Riverius and others in pthifises and internal ulcerations. Malouin recommends a gargarism of the root in the angina. The roots appear to be considerably astringent, both by their taste and by their striking a black colour with solution of chalybeate vitriol. Lewis Mat. Med. Murray Mat. Med. vol. ii. p. 154. 6. *A. decumbens*, Japanese bugle, decumbent and villous; leaves obovate and toothed; with flowers in whirls, small and blue; classed by Loureiro as a variety of *A. reptans*.

To this genus Dr. Smith adds (Flor. Brit. vol. ii. p. 605.) the *TEUCRIUM chamapitys* of Linnæus, the ground pine of English writers. Accordingly the *A. chamapitys* is described as having a spreading ramose stem, trifid linear entire leaves, and solitary axillary flowers. It grows in sandy fallow fields in Cambridgeshire and Kent; is annual, and flowers in April and May. The leaves of ground pine are moderately bitter, and of a resinous smell, approaching in this respect, as well as in their external form, to those of

the pine-tree. Their virtues are extracted both by water and spirit, but most perfectly by the latter. The aqueous tincture is yellowish, and the spirituous green. The watery extract is bitter and astringe; the spirituous is slightly sweetish and warm. The oil, collected by distilling large quantities of the herb, approaches in quality to that of turpentine. The leaves are recommended as aperients, and corroborants of the nervous system; and are said to be particularly serviceable in female obstructions, paralytic disorders, and when continued for a long time, in rheumatic, ischiadic, and gouty pains. It was denominated by some of the ancient botanists *yua arbutica*, from its use in arthritic pains. It has been recommended by foreign writers in slow fevers, asthma, and apoplectic seizures; and also in infarctions of the viscera and jaundice; and externally for cleaning and consolidating ulcers, as well as for an antidote to the cancer. But its medical reputation has, in later times, considerably declined. Lewis's Mat. Med. Murray Mat. Med. vol. ii. p. 152.

The first species of *Ajuza* may be propagated by seeds, sown when they are ripe in a pot filled with earth, and placed in a shady situation till Autumn, and then removed under a frame. In the Spring, they should be transplanted into separate pots. In the hard frost of Winter they should be covered. This species may be also more slowly increased by off-sets, of which it affords but a few. The sixth sort may be propagated in the same manner. As for the rest, they are hardy and easily multiplied by the side shoots: they delight in a moist shady situation, and are apt to spread too much. Martyn.

AJURU Parrot, *Psittacus Æstivus*, in *Ornithology*, the *Ajuru-Curau* of Maregrave, the *Aourou-Courau* of Buffon, the middle-sized parrot of Willughby, and the common Amazons parrot of Latham, is of a green colour, slightly spotted with yellow; with a blue front, blood-red shoulders, and flesh-coloured orbits. It is 12 inches long, and its body about the size of a pigeon: the back has a number of tawny yellow feathers, scattered through its green plumage. The face is yellow, with a blue forehead and white crown; the tail-quills are green with paler tips: the first, second, and third on each side are red on their inner webs near the base; the outer web of the first being blue: the shoulders are either tawny or blood-red; the primary wing-quills are black, with bluish tips, the outer webs being green, and the inner black; the first four or five of the secondaries have their outer webs red near the base; the bill is black at the tip. This species of parrot inhabits Amazonia, Guiana and Brasil; and it has several varieties, to the four first of which the above description is applicable: *e. g.* 1. The A. of Jamaica, with the head and breast yellow, the front and chin bluish, the edges of the wings and ventlet red. This is the *psittacus viridis melanorinchos* of Aldrovand, the black-billed green parrot of Willughby, and the Jamaica parrot of Brown and Latham. 2. The main A. parrot, with the lesser wing coverts red; the crown yellow, the cheeks and chin paler; the forehead blue; the under half of the five middle wing-quills, and the inner webs at the base of four tail-quills on each side, red. This variety inhabits Guiana and Amazonia. 3. Brazilian A. parrot, with cap blue, variegated with black; a yellow spot on the crown, and one on each side below the eyes, and a blue chin. This is the *ps.* Brasil. *cyanocephalos* of Brisson, the *Ajuru-curuca* of Maregrave, Ray and Willughby, and the blue-topped parrot of Latham. The primary wing quills, according to Mr. Latham, are variegated with yellow, red and violet blue. It inhabits Brasil. 4. Varied A. parrot, with the crown, cheeks and chin yellow,

Vol. I.

and the front blue. The crown is varied with blue, the serag and upper part of the back with yellow, and the bill is ash-coloured. This is the *Ajuru-Curau secundus* of Maregrave and Ray, and the West-India green parrot of Edwards and Latham. 5. Amazonian A. parrot, pale green, with a pale yellow front and tawny temples. This is the *ps.* *amazonicus* of Gmelin, and the Brazilian yellow fronted parrot of Latham. It inhabits Brasil and Amazonia. This variety is almost twice the size of those above-mentioned. 6. Great A. parrot, green, with a blue forehead; the crown, cheeks and chin, and middle of the belly yellow. It is nearly as large as the former, and inhabits Brasil. 7. Yellow-necked A. parrot, green, with yellow head and neck, and red shoulders; of the size of the former, and like it, the wing-quills are marked with a red spot, and the lateral tail-quills are red at the base. 8. Counterfeit A. parrot, green, variegated with yellow, having a blue forehead and red shoulders. It inhabits Brasil. Gmelin's Linn. tom. i. p. 340. Kerr's Linn. p. 598. Buffon's Birds, vol. vi. p. 187.

AJURU-CATINGA, the Guiana red billed parrot, a variety of the *PSITTACUS rufirostris*, the *psittaca aquarum Lupiarum insule* of Brisson, the Guiana green parrot of Baurcroft, and of Latham; has the bill, legs, feet and claws of a whitish red colour, and the orbits ash-coloured. It inhabits South America; and is about the size of a thrush, and the irides have two coloured circles, of which the outer is reddish, and the inner ash-coloured.

AJURU-PARA, a Brazilian species of parrot of a small size, all over of a beautiful green, and with white legs, a white beak, and white skinny circles round its eyes. Maregrave.

AIUS LOQUENS, or **LOCUTIUS**, *i. e.* a speaking voice, in *Mythology*, the name of a Roman deity, to whom a temple was erected at Rome, on the following occasion.—M. Cæditius, a plebeian, informed the tribunes, that, as he was passing through the New Street in the night, he heard a supernatural voice near the temple of Vesta, which warned the Romans of the approach of the Gauls; but the warning was disregarded on account of the meanness of the person who reported it, in consequence of which, the Romans suffered very much from their invasion. Camillus, however, delivered them, and advised them to expiate the offence by erecting a temple in the New Street to this imaginary deity. Cicero, de *Divin.* lib. i. § 45. Oper. tom. iii. p. 45. Ed. Olivet. Plutarch in *Cam.* Oper. tom. i. p. 144. Ed. Xyland. Livy lib. v. c. 50. Oper. tom. ii. p. 220. Ed. Drakenb.

AJUTAGE, or **ADJUTAGE**, formed of the verb, *ajouter*, to adapt, in *Hydraulics*, part of the apparatus of an artificial fountain, or *jet d'eau*; being a sort of tube, fitted to the mouth or aperture of the vessel, through which the water is to be played, and by it determined into any figure and direction.

It is chiefly the diversity in the *ajutages*, that makes the different kinds of fountains.—And hence, by having several *ajutages* to be supplied occasionally, one fountain comes to have the effect of many.

Marriotte inquires into the best kind of *ajutages*, or spouts, for *jets d'eau*, affirming, from experiment, that an even polished round hole, in the end of the pipe, gives a higher jet than either a cylindrical, or a conical *ajutage*: of which, however, the latter is the better. Vide *Trait. du Mouvem. des Eaux*, part. iv. Phil. Trans. N^o 181.

The quantity of water discharged by *ajutages* of equal area, but of different figures, is the same. But for those of like figures, and different sizes, the quantity discharged is

directly proportional to the area of the ajutage, or to the square of its diameter, or of any side or other linear dimension: thus, an ajutage of a double diameter or side will discharge four times the quantity of water, of a triple diameter, nine times the quantity &c.; supposing that they are at an equal depth below the surface or head of water. But if the ajutages be at different depths, the celerity with which the water flows, and consequently the quantity issuing in any given time, is directly proportional to the square root of the altitude of the head, or the depth of the hole, so that at four times the depth, the celerity, and of course quantity, are double; at nine times, triple, &c. It has been found by experiment, that the jet is higher or lower according to the size of the ajutage; that a circular hole of about an inch and a quarter in diameter jets highest; and that it is worse as it recedes from that size. Experience also shews, that the pipe leading to the ajutage should be much larger than the ajutage itself; and if the pipe be long, it should be wider according to its distance from the ajutage. *Encyclopedic Physique*, tom. i. p. 152. Hutton's Dict.

For the various sorts of ajutages, their structure, application, &c. see FOUNTAIN. See also FLUID and JET D'EAU.

AIX, in *Geography*, a city of France, the capital of the department of the Bouches du Rhone, formerly Provence, and one of the most pleasant and best-built cities in the kingdom. It is situated north of the river Arc, between hills planted with olives and vines. It is said to have been founded by C. Sextius Calvinus, a Roman consul, who established a Roman colony in it A. U. C. 630, about 124 years before Christ, and called it *Aqua Sextia* from his own name, and the warm baths which he found there. It is rather populous than large; its houses are well built, and its streets are straight and well paved; and within the city there is a spacious walk called Orbitelle, which consists of three rows of trees interspersed with fountains, and surrounded by many handsome and spacious buildings. The preacher's square, as it is called, is seated on the side of a hill, about 160 yards long, encompassed with trees and lofty houses built with stone. Of the public buildings some of the principal are the town-hall, the hall of audience, the hotel of the city, the cathedral church, which is a fine gothic structure, the church of the fathers of the oratory, the chapel of the blue penitents, and the convent of the preachers, in whose church is a silver statue of the Virgin Mary, almost as big as life. There are also other churches and buildings, which contain many paintings and other rarities. Adjoining to the baths, which were re-discovered in 1704, there are many edifices that have been raised at a great expence for the accommodation of those who use the waters. These waters were formerly supposed to possess peculiar virtues in cases of debility; as several altars consecrated to Priapus, and bearing inscriptions expressive of gratitude for his assistance, have been dug up in their vicinity. Aix was an archbishopric with five suffragans, and 84 parishes; and it was the place of resort of the nobility of Provence and of literary men. The neighbourhood affords excellent wines; but its chief article of trade is oil. Some stuffs are also manufactured here. It is distant five leagues north from Marseilles, and 163 south-east of Paris. N. lat. $43^{\circ} 31' 35''$. E. long. $5^{\circ} 26' 15''$.

AIX, a town of France, in the department of the Upper Vienne, in the district of Limoges; two leagues west-south-west of Limoges.

AIX, *Aqua Gratiana*, or *Subaulica*, *Allobragum*, a small town of Savoy, situate near the lake of Bourget, between

Chambery, Annecy and Rumilly, with the title of a Marquisate. The hot baths, which were originally constructed by the emperor Gratian, are free of access without expence, and are much frequented. In this place are seen the ruins of a Roman triumphal arch. N. lat. $45^{\circ} 40'$. E. long. $5^{\circ} 48'$.

AIX, a small island on the west coast of France, between the isle of Oleron and the Continent; about 12 miles north-west of Rochfort, and as far south-south-west of Rochelle. Its fort was destroyed by the English in 1757, and again in 1761, but afterwards rebuilt. N. lat. $46^{\circ} 5'$. E. long. $1^{\circ} 8'$.

AIX en Othe, a town of France, in the department of the Aube, in the district of Evry; five leagues west of Troyes.

AIX d'Anguillon, a town of France, in the department of the Cher, in the district of Bourges; three leagues north-east of Bourges.

AIX-LA-CHAPELLE, a free Imperial city of Germany, in the circle of Westphalia and duchy of Juliers, and the capital of the department of Roor. This is a very ancient city; and appears from the testimonies of Cæsar and Tacitus, to have been occupied and fortified by Roman colonies in their wars with the Germans. It was called in Latin *Aquis-Graunum*, or the waters of Granus, *Aque*, and *Urbs Aquis*; in German, the city of Aachen or Achen, and also *Aach*; and derived its name from its warm baths, which have been long held in high estimation. By the French it is denominated *Aix-la-Chapelle*, by way of distinction from other places called Aix, on account of a chapel of the Holy Virgin built by Charlemagne, who repaired and beautified the city, which had been destroyed by the Huns in the reign of Attila in 451, and who made it the place of his usual residence. The king of the Romans or emperor, was generally crowned in this city, as the place appointed by the golden bull for this purpose; and on this account called the Royal city; and it is the depository of the sword of Charlemagne, the belt, a book of the gospels, and other jewels of the empire, that are used in the ceremony of coronation. Charles V. was crowned here in 1520, and Ferdinand his brother was crowned king of the Romans in this place in 1531. Charlemagne died and was buried in this city, to which he had always manifested a peculiar attachment, and on which he conferred many signal privileges. On the Rhenish bench, in the college of the cities of the empire, and among the Imperial cities which have a feat and voice at the Diets of the circle of Westphalia, *Aix-la-Chapelle* possesses the second place; and it lays claim to the first on the Rhenish bench. The town is situated in a valley, and though surrounded with mountains and woods is not unwholesome. It consists in reality of two cities, enclosed one within the other. The inner city, which is the most ancient, is flanked with ten towers, and is about three quarters of a league in circumference; the outer, founded about the year 1172, has eight gates, and the circuit of it is about two leagues. There are several rivulets which run through the city, and 20 public fountains, besides several private ones. The principal buildings, which are constructed of stone from quarries in the vicinity of the town, are the stadthouse and the cathedral. The stadthouse is adorned with the statues of all the emperors since Charlemagne; and in the front of it there is a fountain, on the top of which is placed the statue of this emperor, made of brass gilt, holding in his right hand a sceptre, and in his left a globe. The upper story of this building consists of one room, 162 feet long and 60 broad, in which the newly elected emperor formerly entertained all the electors of the empire. The government of this city is entrusted with the great and little senate;

senate; the former composed of 129 persons, who judge in criminal cases, and the latter of 41 members, who have jurisdiction over the police and commerce of the city, and the management of the public revenues. The duke of Brabant is protector of the city; and the duke of Juliers is burgo-masser or perpetual mayor of the burghers. The title of its magistracy is that of burgo-masser, sheriff, and council of the holy Roman Imperial free city of Aix-la-Chapelle. The prevailing religion is the Roman Catholic; and the Protestant inhabitants, both Lutherans and Calvinists, not allowed the free exercise of their religion within the city, celebrate their worship at Vaels, about an hour's journey from the city in the duchy of Limburg. The manufactures of the city are those of cloth, copper and brass. Councils have been held in this city in the eighth and ninth centuries, and treaties of peace have been concluded here; particularly those between France and Spain in 1668, and between France and England, and other belligerent powers in 1748. Busching. vol. iv. p. 369. Mod. Un. Hist. vol. xxxii. p. 223.

It was taken by the French in 1792, lost after a severe battle in 1793, and retaken in 1794. It is 21 miles from Spa, 30 west from Cologne, and 36 north-east from Liege. N. lat. 51° 55'. E. long. 5° 54'.

Aix-la-Chapelle, says Mr. G. Forster, in his Travels 1792, which once contained above 100,000 inhabitants, has not now a third part of this number, and has lost all its ancient wealth and prosperity; owing partly to the rise of rival towns, but principally to religious intolerance and a bad government. The streets now swarm with beggars, and the morals of the people are licentious and corrupt. Those whose skill and industry might have enriched the city are driven from it by the partial and oppressive conduct of the guilds, and have established their manufactories in other places, where they enjoy greater liberty. Those, he adds, of Burscheid, Vaels, Eupen, Monjoia, and of other places in the duchy of Limburg, are in a very flourishing state; the wool is imported from Spain, and the cloth is exported chiefly to the Levant. Vaels, which 30 years ago, was an inconsiderable village, is now become a respectable town; the protestants, weary of the oppression and bigotry which they had experienced at Aix-la-Chapelle, were easily induced to settle in a place where they were allowed the advantages of religious freedom; and it has now five different churches, in which Roman Catholics, Lutherans, Calvinists, Baptists, and Jews, worship the Deity according to their several sentiments, and live peaceably with each other.

AIX-LA-CHAPELLE, or AIXEN Waters. *Therma Aquis-granenses.*

The thermal sulphureous waters of Aix-la-Chapelle have long held a most distinguished place among the mineral springs of Europe, and have not a little contributed to the celebrity and opulence of this ancient city.

These mineral waters rose to very high reputation in the time of Charlemagne, who made Aix his Imperial residence; and he appears to have much delighted in the use of its baths, which he rebuilt and improved.

The hot sulphureous water rises in great abundance from several copious springs in different parts of the town; and is more than amply sufficient to supply the numerous baths and reservoirs in which it is collected. The principal spring is enclosed in a square stone cistern, the upper part of which is vaulted and contracted in its dimensions; and over the top a large stone is fitted in, and closely cemented, to prevent the escape of the sulphureous vapours, on which depends so much of the efficacy of the water. A remarkable circumstance takes place in this cistern, which is, the actual sublimation of a quantity of pure sulphur, which

is carried up from the water along with the sulphureous gas, and is deposited beneath the upper stone, to which it adheres in the form of a fine powder. This is taken out from time to time, and sold under the name of *Aix sulphur*.

The baths of this city are numerous, and very commodious for the purpose of warm and vapour bathing. The natural heat of the water is sufficient for both these purposes; and for the latter, openings are made in the brick channels that convey the water to the baths, through which the vapour ascends. These vapour baths are so constructed that the whole, or any part of the body may be exposed to its action; and likewise many of the baths are furnished with pumps, from which the hot water may be dashed on any part of the patient. This operation is known by the technical name of the *douche*.

Aixen water possesses very striking sensible properties, particularly to the feeling and the smell. The water rises with great rapidity through the springs; and at the same time sends forth very copious air-bubbles, which break on the surface with a slight explosion. It is at first perfectly clear and colourless, and emits a large volume of steam, mixed with sulphurated hydrogen gas of great volatility and pungency. The odour of this vapour, (which resembles that of Harrowgate water, is so powerful as to be perceived by strangers at a considerable distance from the spring head. The inhabitants, from long custom, scarcely regard it.

The temperature of Aix water is various, according to the distance from the spring at which the observation is made. The highest is about 143° of Fahrenheit; and at the pump, where it is drawn for drinking, it is about 112. The heat is therefore so great, that the water requires to stand for 15 or 18 hours before it can be used as a bath.

This water, though perfectly clear when first drawn from the spring, becomes turbid and somewhat milky as it cools, and deposits a calcareous sediment, at the same time it loses its sulphureous smell. To the touch, the water is soft and somewhat saponaceous, owing doubtless to the small quantity of soda which it contains. It will even, in some degree, lather by agitation; and is used for fulling and cleansing wool and linen, to which also, the heat much contributes.

The chemical analysis of this water is curious and interesting. The most striking feature is its gaseous contents, which are a small quantity of carbonic acid, but especially much sulphurated hydrogen gas; not merely in the state in which it is found, in the cold sulphureous waters of Great Britain, but highly supersaturated with sulphur, which is sublimed in a solid form, as we have just mentioned. The whole of the sulphur contained in the water is volatilized by evaporation, for no traces of this inflammable substance are to be detected in the residuum of any quantity of the water boiled down to dryness.

The solid contents of this water are few. The most important of these is a quantity of uncombined soda, sufficient to give the water the properties of a very dilute alkaline solution; and which probably assists in the union of so large a portion of sulphurated hydrogen, and causes it to adhere to the water with somewhat more force than it would do if no alkali were present. Hence it is, that even after the water has stood for many hours in the baths to cool, it still retains enough of the sulphureous vapour to give it all the requisite medical virtues. The other solid contents are, a small quantity of common salt and carbonated lime, which last is deposited as the water cools, and the carbonic acid escapes.

No traces of metal of any kind are discoverable in this water.

The solid contents of Aix water are variously estimated as to quantity. From Bergman's analysis, we may reckon the following to approximate pretty accurately to the truth. A wine pint (English weight and measure) contains

Of carbonated lime, four grains and three quarters.

Of common salt, five grains.

Of carbonated soda, twelve grains.

The proportion of the gaseous contents has not been ascertained with accuracy.

The above analysis will explain the appearances which take place with the common reagents.

Solutions of Lead and silver, added to the hot fresh water, produce a blackish precipitate, composed of the sulphurated metal, but mixed with the muriate; for, when the same solutions are added to the cooled water, the precipitate is white.

A piece of polished lead, suspended in the vapour of the water, is soon blackened, and in a few days corroded throughout.

Syrup of violets changes to a green, even after the carbonate of lime has precipitated by cooling, indicating thereby the presence of an alkali in excess.

The effects of this water, as a medicine, are very striking and well established. Its immediate operation, when drunk in a moderate quantity, is to raise the spirits, and in some persons to produce a degree of vertigo. This is the greater, *ceteris paribus*, the hotter the water is. It afterwards proves diuretic, increases perspiration, and keeps the skin in a soft, moist state, highly favourable to the removal of many disorders.

The waters are resorted to for a great variety of complaints, particularly in the complicated disorders of the digestive and biliary organs, which follow a long habit of free living. They are also highly serviceable in diseases of the kidneys and bladder.

Aken waters, like all the most celebrated thermal springs, were long in high repute as baths, before physicians ventured to prescribe them internally. The vast profusion of water which is thrown up, the high temperature which it possesses, its strong impregnation with sulphur in a very active form, and its alkaline ingredient, give it most valuable properties for external uses. It is employed to stimulate cold paralytic limbs; and to soften the rigidity of the joints and ligaments left by gout and rheumatism. It is also of great service in cutaneous complaints, to the cure of which, the sulphur and the alkali probably highly contribute. A long continued course of this, (as of every other) sulphureous water, causes the whole body to acquire a smell of sulphur, and tarnishes silver kept in the pockets.

These waters have been imitated artificially by passing sulphurated hydrogen gas through a hot and very weak alkaline water, but the imitation is attended with much difficulty.

See Blondel's *Descript. Therm. Aquigranensium*—Lucas on *Mineral Waters*—and Saunders's *Treatise on Mineral Waters*, 1800.

AIXO, or ΑΙΧΟΣ, flats or shallows within the second fort, at the entrance into Carthage harbour, on the Spanish main, South America, which stretch out nearly south-south-east, towards the main land within the islands that lie before the harbour.

AIZENAY, a town of France, in the department of Vendée, in the district of La Roche sur Yonne; ten leagues south of Nantes.

AIZOON, Αἰζών, *semper-vivum*, or *ever-living*, in *Botany*, a genus of the *icofandria pentagynia* class and order, of the natural order of *succulenta*, and of the *ficoidea* of Jussieu.

In Gmelin's *Linnaeus*, it is a genus of the *polyandria pentagynia* class and order. Its characters are, that the calyx is a one-leaved perianthium, divided into five lanceolate, permanent segments; no corolla: the stamina have very many capillary filaments, inserted by bunches into the sinuses of the calyx, the anthers simple; the pistillum has a germ five-cornered, superior, the styles five and simple, the stigmas simple: the pericarpium is a five-celled, five-valved, swelling and retuse capsule; the seeds are several, roundish or kidney-shaped. There are ten species, *viz.* 1. *A. canariensis*, purslane-leaved *A.* with leaves wedge-ovate, flowers sessile; the *ficoidea* of Nissolinus, and *kali* of Plukenet: a native of the Canary islands; annual; cultivated in 1731. 2. *A. hispanicum*, Spanish *A.* with leaves lanceolate; flowers sessile; the *ficoidea* of Dillenius; an annual plant, growing naturally in Spain and Africa; a variety of this was brought from the Cape, and cultivated in 1728. 3. *A. lanceolatum*, panicle *A.* with leaves lanceolate, flowers panicled; biennial; growing naturally at the Cape of Good Hope; cultivated in 1759. 4. *A. farmentosum*, with leaves linear-filiform, panicle dichotomous, flowers solitary, peduncled; brought from the Cape by Sparrman. 5. *A. paniculatum*, shaggy, leaves lanceolate, flowers sessile, branches erect. 6. *A. perfoliatum*, downy, leaves inversely-ovate, conjoined, crystalline-dotted-flowers, peduncled. 7. *A. glinoides*, hairy *A.* shaggy, herbaceous, procumbent, leaves ovate, flowers sessile, distinct. 8. *A. fecundum*, shag-hoary, herbaceous, procumbent, leaves ovate, flowers sessile, imbricate, one-ranked. 9. *A. fruticosum*, shrubby *A.* shrubby, erect, smooth, leaves lanceolate, flowers sessile. 10. *A. rigidum*, stiff *A.* shrubby, procumbent, downy, leaves ovate, flowers sessile, remote. The six last species were brought from the Cape by Thunberg. The three first species may be raised on moderate hot-beds, in the spring; and the other species must be managed like other Cape plants.

AIZOON. See *SEDUM*.

AIZU, in *Geography*, a town of Japan, and capital of a small country of the same name.

AKABA, a gulf or arm of the Red-Sea, formed by a tongue of land, which is part of Arabia, that separates this gulf from that of Suez; about 30 leagues long and 3 wide.

AKABAR, or CALAAT EL AKABA, a town of Arabia, on the gulf to which it gives name; 57 leagues south Jerusalem, and 53 leagues east Suez.

AKACHAN, a river of Siberia, which joins the Judoma. N. lat. 60° 8'. E. long. 139° 22'.

AKALCALAKI, a town of Georgia, in Asiatic Turkey, about 70 miles south-west of Teflis, and 88 miles north-west of Erivan.

AKALZIKA, or ACALZIKE, a town of Asiatic Turkey, in the province of Satabago, a country of Georgia. See *ACALZIKE*.

AKAM, or ACAM, a country of Africa, on the coast of Guinea, near the source of the Volta.

AKANIMIMA, a town or village of Africa, on the Ivory coast, near Cape Apollonia. It stands on rising ground, and commands an extensive sea and land prospect.

AKANNI. See *ACHEM*.

AKANSA, a town of North America, in South Carolina, situate on the river Mississippi, near a river of the same name. N. lat. 36°. W. long. 89° 46'.

AKAOT, a town of Hindostan, in the district of Berar. N. lat. 21° 13'. E. long. 77° 38'.

AKARA, in *Botany*, a species of *CALOPHYLLUM*.

AKAS, in *Geography*, a small town of Pennsylvania, between the river Carasna and a branch of that river, not far from Zaturan.

AKASAKI,

AKASAKI, a town of Japan, in the province of Mikava.

AKASI, a town of Japan, in the province of Farina.

AKASSEB-ASSELAM, a town of Egypt, marking the boundary of Asia and Africa.

AKAST, a town of Arabia, 25 leagues east of Jerusalem.

AKBAR, or AKBER, SULTAN, in *Biography and History*, the sixth of the descendants of Timur Bek or Tamerlane, who reigned in Hindostan under the appellation of Moguls, was born in 1542, and succeeded his father Hemaïum in 1556. He was proclaimed emperor at Calanor, in the province of Labore, and assumed the title of *Jilal O'din, q. d.* the aggrandizer of religion. Having overthrown the Patans and taken possession of Dehli, he was inaugurated in this city, and assumed the government which had been at first administered by his tutor, Beyram Khan. He then made himself master of the strong fortrefs of Chitor, after a severe engagement with a rebel chief, and quelled other insurrections; and having obtained an interval of tranquillity, he made a pilgrimage, barefoot, to Azmir, at the distance of 200 miles, for the purpose of visiting the tomb of Haji Mondi, and of obtaining children by the intercession of this saint. During his abode at Pettipur on his return, he was informed of a rebellion at Guzerat, which hastened his march to this province; and having subdued the rebels, reduced the castle of Surat, and secured the province by fortifying Ahmed-abad, he returned to Hindostan. In this year he finished the castle of Agra at an expence of two millions 500 thousand rupees, laid out 1½ million on the walls and palace of Pettipur, and began to erect the sumptuous sepulchres of his family at Schander, five miles from Agra. At this time he directed his views to the conquest of Bengal, and having, after a long siege, taken possession of Patan, he became master of the whole country. His next acquisitions were Kabul, Kandahar, Kashmir and Sindi. Having united these countries to his empire, he employed a powerful army in the invasion of Dekan, which, notwithstanding vigorous resistance on the part of the queen of this country, subdued several provinces and annexed them to the Mogul empire. Whilst Akbar was engaged in the prosecution of the Dekan war, his prosperity was interrupted by a concurrence of domestic misfortunes. He was deprived of two of his sons, *viz.* Sultan Morad, in 1598, and Sultan Danul, in 1604, by intemperance; and his son Selim took the advantage of his absence, for seizing his treasures and marching a numerous army towards Agra, in order to take possession of his father's throne. Akbar, as soon as he received intelligence of his son's rebellion, hastened back to Agra, and having made ineffectual overtures of accommodation, in enforcing which his Vizir ABUL FAZL lost his life, he resolved to turn his arms against Selim. But as he had lost his other sons, he once more attempted to persuade his son into submission. With this view he employed the tutor of Selim to convey letters to him, in which he reproached him for his rebellion; but at the same time declared, that, as he was his only son and heir, he was ready to receive him to favour. The father's letters and the tutor's arguments produced effect; Selim returned to Agra and submitted. Akbar at first treated him with austerity, but at length pardoned him, though he still retained suspicions of his son's fidelity. The emperor did not long survive this reconciliation. Being incensed against a Mirza, who governed one of his provinces, he resolved to remove him by poison; and for this purpose he ordered two pills of opium, in one of which there was poison. Having held these in his hand for some time, he gave one to the Mirza, and by mistake took the poisoned one himself. The consequence, notwithstanding the use of remedies as

soon as the mistake was discovered, was fatal. When Selim paid his dying father a visit, he put his own turban on the prince's head, and girt him with his father Hemaïum's sword; but on the 12th day after he had taken the poison, Akbar died, A. D. 1605, at the age of 63 years, and was buried in the family sepulchre near Agra.

Akbar was distinguished by his conquests, and by his success in reducing almost the whole of India to obedience. He was also one of the few sovereigns intitled to the appellation both of Great and Good, and the only one of the Mohammedan race, whose mind was so far divelled of the illiberal prejudices of the fanatical religion in which he was educated, as to be capable of forming a plan worthy of a monarch who loved his people, and was solicitous to render them happy. Although he was not attached by profession to any form of religion himself, he was not a persecutor of any. In 1582 he wrote a letter to the king of Portugal, preserved by Frazer, and containing an avowal of sentiments liberal and enlightened; in which he desires that a translation of the Christian scriptures into Arabic or Persian might be sent him, and at the same time a learned person to explain the Christian religion. One Geronimo Xavier was deputed, and with this view learned the Persian language; but the gospels, which were translated into this language, and presented to the Mogul in 1602, were so intermixed with popish legends, that they were not likely to be very intelligible or to produce any very good effect. As in every province of his extensive dominions, the Hindoos formed the great body of his subjects, Akbar endeavoured to acquire a perfect knowledge of their religion, their sciences, their laws, and their institutions; in order that he might conduct every part of his government, particularly the administration of justice, in a manner as much accommodated as possible to their own ideas. In these generous views he was seconded by Abul Fazl, a minister whose understanding was not less enlightened than that of his master. By their assiduous researches, and consultations of learned men, such information was obtained as enabled this Vizir to publish a brief compendium of Hindoo jurisprudence in the *Ayeen Akbery*, which may be considered as the first genuine communication of its principles to persons of a different religion. In what estimation the mild government of Akbar was held by the Hindoos we may learn from a beautiful letter of Jesswant Sing, Rajah of Joudpore, to Aurengzebe, his fanatical and persecuting successor. "Your royal ancestor, Akbar, whose throne is now in heaven, conducted the affairs of this empire in equity and firm security for the space of 52 years, preserving every tribe of men in ease and happiness. Whether they were followers of Jesus, or of Moses, of David, or of Mahomed; were they Brahmins, were they of the sect of Dharians, which denies the eternity of matter, or of that which ascribes the existence of the world to chance, they all equally enjoyed his countenance and favour; inasmuch that his people, in gratitude for the indiscriminate protection which he afforded them, distinguished him by the appellation of *Juggot Groco*, guardian of mankind.—If your Majesty places any faith in those books, by distinction called divine, you will there be instructed, that God is the God of all mankind, not the God of Mahomedans alone. The Pagan and the Musulman are equally in his presence. Distinctions of colours are of his ordination. It is He who gives existence. In your temples, to his name the voice is raised in prayer; in a house of images, where the bell is shaken, still He is the object of adoration. To vilify the religion and customs of other men, is to set at naught the pleasure of the Almighty. When we deface a picture, we naturally incur the resentment of the painter; and justly has the poet said,

said, presume not to arraign or to scrutinize the various works of Power divine." For this valuable communication, we are indebted to Mr. Orme; Fragments, notes, p. 97. Frazer's Hist. Nadir Shah, p. 11—18. Mod. Un. Hist. vol. v. p. 365—375. Robertson's Hist. Disquisition concerning India, p. 424.

AKBEIK-BABA, in *Geography*, a town of Natolia, in Asiatic Turkey, 12 leagues north of Kutaja.

AKDASCH, a large and flourishing market town of Schirwan, in the territory of the Chan of Scheki; situate to the south of Nuchi, on the bank of the Kur, and consisting of about 300 houses. To this town all the neighbouring nations resort for trade and the barter of their commodities.

AKEARADI, a country of Africa, on the Gold Coast.

AKEFORD BAY, lies on the north side of the island Holmsby, to the west of the North Cape. N. lat. 71° 10'. E. long. 24 30'.

AKEN, JOHN VAN, in *Biography*, an engraver, who, from the style of his etchings, is supposed to have lived in the 16th century. He is a different person from Achan the painter.

AKENSIDE, MARK, M. D. more known as a poet than as a physician, was born at Newcastle-upon-Tyne, in 1721, and intended by his parents for a minister among the Protestant Dissenters; and with this view he was sent to Edinburgh, in 1739, at the age of 18. Having here acquired a stronger propensity to the study of physic than to that of divinity, he removed to Leyden in 1742, and took his degree of doctor in that faculty in 1744. In that year, besides his thesis, "De ortu et incremento fetus humani," delivered on account of his degree, he published his celebrated poem "on the Pleasures of the Imagination," which was received with great applause, and advanced the author to poetical fame. It is said, that when Pope was shewn the poem in manuscript by Doddsley, to whom it had been offered for a larger sum than he was inclined to give, he advised the bookseller not to make a niggardly offer, for the author of it was no every day writer. It has been also furnished, that this poem and some others were written before he went to Edinburgh. The poem, on its publication, was severely attacked by Mr. (afterwards bishop) Warburton, not on account of its poetry, but for some remarks which the author had introduced on the nature and objects of ridicule; and vindicated by an anonymous friend, since known to be Mr. Jeremiah Dyson. The next publication was "an Epistle to Curio," which contained a warm invective against Pulteney, earl of Bath, on account of his political conduct. In 1745, our author published ten odes on different subjects, and in different styles and manners. In his subsequent publications he was more slow. His ode to the earl of Huntingdon appeared in 1748; and in 1758, he attempted to rouse the national spirit, by an ode to the country gentlemen of England. Most of his remaining poetical effusions appeared in Doddsley's collection; and of these the most considerable is, a "Hymn to the Naiads." His poems were collected and published in a quarto volume, in 1772, by Mr. Dyson.

On his return from Leyden, he settled as physician at Northampton; from thence he removed to Hampstead; where he continued about two years and an half; and finally settled in London, where his friend, Mr. Dyson, allowed him 300l. a year, in order to enable him to maintain his rank as a physician. His medical reputation and practice gradually increased, and he was chosen a fellow of the Royal Society, appointed physician to St. Thomas's hos-

pital, admitted by mandamus, to the degree of doctor in physic, in the university of Cambridge, elected a fellow of the Royal College of Physicians in London; and, upon the establishment of the queen's household, advanced to the rank of one of her majesty's physicians. Notwithstanding his acknowledged abilities, and the singular patronage by which he was distinguished, he never arrived at any very considerable eminence in his profession. It has been said, that he had a kind of haughtiness and ostentation in his manners, which were not calculated to ingratiate him with his brethren of the faculty, or to render him generally acceptable.

He died of a putrid fever in June 1770, in the 49th year of his age, and was buried in the parish-church of St. James's, Westminster. His books and prints, of which he was a curious collector, came, after his death, into the possession of Mr. Dyson.

His medical writings were his "Dissertatio de Dysenteria," written in Latin, and much admired for the elegance of the language, published in 1764, and twice translated into English; "Observations on the origin and use of the Lymphatic vessels in animals," printed in the Phil. Transf. for 1757; and vindicated against the remarks of Dr. Alex. Monro, in a small pamphlet, published in 1758; "An account of a Blow on the Heart and its effects," published in the Phil. Transf. for 1763; "Oratio Anniversaria, ex instituto Harveii, &c." read in 1759, and published in 4to in 1760; "Observations on Cancers;" "Of the use of Ipecacuanha in Asthmas;" "A method of treating White Swellings of the Joints," all published in the first volume of the Medical Transactions.

In Dr. Aken-side's poems, and the notes annexed to them, we may discover his extensive acquaintance with ancient literature, and his ardent attachment to the cause of civil and religious liberty. His politics were thought to incline to republicanism, but no evidence to this purpose is deducible from his poems; and his theology is supposed to have verged towards deism: and yet, in his ode to Hoadly, and to the author of the Memoirs of the House of Brandenburg, he has testified his regard for pure Christianity, and his dislike of attempts for setting men free from the restraints of religion. Our readers may be gratified with the following extract from the first of these odes.

"To him the teacher blest'd,
Who sent religion from the palmy field
By Jordan, like the morn to cheer—the west,
And lifted up the veil which heav'n from earth conceal'd,
To Hoadly thus his mandate he address'd:
Go, then, and rescue my dishonour'd law
From hands rapacious, and from tongues impure:
Let not my peaceful name be made a lure,
Fell persecution's mortal snares to aid:
Let not my words be impious chains, to draw
The free-born soul in more than brutal awe,
To faith without assent, allegiance unrepaid."

Dr. Aken-side's rank among the English poets is assigned to him in consequence of his "Pleasures of the Imagination," founded on Addison's well known papers on the same subject, in the Spectator:—"the most beautiful didactic poem," says Mr. Cooper, in his letters concerning taste, "that ever adorned the English language;" and though abstracted in its nature, so popular, that when it first appeared, it passed through several editions, and "is still read," says an excellent judge (Dr. Aikin), "with enthusiasm by those who have acquired a relish for the lofty conceptions of pure poetry, and the strains of numerous blank verse." The merit of this poem, and of the writer,

is so justly appreciated by Mrs. Barbauld in an Essay prefixed to an ornamented edition of this poem, published in 1795, that we shall gratify our readers by subjoining a part of the summary with which it concludes. "If the genius of Akenfide is to be eliminated from this poem, it will be found to be lofty and elegant, chaste, correct, and classical; not marked with strong traits of originality, not ardent nor exuberant. His enthusiasm was rather of that kind which is kindled by reading and imbibing the spirit of authors, than by contemplating at first hand the works of nature. As a versifier, Akenfide is allowed to stand amongst those who have given the most finished models of blank verse. His periods are long but harmonious; the cadences fall with grace, and the measure is supported with uniform dignity. His muse possesses the *mien erect, and high commanding gait*. We shall scarcely find a low or trivial expression introduced; a careless and unfinished line permitted to stand. His stateliness, however, is somewhat allied to stiffness. His verse is sometimes feeble through too rich a redundancy of ornament, and sometimes laboured into a degree of obscurity from too anxious a desire of avoiding natural and simple expressions." Biog. Brit. Gen. Biog.

AKERKUF, in *Geography*, a mountain of Asiatic Turkey, east of the Euphrates, in the government of Bagdad. Tavernier placed it between the Euphrates and the Tigris, supposing that the ruins found here are those of the tower of Babel.

AKERMAN, or BIELGOROD, in *Geography*, a town of Bessarabia, on the coast of the Black Sea, at the mouth of the Dneister, 22 miles south-east of Bender. E. long. $31^{\circ} 14'$. N. lat. $46^{\circ} 8'$.

AKERSLOOT, WILLIAM, in *Biography*, a painter and engraver, who lived at Haarlem, and flourished in 1624.

AKERSUND, in *Geography*, a bay on the coast of Norway, ten leagues west-north-west of Frederickstadt.

AKHISAR, q. d. *white-castle*, a name given by the Turks to the ancient THYATIRA, on account of the white marble that abounds there. It is a town of Natolia, in Asiatic Turkey, 13 leagues east-south-east Pergamo; situate in a fertile plain on the river Hermus, abounding with grain and cotton, and carrying on a commerce of opium and Turkey carpets. N. lat. $38^{\circ} 50'$. E. long. $28^{\circ} 30'$.

AKI, a province of Japan, in the western part of the island of Nippon; with a town of the same name.

AKIBA, in *Biography*, a famous Jewish Rabbi, lived in the first century of the Christian æra, soon after the destruction of Jerusalem, and devoted himself to the study of the Cabbalistic philosophy. In the earlier period of his life, and till he was 40 years of age, he was a shepherd in the service of a rich citizen of Jerusalem; but his master's daughter having promised to marry him, if he became a learned man, he assiduously applied to study. So successful was his application, that he became one of the most famous teachers in the schools of Jewish learning, first at Lydda, and afterwards at Jafna; and if the Jewish accounts may be credited, he had 24,000 disciples. The Jews of Palestine esteemed him so highly, that they scrupled not to say, that God revealed to him what he had concealed from Moses. The book intitled Jetzirah, which has been ascribed to Abraham, is said to have been written by him, and, though it abounds with trifles and absurdities, it was quoted by the Jews at this period, as of divine authority. Towards the close of his life, Akiba joined the standard of the impostor Barchochebas, who appeared under the character of the Messiah, to deliver his countrymen from the power of the emperor Adrian. When this impostor was taken prisoner, and his followers put to the sword, Akiba and his son Pap-

pus were slayed alive. This happened, according to the Jewish chronologists, in the year 120; but, according to Balaage (lib. vii. c. 12.), in 138. Akiba was honoured by the Jews, after his death, as an eminent doctor of their law; and his tomb, supposed to be at Tiberias, was visited with great solemnity. He is said to have altered the Hebrew text of the Bible, with respect to the age of the patriarchs, when they began to have children, which is greater according to the Septuagint than in the Hebrew text; and he did this, it is said, to put off the period of the Messiah's advent, which, according to the tradition of the Jews, was not to take place till the completion of 6000 years. It has been argued, that the translation of Aquila, which was published in the 12th year of Adrian, agrees with the Hebrew text of this time, and that this Aquila having gone over from the profession of Christianity to that of the Jewish religion, and enlisted among the disciples of Akiba, persuaded his master to make this alteration. Pezron Antiqu. c. 16. This charge, however, is feebly supported, and the dissonance between the two texts is a difficulty that remains still to be satisfactorily solved. Gen. Dict. Brucker's Philos. by Entfield, vol. ii. p. 200.

AKIM, in *Geography*, a town of Africa, on the Gold Coast.

AKIURECK, a town of Asiatic Turkey, in Natolia, eight leagues east-south-east of Kaltamoni.

AKKER, a city of Syria, situate upon mount Bargylus, about nine leagues to the south-east of Tortosa; also a river that runs by it. This, says Dr. Shaw, (Trav. p. 269.) must have been formerly as noted for its strength, extent, and beauty, as it is now for the goodness of the apricots, peaches, nectarines, and other fruit, which it produces; and he suggests that it is the *Kir*, i. e. the city, mentioned in Scripture. Amos. ix. 7.

AKKIA, an island near the west coast of East Greenland. N. lat. $60^{\circ} 38'$. W. long. 46° .

AKKIAH, a town of Romania, in European Turkey, eight miles east of Burgas.

AKOND, an officer of justice in Persia, who takes cognizance of the causes of orphans and widows; of contracts, and other civil concerns. He is the head of the school of law, and gives lectures to all the subaltern officers; he has his deputies in all the courts of the kingdom, who, with the second *sadra*, make all contracts.

AKOUSCHY, in *Zoology*, the *CAVIA Acusehy*, the *olive cavy* of Pennant, has a short tail, with the upper parts of the body of an olive colour, and the under part whitish. Some have reckoned this animal a variety of the *AGOUTI*; but it differs from it in having a tail, which the other wants, or rather a longer tail than that of the other; in being smaller; and in having its hair of an olive, and not a red, colour; which are differences, says Buffon, sufficient to constitute two distinct species. It is about the size of a half-grown rabbit, is easily tamed, is hunted with dogs, and reckoned the finest game in South America. Its flesh is white and delicate, and much esteemed by the inhabitants of Guiana, Cayenne, and Brasil, where this animal is found. It inhabits the woods, and lives on fruits; has such a dread of water, that it will submit to be seized by the dogs rather than go into it; and it will sometimes, though rarely, cry like the restless cavy. Buffon by Smellie, vol. v. p. 61. vol. viii. p. 270.

AKQUEDAN, in *Geography*, a town of Africa, with a Dutch factory, on the Gold Coast.

AKRIDA, a town of Macedonia, in European Turkey, situate on the Drino, 124 leagues west of Constantinople, and 45 leagues south-east of Ragusa. N. lat. $41^{\circ} 46'$. E. long. $20^{\circ} 36'$.

AKSE,

AKSA, a river of Georgia in Asia, that runs into the Caspian Sea, near Zitrach or Tercek.

AKSCHINSKA, a town and fortress of Russia, 16 leagues south of Doroninsk.

AKSERAI, a town of Asia, in Asiatic Turkey, 20 leagues east-north-east of Konieh, or Cogni. N. lat. 38° 26'. E. long. 34° 14'.

AKSHEBSHAR, a town of Asia, nine leagues south-west of Eregri.

AKSHEHR, a town of Asia, 23 leagues west of Konieh. N. lat. 38° 26'. E. long. 31° 36'.

AKSU, a province of Little Bukharia, to the north of Kalkhar, and west of the province of Turfan, about 350 miles long, and 70 in breadth. Its chief town, of the same name, lies on the north side of a small river, which runs south-east, and loses itself in the sands. N. lat. 42° 30'. E. long. 83° 26'.

AKULA, an ancient city of Asia, situate on the eastern bank of the Tigris.

AKUN, ΔΕΥΝΟΚ, and ΑΚΥΤΑΝ. See *Fox Islands*.

AKURA, a town of Asiatic Turkey, in the government of Tarabuc, or Tripoli of Syria; seven or eight leagues from mount Libanus. It has a Maronite bishop.

AL, an Arabic particle, prefixed to words, to exalt, or give them a more emphatical signification.—As, in *Alkoran*, *Algebra*, &c.

AL, or ALD, in our *Ancient Writings*, signifies as much as *old*, *ancient*.—This being prefixed to the names of places, expresses their antiquity; as *Aldborough*, *Aldgate*, &c.

ALA, a Latin term, literally signifying wing, used, in *Anatomy*, for several parts of the body, which bear some resemblance to the figure of a wing.

Thus, the lobes of the liver are sometimes called *alæ*.

The soft spongy bodies in the *pubendum muliebre*, usually called the *nymphæ*, are denominated *alæ*.

The two cartilages of the nose, which form the nostrils, are called *alæ*.

And the same denomination is given to the tip of the *auricle*; and to the whole cartilaginous part of the ear, by way of distinction, from the tip and pendent part below, called the lobe. It is also applied to the process of the *os sphenoides*.

The term *alæ* is sometimes applied to the arm-pits, otherwise called *axillæ*. These parts abound with glands, and are great receptacles of humours; whence a rank smell sometimes exhales, called *fætor alarum*.

ALA, in *Botany*, a name given by the Latin writers of *Medicine*, in the later ages, to the *belenium*, or *ELECAMPANE*.

ALA is also used in *Botany*, for the angle which the leaves, or the stalks, or pedicles of the leaves, form with the stem, or branches of the plant from which they arise. This angle is usually acute, and always is directed upwards.

ALA is sometimes also applied to the angle formed by the branches themselves with the stem, which is also observed to be very regular and uniform.

ALA has several other different significations. It most frequently is used to express the hollow of the stalk of a plant, which either the leaf or the pedicle of the leaf, makes with it; or it is that hollow turning, or *sinus*, placed between the stalk, or branch of a plant, and its leaf, from whence a new offspring is wont to put forth. Sometimes it is taken also for a little branch, as when we say, a stock, or stem of a plant, is armed with many *alæ*; because these small branches stand out from it, in form of so many wings.

ALÆ is also used to signify those petals, or leaves of the papilionaceous flowers, placed between those others which are

called the *vexillum* and the *carina*, which make the top and bottom of the flower. Instances of flowers of this structure are seen in the flowers of peas and beans, in which the top leaf or petal, is the *vexillum*, the bottom the *carina*, and the side ones the *alæ*.

ALÆ is also used for those extremely slender and membranaceous parts of some seeds, which appear as wings placed on them, as in the plumaria, the fruit of the trumpet-flower, the fruit of the maple, and the like, which are called by botanists *alated* seeds.

ALÆ is finally used also for those membranaceous expansions, which run all the way along the stems of some plants, and are therefore called *alated* stalks.

ALÆ, in the *Military Art*, the two wings or extremes of an army ranged in form of battle.

An *ala* of horse, amongst the Romans, consisted of 300 horsemen, and was divided into *turmæ* and *decuriæ*; each *turma* consisting of 30 men, and each *decuria* of ten; so that there were in every *ala* ten *turmæ*, and in every *turma* three *decuriæ*.

ALA, in *Geography*, a town of Japan, in the province of Satzuma.

ALA, or AL, a town of Arabia, 21 leagues north-east of Hagiaz.

ALA-MILIARENSIS, in *Ancient Geography*, an episcopal city of Africa, in the Mauritania Cæsariensis.

ALA-NOVA, a town of Pannonia, according to Antonine.

ALABA, a small island in the Indian ocean, near Taprobana, according to Ptolemy.

ALABA, or ALAVA, in *Geography*, a small district or province of Spain, extending along the river Ebro, from the mountains of Biscay to the frontiers of Navarre, and comprehending about seven or eight leagues in length, and six or seven leagues in breadth. The soil is fruitful in rye, barley, vines, and several sorts of fruits; and the iron mines of the country furnish materials for the manufacture of arms and other utensils, which furnish articles of commerce. The chief town is *Victoria*.

ALABA, a large kingdom of Africa, forming a part of *MONEMUGI*, is situate to the east of Cambate, and extends to the coast of Zanguebar. It is inhabited by a cruel people, called *Gallas*.

ALABAGIUM, in *Ancient Geography*, a promontory of Asia, in Carmania, upon the borders of the *Ichthyophagi*, according to Ptolemy.

ALABAHA, in *Geography*, a considerable river of America, in East Florida.

ALABAMA, an Indian village, delightfully situate on the banks of the Mississippi. The inhabitants are the remains of the ancient Alabama nation, which inhabited the east arm of the great Mobile river, that still bears their name, now possessed by the Creeks, or *Muscogulges*, by whom they were conquered.

ALABAMA is also the name of a river in America, which is formed by the junction of the Coofee or High-town river, and Tallapoofee river, at Little Tallassee, and runs in a south-west direction, until it meets Tombigbee river from the north-west at the great island which it there forms, 90 miles from the mouth of Mobile bay, in the gulf of Mexico. This beautiful river has a gentle current, pure waters, and excellent fish; and its banks abound with valuable productions in the vegetable and mineral kingdoms. Travellers have sailed down this river in boats, in the month of May, in nine days from Little Tallassee to Mobile bay, a distance of about 350 miles.

ALABANA, a town of Arabia Felix, placed by Ptolemy in long. 74° 30'. and lat. 20° 15'.

ALABANDA,

ALABANDA, a town of Caria, in Asia Minor, south of the river Mæander. It was founded by Alabandus, who on this account was worshipped by its inhabitants, called Alabandi, Alabandii, and Alabandenses. In the time of Pliny it was a free city, whence it was proverbially denominated the most fortunate city of the Carians. Strabo (vol. xii. p. 976.) represents the Alabandenses as luxurious and gluttonous, and devoted to pleasure. Some writers have given the name Alabanda to ANTIOCHIA.

ALABARCHA, in *Antiquity*, a kind of magistrate among the Jews of Alexandria, whom the emperors allowed them to elect, to have the superintendency of their policy, and to decide differences and disputes which arose among them.

ALABARDA, the name of a spear anciently used by the Helvetians and Germans.

ALABASTER, WILLIAM, in *Biography*, an English divine, was born at Hadleigh, in Suffolk, in the 16th century, educated in Trinity college, Cambridge; and accompanied the Earl of Essex, as his chaplain, in his expedition to Cadiz, in the reign of Queen Elizabeth. Fickle in his temper, unsteady in his principles, and dissatisfied with his situation, and at the same time seduced by the pomp of the Romish worship and the respect paid to its priests, he became a convert to the church of Rome. But in his new connection he was disappointed; and upon his return to England, he resumed the Protestant profession, and obtained preferments in the English church; being appointed to a living in Hertfordshire and a prebend of St. Paul's. He was well acquainted with the Hebrew language; but so much attached to the unintelligible mysteries of the Jewish cabbala, that his knowledge of the original language of the Old Testament was of little service to him in the interpretation of scripture. Of his talents as a Biblical commentator, we may form some judgment by the sermons which he preached on taking his degree of doctor in divinity at Cambridge. His text was 1 Chron. i. 1. Adam, Seth, Enos; and having just touched upon the literal sense, he enlarged on its mystical meaning; explaining Adam by misfortune and misery, and so of the rest. He wrote a *Lexicon Pentaglotton*, which was printed in folio, in 1637; and other works of a mystical kind, viz. "Apparatus in Revelationem Jesu Christi," printed at Antwerp, in 1607; "Spiraculum Tubarum seu fons Spiritualium expositionum ex equivocis Pentateuchi significationibus," and "Ecce Sponsus venit, seu Tuba pulchritudinis, hoc est, demonstratio quod non sit illicitum, nec impossibile, computare durationem Mundi et tempus secundi adventus Christi," all printed in London. He was also the author of a Latin tragedy, intitled *Roxana*, which, at its exhibition in a college at Cambridge, produced a singular accident. When the last words, *sequar, sequar*, were pronounced, the voice and manner of the actor so terrified a lady who was present, that she irrecoverably lost her senses. Alabaster died in the year 1640. Gen. Dict.

ALABASTER, *albâtre*, Fr. *alabastrites* of Pliny, in *Mineralogy*. Some derive the word from *albus*, because of the whiteness of this stone. Others from *αλαβαστρον*, which they form from the privat. *α*, and *λαβανω*, *capio*, to take; this stone being too smooth and slippery for the hand to fasten hold of it. Under this name are confounded two minerals, wholly distinct from each other when pure, but which, in some of the varieties, are occasionally mixed together.

The compact gypsum of Kirwan (*Alabastrite*, *La Meth.* *albâtre gypseux de Liffle*. Dichter *Gypstein*, *Werner*) when of a white or yellowish, or greenish colour, semi-transparent, and capable of receiving a polish, is known

among statuaries by the name of alabaster, which term is also retained as a secondary appellation in most books of mineralogy; and is certainly the alabastrites of Pliny, which is characterized by that author as a stone resembling gypsum. When its colours are disposed in bands or clouds, it is called, in the first case, onyx alabaster, and in the latter, agate alabaster. It not unfrequently contains a sufficient portion of carbonated lime to produce a brisk effervescence with nitrous acid; and hence has originated the confusion of authors, who make the circumstance of effervescence an essential distinctive character between the gypseous and calcareous alabasters. Its specific gravity seldom exceeds 1.9. Its fracture is compact—splintery, sometimes verging on the fine-grained foliated. In transparency, it is considerably superior to white wax, allowing light to pass readily through it, but not transmitting the forms of objects. By slight calcination it is converted into Paris plaster.

Gypseous alabaster is very easily worked, but is not susceptible of a polish equal to marble. It is made into vases, columns, tables, and other ornamental articles of furniture; thin slabs of it have even been used in one of the churches of Florence instead of window glass. Its brittleness however, and want of lustre, have caused it to be almost wholly superseded by more durable materials. Among the ancients, the most esteemed came from Carmania, Upper Egypt, and Syria: of the variety called *onyx*, the boxes for holding perfumes were mostly fabricated; thus, in Horace, we meet with "Nardi parvus onyx."

The *calcareous alabaster*, or *sinter* (*albâtre calcaire*), is a stone of the same family as *stalactite*, consisting chiefly of carbonat of lime, and exhibiting a considerable variety of colours; such as pure white, yellowish, greenish, reddish, and bluish grey: its fracture is striated or fibrous, the striæ sometimes parallel and sometimes divergent: its hardness is somewhat inferior to that of marble, which nevertheless does not prevent it from receiving a good polish: its specific gravity from 2.4 to 2.8: its transparency is nearly equal to that of white wax: it effervesces with acids and burns to lime. Two sorts of alabaster are distinguished by statuaries, the common and oriental; under the latter of these are ranked the hardest, the finest, and the best coloured pieces; a number of sub-varieties are also produced by the colours being in veins, or dendritic, or in concentric undulating zones. Italy and Spain yield the most beautiful specimens; the inferior kinds are found in Germany and France. It is manufactured, like the gypseous alabaster, into tables, vases, statues, chimney-pieces, &c.

Many of the hot sulphureous waters rise out of the ground of a turbid wheyish colour, on account of a large quantity of gypsum and chalk, which they hold suspended, and in a state of half solution; as these grow cool and lose their carbonic acid, the earthy particles are for the most part deposited, lining the bottom and sides of the channels in which they flow with a compact alabaster. Advantage has been occasionally taken of this circumstance to obtain very beautiful impressions of bas reliefs, by exposing the moulds to a current of such water, till they have become filled with the earthy deposit. The most remarkable of these springs in Europe, is that which supplies the baths of St. Philip in Tuscany: it is situated on a mountain near Radicofani, and forms the source of the little river Paglia. The water as it issues forth is very hot, springs out with great impetuosity, has a strong sulphureous odour, and holds in solution a large quantity of calcareous matter. From its very source it flows in deep channels, covered with a thick crust of stalactite, of a dazzling white, especially when the sun shines upon it; and which is harder or softer

in proportion to the rapidity of the stream, and the obliquity of its fall. This circumstance suggested to Dr. Vegni the idea of establishing, on this mountain, a manufacture of artificial alabaster. For this purpose, he first collected a number of plaster models, of the best bas-reliefs, in Rome and other places of Italy. These models serve to form the hollow moulds, which are made of sulphur, according to the following process. The plaster model is rubbed over with boiled linseed oil, and surrounded with an edging of plaster, of the same height as the intended thickness of the subsequent bas-relief. Then sulphur, melted with just sufficient heat to make it flow, is poured on the plaster model, and fills it to the height of the edging. The sulphur mould thus made, is placed in a kind of wooden tub, roughly put together, open at top and bottom, and of less diameter below than above. This tub has on the inside a false bottom, made of slips of wood laid cross-wise, in order to detain, for a short time, the water which dashes on them. Just above this, is a row of wooden pegs, fastened to the tub, around its whole inner circumference, on which the sulphur mould is let down, and thus supported. The whole is then placed under the boiling spring, and inclosed with walls, to prevent it from being displaced by the wind. The water, which thus dashes on the moulds, deposits its earth both within and without them, giving the impression in bas-relief within, and disposing itself in an undulated surface on the outside. The hardness of the alabaster depends on the degree of obliquity at which the mould is placed, in order to receive the dashing of the water. The more vertical its position, the harder is the alabaster. However, as the hardest models are not so white as the softer, the water is in some cases caused to make a circuitous course, in order to deposit all its grosser particles before it arrives at the mould. Even the softer ones, however, are as hard as Carrara marble, and surpass it in whiteness. The time required for these productions varies, according to the thickness, from one month to four. When the sulphur mould is sufficiently filled, and the ground of the model has acquired a thickness capable of supporting the figures, the whole is removed from the water; the wooden supports are broken by gentle strokes of the hammer, and the incrustation on the outside of the mould is chipped off by repeated strokes. Then the tub is struck with a smart blow of a hammer, which separates the model from the mould; generally, however, cracking the latter. The brilliancy of the models is completed by brushing them with a stiff hair-brush, and rubbing with the palm of the hand.

The composition of this alabaster is gypsum, mixed with a small proportion of carbonated lime. Dr. de Vegni has, after many attempts, succeeded in giving a fine black, or flesh colour to the figures thus formed, by putting a vessel half full of colouring matter into the water, before it arrives at the mould. The colouring may also be varied, by protecting particular parts of the mould, while the water continues charged with colouring matter.

A spring of the same kind as that just described, and applied to similar purposes, is that of Guancavelica in Peru. The water rises from the ground into a large basin boiling hot, and of a muddy yellowish white colour. At a little distance from the basin, the water becoming cool, deposits calcareous matter in such vast abundance, as to fill large moulds with a compact stone, of which some of the houses of the town are constructed. The moulds of statuaries, in like manner, being exposed to the water, are filled with hard confusedly crystallized alabaster, and the bas-reliefs thus produced, by polishing, become semitrans-

parent and very beautiful. The images made use of by the Catholics of Lima, in their religious ceremonies, are said to be all formed in this manner.

Pliny Nat. Hist.—Hay, *Traité de Minéralogie*.—Kirwan's *Mineralogy*.—Bomare, *Diét. d'Hist. Nat.*—*Journal de Physique*, vol. ix.

ALABASTER, in *Antiquity*, is also used for a vase, wherein odoriferous liquors were anciently put.

The reason of the denomination is, that vessels for this purpose were frequently made of alabaster-stone, which Pliny and other ancients represent as peculiarly proper for this purpose.

Several critics will have the box mentioned in the Gospels as made of alabaster, to have been of glass. And though the texts say, that the woman broke it, yet the pieces seem miraculously to have been united, since we are told, the entire box was purchased by the emperor Constantine, and preserved as a relic of great price.

Others will have it, that the name alabaster denotes the form rather than the matter of this box. In this view, they define alabaster, by a box without a handle, deriving the word from the privative α , and $\lambda\alpha\beta\eta$, *ansa*, handle.

The expression, $\sigmaυντριψατα\ τ\o\ αλαβαstr\o\ν$, used by the evangelist Mark, (xiv. 3.) and which our translators have rendered "She brake the box," has occasioned some difficulty in the interpretation of this passage; but by referring the term $\sigmaυντριψατα$ to the ointment, and not to the alabaster box; and rendering the words, with Bishop Pearce, "breaking she poured the box," *i. e.* breaking the parts of the ointment, and liquefying them by shaking it, she poured some of the ointment out of the box upon his head; or, with Mr. Wakefield, "After shaking the box together, she poured it out upon his head," the difficulty is obviated. To justify this translation, and interpretation of the word $\sigmaυντριψατα$, it may be observed, that Luke (ix. 39.) uses $\sigmaυντριβων$ for *bruising*. Blackwall, *Sacred Classics*, vol. ii. p. 166. has remarked, that the shaking of liquids of this nature breaks and separates their parts, and thereby makes them more liquid and fragrant; and that the word $\sigmaυντριψατα$ is an excellent one for that purpose; and he very justly quotes, on this occasion, Plato in Phædone, $\Deltaιατριψας\ τ\o\ φαρμακον$: Martial's *Epigrams*, iii. 55. Ed. Delphin.

— "Et fluere *excusso* cinnama fusa vitro."

and Lucretius iv. 700.

— "Fracta magis redolere videntur
Omnia quod contrita."

See Pearce's *Com.* vol. i. p. 276. Wakefield's *Silva critica*. Pars. 1ma. p. 156.

Sir Edward Knatchbull and Dr. Hammond have suggested the same interpretation of this passage.

ALABASTER is also said to have been used for an ancient liquid measure, containing ten ounces of wine, or nine of oil, and in this sense the alabaster was equal to half the sextary.

ALABASTER *Island*, in *Geography*. See ELEFTHERA.

ALABASTRA, in *Botany*, are those little herbaceous leaves which encompass the bottoms of flowers, particularly the rose. See CALYX, &c.

Some, with Jungius, explain alabaster, by the globe or roundish bud of the rose just peeping out.

ALABASTRA, in *Ancient Geography*, a town of Phrygia, mentioned by Steph. Byz. on the authority of Herodotus, but probably mistaken for Alabanda. Ptolemy mentions a town of this name in Egypt.

ALABASTRITÆ,

ALABASTRITÆ, *alabasters*, in *Natural History*, the name of a genus of fossils allied to the marbles, and defined to be stones composed of large separate concretions, of great brightness, and an elegant, but shattery structure, not very hard, not giving fire with steel, effervescing with and soluble in acids, and calcining in a slight fire. See ALABASTER.

ALABASTRITES is often used as synonymous with alabaster. But Anselmus Boetius distinguishes between alabaster and alabastrites, in making the criterion of the former to be so soft, that it may be cut with a knife; and of the latter, that it is so hard that it cannot be so cut.

Grew speaks of a sort of alabastrites representing the transverse section of the trunk of a tree.

ALABASTRUM *dendroide*, a name given by authors to a species of alabaster, found in great abundance in the province of Hohenstein, and famous for the elegant delineations of trees and other figures described in it. See ALABASTER.

ALABASTRUM, in *Ancient Geography*, a town of the Thebaid, in Egypt, where Pliny says topazes were found.

ALABASTRUS, a river of Troas, which flowed from Mount Ida.

ALABATER, a promontory of Carmania.

ALABON, or ALABUS, now *Cataro*, a river of Sicily between Myla and Megara, which Diodorus (lib. iv. c. 78. tom. i. p. 321.) represents as a large river, which discharged itself into the neighbouring sea. Stephanus Byz. (vol. i. p. 58.) mentions also a city of this name.

ALABORG, a town of the ancient Rufsland, situate in the present government of Olonetz.

ALABUA, in *Geography*, a small town of Arabia Petraea, where it is said Abdalla, the father of Mahomet, died, and which is a station of the pilgrims that visit Mecca.

ALABURIUM, in *Ancient Geography*, a town of Syria, mentioned by Stephan. Byz.

ALACH, in *Geography*, a præfecturæ belonging to the territory of Erfurt, containing 13 parishes.

ALACHUAH SAVANNAH, a level green plain in the country of the Indians of that name in East Florida, situate about 75 miles west from St. Augustine. It is about 15 miles wide and 50 miles in circumference, and encircled with high sloping hills, covered with waving forests, and fragrant orange groves, which rise from a very fertile soil. The ancient Alachuah town stood on the borders of this Savannah, but the Indians removed to Cuscowilla, about two miles distant, on account of the insalubrity of the situation. The horned cattle and horses bred in these meadows are large and fat, but they are subject to mortal diseases, such as the water rot or scald, occasioned by the warm water of the Savannah.

ALACRANES, a range of rocks and shoals on the south side of the gulf of Mexico, situate over against the peninsula of Yucatan; east from Stonebank, and west from Cape St. Antonio, within the 23d degree of north latitude, and between 89° and 91° W. long. They are said to derive their name from the great number of scorpions that are found there.

ALADA, an island in the Indian Ocean, near the coast of Siam. N. lat. 9° 27'. E. long. 97° 52'.

ALADAG, or AMADAG, the highest mountain of Natolia, in Asia, north of Angora, and not far from the Cape of Coromba. N. lat. 40° 10'. E. long. 52° 40'.

ALADINISTS, a sect among the Arabs, answering to free-thinkers among us.

The Aladinists multiplied greatly under the two learned kings Almanfor and Miramolius.

ALADULIA, a considerable province of Turkey in

Asia, between Amasia and the Mediterranean, towards Mount Taurus. Some have represented it as the third division of Asia Minor, and made it to comprehend Cappadocia and Lesser Armenia. It joins on the south to Trebizond, and is called by the Turks the beghebegate of Marasch, and sometimes Dulgadir. The soil is unfit for tillage, but affords abundance of pasture, which breeds a great number of cattle, especially horses and camels, and large herds of sheep and goats. Cappadocia, besides its pasture grounds, produces wines and fruits in great plenty; and its mountains, particularly the chain called Antitaurus, have mines of silver, copper, iron and alum. Marasch and Cæsarea are well built and populous cities. Armenia the lesser, so called by way of distinction from the greater Armenia, has this country which belongs to Persia on the east, Syria on the south, the Euxine on the west, and Cappadocia on the north. The people are addicted to war and plunder.

ALÆNUS, in *Ancient Geography*, a river of Britain, according to Ptolemy, supposed to be the river Ax, and its mouth Ax-mouth. It was so called perhaps from the British *A laun iu*, the full river.

ALÆSA. See ALESA.

ALAFOENS, in *Geography*, a district of the province of Beira, in Portugal, containing 37 parishes, and erected into a duchy in 1718, by John V.

ALAGNON, a rapid river of France, in the late province of Auvergne, whose source is at Cantal, and which falls into the Allier.

ALAGOA, a town of Africa, in Upper Guinea, where the Portuguese have an establishment.

ALAGOA bay lies on the eastern coast of Africa, in the Indian Ocean. S. lat. 25° 30'. E. long. 33° 28'.

ALAGOA is also the name of a town of South America, in the country of Brasil, and government of Fernambuc.

ALAGON, a river of Spain, which rises in the mountain of Leon, and runs into the Tagus, a little above Aleantara. It is also the name of a small town of Aragon, standing on a peninsula formed by the rivers Ebro and Xalon, about four leagues from Saragossa.

ALAGTAGA, in *Zoology*, the Tartarian name of the Siberian JERBOA, signifies an animal which cannot walk. Buffon (Nat. Hist. by Smellie, vol. vii. p. 202.) characterises it as having legs like those of the Jerboa, but with five toes on the fore feet, and three on the hind, with a spur, that may pass for a thumb or fourth toe, much shorter than the others.

ALAIGNE, a town of France, in the department of the Aude, and district of Limoux, two leagues north-west of Limoux.

ALAIN, CHARTIER, in *Biography*, secretary to Charles VII. king of France, was born in 1386. He was the author of several works in prose and verse; but his considerable work was the "Chronicle of king Charles VII." It is said that Margaret, daughter to the king of Scotland, and wife of the dauphin, finding him asleep saluted him before all who were present: and when they expressed their surprize at her condescension to a person who possessed so few charms, she replied, "I did not kiss the man, but the mouth, from which proceed so many excellent sayings, so many wise discourses, and so many elegant expressions." On this incident Fontenelle has founded one of his Dialogues of the dead. Pasquier extols the character of Alain, and compares him to Seneca, on account of the infinite number of beautiful sentences, that are interspersed in his writings. Gen. Dict.

ALAIN, *John*, a Danish writer, was born in 1563, and died in 1630. He published a treatise "On the Origin of the Cimbri, and their various Establishments;" another "On Logic, natural and artificial;" and a third "On the

pronunciation of the Greek Language, with an Apology for Saxo Grammaticus."

ALAIN, *De Lifle*, a native of Lifle, in Flanders, flourished in the thirteenth century, with such reputation for his skill in theology, philosophy and poetry, that he was called the Universal Doctor. He died in 1294, and left behind him many pieces in prose and verse, which were collected into one volume in folio, at Antwerp, in 1653. His fame was so great, that it was thought a happiness to know him; and it was proverbially said, "Suffice it to have seen Alain." Dupin. *Ecl. Hist.* vol. v. p. 57. Cave. *H. L.* tom. ii. p. 287.

ALAINE, in *Geography*, a small river of France, in the department of Nièvre.

ALAJOR, one of the four quarters into which the island of Minorca is divided, so called from a small place near it.

ALAIS, or ALFZ, a large and populous city of France, in the department of the Gard, situate on the river Gard, at the foot of the Cévennes. Julius Cæsar in his commentaries calls it Alafia. A bishopric was founded in this place in 1691, with a view, as it is said, of converting the protestants, who were numerous; and a citadel had been built in 1689, in order to awe them. The diocese consists of 80 parishes. The country about it is well cultivated, and produces grain, olives and mulberries, but the principal wealth of the place has formerly arisen from its manufactures of serges and ratteens, and from its exportation of raw and wrought silk. It is distant 14 leagues north of Montpellier, and 140 south-east of Paris. N. lat. 44° 8'. E. long. 3° 46'.

ALAJSEE, in *Heraldry*, the same with *hunnetty*, or RACOURCY.

ALAISKIAN Mountains, in *Geography*, a part of the ALTAY mountains in Russia, comprising that range which advances from the origin of the Alay to the two sides of this river, and between it and the Ouba and Irtilis, and runs out into the great Saline plain, which is skirted by the Alay, the Irtilis, and the Oby. See SLUDINA.

ALALCOMENIA, in *Ancient Geography*, a town in the island of Ithaca, where, according to Plutarch, Ulysses was born.

ALALCOMENIUM, or ALALCOMENÆ, a small town of Bœotia, south-east of Chæronæa, near the lake Copais, founded according to Pausanias (in Bœotic, lib. ix.) either by Alalcomenius, foster-father of Minerva, or by Alalcomenia, one of the daughters of Ogyges, the nurse of Minerva, near which she had a temple, and a statue of ivory, which was removed by Sylla to Rome. Hence Homer deduces the epithet Alalcomeniæ, ascribed to Minerva.

ALALCOMENIUS, in *Ancient Chronology*, the Bœotian name for the Athenian month MÆMACTERION, which was the fourth of their year, and answered to the latter part of our September and beginning of October.

ALALIA, or ALALIS, in *Ancient Geography*, a town of Syria, placed by Ptolemy in the Palmyrene, near the Euphrates, and by M. d'Anville, north-west of Refasa.

ALAMA, a town of Asia, in Mesopotamia, situate on the river Bilicha, north-west of Nicephorium.

ALALOEI, small islands in the Arabian gulf, where, according to the Periplus of Arrian, turtles were found; the same with the Alloeu of Pliny.

ALAMAGAN, or *the island of the Conception*, in *Geography*, one of the LADRONES, or Marianne islands, about 10 miles from Guguan, and 18 miles in compass. There is a volcano on the north-west part of this island, which stands close to the sea, forming a cone in height about 500 yards, with a base of about 400 yards; and the sides are marked by streams of black lava, which, passing through a rich vegetation of cocoa-nut trees, may be traced to the shore, where they have entered the sea. This cone is encompassed

with cinders, which, at the distance of about a mile and a half, are covered with a black vegetable soil, which produces trees as large as any upon the island. At a nearer distance there is not for several acres the least sign of vegetation. In the year 1799, the volcano seemed to be preparing by its rumbling noise, and the smoke that issued from it, for a new eruption. The lower parts of the island are covered with trees of a thick foliage; some few open spots produce a thick and long grass; but the most plentiful productions of the island are the cocoa-nuts, which grow in clumps near the shores close down to the beaches, and which may be easily obtained in great abundance. Trees, resembling the pines of Port Jackson, bearing a small cone, and rising to the height of 30 or 40 feet, are very numerous. A supply of the fruit of the papau tree may be gathered about the middle of August. No quadrupeds have been observed upon this island except green-tailed lizards; land crabs are numerous and large; partridges and quails, owls, thrushes, bullfinches and pigeons are found here. The island may be seen at the distance of 12 or 14 leagues. Its shores are rocky to windward, but in the bay to leeward there are two or three beaches. On the west or left side of the island the shore bends into a kind of bay, where, as the trade wind in general blows steadily to the eastward, ships might ride securely as long as they had occasion to stay. N. lat. 18° 5'. E. long. 146° 47'. The variation of the compass in 1799 was 4½ east.

ALAMAN, a town of Switzerland, in the Canton of Berne, three leagues north-east of Nion.

ALAMANDUS, LEWIS, Fr. *Aleman*, in *Biography*, archbishop of Arles and cardinal of St. Cecilia, was one of the greatest men in the 15th century. He presided in the council of Basil, which deposed Eugenius IV. and elected the Antipope Felix V. Æneas Sylvius highly commends him, as a man admirably formed for presiding in such assemblies, firm and vigorous, illustrious by his virtue, learned, and endowed with a memory, which enabled him to recapitulate every thing that had been said by the orators and disputants. Although he was deprived of his dignities by pope Eugenius, and very injuriously treated, he is said to have performed miracles at his death, and he was beatified by Clement VII. in the year 1527. He died at the age of 60 years, in 1450. Gen. Dict.

ALAMANNI, LUIGI, or LEWIS, was born at Florence, of a family of distinction, in 1495; and by his early progress in philosophy and Greek literature, acquired great reputation. He was at first attached to the Medici family, but having entered into a conspiracy against Cardinal Julius de Medici, who became pope Clement VII., he was obliged to take refuge at Venice. He was afterwards imprisoned at Brescia, and upon his release he was under a necessity of abandoning his country, and of wandering, as an exile in France and in Genoa, till the year 1527, when he was recalled to Florence, on the expulsion of the Medici family. When the authority of that family was re-established in 1530, he was again disgraced, and retired to France, where he was chiefly occupied in poetical compositions. At length Francis I. called him to court, invested him with the order of St. Michael, appointed him to a considerable office in the household of Catharine de Medici, and employed him in various concerns at Rome and Naples. In 1544 he was sent on an embassy to the emperor Charles V.; and having been entrusted with different negotiations by Henry II. he died at Amboise in 1556, and left two sons, one of whom was made bishop of Maçon. The works of Alamanni consist of Italian poetry. The first publication of them at Lyons in 1532 and 1533, contained elegies, eclogues, satires, sonnets, hymns, psalms, &c. and a translation of the Antigone of Sophocles; which

which are much esteemed for their elegance. A didactic poem on Agriculture, in blank verse, "Della Coltivazione" first printed at Paris in 1546, added to his reputation. A piece of greater bulk, intitled, "Gironc il Cortese," taken from a French romance, "Gironc the Courteous," was published in 1548. His epic poem, called "l'Avarchide," on the siege of Bourges, and his comedy "La Flora," which he left behind him, did not much succeed. But his Tuscan epigrams, a species of writing, first attempted by himself, were well received, and produced many imitators. Alamanni is considered upon the whole, as a writer to whom Italian poetry lies under particular obligations.

Antonio Alamanni, whose burlesque poems were printed with those of Burchiello, was a relation of Luigi. Gen. Dict.

ALAMANNICUM, in *Antiquity*, a tribute imposed on the people by the emperor Alexius Angelus, for raising the sum of sixteen talents of gold, to be paid the *Alamanni*, on the conditions of a peace stipulated with them.

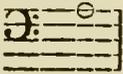

The ecclesiastics themselves were not exempted from this tax.

ALAMATOU, in *Botany*, the fruit of a tree that grows in Madagascar, resembling in its taste the black plum, but instead of the stone of the plum, it has 10 or 12 flat kernels; the leaf of the tree is like that of the plum-tree. There are two sorts of this fruit, one like the plum and the other like the fig, which is dangerous when taken to excess.

ALAMBAY, in *Geography*, one of the Sonda islands in the Pacific Ocean, 30 leagues south of Borneo.

ALAMEH, a town of Asiatic Turkey, in Natolia, 53 leagues south of Kutaja. N. lat. 35° 35'. E. long. 31° 29'.

A-LA-MI-RE, in the *Guidonian Scale of Music*, or *Gammut*, is the octave above A-RE, or A in the first space in

the base . As A is the note above G in every

part of an instrument, it is, of course, the third found below each tenor clef; and is likewise the found that occupies the second space, and the sixth line in the treble. The letter A itself is an abbreviation of A-RE and A-LA-MI-RE in the scale of Guido; and is the found to which all instruments are tuned at an opera, concert, or other musical performance. A in the Italian musical language, when it precedes a substantive, has the power of *in*; as *A battuta*, in time, or measure, after recitative, or an *ad libitum*. *A capella*, sacred music, compositions in the church style. See **GAMMUT** and **GUIDONIAN SCALE**.

ALAMODALITY, *alamodalitas*, is defined by a late writer, a study or endeavour to accommodate a man's self in point of behaviour, dress, conversation, and other actions of life, to the reigning taste or custom, from a motive of complaisance, and to avoid the imputation of ill-breeding.

ALAMODALITY of writing, *alamodalitas scribendi*, is defined by the same person, a particular study or endeavour of learned men to adapt the productions of their minds, both as to the choice of subject and the manner of treating it, to the genius or taste of the times, in order to render them more acceptable to the readers.

A German writer, under the name of Geamoenus, has a dissertation on alamodality in writing.

ALAMODE, in *Commerce*, a thin, light, glossy, black silk, not quilled or crossed; chiefly used for woman's hoods, and men's mourning scarves.

The name is French, though not given in that country to this fabric, for which they have no other name than *tafetis noir lustré*.

ALAMOS, **BALTHAZAR**, in *Biography*, a Spanish writer, was born at Medina del Campo, in Castile. He studied the law at Salamanca, served in a subordinate office under Philip II. was imprisoned upon the disgrace of his patron, Anthony Perez, secretary of state to this prince, and after a confinement of 11 years, released by Philip III. By the duke of Olivarez, the favourite of Philip IV. he was called to public employments. He was deemed a man of wit and judgment. He died in the 88th year of his age; and his Spanish translation of Tacitus, with marginal aphorisms, was published at Madrid, in 1614. Biog. Dict.

ALAMPO, **ALANPY**, or **LAY**, in *Geography*, a town on the gold coast of Africa, east of Ningo, and four leagues from the mountain Redondo, which presents itself in the form of a sugar-loaf to the north-north-west. The town is situated on the declivity of a mountain, which has a northern aspect; and the adjacent coast is bounded by hills of considerable height, that are covered with palm-trees. The inhabitants are gentle and timid; their principal commerce is that of slaves. The anchorage of this port is very good. N. lat. 5°. W. long. 3°.

ALAN, or **LYNN**, *Alanus de Lynna*, in *Biography*, an English divine of the 15th century, was born at Lynn, in Norfolk, -educated at Cambridge, and distinguished as a student and a preacher. He was addicted to allegorical interpretations of Scripture, and to the application of the historical parts of the Old Testament, to the concerns of religion and moral conduct, a practice blamed by Bale, but commended by Pits. He wrote tracts on the interpretation of Scripture, sermons, and elucidations of Aristotle; and he was famous for the pains which he took in making indexes to most of the books he read, of which Bale has given a long list. He at length became a Carmelite in the town of his nativity, and was buried in the convent of his order.

Another person of this name was abbot of Tewkesbury, about the year 1177, and died in 1201. He wrote a book, "De Vita et Exilio Thome Cantuariensis. Biog. Brit.

ALAN, **ALLEN**, or **ALLYN**, **WILLIAM**, a cardinal-priest of the Roman church, was born at Rossal, in Lancashire, in the year 1532; and entered, in 1547, at Oriel college, in the university of Oxford, where he made a considerable proficiency, particularly in logic and philosophy, and passed through several gradations of honour. In 1556, he became principal of St. Mary's hall, and one of the proctors of the university; and in 1558, he was made canon of York. But on the accession of queen Elizabeth, as he was a zealous catholic, he lost all hopes of preferment; and in 1560, retired to Louvain in the Spanish Netherlands, where he connected himself with the English college, and was much esteemed on account of his learning and the urbanity of his manners. In this situation he distinguished himself by writing in favour of the catholic cause; and his first piece was "A defence of the Doctrine of Catholics, concerning Purgatory and Prayers for the Dead," printed at Antwerp, in 1565, which commenced a controversy of some continuance. The state of his health, which had been injured by his application to study, rendered it advisable to return to his native country, in 1565; but he soon became obnoxious by the zeal of his attachment to the principles and profession of popery, and by his industry in making profelytes; and he was under a necessity of concealing himself in the neighbourhood of Oxford. In this retreat he wrote an apology for his party, intitled, "Brief Reasons concerning the Catholic Faith;" and he prosecuted his labours for reclaiming apostates and encouraging the wavering, to such a degree, as to make it necessary for him, notwithstanding the patronage

patronage he enjoyed, to leave the country and to retire to Flanders, in 1568. Such was the reputation which he had gained by his learning and labours, that on his settlement at Mechlin he opened a divinity lecture, which was received with great applause; at Douay, he was honoured with the degree of doctor of divinity; and he was advanced to the distinguished preferment of canon of Cambray, and afterwards to that of Rheims. Having established a seminary at Douay for the education of English scholars, he transferred it to Rheims; he procured others to be established for the same purpose at Rome and in Spain; and he persevered in writing a variety of tracts in defence of the doctrines and practices of the catholics, which were conveyed to England, and which were prohibited, by royal proclamation, to be sold or read. Dr. Allen was now considered as an avowed enemy, not only to the protestant religion but to the English government; correspondence with him was regarded as a treasonable offence; and Thomas Alfield, a jesuit, was tried and executed in 1585, for bringing some of his traitorous books into his majesty's dominions. Amongst other exceptionable and offensive passages contained in his writings, and particularly in his "Defence of the twelve Martyrs in one year," which tend to dissolve all social obligations, he expressly asserts, "that parents who become heretics, lose the superiority and dominion they have by the law of nature over their own children. Therefore, let no man marvel, that in case of hereby, the sovereign loseth the superiority over his people and kingdom." But Allen was not satisfied with avowing his hostility to the religion and government of England by his writings, he proceeded, under the instigation and with the advice of his friend, Robert Parsons, the jesuit, to unite with some fugitive English noblemen, who resided in Flanders, in persuading Philip II. of Spain to invade England. At the same time he wrote a vindication of the safe conduct of Sir William Stanley and the forces under his command, who garrisoned Davenport, in surrendering it to the Spaniards. In recompence of this treasonable practice, he was created cardinal in 1587, and appointed by the king of Spain, to an abbey of great value in the kingdom of Naples, with assurances of greater preferment, which were duly fulfilled. Thus encouraged, he was active in forwarding the designs of the Spanish armada, in 1588; and for this purpose he either himself wrote, or concurred with Parsons and other jesuits, in writing a book, of which many thousand copies were printed at Antwerp, and which were intended for dispersion in England, upon the landing of the Spaniards. This book consisted of two parts; the first was intitled "A declaration of the sentence of Sixtus V." in which it is maintained, that by virtue of the pope's bull, queen Elizabeth was accused and deprived of her crown, which was transferred to the king of Spain; and the second part was "An admonition to the nobility and people of England," pronouncing Elizabeth a schismatic and heretic, a pretended queen, and usurper, who had committed actions which rendered her incapable of reigning, and even unworthy of life; and declaring all her subjects absolved from their oath of fidelity. When the enterprize failed, most of these books were destroyed; but some of them were preserved, and their contents are said to have been universally disliked by all sober catholics as well as protestants. The earl of Arundel, who had been three years in prison under a charge of high treason, was tried and found guilty by his peers, and his chief crime was his correspondence with cardinal Allen. Allen, however, was promoted by the king of Spain to the archbishopric of Mechlin; but continued to reside at Rome, where he lived

in great splendour, and employed his interest in serving his fugitive countrymen and the catholic faith. Towards the close of his life he is said to have repented of the measures which he had been instrumental in promoting against his country, and to have disapproved the disposition and conduct of the jesuits with whom he had acted. This change of sentiment is inferred from a letter, dated in 1593, and found among the papers of lord Burleigh, in which he professes affection to his native country, solicitude for its welfare, and a desire of effecting a reconciliation between the protestants and catholics. It is further alledged, that he wished on his death-bed to have an interview with the English students at Rome, but was prevented by the attending jesuit. He died in 1594, not without suspicion of being poisoned by the jesuits, and was buried with great pomp, in the chapel of the English college at Rome, where a monument was erected to his memory, with a Latin inscription in the highest style of panegyric.

As a zealous catholic, Allen might unquestionably alledge the obligations devolved upon him by the conviction of his mind; but how far the plea of conscience will justify the avowal of sentiments, and the encouragement of practices, incompatible with the fundamental principles of personal and social virtue, we must leave for those who undertake the vindication of his character to determine. As an English subject, he was undoubtedly a traitor and rebel; and no casuistry can justify his attempts to overturn the government of a country, deserted by himself, but approved by a majority of its inhabitants. As a writer he may be justly considered as one of the ablest advocates of the Romish church, at the period in which he lived. His works, besides those already mentioned, are, "A defence of the lawful power and authority of the priesthood to remit sins," to which are annexed two other tracts, *viz.* "The people's duty in confessing," and "An explanation of the doctrine of the Catholic church, with respect to indulgences;" printed at Louvain in 1567, 8vo; "of Sacraments in general, of the Eucharist, of the sacrifice of the mass; three books, addressed to pope Gregory XIII." printed at Antwerp in 1576; "Of the worship due to saints, and their relics;" "A true, sincere, and modest defence of Christian Catholics, that suffered for their faith at home and abroad, &c." printed in 1583, which was an answer to a book written by lord Burleigh, and esteemed the best of the cardinal's writings; so that the learned Edmund Bolton says of it, "a princely, grave, and flourishing piece of natural and exquisite English is Cardinal Alan's Apology. Biog. Brit.

ALAN, in *Geography*, a town and province of Turkestan in Persia.

ALAN, or CAMEL, a river of England, rises north of Camelford, and runs into the sea two miles below Padstow, in Cornwall.

ALAN Bay, lies on the west side of Corfica, in the Mediterranean.

ALANA, in *Ancient Geography*, a town of Ethiopia in Egypt, according to Pliny.

ALANCH, in *Geography*, a town of France, in the department of the Mouths of the Rhone, two leagues north-east of Marseilles, and four fouth of Aix.

ALAND, an island in the Baltic, at the entrance of the Gulf of Bothnia, situate between the province of Upland in Sweden and Finland, gives name to a cluster of islands, and is about 40 miles in length, and from 12 to 16 in breadth. It contains about 15 villages, and 9000 inhabitants, who speak the Swedish language; but are included under the government

government of Finland, since the year 1634, both as to spiritual and temporal affairs. The basis of the soil seemed to Mr. Coxe, who visited it, to be granite. It is so fertile, that the inhabitants seldom experience any scarcity of corn; it has also rich pastures, forests of wood, and lime-stone quarries. The inhabitants chiefly subsist by agriculture, hunting, and fishing; and they traffic in butter, wooden-ware, coals and lime. The principal place is Castellholm. This cluster of islands appears like a ridge of rocks, which had been once joined to each other, and the continent, but undermined and separated by the sea. N. lat. 60° 18'. E. long. 19° 40'.

ALAND is also the name of an island on the Norway coast, nearly west of Bergen.

ALAND, a river of Germany, which runs into the Elbe, near Schnackenburg, in the principality of Lunenburg.

ALAND'S Bay, lies on the south coast of Ireland, between the harbour of Waterford and Tramore bay; eight miles south of Waterford.

ALANDER, in *Ancient Geography*, a river of Asia Minor, the source of which is referred by Livy to Phrygia Major.

ÅLANDSHAGE, a cape at the southern extremity of the island of Amack.

ALANS, or ALANI, a people who, like the Huns, were of Asiatic origin, but represented by Ammianus Marcellinus, as "victu mitiores et cultu;" more polished in their customs and manners. Pliny (H.N. lib. iv. c. 12.) erroneously places them in Europe, beyond the mouth of the Danube: but Josephus (De Bell. Jud. lib. vii. c. 29.) traces their origin more accurately, and describes them as Scythians, who dwelt between the river Tanais and the lake Mæotis. Ptolemy mentions two sorts of Alans, the one in Europe and the other in Asia. From M. de Guignes, Hist. Huns, tom. ii. who has taken pains in investigating their origin and history, we learn that the name *Alin* signifies mountain, and that these people derived their appellation from the mountains which they inhabited towards the sources of the Jaick and near the districts of Oufa, and Solemskoi. In process of time they migrated southward, to the plains that are situated to the north of Circassia and Derbend. About A. D. 73, they formed an alliance with the king of Hircania, and entered Media; but being prevented at this time, and afterwards by Adrian, A. D. 130, from pursuing their march to the south, they directed their course westward, and established themselves on the borders of the Danube. About the year 406, they advanced from the banks of the Danube to the Rhine, and being joined by the Vandals, and some other nations, they traversed Gaul, and settled at the foot of the Pyrenees. In 409 they took the advantage of the revolt of those troops who were stationed to guard the passage of these mountains, and proceeded into Spain, where they settled in 411. Some of them entered Lusitania, and others the province of Carthage: and many of them remained in Gaul, particularly in Brittany and Normandy. The Goths in Spain, and the Franks in Gaul, dispersed the Alani, so that they were at length confounded with their conquerors. The Alani, according to Ammianus Marcellinus, had no other houses than their waggons, which they removed to such places as they found most convenient for their flocks and herds, which constituted their wealth, and supplied, with their flesh and milk, the means of their subsistence. War was their chief occupation; and whilst their wives and children were left at home, all who were able to bear arms renewed, from time to time, and as they advanced in their progress, their military sallies against their neighbours. They deemed it dif-

graceful to grow old and die peacefully with their families; those were reckoned the happiest who died in battle, and who had killed the greatest number of their enemies; the scalps of those whom they slew formed the costly trappings of their horses; and so devoted were these people to military occupations, that a naked scymetar planted in the ground was the only object of their religious worship. Their divinations were performed by means of rods, chosen with proper charms.

On the banks of the Tanais, says Mr. Gibbon, the military power of the Huns and the Alani encountered each other with equal valour, but with unequal success. The Huns prevailed; the king of the Alani was killed; and the remains of the vanquished nation were dispersed by the ordinary alternative of flight or submission. A colony of exiles found a secure refuge in the mountains of Caucasus, between the Euxine and the Caspian, where they still preserve their name and independence. Another colony advanced with more intrepid courage, towards the shores of the Baltic; associated themselves with the northern tribes of Germany, and shared the spoil of the Roman provinces of Gaul and Spain. But the greatest part of the nation of the Alani embraced the offers of an honourable and advantageous union; and the Huns, who esteemed the valour of their less fortunate enemies, proceeded with an increase of numbers and confidence, to invade the limits of the Gothic empire. Ammianus xxxi. 2. M. de Guignes Hist. des Huns. tom. ii. p. 279. Gibbon's Hist. of the Decl. and Fall of the Rom. Empire. vol. iv. p. 373.

ALANI, a mountain of Scythia, on one side of Imaus, and east of the Hyperborean mountains.

ALANGUER, or ALENQUER, in *Geography*, a town and district of Portugal, in Estremadura. The town is said to have been built by the Alani, and was anciently called *Alenker Kana*, i. e. the temple of the Alans. It contains about 2500 inhabitants, five churches, one casa da misericordia, one hospital, and three convents; and it is the chief town of the queen's estates.

ALANORARIUS, in our *Ancient Customs*, a keeper or manager of spaniels, or setting-dogs, for the sport of hunting, hawking, &c. The word is formed from the Gothic, *alan*, a greyhound.

ALAPA, in *Geography*, mountains of Asiatic Russia, in Siberia, extending from the lake of Jaiokai to the confines of Baskiria, all having mines of very rich copper.

ALAPÆV, a town of Russia, in the government of Perm, on the river Tagil. N. lat. 58°. E. long. 61° 14'.

ALAPI, in *Ornithology*, is a species of TURDUS, in the Linnæan system by Gmelin, and the white-backed thrush of Latham; its specific characters are, that the colour above is olive-brown, the throat and breast black, the abdomen cinereous, and the tail wedge-shaped and blackish. Its legs are yellowish, the wings above cinereous-brown, and superior coverts spotted with white; the male has a white spot on the middle of the back; the female has none, but its chin is white, the rest of the under-part of the body and the points of the coverts of the wings rusty. Its length is six inches; it feeds on ants; seldom flies for any time, though very agile, and is found in the thick woods of Guiana.

ALAPIA, in *Ancient Geography*, a town of Cælo-Syria, called also *Nerca*.

ALANGIUM, in *Botany*, a genus of the *decandria monogynia* class and order: the characters of which are, that it has from six to ten linear petals, from 10 to 12 stamina, the calyx dentated, in six to ten notches, and superior; the fruit a spherical berry, slightly coraceous, single celled, and

and containing from one to three seeds. There is one species, *viz.* the *A. pinguis* of Justiciu.

ALAPOULI, in *Botany*, the name of an East-Indian tree, a species of the bilrabi, which is used in medicine as a purge and vomit, mixt with the seeds of mustard.

ALAPTA, in *Ancient Geography*, a town of Macedonia, near Acanthus.

ALAUQUECA, a medicinal stone brought from the Indies, in small glossy fragments; much praised by some for its efficacy in hemorrhages, when applied externally.

ALAR, in *Geography*, a river of Persia, which runs into the Caspian sea.

AL-ARAF, formed from the Arabic verb *arafa*, to *distinguish*, in the Mahometan *Theology*, the partition wall that separates heaven from hell.

Alaraf gives the denomination to the seventh chapter of the Alcoran, wherein mention is made of this wall. Some take it for a sort of *limbus* for the patriarchs, prophets, &c. others place here such whose good and evil works so exactly balance each other, that they neither deserve reward nor punishment. Others again appropriate this intermediate space to those who go to war without the leave of their parents and die, and are excluded paradise for their disobedience, but escape hell as martyrs. Sale's Prel. Discourse to the Koran, p. 95.

ALARBES, a name given to those Arabians who dwell in tents, and who are distinguished by their dress from others who live in towns.

ALARCON, in *Geography*, a town of Spain, in the western part of New Castile, on the river Xucar. It was ruined in 1178, under the reign of the Moors, and rebuilt by Alphonus IX. N. lat. 39° 40'. W. long. 3°.

ALARES, in *Antiquity*, are supposed by some authors to have been a kind of *militia*, or soldiery, among the Romans; so called from *ala*, a *wing*, because of their lightness and swiftness in the combat.

Others make them a people of Pannonia; but others, with more probability, take alares for an adjective, or epithet, and apply it to the Roman cavalry; because they were placed in the two wings, or *ale*, of the army; for which reason, a body of horse was called *ala*.

An *ala*, or wing of auxiliary horse, consisted of 400, and there were two of these wings annexed to each legion; and therefore, the whole number of cavalry belonging to a legion was 1200, of which 400 were Romans, and 800 auxiliaries.

ALARES *musculi*, in *Anatomy*. See PTERYGOIDEUS.

ALARIC I., in *Biography and History*, king of the Visigoths, was descended from the noble race of the Balti, or bold, the most illustrious of the Gothic nation, next to that of the Amali. With his countrymen, who were expelled by the Huns, and whose number is said to have amounted to near a million of persons, of both sexes and of all ages, and of whom about 200,000 men were Gothic warriors, Alaric passed the Danube, A. D. 376; and served with great reputation in the war between the Romans and the Goths, which lasted from that time to the year 382, when they all submitted to Theodosius, and were allowed to settle in Thrace, on condition of serving in the Roman armies. Accordingly, he attended Theodosius in his expedition against the usurper Eugenius, with a body of his countrymen under his command. But being refused that preferment to which he aspired, he was dissatisfied; and after the death of Theodosius, and, as it is said, at the instigation of his minister Rufinus, he assembled a numerous army, consisting chiefly of his countrymen, and having first

ravaged Pannonia and Dacia, he proceeded in 396 to make an irruption into Greece. Having marched through Macedonia and Thessaly, he passed through the straits of Thermopylae without opposition on the part of Antiochus, proconsul of Achaia, or Garontius, who was appointed to guard them, and laid waste the fairest realms of ancient Greece. The Athenians preserved their city by delivering to the emperor the greatest part of their wealth; but the whole territory of Attica, from the promontory of Surium to the town of Megara, was desolated by the march of his army; so that Athens itself, according to the allusive language of a contemporary philosopher, resembled the bleeding and empty skin of a slaughtered victim. The Gothic prince, having been liberally and splendidly entertained at Athens, penetrated without delay into Peloponnesus, and wherever he came desolation and distress marked his footsteps. Those only could be deemed happy, whose premature death prevented their witnessing the dishonour of their females, the slavery of their families, the conflagration of their cities, and the destruction of every thing valuable and curious which they possessed. In this peninsula, the famous general Stilicho, with his fleet and army, came up with Alaric, and obliged him to retreat to the mountain of Pholoe in Arcadia, and there invested his camp; but either by negligence or connivance permitted him to escape across the gulf of Corinth, to Epirus. Being in full possession of this important province, Alaric had sufficient time to conclude the treaty, which he secretly negotiated with the ministers of Constantinople. In consequence of this treaty, he was declared master-general of the eastern Illyricum, which comprehended the cities and provinces he had so lately laid waste; and the enemy of Rome became the ally and servant of the emperors of the east. Whilst the Gothic prince was thus preferred by Arcadius, Stilicho was declared a public enemy, and his eastern possessions seized and confiscated. At the same period, A. D. 398, Alaric, with the unanimous consent of the barbarian chieftains, was elevated, according to ancient custom, on a shield, and solemnly proclaimed king of the Visigoths. In the plenitude of power which he had thus acquired, by the grant of Arcadius, and the suffrage of his own nation, he avowed his resolution of invading the dominions of the west; and having amused both Arcadius the emperor of the east, and Honorius the Roman emperor, by deceitful promises, till he was prepared for the execution of his purpose, he entered Italy in the year 400, laid waste the country, and carried off a great quantity of spoil and an incredible number of captives. In 402 he ravaged the provinces of Venetia and Liguria; in 403, advanced towards Milan, whence Honorius hastily fled; and pursued the timid emperor to the fortrefs of Asta, a town of Liguria, on the banks of the Tanarus. In the mean while Stilicho, at the head of a chosen and intrepid vanguard, marched to the relief of the Imperial captive, and arrived soon enough to prevent the indignity of a surrender by capitulation, which the barbarians had proposed. By a successful action, in which he forced his way through the Gothic camp to the walls of Asta, he revived the hopes, and vindicated the honour of Rome. On this occasion, a military council of the Gothic nation was assembled, in which Alaric displayed the spirit of the conqueror of Rome, and concluded an animating speech, by the solemn and positive assurance, that he was resolved to find in Italy either a kingdom or a grave. Whilst the Christian Goths were devoutly employed in celebrating the festival of Easter, Stilicho determined to attack them. The camp of the Goths, which Alaric had pitched in the neighbourhood

neighbourhood of Pollentia, was thrown into confusion by the sudden and impetuous charge of the Imperial cavalry: the engagement which succeeded was long maintained with equal valour and success; but at the moment when the victory of Alaric was almost decided by the defeat of the cavalry, Stilicho led the Roman and Barbarian infantry to the attack, and determined the fate of the day. The Goths retreated from the field of battle; the intrenchments of their camp were forced; and the scene of rapine and slaughter made some atonement for the calamities which they had inflicted on the subjects of the empire. The magnificent spoils of Corinth and Argos enriched the veterans of the West; the captive wife of Alaric was reduced to the necessity of imploring the mercy of the insulting foe; and many thousand prisoners, released from the Gothic chains, dispersed through the provinces of Italy the praises of their heroic deliverer. Alaric still maintained that invincible spirit, which rises superior to every misfortune, and derives new resources from adversity; and he boldly resolved to break through the unguarded passes of the Apennine, to spread desolation over the fruitful face of Tuscany, and to conquer or die before the gates of Rome. But Stilicho saved the capital, entered into a negotiation with the enemy, and induced him to repass the Po, with the remains of the flourishing army which he had led into Italy. In his retreat, however, he took possession of Verona; but having been defeated in a bloody action near the walls of this city, he escaped by the swiftness of his horse. After this disaster he retired with the shattered remains of his army to the mountains, where he lost the greatest part of them by hunger and disease, and by desertion; and from hence he finally retreated into Thrace, and thus Italy was liberated.

It was not long after this event before Alaric was recommended by Stilicho to Honorius, and appointed by this weak prince master-general of the Roman armies in Western Illyricum. Whilst Stilicho resumed his pretensions to the provinces of the East, and was anxious to employ Alaric and his forces at a distance from Italy, the Gothic king perceived his design; and protracting his languid operations in Thessaly and Epirus, he held a doubtful, and perhaps a treacherous, correspondence with the two rival courts, and advanced to Æmona, on the confines of Italy, with a view of enforcing his demand on the Roman court, for the recompence of ineffectual services. The demand was supported by Stilicho, who lost his life during the hesitation of the senate; and the delay furnished Alaric with a pretext for again entering Italy, in 408. By bold and rapid marches he passed the Alps and the Po; pillaged the cities of Aquileia, Altinum, Concordia, and Cremona, which yielded to his arms; increased his forces by the accession of 30,000 auxiliaries; and at length pitched his camp under the walls of Rome. The city was soon reduced to the utmost extremities of famine and pestilence, and a negotiation was commenced and terminated in a ransom, the payment of which induced Alaric, A. D. 409, to raise the siege, and to withdraw his army into Tuscany. Here the Gothic standard became the refuge of 40,000 Barbarian slaves, who had broke their chains, and aspired, under the command of their great deliverer, to revenge the injuries, and the disgrace, of their cruel servitude. About the same time he received a reinforcement of Goths and Huns, whom Ataulphus, or Adolphus, the brother of his wife, had conducted, at his pressing invitation, from the banks of the Danube to those of the Tiber, and who had cut their way, with some difficulty and loss, through the superior numbers of the Imperial troops. Alaric was now at the head of 100,000

fighting men; and though Italy pronounced his name with terror and respect, he professed moderation, and repeatedly declared, that it was his desire to be considered as the friend of peace, and of the Romans. Ambassadors were sent to the court of Honorius at Ravenna to negotiate a treaty; but he insisted on his military rank in the empire, and the possession of some of the provinces between Italy and the Danube. The terms were rejected; and Alaric again advanced to Rome, A. D. 409. Having taken possession of the port of Ostia, he compelled the city to surrender, and elevated Attalus, the prefect of the city, to the dignity of Emperor. He then conducted the new emperor to the gates of Ravenna, with a resolution of depriving Honorius; but Attalus himself was disgraced with Alaric and deposed. The court of Ravenna, however, instead of taking the advantage of this circumstance to effect a peace, offered an insult to Alaric, which provoked his resentment and induced him to march back to Rome with a determination to satiate his appetite for plunder and vengeance. On the 24th of August, A. D. 410, the Gothic army entered Rome; and thus 1163 years after the foundation of the Imperial city, which had subdued and civilized so considerable a part of mankind, it was delivered to the licentious fury of the tribes of Germany and Scythia. As some of the Goths were Christians, they spared the lives of the unresisting citizens, and respected the churches as holy and inviolable sanctuaries; but the Huns, and other Heathen Barbarians, committed the most horrid massacres, rapes, and violence of every kind, without restraint. After a pillage and devastation of six days, the Gothic army evacuated Rome; and their intrepid leader, at the head of an army, encumbered with rich and weighty spoils, advanced to the southern parts of Italy, destroying whatever dared to oppose his passage, and contenting himself with the plunder of the unresisting country. Having arrived at the extremity of Italy, his ambition was excited by the near prospect of the fertile island of Sicily. But when the first division of the Goths had embarked, in order to pass the Straits of Rhegium and Messina, a tempest arose, which sunk or scattered many of the transports, and daunted the mariners, and their whole design was defeated by the premature death of Alaric, which fixed, after a short illness, the fatal term of his conquests, A. D. 410. His funeral was celebrated with mournful applause; his body was buried in the bed of the small river Busentinus, which washed the walls of Consentia, and which for this purpose was diverted from its course and then restored; and the place of his interment was concealed by the massacre of the prisoners who had been employed in the work. Of the character of Alaric it is sufficient to say, that he possessed more humanity, moderation, and fidelity to his engagements than many of the class of Barbarian conquerors; and that his exploits have rendered his name memorable in the most civilized parts of the world. Alaric, says Lardner, (Works, vol. ix. p. 180), was a Goth, and therefore called a Barbarian; but he was a man of a great and generous mind, and a Christian of the Arian denomination. When Rome was sacked and plundered, the calamity was attended with some favourable circumstances, resulting from the generosity of Alaric, and his profession as a Christian. By ordering the lives of men to be spared as much as possible, and the churches to be respected, many Christians and Pagans were preserved. Although, adds this candid writer, the taking of Rome by Alaric was the occasion of many reflections upon the Christians, from which they have been vindicated both by Augustine and Orosius, the event was very prejudicial to the interests of Gentilism, and consequently conducive to the progress of the Christian religion. Anc. Un. Hist. vol. xvii.

p. 191—197, 8vo. Gibbon's Hist. of the Decline and Fall of the Roman Empire, vol. v. p. 178—330, 8vo.

ALARIC II. king of the Visigoths, succeeded his father Euric in 484, and reigned over all the country between the Rhone and the Garonne; adapting to his own statutes the Theodosian collection of laws, which he published as the law of the Visigoths, and which has been since known by the title of the code of Alaric. By permission of this Arian prince, the orthodox prelates held a council at Agde in 506; but notwithstanding this influence of toleration, Clovis, the powerful king of the Franks, engaged in a war with a view of dispossessing him of his dominions, and alledged as the motive of it, that he was grieved to see the Arians proprietors of the fairest portion of Gaul: "let us march," says he in his speech to the Nobles at Paris, "and with the aid of God vanquish the heretics, and then possess and divide their fertile provinces." After holding a conference with Alaric, in a small island of the Loire, near Amboise, which seemed to terminate amicably, Clovis marched against him with the confidence and enthusiasm of a messenger commissioned from heaven, and having passed the ford of the Hart, over the Vivonne, to which he was guided by a white hart of singular size and beauty, he hastened, under the direction of a flaming meteor that hovered over the cathedral of Poitiers, to attack the Gothic army, more numerous than his own, but enfeebled by a long and luxurious peace. At a village about ten miles south of Poitiers, still named Champagné St. Hilaire, the two armies engaged; but that of the Goths was prepared for a defeat by terror and confusion. They rallied, however, in their extreme distress, and the martial youths, who had clamorously demanded the battle, refused to survive the ignominy of flight. The two kings encountered each other in single combat. Alaric fell by the hand of his rival, A. D. 507, and the victorious Frank was preserved by the goodness of his cuirass, and the vigour of his horse, from the spears of two desperate Goths, who furiously rode against him, to revenge the death of their sovereign. Alaric was succeeded by a natural son, Gesalaic, who took possession of his throne. Mod. Un. Hist. vol. xvi. p. 6. Gibbon's Hist. &c. vol. vi. p. 330—335.

ALARIO, in *Ornithology*, *Cape finch* of Latham, or *sparrow* from the Cape of Good Hope of Albinus, a species of **FRINGILLA**, with the head and breast black, the body chestnut-colour and under white, and the four lateral feathers of the tail marked with a small black line. It is in length about $4\frac{1}{2}$ inches, and found at the Cape of Good Hope.

ALARIS vena, in *Anatomy*, the inmost of the three veins in the bend of the arm.

ALARM, in the *Military Art*, properly denotes a sudden apprehension, conceived from some noise, or report, called also alarm, and signified by firing a cannon, beat of a drum, &c., which makes men run to their arms, and stand on their guard.

The word is *French*, formed from the Italian *all' arme*, to arms; whence *gridare all' arme*, q. d. to call to arms.

Alarms are either true, that is, founded on just notice, or false. False alarms are frequently given by an enemy, either to fatigue the other's army, or by way of diversion; to keep themselves safe and quiet from attacks. Alarms of this kind are sometimes designed to try the vigilance of the picket-guard, and to render them strictly attentive to their duty. To remedy the inconveniences of formal alarms, and prevent the horror and confusion of trumpets, and noise of warlike cries, the captains usually give the alarm, by silent advice, without noise.

ALARM bell, that which is rung to call the people to-

gether, on some such occasion as a fire, mutiny, or the appearance of an enemy. This is what the French call *toisin*. See **BELFRY**.

ALARM-post, is the ground appointed to each regiment, by the quarter-master-general, to which it is to march in case of an alarm. In a garrison, the alarm-post is the place where every regiment is ordered to draw up, on ordinary occasions.

ALARM, in *Fencing*, denotes a step, or stamp, made on the ground with the advancing foot.

This coincides with what is otherwise called an *appel*, or challenge.

ALARM, or rather **ALARUM**, is also used for an instrument to awaken persons at a certain hour; one very simple contrivance of this kind, is that used by weavers. See **WEAVER'S Alarm**.

ALARO, in *Geography*, a river of Italy, which rises in the Apennine, and runs into the sea near Cape Stilo, in Calabria Ultra.

ALARODII, in *Ancient Geography*, a people who probably inhabited a country near Colchis, which was terminated by the western part of the Euxine sea. Stephan. Byz. Not. Herodot. lib. vii. c. 79.

ALARUM THRUSH, in *Ornithology*. See **BELFRY**.

ALARYS BAY, in *Geography*, lies on the west coast of Ireland, nearly south-east from Achill-head.

ALASARNE, a nation of the island of Cos.

ALASCANI, in *Church History*, a sect of Antilutherans, whose distinguishing tenet, besides their denying baptism, is said to have been this, that the words, *This is my body*, in the institution of the eucharist, are not to be understood of the bread, but of the whole action, or celebration of the supper. They are said to have taken the name from one Joannes a Laseo, a Polish baron, superintendent of the church of that country, in England.

ALASCHA, or **ALASKA**, in *Geography*, a long peninsula on the north-west coast of America, formed by Bristol bay and the ocean on the north-west and north, and by the ocean and the waters of Cook's river, on the south and south-east. A number of islands, at its extremity, of which the chief in their order westward, are Oonemak, Oonak-laka, and Ocumnak, form part of the cluster of islands, called the Northern Archipelago. N. lat. $55^{\circ} 30'$ to 58° . W. long. 159° to 162° .

ALASCHEIR, a town of Natolia, which, according to some Geographers, is the ancient Hypsus; and according to others, Philadelphia.

ALASCO JOHN, in *Biography*, a Polish nobleman, uncle to the king of Poland, as Fox (*Acts and Monuments*, vol. iii. p. 32.) informs us, was a member of the Catholic church, and, as it is said by some writers, possessed episcopal dignity. But inbibing the principles of the Reformation, he became a Protestant Divine; and being under a necessity of leaving Germany by the persecution that followed the imposition of the Interim, he and his congregation found an asylum in London, under the protection of Edward VI. This excellent prince granted them the church which had lately belonged to the Augustin Friars; and by a charter, A. D. 1550, erected their congregation into a corporation. John Alasco was appointed superintendent, and four other ministers were associated with him. There were also 380 of the congregation, that were made Denizens of England. Burnet says, that he did not conduct himself with that decency which became a stranger who was so kindly received; as he wrote against the orders of the English church, "both in the matter of the habits, and the posture of the sacrament, being for sitting rather than kneeling. After the accession of Queen Mary, in 1553, their con-

gregation was dissolved, their charter revoked, and they were ordered to leave the kingdom. Some few of them remained with two of their teachers; but the greater number sought refuge in foreign countries. Alasco, and many of his companions, embarked for Denmark; but when it was understood that they were of the Helvetic confession, they were required to depart in the midst of winter within two days. From thence they emigrated, first to Lubeek, then to Wismar, and afterwards to Hamburg; where disputes about the mode of Christ's presence in the sacrament excited such animosities, that after much barbarous usage, they were banished out of all these towns, and could find no settlement, till the spring of the following year, when they were kindly received at Embden, in Friesland, and permitted to remain unmolested. Such were the eminent talents and virtues of Alasco, that, during his short residence in England, he had formed a friendship with several considerable persons; and his character was so highly esteemed by Queen Elizabeth, that when she came to the crown, he wrote letters of advice and encouragement to her on the reformation of religion. Among his friends were Melancthon and Erasmus. The former addresses him in terms of high respect, and calls him his patron, and apprehending the necessity of seeking an asylum with him, he assures himself of an hospitable reception with one who could adopt the sentiment of the exiled queen. "Non ignara mali, miseris succurrere disco."

"Touch'd with misfortunes I myself have known,
I view with pity woes so like my own."

Virgil, *Æn.* i. 634.

Erasmus, in a letter written in 1527, says of him, that he should have thought himself sufficiently happy in his single friendship; and in another letter, after enumerating his excellent qualities, he adds, "that which the young ought to learn of the aged, I, an old man, have learned of this youth." The friendship between them continued as long as Erasmus lived; and Alasco was probably with him in his last sickness, as he purchased of him, when he lay on his death-bed, his valuable library.

Alasco, by the favour of Sigismund, passed his last years in his native country, where he died in 1560; "having, in times and circumstances of peril, supported a consistent, amiable, and respectable character." Burnet's *Hist. Reform.* vol. ii. p. 154—250. Gen. Biog. See ALASCANI.

ALA SHAKR, i. e. *beautiful city*, in *Geography*, a name given by the Turks, to the ancient city of Philadelphia, on account of its beautiful situation.

ALASIA, a province of THIBET in Asia.

ALASSAC, a town of France, in the department of the Correze, and district of Brive, two and an half leagues north north-west of Brive.

ALATA, a name given by Ptolemy to two towns, one in Arabia Deserta, and another in Arabia Felix.

ALATA CASTRA, a town of Britain, placed by Ptolemy near the Ætuary of Bodotria, supposed to be the site of Edinburgh.

ALATAMAHA, a navigable river of Georgia in North America, rises in the Cherokee mountains, traverses the hilly country though a distance of 250 miles, and then passing through the flat country, under the name of Oakmulgee, for 150 miles, and receiving the Oconee, assumes the name of Alatomaha. After this junction, it flows with a gentle current for 100 miles, and discharges itself by several mouths into the Atlantic. The north channel enters the ocean between Sapelo and Wolf Islands; the South channel, which is the largest and deepest, pursues its course

between McIntosh and Broughton islands, and by the west coast of St. Simon's sound, between the south end of the island of that name, and the north end of Jekyll island. At its confluence with the Atlantic, it is 500 miles broad.

ALATED, or WINGED, in *Botany*, an epithet applied to the seed, stem, or leaf-stalk. A seed is alated, when it has an ala or membrane affixed to it, which by its flying serves to disperse it. See SEED. The foot-stalk, or petiole of a leaf, is alated, when it spreads out on the sides, or is winged with membranes. Alated leaves, are those made up of several pinnated ones, or when the sides of a single petiole connect many folioles. See LEAF.

ALATED *Quadrupeds*, in *Zoology*. See QUADRUPED.

ALATERNOIDES, in *Botany*. See PHYLLICA, CLUTIA, CEANOTHUS, and MYRICA.

ALATERNUS. See RHAMNUS and PHYLLICA.

ALATLI, in *Ornithology*. See ACHACHACTLI.

ALATRI, or ALATRO, an ancient city of Italy, in the Campagna di Roma, which is the see of a bishop, and a dukedom, five leagues south-east of Agnani, and 16 south-east of Rome. N. lat. 41° 44'. E. long. 13° 12'.

ALATUNGA, in *Ichthyology*, a species of the SCOMBER, with the first pectoral fins very long, and seven small fins on each side of the tail. It is found periodically gregarious in the Mediterranean.

ALATYR, in *Geography*, a town of Russia, in the government of Kasan, and circle of Alatyrsk, 80 miles west-north-west of Simbirsk. N. lat. 54° 55'. E. long. 46° 14'.

ALATYR, a river of Russia, which runs into the Sura, near Alatyrsk.

ALAVA, ESQUIVEL, DIEGO, in *Biography*, a Spanish divine, bishop of Cordova, was born at Victoria in Alava, and assisted in the council of Trent, where he proposed the prohibition for holding livings in *commendam*, and of all ecclesiastical pluralities. He died in 1562: and wrote a valuable work, intitled "De Conciliis Universalibus, &c." i. e. of general councils, and the regulations that seem necessary to reform the religion and state of the church.

ALAVA, in *Geography*. See ALABA.

ALAUDA, in *Entomology*, a species of CURCULIO, cinereous; subglobose thorax, back marked with a transverse band and black spots, and brown legs: found in Pomerania.

ALAUDA *non cristata*, in *Ichthyology*, a name given by Rondeletius and Gesner to the BLENNIUS *pholis* of Linnæus, or smooth BLENNY.

ALAUDA, LARK, in *Ornithology*, a genus of birds of the order of *passeres*; the characters of which are, that the beak is cylindrical, subulate, and straight, bending towards the point; the mandibles are of equal size and opening downwards at their base; the tongue is bifid; and the hinder claw is straighter and longer than the toe. Pennant adds, that the nostrils are covered with feathers or bristles, and the toes divided to their origin.

The name *alauda* is, according to Pliny, Suetonius, and Varro, of Gaulish extraction; and hence the French term, *alouette*.

The Greeks were acquainted with two species of larks; the one had a tuft on its head, and was denominated *κορυδαλος*, or *κορυδαλος*, from *κορυς*, a helmet, which the Latins render *galerita*, or *casita*; the other, a common lark, wanted this tuft: though Willughby and Pennant say, that it sometimes bristles the feathers on its head so as to form an occasional crest, which M. Buffon affirms also, from his own observation, with respect to the male. The Germans call it *lerche*, pronouncing it sometimes *leriche*, in imitation of its notes; for, according to Linnæus, it prolongs its *tirile, tirile, tirile*.

Gmelin enumerates 33 species. 1. *A. Arvensis, vulgaris* of Olin, *Cochipeta* of Klein, *alauda non cristata* of Gefner and Aldrovand, *Palouette* of Buffon, and *field-lark* or *sky-lark* of Ray, Willughby, Pennant, Latham, &c. the specific characters of which are, that the two outermost quills of its tail are white lengthwise externally, and the intermediate ones are ferruginous on the inside: the length is about seven inches. The males of this species are somewhat browner than the females; they have a black collar, and more white on the tail; their size is larger, and their aspect bolder; and they exclusively possess the faculty of singing. When the female is impregnated, she forms her nest between two clods of earth, and lines it with herbs and dry roots, being no less attentive to the concealment than to the structure of it. It sometimes builds its nest among corn and in high grass. Each female lays four or five eggs, which are greyish, with brown spots; and the period of her incubation is about 15 days. The young may be taken out of the nest when they are a fortnight old, and they are so hardy, that they may be easily brought up. Some have said, that she hatches three times in the year; but this must depend on the temperature of the climate. The parent is very tender of her young; and though she does not always cover them with her wings, she directs their motions, supplies their wants, and guards them from danger. The common food of the young sky-larks is worms, caterpillars, ant's-eggs, and even grasshoppers; and in maturity, they live chiefly on seeds, herbage, and all vegetable substances. Those birds, it is said, that are destined for singing, should be caught in October or November; and the males should, as much as possible, be selected: and when they are untractable they should be pinioned, lest they injure themselves by their violence against the roof of the cage. As they cannot cling by the toes it is needless to place bars across their cage; but they should have clean sand at the bottom of the cage, that they may welter in it and be relieved from the vermin which torment them. In Flanders, the young ones are fed with moistened poppy-seeds, and soaked crumbs of bread; and when they begin to sing, with sheep's and calves' hearts, hashed with hard eggs; to which are added, wheat, spelt, oats, millet, linseed, and the seeds of poppy and hemp, steeped in milk. Their capacity of learning to sing is well known; and so apt are some cock larks, that, after hearing a tune whistled with the pipe, they have caught the whole, and repeat it more agreeably than any linnæus or canary bird. In summer the larks seek the highest and driest situations; but in winter they descend to the plains, and assemble in numerous flocks. In the former season they are very lean, and in the latter very fat, as they are always on the ground, and constantly feeding. In mounting to the air, they ascend almost perpendicularly, by successive springs, and hover at a great height; but in descending, they make an oblique sweep, unless they are pursued by a ravenous bird, or attracted by a mate, in either of which cases they fall like a stone. These small birds, at the height to which they soar, are liable to be wafted by the wind; and they have been observed at sea, clinging to the masts and cordage of ships. Sir Hans Sloane observed some of them 40 miles from the coast, and count Marfigli met with them on the Mediterranean. It is conjectured, that those which are found in America have been driven thither by the wind. Some have supposed, that they are not birds of passage, at least in the more southern and milder climates of Europe; but they are occasionally concealed under some rock or sheltered cave; and this concealment was known to Aristotle (Hist. Anim. lib. viii. 16.), and has been ascertained by Klein. Thevenot (Voyage du Levant, tom. i.

p. 493.) says, that the larks appear in Egypt in the month of September, and continue there till the end of the year. See MIGRATION.

The lark is found in all the inhabited parts of both continents, as far as the Cape of Good Hope; though Villault says, that it is not found on the Gold coast; nor, according to Averroes, in Andalusia.

This bird, and the wood-lark, are the only birds which sing whilst they fly. The higher it soars, the more it strains its voice, and lowers it till it quite dies away in descending. When it ascends beyond our sight, its music is distinctly heard; and its song, which is full of swells and falls, and thus delightful for its variety, commences before the earliest dawn. Milton, in his Allegro, has admirably expressed these circumstances; and bishop Newton observes, that the poet gives a fine picture of the state of the mind, whilst he is beautifully describing the scene of rural cheerfulness, in a situation,

“ To hear the lark begin his flight,
And singing startle the dull night,
From his watch-tower in the skies,
Till the dapple dawn doth rise.”

In a state of freedom, the lark begins its song early in the spring, which is its season of love and pairing, and continues to warble during the whole of the summer. The Hon. Daines Barrington (Phil. Trans. vol. lxxiii. part ii. p. 282.) reckons this among the best of the singing larks: and as it copies the warble of every other bird, he terms it a mocking-bird. See SONG of *Birds*.

These birds, which are esteemed a delicacy for the table, though Linnæus thinks the food improper for gravelly complaints, are taken with us in the greatest numbers, in the neighbourhood of Dunsfable. The season begins about the 14th of September, and ends the 25th of February; and during this time, about 4000 dozen are caught for supplying the London markets. Those caught in the day, are taken in CLAP-NETS, till the 14th of November. See DORING. But when the weather becomes gloomy; and also in the night, the larker makes use of a trammel-net, 27 or 28 feet long, and five broad, which is put on two poles 18 feet long, and carried by men under each arm, who pass over the fields, and quarter the grounds as a setting dog. When they see or feel a lark strike the net, they drop it down, and thus the birds are taken. The darkest nights are the most proper for their sport; and the net will not only take larks, but all other birds that roost on the ground; among which are woodcocks, snipes, partridges, quails, field-fares, and several others. In the depth of winter people sometimes take great numbers of larks by nooses of horse-hair. The method is this: take 100 or 200 yards of packthread; fasten at every six inches a noose made of double horse-hair; at every 20 yards the line is to be pegged down to the ground, and so left ready to take them. The time to use this is, when the ground is covered with snow, and the larks are to be allured to it by some white cats, scattered among the nooses; they will soon fly to these, and in eating will be hung by the nooses. They must be taken away as soon as three or four are hung, otherwise the rest will be frightened; but though the others are scared away just where the sportsman comes, some will be feeding at the other end of the line, and the sport may be thus continued for a long time. As the sky-lark is a kind of mocking-bird, and apt to catch the note of any other which hangs near it, even after its own note is fixed; the bird-fanciers often place it next to one which hath not been long caught, in order, as they term it, to keep the caged sky-lark honest.

The

The method of catching larks by lime-twigs, practised in French Lorraine, is as follows. For this purpose, 1500 or 2000 willow rods, about three feet, ten inches long, straight and well smoothed, are provided. These are sharpened and slightly burnt at one end, and the space of about a foot from the other end is covered with bird-lime. The flakes are planted in parallel rows, in a situation which abounds with larks; the rows are at such a distance as to admit a person passing between them; and the flakes are fixed at the distance of a foot from each other, and opposite to the interval in the next row. The chief art consists in so placing them, that they shall retain their perpendicular position till they are touched, and fall immediately upon a lark's brushing against them in its flight. When the limed rods are planted, an oblong square is traced, with one of its sides presented to the ground where the larks are lodged, and at each corner is erected a flag, which serves as a mark to the fowlers, and sometimes as a signal for their manœuvres. In Autumn, about four or five o'clock in the afternoon, the company attending this sport is divided into two detachments; one is assembled at the flag on the right, and the other at that on the left; and each observing the most profound silence, extends itself in an arch, so as to meet at the distance of half a league from the front, and then form one rank, gradually closing as it advances to the rods, and thus driving the larks before it. About sun-set, the middle of the line ought to be within two or three hundred paces from the front; and this is the time when they *charge*: that is, they proceed cautiously, pause or lie on the ground, rise up or push forward, according to the commands of their leader. Upon the proper conduct of these manœuvres depends the success of the sport; for thus the larks will be enclosed, and mounting no higher than three or four feet, they will rush forward and be caught among the lime-rods, and falling to the ground with these, they may be picked up by the hand. If it be not too late, a second line is made on the opposite side, at the distance of 50 paces, which drives back the larks that had escaped; and this is called *tacking about*. One hundred dozen of larks or more are sometimes caught in one of these sweeps, and the sport is reckoned bad when only 25 dozen are taken. Although such numbers are taken in this way, and others destroyed by the voracious tribes, their fecundity is very great; and they are naturally long-lived, the term of their existence being, according to Olina, ten years, and as others say, 12, 22 and even 24 years. Larks abound in various parts of Germany, and Keyser (Travels, vol. iv. p. 315.) informs us, that those about Leipsic, where they are very numerous, are very fat, and have a very delicate flavour. The excise on these birds produces 6000 dollars, or about 900*l.* sterling annually. They are also taken in great numbers in the country about Naumburg, Meseburg, and Halle. Of this species there are three varieties; *viz.* the *white sky-lark*, which is seldom of a snowy white colour, but tinged with yellow or brown, and which is chiefly found on the northern shores of the Baltic, in Denmark and Sweden, and in Norway; and occasionally in the vicinity of Hildesheim in Lower Saxony, and in other places. A second variety is the *black sky-lark*, represented by Albin as entirely of a dull brown and reddish colour, verging to black, excepting the back of the head, which is of a dun yellow, and the lower part of the belly, which has feathers edged with white: the feet, toes and nails, being of a dirty yellow. The subject of this description was caught in a meadow near Highgate, where such birds are found. A perfectly black lark is mentioned by Mauduit, which was caught in the plain of Mont-

rouge near Paris. A third variety is the *long-legged lark* of Latham.

2. *A. pratensis*, or *pratensis*, *spipola akera* of Aldrovand and Willughby, *abutte de pres*, or *la fuloise* of Buffon, *tit-lark* of Pennant, Ray, Albin, and Latham, &c. of which the specific characters are, that above it is greenish brown; its two outermost tail-quills are externally white, and it has a white line on its eyebrows. This bird is of an elegant slender shape; five inches and a half long; its bill is black; the back and head of a greenish brown, spotted with black; the throat and lower part of the belly are white; the breast yellow, marked with oblong spots of black; the tail is dusky; the exterior feather is varied by a bar of white, which runs across the end and takes in the whole outmost web; the claw on the hind toe is very long, and the feet yellowish. The male has in general more yellow than the female, on the throat, breast, legs and feet. The tit-lark is found generally in meadows and low marshy grounds; and, like other larks, it makes its nest among the grass, and lays five or six eggs; which are roundish, of a dusky red colour, with many small spots. While the female hatches, the male sits on a neighbouring tree, and rises at times, singing and clapping his wings. It feeds chiefly on the worms and insects which it finds in new-ploughed lands; and it will live for a long time on no other food than small seeds. Like the wood-lark, it sits on trees; but it is flushed at the least noise, and shoots with a rapid flight: it has a very remarkable fine note, singing in all situations; on trees, on the ground, while it is sporting in the air, and particularly in its descent. This bird, and many others, such as the thrush, blackbird, willow-wren, &c. become silent about Midsummer, and resume their notes in September; hence this interval is the most mute of the year's three vocal seasons, Spring, Summer and Autumn. Perhaps the birds are induced to sing again as the autumnal temperament resembles the vernal. The tit-lark inhabits England, France, Germany, Italy, and Sweden. Albin says, that it appears in England about the beginning of April, and that it departs about the month of September. It is said to be fond of the company of its fellows; and when it cannot get the society of these, it will intermingle with the flocks of finches and linnets, which it meets with in its passage. The varieties of this species are the *white tit-lark*, differing from the preceding in its plumage, which is yellowish white, but yellower on the wings, with brown bill and feet, seen by Aldrovand in Italy, and reckoned by Rzaczynski among the birds of Poland; and the *tit-lark with black feet*.

3. *A. arborca*, *le cujler* of Buffon, *wood-lark* of English writers, is specifically characterized by a white annular belt, encircling its head. This bird is smaller than the sky-lark, and of a shorter thicker form; the colours of the plumage are paler; the first feather of the wing is shorter than the second; the hind claw is very long and somewhat bent; it perches on trees; it haunts the uncultivated tracts near copes, without penetrating the woods, whence its name; its song resembles more the warble of the nightingale, or the whistling of the blackbird, than that of the sky-lark; its note being less sonorous and less varied, though not less sweet; and it is heard not only in the day but in the night, both when it flies and when it sits on a bough.

This bird builds on the ground, and forms its nest on the outside with moss, and on the inside with dried bents, lined with a few hairs, and conceals it with a turf; and the situation it selects is ground where the grass is rank, or become brown. It lays four or five eggs, which are dusky and blotched with deep brown; its fecundity is inferior to that

that of the sky-lark, and its numbers are not so great: it breeds earlier, since its young are sometimes flown in the middle of March, and therefore they pair in February, at which time, and not before, they part with their last year's brood; whereas the common lark does not hatch before the month of May. This is a very tender and delicate bird; so that, according to Albin, it is impossible to rear the young taken out of the nest: but this is the case only in England and such cold climates, for in Italy they are removed from the nest, and reared at first like the nightingale, and afterwards fed upon panic and millet. The wood-lark feeds on beetles, caterpillars, and seeds: its tongue is forked; its stomach muscular and fleshy; and it has no craw, but a moderate dilatation of the lower part of the oesophagus, and its cæca are very small. It lives ten or twelve years. The males are distinguished from the females by their larger size; the crown of the head is also of a darker colour, and the hind nail longer; its breast is more spotted, and its great wing-quills edged with olive, which in the female is grey. The wood-lark mounts high, warbling its notes, and hovering in the air; it flies in flocks during the winter colds; it is found in Sweden and Italy, and is probably dispersed through the intervening countries, and consequently over the greatest part of Europe. It is also found in Siberia, as far as Kamtschatka, and in the island of Madeira. Of these larks, like the common sort, some are migratory, and some stationary. In autumn the wood-lark is fat, and is then excellent for food. There are three seasons, according to Albin, for catching wood-larks. The first is the summer, or the months of June, July, and August, when the small branches begin to chirp, before they undergo the moulting. The second is the month of September, when they fly in flocks and roam from one country to another, roving over the pasture grounds, and perching on trees near lime kilns. The young birds now change their plumage, and are not distinguishable from the old ones. The third and the most favourable season for catching wood-larks, begins with the month of January, and lasts till the end of February, when they separate to pair. The young birds, which are then caught, make generally the best singers; they chirp a few days after, and with a clearer tone than those that are caught at any other season. Those that are taken in the Summer months are usually taken in nets, by the help of a hawk. With this view, the sportsman is to go out in a dewy morning, and fixing on some hill, he is to go to that side of it which faces the rising sun; for this is the place which they are sure to frequent. He is then to take out a hawk, and a small net at the end of a stick: when he sees a bird, he is to shew the hawk, upon which it will squat down; and on his approaching near, and making the hawk flutter over the place, the bird will only lie so much the closer, so that he may go up and lay the net over it, and thus take it without injury. The best wood-larks that are kept in cages, have been caught in this manner. A better way of taking numbers of them, is to prepare a net made like that for taking partridges, only with much smaller meshes; three or four persons are to go out with this, and one of them is to take out a hawk, which serves in the same manner for the larks, as the setting-dog does for the partridges. Wherever a flock of these larks is seen together, which is very common, the whole flight keeping with the female till the next coupling season, the hawk is to be shewn; and on his hovering, they will all lie still, and the net may be easily drawn to completely over them, that not one can escape. The best time for taking this bird for the cage is July, or the preceding or following month. Those that are put

into the cage at this time, sing presently, but their song-time is not lasting, for they soon fall to molting, in which state many die; but if they get over it, they commonly prove very healthful afterwards, become very tame and familiar, and sing sweetly. Those which are taken in the latter end of September are generally very strong and sprightly; but they do not sing till after Christmas. Those taken in January and February finally prove the best of all; they generally begin singing in two or three days, or at the utmost in a week after they are taken.

The method of keeping them in health in the cage is this: there must be two pans of food, the one containing meat, the other oatmeal and hempseed. The following is very good food: boil an egg very hard, to which add the crumb of a half-penny loaf and as much hemp-feed; let the egg be chopped very small, and the hempseed bruised in a mortar; when these are mixed, the bread is to be crumbled in among the rest, and the whole to be rolled together with a common rolling-pin, and kept for use. There must be some fine small gravel strewn at the bottom of the cage, and renewed at farthest once in a week. This will prevent the bird's feet from injury by being clogged with dung; and his basking in this will also keep him from being lousy, after which few birds are of much use. A perch must be in the cage, and it should be lined with green baize, or made of fine matting, of which the lark is very fond. When the bird is first taken, some meat should be strewn on the sand in the bottom of the cage; for the bird will be sometimes almost famished before he finds the meat in the pan. The cock-bird of this kind is known from the hen by the loudness and length of his call, by his tallness as he walks about the cage, and by his doubling his notes in the evening, as if he were going with his mate to roost. A better rule than all others, however, is his singing strong; for the hen wood-lark sings but very weakly. Both the cock and hen of this kind are tender, and subject to many disorders; the principal of these are, cramps, giddiness of the head, and breeding lice. Cleanliness is the best cure for the first and the last of these complaints; but we know of no cure for the other. A good strong bird will last very well for five or six years, and frequently improve during the whole of this time. The lark is not only a very agreeable bird for the cage, but it will also live upon almost any food, so that it have once a week a fresh tuft of three-leaved grass put into the cage with it. The wood-lark is one of the sweetest of our singing-birds, and is indeed very little inferior to the nightingale, when in good health; but we are not to judge by such as are made feeble by improper food, or want of cleanliness in their cages.

4. *A. Campestris*, la *Jpipolette* of Buffon, *glareana* of Gerner, &c. in German *gickerlin*, *bracklerbe* and *krautlerbe*, meadow-lark of Latham, is rather larger than the tit-lark; being six inches and a half in length. Its specific characters are, that its tail-quills are brown; the lower half, except two intermediate quills, white; the throat and breast, yellow. According to Willughby, the meadow-lark differs from the other larks by the blackness of its bill and feet; he adds, that its bill is slender, straight, and pointed, and the corners of its mouth edged with yellow; that it has not, like the wood-lark, the first quills of the wings shorter than the succeeding; and that in the male the wings are rather darker than in the female. Though the males are hardly to be distinguished from the females by their external appearance, yet if another male be presented, shut up in a cage, they will instantly attack it as an enemy or a rival. This bird has a slenderer body than the sky-lark, and is distinguished from it by the shake of its tail, like that of the wagtail

wagtail and tit-lark. It inhabits heaths and uncultivated tracts, and frequently the oat-stubble, after the corn is reaped, where birds of this species gather together in numerous flocks. In spring, the male perches to discover or to woo his mate, and sometimes he mounts into the air, singing with all his might, and then descends quickly to pair on the ground. When a person approaches the nest, the female betrays her fear by her cries; whereas, other larks are silent and unmoved, when danger is apprehended. They make their nest close to the ground, sometimes in furze-bushes, and form it of moss, lined with straw and horse-hair. The egg is half the size of that of the sky-lark, which it resembles, and its tints are lighter. Where the young males are reared for the sake of their song, they require great attention. The cage must be covered with a green cloth, little light be admitted, and plenty of ant's eggs must be provided. By degrees bruised hemp-feed, mixed with flour and yolk of eggs, may be substituted. The meadow larks are caught like the sky larks, with the drag-net, and also with lime twigs, placed in the trees which they haunt. They associate with the liches; and both arrive and depart with these. They are found in Italy, Germany, England, Sweden, &c. They live on small seeds and insects: and their flesh, when fat, is excellent. The meadow-lark of Britain differs from that of Linnæus; as in that of the latter, all the quills of the tail, except the two middle ones, are white from their origin to half their length, but in that of the former, the two outermost quills only are white. Of this species there is a variety, *viz.* the *spinoletta*.

5. *A. trivialis*, *A. sepiaria* of Brisson, *spipola s. anthus* of Aldrovand, *L'alouette pipi* of Buffon, the *snail lark* of Ray and Willughby, the *pipit lark* of Albin, the *grasshopper warbler* of Latham, is distinguished by brown tail-quills, the outermost half white, the second white at its wedge-like tip, with a double whitish line on the wings. The German epithet *piep*, and the English *pippit*, formed from the Latin *pipio*, which signifies to utter a feeble cry like chickens, alludes to the sibilous notes of this bird. Its cry, especially in winter, is like that of the grasshopper, but stronger and shriller, and it utters this, both when perched on the tallest branches among the bushes, and when it is on the wing. Its tones are soft, harmonious and clear. This little bird builds its nest in solitary spots, concealed under a turf, and its young are frequently a prey to the adders. It lays five eggs, of a light grass-green colour, thinly sprinkled with deeper coloured specks. The grasshopper larks appear in England about the middle of September, and great numbers of them are caught in the environs of London. They are found in Sweden and Germany, as well as in England: they frequent the heaths and plains, and flutter at a moderate height; they chiefly feed, as the slender form of their bill indicates, on insects and small seeds, and from the diminutive size of this bird, being about five inches and a half long, it may be inferred, that it is not long-lived.

6. *A. cristata*, Κορυδαλος: τοσυν εχρησα, *i. e.* the helmet-lark having a crest of Aristotle; the *galerita* of Pliny and *galeritis* of Varro; *A. cristata* of Brisson, *A. cristata major* of Ray, Aldrovand, and Gesner, *ledola capelluta* of Olinia, *le cochevis* of Buffon, *heidelerche* of the Germans, and *crested lark* of Willughby, Albin and Latham, is distinguished by black tail-quills, the two outermost white at their exterior edge, its head crested, and its feet black. Its length is about six inches and three quarters. It lives in the meadows and fields, on the sides of ditches and the backs of furrows; it is often seen at the margin of water, and on the high roads,

rarely in the skirts of woods, perched on a tree, and sometimes on the tops of houses, and of abbeys, &c. This lark though not so common as the sky-lark, is found in most parts of Europe, in Italy, France, Germany, Poland, Denmark, Russia, Scotland; and does not change its abode in winter. The song of the males is loud, and yet mellow and pleasant: and their warbling is usually accompanied with a quivering of the wings. They are the first to hail the return of spring, and the dawn of the morning, and they sometimes warble in the night; being animated by fine weather, but depressed and silenced by clouds and rain; and they generally sing till the end of September. The male is distinguished, not only by the excellence of his warble, but by the strength of his bill, the bulk of his head, and by a large portion of black on his breast. The female constructs her nest like the common lark, but often near the highways; she lays four or five eggs, which are ash-coloured, with numerous dingy brown spots, and takes little concern in hatching them; but when the young are excluded, she provides for them till they are flown. They are said to breed twice in the year. They are easily reared, but cannot be supported in a cage, without difficulty, for a whole year: their best food is ant's eggs, ox and sheep's hearts minced, and bruised hemp-feed and millet. The proper season for raising these birds is autumn; and great numbers are then caught in a plump state on the verge of the forests. They may be decoyed by the call, and thus differ from sky-larks; besides, they never consort in flocks; their plumage is less varied and more white; the bill longer, the tail and wings shorter; they do not mount so high in the air, are less able to struggle with the wind, and return sooner to the ground. In other respects the two species are alike.

The crested lark is the only one that may be instructed in a month; it learns many airs perfectly, which it repeats without confusion, and retains nothing of its native warble; and in these particulars it is superior to the canary.

7. *A. rufa*, *l'Alouette noir a'dos fauve* of Buffon, the *rufous backed lark* of Latham, is specifically distinguished by its blackish brown colour; its neck and back rufous-orange, the tail-quills rufous at their outward margin, the lesser and middle coverts of the wings blackish and fulvous, or of a deep yellow at their margin. Its length is scarcely five inches, is much smaller than the common sky-lark, and found at Buenos-Ayres. Buffon observing its plumage to exhibit so striking a resemblance to that of the sky-lark, considers it as a variety of that species.

8. *A. capensis*, *A. capitis bona spei* of Brisson, *la cravatte jaune ou calandre du cap de bonne esperance* of Buffon, *cape lark* of Latham, has its three lateral tail-quills tipped with white, its throat yellow, margined with black, and its eyebrows yellow. Its length is eight inches, and it is found at the Cape of Good Hope.

9. *A. calandra*, *A. non cristata major* and *tetrao parva* of Gesner, *calandre* of Buffon, *calandra* of other writers, *calandre lark* of Latham, is specifically described as having its outermost tail-quill externally altogether white, the second and third tipped with white, and a brown stripe on the breast. This bird is mentioned by Oppian in the second century of the Christian Era, under the appellation of Καλάνδρα; and he describes the best method of catching it, since recommended by Olinia, which is to spread a net near the brook to which it usually resorts to drink. It is larger than the sky-lark, its length being seven and one-fourth inches, and its bill stronger and shorter: in other respects it exactly resembles the common lark. Its warble is more sonorous, but not less pleasant; so that in Italy a person who sings well is complimented

complimented by saying, that he sings like a calandre. It can, like the common lark, imitate the notes of several birds, and even the chirping of chickens and the love-squall of the she-cat. When calandres are to be caged, in order to have good singers, they should be taken from the nest before the first moult, and those are to be preferred which are hatched in August. Their food should be pulse mixed with sheep's heart, together with seeds and crumbs of bread; and rubbish should be laid in the cage for wetting their bill, and sand for them to welter in when teased with vermin. Their wings should at first be pinioned, and instead of the top of the cage, a canvas should be substituted. When they are reconciled to their situation, they will sing incessantly, and even neglect their food to repeat their warble. The male is larger and blacker round the neck than the female, which has only a very narrow collar. The calandre nestles on the ground, like the common lark, under a grassy tuft, and lays four or five eggs. It is found in Italy, Sardinia, Provence in France, the Pyrenees, Syria, near Aleppo, the southern part of Russia, the deserts of Tartary, and even America whither it might have been driven by the winds across the Atlantic, and there thrive and become naturalized. Adanson regards the calandre as intermediate between the sky-lark and the thrush; but this is an analogy which must be restricted to the plumage and external form, for the habits of this bird and the thrush are very different.

10. *A. alpestris*, *A. virginiana* of Brisson, *hauffe-col noir* of Buffon, *lark, with a yellow throat* of Catesby, and *shore-lark* of Pennant, Latham, &c. has these specific characters; the tail-quills are half white on the inside, the throat is yellow, the stripe under the eyes, and on its breast, is black. Its length is six and an half inches, and in bulk and habit it resembles the common lark. It inhabits North America, Siberia, Russia and Poland; migrates in flocks, feeds on oats and other grains and grasses; lives upon the ground; has little or no song, and its flesh is delicious.

11. *A. magna*, *merula americana torquata* of Brisson, *la fer-a-cheval ou merle a collier d'amerique* of Buffon, *large lark* of Catesby, and *crescent star* of Pennant and Latham, is characterized by Linnæus as having the under-side of the body yellow, a black curved band on the breast, and the three lateral quills of the tail white. Above, says Latham, it is variegated with rusty brown and blackish, below yellow, with a black curved stripe on the breast, and the three lateral quills of the tail white. Its length is 11 inches. It is found not only in Virginia and Carolina, but in almost the whole Continent of America; and Linnæus asserts that it occurs also in Africa. In the state of New York it appears in the beginning of April, breeds in June, and retires in September or October. It nestles on the ground, and its eggs are whitish. It lives in Savannas, perches on the tops of bushes, has a brisk motion upwards and downwards of its tail, eats scarcely any thing but the small feeds that are found on the ground, such as those of the yellow flowered *ornithogalum*; sings agreeably in the spring; and is reckoned good food.

12. *A. minor*, *lesser field lark* of Willughby, *field lark* of Latham, is of a reddish brown colour, and the two outer quills of the tail are externally white. The throat is yellow; the breast also yellow, marked with large black spots; the belly and vent feathers white; the coverts of the wings dusky, edged with white; and the legs of a very pale brown. It is larger than the tit-lark, but distinguished from it by the very short claw on the hind toe.

13. *A. Italica*, *girola* of Ray and Willughby, *girole* of Buffon, and *Italian lark* of Latham, has the middle quills

of the tail bay, the last but one white at the tip, the two outermost entirely white. Its size is that of the sky-lark, and it has a long nail projecting from each foot. Its head, neck, back, and wings are of a mottled colour, resembling that of the quail. The general colour of the feathers is a chestnut brown, and their edges are variegated with white, yellow and red; the back part of its head has a sort of crown or ring of white feathers; its belly is white; its bill red; and the corners of the mouth yellow, and its tail is so short, that it seems to have none; it is bifid, however, and elegantly variegated with chestnut-colour and white. The feet are flesh-coloured and the nails whitish. It is eight inches long, and inhabits Italy.

14. *A. ludoviciana*, *farlouzanne* of Buffon, and *Louisiana lark* of Latham, resembles the tit-lark. Its specific characters are, that the last quills but one of the tail are tipped with white; the outermost are partly brown, partly white. Its length is seven inches. It is found in Louisiana.

15. *A. rubra*, *A. Pennsylvania* of Brisson, *alouette aux joues brunes de Pensylvanie* of Buffon, and *red-lark* of Pennant and Latham, is of a brown colour, and has the space about its eyes black, and the two outermost quills of the tail white. It is about the size of the meadow-lark. Its bill, feet, and nails are of a deep brown colour; its neck, breast, and underpart of the body, of a reddish fulvous colour, speckled with brown; and the brown spot that surrounds the eyes defends on the cheeks and is bounded by a zone, partly white and partly bright fulvous. This is a migratory bird, common to both continents. It appears in Pennsylvania in the month of March, and advances northward at the end of May; and it was seen by Mr. Edwards in the vicinity of London. He remarks, that when the wing is gathered up, the third primary feather reaches to the tip of the first.

16. *A. mosellana*, *la rouffeline* of Buffon, and *marsh-lark* of Latham, is rufous, below rufous white; its cheeks and breast are marked with brown lines; its tail is black with a rufous margin. Its length is six and one-fourth inches. The bill, feet and nails are yellowish. It haunts wet situations, frequents the sandy margin of the Moselle, and sometimes breeds on its banks, near Metz, where it appears annually in October, and some few are caught. It begins its song at dawn, which is said to be very pleasant.

17. *A. malabarica*, *Malabar lark* of Latham, has the primary and secondary wing-feathers and the tail, of a fordid brown colour, tawny at their margin. The bill is black, the feathers that form the crest on the head are brown, and their apex white; those on the neck are tawny with a black longitudinal streak passing along the middle; the throat and abdomen reddish white; the feathers of the back and the coverts of the wings brown, towards their edge tawny, and marked with a white spot, and the feet are tawny. This is a beautiful species and found in Malabar.

18. *A. gingica*, *Gingi lark* of Latham, has the upper part of the body cinereous brown, its under side black. The bill and feet are reddish grey. Its length is four and one-half inches, and it is found in Coromandel.

19. *A. tartarica*, *A. nigra* of Falck, and *black lark* of Latham, has a subbifurcated tail, the two intermediate quills of the tail slightly white at their limb, the next whitish at the apex, and the lateral very black. This bird inhabits the very dry salt deserts between the rivers Volga and Ural, the Caspian deserts, and the whole southern desert of Tartary; it is gregarious in winter, solitary in summer, and has scarcely any song.

20. *A. mutabilis*, *mutable lark* of Latham, has a black forked

forked tail, the outer quills of the tail on both sides unspotted, the rest grey at their apex, and the bill whitish. It is about seven inches in length, and inhabits the deserts of Astracan. This bird, when young, is wholly cinereous, and the colour gradually changes into black.

21. *A. nemorosa*, *A. cristata minor* of Ray and Brisson, *le lulu* of Buffon, and *lesser crested lark* of Pennant, Willughby and Latham, is characterized by black tail-quills, the two outermost white on their exterior edge, its head crested, and its feet red. The crest is very long in proportion to its size. This bird is distinguished by its cry, *lu, lu, lu*, which is disagreeable, and never uttered except it flies; it likewise mimicks oddly the songs of other birds; it frequents heaths, commons, and even woods, where it builds its nest; and in the rigour of winter, when the ground is covered with snow, it resorts to dunghills, and picks up its food about barns, and also haunts the highways for the same purpose. It is found in Italy, Austria, Silesia, and Poland, and seen in flocks in the northern counties of England. It remains in Germany through the winter, and leaves the country about the equinox.

22. *A. undata*, *coquillade* of Buffon, *undated lark* of Latham, has its tail-quills brown, tawny at the edge, its feet yellowish, and the feathers of its crest black, edged with white. Its length is six and three-fourth inches. This bird can elevate its crest at pleasure; it is properly the bird of the morning, as it begins its song with the earliest dawn, and seems to rouse the other birds. The male does not leave his mate when she hatches, and when the one is employed in seeking their food, which consists of caterpillars, grasshoppers, and snails, the other keeps watch, to give signal when danger threatens. It was found by M. Guys, in Provence; and Sonnerat brought a bird very like it from the Cape of Good Hope, only that it had no crest, that the colour of the under part of the body was more yellowish, and that none of the quills of the tail or wings were edged with white. It was perhaps a female, or a young bird of the year's hatch.

23. *A. senegalensis*, *A. senegalensis cristata* of Brisson, *la grisette* of Buffon, and *Senegal lark* of Latham, has the two middle quills of the tail grey, the rest brown, the outermost rufous white on the outer side, and the head somewhat crested. Its length is six and a half inches. It inhabits Africa, and perches on the trees, which grow on the banks of the Niger; and is also seen in the island of Senegal.

24. *A. testacea*, *testaceous lark* of Latham, has the four intermediate quills of the tail black, the rest testaceous white, the body above testaceous, and below testaceous white. It inhabits the vicinity of Gibraltar.

25. *A. lusitana*, *Portugal lark*, has the quills of the tail tawny lutescent, the exterior ochroleucous, the feet flesh-coloured, and the bill red. It is found in Portugal.

26. *A. africana*, *le sirlè du cap de bonne esperance* of Buffon, *African lark* of Latham, has the tail, the quills, and the coverts of the wings brown, edged with white, the inferior part of the body white, variegated with oblong brown spots. Its length is eight inches. It is found at the Cape of Good Hope.

27. *A. cinerea*, *la cendville* of Buffon, *cinereous lark* of Latham, is of a cinereous colour; its belly and vent white; the quills of its wings and tail brown, the outermost externally white near the tip. Its length is six inches. Buffon queries whether there be any analogy between this bird and the cinereous lark which Dr. Shaw saw in great numbers near Biserta, in Africa?

28. *A. rufa*, *la variole* of Buffon, *rufous lark* of Latham, has its tail-quills brown, the eight intermediate ones rusty-

coloured at the edge, and the outermost white at the edge. The bill is brown; the body blackish above, variegated with rufous tints, and below white; the feet are yellowish; the length five and one-fourth inches. Comerfon brought this beautiful bird from Buenos Ayres, near the river de la Plata.

29. *A. Nova Zeelandiae*, *New Zealand lark* of Latham, has white eyebrows, a black bar on each eye, its vent cineraceous or ashy, and its feet reddish cinereous. It is seven and a half inches long. The bill is ashy black above; the body black above, white below, the feathers edged with ashy colour; the claws black, the hind one almost straight. It is found in New Zealand.

30. *A. mongolica*, *mongolian lark* of Latham, has the crown of the head ferruginous, bound with a white annular fillet, and in the middle a white spot. It is larger than the calandre, which it resembles; it sings sweetly on the ground, and inhabits the saline marshes that lie between the rivers Onon and Argon.

31. *A. sibirica* has the secondaries white, the crown of the head, ears and shoulders ferruginous, and the outer tail quill externally altogether white. It inhabits the fields of Siberia, near the Irtsi, nestling on the ground, in its flight and song inferior to the sky-lark, in stature larger, and similar to the calandre.

32. *A. flava*, *la ceinture de pretre* of Buffon, has the upper part of its body red and grey, varied with brown, the under part whitish, the face, throat and sides of the head yellow, the tail-quills black, edged with grey, except the outermost which are white at their margin. The yellow of the face, &c. is set off by a black spot between the eye and the bill, that joins to another larger one immediately below the eye; and the breast is ornamented with a broad black girdle. The bill and feet are leaden-grey. Its length is five and three-fourth inches. It inhabits Siberia, but is rarely found. Of all the birds denominated larks, this is the most conspicuous for beauty of plumage.

33. *A. obscura* has the under part of the body white without spots, and the posterior claw shorter than the toe. It inhabits Sardinia, and agrees with the common lark in its size and nearly in its colour, but as the hind claw, though longer than the others, is shorter than the toe, Gmelin queries whether it belongs to the genus *alauda*.

The *alauda yeltonensis*, or yellow lark, is black, variegated with rufous and white. It is found at the lake Yelton, beyond the Volga; is gregarious, and in the month of August is fat and delicious.

The *A. obscura* of Latham, or *dusky lark* of Lewin, is now described under the name of the *A. petrosa*, or *rock lark*, by Mr. G. Montagu. Its specific characters are, that it is olive brown, yellowish under the body, the sides of the neck and breast are spotted with brown, and the half of the outermost tail-quill is white. Mr. M. in 1791 discovered this bird to be a native of the coast of South Wales, in all the rocky situations; and it was known to the fishermen, under the name of the rock lark. Mr. Pennant is supposed to have met with this bird, as in his folio edition of British Zoology, he has given a variety of the tit-lark (*A. pratensis*) with dusky legs, shot on the rocks on the coast of Carnarvonshire. This bird affects only the rocky parts of the coast; and in winter it is occasionally found in the marshes, seeking its food, which is marine insects. It begins its song early in the Spring, which very much resembles that of the *A. pratensis*; as it mounts in the air like that bird, and returns again to the ground, or to some neighbouring rock, with motionless wing. It breeds early in the Spring, a nest with five eggs having been found on the 16th of April; it was placed upon the shelf of a rock, behind a tuft of coarse

grafs, under a small bush, and was formed of dry grafs, marine plants, and dry mofs externally, and lined with finer grafs and a few long hairs. The eggs were of a dirty white, sprinkled with numerous fpecks of brown. The length of the bird was fix and three-fourth inches. Mr. M. has lately obferved this bird on the coaft of Kent and Suffex. Tranfact. of Linnæan Society, vol. iv. p. 41—43. Gmelin's Linnæus's Syfl. Nat. tom. i. p. 791—801. Buffon's Birds, vol. v. p. 1—77.

ALAUNA, in *Ancient Geography*, a town of Britain, belonging to the *Damni*, fituated, according to Horsley, near Falkirk, upon the Roman wall, at a place called Camelou, where are ftill fome veftiges of a Roman town; but Baxter maintains, that it was where Stirling now ftands. Alauna was alfo a town of Gaul, placed by M. d'Anville among the *Unelli*, north of *Coffedia*, and weft of *Crociatonum*.

ALAUNI, a people placed by Ptolemy in Noricum, and alfo in European Sarmatia; probably the fame with the *Alani*.

ALAUNIUM, a town of Gaul, placed by M. d'Anville in the mountains between *Saguftero* to the north-eaft, and *Apta-Julia* to the fouth-eaft.

ALAUNUS, a river of Britain, which Horsley fupposes to be the Tweed, but Camden and Baxter think it is the river Alne, in Northumberland; and their conjecture is favoured by the affinity of the names.

ALAUNUS *mons*, a name given by the ancient geographers to the *VALDAY* mountains of Ruffia.

ALAUZA, or *ALOSA*, in *Ichthyology*, a fpecies of *CLUPEA*. See *SHAD*.

ALAUZI, or *ATUASI*, in *Geography*, a town of South America, in the jurifdiction of *Cuença*, in *Terra Firma*.

ALAUT, or *ALT*, a river of Turkey in Europe, which rifes in the mountains that feparate *Moldavia* from *Tranfylvania*, and runs into the *Danube* near *Nicopolis*, in *Bulgaria*.

ALAY, denoting, in the Turkish language, “the triumph,” in *Modern Hiftory*, a ceremony which accompanies the aflembly of the forces of the Turks upon the breaking out of a war. It is defcribed by Baron Tott, in his memoirs, as a kind of mafquerade, in which perfons of the feveral trades and manufactures prefent to the fpectators the implements and exercife of their refpective occupations. The labourer draws his plough, the weaver handles his fhuttle, the joiner his plane; and thefe perfons are feated in cars, richly ornamented, and commence the proceffion; then follows the ftandard of Mahomet, which is brought out of the feraglio, and carried to the army, in order to ensure victory to the Ottoman troops. An emir precedes this banner, proclaiming with a loud voice; “Let no infidel dare to profane with his prefence the holy ftandard of the prophet; and let every muffulman who perceives an unbeliever, make it known, under pain of reprobation.” From this moment, a religious fury feizes the people, and impels them to commit acts of the moft fhocking barbarity. No regard is paid to fex or age, and many fall facrifices on the occafion.

ALAYA *Cape*, in *Geography*, the eaftern extremity of *Venezuela*, or *Little Venice*, which extends to and from the entrance of the gulf of that name, 130 leagues.

ALAYMO, *MARC ANTHONY*, in *Biography*, a Sicilian by birth: in the year 1610, being then only 20 years of age, was made doctour in medicine. He then went to *Palermo*, where he was particularly celebrated for his fuccefs in treating the plague, which raged in that city, in the year 1623. He died 1662, aged 72 years, and was buried

in the church of *St. Mary of the Agonifers*. In what estimation he was held by his fellow-citizens may be judged by the following lines, part of the infcription on his monument.

“En humi fternitur,
Qui ab humo ipfe totam Siciliam dira feviente
pette liberavit.”

He left feveral works, part in manufcript, the following were printed: *Difcorfo intorno alla prefervatione del morbo contagiofo e mortale, che regna al prefente in Palermo*, &c. 1625. 4to. *Confultatio pro ulceris Syriaci nunc vagantis curatione, Panormi*, 1632, 4to. *Dialecticon five de fuccedaneis medicamentis*, 1637. 4to.; *Configli medico-politici*, &c. della pefta. 1652. 4to.

ALAZEIA, in *Geography*, a river of *Siberia*, which runs into the *Frozen Ocean*. N. lat. 72° 40'. E. long. 142° 14'.

ALAZEISKOI, a fettlement in *Siberia*, on the river *Alazeia*, 30 leagues weft-north-weft of *Niznei Kovinskoi*. N. lat. 69° 40'. E. long. 144° 14'.

ALAZIA, in *Ancient Geography*, a town of *Asia*, fituate on the river *Rymus*, which paffed through *Mygdonia*. *Strabo*. *Geog.* tom. ii. p. 828.

ALAZONES, a people of *Asia*, mentioned by *Strabo*, *Stephanus Byz.* &c. whose origin and hiftory are unknown. They were reckoned among the *Seythians*, who dwelt on the borders of the *Euxine fea*, and *Alazia* was probably their capital. *Apollo* was the object of their worfhip.

ALAZONIUS, a river of *Asia*, which defcended from mount *Caucafus*, and ran into the *Cyrus*; but *Pliny* fays, that this river feparated the *Iberians* from the *Albanians*, and was therefore more to the weft. *Strabo*. tom. ii. p. 764.

ALB. See *ASPER*.

ALB, in *Geography*, a river of *Germany*, which rifes three miles weft-north-weft of *Wildbad*, in the circle of *Suabia*, and runs into the *Rhine*, about five miles weft-north-weft of *Durlach*.

ALBA, a city of *Italy*, in the duchy of *Montferrat*, fituate on the river *Tanaro*; the fee of a bifhop, who is fuffragan to the archbifhop of *Milan*, and whose diocefe is of confiderable extent. Befides the cathedral, it has three parochial and three other churches, with feveral convents. It is 18 miles fouth-eaft of *Turin*. N. lat. 44° 40'. E. long. 7° 51'.

ALBA, in *Ancient Geography*, a city of *Dacia*, which fome fuppofe to have been the fite of the prefent *BIELGOROD*.

ALBA, a town of *Spain*, in the country of the *Baftitani*, fouth-eaft of *Bafti*.

ALBA, now *Elvas*, a city of *Lufitania*.

ALBA, a river of *Gaul*, now *Aube*.

ALBA FIRMA, or *ALBUM*, in *Antiquity*, was a yearly rent, payable to the chief lord of a hundred; fo called, becaufe it was paid in white money, or filver, and not in corn, which was called *black mail*.

ALBA *Fucenfis*, now *ALBI*, in *Ancient Geography*, a town of *Italy*, to the north-weft of the *lacus Fucinus*, in the country of the *Marfi*. It was denominated *Fucenfis*, in order to diftinguifh it from other *Italian cities* of the fame name, and particularly from *Alba longa*. The inhabitants were denominated *Albenfes*. *Silius Italicus* (*Punic. lib. viii. v. 508.*) refers to it:

“ ——— Interiorque per udos
Alba fedet campos, pomique rependit ariftas.”

This town was fituated in the centre of *Italy*, amidft mountainous

mountainous passes, and secluded from all means of escape; and it was therefore chosen for the state-prison, to which the Romans consigned captive princes, after having barbarously dragged them through the streets of Rome, at the chariot-wheels of a triumphant consul. Here Perseus, king of Macedon, and his son Alexander, terminated their career, after the triumph of Paulus Æmilius. Syphax, the Numidian, and Bituitus, king of the Averni, were also condemned to this gaol, by the particular clemency of the senate, which sometimes indulged its savage disposition, by putting its captives to death. The natural security of this place was augmented by artificial fortifications; the ruins of which prove, at this day, their ancient solidity. For the entertainment of the garrison, which was required in a place of such importance, an amphitheatre was erected, the shattered remains of which are still visible, as well as the foundations of a temple, and other buildings, of Roman times. Lucius Vitellius, brother of the emperor of the same name, had a villa near this place, famous for the variety and excellence of its fruit-trees, which he brought from Syria. His gardens were the nurseries, where several of the most delicious stone-fruits that are now so common in Europe, were first cultivated and multiplied. Against the severity of this climate, in which the adjoining lake is frequently frozen over, it was necessary to shelter the trees transplanted from Asia, and to treat them with peculiar attention, in order to rear them to perfection. Swinburne's Travels, vol. iv. p. 367.

ALBA *Helviorum*, or *Albaugusta*, i. e. *Alba Augusta*, a town of Gaul, in the *provincia Narbonensis*, was the capital of the Helvii, and situated at a small distance from the Rhone. Hence the Helvii were denominated *Albenses*. This town was afterwards called *Vivarium*, and it is now *Viviers*.

ALBA *Julia*, now *Weissenburg*, a town of Transylvania, on the river *Maurusius* or *Marisch*, supposed to be called *Alba Julia*, after *Julia Domna*, the wife of *Severus*, and mother of *Caracalla*. There are several inscriptions, however, near this place, which bear *COL. APUL. I. E. colonia Apulensis*, without the least mention of *Alba Julia*, though they were inscribed after the time of *Caracalla*. Besides, *Ulpian*, reciting the colonies of *Dacia*, calls this colony *Apulensis*, and neither *Alba* nor *Julia*. From these circumstances it has been inferred, that *Alba Julia* is a corruption of *Apulum*. It was also called *Apulum Augustum*. *Cellarius*, tom. i. p. 381.

ALBA *Louga*, a city of Italy in *Latium*, south-east of *Rome*, founded by *Afcenius*, the son of *Æneas*, and a colony from *Lavinium*, at the foot of *mount Albanus*, according to *Blair's Chronology*, in the year 1152 before *Christ*, or 399 years before the foundation of *Rome*; and selected by him as the place of his residence, and the capital of his kingdom. It was called *Alba*, we are told, from a white sow found by *Æneas*, which furrowed 30 pigs on that spot, and which afforded an omen, that a city would be built there within 30 years. See *Varro*, *R. R.* (l. xi. c. iv.) *Aurelius Victor* de orig. Rom. gentis, and *Propertius*, lib. iv. eleg. i. ver. xxxv.

“ Et stetit Alba potens, albæ suis omine nata.”

The epithet *louga*, was added to distinguish it from the *Alba* of the *Maris*, or to express its length, as it was extended along the lake near which it was built. Its situation was at an equal distance between the lake and the mountain; probably between the present city of *Albano* and the lake of *Castel Gandolfo*, and peopled by a mixed colony of

Latins and *Trojans*. The inhabitants of this city were called *Albani*. It was 30 years after *Lavinium* was built, that *Afcenius* fixed his abode at *Alba*; and there he died, after a reign of about 38 years, 12 of which he passed at his new settlement. Upon the death of *Afcenius*, the *Latins* resolved to unite *Alba* and *Lavinium* into one sovereignty, under *Sylvius*; and *Sylvius* was succeeded by 13 kings of the same race, who, for near 400 years, reigned at *Alba*. *Procas*, one of them, bequeathed the throne to his eldest son *Numitor*; but he was dispossessed of the kingdom by his brother *Amulius*, who, in order the more effectually to secure himself, killed the son of *Numitor*, and consecrated his daughter, *Rhea Sylvia*, to the worship of *Vesta*. *Rhea*, however, was delivered of the twins, *Romulus* and *Remus*; who, after having been rescued from the *Tiber*, into which they were thrown by order of *Amulius*, were suckled by *Acca Laurentia*, the wife of *Faustulus*, and educated by the *Gabii*, under the direction and order of *Faustulus*. Upon a quarrel between the herdsmen of *Amulius* and those of *Numitor*, the two brothers took part with the former against the latter; and, in consequence of the fray that was thus occasioned, *Remus* was carried before *Numitor* to receive punishment. When he was questioned concerning his birth and parentage, his reply excited, in the mind of *Numitor*, a lively remembrance of his two grandsons, and his anger was changed into tenderness. The two brothers concurred at length in dethroning *Amulius*, and restoring their grandfather *Numitor* to the throne. They then, by the advice of *Numitor*, undertook to found a new colony on the lands near the *Tiber*, where they had been taken up, and which he granted them for this purpose. *Romulus* and *Remus* differed concerning the precise spot where the new city was to be erected; the latter declaring for the *Aventine*, and the former for the *Palatine mount*. *Remus*, as it is said, fell in the contest that was then occasioned, and *Romulus* prevailed, and laid the foundations of the new city, which was called *Rome*, after his name. *Rome*, in a little while, became the rival of *Alba*; and soon after the accession of *Tullus Hostilius* to the throne, a dispute arose between the *Albani* and the *Romans*, and preparations were made for war. In an interview that occurred between *Tullus* and *Fuffetius*, or, as others call him, *Suffetius*, the *Alban* general *Tullus*, proposed to determine the dispute by a single combat between himself and *Fuffetius*, which the latter declined. It was at length agreed, that three champions should be selected out of each camp to decide the difference. The champions, on the part of *Rome*, were the *Horatii*; and on that of *Alba*, the *Curatii*. *Rome* ultimately gained the victory over *Alba*, her mother-city. When *Tullus* afterwards made war upon the *Veientes*, *Fuffetius* joined him with the *Alban* troops, but afterwards proved treacherous and deserted him. This treachery being known, *Tullus* detached *Horatius*, who had conquered the three *Albani*, with a chosen body of horse and foot, to demolish *Alba*, as he had previously concerted the business with the senate. *Fuffetius* was ordered to be fastened to two chariots drawn by horses, and to be torn asunder: his accomplices were put to the sword; but the rest of the *Alban* soldiers were carried to *Rome* with the citizens, and the chief men among them were even admitted into the *Roman* senate. Thus fell, *A. U. C.* 89, ante *Christ.* 665, the city of *Alba*, famous for its riches, the number of its inhabitants, and, above all, for being the mother of *Rome*. The temple only, says *Strabo*, was preserved. *Dion. Hal.* lib. i. p. 52. lib. iii. p. 152—165. tom. i. Ed. *Oxon.* *Livy*, lib. i. c. 3—7. c. 24—29. tom. i. p. 22—38. p. 101—124. Ed. *Drakenb.* *Plut.*

Plut. in Romul. Oper. tom. i. p. 19. Ed. Nylandr. Strabo Geog. tom. i. p. 350—353.

ALBA *Martina*, a city of Dalmatia.

ALBA *Pompeia*, a city of Italy in Liguria, near the river Ceba or Ceva, where the emperor Pertinax was born. It was a colony either established at first by Ptolemy, or restored, after having been first settled by Scipio. The inhabitants were called *Albenses Pompeiani*. It is now called ALBA, without any epithet.

ALBA *Regalis*. See STUHL-WEISSEBURG.

ALBA TERRA, in *Alchemy*, one of the many names that were anciently given to the philosopher's stone.

ALBACETE, or ALBAZETE, in *Geography*, a small town of Spain, in the canton of La Sierra, in the eastern part of New Castile, situate in a fertile vale not far from the mountains that separate La Mancha from the country called the Desert. W. long. 1° 46'. N. lat. 38° 55'.

ALBACHSEN, or ALBASEN, a town of Germany, in the circle of Westphalia, three miles north of Corvey.

ALBACK, a town of Persia, in the province of Aiderbeizan, 55 leagues south-west of Tauris.

ALBACK, is situated on the western coast of Africa, in N. lat. about 27° 15'. and about 35 leagues south-south-west from the river Orodus. It has a bay so called, and a cape denominated Chabi.

ALBAN, (ST.), in *Biography*, the first Christian martyr in England, and usually called the protomartyr of Britain, was born at Verulam, of Pagan parents, and flourished in the third century. In his youth, he went to Rome, with Amphibalus, a monk of Caerleon, and served seven years in the army of Dioclesian. On his return to England, he was instructed by Amphibalus in the Christian faith, became a convert, and lived in the profession of Christianity till the year 303, when the Dioclesian persecution commenced; but being cited before the Roman governor, for having afforded an asylum to his preceptor, who was a Christian, and avowing his own conversion, he was ordered immediately to be beheaded. The traditionary tales of the times report many miracles which happened on occasion of his death. Bede, and other ancient writers, relate, that in his way to execution, a stream was miraculously divided to afford a passage for him and a thousand persons who accompanied him; that the executioner was converted by the miracle; that a fountain opened at the feet of St. Alban, which afforded water in answer to his prayer for allaying his thirst; and that the eyes of the executioner dropped out of his head at the instant of his giving the fatal stroke. We learn from the same authority, that many of the spectators were converted by these miracles. But the testimony of those who report them deserves little credit; and they seem to be duly appreciated by Milton, who, in his History of England, speaking of St. Alban, says: "The story of whose martyrdom, soiled and worse martyred with the fabling zeal of some idle fancies, more fond of miracles than apprehensive of truth, deserves no longer digression." When the east end of the church of St. Alban's was repaired, in 1257, the labourers found some leaden chests, containing relics; and on a plate of lead, the following inscription:—"In hoc mausoleo, inventum est venerabile corpus Sancti Albani, protomartyris Anglorum;" *i. e.* "In this mausoleum is found the venerable body of St. Alban, the protomartyr of the English." Part of the hymn formerly sung on the festival of this saint, is as follows:

"Ave protomartyr Anglorum,
Miles regis angelorum,
O Albane, flos martyrorum."

"Hail, protomartyr, of the English,
Soldier of the King of Angels,
O Alban, flower of the martyrs!" Biog. Brit.

See AMPHIBALLUS.

ALBAN, JOHN DE ST. in *Biography*, so called from the place of his birth, and de St. Quatrie, a church of that name in Picardy, where he was made a dean (doyen), taught philosophy and medicine at Oxford, towards the end of the twelfth century. In this station he acquired so much celebrity that he was invited to Paris by Philip Augustus, and made his physician. After residing some years at Paris, he went to Montpellier, to hear the professors of that place, then famous for its school of physic. Being distinguished for his great learning and abilities, he was soon invited to fill a professor's chair. In 1223, he returned to England, Matthew Paris says, to attend Robert Grossette, bishop of Lincoln. The time of his death is not known. He was doctor and professor of theology, as well as of medicine, a junction at that time by no means uncommon.

ALBAN, in *Geography*, a town of France, in the department of Tarn, and district of Alby, five leagues east-south-east of Alby.

ALBANA, in *Ancient Geography*, a sea-port town of Albania, on the Caspian sea; now called Bachu or Baka, whence this sea is called *mer de Bachu*. N. lat. 40°. E. long. 49°.

ALBANELLA, in *Geography*, a town of Naples, in the Principato Citra, 20 miles south-east of Salerno.

ALBANENSES. See ALBIGENSES.

ALBANESIUS, GUY ANTHONY, in *Biography*, taught medicine in the university of Padua, from 1632 to 1657, in which year he was assassinated by one of his pupils. He published, "Aphorismorum Hippocratis expositio peripatetica." Patavii, 1649. 4to.

ALBANI, in *Middle Age writers*, denote strangers or foreigners; corresponding to those whom we call aliens.

ALBANI, in *Antiquity*, a college of SALII, or priests of Mars, instituted by Tarquin, and denominated from mount Albanus, the place of their residence.

ALBANI, or ALBANO, FRANCIS, or FRANCESCO, in *Biography*, an eminent painter, was born at Bologna, in 1578, and educated with Guido, who assisted his early studies, first at the school of Dennis Calvart, and afterwards under the Caracci. He completed his studies at Rome, working after the best models, and became one of the most agreeable painters of the Roman school. At Rome, where he resided 18 years, he was employed in some great works, and where he married his first wife, who died in child-birth. From hence he removed to his native town, and married a beautiful woman, by whom he had 12 children, who served him for models in the practice of his art. Albani converted his children, who were very beautiful, and who were placed in different attitudes, into Cupids, and the mother into a Venus or grace; but, graceful as were his models, by constantly painting after them, he preserved too great a similitude in his figures, and in the airs of his heads. His manner, however, may be thus easily distinguished. In the summer months he retired to one of his country houses, which was adorned with fountains and groves, and here he was furnished with landscape scenery, in his favourite subjects of loves and graces, which he treated with an elegance of design, harmony of colouring, and delicacy of finish, that are the characteristics of his pencil. All his pictures, indeed, have not the same force of colour, but though some are weaker than others, they are all delicate and pleasing. His boys and female forms were lovely and graceful;

but

but his figures of the other sex were usually lean and without masculine beauty, except in some of his heads. In his drawings he was sometimes hasty and incorrect. His pictures of the four elements in the palace of the king of Sardinia, at Turin, are of an extraordinary beauty, and well preserved; the design is excellent, the draperies perfectly elegant, the colouring lovely, and the whole very correct. His other principal works are at Rome and Bologna; but as he was extremely industrious, and the productions of his pencil were highly esteemed, his cabinet pictures are found in all considerable collections. As an engraver, he made one small folio etching of Dido killing herself, in which he did not succeed; and in this art he did not add to the character which his other works have established. He was fond of Italian poetry, and lamented that his early education had not enabled him to read the originals of the Latin poets. In private life he was modest, affable, unaffected, attached to his family, pleasant in conversation, condescending to his pupils, whose works he occasionally retouched and improved. His life and faculties were continued to old age; and he died at Bologna, in 1660, aged 82 years. Pilkington and Strutt. Gen. Dict.

ALBANI, GIOVANNI BATTISTA, was the brother and disciple of the former, and became an admirable painter in the style, manner, and colouring of his brother. He excelled in landscape, which he designed in an exquisite taste, touching the trees with great spirit, and giving them a peculiar sweetness of colour. He died in 1668. Pilkington.

ALBANI, JOHN JEROM, was born at Bergamo, of a noble family, and devoted himself to the study of the civil and canon law. By the zeal with which he prosecuted some of his own relations in the Inquisition, he recommended himself to Cardinal Alexandrinus, the inquisitor, who, upon his being advanced to the papal see, under the name of Pius V. conferred upon Albani a cardinal's hat. He died in 1591. His works were a treatise "De immunitate Ecclesiarum;" published in 1553; another, "De potestate Papæ et Concilii," printed at Venice, in 1561; and a third, "De Cardinalibus, &c." Nouv. Dict. Hist.

ALBANI, in *History*, the inhabitants of ALBANIA, in Asia, who are said by some writers to have derived their name from their fair complexion. Ptolemy mentions a people of this denomination on the confines of Macedonia.

ALBANIA, in *Ancient Geography*, a country of Asia, was bounded on the west by Iberia, on the east by the Caspian sea, on the north by mount Caucasus, and on the south by Armenia. The cities which it contained, and mentioned by Strabo, Ptolemy, and Pliny, were Teleba, Thalbis, Gelda, Thiauna, Thabilaca, Albana, Chadaca, Misia, Boziata, and Cabalica, which last Pliny calls the metropolis of Albania. Its chief rivers were Cyrus, now Kur, Albanus, Casius, Gerrhus, Soana, Cambyfes, and Alazon, all of which discharged themselves into the Caspian sea. The whole country, now known by the names of Schirwan and East Georgia, is extremely fertile and pleasant. Strabo (tom. ii. p. 767.) describes the inhabitants as tall, robust, and graceful in their persons, excelling those of other nations in comeliness as well as in stature, and as very simple in their manners. He adds, that they were unacquainted with weights and measures, and the use of money; that they could not count above one hundred, and that they carried on trade by exchange. They chiefly devoted themselves to pasturage, and had some resemblance of the wandering tribes; they were not altogether unacquainted with the art of war, nor unused to the practice of it; their common weapons were bows and arrows; they defended themselves with shields, and bore on their heads helmets made of the

skins of wild beasts. They excelled in hunting, and were famous for the dogs which they reared for this purpose. They respected age, both in their parents and others; they thought it wrong to take any notice of the dead; they buried their money with them, and lived in poverty, as they had thus no patrimony. They worshipped, as gods, the sun, Jupiter, and the moon; and the priest was next in honour to the king. Pliny (II. N. tom. i. p. 371.) says, that they were of a white complexion, and that they could see by night as well as by day. Tacitus (lib. v.) and Pliny (tom. i. p. 311.) trace their origin to the Thessalians, who attended Jason in his expedition to Colchis, and settled in this part of the isthmus, between the Euxine and Caspian seas. According to Justin (lib. xiii.), they were descended from the inhabitants of Alba in Italy; and Ammianus Marcellinus derives them from the Massagætæ. Albania was anciently divided into several small kingdoms; and Strabo (*ubi supra*) says, that the country had 26 different languages, and as many kings and kingdoms as languages. But the Albani, in process of time, overcame the other petty princes, and made themselves masters of the whole country. In the time of Pompey, as we learn from Strabo, they could bring into the field 60,000 foot and 20,000 horse. Of their kings we have no account, before the reign of Alexander the Great, to whom the king of Albania is said, by Pliny (tom. i. p. 465.), to have presented a dog of extraordinary size and swiftness. The next king, mentioned in history and named Orates, was defeated by Pompey, and obliged to retire to mount Caucasus. Another king of Albania, named Pharasmenes, committed great devastations in Armenia, Cappadocia, and Media, in the time of Adrian, and was summoned by the emperor to Rome. Instead of attending, he sent a number of such great coats as were then worn, made of cloth of gold, in which the emperor, as an insult to the king, ordered 300 criminals to be clad, and in that attire to fight the wild beasts in the public theatre. Upon Adrian's death, the Albanian king attended the summons of Antoninus Pius, who received him with respect and dismissed him with presents. Two other kings are mentioned; one the contemporary of Valerian, and the other of Constantius the son of Constantine the Great. The Albanians continued to be governed by their own princes till the reign of Justinian II. who is said by Zonaras and other writers to have subdued Albania by his general Leontius. Anc. Univ. Hist. vol. ix. p. 122—126.

ALBANIA, a city of Asia in Assyria, was situated to the east of the river Titana.

ALBANIA, in *Modern Geography*, sometimes called *Arnaut*, a province of Turkey in Europe, comprehending the ancient Illyricum, and Epirus, situate in the Adriatic, and bounded on the north by Dalmatia and Servia, on the east by Macedonia and Thessaly, on the south by Livadia, and on the west by the Adriatic. Its length is about 80 leagues, and its breadth about 20. Its capital was formerly Albanopoli; but it is now Durazzo. The other principal towns are Scutari, Dulcigno, Antivari, Croya, Aleffo, Velona, Dataro, Dibra, &c. The most remarkable river is Delichi, formerly Acheron; amongst the lakes we may reckon Scutari, and to the class of mountains we may refer the Acroceraunian, or mountains of Chimæra. The soil of this province is fertile, and produces excellent wine. Its manufacture is chiefly carpets. Its inhabitants are robust and courageous, and make good soldiers, especially cavalry. In the Turkish army, they are distinguished by the name of *arnauts*. The religion of Albania is that of the Greek church. This province was annexed to the Ottoman empire,

pire, in 1467, by Mahomet II. by whom it was conquered, after the death of Scanderberg, who had the courage to maintain it against the Turks and the Venetians. A small part of the west still belongs to the Venetians, and is divided by them into sangiacs or governments. N. lat. 39° to $43^{\circ} 30'$. E. long. $18^{\circ} 32'$ to $21^{\circ} 54'$.

ALBANIE Pyle, or *Porta*, the *Albanian Ports*, a place situate on the Caspian Sea, north of Cabanaca.

ALBANO, a town of Italy, in the Campagna of Rome, situate within 15 miles south-east of Rome, on a lake of the same name, at the distance of a mile from Castello Gandolfo, which was the favourite residence of pope Clement XI.; and built in the time of Nero on the ruins of the ancient *Alba Longa*. This place, on account of the pleasantness of its situation and the salubrity of the air, serves as a summer recess for the nobility of Rome. It is famous for its excellent wine. It has the title of a principality, and is the see of one of the six cardinal bishops. At its entrance is the ruin of a mausoleum, said to be the tomb of Afcenius; and there is another mausoleum 45 feet square with five pyramids 10 feet in diameter, which report alleges to be the tomb of the Horatii and Curatii; and which some think to be that of Pompey the Great. Among other venerable remains of antiquity in and near this place, there is seen the ruin of a palace of Domitian. The lake of Albano is about seven miles in circuit and of an oval form, and is surrounded by high mountains. The waters of the lake are conveyed by a canal, which is said to have been made 398 years before Christ. The mountain of Albano, called Monte Cavo, has, on the top of it, the ruins of a temple, dedicated to Jupiter and Juno. N. lat. $41^{\circ} 43'$. E. long. $12^{\circ} 29'$.

ALBANO is also a town of Naples, in the Basilicate; 13 miles south-south-east of Acerenza.

ALBANOPOLI, a town of European Turkey in Albania, situate upon the Drin, 16 leagues from Alessio. N. lat. $51^{\circ} 48'$. E. long. $20^{\circ} 18'$.

ALBANOPOLIS, in *Ancient Geography*, a town of Greater Armenia.

ALBANS, (*St.*) in *Geography*, a market-town in Hertfordshire, in the north west road, about 21 miles from London. It is a borough town, sends two members to parliament, gives the title of duke to the Beaulere family, and has an excellent market for wheat. The market days are Wednesday and Saturday. This town was built near the site of the ancient Verulam. In the year 795, Offa, king of the Mercians, erected a monastery in the place where St. Alban suffered martyrdom, and near to which the town was afterwards built. The abbot was reputed, by favour of pope Adrian IV. who was born near Verulam, the first in dignity of all the abbots. The church of this monastery is still in being, and much admired for its size, beauty, and antiquity. When the monks were turned out, it was purchased by the townsmen for 400 pounds, and converted into a parochial church. N. lat. $51^{\circ} 44'$. W. long. $0^{\circ} 12'$.

ALBANS, *St. Higbland*, lies on the coast of Dorset, in the English channel, east of Weymouth, and eight leagues west of Dunnofe, on the back of the isle of Wight. N. lat. $50^{\circ} 15'$. W. long. $2^{\circ} 5'$.

ALBANS, *St. Jersey Island*, is in N. lat. $49^{\circ} 10'$. W. long. $2^{\circ} 25'$, towards the south-west point of the island. Its haven is within a deep bay, before which are Halier island to the east, and St. Alban's island to the west, nearly before the town of that name, on the west side of the bay.

ALBANS, *St.* a township of America, in Franklin county, Vermont, on Lake Champlain, opposite North Hero island. It contains 256 inhabitants.

ALBANUM, in *Ancient Geography*, a town of Pannonia.

ALBANUM Pompeii, a name anciently given to the present **ALBANO**.

ALBANUM mare, a name given by Pliny to that part of the Caspian sea, which bordered on Armenia.

ALBANUS, **JOANNES**, in *Biography*, was received Doctor in Medicine at Bologna, in the year 1616, where he taught the theory and practice of physic several years, and published a treatise on the regimen to be observed by convalescents.

ALBANUS, in *Ancient Geography*, a river of Albania, thought by M. d'Anville to be Samura.

ALBANUS Mons, the mountain adjoining to *Alba Longa* or **ALBANO**; and also a part of the *Albius Mons* of Strabo, which the Ancients considered as forming the extremity of the Alps, and together with the Montes Bæbii separating the further Liburnia and Dahmatia from Pannonia.

ALBANY, a county of America, on Hudson's river, in the state of New York, lies between Ulster and Saratoga. Its extent is 46 miles by 28. By the census in 1796, the number of electors in this county was 6087, and the number of towns 11.

ALBANY, the chief town of the above county, is situated on the west bank of Hudson's river, 160 miles north of the city of New York, and 340 south of Quebec. N. lat. $42^{\circ} 39'$. W. long. $73^{\circ} 30'$. This city and the suburbs, in 1797, contained 6021 inhabitants. The situation of Albany is peculiarly favourable for residence and for commerce. It is at the head of a sloop navigation, on one of the noblest rivers in the world; the air is salubrious; and by the improvements of roads and canals, which are contemplated, it is expected to encrease and flourish. The public buildings in this town are a low Dutch church of ancient and curious construction, one for the Episcopalians, two for Presbyterians, one for Germans or High Dutch, and one for Methodists; an hospital, city hall, and well-built brick gaol. The corporation consists of a mayor, recorder, six aldermen and as many assistants. In the vicinity of this city there are extensive works, in which the machinery is moved by water, for the manufacture of Scotch and Rappee fluff, roll and cut tobacco, chocolate, mustard, starch, hair-powder, split pease, and hulled barley.

ALBANY, a British fortress in New South Wales, in North America, situated on a river of the same name. N. lat. $52^{\circ} 14'$. $40''$. W. long. $81^{\circ} 59'$. $58''$.

ALBANY River, a river of North America, which, after running in a north-east direction, and communicating with several small lakes, falls into James's bay, in N. lat. $51^{\circ} 30'$. W. long. $84^{\circ} 30'$.

ALBARA, in *Botany*. See **CANNA**.

ALBARA, in *Ancient Geography*, a town of Syria, on the borders of Phœnicia.

ALBARAZIN, or **ALBARACIN**, in *Geography*, a fortified town of Spain, in the kingdom of Aragon, on the river Guadalavir, and near the frontiers of New Castile, is the see of a bishop, suffragan to the archbishop of Saragossa, and famous for its excellent wool, called by this name. It is 30 miles south-west of Saragossa, and 40 miles east of Madrid. N. lat. $40^{\circ} 32'$. E. long. $2^{\circ} 10'$.

ALBARDEOLA, in *Ornithology*, a name given by many authors to the *spoon-bill*.

ALBARI, in *Antiquity*, properly denoted those who gave the whitening to earthen vessels, &c. In which sense they stood contradistinguished from *dealbatores*, who whitened walls.

ALBARIUM opus, in the *Ancient Building*, the incrustation or covering of the roofs of houses with white plaster, made of mere lime. The workmen were called *albarii*, or *albarii*.

This

This is otherwise called *opus album*. It differs from *testorium*, which is a common name given to all roofing or ceiling, including even that formed of lime and sand, or even lime and marble; whereas Albarium was restrained to that made of lime alone.

ALBAS, in *Geography*, a town of France, in the department of Lot, three leagues west of Cahors.

ALBASANO, a town of Albania, in European Turkey, 132 leagues west of Constantinople. N. lat. $41^{\circ} 30'$. E. long. $20^{\circ} 15'$.

ALBASTRA, an ancient town of Egypt, on the Arabian coast; the inhabitants of which are called by Euphianus Alabastrides.

ALBATEGNI, in *Biography*, a celebrated astronomer of the ninth century, was a native of Batan, in Mesopotamia, and hence called Al Battani, or Albatani. As Batan was one of the dependencies of Harran, he was also denominated Mohammed Ebn Jaber Ebn Senan Abu Abdallah al Harrani and Mohammed of Aractus. His astronomical observations were made about the years 882 and 883, at Antioch, and at Araca or Aractus, a town of Chaldaea; and Blair, in his chronology, states the time of his death about the year 888. Dr. Halley highly commends him (Phil. Transf. for 1693, n^o 204.), as a man of admirable genius, and an excellent observer, though he detects many errors in the editions of his works. He observed the autumnal equinox at Aractus on September 19th, one hour and 15 minutes after midnight, A. D. 882; and he also observed, about 883, that the first star of Aries was $18^{\circ} 2'$ from the equinoctial point; he states the obliquity of the ecliptic at $23^{\circ} 35'$, and the motion of the sun's apogee, since Ptolemy's time, as well as the motion of the stars, one degree in 70 years. He computed new astronomical tables, instead of those of Ptolemy, which were imperfect, and adapted them to the meridian of Aracta or Raca; and they were long used as the best among the Arabs. He also composed a work, entitled "The Science of the Stars," comprising all parts of astronomy, according to his own observations and those of Ptolemy. This work was translated into Latin by Plato of Tibur, and published at Nuremberg in 1537, with some additions by Regiomontanus; and reprinted at Bologna in 1645, with the notes of this author. The Alphonsine tables of the moon's motions were founded on the observations of Albategni. The original Arabic of this work, which was never published, is in the library of the Vatican. Blair's Chronol. N^o 38. D'Herbelot Bibl. Orient. Hutton's Math. Dict. vol. i. p. 59, &c.

ALBATEL, in *Geography*, a Cape on the coast of Barbary, about 12 leagues north-east of Cape de Tenes, within which are several good roads, particularly at Marfolach, to the west of Cerelli island and point.

ALBATENIUS, an Arabian physician, lived towards the end of the 11th century, cotemporary with Serapion. He translated the works of Galen into Arabic.

ALBATI equi, in *Antiquity*, was a denomination given to those horses in the games of the circus, which were distinguished by white cloths or furniture. In which sense, they are contradistinguished from *rustati*, *prafini* and *veneri*.

ALBATROSS, in *Ornithology*. See DIOMEDEA.

ALBAZIN, in *Geography*, a town of Great Tartary, in the road from Pekin to Moscow, situated on the river Amur, and defended by a good fortress against the attacks of the Chinese and Tartar Monguls. N. lat. 54° . E. long. $104^{\circ} 14'$.

ALBE, in *Commerce*, a small coin, current in Germany, valued at a French sol and seven deniers.

ALBEC, in *Geography*, a river of Switzerland, runs into the Rhine, near Furlenau.

ALBECK, a town of Germany, in the district of Ulm, which is the capital of a prefecture of the same name, is situated on the river Alb, five miles north-east of Ulm, and eight miles west-north-west of Augsburg. N. lat. $48^{\circ} 29'$. E. long. $9^{\circ} 58'$.

ALBECOR, in *Ichthyology*, the SCOMBER THYSSUS of the Linnæan system.

ALBEGNA, in *Geography*, a river of Tuscany, runs into the sea between Telamou and Orbitella.

ALBEKIRK, a town of Holland, $1\frac{1}{2}$ league south-west of Medemblick.

ABEL, a river which rises in Mount Abel, in the country of the Grisons, and discharges itself into the Rhine near Bergun.

ABELDA, a town of Spain, on the river Iregua, in the country of Rioja.

ABELLEN, in *Ichthyology*, called also ALBULA, and resembling the *surra*, caught in the German and other lakes, is a fish of a fine silvery white colour, and from five or six to twelve pounds in weight.

ABELLIA, in *Conchology*, a species of HELIX, with an umbilicated smooth shell, the under part gibbous, and a femicordated aperture; found on the rocks of Europe.

ABELLUS, in *Ornithology*, a species of MERGUS. See SMEW.

ALBEMARLE, AUMARLE or AUMALE, in *Geography*, a town of France, which gives the title of Earl to the noble family of Keppel. See AUMALE.

ALBEMARLE, a county of America, in the state of Virginia, lies between the Blue Ridge and the Tide Waters, and contains 12,585 inhabitants, in an extent of about 35 square miles.

ALBEMARLE Port, a spacious bay or harbour, on the southern coast of Falkland islands, is situated between Fox bay and Port Stephens, and may be known by a small island off the entrance.

ALBEMARLE Sound, an inlet of the sea, on the coast of North Carolina, 60 miles long, and from eight to 12 broad. It communicates with Pamlico sound, and with Currituck inlet, and receives Roanoke and Meherrin rivers. The passage into it from the sea is called Roanoke inlet. N. lat. $35^{\circ} 50'$. W. long. $76^{\circ} 10'$.

ALBEN, a town of Austria, in the Inner Carniola, is environed on all sides with high mountains, large forests and deserts, and is distant two miles north-west from Cirknitz. There are mines of mercury in the vicinity of this town. From the mountain of the same name on which it is situated, called also *Monte del carfo* the river Alben flows, which runs into the gulf of Venice, between Laubach and Capo d'Istria.

ALBEN-see, a lake of Austria, 13 miles west of Windisch-Garten.

ALBENGA is a small island on the coast of Genoa, opposite to the town of Albenga, and called also Gallinara.

ALBENGUA, or ALBENGA, anciently *Allium Ingau-num*, or *Albingaunum*, a sea-port town of Italy, in the territory of Genoa, is the see of a bishop, suffragan to the archbishop of Genoa. It was formerly a very considerable and well-fortified town, but has suffered by the wars, and is deserted on account of the insalubrity of the air. The vicinity abounds with olive trees, and produces great quantities of hemp. It was burnt by the Pisans in 1175, but rebuilt by the Genoese. It is about 15 leagues south-west of Genoa. N. lat. $44^{\circ} 42'$. E. long. $8^{\circ} 13'$.

ALBENQUE,

ALBENQUE, a small town of France, in the district of Cahors and department of Lot, distant 6½ leagues from Moitauban.

ALBEOLEA, in *Ornithology*, the *Anas albeola* of the Linnæan System by Gmelin, the *querquedula ludoviciana* of Brisson, little black and white duck of Edwards, the *spirit* of the Arctic Zoology, and the white and black *farcelle* or nun of Buffon, is specifically distinguished by a white colour; black back and wing-quills, bluish head, and back of the head white. Its white robe, and white band with a black cap and mantle, have given occasion for calling it *religieuse*, or nun. The back of the head is decorated with green and purple lustre, and the white band encircles it behind from the eyes. The Newfoundland fishers call it *spirit*, as Edwards suggests, because it is a very nimble diver, appearing at a great distance, very soon after it has plunged. It is found in America, from Hudson's bay to Carolina, and forms its nest in trees near fresh water.

ALBERCHE, in *Geography*, a river of Spain, which runs into the Tagus, near Talavera.

ALBERDÖRF, a town of Austria, on the river Bulekau, seven miles east of Schtrattental.

ALBERGOTTI, FRANCIS, in *Biography*, an eminent civilian, of the 14th century, studied under Baldi, and exercised his profession at Arezzo, in the state of Florence; but removing to Florence, he was there ennobled. His character for integrity is no less applauded than his skill in the law; so that the appendage annexed to his name is, "solidæ veritatis doctor;" or the teacher of solid truth. He wrote "Commentaries on the Digest," and some other pieces in law; and died in 1376. Gen. Biog.

ALBERGUS, JOHN, a native of Mazarain, in Sicily, where he practised medicine with success, towards the end of the 17th century, published at Palermo in 1703, "Summa Tractatum Chirurgicæ praxeos, 12mo."

ALBERIC, or ALBERT, a French historian, was canon of the church of Aix in Provence, in the 12th century, and wrote a history of the first crusade, from the reports of those who attended it. His narrative extends from 1095 to 1120, and is contained in two distinct works, viz. "Chronicon Hierosolymitanum," printed in 4to., at Helmsstadt in 1584; and "Gesta Dei per Francos," in folio, 1611. Gen. Biog.

ALBERIZZI, PETER JOSEPH, studied medicine at Pisa, and practised several years at Milan, where he died 1722, aged only 31 years. He published "Critologia Medica de causis suis pestiferæ, ejusdemque cura, qua vermiculi, de quibus somniarunt nonnulli, exploduntur."

ALBERNUO, in *Commerce*, a kind of camblet brought from the Levant, by way of Marcellis.

ALBERONE, in *Geography*, a town of Naples, in the province of Capitanata, eight miles south-south-east of Volturara.

ALBERONI, CARDINAL, in *Biography*, a celebrated statesman, was born at Placentia in Italy, in 1664, and employed till the age of 14 in the occupation of his father, who was a gardener. Having relieved M. Campistron, secretary to the duke of Vendome, when he was robbed near the village where he lived, he was recommended by him to his general, who took him into Spain. From this menial low state he rose by several gradations to the dignity of cardinal and archbishop of Valentia, and to the office of prime minister, in the court of Spain. For both these honours he was indebted to the patronage of the princess of Parma, whose marriage with Philip V. he had projected and accomplished. His disposition was intriguing and enterprising; and not content with effecting some domestic reforms and arrange-

ments, he formed the design of an expedition against Sardinia and Sicily, and in order to prevent the interference of other powers, he made an alliance with Czar Peter, Charles XII. of Sweden, and, as some say, with the Ottoman Porte. He also proposed exciting the Turks to make war on the emperor, to advance the Pretender to the throne of England by means of Peter and Charles, to divest the duke of Orleans of the regency of France, and to annihilate the German power in Italy. But an union between England and France was the result of the discovery of this plan; and both these powers concurred in declaring war against Spain in 1719, and the condition of peace was the removal of Alberone, and his banishment from the kingdom. Having received an order in Dec. 1720, to quit Madrid in 24 hours, and to leave Spain in a fortnight, he retired with great wealth; nor was it discovered before he had been two days on his journey, that he had taken with him the testament of Charles II. of Spain, which appointed Philip universal heir of the Monarchy. The instrument was wrested from his possession by force; and pursuing his journey to Genoa, he was there arrested by order of the pope, on the charge of negotiating with the Turks. On his exculpation, and subsequent liberation from the convent of the Jesuits, to which he was confined for a year, he engaged in new intrigues, and particularly in an unsuccessful enterprise against the small republic of St. Marino. A *bon mot* of Benedict XIV. on this occasion was very generally circulated: "Alberoni is like a glutton, who, after having eaten a large salmon, cannot help casting a wishful eye at a minnow." His views were more laudably directed to the establishment and endowment of a seminary of education for poor scholars in his native city. Alberoni preferred his health and vivacity to old age; his conversation chiefly turned on the recital of his own exploits, and was instructive and amusing; though in his temper he was irascible and impatient of contradiction. He died in 1752, at the advanced age of 87, and left behind him the character of "a great politician, as daring as Richelieu, and as supple as Mazarin, with as little principle as either. His life, to the year 1719, has been published by John Rouffet, translated from the Spanish. A pretended "Political Testament," in the name of cardinal Alberoni, printed in 1753, is considered as spurious. Nouv. Dict. Hist. Gen. Biog.

ALBERT I. duke of Austria, and emperor, was the son of the emperor Rodolphus, and a competitor for the Imperial crown with Adolphus of Nassau, whom he defeated and killed in battle. Before this victory, he had been elected king of the Romans; but apprehending that his election would be contested, he obtained the confirmation of it, and was solemnly crowned at Aix-la-Chapelle, in the year 1298. He began his reign with renewing the ancient leagues between the emperor, and with forming a treaty of marriage between his son Rodolphus and Blanche, the daughter of Philip the French king. The alliance with France was protested against by the three ecclesiastical electors, and upon the emperor's appeal to pope Boniface, with a demand that he would ratify his election, the pope declared that it was null and void, and that Albert ought to be treated as a murderer. Boniface proceeded, upon the complaint and remonstrance of the electors, to prohibit the subjects of the empire from acknowledging the claims of Albert, and to release them from the obligation of their oath of allegiance. The emperor, incensed at the conduct of the ecclesiastical electors, declared war against them, and soon compelled them to sue for peace. In 1303, the pope having quarrelled with Philip the Fair of France, made advances to Albert,

Albert, confirmed his election, invited him to Rome to receive the Imperial crown, and exhorted him to declare war against Philip, whom he had excommunicated. The conditions, however, were humiliating; but the emperor acquiesced, and agreed to take the oath of allegiance to the pope, after acknowledging that kings and emperors received the power of the temporal sword from the holy see, and consenting to perform all the promises made by Rodolphus and his predecessors, and to defend the rights of the holy see against all its enemies. Before this reconciliation between the pope and the emperor took place, Albert had engaged in an unsuccessful war with John d'Avenes, next heir to John count of Holland, who had lately died, under a claim of his dominions, as fiefs reverfible to the empire. The war terminated with a stipulated condition that John d'Avenes should enjoy the countries of Holland, West Friesland, and Zealand, in consideration of doing homage to the emperor, from whom he accordingly received the investiture of these dominions. Albert, likewise, in 1302, invaded Bohemia, but was obliged to retreat with loss. But upon the death of Wincenslaus the younger, who was assassinated by his subjects, and who died without issue, the emperor seized Bohemia, and placed his son Rodolphus on the throne; but Rodolphus dying suddenly, Albert could not secure the crown for his next son, Frederic. His next object was to support Philip of Nassau, brother of Adolphus, the late emperor, in an unjust attempt to recover Misnia and Thuringia from the rightful possessors; but this exploit terminated in a disgraceful defeat. In another instance he was no less mortified, but the event proved singularly important. The three cantons of Ury, Switz, and Underval, though they do not seem to have been in any respect dependent upon the house of Austria, had voluntarily sought the protection of Rodolphus; and he treated them with great indulgence, and defended their rights and privileges, without ever considering them as fiefs of the house of Austria. But the conduct of his son Albert was directly the reverse: he wished to govern them as an absolute sovereign, and had formed a scheme for converting Switzerland into a principality for one of his sons. By his own insolence and oppression, and the similar conduct of the governor whom he appointed, they were so aggrieved and incensed, that the three cantons above-mentioned formed a confederacy for the purpose of emancipating themselves from the Austrian yoke. They succeeded in their efforts, and retrieved that liberty which they have since enjoyed. The other cantons soon engaged in the confederacy, and thus was laid the foundation of the Helvetic republic. Albert was uniformly influenced by a spirit of rapacity and an unwarrantable desire of aggrandizing his own family; and he at length fell a sacrifice to his ambition and avarice. Having refused to put his nephew John, duke of Suabia, in possession of his paternal estates, which, it was thought, he designed for one of his own sons, the nephew formed a conspiracy against him. With this view, he engaged three confederates, who contrived to meet Albert on his progress from Basil to Rhinfeld, after he had crossed the river Rhees, near Schaffhausen; and John, having stabbed him in the throat, his accomplices completed the murder in the sight of his son and their attendants, who were incapable of affording him any succour. In the place where the emperor was slain, A. D. 1308, a cloister was built, and called Konigsfelt, from whence his body, after having been deposited there for some time, was carried to Spire, and kept among his predecessors. His character has been differently appreciated by different writers. Some represent him as a prince of a brutal disposition and manners, and of the most fordid ava-

rice: whilst others describe him as a prince of singular courage and address, and distinguished by an excellent understanding, and an inviolable attachment to truth. All agree, however, in charging him with an insatiable degree of avarice. It is said, that he equally abhorred flattery and slander; and that there were three sorts of persons for whom he had a particular regard, viz. women of honour, men of courage, and pious ecclesiastics. He was called "*the Triumphant*," on account of his generosity and valour, and the many victories he obtained over his enemies; and the "one-eyed," because he had lost one eye by the operation of poison, which was given to him at his own palace in Vienna, about three years before he was elected emperor. Albert, by his wife Elizabeth, daughter of the duke of Carinthia and Gorecia, had six sons and five daughters. By his youngest son Albert, surnamed the "Counterfeit," the male issue of the family is derived. Mod. Un. Hist. vol. xxvi. p. 130, 142.

ALBERT II. duke of Austria, and emperor, surnamed the "Grave" and "Magnanimous," was the son of Albert of Austria, called the "Wonder of the World," and married Elizabeth, daughter of the emperor Sigismund. By his wife conduct he re-established the security of his Austrian subjects, which had been for a long time interrupted by intestine wars and rapine; and if his life had been prolonged, he would probably have been the greatest prince that ever sat upon the Imperial throne. In one year, he was honoured with three crowns. To the Hungarian throne he was advanced in consequence of the will of Sigismund, whose daughter and heiress he had married; and he was elected king of Bohemia, in consequence of a convention between the two families, which stipulated, that when the lawful heir male of the house of Bohemia should chance to fail, the crown should devolve upon a prince of the house of Austria. The throne, however, was disputed by Casimir; but after a successful struggle secured by Albert, who was crowned at Prague. During his conflict with Casimir, he was elected emperor at Frankfort. After his election and coronation at Aix-la-chapelle, it was his chief care to reform the administration of justice, and to abolish the tribunal, called the secret or Westphalia judgment, which condemned without trial, or even public accusation. He also confirmed the neutrality which had been adopted by the German electors and princes, with respect to pope Eugenius and the council of Basil, and by the mediation of the pope and council he concluded a peace between Hungary and Poland. When Bulgaria was invaded by Amurath, the Turkish Sultan, Albert took arms in its defence, and marched to Buda; but being there seized with a violent dysentery, he was under a necessity of returning to Vienna; and in his way thither the disorder proved fatal, A. D. 1439; and he was interred at Weissenburg. He left a posthumous son and two daughters. In one of the diets which were held at Nuremberg during the short reign of this prince, Germany was divided into four circles, viz. Bavaria and Franconia, the countries about the Rhine together with Almania, Westphalia, and the Low Countries, and Saxony. In another diet, it was proposed to divide the empire into six circles, and this division was established by the emperor Maximilian I. Albert was of tall stature and great strength, liberal and just in his disposition, and of a virtuous character; he cherished a warm affection for his people, a great zeal for religion, and an uncommon esteem for learned men. Mod. Un. Hist. vol. xxvi. p. 273—278.

ALBERT the Great, so called on account of his great erudition, in *Biography*, was born at Lawingen in Suabia, about the year 1193, or, as some say, 1205. He

was educated at Pavia, and in 1236 he was made doctor in medicine at Paris; where having heard father Jourdain, the Dominican, preach, he was induced to take the habit; and on the death of Jourdain, was made vicar-general, then provincial of that order. He taught philosophy, medicine and theology, at Cologne, and at Paris, to numerous auditors. At Cologne St. Thomas Aquinas was his pupil. In 1260, he was made bishop of Ratisbon; but at the end of three years he resigned that dignity, and retired to Cologne. From hence he went to Germany and Bohemia, to preach the crusade; and in 1274, he attended the council of Lyons. Allowing for this occasional absence, he continued to instruct the religious of his order in this city, till the 15th of November 1280, the time of his death. His works, which were very voluminous, were collected by father Janani, a Dominican of Grenoble, and published at Lyons in 1615, in 21 volumes in folio; but many of them are supposed to be spurious. The treatise "De secretis Mulierum, item de virtutibus herbarum, lapidum, et animalium," published under his name, was written by Henry of Saxony, one of his pupils. He was undoubtedly the author of several works on the mathematical sciences; as arithmetic, geometry, perspective or optics, music, astrology and astronomy; under the titles,—*"De Sphæra, de Altitris, de Astronomia, item speculum Astronomicum."* As he was a man of genius and knowledge superior to his contemporaries, and particularly devoted to mathematical disquisitions, he was charged, according to the cant of the times, with being a magician. He is said to have contrived a kind of androides, or machine in the human form, which he had brought to such perfection, that it could speak: and of this machine many tales are related, but they are not worth recording. It is not at all incredible, that by his knowledge of mechanics and acoustics, he might have constructed a machine, which, by means of the air and certain springs, produced sounds, resembling those of the human voice; and that he might apply his knowledge in chemistry to the production of artificial flowers and fruits. Some have, without foundation, ascribed to Albert the invention of fire-arms. The chief object of his investigation, was probably the philosopher's stone, as this was the "*ignis fatuus*" of the age. Gen. Dict. Hutton's Dict. Dupin cent. xiii. Brucker's Hist. Philos. by Lefield. vol. ii. p. 371-372.

ALBERT of Aix, or ALBERTUS *Aquensis*, was a canon of Aix-la-Chapelle, in the 12th century, who travelled into the Holy Land, and wrote in Latin, "A History of the Expedition to Jerusalem, under Godfrey of Boulogne, and other Leaders." This history comprehends a period of 24 years, terminating in 1120, and is esteemed accurate. It was printed by Reineccius, in 1584. Cave. H. L. tom. ii. p. 206.

ALBERT, ERASMUS, a German divine of the 16th century, was born at Frankfort: from a book entitled, "The Harmony between Jesus Christ and St. Francis;" and highly valued by the Franciscans, he collected many absurdities in a book which he entitled—"The Alcoran of the Cordeliers." To this book Luther, of whom Albert was a disciple, prefixed a preface, and it has passed through a great number of editions. The author wrote other works in Latin and German, and died in 1551.

ALBERT, KRANTZ, an historical writer, was professor of divinity at Hamburg, in the beginning of the 16th century. His works are—"Metropolis;" or, A History of the Churches established or restored in the reign of Charlemagne;"—"A History of Saxony;"—"A History of the Vandals;" and "A Chronicle of the Affairs of the

North, from the time of Charlemagne to the year 1504." He died in 1517. He is said to have collected facts with diligence, and to have related them with fidelity and freedom. Voss. de Hist. Lat. Cave. H. L. tom. ii. p. 243.

ALBERT of Stade, a benedictine monk, flourished about the middle of the 13th century. He wrote "a Chronicle," comprehending the whole period, from the beginning of the world to the year 1256, which was published with notes, by Reineccius, in 1587. Cave.

ALBERT of Strassburg, or ALBERTUS ARGITENSIS, flourished in the 14th century, and published in Latin, "A History or Chronicle of Affairs from the Reign of Rodolphus I. in 1270 to the Death of Charles IV., in 1378." This work, which is faithfully written, was edited by Ursilius, in a collection of authors, who wrote on the affairs of Germany. Vossius. Cave.

ALBERT, SOLOMON, a pupil of Fabricius ab Aquapendente, a learned and ingenious anatomist, studied medicine at Wittenberg, where he was several years professor. He is said to have discovered the valve of the colon, first in a castror, afterwards more distinctly in the body of a man, and to have made many other improvements in anatomy. Haller Biblioth. Anatomic. vol. i. p. 251. His works are—"Historia, &c. humani corporis partium in usum Tyronum edita, figuris illustrata, Wittenberg, 1583, 8vo." The plates, with the exception of two, are from Vesalius. This work has passed through several editions. "Tres orationes, quarum tertia agit de disciplina anatomica, quo orsu caperit, &c. tum de Galeni libro qui de ossibus inscribitur. Annexum est thema de lachrymarum utilitate in levando animi affectu." Norimbergæ 1585, 8vo. This Discourse on the Efficacy of Tears, in alluaging the Affections of the Mind, is inserted in Haller's collection of dissertations. "Oratio de surditate et mutitate;" Norimb. 1591. 8vo." "Orationes quatuor, de felle restagnante, de sudore cruento, &c. ibid." 1590, &c. He died March 29th, 1600. His age is not known.

ALBERT, in Geography, a town of France, in the department of Somme, and district of Peronne, five leagues north-east of Amiens, and four north-west of Peronne.

ALBERTI BORGHEGIANO, CHERUBINO, in Biography, an eminent painter and engraver, was born at Borgho S. Sepulchro in 1552, and died in 1615. The rudiments of historical painting he acquired from his father, Michael Alberti; and in this art he made very considerable progress. His best works are in Fresco at Rome; and there are also paintings in oil, which are admired for their judicious disposition, lively and beautiful colouring, and fine expression. His superior merit, as an engraver, is also acknowledged; and in this respect his best style of execution seems to have been founded on the prints of C. Cort and Agostino Carracci, whilst in his friezes and other slighter plates, he was indebted to the works of Francesco Villenena, whose freedom of handling the graver is justly admired. He worked entirely, like these artists, with the graver, and seems never to have called in the assistance of the point. His engravings are never highly finished, or powerful in effect. The great fault of his time was the little attention paid to the chiaro-scuro. The lights are scattered and left untinted, as well upon the distances, as upon the principal figures of the fore ground, which destroys the harmony, and prevents the proper gradation of the objects. The drawing of the naked parts of the figure, in the works of this artist, is rarely incorrect: the extremities are well marked; and the characters of the heads generally very expressive; but his draperies are apt to be rather stiff and hard. His prints

prints may be considered as very extraordinary efforts of a great genius; whilst the art was at a considerable distance from perfection. The number of plates engraved by Alberti, amounts to nearly 180; of which 75 are from his own compositions, and the rest from Michael Angelo, Buonaroti, Raphael, Polidoro, Andrea del Sarto, &c. Of these we shall enumerate the following, viz.—A large nativity; a dead Christ, supported by an angel; St. Jerom seated in a landscape, meditating upon the cross; the resurrection of our Saviour; a holy family; creation of Adam and Eve, their expulsion from paradise, their subjection to labour; and the miracle of St. Philip Benizzo, where the men, who despised the exhortations of the faint, are struck dead with lightning, which is esteemed one of the most excellent prints of this master. Pilkington and Strutt.

ALBERTI, DOMENICO, a Venetian *dilettante*, gifted with genius and an exquisite taste. He was of the *corps diplomatique*, and secretary to the Venetian ambassador at Madrid. At a time when there was little melody in harpsichord lessons, he brought about a revolution in the style of playing that instrument, by giving a singing treble to a rapid base, composed of chords broken into groups of semiquavers, which it was so easy to imitate, that composers and players soon grew tired and ashamed of it. Jerig at Paris, and Vento in London, glutted the public with whole volumes of lessons upon Alberti's base, but none ever composed such elegant treble parts for keyed instruments; the melody of which still stands its ground, through all the vicissitudes of 60 years:—a prodigious longevity for a musical production in point of taste! There is a little history, belonging to the publication of Alberti's lessons in England, worth recording, as a beacon to plagiarists. The first time these lessons were heard in London, was at Hickford's room, when they were admirably performed by Jozzi, the second singer at the Opera, at his own benefit; who, not only passed them off for his own compositions, but printed them, and had the courage to affix his name to the title-page, and the conscience to sell them for a guinea a book, equal at least to two guineas now. Unluckily for the author of this fraud, but not before many copies were sold, a gentleman, just returned from Venice, being possessed of a MS. copy of these sonatas in Alberti's own hand-writing, made Walsh, the music-seller, a present of the book, on purpose to expose the transaction. Walsh having obtained the MS. upon such easy terms, sold the eight charming sonatas for six shillings a book. The style being new, and so much more within the power of gentlemen and ladies to execute, than the rich and complicated pieces of Handel, and wild and original legerdemain of Searlatti, had a prodigious sale, and soon obliged Jozzi to make a precipitate retreat to Holland, where he practised the same trick, but not with equal profit.

ALBERTI, DURANTE, flourished in 1590, and died at Rome in 1613, at the age of 75. He, and his two brothers, Cosmio and Giorgio, who were painters and engravers, were natives of Borgo S. Sepulchro. The two first engraved upon copper and wood; the last upon copper only, and died young in 1597. They are not supposed to have been artists of any great note. The son of this artist, viz. Pietro Francesco Alberti, was born in 1584, and died in 1638. He was an historical painter, and we have a print, called the "Academia de Pittori," and containing many figures slightly etched, but with spirit and in a style that indicates much of the master.

ALBERTI, GIOVANNI, a painter of perspective and history, brother of Cherubino, was born at Florence in 1558, and

died in 1601. After receiving early instruction from his father, he went to Rome, where he studied geometry, and the works of Buonaroti and other great masters. His principal attention was devoted to perspective, in which he arrived at great eminence. He was distinguished by the elegance of his composition, the firmness and delicacy of his pencil, the grandeur of his thoughts, the judicious distribution of the parts, and the spirit visible through the whole. Pilkington.

ALBERTI, JOHN, a learned German lawyer, was born at Widmanstadt, and flourished in the 16th century. He was well acquainted with the oriental languages, and wrote "An Abridgment of the Koran," with notes, published at Nuremberg in 1543. In 1556, he published in 4to., at Vienna, at the expence of the emperor Ferdinand I. a New Testament in the Syriac character and language, for the use of the Jacobite sect, in which book are omitted the second epistle of Peter, the second and third of John, the epistle of Jude, and the Revelation. Alberti also wrote a Syriac grammar, with a preface, tracing the progress of the oriental languages among the Latins. *Nouv. Dict. Hist. Gen. Biog.*

ALBERTI, LEANDER, of Bologna, a Dominican, and an Italian historian of some celebrity, was born in 1479. His works are in Latin, "A History of illustrious Men of his Order," fol. 1527; in Italian, "A History of Bologna;" and "A Description of Italy," printed in 1550, and translated into Latin by Kirlander, which abounds with curious information. *Vossius. Hist. Lat. Gen. Biog.*

ALBERTI, LEONI-BAPTISTA, an eminent architect of Italy, was born of a noble family at Florence in 1398, and pursued his studies at the University of Bologna with such success, that at the age of 20 he composed a Latin comedy, intitled "Philodexaos," under the name of Lepidus, which Aldus Manutius conceived to be antique. Here he took the degree of doctor of laws, and was ordained priest. However he chiefly devoted himself to the study of design, and to the examination of ancient edifices; and at Rome he was employed by pope Nicholas V. in several works of architecture. He also planned several considerable buildings at Mantua, Rimini, and Florence. Alberti was a painter, and a good mechanic; and invented an instrument for the practice of perspective; but he is principally known as a writer. His Latin work "On the Art of Architecture," in 10 books, was printed in 1481, much esteemed, and translated by Bartoli, into Italian, in 1546, and afterwards into French. He also wrote, in Latin, a work upon sculpture and painting, in three books, which was translated by Domenichi. He lived to an advanced age, and died at Rome in 1480, as some say, but according to Tiraboschi, in 1472. His funeral oration was pronounced by Angelo Poliziano, and he was celebrated by the contemporary Italian poets. *Gen. Biog.*

ALBERTI, MICHEL, professor of medicine at Hall, in Saxony, and member of the Royal Academy at Berlin, a strenuous defender of the principles of Stahl, against the mechanical physicians, particularly against Heister, was born at Fribourg, November 13th, 1682: he published "Epistola qua Thermarum et Acidularum idolum medicum destruit," Halle 1714, 4to. "Introductio in Universam Medicinam," *ibid.* 1718, 1719, 1721, 3 vols. 4to., containing a multitude of theses on different parts of medicine. For the titles of these, see Haller's *Bibliotheca Medicinæ Practicæ*, vol. iv. p. 386, &c. "Systema jurisprudentiæ medicæ Schneeberg," 4to. 1725. Haller gives a particular account of this work, which he highly commends. See as above; also for accounts of the remaining works of the author, who died at Hall, May 17th, 1757.

ALPERTINI, FRANCIS, a Cambrist, resigned a rich abbey in order to become a Jesuit. He died in 1619. In his "System of Theology," two vols. fol. he attempts to reconcile divinity with philosophy; and in a treatise "De Angelo Custode," he endeavours to prove, that brutes have their guardian angels. Eng. Dict.

ALBERTINUS, MESSATIUS, an historian and poet of Italy, was born at Padua, and flourished in the ninth century. He wrote concerning the reign of the emperor Henry VII., 12 books on the affairs of Italy after Henry VII., and a third part of the history of Lewis of Bavaria; and he has been esteemed a judicious, faithful, and for the time in which he lived, an elegant historian. He also wrote a tragedy on the tyranny of Acciolini, which, with other poetical productions, gained him distinguished honours in the University of Padua. Petrarch mentions him with respect, as a diligent and accurate inquirer into facts. He died in 829. Vossius. Gen. Biog.

ALBERTISTS, a sect of Scholastics, were thus denominated from their leader Albertus Magnus.

ALBERTO, BAXOS DE, in *Geography*, a shoal of rocks before the city of St. Salvador, in the bay of All Saints, on the coast of Brasil. On one of them is a strong fort which commands the road, and between them and the city is a very good harbour, where ships may ride with safety.

ALBERTON, or PORT ALBERT, a sea-port town of Africa, in the kingdom of Barca, on the confines of Tripoli, 50 leagues from Alexandria.

ALBERTUS, in *Commerce*, a gold coin, worth about 14 French livres, which was struck during the reign of Albertus, Archduke of Austria.

ALBESIA, in *Antiquity*, a kind of shield used by the ancient Albanes, a nation of the Maris.

ALBESTROFF, in *Geography*, a town of France, in the department of the Meurte, three leagues north-north-east of Deuze.

ALBETROSS point, a rocky prominence on the coast of New Holland. S. lat. 38° 4'. W. long. 184° 42'.

ALBI, a town of Italy, in the province of Abruzzo Ultra. See *ALBA Fucens*.

ALBI is also a town of Savoy in the Genevois, nine miles north-north-east of Aix.

ALBI, or ALBY, Albiga or Civitas Albiensium, a city of France, in the department of the Tarn, and situate on the river Tarn, was, before the revolution, the capital of a small country called the *Albigensis*, in Upper Languedoc. It has been the residence of a royal tribunal, and since 1677 the see of an archbishop. Its cathedral is dedicated to St. Cecilia, and has one of the finest choirs in the kingdom. The archbishop was metropolitan of five bishops, and they reckon 30 cardinals, who had been bishops of this see. The diocese contained about 327 parishes, and produced about 95,000 livres. It stands upon an eminence, and the number of inhabitants has been estimated at 10,000. In the cathedral was a valuable silver shrine, of the Mosaic kind, and of exquisite workmanship, which contained the reliques of St. Clair, said to have been the first bishop of this city. There is a pleasant walk, called La Lice, a little above the city; and the archiepiscopal palace is very magnificent, and the small town of Chateaufieux serves as a suburb. The river washes the walls of the city, and serves both for an ornament and a defence. It is 35 miles north-east of Toulouse, and 250 miles south of Paris. The territory of the Albigensis, is about 10 leagues long and seven wide, is well peopled, and produces abundance of grapes, corn, wood, saffron, and sheep. It has also coal-mines. The trade of this district consists of dried prunes, grapes, wine, and a coarse

kind of cloth. N. lat. 43° 55' 44". E. long. 2° 8' 45". See *ALBIGENSES*.

ALBI, in *Eccelesiastical History*. See *White BRETHREN*.

ALBIANI, in *Geography*, a town on the Ivory coast of Africa, six miles east of Iffini.

ALBIANKIA Cape, lies on the north-west point of the island of Cyprus, near the eastern extremity of the Mediterranean. N. lat. 35° 20'. E. long. 32° 18'.

ALBIAS, a small town of France, in the district of Quercy, divided into two parts by the river Aveyron.

ALBICILLA, in *Ornithology*, a species of *FALCO*, in the Linnæan system, the *aquila albicilla* of Brisson, the *pygargus*, *albicilla hirundinaria* of Bellon, Gesner and Ray, the *grand pygargue* or great *erne* of Buffon, *braun fahler adler* of Frisch, *white-tailed eagle* of Willughby, and *cinereous eagle* of Pennant and Latham. Its specific characters are, "that its cere and feet are yellow, the tail-feathers white, and the intermediate ones black at their vertex." It is of the size of a peacock, being two feet nine inches long; its head and neck are of a pale ash colour; the iris and bill pale yellow, and the bill elongated at its base; the front between the eyes and the nostrils naked, with small scattered bristles, and of a cœrulean hue. The body and wings are cinereous, intermixed with dun; the tail white; the legs woolly below the knees, and of a bright yellow; the claws black. It inhabits Europe, particularly Scotland, and the adjacent islands, and preys upon large fish. Aristotle (Hist. Anim. lib. ix. c. 32. tom. i. p. 937.) gives this species the epithet of *Hinnularia*, denoting that it preys upon fawn, that is, young stags, deer and roe-bucks; and he represents it as haunting the plains, graves, and towns, and also resorting to the mountains and forests.

ALBICILLA, in *Conchology*, is a species of the *NERITA*, with a striated shell, subdentated lips, the interior tuberculated. It is found at the Cape of Good Hope and in the Indian sea.

ALBICUS, in *Biography*, an archbishop of Prague, was raised to that dignity by Sigismund, king of Bohemia, and distinguished by the liberality of his sentiments. His character has been reproached by the papists on account of the indulgence which he exercised towards John Huss and the other disciples of Wickliff. He composed three medical treatises, viz. "Praxis Medendi," "Regimen Sanitatis," and "Regimen Pestilentie;" printed at Leipzig, in 1484, 8vo. long after his death.

ALBIGAUNUM, or Albium Ingaunum, in *Ancient Geography*. See *ALBENGUA*.

ALBIGENSES, in *Eccelesiastical History*, a sect or party of reformers, who appeared about Toulouse and the Albigensis, in Languedoc, in the 12th century; and who derived their name, not from Albi's being the place of their birth, or residence, or the seat of their principal assembly; but from their having been condemned in a council held in that town, in the year 1176. Their origin may be traced to the *PAULICIAN*s, who, with a view of propagating their opinions, or of escaping oppression and persecution, retired from Bulgaria and Thrace, and formed settlements in other countries. Their first migration was into Italy, whence, in process of time, they sent colonies into almost all the other parts of Europe, and gradually formed a considerable number of religious assemblies of persons who adhered to their sect, who were severely persecuted by the Roman pontiffs. About the middle of the 11th century many of the Paulicians settled in Lombardy, Insubria, and principally at Milan; and from hence they migrated to France, Germany, and other countries, where by their piety and zeal they captivated the admiration and esteem of the multitude. In Italy they

they were called Paterini, and Cathari or Gazari; in France they obtained the appellation of Albigenses, from the circumstance already mentioned; and they were also denominated Bulgarians, because they originally came from Bulgaria; Publicans probably by corruption from Paulicians, Boss-Hommes, or Good Men; Petro-Brunians from Peter Bruys, who is said by some to have first brought them into Languedoc; Arnolds, Abelardists, Henricians, from the names of Arnold de Bresse, Peter Abelard, and Henry, who adopted their opinions. They were also called Passagers, Albi, and Albancens; but some consider the latter as distinct from the Albigenses, though they avowed similar sentiments, and trace their origin to the 8th century. As the Albigenses were distinguished by their opposition to the discipline and ceremonies of the church of Rome, the Popish writers have comprehended all the adversaries of this church under the same appellation. Accordingly they have confounded them with the Waldenses, or VAUDOIS, who sprang up at a later period, and differed from them in some of their opinions. Bossuet, the bishop of Meaux, contends, that they were different sects; and he alleges, that the Albigenses were heretics and manichees; and that the Waldenses were merely schismatics, who were found as to articles of faith, and separated from the church of Rome on account of forms and discipline. But they were unquestionably agreed in their opposition to the papal hierarchy, and in asserting the usurpation, tyranny, and idolatry of the Romish church, and in representing the pope as Antichrist. The learned Limborch has taken pains to investigate and ascertain the difference between these two sects; and he states, in detail, the several opinions and practices in which they both agreed and differed. They concurred in maintaining the unlawfulness and sinfulness of every kind of oath, and the inutilty of confession to the priest, and the inefficacy of absolution, and in representing the church of Rome as antichristian. The opinions in which they disagreed were those of the manichees, which he inclines to think were adopted by many of the Albigenses, but which are not justly chargeable against the Waldenses. The former are said, upon the authority of the book of the Sentences of the Inquisition at Toulouse, to which this writer refers, to have believed, that there are two Gods and Lords, the one good, the other evil; that all things visible and corporeal were created not by God, our Heavenly Father, and the Lord Jesus Christ, but by the devil, the evil god, who is the god of this world, and the maker and prince of it. They also maintained, that the sacraments of the church of Rome are vain and unprofitable; *viz.* the eucharist, baptism, confirmation, orders and extreme unction. In the eucharist they believed, that there was not the body of Christ, and nothing but mere bread; and the baptism of water they condemned as unavailing, and particularly that of children; extreme unction was, in their judgment, of no avail; and as to the orders of the church of Rome, they reproached and condemned its whole constitution; matrimony was sinful, and not appointed by the good God; they also denied the incarnation of Christ; and maintained, that he did not take a real human body, nor rise again with it, but merely with the likeness of it; and that it was impossible for God to be incarnate; they are also charged with denying the resurrection of bodies, alledging that though the souls of men shall come to judgment, they shall not then appear in their bodies; they objected to the adoration of the cross, the sign of which they represented as a detestable emblem of the devil; and they believed, that the souls of men were spirits banished from heaven because of their sins. The Albigenses differed also from the Waldenses in their rites and customs, as well as in their doctrines.

Of the former, it is said, there were two sorts, some professed their faith, and conformed to the customs of their sect, and were called *perfecti* or *consolati*, perfect or comforted. Others only entered into a covenant with these perfect persons, which they call *La Convenensa*, the agreement, that at the end of life they would be received into their sect; for this reception they were prepared by certain abstinences or fasts; and the admission, called spiritual baptism, was believed to save the soul of the person admitted, and was delayed to the last sickness, when there were no hopes of recovery. Those who were thus received were commanded to make use of the *evlura*, *i. e.* fasting themselves to death, and even to hasten their death by opening a vein and bathing. Of the manichæism of the Albigenses, and other opinions and practices, which have been charged upon them by inquisitors and popish writers, they have been excusated by protestant authors; and the charges have been ascribed to that malignant zeal, which has induced persecutors to vindicate their own conduct, and to fix reproach on those who have been deemed heretics. The errors and crimes of individuals have been, not unfrequently, charged upon whole bodies of men; and we have reason to think, that this has been very much the case in the present instance. However this be, the Albigenses became so formidable, both by their number and zeal, that a holy league, or crusade, was agreed upon among the Catholics; and pope Innocent III. exhorted all princes to oppress them as much as possible, and to expel them from their dominions. Raymond, earl of Toulouse, afforded them temporary protection and favour; upon which the pope ordered him to be excommunicated as a favourer of heretics. He also sent his legate, with letters to many of the prelates, commanding them to make inquisition against the Albigenses, and to destroy them. He also engaged Philip, king of France, to concur in this work of extirpation. The pope's legate was accompanied by 12 abbots of the Cistercian order, preaching the cross against the Albigenses, and promising, by the authority of Innocent, a plenary remission of all sins to all who took upon them the crusade. To these Dominick joined himself, and in that expedition invented the INQUISITION: and he deputed those who were denominated *CROSS-BEARERS* to unite their efforts for suppressing these heretics. When these deputies of Dominick and the pope were suspected of being less zealous than they wished them to be, a plenary indulgence was proclaimed in order to engage a greater number of assistants in this warfare of intolerance and blood. The *CROSS-BEARERS* on this occasion wore the cross on their breasts, as those who took it up against the Saracens bore it on their backs or shoulders. Raymond, who was still forbearing and indulgent, was excommunicated by a bull of Innocent, his subjects were absolved from their oath of allegiance, and power was given to any catholic, not only to act against his person, but to take possession of his country. The Earl was at last overcome, promised obedience, and sought reconciliation with the church. After the reconciliation of the earl, the *CROSS-BEARERS* were busily employed in attacking the heretics, seizing their cities, filling all places with slaughter and blood, and burning many whom they had taken captives. In the year 1209 Biterre was taken, the inhabitants without distinction put to the sword, and the city burnt. Carcassone was also destroyed; and Simon, earl of Montfort, made governor of the whole country, for the purpose of extirpating heretics, which he faithfully fulfilled. In the next year a new expedition of the *CROSS-BEARERS* was undertaken against the Albigenses. They seized Albi, and other towns, and either hanged or burnt those heretics, whom they captured. The earl of Toulouse was alarmed by the destructive

progress of Simon Montfort, and fearing for himself, and for his country, raised a large army, and received succour from the kings of England and Aragon, to whom he was related. Having been deprived of his dominions by Montfort, he appealed, for redress, to the council of Lateran in 1215, but without avail. The synod decreeing him for ever excluded, he went to Spain, and his son Raymond to Provence, in order to collect auxiliary forces; and with these he recovered part of his dominions, and the city of Toulouse itself. Montfort was killed at the siege in his endeavour to retake it. The earl died in 1221, and was succeeded by his son, who was unable to procure christian burial for his father. When Raymond had recovered his father's dominions, the Inquisition was banished from the country of Toulouse; but pope Honorius III. used every effort to render him obnoxious, and earnestly urged king Lewis of France to take up arms against the Albigenses. The French king undertook the expedition against Raymond and the heretics, and laid siege to Avignon; where he and many of his army died of a dysentery and other diseases. Avignon was at length taken by treachery, and Toulouse was compelled to surrender. Raymond obtained peace upon very humiliating conditions; being required to abjure his heresy, and to be for ever subject to the see of Rome, to expel all heretics, and in no case to defend them; to pay a fine of 2000 marks, and to surrender a considerable part of his dominions to the king and the church. He was then led to the high altar, in a linen garment and with naked feet, and absolved from the sentence of excommunication. Oppressed afterwards by a series of misfortunes, he bowed his neck to the papal yoke, and signified to the pope his desire that heresy might be wholly extirpated from his dominions. Soon after this act of servile humiliation, *viz.* in 1249, he died, and was the last earl of Toulouse of that line. In consequence of these events, the Albigenses were dispersed, and they were little known or heard of till the time of the Reformation, when those who remained fell in with the VAUDOIS, and conformed to the doctrine of Zuinglius, and the discipline of Geneva. Limborch's Hist. of the Inquisition by Chandler, vol. i. p. 42—70. Mosheim's Eccl. Hist. vol. ii. p. 580. 8vo.

ALBIN, in *Geography*, a town of France, in the department of the Aveyron, six leagues north-west of Rhodes.

ALBINA, in *Conchology*, a species of HELIX, with a smooth perforated white shell, gibbous below, and quadrangular aperture. It resembles the *Albella*.

ALBINALI, in *Geography*, a town of Asia, in Arabia Felix.

ALBINATUS *Jur.* See AUBAINE.

ALBINE. See ASSINE.

ALBINELLA, in *Entomology*, a species of PHALÆNA TINEÆ, with brown wings, and a single golden line, arched on the fore part, found in the groves of the northern part of Europe.

ALBINEN, or ALPEN, in *Geography*, a town of Switzerland, in the Valais, 22 miles east of Sion.

ALBINGAUNUM, or ALBIUM INGAUNUM, a town of Italy on the north east side of Liguria. See ALBENGA.

ALBINI, in *Antiquity*. See ALBARIUM OPUS.

ALBINOS, in *Zoology* and *Geography*, a denomination given to the white negroes of Africa, who have light hair, blue eyes, and a white body, resembling that of the Europeans, when viewed at a distance; but, upon a nearer approach the whiteness is pale and livid, like that of leprosy persons, or of a dead body. Their eyes are so weak that they can hardly see any object in the day, or bear the rays of the sun, and yet, when the moon shines, they see as well, and run through the deepest shades of their forests, with as much ease and activity, as other men do in the brightest daylight. Their complexion is delicate; they are less robust

and vigorous than other men; they generally sleep in the day, and go abroad in the night. The negroes regard them as monsters, and will not allow them to propagate their kind. In Africa this variety of the human species very frequently occurs. Wafer informs us, that there are white Indians of the same general character among the yellow or copper-coloured Indians of the isthmus of Darien; and the CHACRELAS of Java, as well as the BEDAS of Ceylon, seem to be of the same description. M. Buffon observes, that this variation of nature takes place from black to white only, and not from white to black; and that all the people in the East Indies, in Africa, and in America, among whom these white men appear, lie under the same latitude: the isthmus of Darien, the Negro country, and the island of Ceylon being under the same parallel. It has been a subject of inquiry, whether these men form a peculiar and distinct race, and a permanent variety of the human species, or are merely individuals who have accidentally degenerated from their original stock. Buffon inclines to the latter opinion, and he alleges in proof of it, that in the isthmus of America a husband and wife, both of a copper colour, produce one of these white children; so that the singular colour and constitution of these white Indians must be a species of disease which they derive from their parents; and the production of whites by negro parents, which sometimes happen, confirms the same theory. According to this author, white appears to be the primitive colour of nature, which may be varied by climate, food, and manners, to yellow, brown, and black; and which, in certain circumstances, returns, but so much altered, that it has no resemblance to the original whiteness, because it has been adulterated by the causes that are assigned. Nature, he says, in her most perfect exertions, made men white; and the same nature, after suffering every possible change, still renders them white: but the natural or specific whiteness is very different from the individual or accidental. Of this we have examples in vegetables, as well as in men and other animals. A white rose is very different, even in the quality of whiteness, from a red rose, which has been rendered white by the autumnal frosts. He deduces a farther proof that these white men are merely degenerated individuals from the comparative weakness of their constitution, and from the extreme feebleness of their eyes. This last fact, he says, will appear to be less singular, when it is considered, that, in Europe, very fair men have generally weak eyes; and he has remarked, that their organs of hearing are often dull: and it has been alledged by others, that dogs of a perfectly white colour are deaf. This is a subject which demands farther investigation. Buffon, Nat. Hist. by Smellie, vol. iii. p. 179—182.

M. Saussure, in his "Voyages dans les Alpes," gives an account of two boys at Chamouni, whom he refers to the class of Albinos. One of them was about 20 or 21 years of age, and the other about two years younger. The eldest had a dull look, with thickish lips, but his features in other respects were not different from those of other people. The youngest was of a more agreeable figure, and more sprightly. Their eyes were not blue; the iris was rose-coloured; and the pupil, when viewed in the light, appeared red; whence he infers, that the interior membranes were deprived of the uvea, and of the black mucous matter by which they should have been lined. In their infancy, their hair, eye-brows, eye-lashes, and the down upon their skin, were very fine, and of a perfect milk-white colour; but at the age above-mentioned, the hair was of a reddish cast and more strong. Their sight was also strengthened, and, even in their infancy, was not much

offended by the light of the day. They were unable to labour with persons of their age, and were maintained by the charity of a relation. Although they had not the thick lips and flat noses of the white negroes, this difference is owing, as M. Saussure thinks, to their being Albinos of Europe, and not of Africa. The malady that affects the eyes, the complexion, and the colour of the hair, enfeebles also their strength, without altering the conformation of their features; and of this malady, he apprehends, there are different degrees; so that it produces, in various instances, different effects. He at first ascribed it to an organic debility; in consequence of which, a relaxation of the lymphatic vessels within the eye, might admit the globules of the blood in too great abundance into the iris, uvea, and even the retina, and thus occasion the redness of the iris and of the pupil. This debility, he supposed, might account for the intolerance of the light, and for the whiteness of the hair. But M. Blumenbach, professor in the university at Göttingen, attributes it to a different cause. He has observed the same phenomenon in brutes, in white dogs, and in owls; and he says, that it generally occurs in the warm-blooded animals, and that he has never found it in those with cold blood. This ingenious physiologist is of opinion, that the redness of the iris, and of the other internal parts of the eye, as well as the extreme sensibility that accompanies it, is owing to the total privation of that brown or blackish mucus, which, about the fifth week after conception, covers all the interior parts of the eye in its found state. He observes, that Simon Pontius, in his treatise, "De coloribus oculorum," long ago remarked, that the interior membranes of blue eyes are less abundantly provided with this black mucus, and are therefore more sensible of the action of light. He adds, that this sensibility of blue eyes is very conformable to the situation of northern people, during their long twilight; and that, on the contrary, the deep black in the eyes of negroes enables them to bear the strong glare of the sun's beams in the torrid zone. As to the connection between this red colour of the eyes, and the whiteness of the skin and hair, he says, it is owing to a similarity of structure. This black mucus is formed, as he asserts, only in the delicate cellular substance, which has numerous blood-vessels contiguous to it, but contains no fat, like the inside of the eye, the skin of negroes, the spotted palate of several domestic animals, &c. and the colour of the hair generally corresponds with that of the iris. *Gazette Litt. de Göttingue.* Oct. 1784.

M. Buzzi, surgeon to the hospital at Milan, published, at the same time, in the "Opusc. Scelti de Milan, 1784. tom. vii. p. 11." a very interesting memoir, in which he demonstrates, by dissection, the hypothesis of M. Blumenbach. Having an opportunity of dissecting the body of a peasant, who died at the age of 30 years, in the hospital of Milan, of a pulmonary disorder; and who was remarkable for the uncommon whiteness of his skin, hair, beard, and all the other covered parts of the body: he found the iris of the eyes perfectly white, and the pupil of a rose-colour; and the eyes were altogether destitute of that black membrane, called the uvea, which was not discernible, either behind the iris or under the retina. Within the eye, there was only found the choroid coat, extremely thin, and tinged of a pale red colour, by vessels filled with discoloured blood. The skin, when separated from different parts of the body, appeared to be almost wholly divested of the rete mucosum, nor was the least trace of it to be discovered by maceration, even in the wrinkles of the abdomen, where it is most abundant and most visible. The

whiteness of the skin and hair is ascribed by M. Buzzi to the absence of the rete mucosum, which, in his judgment, gives the colour to the cuticle, and to the hairs that are scattered over it. In proof of this opinion, he alleges a well-known fact, that if the skin of the blackest horse be accidentally destroyed in any part of the body, the hairs that afterwards grow on that part are always white, because the rete mucosum, which tinges those hairs, is never regenerated with the skin. M. Buzzi having assigned the probable proximate cause of this phenomenon, it still remains to determine, what is the remote cause of it, or how the rete mucosum is destroyed in such subjects. It seems to be a fact, very generally admitted, that persons of this description do not form a distinct species, as they are produced from parents with dark skins and black eyes. This was the case with respect to the Albinos of Chamouni. M. Buzzi relates a fact, cited by M. Saussure, which seems to throw some light on the subject. A woman of Milan had seven sons, of whom the two eldest, and the two youngest had brown hair and black eyes; the other three had white skins, white hair, and red eyes. During the pregnancies that produced these Albinos, the woman had a constant and immoderate appetite for milk, which she took in great quantities, but when she was pregnant with the other four, she had no such desire. But it does not appear, that this preternatural appetite was not the effect of a certain heat, or internal disease, which destroyed the rete mucosum in the children before they were born. M. Saussure observes, that this faulty conformation is more rare among women than among men; and it does not seem to be owing to the air of the mountains; for though he traversed the greatest part of the Alps, and the other mountains of Europe, he met with no other individuals of this kind.

ALBINOVANTES, PEDO, in *Biography*, a Latin poet, to whom Ovid addresses his 10th epistle, "Ex Ponto." *Opus.* tom. iii. p. 876. Ed. Burmann. There are extant of his writings, his *Elegy on Drusus*, and another on the death of *Mecænas*, published by Le Clerc in 1703, 8vo. and in 1715, 12mo. at Amsterdam, with a prolix commentary.

ALBINTEMELIUM, or ALBIUM INTEMELIUM, in *Ancient Geography*, now *Vintimiglia*, a town of Liguria, or the present territory of Genoa. See *VINTIMIGLIA*.

ALBINUS, BERNARD, called *WEISS* or *White*, in *Biography*, was born at Dessau, in the province of Anhalt, in Saxony, January 7th, 1653, and studied medicine at Leyden. In 1676, having taken his doctor's degree, he returned to his own country, where he soon distinguished himself for his sagacity and learning. In 1680, he was nominated professor of medicine at Frankfort on the Oder, and became so celebrated for the perspicuity of his lectures, that pupils flocked to him from all parts of Germany. In 1694, Frederic, elector of Brandenburg, appointed him his physician, with a pension of 600 florins, and soon after gave him a canonry at Magdeburgh. In 1702, he was chosen professor of medicine at Leyden. Having filled that office 19 years with the highest reputation, he died on the 7th of September 1721, aged 68 years.

A large collection of *Theses* is published under his name, the titles of which may be seen in Haller's *Bibl. Med. Pract.*

ALBINUS, BERNARD SIGEFRED, son of the former, prosecuted his studies with so much zeal and success, that on the recommendation of Boerhaave, he was appointed professor of anatomy and surgery at Leyden, in 1718, when he was only 20 years of age. This office he

continued.

continued to fill by an uncommon felicity, Haller says, for 50 years, and acquired a greater degree of reputation, as teacher, or demonstrator in anatomy, to which he exclusively dedicated himself, than had been enjoyed by any of his predecessors. He died, Sept. 9th, 1770, aged 73 years. His first work, entitled, "*Historia musculorum hominis*," 4to. appeared in 1734. In composing this, he took great pains to measure and describe all the insertions of the muscles in the bones, and to mark them in with aqua fortis, which he afterwards caused to be drawn by an excellent artist. In 1737, he gave some coloured plates of the arteries and veins of the intestines, and some elegant figures of the bones of the fœtus. An anatomical explanation of the plates of Eustachius, with a new edition of the plates themselves, was published by him in 1743, and republished with improvements in 1761. His own large tables of the skeleton and muscles appeared in 1747; and about the same time, seven tables of the gravid uterus. His great tables of the bones was edited in 1753; and again, in an improved state, in 1762. Eight volumes, 4to, of "*Anatomical Annotations*," replete with curious matter, but too much occupied with controversy, appeared successively from 1754 to 1768.

Besides his original works, which are numerous, and highly illustrative of the science, he published in 1725, an edition of the works of Vesalius, with an account of his life; in the same year, "*Index suppellectilis Ravianæ*;" and in the year 1737, "*Gulielmi Harveii Opera, et Hieronimi Fabricii ab Aquapendente*." See Haller's *Bibliotheca Anatomica*, vol. ii.

ALBINUS, CHRISTIAN BERNARD, though eclipsed by the superior fame of his brother, was so much esteemed for his skill and diligence, as to be raised to the chair of professor of anatomy, at Utrecht. He died April 5, 1752, aged 56 years. He published, in 1722, "*Specimen Anatomicum, exhibens novam tenuium hominis intestinorum descriptionem*," 4to.; and the next year, "*De anatome errores detegente in Medicina*," also in 4to.

Two other authors of the same name are noticed by bibliographers; James, a native of Hamburgh, who published in 1720, a "*Dissertation on the Scurvy*;" and Eleazer, who published natural histories of Birds and of Insects.

ALBINUS, PETER, or WEISS, a celebrated historian and good poet of the 16th century, was born at Sneeberg in Misnia, and became professor of poetry and mathematics in the academy of Wittemberg, and then secretary to the elector at Dresden, where he published a second enlarged edition of the "*Chronicles of Misnia*," which he had printed at Wittemberg in 1580. His other works, principally historical, were much esteemed. *Biog. Diët.*

ALBINUS, DECIMUS CLODIUS, was born at Adrumetum in Africa, and called Albinus, on account of his fair complexion at his birth. In his youth he was instructed in the Greek and Latin languages, and he is said to have written a treatise on agriculture, and a collection of Milesian tales, which was a licentious performance; but his prevailing taste inclined to a military life, and he was accustomed at school to repeat frequently, and with peculiar pleasure, the following verses from Virgil:

"Arma amens capio, nec fat rationis in armis,"

ÆNEID, ii. v. 314.

"With frenzy seiz'd, I run to meet th' alarms;

"Resolv'd on death, resolv'd to die in arms!"

DRYDEN.

He commenced his career under the emperor Antoninus, whose esteem he acquired; and after some previous gradua-

tions of advancement, he commanded the army in Dithynia, when Avidius Crassus revolted against Marcus Aurelius. On this occasion he distinguished himself by his fidelity to his prince, and by his active service, for which he was rewarded, as it is said, with the consulship. Under Commodus he acquired reputation in several battles on the Rhine and on the Danube, and he was at length appointed commander of the legions in Britain. Whilst he governed Britain, Commodus, by the account of Capitolinus, which is not generally credited, indulged him with permission to assume the title of Cæsar, with all the ensigns appropriate to that dignity. However this be, Severus, as we are informed by Dion Cassius and Herodian, soothed his ambition and engaged his attachment, by giving him this title. Albinus was deluded by this honour, and by the expectation which the emperor led him to entertain of sharing with him in the Imperial government. Severus also appointed him his colleague in the consulship in the year 194, ordered statues to be erected to him, and conferred upon him other distinctions, which afforded an opportunity ultimately of destroying him. Having defeated and killed Niger, whom he had amused and deceived by the same kind of dissimulation which he was practising on the credulous Albinus, he determined to get rid of this rival, whose character, contrasted with his own, induced the senate to exchange one master for another. Some say that, before he had recourse to open force of arms, he tried the base and perfidious means of assassination; but Dion Cassius's account is more probable, who says, that Severus, after his victory over Niger, deprived Albinus of the title and prerogatives of Cæsar; and that Albinus, on the other hand, pretended even to the title of Augustus. Accordingly Albinus was proclaimed under this appellation, engaged Gaul and Spain in his interest, and hastened with a powerful force to meet Severus, who had proclaimed him a public enemy. The two rivals, after some previous skirmishes, decided the contest for the empire in the plain between Lyons and Trevoux. Their two armies were equal in number, each of them consisting of 150,000 men, and they were led on by the two emperors. The troops on each side fought with great valour. The British legions under Albinus were not inferior to those of Illyricum; but Severus was thought to be an abler general than his competitor. The victory was long doubtful, but at length Severus prevailed; and Albinus was compelled to fly with the shattered relics of his army, first to Lyons, and then to a house near the Rhone, where he either destroyed himself with his own sword, or made one of his slaves perform the fatal office for him. He was not quite dead, when a detachment of the enemy arrived, cut off his head, and carried it to Severus. His wife and children were at first pardoned; but afterwards inhumanly massacred, and their bodies thrown into the river. The whole family of Albinus, all his friends, and most distant relations, without distinction of age or sex, were, by the orders of Severus, barbarously slaughtered, and their estates confiscated. Most of the great men of Gaul and Spain, who had manifested any attachment to Albinus, underwent the same fate. By means of these murders and confiscations, Severus amassed an immense treasure, enriched his soldiers, and, at his death, left incredible wealth to his children. This event happened on the 19th of February, according to Tillemont, A. D. 197, the 4th year of Severus's reign.

Of the character of Albinus, different accounts have been given. Capitolinus, on whose report we cannot much depend, represents him as stern, reserved, unsocial, rigid to cruelty in his discipline, gluttonous and brutal. But this account is not very credible, when it is considered that his soldiers

soldiers were attached to him, and that he was exceedingly beloved by the senate, and applauded for his justice and humanity. He seems, however, to have been a brave warrior, who had the art of making himself beloved; but who had not cunning enough to guard against the artifices of his enemy, and this was the cause of his ruin. Crevier, *Hist. of the Emperors*, vol. viii. p. 63—96. *Anc. Un. Hist.* vol. xiii. p. 374—393.

ALBINUS, A. *Posthumius*, the colleague of Licinius Lucullus in the consulship, in the year before Christ 151, wrote a History of the Affairs of Rome, in the Greek language. He is mentioned by Cicero in his *Brutus* (*Oper. tom. i. p. 399.* Ed. Olivet.) as a man of learning and eloquence. Upon his making an apology, and intreating pardon for the improprieties of expression that occurred in a work written in a language so different from that of his own country, Cato facetiously asked, “Why did you chuse rather to solicit pardon for a fault than not to have committed it?” His conduct however in this respect needed no apology, as the Greek language was known to almost all nations, whilst the latter was almost wholly confined to the Roman territory, and therefore his history would be more extensively read. See Cicero per Archia, *Oper. tom. v. p. 405.*

ALBIOECE, or ALEBECE, in *Ancient Geography*, called also *Reji Apollinares*, from their worship of Apollo, and *Civitas Rejensium*, was a Roman colony of Gallia Narbonensis. It is now *Riez* or *RIEUX*, in Provence.

ALBION, a name formerly given to the island of Britain, comprehending England, Scotland and Wales, by way of contradistinction from Hibernia, and the other British islands. Thus Agathemerus, (*lib. xi. c. 4.*) speaking of the British islands, says, they are many in number; but the most considerable are Hibernia and Albion; and Ptolemy (*lib. ii. c. 3.*) calls Albion a British island. Pliny also (*H. N. lib. iv. c. 16. tom. i. p. 222.*) observes, that the island of Britain, so much celebrated by the Greek and Latin writers, was formerly called Albion; the name of Britain being common to all the islands round it. The etymology of the name is uncertain. Some derive it from the Greek *αλβον*, *alphon*, signifying white, in reference to the chalky cliffs on our coasts; others pretend that its name was borrowed from a giant, the son of Neptune, mentioned by several ancient writers. Some of our etymologists have recourse to the Hebrew tongue, and some to the Phœnician; *alben* in the former signifying *white*, and *alp* or *alpin*, in the latter, denoting *high* and *high* mountain, the land appearing so as you approach it from the continent. The derivation from the Greek or Hebrew word signifying *white*, seems to be countenanced by the British poets, who call Britain *Inis Wen*, i. e. the White Island. Selden's notes on Polyalbion, p. 20.

ALBION, *New*, in *Geography*, the name given by Sir Francis Drake to California, and part of the north-west coast of America, when he took possession of it in 1578. Captain Cook discovered the coast of New Albion, March 7, 1778, and landed in a place situate in N. lat. 44° 33'. E. long. 235° 20'. He describes the land as abounding with mountains, the summits of which were covered with snow; but the vallies that lay between them and the sea-coasts, high as well as low, produced a great number of trees, which appeared like a large forest. The inhabitants at first seemed to prefer iron to every other article of commerce; but they afterwards shewed such a predilection for brass, that scarcely a fragment of it was left in the ships except that which belonged to the necessary instruments. They were also observed to be much more tenacious of their property than those of the other savage nations which the voyagers had met with, so that they would not part with wood, water,

grafs, or even the most trifling article, without a compensation; and they were sometimes very unreasonable in their demands. The place in which the Resolution anchored was called by Captain Cook, *St. George's Sound*; but he afterwards understood that the natives gave it the name of *Νοοτκα*. Its entrance was situated in the east corner of Hope bay, in N. lat. 49° 33'. E. long. 233° 12'. The climate seemed to be much milder than that on the eastern coast of America, in the same parallel of latitude; and the thermometer, even in the night, never fell lower than 42°, and in the day-time frequently rose to 60°. The trees of this country are chiefly the Canadian pine, white cypress, and some other kinds of pine. The birds were few, and much harassed by the natives, who use their feathers as ornaments for their dress, and their flesh for food. The people are acquainted with the use of metals, having many iron tools; and two silver spoons were procured, which were similar in their construction to those seen in some Flemish pictures, and were worn by one of the natives as an ornament round his neck. These metals had probably been conveyed to them by the way of Hudson's bay and Canada, or some of them might have been introduced from the north-western parts of Mexico.

On the 18th of April, 1792, Captain Vancouver, employed in an expedition for completing the survey of the western coast of North America, from the latitude of 30° N. to 60° N., fell in with the coast of New Albion in N. lat. 39° 27'. E. long. 236° 25'. As he approached the land, the shore seemed to be perfectly compact, formed, generally speaking, by cliffs of a moderate height and nearly perpendicular. The inland country, which arose in a pleasing diversity of hills and dales, was completely clothed with forest trees of considerable magnitude, and those spots, which were destitute of wood, were beautifully green, with a luxuriant herbage, interrupted by streaks of natural earth. This part of the coast abounded with whales, most of which were of the tribe called the Greenland finners. In directing their course along the coast northward, they passed Cape Mendocino, in lat. 40° 19', long. 235° 53'. This Cape is the highest on the sea-shore of this part of New Albion. The mountains behind it are considerably elevated, and form a high steep mass, composed of various hills that rise abruptly, and are divided by many deep chasms. Dwarf-trees were thinly scattered in the chasms and on the ridges of the hills; and the general surface was covered with vegetables of a dull green colour, occasionally interspersed with perpendicular strata of red earth or clay. As they advanced further north, the distant interior country was composed of mountains of great elevation, before which were perceived hills and dales, with woodland and clear spots, as if they were in a state of cultivation; but they could discern neither houses, huts, smoke, nor any other signs of its being inhabited. On the coast to which they next approached, and which was formed by rocky precipices, the most projecting part, situate in lat. 41° 8'. long. 236° 5', was called *Rocky Point*. Near this point the colour of the sea changed to a light river-coloured water, which gave reason for concluding that some considerable river or rivers were in the neighbourhood; but pursuing their course they arrived again, in oceanic-coloured water, in lat. 41° 36'. long. 235° 58'. The land in this part, formed a conspicuous point, which was denominated *Point St. George*, in lat. 41° 46½', and long. 235° 57½', and a dangerous cluster of rocks extending from thence, the *Dragon rocks*. The point forms a bay, and the north point of it was called *St. George's bay*. The inland mountains were much elevated, and clothed with a variety of trees, chiefly of the pines, and some spreading trees of considerable magnitude were observed. Proceeding further along the coast they cast anchor in lat.

42° 38'. long. 235° 44'; a cliff which projected into the sea near their station, and terminated in the form of a wedge, was called *Cape Orford*, lat. 42° 52'. long. 235° 35'. Some canoes came from the coast to visit the ships, and approached alongside of them with the greatest confidence. The people were distinguished by a pleasing and courteous deportment; their countenances indicated nothing ferocious; their features partook of the European character; their colour was a light olive; and besides being punctuated like that of the south-sea islanders, their skin had many other marks, which were either the effects of injury in roving through the forests with thin clothing, or purely ornamental. Their stature did not exceed five feet six inches; they were well-limbed, but slender in their persons, bore little or no resemblance to the people of Nootka; nor did they seem to have the least knowledge of their language. They preferred cleanliness to the painting of their bodies; in their ears and noses they had small ornaments of bone; their hair, which was long and black, was clean and neatly combed, and generally tied in a clab behind, and some of them had it thus tied in front. They were dressed in garments, nearly covering them, made principally of the skins of deer, bear, fox, and river otter. Their canoes, capable of carrying about eight people, were rudely wrought out of a single tree, resembling in shape a butcher's tray, and appearing to be unfit for either a sea voyage or any distant expedition. They brought but a few articles to barter, and they anxiously solicited in exchange iron and beads. In their traffic they were scrupulously honest in fixing their bargain with the first bidder, and in refusing any presents without an equivalent in return.

In their progress from their last station near Cape Orford, they discovered a point of land which they considered to be the *Cape Blanco* of Martin d'Aguilar, in lat. 43° 23'. long. 235° 50', and the *Cape Gregory* of Captain Cook; and they sought for the river or straits, which are said to have been discovered by this navigator. They next arrived at a promontory, which Captain Cook calls *Cape Perpetua*, in latitude 44° 12'. longitude 236° 51'; and pursuing their route, they passed *Cape Foulweather*, which is a conspicuous promontory, in latitude 44° 49'. longitude 236° 4'. They next proceeded to *Cape Lookout*, in latitude 45° 32'. longitude 236° 11', which is a small projecting point, that had been seen by Mr. Mears, and off which are four rocks, one of them being perforated as he has described it. They afterwards passed *Cape Disappointment* of Mr. Mears, in latitude 46° 19'. and longitude 236° 6', and the opening to the south of it called *Deception Bay*. The country before them presented a luxuriant landscape; the interior parts were elevated and diversified with hills, and the whole had the appearance of a continued forest, as far as the eye could reach. They wished to find a bay in the vicinity of a country that presented so delightful a prospect of fertility; but they were under a necessity of pursuing their course; and having passed the *Low point* of Mr. Mears, and his *Shoal-water* bay, they arrived at *Point Grenville*, in latitude 47° 22'. longitude 235° 58½'. The coast from hence northward rose regularly in height, and the inland country acquired a considerable degree of elevation; and here they saw that land, called by Mr. Barclay, *Desolation Island*, in latitude 47° 37'. longitude 235° 49'; which is the largest detached land that they had observed on the coast, and presented a very barren aspect. A canoe or two were seen paddling near the island. "It is a fact," says Mr. V. "not less singular than worthy of observation, that on the whole extensive coast of New Albion, and more particularly in the vicinity of those fertile and delightful shores we had lately passed, we had not, excepting to the

southward of *Cape Orford*, and at this place, seen any inhabitants, or met with any circumstances, that in the most distant manner indicated a probability of the country being inhabited." Since they had passed *Cape Orford*, they had a constant current, setting in the line of the coast northward, at an uniform rate of near half a league per hour. In this part of the coast the most remarkable mountain which they had seen, presented itself: its summit, covered with perpetual snow, was divided into a very elegant double fork, and rose conspicuously from a base of lofty mountains clothed in the same manner, which descended to hills of a moderate height, and terminated in low cliffs, falling perpendicularly on a sandy beach. This was considered to be the mount *Olympus* of Mr. Mears, in latitude 47° 10'. though the latitude of the observers was 47° 38', and the mountain was north of them. Pursuing their course further northward, they distinguished the fourth point of entrance into De Fuca's straits, and on the opposite side of the straits an opening of considerable extent. They perceived that this coast, like that which had been explored from *Cape Mendocino*, was firm and compact, without any opening into the Mediterranean sea, as stated in latitude 47° 45', or the least appearance of a secure harbour, either in that latitude, or from it southward to *Cape Mendocino*; although, in that space, geographers have thought it expedient to furnish many. They now saw several villages scattered along the shore, whose inhabitants came off, as it was supposed, for the purpose of trading. Having passed between *Tasooche's Island*, and a rock, called *Rock Duncan*, along the southern shore of the supposed straits of De Fuca, they anxiously looked for the point which Captain Cook had denominated *Cape Flattery*; and at last concluded, that *Classet*, a projecting and conspicuous promontory, at the south entrance of the inlet, is the point, with an island lying off it, which Captain Cook called *Cape Flattery*. The village of *Classet* is situated about two miles within the cape, and appeared to be extensive and populous. The few natives, who came off to the ship, resembled in most respects the people of Nootka: their persons, garments and behaviour, were very similar; but instead of the ornamental crescent at the nose, used by the inhabitants of Nootka, they wore straight pieces of bone; their canoes, arms and implements were the same, and they spoke the same language. They anchored about eight miles within the entrance, on the southern shore of the supposed straits of De Fuca. The shores on each side of the straits are of a moderate height; those on the south side are composed of low sandy cliffs, and from the top of these the land appeared to ascend gently, and to be covered with trees, chiefly of the pine tribe, until the forest reached a range of high craggy mountains, the summits of which were covered with snow. The northern shore did not appear quite so high, nor were the mountains, which formed a compact range, so much covered with snow. Steering to the east, along the southern shore, their latitude was 48° 19', and longitude 236° 19'; and the variation of the compass 18° east. The north promontory of *Classet* was situated in latitude 48° 23½', longitude 235° 38'. Proceeding forward, they came to anchor in 14 fathoms water, about three miles from a low sandy point of land, resembling Dungeness in the British Channel, and called *New Dungeness*: whence they discovered a lofty mountain, which they called *Mount Baker*, apparently at a very remote distance. "We had now," says Mr. V. "advanced further up this inlet than any other person from the civilized world; although it should hereafter be proved to be the same which is said to have been entered

tered by De Fuca; in support of which, oral testimony is the only authority produced, a tradition rendered still more doubtful, by its entrance differing at least 40' in latitude. This difference of latitude, however, is not sufficient altogether to discredit the traditionary accounts to which Mr. V. refers; and as a strait, with a considerable extent of sea, has been actually found, and to the north of the strait many islands, or an archipelago of islands, it is much more reasonable to suppose that some error has been introduced into the old accounts, or that the situations may have originally been erroneously described, than that an assertion of the existence of a strait and of an archipelago of islands should have been the mere result of random conjecture.

It must be considered as a very singular circumstance, that in so great an extent of sea coast, as 215 leagues, to which the inquiries of these navigators had been directed, they should not till now have seen the appearance of any opening on its shores, which afforded any certain prospect of affording shelter; the whole coast forming one compact, solid, and nearly strait barrier against the sea. The huts observed to the eastward of Classet, were built exactly like the houses at Nootka; and were composed of a few mats thrown over cross sticks, and plainly indicated the residence of the natives to be merely temporary. The inhabitants viewed their European visitors with the utmost indifference; they traded with them in a civil and friendly manner; but did not appear to understand the Nootka language. Their next remove was to a harbour called *Port Discovery*, where they moored about a quarter of a mile from the shore under a kind of promontory, which afforded them shelter; and which they called *Protection Island*. The entrance of port Discovery is situated in lat. $48^{\circ} 7'$. long. $237^{\circ} 20\frac{1}{2}'$. The country in its neighbourhood is bounded on the west side by mountains covered with snow; the soil is generally a light sandy loam, which being mixed with decayed vegetables, forms a rich fertile mould. Iron ore was generally found here, and appeared tolerably rich. Quartz, agate, the common flint, and a great intermixture of other siliceous matter, with some variety of calcareous, magnesian, and argillaceous earths, were the mineral productions commonly found. The vegetables that grew most luxuriantly were the Canadian and Norwegian hemlock, silver pines, the Turamaliac and Canadian poplar, arbor-vitæ, common yew, black and common dwarf oak, American ash, common hazel, sycamore, sugar, mountain, and Pennsylvania maple, oriental arbutus, American alder, and common willow. These, with the Canadian elder, small fruited crab, and Pennsylvania cherry-trees, constituted the forests. Of esculent vegetables few were found; the white or dead-nettle, and samphire, the wild orache and the vetch were the most common. Two or three sorts of wild peas, and the common hedge mustard were met with occasionally; they were excellent of their kind, and proved extremely agreeable and useful. The only living quadrupeds that were seen were a black bear, two or three wild dogs, as many rabbits, several small brown squirrels, rats, mice, and the skunk of a peculiarly offensive smell. The aquatic birds were few, and so timid that they could not be killed. About the shores and on the rocks were found some species of the tern, the common gull, sea pigeon of Newfoundland, curlews, sand-larks, shags, and the black sea-pye, like those in New Holland and New Zealand; but not in great abundance. In the woods they saw two or three spruce-partridges; few small birds were discovered, and of these the humming birds were the most numerous. At the outskirts of the woods, and about the water side, they saw a great number of the white-headed and brown eagle, ravens, carrion crows, American king-fisher, and a very

handsome wood-pecker, and also a bird unknown to them, which they considered as a species of crane or heron, the eggs of which were of a bluish cast, larger than those of a turkey, and well tasted, with long legs and necks, of the size of the largest turkey, and with a light brown plumage. Some blue, and some nearly white herons of the common size were also seen. The supply of fish was scanty, and consisted in general of the common sorts of small flat-fish, elephant fish, sea bream, sea perch, a large sort of sculpin, weighing six or eight pounds, with a greenish colour about their throat, belly and gills, and affording coarse, but not unwholesome food, a few trout, and a small eel of a yellowish green colour and well tasted. Of the reptile tribe they found a small common black snake, a few lizards and frogs, together with a great variety of common insects.

The country, in an agricultural view, seemed capable of improvement, though the soil was light and sandy. The spontaneous productions are nearly the same, and grow in equal luxuriance with those under the same parallel in Europe. The climate is mild, and every species of plants forward in its growth. Fresh water is very scarce; but sufficient for common domestic purposes. As for the inhabitants, they are thinly scattered along the shores. From New Dungeness to Port Discovery, our voyagers traversed near 150 miles of these shores without seeing as many inhabitants. Those whom they observed, nearly resembled the people of Nootka; but were not so stout in stature, nor so filthy in their habits. Their weapons, implements, canoes, and dresses nearly the same. Their native woollen garment was most fashionable, and next to this the skins of deer, bear, &c.; and some few wore dresses manufactured from bark, which, like their woollen ones, were very neatly wrought. Their spears, arrows, fish-gigs, and other weapons, were shaped like those of Nootka; but none of them were pointed with copper or muscle-shell. The three former were generally barbed, and those of their own manufacture were pointed with common flint, agate, and bone. Their arrows were pointed with thin flat iron; and their bows were of a superior construction, and made of yew, and the bow-string of the sinew of some marine animal. From the form and structure of their habitations, they seemed frequently to change them; and their deserted villages indicated their being migratory in their disposition and habits. Mr. V. supposes, however, that though the country seems to be thinly inhabited, it was once much more populous. In different excursions, they found the skulls, limbs, ribs, and back-bones, or other vestiges of the human body, scattered about in great abundance; and hence it is inferred that there has been occasionally, and not at any very remote period, a great waste of human life. Several skeletons were found deposited in caves, and suspended on the branches of trees about 12 feet from the ground; these were probably the remains of the chiefs, priests, and leaders of particular tribes, to whom they paid particular respect. Baskets, containing the skeletons of young children, were also found in the same situation; and in other places, dead bodies were discovered in holes, which were slightly covered over, and in different states of decay. But the skeletons found in canoes and baskets bore a very small proportion to the skull and other human bones indiscriminately scattered about the shores. Whether these were the result of epidemic disease, or of recent wars, our navigator does not determine. From the character of the people, he thinks the latter cause not to be probable; for he represents them as uniformly civil and friendly, without manifesting the least sign of fear or suspicion at the approach of strangers, or any indication of their having been injured to hostility. The

small-pox seemed to have been very fatal amongst them. The present depopulation, it is apprehended, may have arisen, in some measure, "from the inhabitants of this interior part having been induced to quit their former abode, and to have moved nearer the exterior coast, for the convenience of obtaining in the immediate mart, with more ease and at a cheaper rate, those valuable articles of commerce that within these late years have been brought to the seacoasts of this continent by Europeans and the citizens of America, and which are in great estimation among these people, and possessed by all in a greater or less degree."

From Port Discovery, our navigators pursued their route up the inlet, viewing in their progress a very picturesque and fertile country, and seeming to require only inhabitants and cultivation; having found a convenient roadstead, they anchored near a village in which the inhabitants were employed, in their temporary huts, in curing, by the smoke of the fire, clams, mussels, and a few other kinds of fish, which seemed to be intended for their winter's subsistence. Several of them were busily engaged, like swine, in rooting up a beautiful verdant meadow, in quest of a species of wild onion and other roots, for the sake of which they appeared to be attached to this spot. One of these roots resembled the Saranne, and was gathered with great industry and avidity, for the purpose of making a paste with which they filled small boxes, placed in the baskets containing the skeletons of their children. In their manner, these people were friendly and hospitable, and very thankfully received the presents that were given them. They also bartered for any articles that were offered them; but they chiefly preferred copper. Bows and arrows, woollen and skin garments, and a few indifferent otter skins, composed the whole of their assortment for trading; and these they exchanged, in a very fair and honest manner, for copper, hawk's bells, and buttons, articles that greatly attracted their attention.

The dogs belonging to this tribe of Indians were numerous, and resembled those of Pomerania, but were larger in size. They were all shorn close to the skin, like our sheep; their fleeces were compact, and composed of a mixture of a coarse kind of wool, with very fine long hair, capable of being spun into yarn. It was conjectured, that their woollen clothing might be formed partly of this material, mixed with a finer kind of wool from some other animal, which, though it must have been very common, was not discovered.

Here was discovered a narrow passage, which seemed to communicate with an opening of some extent, and to this harbour was given the name of *Port Orchard*. In their present situation, they were presented by some of their Indian friends with a whole deer, in the chase of which and another they and their dogs had been busily engaged for almost a whole day. It was found that these people had a great aversion for human flesh; for conceiving that some pieces of the deer that were offered them were of this kind, they threw them away with gestures of great displeasure. Hence it was inferred, that the character given of North-west America does not attach to every tribe: but though these people were not in this respect savages, they were not wholly exempt from the general failing attendant on a savage life; for one of them secreted a knife and fork under his garment, and when detected gave them up with the utmost good humour and unconcern.

Our navigators, having advanced into an opening, situate in lat. $47^{\circ} 19\frac{1}{2}'$, and long. $237^{\circ} 42'$, halted on an island about a mile from the eastern shore, which was one of the most extensive islands discovered in the examination of this coast, and which they called *Vashon's Island*. In one inlet

which they examined, they found a tribe of Indians, who manifested hostile dispositions, and prepared their bows and arrows for an attack. Upon the firing of a gun, though they expressed no astonishment or concern, they unstrung their bows, and commenced a friendly traffic. The village point near their present station, situate in lat. $47^{\circ} 30'$, long. $237^{\circ} 46'$, was called *Restoration Point*. Their next anchorage was in an excellent harbour, sheltered from all winds, in lat. $48^{\circ} 21'$, long. $237^{\circ} 57\frac{1}{2}'$. The inlet, which they had spent a fortnight in examining, they denominated *ADMIRALTY Inlet*. On the 5th of June, they quitted this inlet, sailing down *Possession Sound*, and proceeded northward; the north point of this inlet, lat. $48^{\circ} 16'$, long. $237^{\circ} 31'$, they called *Point Partridge*; and the west point, lat. $48^{\circ} 10'$, long. $237^{\circ} 31'$, they denominated *Port Wilton*. On the west side of *Strawberry Bay*, where they anchored, there was an island, which producing abundance of upright cypress, they called *Cypress Island*, lat. $48^{\circ} 36\frac{1}{2}'$, long. $237^{\circ} 34'$. It was also found, that the eastern shore of the gulphs, from the passage into *Port Gardner*, called *Deception Passage*, in lat. $48^{\circ} 27'$, long. $237^{\circ} 27'$, to the north point of the entrance into *Possession Sound*, in lat. $47^{\circ} 53'$, long. $237^{\circ} 47'$, was an island about 10 miles wide in its broadest part; and it was distinguished by the name of *Whidbey's Island*. In pursuing their investigation, they denominated a point, in lat. $48^{\circ} 57'$, long. $237^{\circ} 20'$, *Point Roberts*; another, in lat. $49^{\circ} 19'$, long. $237^{\circ} 6'$, *Point Grey*; a third, about a league distant, *Point Atkinson*; an island which they passed, *Passage Island*; and a canal near it, *Burrard's Canal*; and another island, in lat. $49^{\circ} 30'$, long. $237^{\circ} 3'$, *Anvil Island*, from the shape of the mountain that composes it; a fourth to the southward, *Howe's Sound*; and a point in lat. $49^{\circ} 23'$, long. $236^{\circ} 51'$, *Point Governor*, near which is an extensive group of islands of various sizes. In their return to their ships, they reached the north point of the inlet, which producing the first Scotch firs that had been seen, was called *Scotch-fir Point*, in lat. $49^{\circ} 42'$, long. $236^{\circ} 17'$; and to the arm of the sea they gave the name of *Ferri's Canal*. The south point of the land which they passed in lat. $49^{\circ} 28\frac{1}{2}'$, long. $236^{\circ} 24'$, was called *Point Upwood*; and a shoal, near which they purchased of the natives some excellent sturgeon, weighing from 14 to 200lb. each, they called *Sturgeon Bank*. Near a cluster of islands, in lat. $48^{\circ} 36'$ to $48^{\circ} 48'$, and long. $237^{\circ} 50'$, at its eastern extremity, they found an extensive bay, which was distinguished as *Bellingham's Bay*. In their progress northward, the forests were composed of a much less variety of trees, and their growth was less luxuriant. Those most common were pines of different sorts, the arbor vitae, the oriental arbutus, and some species of cypress. On the islands were seen some few small oaks, with the Virginian juniper; and at the place where their ships were last stationed, the Weymouth pine, Canadian elder, and black birch, which gave it the name of *Birch Bay*, situate in lat. $48^{\circ} 53\frac{1}{2}'$, long. $237^{\circ} 33'$. From this bay they sailed northward, June 24th, directing their course through the canal del Neutra Signora del Rosario, in extent about ten leagues from *Point Upwood* to *Point Marshall*, the north-west point of the island of Feveda, in lat. $49^{\circ} 48'$, long. $235^{\circ} 47\frac{1}{2}'$; near which is another island, called *HARWOOD Island*, and not far off, in lat. $49^{\circ} 57\frac{1}{2}'$, long. $235^{\circ} 54\frac{1}{2}'$, *Savary's Island*. In lat. $50^{\circ} 4\frac{1}{2}'$, long. $235^{\circ} 25\frac{1}{2}'$, was a point which they called *Point Sarab*; and the opposite point, about half a league distant, they called *Point Mary*. In a canal, denominated *Bute's Canal*, they found an Indian village on the face of a steep rock, lat. $50^{\circ} 24'$, long. $235^{\circ} 8'$, containing about 150 of the natives, who plentifully supplied them with fresh herrings and other fish

in barter for nails. Before the entrance into this canal was a round island, three or four miles in circuit, which obtained the name of *Stuart's Island*. Quitting *Desolation Sound*, in lat. $50^{\circ} 11'$. long. $235^{\circ} 21'$. they passed through an assemblage of islands and rocks, and in the midst of whales and seals, to more pleasant shores, from which the friendly Indians came to visit them, with young birds, mostly sea-fowl, fish, and some berries, which they bartered for tunkets; and they anchored about half a mile to the northward of *Point Mulge*, in lat. 50° . long. $235^{\circ} 9'$, where was a large village of the natives, who conducted themselves with great civility and respect, and who were not fewer in number than 300 persons. Near *Johnstone's Straits* was a point, called *Point Chatham*, in lat. $50^{\circ} 19'$. long. $234^{\circ} 45'$. About ten miles from this point they anchored under a narrow island, distinguished by the name of *Thurlov's Island*. To a snug and commodious port, to which they afterwards arrived, they gave the name of *Port Neville*; near which was a large village, the inhabitants of which understood the language of Nootka, and who bartered with the skins of the sea-otter of excellent quality, for sheet-copper and blue cloth. Here they found the fabrication of mats for various purposes, and a kind of basket, wrought so closely as to contain water without the least leakage; and in this manufacture the women were chiefly employed. They next proceeded by *Call's Canal*, in lat. $50^{\circ} 42'$. long. $234^{\circ} 3\frac{1}{2}'$. *Knight's Canal*, in lat. $51^{\circ} 1'$. long. $234^{\circ} 13'$. and *Deep-sea Bluff*, a point of land in lat. $50^{\circ} 52'$. long. 232° , through an extensive cluster of islands, rocky inlets and rocks, called *Broughton's Archipelago*, to a station in lat. $50^{\circ} 35'$. long. $233^{\circ} 19'$. Afterwards they entered a channel called *Fife's Passage*, and found its eastern point, named *Point Duff*, to be in lat. $50^{\circ} 48'$. long. $233^{\circ} 10'$. Passing *Point Philip*, at the distance of eight miles from Deep Sea Bluff, they reached the base of a remarkable mountain, in lat. $51^{\circ} 1'$. long. $233^{\circ} 20'$, called *Mount Stephens*, which is thus marked in the author's chart, and may seem as an excellent guide to the entrance of the various channels with which this country abounds. The next place of their meeting was named *Point Beyles*, in lat. $50^{\circ} 51'$. long. $232^{\circ} 52'$. near the west point of a channel called *Wells's Passage*. Having pursued their course through a channel not more than half a mile wide, bounded on one side by islands, rocks, and breakers, which appeared almost to meet the continental shore on the other, they anchored in lat. $51^{\circ} 2'$. long. $232^{\circ} 25'$. They afterwards proceeded through a channel about two miles wide, between rocks and rocky isles, which seemed to be connected with the southern broken shore, and reached that part of the coast that had been visited and named by several of the traders from Europe and India. The inlet through which they had lately passed was *Queen Charlotte's Sound*, so called by Mr. S. Wedgborough, in August 1786; an opening on the continental shore had in the same year been named *Smith's Inlet*, by Mr. J. Hanna; a high distant mountain that appeared to be separated from the main land, formed part of a cluster denominated by Mr. Duncan, *Calvert's Islands*; and the channel between them and the main land had been called by Mr. Hanna, *Fitzhugh's Sound*. Their estimated latitude in this situation was $51^{\circ} 4'$. and long. $232^{\circ} 8'$. They next stood across *Charlotte's Sound* for the entrance of *Smith's inlet*; afterwards steering along the eastern side of *Calvert's island*, they sought for *Port Safety*, laid down in Mr. Duncan's chart, or some other convenient anchorage. A cove within the south entrance of *Fitzhugh's Sound*, afforded them a secure and comfortable retreat from the dangers to which they had been exposed, and they called it *Safety Cove*. Determining to

abandon the northern survey of the continental shore for this season, they made the best of their way towards *Nootka Sound*, at which port they anchored on the 28th of August 1792. In this survey, they had traced the western continental shore of America, with all its various turnings, windings, numerous arms, inlets, creeks, bays, &c. from the lat. of $39^{\circ} 5'$. long. $236^{\circ} 36'$. to point *Menzies*, in lat. $52^{\circ} 18'$. long. $232^{\circ} 55'$; and they found that none of the channels which they explored extended more than 100 miles to the eastward of the entrance into the strait of *Juan de Fuca*: they also found that the land forming the north side of that strait is part of an island, or rather of an Archipelago, extending nearly 100 leagues in length from south-east to north-west; and on the side of this land most distant from the continent is *Nootka Sound*. In October 1792, our navigators left *Nootka Sound*, and proceeded to re-examine the coast of *New Albion* to the southward, and particularly a river and a harbour discovered by Mr. Gray, commander of the *Columbia*, between the 46th and 47th degrees of north latitude. They directed their course towards *Cape Clasket*, to which they restored *Captain Cook's* original appellation of *Cape Flattery*. One of the most conspicuous promontories southward from this cape was *Point de los Reyes*, as it is called by the Spaniards, in lat. $38^{\circ} 0'$. long. $237^{\circ} 24'$. Southward of this point, the shore forms the north point of a bay, in which, according to the Spaniards, *Sir Francis Drake* anchored, in the vicinity of which is a port called by the Spaniards *Bodega*. They next proceeded to port *St. Francisco*, a Spanish settlement, in lat. $37^{\circ} 48' 30''$. and long. $237^{\circ} 52' 30''$. The mean variation of the compass was $12^{\circ} 48'$. east. Leaving this port, they sailed to *Monterrey*, another Spanish settlement. From hence they steered towards the *Sandwich islands*.

In April 1793 our navigators again visited the coast of *New Albion*; they first saw the coast at *Cape Mendocino*, and anchored, on the 2d of May, in *Porto de la Trinidad*, so called by the Spaniards, who discovered it in 1775; but they found it a less convenient harbour than they had been led to expect from the description given of it in the journal of *Don Francisco Maurelli*, translated by the Honourable *Daines Barrington*. The inhabitants of an Indian village in this neighbourhood, who visited the ships in their canoes, singing like the other Indians as they drew near, and trafficked in bows and arrows, inferior sea-otter skins, small herrings, and flat fish. They were stoutly made, but of a lower stature than any other Indians on this coast. Their persons were mutilated or disfigured, either for ornament or from a regard to some religious institution, or for some other unknown purpose. All the teeth of both sexes were, by some process, ground uniformly down, horizontally, to the gums; the women especially, carrying the fashion to an extreme, had their teeth reduced even below this level; and ornamented their lower lip with three perpendicular columns of punctuation, one from each corner of the mouth, and one in the middle, occupying three-fifths of the lip, and chin. The latitude of the ship's station was $41^{\circ} 3'$. and that of *Rocky Point*, five miles to the north, $41^{\circ} 8'$. and the longitude of *Trinidad bay* $236^{\circ} 6'$. From *Trinidad*, pursuing their course to latitude $47^{\circ} 53'$. longitude $233^{\circ} 17'$. they saw the coast of the island of *Quadra* and *Vancouver*, and were within a league of *Punta de Ferron*; and passing along the shore of the *isle de Ferron*, they proceeded to *Nootka*, and anchored in *Friendly Cove*. From hence they sailed to *Fitzhugh's Sound*, and recommenced their examination at the part where it had been discontinued in the preceding year. The survey now made, in most of its circumstances, resembled the former. They found the same kind

kind of broken coast, with inlets and channels almost innumerable, and the same extraordinary depth of water close to the shore, and in places inclosed within the land. In the space of four months, devoted to this northern survey, they advanced little more than four degrees northward, leaving off between the 56th and 57th degrees of north latitude. In a place near *Fisher's Canal*, in lat. $52^{\circ} 20\frac{1}{2}'$. long. $231^{\circ} 54'$. the natives offered for sale the skins of the animals whose wool is manufactured into the garments worn by the inhabitants of north-west America. They were too large to belong to any of the canine race, as our navigators had formerly supposed. Exclusively of the head or tail, they were 50 inches long, and 36 inches broad, exclusively of the legs. The skin afforded but little wool in proportion to its size; and it is chiefly produced on the back and towards the shoulders, where a kind of crest is formed by long bristly hairs, protruding themselves through the wool, and the same sort of hair forms an outer covering to the whole animal, and entirely hides the wool, which is short and of a very fine quality. The skins were cream-coloured, the pelt was thick, and appeared to be of a strong texture; but they were too much mutilated for ascertaining the animal to which they belonged. The females of this part adopted a singular ornament. An horizontal incision was made about three-fourths of an inch below the upper part of the under lip, extending from one corner of the mouth to the other, entirely through the flesh: this orifice was then stretched sufficiently for admitting an ornament of wood, of an oval form, and hollow on both sides; which was confined closely to the gums of the lower jaws, and whose external surface projected horizontally. The clothing of the natives was formed either of ~~other~~ skins or of the pine bark, and ornamented with woollen yarn, very fine, well spun, and dyed with a very lively and beautiful yellow. As to their dispositions and manners, they seemed to be civil, good-humoured and friendly; and they manifested a considerable degree of vivacity and humour. They approached and left the ships with songs; they appeared to be happy and cheerful, and to live in the strictest harmony and good fellowship with one another. They were well versed in commerce. In examining some of the openings, which presented themselves in the continental shore, and which Mr. V. traversed in boats for 23 days, through a distance of 700 geographical miles, he was attacked by a party of Indians, under the direction of an old woman, who seemed to be their leader. In this survey they discovered a river, in 55° N. lat. on a bay, in the eastern side of the entrance of an arm of the sea, named by Captain V., *Observatory Inlet*. This small river, and another in Port Effington, were the only two streams that had yet been discovered to the north of the river *Columbia*. In September our navigators returned from between 56° and 57° , the highest latitude to which they advanced in this voyage, towards the south, keeping at a distance from the continent, and to the westward of *Queen Charlotte's islands*. Having finished their survey of the coast of north-west America, from the 30th to the 56th degree of north latitude, they concluded that no navigable communication exists between the north Pacific, and north Atlantic oceans; nor between the waters of the Pacific, nor any of the lakes or rivers in the interior part of the continent of North America.

In a third voyage, in 1794, Capt. Vancouver and his associates surveyed the higher latitudes of the north-western coast of America. Their first object was *COOK'S Inlet*; hence they proceeded to examine *PRINCE WILLIAM'S Sound*; passing some points and capes of less note, they steered southward from *Cape Fairweather*, in N. lat. 58°

$51'$, to *Cape Spencer*, in N. lat. $58^{\circ} 13'$; but they do not mention *Port des Français* of M. de la Pérouse, which he places in $58^{\circ} 37'$. N. latitude. In examining the upper part of an arm of the sea within *Cross Sound*, they found that it approached nearer to those interior waters of the continent, which are said to be known to the traders and travellers from the opposite side of America, than any of the waters of the north Pacific in any other instance. It was called *LYNN Canal*. On the 19th of August, the voyagers had completed their survey from *Cook's inlet* to the part of the coast at which they broke off in the preceding year. To the harbour in which the ships lay, they gave the name of *Port Conclusion*, in latitude $56^{\circ} 14' 55''$. longitude $225^{\circ} 37' 30''$.

Although we have given a brief abstract of the principal observations that occurred in the three voyages of Vancouver, on the American coast; yet it is necessary to observe, that the appellation of *New Albion*, though, generally speaking, applied to the north-west coast of America, is in reality of a much more limited extent. In Vancouver's chart, its southern limit is the 30th degree of north latitude, and its northern termination is about 45° . The more northerly parts of this coast are *New Georgia*, *New Hanover*, *New Cornwall*, and *New Norfolk*.

The mission of St. Domingo is the southernmost of the Spanish settlements, in *New Albion*; or of those new establishments that were formed after the year 1769, when sea and land expeditions were undertaken to settle *Monterrey* and *St. Diego*. At this period, their north-westernmost possession on this coast was *Velicata*, and *Santa Maria* on the coast of the peninsula, in the gulf of California. These two missions had, till that time, formed a kind of north-western barrier, or frontier to the Spanish Mexican colonies. But Russia, by its rapid strides, roused the apprehensions and jealousy of the Spanish court, and gave occasion to these expeditions. Since that time, all the new establishments have been formed; and the mission of *Velicata* is removed some leagues to the north-westward, nearer the exterior coast of California. The new settlements are committed to four jurisdictions, the principal of which is *Monterrey*; as it is also the residence of the governor, who is captain-general of the province, and of the father president of the Franciscan order of missionaries. In each of the divisions is fixed one military post, called the *Presidio*, governed by a lieutenant, who has under him an ensign, with serjeants, corporals, &c. The most northern *Presidio* is that of *St. Francisco*, which has under its protection the missions of *St. Francisco* and *Santa Clara*, the pueblo of *St. Joseph*, about three or four miles from *Santa Clara*, and an establishment in the southern opening of port *Bodega*, to which they have given the name of *Port Juan Francisco*. The next in succession southward, is that of *Monterrey*, the capital of the province, under which are the mission of *Santa Cruz*, near *Point Anno Nuevo*, established in the year 1789 or 1790, and some others of less note. South and east from *Monterrey* are the missions of *St. Carlos*, *St. Antonio*, *St. Luis*, and *Santa Rosa la Purissima*, near the entrance of the canal of *Santa Barbara*. The next and smallest division is that of *Santa Barbara*, established in 1786, to which belong that of *Buena Ventura*, founded in 1784, and the pueblo of *los Angeles*, formed in 1781; which latter is said to be subject to the controul of the *presidio* at *St. Diego*, which is the fourth or southernmost of these new settlements. The climate of the country between the bay and port of *St. Francisco*, or from the 38th to the 30th degree of north latitude, is subject to much drought.

drought. The rainy season is from the month of December to March; the autumn in general being very dry. However the absence of rain is compensated by dews, which serve to supply, in some measure, the want of moisture from running streams, which are few. The climate at the settlements is, upon the whole, healthy; the soil is of a light and sandy nature, generally fertile, and capable of improvement; but in some places it is so barren and unproductive, that good mould has been brought from a distance, to places where they wished to establish missions. The Spaniards have not turned to any solid advantage even the most fertile part. They have excellent sheep and poultry in the vicinity of Santa Barbara, which is the most barren part; and the sea affords an ample supply of good fish. The neighbourhood of Buena Ventura furnishes fruit in great abundance, and of excellent quality. The fruit consists chiefly of apples, pears, plums, figs, oranges, grapes, peaches and pomegranates, together with the plantain, banana, cocoa-nut, sugar-cane, indigo, and a great variety of the most useful kitchen herbs, plants, and roots. The pueblos differ from the missions and presidios, and may be better expressed by the term villages. They are composed of about 30 or 40 old Spanish soldiers, or creoles, who, having served in the missions or presidios, are exempted from any farther military duty; and they plant colonies in some of the most fertile spots of the country. The number of the natives, at this period, who have embraced the Roman Catholic religion, under the Franciscan and Dominican missionaries in New Albion, and through the peninsula of California, amounts to about 20,000, and they are estimated at about an eighth or tenth of the whole native population; and their progress towards civilization is very slow. The number of the military does not exceed 400 men. Mr. Vancouver says, that the natives neither are, nor can be tributary; because they possess no tribute to offer. But this declaration seems to undervalue a country, which has, in many parts of it, a peculiarly fertile soil, and the coast of which abounds with sea-otters. The labour of the natives is subject to the direction and controul of the Spanish missionaries, who are absolutely under the authority of the Spanish government; and we learn from the unfortunate navigator M. de la Pérouse, that it was the plan of the viceroy of Mexico, to reserve for government the exclusive trade of sea-otter skins; and that the Spanish settlements furnish 10,000 annually, and are capable, if duly collected, of supplying 50,000 annually. Vancouver's Voyage of Discovery to the north Pacific Ocean, &c.—three vols. 4to. 1798.

ALBIREO, in *Astronomy*, a star of the third or fourth magnitude, in the constellation of Cygnus.

ALBIS, in *Ancient Geography*, now the *Elbe*, ran through the middle of Germany, and marked the limit of the knowledge of the Romans, with regard to this country. The only Roman, who passed this river with his army was L. Donitius Ahenobarbus, A. U. C. 744; and though he made no further progress, the passage of the Albis was deemed worthy of a triumph. See Tacitus, *Annal.* iv. c. 44. Drusus and Tiberius were the only Romans who had advanced to this river. In the latter period of the Roman state, the Albis became the boundary of Germany to the north; the Sarmatæ having possessed themselves of that part which lay beyond it, called Transalbin Germany. See ELBE.

ALBIS, in *Geography*, a town of Switzerland, in the canton of Zurich, three miles south-west of Zurich. It is also the name of a mountain in the same canton.

ALBISOLA, a town of Italy, in the state of Genoa; having in its vicinity the country houses of the Genoese nobility, and also a manufacture of porcelain. This town was bombarded by the English in 1745. N. lat. 44° 15' E. long. 8° 20'.

ALBISTRUM, or ABISTRUM, in *Ancient Geography*, a town placed by Ptolemy, in Magna Græcia.

ALBIUM INGAUNUM and INTEMELIUM. See ALBINGAUNUM and ALBITEMELIUM.

ALBIUS MONS, was the name given to one of the mountains of the Alps, on the side of Rætia and Carnia.

ALBIZI, or BARTHELEMI of Pisa, in *Biography*, a Franciscan of the 14th century, who, in a book intitled, "The Conformities of St. Francis with Jesus Christ," attempts to exalt his favourite saint not only above all the other saints, but to an equality with Jesus Christ. It has been often printed, and much sought after as a curiosity. It was printed at Cologne, in 1632, with alterations, under the title of "Antiquitates Franciscanæ." Another calligraphed edition was printed by Maræus, at Liege, in 1658.

ALBO, in *Geography*, a river on the eastern boundary of the Gold Coast of Africa.

ALBOCELLA, in *Ancient Geography*, a town of Spain, which, according to Ptolemy, belonged to the Vaccæi.

ALBOCENSIS, a town of Dacia, the inhabitants of which were denominated Alboensii.

ALBOGALERUS, in *Roman Antiquity*, a sacerdotal cap, or ornament worn by the flamen dialis; otherwise called galerus.

ALBOIN, in *Biography and History*, king of the Lombards, was the son of Audois, under whose conduct they obtained leave of the emperor Justinian to settle in Pannonia, and succeeded his father in the kingdom. Whilst he was fighting under his father's standard, he encountered and slew the son of Turisfund, king of the Gepidæ; and in consequence of this act of youthful heroism, the Lombards unanimously solicited that his father would admit him to take his seat at the royal feast which was kept in celebration of the victory. But according to the custom of the country, no prince was permitted to sit at table with his father, till he had been invested with arms by a foreign sovereign. For this purpose Alboin, with 40 select companions, visited the court of Turisfund, who, according to the usual laws of hospitality, entertained even the murderer of his son. At the banquet, when Alboin occupied the seat of the youth whom he had slain, Turisfund, the father, could not dissemble his agitation; Cunimund, his surviving son, and the Gepidæ who were present perceived it; and determined to be revenged. They prepared for the assault by contemptuous and reproachful language: "the Lombards," said they, "resemble, in figure and in smell, the mares of our Sarmatian plains;" referring by this coarse allusion, to the white bands which envelopes their legs. As soon as these insulting words were pronounced, the Gepidæ started from their seats, and Alboin, with his 40 companions, laid their hands on their swords. Turisfund, however, appeased the tumult, saved the life of Alboin, and dismissed him with the bloody arms of his murdered son. On his succession to the crown, Alboin, though previously contracted to the grand-daughter of Cloris, asked in marriage the beautiful Rosamond, the daughter of Curimund, who, upon his father's death, ascended the throne of the Gepidæ. His request was refused, and he prepared to obtain by force of arms the object of his wishes. With this view he engaged the support of the Avars on very lucrative conditions, and with their assistance he utterly destroyed the kingdom of the Gepidæ.

Gepids, A. D. 566. The skull of Cunimund, who fell in battle, was fashioned into a drinking cup, either to satiate the hatred of the conqueror, or to comply with the savage custom of the country; a custom which was common, as we are informed by Strabo, Pliny, and Ammianus Marcellinus, among the Scythian tribes. In consequence of this event, the nation of the Gepids was dissolved, the Avars took possession of their country, comprehending Walachia, Moldavia, and Transylvania, and the parts of Hungary beyond the Danube; and Alboin, besides his moiety of the spoil, persuaded or compelled the fair Rosamond to acknowledge the rights of her victorious lover. The fame of Alboin being thus established, he extended his views to the conquest of Italy, and he contrived by various artifices to gain an accession of strength from the adventurous youth of Germany and Scythia. The Lombards retained only that portion of their wealth, which was portable, and which would serve the occasions of their expedition; but they relinquished their lands to the Avars, who promised to restore them if they failed in the conquest of Italy. Narfes, who had been offended by the Byzantine court, which had recalled him from Italy, contributed to excite and encourage the Lombards in their present undertaking; but he did not live to witness its termination. In 568 Alboin crossed the Alps, and without a battle or a siege, the inland regions of Italy, from the hills of Trent to the gates of Ravenna and Rome, became the lasting patrimony of the Romans. Before Pavia, however, the royal camp was stationed for three years; famine at length compelled the besieged to surrender; and the conqueror, more influenced by superstition than by humanity and honour, was prevented from fulfilling his vow of massacring the inhabitants without distinction of age, sex or dignity, by a regard to the omen of his horse's fall as he entered the gates. This circumstance induced Alboin to pause and relent; and to proclaim to the trembling multitude, that they should live and obey. In this city he fixed his seat of empire, and Pavia, during some ages, was respected as the capital of the kingdom of Italy. "The reign of the founder," says an elegant historian, "was splendid and transient; and before he could regulate his new conquests, Alboin fell a sacrifice to domestic treason and female revenge. "In a feast prepared at Verona for his companions in arms, the cup formed of the skull of Cunimund was introduced, and it was sent by the brutal savage to Rosamond. She touched it with her lips, and at the same time formed the solemn purpose, that the insult should be washed away in the blood of Alboin. With a view to the accomplishment of her purpose she engaged Helmichris, the king's armour-bearer, with whom she had a criminal correspondence, to be the minister of her vengeance. But Helmichris trembled in the prospect of perpetrating such a deed; and Rosamond was under the necessity of procuring the assistance of a less timid and more daring accomplice. Penedeus, one of the bravest champions of the Lombards, was selected; but he had scruples, which it required some art to remove. The licentious and revengeful queen secured Penedeus by a stratagem. Supplying the place of one of her female attendants to whom he was attached, and contriving some excuse for darkness and silence till her intention was accomplished, she then told her deluded companion, that, as he had indulged in criminal intercourse with the queen of the Lombards, his own death, or the death of Alboin, must be the consequence of such treasonable adultery. In this alternative he chose rather to be the accomplice than the victim of Rosamond, who, availing herself of Alboin's afternoon slumbers, when he retired from the table for

repose, introduced the conspirators, and urged them to the execution of the deed. Upon the first alarm Alboin started from his couch and attempted to draw his sword, but Rosamond had taken care previously to fasten it to the scabbard. He for some time defended himself with a stool, the only instrument of hostility or of defence to which he had access; he was soon, however, overpowered and dispatched by the spears of the assassins. "The daughter of Cunimund smiled in his fall; his body was buried under the stair-case of the palace; and the grateful posterity of the Lombards revered the tomb and the memory of their victorious leader." The ambitious Rosamond, having procured the death of the king, A. D. 573, aspired to succeed him; but neither she nor her daughter occupied the throne, which was filled by Clepho, one of the noblest chiefs, in consequence of the free suffrage of the nation. Having poisoned Helmichris by a cup of liquor which she presented to him, he was compelled to drink of the same cup by her discarded lover, as soon as he perceived its fatal operation on himself; and the death of the one was in a few minutes succeeded by that of the other. In the character and exploits of Alboin we see savage valour combined with military talents, and a considerable degree of proficiency in the art of government. He is said to have been the inventor of several instruments of war, that were in use long after his time. *Un. Hist.* vol. xvii. p. 337—342. *Gibbon's Hist.* vol. viii. p. 117—132.

ALBOLODUY, in *Geography*, a small town of Murcia, in Spain, situate at the confluence of two rivers, which flow from the mountains called *Los Alpujarras*, between Almeria and Guadix. N. lat. 35° 54'. W. long. 2° 16'.

ALBON, JAMES D', in *Biography*, Marquis of Fronsac, was one of the greatest generals of the 16th century; and rose to high military eminence, in the reigns of Henry II. and Charles IX. of France. By the former he was made Marshal of France in 1547, and he was chosen to carry the collar of his order to Henry VIII. of England, who decorated him with that of the garter. He acquired great reputation in the wars of 1552 and 1554, and in 1557 he was made prisoner at the battle of St. Quintin. After the death of Henry II. he was one of the triumvirate who governed the kingdom four or five years in spite of Catharine of Medicis. He was killed in 1562, at the battle of Dreux, by a person whose confiscated estate he possessed. The Huguenots, who did not love him, used to call him "the Harquebuseer of the west." He had the qualities of a soldier and a courtier; was addicted to every kind of pleasure and luxury, excelled in politeness and the amiable accomplishments, and on the day of battle was distinguished by his prudence and his courage. His daughter and heiress is said to have been poisoned by her own mother for her property. *Gen. Biog.*

ALBONA, in *Geography*, a town of Istria, belonging to Venice, situate at the foot of a mountain, near the gulph of Carnero; 16 miles east of Rovigno.

ALBONA is also a river of Italy, which runs into the Po, nine miles east-south-east of Lumello.

ALBONNAL, a town of Spain, in the province of Grenada, six leagues east-north-east of Motril.

ALBOR, or **ALVOR**, a mountain of Portugal, in the province of Algarva, one league west of Lagos. In a castle on this mountain, John II. king of Portugal, died in 1495.

ALBORAK, in the Mahometan *Theology*, the beast on which the prophet is said to have rode in his extraordinary aerial journeys. It is represented as of an intermediate shape and size between an ass and a mule; and many
fabulous

fabulous accounts are given of it by the Arabian commentators.

ALBORAN, an island in the Mediterranean, near the coast of Fez. N. lat. 36° . W. long. $2^{\circ} 32'$.

ALBORNOS, GILES ALVAREZ CARILLO, in *Biography*, cardinal and archbishop of Toledo, and one of the most celebrated statesmen of the 14th century. He was born of noble parentage at Cuenca, in New Castile; having studied canon law at Toulouse, he took orders and became almoner to Alfonso XI., king of Castile, and gradually rose to the primacy of Spain. As soon as he was created cardinal by pope Clement VI., who resided at Avignon, he resigned his archbishopric. Having been sent to Italy as legate by pope Innocent VI., he brought all the revolted states to submission to the holy see. Upon his return to the succeeding pope, Urban V., and upon being questioned with regard to the disposal of the large sums of money with which he had been entrusted, he caused a carriage, laden with locks and keys, to be brought under the windows. "There," said he to the pope, "is my account of the money. I have made you master of all the towns, the keys and locks of which you see in that carriage." The pope embraced him, and warmly expressed his obligations. Albornos retired to Viterbo, and spent his remaining days in acts of piety. He died in 1367, and was buried at Toledo. He founded a magnificent college at Bologna. Gen. Biog.

ALBORO, in *Ichthyology*, a name by which the ERYTHRINUS, a small red fish, caught in the Mediterranean, is commonly known in the markets of Rome and Venice.

ALBOURG, in *Geography*. See AALBURG.

ALBOURS, a volcanic mountain, near mount Taurus, eight leagues from Herat.

ALBOUZEME, in *Geography*, a town of Africa, on the coast of Barbary. Before it is a bay formed by Cape Mourou, or Befancour on the west, and Cape Quilate on the east. It is otherwise called Buzemar, or the bay of Burema.

ALBRECHT, JOHN WILLIAM, in *Biography*, born at Erfurt, in Upper Saxony, the 11th of August, 1703, was several years professor of anatomy, surgery, and botany, at Gottingen. The late Baron Haller, who succeeded him in those offices, in January 1736, speaks very favourably of his talents, and gives the following list of his works: "Observationes anatomicæ circa duo cadavera masculina," Erford, 1730, 4to. "De effectibus mucicæ in corpus animatum," ibid. 1735, 8vo. "Parænesis ad artis medicæ cultores," Gottig. 1735, 4to. "De vitandis erroribus in medicina mechanica." Vide Bib. Anatom. vol. ii. p. 238. Haller.

ALBRECHTSPERG, in *Geography*, a town of Germany, in the archduchy of Austria, nine miles west from S. Polten.

ALBREDA, a town of Africa, in the country of Senegal.

ALBRET, or LABRIT, a small town of France, in the late province of Gasconne, and duchy of Albret. It is situate in the department of Landes, in a sandy territory, 15 leagues south from Bourdeaux. N. lat. $44^{\circ} 10'$. W. long. $16'$.

ALBRICIUS, in *Biography*, an English philosopher and physician of the 11th century, studied in the Universities of Oxford and Cambridge, and travelled for further improvement. He excelled in polite literature, and was eminently distinguished by his natural genius and acquired knowledge. Bale mentions the following works, viz. "De origine Deorum;" "De ratione Veneni;" "Virtutes Antiquorum;" and "Canones Speculativi." He wrote other books

of philosophy and physic, which are dispersed in several libraries of England. Gen. Diet.

ALBUCA, formed from *allur*, white, in *Botany*, a genus of the *hexandria monogynia* class and order, of the natural order of *lilia* or *liaca*, the *coronarie* of Linnæus, and the *asphodeli* of Jussieu; the characters of which are, that it has no calyx; the corolla has six oblong-oval permanent petals, the three outer spreading, and the three inner converging; the stamina have filaments shorter than the corolla; three opposite to the inner petals, linear-subulate, complicate a little above the base, then flat, three opposite to the outer petals, thicker; anthers on the former oblong, fixed to the inflex tip of the filament below the middle, uprightly on the latter, similar but effete, or none; the pistillum has an oblong, triangular germ, style three-sided, stigma a triangular pyramid; the pericarpium an oblong, obtuse, triangular, three-celled, three-valved capsule; the seeds numerous, flat, lying over each other, and widening outwards. There are eight species, of which the first five have only three stamens fertile, and the others have all the stamens fertile. 1. *A. alissima* or tall, with interior petals glandulose and bent in at the tip, leaves subulate, channelled, convolute: flowers in April and May, and was introduced about 1780, by Messrs. Kennedy and Lee. 2. *A. major*, with interior petals, glandulose and bent in at the tip, leaves linear-lanceolate, flattish, flowers in May, and was introduced about 1767, by Mr. W. Malcolm. 3. *A. minor*, with interior petals, glandulose and bent in at the tip, leaves linear-subulate, channelled, flowers in May and June, and was cultivated by Mr. Miller in 1768. 4. *A. cœarata*, or channel-leaved, with interior petals vaulted at the tip; leaves smooth, linear-subulate, channelled, peduncles the length of the bractes; flowers in May, and was introduced in 1774. 5. *A. spiralis*, or spiral-leaved, with interior petals vaulted at the tip, and leaves spiral. 6. *A. fastigiata*, or upright-flowered, with interior petals vaulted at the tip, leaves smooth, peduncles very long, flowers in May, and was introduced in 1774. 7. *A. viscosa*, with interior petals vaulted at the tip, leaves hairy-glandulose, flowers in May and June, and was introduced about 1779, by Dr. J. Fothergill. 8. *A. abyssinica*, *A. alba* of Lamarek, with leaves linear, channelled, and smooth. To the above species Willdenow has added *A. flaccida*, with interior petals glandulose, and bent in at the tip; peduncles spreading at right angles, leaves lanceolate-linear, and obliquely bent. *A. viridiflora*, with interior petals like the former, scape erect flexuous, flowers hanging downwards, leaves linear-subulate canaliculate, and externally hairy. *A. caudata*, with petals like the last, leaves linear-lanceolate, convolute at the margin, shorter than double the scape, peduncles very long and spreading at right angles, and straight flowers. *A. fetida*, with petals as before, leaves linear-lanceolate and smooth, peduncles rectangularly patent and erect flowers. *A. aurea*, with petals and leaves like the last, peduncles very long, erect and spreading, and erect flowers. *A. fragrans*, with interior petals vaulted at the apex, leaves linear-lanceolate, channelled, panicles spreading of the length of the nodding flower, and very short bractes. All the species are brought from the Cape of Good Hope. They may be cultivated by keeping the roots in pots, filled with light earth, and sheltered under a hot-bed frame in winter, in which case they will thrive and produce flowers; but the best method is to have a border in the front of a green-house or stove, where the roots of most of the bulbous flowers may be planted in the full ground, and screened in winter from frost; in such situations they thrive much

better, and flower stronger, than when kept in pots. Martyn's Miller.

ALBUCASIS, in *Biography*, an Arabian physician and surgeon, of singular merit. At what time he lived is not precisely known; but as he describes the art of surgery, as greatly degenerated in his time, and gives proofs of the ignorance of many of his contemporaries, it is thought he could not be earlier than the middle of the 12th century; that is, about an hundred years after Avicenna, when surgery was successfully cultivated. It appears by a MS. in the Escorial library, (Bib. Ar. Hisp. tom. ii. p. 136.) that he died in 1106. Much of what he has left on the subject of his art, is copied from Rhazes, from Paulus Aegineta, and other preceding writers; but there are also many original observations; and although in the present improved state of surgery, little can be learned from him, yet by those who love to see the first dawns of improvement in science, his works will be still turned over with pleasure. He insisted on the necessity of a surgeon's being skilled in anatomy, to enable him to operate with success; he also held it to be equally necessary that he should be acquainted with the *Materna Medica*, or the properties of the medicines employed in curing diseases; and inveighs against those who undertake for gain the cure of diseases, of the nature and causes of which they are unacquainted. It appears from his writings, that he extracted polypi from the nostrils, performed the operation of bronchotomy, and used a preparation similar to the lapis infernalis, as a caustic. He made great use of the actual cautery, and is extravagant in his elogia on its properties. He is the first writer who left distinct descriptions and delineations of the instruments used in surgery, and of the manner of employing them. His works, which have been translated into Latin, at satis barbarè, Haller says, have passed through several editions; the most esteemed is that published 1541, under the following title:—"Medendi Methodus certa, clara, et brevis, pleaque quæ ad Medicinæ partes omnes, præcipuè quæ ad Chirurgian requiruntur, libris tribus exponens." Basilee, 1541, folio, "Cum Chirurgia Guidonis de Chauliaco."

Haller has given a detailed, and pretty extended account of the subjects treated of in the volume. Vid. *Bibliotheca Chirurgica*, vol. i. p. 137.

Mr. Channing has published an edition of Albucasis, in Arabic and Latin, from the Clarendon press: "Albucasis de Chirurgia, Arab. and Lat. curâ J. Channing." Oxon. 1778.

ALBUGINEA Tunica Oculi, in *Anatomy*, has been said to be the expansion of the tendons of the four straight muscles of the eye, on the front of the scleroticæ. Modern anatomists, however, do not speak of a tunica albuginea; the whiteness of part of the eye-ball being owing to the colour of the tunica conjunctiva, where it covers the front of the scleroticæ. See **CONJUNCTIVA**.

ALBUGINEA Tunica Testis, one of the coats of the testis, which is white and strong, and closely invests its glandular structure.

ALBUGINEUS is applied by some, to denote the aqueous humour of the eye.

ALBUGO, or **ALBUM oculi**, the same with *albuginea*, or the *white of the eye*.

ALBUGO, in *Surgery*, otherwise called **LEUCOMA**, is a whitish opaque speck, on the transparent part of the eye. It is denominated by popular writers, a *scar*, *film*, *baro*, *pearl*, *dragon*, &c. The transmission of the rays of light through the cornea being obstructed by this density of its coats, is followed by a partial or total blindness, according to the extent of the disease. There are different stages and causes of the *albugo*, accompanied with more or less inflam-

mation. The cure will be difficult in proportion to the degree of opacity, and the concomitant circumstances. Sometimes it entirely baffles the skill of the surgeon; and at other times, it disappears without any attention.

When the disease is accompanied with much active inflammation, leeches should be applied on the temples or under the eye. If a superficial turbid blood-vessel be observed going into the affected part, and keeping up the disorder, it may be safely divided by the point of a lancet. But when there is no inflammation, and especially, if there be a fluid interposed between the anterior membranes of the cornea, lightly stimulating applications should be employed; such as a stream of electric effluvia, drawn from a wooden point; or the vapour of warm camphorated spirits, or oil of turpentine; or a composition of pulverised sugar, aloes, and finely levigated glass, blown through a quill. Great caution, however, should be observed in the use of these remedies; for, by injudicious management, the case may be much aggravated, and even rendered incurable.

Some persons advise us to excite the absorbents of the eye by collyria of alum, nitrated silver, vitriolated zinc, vitriolated copper, or a very weak solution of muriated mercury; accompanied with repeated small doses of calomel and cinchona; but it too frequently happens that more harm than good is done by strong irritating applications to so tender an organ. The cutting of an issue in the arms, or a seton in the neck of the patient, has been also recommended in *albugo*; although we think their efficacy is very problematical.

It has been supposed that **TOBIT'S** blindness, mentioned in the second chapter of that apocryphal book, was the disease of which we have here treated. Vide *Tobia Leucomata* Dissert. med. dilucid. Prof. Mauchardt, &c. Tubing. 1748; in Haller, *Disp. Chirurg.* vol. i. p. 366, 4to.

ALBUHAZAN-IBUN-HAIDOR, philosopher, physician, and astrologer, at Fez, in Barbary, physician to several of their kings, died of the plague in 1415, and left a treatise on the cure of that disease. *Eloy. Dict. Hist.* vol. i. p. 73.

ALBULA, in *Ancient Geography*, a town of Mauritania, in Africa.

ALBULA, in the Linnæan system of *Ichthyology*, a species of **SALMO**. It is also the name of a species of **MUGIL**, with the anterior dorsal-fin quadriradiated, the *albula Bahamensis* of Catesby, and the lesser silvery mugil of Brown (*Jam.*), with the anterior dorsal-fin composed of four rays. It is found in America.

ALBULA Indica, the name of a small fish, resembling a herring, caught about the shores of the East-Indies, and called by the Dutch, the *WIT-fish*. Ray.

ALBULA nobilis, of Willughby and Ray, the *Lavartus SALMO* of the Linnæan system, and the **GWINIAD** of the British Zoology.

ALBULA, is also the name given by some writers to the *Leuciscus CYPRIUS* of the Linnæan system, and the **DACE** of English writers.

ALBULA is also the name of a species of **NERITA**, called *mammilla*, in the Linnæan system of Zoology.

ALBULA, is also a name given by some naturalists, to mineral waters of the luminous kind, endued with an astringent quality, and of use in wounds.

ALBULUS, in the Linnæan system of *Zoology*, a species of **TURBO**, with an imperforate smooth shell, and spines rounded and striated; found, rarely, in the deep seas of Greenland.

ALBUM, in *Antiquity*, denotes a white table, or register, in which the names of magistrates, public transactions, &c. were to be inscribed or entered.

Hence we meet with *album prætoris*, *album decurionum*, *album iudicum*, &c.

Album Decurionum was the register of the Decuriones, called also *matriculatio Decurionum*.

Album Indicum, contained the names of those persons of the decurie who at certain times performed the office of judges.

Album Prætoris, was a register of the formula of all actions, and the names of such judges as were appointed by the prætor for certain causes.

Album Senatorum contained a list of the names of senators, first introduced by Augustus, and renewed yearly.

The high-priest entered the chief transactions of each year into an album, or table, which was hung up in his house for the public use.

ALBUM, among *Chemists*, is used for white lead, popularly called *cerufs*.

ALBUM is also used, among *Alchemists*, for a tincture pretended to transmute metals.

ALBUM, in *Ancient Geography*, a promontory of Palestine, to the north-west of Upper Galilee, south of Tyre, and near Alexandria.

ALBUM was also the epithet of a promontory of Africa, situate in the straits of Hercules or Gibraltar, east of Ampelusia, west of mount Abyla, and opposite to Mellaria, on the coast of Spain.

ALBUM, in *Literary History*, is used to denote a kind of table, or pocket-book, wherein the men of letters with whom a person has conversed, inscribe their names, with some sentence or motto.

This is called by divers names and titles, as *album amicorum*, *repositorium amicorum*, &c.

The famous Algernon Sydney, being in Denmark, was by the university of Copenhagen presented with their *album*, whereupon he wrote these words:

“ ——— Manus hæc inimica tyrannis
Ense petit placidam sub libertate quietem.”

ALBUM is also applied, in *Pharmacy*, as a title, or epithet, of divers compound medicines. Thus we meet with *unguentum album cum camphora*, &c.

ALBUM *Græcum*, dogs white dung, a medicinal drug, formerly used with honey, to cleanse and deterge, chiefly in inflammations of the throat; and for the most part outwardly, as a plaster; but, as Dr. Quiney observes, seldom to any great purpose. See Neumann's Works, p. 585.

Some speak of its use internally, in the *angina*, and other inflammations; as also in the dysentery, colic, &c. and to prevent burns from rising into blisters.

Medicines of this kind have long since sunk into disuse.

Album *græcum* is in much request among the leather-dressers, for softening down the leather after the application of lime.

ALBUM *nigrum* is used, among *Medical Writers*, for micedung, by some also called *muscerda*.

ALBUM *oculi*, among *Anatomists*, denotes the *tunica adnata*; sometimes also called *albugo*; popularly the white of the *eye*.

ALBUMAZAR, or ALBUASSAR, Al Abu Masnar, the father of Maasnar, in *Biography*, a celebrated Arabian philosopher and astrologer, who lived, according to some writers, in the 9th or 10th century; but, according to others, at a much earlier period. The time of his death is not mentioned in the *Escorial* catalogue, but he is said to have lived to the age of 100 years; and if he died, as it is supposed, in the year 885, his birth must have been 15 years prior to the date assigned by Herbelot. Some have represented him as one of the most learned astronomers of

his age. He wrote an astrological work, intitled, “*De magnis conjunctionibus annorum revolutionibus, ac eorum perfectionibus*,” printed at Venice in 1515; and “*Introductio in Astrologiam*,” printed in 1489. It is said, that he observed a comet above the orb of Venus. Hutton's *Math. Dict.* Russell's *Acippo*, vol. ii. p. 100.

ALBUMEN, in the Linnæan system of *Zoology*, a species of *NERITA*, with a convex shell, subcordated umbilicus, and a distinct lobe. It is found very rarely at the Cape of Good Hope, and on the shores of the islands of Nicobar and the Moluccas.

ALBUMEN, *Albuminous matter*. *Albumine*. Fr.—This word, which in the Latin language whence it is borrowed, signifies the white of an egg, is at present introduced into the modern chemical nomenclature, as the name of a peculiar substance, which, though existing in the greatest purity and abundance in the white of eggs, is to be found in various natural compounds, both of animal and vegetable origin.

Pure albumen is a fluid of a somewhat viscous consistence, perfectly soluble in pure water at the common temperature; but when exposed to a heat above 134° Fahr. it coagulates, and is then no longer soluble in water.

Animal albumen, in its purest natural state, constitutes the white of all birds' eggs, and the serum of blood: the vitreous and crystalline humours of the eye, the liquor that fills the abdominal cavity in cases of dropsy, and the fluid contents of the lymphatic vessels also contain a considerable portion of this substance. In the vegetable kingdom, it is found principally in the tetradynamious or cruciform plants, in the farinaceous seeds, and in the young succulent shoots of trees and shrubs.

ALBUMEN, ANIMAL, has a slight subsaline taste, and never fails to turn the blue colour of syrup of violets green, thus indicating the presence of disengaged or carbonated alkali. When heated to about 133° Fahr. a number of white fibres begin to make their appearance, and these rapidly increasing, the whole mass is in a short time converted into a white opaque concrete solid, considerably elastic, and of a smooth compact fracture. By exposure to a dry heat, not exceeding that of boiling water, the coagulated albumen loses the greatest part of its moisture, shrinks in consequence in its volume, becomes hard, transparent, and very similar to horn; and when broken, exhibits a bright polished surface, and vitreous fracture. The application of a stronger heat destroys the equilibrium of its elementary parts, and produces the disengagement of ammoniacal gas, of carbonated ammonia, of a fetid empyreumatic oil, and sulphurated hydrogen; there remains behind in the retort a spongy coal, from which may be obtained by lixiviation, muriat, phosphat, and carbonat of soda.

Liquid albumen is completely soluble in fresh distilled water, but if this last is charged with atmospheric air, the mass upon mixture becomes in some measure turbid, and a flocculent precipitate is by degrees deposited. The action of acids, more especially of the three mineral ones, causes an immediate coagulation, and the same effect is produced by all the metallic salts. Caustic alkalies, on the contrary, hold albumen, whether liquid or coagulated, in permanent solution. The addition of lime water occasions a precipitation, but the substance thus deposited, being phosphat of lime, shews that this is not so much a chemical action on the albumen itself, as a decomposition of the phosphated soda which it contains.

There has been a considerable diversity of opinion among chemists respecting the cause of the coagulation which is observed to take place in liquid albumen. Scheele, in his admirable essay on milk, attributes it to a combination with caloric; this is effected in the simplest way by the direct

addition of heat; and during the process, there does not appear to be any increase or diminution of weight. In further confirmation of this method of accounting for the fact, the following ingenious experiments were invented by the Swedish chemist. Having mixed one part of white of egg with four parts of water, he divided the mass into two equal parts, and added to one a solution of caustic alkali, and to the other the same quantity of carbonated alkali; the liquor, in both cases, remained perfectly clear; then, upon dropping into the first a little muriatic acid, an immediate coagulation took place, while a like quantity of acid produced no effect on the latter solution. This is accounted for by Scheele in the following manner. By the combination of acid with caustic alkali, the heat given out is absorbed by the albumen which thus coagulates, but when the acid is added to the carbonated alkali, the whole of the caloric is taken up by the disengaged carbonic acid, and in consequence no coagulation is the result.

According to Fourcroy, the coagulation of albumen is owing to an absorption of oxygen, and the facts which appear to him to prove this are the following: If the red oxyd of mercury is triturated with albumen, it is reduced to the state of black oxyd, at the same time that the albumen becomes opaque, thick, and in some degree coagulated. The white of a fresh laid egg is incapable of being reduced by boiling to so firm a consistence as that of an egg which has been kept several days.

On the other hand, Carradori has shewn that albumen is coagulable by heat without the access of air, and even that when this effect takes place in oxygen gas, there is not the smallest portion of air absorbed.

It was the opinion of Buequet, that albumen is a kind of natural soap, and that its coagulation by acids was merely owing to their combination with the soda which it contains.

These differences between chemists of acknowledged ability, founded also upon undisputed facts, appear to arise from a mistaken necessity of considering coagulation as the constant effect of some one uniform cause, when a little consideration cannot fail of convincing us of the very equivocal nature of this phenomenon. Albumen certainly concretes by the mere action of heat unassisted by any other substance; and this is probably owing in part to the fixation of caloric, and in part to the disengagement of sulphurated hydrogen, as is manifest from the tarnishing of silver, and the blackening of acetated lead, by the white of a newly boiled egg; that the extrication of sulphurated hydrogen is a necessary concomitant in most cases of the coagulation of albumen, is obvious also from certain other facts; thus coagulated albumen is soluble in a very dilute acid, and upon the addition of a few drops of a more concentrated one, is immediately precipitated, at the same time that a strong smell of sulphurated hydrogen is manifested. Again, nitrated silver instantly coagulates albumen, and black streaks at the same time begin to appear, owing to the formation of hydrosulphuret of silver. The coagulation produced by the red oxyd of mercury may be occasioned by the absorption of oxygen, if indeed the blackness of the mercury is not rather produced by combination with sulphurated hydrogen; and this is the more probable, as even metallic mercury undergoes a similar change. The thickening produced by metallic salts, is neither caused by the mere communication of heat nor of oxygen, since the coagulum is an imputrescible combination of the albumen with the metallic oxyd. In like manner a coagulation is formed by the combination of albumen with TANNIN, which has also a specific chemical action. Lastly, pure alcohol will coagulate albumen, probably by the mere abstraction of the water necessary to its liquidity, since the curd thus

obtained is resolvable in water, without any remarkable change of properties.

Besides the general effect of acids on albumen, some of them produce peculiar changes which require notice. By concentrated sulphuric acid it is blackened and charred, exhaling at the same time a nauseous odour; while, by the same acid diluted, it is merely coagulated and preserved from further change. Strong muriatic acid gives a violet tinge to the coagulum, and by long contact effects a partial decomposition, so far as to become saturated with ammonia. Nitrous acid, at the temperature of about 70° Fahr., causes a plentiful disengagement of azotic gas; if further heated, a quantity of prussic acid is formed; and this change is immediately rendered sensible, by the peculiar odour of this acid, similar to that of bitter almonds; this is succeeded by the separation of carbonic acid and carbonated hydrogen; and as soon as this change comes on, the residue in the retort is found to consist of little else than water, covered with a lemon-coloured fat oil, and holding in solution oxalic acid, which may be afterwards separated by crystallization. If dry caustic potash or soda be triturated with albumen, either liquid or solid, ammoniacal gas is set at liberty; and the calcination of the residue yields a prussiated alkali, capable of producing a blue precipitate with the salts of iron.

The neutral salts appear to have little or no action, except that of preserving the albumen from putrefaction.

By spontaneous decomposition in the open air, albumen passes rapidly, and probably without first becoming acid; into the putrid fermentation; in this state it exhales a fetid odour, assumes a brown colour, gives out ammonia, and remains a considerable time before the decomposition is completed.

Animal albumen, as contained in milk, blood, and eggs, forms a considerable part of the food of man. Advantage is taken of its property, of coagulating by heat, to clarify liquors of various kinds: it is largely used in the arts of leather dressing and sugar refining, and the more transparent kinds are employed for varnishes. Dict. Method. Art. Albumine. Fourcroy Syst. des Connais. Chimiq. vol. ix. Scheele's Essays. Annales de Chimie, vol. xxxix.

ALBUMEN, VEGETABLE. The discovery of albumen in vegetables is due to Fourcroy. This chemist having observed that the clarification of the expressed juices of the antiscorbutic plants was effected by the spontaneous coagulation of their colouring matter, at the temperature of boiling water, was induced to examine whether this property did not depend on the presence of albumen. For this purpose, having obtained the juice of two pounds of young cresses, he filtered it while cold, through blotting paper, and by this means separated the grosser parts of the colouring fecula: the liquor was, however, still of a bright green, but upon being exposed in a broad shallow vessel to the air, at a temperature of about 80° Fahr., in two hours it became turbid and deposited a greenish matter, becoming itself almost colourless; in this state it was exposed to the heat of boiling water, and in a few minutes there separated a large quantity of whitish flocculent matter. Another portion of the same clarified liquor being exposed to the air, deposited at the end of two days a similar coagulum; and the same effect was produced on a third portion by the addition of sulphuric acid. The substance thus obtained being first repeatedly washed in cold water, exhibited all the properties of animal albumen. It was easily and quickly dissolved by any of the alkalies; it experienced no change in boiling water, except that of becoming more solid; it converted the purple juice of mallows to green, and by distillation, yielded a notable quantity of ammonia:

when

when exposed with a little water to a warm air, it swelled considerably, exhaled a fetid ammoniacal odour, and gave all the usual signs of active putrefaction; hence explaining the reason of the rank disagreeable smell that characterises the spontaneous decomposition of all the cruciform plants. When dried, by pressure between two pieces of paper, it exhibited a considerable degree of ductility and transparency, like glue.

Albumen was afterwards found in the roots of various vegetables, especially of the *rumex-patientia*; also in wheat and in the farinaceous seeds; and in general in all the green and succulent parts of plants. The acid pulps of fruits are totally destitute of this substance, but abound with jelly; and it is the opinion of Fourcroy, that in all these cases there is a conversion of albumen into jelly, by the gradual evolution of the acid, and consequent fixation of oxygen. *Dict. Method. Art. Albumine Vegetal.* Fourcroy *Syll. des Conn. Chimiq.* vol. viii.

ALBUNEA FONS, or *Albule aquæ*, in *Ancient Geography*, a fountain and small river in the country of the Sabines, west of the Tiber. It was famous for its sulphureous waters, which occasioned baths to be erected near them, mentioned by Suetonius, and Hygeia the goddess of health to be worshipped there.

ALBUNUELAS, in *Geography*, a town of Spain, in the province of Grenada, four leagues east of Alhama.

ALBUOLA, a town of the kingdom of Naples, in the province of Basilicata, eight miles south of Potenza.

ALBUQUERQUE, a town of Spain, in the province of Estremadura, on the frontiers of Portugal, situate on an eminence, and defended by a strong castle. It has a considerable trade of wool and woollen manufactures. N. lat. $38^{\circ} 52'$. W. long. $6^{\circ} 6'$.

ALBUQUERQUE, ALPHONSO DE, in *Biography*, a Portuguese governor of the Indies, contributed more than any other to extend the territories and to establish the power of the court of Portugal in that country. The first exploit which he performed, after being appointed governor, was the reduction of Calicut; which he attacked at once by land and sea, with such fury, that he soon became master of the town, which he burnt; and of the fortrefs, which he demolished. As soon as he recovered from an accidental injury which he received on this occasion, he proceeded against Goa, and took it. This city, in 1559, became the residence of the governor, and the see of an archbishop and primate of the Indies. His next object was, Malacca, which he attacked by sea and land, took by storm, and delivered to the pillage of the Portuguese soldiers. The clear fifth reserved for the king, amounted in value to 200,000 pieces of gold. The last enterprise of any moment in which he was engaged, was the siege and capture of Ormuz. He had formed other great projects, which, however, he did not live to execute. One of these regarded the revival of the Indian trade by way of Alexandria, in which he knew the Venetians would have assisted the Turks, or any other persons, for their own emolument. He proposed, therefore, to the emperor of Ethiopia, that for his own security, he should divert the channel of the Nile, by cutting a passage for it into the Arabian sea before it reached Egypt; and by so doing, he would have rendered the greatest part of Egypt uninhabitable; and at the same time made it impracticable to renew the old mode of transporting East-India commodities from the Red Sea to Alexandria, which was the object he had principally in view. Another project was to transport 300 horse from the island of Ormuz to the opposite coast of Arabia, and thus to plunder the tomb of Mahomet at Mecca, which he

conceived would be beneficial in a variety of respects, and chiefly in rescuing the trade of the east out of the hands of the Turks and other Mahometan nations. But death prevented the accomplishment of his various purposes; for after his return to Goa, he was seized with a disorder which in a few days proved fatal; so that he died, Dec. 16, 1515, at the age of 63. He was called by the Mahometans, *Albuberque Malandy*, because he was born at Melinda in Africa; but, by the Portuguese, he was justly denominated *Albuberque the Great*. He was the ablest statesman, and the most consummate general they ever had in India, and left their affairs in the best situation; and yet he performed his numerous exploits with a very inconsiderable force. With 30 ships he took Calicut; with 21 he became master of Goa; with 23 he surprized Malacca; and he had no more than 22 in his expedition against Ormuz. His funeral was performed with great solemnity, and his body interred in a chapel built by him at Goa, and dedicated to the blessed Virgin, which chapel was much enlarged by his son, Alphonso Albuberque, who lived to the age of 80, and wrote a large book of Memoirs, in which he recorded his father's actions.

He studied the disposition of the people among whom he lived, and conformed in outward pomp and magnificence on public days to the habits of the Indians; though in his private mode of living, he was strict and abstemious. In exacting the dues of the crown, he was severe; but as to his personal fortune, he had scarcely any thing which he could call his own. His officers were his children, to whose instruction he was as attentive as the most affectionate parent is to the education of his sons. Whilst he overlooked trivial faults, he punished treachery or neglect of duty with inexorable severity. He was liberal in bestowing recompence and applause on those officers who distinguished themselves by any great actions; at the same time he was not only silent as to his own, but would not permit others to commend them. It was a maxim which he often repeated, "that he was afraid of nothing but flattery;" and it was observed, that he never preferred any who attempted to gain his favour in that way. Some of the Portuguese historians have observed, that the vanity of his predecessor Almeida, made him affect the state of a prince when the Portuguese power was very imperfectly established; whereas the modesty of Albuberque was most conspicuous when his victories left him nothing to fear, and when the greatest princes of the east sent ambassadors to solicit his friendship. Albuberque, however, was actuated by boundless ambition; and his extravagant desire of extending the dominions of Portugal, made him regardless of the measures which he adopted for this purpose. In private life, he was a man of the strictest honour; but in his public character, liable to just reproach and censure. After serving his prince and country with singular zeal and success, he had the misfortune to die in disgrace. His ambition, austerity, and strict regard to justice, had raised enemies, who were assiduous in their endeavours to prejudice the king against him; and as he had solicited with a view to the preservation of Goa, the grant of it, together with the title of a duchy, as a reward for his services, this was made a pretence for exciting and increasing the jealousy of the king: and thus, before his death, he was displaced from the office of governor, and another person appointed in his room. When Albuberque heard of this appointment, he is said to have exclaimed: "I incurred the hatred of men by my love for the king, and am disgraced by him through his prepossession for other men. To the grave, unhappy old man; it is time thou wert there; to the grave!" His letter to the king,

king, recommending his natural son to his favour, closes with these words: "I say nothing of the Indies; they will speak for themselves, and for *n.c.*" *Mod. Un. Hist.* vol. viii. p. 43—50.

ALBUQUERQUE COELHO, EDWARD, marquis of Basso, count of Fernambuco in Brazil, and gentleman of the chamber to Philip IV. king of Portugal, was distinguished by his valour in the Portuguese army, against the Dutch at Bahia. He wrote a "Journal of the War," from the year 1630, which was printed at Madrid, in 4to. in 1654. He died at Madrid, in 1658. *Gen. Biog.*

ALBURN, or **AUBURN**-colour, a whitish brown, or a mixt colour, partaking of red and white. Skinner derives the word, in that sense, from the Latin, *albus*, white; and the Italian, *burno*, from *bruno*, brown.

ALBURNUM, in *Phytology*, denotes the white, soft substance that lies between the inner bark and the wood of trees, composed of layers of the former, which have not attained the solidity of the latter. In this state, dealers in timber call it the sap.

ALBURNUM, in the Linnæan system of *Zoology*, a species of **ALCYONIUM**, white, very ramose, attenuated, and subdivided, with terminal tubulous pores. It is found in the Indian sea.

ALBURNUS, in *Ichthyology*, a species of the **CYPRINUS** of Linnæus, and the **BLEAK** of Ray and Pennant.

ALBURNUS is also a species of the **PERCA**.

ALBURNUS Portus et Mons, in *Ancient Geography*, lay to the north of Paestum, in that part of Magna Græcia, called Lucania.

ALBUS Pagus, or *Vicus*, a village of Arabia, mentioned by Strabo, and called, according to the Greek idiom, *Αλευν χωριον*.

ALBUS piscis, in *Ichthyology*, the white fish, a name by which Sylvian has distinguished the fish, more usually called the *capito-lacusfris*, and seeming to be the same with the blue chub; or, as it is more generally called, the **JENTLING**. It is the **CYPRINUS Jeses** of the Linnæan system.

ALBUSEIRA, in *Geography*, a small town of Algarve in Portugal, consisting of two parishes, and containing about 1000 inhabitants. It is situated on the sea-coast, between Lagos on the north, Faro to the east, and Sylves to the north. N. lat. 37°. W. long. 3° 21'.

ALBUSEIRA is also a lake in the island of Majorca, in the Mediterranean.

ALBUTIUS, SILVUS (Caius), in *Biography*, an orator of some celebrity at Rome, in the time of Augustus, was born at Novara, and advanced to the office of *Ædile*; but receiving a public insult, by being dragged from the tribunal, in consequence of a judgment he pronounced, he left his native place and settled at Rome. Here he formed a friendship with the orator Munatius Plancus, and afterwards became his rival. In his public pleadings he was too free in the use of rhetorical figures, and sunk into disrepute, so that he renounced the bar. In advanced life he returned to Novara, where he laboured under an asthma, and having delivered a discourse in justification of suicide, he starved himself to death. The elder Seneca commends him as a man of eminent probity, for not knowing how to offer or to bear an injury. From a passage in Quintilian it appears that he was the author of a treatise on rhetoric. *Suetonius de Clar. Orat.* c. vi. *Quintil. Inst. lib. ii. c. v.* *Gen. Dict.*

ALBUTIUS, TITUS, a Roman philosopher of the Epicurean sect, flourished about 120 years before Christ. Having been educated at Athens, he became so attached to Grecian manners, that he preferred being regarded as a Greek rather than a Roman. According to Cicero, (*De*

Finibus, lib. i. c. 3. and *De Oratore*, lib. iii. c. 43.), Scævola often rallied him on account of this affectation. Thus, he compares his style to a kind of inlaid or mosaic work.

"Quam lepide lexis compositæ, ut tessellæ omnes
Arte pavimento, atque emblemate vermiculato."

"How neatly are his polish'd words inlaid!

Not nicer skill the artist has display'd,

Whose patient hand, on smooth mosaic ground,
Figures that live and speak, has strew'd around."

Whilst he was proprætor of Sardinia, he celebrated a kind of triumph in his province; and this arrogance induced the senate to refuse him a "supplication" or public thanksgiving to the gods in honour of his exploits. On his return from Sardinia he was accused of peculation in his office, and sentenced to exile. He withdrew to Athens, and devoted his remaining days to the study of philosophy. Although he possessed some talents for oratory, they were of the inferior kind; and he had no claim on the character of a statesman or a philosopher. From the sarcastic appellation of "Græcus Homo," bestowed upon him by Cicero (in *Brut.*) he appears to have been an affected trifler. *Gen. Dict.*

ALBUTIUS, ARUNTIUS, CALPETANUS and **RABRIUS**, four physicians, all lived in the time of Augustus, and acquired considerable wealth by practising medicine at Rome. *Haller, Bibl. Med.* vol. i. p. 166.

ALBUTIUS, JOHN PETER, a celebrated philosopher and physician of the 16th century, taught medicine at the University of Padua, for forty years, where he also practised, we are told, with great reputation and success, particularly in the plague which raged in that city, in the year 1577. He died February 14th, 1583, aged 75 years. His son John Francis, who succeeded him in his practice, procured him to be buried at the church of St. Cufforga, at Milan, where a handsome monument was raised to his memory, with an inscription, at once celebrating his talents, and virtues, the piety of his son, and the gratitude of his fellow citizens.

ALBUZINSKA, a fortress which the Czarina possessed on the river Amura, in Mongolian Tartary, about 1200 leagues from Moscow.

ALBY. See **ALBI**.

ALCA, in *Geography*, a small and very fertile island in the Caspian sea, on the coast of Tabristan.

ALCA, Auk, in *Ornithology*, a genus of the order of *Anseres*, in the Linnæan system, and of the *Palmipedes*, in the distribution of Latham; the characters of which are, that the bill is without teeth, short, compressed, convex, frequently furrowed transversely; the inferior mandible is gibbous before the base; the nostrils are behind the bill; and the feet have generally three toes. This genus comprehends 12 species, *viz.* 1. *A. tarda*, with four furrows on the bill, and a white line on each side running from the bill to the eyes. This is the *alea* of Clutius, Wormius, and Brisson; the plantain tonsor of Klein; the pingouin of Buffon; and the razor-bill, auk, or murre of Pennant, Ray, Willughby, Albinus, Edwards, and Latham; the falk of Martin, and the marrot of Sibbald. This species weighs about 22½ ounces, its length is about 18 inches, and alar breadth 27; the bill is two inches long and black; the grooves of the upper mandible are four, and of the lower three, and the widest of them is white; the inside of the mouth is of a fine pale yellow; the head, throat, and whole upper side of the body are black; the wings are of the same colour, except the tips of the lesser quill-feathers which are white; the tail consists of 12 black feathers, and is sharp pointed; the whole under side of the body is white, the legs are black. The female, says Buffon, wants the white streak between the bill and the eye,

but its throat is white. These birds, in company with the guillemot, appear in our seas in the beginning of February; but do not settle in their breeding-places till they begin to lay, about the beginning of May. When they take possession of the ledges of the highest rocks that hang over the sea, they sit close together and in rows one above another, and form a very grotesque appearance. They lay only one egg at a time, which is of a large size, in proportion to that of the bird, being three inches long, either white or of a pale sea-green, irregularly spotted with black; if this egg be destroyed, both the auk and the guillemot will lay another, and if this be taken, a third; as they make no nest, they deposit the egg on the bare rock, positing it in such a manner as no human art can effect, and fixing it by means of the viscous moisture that bedews its surface on its exclusion; and though such multitudes of eggs are contiguous to each other, each bird distinguishes its own. These eggs serve as food to the inhabitants of the coasts which the birds frequent, and are procured with great hazard by persons let down with ropes, held by their companions, and who for want of stable footing, are precipitated down the rocks and perish together. These birds are found in the northern parts of America, Europe, and Asia. They come to breed on the Ferroe islands, along the west of England, and on the isle of Wight, where they add to the multitude of sea-fowl that inhabit the great rocks, called the Needles. Their winter residence is not positively ascertained. As they cannot remain on the sea in that season, and never appear on shore, nor retire to southern climates, Edwards supposes that they pass the winter in the caverns of rocks, which open under water, but rise internally as much above the level of the flood as to admit a recess, and here, as he apprehends, they remain torpid, and live upon their abundant fat. The pace of this bird is heavy and sluggish; and its ordinary posture is that of swimming or floating on the water, or lying stretched on the rocks or on the ice.

2. *A. pica*, *A. minor* of Brill. *mergus* of Bellon. Aldrov. Johnst. Will. and Ray, *alea unifoveata* of Brunn. and Muller, and black-billed auk of Pennant and Latham, has its bill smooth and compressed, the whole under side of the body, and the tips of the posterior wing-quills, white, and its legs red. This species weighs 18 ounces, its length is 15½ inches and breadth 25 inches; the bill is of the same form with that of the preceding, but is entirely black. The cheeks, chin and throat, are white; in all other respects it agrees with the former species. It has been found on our coasts in winter, when the other sort has left them. It is very common in Greenland, where it breeds on the cliffs, feeds on marine insects and grows very fat. In winter these birds pass the day in the bays, and in the evening retire to the sea. The Greenlanders eat their flesh half putrid, suck their raw fat, and clothe themselves with their skins. When this bird is dressed with its entrails, it is esteemed by those people a great delicacy. Some have doubted whether these birds migrate so far southward as the Mediterranean, whilst others affirm that they have been found on the coast of Candia; and Mr. Latham says, that they are common in the bay of Gibraltar, where they have been particularly noticed on account of the adroitness and activity with which they plunge into the water, and move through it in pursuit of their prey.

The *A. baltica* of Brunnick, with black tail and wings, is a variety of this species.

3. *A. impennis*, *A. major* of Brisson, *mergus americanus* of Cluvius, *choenalopex* of Moehring, *goisfugel* of Cluvius, Nieremb. and Jonst. Penguin of Worm. Will. Ray, Martin, Edwards, &c. *gare* of Sibb. *grand pingouin* of Bufton,

and great auk of Pennant and Latham, has its bill compressed and furrowed on both sides, and has an oval spot on each side before the eyes. Its length to the end of its toes is three feet; the bill to the corner of the mouth is 4½ inches; part of the upper mandible is covered with short, black, velvety feathers; the head, neck, back, tail and wings are of a glossy black, the tips of the lesser quill-feathers white, the whole under side of the body white, and the legs black. The wings are so small as to be useless for flight, their length, from the tip of the longest quill-feathers to the first joint, being only 4½ inches; and these birds are therefore observed by seamen never to wander beyond soundings, and by the sight of them they are able to ascertain the nearness of the land. They can scarcely even walk, and of course continue on the water, except in the time of breeding. According to Mr. Martin, they breed on the isle of St. Kilda, appearing there in the beginning of May and retiring in the middle of June. They lay one egg, six inches long, of a white colour; and if the egg be taken away, no other is laid in the same season. Some eggs are irregularly marked with purplish lines crossing each other, and others are blotched black and ferruginous about the thicker end. Mr. Macaulay, in his history of St. Kilda, p. 156, observes, that this bird does not visit that island annually, but sometimes keeps away for several years together; and that it lays its eggs close to the sea-mark, as it is incapable, by the shortness of its wings, of mounting higher. Birds of this species are said not to be numerous; they seldom appear on the coasts of Norway. They are met with near Newfoundland and Iceland. They do not resort annually to the Ferroe islands, and they rarely descend more to the south in the European seas. They feed on the cyclopterus, and such fish, and on the rose-root and other plants. The skins are used by the Esquimaux for garments. The akpa of the Greenlanders, which is about the size of a duck, with the back black and the belly white, and which can neither run nor fly, is supposed by M. Buffon to be this bird. These birds live in flocks at sea, and never approach the land except in very severe cold; and in this case they are so numerous that they cover the water like a thick dark fog. The Greenlanders drive them on the coast and catch them with the hand, as they can neither run nor fly. At the mouth of the Ball river they afford subsistence to the inhabitants in the months of February and March, and their down serves to line winter garments.

4. *A. arctica*, *anas arctica* of Cluv. Ray, Worm. Will. Olear. Alb. and Sibb. *lunda* of Nieremb. and Jonst. *fratercula* of Brisson, *bowger* of Martin, *puffinus anglicus* of Gesner, *macareux* of Buffon, and *puffin* of Pennant and Latham; has its bill compressed, channelled on each side with four furrows, the orbits and temples white, and its upper eye-lid pointed. For a further account of this species, see PUFFIN.

5. *A. alca*, *uria minor* of Brisson, *mergulus melanoleucus*, with a short sharp bill of Ray, small black and white diver of Will. and Edwards, Greenland dove or sea-turtle of Albin, *rotges* of Martin's Spitzb. and little auk of Pennant and Latham, has a smooth conical bill, the whole under part of the abdomen and the tips of the posterior wing-quills white, and the legs black. The bill is short, strong and black; the cheeks, throat, and under side of the body white, the crown of the head, hind part of the neck, back, tail, and wings black, the inner coverts of the wings grey, the scapular feathers black and white; the legs and feet covered with dirty greenish white scales; the webs black. The size of the bird, from which this description was taken by Pennant, was not superior to that of a blackbird. Mr. Edwards describes another

another varying very little from this, which by some is dated only in sex; the head and neck are wholly black and the inner coverts of the wings barred with a dirty white. Gmelin mentions two varieties, *viz.* *A. canifila*, or white of Brunnick, and the *A.* with a red breast. This species inhabits America and Europe, especially in the arctic sea, is found sometimes among fragments of ice, about nine inches long, as to the disposition of its legs, nest, food, and manners resembling the other species, but more capable of walking, laying two bluish white eggs, flying swiftly, and becoming fat in stormy weather, in consequence of the small fish that are brought within its reach; whilst at rest on the water or swimming, it is perpetually dipping its bill in the water. In Greenland it is called the ice-bird.

6. *A. Labradorica*, or Labrador auk of Pennant and Latham, has a keel-shaped bill, its lower mandible angulated, the linear nostrils covered with an obscure membrane. The bill is narrow, the upper mandible of a dark red colour, the lower whitish, spotted with black, the temples dull white, the throat, wings, and short tail of a dark colour: and the legs red. It is about 12 inches long, and found in the country of Labrador.

7. *A. cristatella*, or crested auk of Pennant and Latham, has its bill somewhat ascending, conoidal, crimson-coloured, white at the tip, with a furrow running on each side of the lower mandible from the throat, and a crested front. It is about the size of the thrush, 12 inches long, and found in the islands adjacent to Japan, and in Bird Island, situate between America and the northern part of Asia, in the day swimming on the sea, and at night in the rabbit holes of the shore and the clefts of rocks.

8. *A. tetraœula*, or dusky auk of Pennant and Latham, has an ascending bill conoid, of a dingy brown colour, the lower mandible triangular, and the front somewhat crested. It is 11 inches long, and found in the sea of Kamtschatka, on the sea by day, and in the night concealed in the rabbit holes, caves and fissures of rocks, where it forms its nest; it walks and flies very indifferently, stands erect, swims swiftly on the water, and dives well.

9. *A. pſittacula*, or perroquet auk of Pennant and Latham, has its bill fubovated, compressed and crimson-coloured, with a single furrow in each mandible, with a white spot in the middle of the upper eye-lid and below the eye. The head and upper part of the body are dusky, the lower whitish, varied with black edges; from the remote corner of each eye a tuft of white feathers hangs down the neck; the tail is very short, the legs of a dirty yellow, and the membrane connecting the toes brown. This species is about the size of the little auk, is found in the sea that lies between the northern parts of Asia and America, sometimes by day in flocks swimming on the water, though not very far from land, unless driven out by storms, and in the night harbouring in the crevices of rocks. About the middle of June they lay upon the rock or sand a single egg, about the size of that of a hen, of a dirty white or yellowish colour, spotted with brown, which is esteemed good. These birds, like others of the same class, are stupid, and are mostly taken by the natives, who place themselves in the evening among the rocks, dressed in garments of fur with large open sleeves, into which the birds fly for shelter as the night comes on, and thus they become an easy prey. They sometimes at sea mistake a ship for a roosting-place, and thus warn navigators of their being near the land at the access of night, or on the approach of storms.

10. *A. Cirrhata*, macareux of Kamtschatka of Buffon, or tufted auk of Pennant and Latham, is entirely black, has four furrows in its bill, the sides of the head, the space

about the eyes, and the corner of the throat white, and a yellowish longitudinal tuft from the eye-brows to the nape. This tuft is white near the head, and afterwards of a buff-yellow; the bill and legs are crimson. It resembles the puffin in its appearance and manners, but is somewhat larger, being about 18 inches long; swimming about for whole days in the sea, where it dives well, and occasionally flies swiftly, but never departing far from the rocks and islands; and feeding on shrimps, crabs, and shell-fish, which it forces from the rocks with its strong bill; in the night it comes to shore, burrows about a yard deep under ground, and makes a nest with feathers and sea-weed, in which it lodges with its mate, being monogamous. It lays one egg in May or June, which is fit to be eaten and used for food, but the flesh of the bird is hard and insipid. This species inhabits the shores of Kamtschatka, the Kurile islands, and those that lie between Kamtschatka and America. The young women of Kamtschatka form an ornament of the glutton's skin, in the shape of a crescent, which they suspend behind each ear, resembling the tufts of this bird; and a present of this kind from a lover to his mistress is in high estimation. The bills mixed with those of the common puffin, and the hairs of the seal, were formerly regarded by these people as a powerful amulet: they are now used as an appendage to their dress, and the skins of the birds are sewed together as garments. This bird is called by the natives, monichagatha, or mitchagatchi, and igilma.

11. *A. antiqua*, or ancient auk of Pennant and Latham, has a black bill white at the base, covered with down, a small whitish crest on each side of the head, and another long white one on the neck. The crown of the head and throat are black; the back, wings, and tail are fuliginous. This species is somewhat larger than the little auk, being almost 11 inches long, and is found near Kamtschatka, and the Kurile islands.

12. *A. pygmaea*, or pygmy auk of Pennant and Latham, has a black bill, the crown of the head, neck, back, wings, tail, and feet of a dusky colour, the throat and breast grey, the abdomen dirty white. The bill is furrowed on the back and slightly bent at the ends. This species is less than the little auk, or seven inches long, is found in large flocks about Bird islands, between the northern parts of Asia and America. See Linnæus by Gmelin, Buffon, Pennant, and Latham.

ALCABENDAS, in *Geography*, a small, but beautiful town of Spain, in New Castile, situate about three or four leagues north of Madrid. N. lat. 40° 35'. W. long. 3° 26'.

ALCACAÇON, in *Botany*, the name of a plant, which is produced in the neighbourhood of Colima in Mexico, and which the inhabitants reckon a catholicon in all decayed, enervated, and emaciated constitutions. The natives apply the leaves to the parts chiefly affected, and judge of their efficacy by their sticking or falling off.

ALCÁCENAS, in *Geography*, a small town of Portugal, south-east of Evora, upon a branch of the river Zadeon. N. lat. 38° 25'. W. long. 6° 21'.

ALCADETE, a small town of Spain in New Castile, on a small river which runs near it into the Tagus. N. lat. 39° 30'. W. long. 3° 56'.

ALCADIN of Syracuse, in *Biography*, a learned philosopher and physician, taught medicine at Salernum, towards the end of the 12th century. He was physician to the emperor, Henry the Sixth, and wrote an account of the virtues of the baths of Puzzoli, in verse, which is inserted in a collection of treatises on baths, printed at Venice, 1553, fol. and again in a work, "De Balneis Putecolorum Bajorum, &c. Naples, 1591. 8vo.

ALCÆUS, in *Classical Biography*, a famous Greek lyric poet, was born at Mitylene in the island of Lesbos, and flourished in the 44th olympiad, about 604 years before Christ, and was contemporary with Sappho, to whom it is said he was affectionately attached. A verse, insinuating his passion to Sappho, with her answer, is preserved by Aristotle, (*Rhet. lib. i. c. 9.*), thus translated:

Alcæus.—“ I fain to Sappho would a wish impart,
But fear locks up the secret in my heart.”

Sappho.—“ Thy down-cast looks, respect, and timid air,
Too plain the nature of thy wish declare;
If lawless, wild, inordinate desire,
Did not with thoughts impure thy bosom fire,
Thy tongue and eyes, by innocence made bold,
Ere now the secret of thy soul had told.”

The invention of lyric poetry is by some attributed to Alcæus, and it seems to be implied by Horace (*Od. xxxii. lib. i.*), unless he only intimates that he invented the barbiton, or harp. From him, however, the lyric measure, called “the Alcæic verse,” derived its name. He was no less a votary of Mars than of love and the muses. He strenuously asserted the liberty of his country against the tyrants who usurped dominion, and particularly against Pittacus; and took up arms in its defence. But his courage failed him in the day of battle, and he attempted to save himself by flight, when his party was defeated, but was taken prisoner by Pittacus, who generously granted him both his life and liberty. He was afterwards sentenced to exile; but what was the issue of his conflicts, and how and where his life terminated, history does not inform us. Horace seems to intimate, that he became a corsair. His poetical talents have never been disputed. His poems, of which only a few fragments now remain, collected by Neandrus, H. Stephens, and Urfinus, were written in the Æolian dialect, and in the measure of his own invention. The subjects of them were very various, sometimes amatory and bacchanalian, but more generally grave and political. They are described by Horace in the following verses:

“ Et te sonantem plenius auro,
Alcæe, plectro dura navis,
Dura fugæ mala, dura belli!
Utrumque sacro digna silentio
Mirantur umbrae dicere: sed magis
Pugnas, et exactos tyrannos
Denfum humeris bibit aure vulgus.”

Od. xiii. l. ii.

“ Alcæus strikes the golden strings,
And seas, and war, and exile sings:
Thus while they strike the various lyre,
The ghosts the sacred sounds admire;
But when Alcæus lifts the strain,
To deeds of war and tyrants slain,
In thicker crowds the shadowy throng,
Drink deeper down the martial song.”

FRANCIS.

Quintilian (*Inst. Orat. lib. x. c. 1. tom. ii. p. 896. Ed. Burman.*) says, that his style was concise, sublime, and accurate, and much resembling that of Homer; but that his pieces of the lighter kind were inferior to his other poems. *Fabr. Bib. Græc. lib. ii. c. 15. tom. i. p. 565. Rollin's Anc. Hist. vol. ii. p. 349. Burney's Hist. Mus. vol. i. p. 388. Gen. Dict.*

There were other ancient poets of this name (see *Fabr. Bib. Græc. ubi supra.*); such as an Athenian tragic poet, who is said by some to have been the

first composer of tragedies; and who, according to Suidas, is different from Alcæus, the son of Micæa, a comic poet, the fifth author of the ancient comedy. One of his pieces, intitled *Pasiphaë*, was produced in his dispute with Aristophanes in the fourth year of the 97th olympiad. Plutarch (*in Flamin. Oper. tom. i. p. 373.*) mentions another Alcæus, who lived in the 145th olympiad, A. U. C. 555. B. C. 199, and who ridiculed Philip, king of Macedonia, on account of the battle which Titus Flaminus gained over him in Thessaly. An Alcæus of Messenia also lived in the time of Vespasian and Titus, of whose epigrams some are preserved in the *Anthology*. One of these is supposed to have suffered a singular kind of death for his lewdness; which was the punishment said to have been inflicted by means of a radish, or the fish called a mullet, on adulterers, and referred to by Juvenal, *Sat. x. v. 317. p. 295. Ed. Calaub.*

—“ quosdam mocos et mugilis intrat:”

and also in the menace of Catullus, *epig. 51. ad Aurelium*:—

“ Ah tum te miserum, malique fati
Quem attractis pedibus, patente porta,
Percurrent raphanisque, mugileque.”

“ Ah wretched thou, and born to luckless fate,
Who art discover'd by the unshut gate!
If once, alas! the jealous husband come,
The radish or the sea-fish is thy doom.”

ALCÆUS, in *Mythology*, the son of Perseus and Andromeda, the father of Amphitryon, the supposed father of Hercules; hence called Alcides.

ALCAI, in *Geography*, a high and fertile mountain of Africa, in the kingdom of Fez, about 12 leagues from the capital. It is inhabited by many rich and powerful peasants.

ALCAICS, in *Ancient Poetry*, a name common to several kinds of verses; so called from the poet Alcæus, the inventor of them.

The first species of alcæics consists of five feet, of which the first may be either spondee, or iambic; the second, is an iambic; the third, a long syllable; the fourth a dactyl; and the fifth, a dactyl, or amphimacer: as these of Horace.

“ Omnes eodem cogimur, omnium
Versatur urna, serius, ocius,
Sors exitura.”

The second species of alcæics consists of two dactyls, and two trochees; as,

“ Exsilium impositura cymbæ.”

Besides these two kinds of verses, which are properly called *dactylic alcæics*, there is a third sort, called simply *alcæic*; whereof the first is an *epitrite*, the second and third are *choriambuses*, and the fourth a *bacchius*; as,

“ Cur timet flamma | vum Tiberim | tangere? cur | olivum?”

ALCAIC Ode, consists of four strophes, each of which contains four verses: the two first are alcæic verses of the first kind: the third an iambic diameter hypercatalectic, *i. e.* of four feet and a long syllable: as,

“ Sors exitura, et nos in æternum.”

The fourth is an alcæic of the second kind—The entire alcæic strophe is as follows:

“ Omnes eodem cogimur: omnium
Versatur urna, serius, ocius
Sors exitura, et nos in æternum
Exsilium impositura cymbæ.”

Hor. lib. ii. od. iii.

The following is also of this species which Horace calls *minaces Alcei canens* :

“ Non possidentem multa vocaveris
 Recte beatum ; rectius occupat
 Nomen beati, qui deorum
 Muneribus sapienter uti,” &c.—Od. ix. lib. iv.

ALCAID, in matters of *Policy*, an officer of justice among the Moors, Spaniards, and Portuguese.

The word is also written *alcade*, *alcalde*, and *alcayd* : sometimes also *alvacide*.

It is originally Arabic, compounded of the particle *al*, and the verb *kad*, or *akal*, to rule, govern, administer.

The emperor of Morocco's court consists chiefly of seven or eight *alcuids*, his devoted slaves.

The *alcuid*, or governor of a city or castle in Barbary, hath sovereign jurisdiction in civil and criminal concerns ; and all fines and punishments are inflicted at his pleasure.

In some places the *alcuids* are much the same with the emperor's tax-gatherers.

Alcaid, among the Spaniards, &c. is a kind of inferior judge, or minister of justice, who takes cognizance of causes in the first instance, and answers in good measure to the French *prevost*, and an English justice of peace.

They had also their *alcayd* of the whores, who took cognizance of cases of whoredom and adultery. This officer was otherwise called *alcayd* of honour. Du-Cange.

ALCALA *de los Gazules*, in *Geography*, a very ancient town of Spain in Seville, situated on a mountain, and surrounded by a fertile plain, 10 miles east-north-east from Medina Sidonia.

ALCALA *de Guadaira*, a small town of Spain in Seville, on the river Guadaira, two leagues south-east from Seville. N. lat. 37° 22'. W. long. 5° 6'.

ALCALA *de Henares*, anciently *Complutum*, a town of Spain, in New Castile, situated on the river Henares, in a beautiful plain, and consisting of well-built houses, which form handsome streets, and which are disposed in a kind of oval figure. N. lat. 40° 35'. W. long. 4° 20'. It is surrounded by piazzas, where the tradesmen keep their shops, which are well supplied with a variety of goods. The adjoining land, watered by the Henares, is fertile and well cultivated, and yields plenty of grain, good muscat wine, and excellent melons. Near the town is a spring, the water of which is preserved, on account of its peculiar purity, for the king's use, and conveyed to Madrid. This town belongs to the archbishop of Toledo. It has a collegiate church, and a celebrated university, which was restored in 1494, by Cardinal Ximenes ; and in the church belonging to it this Cardinal was buried. This university possessed a very considerable library, and many curious manuscripts. Gomez says, that they cost 4000 aurei, and that among them were seven of the Hebrew Bible. Here, it is probable, were deposited, the Greek manuscripts used for the Complutensian edition of the Greek testament. Professor Moldenhawer went to Alcalá, in 1784, with a view of discovering these manuscripts ; but, to his extreme astonishment, he found that about 35 years before that time, a very illiterate librarian, who wanted room for some new books, sold the ancient vellum manuscripts to one Toryo, who dealt in fire-works, as materials for making rockets. Martinez, a Greek scholar, as soon as he heard of this savage act, hastened to save these treasures from destruction ; but they were actually destroyed, except a few scattered leaves, which are now preserved in the library. It is added, as a circumstance of

aggravation, that the number of manuscripts was very considerable. However, as rockets are not made of vellum, a learned writer consoles himself with the reflection, that the manuscripts were written on paper, and therefore of no great antiquity. Michaelis's *Introd. to the New Test.* by Marsh, vol. ii. p. 441. vol. iii. p. 844.

ALCALA *real*, a town of Spain in Cordova, lies in a hilly country, but produces fine fruits and good wine. It is 12 leagues south-east from Cordova. N. lat. 37° 18'. W. long. 4° 15'.

ALCALA *del Rio*, a town of Spain in Seville, on the Guadalquivir, two leagues above Seville.

ALCALI and ALCALIZATUM. See ALKALI and ALKALIZATION.

ALCAMENES, in *Biography*, a statuary, the scholar of Phidias. Pliny, xxxvi. 5. Cicero de Nat. D. i. 30.

ALCAMO, in *Geography*, a considerable town of Sicily in the valley of Mazara, about 20 miles south-west from Palermo. It is situated on high ground, in a fine open cultivated country, and well sheltered by large woods of olive trees. The number of inhabitants is about 8,500. It derives its name from Adalcam, the caliph's lieutenant, who, in 827, conquered Sicily, and who erected a fortress in Monte Bonifati ; but Frederick of Swabia, having dispossessed the Saracens, destroyed the fort, and erected the burgh of Alcamo at the foot of the mountain. Having passed through several Spanish families, it now belongs to the duke of Ferrandina, heir to the possessions of Toledo duke of Alba. The church is adorned with some good pictures by Pietro Novello, commonly called the Raphael of Sicily ; and with alto-relievos of great merit by Gagini. The streets of the town command a superb view : the best land in the vicinity is sown with corn, the next sort is planted with vines, and the worst soil is cultivated with myrtle-leaved fumach, the leaves and flowers of which are dried and pulverized, and exported in bags, for the purpose of tanning fine leather. N. lat. 38° 2'. E. long. 12° 56'. Swinb. Trav. vol. iii. p. 346.

ALCANDRO, a town of Spain in Old Castile, situated on the Ebro ; four leagues from Calahorra.

ALCANI, or ALKAN, a town of Africa in Egypt, on the western branch of the Nile, 30 miles N. N. W. of Cairo.

ALCANITZ, or ALCANIS, a town of Spain in Aragon, on the river Guadaloupe, and the frontiers of Catalonia, 15 leagues south-east from Saragossa. It was formerly the capital of the Moors, but now belongs to the order of Calatrava. It has a collegiate church and a fortress, and is surrounded with gardens and fruit-trees. A fountain in this town throws up water through 42 pipes. N. lat. 41° 10'. W. long. 0° 10'.

ALCANIZOS, a town of Spain in Leon, on the frontiers of Portugal, four leagues west from Zamora.

ALCANNA, or ALKANNA, in *Commerce*, by the Turks called *knab*, a dying drug, brought from Egypt on the Levant, being the leaves of a plant called *ligustrum Ægyptium*, the Egyptian privet, or the LAWSONIA *inermis* of the Linæan system. The tree is also called *ehanna*, *tamarhendi*, *poutaletsie* of Rhod, and grows in the East Indies, as Malabar and Ceylon, in Egypt, and also in Cyprus, and in all parts of Syria. The colours drawn from these leaves is either red or yellow, according to the mode of preparing it ; yellow, when steeped in common water ; and red, when infused in vinegar or alum water. The people of Cairo make a considerable traffic of these leaves, which they reduce to a powder, called *archenda*, much used by the women to dye their nails, hands, hair, and other parts of the body of a golden yellow hue. They apply it also for the same purpose to the manes and tails of their horses. This

custom amongst the oriental nations is very ancient, and has generally prevailed. This powder has been also used as an astringent, for the purpose of drying ulcers of the gums, and for removing the fetid smell of the feet; and many other virtues are ascribed to it by Rumphius. It is seldom met with in the shops, but may be used without injury. The root of the *ANCHUSA tinctoria* is substituted for it, principally for giving a red colour to tinctures, decoctions, and ointments. Murray. Mat. Med. vol. ii. p. 112. 129.

From the berries of Alcamna an oil is extracted of a very agreeable smell, and which has been of some use in physic, as a calmer, called oil of Cyprus, a name which is sometimes also given to the plant. Phil. Trans. abr. vol. x. pt. ii. p. 741.

ALCANTARA, in *Geography*, a small but strongly fortified town of Spain in Estremadura, situated in a fertile country on the banks of the river Tagus. It takes its name, which signifies a stone-bridge, from an old bridge, erected in the time of the emperor Trajan over the Tagus, at the expense of several Lusitanian nations. This bridge was 200 feet high, 670 in length and 28 broad; and on account of the bridge the Moors built the city. A chapel hewn out of a rock at the entrance of the bridge, was dedicated by the ancient Pagans to Trajan, and by the Christians to St. Julian. It was taken from the Moors in 1214, by Alphonso IX. king of Castile, and given to the knights of Calatrava, who afterwards assumed the name of Alcantara. In April 1706, it was taken by the Portuguese and the earl of Galloway, and retaken by the French in the November following. It is 45 leagues west-south-west from Madrid, and 38 west from Toledo. N. lat. 39° 32'. W. long. 7° 12'.

ALCANTARA, or ALCANTARILLA, a town of Spain in Andalusia, near the Guadalquivir, five leagues from Seville.

ALCANTARA, a district of Portugal, about a league from Lisbon. On a hill in this district there is a remarkable mine of saltpetre.

ALCANTARA, one of the most considerable rivers of Sicily, rises on the north side of mount Ætna, and marks out the boundary of the mountain for about 60 miles. In many places its course has been interrupted by the eruptions of the volcano; and in others, its current, which is very rapid, has worn down the solid lava to the depth of 50 or 60 feet. Its rise is attributed to the melting of the snows on the mountain; as its waters resemble by their whitish colour those that run from the Glaciers amongst the Alps. Brydone's Tour, vol. i. p. 119.

ALCANTARA, *Order of*, an ancient military order of Spain, which took its name from the city above-mentioned. The precise year of its institution is not settled among antiquaries.

The knights of Alcantara make the same vows as those of Calatrava, and are only distinguished from them by this, that the cross fleur de lis, which they bear over a large white cloak, is of a green colour: they possess 37 commanderies.

By the terms of the surrender of Alcantara to this order, it was stipulated, that there should be a confraternity between the two orders, with the same practice and observances in both; and that the order of Alcantara should be subject to be visited by the grand-master of Calatrava. But the former soon released themselves from this engagement, on pretence that their grand-master had not been called to the election of that of Calatrava, as had been likewise stipulated in the articles.

After the expulsion of the Moors, and the taking of Granada, the sovereign of the order of Alcantara, and that of Calatrava, was settled in the town of Castile, by Ferdinand and Isabella.

In 1540, the knights of Alcantara sued for leave to marry; which was granted them.

The history of this order was chiefly taken up in expeditions against the Moors, and broils with their neighbours. See CALATRAVA.

ALCARAZ, in *Geography*, a town of Spain, in the canton of la Mancha in New Castile, situated on an eminence near the river Guardamena, in a very fertile country, defended by a strong castle, and remarkable for an ancient aqueduct. It is famous for a breed of small horses that are very fleet and strong. It is ten leagues north of the confine of Andalusia, 43 south of Cuenza, and 55 south-east of Madrid. N. lat. 38° 28'. W. long. 2° 3'.

ALCARIZ, a town of Spain, in the province of Galicia, on the river Amoya, eight miles south of Orense.

ALCARRAZAS, in *Pottery*, are a kind of vessels used in Spain for cooling water. What distinguishes them essentially from other kinds of earthen ware is their porosity: this is so considerable as to allow the liquor to ooze slowly through, and stand in small drops on the outside; hence there is a constant evaporation from their surface when immersed in a current of warm air, by which means the water remaining in the jar continues at a temperature much lower than that of the atmosphere.

These vessels appear to have been first introduced into Spain by the Saracens; and their use has since been extended into all the Spanish colonies in America and India. They have also been known from time immemorial in China, Hindostan, Persia, Arabia, Egypt, and Syria.

The most celebrated manufactory of this kind in Spain, is at Anduxar in Andalusia, the best earth for the purpose being found in the neighbourhood, on the bank of the little river Tamuforo. This is a kind of white marl, consisting principally of carbonated lime, with about 30 per cent. of silex, and a little alumine, and oxyd of iron.

The process of the manufacture is very simple, and is as follows. The fresh dug earth is first dried in the sun till it becomes pulverizable; and when beaten to powder it is passed through a fine sieve, in order to separate with accuracy all the stones and coarse sand that may be mixed with it: being then put into a wooden or copper vessel with water, it is tempered by hand to the consistence of a soft uniform paste. In this state it continues twelve hours, and is then spread upon bricks, previously covered with wood ashes, till the appearance of cracks upon its surface, owing to the draining off of part of the moisture.

This first preparation being completed, the tempered earth is weighed and put into a broad shallow vessel, where it is trodden with the naked feet, and at the same time mixed with salt, in the proportion of seven pounds for every 150 of earth, to be made into large jars, and of half the above quantity of salt for the manufacture of jugs and other small articles. The reason of this difference is obvious: the greater the vessel is, the thicker must its sides be, to give it the necessary strength; but as its porosity would be diminished in the same proportion, a greater quantity of soluble matter must be mixed with the earth. After this a sufficient mass of the material being put on a potter's wheel, it is shaped in the usual manner into a jar or other vessel; being then gradually dried, it is baked in a common pottery oven for 10 or 12 hours, according to the heat, care being taken that the salt be not so far decomposed as to become insoluble in water.

There is scarcely a house in Spain where Alcarrazas are not in constant use. Being filled with water, and exposed for a few hours to a current of air, a very small portion of the fluid is lost by evaporation, and the remainder will

have acquired a degree of coolness very grateful in that warm climate.

Estremadura possesses a manufacture of large red jars called *Bucaras*, which are applied to the same purposes as the true Alcazazas, but are much inferior, in being less porous, and communicating to the water an unpleasant earthy taste.

Another use to which these vessels are applied in Portugal, is that of moistening snuff or tobacco. For this purpose, the jar being filled with snuff is placed in water, which filtering through its sides very slowly, gives in a few hours, to the inclosed powder, the requisite humidity. *Journal des Mines*, vol. vi. p. 791.

The editor of the *Journal de Physique* is of opinion that the mixture of fossil meal with common potter's earth might afford an useful substitute both for the Alcazazas and the filtering stones. The *fossil meal* is that earth of which the floating bricks of Tuscany are made; and which, according to the testimony of Pliny and Strabo, was anciently found in great plenty, both in Asia and Spain. To the proposed use, however, of this substitute, the earthy flavour which it would communicate to the water is a radical objection.

ALCASAR, Louis de, in *Biography*, a Spanish jesuit, was born at Seville in 1551, and was at first a teacher of philosophy, and afterwards of divinity at Cordova and at Seville for above 20 years. He directed for so many years his chief attention to the study of the book of Revelation, and his work on this subject, intitled, "Vestigatio arcani sensus in Apocalypsi," is much esteemed among the Catholics, and has been printed several times. Grotius is said to have borrowed many of his ideas from this book. His works, comprehending a commentary on such parts of the Old Testament as had in his judgment any relation to the Apocalypse, and including a treatise "On Sacred Weights and Measures," and another "On bad Physicians," form two folio volumes. Heydegger in his "Mythærum Babilonis magnæ," published at Leyden in 1687, has examined some of his apocalyptic hypotheses. Alcasar died at Seville, June 16, 1613, at the age of 60 years. *Gen. Dict.*

ALCASSAR, or ALCAZAR, in *Geography*, formerly Cæsar al Cabiris, a city of Africa, on the coast of Barbary, in the kingdom of Fez. It is said to have been built by Jacob Almanzor, about the year 1180, during his war with Spain, and intended as a depot for the immense stores that were collected for this purpose. It was formerly the residence of a governor, and a town of good trade, till the Portuguese made themselves masters of it in 1458; but, though it was not long in their possession, it gradually sunk into decay, and lies now in a ruinous condition. Its situation is so low, that it is overflowed with water in the winter, and molested with heat in summer. The storks of this place are so numerous and so familiar, that they occupy the tops of the houses and mosques without molestation; the inhabitants esteeming them sacred birds, and thinking it sinful to disturb them. The bashaw of Tetuan now appoints a governor for this town, which is the last of his dominions towards Mequinez. In the vicinity of this town, there is a ridge of mountains running towards Tetuan, whose inhabitants are a band of robbers, whom it has not been possible to restrain or extirpate, as they find an inaccessible shelter in their mountainous forests. It was near this town, on the river Elma-hassan, that a famous battle was fought in 1578, when three kings were slain, viz. Abdemelech king of Morocco, Mahomet the usurper, and Sebastian king of Portugal. The Portuguese indulge a fanciful notion, that Sebastian was transported to an enchanted island, and they expect his return to establish their

power, and to render their kingdom the first on the globe. This city, N. lat. $35^{\circ} 15'$. W. long. $12^{\circ} 35'$, is called *Alcaassar quibir*, or the great castle, to distinguish it from the alcassar of the next article.

ALCASSAR Zequir, or *Ceguer*, q. d. the little palace, a town or fortress of Africa, in the kingdom of Fez, between Tangiers and Ceuta. It was taken by Alphonso king of Portugal, in 1458, but soon after abandoned to the Moors. It lies on the south-side of the straits of Gibraltar, and a shallow bay between two points of land, affords anchorage for ships, and on the west of this are two long narrow islands, parallel to the coast. N. lat. $35^{\circ} 48'$. W. long. $5^{\circ} 36'$.

ALCASSAR de Guete, a town of Spain, in New Castile, almost between Cuenza and Guete, with which it forms nearly a triangle. N. lat. $40^{\circ} 10'$. W. long. $2^{\circ} 16'$.

ALCASSAR do Sal, a town of Portugal, in Estremadura, six leagues from the sea, on the confines of Alentejo, guarded by a castle, which is said to be impregnable. The salt-work in this town yields very fine white salt, and gives it its name. Of the rushes that are gathered in the adjoining fields, mats are made for exportation. N. lat. $38^{\circ} 18'$. W. long. $9^{\circ} 10'$.

ALCATILE, a town of India in the Carnatic, west of Madras.

ALCATRASES, an island in the Pacific Ocean, about 21 leagues from Acapulco; and half a league from the continent. N. lat. $15^{\circ} 50'$. W. long. $102^{\circ} 30'$.

ALCATRAZ, in *Ornithology*, a name given by the Spaniards, also by Fernandez, Hernandez, and Nieremberg, to the PELICAN of Mexico; and erroneously by Clusius and others after him, to the Indian horn-bill, or BUCEROS-Hydro-corax.

ALCAVALA, in *Politics*, a tax upon transferrable property imposed by the Spanish government. It was at first 10, afterwards 14, and at present it is only 6 per cent. upon the sale of every sort of property, whether moveable or immovable; and it is repeated every time the property is sold. The levying of this tax requires a multitude of revenue-officers, sufficient to guard the transportation of goods, not only from one province to another, but from one shop to another. It subjects not only the dealers in some sorts of goods, but those in all sorts; every farmer, every manufacturer, every merchant and shop-keeper; to the continual visits and examinations of the tax-gatherers. Through the greater part of a country, in which a tax of this kind is established, nothing can be produced for distant sale. The produce of every part of the country must be proportioned to the consumption of the neighbourhood. It is to the Alcavala accordingly, that Ustaritz imputes the ruin of the manufactures of Spain. He might have imputed to it likewise, says a very competent judge, the declension of agriculture; as it is imposed not only upon manufactures, but upon the rude produce of the land.

In the kingdom of Naples, there is a similar tax of three per cent. upon the value of all contracts, and consequently upon that of all contracts for sale. This is both lighter than the Spanish tax, and the greater part of towns and parishes is allowed to pay a composition in lieu of it; which composition is levied in any mode they please, and generally so as to give no interruption to the interior commerce of the place. The Neapolitan tax is therefore not nearly so ruinous as the Spanish one. *Smith's Wealth of Nations*, vol. iii. p. 381.

ALCAUDEFTE, in *Geography*, a beautiful town of Spain, in the province of Andalusia and district of Cordova, between

between Cordova and Jaen. N. lat. 37° 35'. W. long. 3° 26'.

ALCAZAR, or ALCAÇAR, ANDREW, of Guadalaxara, in New Castile, in *Biography*, a celebrated physician of the 16th century, published in 1575, at Salamanca, "Chirurgia libros sex, in quibus multa antiquorum et recentiorum fubofeura loca hæcenus non declarata interpretantur," fol. In the fifth book, he treats, "De pudendagra vel inentagra vel lichenis, vulgo, morbo Gallico." He contends this disease was known to the ancients, and cites Pliny, and various other writers in proof of this position; but admits, that in certain stages of the disease, it is only to be cured by mercurial inunction. See a full account of this work, and a refutation of his opinion of the antiquity of the lues, in Astruc's treatise, *De Morbis Venereis*, vol. ii. p. 792.

ALCE, in *Ancient Geography*, a town of Peloponnesus, mentioned by Plutarch, in his life of Cleomenes. Alce is also, according to Livy, a town of Spain, belonging to the Celtiberians. It is likewise a name given by Pliny to a river of Bithynia.

ALCE, in *Ornithology*, a species of auk or ALCA.

ALCE, in *Zoology*, a species of CERVUS. See ELK.

ALCEA, HOLLYHOCK, *Malva* of Tournefort, in *Botany*, a genus of the *monadelphia polyandria* class and order, of the natural order of *columnifera*, and the *malvaceæ* of Jussieu. Its characters are, that the calyx is double, each one-leaved; the outer cut half way into six parts, permanent and very spreading; the inner cut half-way into five parts, larger and permanent; the corolla consists of five, obcordate emarginate, spreading petals, coalescing at their bases; the stamina are filaments uniting into a sort of five-angled cylinder at bottom, loose at top, and inserted into the corolla; the anthers almost kidney-shaped; the pistillum has a germ orbiculate, style cylindrical, short, stigmas about 20, setaceous, of the length of the style; the pericarpium is composed of many jointed arils, in a ring round a columnar flattened receptacle, parting and opening on the inside; the seed is one, flat, kidney shaped in each aril. Schreber and Jussieu join this genus to *Althæa*.

Professor Martyn enumerates three, and Gmelin five species; viz. 1. *A. rosea*, common hollyhock, with leaves sinuate-angular. 2. *A. fuenfisi*, with cordated, rough, crenated, angular leaves, and stem below ramose. 3. *A. acaulis*, with numerous cordated rotundo-lobated leaves, spicate flowers, and a stem thick and very small. 4. *A. coromandeliana*, with subtriangular crenated obtuse quinquenerved subtrilobe leaves, and solitary flowers. The *A. Africana* or African H. of Martyn, is described as having leaves three-lobed crenate, flowers solitary axillary, both calyxes six-parted. 5. *A. ficifolia*, fig-leaved H. with inferior palmated seven-lobed crenated leaves, the superior hastated. Linnæus doubts, whether the first and fifth species, above enumerated, are distinct, and seems to think that the last is a variety of the first. But Prof. Martyn observes, that the difference in the form of their leaves always continues. Both these sorts were cultivated by Gerard in 1597. Allione says, that the hollyhock grows wild in the county of Nice. The colour of the flowers is accidental, and the double flowers are only varieties proceeding from culture. The various colours that have been noticed are white, pale, red, deep-red, blackish-red, purple, yellow, and flesh colour. Prof. Martyn informs us, that he has seen some plants with variegated flowers, raised from seeds which were brought from China. Although these varieties of double hollyhocks are not constant, yet the greatest number of plants, produced by seeds carefully saved from the most double flowers, will arise nearly the same with

the plants from which they were taken, provided they are kept separate from single or bad coloured flowers.

The first species grows naturally in China, the fifth in Itria, and has also been brought from Madras. Linnæus refers it to Siberia. A dwarf sort, with beautiful double variegated flowers, has been for some years in great esteem, under the name of Chinese hollyhock. These plants, though natives of warm countries, are sufficiently hardy to thrive in the open air in England, and have contributed much to the ornament of gardens towards the close of summer. In large gardens, they make a fine appearance; a succession of spikes arising on the same stem for two months. The flowers on the lower part of the spike appear in July, and new flowers will be produced till the end of September. In good ground the stalks will often rise to the height of eight or nine feet, and near six feet of each will be garnished with flowers. The African hollyhock is a native of the eastern shore of Africa; and the alcea indica of Burm. ind. p. 149, agrees with this in having three-lobed crenate leaves; but differs from it in having the flowers terminating and yellow; with the inner calyx five-cleft. The hollyhocks are propagated by seeds, which should be saved from plants of the best colours and of the most double flowers, and they should be sown in a bed of light earth, about the middle of April, and covered about half an inch deep. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, at a foot distance from each other, watering them till they have taken root, and afterwards keeping them clean from weeds till October, when they should be removed to the situation where they are to remain.

ALCEA. See HIBISCUS and MALVA.

ALCEA *Floridana*. See GORDONIA.

ALCÆE, in *Entomology*, a species of *PAPILIO Plebejus*, with divaricated wings, of brown and cinereous colour, the primæ marked with points, and the posterior cinereous underneath; found in the southern parts of Russia.

ALCEDO, *king-fisher*, in *Ornithology*, a genus of the order of *Picæ*. The characters are, that the bill is three-sided, thick, straight, long and pointed; the tongue is fleshy, very short, flat and sharp, and the feet are for the most part greffory. The species enumerated by Gmelin, besides several varieties, amount to 41. These birds are dispersed over the whole globe; inhabiting chiefly the water and living upon fish, which they catch with surprising alertness and swallow whole, rejecting afterwards the undigested parts; though their wings are short, they fly swiftly; their prevailing colour is sky-blue; their nostrils are small, and generally covered. 1. *A. cristata*, *A. amboinensis cristata* of Seba, *Ispida philippensis cristata* of Brisson, vintli of Buffon, and crested king-fisher of Latham, is short tailed, sky-blue above, rufous beneath, and has its crest undulated with black. The bill is black, crest greenish, on each side of the neck is a bluish break beginning from the eye; the shoulders, the upper coverts of the wings, and the margins of the wing-feathers and tail-feathers, and the whole of the intermediate tail-feathers are violet, the chin rufous, the throat rufous, and white, the wing-feathers, brown, and the legs with the claws reddish. It is about five inches long, and found in Amboyna and the Philippine isles. The *ispida indica cristata*, or *A. cristata elegantissima picta* of Seba is a variety. 2. *A. inda*, spotted king-fisher of Edwards and Latham, is short tailed, greenish, yellow beneath, with a nebulous pectoral fascia. The bill is black, the line above and below the eyes yellow, the wings punctated with white, and the feet red. It is seven inches long, and found in Guiana. 3. *A. ispida*, *ispida* of Gesner, Ray, Olin,

Olin. Aldr. and Briff., aleyon of Gefn. and Aldr., martin-pecheur or aleyon of Buffon, king-fisher of Albin. and Will. European king-fisher of Pennant, and common king-fisher of Latham, is short-tailed, sky-blue above, fulvous below, and its stram are rufous. This bird is seven inches long and 11 broad, of a clumsy shape, the head and bill being very large, and the legs disproportionately small; the bill is two inches long, the upper mandible black, and the lower yellow; and the irides are red; but the colours of its plumage amply compensate for the inelegance of its form. The crown of the head, and the coverts of the wings are of a deep blackish green, spotted with bright azure; the scapular feathers and coverts of the tail are also of a resplendent azure; the whole underfide of the body is orange-coloured, and a broad mark of the fame paffes from the bill beyond the eyes; beyond that is a large white spot; the tail is fhort, and confifts of 12 feathers of a rich deep blue; the feet are of a reddish yellow; the three lower joints of the outmoft toe adhere to the middle toe, and the inner toe adheres to it by one joint.

The king-fisher frequents the banks of rivers, and feeds on fifh. It takes its prey fomewhat in the manner of the osprey, balancing itfelf at a certain diftance over the water for fome time, and then darting below the furface brings the prey up in its feet. When it remains fufpended in the air, in a bright day, the plumage exhibits a moft beautiful variety of the moft dazzling and brilliant colours. To this attitude the ancients refer; for Ibycus, quoted by Athenæus (Deipnof. lib. ix. p. 388.) calls thefe birds *ἀλκυονες τετυγνιπτερά*, the halcyons with expanded wings. It makes its neft in holes in the fides of the cliffs, which it fcoops to the depth of three feet, and lays from five to nine eggs, of a moft beautiful femi-transparent white. The neft is very foetid, on account of the refuse of fifh with which the young are fed. It begins to hatch its young early in the feafon; and excludes the firft brood in the beginning of April. Whilst the female is thus employed, the male is unintermitting in his attention, fupplying his mate with fifh in fuch abundance that fhe is found at this feafon plump and fat. He ceafes to twitter at this time, and enters the neft as quietly and privately as poffible. The young are hatched in about 20 days, but differ both in fize and beauty. The ancients believed that the halcyons were fo amorous, that the male died in the embrace, and Aristotle afferts (lib. ix. c. 14.) that they begin to breed when only four months old. The fpecies now defcribed is the *αλκυοναφιδος*, or mute halcyon of Arift. (Hift. An. 892. 105.) which he defcribes with a precision, to which he is not accuftomed. His defcription of the bird is followed by that of the neft; which, he fays, refembled thofe concretions that are formed by the fea-water; that it was like the long-necked gourd, hollow within and having a narrow entrance, fo that if it overfet the water could not enter; that it refifted any violence from iron, but might be broken with a blow of the hand; and that it was compofed of the bones of the *βελων*, or fea-needle. The neft was called *halcyoneum*, and medical virtues were afcribed to it. Mr. Pennant inclines to credit part at leaft of Aristotle's account, as to the form of the neft, which agrees with the defcription given of it by Count Zinanni; and as to the materials of which it is compofed, and the fragments of bones and feales of fifh that were found in it, he adds, that thofe who will not allow this to be a bird that frequents the fea fould recollect that Aristotle made his obfervations in a milder climate than our's, and yet from Zinanni we learn, that even in Italy the king-fisher breeds in May on banks of freams that are near the fea, and the ancient Stagiritæ allows, (Hift. An. 1050.) that the halcyon fometimes afcended rivers poffibly to breed. M. Buffon is of opinion,

that the halcyonia, of which Pliny, (lib. xxxii. 8.), reckons four kinds, and which fome have fuppofed to be the nefts of king-fifhers, are only clufters of fea-weeds; and with regard to the nefts of Tonquin and China, which are efteemed fuch delicacies, and have alfo been afcribed to the halcyon, they are the indifputable productions of the efculent fwallow. On the precarious foundation laid by Aristotle, very abfurd and incredible tales have been formed by fubfequent writers; and the poets, indulging the powers of imagination have added many fictions to the account of the philofopher. Accordingly the neft has been reprefented as a floating one:

“Incubat halcyone pendentibus æquore nidis.”

OVID. Met. lib. xi.

It was therefore neceffary to place it in a tranquil fea, and to fupply the bird with charms to allay the fury of a turbulent element, during the feafon of incubation. At that time it had, therefore, controul over the fea and the winds:

“X' ἀλκυονες ζῆρσι νηὶ τα κυμαλά τιντε θαλασσαί
Τον τε νόσον, τον τ' εὐρον, ἐς ἐσχολά φυκία κινεῖ.
Ἀλκυονες, γλαυκαί; Νηρηϊοὶ τὰι τε μαλίστα
Οὐρίθων ἐφίλαθεν.”—THEOCRIT. Idyll. vii. l. 57.

“May halcyons fmoother the waves, and calm the fea,
And the rough fouth-eaft fink into a breeze;
Halcyons of all the birds that haunt the main,
Moft lov'd and honour'd by the Nereid train.”

FAWKES.

Thefe birds were equally favourites with Thetis, as well as the Nereids:

“Dilectæ Thetidi Halcyones.”

VIRG. Georg. i. 399.
