## BOOK-KEEPING.

**B**OOK-KEEPING, is the art of recording mercantile transactions in a regular and systematic manner.

A merchant's books should exhibit the true state of his affairs. They should shew the particular success of each transaction, as well as the general result of the whole; and should be so arranged as to afford correct and ready information upon every subject for which they may be consulted.

Books may be kept either by single or double entry.

*Single Entry* is chiefly used in retail business; it is the most concise and simple method of book-keeping; but not the most perfect, being defective in some essential particulars.

*Double Entry* is generally used in wholesale and mercantile affairs; whence it is sometimes called *Merchants' Accounts*. This method is universally preferred in extensive commerce, being the most comprehensive and systematic in its principles, and the most certain in its conclusions. Book-keeping, as a science, is, therefore, understood to mean the method by double entry; and in this sense we shall use the term, unless when there is occasion to distinguish double from single entry.

*BOOK-KEEPING, History of.* The origin of book-keeping, like that of most other useful arts, is involved in great obscurity. It is generally supposed to have been first practised at Venice, in the fifteenth century, when that city was the grand emporium of Europe. Some authors, however, think that double entry was known to the ancients, and revived only in Italy, with the revival of commerce; and certain quotations are adduced in support of this opinion. Thus Pliny, in speaking of fortune, says, "Huic omnia expensa; huic omnia feruntur accepta; et in tota ratione mortalium sola utramque paginam facit," lib. ii. cap. 7.

Similar passages may be likewise quoted from others, which shew, that the ancients entered the receipts and pay-

ments of money on opposite pages, in the way of debtor and creditor; but nothing beyond single entry can be inferred from this practice; nor is it probable that any thing more was wanted in the rude and simple state of ancient commerce. Insurances, bills of exchange, and other modern improvements required, and, in all probability, produced corresponding improvements in the mode of keeping accounts; but the circumstance which places the question in the clearest light is, that the terms of this art cannot be traced to any ancient language, but seem immediately derived from the Italian, as adopted in the other languages of Europe. When Snellius translated Stevin's book-keeping into Latin, he was obliged to invent or adopt new terms. Thus he calls book-keeping, *apologistica*; the ledger, *codex accepti expensive*; the waste-book, *liber deletitius*; the stock account, *fors*; and the balance-account, *epilogismus*.

From the principles of book-keeping, conjectures may be formed of its origin. The double purpose of a bill of exchange, and the manner of recording the same, might have naturally suggested the idea of double entry. The principle might have been even deduced from the axioms of Euclid, or the properties of an algebraic equation; and it is remarkable that the first European author on algebra, Lucas de Burgo, wrote the first treatise on book-keeping, which is thus described by de la Porte. "Vers l'an. 1495, Frère Luc Italien de nation, en fit imprimer un traité en Italien (c'est le plus ancien auteur que j'aie vu sur cette matière), il fut suivi par plusieurs auteurs du même Pays, & par des François, qui au commencement du siècle suivant nous en ont donné des Méthodes imprimées. Mais l'ordre embarrassant, & le style long & embrouillé de ces ouvrages comparés à la netteté & à la brièveté qui sont en usage aujourd'hui, font voir combien l'expérience a poli & abrégé cette Science." La Science des Négocians et Teneurs de Livres, par M. De la Porte, p. 12. Paris, 1753.

La Porte's remarks on the want of method and arrangement in the old systems of book-keeping, will, in some measure, apply to his own, though it still continues a favourite work in France. We shall, however, take no further notice here of foreign publications, but confine our observations to those of our own country, where every subject connected with commerce seems to have been cultivated with the greatest assiduity and success.

The first treatise on book-keeping, in the English language, of which there is any account, was published in the year 1543 by Hugh Oldecastle, a schoolmaster; and it was reprinted, in 1588, by John Mellis, under the following curious title: "A briefe instruction and maner how to keepe bookes of accompts, after the order of debitor and creditor, and as well for proper accompts, partible, &c. by three bookes, named the memoriall, journall, and leager. Newly augmented and set forth by John Mellis, schole-maister of London. Imprinted by him at the Signe of the White Beare, nigh Baynard's Castle, 1588, 12mo." In his Epistle to the Reader, Mellis says, "And knowe ye for certain, that I presume ne vnrpse not to set forth this worke of mine own labour and indullrie, for truly I am but the reneuer and reuiner of an auncient old copie printed here in London the 14th of August 1543." See Ames's *Typographical Antiquities*, vol. ii. p. 753.

In 1569, a system of book-keeping was published in London by James Peelle, who says, in his preface, "that he had instructed many mercantile people in this art, which had been long practised in other countries, though then new in England."

There is no trace of any other work of the kind until the year 1652, when John Collins, an eminent mathematician and accountant, published a large work, entitled, "An Introduction to Merchants' Accounts," which served long as a standard book on the subject.

About the beginning of the following century, several smaller systems were written, chiefly by Snell, Hatton, Malcolm, Webster, Miers, and Stevens; but the most popular work that had yet appeared, was Mair's "Book-keeping methodized," published in 1738, which, after passing through three editions, was re-printed, with alterations, in 1768, under the new title of "Book-keeping modernized;" and these alterations, he says, became necessary, "in consequence of the constant change and perpetual flux in the forms and fashions of accountship." But it may be observed, that if this edition was modelled after the real practice of that time, the forms and arrangements of merchants' accounts must have since undergone great changes, and manifest improvements. In Mair's book-keeping, however, the principles of double entry are correctly explained; but the rules and examples are too numerous and verbose for school practice.

From the first appearance of this work, to the year 1789, numerous other systems were published, better adapted to the purposes of teaching the art, though differing but little in arrangement. The most generally approved were those of Dodson, Weston, Donn, Hutton, Hamilton, Gordon, Dowling, and Jackson. Treats were also written, within the above period, by Crosby, London, Shortland, Wood, Cooke, Sedger, and Dilworth.

On a review of the foregoing publications, it does not appear that the theory of book-keeping had hitherto kept pace with the improvements of practice. While merchants were constantly adopting plans of arrangement, which promoted perspicuity and correctness, and diminished the labour of the counting-house; schoolmasters, the chief authors on book-keeping, seemed only to consult or imitate each

other's works, which had been long considered by men of business as obsolete or impracticable.

A work of a very different description was published in 1789, by Benjamin Booth, a merchant, who thus observes in his preface: "It is surprising that in a commercial country like this, there should not be a treatise on the subject (book-keeping), which, when applied to a large scale of business, can be reduced to practice. Those I have seen, appear to have been written by persons who had not abilities sufficient for the undertaking, or by such as never had an opportunity of bringing their theories to the test of experience." This elaborate work, which is evidently the result of experience, contains various examples of judicious arrangement; but it is not elementary, having only a journal and ledger.

Some smaller publications followed, which deserve commendation, particularly those of Mr. Wicks and Mr. Shires. The latter work is stated to be the result of thirty years' experience. It exhibits much neatness and ingenuity in the arrangement; but, like Booth's *Book-keeping*, it contains only a journal and ledger.

In tracing the progress of Italian book-keeping, something should be said of a rival method, entitled the "English Book-keeping," published by Mr. Jones in 1796, a work chiefly remarkable for the enormous subscription raised on the occasion. A prospectus of this performance was previously circulated, announcing the discovery of an infallible method of book-keeping by single entry, and at the same time representing the Italian method as delusive and erroneous. By high promises and accredited recommendations, subscriptions (at a guinea each) are said to have been obtained, to the amount of six or seven thousand pounds. The work, however, did not answer the expectations of the public. Several ingenious tracts soon appeared, defending double entry, and exposing the insufficiency of this new system; and one of peculiar merit, written by Mr. Mill, closed the controversy. This gentleman, in order to form a comparative estimate between the English and Italian methods, arranged Mr. Jones's materials into a journal and ledger, by double entry; and, in the course of the operation, detected an essential error;—a detection which completed the triumph of double entry.

The English system of book-keeping, though universally rejected, has proved useful to the public as well as to the author. It gave rise to much investigation on the subject; and the extraordinary eagerness manifested in the subscription, shewed that men of business wished for a more practical system of merchants' accounts than had been hitherto offered to their notice.

In 1801, Mr. Kelly published a work, entitled "The Elements of Book-keeping," which appears to have met with very general approbation, and from which the present article is, by permission, extracted. The subsequent editions of this publication have been considerably enlarged by tracts on exchange, banking, and other commercial subjects; but its principal object (as stated in the preface) is to explain and illustrate the modern improvements of merchants' accounts. Of what these improvements consist, may be known from the following account of the work, given in *Nicholson's Philosophical Journal*, Feb. 1802.

"The improvements, which time and experience have effected in book-keeping, do not comprehend any change in the original principle of double entry, but in the arrangement and classification of similar accounts, which facilitate the operations of commerce nearly in the same manner that the business of manufactures is expedited by the division of labour. The elementary treatise before us (Kelly's *Book-keeping*)

# BOOK-KEEPING.

ing) exhibits these improvements. Here the waste book is divided into a number of subsidiary books, each of which is the register of its peculiar portion or department of business; and each book is divided into monthly transactions. By these means the journal is greatly shortened and simplified; but the principal advantage of such arrangement consists in posting the books; for here a whole month's cash, bills, commission, insurance, and interest, are each carried in one sum, or entry, from the journal to the ledger. This method, by which repetitions are avoided, and labour considerably diminished, is now generally adopted in our principal mercantile houses."

## PRINCIPLES OF BOOK-KEEPING BOTH BY SINGLE AND DOUBLE ENTRY.

**SINGLE ENTRY** chiefly records transactions on credit, and for this purpose two books are required, called the *Day Book* and the *Ledger*.

The *day book* begins with an account of the owner's property, debts, &c.; then follows a detail of the occurrences of trade, set down in the order of time in which they take place.

The name of the person, or customer, is first written with the term *Dr.* or *Cr.* annexed, according as he becomes debtor or creditor by the transaction; and this may be distinguished by the following general rule:

"The person who receives is *Dr.* and the person who gives or parts with any thing is *Cr.*"

Thus, if I sell goods on credit, I enter A. B. the buyer, *Dr.* to the goods, specifying their quantity and value.

If I buy goods on credit, I enter C. D. the seller, *Cr.* by the goods, specifying their quantity and value.

By the same rule, if I pay money, the person to whom I pay it is made *Dr.* to cash for the amount; and if I receive money, the person from whom I receive it, is made *Cr.* by cash, for the amount.

And if debts be contracted or discharged by any other means, the same rule is observed; the person, who becomes indebted to me, is entered *Dr.* and the person to whom I become indebted, *Cr.*—Also, the person whose debt I discharge is made *Dr.*; and he that discharges a debt due by me, is *Cr.*

The *ledger* collects together the dispersed accounts of each person in the day book, and places the *Drs.* and *Cr.* upon opposite pages of the same folio. The person's name is written in large characters as a title: on the left hand, or first page, he is styled *Dr.*; and on the opposite, or right hand page, *Cr.* On these pages the transactions are en-

tered as they stand *Drs.* or *Cr.* in the day-book. For instance, A. B. is debited for whatever he has bought of me; and on the opposite page, he is credited for the payments he has made. In short, whatever I have given him, is on the *Dr.* side, and what he has given me on the *Cr.*; and the difference between the *Dr.* and *Cr.* sides is called the "balance."

### *A short Specimen of Single Entry.*

January 1, 1805.

Suppose John Smith owes me 100*l.* which is my sole property, or the net of my estate; and suppose that on the 2d of January, I buy of him 80 yards of cloth, at 15*s.* per yard; on the 3d, I sell James Taylor, on credit, 60 yards of the said cloth at 18*s.* 4d. per yard; and on the 4th, James Taylor pays me in part 40*l.* Required the day book and ledger of the foregoing transactions, according to single entry, and also the profit or loss.

#### *Day Book.*

Folio of Ledger.	—Jan. 1, 1805.—	£.	s.	d.
	John Smith, <i>Dr.</i>			
	To Balance from Ledger A -	100	0	0
	2.			
	John Smith, <i>Cr.</i>			
	By Cloth for 80 yards, at 15 <i>s.</i> per yd.	60	0	0
	3.			
	James Taylor, <i>Dr.</i>			
	To Cloth for 60 yds, at 18 <i>s.</i> 4d. per yd.	55	0	0
	4.			
	James Taylor, <i>Cr.</i>			
	By Cash received in part - -	40	0	0

#### *To post the foregoing Accounts into the Ledger.*

The ledger being ruled in folio form, according to the following specimen, with the left side for *Dr.* and the right side for *Cr.* also a margin for the date, and near the money columns, one for reference to the day book, proceed as follows:

Open an account for John Smith, and debit him, on the left hand page, for 100*l.*; and for the 2d day's transaction, credit him for 60*l.* on the opposite page.

For the 3d day, open an account for James Taylor, debiting him for 55*l.*; and for the 4th day, credit him for 40*l.*

When every transaction is thus posted, each account is balanced, by subtracting the less sum or side from the greater, and then putting the difference or balance under the smaller side, by which both sums are made equal.

## LEDGER BY SINGLE ENTRY.

		Page of Day Book	£.	s.	d.		Page of Day Book	£.	s.	d.
Jan. 1.	JOHN SMITH <i>Dr.</i>					Jan. 2.	CONTRA. <i>Cr.</i>			
	To Account from Ledger A -		100	0	0		By Cloth for 80 yards, at 15 <i>s.</i> per yd.	60	0	0
							By Balance - - - -	40	0	0
								100	0	0
Jan. 3.	JAMES TAYLOR <i>Dr.</i>					Jan. 4.	CONTRA. <i>Cr.</i>			
	To Cloth for 60 yards, at 18 <i>s.</i> 4d. } per yard - - - - }		55	0	0		By Cash received in part - - -	40	0	0
							By Balance - - - -	15	0	0
								55	0	0

By the above ledger it appears that the balances are in my favour; and if these be added to the cash I have in hand, and the value of the goods unsold, the sum is the net of my

estate; which, compared with my original stock, shews my profit or loss. Thus it appears that

# BOOK-KEEPING.

John Smith owes me - - -	£. 40
James Taylor owes me - - -	15
I have in Cash - - - - -	40
I have unfold 20 yards of cloth,	} 15
at 15s. per yard (the prime cell)	
110 The net of my estate.	
100 Stock beginning.	
£. 10 gain.	

Hence I have cleared 10l. by the sale of 60 yards of cloth at a profit of 3s. 4d. per yard.

### Remarks on single Entry.

By single Entry I cannot tell what goods are unfold, or my profits or losses by my books only, except when the transactions are but few, as in the foregoing examples. For as the ledger here contains only the accounts of persons dealing on credit, it affords no other knowledge to the owner, than what debts are due to him, and what he owes.

But if he wish to know what goods are undisposed of, and what he has gained or lost by the whole or any part of his dealings, he cannot obtain this knowledge by single entry, without "taking stock;" that is, he must weigh or measure what goods he has unfold; and their value, added to the cash in hand, and the balance of debts, will shew the net of his estate, and this, compared with his original stock, will shew his profit or loss.

Hence book-keeping by single entry is essentially defective, as it affords no method of ascertaining the state of a merchant's affairs, without taking stock; a task which is both laborious and liable to error, and which at best affords no adequate means of preventing embezzlement or detecting fraud; but these objects are attained by double entry, perhaps as effectually as human ingenuity can devise.

### DOUBLE ENTRY.

In double entry, three principal books are required; the *waste book*, *journal*, and *ledger*.

The *waste book* gives a regular detail of the transactions of business, set down in the order of time in which they take place, and stated in a clear, simple, and circumstantial manner.

The *journal* records the same transactions as the *waste book*, but they are differently expressed; for here, the *Dr.* and *Cr.* of the various accounts are ascertained, in order to transfer them with more ease to the ledger.

The manner of ascertaining the *Dr.* and *Cr.* of each transaction here is the same, in effect, as in single entry; but in double entry, things, as well as persons, are made *Dr.* and *Cr.*; and one thing or person is made *Dr.* to another thing or person.

Thus, if I sell cloth to A. B. on credit, I enter it in the journal, A. B. *Dr.* to Cloth. If I buy cloth of C. D. on credit, I journalize it, Cloth *Dr.* to C. D.; and if I buy or sell for ready money, or barter one kind of goods for another, the following general rule must be observed:

"What I receive is *Dr.* to what I give or part with."

For instance, if I buy cloth for ready money, the journal entry is "Cloth *Dr.* to Cash;" and if I sell it for ready money, "Cash *Dr.* to Cloth;" always specifying the quantity, price, and amount.

When two or more persons or things are included in the same account, they are expressed by the term "Sundries," or "Sundry Accounts;" thus, if I sell cloth for part money, and the rest on credit, I journalize it, "Sundries *Dr.* to Cloth;" and then specify the particulars.

The following rules for distinguishing *Dr.* and *Cr.* will apply in all cases:

The person to whom, or for whose account I pay, or furnish the means of payment, is *debtor*.

The person from whom, or for whose account, I receive, or who furnishes me with the means of payment, is *creditor*.

Every thing which comes into my possession, or under my direction, is *debtor*.

Every thing which passes out of my possession, or from under my direction, is *creditor*.

The word *inoc* is sometimes used to assist the memory as being composed of the initials of the rule—*In Debtor, Out Creditor*.

The following lines may likewise assist the memory in journalizing:

By journal laws, what I receive,  
Is debtor made to what I give;  
Stock for my debts must debtor be,  
And creditor by property;  
Profit and loss accounts are plain,  
I *debit* loss, and *credit* gain.

The *ledger* collects the scattered items, articles, or transactions, from the journal, and places them under their respective heads, opposing the *Dr.* and *Cr.* of each, on the same principle as in single entry; but here accounts are opened for goods as well as for persons, and every account is entered twice, whence this method is called "double entry."

The accounts of the ledger are distinguished into three kinds, personal, real, and fictitious.

Personal accounts are the same in double as in single entry; and every person is debited or credited as he stands *Dr.* or *Cr.* in the journal.

Hence every personal account, suppose that of A. B., contains on the *Dr.* side all items or articles, by which he becomes indebted to me, and on the *Cr.* side all items or articles, by which I become indebted to him:

Real accounts are those opened for merchandize, or any other species of property, such as cash, bills, ships, houses, &c. Here, as in all other accounts, each transaction is entered on the *Dr.* or *Cr.* side, as it stands in the journal. Thus, goods bought are entered on the *Dr.* side; and when these or any part of them are sold, they are entered on the *Cr.* side; by which the quantity on hand, and the profit or loss on each article may be, at any time, ascertained.

Fictitious accounts are those of stock, and profit and loss.

Stock is a term used to represent the name of the merchant or owner of the books. On the *Dr.* side is entered the amount of the debts which he owed when the books were opened; and on the *Cr.* the amount of the cash, goods, debts, and any other property then belonging to him. The difference between the *Dr.* and *Cr.* sides shews his net stock, at that time.

Profit and loss is a general term used for either gain or loss, such as may arise from trade, interest, commission, &c. On the *Dr.* side are entered all transactions of losses; and on the *Cr.* side those of gain—the difference shews the net gain or loss.

### A short Example of Double Entry.

		Received of him on account - - -	40	0	0

### Rules for posting the Journal into the Ledger.

The ledger being ruled with the *Dr.* side to the left, and the *Cr.* side to the right, (as before described) let there be a space allotted to the left of each page, for the day of the month, and to the right, for the page of the journal from whence each account is taken.

The accounts are mofly opened in the ledger, accord-

ing to the order in which they stand in the journal; this is not, however, essential to the truth of the work, but it is the most regular method, and the most clear to learners. The stock account stands first, and, like all other accounts, is debited, or credited as journalized.

Here stock is *Cr.* by John Smith; then, for the second entry, John Smith is *Dr.* to stock, for every *Dr.* must have a *Cr.* and every *Cr.* a *Dr.*

By the same rule the other accounts are entered twice in the ledger; first, in the direct way, as they stand in the journal, and then reversed. Thus, the second day's account is posted, Cloth *Dr.* to John Smith, and then John Smith *Cr.* by Cloth.

In the same manner the third and fourth day's accounts are posted; James Taylor is debited to Cloth, and Cloth credited by James Taylor; Cash is next made *Dr.* to James Taylor, and James Taylor *Cr.* by Cash.

Here it may be observed that, when an account is once opened in the ledger, every following transaction which concerns it, must be brought back, and entered there on the proper side, as an account is never opened twice, though it may be transferred for want of room.

# BOOK-KEEPING.

## *To make a trial balance.*

When every account is posted twice from the journal into the ledger, and on opposite, or contrary, sides, it is evident that all the sums on the *Dr.* side will equal all those on the *Cr.* side.

This trial, or check, is generally made on a separate paper, and it may be performed every day, month, or year, according to the extent of the business. The titles of the ledger accounts are written under each other with *Dr.* to the left, and *Cr.* to the right. Annexed to each, on its proper side, is set down the sum of every *Dr.* and *Cr.*; and both sides will agree if the work be right: as in the following example, from the preceding ledger.

### *Trial balance.*

<i>Dr.</i>				<i>Cr.</i>		
<i>£.</i>	<i>s.</i>	<i>d.</i>		<i>£.</i>	<i>s.</i>	<i>d.</i>
0	0	0	Stock - - - - -	100	0	0
100	0	0	John Smith - - - - -	60	0	0
60	0	0	Cloth - - - - -	55	0	0
55	0	0	James Taylor - - - - -	40	0	0
40	0	0	Cash - - - - -	0	0	0
255	0	0		255	0	0

## *To make the general balance, and close the ledger.*

The journal being all correctly posted, an account must be opened for profit and loss, and another for balance. These two accounts, with that of stock, are not to be closed until the others are balanced.

Proceed, therefore, to the second account, where the difference between the *Dr.* and *Cr.* sides appears to be 40*l.*; set this sum under the smaller side, making both equal.

This balance or difference being on the *Cr.* side, John Smith's account is therefore credited by balance, and on the balance sheet it is entered on the *Dr.* side: for if John Smith be *Cr.* by balance, then is balance *Dr.* to John Smith.

By this simple method all personal accounts are closed; but in real accounts a double operation is necessary, when any of the goods remain unfold, as these must be first balanced.

Thus, in the cloth account, the quantities on the *Dr.* and *Cr.* sides must be compared, and their difference set down under the smaller quantity, making both sides equal.

Here the difference is 20 yards, which, at first cost, is worth 15*l.*; this sum must be entered on the *Cr.* side of the cloth account, and then on the *Dr.* side of the balance account, thus making cloth *Cr.* by balance, and balance *Dr.* to cloth.

When the goods on the *Dr.* and *Cr.* sides are balanced, the money columns must be next compared, and their difference shews the profit or loss upon the article. In the cloth account the *Cr.* side is 10*l.* more than the *Dr.*; hence cloth is made *Dr.* to profit and loss for that sum; and profit and loss *Cr.* by cloth for the same.

James Taylor's account, and the account of cash being next balanced, proceed to prove the work.

## *The proof of book-keeping.*

The accounts being all balanced, except those of stock, profit and loss, and balance, let the profit and loss account be first closed. Here profit and loss is *Dr.* to stock for 10*l.* gained, and therefore stock is made *Cr.* by the same.

The stock account must be next closed, where the balance appears to be 110*l.* Hence stock is made *Dr.* to balance for this sum, and the balance account must therefore be made *Cr.* by stock for the same.

Now if the work be right, both sides of the balance ac-

count will be equal; which is the proof of book-keeping, and which proof necessarily arises from double-entry.

The reason of this proof will also appear obvious from the following considerations:

The balance account contains on the *Dr.* side what goods I have unfold, what cash I have in hand, and what debts are due to me:

And on the *Cr.* side it contains what debts I owe. Therefore the difference between the *Dr.* and *Cr.* side of the balance account is the net of my estate.

Now there is another method of finding the net of my estate, which is, by adding my profits or subtracting my losses from my original stock; and when this sum is put on the *Cr.* side of the balance account, it will make both sides equal, if the books be correct.

This principle, or proof of book-keeping by double entry may be thus mathematically demonstrated:

- Let  $S$  = the net stock at opening the books.
- $p$  = the gain or loss at closing the books.
- $D$  = the *Dr.* side of the balance account.
- $C$  = the *Cr.* side of the balance account.

Then  $S \pm p = N$  = the net stock at closing the books, and  $D - C$  = the net stock at closing the books.

Hence (per. Ax. 1. Euclid)  $D - C = N$ , and therefore  $D = N + C$  which was to be proved; that is, the *Dr.* side of the balance account should equal the *Cr.* side, added to the net stock.

Hence the proof of book-keeping may be considered as consisting of two methods of ascertaining my property, and these must always agree if the work be right. If they differ, the books are certainly wrong.

The converse of this rule, however, does not hold; for the balance account may close when the work is wrong—a false statement, for instance, continued on both sides of the ledger, will not prevent the proof; but there is scarcely a probability that such an error could be continued unobserved; and even intentional mis-statements may be prevented by a “check ledger;” that is, by having two ledgers kept by different persons. The general practice is to examine the books frequently, which is done by one person reading the journal, while another inspects the ledger, in order to see that every account has been regularly posted by double entry. It also promotes accuracy, to have the books regularly written up, so as to make the journal keep pace with the waste book, and the ledger with the journal.

## *The following Set of Books exhibits the modern improvements of Merchants' Accounts.*

This system of book-keeping is performed on the principles of double entry, like the foregoing, with a waste book, journal, and ledger, but it differs in arrangement; for here the waste book is divided into a certain number of subsidiary books, each adapted to a particular kind of business: these are, the CASH BOOK, BILL BOOK, INVOICE BOOK, and SALES BOOK.

The *cash book* is the waste book for all money paid or received.

The *bill book* is the waste book for all bills of exchange received or accepted.

The *invoice book* is the waste book for all goods exported or sent off, whether on commission, or on the merchant's own account.

The *sales book*, or account of sales book, is the waste book for all goods imported and sold on commission.

The *waste book* contains the particulars of such occurrences as cannot be brought under any of the foregoing heads, and it also gives a general account of every transaction,

# BOOK-KEEPING.

tion, with a reference to the subsidiary book, where the particulars are to be found.

In the subsidiary books each month's occurrences are classed together, and so disposed as greatly to simplify the journal; but the principal advantage of this arrangement consists in carrying a whole month's cash, or bills, in one line to the ledger: and the same may be done with a month's commission, interest, insurance, &c. though the practice is not yet become so general. Specimens of both methods are here given.

Besides these advantages of simplicity and conciseness, the subsidiary books have other important uses as originals. Every exporter and importer of goods upon commission, must have an invoice and sales book, and the cash and bill books are necessary in all departments of commerce.

Where subsidiary books are kept for every kind of business, a waste book like the following may be dispensed with: though such will be found highly useful, both as an index and day book. But, in teaching, a book of this kind is essentially necessary, not only as connecting the other books, and giving a ready reference to each, but as affording a regular history of the business, which the learner should always understand.—It is perhaps the want of this knowledge that renders the theory of book-keeping so much more obscure and perplexing than the practice.

## THE WASTE OR DAY BOOK.

This book opens with an inventory of the merchant's property, (supposed to be transcribed from the balance account of a former ledger,) after which, a general register or diary is given of all transactions, in the order of time in which they happened, with a reference to the subsidiary books, where such are regularly entered.—The following are the references:

# BOOK-KEEPING.

## SUBSIDIARY BOOKS;

*Comprehending the Bill Book, Invoice Book, Sales Book, and Cash Book.*

### THE BILL BOOK.

The bill book is an index or register of bills of exchange, whether receivable or payable.

Bills receivable are those which the merchant receives in payment of some debt or contract—and bills payable are such as are drawn upon him, and which he must pay when due.

When Bills receivable come to hand, their particulars are entered in their respective columns of the bill book; and the particulars of bills payable are likewise inserted in their proper columns, when advice is received of their having been drawn, or when they are left for acceptance.

The use of the bill book will be understood by observing how the two following bills are entered.

*Copy of the bill, received from Charles Le Coin, and entered in bills receivable.*

Liv. fol. d.  
2385 11 a 25 $\frac{1}{2}$ .

Paris, Dec. 9th, 1801.

Two months after sight pay to the order of Mr. W. Bing, two thousand three hundred and eighty-five livres eleven fols Tournois, exchange a 25 $\frac{1}{2}$  p ecu. for value received.

Mr. John Carr,  
London.

*Accepted* Jan. 1802.  
*J. Carr.*

H. JONES.

*Copy of the bill drawn on me by George Holland, and entered in Bills payable.*

£. 400 0 0

London, Jan. 2, 1805.

Thirty-one days after date, pay to Mr. George Binns, or order, four hundred pounds for value received.

To Mr. A. B.  
London.

*Accepted,*  
*A. B.*

GEORGE HOLLAND.

### INVOICE BOOK.

An Invoice is a paper sent off with Goods exported on commission. The preamble generally contains the name of the ship, master, place of destination, and of the person to whom the consignment is made.

An account is next given of the quantity and amount of the goods, which are generally charged at the *bona fide* prime cost. The tradesmen's Bills of parcels are either copied or sent with the invoices, and referred to.

The shipping charges are added to the value of the goods, and upon this sum the agent or factor generally charges his commission. When he insures the goods, he has also a small commission on the capital insured, which capital is allowed to be something more than the value of the risk, in order to cover the amount of the risk, premium, and other expences, in case of loss.

The cost of insurance generally concludes the invoice, and the agent signs his name at the bottom with the words, errors excepted; this signature, however, does not appear in the book.

The invoice book, which contains the copies of all invoices sent off, is sometimes called the invoice book outward, to distinguish it from the invoice book inward, which contains copies of invoices received from abroad. But this book is often dispensed with, by preserving the originals, either filed, or in pigeon-holes, or pasted in a blank book made for the purpose.

Invoices of goods received to be sold on commission, are generally copied into the sales book, to which the charges are added.

The following invoice is here deemed a sufficient specimen, and those referred to in the waste book may be understood as arranged in the same manner.

## THE SALES BOOK, OR FACTORY BOOK.

This book is used to trace the net proceeds of any cargo or consignment sold upon commission.

An account sales generally occupies two pages, with a preamble over both, setting forth the names of the goods, ship, and person, from whom the consignment is received. The first, or left-hand page, contains an account of the various charges incurred by the transaction, such as freight, custom, expences of landing and selling, together with the brokerage, and factor's commission, both of which are charged on the gross amount of the Sales. Commission is sometimes charged on money advanced for duty, together with the gross amount of the consignment; and some factors likewise charge interest on all advances.

The second, or right-hand page, contains an account of the quantity, price, and amount of the goods sold, with the buyer's name, and the time of payment. The difference between this gross amount, and the charges, is the net proceeds: for which the factor gives his correspondent credit, and sends him a copy of the account sales, to which he generally signs his name, with the words *Errors excepted*.

In small consignments, an account sales may be comprised in one page, beginning either with the charges, or with the amount of the goods. The forms of these accounts are various, but all tend to the same object, that of ascertaining the net proceeds.

## JOURNAL.

The journal opens with the inventory of stock; after which the subsidiary books are journalized separately, according to the following rules, and then such transactions of the waste book as are not contained in any of the subsidiary books, close the journal for the month.

### *Rules for journalizing the Subsidiary Books.*

#### 1. To journalize the cash book.

For all money received, "Cash *Dr.* to Sundries;" for all money paid, "Sundries *Drs.* to Cash;" specifying particulars, and classing items of the same kind together. See p. 1. and 2. journal.

#### 2. To journalize the bill book.

For all bills received, "Bills receivable *Dr.* to Sundries;" for all bills accepted, "Sundries *Drs.* to Bills payable;" setting forth names, numbers, and other necessary particulars. See p. 2. journal.

#### 3. To journalize the invoice book.

The person, for whose account the invoice is sent, "*Dr.* to Sundries," viz.

"To Merchandize," for amount of goods.

"To Charges on Merchandize," for shipping, and other charges.

"To Commission," for the factor's commission.

"To Insurance," for premium of insurance. See p. 3. journal.

When several invoices are sent by the same ship, they may be arranged in columns, as in p. 5. journal; a method which promotes both accuracy and dispatch, and which might be

also used with the invoice book in general, and with the sales book.

#### 4. To journalize the sales book.

The person, to whom the goods are sold, is debited for the sales; and if they are sold for ready money, the account is entered accordingly in the cash book. Then,

"Sales (p. the ship's name, &c.) *Dr.* to Sundries."

"To Charges on Merchandize," for charges at landing, &c.

"To Interest," for interest, if charged on money advanced.

"To Commission," for the factor's commission.

"To A. B. (the configner)," for net proceeds. See p. 4. and 6. journal.

The above titles vary in different houses; as "Sales of Cotton, Sugar, &c. per the ship, *Dr.*;" "Merchandize imported, *Dr.*;" and the charges on sales and invoices, viz. "Freight," "Convoy," "Duty," and "Customs," are mostly arranged under separate heads. But, however these modes and terms may vary, the principles and result are the same.

*Note.* The pages of the different books are put in parentheses in the corners; and in the ledger the page of the journal, where the article is to be found, is inserted in a column next to the date; and the reference next to the money column shews the folio of the ledger where the second entry is made: but here there can be no figure for "Sundries," as the sundry accounts may occupy different folios; this is an inconvenience which can be only remedied by turning to the journal, where the sundries are specified, and where the folio of each ledger account is marked in the margin.

# BOOK-KEEPING.

(6)		JOURNAL, Jan. 1805.	
Date.	Fol. Ledg.		
31	8	SALES of the Nancy Dr. to Sundries.	
23	3	To Charges on Merchandise	196 11 9
	3	To Commission	8 18 9
	8	To Interest	2 5 2
31	4	To Millman and Son, for net proceeds of 10 pipes of port, as S. B.	149 17 3
			357 12 11

those six invoices been journalized separately, there must have been twenty-four entries in the journal, and the same number in the ledger, which, by this method, are comprised in four.

### 4. To post the journal of the sales book.

Debit the person or persons to whom the consignment is sold—to sales (of the ship's name) for the amount,—and Credit charges, commission, interest, and the configner—by sales for the sums annexed to these titles respectively.

Some merchants open also a general account of sales, to which they transfer the amount of Dr. and Cr. sides of the factory book.

When the other articles of the journal are posted, a trial balance should take place. This useful check may be applied either monthly, weekly, or daily, according to the extent of the business.

In making the general balance, the residue of funded property, houses, lands, furniture, ships, or goods unsold, is set down at the first cost; but in real business, it is more correct and satisfactory to enter such balances at their actual value, and to debit or credit profit and loss for the difference between their present worth and prime cost. Such a valuation becomes necessary, when any change takes place in the firm of a house, or in the terms of copartnership; and in order, at any time, to make a true estimate of profit and loss, interest should be charged on all property as well as on debts.

Partnership accounts are made very obscure and perplexing in most old systems of book-keeping, though in real business no such difficulty occurs. The general practice is to keep the books of a joint concern as if they belonged to one person only:—to open a separate account for each partner like that of any other individual, and on closing the books to divide the profits and losses according to the terms of copartnerships.

### LEDGER.

The rules already laid down in the introductory part will apply in all cases that can occur for posting the journal into the ledger: some further explanations, however, may be here useful with respect to new forms and arrangements.

In the following ledger the accounts are arranged in the same order as in the journal, except in folios 2, 3, and 4, where articles, which are often referred to at the same time, are contiguously placed, to save the trouble of frequently turning to the index. This method of classing accounts of the same description is found very convenient in extensive business; but in the theory of book-keeping it is more obvious and regular to follow the order of the journal.

When all the accounts are opened in the ledger from the inventory of stock, let the subsidiary books in the journal, for each month, be posted in the following manner:

#### 1. To post the journal of the cash book.

Debit the cash account—to sundries, for the amount received.

Credit the cash account—by sundries, for the amount paid.

Then, for the second or double entry.

Credit each account separately—by cash, for the respective sums received.

Debit each account separately—to cash, for the respective sums paid.

#### 2. To post the journal of the bill book.

Debit bills receivable—to sundries, for their whole amount.

Credit each person from whom they have been received—by bills receivable for their respective amounts.—Again,

Credit bills payable—by sundries, for their whole amount.

Debit each person for whom they have been accepted—to bills payable, for their respective amounts.

#### 3. To post the journal of the invoice book.

Debit the person to whom the invoice is sent—to sundries, for the whole amount.

Credit merchandize, charges, commission, and insurance respectively—by the said person, for the respective sums annexed to these terms.

When several invoices are journalized together in columns, (as in page 5 of the journal,) the whole amounts of merchandize, charges, commission, and insurance, are each posted in one entry. This arrangement not only saves labour and repetition in the journal, and affords checks against error, but it also greatly shortens and simplifies the ledger. Had

### Remarks on the Ledger and Subsidiary Books.

As interest should be charged in the ledger upon every article, or debt, from the time it becomes due to the period of settlement, the operation ought to take place before the general balance, and the difference between the interest of the *Dr.* and *Cr.* sides of each account of the ledger should be carried back to the journal, making "Sundries *Dr.* to Interest" for the balance in favour of stock, and "Interest *Dr.* to Sundries" for the balances on the other side. These entries should then be posted to their respective accounts in the ledger; and it is common, at the same time, to insert postage of letters, and other small charges on merchandize.

The manner of inserting the balance, and profit and loss accounts, in the ledger, varies in different counting-houses. In some they are placed as in the foregoing specimen: in others, the particulars of those accounts are inserted at the end of the journal, and the sum total only of each transferred to its proper place in the ledger; a method that is found very convenient in extensive business, where accounts in the ledger may be thus closed as the goods are sold off, which greatly diminishes the labour of the general balance.

Besides the subsidiary books already explained, there are various others peculiar to certain kinds of business; such as *Books of Insurance*, and *Shipping Accounts*. There are also several, the titles of which are sufficiently explanatory of their uses; such as the *Order Book*, *Letter Book*, *Petty Cash Book*, *Diary*, and *Debiture Book*. In some houses, a *Stock Book* is kept, which shows the quantity and price of each article bought and sold; thus serving as a substitute for real accounts in the ledger; a purpose which is sometimes effected by the *Warehouse Book*. It should be observed, that the *Account Current Book* is universally necessary, as it shews the state of each personal account in the ledger drawn out in a detailed and simple form, in order to transmit a copy or du-

plicate of each person's account to him at the period of settlement.

### FACTORAGE AND EXCHANGE ACCOUNTS.

When a merchant and his agent or factor reside in countries where different currencies are used, the factor keeps his employer's accounts in the currency of his own country, and the employer, that their books may agree, keeps the same accounts in the same currency; but he also allots an adjoining column in his ledger for the corresponding value in his own money, by which he ascertains what profits or losses may arise from the fluctuation of exchange.

In order to explain such an exchange account, the following has been selected from the ledger of a London merchant, who (as appears by the statement) remitted bills to his factor at Hamburg, and drew upon him for his reimbursement or returns; he therefore debits his factor for the remittances, and credits him for the drafts; the different amounts are first entered in the inner columns in banco marks, and then in the outer columns in sterling, according to the rate of exchange at which they were negotiated, and hence arises the profit or loss: thus, if the merchant buys the bills which he remits at a cheaper rate of exchange than he sells the drafts which he draws on his factor, there is a gain; but if otherwise, a loss. On the same principle, if he had paid debts which he owed, or received debts due to him at a more advantageous rate of exchange than those debts were contracted for, there would have been a gain, but a loss if the contrary.

An exchange account is balanced by first comparing the inner columns; and when they are equal, there is nothing due from one party to the other. The difference between the outer columns is profit and loss; but if the inner columns be unequal, the balance is what one party owes to the other, which must be carried to the outer column at the

current rate of exchange, and then the difference between the outer columns is the profit or loss.

The letters *M/A* (my account) are used by the merchant in keeping the account which his factor likewise keeps, who, in stating the same transactions, annexes to his employer's name *M/A* (his account); and their ledgers are reversed with respect to the *Dr.* and *Cr.* sides. Thus, the factor, in his account of the following transaction, debits his employer for the drafts or bills drawn on him, and credits him for the remittances which he receives; and as all the bills were drawn in marks (the money of the place where they were to be paid), the factor has no concern with any other money; therefore, he debits his employer for commission, brokerage, discount, and postage, in marks, for which his employer also credits him, and values those marks at the rate of exchange which exists when the account is balanced.

There are other kinds of exchange accounts kept between

Cambists, or dealers in exchange, who reside in different countries, and who agree to transact each other's business (commission free), and divide the gains or losses. Such accounts, like all other partnership concerns, require interest calculations, according as one party may be in advance for the other: this is the case when bills remitted are at a long date, and drafts at a short one, or the contrary; but it frequently happens that one party may be in advance for sums which have not been received by the other party, who is therefore only answerable for the advances in his possession, and the interest on the remainder should be paid out of the general profits.

These exchange accounts are kept by both parties according to the following plan; and when they agree, the *Dr.* side of one account is equal to the *Cr.* of the other, and the inner columns of one to the outer columns of the other, and *vice versa*.

*Book of rates*, is a book established in parliament, shewing at what value goods, which pay the duty of tonnage and poundage, are to be reckoned at the custom-house. See CUSTOM, DUTY, POUNDAGE, and TONNAGE.

The book of rates annexed to the act of tonnage and poundage made in the 12th year of king Charles II. was subscribed with the hand of sir Harbottle Grimstone, then speaker of the house of commons. An additional book of rates of goods and merchandizes usually imported, and not particularly rated in the former, with rules, orders, &c. was signed by Spencer Compton, esq. speaker of the house of commons, 11 Geo. I. c. 7.

Aliens used to pay a larger proportion than natural subjects, generally called the alien's duty; now repealed by stat. 24 Geo. III. sess. 2. c. 16, except as to scavage duties, granted to the city of London. By stat. 27 Geo. III. c. 13, called the "Consolidation Act," all the former statutes, imposing duties of customs and excise, were repealed with regard to the quantum of the duty; and the two books

of rates above-mentioned, were declared to be of no avail for the future; but all the former duties were consolidated, and were ordered to be paid according to a new book of rates annexed to that statute. By the improvement of this statute, the duty upon the exportation or importation of any article may be easily found, or the excise duty to which any commodity is subject, in an alphabetical table.

BOOK-SELLER, a professed trader in books; whether he prints them himself, or procures them to be printed by others, for sale.

Book-sellers, among us, are the same with *bibliopolæ* among the ancients, whose office was distinct from that of *librarii*. Petty dealers, or venders of small wares, like our publishers, were more particularly denominated *libelliones*. At Rome, the *Argiletum* was the mart of books, as St. Paul's Church-yard, or Fleet-street, and Paternoster-row, have been among us; whence that of *Mastial*.

*Argiletanus mavis habitare tabernas,  
Cum tibi, parve liber, scrinia nostra vacent.*

Book.

Book-sellers are a kind of agents, or curators in the republic of letters: in many places they are ranked among the members of universities, and entitled to the privileges of students: as at Tubingen, Saltzburgh, and Paris, where they have always been distinguished from the vulgar and mechanical traders, and exempted from divers taxes and impositions laid on other companies.

Formerly the offices of book-sellers and printers were united in the same persons. Paper, and all other materials, as well as labour, were, in the infancy of the art, exceedingly dear; and, on the other hand, the purchasers of books were few, partly because the price of them was high, and partly because knowledge being less widely diffused, they were not so generally read as at present. For these reasons, many of the principal printers, notwithstanding their learning or ingenuity, became poor. The printers were, therefore, induced to give up the book-selling part of the business, and to retain only that of printing. Sometimes, indeed, there were rich people of all conditions, particularly eminent merchants, more especially in Germany, who caused books, which they sold, to be printed at their own expence. Thus Henry Stephens was printer at Paris to Ulric Fugger at Augsburg, from whom he received a salary for printing the many MSS. which he purchased. In some editions, from 1538 to 1567, he subscribes himself "Henricus Stephanus, illustris viri Hulderici Fuggeri typographus." In like manner, towards the beginning of the 17th century, a society of learned and rich citizens of Augsburg printed a great number of books, which had commonly at the end these words: "Ad insignem pinus." Printing, therefore, thus gave rise to a new and important branch of trade, that of book-selling, which was established in Germany, chiefly at Franckfort on the Mayn, where is a street, consisting of several large book-sellers' shops, and called "Book-street."

Labbe gives a list of learned book-sellers, most of whom were also authors. Of late days, book-sellers have drawn their business into less compass, and leaving the labour of composing books to one set of persons, and that of printing them to another, content themselves with the gainful part; thus ministering to the republic of letters not with the head, or the hand, but the purse only.

In this view, they have been very important and useful agents between authors and the public; and have contributed, in no small degree, to the encouragement of genius and literary industry, and the spread of science. There are few authors, who have undertaken the printing and publishing of any work likely to be transmitted to posterity, without being connected with some book-seller or book-sellers, eminent in their profession.

The fairs of Franckfort and Leipzig are famous for the resort of book-sellers, not only from all parts of the empire, but Holland, Flanders, &c. They have each their shop or warehouse, over which is inscribed the name of some celebrated book-seller of former times; *officina Elzeviriana*, *Frobeniana*, *Morelliana*, *Janssoniana*, &c.

An acquaintance with the book-sellers' marks or signs, frequently expressed on the title pages of their books, is of some use; because many books, especially in the 17th century, have no other designation either of printer, book-seller, or even city. The *anchor* is the mark of Raphelengius at Leyden; and the same with a *dolphin* twisted round it, of the Manutii at Venice and Rome; the *Arion* denotes a book printed by Oporinus at Basil; the *caduceus*, or *pegasus*, by the Wecheliuses at Paris and Franckfort; the *cranes*, by Cramoisy; the *compass*, by Plantin at Antwerp; the *fountain*, by Vascosan at Paris; the *sphere* in a balance, by Jansson or Blaew, at Amsterdam; the *lily*, by the Juntas at Venice, Florence, Lyons, and Rome; the *mulberry-tree*, by

Morel at Paris; the *olive-tree*, by the Stephenses at Paris and Geneva, and the Elzevirs at Amsterdam and Leyden; the *bird between two serpents*, by the Frobeniuses at Basil; the *truth*, by the Commelins at Heidelberg and Paris; the *Saturn*, by Collinæus; the *printing-press*, by Badius Ascensius, &c.

Chevillier shews, that the university of Paris had formerly the sole power of creating and appointing book-sellers, who were to take an oath to the university; and were reputed part of the academical body, and as such entitled to the exemptions of the other members thereof. They were to give security to the university for their behaviour, and produce attestations of their capacity for the discharge of their office: the university also deposed and expelled them at discretion: they were obliged to appear at all assemblies of the university, when summoned, and assisted at the public processions thereof: they were obliged to lend their books to be read, or even copied by such as were disposed to borrow, on certain conditions, prescribed by the university. If they kept any books by them which were not correct, the university punished them: they were not allowed to buy any book of a student, without leave of the rector; nor were they allowed to gain above four *deniers* in a *livre*, by any copies sold to the members of the university. Every book-seller was obliged to have a catalogue of all his books hung up in the shop, with the prices as rated by the university: no book-seller, who had not taken the oaths to the university, might sell a book of above ten *sols* value. *Diff. de l'Orig. de l'Imprim.* l. iv.

This state lasted from the thirteenth century to the invention of printing, and even till the end of the sixteenth century; during which time there were only allowed twenty-four book-sellers, two binders, two illuminers, and two sworn book-writers, or copyists. But from that time the kings of France began to take cognizance of them; Lewis XI. thought fit to prescribe some new regulations in 1467. Under Francis I. the book-sellers were brought wholly under the royal authority, and received statutes from the king.

The chief science of book-sellers, is the knowledge of the titles, different editions, prices, and scarcity of books, without regard to their contents, or qualities, otherwise than as these affect the sale of them. See LITERARY PROPERTY.

BOOK-WORM, in *Entomology*. It would be no easy task to say of what precise description those creatures are, which the old writers meant by the indefinite expression of *Book-worm*. They speak of it as an insect of the mite kind, which afterwards becomes a fly, bred from eggs deposited in the month of August in books, especially in the leaves nearest the covers; and which, upon the whole, bears a strong resemblance to the mite or *blatta* found in *corn*. All this must naturally lead to a conclusion, that, under the general appellation of book-worm, they included every insect of whatsoever kind that was known to be destructive to books. Among this host of latent enemies to our libraries, the mite is highly injurious. When books are carelessly left exposed in damp places for any length of time, they seldom escape the ravages of this imperceptible creature. The species *destructor* is very detrimental, as is likewise *cruditus*; the latter of which directs its attacks to those parts which are sewed together, or glued down. Both species are invisible to the naked eye, but their presence is easily known by the ill effects they produce. Another mischievous creature is the larva of a small moth of the tinea kind, which is insinuated in the egg state into the paper, and, hatching, the larva gnaws cylindrical cavities through the leaves, and spins a web, in which it lies secure, till after passing through the pupa state it becomes a moth. The larvæ of several species of the dermestes, in like manner, prey upon books, attacking the leather covers as

well as the paper. Of this kind, *Dermestes lardarius* is one of the most injurious. The mixture of the juice of worm-wood, and other bitter ingredients, in the paste employed by book-binders, as an expedient for the security of books against the attacks of those insects, is of no utility. Mineral salts are recommended for this purpose instead of it, under an idea, falsely conceived, that insects, in that case, would not prey upon them. Mr. Prediger, among other instructions to German book-binders, printed at Leipzig in 1741, advises their making paste of starch instead of flour; he wishes them to powder slightly the books, the covers, and even the shelves on which they stand, with a mixture of powdered alum and fine pepper; and is also of opinion, that in the months of March, July, and September, books should be rubbed with a piece of woollen cloth steeped in powdered alum. *Mélang. d'Hist. Nat.* t. v. 296. For the preservation of books from the depredations of the insects above described, it will be only requisite to attend occasionally to wipe and dust them, observing that the library be not kept in a damp situation. Wiping, and an exposure of the book to the heat of a good fire, will immediately destroy the mites contracted in the damp, and, of course, prevent farther injury from that race of vermin. Corrosive powders, even arsenic itself, would be employed in vain for the destruction of the larva either of the *tinca*, or the *dermestes*; but the fumigation of tobacco, a close heat, like that of a slow oven, or the scent of camphor, will effectually destroy them. The last remedy we are certain, from experience, to be excellent. Musk might, perhaps, answer nearly as well; or, lastly, if alum be preferred, let it be first burnt to a powder. When M. Prediger recommended his preparation of powder-alum, he did not seem to be aware, that if employed in a crude, unburnt state, it could produce no effect upon the insects intended to be destroyed.

**BOOKING**, among *Merchants*, &c. the making an entry of any matter in the journal. See **BOOK**, **BOOK-KEEPING**, and **JOURNAL**.

**BOOM**, in the *Sea-Language*, a long pole employed in extending the sails of a ship, principally in moderate breezes of wind. Of these there are various kinds, according to the purposes for which they are intended.

**BOOMS**, simply so called, are those employed in extending the lower sails when the ship is going large; which is done by putting one end of the boom into the clew of the sail, and the other end to a but against the side of the ship. These booms are retained in their proper positions by means of ropes called *guys*.

*Driver-boom*, is that which is used in extending the lower part of the driver.

*Jib-boom*, is a spar run out from the bowsprit, and is, therefore, a continuation of it, in the same manner as the top-mast is that of the mast. Upon this boom the jib, in square-rigged vessels, is set; and hence its name. In some vessels, the length of the boom is so much increased, as to carry a flying jib.

*Main-boom*, is that which serves to extend the lower part of the main-sail in vessels having only one mast: in brigs, &c. it extends the lower part of the fore and aft main-sail, the upper part, in either case, being extended by a gaff.

*Spanker-boom*, a boom projecting from the mizen-mast, considerably beyond the taffrail, by which a larger sail can be extended than by the common boom.

*Studding-sail-booms*, are booms run out from the yard arms, from which the studding-sails are suspended.

*To Boom-off*, is to push any thing away, as a ship, &c. by means of a rod or boom.

**BOOM** also denotes a pole with a bush or basket on the top, placed to direct ships how to steer into a channel; otherwise called a beacon.

**BOOM** likewise is used, in *Marine Fortification*, to denote a cable or cables stretched athwart the mouth of a river, or harbour, with yards, top-masts, battlings, or spars of wood, lashed to it, and girded with iron hoops rivetted together and nailed to the spars, to prevent an enemy's entering. Such a boom M. Chateau Renault had with diligence and art prepared at Vigo, for the defence of the plate fleet lying there in 1702; but how strong soever, it was forced by Vice-Admiral Hopson, on the Torbay.

*To lay a boom*, provide a great number of wooden battlings or spars, of about 20, 30, or 40 feet length, and between 5 and 10 inches diameter; then moor two boats, having a sheet-anchor in each, in the place near one side of the river where it is intended the boom shall begin; bend two cables to these anchors, and round them place the spars or poles, frapping on each with rattling stuff, or with four-inch rope, until the boom is 7, 8, 9, 10, or more feet in diameter, according to the hands employed, the cables being in the middle: then, with iron hoops rivetted together, worm the boom, and drive through the hoop a nail into almost every spar. After having wrought a good birth for the anchors, drop them, and continue the work till it is brought near the other edge of the river, and there drop two anchors more, with the cables bent to them. Over all lash the spare yards and top-masts, with the top-chains, so far as the channel goes. To that part of the cable within the boom, over the channel, let two or more cables be fastened, and bent to anchors laid down the stream; over the clinch of these cables let battlings or spars be wrought for near 15 fathoms down the stream, that the enemy may not cut these cables. These will be serviceable when the enemy's ships come "stemlings" against the boom; for if he force it in one place, the whole will not be opened by that fracture. In places where wood is scarce, and spars cannot be readily procured, or in cases where there is not time enough for preparing them, it may be sufficient to woold two cables together with old ropes, lashing to them the oars, top-masts, and yards, and worming the whole about with iron hoops; and let every part be well "payed" with pitch, and small gravel strewed in it while the pitch is warm. A boom so prepared cannot be easily cut. The boom should generally be so contrived, as to open at one end for the passage of vessels; and there are several ways of doing this. One is, to clinch one end of the cable to an end of a large mooring-chain, the other end floating with a buoy, and this end fixed to the ring of an anchor by a shackle. The chain being loosed from the anchor at the ebb, with a slack hawser fixed to it, the boom will swing down the stream during the ebb; and, upon the flood, the boom may be re-laid, if the enemy appear in sight, which he must do at the first of the tide, for, upon the ebb, there is no danger of his coming; because, if the wind is right in, a prudent enemy will not venture against the tide, a ship then making such wild steerage; and should she ground, she must lie there till flood, which may prove fatal to her from the batteries ashore; and, against both wind and tide, the enemy cannot come in. On the contrary, should the boom be carried up the flood, and the enemy appear at the beginning of the next flood, the boom cannot be re-laid till the ebb, and before that time the enemy may have accomplished his design. If access can be had to plenty of timber, a "stockado" may be made, by driving several rows of piles in the channel before the boom; or, if the depth of water should not allow of this work, the trees may be usefully applied in making a raft to ride before the boom by good anchors, so that the cables be made too fall for the enemy to cut them. These rafts may be of singular use, by making fires on them, when the enemy appears, which will produce a consternation, that may cause him to chop to anchor, and lose time, or his tide;

and this may be done each flood, observing not to have the smoke drive into the works, which might give the enemy too great an advantage.

*To lay a boom in a straight channel.* If the wind for the most part blow obliquely across the river or channel, on the starboard quarter going up the river, and the boom be laid directly athwart the channel, which was the case at Londonderry in 1689, when it was forced, the ships coming with the tide of flood, and a leading gale, will run stemlings against it, and possibly break it, by striking with a direct force: whereas, if the boom could be laid obliquely athwart the river, nearly in a line with the wind, so that the ship must take it with her bow, the blow would be diverted by the ship's casting, because, in this position, the enemy cannot run stemlings against it; for, in sailing up the river, the ship must be near before the helm; and to bring her head to a boom laid obliquely, the helm must be put down, and then it will be a great chance if she comes to so nicely as to take the boom; besides, mistakes may be committed in the confusion by the man at the helm, and by him upon the land, and by reason of the smoke; and, exclusively of all these, it may be taken for granted, that the ship would cast along-side the boom; and then the batteries at the end of the boom on the larboard side would rake it fore and aft, while the opposite batteries on the starboard side, playing on the broad-side with double-round and partridge, must make a great slaughter among the men cutting at the boom. And if it should not swing along-side the boom, but lie stemlings against it, the batteries on the starboard side of the river, which are to be made above the weather-end of the boom, will rake it fore and aft, while those on the larboard side play on its quarter, or broad-side. The ships within the boom, protected by it, should be moored in a kind of half-moon, with their broad-sides flanking the boom: and several old, or, at least, useless ships, may be sunk, as soon as a signal is given from one of the forts, signifying that the boom will be cut. For this purpose, those ships should have large scuttles ready cut; and, for a farther security, it would be very proper to have a small boom to divert the enemy, that the ships may be sunk in the channel before he boards them. The chief strength, however, is in the boom; and if a double, triple, or four-fold boom, were laid, provided materials could be procured, and the value of the shipping and cargoes warranted the expence and labour, it would make the place so much the stronger, and the enterprise of the enemy more hazardous. In stretching these booms, the trouble of many anchors may be spared, by making all the cables fast to the first, and so let them float in a bight, and by a small anchor ride upon the ebb, to keep clear of one another.

*To lay a boom in the bend of a river.* From the point formed by its end, stretch two booms across the channel, one towards the middle of the opposite bight, and the other so much higher, as to lie directly athwart the channel, leaving a kind of angular space between them. Next the point from whence the two booms stretch, erect a proper fort or battery, to command the channel below and above the bend. On the other side of the river, erect another fort or battery against the bight a little above the end of the lower boom, and so disposed, that its cannon may rake the channel coming up, as well as command both the booms. From such a disposition, it is a great chance if a ship answer her helm so exactly as to time, in bearing or loosing about the point, as to take the boom stemlings; and if she smite it with her bow, she casts; and, in either case, she will be raked fore and aft by one fort, and have her broadside battered by the other. Let some old vessels be fitted up for fire-ships, and placed be-

tween the two booms; from each ship let two hawfers be carried ashore, one on each side, and fixed to crabs, or capstans set up; so that as soon as the enemy has passed the first boom, these ships being set on fire, and heaved in their way, nothing can hinder the enemy's destruction. The ships to be defended may be moored in a half moon, with their broad-sides so laid as to batter the enemy when he attempts the boom. When no strong attacks by land are to be feared, the mooring of ships behind a point is best, on account of laying the boom. If the boom should be forced, which must be upon the flood, a fire-ship, instead of falling on board a ship thus moored, will, by the tide, be hurried beyond her; and if the place be favourable to the ships moored there, it will be found impracticable to board a ship thus moored, with such a wind and tide as the enemy must have to break the boom, unless he expose his boats in carrying out an anchor to warp over, which will be a very dangerous attempt, or some unaccountable accident intervene.

*Boom, drift,* any yard, spar, &c. by which a boat may ride stem on to the sea in a gale of wind, and drive to leeward. The usual method is to make fast a rope, about twice the length of the spar, to each end of it, and to the middle of the spar the boat-rope is to be bent. By this contrivance, a boat, in a gale of wind, will drive stem on to the sea, and the drift-boom will prevent the sea from breaking over the boat. See **BOAT**.

*Boom-irons,* in a *Ship*, are two flat iron rings formed into one piece one above the other, employed to connect the booms to the yards, &c.; the lower ring is the largest, and is driven on the yard. Some boom-irons fasten on the yards with a crotch or strap, secured by nails and hoops.

*Boom-Tackle.* See **TACKLE**.

*Boom,* in *Geography*, the principal place of a canton, in the department of Deux Neutres, and district of Anvers. The place contains 3428, and the canton 14,519 inhabitants. The territory comprehends  $92\frac{1}{2}$  kilometres and 11 communes.

*Boom-channel.* See **BRANDARIES**.

**BOOMAZOOSE**, a river of Africa, in the province of Constantina, which bounds on one side the plain, in which are found the ruins of the ancient Thubuna, now Tubna; and the river Bareekah bounds it on the other side.

**BOOMBANI**, a town of Africa, in Ludamar, north-east of Jarra, and north-west of Benowm. N. lat.  $15^{\circ} 10'$ . N. long.  $7^{\circ} 12'$ .

**BOOMITES**, a term used by some authors to express a kind of agate, of a very remarkable brightness and transparency, which represents the figures of shrubs, trees, mosses, &c. in the manner of the *dendrachates*, a common *mocho-stone*. This is, however, very different in the degree of transparency and brightness.

**BOOMKIN.** See **BUMPKIN**.

**BOOMLAND**, or *Laland bank*, in *Geography*, is the second bank from the shore, ending nearly against Nieuport, on the coast of Flanders, betwixt that and Ostend. Between that and the first bank, called the Geer, a channel of eight or nine fathoms passes through. All the banks begin off Ostend, being four, and what are called the Flemish banks.

**BOOMOE-Oste-Sando**, a small island near the coast of Norway, 12 miles W. of Surøy.

**BOOMUGGAR**, a district of Africa, in the province of Constantina, which is very fertile, and bears several traces of ancient buildings.

**BOON**, in *Ancient Geography*, a port of Cappadocia on the Euxine sea, between Cotyora and the promontory of Jason, according to Arrian.—Also, a village of Ethiopia, near the Nile, and on the west side of it. Ptolemy.

**Boon-ijland**, in *Geography*, an island of America, on the coast of the district of Maine, between the mouth of York river and Cape Neelock.

**Boon's-Creek**, a small north branch of Kentucky river.

**Boon's-Point**, the most northerly point of the island of Antigua. N. lat. 17° 7'. W. long. 62°.

**BOONDY**, or **BOONDEE**, a town of Hindostan, in the country of Agimere, 84 miles S. E. of Agimere, and 65 S. S. W. of Rantampour. The town is situated on the southern declivity of a long range of hills, which runs nearly from E. to W. The palace of the rajah, a large and massy building of stone, is about half way up; and a kind of stone fortification runs to the top of the hill. The pass through the hill lies to the east of the town, and is secured by a gate at each end. The possessions of the rajah of Bondee have been reduced by the irruptions of the Mahrattas, and encroachments of the Kotah family, to the revenue of six lacks, of which a fourth part, or chout, is paid to the Mahrattas.

**BOONE BAY**, lies on the western side of the island of Newfoundland, 22 leagues N. by E. from St. George's harbour. N. lat. 49° 35'.

**BOONEN, ARNOLD**, in *Biography*, a portrait painter, was born at Dort, in 1669; and after having been for some time a disciple of Arnold Verbuys, placed himself under Godfrey Schaleken, who recommended to him, after having received his instructions for six years, to study nature. By following this advice, Boonen obtained the reputation of a great painter at the age of 25 years. His style of colouring was extremely good; the attitudes of his figures were elegantly disposed; his touch neat. The whole possessed such harmony, and his portraits maintained such a striking likeness, that he was ranked among the ablest artists of his time; he had a number of admirers, and a demand for works which he was unable to execute. He had the honour of painting the portraits of the czar of Moscow, of Frederick I. king of Prussia, of the victorious duke of Marlborough, as well as of many of the princes of Germany, and most of the noblemen who attended the czar. His health was impaired by his excessive application, and he died rich in 1729. Pilkington.

**BOONERSCHANS**, in *Geography*, a fortress of Groningen, on the borders of East Friesland, about a league from Dollart bay; 5 leagues S. of Embden.

**BOONETON**, a small post-town of America, in Sussex county, New Jersey, on the post-road between Rockaway and Sussex court-house; 116 miles from Philadelphia.

**BOONSBOROUGH**, a town of America, in the county of Madison, and state of Kentucky, seated at the mouth of Otter creek, 35 miles S. E. of Lexington, and as far N. E. from Danville. N. lat. 37° 57'.

**BOO-ONK**, or **LONG-NECK**, in *Ornithology*, one of the names of the little Bittern, *Ardea minuta*. *Ruffel's Aleppo*.

**BOOPHTHALMUS**, derived from *βῶς*, an ox, and *ὀφθαλμῶν*, eye, Ox-eye stone, in *Natural History*, a name given by Scheuchzer to a peculiar agate, in which there frequently appear circles of considerable size, resembling some large animal's eye. The ground colour of the stone is grey, and the circles of a deep bluish black.

**BOOPS**, in *Entomology*, a species of *SCHEX* that inhabits Germany, in the environs of Vienna. It is of a black colour, with three segments of the abdomen, and the tarsi of the legs testaceous. Schranck. *Inf. Austr.*—*Obs.* The eyes are large, the abdomen ovate.

**Boops**, in *Ichthyology*, a species of *LARRUS*, found in the seas about Japan. It is specifically distinguished by having the lower jaw rather longer than the upper one, and having two fins on the back. *Houttuyn ad Haarl.* The eyes

of this fish are very large; the teeth in the lower jaw large and acute.

**Boops**, a species of *SPARUS*, of the lineated kind, found in the Japan seas. The body is marked with obscure longitudinal lines, of which the four lowest are gold and silvery. *Artedi* describes this fish. *Gmel.*

**Boops**, in *Zoology*, the specific name of the *Pike headed whale*; *Balena boops*, of *Linnaeus*. It is distinguished by having double spiracles on the snout, and a horny protuberance at the extremity of the back. *Linn.* This is the Jupiter fish of *Anderson*; the French name it *la Jubarte*.

The pike headed whale is a native both of the northern and southern ocean, and grows to the length of forty or fifty feet, and sometimes more. The body is round, especially towards the head, from whence it slopes gradually to the tail. The head is large, and of a somewhat lengthened form, though terminating in an obtuse tip. Before the nostrils are three rows of circular convexities, the utility of which has not yet been ascertained. Above these is the double spiracle through which the animal ejects the water in the same manner as the other whales. The eyes are situated beyond the spiracles on each side of the head. Just behind the orbit of the eyes are the ears, the apertures of which are scarcely perceptible. In the upper jaw are numerous laminae of black whale-bone, not above a foot in length. The tongue is large, fat, spongy, and furnished with an appendage towards the throat, a kind of loose skin like an operculum. The lateral, or pectoral fins are large, oval, entire on the posterior edge, but rounded and crenulated on the front. The dorsal fin is of a fatty-cartilaginous substance; it is placed on the hind part of the back, above the vent, in a position nearly perpendicular. The tail, which is horizontal, is divided into two lobes, both of which are pointed at the extremity. The sides below the pectoral fin, together with the anterior part of the belly, is deeply wrinkled with a number of longitudinal plaits, or furrows, which may be contracted or dilated at the pleasure of the animal. All the upper parts of this kind of whale are of a dark brown, or black colour, obscurely marbled; the prevailing colour beneath is white, except the furrows between the abdominal plaits, which distend as the animal opens its mouth and then appear of a bright red.

This is represented as a very timid creature. There are occasions, however, in which it has evinced a considerable share of courage, such as being stranded on the shore in a storm, when it has been known to defend itself with great vigour, and do no small mischief before it could be overcome. When the male has been stranded with the female, of which instances do sometimes occur in the north, they will defend each other with uncommon spirit, emitting at the same time a most horrible grunting noise, somewhat similar to that of a pig when stuek for killing. Its greatest enemy in its native element is the physeter microps. This species lives principally on the salmo arcticus, the ammodytes tobianus, and on the testaceous, and other vermes. Its flesh and oil are used like those of other whales. The Greenlanders, where those animals are most frequent, call this particular kind *keporkak*.

**BOORS**, in *Geography*, the appellation of a very numerous class of the inhabitants of Russia, usually called simply boors, but more accurately denominated vassal-boors, in order to distinguish them from the free boors, or free peasants. These latter, though often comprehended among the boors in state papers, and in the enumeration of the people, are really of a different class, and form a kind of middle station between the burghers and the vassal-boors. In virtue of their freedom, no man can alienate or sell them; they educate their children as they please; most of them possess im-

moveable

moveable property; what they earn cannot be taken from them, provided they duly pay their common taxes, or perform their stated tasks of labour; nor are they under any arbitrary command, but, like those of superior rank, own no authority besides that of the general laws of the state. Among these, however, there are various gradations, as all of them do not enjoy the same degree of liberty. Some are expressly called boors, and without violation of their freedom are treated as such, though with somewhat more gentleness than vassals. Others possess true civil liberty, and differ only by their place of abode and customary occupations from town's people. To this class belong the foreign colonists, settled here as husbandmen or farmers, so that by their occupation they are boors; but on account of the land which they possess, this appellation does not justly belong to them. To the free-peasants we may also refer the "Odnovortzi," as they are called, or one-house owners, whose persons are free, and who possess their houses with the lands belonging to them, as real property, for which they neither perform feudal services nor give any of their products: but they are obliged to furnish recruits, to pay the pole-tax, and obrok, and they are not allowed to buy villages nor to possess vassals as property. The kozaks, or cossacks, in all their stems and branches, the tartar tribes, the bashkirs, vogules, kalmucks, with most of the monadic tribes, and people of the steppes, possess their lands as real and heritable property, and therefore belong to the same class of free-peasants. This is also the case with respect to disbanded soldiers, who live in the country; emancipated serfs, who have either bought their freedom of their lord, or obtained it gratuitously in reward for faithful service; malo-Russian boors, or boors of Little Russia, who are neither cossacks nor vassals, but free people, and free-peasants, who belong to their land, and can neither be sold nor alienated separately from it.

The vassal-boors, as distinguished from those we have now described, have no civil liberty; their children belong not to them, but to their manorial lord, on whose will they depend; they also, with their children, singly or in families, may be alienated, sold, and exchanged; they possess no immoveable property, but they themselves are treated sometimes as the moveable, sometimes as the immoveable property of another. These boors were originally free, but in Great Russia they became gradually vassals, or heritable serfs. They are commonly divided into three kinds; but it will be more convenient to distribute them into four classes. The first consists of "crown-boors," called vulgarly, in Livonia, public-boors; who are very numerous, and are the people belonging to the crown. It is necessary, however, to distinguish between boors whom the crown can grant away, as its real vassals, and who possess no real property, and those tribes of people who are owners of immoveable possessions, and enjoy certain rights and privileges. But there are, exclusively of these real vassals, boors belonging to the crown, whom the crown cannot with propriety give away, being attached as workmen to the mines, either of the crown, or of private individuals. Most of the crown-boors pay, besides the head-money, the obrok, i. e. a sum of money for every male soul, and this is the only benefit which the crown derives from them. In some districts they do task-work, or pay of their products; or, in Livonia, they do both instead of the obrok. Among these there are some that are not only in good circumstances, but even rich; nor would they be sensible of their vassalage, if the crown did not possess the power of granting them away. Boors of this class are mentioned under several denominations; as boors of the black plough, boors of the empire, imperial boors, post-

boors, and court-boors. In the Russian laws and ukases, the following eight distinct kinds of crown-boors are mentioned, viz. empire-boors, who belong neither to the court, nor to the nobility, nor to the monasteries, but are members, or burghers of the empire; imperial boors, who belong to the monarch personally, or rather to the court; boors of the black plough, inhabiting a great part of the northern Russia, as far as Archangel; poll-boors, who are bound, in lieu of the poll-tax, to keep poll-horses; court-boors, whose service and tributes are destined to the support of the imperial court; monastery-boors, who formerly belonged to the monasteries, but now every where in Great, Little, and White Russia, are under the kameral-hofs; economy-boors, who in Great Russia were those boors, who, about the year 1764, were taken from the monasteries and churches, and made subordinate to a particular college of economy, established for that purpose, but now abolished, so that the boors are under the kameral-hofs, retaining their former name; and peltry tribute paying boors, who deliver their tribute in peltry or furs. One privilege of the crown boors consists in this, that they may buy of noblemen villages and lauds, with the vassals belonging to them.

The second class of crown-boors bears the denomination of "crown-boors," who belonged formerly to the bishops, churches, and monasteries, but were taken from them in the year 1764; they are much the same with those of the crown-boors already mentioned, paying particular taxes, and enjoying certain privileges. The boors of the third class are, "boors of the mines," who can never be separated from particular mines, and can never be sold or exchanged apart, though they are transferrable with the works to another master. The fourth class comprehends "noble, or private-boors;" the condition of these depends very much on the humour or caprice of their lord; nevertheless, those of them who belong to wealthy lords, requiring neither task-service, nor deliveries of products, and contenting themselves with a moderate obrok, live happily, grow rich, and would hardly exchange their condition with that of many who enjoy nominal freedom. However, the dues from these boors to their lord are settled by no laws; some pay the obrok, others perform task-service, or, in lieu of it, deliver certain portions of their natural products; from others all these are demanded; but the obrok alone, where the lord is rich, is the most usual. Many take for every male head only three, others five, and some from the most opulent of the boors, twenty-five rubles, or even more. Those, who fare the worst, are the private boors, who are obliged to perform task-service, in lieu of the obrok, at the mine-works of their lord, which may be at a great distance, and with respect to whom the distance is not considered. The late empress declared it to be her wish and inclination, that vassalage should be abolished; or at least, that the condition of the boors might be ameliorated, and all oppressive abuses restrained. She actually adopted several measures for accomplishing her benevolent wishes, by instituting a regular tribunal for the boors, entirely chosen out of their own body; delivering the boors at the mines from oppression; appointing overseers and guardians to prevent every species of violence; and on every occasion recommending gentleness and humanity, of which she herself is said to have exhibited an illustrious example. Under her administration instances occurred of noblemen, who were brought to a severe account for cruelties exercised on their vassals. The most usual mode by which a vassal becomes such is, by being born of a vassal. By the common law of Livonia, every child born of an unmarried female vassal belongs, without regard to the father, to the estate on which it is born. Peter 1., however, by an ukase,

ukase, in 1716, ordained, that such a child should be free, if a free man have caused it to be baptized in his name, as father. Vassal-boors pay poll-tax, and furnish recruits; but the obrok of the crown-boors is not to be considered as a public tax, but as a sort of rent for the occupancy of the lands allotted to them, or for permission to follow any trade they please. Some of the boors rise by their good behaviour to be officers in the army; and others of them live decently in their houses, and have a sufficiency of wholesome food, are neatly dressed, and accumulate a trifling capital, though, as they have no alienable security of possessing it, they frequently bury it in the ground. In some noble villages the boors display an opulence which would be looked for in vain in other countries. The Russian boor, indeed, may soon become rich, as he understands the art of turning every thing to profit, and of being content with a little; for his clothes cost him nothing, being wholly manufactured at home, and with his diet, which, during the long fasts, is extremely meagre, he is supplied from his husbandry.

The value of an estate in Russia is estimated principally by the number of male boors belonging to it. The national lombard, in all mortgages, which it accepts, takes the boor at forty rubles; but in the sale of an estate they are seldom or never estimated at so low a price. In the government of St. Petersburg every soul is paid for, according to the quality of the estate, from 200 to 300 rubles: in other parts of the empire the price is commonly much lower, but at present hardly any where under 100 rubles. On many estates the boors work three or even four days in every week for the lord. The boors enrolled to the mines have their labours ascertained by an edict issued in 1782; and those belonging to the crown-mines have always experienced a milder lot, as the crown is always interested in their preservation. According to the enumeration of male inhabitants, made from 1781 to 1783, in the forty one viceroalties of which Russia at that time consisted, the number of crown boors was 4,674,603, and of private boors 6,678,239. *Touke's View of the Russian Empire.*

**BOOR-WORM**, in *Natural History*, a name given by Rumphius to a sort of marine worm, that bores through the bottoms of ships; perhaps the *Teredo navalis*.

**BOOS**, in *Geography*, a town of France, in the department of the Lower Seine, the chief place of a canton, in the district of Rouen; the place contains 650, and the canton 11,144 inhabitants; the territory comprehends 107½ kilometers, and 21 communes.

**BOOSE**, in *Rural Economy*, a provincial term, signifying a cow-stall.

**BOO-SHALTER**. See *Boo-Shatter*.

**BOOSHOOANAS**, in *Geography*, a tribe of the kaffers, or caffres, inhabiting a finely cultivated and inclosed country in southern Africa. The capital, called Leetakou, is very large and populous, containing, according to the estimation of some commissioners who visited it in 1801, between 2 and 3,000 houses, and from 10 to 15,000 people. It lies nearly in S. lat. 26° 30', and E. long. 27°. The men are of a tall athletic form; of simple pastoral manners; living almost entirely on milk and vegetables, and following the occupation of shepherds. The women, like other females in savage communities, perform all the drudgery of the family. They break up the ground with a kind of hoe made of iron, and afterwards plant it. They also construct their habitations, and collect the necessary materials. They reap the grain, clear it from the husk, and lay it up in the granaries, which, with other earthen pots and vessels, were the work of their own hands. The men prepare the skins and hides which serve for shoes, and make them up into cloaks for themselves, their wives, and their children. They

also attend the cattle, milk the cows, and hunt the antilopes and other game, with a weapon called the "hassagai," which is used also in battle.

The houses of these people are built in a circular form, being about sixteen feet in diameter. The lower part, to the height of four feet from the ground, is formed of stone laid in clay with wooden spars erected at certain distances. A fourth part of the house, on the east side, is open, and the other three-fourths entirely closed. The whole building is covered with a round pointed roof in the form of a tent, well thatched with long reeds, or the straws of the holcus. From the centre to the back part of the house, a circular apartment is separated, having a narrow entrance, and in this the head of the family takes his nightly rest; while the other members of the family sleep in the fore part, or between the large and small circles of the house. All the houses are enclosed by pallisades; and the space between these and the dwelling serves for a granary, and store for their grain and pulse. The granaries are constructed in the form of oil jars, of baked clay, each of them containing about 200 gallons; and these are supported on tripods, composed of the same material, which raise them about nine inches above the ground. They are covered with a round straw roof erected on poles, and of such a height as to admit an opening into the jars, the upper edges of which are from five to six feet from the ground.

To the north of the Booshoonans are situated, in a cultivated tract of country, under the southern tropic, a much more powerful tribe, called the "Baroloos." The manners of these people are kind and simple; they are said to be acquainted with the art of smelting copper and iron, for which they have erected furnaces; they are extremely rich in cattle; their lauds and houses are much better than those of the Booshoonans; and their chief town is represented as so extensive, that it is said to be a day's journey in length, and extremely populous. *Barrow's Travels into the Interior of Southern Africa*, vol. ii.

**BOOSSEGA**, a river of Africa, in the empire of Morocco, near Tetuan, where the Morocco galleys anchor and winter, under the protection of a bad fort.

**BOOSURA**, in *Ancient Geography*, a small town of the isle of Cyprus, towards the south-west, between Curtum to east, and Palæ-paphos to the north-west. It is mentioned by Strabo.

**BOOT**, a leathern cover or defence for the leg, used chiefly on horse-back, both to keep the body more firm, and defend the part from the injuries of the weather.

Boots seem to have been called thus from their resemblance to a sort of jacks, or leathern bottles, formerly in use, and called *botta*, in the old French *louts*. Borel derives the name from the ancient French word *bot*, a *stump*, because the boot gives the leg this appearance.

It is not long that the boots used on horse-back have been called by this name. In the reign of Charles VII. of France, they were called *houfes*, *bofe*.

The ancient monks usually wore boots; that is, the denomination of *botta*, or *botti*, was given to their buskins.

The Chinese had a kind of boots made of silk, or fine stuff, lined with cotton, a full inch thick, which they always wore at home and abroad.

There are also surgical boots, for the cure of *vari* & *valgi*, or crooked and distorted legs.

The boot was much used among the ancients, by the foot as well as horsemen.

The boot is the same with what was called by the ancient Romans, *ocrea*; in middle-age writers, *greva*, *gamberia*, *bainberga*, *bembarga*, or *benberga*. *Du-Cange Lat. Gloss.*

The boot is said to have been the invention of the Carians; it was at first made of leather, afterwards of brass and iron, and was proof both against cuts and thrusts. It was from this that Homer calls the Greeks brazen-booted. Plin. Hist. Nat. lib. vii. cap. 56. Homer. Il. vii. v. 41.

The boot only covered half the leg, some say only the right leg, which was more exposed than the left, it being advanced forwards in the attack with the sword; but in reality it appears to have been used on either leg, and sometimes on both. Those who fought with darts, or missile weapons, advanced the left leg foremost; so that this only was booted. Veget. lib. i. cap. 20. Pitisc. Lex. Ant. tom. ii. p. 309. and Aquin. Lex. Mil. tom. ii. p. 102.

**BOOTS, *fishing*,** are a thick strong sort used in dragging ponds, and the like. Hunting-boots, a thinner kind, used by sportsmen. Jack-boots, a kind of very strong boot, used by the troopers.

**BOOT, *bordequin*,** is likewise a kind of torture for criminals; to extort a confession, by means of a boot, flogging, or buskin of parchment; which being put on the leg moist, and brought near the fire, in shrinking squeezes the leg violently, and occasions intolerable pain.

There is also another kind of boot, consisting of four thick strong boards bound round with cords; two of these are put between the criminal's legs, and the two others placed one on the outside of one leg, and the other on the other; then squeezing the legs against the boards by the cords, the criminal's bones are severely pinched or even broken, &c.

The boot is now disused in England; but it subsists still in some other countries.

**BOOT-housing.** See HOUSING.

**BOOT Islands,** in *Geography*, the most westerly of some small islands, about 3 leagues on the north of Cajana, or Cayenne, opposite to the river so called, on the eastern coast of South America.

**BOOT-*loft*,** a wooden cylindric instrument, used by shoemakers for widening the leg of a boot. It is slit in two parts, between which a wedge is driven when it is put into the boot.

**BOOT-*top*,** that part of the side of a ship which is contained between the light water mark and the lower edge of the wales. This part is commonly painted white, and, in that case, the ship is said to have white boot-tops.

**BOOT-*topping*,** in *Sea Language*, the act of cleaning the upper part of the ship's bottom, or that part which lies immediately under the surface of the water, and daubing it over with tallow, or with a coat or mixture of tallow, sulphur, resin, &c.

**BOOT, GERARD,** in *Biography*, of a noble family, was born at Gorcum, in Holland, in 1604. After taking his degree of doctor in medicine, he came to England, and was in such estimation for his skill in his profession, that he was made physician to king Charles I. On the death of that prince he settled in Dublin, but died soon after, viz. in 1650. In 1630, he published "Heures de recreation," 4to. in the Dutch language; and in 1640, "Philosophia naturalis reformata," which are not however much esteemed.

**BOOT, ARNOLD,** brother to Gerard, and of equal celebrity with him, was well versed in the Latin, Greek, Hebrew, and Syriac languages. After taking his degree of doctor in medicine he came also to London; but on the breaking out of the troubles here, he removed to Ireland, where he practised with success and reputation for some years. Tired at length with the hurry and confusion incident to civil commotions, and having experienced some losses, he went to Paris, and there passed the remainder of his life in

retirement and study. He died in 1653. He published, in 1649, "Observationes medicæ de affectibus a veteribus omisiss," 12mo. Haller gives a particular account of this volume, which contains many interesting and curious observations. Haller Bib. Med. Eloy Dict. Hist.

**BOOTAN,** in *Geography*, a country of Asia, occupying an interval of at least a degree of latitude, according to Mr. Rennell, between Bengal and Tibet. Tibet and Bootan are often confounded together; but the latter is a feudatory, or dependent province of the former, and borders on Bengal. The capital of this southern province of Tibet is Tassafudor, in N. lat. 27° 43', and beyond this is Paridrong, supposed to be in 28° at least, though placed by the map of the Lamas in 27°. This place, and the chain of mountains near it, have been regarded as the common boundary between Tibet and Bengal; but Mr. Bogle, who was sent by Mr. Hastings on an embassy to the grand Lama of Tibet, in 1774, assures us, that Paridrong is the frontier town of Tibet towards Bootan, and not towards Bengal. The western limits of Bootan have not been ascertained by Mr. Turner, to whom we are indebted for a particular account of this country and of Tibet in general. From Mr. Hardwicke's journey to Sirinagur it would seem, that the name of Bootan includes most of the south of Tibet, particularly those regions which are omitted in the doubtful map of the Lamas, who, in their account of these frontiers, use Chinese or Tartaric terms, or, perhaps, invented appellations equally useless, as they are alike unknown to the Hindoos and the natives. Bootan is a very mountainous district. The southernmost ridge of its mountains rises near 1½ mile perpendicular above the plains of Bengal, in a horizontal distance of only 15 miles; and from the summit, the astonished traveller looks back on the plains, as on an extensive ocean beneath him. Through this ridge there are not many passes, and all of them are fortified. The road between Bengal and Tassafudor lies chiefly over the summits of stupendous mountains, or along the borders of craggy precipices; so that it is difficult to ascertain the direct distance. Between Tassafudor and Paridrong is a chain of mountains still higher than the others; they are visible from the plains of Bengal at the distance of 150 miles, and are commonly covered with snow. These are a continuation of the mountains Emodus and Paropamisus of the ancients; and are sometimes by the moderns erroneously called Caucasus. In the Lamas' map, they are called Rimola, and by the people of Hindostan Himmaleh. Mr. Rennell supposes them to be, in point of elevation, equal to any of the mountains of the old hemisphere. Bootan, however, with all its confused and shapeless mountains, is covered with eternal verdure, and abounds in forests of large lofty trees. The sides of the mountains are improved by the hand of industry, and crowned with orchards, fields, and villages. It has not many wild animals except monkeys, and a few pheasants. From Mr. Turner's journey, in 1783, we learn, that Bootan does not, probably, contain any metal except iron, and a small portion of copper. The climate of this province may be considered as temperate when compared with that of Tibet Proper; and yet its winters are very severe. The people of Bootan are said to differ essentially and radically from the Hindoos, and somewhat to resemble the Chinese; whence it may be concluded, with some degree of probability, that they belong to that grand race of men, which approaches the Tartaric, though they cannot be regarded as Mandshurs, Monguls, or Tartars proper. See TIBET.

**BOOTES,** in *Astronomy*, a constellation of the northern hemisphere, being one of the 48 old ones; whose stars, in Ptolemy's catalogue, are 23; in Tycho's 28; in Bayer's

34; in Hevelius's 52; and in Mr. Flamsteed's catalogue 54; of which one, in the skirt of his coat, is of the first magnitude, and called Arcturus; which see. We have some account of the resplendent belt of the stars in Bootes by Dr. Herschel in the Phil. Trans. for 1797, p. 309.

Bootes is represented as a man in a walking posture, with his right hand grasping a club, and his left extended upwards, and holding the cord of the two dogs which seem barking at the great bear. The Greeks give no certain account of the origin of this constellation. The poets say, that Bootes was Icarus, the father of Erigonus, whom Jupiter placed in the heavens. Others suppose him to be Arcas, the son of Callisto. Those, who, at a very early period, supposed the stars, which were afterwards formed into the great bear, to represent a waggon drawn by oxen, made this Bootes the driver of them; from which circumstance he was called the waggoner; others continued the office when the waggon was destroyed, and made it his office to drive the two bears round about the pole; and some, when the greater waggon was changed into the greater bear, wished still to preserve the form of that machine in the stars which constitute Bootes.

This constellation is called by various other names, as Arcas, Arctophylax, Arcturus Minor, Buhuleus, Bubulus, Clamator, Icarus, Lycaon, Plorans, Plautri-Custos, Philometus, Thegnis, and Vociferator; by others, Ceginus, Lanceator, Septentrio; by Hesychius, Orion; by others, Canis Latrans; by the Arabs, Aramech, or Arcamech. Schiller, instead of Bootes, makes the figure of St. Sylvester; Schickhard, that of Nimrod; and Weigelius, the three Swedish crowns. Wolf. Lex. Math. p. 266.

BOOTH, *Botba*, denotes a stall, or standing in a fair or market; the term is also applied to any temporary structure formed of boards and boughs, and designed for shade and shelter.

BOOTH, HENRY, in *Biography*, earl of Warrington, and baron Delamer of Dunham Massey, an upright senator, and distinguished patriot, was descended from a family of great antiquity, and born in 1651. During the life of his father, he was Custos Rotulorum for the county palatine of Chester, and represented that county in several parliaments during the reign of Charles II. His zeal for the protestant religion, and for the liberties of his country, was conspicuous at an early period of his life. He was active in promoting the bill for excluding the duke of York from the throne; he also made a spirited speech in support of frequent parliaments, and against governing by favourites; and he opposed, with a manly firmness, the unjust and arbitrary power assumed by the privy-council, of imprisoning men contrary to law. He was anxious likewise for preserving parliament uncorrupt; and with this view contended for an act to punish those who had received bribes from the court, as members of the parliament denominated the pension-parliament. He also spoke in parliament against the corruption of the judges, charging them with having sold, denied, or delayed justice, and recommended an inquiry into their conduct, and that those who were found guilty might receive merited punishment. His zeal against the papists, and his vigorous opposition to the arbitrary measures of the court, rendered him particularly obnoxious to the governing powers; so that he was turned out of the commission of the peace, deprived of his office, as Custos Rotulorum of the county of Chester, and committed close prisoner to the tower of London, from which, however, he was after a few months released. After the accession of James II. he was twice committed to the tower; and in the beginning of the year 1686, brought to trial, under a charge of high treason. Judge Jefferies maintained, on this occasion, that it was not necessary, in point of law, that there

should be two positive witnesses, in order to convict a man of treason; and that if there was only one positive witness, additional circumstances might supply the place of a second. Lord Delamer, who came to the title in 1684 by the death of his father, made an able defence; and was unanimously acquitted. From this time he lived in retirement at his seat at Dunham Massey; but when matters became ripe for the revolution, he exerted himself in the promotion of that great event. In a note to Dr. Akenfide's ode addressed to the earl of Huntingdon, it is said, that at Whittington, a village on the edge of Scarfdale in Derbyshire, the earls of Devonshire and Danby, and the lord Delamer, privately concerted the plan of the revolution. The house in which they met is at present a farm-house; and the country-people distinguish the room where they sat by the name of the "plotting-parlour." Lord Delamer appears to have been one of the first who took up arms in favour of the revolution. After he had joined the prince of Orange, he was deputed, in December 1688, together with the marquis of Halifax, and the earl of Shrewsbury, with a message to king James, intimating to him, that he must remove from Whitehall. To the respectful manner in which he executed this commission, James bore testimony, after his retirement to France; observing that "the lord Delamer, whom he had used ill, had then treated him with much more regard than the other two lords, to whom he had been kind, and from whom he might better have expected it." His lordship, however, was fully convinced of the necessity of dethroning the king; and in a debate, relative to declaring the throne vacant, he said, that "it was long since he thought himself absolved from his allegiance to king James; that he owed him none, and never would pay him any; and if king James came again, he was resolved to fight against him, and would die single with his sword in his hand, rather than pay him any obedience." Such were his services in support of the revolution, that he was honoured with several official appointments at that period. The offices of lord-lieutenant of the city and county of Chester, and of Custos Rotulorum of that county, to which he was promoted, he enjoyed for life. Lord Delamer, however, seems to have been no favourite at court; his disposition did not seem to have been formed for a pliant courtier under any establishment; and with respect to his political sentiments, he seems to have been one of those who wished for more retrenchments of the regal prerogative than were made at the revolution. But though his lordship was removed from the administration, letters patent were issued, in 1690, for creating him earl of Warrington, in the county of Lancaster, to continue to him and the heirs male of his body; and a pension likewise of 2000*l.* per annum was granted to him, for the better support of that dignity; but it is said, that this pension was paid to him only for the first half year, and afterwards suffered to run in arrear. On the 3d of January 1692-3, the earl of Warrington signed a protest against the rejection of the bill for incapacitating persons in office under the crown, either civil or military, from sitting in the house of commons. This patriotic peer died at London on the 2d of January 1693-4, in the 42d year of his age. He left four sons and two daughters; but his second son dying in 1758, without heirs male, the earldom became extinct. Mr. Granger says, that lord Delamer was "a man of a generous and noble nature, which disdained, upon any terms, to submit to servitude; and whose passions seemed to centre in the love of civil and religious liberty." In every part of his life, indeed, he seems to have been actuated by the same principles; and in his "Advice to his Children," printed in his works, he says, "There never yet was any good man, who had not an

ardent zeal for his country." In private life, he was a man of strict piety, and of great worth, honour, and humanity. His works were published in 1694, in one volume 8vo. They consist chiefly of speeches made by him in parliament, prayers used by his lordship in his family, some short political tracts, and the case of William earl of Devonshire. *Biog. Brit.*

BOOTH, BARTON, an applauded tragic actor, was descended from an ancient and respectable family in Lancashire, born in 1681, and educated under Dr. Busby at Westminster school. Whilst he was at school, he exhibited early indications of those talents which qualified him for his future profession; as, besides his fondness for Latin poetry, he was distinguished by the grace and energy with which he recited several passages selected from it and committed to memory. Flattered by the applause which he received in acting a part in a Latin play, performed at school, he acquired, or at least indulged, an inclination for the stage; and, eloping from school, at the age of 17, very much to the disappointment and grief of his father, who designed him for the university and the church, he accompanied the manager of an Irish theatre to Dublin. On the Dublin stage he performed for three seasons with very distinguished applause; recommending himself, particularly in tragedy, by a grave countenance, good person, an air of dignity in his aspect and manner, a fine voice, and a very manly action. Besides, he spoke very justly, his pronunciation was very correct, and the cadence of his voice was extremely grateful to the ear. The theatrical reputation which he acquired in Ireland, determined him to return to London in 1701; and being recommended to Mr. Betterton, he was treated by him with kindness, and had important parts assigned to him at his theatre. After the death of Betterton, he was received into the Drury-lane company, and, by his acknowledged abilities, he rose to the highest rank in his profession, as a tragic actor. When Mr. Addison's famous play of *Cato* was introduced on the stage in 1712, as it is said, with political views, and to support the cause of the whigs, the part of *Cato* was assigned to Mr. Booth, and it was performed so much to the satisfaction of the house, that both the whigs and Tories of that period concurred in bestowing upon him unusual and unprecedented rewards. On this occasion, it is said, that lord Bolingbroke made him a present of fifty guineas from the stage-box, and that the managers afterwards presented him with the same donation. By the patronage and influence of lord Bolingbroke, he was associated, in 1713, to the patentees of the theatre; and for twenty years conducted himself, both as a manager and an actor, with such distinguished integrity and abilities, as to secure the uninterrupted approbation of the public. He married for his second wife, Mrs. Santlowe, a favourite actress, with whom he lived in great harmony, and to whom, in token of his affection, he left his whole fortune, which, according to his own declaration, amounted to no more than two-thirds of what he had received with his wife upon the day of marriage. At length his health began to decline; but such was the high estimation in which he was held by the public, that his appearance drew together crowded audiences, whenever the intervals of his distemper permitted him to tread the stage. But his constitution rapidly decayed, and he sunk under a complication of diseases, May 10, 1733. He was buried privately, according to his own direction, at the parish church of Cowley, near Uxbridge, the constant place of his summer retirement, and no monument was erected to his memory. His wife, however, who survived him forty years, caused a monument to be erected in Westminster abbey, in 1772.

As an actor, Booth distinguished himself by that solemn

dignity, and rotundity of declamation, which served to mark distinctly the cadence and melody of the versification. Without altogether neglecting the expression of passion, his manner seems to have been better suited to poetical and sentimental parts, such as that of *Cato*, and the heroes of Rowe's tragedies, than to the highly impassioned. Cibber, however, says, that the maller-piece of Booth was *Othello*, a character abounding with sudden turns of passion, united with elevated sentiment and striking imagery. There, says Cibber, he was more in character, and seemed not more to animate or please himself in it than his spectators. To his *Cato* he gives qualified praise, and he ascribes the reputation acquired by it to several temporary and incidental circumstances; but in *Othello*, he adds, we may see him in the variety of nature. Mr. Victor hath taken pains to do justice to Mr. Booth, in opposition to the lukewarm praise of Cibber, and to the reflection contained in Pope's epithet of "well-mouthed," and in the severe illustration of it by his right reverend annotator; and yet, perhaps, Pope's epithet, though invidiously employed, gives a just idea of his general manner.

As a man of letters, Booth appears in a respectable light; though his indolence prevented him from exerting himself much in this way. He translated some odes of Horace, and wrote several songs and other small pieces of poetry, which were well received; and he composed for the stage a mask, entitled "*Dido and Æneas*." In his private character, he was just and upright; ready to acknowledge and reward merit wherever he found it; somewhat rough in his manner, and hasty in his temper, but frank and sincere in declaring his sentiments; kind and liberal in his conduct as a manager; respectful to his parents; affectionate to his brother and sister; and polite and generous to his friends and acquaintance. He was generally esteemed by those who knew him; and his death was much regretted. *Biog. Brit.*

BOOTH BAY, in *Geography*, a town and bay of America, on the coast of Lincoln county, in the district of Maine, about two miles west of Pemaquid point. N. lat. 43° 42'. The bay stretches within the land about 12 miles, and receives two small streams. On it is a town, having 997 inhabitants.

BOOTIA, in *Botany* (De Neck). See *SAPONARIA Officinalis*.

BOOTY, in the *Military Art*, the moveables taken from an enemy in war, which belonged to the conquerors. Among the Greeks, the booty was divided in common among the army, the general only claiming a larger share. The right of making a distribution of it was always considered as one of the prerogatives of the general. During the Trojan war, it was laid at his feet; one part he reserved for himself, and divided the remainder either among the chiefs or the soldiers. As soon as a victory was obtained, the armour was seized by the conquerors, or great commanders; and the common soldiers were permitted to gather the spoils of the dead. *Hom. Il.* x. 458. §. 66.

The Lacedæmonians were forbidden to meddle with the spoils of the conquered; and the Spartans had always 300 men appointed to observe their actions. Instances, however, occur of their dedicating part of their booty to the gods. When any booty of great value was taken, the soldiers presented their general or commander with it; but before the distribution of the spoils, they selected the best as an offering to the gods. Eight hundred years after the Trojan war, the generals regulated the partition of the spoils taken from the Persians after the battle of Platæa. They were shared among the soldiers, after setting apart a certain portion to decorate the temples of Greece, and decreeing proportionable re-

wards to those who had distinguished themselves in the action. From that time, the Grecian general disposed of the spoils arising from the sale of the plunder; sometimes donating them to the public treasury; at other times assigning them to defray the expence of public works, or the decoration of temples; enriching their friends and soldiers with them; adding them to their own wealth; or at least appropriating to themselves the third part, which in certain countries was regularly assigned them by constant usage. Polyb. Hist. lib. p. 147.

By the military discipline of the Romans, spoils taken from the enemy belonged to the republic; particular persons having no right to them. The generals who prized themselves on their probity, carried it wholly to the public treasury. Sometimes, indeed, they divided it among the soldiery, to animate them, and serve in lieu of reward. But this distribution depended on the generals, who were to conduct themselves herein with great equity and moderation; otherwise it became a crime of peculation to lay hands on the pillage, as regularly belonging only to the state. The consuls Romulus and Veturius were condemned for having sold the booty taken from the Æqui. Liv. lib. iii.

Among the Jews, the booty was divided equally between the army and the people, though under the kings a different kind of distribution obtained. Numb. xxxi. 27.

Among the Mahometans, two thirds of the spoils are allowed to the army; the other third to God, to Mahomet, and his relations, and to the orphans, the poor, and the pilgrims. Calmet. Dict. Bib. tom. i. p. 321.

Among us, formerly, the booty was sometimes divided among the soldiery. If the general be in the field, every body takes what he can lay hold on: if the general be absent, the booty is distributed among the soldiers, two parts being allowed to the cavalry, and one to the infantry. A captain is allowed ten shares, a lieutenant six, and a cornet four. See PRIZE.

BOUROU, in *Geography*, an island near the east coast of Otaheite.

BOPAL, or BOPALTOL, a town of Hindostan, in a district of the same name, in the country of Malwa; placed by Mr. Rennell in N. lat. 23° 14'. E. long. 77° 28'. The town is extensive, and surrounded with a stone wall; the streets are wide and straight. On a rising ground, to the south-west of the town, is a fort called "Futteh-gurh," newly erected, and not quite finished. It has a stone wall, with square towers, but no ditch. The spot on which it is erected is a solid rock. To the south-west, under the walls of this fort, is a very extensive tank or pond, formed by an embankment, at the confluence of five streams issuing from the neighbouring hills, which form a kind of amphitheatre round the lake. Its length is about six miles; and from it the town has the addition of "Tal" to its name. These hills, and others in the neighbourhood, contain a soft free stone, and a reddish granite, the latter of which seems well fitted for buildings that will resist water, and the injuries of the weather; and it is accordingly used in the new embankment which is building at the east end of the lake. From this part issues the small river "Patara;" and it is said that the "Betwah" takes its rise from another part of the same. The town and territory of Bopal are occupied by a colony of Patans, to whom they were assigned by Aurangzebe. The revenue of Bopal is estimated at 10 or 12 lacs of rupees. It does not pay any regular tribute to the Mahrattas; but a handsome present is occasionally sent to conciliate their friendship. The people seem to be happy under their present government; and the Dewan, by his hospitality, and the protection afforded to strangers, has in-

duced the caravans, and travellers in general, to take this road between the Deccan and Hindostan. Asiatic Researches, vol. vi. p. 31.

BOPPART, or BOPPARD, an ancient town of Germany, in the circle of the Lower Rhine, and lower electorate, once imperial, seated on the banks of the Rhine, and formerly belonging to the archbishop of Treves. Since the French revolution, it is the chief place of a canton, in the department of the Rhine and Moselle, and in the district of Coblentz, from which it is distant 8 miles south. The place contains 2220, and the canton 7232 inhabitants. At this town a toll used to be exacted of vessels which passed along the Rhine. Near the river the town is surrounded by high mountains, the summits of which are richly covered with woods; and when the foliage appears upon the trees, the country about it forms a scene truly picturesque and extremely luxuriant. On a mountain behind the town was a Benedictine nunnery, called the abbey of Marienberg; and besides this, there were a convent of Carmelites, and another of Franciscans, in very romantic situations.

BOPPINGEN, an imperial town of Germany, in the circle of Swabia, and county of Oettingen, on the Eger; 5 miles west of Nordlingen, and 28 N.N.E. of Ulm.

BOPQUAM, or *M'Quam* bay, lies on the east side of lake Champlain, in Swanton, Vermont, and has Hog Island on the north at the mouth of Michicouli river.

BOQUET, a river of America, which passes through the town of Willborough, in Clinton county, New York, and is navigable for boats about two miles, and there interrupted by falls on which are mills.

BOQUINEN, a town of Spain, in Arragon; 18 miles N.W. of Saragossa.

BOQUINI, in *Ecclesiastical History*, a sort of Sacramentarian, who asserted that the body of Christ was present only in the eucharist to those for whom he died, that is, the elect. They took the denomination from one Boquinus, a Lutheran divine, who was one of the chief of the party.

BORA, in *Ancient Geography*, a mountain of Macedonia, mentioned by Livy, between Illyria and Epirus.

BORMETA, a town of India, placed by Ptolemy on the other side of the Ganges.

BORABASSOU, in *Geography*, a town of the island of Celebes, where are manufactures of cotton and silk stuffs.

BORACIC ACID, *Acide Boracique*, *Boraxsaure*. This substance was first discovered in 1702, by Homberg; who, by heating together in a subliming vessel a mixture of borax and sulphat of iron, obtained a white crystalline salt, which from its supposed medical properties he named *volatile narcotic salt of vitriol*, or *sedative salt*. The term *boracic acid* was appropriated to this salt by Lavoisier and his associates, at the general reformation of the chemical nomenclature.

Boracic acid may be prepared in two ways; either by sublimation or precipitation. The best method of obtaining it, according to the former of these processes, is as follows:

Take two parts of purified borax reduced to a fine powder, and mix them in a glass alembic with one part of sulphuric acid previously diluted with an equal weight of water. On the application of a gentle heat, the borax will dissolve; and at a boiling temperature, there will first arise an acidulous water, and afterwards, when the mass in the alembic begins to grow thick, a light, white, glittering micaceous salt will collect in the capital, which is the boracic acid. As this salt sublimes only while the last portions of moisture are evaporating, it is necessary to return back the acidulous water repeatedly upon the mass in the alembic, in order to obtain the whole of the boracic acid; but this being a tedious operation, and generally terminating with the fracture of the

the alembic, is at present but little practised. The most expeditious and economical way of preparing the boracic acid, is by precipitation; for this purpose, take a boiling hot saturated solution of purified borax in water, and add to it, by a little at a time, so much sulphuric acid as to make the solution slightly acidulous. The liquor, when cold, will be found to have deposited a considerable quantity of thin crystalline plates of boracic acid, and more may be obtained by successive evaporation and cooling, till crystals of sulphated soda begin to make their appearance. The sulphuric acid is on several accounts preferable to any other for the decomposition of the borax; yet the nitric, muriatic, or even the acetous acids may be made use of, and will effect a separation of the boracic acid from the soda with which it was united in the borax. The proportion of acid obtained by precipitation amounts, according to Beaumé, to nearly one half of the borax made use of; and it is this kind of boracic acid that has been used by most chemists in their experiments on this substance. The precipitated acid is, however, by no means pure, as it retains, according to Cadet, a portion of the acid made use of in its precipitation, and consists, according to Beaumé, of about

56 boracic acid
14 an impure unsublimable salt
30 water of crystallization

---

100

---

Sublimed boracic acid is in the form of very minute thin plates, with a shining silvery lustre, and remarkably voluminous in proportion to its weight. The crystallized acid has the same general appearance, only it is in larger plates, and of considerably greater specific gravity.

The taste of boracic acid is slightly subsaline; it reddens syrup of violets, but exhibits very feeble acid characters. It is very difficultly soluble in cold water, and requires a considerable proportion of hot water; as the hot solution cools, it deposits in crystalline plates nearly the whole of the acid which it had taken up. Alcohol takes up a larger quantity of this salt than water does, and burns in consequence with a green flame. On this account boracic acid has been supposed by some chemists to contain copper. But if a piece of paper is dipped in the alcoholic solution, and then dried, it will burn with a deep yellow flame; hence it is obvious, that the green tinge in question is only caused by a mixture of the yellow flame of the boracic acid with the blue one of the alcohol.

When boracic acid is heated to redness in a silver crucible, it becomes first of a pasty consistence, and then melts into a tenacious glass perfectly colourless and transparent. By exposure to the air, this glass becomes opalescent, but does not undergo any other change; it is soluble in water, and may be obtained, by cooling and evaporation, in the state of crystalline plates as before. When fused in an earthen crucible, it dissolves some of the earth, and forms a semi-transparent glass considerably less fusible than the pure acid; and when dissolved in water, and evaporated, it becomes a gelatinous mass, superficially covered with a few crystals of boracic acid.

Neither the oxygenating nor deoxygenating processes appear to have the smallest effect on this acid; and all attempts to raise it to a higher degree of oxygenation, or to decompose it, numerous as they have been, have not been attended with the smallest success. It unites in the moist way by single affinity with the caustic alkalies, and by compound affinity also with the earths and metallic oxyds; its attraction, however, is so feeble, that it is incapable, when in solution, of

dissolving even the carbonic acid from its basis. But weak as boracic acid is in the moist way, its fixity in the fire enables it to separate, in a high heat, the sulphuric, nitric, muriatic, and all the other volatilizable acids from their bases, forming with them a genus of salts called *borats*, none of which, except the sub-borat of soda, or common BORAX, has hitherto been made the object of chemical investigation.

Boracic acid, besides being obtained from the decomposition of borax, is also found native in certain hot springs and lakes in Tuscany. It is not applied to any medical, chemical, or economical use.

BORACITE, *Borazit, Wurfelslein; Magnésie boratée*, Haüy. The colour of this mineral is yellowish, smoky or ash-grey, passing into greyish or greenish-white. It occurs in small cubic crystals truncated on the angles. The crystals are for the most part opaque, some are semi-transparent, and a few of the smallest are entirely transparent. Their lustre internally is considerable, and of the vitreous kind. The fracture is small and flat conchoidal, passing into uneven and splintery. The crystals are often corroded more or less, and then are easily pulverizable; but when perfect, they are hard enough to give brisk and lively sparks when struck against the steel. Sp. gr. 256.

The boracite, when exposed to a full red heat, becomes opaque, and loses about  $\frac{1}{2}$  per cent. of its weight, but undergoes no other change; when intensely heated in a clay crucible, it runs into a yellowish glass. It is entirely, though with difficulty, soluble in muriatic acid by long digestion. According to the analysis of Westrumb, it consists of

68 boracic acid
13.5 magnesia
11 lime
1 alumine
0.75 oxyd of iron
2 silex

---

96.25

---

Some later experiments, however, of Vauquelin make the proportion of lime to be much smaller; and it appears probable, that the only essential ingredients of this mineral are boracic acid and magnesia.

Boracite is found near Lunenburg, in the duchy of Brunswick, lining the sides of a vein in a hill of sulphat of lime. The crystals from their shape were known in the neighbourhood by the name of wurfelspath, or cubic spar, and were supposed by some mineralogists to be a variety of quartz. The presence of boracic acid in them was not suspected, till the analysis of Westrumb, published in 1788, in the Transactions of the Society Nat. Curios. Emmerling. Haüy. An. de Chim. v. 11.

BORAGE, in *Botany*. See BORAGO.

BORAGINÆÆ, the ninth order of the eighth class of Jussieu, of which he gives the following natural character. *Calyx* five-parted, permanent. *Corolla* most commonly regular. *Stamens* generally five. *Germ* simple, or four-lobed. *Style* one. *Stigma* either bifid, furrowed, or simple. *Seeds* most frequently four, either in a capsule or a berry; or else apparently naked, obliquely attached to the style, and for the most part enclosed in the permanent calyx. *Coraculum* without a perisperm. *Stem* in most herbaceous; in a few, a shrub or a tree. *Leaves* alternate, often rough.

The genera are thrown into five divisions. 1. Fruit, a berry; stem, a shrub or a tree. Patagonula, cordia, ebretia, menais, varronia, tournesortia. 2. Fruit, one or two-cap-sular, herbaceous. Hydrophyllum, phacelia, ellisia, dichondra?

chondra? messerschmidia, cerinthe. 3. Fruit, four naked seeds; throat of the corolla naked; for the most part herbaceous and rough. *Coldemia*, *heliotropium*, *cehium*, *lithospermum*, *pulmonaria*, *onofima*. 4. Fruit, four naked seeds; throat of the corolla closed; herbaceous, and generally rough-leaved. *Symphytum*, *lycopis*, *myofotis*, *anchusa*, *borago*, *asperugo*, *cynoglossum*. Obs. The last two divisions would more logically have been thrown into one, with two subdivisions. They constitute Linnæus's natural order, *asperifolia*. 5. Allied to the boraginæ; herbaceous. *Nolana*, *spionatus*? *falkia*, the connecting link between the boraginæ and convolvuli.

La Marek (*Encyc. Method.*) gives the boraginæ a character which belongs almost exclusively to the *asperifolia* of Linnæus. He has only three divisions: 1. Four germs, or one, four-parted; the proper *asperifolia*. 2. Five germs, or one with five divisions; *nolana*, *monneria*, *raputia*. The natural situation of the last two was left undetermined by Jussieu. 3. One undivided germ; comprehending the first and second division of Jussieu. He has placed this division last, apprehending, and surely not without reason, that it ought to form a distinct order between the boraginæ and convolvuli.

The boraginæ compose the twelfth family of the eighth class of Venterat, in his "Tableau du regne vegetal." It contains only the *asperifolia*, with the Linnæan character, except that, in concurrence with Gærtner, the fruit is considered as consisting of two or four nuts; in the former case each two-celled and two-seeded; in the latter, each one-celled and one-seeded; the seeds attached either to the inner side or base of the nut by a filiform or capillary peduncle or placenta.

**BORAGO** (derivation of the name uncertain). Linn. gen. 188. Reich. 200. Schreb. 248. Willd. 283. Juss. 131. Gært. tom. i. 415. Smith Flor. Brit. 78. Clafs, *pentandria monogynia*. Nat. Ord. *asperifolia*—*Boraginæ* Juss.

Gen. Charac. *Cal.* perianth five-parted, permanent. *Cor.* monopetalous, wheel-shaped; border five-parted, flat; segments acute; throat crowned with five emarginate, obtuse prominences. *Stam.* five, awl-shaped, converging; anthers oblong, fixed to the inside of the filaments in the middle, converging. *Pist.* germs four; style filiform, longer than the stamens; stigma simple. *Pericarp* none; calyx larger, inflated, containing the seeds. Linn. Schreb. La Marek, Juss. *Pericarp*, nuts four, boney, ovate, a little compressed, slightly convex on one side, smooth, shining, light chestnut, obsoletely angular, marked with a longitudinal furrow in the middle, and with parallel, transverse wrinkles, imperforate, one-celled, without valves. *Seed* solitary, ovate-acuminate, almost black. Gært.

Eff. Char. *Cor.* wheel-shaped; border spreading, acute; throat closed with rays.

Species, 1. *B. officinalis*. Eng. Bot. 36. common borage. "All the leaves alternate; calyxes spreading." Linn. Root long, fleshy, tender, white, fibrous; stem about a foot and a half high, branched, hollow, succulent, cylindric; leaves alternate, large, oval-lanceolate, obtuse, wrinkled, deep green, and, as well as the stem, rough, with sharp, rigid, white bristles; the lower on petioles, the upper sessile; flowers terminating on branched peduncles, blue, flesh-coloured, or white; calyx and corolla divided to the base; tube short and white; filaments short, white, springing from the claws of the petal, with a sharp blue process, where the dark purple or blackish anthers are inserted. Said to have come originally from Aleppo, but now naturalized in many parts of Europe, and not uncommon in the neighbourhood of Lon-

don on dunghills and among rubbish, where it is scarcely more than biennial. It was formerly cultivated in gardens, on account of the supposed cordial virtues of its flowers, but they have long lost their reputation, having neither warmth, pungency, smell, nor any other indication of active qualities. Its root, stem, and leaves contain an insipid viscous juice, which, on being boiled a considerable time, form crystals of nitre. A clarified syrup formed from it is prescribed by the French physicians in pleuritis, and other disorders which require a cool treatment. In Italy its young and tender leaves are in common use, both as a pot-herb and a salad. In France its flowers, with those of *nasturtium* (*tropæolum*), are put into salads as an ornament. In England the flowers and upper leaves are used as an ingredient in that summer beverage composed of wine, water, lemon-juice, and sugar, called a cool tankard, to which they seem to give an additional coolness. 2. *B. indica*. "Leaves of the ramifications opposite, embracing the stem; folioles of the calyx sagittate." Linn. "Peduncles one-flowered." Miller. An annual plant, rarely rising a foot high. Stem branching, rough, with small, white, stiffish hairs; leaves lanceolate, rugged, only the lower ones opposite; flowers axillary, shorter than the leaves; folioles of the calyx five-angled, hispid, expanding at the base into two remarkable sharp-pointed auricles; corolla white, pale-blue, or flesh-colour, with five rust-coloured spots. A native of the East Indies. 3. *B. ajricana*. "Leaves of the ramifications petiolate; folioles of the calyx ovate, acute, erect." Linn. "Peduncles many-flowered." Mur. Whole plant hispid, with stiff, fragil bristles, seven or eight inches high, more branching than *B. indica*. Leaves large, ovate, and opposite; floral leaves small and alternate; corolla small, blue, yellow within, with five purplish spots; peduncles terminating, divided, and almost racemed; folioles of the calyx entire. Native of the cape of Good Hope, cultivated by Mr. Miller in 1759. 4. *B. zeylanica*. "Leaves of the ramifications sessile; peduncles one-flowered; calyx without ears." Linn. Mant. Stem hispid, branching, about a foot high; leaves of the stem opposite, lanceolate, hispid; of the branches alternate, more numerous, smaller, and more acute; peduncles axillary, filiform, solitary, longer than the leaves; calyx the length of the corolla, erect. A native of the East Indies. 5. *B. longifolia*. Poir. Barbary. "Leaves linear-lanceolate, sessile, alternate; calyx very hairy at the base." Willd. Allied to the foregoing, but sufficiently distinct. Segments of the calyx linear, without ears. A native of Barbary. 6. *B. orientalis*. "Calyxes shorter than the tube of the corolla; leaves cordate." Linn. Petiolate; peduncles many-flowered; stamens longer than the corolla, hairy. La Marek. Root large, fleshy, black without, whitish within, full of an insipid viscous juice; stem more than two feet high; root leaves large, on long peduncles, cordate; stem leaves alternate, small, ovate, on membranous petioles, channelled at the base; flowers axillary, and terminating, panicled; tube of the corolla longer than the calyx, white; border white, reflexed. A native of the country about Constantinople. 7. *B. cretica*. "Calyxes the length of the tube of the corolla; leaves ovate." Willden. Taken up from Tournefort, cor. 6, and described from a dried specimen. Segments of the calyx ovate rhomboid, very entire; flowers red.

*Propagation and Culture.* The first is a hardy annual, which will sow its own seeds, and come up without care. The seeds of the second, third, and fourth should be sown upon a hot-bed in March, and the plants should afterwards be separately planted in a small pot, with light earth, and plunged in a new hot-bed; in hot weather they should be allowed

allowed a good deal of air. The sixth is a perennial, easily propagated by the root, which may be parted in autumn, and planted in a dry soil and warm situation.

**BORAGO** (Morfon). See *CYNOGLOSSUM ophthalmodes*.

**BORAHS**, Lat. *Bocrofa*, in *Geography*, a town of Sweden, in the province of West Gothland, situate in a mild and mountainous country, on the river Witka. It was founded by Gustavus Adolphus, and in 1622 endowed with several privileges. Its inhabitants are a sort of itinerant pedlars, who deal in linen, and traverse the kingdom for this purpose. This town was destroyed by fire in 1727; but was afterwards rebuilt, and continues in a good condition. It has a spring of medicinal water; and has the forty-third vote in the diet.

**BORAK**, among *Mabometans*, a fabulous animal, supposed to be of a middle kind between an ass and a mule, whereon the prophet was carried in his nocturnal flight from Jerusalem into the Heavens.

This animal the Arabs called *Al Borak*, q. d. *flying*. The night when the journey was performed is called *Leilat al Meerage*, i. e. *the night of ascension*; and the flight itself *Al Mesra*, concerning which there is a multitude of traditions.

**BORANA**, in *Entomology*, a species of *TORTRIX* that inhabits Sweden. This is of a large size, with the head cinereous, and thorax fuscous. Fabricius, who describes it in his *Mantissa*, thus defines it specifically: wings varied with cinereous and fuscous, with elevated scattered dots.

**BORANI**, in *Ancient Geography*, a people of Scythia, who, after having inhabited the borders of the Danube, passed the Cimmeric Bosphorus, under the emperor Justinian, and established themselves in Asia.

**BORANO, CAPE**, in *Geography*, lies near the N.W. extremity of the large gulf of Venice, and forms the N.E. point to the cluster of islands that impede the entrance into that city. N. lat. about 45° 16'. E. long. 12° 30'. An island of the same name lies within the cape.

**BORASSUS**, in *Botany* (*Βορσσος*, Dioscorides). Linn. 1220. Reich. 1336. Schreb. 1689. Class, *appendix palms*, Linn. *diæcia hexandria*, Thunb.

Gen. Char. Male, *ampana*, Rheede Hort. Mal. Cal. spathe universal, compound; spadix amentaceous, imbricate; perianth proper, three-leaved; leaves ovate, concave. Cor. none. Stam. filaments six, thickish; anthers thicker, striated.

Female on a distinct plant, *carimpana*, Rheede. Cal. spathe and spadix as in the male; perianth proper, three-leaved, permanent; leaves roundish, obtuse. Cor. petals three, roundish, permanent; in La Marck's figure exactly similar in form and size to the leaves of the calyx. Pist. germ roundish; styles three, small; stigmas simple. Pericarp, drupe, roundish, obtuse, rigid, one-celled. Seeds three, sub-ovate, compressed, distinct, filamentose.

Species, *B. flabelliformis*. La Marck Illust. Pl. 898. "Frons palmate, cowl'd; stipes ferrate." Linn. A tree twenty five or thirty feet high; two feet thick at bottom, and one at top. Trunk, bark of a dark colour; wood dark rufous red, with a soft pith in the middle; fronds about eight, decussate (umbellate, La Marck), at the top of the trunk; stipe near six feet long, round, and near a span in breadth below, flat, somewhat concave, and not more than a palm above, rough with spines along the edges. The leafy part large, widely expanded, folded like a fan, and used as such in its native countries; at the edges of the folds, furnished with prominent rough ribs; gashed at the extremity; of a dense and thick texture, striated lengthways with close

veins; fruit size of a child's head; external rib or shell, when ripe, blackish and shining near the calyx, longitudinally striated with furrows and fissures greenish yellow above; containing a dense pulp, at first soft and white, afterwards filamentous and succulent, of a sweetish not unpleasant taste, and strong smell. In the pulp are separately imbedded two or three oblong flat nuts, with a thick woody shell, containing, when young, a blue, gelatinous, insipid kernel, of a sweet, pleasant flavour, which finally becomes too hard to be eaten. Ray Hill. Plant. A wine and a sugar are made from the sap of the tree. Native of the East Indies.

**BORAX**, in *Chemistry*. sub-borat of soda.

Borax is a saline substance, which has hitherto been found only in Tibet, an extensive mountainous district to the north of Hindostan. According to the most authentic recent accounts, especially the report of Mr. Saunders, who visited Tibet, in company with Mr. Turner, in the year 1783, borax is procured from a mountain lake, fifteen days' journey from the capital of Tibet. This lake is encompassed by rocky hills, and is entirely supplied by springs, no stream either falling into it or flowing from it. The water has a salt taste, and contains both borax and common salt; and, on account of its elevated situation, is frozen for a great part of the year. The edges and shallows of the lake are covered with a stratum of borax, which is dug up in considerable masses, and the holes thus made are gradually filled by a fresh deposition; from the deeper parts of the lake, rock salt is procured. The borax, in its rough state, is called tincal, and is brought to Europe in the form of a brownish grey impure amorphous salt, or in detached crystals, about an inch in length, of the form of compressed hexahedral prisms.

The purification of borax is an art which was first appropriated by the Venetians, afterwards passed to the Dutch, and is now practised in great perfection by some English chemists. The process is as yet kept a secret, but in all probability consists of calcination and solution.

The crude borax is often covered with an oily or greasy matter, to prevent it from efflorescing, and, on this account, is not easily acted on by hot water. It appears, however, that by exposing the tincal to a calcining heat, lower than its point of fusion, the grease may be burned off, and other inflammable impurities may be got rid of; the residue being then reduced to a fine powder, and digested in boiling water, the saline parts will be dissolved, leaving most of the impurities behind. The further completion of the purification is probably effected by the common clarifying substances, and repeated solution and crystallization.

Borax, when quite pure, is in colourless crystalline masses, very slightly efflorescent on exposure to the air. Its sp. gr. according to Kirwan, is 1.74. Its taste is somewhat sweetish, and sensibly alkaline. It turns syrup of violets green; shewing, therefore, an excess of alkali in its composition. It contains, according to Kirwan,

34 boracic acid
17 soda
47 water of crystallization
—
98

Borax, when exposed to a dry heat, speedily dissolves in its water of crystallization; it then, as the moisture evaporates, becomes of an opaque white colour, and a voluminous spongy texture, like burnt alum. If the heat is increased to a moderate redness, it liquefies, and when cool, appears as a colourless transparent glass. If poured out of the crucible in order to cool, it should be transferred, as soon as it becomes solid, to a covered basin, or other proper vessel, for it always

cracks and flies to pieces before it grows cold. Borax, when thus fused, is called glass of borax; by exposure to the air, it acquires the appearance of chalcedony, on account of the partial efflorescence that it undergoes. If made in a silver crucible, or if *hasily* melted in an earthen one, it is perfectly resolvable in water; but when kept fluid for a long time in a common crucible, it dissolves a portion of the earth of the vessel, and becomes little, if at all, soluble in water.

Crystallized borax requires twelve parts of water at the common temperature for its solution, but only six parts of boiling water; it therefore deposits crystals by mere cooling. Borax is decomposable by all the mineral and vegetable acids when added to excess, the boracic acid being separated, and the soda uniting with the other acid; but if only the excess of soda is combined with the other acid, the whole, by evaporation and cooling, forms a confusedly crystallized mass, consisting of the three ingredients in mutual combination. Borax will also dissolve and combine with nearly half its weight of boracic acid, forming borat of soda. In this salt the acid and alkaline parts completely saturate each other, so that it produces no change on syrup of violets, neither does it possess any longer an alkaline taste; it does not effloresce like common borax, nor are the forms of its crystals the same. The affinity of soda for boracic acid is not so great as that of barytes, strontian, lime, and magnesia. These alkaline earths, therefore, decompose borax; the pure alkali remaining in solution, and the earthy borats forming pulverulent insoluble salts. Potash is also capable of decomposing borax; but borat of potash being very soluble in soda, no precipitation takes place.

Silex and alumine combine in the dry way with borax, the former into a transparent, the latter into an opaque glass. If the ingredients are in nearly equal proportions, the glass is insoluble in the mineral acids; but if a considerable excess of borax is employed, the result is a soluble glass. Of this circumstance Mr. Chenevix has ingeniously taken advantage by substituting borax for caustic potash in the analysis of the more refractory stony compounds, the use of the former salt being much more convenient, on many accounts, than of the latter. Borax will also dissolve most of the metallic oxyds, receiving from each peculiar tinges of colour.

The uses of borax are considerable; it is employed in the laboratory as a very active flux, and as producing a more perfectly limpid fusion than any other substance. For the same reason it is an ingredient in some of the finer kinds of glass; though its dearth prevents it from being employed so often as it otherwise might be to great advantage. Borax is also highly useful to the jewellers and goldsmiths, as a flux for the solder, by which pieces of gold and silver are cemented together; and in the East Indies it is employed in the moist way as a solvent for gum lac.

BORBETOMAGUS, in *Ancient Geography, Worms*, a town of Germany, according to Ptolemy, who says, it belonged to the Vangioni. It was their capital. See WORMS.

BORBO, in *Geography*, a river of Piedmont, which discharges itself into the Tanaro at Asti.

BORBONIA, in *Botany*, (in honour of Gaston Bourbon, duke of Orleans,) a name first given by Plumier to plants of different characters, afterwards transferred by Linnæus to a genus in his class *diadelphica decandria*, which is obscurely defined, and concerning which there are in authors much confusion and inconsistency. La Marck says, that it differs from genista, only in having the segments of its calyx a little longer and sharper, which is surely a slight and indeterminate circumstance; and from aspalathus, in not having its

leaves fasciculated, which is certainly no generic character at all. He follows Linnæus, however, in keeping these three genera distinct, but unites it with liparia, from which he finds no reason to separate it. Linnæus attributes to it only nine stamens, all united, and observes, that liparia (a genus formed by him, late in life, from Thunberg's plants, collected at the cape of Good Hope) differs from it in having a tenth separate stamen. Bosc says, that the borbonia has either nine or ten stamens, eight or nine of which are united at their base. La Marck, without noticing Linnæus's distinction, ascribes to his united genera ten diadelphous stamens; but it ought to be remarked, that all his descriptions are confessedly made from dried specimens, and Bosc informs us that none of the species are now cultivated in the Paris gardens. In this state of uncertainty we shall follow Willdenow in retaining the Linnæan distribution. Linn. 837. Schreb. 1165. Willden. 1329. Juss. 853. Nat. Ord. *Papilionacea—Leguminosa*. Juss.

Gen. Char. *Cal.* perianth one-leaved, semiquinquefid, turbinate, half the length of the corolla; segments lanceolate, acuminate, rigid, pungent, nearly equal, the lower one the longest. *Cor.* pentapetalous, papilionaceous, hirsute on the outside, banner reflexed, obtuse, claw the length of the calyx; wings falcate, a little shorter than the banner; keel two-petalled, lunulate, obtuse. *Stam.* filaments nine, united into a cylinder, delincent longitudinally above, rising at the end; anthers small. *Pist.* germ subulate; style very short, ascending; stigma obtuse, emarginate. *Pericarp.* legume roundish, acuminate, one-celled, mucronate with a spine. Seed kidney-form.

Eff. Char. *Cal.* acuminate-spiny. *Stigma* emarginate. *Legume* mucronate.

Species, 1. *B. ericifolia*. Linn. "Leaves nearly linear, acute, villose beneath, heads terminal." A small, rather villose shrub; leaves alternate, pointed, nerveless and smooth above, villous and channelled beneath; flowers yellow, small; legumes short, very villous within. Its specific name is not a happy one. 2. *B. trinervia*. Linn. "Leaves lanceolate, three-nerved, very entire." Flowers yellow, terminating, each on a separate peduncle. 3. *B. angustifolia*. La Marck, with a doubt whether it may not be *trinervia* of Linnæus. "Leaves narrow-lanceolate, five-nerved, smooth; legumes oblong, pedunculate." A small shrub; stems slender, interruptedly angular; peduncles two or three at the end of each branch. 4. *B. barbata*. La Marck (Mus. t. 619). "Leaves lanceolate, many-nerved, close-set, ciliate-bearded, very acute; flowers villous, subsessile." Stem cylindrical, with diverging branches; leaves imbricated, embracing the stem at their base. 5. *B. ciliata*. Willden. "Leaves cordate, embracing the stem, obtuse, many-nerved, very entire, ciliate." Stem cylindrical, smooth; leaves an inch long, deeply cordate, ciliate at their margin, with long, slender hairs. Nearly allied to the foregoing, if it be more than a variety. 6. *B. lanceolata*. Linn. "Leaves lanceolate, many-nerved, very entire." 7. *B. cordata*. Linn. *cordifolia*; La Marck, who asserts that Linnæus's synonyme to *lanceolata* belong to this species. "Leaves cordate, many-nerved, very entire, smooth; flowers tomentose, subsessile." Branches villose; leaves terminated by a thorny point, crowded; segments of the calyx with thorny points; flowers covered externally with a white and silky down; banner brown within. 8. *B. crenata*. Linn. "Leaves cordate, many-nerved, toothed." Stems with triangular, smooth branches; leaves sessile, or a little embracing the stem, reticularly veined, ending in a point; flowers smooth, pedunculate, three or four in a kind of raceme at the extremity of each branch; bractes setaceous. 9. *B. parviflora*. La Marck.

Marek. "Leaves cordate, many-nerved, smooth, a little toothed; flowers small, sessile, terminating." Branches smooth and angular; leaves sessile, acuminate; flowers two or three together; calyces smooth, with pointed, not spinous teeth; bractes setaceous. 10. *B. perfoliata*. Willd. (La Marek Illust. pl. 619.) "Leaves embracing the stem, very entire." Thun. Branches cylindric, angular towards the end, with scattered hairs; leaves alternate, nerved, veined, denticulate, smooth, terminated by a short point which bends outward, almost perfoliate, terminating; flowers four or six together in a kind of umbel, peduncled; segments of the calyces very sharp-pointed; bractes setaceous. 11. *B. undulata*. Willd. "Leaves embracing the stem, waved with a reflexed point." All the species are natives of the cape of Good Hope.

*Propagation and Culture.* Mr. Miller succeeded only by laying down their young shoots, which are commonly two years before they are fit to be separated from the old plant. The best time for laying them down is the beginning of September. *B. crenata* was introduced into Kew garden from the Cape in 1774, by F. Masson.

*BORBONIA*, *Levigata*, and *Tomentosa*. See LIPARIA.

*BORBONIA*, (*Plumier*). See RHUS, METOPIMUM, and HEISTERIA COCCINEA.

*BORBONIA Astra*, in *Astronomy*, a denomination formerly given by some writers to the solar faculæ, on a supposition that they were satellites, or secondary planets. See FACULÆ.

Fromundus mentions a Frenchman, named Tarde, who had written a book express under the title "Aitra Bourbonia." Phil. Trans. N<sup>o</sup> 330. p. 287.

*BORBONICA*, in *Ornithology*, a species of MOTACILLA, of a greyish fuscous colour, beneath a yellowish soordid grey; quill and tail-feathers brown, edged with grey. This is the *scedula borbonica* of Brisson. Buffon calls it *petit simon*, and *figuer de Pisle de Bourbon*. It is the *Bourbon warbler* of Latham. Inhabits the islands of Bourbon and Madagafcar.

*BORBONICUS*, a species of TURDUS, of a cinereous olive colour; crown black; abdomen and vent olivaceous yellow; tail fuscous, with two obsolete bands near the tip. This inhabits the isle of Bourbon. Its length is about eight inches; beak and legs yellowish; abdomen in the middle white; quill-feathers brown, edged with reddish. This is the *Bourbon thrush* of Latham.

*BORBORITÆ*, or *BORBORIANI*, in *Ecclesiastical History*, a branch of the ancient Gnoetics, in the 11th century, who, to the other errors of that sect, added this, of denying a future judgment. Their name is derived from *βορβορος*, *filth*, on account, as it is said, of a custom they had of besmearing their faces and bodies with it. Epiphani. Heref. 25, an. 26. August. de Heref. c. 5.

Some also have given this appellation, by way of reproach, to the Mennonites.

*BORBORUS*, in *Ancient Geography*, a river of Macedonia, which, according to Plutarch, encompassed the city of Pella.

*BORBORYGMUS*, in *Medicine*, a term employed to denote the rumbling noise produced by air pent up in the intestinal canal; from *βορβορίζω*, *strepitum edo*. It is a common symptom in cases of disordered bowels.

*BORBOTHA*, in *Ichthyology*, a name given by some writers to the eel pout or burbot, *gadus lota*, or, as Willughby names it, *mustella stuviatilis*.

*BORCANI*, in *Ancient Geography*, a people of Apulia, according to Pliny.

*BORCETTE*, in *Geography*, the chief place of a canton, in the department of Roer, and district of Aix-la-Chapelle;

the place contains 3531, and the canton 17054 inhabitants; it has 30 communes.

*BORCH*, a town of Germany, in the circle of Lower Saxony, and duchy of Magdeburg; 4 leagues from Magdeburg.

*BORCHEN*, or *BORREN*, a town of Germany, in the circle of Westphalia, and bishopric of Munster, seated on the Aa, having a manufactur. of cloth; 30 miles W. of Munster.

*BORCHLOEN*, or *Loosz*, a town of Germany, in the circle of Westphalia, and bishopric of Liege, the capital of the county of Looz; 12 miles N. W. of Liege.

*BORCHOLZ*, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn; 8 miles N.N.W. of Warburg.

*BORCHT*, HENRY VANDER, in *Biography*, a painter and engraver, was born at Brussels in 1583, became a disciple of Giles Valkenburgh, and completed his studies in Italy. He was employed by the earl of Arundel in collecting antique curiosities for his lordship in Italy, and retained in his service as long as he lived. After the death of this noble patron, he was employed by the prince of Wales, afterwards Charles II., and continued for several years in England, where his paintings were well esteemed. But retiring to Antwerp, he died there in 1660. His chief excellence consisted in painting fruit and flowers. Among the few etchings which he executed are the "Virgin and Child," from Parnigiano, engraved at London and dated 1637; a "Dead Christ, supported by Joseph of Arimathea," from Perin del Vago. Pilkington and Strutt.

*BORCHWORM*, or *BORGWORM*, or *WAREM*, in *Geography*, a town of Germany, in the circle of Westphalia, and bishopric of Liege; 10 miles W. of Liege.

*BORCKELOE*, or *BORCKLO*, a town of the united states of Holland, in the county of Zutphen, on the confines of the bishopric of Munster, seated on the river Berckel; 15 miles E. N. E. of Zutphen, and 42 W. N. W. of Munster.

*BORCUM*, a small island in the German ocean, near the coast of East Friesland; about N. N. W. from the point of Embden, at its S. W. entrance into the port and river, and about 2 leagues N. E. by E. from the island Rottum. Between them is a channel called the West Channel of the Embs. N. lat. 53° 36'. E. long. 6° 18'.

*BORDA*, CHARLES, in *Biography*, formerly *Chevalier de Borda*, and a *chef d'Escadre*, in the royal navy under the old French government, was born at Dax, May 4, 1733, and distinguished himself in early life as an able mathematician. Of his knowledge in this department of science ample evidence may be found in the Memoirs of the Academy of Sciences, for 1763 and 1767, of which he was admitted a member in 1754. These memoirs contain many excellent papers, communicated by Borda, on different objects of hydraulics; on the resistance of fluids; on water-wheels and pumps; on the projections of bombs; on the method of determining curve lines; on the properties of maxima and minima; and on the best method of choosing by lot. In the years 1771 and 1772, he performed a voyage, by command of the king, with Verdun de la Cranue and Pingré, in the Flora frigate, in which he had the rank of "lieutenant de Vaisseau," to various parts of Europe, Africa, and America, for the purpose of improving the sciences of geography and navigation, and of making experiments with various nautical instruments and time-pieces, with a view of ascertaining accurate methods for determining the longitude. The result of the observations of these three

navigators was afterwards published at Paris in 1778, in 2 vols. 4to., under the title of "Voyage fait par ordre du Roi. in 1771 and 1772, &c." in which Borda's share was not the least considerable. An account of the result of this expedition may be also found in the Memoirs of the Paris Academy for 1773. To Borda the public are likewise indebted for the best chart of the Canary islands, which served as a model for the valuable map of those islands, published in Spain in 1788. In 1774, he undertook a voyage to the Azores, the Cape Verde islands, and the coast of Africa. In the year 1787, he published a valuable work, entitled "Description et usage du cercle de Reflexion," in which he revised the use of the reflecting circle proposed by Tobias Mayer in 1756. He was the first founder of the schools of naval architecture in France, and formed the plan of education, and the regulations to be adopted in these seminaries. He also applied the principles of Euler to the uniform construction of ships, so that all those of the French navy might be equal with respect to sailing. And the advantages, in point of form, with regard to quick sailing and manœuvring, possessed by French ships which are constructed on true mathematical principles, and actually acknowledged by experienced British officers, have been principally owing to the genius, knowledge, and exertions of Borda. He likewise brought into use Mayer's old method of measuring terrestrial angles, after it had been long neglected; applied it to astronomical observations; and invented a circle on a new construction, with moveable telescopes, together with other instruments; such as metallic rules for measuring bases, which were used in the new measurement of an arc of the meridian in France; and to the labours of Borda the accuracy of this measurement has been justly ascribed. He took the most active part in the late reform of weights and measures introduced in France; and he caused to be calculated and printed, at his own expence, the logarithms of the decimal parts of the circle, according to the new division into 400 parts. In 1792, he invented instruments and methods for determining, with a precision before unknown, the length of a pendulum, swinging seconds at Paris. M. Lalande has published, in his Abridgment of Navigation, Borda's new method for gauging vessels, together with the tables. Borda was inspector of the dock-yards, in which situation government put great confidence in his talents; and, in 1797, he was one of the candidates for the office of director of the French republic. Although his health had been much impaired, in consequence of serving in the American war with d'Estaing in 1777 and 1778, he continued to employ himself in a variety of useful labours. At length, however, a dropy of the breast proved fatal to him, on the 20th of February, 1799, in the 64th year of his age. Lalande's Hist. Astron. for 1799.

**BORDAGE**, the condition or service of the *bordarii*. Du-Cange. Gloss. Lat.

**BORDARII**, often mentioned in the Domeſday inquisition, were distinct from the *servi* and *villani*, and seem to be those of a less servile condition, who had a *bord*, or cottage, with a small parcel of land allowed to them, on condition they should supply the lord with poultry and eggs, and other small provisions for his board and entertainment. Though, according to Spelman, the *bordarii* were inferior to *villani*, as being limited to a small number of acres.

**BORDARII** also denote servants, or workmen, employed about the house in the necessary offices of fetching wood, drawing water, grinding corn, cleaning yards, and the like: by which they stand distinguished from *villani*, employed in the tillage of lands. See **VILLAIN**.

**BORDAT**, in *Commerce*, a small narrow stuff which is

manufactured in some parts of Egypt, particularly at Cairo, Alexandria, and Damietta.

**BORD-BRIGCH**, *Borg-bryce*, or *Burgh-brych*, Sax. in *English Antiquity*, a breach, or violation of suretyship, pledge-breach, or breach of mutual fidelity.

**BORDE**, **ANDREW**, or, as he calls himself, *Andreas Perforatus*, in *Biography*, was born at Peverſey in Suffex, in the early part of the 16th century, and entered early among the Carthusians. Quitting his monastery, he went to Montpellier, and applied himself to the study of medicine, and in 1542, was made a doctor in that faculty. He now returned to England, and having been admitted of the university of Oxford, he came to London, and was made fellow of the Royal College of Physicians, which had been lately established here, and one of the physicians to king Henry VIII. at Winchester, where he principally resided and practised. Though advanced to these honours, his works, full of gross and barbarous errors, shew he was but moderately skilled in languages. He, however, affected to be learned, generally beginning his accounts of diseases, with giving the Greek, Latin, and Arabic names by which they were known. His "Breviary of Health," containing a short account of all diseases and their remedies, was published in 1547. This was republished in London in 4to. in 1575, with some additions which the author had called the extravagants. He was also author of a compendious regimen, or dietary of health, made in mount Pyllor, which was published in 1562, and of a book on prognostics, and on urines. Borde was also a wit and a poet. He published "Tales of the mad men of Gotham," a book still remembered: and a very singular work, partly prose, partly in verse, which he called "The Introduction of Knowledge, &c." dedicated to the princess, afterwards queen Mary. Before the first chapter is a wooden print of a naked man, with a piece of cloth and a pair of shears, with this inscription:

"I am an Englishman, and naked I stand here,  
Musing in my mind what raiment I shall wear:

For now I will wear thys, and now I will wear that,  
And now I will wear I cannot tell what, &c."

The thought, Dr. Aikin says, is taken from the Venetians' description of a Frenchman. It was probably in consequence of his having taken more liberty than was allowed at that time with some person in power, that he was thrown into the Fleet prison, where he died in 1549. Haller Bib. Med. Aikin's Biog. Mem.

**BORDEAUX**, in *Geography*, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Die, 10 miles S. W. of Die; the place contains 1181, and the canton 3885 inhabitants: the territory comprehends 132½ kilometres and 9 communes.

**BORDEKOW**, a town of Poland, in the palatinate of Lemberg; 36 miles S. of Lemberg.

**BORDELIE'RE**, in *Ichthyology*, the common French name of a fish included in the *CYPRINUS* genus, that is found in the lakes of cold mountainous countries. This appellation appears to be indifferently applied to the *cyprinus balticus*, and *cyprinus blicca* of Bloch.

**BORDENAVE**, **TOUSSAINT**, in *Biography*, was born at Paris in 1728. Having distinguished himself for his industry and skill in his profession, he was admitted member of the college of surgeons there in 1750, and professor of physiology in the school of St. Come. He was also, in succession, made honorary member of several foreign academies, to whose transactions or memoirs he was a frequent and liberal contributor. His works are "Essai sur la physiologie," 12mo., published in 1756, and again in 1764. An elementary work,

work, composed for the benefit of his pupils: "Remarques sur l'insensibilité de quelque parties," 12mo. 1757. He reckons the tendons and aponeuroses of the muscles among the insensible parts. In 1768, he published a translation of Haller's Elements of Physiology into French; in 1769, "Dissertation sur les antiseptiques," 8vo.; and in 1774, "Memoires sur le danger des cautiques pour la cure radicale des hernies," 12mo. For the titles and account of his dissertations, published by the academies with which he corresponded, see Haller Bib. Chirurg. Eloy. Dict. Hist.

**BORDENTOWN**, in *Geography*, a pleasant town of America, in Burlington county, New Jersey, situate at the mouth of Crosswick's creek, on the east bank of a great bend of Delaware river; 6 miles below Trenton, 9 N. E. from Burlington by water, and 15 by land, and 24 miles N. E. from Philadelphia. This town contains about 100 houses, and is a thoroughfare from New York to Philadelphia.

**BORDER**, in *Gardening*, a narrow stripe or portion of ground running along the sides of the walls, or other fences that inclose gardens, and ornamented lands, and which bound the walks, or serve to separate the different principal divisions of the former, the earth being generally laid out in a gently sloping manner from the front to the back parts. These compartments are either of the useful or ornamental description. Those of the first kind, are such as are carried round the walls of garden-grounds, and which are mostly employed, especially where the aspect is to the south, in planting out various sorts of fruit-trees upon, such as cherries, figs, plums, apples, pears, peaches, nectarines, apricots, &c. in order to their being trained to the walls or fences, so as to form wall-trees, as well as extremely useful in raising different early esculent herbs, roots, and leguminous crops; and on the other aspects, for the sowing, rearing, and pricking out of many sorts of seeds and plants upon, in the summer season, that require a cool situation, or a degree of shade at particular periods of their growth. The general rule in laying out these borders is, that of making them with a breadth in proportion to the height of the walls, or palings towards which they are formed, which should never be less than eight or twelve feet. They were formerly made not more than five or six feet in breadth, which is much too narrow for convenience in the culture of the plants, or the management of the trees that may be planted on them. Where trees are to be planted as espaliers, ten or twelve feet are the breadths that should, in most cases, be allowed.

As to borders intended for the raising and growth of different sorts of flowers, or for small shrubs and herbaceous plants; or flowers being planted out in assemblage or mixture with each other, five or six feet in the former, and eight in the latter, may be proper breadths for the purpose.

Their depths, where trees are to be planted, should never be less than two feet at the walk, gradually increasing to three at the backs or fences. Some fruit-trees, however, require much more, as pears and apples. In other cases, one foot at the walks, and two at the backs, may form a sufficient depth and slope for the perfect culture of the crops that may be grown upon them. For flowers, and the smaller sorts of shrubs, it is often convenient to have them a little rounded on the surface. Where the situations in which the borders are made are of the more moist and retentive kinds, having clayey, or gravelly and cankerly bottoms, proper drains should be formed, and conducted along the fronts of borders to the full depth of the subsoils, in order, effectually, to convey off the injurious wetness that may take place, and allow of a suitable bed being formed for the upper soil. This is often effected by paving the bottoms

of the beds with tiles or bricks. But a much less expensive, and at the same time, equally effectual method is advised by the author of the "Scotch Forcing Gardener," which is, that of letting the bottoms be laid in a sloping direction from the walls to the drains, a fall of six inches being given, first with a layer of good loam, two inches in thickness, being spread evenly, and well rolled down; then a similar stratum of clear pit or river gravel applied over it, and forced down in the same manner; upon this, another coat of loamy earth is to be deposited to the thickness of an inch or more, and well pressed down; the whole being executed while the materials are in a rather dry condition. These should be afterwards a little moistened, and well rolled down till the surface becomes glazed, the waterings and rollings being continued alternately, till the whole acquires a shining hardness, and the gravel begins to show itself clearly through the loamy coat. In this way, it is asserted, bottoms may be formed, through which the roots of no trees can penetrate, and which are at the same time perfectly favourable to the growth of trees and plants.

In constituting the borders, those substances and mixtures of different materials, which are most adapted to the growth and success of particular sorts of trees or plants, will be explained in describing the culture which they require. Where the raising and growth of most sorts of culinary vegetables are the principal object of borders, there should be constantly a due proportion of good vegetable mould, in combination with a proper quantity of rich, mellow, loamy earth, a suitable portion of well-rotted stable dung, according to circumstances, being incorporated with them, which produce them in the greatest perfection.

There is another sort of useful border, which is that which divides or surrounds the principal compartments or divisions of kitchen-garden grounds, and which immediately bounds or verges the main walks, as being convenient for planting ranges of dwarf-apple, pear, plum, cherry, medlar, and other trees upon, as espaliers, as well as for the culture of many herbaceous, esculent plants. The line of espalier trees, in these cases, should be planted at least three or four feet from the outer edges, so that there may be three or four feet borders on the outside next the walks, and a smaller one on the inside of the espaliers, the broader outside borders serving for the rearing and culture of many low-growing, esculent plants; and sometimes, where the kitchen and flower-garden are united, as flower-borders. The smaller inward borders may be found useful in raising many sorts of small plants and herbs, as lettuces, &c.

Borders of the latter, or ornamental sort, as those of pleasure or other grounds, must be formed according to circumstances. It was formerly the taste, in many places, to have almost every walk bounded on each side by a border embellished with various ornamental plants; this taste has now, however, in a great measure, given way to that of planting only on one side. A fine walk, ornamented on each side by spacious borders, fully planted out with curious flowering shrubs, and other plants, have, notwithstanding, a fine appearance and good effect in many situations.

Borders of curious flowers, carried along the boundaries of grass plats, or lawns contiguous to the house, whether formed in a straight or serpentine manner, produce an agreeable effect, and much variety. The borders for particular kinds of flowers, such as the curious sorts of hyacinths, tulips, ranunculuses, anemones, carnations, and various others, may be made either along the sides of walks, or detached in other parts of gardens, or ornamented grounds. Such borders as immediately bound or verge gravel, or sandy walks, should be planted on the sides, with edgings of

some dwarf-evergreen sort of plants, such as those of box, thurst, daisies, pinks, &c.; but the first is the neatest and most durable plant for the purpose. See **BUXUS**, and **EDGING**.

These sorts of borders should always be raised two or three inches or more above the common surface level; such as are detached being generally finished off in a gently swelling or rounding form, in order that they may afford the fullest effects.

**BORDER**, in *Heraldry*. See **BORDURE**.

**BORDE'RES**, in *Geography*, a town of France, in the department of the higher Pyrenees, and chief place of a canton, in the district of Bagnères, four leagues S. of La Barthe; the place contains 398, and the canton 2822 inhabitants; the territory comprehends 207½ kilometres, and 21 communes.

**BORDERS**, among *Florists*, are such leaves as stand about the middle thum of a flower.

**BORDES**, in *Geography*, a town of France, in the department of the Arriège; 7½ leagues W. of Mirepoix.

**BORDEU**, **ANTHONY**, in *Biography*, a physician of considerable eminence, was born at Ilesle, in Bearn, in 1693. After being initiated in the study of medicine by his father, he went to Montpellier, where he was admitted doctor in that faculty in 1719. Invited, in 1723, to Pau, the capital of the province, he acquired so much reputation, as to procure him the offices of physician to the military hospital at Baresges, and of inspector of the mineral waters there. To the waters he paid great attention, and in 1750, he published a small treatise, shewing the effects he had experienced from them in a variety of diseases. He lived to an advanced age, but the precise time of his death has not been noted.

**BORDEU**, **THEOPHILUS DE**, following the steps of his father, attained to a still higher degree of professional eminence. He was born in 1722; and having passed through his studies with singular credit, was created doctor in medicine at Montpellier, in 1743. In 1745, he was appointed to succeed his father, as inspector of the mineral waters, and professor in anatomy, which was his favourite study. In 1747, he was made corresponding member of the Royal Academy of Sciences at Paris, whither he soon after went; and after passing through the usual course of studies, he was admitted doctor in medicine there, in 1754. He was taken off suddenly by a stroke of apoplexy in 1776, being in the 55th year of his age. He was through life diligent and attentive to his professional duties, and seems to have been actuated by a desire of improving his art, and of leaving memorials of his industry and ingenuity. The principal of his works are, "Chylificationis historia," his inaugural thesis, 1742, re-printed at Paris, 1752, 12mo. with his "Recherches sur les glandes." He thought he observed a duct passing from the thyroid gland to the trachea; an opinion, which he repeats in another of his works, but without sufficient ground. "Dissertatio physiologica de sensu genericè considerato," Montpellier, 1743, 8vo.; 1751, Paris, with his "Chylificationis historia." "Lettres contenant des essais sur l'histoire des eaux minerales du Bearn, &c. 12mo. 1746. In these he treats of the properties of the waters, and of the geography of Bearn. "Recherches anatomiques sur la position des glandes et sur leur actions, Paris, 1751, 8vo. "Recherches sur le pouls par rapport aux crises," Paris, 1756, 12mo.; in which he has gone much beyond Solano in his discrimination of pulses, and beyond what can be followed in practice. "Recherches sur le tissu muqueux, et l'organe cellulaire," Paris, 1766, 12mo. Haller accuses him of dissingenuity in attributing to himself the discovery of some properties of the cellular membrane, which had been

before described by him and others, but does not deny the work to have on the whole considerable merit. Hall. Bib. Anat. Eloy. Dict. Hist. Aikin's Gen. Biog.

**BORDEU**, **FRANCIS**, brother to Theophilus, and educated under his father and him, was born at Pau, in 1737. Having taken his degree of doctor in medicine at Montpellier, in 1756, he returned to Pau, and was appointed to supply the place of his brother, as inspector of the waters there. In 1757, he published "De sensibilitate et contractibilitate partium in corpore humano sano," Montpellier.; and in 1760, "Precis d'observations sur les eaux de Baresges," &c. 12mo. collected principally from the works of his father, brother, and other writers on the subject. "Recherches sur les maladies chroniques, leur rapports avec les maladies aiguës, &c. 1775, 8vo.; principally with the view of shewing the utility and the manner of administering mineral waters in the cure of chronical complaints. Haller. Bib. Chirurg. Eloy. Dict. Hist.

**BORD-FREE**. See **FREE**.

**BORD-HALFPENNY**, or **BROD-HALFPENNY**, money paid in markets and fairs, for setting up boards, tables, and stalls, for the sale of wares.

**BORDIGHERA**, in *Geography*, a town of Italy, in the state of Genoa, 3 miles E.N.E. of Ventimiglia.

**BORD-LANDS**, the demesnes anciently kept by the lords in their hands for the maintenance of their board or table. This was anciently called *boardage*.

**BORDO NUOVA**, in *Geography*, a town of Servia, 18 miles E.S.E. of Piltrina.

**BORDOE**, one of the Faroe islands, having a harbour on the N.W. coast.

**BORDONE**, **PARIS**, in *Biography*, a painter of history, portrait, and architecture, was born at Trevisi, in 1513, and at a proper age became a disciple of Titian, whose uncommunicative disposition he had occasion to regret. He studied and imitated the style of Giorgione, and acquired such reputation, that at the age of 18 years he was employed in painting a picture in the church of St. Nicholas. From Venice he removed to Vincenza, in consequence of an invitation to adorn a gallery with paintings in fresco, in which Titian had exhibited a design representing the judgment of Solomon. Bordone composed the history of Noah and his sons, which he finished with such care, that it was not esteemed inferior to the work of Titian. Having finished several considerable works at Venice and Trevisi, he entered, in 1538, into the service of Francis I. of France; and gained additional reputation by various historical subjects and portraits, which were excellently designed, and recommended by a charming tone of colour. On quitting France he visited several cities of Italy, in which he left a number of memorable works, as monuments of his extraordinary abilities. His colouring resembles nature, and his portraits have been very much admired; several of them are still preserved in the Palazzo Pitti at Florence, the colouring of which is clear, fresh, and beautiful. This artist died in 1588, at the age of 75, according to Vasari; but according to Felibien, at the age of 65 years. Pilkington.

**BORD-SERVICE**, called also **BORDAGE**, the tenure of lands on condition of furnishing provision for the lord's board or table.

Some lands in the manor of Fulham, and elsewhere, are still held of the bishop of London, by the service, that the tenants pay sixpence per acre in lieu of finding provision for their lord's table.

**BORDURE**, or **BORDER**, in *Heraldry*, is a partition line running all round the inside of the field, of an equal width, taking up one-fifth from the outer edge of the field, and without any shadow. Arms having a plain bordure, are emblazoned

blazoned *argent, a bordure gules*; but if indented, engrailed, embattled, &c. *argent, a bordure indented, gules*. The bordure always gives place to the *chief, the quarter, and the canton*; for example, *or, a bordure, azure, and a chief, gules*. The chief, therefore, is always placed over the bordure, as are also the quarter and canton. The bordure is continued under the chief, but with the quarter and canton it continues round, until it touches them, and there finishes; but with other ordinaries, as the chevron, fess, bend, &c. the bordure always passes over. In arms empaled with another having a bordure, the bordure must finish at the empaled line, and not proceed round the coat, as is too often practised. When the bordure is charged with bezants, plates, billets, or pellets, it is termed a bordure, gules, *bezantée, platée, billettée, or pelletée*; all other charges are expressly mentioned as to number and colour. The bordure is borne different ways, as *gobone, cheque, vair, bend, &c.* which are explained under the different terms. See *GOBONE, &c.*

The bordure is not considered as one of the honourable ordinaries, but as a mark of difference, to distinguish one family from another.

**BORDURE, Per**, an inner bordure, appearing as two bordures: bordure indented, with the middle line indented.

**BORDURE, point in point** indented, differs from the bordure per bordure indented, as the indents must be from line to line, that is, must touch both sides of the bordure.

**BORDURE of the field**, is merely a partition line, of the colour of the field, running round the arms. This bearing is never used in English armory, but is often borne both in France and Germany.

**BORDURE Entier**, commonly called entoyer, or entoire, a term when charged with inanimate things, as escallop-shells, &c.

**BORDURE Enaluren**, so called when charged with birds.

**BORDURE Enurny**, when charged with lions.

**BORDURE Verdoy**, when charged with vegetables.

**BORDURE Purflewed**, when it is shaped like vair.

**BORDUUN, German**, probably from *Bourden, Fr.* a stop in an organ so called, of which the sounds are an octave lower than the diapason, to which this stop is in the same proportion as the double-bass to the violoncello. In an organ, of which the longest pipe in the diapason is sixteen feet, that of the borduun would require thirty-two feet. See *ORGAN* and *DIAPASON*.

**BORE**, in *Geography*, a town of Asiatic Turkey, in the province of Caramania, 70 miles E. N. E. of Cögni.

**BORE**, a term used to denote a sudden and abrupt influx of the tide into a river or narrow strait. This prevails to a considerable degree in the principal branches of the Ganges, and in the Megna; but the Hoogly river, and the passages between the islands and sands situated in the gulf, formed by the confluence of the Ganges and Megna, are more subject to it than the other rivers. This may be owing partly to their having greater "embouchures," in proportion to their channels, than the others have; by which means a larger proportion of tide is forced through a passage comparatively smaller; and partly to the want of capital openings near them, by which any considerable portion of the accumulating tide might be drawn off. In the Hoogly or Calcutta river, the bore commences at Hoogly point, where the river first contracts itself, and is perceptible above Hoogly town; and its motion is so quick, that it hardly takes up four hours in passing from one to the other, although the distance is near 70 miles. At Calcutta it sometimes occasions an instantaneous rise of five feet: and both here, and in every other part of its track, the boats, on its approach, immediately quit the shore, and seek safety in the middle of the river. In the

channels, between the islands, in the mouth of the Megna, &c. the height of the bore is said to exceed twelve feet; and it is so terrific in its appearance, and dangerous in its consequences, that no boat will venture to pass at spring-tide. After the tide has passed the islands, no vellige of a bore is seen, which may be owing to the great width of the Megna, in comparison with the passages between the islands; but the effects of it are visible enough, by the sudden rising of the tides.

The bores are also high and dangerous in the mouths of the river Indus. To this sudden influx of the tide, in a body of water elevated above the common surface of the sea, may be ascribed the injury suffered by Alexander's fleet, and described by Arrian. He says, those ships that lay upon the land were swept away by the fury of the tide, while those that stuck in the mud were set afloat again without damage. In order to account for this fact it should be considered, that the bottoms of channels, in great rivers, are muddy, while the shallows are formed of sand; and it is the property of the bore to take the shortest cut up a river, instead of following the windings of the channel; consequently it must cross the sand-banks it meets in its way; and it will also prove more destructive to whatever it meets with aground than what is afloat. Rennell's Memoir.

**BORE**, in *Gunnery*; the bore of a gun, or piece of ordnance, is used for the chase or barrel; though it seems rather to denote the diameter of the chase. See *CALIBER*, and *CANNON*.

**BORE, square**, in *Smithery*, denotes a square steel point, or shank, well tempered, fitted in a square socket in an iron wimble, serving to wind holes, and make them truly round and smooth within.

**BOREA**, an ancient name for a species of *JASPER*, of a bluish green colour.

**BOREADES**, in *Mythology*, the patronymic names of Zethus and Calais, the sons of Boreas. Hyginus (fab. xl.) says, that they had wings to their head and feet.

**BOREAL Signs**, in *Astronomy*, the first six signs of the zodiac, or those on the northern side of the equinoctial.

**BOREALIS, AURORA**. See *AURORA Borealis*.

**BOREALIS**, in *Conchology*, a species of *VENUS*. This shell is lentiform, with very remote, erect, membranaceous transverse striae. Gmel. This is a small shell, measuring about an inch and a half in length; colour dirty white. Inhabits the north of Europe. *Donov. Brit. Shells, &c.*

**BOREALIS**, in *Entomology*, a species of *TABANUS*, distinguished by having the eyes with three purplish bands; abdomen black, the segments whitish at the edges. Size of *T. pluvialis*. Inhabits Norway. Gmel. Fabr. The thorax of this insect is brown; abdomen black with a pale glaucous spot on each side of every segment; legs black. This is a rare species.

**BOREALIS**, a species of *COCCINELLA*, of a reddish, or yellowish colour, with twelve black dots on the wing-cases, and four on the thorax. Thunberg, Fabr. &c. This is a native of the Cape of Good Hope. Shape gibbous, beneath of a yellow colour.

**BOREALIS**, in *Natural History*, a species of *CLIO*, of a whitish colour, having the lobes of the head terminated in a flesh coloured pointed papilla; tentacula three, fleshy, and thick at the mouth. Inhabits the north seas. Pallas, &c. This is nearly allied to *Clio retusa*. Gmelin suspects that it may be the same.

**BOREALIS**, a species of *ECHINORHYNCHUS*, found in the intestines of the Eider duck. Gmel. This is called *Sipunculus lendix*, by Phips. it.

**BOREALIS**, in *Ornithology*, a species of *ANAS*, with a narrow bill, the head green, throat and abdomen white. Gmel. This

This is the *Gawland duck* of Latham, who informs us it is a native of Iceland, where it inhabits fens, and is very scarce.

**BOREALIS**, a species of *TRINGA*, the belly and legs of which are fuscous; body above cinereous, beneath white; tail and wings dusky. Found in King George's bay. This is the *Boreal sand-piper* of Latham. The bill is short, black, and somewhat gibbous at the tip; eye-brows white.

**BOREALIS**, a species of *MOTACILLA*, of a green colour; beneath yellow; front, throat, and temples ferruginous; tail rotund, feathers on the sides and at the tips white. A native of Kamtschatka, called by Latham the *Rufy headed warbler*.

Obs. The bill is pale; legs black; and the whole body tinged with olivaceous colour.

**BOREAS**, a Greek name now in popular use, for the north wind. Etymologists usually derive the word from *βον, clamor, noise*; or from *βορρα, food*, because it creates an appetite.

Pezron observes, that anciently, and with much greater propriety, *Boreas* signified the north-east wind, blowing at the time of the summer solstice; he adds, that the word comes from the Celtic *borc, morning*; because their principal light, in that season, came from that quarter, whence also the winds then usually blew.

The Greeks erected an altar to Boreas, whom they considered as a deity, the son of Aëtræus and Aurora, whose seat was in Thrace. He is represented on the temple of the eight winds at Athens with his robe before his mouth, as if he felt the cold of the climate over which he presides, agreeably to the description of Ovid, who calls him *gelidus tyrannus*, the shivering tyrant. Met. vi. ver. 711. But he is usually described by the Roman poets as violent and impetuous. Ibid. ver. 686—ver. 707.

The qualities allowed by naturalists to this wind are coldness and dryness.

**BOREAS**, in *Entomology*, a species of *BOMBUX*, (*Phal.* Linn.) the wings of which are tailed, and varied with cinereous and fuscous; on the first, or anterior pair two dots, on the posterior wings a single transparent one. Fabricius, &c. This is a native of America, and has the anterior wings falcated.

**BOREAS**, a species of *CANCER*, in the family *Aylacus*, that inhabits the north seas; it is distinguished by having the thorax aculeated, and the second and third pair of legs filiform. Fabr.

Obs. The beak of this kind is short, depressed, acute, grooved on each side with a strong tooth beneath.

**BOREAS**, in *Ancient Geography*, a mountain of Arcadia, on which are the remains of an old temple, which, it is pretended, was built by Ulysses after his return from Troy.

**BOREASMI**, were feasts instituted at Athens in honour of Boreas, who was thought to bear some relation to the Athenians, as he had married Orithya, the daughter of Erechtheus; for which reason, when, in a sea-fight, many of the ships of their enemies were destroyed by a north wind, the Athenians imputed it to the kindness manifested by Boreas to the native country of his wife. Pausanias Attic. We are informed by the same author (Arcad.) that solemn sacrifices were offered to Boreas at Megalopolis in Arcadia, where he had a temple, and divine honours.

**BORECH**, in *Natural History*, a kind of salt brought from Ferfia.

**BORECOLE**, or **BOORCOLE**, in *Agriculture*, a plant of the cabbage kind, sometimes cultivated in the field for the purpose of a green winter food for cattle stock. There are

three sorts of it, the common borecole, the green borecole, and the Siberian borecole, or curled cole, or kale. The last sort is the most hardy.

These plants are grown to most advantage in the field, where the soils are rather strong, fresh, rich, and deep, whether of the clayey or loamy kind; and where they have been deeply stirred by the plough, and had a good proportion of manure turned in. See *BRASSICA*.

In Mr. Baker's experiments in planting them in rows at the distance of two feet each way, for the use of the horse hoe; the produce was very considerable. And he supposes that it would be still greater, if they were cultivated at the distance of eighteen inches. If the crops were equally good, there would be, he asserts, from the produce he has already obtained, in the first method, seventeen tons fifteen hundred weight on the acre; and in the latter, more than twenty-three tons twelve hundred. On this account, as well as that of their being capable of being cut over two or three times, and their standing the severest frost, it is concluded that they are highly deserving the grazing farmer's attention as a winter food for cattle and sheep, though it is confessed that the first produce may not be so great as in the common cabbage, but that deficiency is made up by the succeeding ones. There is likewise rather more trouble in collecting the food and conveying it to the animals.

It is suggested, without having been subjected to the test of actual experiment, that the best mode of consuming this sort of food by sheep stock, would be to have two small fields under this kind of crop, proportionate to the number of animals; and to turn the ewes or other sheep into one of them about the beginning of September, or the following month, for a few hours in the mornings and evenings for five or six weeks; lodging them on a portion of grass or fallow ground near it for the rest of the time, in order that they may evacuate themselves, by which much improvement may be produced in such lands; and when all the more luxuriant leaves of this piece have been cropped and consumed, the other field should be managed in the same way. In this method it is supposed that a stock of store sheep might be kept a whole winter at a very moderate expence; and while the produce of one piece was consuming, the other would be coming forward. It is remarked, that the stock should not be kept so long upon the crops as to injure the stems of the plants, as that might check the succeeding growth of the leaves. This plan is obviously confined to ewes or store sheep.

It is doubtful, however, whether the expence of cultivating this sort of crop, except in particular soils, situations, and severe seasons, will admit of its being used as a winter sheep food in preference to turnips, or other similar articles of fodder.

**BORECOLE**, in *Botany*. See *BRASSICA*.

**BOREE**. See *BOURREE*.

**BOREELI CODEX**, in *Biblical History*, a MS. noted F. in the first part of Wetstein's N. T. which contains the four gospels, beginning with Matth. vii. 6. and having the two following chapters, Matth. xiii. 25—58. and Mark vi. 6—16. It was formerly in the possession of John Boreel, Dutch ambassador at the court of London, in the reign of James I. Its present situation is unknown.

**BOREK**, in *Geography*, a town of Poland, in the palatine of Kalish; 28 miles W. of Kalish. Here is a famous image of the virgin Mary, to which pilgrims resort.—Also, a small town of Bohemia, in the circle of Saaz.

**BOREL**, PETER, in *Biography*, born at Castres in Languedoc, about the year 1620, after being initiated in classical literature by his father, James Borel, from whom he also received

ceived a taste for poetry, and for antiquarian researches, prosecuted his medical studies at Montpellier, where he was admitted doctor in medicine, in 1641. Returning to Castres, he acquired so much reputation by his practice there, that in 1653 he was invited to Paris, and made physician in ordinary to the king; and, in 1673, member of the royal academy of sciences. Borel was a diligent collector of natural and artificial rarities, of which he left a cabinet well stored. His publications are, "Les Antiquites, raretés, plantes, mineraux, &c. de la ville et comté Castres, et un recueil des inscriptions Romaines du Languedoc et de Provence, avec la liste de principaux cabinets et autres raretés de l'Europe." Castres, 1649, 8vo. The titles of the articles in his own cabinet are here given. "Historiarum et observationum medico-physicarum, centuriæ quatuor," Castres, 1653, 12mo. A few of the cases are curious and interesting, but far the greater number of them are too insignificant to deserve notice, or too extravagant to be credited by persons who are only moderately instructed in the principles of medicine. To this volume are usually joined the observations of Cattier, of Rhodus, of Arnold Boot, and the consultations of Rossius. "Bibliotheca chymica, seu catalogus librorum philosophicorum hermeticorum," Parisiis, 1654, 12mo. "De vero inventore telescopii, cum brevi omnium conspiciendorum historia," Hagæ Comitum, 1655, 4to. "Trésor des recherches et antiquités Gauloises." "A dictionary of words and phrases, which had become obsolete," 1655, 4to. "Discours prouvant la pluralité des mondes," Genève, 1657, 8vo. "Hortus, seu armarientarium simplicium plantarum et animalium, ad artem medicam spectantium," Parisiis, 1666, 8vo. To each of the articles, which are arranged alphabetically, the author has given a short account of its medical properties. Borel died at Paris in 1678. Haller Bib. Anat. Med. Botan. Eloy Dict. Hist.

BORELLI, JOHN ALPHONSUS, distinguished for his profound skill in mathematics, and in medicine, was born at Castellnuovo in Naples, the 28th of January 1608. Under the tuition of Castelli, at Rome, where he was sent to complete his education, he made such progress, that he was, at an early age, invited to Messina to teach the mathematics. As he had made medicine, as well as philosophy, his study, he there published an account of a malignant fever which had raged in Sicily, in the years 1647 and 1648. "Delle ragioni delle febbri maligni di Sicilia," Cosenza, 1649, 12mo. Disgusted, at length, with his employers, he accepted the offer of the professor's chair at Pisa, in 1656, where he lectured with great applause and success. The fame of his abilities had now conciliated to him the favour of the grand duke Ferdinand, and prince Leopold, who procured him to be elected member of the academy del cimento. It was here probably he first conceived the design of employing mathematical principles, in explaining the functions of animal bodies. He now applied himself diligently to the dissection of animals. Several of his letters, on the subject of anatomy, are published in Malpighi's posthumous works, written between the years 1659 and 1664. In 1658 he published, at Pisa, a second tract on the nature and treatment of malignant fevers. "Della cause, delle febbri maligne," 4to. His first physiological work, "De rerum usu judicium," appeared in 1664, with the treatise of Bellini, "De struttura rerum," printed at Strasbourg, 8vo. In 1669, he gave a dissertation, shewing that in most men the eyes have unequal powers, the one shewing objects more distinctly than the other. "Osservazioni intorno alla virtù ineguale degli occhi," Giornale de Lit. In 1667 he published, "Tractatus de vi percussionis," Bonon. 4to.; and in 1669, "Osser-

vations on a remarkable eruption of mount Ætna," at which he had been present, having the preceding year quitted Pisa, and returned again to Messina. This account was written at the desire of the royal society of London, with which he corresponded, and was printed in their transactions. In 1770, he gave his treatise "De motionibus naturalibus a gravitate pendentibus," a prelude to his great work, "De motu animalium," which did not appear until after his death. At the revolt of Messina, being supposed to have favoured the insurgents, he was obliged to quit that place. Christina, queen of Sweden, who resided, at that time, at Rome, invited him thither, and he continued to enjoy her patronage to the time of his death. That he was not, however, much enriched by her favour, nor had acquired much by his lectures, and by the works he had published, appears by his being obliged, during the two last years of his life, to undergo the drudgery of instructing youth in mathematics, at the convent of St. Pantaleon, called the pious schools, where he died of a pleurisy, December 31, 1679, in the 72d year of his age. The first volume of his work, "De motu animalium," appeared in 1680, Rom. 4to. It is dedicated to Christina, and was printed at her expence; and the second, which completed his design, in the following year. Borelli's principal intention in this work, was to explain the functions of animal bodies, on mechanical principles. He describes the fibres of the muscles, which he supposes to be vesicular; and that these vesicles become inflated by a portion of the nervous juice falling into them, and mixing and fermenting with the blood they contain, whence the muscle becomes swelled, and its fibres shortened. He measures the degree of force or power each of the fibres possess, and the power of them collectively, which, according to his estimate, is immense. He shews how that power is increased or diminished, by the manner in which the fleshy fibres are joined to the tendons. He calculated the power of the heart, in propelling the blood, which he supposed was equal to 180,000 pounds in weight. Though Borelli in this and other of his calculations was shewn to have erred considerably, yet his general principles were for a long time after acknowledged and adopted, and even the operations or effects of medicines, on the human body, were supposed to be explicable on mechanical principles. He also invented an apparatus by which persons might go down a considerable depth under water, remain there, move from place to place, and sink or raise themselves at their discretion; also a boat in which two or more persons might row themselves under water. Haller Bib. Anat. Gen. Biog. Philos. Transactions abridged, vol. ii.

BORER, in *Rural Economy*, an implement invented for the purpose of searching or exploring the nature of soils. This instrument is composed of two rods of iron, each six feet long, and an inch in diameter. The end *a* of *fig. 1.* in Plate on draining implements, screws into the end *b*, of *fig. 2.* after taking out the stopper *c*, the use of which is to hinder dirt or dust from getting into the screw. The screw is an inch and a half long, and three quarters of an inch in diameter: *d. fig. 1.* is a steel point somewhat blunt, to pierce the earth or any substance it may meet with. It should be about three inches long, and made with three, four, or more, sides, as may be thought most convenient. It is screwed into the rod *a* in the same manner, and with a screw of the same size as *a* is screwed into the rod *b*. It has a groove six inches long, a third of an inch wide, and three quarters of an inch deep, rounded in the bottom, and intended to bring up part of each different layer of materials through which it passes. When springs are sought for, a bit of sponge is put into the groove. At the end of the rod, *fig. 2.* is a screw to fix into another rod of the same kind, if it be found necessary

ary to lengthen the instrument: and this may be repeated, by the addition of more rods, to any depth desired; *g h*, *fig. 1.* is the handle of this instrument, two feet and a half long; this handle is fastened to the rod by means of a clasp, *i*, lined with flannel, fixed at one end by a nut, and at the other by the screw *k*, so that it may be placed at any height. *Fig. 3.* is the handle separated from the rod, and marked with the rod, with the same letters as before. *Fig. 4.* is another handle, or rather lever, like the handle already described, except its having only one branch, or lever, marked *g*. This serves to stop the borer in bringing it up from a considerable depth; and also to screw and unscrew the several bars or joints as occasion requires, and to put on and take off the steel point at the bottom. The handle *g h*, *fig. 1.* is that by which the rod is held, and wrought into the earth, either by twisting it round, especially at first, or, after it has penetrated to some depth, by lifting it up, and letting it fall again, which it does with such force as to pierce even the hardest rocks; especially if it works at any considerable depth, and has of course been lengthened accordingly; for every foot of this rod weighs three pounds. Two men will easily sound the depth of twelve feet in less than a quarter of an hour, if they do not meet with many stones. When the rod becomes too heavy to be properly managed by hand, it may be raised by a rope fastened at one end of the handle, and at the other to a roller, or kind of windlass, erected at a proper height, perpendicularly over the hole, and turned with either one or two handles. This will cost but a trifle, and easily raise the rod, which, when let go, will fall with such weight as to strike each time very deep into the earth. The marquis de Turbilly observes, that he has seen it wrought in this manner to the depth of more than a hundred feet.

The toughest iron is the best for making this instrument, which should be well hammered, till its surface is quite smooth and even; for the least roughness and inequality would occasion friction, which would greatly retard its working. For the same reason, and also to increase the force of its fall, it is necessary that it should be perfectly straight; nor should it ever be struck with a mallet, hammer, &c. to force it down, because a blow might bend it, and it would easily break afterwards. The female screw must be turned like that in the breech of a gun-barrel, in a separate piece of iron, cross-ways to the grain; and this piece must be afterwards well soldered on to one of the ends of the rod. The reason for this is, that if the female screw were bored only at the end of the rod, it would, by being hammered out in the same direction with the grain, be stringy and porous, and consequently so weak as to give way, or burst, in the working of the rod; whereas, when made of a separate piece, taken cross-ways of the grain, the threads of the screw will run with the grain of the iron, and be thence considerably strengthened. A bit, like that of an augre, proportioned to the thickness of the rod, may at any time, when necessary, be substituted instead of the steel point, to draw up a sample of the substance from the very bottom of the sounding.

If the only thing wanted be to know the nature of the under soil, and layers of earth, so far as they may affect the vegetation of plants, it will be quite sufficient to bore eight or ten feet deep. A greater depth is only requisite, when water, marble, ore, &c. is sought for, but the common augre may do very well for shallow boring.

By either of these implements there is a certainty of discovering, without much charge or any hazard, not only what earths are under the upper soil, but also whether any other substance of value lies concealed there, such as marble, chalk, fullers' earth, fossile shells, coals, quarries of slate or

stone, ores, &c. many of which lie hid and entirely unthought of in places where their value, was it known, would be ten times more than that of the estate which covers them.

BORETIUS, MATTHEW ERNEST, a learned physician and anatomist of Berlin, published, in 1724, "Anatomie plantarum et animalium analoga," Regiom., 4to; and in 1739, "Museum Boreticum, et catalogus præparatorum anatomiarum renuque naturalium," Regiom., 8vo. Haller. Bib. Anat.

BOREUM, in *Ancient Geography*, a mountain of Greece, in the Peloponnesus, placed by Pausanias, in Arcadia.—Also, the name of a port in the isle of Tenedos, according to Arrian.—Also, a promontory of Africa, in the Cyrenaica, at the extremity of the gulf of the Syrtis Major. Ptolemy.

BORG, or BURG, in *Geography*, a town of Denmark, in the island of Fennern. N. lat. 54° 30'. E. long 11° 8'.

BORGARUCCI, PROSPER, in *Biography*, an Italian physician of eminence, who flourished about the middle of the 16th century. After attending the lectures of Vesalius for some years, he travelled into France, Holland, and England, to improve himself in medical knowledge. On his return he published "Della contemplazione anatomica sopra tutte le parti del corpo umano, libro quinquè," 8vo. 1564, Venet. Some useful observations are made, in this volume, on the great anatomical work of Vesalius, whom our author, however, every where treats with respect. "Trattato di peste," Venet. 1565, 8vo. "De morbo Gallico methodus." Though he describes the method of curing the lues with mercury, he prefers the use of guaiacum, believing that men from using mercury were rendered incapable of procreating. He makes no mention of sarsaparilla, or the China root, though well known in his time. This tract is inserted by Leulinius in his collection of treatises on the disease. Borgarucci taught anatomy and medicine at Padua for some years. In the year 1567, he was called to France, where he was honoured with the title of physician to the king, which he afterwards used. The time of his death is not known. Astruc. de Morb. Ven. Haller. Bib. Anat. Eloy Dict. Hist.

BORGE, in *Geography*, a town in the island of Cephalonia; 2 miles S. of Cephalonia.

BORGE-FIORDS, or BORGAN-FIORDER, a fýssel or district of Iceland, in which are warm baths, built in the 13th century, by the famous historian Snorro Sturlason. They are so spacious and so well contrived, that 100 persons may bathe in them at the same time. Near these is the cross-bath, in which the inhabitants of the western parts of Iceland were baptized, in A. D. 1000; whence its name.

BORGENTRICK, or BORRENRIK, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn; 5 miles N. N. E. of Warburg.

BORGHETTO, a town of Italy, in the Lodosan, 7½ miles S. of Lodi.—Also, a town of Italy in the state of Genoa, 8 miles N. E. of Albenga.

BORGHINI, VINCENT, in *Biography*, a learned benedictine, was born of a noble family at Florence in 1515; and entered among the Benedictines in 1531, devoting himself to study and the offices of a religious life. Duke Cosmo appointed him prior to the hospital Sta. Maria degli Ennocenti at Florence; and he performed the duties of this station with great benefit to the institution, declining the archbishopric of Pisa, till his death in 1680. His reputation for acquaintance with the purity of the Tuscan dialect was such, that he was entrusted with the publication of a corrected edition of the decameron of Boccaccio in 1573; and to him are ascribed the annotations and discourses that accompany it. His own principal work consisted of two volumes of "Discorsi,"

printed at Florence in 1584 and 1585, 4to. which comprehend twelve dissertations on the origin and ancient state of that city, and of others in Tuscany, abounding with a variety of curious erudition. He was likewise well skilled in painting and architecture; and he was entrusted by duke Cosmo with the decorations for the nuptials of his son Francis, and named by him as his substitute in the academy of design. Several of his letters are published in various collections. Gen. Biog.

**BORGHOLM**, in *Geography*, a town of Sweden, in the island of Oeland. Near it is the commodious harbour of Borgia.

**BORGHOLZHAUSEN**, a town of Germany, in the circle of Westphalia, and county of Ravensberg, 6 miles S. W. of Hervorden.

**BORGHORST**, a town of Germany, in the circle of Westphalia, and bishopric of Munster; 3 miles E. of Steinfort.

**BORGI**, in *Ancient Geography*, a people of Asia, placed by Ptolemy in Aria.

**BORGIA**, **CÆSAR**, in *Biography*, a man whose dire ambition deserves to be consigned to perpetual infamy in the page of history, was the second son of cardinal Roderigo, (afterwards pope Alexander VI.) by his mistress, the artful Vanozza. As he was designed for the church, he was invested, whilst a child, with the archbishopric of Pamplona, and sent to Pisa for his education. As soon as his father was elected to the papal see, in 1492, Borgia hastened to Rome, expecting to share in those dignities which his father's elevated station empowered him to bestow. On his arrival, Alexander received him with a grave aspect, and with a lecture on the necessity of restraining his ambitious views, and of seeking honour in the path of virtue. This mode of reception was neither suited to the character of the father nor to the disposition of the son; but the mother of Borgia soon quieted his mind, by ascribing it to its true cause, the artifice and hypocrisy which Alexander thought it necessary to practise on his elevation to the papal throne. Notwithstanding this lesson of moderation, Borgia was immediately made archbishop of Valentia, and, in the following year, promoted to the dignity of cardinal. When the French army, under Charles VIII. entered Rome, in their expedition against Naples, and compelled the pope to a treaty, Borgia was obliged to accompany the king as apostolical legate, or rather as an hostage for the performance of the stipulated conditions; but finding an opportunity to make his escape, and to return to Rome, the treaty was broken, and the king was under a necessity of leaving Italy. About this time Vanozza urged a complaint against the French for having plundered her property, and excited both Alexander and her son to revenge the injury she had suffered. Accordingly they began with administering poison to Geme, brother to Bajazet, who had fled to Italy, as to a sanctuary, from that sultan, and whom the French wished to have in their possession, because, after the taking of Naples, they projected an expedition against the Turks. Not satisfied with this violation of the obligations of hospitality, they proceeded, by means of assassins, to destroy the French who remained at Rome. Borgia, conceiving that his elder brother, the duke of Gandia, obstructed him in the career of his ambition, and that he was his rival in an amour with a lady, said by some to be their own sister, Lucretia Borgia, who was also a very particular favourite of her father, determined to get rid of his competitor. Accordingly, on the eve of his departure to the king of Naples, under the character of his legate a latere, he contrived means to assassinate his brother. This event happened in the year 1497. After the accession of

Lewis XII. to the throne of France, pope Alexander entered into a negotiation with him, particularly with a view to the promotion of his son. For the more effectual attainment of the objects of his ambition, Borgia resigned his dignity of cardinal; and proceeded as ambassador to France, where Lewis created him duke of Valentinois, granted him a pension, and appointed him to a command of cavalry. At this time Lewis had solicited the pope for a dispensation to divorce his wife, and to marry Anne, duchess of Burgundy; and the dispensation for this purpose was conveyed by Borgia. Borgia, however, retained it in his possession, in order to enforce his interest with the king, for obtaining Charlotta, daughter of the king of Naples, who was intended by his father Alexander for his wife. But pretending that he was in daily expectation of receiving the dispensation from Rome, and delaying the delivery of it, the king became impatient; and applying to the bishop of Setra, who was then the pope's nuncio at Paris, he was informed, that Borgia had brought it with him to France. Upon this Lewis convened a number of divines, who authorized him to divorce his wife, and to marry Anne of Burgundy. The marriage having been concluded, Borgia was at length obliged to deliver the dispensation to the king; but he revenged himself on the nuncio by a dose of poison, which proved fatal. Charlotta rejecting his addresses, on account of his infamous character, he married the daughter of the king of Navarre, and was honoured by Lewis with the order of St. Michael. The father and the son, powerfully protected by France, co-operated in a variety of barbarous assassinations, partly for the purpose of revenge for real or imagined injury, and partly with a view of seizing the property of those whom they dispatched, in order to carry on an unjust war, which they had undertaken. The pope, having formed a design of reducing the territory of Romagna to the obedience of the holy see, intended to form it into a principality for his son. Borgia, now duke of Valentinois, came from France with a considerable force, in order to accomplish the purposes of his father; and began his campaign with the siege of Imola and Forli, which soon surrendered; and he afterwards reduced Pefaro, Rimini, and Faenza. In 1501, Borgia obtained from his father the title of duke of Romagna. In the course of this war, conducted with a ferocity and spirit of rapine and revenge seldom paralleled, he proceeded with such success, that the Italian powers were at length alarmed, and formed a confederacy against him. He contrived, however, to defeat this combination, to detach some parties from the alliance, and, with his accustomed perfidy and cruelty, to invite three of the heads of the association to Senigaglia, under a pretence of establishing peace, and there to cause them to be strangled. Borgia and his father concurred in all these detestable measures, and by their united arts, alternately courted the powers of France and Spain, as each appeared to have the greatest influence in the affairs of Italy. In 1503, Borgia lost his father, who was supposed to have died by poison, which they had prepared for a rick cardinal, whose estate they wished to appropriate to themselves, but which they both took by mistake. It proved fatal to the father; but the son, by strength of constitution, escaped with his life, though he long experienced its pernicious effects. Upon the accession of pope Pius III. Borgia came to Rome with a great retinue; but being universally detested, he avoided the assaults of his enemies by sheltering himself in the Vatican; and his life was preserved by the protection of the king of France; but he afterwards, with base ingratitude, quitted his party, and joined that of Spain. During this interval, many of the towns in his territory of Romagna were seized by the Venetians; and pope

Julius II. seized him at Ostia, and confined him in prison, in order to compel him to surrender the rest. As soon as he made his escape from this confinement, he sought refuge in Naples, and was at first treated with respect by the Spanish general, Gonsalvo de Cordova; but in consequence of an order from the king of Spain, he was sent thither, and condemned to perpetual imprisonment in the castle of Medina del Campo. Here he remained two years; but escaping out of a window, by means of a rope, he fled to Navarre, seeking the protection of king John, his wife's brother. From hence it was his intention to have visited France, and to have engaged the assistance of king Lewis in retrieving his fortune; but that king refused to receive him, confiscated his duchy of Valentinois, and withdrew his pension. In this state of humiliation and distress, without territory or revenue, not only friendless but generally detested, he was under a necessity of depending upon his brother-in-law for a subsistence; and being engaged as a volunteer in his service, on occasion of a civil war with one of his rebellious subjects, he was killed in a skirmish before the walls of Viana, in 1507. His body was stripped by the victors; but being afterwards recognized by his servants, it was carried upon a horse, and interred in the cathedral of Pamplona. "Such," says one of his biographers, "was the end of this man, who, for his abilities in forming, and vigour in executing, great schemes for his aggrandizement, unmoved from his purpose by any considerations of justice, honour, or humanity, has been held up to admiration by Machiavel, as the perfect specimen of a "great man." Hated in prosperity, detested in adversity, stripped of all his honours and possessions, even such as he might fairly have claimed, and leaving behind him a name consigned to universal detestation, it would seem that he gained little by being a villain." Borgia's motto was "Aut Cæsar, aut nihil." Mod. Un. Hist. vol. xxiii. Gen. Dict. Gen. Biog.

**BORGIAN MS.** in *Biblical History*, a fragment of a Coptic-Greek MS. brought by an ignorant monk from Egypt, consisting of about 12 leaves, sent to Stephen Borgia, secretary to the Society de propaganda fide. It begins with John vi. 28. and ends vii. 23.; and is divided into two columns, the first containing the Greek text in uncial letters, and without intervals between the words, and the other containing the Coptic. It is an important specimen, says Michaelis, of the Alexandrine edition; and he greatly laments that so much of it is lost. Professor Birch, who collated this MS. described it in his *Prolegomena*, p. 49, and communicated its various readings in his Greek Testament. The whole of it is printed in "Georgii Fragmentum Græco-Copto-Thebaicum," Romæ, 1789, 4to. Birch has likewise described and communicated the readings of two other Borgian MSS.; one supposed to be of the 11th century, containing the four gospels, and the other of the 12th, containing detached parts of the gospels, and of St. Paul's epistles.

**BORGIAN**, in *Geography*, a town of Persia, in the province of Segestan, 90 leagues south of Zareha.

**BORGIANI**, ORAZIO, or HORAZIO, in *Biography*, a painter of history and portraits, and an engraver, was born at Rome in 1630; instructed in the art of painting by his brother, Giulio Borgiani, called Scalzo; and by studying the capital performances of ancient and modern artists, in his native city, he made such progress in his art, that his works were held in high estimation in Spain, where he resided for some time. Upon his return to Rome, he was employed in considerable works for chapels and convents, and also in painting portraits, by which he acquired honour, and lived in affluence. His etchings were performed in a bold and free manner; and more finished than usual, when considered as

the works of a painter. His drawing is not correct; but the style is masterly, and the effect agreeable. His most finished etching is said to be a "dead Christ," with the figure very much fore-shortened, and behind the two Mariæ and St. John, who is killing one of the hands of our Saviour; from a composition of his own, dated 1615. His death, which happened in 1681, was occasioned by the malicious treatment of an envious competitor and contemporary, whose name was Celio. Pilkington and Strutt.

**BORGIE**, in *Geography*, a town of Africa, in the province of Zeb or Zeeb, about 5 leagues from Biscara; a town much more populous than the latter, and the residence of a great number of merchants, mechanics, and labourers of all kinds.

**BORGLUM**, a prefecture of Denmark, in the diocese of Aalborg, including 14 parishes.

**BORGNE**, LE, a town on the north side of the northern peninsula of the island of St. Domingo, 3 leagues west by north from port Margot, and 8 east by south from Port de Paix. N. lat. 19° 49'.

**BORG**, a town of Sweden, in the province of Nyland, in the gulf of Finland, 21 miles N.E. of Helsingfors. This is an ancient sea-port, with an indifferent harbour, a bishop's see, and a good seminary. The inhabitants trade in all kinds of linen. Borgo gives name to a district.

**BORGO**, a town of the Tyrol. N. lat. 46°. E. long. 11° 30'.

**BORGODES**, in *Ancient Geography*, a people placed by Pliny in Arabia Felix.

**BORGOFORTE**, in *Geography*, a town of Italy, in the duchy of Mantua, at the conflux of the Oglio and the Po; 8 miles S.S.W. of Mantua.

**BORGOFRANCA**, a place of small note in the principality of Piedmont, and marquisate of Ivrea, 2½ miles north of Ivrea.

**BORGO DI FORNARI**, a town of Italy, in the republic of Genoa; 10 miles north of Genoa.

**BORGO MANERO**, a small place in the duchy of Milan, and district of Novarese; 12 miles N.N.W. of Novara.

**BORGO DI ST. DOMINO**, a small town of the duchy of Placentia, though it is the see of a bishop, suffragan of the archbishop of Bologna, and the capital of the district; 12 miles N.W. of Parma.

**BORGO DI ST. SEPOLERO**, a town of the duchy of Tuscany, situate near the source of the Tiber, on the borders of the ecclesiastical state, with a fort on a rock; the see of a bishop, suffragan of Florence, and chief of the pope; 48 miles E.S.E. of Florence, and 12 N.E. of Arezzo.

**BORGO DI SESIA**, a town of the duchy of Milan, in a district called "Val di Sesia;" 22 miles N.W. of Novara.

**BORGO DI VAL DI TARO**, a town of the duchy of Placentia, seated on the river Taro, in the district called "Val di Taro;" 23 miles S.W. of Parma.

**BORSTALL**, a town and bailiwick of Germany, in the circle of Upper Saxony, and Old Marck of Brandenburg; 12 miles S.S.W. of Stendal.

**BORIA**, or **BORJA**, a town of Spain in Arragon, seated at the foot of an eminence near Cayo, and in a country which produces plenty of grain, wine, oil, hemp, flax, and most kinds of esculent plants; 34 miles W.N.W. of Saragossa.

**BORJA**, a town of Peru, situate on the head waters of the Amazon river.—Also, a town in Brazil, on the fourth-eastern bank of Uruguay river. S. lat. 29° 15'. W. long. 56° 30'.

**BORIN**, in *Ornithology*. Under this name Aldrovandus, Ray,

Ray, Willughby, and other old writers describe the passivine warbler, *motacilla passerina*, Gmel.

**BORING**, the act of perforating a solid body, or making a hole throughout its whole length or thickness.

Surgeons speak of boring the bones of the skull, properly called trepanning.

**BORING birch**, and other trees, is practised in the spring for their juice, called also *tapping* and *bleeding*. Phil. Transf. N<sup>o</sup> 44. p. 880. See **BETULA**.

**BORING**, in *Farriery*, an operation formerly practised for the cure of horses whose shoulders are wrenched. The method is thus: they cut a hole through the skin in the middle of the shoulder, and with the shank of a tobacco-pipe, blow it as a butcher does a shoulder of veal; then they run a cold flat iron, like a horseman's sword-blade, eight or ten inches up, between the shoulder blade and the ribs, which they call boring; after that they burn him round his shoulder with a hot-iron. This, says Bartlett, is an absurd and useless, as well as a cruel practice.

**BORING of Cannon**, in *Foundery*. See **CANNON**.

**BORING of Masses**, from top to bottom, is proposed by Dr. Hook, as a means of strengthening and preserving them; as this would make them dry and harden the better, and prevent their cleaving and cracking. For want of this, the outside drying, when the inside does not, the former shrinks faster than the latter; the consequence of which is prejudicial.

**BORING**, in *Mineralogy*, a method of piercing the earth by a set of scooping irons, made with joints so as to be lengthened at pleasure. The skilful mineralist will be able to guess where a vein of ore may lie, though there are none of the common outward signs of it upon the surface of the earth; and in this case he has recourse to boring; the scooping irons are drawn back at proper times, and the samples of earth and mineral matters they bring up, are examined; and hence it is known whether it will be worth while or not to open a mine in the place. See **COAL**.

**BORING**, in *Rural Economy*, a practice sometimes employed in order to ascertain the nature of the different strata that lie beneath the surface soil; and also for the purpose of discovering springs, and tapping them, so as to draw off the water that injures the grounds below, or in the neighbourhood. When this last object is in view, boring is generally performed in the bottoms of ditches or drains, previously made in the land, to the depth of several feet. See **DRAINING of Land**.

**BORING Augre**, an implement employed for the purpose of boring the soil, and letting off water confined beneath it, &c. See **BORER**.

**BORING of Water-pipes**. The method of boring alder poles for water-pipes is thus: being furnished with poles of a fit size, horses, or tressels are procured of a due height, both to lay the poles, and rest the augre on in boring; they also set up a lath, whereby to turn the lesser ends of the poles, and adapt them to the cavities of the greater ends of others, in order to make the joint shut each pair of poles together. The outer, or concave part, is called the female, and the other, or inner, the male part of the joint. In turning the male part, they make a channel, or small groove in it, at a proper distance from the end; and, in the female part, bore a small hole to fit over this channel; they then bore through their poles, sticking up great nails at each end, to guide them right; but they commonly bore a pole at both ends; so that if it be crooked one way, they can nevertheless bore it through, and not spoil it. Neve Build. Dict. in voc. Alder.

This operation is now performed with a horse-mill, as at Dorset Stairs for the New River company.

Belidor, in his *Hydraulics*, has described a machine, in which a water-wheel is made use of both to turn the augre, and to bring forward the carriage on which the pipe to be bored rests. This machine (see *Tab. II. Mechanics, fig. 67.*) is put into motion by the water-wheel A, in the axis of which there is a cog-wheel B, that turns the lanterns C and D; the trundles of D turn two small wheels E and F; the first of which is vertical and turns the augre; the other is horizontal and moves the carriage by means of the two arms H and I. H draws the wheel G towards F; and I pushes it in a contrary direction; and these combined actions cause the carriage to advance towards F, and the augre to bore the pipe. The augre being about twelve feet long and proportionally heavy, is supported by the pieces L L; and they are prepared so as to give no obstruction, in the following manner: C C, (*fig. 68.*) are two planks of wood which are fastened to the timber-work of the mill; these encompass another plank, hung by a cord, at the bottom of which are fixed the pieces b b, with joints at e and e, and, that they may not move out of the vertical plane, they are joined by tenons to the plank a, in which they may work freely: on the side of one of these pieces is fixed a spring, g, in order to hinder them from uniting, by forcing them into a mortise, in d; in this situation the two pieces are penetrated with a hole through which the augre is to pass. The cord is fastened to the plank a, as in *fig. 69*, and goes over the two pulleys b b; at the other end of the cord there is hung a weight e, resting on the piece N, which is supported at one end by the piece O, and fixed to the other by a joint to the lever K, which has its centre of motion in the piece of wood H; so that, leaning against the extremity M of the lever, N quits the support O, the weight sinks down, and draws up the piece a; then the sides b b, *fig. 68*, quit the mortise d, and the spring g separates them: and thus the supporter does not in the least hinder the motion of the augre.

**BORJOKFIT**, in *Geography*, a town of Poland, in the palatinate of Podolia; 28 miles east of Kaminiac.

**BORIQUEN**. See **BIEKA**.

**BORQUETTA**, a province of South America, in the country of Terra Firma.

**BORISSOGLEBSK**. See **BARISSOGLEBSK**.

**BORITH**, in the *Holy Scriptures*, an herb thought to be the kali, or saltwort; of the ashes of which some make soap, and a very good ley to wash linen with. It is mentioned in Jeremiah, chap. ii. ver. 22.

**BORKAH**, or **ARDU**, in *Geography*, an ancient empire of the Asconian Turks, which extended on this side of the Volga from Uvieck, near Saratof, quite to mount Caucasus. Some of these were called Kumani or Komani, from the river Kuma, and their town was named Kumager.

**BORKAN**, a town of Persia, in the province of Larissan, 64 miles S.W. of Lar.

**BORKELOE**. See **BORCKELOE**.

**BORKEN**. See **BORCHEN**.

**BORKEN**, a bailiwick of Germany, in the landgravate of Hesse, consisting of eight villages, and a small town of the same name, become almost extinct.

**BORKZOWKA**, a town of Poland, in the palatinate of Podolia, 20 miles W.N.W. of Kaminiac.

**BORLASE**, **WILLIAM**, in *Biography*, an eminent topographical writer, was born of an ancient family at Penenden, in the parish of St. Just, Cornwall, in 1696; and having finished his grammatical education at Penzance, Tiverton, and Plymouth, was entered at Exeter college, Ox-

ford, in 1713; where, in 1719, he took the degree of master of arts. In the following year he took priests' orders, and in 1722 was inducted to the rectory of Ludgvan in Cornwall, on the presentation of the duke of Bolton; and this, with the vicarage of his native parish, was the only preferment he ever obtained. At Ludgvan his situation was pleasant and retired; and he applied with exemplary assiduity to the duties of his profession, and to those studies of natural history and antiquities, to which his inclination led him. The parish of Ludgvan abounded with mineral and metallic fossils; and the various parts of Cornwall presented to his research many druidical remains. To these objects his attention was directed; and he commenced his literary career with "An Essay on Cornish Crystals," which he communicated to the Royal Society, and which produced his election into that society in 1749. In 1754, he published, in folio, his "Antiquities, historical and monumental, of the county of Cornwall, consisting of several essays on the ancient inhabitants, Druid superstition, customs and remains of the most remote antiquity in Britain and the British isles, exemplified and proved by monuments now extant in Cornwall and the Scilly islands; with a vocabulary of the Cornu-British language;" a learned and judicious work, free from those long digressions and fanciful hypotheses, in which antiquarian writers have indulged themselves. A second edition of this valuable work, with several additions, a map of Cornwall, and two new plates, was published at London, in 1769. His next publication was "Observations on the ancient and present state of the islands of Scilly, and their importance to the trade of Great Britain," 4to. 1756. This was followed, in 1758, by his "Natural History of Cornwall," which was justly considered, at the time of its publication, as a very important accession to the mineralogical history of Great Britain. Soon after this publication he presented to the Ashmolean museum at Oxford, a variety of fossils and remains of antiquity, for which he received the thanks of the university, and the honour of the degree of doctor of divinity. Having completed his three principal works, and attained the age of more than 60 years, he persevered in his application to his favourite studies, and in his diligent discharge of the duties of his profession. His communications to the Royal Society were very numerous; and some or other of his papers may be found in its Transactions from the year 1750 to 1772. With a view to his own amusement and improvement, rather than with any design of publication, he composed paraphrases on the books of Job and of Solomon, and wrote other pieces of a religious kind; and he prepared for the press a treatise, which he had written some years before, concerning the "Creation and Deluge;" but increasing infirmities prevented its being printed. His decline commenced with a severe illness in the beginning of the year 1771, and terminated in his decease on the 31st of August 1772, in the 77th year of his age. He was much esteemed by all who knew him, as a kind father, affectionate brother, sincere friend, instructive pastor, and good citizen; and as a man of erudition whose life had been devoted to important and useful pursuits. He had six sons, two of whom survived him, and they were both in the church. Dr. Borlase furnished Mr. Pope's grotto at Twickenham with a great number of the materials that were used in forming it. In Mr. Pope's letter of acknowledgment, he says, "I am much obliged to you for your valuable collection of Cornish diamonds. I have placed them, where they may best represent yourself, *in a shade, but shining;*" alluding to the obscurity of the donor's situation, and the brilliancy of his talents. Biog. Brit.

BORMES, in *Geography*, a town of France, in the de-

partment of the Var, seated on the coast of the Mediterranean, near a flat shore, which serves for a port, whither the vessels, which cannot reach the gulf of Hieres before a tempest, retire; 3 leagues E. of Hieres.

BORMIDA, or BORNIA, a river of Italy, which runs into the Tanaro, near Alexandria.

BORMIO, a county in the territory of the Grisons, lying at the foot and in the midst of the Rhetian Alps, and bordering upon Engadina, the valley of Munster, the Valteline, Tyrol, Trent, and the Venetian territories. It is entirely included within the mountains, except a narrow opening, which connects it with the Valteline; the other accesses to it lie across the rugged Alps, and in winter are frequently impassable. This country, which was once a part of the Milanese, became subject to the Grisons in 1512. (See VALTELINE.) It is divided into five districts; viz. Bormio, comprising the capital and several dependent villages; the valley of Furba; the valley of Pedinof; the valley of Cepino; and the valley of Luveno. In the new division of Switzerland, since the French revolution, the county of Bormio, with the Valteline and Chiavenna, form a part of the Cisalpine republic. Whilst it remained under the government of the Grisons, its inhabitants were exempt from the oppressions exercised by the Grison governors in the other countries subject to their dominion. They paid a fixed and moderate contribution; they collected and enjoyed their own duties upon exports and imports, and were thus secured from injudicious and oppressive taxes; the fines for criminal offences belonged to the community; and as no part was assigned to the governor, he was not interested in convicting criminals; and the chief privilege, which distinguished this country from the Valteline, was the freedom of its government, and the limitation of the podesta's authority.

The supreme magistrate of Bormio, called "Podesta," was sent from the Grisons, and continued two years in office; his authority was very circumscribed, and his power was almost wholly dependent on the concurrence of the councils. In those councils he never gave a vote, except in case of equality; he possessed not the power of arresting a criminal, nor of pardoning or lessening the punishment. His annual stipend of about 80l. arose partly from a payment of money, partly from an allowance of rye, and partly from the costs of suit in civil and criminal causes. The supreme authority resided in the podesta, and councils, consisting of a civil and criminal tribunal, the members of which were annually chosen by the people. The criminal court, or council of sixteen, changed every four months, consisted of two regents, the treasurer, the notary, and 16 counsellors, of whom ten were taken from the town, and two from each of the vallies Furba, Pedinof, and Cepino. This council was convened by the podesta, at the request of the two regents. In order to arrest a criminal, it was necessary to assemble the whole council, or at least seven of the members; in other important cases, the podesta and two regents might give an order of arrest; but this was deemed contrary to law. The process, conducted by the podesta and two regents, was laid before the council; and upon conviction of the criminal, provided he did not confess his crime, the majority of the council determined whether the evidence was sufficient to justify torture; which was applied in the presence of the podesta, the two regents, the treasurer, and notary. If the proofs were insufficient for conviction, the podesta and counsellors received nothing for their attendance; a regulation, which sometimes induced the judges to strain slight circumstances into proofs of guilt, and not unfrequently occasioned the infliction of torture.

The civil tribunal consisted of twelve members taken from  
the

the town of Bormio; and from their decision an appeal lay to the syndicate of the Grisons.

The members of these councils were chosen annually by the assembly of the people. In the choice of the two regents, six persons selected in a peculiar manner by the regent last in office and the treasurer, chose six members of the assembly, three from the district of Bormio, and three from the vallies, who appointed six candidates; the names were then thrown into six bags, and balloted for; and the two, who had the greatest number of ballots, were regents, who remained in office only four months. The revenue of the country amounted in one year to 222*l.* 1*s.* 4*d.*; and the average expences to 212*l.* 2*s.* 2*d.* The expences and receipts are submitted, when the regents retire from office, to the council of sixteen, and cannot pass without their approbation.

The county of Bormio is about 15 miles in length, and 14 in breadth; and the inhabitants are estimated at about 14,000. The mountainous parts produce only pasturage and wood; the lower district about Bormio yields corn, but not sufficient for domestic consumption. The inhabitants export cattle, a small quantity of cheese, and iron, obtained from the mines of Frelì, in the valley of Pedinofò, wrought at the expence and for the profit of a private person, who pays to the community a small annual rent. The honey produced in Bormio is esteemed excellent. Wine is imported from the Valteline, corn from the Tyrol, and rice from Milan, linen from Bergamo and Appenzel, and cloth from Germany. The air is cool, but pure and healthy. The established religion is the Roman catholic; and the exercise of every other worship is prohibited. Spiritual affairs are under the jurisdiction of the bishop of Coire, who has a vicar's court at Bormio, in which all ecclesiastical causes are tried. The priests have peculiar privileges, which are extended even to those who wear a clerical dress. Most of the peasants possess a small portion of land, and, in consequence of the freedom of the government, are happier than the people of the Valteline and Chiavenna. Coxe's Travels, vol. iii.

BORMIO, the capital of the county of the same name, is situated at the foot of the mountains, close to the torrent Fredolfo, which falls at a small distance into the Adda. It contains about 1000 inhabitants, but has a desolate appearance; the houses are of plastered stone, of which some few make a tolerable figure, amidst many with paper windows; and several, like the Italian cottages, have only wooden window shutters. The palazzo, or town-house, contains a suite of wretched rooms for the residence of the podesta, a chamber for the courts of judicature, and an apartment where the representatives of the people assemble. In one of the rooms is an engine of torture, which, in defiance of common sense as well as humanity, is still used in these countries to force confession. The archives are kept in an apartment, the door of which has several keys; so that all the magistrates, who are entrusted with them, must be present, whenever it is opened. The most important of the papers kept in these archives, is the charter, by which the Grisons confirm, in the most ample manner, the immunities granted to this country by the dukes of Milan; it was passed in the diet of Iluntz, under Paul, bishop of Coire, in 1513, the year succeeding that in which the Grisons annexed Bormio to their dominions. Many circumstances have concurred to deter the Grisons from infringing this charter; the two principal are, the situation of Bormio on the confines of the Tyrol, whence they might receive assistance from the house of Austria; and the spirit of freedom which distinguishes the inhabitants, who have watched with a jealous eye the slight-

est advances of encroachment, and never failed to remonstrate with great unanimity and resolution, whenever the podesta has discovered the least inclination to exceed the bounds of his authority. About a mile from the town are the baths of St. Martin Melina, recommended for rheumatic complaints, &c. N. lat. 46° 17'. E. long. 10° 21'.

BORN, IGNAZIUS, *Baron*, in *Biography*, an eminent mineralogist and philologist, was born of a noble family at Carlsburg, in Transylvania, December 26th, 1742. Having studied in the college of the Jesuits at Vienna, he entered into this society, but continued a member only one year and a half. At Prague he studied the law; and, after an extensive tour on the continent, he devoted himself to natural history and mining; and, in 1770, was admitted into the department of the mines and mint of that city. At this period he visited the principal mining districts of Hungary and Transylvania, and kept up a correspondence with the celebrated Ferber, who afterwards published his letters. In this journey he very nearly lost his life, and did permanent injury to his health, by descending into a mine at Felső-Banya, which was full of arsenical vapours that had been raised by the heat employed to detach the ore. Upon his return to Prague, he published, in 1771, a small work of the Jesuit Pada, on the machinery used in mines; and, in 1772, he printed his "Lithophylacium Bornianum," or catalogue of his collection of fossils, which he afterwards sold to Mr. Greville for one thousand pounds. His reputation, as a mineralogist, was now generally known; and he was admitted into various learned societies, among which were those of Stockholm, Vienna, Padua, and London. Unconfined to one branch of study, he engaged in various plans for the advancement of literature and science in Bohemia. He took a part in the work entitled "Portraits of learned men and artists of Bohemia and Moravia;" he engaged in the "Acta Literaria Bohemæ et Moraviæ;" and in 1775, he laid the foundation of a private literary society in Prague, which has published several volumes of Memoirs. In 1776, he was summoned by the empress Maria Theresia to Vienna, to arrange the imperial collection of natural history; and, two years after, he published, with the assistance of the empress, the "Conchology" of it. But it was discontinued on the accession of the emperor Joseph. Born was appointed to instruct the archduchess Maria Anna in natural history; and, as a recompence for his services, the office of counsellor of the mines and mint was conferred upon him in 1779, which obliged him to reside constantly at Vienna. However, he felt severely the consequences of the injury he had sustained at Felső-Banya; so that he became a martyr to the most excruciating colics: and in one of his attacks he swallowed such a quantity of opium as threw him into a lethargy for twenty-four hours. The disorder then fixed in his legs and feet, and he became lame for the rest of his life. Nevertheless, his mind was vigorous and active, and he entered with zeal into every measure that was calculated to enlarge the boundaries of science, and to enlighten and improve mankind. Restricted, under an arbitrary government, from free discussions on the subjects of religion and politics, he connected himself with the society of free-masons, and united with others of a similar turn of mind, in carrying on a kind of masked attack upon superstition and various kinds of error. Born was also a member of the new society of the "Illuminati," whose views at first were directed to the improvement of mankind, and not to the destruction of society. During the reign of popery and arbitrary power, we may reasonably suppose, that their projects of reform were less hostile to religion and government in general, than what has been charged upon their principles, since they have been alled

hied with those of the French revolution. The emperor Joseph seems at this time not to have been adverse to such coadjutors; and he appeared to be pleased with a witty and popular publication of Born, in 1783, entitled "Monachologia," which was a severe attack on the monks, whom he characterized in the technical language of natural history, under the regular divisions of order, genus, and species, used in the Linnæan school. The clergy complained, and their complaints were retorted by Born with more bitter satires, exceeding the bounds of prudence and candour. He defended his associates, the "Illuminati," with great zeal; and when the elector of Bavaria issued an order to dismiss all of this fraternity from his service, Born returned to the academy of Munich the diploma by which he had been admitted as one of its members. The emperor Joseph gradually withdrew his support from these reformers, whom he had at first encouraged; and Born's continued influence was principally owing to his skill in mineralogy and metallurgy, by which he was capable of rendering service to the state. In the process of extracting the noble metals from their ores, by amalgamation with quicksilver, he manifested his superior skill; and to this purpose, a decisive experiment was performed at Chemnitz, by the emperor's order, in the presence of Charpentier from Saxony, Ferber from Russia, Elhujar from Spain, Poda, and other celebrated chemists, which met with universal approbation, and established the utility of his discovery. In 1786, Born published, at the desire of the emperor, his treatise on amalgamation; and in the following year, a farther account of it was published by his friend Ferber. As a considerable saving in wood, time, and labour, attended his process, the emperor gave orders that it should be employed in the Hungarian mines; and as a recompence to the inventor, a third of the sum that should be saved by adopting his method was granted to him for ten years, and for ten years more the interest of that sum. Such, however, was the hospitality of Born, and his readiness to admit and entertain all travellers, and to patronize distressed talents of every kind, that his expences exceeded his income, and he was at last reduced to a state of insolvency. Amidst all his bodily infirmities and pecuniary embarrassments, and notwithstanding the variety of his official avocations, he was indefatigable in his literary pursuits; and in 1790, he published in two volumes, a "Catalogue methodique raisonné," of Mifs Raab's collection of fossils, which is regarded as a classical work on that subject. He employed himself also in bleaching wax by a new chemical process, and in boiling salt with half the wood commonly used for that purpose. Whilst he was engaged in writing the "Fasli Leopoldini," or a history of the reign of Leopold II. in classical Latin, and a work on mineralogy, his disease rapidly advanced, and being attended with violent spasms, terminated his life on the 28th of August, 1791. Townson's Travels in Hungary, 4to. 1796.

BORN, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve d'Agen;  $1\frac{1}{2}$  league N.N.W. of Montlaquin.

BORNA, a town of Germany, in the circle of Upper Saxony, and territory of Leipzig, seated on an island formed by the rivers Wichru and Pleiß. The inhabitants are chiefly employed in manufacturing stuffs; 12 miles S.E. of Leipzig.

BORNE, a river of England, which runs into the Tame, about a mile S.W. of Tamworth.—Also, a river of Savoy, which runs into the Aroë, about two miles north from Bonreville.

BORNEO, an island of the East Indies, which, before

the discovery of New Holland, was considered as the largest island in the world. This island seems to have been the Greater Java of Marco Paolo, which, he says, is about 3000 miles in circuit, being above 900 miles in length by 600 at its greatest breadth. The latest and best account that has yet been given of this island is published in the Transactions of the Batavian Society. The island of Borneo extends from the 4th degree of S. lat. to the 8th of N. lat. and from  $109^{\circ}$  to  $119^{\circ}$  E. long. It is about 780 miles in length, and 720 in breadth. Its climate is almost the same as that of Java; but Borneo is less mountainous, and the land, for 12 or 15 miles, and sometimes more, from the coast, is almost every where marshy, and covered with forests of trees of large size, and of various kinds. The remaining part of the island is sufficiently fertile, and would be productive, if the inhabitants were not too indolent to cultivate the soil, and fonder of searching for gold and diamonds, which they barter with the Javanese for various necessaries of life. The middle of the island is occupied by an extensive ridge of mountains, called the "Crystal mountains," because a great quantity of crystal is found in them. At the foot of these mountains is a large inland lake, which is the source of all the rivers that traverse the whole island. The real natives of this island are the Biadjos, or Bijaos, or Dajakkefe, who live in the interior parts of the country. The sea-coast is inhabited by Malays, Moors, Macassers from Celebes, and Javanese. We have accounts, on which we may depend, only of the countries situated along the coast; the interior parts of the island being little known. The largest kingdom in the island, and the most important on account of its connection with the Dutch East India company, is that of Banjermassing on the southern coast. The great river Pontiana, which is navigable for ships that draw from 12 to 13 feet of water, is very convenient for trade. The sultan Sufuhunan Natahalam, since the year 1771, has transferred his residence from Cagu-Tangie to Martapura, where he caused a large city to be built, and a canal to be dug, which passes through the middle of it, and at the same time he changed the name Martapura into Bumie-Kintjana. The inhabitants of the city, as well as those who reside in places at a distance from the coast, are Mahometans, mixed with a great many Biadjos, or Dajakkefe, who are Pagans. These Biadjos, who inhabit villages, amounting in number to 784, are subject to various petty princes, who acknowledge the sultan as their superior. The factory of the Dutch East India company is situated at the end of the village of Tatas, or Banjermassing. Their fort is of an octagonal form, surrounded by pallisades, which on the east side next the river is furnished with three, and on the west, or land side, with two bastions. The productions of the country, which are sought for as articles of commerce, are pepper, gold (chiefly gold-dull, not very abundant in metal), diamonds, canes, birds-nests, wax, pedra del porco, dragon's blood, and iron. For these the Dutch give in exchange agates of a longish form, rings of red agate, different kinds of coral, all sorts of Chinese articles, such as coarse porcelain, red and other kinds of silk, all sorts of cotton cloth, such as is worn by the Indians, various productions of Java, and also opium, which, being prohibited by the sultan, is privately introduced. See BANJERMASSING.

Sucatan lies in  $0^{\circ} 50'$  S. lat.; and a little north of it is the river Pontiana, which discharges itself into the sea under the line, through a great many mouths. At its mouth it is 12 feet in depth, and at high water 16, so that sloops and small vessels can proceed with great ease in about 12 hours to the company's factory. The river, at the distance of about seven or eight miles from its mouth, separates into

two branches; the southernmost of which flows through the country governed by Pangerang (a term of dignity) Joseph, who, in 1773, was advanced by the company, to be sultan of Sasango and Pontiana, under the name of Sarief Abdulla Rachmann. These two kingdoms extend far into the country; and produce excellent gold, wax, birds-nests, pearls, sago, diamonds, tin, and iron, which are bartered for provisions of all kinds and cotton cloth, but particularly rice and salt. Heavy rains prevail here from November till May; and the thermometer is never lower than  $82^{\circ}$ , nor higher than  $94^{\circ}$ .

Landac lies on the northern arm of the river Pontiana, in N. lat.  $0^{\circ} 35'$ . The Dutch had a resident here 150 years ago. After that period their possessions were destroyed, till the king of Bantam, to whom Landac and Succatana had for many years belonged, made a grant, either voluntary or by compulsion, to the company of all these lands in 1778. From this time the Dutch have considered these lands as their property, and the princes who govern them as their vassals; they then built a fort at Pontiana, between Landac and Succatana, and appointed Pangerang Saidja Nata, as regent of the whole district. The residence of the prince of Landac is situated on the projecting point of a mountain, to which there is an ascent by 118 steps. Two rivers, which are so full of rocks that no vessels can be navigated in them, flow on the right and left of this mountain; and the place is naturally impregnable. It is also well furnished with artillery. In this kingdom there are gold and diamond mines of considerable importance.

Between Landac and Borneo, the most northern kingdom of the island, and from which, probably, the whole country took its name, there are several smaller kingdoms, not yet sufficiently known. Their regents are, in part, vassals of the sultan of Borneo. A small trade is carried on in these districts with gold, diamonds, canes, wax, and other articles of the like kind, which are given in exchange for the productions of Java; but the traffic is unimportant and precarious, as the princes of this part of the country live by piracy.

Borneo is governed by a sultan, who resides in this place, where a considerable trade is carried on with the productions of the country, which are pearls, birds-nests, wax, slaves, rice, and camphor. The camphor of this island is preferred even to that of Sumatra. The camphor of Borneo and Sumatra is produced by a tree with oval, sharp-pointed leaves, and large tulip-like flowers. It is thus distinguished both from the camphor-tree of Japan, and from the other species of the laurel. An hundred weight of the camphor of Borneo costs 3000, and one of that of Sumatra 2000 rix-dollars, but the Japanese costs scarcely 50. Of the camphor of Borneo about 4375 pounds are annually exported. The articles imported are tin, cotton-cloth, and all the productions of Java, except rice, which is cultivated here in great abundance.

The sultan of Borneo lives in great state, and is more feared by his subjects than that of Banjer; but he is said, by those who frequent this part of the coast in small vessels to exchange cotton-cloth for pepper, to be more constant in his friendship, and more faithful in fulfilling his engagements.

Between Borneo and Tidor lie the two small kingdoms of Balangan and Baraoou, where birds-nests, wax, &c. are exchanged for Japanese productions, and a sort of coarse cotton-cloth. Next to these is Danuar, and a little farther are Samunta, and Cotee. Between the two last are many villages, the names of which are not known. The same articles are exported and imported here as at Borneo.

The next place is Appar Karrang, and the last kingdom is Passier. The articles of trade in this country are gold, birds-nests, wax, and canes, which are exchanged for the productions of Java. The inhabitants of Passier are few in number, and therefore they have been unable to expel the Buginese, who have made themselves masters of the river, and also of the trade. Further south lies Simpanahan; and the whole country from this place to the extreme boundaries of Salatang belongs to the king of Banjer-massing, who possesses also the great and small island Pulu-Lauts. There appear to be no other kingdoms in the interior part of Borneo; or, at least, they are not known. The inhabitants of the mountains bring the productions of their lands, and their different articles of manufacture, to the nearest part of the coast for sale.

The most productive diamond mines of Borneo are at Ambanwang, beyond Molucco, in the district of Banjer-massing, and at Landac and Pontiana. Besides these mines, which lie among the mountains, diamonds are also searched for on the banks of various rivers; but they are so scarce that ten or twelve persons may dig and search sometimes for a whole month before they find diamonds to the value of 20 Spanish rials. With regard to the gold mines, the ignorance of the natives as to every thing relative to mining is such, that little advantage is derived from them, though they are supposed to be very rich. In Banjer-massing the gold is found at the depth of about three fathoms; the veins properly so called are of a reddish kind of marl. At Landac the ore is found at the depth of about ten feet, under a crust resembling rotten wood. Of the animals of Borneo the most remarkable is the orang outang.

The Biadjoos or Dajakkefe, who are the native inhabitants of this island, and principally occupy an extensive district in the interior part of the country on the west side of the river Banjer, are of large stature, and well formed, and their women, whom they never bring to the places of trade, are said to be fair and handsome. In their dress they resemble the Malays. The women, and even the wives of their princes, are naked to the middle, and generally wear round the body only a short gown. The men paint their bodies with various kinds of figures. They come to Banjer to sell their gold, canes, and rice, for which they receive in exchange coarse Chinese porcelain, copper, and earthen vessels or tampayangs, on which are represented dragons, snakes, and other figures suited to their taste. Before any one of the Biadjoos can succeed in obtaining a female for his wife, he must give proof of his courage by cutting off the head of an enemy; and when he is accepted by the parents, he carries to his bride a present, which consists of a male or female slave, two dresses, and a water-pot, on which some of their favourite figures are exhibited. On the wedding day, the bride and bridegroom give each a feast at their respective houses; at the conclusion of which, the bridegroom, in his best apparel, is conducted to the residence of the bride, at whose door is one of her relations, who smears him with the blood of a cock, which has been killed for that purpose; and the bride is smeared in like manner with the blood of a hen. They then present to each other their bloody hands, and the solemnity is closed with a second entertainment. If the wife die, the husband cannot contract a second marriage until he has cut off the head of some individual of another nation, and thus avenged the death of his wife. When a married woman commits adultery, the husband, without avenging himself on the adulteress, puts to death two or three of his slaves, and thus frees himself from all shame; the woman is punished merely with words, but sometimes with blows. The Biadjoos are unacquainted with polygamy.

polygamy. If a man wishes to separate from his wife in consequence of her having committed some crime, he retains her clothes and ornaments, and makes her pay a fine amounting to about 30 rials; and each party is then at liberty to marry. When a Biadjo dies, the body is put into a coffin, and kept in the house, until all the remaining males in the family have purchased a slave; who is beheaded on the day when the body is burnt, that he may attend the deceased in the other world; and before he is put to death, he is enjoined fidelity to his master. The ashes of the deceased, together with the head of the slave, are put into a watering-pot, and deposited in a small edifice or tomb constructed for that purpose. Sometimes a whole year elapses before a slave can be procured. The houses of the Biadjos are constructed of boards joined together without windows or partitions, except that which separates a small corner in which they sleep. The whole family reside together with their slaves, and consist sometimes of 100 persons. Their only light is that of a piece of pine-wood, which burns no longer than till about eight in the evening. Over their doors they suspend the bloody heads which they cut off in their skirmishes. In order to procure these they proceed, with great secrecy, to the river Banjer, and surprise in the night, or attack, in open day, some small vessel belonging to Banjer fishermen; and one or two of their unfortunate captives are then destined to become a sacrifice to their insatiable rage for murder. When they return with a head, the men, women, and children of a whole village testify their satisfaction by every demonstration of joy. Gongs, or musical instruments of copper, are beat by those who conduct the conqueror to his own house, where the women dance around him, and taking from him the head, they force into the mouth some food and drink; after which ceremony, accompanied with a repast and dance, they hang it up as a trophy of victory. Before the Biadjos undertake expeditions in quest of Banjerese heads, they endeavour to deduce some omen of good or bad fortune from the flight of a kind of hawk (*falco milvus*). They have scarcely any form of government, and no written laws. If a person be accused of theft, and no sufficient proof can be alleged against him, the culprit and the accuser are carried before one of the oldest inhabitants. An earthen pot with ashes and water is placed on the ground; and across the pot is laid a piece of wood, on which are deposited two small copper buttons. An oath having been administered to each party, the piece of wood is so turned round that the buttons fall into the water; the accused and the accuser take up one of these buttons; and he, whose button appears as if scowered and whitened by the ashes, is deemed to have succeeded. The Biadjos are said to have some idea of a supreme being, to whom they address prayers under the name of Dewatta; and as they believe that this Dewatta not only created, but still preserves and rules the world, they request him to grant them happiness and prosperity. If we may judge from the character of these people, their deity must be a gloomy and revengeful being; no nation on earth having a greater propensity to murder and revenge. The Biadjos acknowledge the sultan of Banjer as their sovereign, and pay him yearly a small tribute in gold dust of the value of 20 rials.

The Portuguese, Dutch, and English have ever since the 16th century endeavoured to establish themselves in this island; but the Dutch have been the most successful. The Portuguese, it is said, wished to form a settlement here in 1526, and with this view presented to the sultan of Landac and Succatana some beautiful pieces of tapestry, on which curious figures were wrought; but the sultan,

conceiving these figures to be animated or magic, and apprehending that they might rush suddenly from the tapestry and strangle him, rejected the present and expelled the Portuguese from the country. The English were not much more fortunate, having quitted Borneo entirely ever since the year 1706. In 1766, they made an attempt to form a settlement in the island of Bulambangan, at the N. extremity of Borneo, which was given up to them by the king of Solon. They placed in it a few Europeans for the sake of trade, and a garrison of 300 soldiers, Europeans and blacks; and intended to establish a factory, where they might exchange the productions of Europe and Hindostan for those brought hither from China and the Indian islands; but in the year 1772, after a part of their troops had been swept off by contagious diseases, the fort they had constructed, being badly fortified, was suddenly attacked, and the whole establishment destroyed. The English have still some establishments on the north coast of Borneo; and the circumjacent Indian nations, and the Chinese carry on a great trade with this island. About Borneo are several small islands, that may be denominated the "Bornean islands," such as the Soloos, Tawca, Pulo Laut, Anamba, Natuna, &c.

BORNEO, a sea-port and capital of the island of this name, is large, populous, and commercial, with a good harbour; it consists of about 300 houses, built on piles, and is situated on the N. W. side of the island. N. lat. 4° 50'. E. long. 115° 0'.

BORNEVALT, a town of Germany, in the circle of Westphalia, and duchy of Berg; 3 miles W. of Lennepe.

BORNEUS, in *Ornithology*, the *long-tailed scarlet lory*. This beautiful bird is of a red colour; quills and tail feathers at the tips green; a blue spot on the wings; orbits fuscous. Inhabits India.

The length of this bird is nine inches and a half. Its bill is orange; orbits of the eyes bare of feathers; quill feathers with blue and green dots; the two exterior feathers inclining to green; lower tail coverts red, bordered with blue. Gmel.—*Lori perruche rouge*, No. 1. Buff. *Pfittaca cocinea bonarum fortunarum insule*. Briff.

BORNHEIM, a village of Germany, in the circle of the Upper Rhine, and territory of Franckfort on the Mayne; 6 English miles N. of Franckfort. This village is said to be notorious all over Germany for its numerous brothels. *Render's Tour*.

BORNHOLM, an island of Denmark, in the Baltic sea, the remotest and most easterly of all the Danish islands, about 18 miles in length, and 10 in breadth. Although it is nearly surrounded by rocks, and the soil is stoney, it is a fertile spot, abounding with excellent pastures; oats, butter, and fish constitute the wealth of the inhabitants. There are some mines of coal and quarries of marble. It was conquered by the Swedes in 1645, and surrendered to them by the treaty of Roskild, in 1658; but the inhabitants revolted in the same year, and restored their island to the Danish dominion, under which it has since continued. Bornholm is distant 75 miles from Zealand, and 15 from the coast of Schonen. N. lat. 55° 12'. E. long. 15° 20'.

BORNII, in *Conchology*, a species of TELLINA, figured by Born. This shell is transversely striated, bent on one side, and reddish, with red rays. This is three quarters of an inch long, and two inches broad. The native place is not known.

BORNOU, in *Geography*, an extensive kingdom of Africa, lying south-east of Fezzan, and bounded on the north by the desert of Bilma, on the west by Kuka, Tagua, and Nubia,

Nubia, on the south by Kauga and Begarmee, and on the west by Zegzeg, Zanfara, and Kassina. The name Bornou, which is given to this kingdom by the natives, is distinguished in Arabia by the appellation of Bernou, or Bernoa, signifying the land of Noah; for the Arabs conceive, that, on the first retiring of the deluge, its mountains received the ark. This is a country of great extent, being comprehended between the 16th and about the 22d degrees of N. latitude. The climate is characterized by excessive, but not uniform, heat. Two seasons divide the year; one commencing about the middle of April, and introduced by violent winds from the S.E. and S., intense heat, a deluge of rain, and such tempests of thunder and lightning as destroy many cattle and people; at this time the inhabitants confine themselves to their houses; the rest of the season, though sultry and rainy, does not hinder the labours of the husbandman and shepherd. The other season commences towards the latter end of October, when the heat becomes less intense, the air more soft and mild, and the weather serene. The inhabitants are numerous, and consist of various nations; and it is reported that thirty different languages are spoken in this empire. The language of the common people of Bornou, though different from, strongly resembles that of the neighbouring negroes, and is very unlike the Arabic, in which, however, the nobles and principal families converse. The art of writing is known among them; and they are taught to express the Bornou tongue in the characters of the Arabic. They are entirely black, but not of the negro cast. Their general dress is composed of shirts of blue cotton, manufactured in the country; a red cap, imported from Tripoli; and a white muslin turban, brought from Cairo by the pilgrims, who return through that city from Mecca. Nose-rings of gold are also worn by the principal people, as a mark of distinction. Wheat and barley are seldom raised in Bornou; but the horse-bean of Europe, and the common kidney-bean are assiduously cultivated, as they are used for food, both by the slaves and by the cattle. They also cultivate a kind of grain peculiar to the country; and the neighbourhood of the city of Bornou is fertile in Indian corn and rice. Gum-trees are thinly scattered; cotton, hemp, and indigo are also to be reckoned among the various productions of its soil. In the culture of the ground, the hoe is the only instrument in use, as the plough is not known; and the women share with the men the labours of their husbandry. The sowing season commences at the end of the periodical rains in April; and such is the rapidity of vegetation, that one species of their grain is reaped in July, and another, of slower growth, in August or September. Two species of roots are used as substantial and wholesome food; one called the "dondoo," whose leaves resemble those of the garden bean, is dried in the sun, and reduced to fine powder, which is mixed with palm oil into the consistency of paste; and the other prepared for use merely by boiling. The fruits of Bornou are grapes, apricots, pomegranates, lemons, limes, and melons. The dates are scarce and indifferent, as are also the apples and plums; but it has a valuable vegetable, called "Kedéyah," resembling the olive in form and height, and the lemon in its leaf, which bears a nut, whose kernel is an esteemed fruit, and shell, when bruised, yields an oil that supplies the lamps with a substitute for the oil of olives. To the class of animals we may refer innumerable flocks of sheep, and herds of goats and cows, (for there are no oxen,) together with multitudes of horses, buffaloes, and camels, the flesh of which is in high estimation, which cover the vales or pasture on the mountains of Bornou. The common fowl is reared by the inhabitants; and their hives of bees are so numerous, that the wax is often thrown away as an

article of no value in the market. Their game consists of antelopes, partridges, wild ducks, and the ostrich, the flesh of which they prize above every other. Their other wild animals are the lion, the leopard, the civet-cat, the small wolf, the fox, the wild dog that hunts the antelope, the elephant, of which, however, they make no use, the crocodile, the hippopotamus, and giraffe. Bornou is much infested with different kinds of dangerous and disgusting reptiles, especially snakes and scorpions, centipedes and toads. Its herds of burthen are numerous and various; of which we may reckon the camel, the horse, the ass, and the mule. The dog appears to be the only domestic animal. In Bornou the same plan of constructing their houses universally prevails. Four walls, inclosing a square, are erected; within the walls, and parallel to them, four other walls are also built; the ground between the walls is then divided into different apartments, and covered with a roof. Thus the space within the interior walls determines the size of the court; the space between the walls, limits the width of the apartments; and the height of the walls regulates the height of the rooms. In a large house the rooms are each about twenty feet long, eleven feet high, and as many in width. On the outside of the house, a second square or large yard, surrounded by a wall, is usually provided for the inclosure and protection of the cattle. The walls are generally composed of earth and sand, but others are formed of stones or bricks and clay; and the roofs consist of branches of the palm-tree, intermixed with brush-wood, covered with layers of earth; and the whole building is white-washed with a species of chalk. The utensils of a house, among the lower classes, are mats covered with a sheep-skin, upon which they sleep; an earthen pot and pan; two or three wooden dishes, a couple of wooden bowls, an old carpet, a lamp for oil, and a copper kettle. Persons of a superior rank also possess leathern cushions, stuffed with wool, brags and copper utensils, a handsome carpet, and a sort of candlestick, which is used for their candles that are made of their bees' wax and the tallow of their sheep. The current species of the empire consists of pieces of metal from an ounce to a pound in weight, formed of copper and brags, melted together and mixed with other materials. The ruling people in Bornou profess the mahometan religion, so that the sultan and his subjects are mussulmen, and the other classes are pagans. The government is an elective monarchy; and the new sovereign, when chosen from among the sons of his predecessor, is invested with all the slaves, and with two-thirds of all the cattle and land, of his father; the remaining third being always detained as a provision for the other children of the deceased monarch. To the four lawful wives of the late sovereign, a separate house with a suitable establishment, is granted by the reigning monarch; and such of his concubines, as were not slaves, are at liberty to return to their friends, with their cloaths and ornaments, and with the permission to marry. The administration of the provinces of Bornou is committed to governors, appointed by the crown; and the expences of the sovereign are defrayed partly by his hereditary lands, and partly by taxes levied on the people. The sultan Alli, who was the sovereign of Bornou, in 1789, though plain in his dress, maintained a magnificent seraglio, accommodating 500 ladies, and was reputed to be the father of 350 children; and the number of horses kept for his own use and that of his servants, amounted to 500. The military force of Bornou consists in a great multitude of horsemen, which renders him a much more powerful monarch than the emperor of Morocco; but his foot-soldiers are few in number, and of little importance. Their weapons of offence are the sabre, the lance, the pike, and the bow; and a shield of hides forms

polygamy. If a man wishes to separate from his wife in consequence of her having committed some crime, he retains her clothes and ornaments, and makes her pay a fine amounting to about 30 rials; and each party is then at liberty to marry. When a Biadjo dies, the body is put into a coffin, and kept in the house, until all the remaining males in the family have purchased a slave; who is beheaded on the day when the body is burnt, that he may attend the deceased in the other world; and before he is put to death, he is enjoined fidelity to his master. The ashes of the deceased, together with the head of the slave, are put into a watering-pot, and deposited in a small edifice or tomb constructed for that purpose. Sometimes a whole year elapses before a slave can be procured. The houses of the Biadjoos are constructed of boards joined together without windows or partitions, except that which separates a small corner in which they sleep. The whole family reside together with their slaves, and consist sometimes of 100 persons. Their only light is that of a piece of pine-wood, which burns no longer than till about eight in the evening. Over their doors they suspend the bloody heads which they cut off in their skirmishes. In order to procure these they proceed, with great secrecy, to the river Banjer, and surprise in the night, or attack, in open day, some small vessel belonging to Banjer fishermen; and one or two of their unfortunate captives are then destined to become a sacrifice to their insatiable rage for murder. When they return with a head, the men, women, and children of a whole village testify their satisfaction by every demonstration of joy. Gongs, or musical instruments of copper, are beat by those who conduct the conqueror to his own house, where the women dance around him, and taking from him the head, they force into the mouth some food and drink; after which ceremony, accompanied with a repast and dance, they hang it up as a trophy of victory. Before the Biadjoos undertake expeditions in quest of Banjerefe heads, they endeavour to deduce some omen of good or bad fortune from the flight of a kind of hawk (*falco milvus*). They have scarcely any form of government, and no written laws. If a person be accused of theft, and no sufficient proof can be alleged against him, the culprit and the accuser are carried before one of the oldest inhabitants. An earthen pot with ashes and water is placed on the ground; and across the pot is laid a piece of wood, on which are deposited two small copper buttons. An oath having been administered to each party, the piece of wood is so turned round that the buttons fall into the water; the accused and the accuser take up one of these buttons; and he, whose button appears as if scowered and whitened by the ashes, is deemed to have succeeded. The Biadjoos are said to have some idea of a supreme being, to whom they address prayers under the name of Dewatta; and as they believe that this Dewatta not only created, but still preserves and rules the world, they request him to grant them happiness and prosperity. If we may judge from the character of these people, their deity must be a gloomy and revengeful being; no nation on earth having a greater propensity to murder and revenge. The Biadjoos acknowledge the sultan of Banjer as their sovereign, and pay him yearly a small tribute in gold dust of the value of 20 rials.

The Portuguese, Dutch, and English have ever since the 16th century endeavoured to establish themselves in this island; but the Dutch have been the most successful. The Portuguese, it is said, wished to form a settlement here in 1526, and with this view presented to the sultan of Landac and Succatana some beautiful pieces of tapestry, on which curious figures were wrought; but the sultan,

conceiving these figures to be animated or magic, and apprehending that they might rush suddenly from the tapestry and strangle him, rejected the present and expelled the Portuguese from the country. The English were not much more fortunate, having quitted Borneo entirely ever since the year 1706. In 1766, they made an attempt to form a settlement in the island of Balambangan, at the N. extremity of Borneo, which was given up to them by the king of Solon. They placed in it a few Europeans for the sake of trade, and a garrison of 300 soldiers, Europeans and blacks; and intended to establish a factory, where they might exchange the productions of Europe and Hindostan for those brought hither from China and the Indian islands; but in the year 1772, after a part of their troops had been swept off by contagious diseases, the fort they had constructed, being badly fortified, was suddenly attacked, and the whole establishment destroyed. The English have still some establishments on the north coast of Borneo; and the circumjacent Indian nations, and the Chinese carry on a great trade with this island. About Borneo are several small islands, that may be denominated the "Bornean islands," such as the Soloos, Tawca, Pulo Laut, Anamba, Natuna, &c.

Persons of a superior rank also possess leathern cushions, stuffed with wool, brass and copper utensils, a handsome carpet, and a sort of candlestick, which is used for their candles that are made of their bees' wax and the tallow of their sheep. The current species of the empire consists of pieces of metal from an ounce to a pound in weight, formed of copper and brass, melted together and mixed with other materials. The ruling people in Bornou profess the mahometan religion, so that the sultan and his subjects are mussulmen, and the other classes are pagans. The government is an elective monarchy; and the new sovereign, when chosen from among the sons of his predecessor, is invested with all the slaves, and with two-thirds of all the cattle and land, of his father; the remaining third being always detained as a provision for the other children of the deceased monarch. To the four lawful wives of the late sovereign, a separate house with a suitable establishment, is granted by the reigning monarch; and such of his concubines, as were not slaves, are at liberty to return to their friends, with their cloaths and ornaments, and with the permission to marry. The administration of the provinces of Bornou is committed to governors, appointed by the crown; and the expences of the sovereign are defrayed partly by his hereditary lands, and partly by taxes levied on the people. The sultan Alli, who was the sovereign of Bornou, in 1789, though plain in his dress, maintained a magnificent seraglio, accommodating 500 ladies, and was reputed to be the father of 350 children; and the number of horses kept for his own use and that of his servants, amounted to 500. The military force of Bornou consists in a great multitude of horsemen, which renders him a much more powerful monarch than the emperor of Morocco; but his foot-soldiers are few in number, and of little importance. Their weapons of offence are the sabre, the lance, the pike, and the bow; and a shield of hides forms

their defensive armour. Fire-arms, though not entirely unknown, are neither used nor possessed by the people of Bornou. As to their habits and manners, the people are singularly courteous and humane. On the road they stop to salute every one they meet; their quarrels, when they occur, are mere contests of words; and though their women share with them in the business of husbandry, their work, which is dropping the seed in the furrows, and removing the weeds with a hoe, is more an amusement than labour. Their attachment to play is manifest; and on the game of draughts, which is the only game with which the lower classes are acquainted, they stake their gold dust, their brass money, and even their cloaths. Persons of a superior rank are equally devoted to chess, in which they are eminently skilful. The articles of export furnished by the empire of Bornou are gold-dust, slaves, procured from BEGARME, horses, ostrich feathers, salt, collected on the shores of the several lakes that produce it, and civet, obtained from a species of wild cat that is common in the woods of Bornou and Kassina. As to their manufactures, they make a coarse linen of the hemp of their country. Their cotton is spun to a very fine thread, and then manufactured into calicoes and muslins about nine inches broad, and in length from fifteen to twenty yards. Such of these cotton manufactures as are enriched with the blue dye of the country, which, from the superiority of the indigo, is preferable to that of the East Indies, are valued more highly than silk. They also fabricate a species of carpet, as a covering for their horses; and tents, of wool and the hair of goats and camels, are made for the use of the army. From the iron ore of their country they form, with little skill, such slight tools as their husbandry requires; and the little silver they have is converted by their own artists into rings. In return for their exports, they receive from Tripoli, by way of Fezzan, copper and brass, which are used as current species; and also imperial dollars, of which they make rings and bracelets for their women; red woollen caps worn under the turban, check linens, light coarse woollen cloths, baize, baracans, small Turkey carpets, and plain Mesurata carpets. Mr. Lucas's Communications in the Proceedings of the African Association.

BORNOU, the capital of the country above-described, is situated at the distance of a day's journey from a river which is called "Wed-el-Gazel," from the multitude of antelopes that feed on its banks, and which is lost in the deep and sandy wastes of the vast deserts of Bilma. It is seated in a flat country, on the banks of a small river. Bornou, though a town of greater extent than Tripoli, consists of a multitude of houses, so irregularly placed, that the intervals between them cannot be called streets; it is furnished with mosques, which are constructed of brick and earth, and with schools, in which the koran is taught, as in the principal towns of Barbary. The royal palace, in which the sultan resides in time of peace, is surrounded by high walls, and forming a kind of citadel, is built, perhaps for security, in a corner of the town. Within the city are markets for the sale of provisions; but for other articles a weekly market, as in Barbary, is held without the walls. This city is surrounded by a wall, fourteen feet high, constructed on a foundation from eight to ten feet deep, of considerable strength. It is secured by a ditch which encompasses the whole; and at sun set, the seven gates, which form the communication with the country, are shut. Brown, in his travels, p. 467, says, that the wall has four gates, opening east, west, north, and south. N. lat.  $19^{\circ}35'$ . E. long.  $22^{\circ}40'$ .

BORNSTETT, a town and bailiwick of Germany, in the circle of Upper Saxony; 4 miles S. W. of Eilschen.

BORNY, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Metz, 2 miles E. of Metz.

BOROCZANE, a town of Poland, in the palatinate of Red Russia; 28 miles S. S. W. of Halicz.

BOROLIBICUS, the wind which blows in the middle between the north and west points; called also the north-west wind.

BORONOO, in *Geography*, a town of Russia, in the government of Archangel; 80 miles S. of Archangel.

BOROS-JENO, a town of Hungary; 28 miles S. of Gros-Warden.

BOROUGH, BURROUGH, BOROW, or BURGH, is frequently used for a corporate town, which is not a city.

Borough, in its original Saxon *borge*, or *borgh*, is by some supposed to have been primarily meant of a tything or company consisting of ten families, who were bound or combined together as each other's pledge.

Afterwards, as Verlegan informs us, borough came to signify a town that had something of a wall or inclosure about it; so that all places which among our ancestors had the denomination of borough, were one way or other fenced or fortified. But in later times, the same appellation was also bestowed on several of the *villa insigniores*, or country towns of more than ordinary note, though not walled. According to Somner, a borough was a place of safety, protection, and privilege; and in the reign of king Henry II. boroughs were so highly privileged, that if a bondman or servant remained in a borough a year and a day, he was by such residence made a free-man. Gleanville. These were denominated free-burghs, and the tradesmen who inhabited them free-burghesses, because they enjoyed a freedom to buy and sell without molestation, and with exemption from toll, &c. granted by charter.

The ancient Saxons, according to Spelman, gave the name burgh to those called, in other countries, cities. But divers canons being made for removing the episcopal sees from villages and small towns to the chief cities, the name city became attributed to episcopal towns, and that of borough retained to all the rest; though these too had the appearance of cities, as being governed by their mayors, and having laws of their own making, and sending representatives to parliament, and being fortified with a wall and castle, and the like. See CITY.

BOROUGH, or *burgh*, is now particularly appropriated to such towns and villages, as send burghesses or representatives to parliament.

Boroughs are equally such, whether they be incorporated or not; there being great numbers of our English boroughs not incorporated; and, on the contrary, several corporations that are not boroughs; e. gr. Kingston, Deal, Kendal, &c.

Boroughs are distinguished into those by charter or statute; and those by prescription or custom.

The number of boroughs in England and Wales, including cities and cinque ports, which elect members, is 215; some whereof send one, some two representatives.

It has been a subject of controversy among antiquaries, at what time the representatives of boroughs formed a part of the great council of the nation. Some have traced their origin as far back as the Saxon *Wittenagemot*; and have supposed that they were the *wites*, *sapientes*, or wise men, who, besides the prelates and aldermen, are mentioned as a component part of this assembly. Others, however, have maintained, that these wites were the judges, or men learned in the law. Others who exclude the burghesses, or commons, from the Saxon wittenagemot,

allege, that the expressions, employed by all ancient historians, in mentioning this national council, seem to contradict the former supposition. The members, it is said, are almost always called the *principes, satrape, optimates, magnates, proceres*; terms which seem to suppose an aristocracy, and to exclude the commons. The boroughs also, from the low state of commerce, were so small and so poor, and the inhabitants lived in such dependence on the great men, that it does not seem probable they would be admitted as a part of the national councils. It appears from Domesday that the greatest boroughs were, at the time of the conquest, scarcely more than country villages; and that the inhabitants were of a station little better than servile. If it be unreasonable to think that the vassals of a barony, though their tenure was military, and noble, and honourable, were ever summoned to give their opinion in national councils, much less can it be supposed, that the tradesmen or inhabitants of boroughs, whose condition was so much inferior, would be admitted to that privilege. These boroughs were not then so much as incorporated; they formed no community; they were not regarded as a body politic; and being merely formed of a number of low dependent tradesmen, living without any particular civil tie, in neighbourhood together, they were incapable of being represented in the states of the kingdom. The commons are well known to have had no share in the governments established by the Franks, Burgundians, and other northern nations; and as the Saxons remained longer barbarous and uncivilized than these tribes, they could never think of conferring such an honourable privilege on trade and industry. The military profession alone was honourable among all those conquerors; the warriors subsisted by their possessions in land; they became considerable by their influence over their vassals, retainers, tenants, and slaves; and it requires strong proof to convince us, that they would admit any of a rank so much inferior as the burghers, to share with them in the legislative authority. The first corporation, even in France, which made more early advances in arts and civility than England, is sixty years posterior to the conquest under the duke of Normandy; and in Normandy, the constitution of which was most likely to be William's model in raising his new fabric of English government, the states were entirely composed of the clergy and nobility; and the first incorporated boroughs, or communities, of that duchy, were Rouen and Falaise, which enjoyed their privileges by a grant of Philip Augustus, in the year 1207. All the ancient English historians, when they mention the great council of the nation, call it an assembly of the baronage, nobility, or great men; and none of their expressions, says Mr. Hume, (*ubi infra*,) though several hundred passages might be produced, can, without the utmost violence, be tortured to a meaning, which will admit the commons to be constituent members of that body. When historians mention the people, *populus*, as a part of the parliament, they always mean the laity, in opposition to the clergy: and though the word *communitas* sometimes occurs, Dr. Brady maintains, that it always means *communitas baronagii*. If, therefore, in the long period of 200 years, which elapsed between the conquest and the latter end of Henry III., and which abounded in factions, revolutions, and convulsions of all kinds, the house of commons never performed one single legislative act, so considerable as to be once mentioned by any of the numerous historians of that age, they must have been totally insignificant; and in that case, what reason can be assigned for their ever being assembled? can it be supposed, that men of so little weight or importance possessed a negative voice against the king and the barons? Every page of the subsequent histories discovers their existence; though

these histories are not written with greater accuracy than the preceding ones, and indeed scarcely equal them in that particular. The magna charta of king John provides, that no scutage or aid should be imposed, either on the land or towns, but by consent of the great council; and for more security, it enumerates the persons entitled to a seat in that assembly, the prelates and immediate tenants of the crown, without any mention of the commons: "An authority (says Mr. Hume) so full, certain, and explicit, that nothing but the zeal of party could ever have procured credit to any contrary hypothesis." The same writer adds, that it was probably the example of the French barons, which first emboldened the English to require greater independence from their sovereign; and it is also probable, that the boroughs and corporations of England were established in imitation of those of France.

In ancient times, men were not very solicitous to obtain a place in the legislative assemblies; and rather regarded their attendance as a burden, which was not compensated by any return of profit or honour, proportionate to the trouble and expence. The only reason for instituting these public councils was, on the part of the subject, that they desired some security from the attempts of arbitrary power; and on the part of the sovereign, that he despaired of governing men of such independent spirits without their own consent and concurrence. But the commons, or the inhabitants of boroughs, had not yet reached such a degree of consideration as to desire *security* against their prince; or to imagine, that even if they were assembled in a representative body, they had power or rank sufficient to enforce it. For protection against the violence and injustice of their fellow citizens, to which alone they aspired, they directed their views to the courts of justice, or to some great lord, to whom, either by law or by choice, they were attached. On the other hand, the sovereign was sufficiently assured of obedience in the whole community, if he procured the concurrence of the nobles. The military sub-vassals could entertain no idea of opposing both their prince and their superiors; and much less could the burghers and tradesmen aspire to such a thought. Thus, if history were silent on the head, there is reason to conclude, from the known situation of society during those ages, that the commons were never admitted as members of the legislative body.

The first time in which, according to the opinion of those who admit the conclusiveness of the above reasoning, historians speak of any representatives sent to parliament by the boroughs, was the year 1265, during the reign of Henry III.; when the earl of Leicester usurped the royal power, and summoned a new parliament to London, where he knew his power was uncontrollable. Besides the barons of his own party, and several ecclesiastics, who were not immediate tenants of the crown, he ordered returns to be made of two knights from each shire, and also of deputies from the boroughs; an order of men, it is said, which, in former ages, had always been regarded as too mean to enjoy a place in the national councils. Accordingly, this period is commonly esteemed the epoch of the house of commons in England. But though that house derived its existence from so precarious, and even so invidious an origin, as Leicester's usurpation, it soon proved, when summoned by the legal princes, one of the most useful, and, in process of time, one of the most powerful members of the national constitution; and gradually rescued the kingdom from aristocratical as well as from regal tyranny. But Leicester's policy, if we ascribe to him so great a blessing, only forwarded by some years an institution, for which the general state of things had already prepared the nation. It was not, however, till the 23d

year of the reign of Edward I. (A. D. 1295), that the deputies of towns and boroughs were, by a regal summons, admitted into parliament. This is therefore regarded as the legal and true epoch of the house of commons, and the faint dawn of popular government in England. Leicester's usurpation produced only a temporary effect, and the summons of representatives from boroughs was discontinued in subsequent parliaments; but from this period burgesses became a permanent part of the British legislature. The necessities of Edward, occasioned by his continual wars, and by the diminution of his demesnes, induced him to recur to this measure for obtaining requisite supplies; and he became sensible, that instead of imposing taxes by his prerogative, and enforcing his edicts for this purpose, a more expeditious and effectual mode was to assemble the deputies of all the boroughs, to lay before them the necessities of the state, to discuss the matter in their presence, and to require their consent to the demands of their sovereign. With this view he issued writs to the sheriffs, enjoining them to send to parliament, along with two knights of the shire, two deputies from each borough within their county, and these provided with sufficient powers from their community, to consent in their name, to what he and his council should require of them. Accordingly, writs were issued to about 120 cities and boroughs. "As it is a most equitable rule," says he in his preamble to this writ, "that what concerns all should be approved by all, and common dangers be repelled by united efforts;" a noble principle, which may seem to indicate, says Mr. Hume, a liberal mind in the king, and which laid the foundation of a free and an equitable government. The writs of the parliament immediately preceding remain; and the return of knights is there required, but not a word of the boroughs; a demonstration, according to Brady (of Boroughs), that this was the very year in which they commenced.

After the election of these deputies by the aldermen and common-council, they gave sureties for their attendance before the king and parliament; their charges were respectively borne by the borough which sent them; and they had so little idea of appearing as legislators,—a character so remote from their low rank and condition,—that no intelligence could be more disagreeable to any borough, than to find that they must elect, or to any individual, than that he was elected to a trust, from which no profit or honour could possibly be derived. Properly speaking, they did not compose any essential part of the parliament; they sat apart both from the barons and knights, who disdained to mix with such mean personages; and after they had given their consent to the taxes required of them, their business being then finished, they separated, even though the parliament still continued to sit and to canvass the national business. As they were all real burgesses of the places from which they were sent, the sheriff, when he found no person of abilities or wealth sufficient for the office, often took the liberty of omitting particular boroughs in his returns; and as he received the thanks of the people for this indulgence, he gave no displeasure to the court, which levied on all the boroughs without distinction the tax agreed to by the majority of the deputies. It was not till the reign of Richard II. that the sheriffs were deprived of the power of omitting boroughs at pleasure. 5 Ric. II. cap. 4.

The union of the representatives from the boroughs gradually gave more weight to their whole order; and it became customary for them, in return for the supplies which they granted, to prefer petitions to the crown for the redress of any particular grievance, of which they found reason to complain. These petitions received the sanction of royal authority, and acquired validity, even without the consent

of the nobles. Afterwards, however, the house of peers, the most powerful order in the state, reasonably expected, that their assent should be expressly granted to all public ordinances; and in the reign of Henry V., the commons required that no laws should be framed merely upon their petitions, unless the statutes were worded by themselves, and had passed their house in the form of a bill. At this time, the commons were much below the rank of legislators; and throughout the reign of Edward I. their assent is not once expressed in any of the enacting clauses; nor in the reigns ensuing, till the 9th of Edward III. nor in any of the enacting clauses of 16 Ric. II. Nay even so low as Henry VI. from the beginning till the 8th of his reign, the assent of the commons is not once expressed in any enacting clause. Pref. to Russell's edition of the statutes, p. 7. The commons were so little accustomed to transact public business, that they had no speaker till after the parliament 6th Edw. III.; and in the opinion of most antiquaries, not till the 1st of Richard II. The house of representatives from the counties was gradually separated from that of the peers, and formed a distinct order in the state. Nevertheless the knights of shires did not form the same house with the burgesses. But by degrees the growth of commerce augmented the private wealth and consideration of the burgesses; the frequent demands of the crown increased their public importance; and as they represented particular bodies of men, resembling in this respect the knights of shires, they were united together in the same house. Mr. Carte, after having carefully consulted the rolls of parliament, affirms (Hist. vol. ii. p. 451.), that they never appear to have been united till the 16th of Edward III. But this union does not seem to have been final; for, in 1372, the burgesses acted by themselves, and voted a tax after the knights were dismissed; and instances occur at later periods of their acting separately. The chief baron Gilbert (Hist. of the Exchequer, p. 37.), is of opinion, that the reason why taxes always began with the commons, or burgesses, was, that they were limited by the instructions of their boroughs. In the manner above stated, the third estate, or that of the commons, reached at last its present form; and as the country gentlemen made thenceforwards no scruple of appearing as deputies from the boroughs, the distinction between the members was entirely lost, and the lower house thence acquired a great accession of weight and importance in the kingdom. Still, however, the office of this estate was very different from that which it has since exercised with so much advantage to the public. Instead of checking and controlling the authority of the king, they were naturally induced to adhere to him, as the great fountain of law and justice, and to support him against the power of the aristocracy, which was at once the source of oppression to themselves, and disturbed him in the execution of the laws. The king, in his turn, gave countenance to an order of men, so useful, and so little dangerous; the peers were also obliged to pay them some consideration; and thus the third estate, formerly so abject in England, as well as in all other European nations, rose by slow degrees to its present importance; and in its progress, made arts and commerce, the necessary attendants of liberty and equality, flourish in the kingdom.

In addition to what has been already advanced, Mr. Hume alleges a further evidence, that the commencement of the house of burgesses, who are the true commons, was not an affair of chance, but arose from the necessities of the present situation; viz. that Edward, at the very same time, summoned deputies from the inferior clergy, the first that ever met in England, and required them to impose taxes on their constituents for the public service.

On the other hand, it has been argued by the advocates of the higher antiquity of the commons, that if we look to the best accounts of the original customs of the ancient German nations, we shall find, that, in their communities, all the freeholders enjoyed an equal right with the nobles to assist in deliberations on affairs of great moment. See Tacitus de Moribus German. c. 25. Upon their first settlement in any foreign country, and while their number was small, this right might be exercised, without much inconvenience, by the whole body of the freeholders assembling together on open plains. To this purpose, Matthew of Westminster (Sub. Ann. 1213. Johan. 15.) intimates, that the Anglo-Saxons, after they came into Britain, exercised their right in this manner; for he says, that the meadow near Staines, in which king John granted the great charter, was called "Runemced," denoting in the Saxon language the "meadow of counsel," because from ancient times it had been usual to consult there upon business which concerned the peace of the kingdom. But this custom had been disused under, and even before, the government of the Normans; perhaps from the time in which the Saxon heptarchy was united into one kingdom. The only instance that occurs of its having been revived is the meeting in the reign of king John; all the parliaments, or great councils, of which we have any account before, were held in churches, abbeys, or royal castles; and therefore, if the right of the freeholders continued, the greater part of them must have exercised it, not personally, as in ancient times, but by their representatives. By a record cited by Dr. Brady, so late as the fifteenth year of king John, it appears, that not only the greater barons, but all the inferior tenants in chief of the crown, had a right to be summoned to parliament by particular writs; and therefore we may conclude, that till that time, no representatives had been sent by any of these to serve for them in parliament; but they attended the great councils of the nation in their own persons: and their number was not so considerable, as not to allow of their being accommodated in the body of a church, or the great hall of an abbey or castle. But these were far from being all the freeholders of the kingdom; for this description comprehended all who held of the barons, either by knight-service, or free socage, and all the possessors of allodial estates, with all the free inhabitants of cities and boroughs not holding of the crown. The number of all these was too great to be contained in any building however spacious. But were these men either wholly excluded from parliament, or were they present there by any kind of representation? Some learned writers have supposed, that every superior lord, who held of the king immediately and in chief, gave an opinion on matters of government, which bound all his vassals. But if this were the case, the possessors of allodial estates, to which class we may refer all the parochial clergy, having no superior lord to act for them in parliament, could not be thus represented, or virtually bound by the acts of the king's barons, to whom they were not attached by any feudal connexion, and of whom they held nothing. Besides, the knights, citizens, and burgesses, who are now representatives of the commons of England, are elected by those for whom they serve; and on occasion of every new parliament, the electors are at liberty to make a new choice: whereas, the representatives, in the above hypothesis of sir H. Spelman, were neither elected, nor liable to be changed at any period of time, by those whom they represented; their right to sit in parliament not arising from any trust conferred by the people, but wholly from their tenures. It is also certain, that the feudal superiority was the same under the government of Henry III. as of William I., and continued so for some ages. If therefore the barons, and superior lords of

great fiefs, holden immediately of the crown, had, by virtue of the institutions of William I., been supposed to represent their vassals in parliament, and the notion then was, that every feudatory, holding by a mesne tenure, was bound by the parliamentary acts of his lord. how came that notion to be discarded in the 49th year of Henry III. or under the reign of his son, or at any time afterwards? A baron, who held of the crown, was to all intents and purposes the head of his vassals, in the reigns of Edward I. and Edward III., as much as in any of the preceding reigns. How happened it then, that the consent of these vassals to the making of laws, or any other act of moment to the public, was not still included in the vote of their lord? Why was it given, against the course of former proceedings, not by him, as their representative, but by knights of the shire, or by citizens, or by burgesses, chosen by the vassals? Some have referred this change, as we have above stated, to the earl of Leicester, in the 49th year of Henry III. But an existing record, it is said, demonstrates this date to be false. A writ of summons, directed to the sheriffs of Bedfordshire and Buckinghamshire, and requiring two knights to be sent for each of these counties, is extant in the close roll of the 38th year of Henry III. And there is also a clause in the great charter of the 9th of the same king (see Dr. Blackstone's edition of the charter), whereby it is declared, that, together with the spiritual and temporal lords, other inferior freeholders, *et omnes de regno*, by which words lord Lyttelton understands "the whole commonalty of the realm," granted to the king the fifteenth part of all their moveable goods, in return for the liberties acceded to them in that charter. "Nor," says his lordship (*ubi infra*), "can I discover in the history of those times any reason sufficient to render it probable, that so great an alteration should then have been made in the constitution of England." Such an alteration must have produced disputes, which would have been noticed by some of the numerous historians of that age. But the English history is altogether silent as to any disputes between the nobility and the people, on this account, from the earliest times of the Saxon government down to the reign of Charles I. Hence it may be reasonably presumed, that the right of the commons must have been incontestably established by custom, and interwoven into the original frame of our government. It is hardly conceivable, that the admission of all the lower orders of freemen, or indeed of any large number, to the great council of the kingdom, and to a participation of the legislative power, to which they had no right before, should have been brought about, and yet pass unobserved by any writer who lived in that age. If we suppose, as some have done, that the sitting in parliament was at this time regarded only as a trouble and burden, the imposition of such a burden on orders of men, who had been before exempt from it, must have been on their part resisted and opposed. But from the act of the 4th of Edward III., which is thus worded, "It is *accorded*, that a parliament shall be holden every year once, and more often, if need be," we may infer, that it was generally regarded in a very different light, rather as a privilege, of which they earnestly desired the frequent enjoyment, than as a burden, from which they wished to be exempt. It is true, some boroughs, which, on account of their poverty, were unable to bear the expence of sending members to parliament, declined the exercise of that privilege; but it would be unfair to allege this circumstance, which occurred in particular instances, as an argument in favour of the general sense of the commons in counties, cities, or other more wealthy boroughs. Besides, there are some instances of boroughs that petitioned to be restored to the use of the privilege of sending members to parliament, after a very long interruption.

interruption. Moreover, it seems incredible, that if the whole legislative power had, before the reign of Henry III., been always placed in the nobility and the king, they should not have opposed the extension of it to so many persons of lower rank in the state: more especially as the power of the nobility was never higher than it was in this reign. With regard to the earl of Leicester, it was not his interest, while he was acting at the head of the nobles and people, in a very dangerous contest against the crown, to make any innovations offensive or distasteful to either of those bodies; nor is it probable, that any new institution, begun by that earl, should have been confirmed and perpetuated by Edward I. Among the close rolls of the 24th of this king, there is a writ of summons to parliament, already cited, in which it is asserted, not as an innovation introduced by the earl of Leicester, but "a maxim grounded on a most equitable law, established by the foresight and wisdom of sacred princes, that what concerns all, should be done with the approbation of all; and that dangers to the whole community, should be obviated by remedies provided by the whole community." If the earl of Leicester, or even if Edward I., or his father, had introduced the practice of summoning the commons to parliament, Edward could not with propriety have used this language. It is further alleged, that there is not in any of the oldest writs for sending up representatives from cities or boroughs the least intimation, that such elections were a novelty then introduced. Some writs are taken notice of by Mr. Tyrrel, an industrious searcher of records on this subject, which set forth a claim of certain tenants in ancient demesne, before the 15th year of Edward II., that they ought not to be charged with wages to knights of the shire; "forasmuch as they and their ancestors, tenants of the same manor, had, from time beyond memory, been always exempted, by custom, from the expences of knights, sent by the community of their county to the parliaments of the king, and of his royal progenitors." A time beyond memory is defined by our law-books to be a time antecedent to the beginning of the reign of Richard I.; and if no wages had been ever paid to knights of the shire till the reign of Henry III., it would have been preposterous for these persons to tell the grandson of that king, that they had enjoyed a customary privilege of not paying wages from time beyond memory, which must be supposed, when this exemption was claimed, to go much further back than the reign of Richard I.

With regard to cities and boroughs, there are likewise extant two claims, made in the reigns of Edward II. and Edward III., which seem to decide the sense of that age concerning the antiquity of the custom of citizens and burgessees coming to parliament, and from towns that were held under subjects, not immediately of the crown. These are the claims of the towns of St. Albans and Barnstable. In the petition of the borough of St. Albans, first taken notice of by Selden, and then by Petyt, Brady, Tyrrel, and others, and presented to parliament in the reign of Edward II. the petitioners assert, that though they held *in capite* of the crown, and owed only for all other service their attendance in parliament, yet the sheriff had omitted them in his writs; whereas, both in the reign of the king's father, and all his predecessors, they had always sent members. This exemption, it is alleged, could not have been used, if the commencement of the house of commons were in the reign of Henry III. However, Madox, in his "History of the Exchequer," p. 522, &c. has endeavoured to destroy the authority of this petition for the purpose to which it is adduced. He asserts, first, that there was no such tenure in England, as that of holding by attendance in parliament, instead of all other service; and secondly, that the borough

of St. Albans never held of the crown at all, but was always demesne land of the abbot. It is no wonder, therefore, says Mr. Hume, that a petition, which advances two falsehoods, should contain one historical mistake, which indeed amounts only to an inaccurate and exaggerated expression; no strange matter in ignorant burgessees of that age, who wanted to shake off the authority of their abbot, and to hold of the king, without rendering any services even to the crown. See the discussion of this subject, and an examination of the reasoning of Madox and Dr. Brady, in Lyttelton's Hist. of Eng. vol. iii. p. 495, &c. The advocates for the antiquity of borough representatives further refer to a statute of the 5th year of Richard II. stat. 2. which enacts, "that all and singular persons and commonalties, which from henceforth shall have the summons of the parliament, shall come from henceforth to the parliaments in the manner as they are bound to do, and have been accustomed within the realm of England, of old times. And if any person of the same realm, which from henceforth shall have the said summons (be he archbishop, bishop, abbot, prior, duke, earl, baron, banneret, knight of the shire, citizen of city, burgesse of borough, or other singular person or commonalty), do absent himself, &c. he shall be amerced, and otherwise punished, according as of old times hath been used to be done within the said realm in the said case." Upon this statute it is argued, that it makes no distinction between the antiquity of summons to parliament sent to the greater nobility, and those to citizens, burgessees, and knights of the shire. Besides this remarkable testimony of the whole legislature in the reign of Richard II. to the antiquity of the custom of the commons coming to the parliament, we have a petition of the commons in the second parliament of the reign of Henry V., which sets forth to that prince, "that as it hath ever been their libertie and freedom, that there should no statute nor law be made, unless they pass thereto their assent, considering that the commune of your land, the which is and ever hath been a member of your parliament, be as well assenters as petitioners, &c." This claim was not disallowed either by the lords or the king. Besides these authorities drawn from statutes and records, it is said, that very evident indications of the presence of the people in the national councils, and of their being constituent parts thereof, though in a disorderly manner, are to be found in some ancient histories, and contemporary accounts of transactions in parliament, from the death of Edward the Confessor to that of Henry II. Several instances to this purpose, occurring in the reigns of William the Conqueror, William Rufus, Henry I., Stephen, Henry II., &c. are produced by lord Lyttelton, in the Notes to his History, vol. iii. p. 421, &c. We may further add, that the presence of the *people* in the Saxon councils, and their having had a share in the highest acts of legislature and government, even till the entrance of the Normans, seems to be proved very strongly from the preambles of laws and other proceedings of those councils, and from the words of the best historians who lived near to those times. On this long usage, says lord Lyttelton, their right was established; and it appears to have been continued under William the Conqueror, with other customs and rights confirmed by him to the nation, and under his successors, by like sanctions of ancient liberties granted in repeated royal charters. In ancient times, however, the property of the commons was so unequal to that of the nobles, and the feudal obligations of the inferior landholders to the lords under whom they held, created such a dependence of the former on the latter, that although, in the idea and scheme of the government, a popular power was mixed with the regal and aristocratical, yet, in reality, the scale of the people was not weighty enough

to make a proper counterpoise to either of the others. The commons usually declined to give their opinion or advice to the crown, in certain matters of state, and submitted their judgment respecting them to the king and his council, or to them and the lords. While the representatives of cities, towns, and boroughs, were chosen only out of persons resident in them, they were generally people of low degree and condition, whose education and way of life rendered them very unfit to judge of arduous questions concerning foreign affairs, and treaties with foreign states. Nevertheless, even in the earliest times, so far back as we have any rolls of the parliament, all the commons appear to have given their advice with great freedom in matters concerning the internal government and order of the kingdom. What they declined to advise in, upon some occasions, were questions that related to the making of peace or war. Mr. Hume, indeed, asserts, on the authority of a citation from sir Robert Cotton's abridgment of the records in the Tower, that the commons in these times were much below the rank of legislators, and that they were considered by the king merely as petitioners, or destitute of any proper legislative authority. But the whole passage, cited by lord Lyttleton, seems to confirm, instead of denying their legislative authority. In the king's answer to their application, they are truly told, that the power of judicature does not appertain to them, but to the king and the lords; and this was the question to which their prayer related: but in statutes they were to judge, as well as in grants, subsidies, &c. Their being petitioners was certainly no argument against their being legislators; since the course of proceedings then was, that their petitions, if assented to by the lords and the king, should be turned into statutes, as all the old records of parliament unquestionably shew.

Burgesses were first admitted into the Scottish parliaments by Robert Bruce, A.D. 1326; and in the preamble to the laws of Robert III. they are ranked among the constituent members of that assembly. Brady of Boroughs. Petyt's Right of the Commons. Brady's Answer to Petyt. Tyrrel's Appendix to his History of England. Hume's Hist. of England, vol. i. and ii. Appendix i. and ii. Lyttleton's History of Henry II. vol. iii. Robertson's Hist. of Scotland, vol. i. p. 79. 8vo. See WITTENAGEMOTE, and PARLIAMENT.

BOROUGH, in *Scots Law*, is a body corporate, consisting of the inhabitants of a certain tract of ground, erected by the sovereign, with jurisdiction annexed to it. Boroughs are erected, either to be holden of the sovereign himself, which is the general case of royal boroughs, or of the superior of the lands so erected, as boroughs of regality and barony. The former are empowered, by their charters, to choose annually certain office-bearers, or magistrates; but in the latter, the nomination of magistrates is, by their charters, lodged sometimes in the inhabitants, sometimes in the superior. Bailies of boroughs have jurisdiction in matters of debt, service, and questions of possession betwixt the inhabitants. Their criminal jurisdiction comprehends petty riots, and reckless fire-raising. The dean of guild is that magistrate of a royal borough, who is head of the merchant-company; to him belong the cognizance of mercantile causes within the borough, and the inspection of buildings, that they encroach neither on private property, nor on the public streets; and he may direct insufficient houses to be pulled down. His jurisdiction has no dependence on the court of the borough, or baillie-court.

BOROUGH, *Royal*, in Scotland, are corporations made for the advantage of trade, by charters granted by several of their kings; having the privilege of sending commissioners to represent them, besides other peculiar privileges.

These form a body of themselves, and send commissioners, each to an annual convention at Edinburgh, to consult the benefit of trade, and the general interest of the boroughs. According to Chamberlayne, they have the sole power of trade and merchandize, exclusive of all others, a power of holding courts, exercising the jurisdiction of sheriffs, making bye-laws, &c.

The company of merchants in a royal borough make what is called a guild; the chief of which is a dean of guild, who is next magistrate to the bailiff. See GILD.

The royal boroughs are not only so many distinct corporations, but do also constitute one entire body, governed by, and accountable to one general court, anciently called the "court of four boroughs," held yearly to treat and determine concerning matters relating to the common advantage of all boroughs. The four boroughs which composed this court were Edinburgh, Stirling, Roxburgh, and Berwick; which two last falling into the hands of the English, Linlithgow and Lanerk were put in their places; with a saving to the former, whenever they should return to their allegiance. But this court not being sufficient to answer the necessities of the royal boroughs, they were all empowered, under James III. in 1487, to send commissioners to a yearly convention of their own, which was then appointed to be held at Inverkeithing, and is now held at Edinburgh, under the denomination of the *convention of boroughs*, vested with great power.

BOROUGH-COURTS, in *Law*, are certain courts held in boroughs, by prescription, charter, or act of parliament: such are the sheriff's court, and court of hustings in London. See COURT.

BOROUGH-*English*, so named in contradistinction, as it were, to the Norman customs, and noticed by Glanvil (l. 7. c. 3.), and by Littleton (§ 165.), denotes a customary descent of lands or tenements in some ancient boroughs and copyhold manors, whereby they come to the youngest, instead of the eldest son; or if the owner hath no issue, to the youngest, instead of the eldest brother; because, according to Littleton, the youngest is supposed, in law, the least able to shift for himself. 1 Inst. 110. b. And in support of this reason, other usages in favour of the youngest are alleged, as that in Kent, where the lands being equally divided among all the sons, the youngest is to have the privilege of a fire or hearth in the mansion-house, in his share, as being supposed the tenderest, and more in need of warming. Others; notwithstanding, suspect a different reason for the rise of borough-English, viz. that the places, where this custom now obtains, were anciently liable to that custom granted to the lords of manors in Scotland by king Eugenius, who had the privilege of enjoying the first night of their tenants' brides; so that the eldest son being presumed to be the lord's, they usually settled their lands on the youngest son, whom they thought their own; which being practised a long time grew at length into a custom. The custom, however, never obtained in England, though it did in Scotland, under the name of "mercheta," or "marcheta," till it was abolished by Malcolm III. Perhaps, says judge Blackstone, the origin of this practice may be illustrated by that of the Tartars, mentioned by Du-Halde, among whom the same custom of descent to the youngest son prevails. As the nation is composed of shepherds and herdsmen, the eldest sons migrate from their father with an allotment of cattle, to seek a new habitation. The youngest son, continuing latest with his father, is naturally the heir of his house; the rest being already provided for. This custom of migrating obtained in many other northern nations; and borough-English may be a remnant of that pastoral state of our British and German.

near ancestors, which Cæsar and Tacitus describe. Blackstone's Comm. vol. ii. p. 81, 84.

This custom goes with the land, and directs the descent to the youngest son, although there be a devise to the contrary. 2 L. v. 1, 5. If a copyhold in borough-English be surrendered to the use of a person and his heirs, the right will descend to the youngest son, according to the custom. 1 Mod. 102. And a youngest son shall inherit an estate in tail, in borough-English. Nov. 16. But an heir at common law shall take advantage of a custom annexed to borough-English land; though the youngest son shall be entitled to all actions in right of the land. 1 Nelf. Abr. 396. And the eldest son shall have tythes arising from borough-English land; for tythes of common right are not inheritances descendible to an heir, but come in succession from one clergyman to another. Ibid. 347. Borough-English land being descendible to the youngest son, if a younger son dies without issue male, leaving a daughter, such daughter shall inherit "jure representationis." 1 Salk. 243. By this custom the widow shall have the whole of her husband's lands in dower, called her "free-bench;" and it is given to her to enable her the better to provide for the younger children entrusted to her care. Co. Litt. 3; 111. F. N. B. 1; 10. Mo. Pl. 566. As borough-English is particularly noticed by the law, it is unnecessary to prove that such custom actually exists, but only that the lands in question are subject to it. 1 Comm. 76. But the extension of the custom to the collateral line must be specially pleaded. Robinf. on Gavelkind, 38. 43. 93.

**BOROUGH-HEAD**, or **HEAD-BOROUGH**, was one of the lowest magistracies among the Anglo-Saxons, and the chief man of the decenary, tithing, or free-burg, consisting of ten families; chosen by the rest to speak and act in their behalf. He is also called the tithing-man, and, in some countries, the borough-holder, bors-holder, or borough's-elder, being supposed the discreetest man in the borough, town, or tithing.

According to the institution of Alfred, every householder was answerable for the behaviour of his family and slaves, and even of his guests, if they lived above three days in his house; and ten neighbouring householders formed themselves into a corporation, under the name of a decenary, or tithing, of which the head-borough, or bors-holder (derived from the Saxon words *bork*, a surety, and *older*, a head or chief), was the president, and they were answerable for the conduct of each other. Every man was punished as an outlaw, who did not register himself in some tithing; nor could any one change his habitation, without a warrant or certificate from the bors-holder of the tithing to which he formerly belonged. When any person in any tithing was guilty of a crime, the bors-holder was summoned to answer for him; and if he were not willing to be surety for his appearance and his clearing himself, the criminal was committed to prison, and there detained till his trial. If he fled, either before or after finding sureties, the bors-holder and decenary became liable to inquiry, and were exposed to the penalties of the law. Thirty-one days were allowed them for producing the criminal; and if they did not find him within that time, the bors-holder, with two other members of the decenary, was obliged to appear, and, together with three chief members of the three neighbouring decennaries (making twelve in all), to swear that his decenary was free from all privacy both of the crime committed, and of the escape of the criminal. If the bors-holder could not find such a number to answer for their innocence, the decenary was compelled by fine to make satisfaction to the king, according to the degree of the offence. The severity of this regulation was afterwards a little mitigated, and the oaths of all the members of the tithing to

which the criminal belonged, to the above effect, were admitted as a sufficient exculpation, provided that, at the same time, they promised, upon oath, to present him to justice, as soon as they could apprehend him. By this institution, every man was obliged, from his own interest, to keep a watchful eye over the conduct of his neighbours; and was in a manner surety for the behaviour of those who were placed under the division to which he belonged; and hence these decennaries received the name of frank-pledges. See **TITHING**.

In many parishes, head-borough also signifies a kind of head constable, where there are several chosen as his assistants, to serve warrants, &c. See **CONSTABLE**.

**BOROUGH**, or *Borge*, denotes a pledge or security for another's keeping the peace, and conforming to the laws. The word is Saxon, and is sometimes also written borough; in Latin writers, *borgha* and *burgha*.

**BOROUGH-BREACH**, *Borgi fractura*, in *Ancient Law Writers*, denotes a breaking of the pledge or security given by the members of tithings for the behaviour of each other.

This is the same with what is otherwise called *borg-brege*, *borg-brege*, *borg-breche*, and *borgi fractura*.

**BOROUGH**, *Law*, or *Borrows*, in the law of Scotland, the same with what in England is called *binding to the peace*. In case of a contravention of law-boroughs, the surety or cautioner is equally liable with the principal for the penalty specified therein, the one half to the king, and the other to the complainer.

**BOROUGH-BRIDGE**, in *Geography*, an ancient borough town of Yorkshire, in England, derives the latter part of its name from a handsome stone bridge over the river Ure. This place was formerly called *New-borough*, in contradistinction from *Aldborough* or *Old-borough*, a village about one mile distant. Each of these places has the privilege of sending two members to parliament; and as both are included in one parish, that parish has the singular power of returning four members. Aldborough first made a return in 1558, and New-borough in 1553. The former place is attributed, by many respectable writers, to Roman origin, and is said to be the station *Isurium*, which was placed on the Watling-street, 17 miles from Eboracum, or York. The ancient walls of this town (*Isurium*), observes Mr Gough, though level with the ground, may easily be traced in a circumference of more than a mile and a half. They inclose an area of an oblong square, containing about 60 acres, which slope to the river Ure. The walls, nearly four yards thick, were founded on large pebbles, which were laid in a bed of blue clay. Near the centre of the station was a hillock, called *Borough-hill*, which seems to have been the citadel, where foundations of buildings, mosaic pavements, &c. have been discovered. A sudyatory, with sculptured altars, numerous coins, urns, and other relics of the Romans have been found at this station, which was evidently of much consequence in Roman Britain, although probably subordinate to the great one at Eboracum. It is generally written *Isurium Brigantum*, whence Horsley infers that it was the capital of the Brigantes. A particular account of the antiquities found here, with engravings, may be seen in Gough's edition of Camden vol. iii. p. 59, &c. and a very judicious account in Hargrove's *History of Knaresborough*, fifth edition, 12mo. 1798.

Borough-Bridge is only a small town, with 114 houses and 680 inhabitants. It belongs to the parish of Aldborough, and has a chapel of ease to the mother church. In the centre of the town is a cross, or obelisk, about twelve feet high, of the same species of stone as the *Devil's Arrows*, which are at a short distance west of the town. These singular stones have excited much curiosity among antiquaries, and furnished a theme for various conjectural dissertations.

There

There were formerly four stones, raised upright in the ground, but one of them was demolished in the last century. The remaining three stand about two hundred feet from each other, are of an obeliskal shape, and of a stupendous size. The tops seem as if split, and the sides are indented, or furrowed, for a certain space downwards. This appearance induced some writers to assert that they were fluted by art; but it is more probable that the weather effected this operation. The height of the tallest stone is twenty-two feet and a half from the ground, and its greatest circumference sixteen feet. Its depth in the ground is four feet and a half. Another stone measures twenty-one feet high, by seventeen feet in girth; and the third stone is seventeen feet high, by twenty-two feet in circumference. Mr. Drake (in his history of York) supposes they were trophies raised by the Romans; Leland is of the same opinion; but Dr. Gale conjectures, that they were Hermae, and from their particular position pointed to four different Roman roads that met at this place. Doctors Plott and Stukely attribute them to the Britons, and this seems the more probable, as we are well assured that the primeval inhabitants of Britain raised various single upright stones, and different circles of stones of varied diameter and magnitude. These, says Mr. Pennant, were either monumental memorials of departed heroes, or the rude objects of worship, such as the Israelites bowed to, when they departed from the purity of adoration. Such objects are styled in Wales Meini-hirion, or the long stones, and Meini-gwyr, or the ambrosial stones, as described by Bryant and others.

The river Ure is not navigable higher than Borough-bridge, near which the canal from Ripon communicates with it by means of a lock. About two miles and a half below the town, the river Swale joins the Ure. Borough-bridge, Aldborough, and the manor, honour, and castle of Knaresborough were, in the 13th of Henry III. granted to the famous Hubert de Burgh, upon his paying 100l. a year into the exchequer, but were forfeited by his son in the same reign for joining Simon de Montfort at the battle of Evesham. Borough-bridge remained in the crown till the reign of Edward II. who bestowed it on his insolent favourite Piers Gaveston. It now belongs, with the interest of the two boroughs, to the duke of Newcastle. Near this place, in 1322, a battle was fought between the soldiers of Edward II. and prince Thomas, earl of Lancaster, when the latter was taken prisoner, and, after suffering various indignities, was beheaded. Most of his partizans were taken, and some were slain; among whom was John de Bohun, earl of Hereford, who, in passing over the wooden bridge of this place, was killed by a lance from a soldier lurking beneath the bridge.

This town has a weekly market on Saturdays, and several fairs annually; the principal of which, in June, continues for a week, and is much frequented by the manufacturers from Sheffield, Birmingham, Wolverhampton, &c. Hargrove's History of Knaresborough. Gough's edition of Camden's Britannia. Pennant's Tour from Alton Moor to Harrowgate, 4to. 1804.

**BOROVITCHI**, a town and district of Russia, in the government of Novogorod, situated on the river Mita; 88 miles E.S.E. of Novogorod, and 168 S.E. of Petersburg.

**BOROWA**, a town of Bohemia, in the circle of Czaflau, 8 miles E.N.E. of Tentsch Brod.

**BOROWICA**, a town of Poland, in the palatinate of Volhynia; 20 miles N. of Lucko.

**BOROWICK**, a town of Poland, in the palatinate of Kiou, 32 miles S.E. of Czerkafy.

**BOROWNIZA**, a town of Bohemia, in the circle of Koniggratz, 18 miles S.E. of Koniggratz.

**BOROWSKO**, a town of Bohemia, in the circle of Czaflau; 7 miles W. of Ledetsch.

**BOROZAIL**, in *Medicine*, a disease which resembles the yaws, frequent among the Africans inhabiting the banks of the river Senegal. See **YAWS**.

**BOROZDINKA**, in *Geography*, a fortress of Russian Tartary, in the government of Caucasus, on the Ural; 32 miles N. of Guriel.

**BORRAGO**, in *Botany*. See **BORAGO**.

**BORRELISTS**, in *Ecclesiastical History*, a sect or sort of Anabaptists in Holland, who allow of no use of sacraments, public prayers, or other external worship, nor of any human gloss or explication of scripture; but profess to adhere to the faith and manners of the New Testament times in all their simplicity.

They took their denomination from their founder, Borrel, a person of great learning in the Hebrew, Greek, and Latin tongues, and brother of M. Borrel, ambassador of the States to the French king.

**BORRI**, **JOSEPH FRANCIS**, in Latin *Burrhus*, in *Biography*, an impostor and empiric of the 17th century, was born at Milan, about the year 1625, and educated in the Jesuits' seminary at Rome. In early life he was notorious for his licentious conduct; but afterwards assuming the character of a religious devotee, he declaimed against the corruption of the age, and pretended to supernatural visions and revelations. Dreading the powers of the inquisition at Rome, he removed to Milan, where he established a new sect, consisting of persons whom he attached to himself and his cause by vows of secrecy, and whom he deprived of their property by enforcing the obligation of voluntary poverty. With the assistance of his deluded followers, and by means of a sword which he pretended to have received from heaven, he proposed to compel all mankind to unite in one sheep-fold, of which he was to be the shepherd and superintendent. Among his other fancies and chimeras, one of his most distinguishing doctrines was that of the deification of the virgin Mary, whom he conceived to be the only daughter of God, and the Holy Ghost incarnate. Arrrogating to himself a divine mission, he assumed the privilege of conveying illumination to his followers by the imposition of hands; and after gaining a sufficient number of adherents, it was his intention to open his commission at the great square of Milan, and there to inveigh against the civil and ecclesiastical abuses of government, to animate the people to recover their liberty, and to seize the city and its territories, with a view to more extensive conquests and dominions. As soon as some of his disciples were arrested and imprisoned, he made his escape; and the inquisition proceeding against him, declared him contumacious, condemned him as a heretic, and caused his effigy to be publicly burnt at Rome. At this time, viz. in 1661, he sought an asylum at Amsterdam, and here he found a convenient theatre for the further exercise of his impostures. Having assumed the characters of a chemist and a physician, he pretended to extraordinary skill in the cure of all kinds of distempers, set up a splendid equipage, and usurped the title of excellence. But when his credit sunk, and his resources derived from the art of swindling failed, he fled from Amsterdam in the night, taking with him all the money and jewels he could collect, and removed to Hamburg, where he imposed upon queen Christina, by pretending to the secret of the philosopher's stone; but when her means of encouraging this delusion failed, he removed to Denmark, and obtained from the king profuse supplies. Upon the death of the king, he thought it most prudent to make his escape, and in his flight towards Turkey, he was apprehended on the German frontier by mistake, as a political criminal. His

name being accidentally mentioned to the emperor in the presence of the pope's nuncio, he was demanded as an heretical offender, and delivered up by the emperor on condition that his life should be preserved. Upon his arrival at Rome, he was sentenced to abjure his errors, to do public penance, and to be imprisoned for life. In prison he was visited by several persons of rank, who resorted to him in consequence of the fame of his adventures; and having performed a cure on the duke d'Etrece, the French ambassador, who had been given over by several physicians, he obtained some degree of liberty, and at length a removal to the castle of St. Angelo, where he was allowed to prosecute his chemical experiments, and where he died in 1665. Some writings were attributed to him, and printed at Geneva in 1681; one, entitled "La Chieva del Gabinetto;" i. e. the key of the cabinet, being a series of letters relative to alchemy and the Rosierucian philosophy; and the other, "Istruzioni Politiche," or a set of political aphorisms, with a commentary addressed to the king of Denmark. The *Bibliotheca Medicorum* mentions also two of his letters, printed at Copenhagen in 1669, and written to Bartholine; one, "De ortu cerebri et usu medico;" the other, "De artificio oculorum humores retinendi." Konig attributes to him another piece, entitled "Notitia gentis Burthorum."

Borri combined a considerable portion of cunning and artifice with his enthusiasm, and thus became capable of practising more successfully on the credulity of mankind. His fancies with regard to the new celestial kingdom, which he pretended a commission to establish, and the downfall of the Roman pontiff, which he threatened to accomplish, are so extravagant, childish, and absurd, that they can be viewed by sober persons in no other light than as the crude reveries of a disordered brain. In his conduct he manifested, on various occasions, the greatest vanity and levity, accompanying that spirit of imposture which is usually displayed by quacks and mountebanks; and, indeed, says Mosheim, "in the whole of his behaviour, he seemed destitute of sense, integrity, and prudence." *Gen. Dict. Mosheim's Eccl. Hist.* vol. v. p. 240.

**BORRIANO**, in *Geography*, a town of Spain, at the mouth of the river Millas, in the gulf of Valencia; 7 leagues N. of Valencia.

**BORRICHIOUS**, **OLAUS**, in *Biography*, the son of a Lutheran minister at Ripen in Jutland, was born April 6th 1626. At the age of 18 he was sent to Copenhagen, where he applied with so much assiduity to his studies, as to gain him the friendship of the superiors of the college, by the recommendation of whom he obtained the canonry of Lunden. By continuing this course of life, his reputation for learning and diligence was so established, that in 1654, when he was only 28 years of age, he was invited to accept the regency of the academy at Herlow. But as he had determined to dedicate his time to the acquirement of the knowledge of medicine, he refused this offer, purposing to spend a few years in visiting foreign academies, and hearing the most celebrated professors in the different branches of that art. The execution of this project was, however, postponed, at the instigation of M. Gersdorff, the prime minister of Denmark, who entertained him at his house as preceptor to his sons. Here he continued five years, at the end of which time, as a proof of the satisfaction he had given, and of the opinion of the minister had conceived of his various endowments, he was at once created professor in philosophy, poetry, chemistry, and botany, in all of which he eminently excelled. Before he entered on the duties of his offices, he was permitted, agreeably to his original intention, to visit the different schools of Holland, England, France, Germany, and Italy,

accompanied by the two sons of the minister, his pupils. Having spent six years in his tour, and stored his mind with the knowledge of all that was curious or useful, in the countries he passed through, and taken his degree of doctor in medicine at Angers, he returned in October 1666 to Copenhagen. He now undertook the duty of lecturer in chemistry and in botany; and by the excellency of his discourses on these subjects, confirmed his countrymen in the high opinion they had entertained of his talents. Though the time necessarily spent in this employment, and in preparing his numerous publications, left him, one would have thought, but little leisure for the practice of physic, yet from the great number of valuable observations furnished by him to the *Acta Hassniensia*, he must have had no inconsiderable share of business in that way. In 1686, he was made counsellor in the superior court of justice; and, in 1689, counsellor in the royal chancery. He died the 3d of October, in the following year, three weeks after having undergone the operation for the stone in the bladder. As Borrichius had never been married, he left a considerable part of the large possessions he had acquired by his practice, for erecting and endowing a college for poor students in medicine. His principal medical productions consist of observations published in the *Acta Hassniensia*, and other similar collections, and of the letters sent by him while on his travels, to F. Bartholine, under whom he had been educated. The letters, Haller observes, are the most valuable of those published by Bartholine in his "*Epistolæ Medicæ*;" but the works by which he acquired his principal celebrity, were "*De ortu et progressu chemiæ*," published in 1668, 4to.; and his "*Hermētis Ægyptiorum et Chemicorum sapientia, ab H. Conringio vindicata*," 1674. In this very learned and elaborate work, the author defends the character of the ancient Egyptians, against the strictures of Conringius; attributing to them the invention and perfection of chemistry, and even of alchemy; persuading himself that among their secrets they possessed the art of transmuting metals. But either from infatuation, or a desire of victory, he cites several manuscripts, since known to be spurious, as genuine, and some written since the time of our Saviour, as of much higher antiquity. Notwithstanding these blemishes, the works have great merit. He shews from undoubted authority, that the Egyptians were early acquainted with the medical properties of several of their plants; that they used saline, and even mineral preparations, some of them prepared by chemistry; that incubation, or the method of hatching eggs by artificial heat, was first used by them; in fine, that the art of medicine, invented by them, passed from them to the Grecians. Borrichius was also author of "*Conspectus præstantiorum scriptorum linguæ Latinæ*;" "*Cogitationes de variis linguæ Latinæ ætatibus*;" "*Asseclta philologica, et judicium de lexicis Latinis Græcisque*," and various other philological works. *Eloy. Dict. Hist. Gen. Dict.* and Haller's *Bib. Med. Pract.* where will be found the titles of the dissertations, and an analysis of the principal works.

**BORROMEAN ISLANDS**, in *Geography*, two islands situate in the bay of the lake called "*Lago Maggiore*," or "*Lago di Locarno*," in the Milanese, so denominated from their having belonged to the Borromeo family. One of these islands is called "*Isola-Bella*," and the other "*Isola-Madre*." They are about a league distant from one another, and derive the various beautiful scenes and objects which they present from the taste and liberality of the counts Renuis and Vitalian Borromeo. They were originally barren rocks; but, with immense labour and expence, they were furnished with numerous terraces, grottoes, gar-

dens, fountains, groves of cedars, cypress, citron-trees, orange-trees, laurel, &c. which render them scenes of enchantment, and a kind of terrestrial paradises. For a particular description of them, see Keysser's Travels, vol. i. p. 374, &c.

**BORROMEO, CHARLES**, Cardinal, in *Biography*, the son of count Gilbert Borromeo, and a sister of pope Pius IV. was born at the castle of Arona, in 1538; and having made a considerable progress in literature, he was called to Rome on the accession of his uncle to the papal chair in 1539, and invested with the dignities of cardinal-nephew, archbishop of Milan, and penitentiary, legate of Ancona, Bologna, and Romagna, and protector of several crowns and religious orders. At the age of 22, he was entrusted with the government of the most important affairs of the church; and he principally contributed to that encouragement of literature and patronage of learned men which distinguished this pontificate. He instituted at his house an academy, to which all the learned men at Rome repaired, when the business of the day was concluded, to discuss literary questions, and particularly such as related to sacred subjects. The works of this society have been published in several volumes, under the title of "Noctes Vaticanæ," so denominated because its assemblies were held at night in the Vatican. In conformity to the directions of his uncle, he began his public career with great magnificence and splendour, more anxious to do honour to the pope and the rank assigned him by his favour, than to gratify his own inclinations; but when the council of Trent issued its decrees for the reformation of clerical manners, he set an example of obedience by dismissing at once 80 domestics, discarding silk from his dress, and fasting once every week on bread and water. In co-operation with the designs of the council, he exerted himself in promoting a better education among the clergy; and with this view he instituted a number of seminaries in his own diocese, and in other places. He founded the Jesuits' college at Milan, and was eminently instrumental in erecting a magnificent edifice for the university of Bologna. He took pains in correcting the writings of some doctors of the church, which had been corrupted, and employed Achilles Statius for this purpose; and he was also active in establishing the congregation of eight cardinals, for resolving doubts and obviating difficulties that might arise in the explication of the decrees of the council of Trent. Although he was urged by his parents, and even by the pope, to prevent his family from becoming extinct by entering into a married state, he preferred continuing in the church; and notwithstanding many impediments arising from ill health, a weak voice, and defective articulation, he determined to become a preacher, and by assiduous and persevering application overcame all difficulties. After the death of his uncle, he removed to his archbishopric, and devoted himself to the duties of his pastoral office, which he performed with great honour to himself, and very much to the satisfaction and edification of the people. He took great pains in the reformation of religious orders, and in administering consolation to the remotest parts of his diocese. During the plague, which afflicted the city and diocese of Milan in 1576, he continued in the scene of danger, by his presence imparted comfort to the sick and dying, and sold his goods in order to furnish himself with means for relieving their indigence and distress. He also convened several provincial councils and synods, and obtained their sanction in enacting and enforcing various useful regulations for the government of the church. His incessant labours and austerities impaired his feeble constitution, and terminated his course of active and exemplary service at the early age of 47 years, in 1584; and pope Paul V. bestowed

upon him, in 1610, the honours of canonization. Few saints in the calendar better deserved this distinction. Borromeo's writings on subjects of faith and morals were numerous; they were collected in 5 vols. fol. and printed at Milan in 1747. His "Acta Ecclesie Mediolanensis" was published in folio, in 1519. Moreri. Nouv. Dict. Hist. Fabr. Bib. Græc. t. xi. p. 718. The life of Borromeo was published by Pere l'ouron, in 3 vols. 12mo. Paris, 1761.

**BORROMINI, FRANCIS**, an Italian architect, was born in 1599, at Bissola, in the diocese of Como, and studied sculpture first at Milan, and afterwards at Rome. Under the patronage of Maderno, his relation, who was the architect of St. Peter's, he directed his principal attention to architecture; and upon the death of Maderno in 1629, he worked under his successor Bernini; and protected by pope Urban VIII. he was employed about the church of Sapienza and the Barberini palaces. At length he became the rival of Bernini; and acquired such a degree of reputation, that the king of Spain engaged him to furnish a design for the enlargement of his palace at Rome; and though it was never executed, he received a liberal recompense in money, and was honoured with the order of St. James. The pope also bestowed upon him the order of Christ, and a pension. In this career of prosperity, the extravagance of his taste incurred the censure of several critics; and he was charged, by Bernini, with corrupting the sound principles of the art. The clamour against him prevailed, and his rival obtained the direction of a building for which he had prepared the designs; upon which he retired in disgust into Lombardy. On his return, he employed himself in preparing a set of grotesques for engraving; but the mortification he experienced preyed upon his spirits, and produced occasional derangement of mind; and in one of his paroxysms, he seized a sword and gave himself a mortal wound, in his 68th year. Borromini affected singularity, and indulged a capricious and fantastic taste in his designs and decorations, which was utterly inconsistent with simplicity and propriety. Accordingly some have represented his style in architecture as resembling the literary style of Seneca, and of the poet Marino. Vain of his own imagined superiority, and jealous of his brethren, he declined to concur with them; and before his death, destroyed all his designs, lest any other architect should pass them off as his own. His best work, among many performances, in churches and palaces at Rome, which blend striking beauties with singularity, is accounted to be the college of the Propaganda. The oratory of the Chiesa Nova, and the house of the fathers are also admired. D'Argenville. Gen. Biog.

**BORROWDALE**, in *Geography*, a picturesque district of Cumberland, near Kewick, south of Derwent-lake, commencing at the cataract of Lowdore, and spreading its tremendous rocks in a vast sweep round the head of the lake, at the distance of about half a mile from the shore, which is bounded by meadow-land to the brink of the water. The aspect of these rocks, with the fragments that have rolled from their summits, and which lie on each side of the road, prepare the curious traveller for the awful ruin to which he approaches in the gorge or pass of Borrowdale, that opens from the centre of the amphitheatre, which bounds the head of Derwent-water. Dark rocks yawn at its entrance, and disclose a narrow pass, running up between mountains of granite, that are shivered into almost every possible form of horror. Above, the whole scene resembles the accumulations of an earthquake or volcanic eruption, splintered, shivered, and amassed in piles over one another. Huge cliffs have rolled down into the glen below, where, however, remains a miniature of the most delightful pastoral beauty

beauty on the banks of the river Derwent. Among the most striking of the fells are Garganum, exhibiting rock upon rock, and Eagle-crag, where that bird till of late has been accustomed to build its nest: but the depredations annually committed on its young, have driven it from the place. Hence the pass extends for a mile over a frightful road, that climbs among the crags of a precipice that hangs over the river, with frequent glimpses into glens and chasms, seemingly obstructing further progress by fallen slivers of rock, and at length reaching the gigantic stone of Boulder, that appears to have been pitched into the ground from the summit of a neighbouring fell, and in its shape resembles the roof of a house reversed, the side towards the road projecting about 12 feet over the base. The dimensions of this huge mass are as follow: its length is 62 feet, its perpendicular altitude 36 feet, its circumference 87 feet, and it contains 230,000 solid feet; its weight is 1771 tons 13 hundred. The returning traveller is presented with an opening view over the Derwent lake of the Skiddaw-mountain, and the upper steep of Saddle-back obliquely seen towards the east, and rearing itself far above all the heights of the eastern shore. At the entrance of the gorge, the village or hamlet of Grange lies picturesquely on the bank of the Derwent, among meadows and woods, and shelters itself under the ruinous fell, called Castle-crag, deriving its name from the castle or fortress, which from its summit once guarded this important pass. Borrowdale abounds in valuable mines, among which some are known to supply the finest wadd, or black lead to be found in England. These mountains also furnish great quantities of iron-stone, slate, and various kinds of free-stone. Radeliffe's Journey in 1794, vol. ii. p. 350, &c.

**BORROWSTONNESS, or BOWNESS,** a town of Scotland, in the county of Linlithgow, having a harbour on the south side of the frith of Forth, and surrounded with coal-pits and salt-works, which produce the principal exports of the place. It has a good pier and harbour of late construction: 15 miles W. of Leith and 4 N. of Linlithgow.

**BORSALO, or BURSAL,** a town and kingdom of Africa, in Negroland, not far from the sea-coast, and extending along the northern bank of the river Gambia, as far as Tantalagonda. The town of this name is in the middle of the country, about 45 leagues from the coast. In the country which is little known, there is a river of the same name.

**BORSELLA,** in the *Glass Works*, an instrument wherewith they extend or contract the glasses at pleasure; also smooth and levigate them.

**BORSEHOLDER.** See *Borough, Head*.

**BORSET,** in *Geography*, an abbey about half a league from Aix-la-Chapelle, celebrated for its mineral waters, of the same general quality with those of Aix-la-Chapelle, and recommended as warm baths in similar diseases, and also in dropical and oedematous cases. They consist of the upper and lower springs; those of the former, which supply the baths, raising the thermometer to 158°, and those of the latter to 127°. They are less sulphurous than those of Aix-la-Chapelle; and abound much with selenites, which incrusts the pipe through which they pass, and also the sides of the bath.

**BORSIPPA, or BARSITA,** in *Ancient Geography, Semanat*, a town of Babylonia, according to Josephus and Strabo; represented by the latter as consecrated to Diana and Apollo, and placed by M. d'Anville on the eastern bank of the Euphrates, about the 32d degree of latitude.

**BORSK,** in *Geography*, a town and district of Russia, in the government of Upha, seated on the river Bielaya. N. lat. 55° 20'. E. long. 55° 15'.

**BORSNA, or BORNNA,** a town and district of Russia, in the government of Tchernigof, seated on a rivulet of the same name, falling into the Desna; 5 miles S. E. of Tchernigof, and 54 S. of Petersburg.

**BORSÖD,** a town of Hungary, and the capital of a country of the same name; inhabited by Hungarians, Selavonians, Bohemians, and Germans, and furnishing good wine and grain.

**BORSÖE,** a small island of Denmark, 2 leagues N. E. from Apsurade, on the east coast of Slefwick.

**BORSTEL,** a town of Germany, in the circle of Westphalia, and bishopric of Osnabruck, 8 miles N. of Furstenau. — Also, a town of Germany, in the duchy of Holstein, 14 miles S. E. of Bramlede.

**BORSTLING,** in *Ichthyology*, synonymous with barbling, or barfching, the common perch, *perca fluviatilis*. See *Mar-fish, Danub*.

**BORSUC,** in *Zoology*, the name of the badger, *ursus meles*, in Poland. The same animal also bears the names of *jaxwiec, koldziki, and zlik*, in that country.

**BORSZEJOWKA,** in *Geography*, a town of Poland, in the palatinate of Kiow; 10 miles W. of Kiow.

**BORT,** a town of France, in the department of the Correze, and chief place of a canton, in the district of Uffel. The place contains 1792, and the canton 6563 inhabitants: the territory comprehends 140 kilometres, and 10 communes: distant 4 leagues S. E. from Uffel.

**BORTHWICK,** in *Topography*, a parish and village in the county of Edinburgh, Scotland, is noted in the historic page for a magnificent castle which was built here by William I. lord Borthwick, about the year 1430. In its complete state it was very extensive, and considered almost impregnable, but Oliver Cromwell laid siege to it in 1650, and forced the garrison to surrender. "It is seated," observes Mr. Pennant, "on a knoll, in the midst of a pretty vale, bounded by hills, covered with corn and woods; a most picturesque scene. It consists of a vast square tower, 90 feet high, with square and round bastions at equal distances from its base. The state rooms are on the first story, once accessible by a draw-bridge. Some of the apartments were very large; the hall 40 feet long, and had its music gallery; the roof lofty, and once adorned with paintings. This place was once the property of the earl of Bothwell, who, a little before the battle of Carbury hill, took refuge here with his fair consort." The parish contains 200 houses, and 668 inhabitants. Pennant's Tour in Scotland, 4to. vol. iii.

**BORTZUTIM,** a town of Transylvania, 12 miles N. of Clausenburg.

**BORUA,** a town of Portugal, in the province of Alentejo, 2 leagues from Villa Viciosa.

**BORVIASIA,** a town of Russian Tartary, on the north side of the Don, 64 miles E. N. E. of Azof.

**BORYSOW,** a town of Lithuania, in the palatinate of Minsk, seated on the river Berezyna, 36 miles E. N. E. of Minsk. N. lat. 54°. E. long. 29° 5'.

**BORYSTHENES,** in *Ancient Geography*, a river of European Sarmatia, forming almost the whole western boundary of Sarmatic Scythia. Its name is said to be derived from the language of the Sclavi or Slaves, who, in their migration, blended themselves with the Scythians. It signifies "a rampart formed by a forest of pines," being derived from *bor*, a forest of pines, and *stena*, a wall. As a confirmation of this etymology, it is alleged that the shores of the Borysthenes are covered with forests of pines. Mela, deducing his description of this river from Herodotus, (l. iv. § 53.) represents it as flowing through a country of the same name,

name, and as the most pleasant river of Scythia, more gentle in its course than any other, and affording water more agreeable to drink. He adds, that it enriched many pleasant pastures, and that it supplied very large fishes without bones. It flowed from distant and unknown springs, which lay, according to Ammianus, (l. xxii. c. 18.) in the mountains of the Nauri, and was navigable through a course of 40 days' sailing; and in this interval received many large rivers. After its junction with the Hypanis, it discharged itself into the northern part of the Euxine sea. It is now called *Dnieper* or *Nieper*, which see.—Also, a town of European Sarmatia. Stephanus Byz. represents it as a Greek city, being a colony of Milesians, seated near the mouth of the river of the same name. By some it was called *B rylthenes*, by its inhabitants *Olbia*, and by Pliny *Miletopolis*; probably the same that is now denominated *Oczakow*, which see.

BORYZA, a city of Pontus. Steph. Byz.

BORZA, in *Geography*, a town of Persia, in the province of Alderbeitzan, 80 miles S. of Tauris.

BORZINSKOL, a town of Siberia, on the Argun; 144 miles S. E. of Nertchinsk.

BOS, in *Antiquity*, was peculiarly used for an ancient Greek silver coin, which was *didrachmus*, or equivalent to two drachms.

BOS, LAMBERT, in *Biography*, an eminent philologist, was born at Woreum, in Holland, in 1670, and became Greek professor at Franeker, in the exercise of which office he acquired great reputation, and where he died in 1717. His profound erudition is honourably mentioned by several writers, and particularly by Fabricius, and by Hemsterhusius in his oration "De linguæ Græcæ præstantia." His treatise on the Greek ellipses is held in high estimation by grammarians. His other principal works are, "A new edition, with additions, of the Greek grammar of Vilerus;" "an edition of the Septuagint, with prolegomena and various readings," 2 vols. 4to. Franek. 1709; "Thomæ Magistri eclogæ cum notis;" "Exercitationes Philologicae, quibus Novi Fæderis loca nonnulla illustrantur," 1700 and 1713, 8vo; "Mysterii Ellipticos Græcæ expositi specimen;" "Antiquitatum Græcarum descriptio;" and "Animadversiones ad scriptores quosdam Græcos." Nouv. Dict. Hist.

BOS, JOHN BAPTIST DU, the son of a considerable merchant and magistratè of Beauvais, in France, was born at that place in 1670, and finished his studies at the Sorbonne. He afterwards became a distinguished writer, and a member of the French academy. In 1695 he was one of the committee for foreign affairs under Mr. Torcy, and was afterwards charged with some important transactions in Germany, Italy, England, and Holland. After his return to Paris, he was made an abbé, and had a pension. He was also chosen perpetual secretary of the French academy; and in this situation he died at Paris, March 23, 1742. His principal works are, "Critical reflections upon poetry and painting;" of which the best edition is that of Paris, 1740, 3 vols. 12mo.; "A critical history of the establishment of the French monarchy among the Gauls;" of which the best editions are those of 1743, in 2 vols. 4to. and in 4 vols. 12mo.; "The interests of England ill understood in the present war," 1714; "The history of the four Gordians, confirmed and illustrated by medals;" and "The history of the league of Cambray, formed in 1708, against the republic of Venice," of which the best edition is that of 1728, in 2 vols. 12mo.

BOS, or BOSCHE, JEROM, an ancient painter and engraver, was born at Bois-le-Duc, and took pleasure in painting devils, witches, and enchantments. His pictures, distinguished by the freedom of his touch, and the strength of

his colouring, are held in high estimation, though, from the nature of the subjects which he selected, they excite a degree of horror blended with admiration. The most remarkable painting of this master, among several others of a similar kind, in which he indulges a wildness of imagination, is an allegory of the pleasures of the flesh; representing the principal figure, drawn by monstrous imaginary forms, preceded by demons, and followed by death. He was also an engraver, and the first artist who attempted to engrave in the grotesque style; and he is said to have been more distinguished by fertility of invention than by a correct judgment. The two plates, most deserving of mention, are one representing "St. Christopher," carrying the infant Jesus across the water and bending under his load; on the left is a hermit, coming from his cell with a lantern, and the whole composition is surrounded with small grotesque figures of all shapes, in the most ridiculous attitudes; and another is the "Last judgment," in which Christ appears seated on a rainbow, with two angels on each side and sounding trumpets, having on their labels this inscription, "Hic est dies quem fecit; surgite mortui, venite ad judicium;" and at the bottom are small figures of men and devils of all shapes intermixed. To both these prints is affixed his name, "Bosche." He died in 1500. Pilkington and Strutt.

BOS, LEWIS JANSSEN, or JOHN LEWIS DE, a painter, was born at Bois-le-Duc, and having received instructions in painting from the artists of his native city, he applied himself to study after nature, and became eminent for the truth of his colouring, and the neatness of his handling. His favourite subjects were flowers and curious plants, which he grouped in vases of glass or crystal, half filled with water, and to which he gave a peculiarly natural and pleasing appearance. He also exhibited on the leaves of his subjects the drops of dew with singular transparency, and embellished them with butterflies, bees, wasps, and other insects, in a manner superior to that of any co-temporary artists. In the style of his portraits he was no less excellent than in his composition of still life. He died in 1507. Pilkington.

BOS, in *Zoology*, the *Ox*, a genus of animals in which the horns are concave, or hollow, turned outwards, lunated and smooth; front teeth in the lower jaw eight; canine teeth or tusks none.

There are but few species of this tribe that appear to be really distinct; but the number of varieties into which they are divided, arising from the differences of climate, domestication, and other causes, are endless. They are a most valuable race of animals to mankind, their flesh and milk affording excellent nutritious food: they are useful as beasts of burthen; and their hides serve many domestic purposes. The species are TAURUS, or the common ox, which comprehends the varieties of *ferus* and *domesticus*, *Americanus*, *moschatus*, *grunniens*, *bubulus*, *caffer*, according to Gmelin. To these are added, by later writers, the *Bos arnee* of Kerr; the *Baas* of the Cape; with the *Dwarf ox* of Africa, under the names of *Bos barbatus*, and *pumilus*; which see.

*Bos strepticeros*, Aldrovandus. See STREPTICEROS *bos*.

BOSA, in *Geography*, a maritime and episcopal town of Sardinia, situate on the western coast of the island, near a river of the same name. It is defended by a castle, and has a good fort; distant 18 miles S. S. W. from Algeri, and 36 S. S. W. of Sassari, to which it is suffragan. N. lat. 40° 18'. E. long. 8° 34'.

BOSARA, in *Ancient Geography*, a town of Arabia Felix, according to Ptolemy.

BOSARADDAHEBA, or JESARDFCHER, a town of Asia, in the province of Sablestan; 21 leagues S. of Candahar.

**BOSPOCK**, **BOSBOC**, **BOUC DES BOIS**, and **FORIST ANILOFF**, in *Zoology*, the name of *Antilope Sylvatica* (*Gmel.*) by different writers. See *SALVATICA*.

**BOSC**, **CLAUDE DU**, in *Biography*, an engraver, was a native of France, and being invited to England by Nicholas Dorigny, assisted him for some time in engraving the cartoons of Raphael; and afterwards separating from Dorigny, he undertook to engrave the cartoons for the print-sellers. He also engraved the duke of Marlborough's battles, for which he received Sol. per plate; and, assisted first by Du Guernier, and afterwards by Beauvais and Baron, he completed them within two years in 1717. He then became a print-seller, and published, by subscription, the translations of Picart's Religious Ceremonies. As an engraver, he possessed no great merit: his style is coarse and heavy, and the drawing of the naked parts of the figure in his plates is very defective. However, he engraved from several great masters. The "Continence of Scipio," from a picture of Nicholas Poussin, in the Houghton collection, is one of his plates. He flourished in 1714. *Strutt*.

**BASC**, **PETER DU**, an eminent protestant preacher of France, was born at Bayeux in 1623, educated at Montauban and Saumur, and in 1645 ordained one of the ministers of Caen. The fame of his eloquence was very extensive; and he was warmly solicited by the churches of Charonton and Paris to become their pastor, but he preferred continuing at Caen. His reputation excited envy and alarm; and he was falsely charged with having used offensive language with regard to aricular confession, and on this charge exiled to Chalons. But his talents and character were held in such high estimation, that powerful intercession was made in his favour, so that he was permitted to return in the same year, 1654, to Caen. His return was the occasion of very general rejoicing among persons of all parties; and it was celebrated in a very singular manner by a Catholic of free character, who invited two Franciscans to an entertainment, and urged drinking to such a degree, that one of them died on the spot. Next day he paid his respects to M. Du Bosc, and informed him, "that he had thought it his duty to sacrifice a monk to the public joy; that the offering would have been more suitable if it had been a Jesuit, but he hoped it would not be unacceptable, though only a Franciscan." M. Du Bosc was selected, on account of his distinguished character and address, to draw up remonstrances against the severities which were exercised by the Catholics against the Protestants; and on all occasions he expressed such loyalty to the king, and such a disposition to submit to civil authority, that he frequently succeeded in obtaining relief, and in checking the rage of persecution. At length, however, viz. in 1665, the violence of the adversaries of the Protestants became irresistible, and the parliament of Normandy issued an arret, which prohibited Du Bosc from the exercise of his ministry. Upon this he retired to Holland, and discharged the duties of his ministerial office at Rotterdam, till his death, which happened in 1692. During his life he printed two volumes of sermons; and after his death, his son-in-law, M. le Genre, published a collection of public papers, speeches, letters on theological subjects, Greek, Latin, and French verses, &c. *Gen. Dict.*

**BOSC**, **HIPPOLITUS**, taught anatomy and medicine at Ferrara, towards the end of the 16th century. He was also a distinguished practitioner of surgery. His works are "De vulneribus a bellico fulmine illatis," Ferraræ, 1596, 4to. He attributes the principal part of the mischief in gun-shot wounds to the heat of the ball. "De læsione motus digitorum, et macie brachii." This was published by J. Lauterbach, in his *Concilia*, at Franef. in 1605, 4to.

"De curandis vulneribus capitis, brevis methodus," Ferr. 1609, 4to.; "De facultate anatomica, læsiones viij. cum quibusdam observationibus," 1600, 4to.; a judicious and useful compendium, interspersed with some valuable notes and observations by the author. *Haller. Lib. Anat. et Chirurg.*

**BOSC**, or **BOSCIUS**, **IGNATIUS**, published at Ingoldstadt, 1580, 4to. "De lapidibus qui nascuntur in corpore humano ac precipue renibus, ac vesica, et ipsorum curatione." *Ibid.*

**BOSCAGE**, denotes a place set with trees, a grove, or thicket.

**BOSCAGE**, *boscagium*, from Ital. *bosco*, wood, in a *Law sense*, signifies mast or such sustenance as woods and trees yield to cattle.

According to Manwood, to be quit *de boscagio*, is to be discharged from paying any duty of wind-fall wood in the forest.

**BOSCAGE**, among *Painters*, is said to denote a picture or landscape representing much wood and trees.

**BOSCAGE** sometimes denoted a tax or duty laid on wood brought into the city.

**BOSCAGER**, **JOHN**, in *Biography*, an eminent French lawyer, was born at Beziers in 1601, and removing at an early age to Paris, officiated for his uncle, La Foret, during his illness, as teacher of law, when he was only 22 years old. After having acquired great reputation at the university of Padua, he succeeded his uncle, and occupied his chair till his death. His mode of instruction manifested an accurate and comprehensive judgment; for he reduced all law to certain principles or definitions, from which he deduced consequences, that comprised all the particulars of each topic. Some Latin treatises, which he composed, were translated into French, at the request of Colbert, and published under the title of "Institute of the Roman and French law, with remarks by Francis de Launay," 4to. 1686. Another work was published after his death, entitled, "De Iustitia et Jure," 12mo. 1689. His death happened by a fall into a ditch, from which he could not extricate himself, after he had attained the age of 87 years. *Moreri*.

**BOSCAN**, **MOSEN JUAN ALMOGAVAR**, a reformer of Spanish poetry, was born at Barcelona towards the close of the 15th century. By the advice of Andrew Navagero, ambassador from Venice to Charles V., he attempted to introduce into the Spanish poetry, which was before harsh and barbarous, the Italian measures and taste; and he was the first, who, with the assistance of his intimate friend, Garcilaso de la Vega, succeeded in the attempt. A collection of the works of these coadjutors was published together in 1544. Garcilaso's testimony to his genius and virtue is thus translated by Mr. Southey:

"Then hand in hand

A you'h approached, with Phœbus; in his face  
The skilful eye might read benevolence  
And wisdom; he was perfected in all  
The love and various arts of courtesy  
That humanise mankind; the graceful port,  
And the fair front of open manliness  
Discovered Boscan; and that fire illumed  
His generous face, that animates his song,  
With never-fading splendour there to shine."

Boscan is said to have possessed more learning than taste, and more taste than genius. Without being sublime, some of his turns are neat and ingenious. In prose he translated the courtier of Castiglioni. He died in 1542 or 1543. *Moreri. Gen. Biog.*

**BOSCAWEN**, in *Geography*, a township of America, in Hillsborough county, New Hampshire, seated on the western bank

bank of Merrimaek river, above Concord; 43 miles N.W. from Exeter. It contains 1108 inhabitants; and in its vicinity are the Boscawen hills.

**BOSCAWEN'S Island**, a name given by captain Wallis, in 1767, to an island in the Southern Pacific Ocean; called by the natives "Kootahē." It is separated from Keppel's island, called "Neootabootaboo," by a channel 3 miles broad. They are both situate in S. lat. 15° 55'. W. long. 173° 48'. Kootahē is very lofty, of a conical form, between two and three miles in diameter, and lies N.E. from the other. Both are populous and fertile. They were discovered by Schouten and le Maire, May 10, 1616. Schouten, who, after bartering with the natives for cocoa-nuts, in return for nails and beads, was attacked by them from their canoes, called them 'Traitors' and Cocoa islands, in consequence of the reception he met with. Captain Wallis exchanged with the inhabitants of Neootabootaboo some nails for fowls, fruit, and one of their clubs. Perouse saw Kootahē Dec, 20, 1787, and having examined both the islands, lay to in a bay upon the west coast of the larger division of Neootabootaboo. The natives brought off the finest cocoa nuts he had ever seen, with other vegetables, as well as some fowls and a hog; they seemed to manifest no apprehension, and traded very freely. They resembled the more southern islanders in every thing, except that their looks indicated a ferocity, like that which characterizes their northern neighbours. A rocky bank, two or three leagues N. of Kootahē, was found in 1616, covered with 14 fathoms of water. *Missionary Voyage, Introd. p. 67.*

**BOSCH, BALTHASAR VANDEN**, in *Biography*, a painter of conversations and portraits, was born at Antwerp in 1675, and first studied, after the manner of Teniers, those subjects which were apartments decorated with busts, vases, pictures, and other curiosities; but in process of time he employed his pencil on subjects of a more elegant and elevated kind, and acquired a superior style of performance. He also painted portraits with great reputation, and particularly a portrait of the duke of Marlborough on a horse, painted by Van Bloemen. His paintings fetched an extravagant price, exceeding that produced by the performances of Teniers or Ostade, with which they cannot, in reality, pretend to any competition. His pencil is light, his touch spirited, and his figures, more elegant than those of most of his contemporaries, are dressed in the mode of the time. In some of his works the composition and design, and also the colouring, are very good, and the subjects are judiciously chosen. He died in 1715. *Pilkington.*

**BOSCH, JACOB VANDEN**, a painter of still life, was born at Amsterdam in 1636, and painted summer fruits of various kinds with a neat pencil, and with such an exact imitation of nature, that they appeared delicious, and almost real. He died in 1676. *Pilkington.*

**BOSCHADIS**, in *Zoology*, a species of *ECHINORHYNCHUS*, that infests the intestines of the domestic duck. The neck is filiform, and the proboscis slightly echinated. *Goeze Eingew.*

**BOSCHAS, Anas Boschas**, in *Ornithology*, the *Common Mallard*, or *Wild Duck*, the specific distinction of which consists in the plumage being of a cinereous colour; the tail feathers (of the male) recurvate; bill straight; collar white. *Linn. Fu. Sæc. &c.*

Gmelin mentions several distinct varieties of this bird, in the *Sylt. Nat.* the characters of which are described as follows:—*Cirrhata*, above grey, beneath white, crest cinereous; *persica*, head and upper parts of the neck cinereous, beneath yellowish; *major*, back sooty. This is larger than the others,

measuring two feet and a half in length. *Grisea*, entirely cinereous, with the legs and bill black; *nevica*, with the back black, spotted with yellowish; *nigra*, having the head and collar black.

The natural history of the wild duck is detailed so amply by different writers, that nothing new remains to be added by us. Dr. Latham, in particular, has entered at great length in his judicious compilation on this subject. The wild ducks, observes this writer, are frequent in many parts of England, but no where in more plenty than in Lincolnshire, where prodigious numbers, according to Mr. Pennant, are taken annually in the decoys, each decoy paying from five pounds to twenty, annual rent. In Somersetshire the rental of a decoy yearly has been known to amount to even thirty pounds.

With us these birds pair in the spring. They breed in all the low marshy grounds, laying from ten to sixteen eggs. It is observed of the young, that they always take to the water as soon as they are hatched. The old birds are very artful. They do not constantly build their nest close to the water, but many times at a distance from it; in which case the female takes the little brood in its beak, or between its legs, one or two at a time, to the water side, and going into it herself, the young ones follow instinctively. Wild ducks are known sometimes to lay the eggs in a high tree, in the deserted nest of a crow, or a magpie. Dr. Latham speaks of an instance that took place at Etchingham, in Sussex, in which the female was found sitting upon nine eggs, in an oak twenty-five feet from the ground. The eggs were supported by some small twigs laid crossways.

In England only a comparatively small number of wild ducks are found in the summer; because, at that time, they remain in the more northern parts of Europe, and only return to us towards the winter. In France this species is not often seen till the winter; appearing in October, and again departing northward in the spring. They are caught in that country, as with us, in decoys, the chief of which are in Picardy, where prodigious numbers are taken, especially on the river Somme. They have also another method: a sportsman, with a cage of tame decoy ducks, takes his station in a certain place, near which, it is conceived, the flock will pass. If they approach so near as to allow him to fire, he takes them with little trouble; but if otherwise, he lets fly one of the tame decoy ducks, then a second, and so on: these tame birds entice the wild ducks in small parties within reach of the sportsman's fowling-piece, who is thus enabled to kill six or seven birds at every shot. They are now and then taken also by means of a hook, baited with a bit of sheep's lights, which, swimming on the water, the bird swallows the bait, and hook with it. Divers other methods of catching the wild duck are peculiar to different nations, of which one seems worth mentioning, on account of its singularity; and this is the practice in India. The person wishing to take these, wades into the water up to the chin, and having his head covered with an empty calabash, approaches the place where the ducks are; when they, not regarding an object of this sort, suffer the man freely to mix with the flock; after which he has only to pull them by the leg under the water, one after another, till he is satisfied; returning as unsuspected by the remainder as when he first came among them. This mode of capture is common on the river Ganges, only that the duck-hunters use the earthen vessels of the gentoos, instead of calabashes. These vessels are what the gentoos boil their rice in, and are called kuteharee pots, which, after being once used, they look upon as defiled, and in consequence throw them into

the river as useless. The ducks, from constantly seeing the water flow down the stream, regard them as little as the caldrons; and the duck hunter, concealing his head in one of them, can seize upon them without exciting the least suspicion. A similar method is also practised in China, and in South America, to take the wild duck.

**BOSCHIA**, *Anas fesa sive Bosphus mexicana*. Brisson. A synonyme of *Anas Clypeata*, the Shoveler, var. 7. See **Clypeata**.

**BOSCHAS**, *Bfhus Bellonii*. The Garganey. **ANAS QUERQUEDULA** is called by this name, both in Gesner's book, and the Ornithology of Aldrovandus.

**BOSCHI**, Bosen, or Bosco, in *Geography*, a town of Italy, in the Alexandria of the Milanese, seated on the river Orbe, five miles E. from Alexandria.

**BOSCIA**, in *Botany*, (in honour of Bose, author of part of the Zoological and Botanical articles in "Nouveau Dictionnaire d'Histoire Naturelle," now publishing at Paris.) Willdenow, 266. Class, *tetrandria trigynia*. Gen. Char. *Cal.* perianth, four-toothed. *Cor.* four-petalled. *Pericarp.* capsule, four-celled.

Species *B. undulata*, Thunberg, "Leaves opposite, lanceolate, waved." A shrub. Native of the Cape of Good Hope.

**BOSCIA**. La Mark (Illust. Pl. 395.) Class, *dodecandria monogynia*. Gen. Char. *Cal.* perianth, four-leaved. *Cor.* none. *Stam.* filaments long; anthers didymous. *Pist.* germ on a pedicel, as long as the filaments; style, none; stigma pointed. *Pericarp.* a nut. *Seed.* one.

Species *B.* A shrub. *Leaves*, oblong-ovate, alternate, on short petioles, strongly reticulated, coriaceous. Flowers in a terminating corymbus. A native of Africa, in the neighbourhood of Goree, where the negroes eat the kernel of the nut. This plant does not appear to be known to Willdenow. It will, doubtless, soon receive another name, as Thunberg's plant seems to have got the first possession.

**BOSCIUS**, JOHN, in *Biography*, a native of Liege, of considerable learning and abilities, was invited, in 1558, to the chair of professor of medicine, at Ingolstadt, which he held with credit several years. His works are, "De peste liber," published originally in German, in 1562, 4to.; "Concordia philosophorum, ac medicorum, de humano conceptu, atque factus incremento, animatione, mora in utero, ac natiuitate," Ingolds. 1576, 4to. and 1588; "Oratio de optimo medico, et medicinæ auctoribus, inter orationes Ingoldstadienses." Haller Bib. Anat.

**BOSCO**, in *Law*. See **ATTACHAMENTA de bosco et spinis**.

**BOSCOBEL**, in *Topography*, in the parish of Donnington, in Shropshire, is a place memorable in English history, for the oak tree, wherein King Charles the Second secreted himself, after the desperate battle at Worcester. Finding it impracticable either to escape into Wales, or to reach the metropolis in safety, and knowing that many of his enemies were searching for him, in the immediate neighbourhood, he was prevailed on by Major Carless (who accompanied him) to seek protection in a large oak tree. Here they seated themselves one whole day, and saw some of Cromwell's soldiers seeking for the king in an adjoining wood. After the restoration, this tree became highly venerated, and numerous persons went on pilgrimage to see it. A great part of it was cut away, and converted into tobacco stoppers, hafts of knives, and other memorials; and many plants were propagated from its acorns. Its remains are inclosed with a brick wall, the inside of which is covered with laurel. The 29th of May, the day of his birth, and of his resto-

ration, is still commemorated in England, by an annual festival and holiday; and various classes of the community display branches, leaves, and apples of the oak tree. Near Boseobel is Whiteladies, so named from being a nunnery of white, or Cistercian nuns. The ruins of this are still considerable, and the church is ornamented with circular arches, &c. Gough's Edition of Camden's Britannia, vol. ii. Carte's History of England, vol. iv. Granger's Biographical History of England, vol. iii.

**BOSCOI**, or **BOSCI**, in *Ecclesiastical History*, denotes a species or tribe of monks in Palestine, who fed on grass, like the beasts of the field.

The word is Greek, βόσκω, q. d. grazers; formed from βόσκω, *pasco*, I feed.

The Boscoi are ranked among the number of Adamites, not so much on account of their habit as food. They took no care about provision; but when eating-time came, or any of them were hungry, went into the fields, with each his knife in his hand, and gathered and eat what he could find.

**BOSCOLI**, **ANDREA**, in *Biography*, an historical painter, was born at Florence, in 1553, and educated under Santi di Titi. He was the first person who had a just notion of the chiaro-scuro, and used it successfully in the Florentine school; where, though it had been happily practised by Giorgione, at Venice, and also by Titian, it was not well understood before his time. He possessed great freedom of hand, and gave a surprising force of colour; and both in design and composition the grandeur of his stile resembled that of his master. He studied after nature; and in his travels he drew sketches of any particular objects that struck him; but pursuing this practice at Loretto, with regard to the fortifications of the city, he was seized by the officers of justice, and condemned to be hanged; but he happily escaped, within a few hours of execution, by the interposition of Signior Bandini, who explained to the chief magistrate his innocent intention. He was also an engraver; but the subjects of his plates are not specified either by Marolles or Florent le Comte. He died in 1606. Pilkington.

**BOSCOVICH**, **ROGER JOSEPH**, an eminent mathematician and natural philosopher, was born of very respectable parents, in the free city of Ragusa, on the coast of Dalmatia, the 18th of May, 1711. He was the youngest of nine children, and his mother lived to the extraordinary age of 103. Six sons received the best education that their father's circumstances could afford; and all of them, particularly the eldest, who became a priest, were distinguished by a happy vein for poetry. Having finished his grammatical course with applause, the young Boscovich, prompted by the example of his brother, in his fifteenth year took the habit of the noviciate, and entered the Jesuits' College at Rome. There the original bent of his genius discovered itself, by the enthusiastic ardour with which he plunged into the study of the mathematics. His progress in that important branch of knowledge was so rapid as to astonish, and soon outrun his preceptors. Under their instruction he acquired the elements of geometry and algebra, but was left to the exercise of his own application in prosecuting the higher parts of mathematics. He studied by himself the principles of the differential calculus; and thus prepared, he began the *Principia* of Newton, and devoured that immortal work with the most eager avidity. He was transported by the vast display of new and splendid truths which were unveiled; and while, with the torch of geometry, he traced the secret links of nature's operations, and seemed to penetrate the counsels of heaven, he felt his passion for distinction wonderfully inflamed: nor, in the warmth of his temper, could

he suppresses the movements of self-gratulation, which the consciousness of his powers and acquisitions excited in his breast. By his persuasion, Noceti, his master in philosophy, was induced to reprint a small poem on the rainbow, and another on the aurora borealis, both of which Boscovich enriched with ingenious notes and illustrations. The publication of this tract spread his fame beyond the precincts of the college, and beyond the Alps. Mairan, whose opinion concerning the aurora borealis he had espoused, noticed it with loud commendation, in the second edition of his dissertation; and the praises bestowed by the French philosopher, with the title conferred on him of correspondent of the Academy of Sciences, could not fail to prove highly gratifying to his youthful vanity.

After Boscovich had completed the usual course of philosophy, he was obliged, by the rules of the institution, to teach grammar and the classics; but he never lost sight of his favourite studies, and he was invited by his mathematical master, to defend annual theses, and deliver public dissertations on such subjects as occasion suggested. These being printed in succession, extended farther his reputation. The first appeared in 1736, and contained a theory of the solar spots, very similar to that which was afterwards so ingeniously supported by professor Wilson, of Glasgow. It supposes the sun to have two atmospheres, the lower being dense, and sometimes sprinkled with clouds; the upper rare, and subject to variation of height. Next year produced two dissertations; one on the transit of Mercury, and another on a remarkable aurora borealis.

Five years had Boscovich spent in the drudgery of teaching Latin, and three more were consumed in the unprofitable study of scholastic theology, when, by a very singular indulgence, he was exempted by his superiors from the fourth year's attendance, and permitted to relinquish that dark and thorny path, and thenceforth employ his talents in exploring Nature's wide domain. His situation now, as supernumerary prefect of the Roman College, was entirely suited to his taste. To communicate mathematical instruction was to him a delightful task; and he prepared, for the use of his pupils, a short system of geometry, which comprized all the capital truths of that science in fourteen propositions. In the selection of the materials, in their disposition and arrangement, he exhibited the clearness, the precision, and noble elegance, formed after the model of the ancients. He composed the elements of trigonometry with the same purity of taste. But the capital part of the system, his theory of the Conic Sections, was reared by repeated efforts, and at distant intervals, and was not published until the year 1755. Boscovich considered these curves as described in *plano*, and assumed, for his generic definition, the beautiful property of the *directrix*, which is common to them all, the parabola being only its simplest case. In the ellipse, the ratio of a line, drawn from any point to either of the *foci*, is to a perpendicular from the same point to the *directrix*, in the ratio of a less to a greater; in the hyperbola, it is that of a greater to a less. But the author did not stop here; he likewise investigated the properties derived immediately from the section of the cone. He supposed it cut by a moveable plane, and showed how the several curves would thence be successively produced. The same luminous idea he transferred to the cylinder, the spheroid, and the conoids. His imagination loved to contemplate the fine mutation and transition of mathematical figure, and to trace the series of successive, yet apparently connected changes, which have suggested the *law of continuity*. On that metaphysical principle, as elucidated by the transformation of geometrical *loci*, he gave an exquisite dissertation. Other dissertations,

remarkable for their ingenuity, were successively delivered to a crowded audience, at the annual examination of his school. These treated on various difficult points in geometry, astronomy, and optics; on osculating circles, the nature of infinitesimals, trajectories, the inequality of gravity over the earth's surface, the centre of magnitude, the laws of bodies, living forces, the flux and reflux of the sea, the annual aberration of the fixed stars, the limits of astronomical observations, the use of lenses and dioptric telescopes, and a new method of employing the observation of the phases in lunar eclipses, on the determination of a planet's orbit, by help of catoptrics, and on the atmosphere of the moon, which he held to be very different from that of the earth, and more analogous to water. In one of these dissertations he pointed out a mistake of the famous Daniel Bernoulli, who had hastily concluded, that the tides of the atmosphere must rise higher, in proportion to its rarity, than those of the ocean; in another, he shewed that the question, concerning the measure of forces, which then so vehemently agitated the scientific world, as it generally happens, was merely a dispute of words; in a third, he sketched the outlines of that bold structure, which has obtained such deserved celebrity among the learned—his sublime theory of the constitution of matter.

While Boscovich was thus usefully and honourably engaged in directing the studies of youth, and enlightening the learned world by his elegant and ingenious writings, the pleasure of his conversation was eagerly courted at Rome. In every house of note he was always a most welcome guest, and he reigned in every society by the ascendancy of his talents. Before mixed companies he would freely talk of his own speculations, which he had a singular felicity in rendering intelligible and interesting to the most ordinary minds; and though, on these occasions, he was not accustomed to conceal his inward satisfaction, or decline bestowing upon himself the merited encomiums, these frequent sallies of vanity seemed to flow merely from the warmth of his character, and were effaced in the general blaze of admiration entertained for his superior talents. Nor was his ambition confined within the circle of abstract science; indulging the excursive flights of fancy, he often sacrificed to the Muses. He composed Latin verses, on a great variety of subjects, and which consequently possessed very different degrees of merit. Every occurrence he was ready to seize, whether public or private, serious or comic; wars, nuptials, jocular and domestic incidents, were all indiscriminately his theme. He had a wonderful knack in composing those verses, with a memory not less astonishing for retaining them; and at the tables of his friends he took pleasure in reciting elaborate passages. Surrounded by his disciples and partial admirers, the sort of idolatry which he received appears, however, to have had rather an unfortunate effect on his character, by tempting him to overrate the measure of his powers, and extent of his attainments. Once, and once only, he entered the lists with his illustrious contemporaries. It was in answer to the question, proposed by the Academy of Sciences at Paris, to determine the inequalities produced by the mutual action of Jupiter and Saturn, especially near the time of their conjunction. His memoir was returned with much commendation, and very few mathematicians assuredly would have felt themselves lowered in yielding the premium to the great Euler. But Boscovich was piqued at what he conceived to be an unfair decision, and would never afterwards engage in any public competition.

A philosopher, residing in Rome, amidst the venerable remains of ancient splendour, was powerfully drawn to examine those monuments. Boscovich wrote several disserta-

tions on the subject of antiquities, two of which were printed, and the rest circulated in manuscript. His zeal, activity, and fondness of applause, rendered him at all times accessible, and in a multitude of cases, his advice was ardently sought by individuals. Benedict XIV. a great patron of learned men, and his enlightened minister, cardinal Valenti, consulted him on various important objects of public economy, the clearing of harbours, and the constructing of roads and canals. On one occasion, he was joined in a commission with other mathematicians and architects, invited from different parts of Italy, to inspect the cupola of St. Peter's, in which a crack had been discovered. They were divided in opinion; but the sentiments of Boscovich, and of the Marquis Poleni, prevailed. In stating, however, the result of the consultation, which was to apply a circle of iron round the building, Poleni forgot to refer the idea to its real author, and this omission grievously offended the Ragusan geometer. Other incidents had concurred to mortify his pride: he became at last disgusted with his situation, and only looked for a convenient opportunity of quitting Rome. While in this temper of mind, an application was made by the court of Portugal to the general of the Jesuits, for ten mathematicians of the Society to go out to Brazil, for the purpose of surveying that settlement, and ascertaining the boundaries which divide it from the Spanish dominions in America. Wishing to combine with that object the mensuration of a degree of latitude, Boscovich offered to embark in the expedition, and his proposition was readily accepted. But cardinal Valenti, unwilling to forego the lustre reflected by a man of such distinguished abilities, commanded him, in the name of the pope, to dismise the project, and persuaded him to undertake the same service at home in the Papal territory. In this fatiguing, and often perilous operation, he was assisted by the English Jesuit, Mayer, an excellent mathematician, and was amply provided with the requisite instruments and attendants. They began the work about the close of the year 1750, in the neighbourhood of Rome, and extended the meridian line northwards, across the chain of the Apennines as far as Rimini. Two whole years were spent in completing the various measurements, which were performed with the most scrupulous accuracy. In the intervals, while this great work was carrying on, the active disposition of Boscovich sought amusement and occupation in other pursuits. At night he was busy in drawing out his Elements of Conic Sections; and in the mornings and evenings, during his excursions to and from the remote stations among the mountains, he composed on horseback the greater part of his elegant Latin poem on *eclipses*. This singular fact reminds us of what is reported of the late Dr. Darwin, who is said to have framed, in his mind, the beautiful and harmonious episodes of the *Botanic Garden*, while driving in his chariot, on visits to his country patients.

This important operation of measuring two degrees on the surface of Italy, is elaborately described by Boscovich, in a quarto volume, written in his usual diffuse manner, and full of illustration and minute details. But the book is rendered the more valuable by the addition of several opuscles, or detached essays, relating to the subject, and which display great ingenuity, conjoined with the finest geometric taste. We may instance, in particular, the discourse on the rectification of instruments, the elegant synthetical investigation of the figure of the earth, deduced both from the law of attraction and from the actual measurement of degrees, and the nice remarks concerning the curve and the conditions of permanent stability. This last tract gave occasion, however, to some strictures from D'Alembert, to which Bos-

covich replied, in a note annexed to the French edition of his works.

The arduous service which Boscovich had now performed was but poorly rewarded. From the pope he received only a hundred sequins, or about forty-five pounds sterling, a gold box, and *abundance of praise*. He now resumed the charge of the mathematical school, and besides discharged faithfully the public duties of religion, which are enjoined his order. A trifling circumstance will mark the warmth of his temper, and his love of precedence. He had recourse to the authority of cardinal Valenti, to obtain admission into the oratory of Caravita, from which his absence excluded him, and which yet did afford only the benefit of a free, but frugal supper. In presiding at that social repast, the philosopher relaxed from the severity of his studies, and shone by his varied, his lively, and fluent conversation. He lived in habits of intimacy with his colleagues, and especially with his compatriot, Benedict Stay, known to the learned world by an excellent didactic poem, entitled "*Philosophia Recentior*," and which he elucidated by notes, containing, in a very neat compressed form, the elements of mechanics.

At this time a dispute arose between the little republic of Lucca, and the government of Tuscany, on the subject of draining a lake. A congress of mathematicians was called, and Boscovich repaired to the scene of contention, in order to defend the rights of the petty state. Having waited three months in vain, expecting the commissioners, and amused with repeated hollow promises, he thought it better for the interest of his constituents, to proceed at once to the court of Vienna, which then supremely directed the affairs of Italy. The flames of war had been recently kindled on the continent of Europe, and Boscovich, like a true courtier, took occasion to celebrate the first successes of the Austrian arms, in a poem, of which the first book was presented to the Empress Theresia; but the military genius of Frederic the Great of Prussia soon turned the scale of fortune, and our poet was reduced to silence. More honourably did he employ some leisure in the composition of his immortal work, "*Theoria philosophiæ naturalis reducta ad unicam legem virium in naturâ existentium*," printed at Vienna, in the year 1758. This he drew up, it is alleged, in the very short space of thirty days, having collected the materials a considerable time before; yet we must regret the appearance of haste and disorder, which deforms a production of such rare and intrinsic excellence.

After a successful suit of eleven months at Vienna, Boscovich returned to Rome, and received from the senate of Lucca, for his zealous services, the handsome present of a thousand sequins, or about £450. Thus provided with the means of gratifying his curiosity, he desired and obtained leave to travel. At Paris he spent six months, in the society of the eminent men, who then adorned the French capital; and, during his stay in London, he was elected, in 1760, a fellow of the Royal Society, and he dedicated to that learned body his poem on *eclipses*, which contains a neat compendium of astronomy. The expectation of the scientific world was then turned to the transit of Venus, calculated to happen in the following year. Boscovich, eager to observe it, returned through Holland and Flanders to Italy, and joined his illustrious friend, Correr, at Venice, from whence they sailed to Constantinople, having, on their way, visited the famous plain of Troy. In Turkey, he scarcely enjoyed one day of good health, and his life was repeatedly despaired of by the physicians. After spending half a year in this miserable state, he returned in the train of Sir James Porter, our ambassador at the Porte; and having traversed Bulgaria, Moldavia, and part of Poland, his intention was to penetrate

into Russia, if the agitation which there prevailed, on the sudden death of Peter, had not deterred him from executing the project. The diary of his journey, which he published in Italian and French, is but a poor book, full of pedantry, and patched up of trifling and insipid remarks. Yet such were his pride and blind partiality, that he regarded, with contempt, the wholesome criticisms to which it gave occasion. Boscovich began his travels at too late a period of life to profit much by them.

At Rome his arrival was welcomed, and he was again consulted on various plans of public improvement. But in the spring of 1764, he was called by the Austrian governor of Milan, to fill the mathematical chair in the university of Pavia. The honours which he received provoked the jealousy of the other professors, who intrigued to undermine his fame. He took the most effectual mode, however, to silence them, by publishing his dissertations on optics, which exhibit an elegant synthesis and well-devised set of experiments. These essays excited the more attention, as, at this time, the ingenuity of men of science was particularly attracted to the subject, by Dollond's valuable discovery of achromatic glasses.

The expulsion of the Jesuits from the dominions of Spain prevented Boscovich from going to California, to observe the second transit of Venus, in 1769, and which expedition the Royal Society of London had strongly solicited him to undertake. And as his rivals began now to stir themselves again, he sought to dispel the chagrin, by a second journey into France and the Netherlands. At Brussels he met with a peasant, famous for curing the gout, and from whose singular skill he received most essential benefit. On his return to Italy, he was transferred from the university of Pavia to the palatine schools at Milan, and resided with those of his order, at the college of Brera, where he furnished, mostly at his own expence, an observatory, of which he got the direction. But he was still doomed to experience mortification. Some young Jesuits, who acted as his assistants, formed a conspiracy, and, by their artful representations, prevailed with the government to exclude his favourite pupil and friend from holding a charge of trust. This intelligence was communicated to him at the baths of Albano, and filled him with grief and indignation. He complained to prince Kaunitz, but implored his protection in vain. To the governor of Milan he wrote, that he would not return, unless things were restored to their former footing. He retired to Venice, where, having staid ten months in fruitless expectation of obtaining redress, he meditated spending the remainder of his days in honourable retirement at his native city of Ragusa. But while he waited for the opportunity of a vessel to convey him thither, he received the afflicting news of the suppression of his order in Italy. He renounced his scheme, and seemed quite uncertain what step he should take. Having come into the Tuscan territory, he listened to the counsels and solicitation of Fabroni, who held forth the prospect of a handsome appointment in the Lyceum of Pisa. In the mean time he accepted the invitation of La Bord, chamberlain to Louis XV. and accompanied him to Paris. Through the influence of that favourite, he obtained the most liberal patronage from the French monarch; he was naturalized, received two pensions, amounting to 8000 livres, or £333, and had an office expressly created for him, with the title of "Director of optics for the marine." Boscovich might now appear to have attained the pinnacle of fortune and glory; but Paris was no longer for him the theatre of applause, and his ardent temper became soured by the malign breath of jealousy and neglect. Such extraordinary favour bestowed on a foreigner, could not fail

to excite the envy of the *scavans*, who considered him as rewarded greatly beyond his true merit. The freedom of his language gave offence, his perpetual egotism became disgusting, and his repetition of barbarous Latin epigrams was most grating to Parisian ears. Besides, the name of a priest and a jesuit did not now command respect; and the sentiments of austere devotion, which he publicly professed, had grown unfashionable, and were regarded as severely besetting the character of a philosopher. Mirabeau, in his letters from Prussia, mentions Boscovich with a degree of slight bordering on contempt, and warmly recommends it to his court to invite from Berlin the celebrated Lagrange, a mathematician of the very highest order, and blessed with the mildest disposition.

But the geometer of Ragusa was not idle. He applied assiduously to the improvement of astronomy and optics; and his diligence was evinced by a series of valuable memoirs. He revised and extended his former ideas, and struck out new paths of discovery. His solution of the problem to determine the orbit of a comet from three observations, is remarkable for its elegant simplicity; being derived from the mere elementary principles of trigonometry. Not less beautiful are his memoirs on the micrometer, and on achromatic telescopes. But his situation had become extremely irksome; and in 1783, he desired and obtained leave of absence. Two years he spent at Bassano, in the Venetian state, where he published his opuscles, in five volumes, 4to. composed in Latin, Italian, and French, and containing a variety of elegant and ingenious disquisitions connected with astronomical and optical science. During that time he lived with his editor Remondini, and occupied himself in superintending the press. After finishing his task, he came to Tuscany, and passed some months at the convent of Valombrosa. Thence he went to Milan, and issued a Latin prospectus, in which he proposed to reprint the philosophical poem of Stay, enriched with his annotations, and extended to ten books. But very few subscribers appeared; his opuscles experienced a slow sale; and the imperial minister neither consulted nor employed him in some mathematical operations which were carrying on. Every thing but too keenly reminded him that he was no more a favourite of the Italian public. The visions of glory melted away. This mortifying reflexion preyed upon his spirits, and made the deeper impression, as his health was much disordered by an inflammation of the lungs. He sunk into a stupid, lillies melancholy, and after brooding many days, he emerged into a childish insanity, and at last became furiously mad. It was truly pitiable to behold a man of his eminent talents reduced to such an humiliating condition. The Milanese government provided for his custody. During the heat of delirium, he frequently exclaimed, that he would die poor and inglorious. His religious feelings acquired new force, and he seemed to look forward with anxious hope for that distinction in a future world, which he thought was unjustly denied him in this clouded state of existence. In his short lucid moments, or fits of exhaustion, that intervened, he regretted having spent his time in curious speculation, and considered the calamity with which he was visited as a kind of chastisement of heaven for neglecting the spiritual duties of his profession. In this temper of resignation, his imposthume burst, and he expired on the 15th of February, 1787. He was interred decently, but without pomp, in the parochial church of S. Maria Pedone. "Such was the exit," says Fabroni, "of this sublime genius, whom Rome honoured as her master, whom all Italy regarded as her ornament, and to whom Greece would have erected a statue, had she for want of space been obliged even to throw down some of her heroes."

The abbé Boscovich was tall in stature, of a robust constitution, with a long pale visage. His temper was open and friendly, but irritable, vehement, and impatient of contradiction. James Boswell, in his amusing *Life of Dr. Johnson*, incidentally mentions, that the English moralist chancing to meet Boscovich in London, had a very keen dispute with him in Latin on some metaphysical topic. There was much heat on both sides; and the Gohah of literature treated the mathematician in his usual bearish manner.

Boscovich was more distinguished by the elegance of his mathematical genius, than for talents of invention. The predilection he entertained for the geometry of the Greeks, led him perhaps to undervalue the modern analysis, and rather to neglect the cultivation of the integral calculus, that astonishing instrument of discovery, which is indispensable in making any great progress in the deeper parts of physical and astronomical science. His example, with similar ones in this country, shows the danger of indulging a taste so laudable in itself, but which has a tendency to circumscribe the powers of human intellect.

The only work of Boscovich that has appeared in English, is his "Elements of the Conic Sections," which was, within these few years, translated, abridged, and somewhat altered by the Rev. Mr. Newton of Cambridge. This little treatise, we are sorry to observe, has not yet received such attention from the public as it well merits. For a view of his theory of matter, see the article *CORPUSCULAR PHILOSOPHY*.

**BOSCUS**, in *Ancient Latin-Writers*, signifies a wood of any kind. It is formed from the Greek, *βόσκος*, *I feed*, as serving for pasture. In which sense, *bosus* amounts to the same with the Italian *bosco*, and French *bois*. *Boscus* is divided into high wood, or timber, called also *salvus*, and *haut-bois*; and coppice, or underwood, *sub-boscus*, or *sub-bois*.

**BOSEA**, in *Botany*, (in honour of Bose, a senator of Leipzig). Linn. 315. Reich. 344. Schreb. 442. Willden. 504. Juss. 83. Gært. 490. Class, *pentandria digynia*. Nat. Ord. *atriplexes*. Juss.

Gen. Char. *Cal.* perianth five-leaved, equal; folioles roundish, concave, erect, thinner at the edge. *Cor.* none. *Stam.* filaments subulate, longer than the calyx; anthers simple. *Pist.* germ ovate-oblong, cuspidate; style none. *Pericarp.* berry globular, one-celled. *Seed* one, round, acuminate.

Eff. Char. *Calyx* five-leaved. *Cor.* none. *Berry* one-seeded.

Sp. B. *yervamora*. A small shrub. Leaves simple, alternate, petioled, ovate, pointed, entire, smooth, with fine purple nerves; flowers reddish, in loose axillary racemes. Cultivated by Mr. Miller before 1728. A native of the Canary islands. La Marck intimates a doubt whether Sloane's Jamaica plant be the same.

**BOSEN**, in *Geography*, a town of Prussia, in the province of Natangen, seated on the Satten lake; 50 miles S. of Konigsberg.

**BOSENBRUNN**, a town of Germany, in the circle of Upper Saxony, and the Vogtland; 3 miles S. W. of Oelsnitz.

◦ **BOSHAM**, a town of Abyssinia, near the source of the river Lebec. N. lat 7° 40'. E. long. 36° 30'.

**BOSHOND**, in *Zoology*, (*Jachhals* vel *boshond*). Boffin-guin, p. 291. The spotted hyæna, *canis crocata*.

**BOSIO, JAMES**, in *Biography*, a native of Milan, who flourished about the end of the 16th century, and being knight-servitor of the order of Malta, conducted its concerns at Rome for a long time with reputation. Disappointed in the expectation of the advancement of his patron, cardinal Petruochini, to the papal chair, he retired and devoted the

remainder of his life to pious exercises. As a writer he is known by his voluminous history of the order of Malta, entitled "Dell' istoria della sacra religione dell' illustrissima militia di san Gioano Gierosolimitano," 3 vols. fol. printed at Rome, in consequence of the arrangement of two cardinals, in 1621, 1629, and 1684. This is the source whence later historians of the order have derived their chief materials. Some idea may be formed of Bosio's understanding and disposition, from the veneration which he manifested to the wood of the real cross, of which he wrote the history from its discovery in the time of Constantine. *Antonio Bosio*, the nephew of the preceding, who was also agent at Rome for Malta, published in 1632, the result of his researches into the vaults and catacombs of Rome in a folio volume, entitled "Roma Sotteranea," a work that contains all the monuments and epitaphs which he could find of the first Christians. An improved edition was published in Latin by Paul Aringhii in 1651. Moreri. Nouv. Dict. Hist.

**BOSLÉ**, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Beaugency; 2 miles N. of Beaugency.

**BOSNA, SERAI**. See *SERAJO*.

**BOSNA**, a river of Bosnia, which passes by Serajo, and joins the Save, 50 miles N. of that town.

**BOSNIA**, called also *Rama*, a province of Turkey in Europe, being a part of ancient Pannonia, or of Turkish Illyricum, and deriving its name from the river Bosna, or from the people called Boseni. It is bounded on the north by the river Save, which separates it from Slavonia, on the east by the Drino, which parts it from Servia, on the west by the Verbas, Croatia, and Dalmatia, and on the south by a chain of mountains, which separates it from Dalmatia. It is about 40 leagues long, and 24 broad; and though mountainous, it is fertile, more especially near the rivers; its arable land producing good wheat, and its pastures feeding many cattle; its mountains contain some mines of silver. Its air, soil, produce, language, and inhabitants, resemble those of Servia. Bosnia and Servia were formerly united to Hungary, and governed by their own princes; but in 1465, the Turks took possession of them; Stephen V. their last sovereign being taken prisoner by Mahomet II. and slayed alive; from that time they have been a province of the Turkish empire, which appoints beglerbeys and sangiacs over them. Bosnia is chiefly inhabited by Greek Christians, together with some Mahometans, Jews, and Catholics. Its principal towns are Banjaluka, Orbach, Serajo, and Zwernick.

**BOSOK**, a town of Hungary, 3 miles E. of Baia.

**BOSON**, in *Conchology*, the *turbo muricatus*, so called by Adanson.

**BOSOWKA**, in *Geography*, a town of Poland, in the palatinate of Braclaw. N. lat. 49° 20'. E. long. 30°.

**BOSPHORICUM Marmor**, a name given by the ancients to a species of marble, of a yellowish white colour, with beautiful veins of a somewhat darker hue; called also, from its transparency, *phengites*.

**BOSPHORUS**, or **BOSPORUS**, formed from *βος*, *bos*, and *πορος*, *passage*, in *Geography*, a long and narrow sea which it is supposed a bullock may swim over; in a more general sense, a long narrow sea running in between two lands, or separating two continents, and by which two seas, or a gulf and a sea, are made to communicate with each other.

In which sense bosphorus amounts to the same with what we otherwise call an arm of the sea, channel, or strait; the Italians, *favo*; the Latins, *fretum*, and the French *pas*, *manche*.

The name *bosphorus* is chiefly confined to two straits, in

in the Mediteranean sea, viz. the "Bosphorus of Thrace," commonly called the "Streights of Constantinople," or "Channel of the Black Sea;" and the "Cimmerian, or Scythian Bosphorus," so called, it seems, from its resemblance to the Thracian: now more commonly the "Streights of Caffa," which unites the sea of Azof with the Euxine or Black Sea.

The origin of the name is better agreed on than the reason why it was first given to the Thracian Bosphorus. Nymphius tells us, on the authority of Accarion, that the Phrygians, desiring to pass the Thracian streight, built a vessel, on whose prow was the figure of a bullock, and which was hence called *Βουξ*, *bullock*; and which served them for a ferry-boat.—Dionysius, Val. Flaccus, Callimachus, Apollodorus, Marcellinus, &c. say, that Io, being transformed into a cow by Juno, passed this streight swimming, which hence was called Bosphorus.—Arrian tells us, that the Phrygians were enjoined by the oracle, to follow the route which a bullock should mark out to them; and that upon stirring one up, it jumped into the sea to avoid their pursuit, and swam over this streight. Others say, that an ox, tormented by a gad-fly, threw itself in and swam over; and others, that anciently the inhabitants of these coasts, when they would pass over, joined little boats together, and had them drawn over by bullocks, &c.

Some late writers rather suppose Bosphorus to have been so called, because here was anciently the beast-market. Tournef. Voyag. tom. ii. let. 12. and 14.

The "Thracian Bosphorus," called also the "Myrsian Bosphorus," because the Mysians inhabited the country opposite to Thrace, connected the Euxine with the Propontis, or present sea of Marmora, and formed a winding channel, separating Europe from Asia, through which the waters of the Euxine flow, with a rapid and incessant course, towards the Mediterranean. This streight has been very minutely described by Dionysius of Byzantium, who lived in the time of Domitian, (See Hudson's Geograp. Minor. tom. iii.) and by Gilles or Gyllius, a French traveller of the 16th century. On the steep and woody banks of this channel the ancients profusely scattered a crowd of temples and votive altars, attesting the unskilfulness, the terrors and the devotion of the Greek navigators, who, after the example of the Argonauts, explored the dangers of the inhospitable Euxine. On these banks tradition long preserved the memory of the palace of Phineus, infested by the obscene harpies, which Le Clerc conjectures to have been only locusts; and of the Sylvan reign of Amycus, who defied the son of Leda to the combat of the Cestus. The residence of Amycus was in Asia, between the old and the new castles, at a place called Laurus Infana; and that of Phineus was in Europe, near the village of Mauromole and the Black Sea. The streights of the Bosphorus are terminated by the Cyanean rocks, which, as the poets described them, had once floated on the face of the waters; and were destined by the gods to protect the entrance of the Euxine against the eye of profane curiosity. At present there are two small islands, one towards either shore; that of Europe being distinguished by the column of Pompey. From the Cyanean rocks, to the point and harbour of Byzantium, the winding length of the Bosphorus extends about 16 miles, and its most ordinary breadth may be computed at about  $1\frac{1}{2}$  mile. According to the statement of Olivier, (Travels in the Ottoman Empire, p. 77.) it is nearly 7 leagues long, and about 20 miles from the point of the Seraglio of Constantinople to the Cyanean islands. In its greatest breadth it is not two miles; and in several places it is so narrow, that some ancient authors say, that a person may hear the birds sing from one shore to the other, and that

two persons may hold a conversation across the channel. Herodotus, Polybius, and Arrian estimated its length from the temple of Jupiter to the city of Byzantium at 120 stadia, or 15 Roman miles, i. e. 13 miles 5 furlongs and 191,336 yards in English measure. Its breadth was various. At its entrance they reckoned it 4 stadia, or 805 yards; and at the other extremity 14 stadia, or 2825 yards. But the ancients, as well as the moderns, differ very much about these measures. In certain places its waters formed large basons and deep bays. The new castles of Europe and Asia are constructed, on either continent, upon the foundations of two celebrated temples of Serapis and of Jupiter Urius. The old castles, erected by the Greek emperors, command the narrowest part of the channel, in a place where the opposite banks advance within 500 paces of each other. Mahomet II., when he meditated the siege of Constantinople, restored and strengthened these fortresses; but he was not apprized, that near 2000 years before his reign, Darius had chosen the same situation to connect the two continents, by a bridge of boats, and thus to transport 700 thousand men against the Scythians. At this place the crusaders entered Asia, when they prosecuted the scheme of rescuing the holy land from the yoke of the Mahometans. At a small distance from the old castles, we discover the little town of Chrysopolis or Scutari; and as the Bosphorus begins to open into the Propontis, it passes between Byzantium and Chalcedon.

The harbour of Constantinople may be considered as an arm of the Bosphorus, and in a very remote period obtained the denomination of the "Golden Horn," from the resemblance which the curve it describes bears to the horn of a stag, or rather of an ox, with the epithet golden, expressing the riches which every wind wafted from the most distant countries into the secure and capacious port of Constantinople; which see. From the mouth of the Lycus, formed by the conflux of two small streams, and supplying the harbour with fresh water, by which the bottom of the harbour is cleansed, and shoals of fish are invited to make it their retreat, to that of the harbour, this arm of the Bosphorus is more than seven miles in length: the entrance is about 500 yards broad, and a strong chain might be occasionally drawn across it, to guard the port and city from the attack of an hostile navy. The navigation from the issue of the Bosphorus to the entrance of the Hellespont is about 120 miles. See HELLESPOINT, and PROPONTIS.

The "Cimmerian Bosphorus," now called the streights of Caffa, derived its name from the "Cimmerians," a people who inhabited the adjacent country; separated between Cherfoncus Taurica, belonging to Europe, and the territories of Asia; and joined the Euxine sea, with the Palus Mæotis. Its breadth is about 4 leagues. See *Sea of Azof*.

BOSPHORUS, or *Cimmerian Bosphorus*, the name of an ancient kingdom, comprehending all the provinces that were subject to the Bosphoran princes, and bounded on the east by Colchis, on the west by the gulf Carcinites, on the south by the Euxine sea, and on the north by the Tanais, where that river falls into the Palus Mæotis; so that it comprised the Cherfoncus Taurica in Europe, and in Asia the whole tract which lies between the Palus Mæotis and the Euxine sea. Diodorus Siculus (l. xii.) confines the kingdom of Bosphorus within the Bosphorus Cimmerius, the boundary of Europe and Asia on that side; but Strabo (l. vii.) extends it to the gulf Carcinites, which, with the Palus Mæotis, forms the isthmus of the Cherfoncus. The chief cities of the Asiatic Bosphorus were Phanagoria, the metropolis of Bosphorus in Asia, according to Strabo, Cepi, Hermonassa, Stratoclea, Cim-

Cimmerium, Situla on the Palus Meotis, Tanais at the mouth of the river bearing that name, where the city of Azof now stands, Papiardis, Tyranché, and Gerafum, called by Ptolemy a Cimmerian village. The country bordering on the Palus Meotis and the Bosphorus, which was inhabited by the Cimmerii, is represented by the ancients as inhospitable, covered with thick forests and continual fogs, through which the rays of the sun could not penetrate. See CIMMERII.

The Bosphorani were governed by their own princes in the earliest times; but the history of them by Trogus Pompeius is lost, so that little certainty is known concerning them. The first recorded in history, and mentioned by Strabo, (l. vi.) was Leucon; and he was succeeded by several others, whose history is involved in great obscurity. The kingdom of Bosphorus, as we are informed by Diodorus Siculus, was voluntarily surrendered by Parisades III. to Mithridates the Great, king of Pontus, after it had been held by his ancestors for the space of 400 years. In the time of the last Mithridatic war, the Bosphorani revolted from Mithridates, and admitted Roman garrisons into the cities of Phanagoria, Theodosia, Chersonesus, and Nymphæum; but upon the death of that prince, the whole country was restored by Pompey to his son Pharnaces, whom he honoured with the title of friend and ally of the Roman people. During the civil war between Cæsar and Pompey, Pharnaces, not satisfied with the kingdom of Bosphorus, attempted the recovery of his father's dominions; crossed the Euxine sea, and reduced Colchis, Armenia Minor, and several places in Cappadocia, Pontus, and Bithynia. After the battle of Pharfalia, Cæsar sent against him a considerable force under the command of Domitius Calvinus; Domitius being overcome in battle, Pharnaces made himself master of the remaining part of Pontus and Cappadocia, and of all Bithynia; but as he was advancing into Asia, properly so called, Cæsar left Egypt, traversed Syria, and came unexpectedly upon Pharnaces, and gained a complete victory. After this defeat Pharnaces fled to Sinope, and from thence sailed back into Bosphorus; where, upon his landing, Afander, whom he had appointed governor of that country during his absence, seized and put him to death, and took upon himself the title of king of Bosphorus. Cæsar, however, conferred the kingdom of Bosphorus on Mithridates the Pergamian, in recompence of services which he had performed in Egypt. But in endeavouring to secure the possession of it, he was vanquished and slain in battle by Afander, who, after his death, held the kingdom without any farther molestation. Afander, being disgusted by the emperor Augustus, who gave the command of the Bosphorean troops that served in the Roman army to Scribonius, abstained from all food, and thus ended his life in the 93d year of his age. Upon his death Scribonius, pretending that he was the grandson of Mithridates, and marrying Dynamis, the daughter of Pharnaces, took possession of the Kingdom of Bosphorus, but was expelled from it by Polemon, on whom the kingdom had been bestowed by Augustus. Polemon was succeeded by his son Polemon II.; who exchanged the kingdom, in the reign of Claudius for part of Cilicia. Trajan, as Eutropius informs us, took the king of Bosphorus under his protection; and Lucian tells us, that the Bosphorani, in his time, had a king named Eupator; but we have no record of the period previous to the division of the Roman empire in which this kingdom terminates.

**BOSPHORUS**, *Promontory of*, was a promontory of Thrace, at the entrance of the harbour of Byzantium, situate on the Thracian Bosphorus, near the Propontis, and N. W. of the promontory of Chalcedon in Asia Minor.

**BOSPHORUS**, a city of Chersonesus Taurica, seated near the Cimmerian Bosphorus, and supposed by some writers to have been the same with Panticapæum, which, according to Strabo, was the metropolis of the European Bosphorus. But Pliny, Eutropius, and Stephanus Byz., speak of them as two different cities. Strabo and Ptolemy take notice of Panticapæum, but say nothing of Bosphorus; but Procopius often mentions the latter, but never takes notice of Panticapæum; from which circumstance it has been inferred, that these two names belong, at different periods, to the same city; Panticapæum being its most ancient name, recognized by Pliny, Strabo, and Ptolemy, and Bosphorus the name given to it by Procopius. Pliny, however, says, that some persons called it Bosphorus, and that, in its origin, it was a colony of Milesians.

**BOSPHORUS**, a town of India. Steph. Byz.—Also, the name of a town placed by Suidas towards the Hellespont, which was ravaged under the empire of Justinian.

**BOSQUET**, FRANCIS, in *Biography*, one of the most learned prelates of France in the 17th century, was born at Narbonne, in 1605, and educated at Toulouse. Before he assumed the ecclesiastical profession, he exercised various civil employments, viz. those of intendant of Guienne and of Languedoc, solicitor-general to the parliament of Normandy, and counsellor of state. But, in 1648, he was nominated bishop of Lodeve, and entrusted by the king with the management of the national concerns; and in 1657 took possession of the bishopric of Montpellier, in which situation he continued till his death in 1676. He was held in high estimation, for his learning, piety, and charity. As an author, he acquired betimes a considerable degree of reputation by his Latin translation, with notes, of the synopsis of civil law, composed in Greek verse by Michael Pfellus. He also wrote a "History of the popes, who resided at Avignon," from 1305 to 1394; and published several epistles of pope Innocent III. with learned notes. But his principal work was, a "History of the Gallican church, in the reign of Constantine," written in Latin, and published with considerable augmentations in 1636, 4to. but with the omission of some liberal and spirited reflections on the fictions and errors introduced into the early accounts of the Gallican church. He also left behind him some MS. observations on the liberties of the Gallican church, and some notes on the canon law. Gen. Dict.

**BOSQUET**, in *Ornamental Gardening*, is a term applied to detached clumps or other parts of gardens, pleasure or ornamented grounds, planted with a variety of deciduous evergreen trees, and shrubs, and herbaceous perennial flowers, either in a regular or irregular manner. They should be laid out in form suited to the nature, extent, and particular circumstances of the ground, so as to produce the greatest possible variety and effect; some being made circular, others oval or oblong, and with bending sweeps or swells outwards or inwards, and longer or smaller as may be necessary. They may be disposed with the greatest effect on the confines of extensive lawns, or other open spaces in grass; also in parks, paddocks, the terminations of spacious avenues and carriage ways leading to the houses, especially where of considerable dimensions, being varied in situation, and distributed at such distances as to leave large intervening spaces of open land in grass.

In the planting of compartments of this nature, in order to produce the best effect, much attention should be bestowed in regulating the sizes of the plants, their shades, and times of flowering, as well as in the disposing them in the order of their different growths, so that they may rise regularly from the sides to the centres, and display themselves in

the best and most advantageous manner in their heads and branches. It was formerly the practice to plant trees and shrubs of the deciduous and evergreen kinds, chiefly together in separate patches, but by a judicious mixture of both sorts a great richness and variety of effect are produced; various sorts of tall herbaceous perennial plants, as well as low flowering ones, may be introduced on the sides and edges, such as those of the golden rod, and other similar kinds, with daffodils, violets, polyanthus, primroses, and many others of the same sort.

In the less extensive kinds of ornamented grounds these sorts of bosquets should always remain perfectly open and wholly exposed to view, in order that the full variety of the plants may be shown; but in extensive parks, and other similar grounds where they are chiefly planted with the more large and coarse hardy trees and shrubs, they may be inclosed with open hurdles to defend them from the cropping of cattle or other animals, especially until they have acquired a sufficiently hardy and large growth.

These clumps, after being thus planted, only require the earth among the plants to be slightly dug over in the autumn, or very early spring, and once or twice hoed over in the summer to keep weeds from rising; the dead wood and irregular branches of the different plants or trees being cut out, shortened, and removed, to preserve them distinct and keep them in order. See CLUMP.

When well arranged and kept in neat order these sorts of bosquets or clumps produce much diversity and ornamental effect, both in large gardens and pleasure grounds.

BOSRA, in *Geography*, a town of Arabia Petrea, sunk into decay and inconsiderable note, though it is considered as the capital of the country. It is seated in the midland, on the back of Palestine, on the other side Jordan, and about 150 miles from the lake, or sea, of Galilee. See BOSTRA.

BOSS, or BOSSE, in *Sculpture*, signifies relievè, or prominence. The word is French, *bossè*, which signifies the same; whence also to emboss. See EMBOSSE.

Boss of a buckler, among the *Ancients*, the *umbo*, or *μυρσιν*, which juts out in the middle.

Boss, among *Bricklayers*, denotes a wooden utensil where-in the labourers put the mortar to be used in tiling. It has an iron hook, whereby it may be hung on the laths, or on a ladder.

BOSS, GASPAR VANDER, in *Biography*, a painter of ships, sea-views, calms, and storms, was born at Hoorn, in 1634, and manifesting an early genius for the art of painting, applied with assiduity to the study and practice of it, and distinguished himself by the excellence of his composition, by a light free touch, by an agreeable tint of colour, and by a very artful manner of handling. His application was so intense as to impair his health, so that he died much regretted at an early age in 1666. Pilkington.

BOSSAGE, in *Architecture*, a projecting stone, laid rough in building, to be afterwards carved into mouldings, capitals, arms, or the like.

BOSSAGES, also denote stones which seem to advance beyond the naked of a building, by reason of indentures, or channels left in the joinings; used chiefly in the corners of buildings, and thence called rustic quoins.

The cavities or indentures are sometimes round, sometimes square, sometimes chamfrained, or bevelled, sometimes in the diamond form: sometimes they are enclosed with a cavetto, sometimes with a listel.

BOSSCHART, THOMAS WILLEBORTS, in *Biography*, a painter of history and portraits, was born at Bergen-op-zoom, in 1613, and studied at Rome under Gerard Segers,

with whom he continued four years. His taste of design was fine and correct, his touch free and spirited, his colouring transparent and true, and his carnations possessed so much softness and life, that he was thought to approach near to Vandyck in portrait and history; and his works were eagerly purchased. His merit recommended him to the patronage of the prince of Orange, in whose service he was employed for several years. The large picture of "War and Peace," at the Hague, and the "Martyrdom of St. George," in the great church, are much commended for goodness of expression, for excellent colouring, and for being exquisitely finished. Pilkington.

BOSSÉ, ABRAHAM, a French engraver, was born at Tours, and flourished in 1630. In his performances he successfully imitated the coarser manner of Callot; and most of his works are executed from his own designs. The figures, with which he commonly embellished his plates are drawn in a spirited style, and etched with great freedom. He afterwards retouched the etching with the graver in a bold, expeditious manner. The effect of his plates is clear and pleasing, though his lights are usually too much feathered. He was most successful in small subjects. We have a treatise by him "On the art of drawing;" the best edition of which is said to be that with the additions and corrections of M. Cochin; "The school of the painter and sculptor;" "The workshop of a copper-plate printer;" "The school-maister and misters;" and several other plates from his own designs; and also, "The history of the Maid of Orleans," from the designs of Vignon, &c. &c. Strutt.

BOSSEE, in *Geography*, a town of Germany, in the duchy of Holstein; 6 miles E. S. E. of Rendsburg.

BOSSIAEA, in *Botany*, Willden. 1242. Class, *diadelphia decandria*.

Gen. Char. Cal. bilabiate, upper lip obcordate. Cor. banner biglandular at the base: keel two-petalled. *Pericarp*, legume peduncled, compressed, many-seeded.

Species, *B. heterophylla*. Ventenat. A shrub two feet high. Branches compressed. Leaves alternate, smooth, petioled, the lower elliptic, the upper lanceolate. Peduncles one-flowered, axillary. Banner and rings yellow. Keel purple. A native of New Holland.

BOSSINEY, in *Geography*, an ancient borough of Cornwall, in England, is reduced from its original consequence, and now consists of only a few miserable cottages; yet some of the occupiers of these dwellings have the power of electing two members of parliament. This place, with many other towns in the county, was made a chartered borough by Richard earl of Cornwall, brother of Henry III.; but the town has never been incorporated. The right of election is vested in all persons who possess lands within the borough, and live in the parish, but this number is now reduced to five or six.

Bossiney is in the parish of Tintagel, where are the remains of a castle occupying a very singular situation. The fortress stood partly on the main land and partly on a bold flat promontory, which was separated from the shore by an immense chasm in the cliff, over which there was formerly a drawbridge. What remains on the peninsular part is a circular ruinous wall, which incloses some buildings that appear to have been the keep. Beneath is a passage through the rocks, where boats could pass at the time of high tides. From the extent and character of the ruins it is presumed, that this fortress has been a place of great strength and security. It is asserted by many writers, that it was the birth-place of the celebrated British king, Arthur, but this assertion is not satisfactorily substantiated. See ARTHUR. The bold, stupendous cliffs about Tintagel, and along the northern coast

coast of Cornwall, cannot fail to excite emotions of admiration and terror in the minds of most spectators.

From Tintagel to Boscastle the road winds through various rocky chasms. The latter village is seated at the bottom of a deep valley, washed by a small inlet of the sea, whilst mountainous eminences encircle it. This place was formerly noted for a castle, built by one of the Botreaux family; but no fragments are now remaining. History of Boroughs, vol. i. 8vo.

BOSSO, MATTHEW, in *Biography*, an ecclesiastic distinguished for his learning and virtues, was born at Verona, in 1428, and educated first at Milan, and after his admission into the congregation of canons regular of the Lateran, at Padua. His merit advanced him to several eminent offices in his order; and at Fiesole, where he superintended the canonry of St. Bartholomew, he became acquainted with Lorenzo de Medici, who appointed him his confessor; and it was from his hands, and in his church that John, the son of Lorenzo, afterwards pope Leo X. received the insignias of the cardinalate. He was offered a bishopric by pope Sixtus IV. for his services in checking the disorders that prevailed in the nunneries of Liguria, and the adjacent provinces, but refused to accept it. After having five times sustained the office of visitor, and twice that of procurator-general of his order, he died at Padua in 1502. Of his works the principal are the following, viz. "De salutaribus animi gaudiis;" "De instituyendo sapientia animo;" "De tolerantis adversis;" "De gerendo magistratu;" "De immoderato mulierum cultu;" and a collection of letters and small pieces, entitled "Recuperationes Fesulanæ," printed at Bologna, in 1493, and furnishing one of the finest specimens of typography of the 15th century. Gen. Dict. Roscoe's Lorenzo de Medici, vol. ii.

BOSSON, in *Geography*, one of the five glaciers of Switzerland, that stretch towards the plain of Chamouny, and unite at the foot of Mount Blanc. See GLACIER.

BOSSU, RENÉ LE, in *Biography*, a polite scholar and eminent critic, was born at Paris in 1631; and having received the rudiments of his education at Nanterre, he was admitted a canon regular in the abbey of St. Genevieve, at the early age of 18 years, and pursued the study of philosophy and divinity. After having received priest's orders, in 1657, he indulged his inclination to the Belles Lettres, and devoted himself for several years to the employment of teaching them. At length he retired to pass his time in tranquil study at the abbey of St. Genevieve; and in this retreat, where he was sedulously employed, published his "Parallel of the philosophy of Descartes and of Aristotle," and his more popular "Treatise on epic poetry." He also published a small piece in favour of Boileau against St. Sorlin; but the greater number of his compositions remain in MS. at the abbey of St. John, at Chartres, of which he was made sub-prior in 1677. He died in 1680. Bossu was distinguished by a sound judgment, well regulated, but lively imagination, and a mild, benevolent character. His work on epic poetry furnishes many judicious rules, of which however, Voltaire says, that they will never make a poet. It was left in an imperfect state; the author having intended to exemplify his rules from Horace and Virgil. The best edition is that of the Hague, in 1714, with a memoir on the life and writings of the author by father Courayer. Gen. Dict.

Bossu, in *Geography*, an island about 3 or 4 leagues N. E. from Trinity Point, on the north coast of the gulf or river of St. Lawrence.

BOSSUET, JAMES BENIGNUS, in *Biography*, a famous French divine, celebrated for popular eloquence, for his ta-

lents as a controversial divine, and for his elaborate vindication of the Roman catholic faith, was born at Dijon in 1621; and having for some time pursued his studies under the care of the Jesuits, who wished him to enter into their order, he was released from them by the interposition of his uncle, and in 1642 sent to Paris to finish his studies at the college of Navarre. As he had devoted himself to the clerical profession, theology was the object of his particular attention; and his favourite author was Augustin. To the study of polite literature he dedicated a portion of his time; and whilst he was a professed admirer of Homer, he disapproved the introduction of mythology into modern poetry. And though the range of his studies was very extensive, he disregarded mathematics from a preconceived notion, that they would not contribute to make him a sounder divine, or a more eloquent preacher. The philosophy of Descartes recommended itself to him by its novelty, and he adopted it, notwithstanding the reproach and persecution which it underwent. After completing his theological course, he received the degree of doctor of the Sorbonne in 1652, and then removed to Metz, when he was appointed canon of the church. Here he wrote his first polemic piece, which was a refutation of the catechism of a Huguenot minister of that town, with whom, however, he lived on terms of uninterrupted friendship. Upon his return to Paris, his eloquence as a preacher recommended him to royal patronage. In 1661, he preached before the king, and his conduct during his residence at Versailles was suited to the dignity of his profession. He soon obtained, without any solicitation on his own part, the bishopric of Condom; but when he was appointed preceptor to the dauphin, in 1670, he resigned this preferment, and devoted himself entirely to the discharge of the duties of this honourable and important office. In this situation he composed for the use of his pupil, his discourse on universal history, which, notwithstanding some objections that have been urged against it, is considered as his principal performance, and much more instructive and useful than all his theological and controversial writings. As soon as he had completed the education of the prince, Lewis XIV. advanced him, in recompence of his attention to this object, in 1681, to the see of Meaux; and in this situation of greater leisure, he employed himself in the defence of the church against both infidels and protestants. In his polemic writings he displayed much logical acuteness and dexterity in illustrating the doctrine of the church, and the variations subsisting among protestants; and he deduced his chief arguments in favour of the former, and in opposition to the latter, from the antiquity and unity of the churches; the authority of fathers, councils, and popes, during a long series of ages; the novelty of the pretensions of the reformers; the necessity of an umpire in the province of religion for settling disputes, explaining the scriptures, and maintaining order and peace; and the necessity of submitting to such an umpire, in order to prevent that dis-union and variety of sects, each professing its right to interpret the divine word, and claiming the honour of being the true church, which disgraced the cause of the protestants. The latter were ably defended by the French Calvinists, and particularly by the celebrated Claude, to whom, in the controversy, some even of the catholics have allowed the superiority. Leibnitz also became a party in the dispute between the protestants and papists, and recommended, for the sake of unity and peace, mutual concessions. But Bossuet remained inflexible, and conceded only that the sacramental cup might be allowed, as a matter of favour, to the laity. He was, however, no advocate for the infallibility of the pope, or for his assumed right of deposing kings; but zealously opposed both these claims,

claims, when urged by Innocent XI. against the independence of the crown, and the liberties of the clergy of France. The consequence of his opposition was the loss of the cardinal's hat, which the pope offered him as an inducement to his desisting from prosecuting this dispute.

Bossuet, not content with writing on general subjects, such as the defence of the Christian religion, the catholic faith, and the Gallican church, undertook to refute the notions of the amiable Fenelon concerning quietism; either because he considered these notions as erroneous and dangerous, or because he wished to degrade in the general estimation the character of a person, whom he regarded as a rival. Fenelon complained of the harshness with which he was treated; and such indeed were the impetuosity and zeal with which he entered into this dispute, that being once at court he maintained his opinion with a degree of ardour, which led the king to say to him, "What would you have done, if I had taken part with Fenelon against you?" Bossuet replied with great spirit; "I would have spoken ten times as loud." On another occasion, however, he was less disposed to give offence; for though he had condemned theatrical exhibitions, to which Lewis was addicted, yet being asked, what he thought of attending them, he replied with a considerable degree of address, "For it there are great examples, and against it strong arguments."

Of his talents as a speaker Bossuet exhibited a specimen that was much admired, at the early age of 16; and as to his style of preaching, it was lofty, free, animated, and energetic. As he possessed a retentive memory, he seldom wrote down more than the heads of his discourses, and supplied the intervals extempore, but as the result of previous meditation. Hence it happens, that his printed sermons are rather bold and masterly sketches than finished compositions; and however much they have been admired, they are far excelled by the discourses of Massillon and Bourdaloue. But his funeral orations are considered as surpassing all others with respect to sublimity and pathos. Of the seven which he delivered and published, the three that have claimed pre-eminence are those for the queen of England, widow of Charles I., in which is introduced a fine delineation of Cromwell's character and politics; for the duchess of Orleans, sister to Charles II.; and for the famous prince of Condé.

In the exercise of his episcopal and pastoral functions Bossuet was entitled to great respect and commendation. He was eminently distinguished by his attention to the duties of his office; by his diligence in communicating instruction to the ignorant, and comfort to the afflicted; and by the exercise of an exemplary hospitality to the indigent. In his clerical visits he paid particular attention even to peasants and children. Whilst he was thus amiably employed, he closed a studious and dignified life, in the year 1704. It ought to be recorded to his honour, that, though he was a zealous advocate for the doctrines of the church of Rome, he was no friend to persecution, and expressed his disapprobation of the severity exercised toward the Huguenots. Nevertheless, it does not appear that he ever represented to the king the injustice, cruelty, and impolicy of this conduct.

"The behaviour and manners of Bossuet always commanded respect, but they often betrayed haughtiness, a domineering disposition, and a high opinion of himself; and shewed he had but little of that spirit of meekness and gentleness, which in the archbishop of Cambrai was joined to every virtue that inspires veneration. The difference of their characters is easily discerned in their writings. In those of Bossuet, the reader admires vigour of mind and strength of rea-

soning; in those of Fenelon, he feels the persuasive power arising from the union of a fine genius with genuine benevolence. Accordingly, the former has been said to have demonstrated the truth, and the latter to have exhibited the amiableness of religion."

Of the works of Bossuet a collection was made in 1743, in 12 vols. 4to. to which was added, a supplement of 5 vols. 4to.; and the Benedictines of St. Maur have published 12 vols. of a new and improved edition. He also wrote in Latin a defence of the declaration of the French clergy on ecclesiastical power. Bossuet was a distinguished member of the French academy, into which he was admitted in 1671. *Eloge Academique par d'Alenbert. Nouv. Dict. Hist. Moreri. Gen. Biog.*

BOST, or BUST, in *Geography*, a town of Persia, in the province of Segistan, or Seistan, seated on the banks of the river Heermund, or Hindmend; distant about 75 miles S.W. from Candahar. N. lat.  $32^{\circ} 30'$ . E. long.  $64^{\circ} 25'$ . From this town *Abulfeth Ali Ben Mohammed al Kateb*, one of the most illustrious poets who flourished under the dynasty of the Samanides, derived the appellation of *Al Bostli*. *Herbelot.*

BOSTAN, a town of Asiatic Turkey, in the province of Room, seated in a fertile plain of the same name, watered by the river formerly called "Sarus," and surrounded with mountains, on the northern side of mount Taurus. The town is small; and its inhabitants present a striking contrast to the more polished natives of Syria. Their common dress is a short jacket and a fringed turban. The women, whose complexion is fair and florid, wear on their heads flat pieces of metal, some of silver, and others of copper, according to their rank, which they tie under the chin, and thus shelter their faces from the sun and rain. N. lat.  $38^{\circ} 12'$ . E. long.  $36^{\circ} 28'$ .

BOSTANGI-BASCHI, or *Bostangee Bachi*, in the *Turkish Affairs*, an officer in the grand seignior's household, who has the superintendance of all the gardens, water-works, and houses of pleasure, with the workmen employed in them. The post of bostangi-baschi, or chief gardener, is one of the most considerable in the Turkish court; and his power is very extensive. He has the emperor's ear, and on that account is much courted by all who have business depending at the Porte; he is governor of all the villages on the channel of the Black sea, and has the command of above ten thousand bostangis, or gardeners, in the seraglio, and other places about Constantinople. He represses debauchery, and punishes theft and other offences. But that which gives him the greatest eclat is the honour he has of holding the rudder whenever the grand seignior takes his pleasure on the water, and of accompanying him every where on horseback, whenever he goes out in state. This officer is of the number of the four "Rickab agaleri," or officers of the court, who are obliged to attend the sultan on all solemn occasions; the other three are called "Buyuk-imbrohör," or great equerry, "Kurchuk-imbrohör," or little equerry, and "Capidjilar-kiaiyassi," or great chamberlain. The bostangees are generally sons of Mussulmans; their pay is tolerably good, and they are almost all married. They were established under the reign of the first emperors, and for a long time furnished a nursery of the best soldiers. Those of them who displayed the greatest courage and strength, and more especially the highest degree of fanaticism, were transferred to the janzarics.

BOSTON, in *Geography*, is a large commercial borough-town of Lincolnshire, in England. It stands in that division of the county called Holland, and is nearly surrounded by the fens; the greater part of which having been inclosed and drained, is now appropriated to arable and meadow

lands. Previous to this great national undertaking, Boston had had much of its population and trade; but this event has renovated the town. It stands on the banks of the river Witham, which empties itself into the sea about five miles out of the town. Here is a commodious, well-frequented haven; and formerly a great trade was carried on in the exportation of wool; that being prohibited, the merchants were necessitated to seek for profit in other commodities, and have nearly kept pace in the characteristic commercial spirit of the country, by advancing the population, opulence, and trade of Boston. It is now one of the most considerable towns and ports in the county of Lincoln; and, besides two weekly markets, has four annual fairs.

Boston, according to Bede, was anciently called Botolph's town, from St. Botolph, a Saxon, who founded a monastery here, which, according to the same venerable writer, gave origin to the town. Other writers state, that the Romans had a station here, and in support of this opinion refer to some ancient foundations of buildings, hewn stones, and urns, that were discovered here in 1716. This town sent representatives to three national councils, 11th, 26th, and 27th of Edw. III. and first returned regular members in Edw. VI.'s time. It was incorporated in the last year of Henry VIII.'s reign. The number of voters amounts to nearly 200. About the end of Henry I.'s reign, a man, named Robert Chamberlain, with some accomplices, disguised in the habits of monks, set the town on fire in several places, for the purpose of plundering the inhabitants. Chamberlain was taken, and executed, but refused to impeach his accomplices.

The corporation, by whom the town is governed, consists of a mayor, who is chief clerk of the market, and admiral of the coast, a recorder, twelve aldermen, eighteen common-councilmen, a judge, and marshal of the admiralty, a coroner, two serjeants at mace, and other inferior officers.

The river Witham is navigable at spring-tides for vessels of ten to eleven feet water; and many of them are employed in the corn-trade to London. A communication is opened between this place and Lincoln, by means of a canal; and another cut communicates to Sleaford, Horncastle, &c.

Boston had formerly, besides St. Botolph's monastery, a priory, four friaries, and three colleges. It had also two churches; but that of St. John's is entirely destroyed. The other, dedicated to St. Botolph, is a large, elegant pile of building, with a lofty tower, which is justly admired for the lightness, neatness, and beauty of its various compartments. In the year 1309 was laid the foundation of this structure, which has since proved the pride and boast of the Bostonians. It is 300 feet in height, and is said to be the loftiest tower in England. From its top is a most extensive view over the flat fens of Lincolnshire. The whole height is divided into four compartments, of which the uppermost is formed into an octagon-shaped lanthorn, each side perforated with pointed arched windows, and filled with mullions and tracery. This is attached to the square tower by flying buttresses, terminated by pursled pinnacles. The three other compartments are ornamented with highly decorative windows and tracery; and at each corner are two strong ornamented buttresses. The church, though more ancient than the tower, displays a fine example of English florid ecclesiastical architecture. Large in dimensions, lofty and light in its general character, and richly elegant in the various decorative ornaments of windows, oratories, door-ways, &c. it will be examined with delight by the architectural antiquary. It consists of a nave, chancel, side aisles, south porch chapels, &c.; and is one hundred feet in width, by three hundred feet in length. In the upper part of the nave are twenty-eight pointed windows, between which are fourteen groined arches, with light

spandrels curiously moulded. These, with their interfections and embossments, produce a very beautiful effect, which is improved by the lofty columns and arches that divide the centre from the side aisles.

The general appearance and convenience of Boston have been much improved within the last twenty years. Many obstructions have been removed, and new buildings erected. The market-place is spacious, and is ornamented with a handsome market-cross. In 1772, the corporation built an excellent fish-market, which is abundantly supplied with sea and river fish. Queen Elizabeth gave the corporation a court of admiralty over all the adjacent sea-coast. Vessels arrive here from Stanton's wharf, London, every ten days; and from Hull and Lynn, every spring tide. Several foreign ships trade here in summer with timber, rye, wine, &c. Boston is 35 miles east of Lincoln, and 116 miles N.E. of London. It contains 1252 houses, and 5926 inhabitants. History of the Boroughs of Great Britain, vol. ii. Howlet's Select Views of Lincolnshire, 4to.

Boston, the capital of the state of Massachusetts, in America, the largest town of New England, and the third in size and rank in the United States, lies in N. lat. 42° 23' 15", and W. long. 70° 58' 53". This town, together with the towns of Hingham, Chelsea, and Hull, constitute the county of Suffolk; and it is distant 61 miles S. by W. from Portsmouth, 164 N. E. from New Haven, 252 N. E. from New York, 347 N. E. from Philadelphia, and 500 N. E. from the city of Washington. It is built upon a peninsula of irregular form, at the bottom of Massachusetts's bay, and is joined to the land by an isthmus at the fourth end of the town leading to Roxbury. Its length, including the neck, is 3 miles; that of the town itself is not quite 2 miles; its widest part, 726 yards. The peninsula contains about 700 acres (some say 1000), in which are 2376 dwelling-houses. The number of inhabitants, in 1790, was 18,038; but it has since been much augmented. The town is intersected by 97 streets, 36 lanes, and 26 alleys, besides 18 courts, &c. many of which are irregular and incommodious. State-street is very spacious, and connecting in a line with Long wharf, where strangers usually land, exhibits a flattering idea of the town. Boston contains 19 edifices for public worship; 9 for congregationalists, 3 for episcopalians, and 2 for baptists. The Friends, Roman catholics, methodists, Sandemanians, and universalists, have also one appropriated to each. Most of them are ornamented with beautiful spires, and furnished with clocks and bells. The other public buildings are the state-house, court-house, two theatres, concert-hall, Faneuil hall, gaol, alms-house, work-house, bridewell, and powder magazine. Franklin place, adjoining Federal street theatre, contains a monument of Dr. Franklin, and is reckoned a great ornament to the town. A magnificent state-house is also erected on the fourth side of Beacon-hill, fronting the mall, and overtopping the monument on Beacon-hill. The market-place, in which Faneuil hall is situated, is plentifully supplied with all kinds of provisions, both from the country, and from the ocean, and rivers.

The harbour of Boston is formed by point Alderton on the south, and by Nahant point on the north. It is sufficiently capacious to admit 500 vessels to ride at anchor in good depth of water; but the entrance is so narrow, as hardly to allow two ships to pass a-breast. It is diversified with about 40 islands, the greatest number of which consist of rocks and banks of sand, slightly covered with verdure; but about 15 of them afford excellent pasturage, hay, grain, and agreeable places of resort in summer to parties of pleasure. At the distance of about three miles from the town is Castle-  
island, the fortifications of which, formerly called Castle-

William, defend the entrance of the harbour, and are garrisoned by about 50 soldiers, who guard the convicts, sent hither for hard labour, and chiefly employed in making nails. The light-house stands on a small island at the north entrance of the channel (point Alderton and Nantasket heights being on the south), and is about 65 feet high. In steering for it from cape Cod, the course is W.N.W. when within one league of the cape; the distance from cape Cod to the light-house is about 16 leagues: and from cape Ann the course is S.W. distant ten leagues. A cannon is lodged and mounted at the light-house, to answer signals. Of the islands seven only are within the jurisdiction of the town, and taxed with it; viz. Noddle's, Hog, Long, Deer, Spectacle, Governor's, and Apple islands. The wharfs and quays in Boston are about 80 in number, and very convenient for vessels. Long wharf, or Boston pier, extends from the bottom of State-street 1743 feet in a straight line into the harbour; its breadth is 104 feet, and at the end of it are 17 feet of water at ebb-tide. Adjoining to this wharf on the north, is a convenient wharf, called from its former proprietor, and its form, Minot's T. Here vessels are supplied with fresh water from a well surrounded by salt water, and dug at a great expence. On the north side Long wharf is covered with large and commodious stores; and a canal has been cut, in order to connect this harbour with Roxbury.

In approaching Boston from the sea, it presents a beautiful and picturesque object. It lies in a circular but irregular form round the harbour, and is ornamented with spires, above which the monument of Beacon-hill rises pre-eminent, bearing on its top a gilt eagle, with the arms of the Union; and on its base, a variety of inscriptions commemorating some of the most remarkable events in the late war. Beacon hill is the highest point of land on the peninsula; the common below it contains about 45 acres, refreshed by perpetual breezes; and on its east side is the Mall, a pleasant walk, about 600 yards long, adorned with rows of trees. Charles river, and West Boston bridges are highly useful and ornamental to Boston; and both are erected on Charles river, which mingles its waters with those of Mystic river in Boston harbour. Charles river bridge connects Boston with Charlestown, in Middlesex county, stands on 75 piers, and is 1503 feet long and 42 feet broad. West Boston bridge stands on 180 piers, and is 3483 feet long, and 40 feet wide. Both bridges have draws for the admission of vessels, and lamps for the benefit of evening passengers. Boston has seven free schools, supported at the public expence, in which the children of all citizens are freely admitted; and besides these, many private schools.

The principal societies in the commonwealth hold their meetings in this town; these are the Marine Society, American Academy of Arts and Sciences, Massachusetts Agricultural Society, Massachusetts Charitable Society, Boston Episcopal Charitable Society, Massachusetts Historical Society, Society for propagating the gospel, Massachusetts Congregational Society, Medical Society, Humane Society, Boston Library Society, Boston Mechanic Association, Society for the Aid of Emigrants, Charitable Fire Society, and seven respectable lodges of free and accepted masons.

For the support of the foreign and domestic trade of Boston, which is very considerable, there are three banks; viz. the branch of the United States bank, the Union, and the Massachusetts bank; the latter consists of 800 shares of 500 dollars, equal to 400,000; the capital of the Union bank is 1,200,000 dollars, 400,000 of which is the property of the state. The principal manufactures of Boston consist of rum, loaf-sugar, beer, sail-cloth, cordage, wool and cotton cards, playing cards, pot and pearl-shes, paper-hang-

ings, hats, plate, glass, tobacco, and chocolate. It has 30 distilleries, 2 breweries, 8 sugar-houses, and 11 ropewalks. The number of the different stages that run, through the week, from this town, is upwards of 20; and on the great road between Boston and New Haven, there are constantly employed 20 carriages and 100 horses.

For the government of Boston nine select men are annually chosen; and at the same time are chosen a town-clerk, a treasurer, twelve overseers of the poor, twenty-four stewards, twelve clerks of the market, twelve scavengers, twelve constables, and a number of other officers. Besides those called "trained bands," there are four other military companies in Boston; viz. the ancient and honourable artillery company; the cadets, fusileers, and artillery.

The settlement of Boston took place as early as the year 1631 from Charlestown. It was called by the Indians Shau-mut, and by the settlers from Charlestown Trimountain, from the view of its three hills; and it derived its present name from respect to the Rev. Mr. Cotton, a minister of Boston, in England, and afterwards minister of the first church in this place. In 1727, it was much damaged by an earthquake, and has since frequently suffered severely by fires, its houses having been mostly built of wood. The revolution, whence America dates its independence, commenced at Boston. Morse.

**BOSTON CORNER**, a tract of land adjoining mount Washington, in Berkshire county, and state of Massachusetts, containing 67 inhabitants.

**BOSTON, New**, a township of Hillsborough county, New Hampshire, containing 1202 inhabitants; 12 miles S.W. by W. from Amoskeag falls, 60 miles W. of Portsmouth, and equally distant N.W. from Boston.

**BOSTRA**, **BOTSRA**, **BOSKA**, or **BOZRAH**, in *Ancient Geography*, one of the principal towns of Arabia, and the capital of a canton or province called "Auranite." It was the capital of the eastern Idumæa, and the royal residence of Joba, the son of Zerah, duke of Edom; and in scripture history, it is commonly mentioned as situate in a wilderness, because it stood on the confines of Arabia Deserta. It was, however, in those times to which the ancient biblical history refers, a considerable place; having been made a Levitical city by Joshua, and a city of refuge. It is likewise celebrated by ancient writers and medals; and several of its bishops, at a later period, assisted at some of the ancient councils. It was distant four days' journey from Damascus, had a very strong castle, a gate 20 cubits high, and one of the largest basons or reservoirs in the Levant. It was captured by Alexander the Great after the battle of Issus, and he seems to have been much attached to it; but after his death it became subject to the Seleucidan kings of Syria, until the time of Antiochus Dionysus, when it was conquered by an Arabian prince. Under the reign of Trajan, it was subjected to the dominion of the Romans. At this time it was comprehended in a province of Arabia; and Trajan adorned it with many sumptuous edifices, established it as a new city, and gave the inhabitants permission to denominate it "Trajana." The emperor Septimius Severus enlarged this city, whence some have regarded him as its founder. This prince, or his immediate successors, conferred upon it the names and honours of a metropolis. Under the reign of Alexander Severus, it was considered as a place of importance, on account of its situation on the frontiers of the empire; and it was thought worthy of receiving a Roman colony. In honour of Alexander Severus, it assumed the name of "Alexandrianna." The two principal divinities worshipped at Botra were Bacchus and Urania. Bacchus Dionysus was, according to Diodorus Siculus, the Osiris of

the Egyptians; and this deity was denominated "Dufares" by the Nabatæan Arabs in the vicinity of Bosra. Accordingly, the inhabitants of this city engraved a figure of their god Dufares on their medals at Bosra. There was also a temple of the goddess Urania, which was engraved on a medal of Septimius Severus, and also on one of the empresses Mammæa. The worship of Jupiter Ammon, and of Serapis, was also admitted into Bosra, and they received from the Greeks that of Jupiter Pius or Amicus. The citizens of Bosra regarded Urania as the tutelary deity of their city. The Dufarian games, which were first discovered on medals under the reign of the emperor Philip, were celebrated at Bosra in honour of Dufares, the Bacchus of the Arabians. When Arabia was divided, after the conquest of it by Trajan, Bosra was appointed the metropolis of that part which retained the name of Arabia; and its bishop afterwards became the metropolitan of the ecclesiastical province. See BOSRA.—Another town of the same name, but less celebrated, is mentioned among the Moabite cities, in Jer. ch. xlviii. v. 24.

**BOSTRYCHITES LAPIS**, derived from βοστρυχιζω, *I fold the hair in braids*, in *Natural History*, a name given by some to a stone supposed to contain women's hair included in it: some have understood by it, those pieces of crystal which have accidental foulnesses in them, resembling hair, or pieces of hair, caused by earthy or metalline matter; others call by this name those German agates, which contain either the conservæ or other capillary water plants, or other foulnesses running into their form; the first of these very frequently have the conservæ of great length, and variously undulated and turned about, so as very elegantly to represent a loosely flowing lock of hair.

**BOSTRYCHITES** is also a name given by some authors to a species of pyrites, whose irradiations were supposed to imitate hair.

**BOSTRICHUS**, in *Entomology*, a genus of **COLEOPTEROSUS** insects distinguished by having the antennæ clavated; the club solid; thorax convex, with a slight margin; head insected, and concealed under the thorax. Gmel. Fabr. &c. The species of this genus are capucinus, flavicornis, elongatus, tytophagus, chalcographus, polygraphus, micrographus, bidentatus, scolytus, crenatus, pygæus, ligniperda, piniperda, testaceus, varius, vittatus, minutus, maculatus, bifasciatus, limbatus, fuscus, and pilosus; which see.

**BOSULS**, in *Geography*, a town of France, in the department of the Aveyron;  $3\frac{1}{2}$  leagues N. E. of Rhodéz.

**BOSWELL, JAMES**, in *Biography*, son of Alexander Boswell, lord Auchinleck, one of the judges in the supreme court of session, and judiciary in Scotland, was born at Edinburgh, Oct. 29, 1740, and received the first rudiments of education in that city. He afterwards studied civil law in the universities of Edinburgh and Glasgow; and during his residence in these cities, he formed an intimate acquaintance with some English students, which produced a predilection for their manners, that contributed in a great degree to his future habits and attachments. Ambitious, in early life, of distinguishing himself by his literary talents, he was so fortunate as to obtain the patronage of the late lord Somerville, of which he always retained a grateful remembrance. In 1760, he visited London, to which he became much attached, and where he fixed his principal residence. Here he enjoyed the advantage of cultivating an acquaintance with several persons of literary character, to whom he recommended himself by his attention, and by the urbanity of his manners. Although his father had intended him for the profession of the law, his own inclination led him to wish for a commission in the army; but he gave up this object in deference to lord

Auchinleck's persuasion, and at his desire returned to Scotland; and renewing his attention to the law, pursued a course of regular instruction, and passed his trials as a civilian at Edinburgh. In compliance with his father's wishes, he attended the lectures of an excellent civilian at Utrecht, in the winter of 1762; and afterwards obtained permission to make his grand tour of Europe. During his winter's residence at Utrecht, he visited several parts of the Netherlands, and then commencing his projected travels, he passed from Utrecht to Germany, and pursued his route through Switzerland to Geneva; from hence he crossed the Alps into Italy, paying his respects in the course of his journey to Voltaire at Ferney, and to Rousseau in the wilds of Neuchâtel. In Italy, he associated with lord Mountstuart, to whom he afterwards dedicated his "*Theses Juridicæ*." From Italy he sailed to Corsica, and, traversing the island, he obtained the friendship of Pascal de Paoli, in whose palace he resided during his stay. From Corsica he went to Paris; and returning to Scotland in 1766, he soon after became an advocate at the bar in that country. In the famous Douglas cause, which was at that time a subject of discussion, he published a pamphlet entitled "*The Essence of the Douglas Cause*," which contributed to his popularity. In 1768, appeared his "*Account of Corsica, with memoirs of general Paoli*," which was highly spoken of by Dr. Johnson, and translated into the German, Dutch, Italian, and French languages. His prologue, written in the winter of this year, on occasion of opening the theatre royal at Edinburgh by David Ross, esq. was flattering to the author, and beneficial to the manager, as it secured to the latter the uninterrupted possession of his patent till his death in Sept. 1790. In the celebration of the Shakspeare jubilee at Stratford upon Avon, in 1769, Mr. Boswell took a conspicuous part, appearing at the masquerade exhibited on that occasion, under the character of an armed Corsican chief. In 1783, he published his letter to the people of Scotland, which, according to the opinion given of it by Dr. Johnson, in a letter to the author, "contains very considerable knowledge of history and the constitution, very properly produced and applied." As this letter was sanctioned by the approbation of Mr. Pitt, it was soon followed by another, in which Mr. Boswell displayed his usual energy and political talents. In 1785, he published "*A Journal of his Tour to the Hebrides*," with Dr. Johnson; and in the same year he removed to London, where he was called to the English bar. But his profession seems to have been less the object of his attention than the "*Life of Dr. Johnson*," for which he had been collecting materials from the commencement of his acquaintance with him in the year 1763, to the time of his death, and which was published in 2 vols. 4to. in 1791. Few persons can be supposed to be better qualified for this undertaking than Mr. Boswell; for he had known, and he had familiarly, and almost daily, conversed with Dr. Johnson for more than twenty of the last years of his life; during which, he was happy in the kind regard and unreserved confidence of his venerable friend, who, as we are informed by Mr. B. himself, was fully apprized of his biographical intention, and manifested no disapprobation of it. Of this work, which of course became very popular, it will be sufficient to observe, that it exhibits a faithful history of Johnson's life, exemplified in a variety of anecdotes, that rendered it equally instructive and entertaining. The last literary performance of Mr. Boswell was the preparation of a second edition of this work. Mr. Boswell combined, with considerable intellectual powers, a gay and active disposition; and he often experienced an unaccountable depression of spirits. In one of his gloomy intervals he composed a series of essays under the

title of the "Hypochondriac," which appeared in a periodical publication about the year 1782, and which he once thought of collecting into a volume. Soon after his return from a visit to Auchenleck, he was seized with a disorder which put an end to his life, in Portland Street, June 19th, 1795, in the 55th year of his age. At the close of his journal of the tour to the Hebrides, after having given a sketch of his own character, he introduces, not indeed without an apology, the encomium of Dr. Johnson, whose friendly partiality to the companion of his tour represents him as one "whose attentions would help my inquiry, and whose gaiety of conversation and civility of manners are sufficient to counteract the inconveniences of travel in countries less hospitable than we have passed." He lost his wife, to whom he was married in 1769, in the year 1790, and she left him two sons and three daughters. She was a lady, who to the advantages of a polite education united a superior understanding; and on occasion of her death he honoured her memory with an affectionate tribute. *Biog. Dict.*

**BOSWORTH, MARKET**, in *Topography*, a town in Leicestershire, England; situated on a hill, and celebrated in history as the nearest place of note to the scene of battle between Richard III. and Henry earl of Richmond. The manor anciently belonged to the earls of Leicester, and by a partition came to Saer de Quincy, earl of Winchester, who, in the reign of king John, gave it to Richard de Harcourt, of Stanton Harcourt, in Oxfordshire, whose descendant Richard Harcourt, when lord of the town, obtained from Edward I. the privileges of a market (Wednesday) and a fair. The manor continued in this family till Henry VIII.'s reign, when it came to the marquis of Dorset; and from him, by the earl of Huntingdon, to sir Wolstan Dixey knight, whose heirs are, or lately were, owners of it. Bosworth is 106 miles N.W. from London, and contains 120 houses and 791 inhabitants. The church is large, contains some ancient arms and monuments, and has a beautiful spire; it had five chapels belonging to it. There is a free-school, of which Anthony Blackwall, a learned divine, was master, and Samuel Johnson (afterwards LL.D. so celebrated in the literary world) his usher. Thomas Simpson, the mathematician, was born here in 1710, who, from indigent circumstances, and the business of stuff-weaving, acquired so deep a knowledge of mathematics, as to rank him with the most scientific men of the age, and to raise him to the professorship at Woolwich, and F.R.S. He died at Bosworth, 1761. See SIMPSON. Nichols' History of Leicestershire, see *Market Bosworth*, et seq.

**BOSWORTH, Battle of**, in *History*. This battle, on which the kingdom of England depended, and which terminated the civil war between the houses of York and Lancaster, was fought August 22, 1485, on a large flat plain, called Radmore plain, 3 miles from Bosworth, and 4 miles from Hinckley, between Henry earl of Richmond at the head of 6000 men, and king Richard III. with an army above double that number: about 100 of the former were slain, and about 4000 of the latter. The battle, which lasted little more than two hours, was decided by the death of Richard, as his followers then sought safety in flight, and left Richmond master of the field and kingdom. Richard fought with singular intrepidity; his body, being found among the slain, was ignominiously thrown across a horse, and carried to Leicester, where it was interred in the Grey Friars church. Many relics of this battle have at various times been found by digging and ploughing in the field. These were spurs, rings, armour, cross-bows, arrow-heads, &c. King Richard's well, and Crown hill, where Richmond harangued

his army, preserve the identity of the place. Henry's Hist. of England.

**BOTABA**, in *Geography*, the name of one of the Ladrones, or Marian islands.

**BOTABOTA**, in *Ornithology*, a name given by some writers to that species of sea swallow (*Hirundo fulvula*), whose nests are so famous for soups in China, and in some of the islands in the Indian ocean. See *ESCULENTA Hirundo*. The nests are supposed to be restorative, and greatly provocative to venery; for which last quality it is that the eastern nations in general are so fond of them. See *BIRD'S Nests*.

**BOTAGIUM**, in *Middle Age Writers*, a fee paid for wine sold in *bote*, or *buts*.

Wine that tastes of the cask is called *vinum botatum*.

**BOTALE FORAMEN**, in *Anatomy*, an aperture in the heart of a fœtus, whereby the blood is enabled to circulate, without going into the lungs, or the left ventricle of the heart. See *FUTUS*, *CIRCULATION*, and *HEART*.

**BOTALLUS, LEONARD**, in *Biography*, an eminent physician of Piedmont, flourished about the middle of the 16th century. He was a disciple of Fallopius, and took his degree of doctor in medicine at Padua. It appears by his writings, that he was a diligent observer, and enjoyed a considerable share of practice. That he was in great estimation, appears by his having been made in succession physician and aulic counsellor to Charles IX. Henry II. of France, and to William prince of Orange. He was also skilled in the practice of surgery, having been instructed under his brother in the camp of the prince of Orange, whom he cured of a wound, in which the carotid artery had been injured. His works are, "De curandis vulneribus felopetorum," 8vo. 1560, Venet. This has been frequently reprinted, and continued, for a long time, to be esteemed the most useful manual that had been published on the subject. "Commentarioli duo, alter de medici, alter de ægroti, munere," 1565, Lion, 8vo.; in this he lays down rules for the conduct of the physician, the surgeon, and the apothecary, in their attendance upon the sick. But the work by which he is most known, and which produced an important revolution in the practice of medicine, is his "De curatione per sanguinis missione, de incidendæ venæ, cutis scarificandæ, et hirudinum affigendarum modo," Antw. 1583, 8vo. Though bleeding had always been occasionally used in the cure of diseases, yet in his time it was nearly constantly superseded by purging medicines, or it was too sparingly used, and seldom repeated. Our author made frequent recourse to it, with complete success, he says, in diarrhœa, dysentery, in fever, the plague, and during pregnancy, in which cases it was nearly prohibited. Flattered with the success with which his practice was attended, he became, as he advanced in life, more and more bold and free in the use of the lancet, and has left records of cases, in which he bled his patients ten times, or oftener. He even recommends bleeding in quartan fevers, and in dropsies. The reputation the author acquired, soon procured him proselytes; and bleeding became a general remedy all over Europe: but in no country was it carried to such excess as in France, where the professors of medicine, for their too frequent recurrence to it, were held up to ridicule by Le Sage, in his inimitable novel of Gil Blas. The mania has at length subsided; and bleeding is now considered by them as a valuable, but not as an universal remedy. The works of Botallus were collected, and published under the title of "Opera Omnia," in 1660, at Leyden, by I. V. Horne. Haller. Bib. Med. Pract. et Chirurg. Eloy. Bib. Hist.

**BOTANIST**, a person who understands the nature, history, and distinction of vegetables, on settled and certain principles, and can call every plant by a distinct, proper, and intelligible name. *Linnaei Fundam. Botan. p. i.* See **BOTANY**.

**BOTANOMANCY**, formed of *βότανος*, herb, and *μαντήρ*, divination, a species of ancient divination by means of plants, particularly sage and fig-leaves. The persons who resorted to it, wrote their own names and their questions on leaves, which they exposed to the wind; and as many of the letters as remained in their own places, were taken up, and being joined together, contained the required answer.

**BOTANOPHILI**, among the writers on the subject of vegetables, those who have treated of them, not as botanists, or their natural and established distinctions, but in regard to different applications, as gardeners, physicians, &c.

**BOTANY**, is that branch of natural history which relates to what is usually called the vegetable kingdom, the second of the three grand assemblages into which all terrestrial objects are divided. Its name, *βότανος*, is the Greek word for grass, and is derived from the verb *βόω*, or *βοσκω*, which signifies to feed; because grass is the chief food of those animals which are most useful to man. By a process not uncommon in language, its meaning has been extended to the whole vegetable creation; and, by a familiar figure of speech, it is now employed to denote the natural history of plants.

Botany, as a science, is not confined to the description and classification of plants, as ignorance has often been pleased to represent it, but comprehends many other important particulars. Its various objects may be conveniently arranged under the following general heads.

I. The terminology, or description and nomenclature of the several parts of a plant which are externally visible.

If all natural objects were simple in their form, it would not be easy to distinguish one from another; nor would it be possible to describethem, so as to give a clear and precise idea of them. Hence a boundless variety, connected with general resemblances, is wisely and benevolently made their universal character. Every plant is composed of several parts, which differ from each other in their outward appearance, and which cannot fail to strike the most careless spectator. Many of them also are themselves compound, and are obviously capable of being divided into subordinate parts.

The first grand division, adopted by most botanists, is into the *root*; the *body* of the plant; and the *fructification*. The last, or something equivalent to it, is essential to all plants; the first is visible in almost all; and the second is not wanting in many.

The *root* is stated by Linnæus to consist of the *radicle*, and the *descending caudex*. The *radicle* is that fibrous part which draws nourishment from the earth, and in many plants constitutes the whole of the root. The *descending caudex* is properly part of the stock, or body of the plant, which extends itself below the surface of the ground, as the ascending caudex rises above it. That the ascending and descending caudex have precisely the same nature is evident from the well-known fact, that if a young tree be inserted, what was before the root will produce leaves, while the former stem throws out radicles.

Roots are divided, according to the term of their duration, into *annual*, *biennial*, and *perennial*. The *annual* and *biennial* produce flowers and fruits only once, and then soon die; the former passing through all the stages of vegetable life in one season; the latter throwing out root leaves the first year, but not completing the fructification till the next. The *peren-*

*nial* root has within itself a principle of continued life, and gives being to new flowers and seeds, year after year, to an ind finite length of time. Of the roots that are called *perennial*, some are truly, others imperfectly such. In the true perennial root, the descending caudex and the radicle preserve the same individual organization, and increase in size as long as the plant continues to flourish. The imperfectly perennial, are the bulbous and the tuberous, which perish themselves, after producing the bulbs, the tubers, or the tubercles, which are to be the parents of future plants. See **ROOT**, **CAUDEX**, **BULB**, **TUBER**, and **TUBERCLE**.

The *body* of the plant springs from the root, and is terminated by the fructification. It is called by Linnæus the *herb*, and, according to him, consists of the *trunk*, the *leaves*, the *stipulae*, prods or supports, and the *hybernacula*, or buds; all which will be explained under their respective articles.

The *fructification* is a temporary part of the vegetable, designed to perpetuate the species, by producing a perfect seed, in which is contained the rudiment of a plant, similar to that by which it was generated. Its essential parts are the *stamen* and the *pistil*; the former corresponding with the male, and the latter with the female, in the animal kingdom. The stamen consists of the filament and the anther; the pistil of the germ, or seed-bud, the style, and the stigma. They are generally protected by two coverings; the outward called the *calyx*, and the inward the *corolla*; but in many kinds of plants, either one or the other, and, in some, both of them are wanting. The pistil, in the last stage of its growth, is the parent of the seed, or seeds, which are either naked, or enclosed in a *pericarp*, or seed-vessel. The *receptacle* or base on which the fructification is situated, is commonly considered as one of its parts; and connected with it there is in many plants a visible *nectary*, or honey-cup. See the articles **FRUCTIFICATION**, **STAMEN**, **PISTILLUM**, **CALYX**, **COROLLA**, **SEED**, **PERICARP**, **RECEPTACLE**, and **HONEY-CUP**.

II. The classification or arrangement.

A knowledge of the different parts of a plant must necessarily be gained before it can be described. But amidst the numerous vegetable productions of even a single country, this, of itself, would avail but little. To give a peculiar name to every individual, would be a labour which no invention or diligence can perform; and, if accomplished, would produce a burden which no memory can sustain. It is necessary, therefore, to pursue resemblances and differences through a number of gradations, and to found on them primary and subordinate divisions; either ascending from particulars to generals, or descending from generals to particulars. The former is the method in which science of every kind is slowly formed and extended; the latter, that in which it is most conveniently taught. The number of stages through which these subdivisions should be carried, is either not pointed out by nature, or enough of nature is not known to fix them with precision. They differ, therefore, in different systems, and, unfortunately, corresponding ones have not always been called by the same names. Linnæus has employed four principal divisions, which he has called *classes*, *orders*, *genera*, and *species*; occasionally introducing an intermediate one between the order and the genus, and another between the genus and the species.

A *species* consists of individuals, resembling each other in the form, position, proportion, and general appearance of their several parts, produced from similar individuals, and having a power to produce other individuals of the same kind; or, as it is concisely defined by Jussieu, it is a perennial succession of similar individuals, deriving their origin from a successive

successive generation. These individuals are not, indeed, exactly like each other in every minute respect; such a perfect conformity does not exist in any two individuals, either of animate or inanimate organized nature. But the difference between those of the same species, though sufficiently discernible by the eye, cannot easily be expressed in words. With a strongly marked resemblance in all their parts, there is a perpetual variation in their outline, and other particulars; so that no two individuals, lying one upon the other, will entirely correspond. They are formed after the same model, not cast in the same mould. In the general, an accurate description of all the parts belonging to any individual, will discriminate the whole species. There are, however, some sensible qualities of importance enough to be distinguished by proper names, which are, in many cases, too uncertain to enter into a specific character. Of these, size, colour, smoothness, or hairiness of surface, and luxuriance of one part at the expense of another, are the chief; and they are owing either to difference of soil, climate, particular exposure, and other accidents; or, to artificial cultivation, the most abundant source of perpetual varieties.

A *genus* is an assemblage of species, connected with each other by one or more common characters, but still preserving their specific distinctions.

An *order* is a similar assemblage of genera.

A *class* bears the same relation to its orders; and as it stands at the top of the series, it seizes the most general and most widely diffused resemblances, and comprehends the greatest number of particular differences.

A natural arrangement of the species, genera, orders, and classes, free, in every instance, from heterogeneous combinations, and disturbing no real affinities, is the *ne plus ultra* of classification. It is a consummation devoutly to be wished; it is the point of perfection which every naturalist should labour to approach, though what no one can expect actually to reach. To have formed the idea is no small advance in the progress towards it, and implies a very considerable acquisition of knowledge.

Most of the systems which have hitherto been proposed, are professedly artificial; that is, founded on a few parts of a plant, with little or no regard to the rest. The calyx, the corolla, the sexual parts of the fructification, and the mature fruit, have, each in their turn, been selected for this purpose by different systematic writers. A slight sketch of some of the principal systems will be found below in the history of botany, and a fuller explanation will be given, with critical remarks, under the article CLASSIFICATION. But, as the system of Linnæus is that which has been adopted in this work, we shall now briefly illustrate its general principles.

In this system, the fructification has been justly considered of the first consequence. The characters of the classes, orders, and genera, are accordingly taken entirely from it.

In the greater number of plants, the parts of fructification may be readily discerned by the naked eye, or with the assistance of a common lens; but there are also not a few in which they have not been satisfactorily discovered, or are too minute to be described with sufficient accuracy, for the purpose of systematic arrangement.

In most of those whose parts of fructification have been clearly ascertained and distinctly described, the stamens and pistils are inclosed within the same envelope; or, at least, are absolutely contiguous; but, in some, they are contained in separate flowers, or placed at a distance from each other. In both cases, there is much variety with respect to their number, position, and other circumstances.

On these distinctions the distribution into classes and orders is founded. The characters of the classes are taken ex-

clusively from the stamens; those of the orders, either from the stamens or the pistils, but most generally from the pistils.

The first eleven classes, with the exception of the fourth and sixth, regard simply the number of the stamens, and derive their names from the Greek word *ανηρ*, which signifies a male, or husband, compounded with the numerals, *μους*, alone, or one; *δύο*, two; *τρία*, three; *τέτρα*, four; *πεντε*, five; *εξ*, six; *επίξ*, seven; *οκτώ*, eight; *εννεα*, nine; *δεκα*, ten; *δωδεκα*, twelve.

Class,	1. Monandria.	Flowers with	1 stamen.
	2. Diandria.	- - -	2 stamens.
	3. Triandria.	- - -	3 stamens.
	4. Tetrandria.	- - -	4 stamens, all of the same length.
	5. Pentandria.	- - -	5 stamens.
	6. Hexandria.	- - -	6 stamens, all of the same length.
	7. Heptandria.	- - -	7 stamens.
	8. Octandria.	- - -	8 stamens.
	9. Enneandria.	- - -	9 stamens.
	10. Decandria.	- - -	10 stamens.
	11. Dodecandria.	- - -	12 stamens.

The twelfth and thirteenth classes are called, from the general number of their stamens, *icofandria* and *polyandria* (*εικοσι*, twenty, *πολυς*, many); but their real character depends entirely on the part to which they are attached; for there are *icofandrous* plants which have more, and *polyandrous* ones, which have fewer than twenty stamens.

12. *Icofandria*. Flowers with about twenty stamens attached to the calyx, or sometimes, in part, to the corolla.

13. *Polyandria*. Flowers most commonly with more than twenty stamens, attached to the receptacle.

The fourteenth and fifteenth classes have always two stamens shorter than the rest. Their names are taken from the number of those which are longer, compounded with the Greek word *δυναμις*, power, implying a superior rank or dignity.

14. *Didynamia*. Flowers with two longer stamens.

15. *Tetradynamia*. Flowers with four longer stamens.

The next three classes are determined by the union of the filaments, or lower parts of the stamen, into one or more bundles or brotherhoods. Their names are derived from the Greek word *αδελφος*, brother, compounded with the numerals, one, two, and many.

16. *Monadelphia*. Filaments united into one brotherhood.

17. *Diadelphia*. Filaments forming two brotherhoods.

18. *Polyadelphia*. Filaments forming more than two brotherhoods.

In the nineteenth class the anthers, or superior part of the stamens, are united, and compose a hollow cylinder, through which the style of the pistil passes. It is called *syngenia*, from the Greek word *συγγενεις*, to denote the union of the parts which possess the power of rendering the pistil fertile.

19. *Syngenia*. Anthers united.

The twentieth class is called *gynandria*, from *γυνη*, female, and *ανηρ*, male; it is distinguished by the attachment of the stamens to the pistil itself, and not, as in other flowers, either to the receptacle, calyx, or corolla.

20. *Gynandria*. Stamens on the pistil.

The twenty-first and twenty-second classes consist of plants which have the stamens and pistils in separate flowers, growing from the same or from different roots. Their names are derived from *οικος*, a house, compounded with the numerals, one and two.

# BOTANY.

21. *Monœcia*. Stamiferous and pistiliferous flowers on the same plant.

22. *Diœcia*. Stamiferous and pistiliferous flowers on different plants.

The twenty-third class has been formed for such plants as have some flowers with both stamens and pistils, and others with only stamens or pistils. It is called *polygamia*, from *πολυ*, many, and *γάμος*, marriage, implying a diversity in the mode of connection between the stamens and pistils.

23. *Polygamia*. Different dispositions on the same plant.

The twenty-fourth and last class comprehends all the plants which have inconspicuous flowers, and of which the fructification is consequently, in a great measure, unknown. It derives its name from *κρυπτος*, private, and *γάμος*, marriage.

24. *Cryptogamia*. Flowers inconspicuous.

The principles on which the classes are formed in the sexual system, will be distinctly seen in the following synoptic table :

## SYNOPTIC TABLE OF THE LINNÆAN CLASSES.

Flowers	{	visible	{	Stamens and pistils in the same flower.	{	Stamens and pistils not united in any of their parts.	{	Relative length not regarded	1 stamen - - - -	1. Monœndria.			
									2 stamens - - - -	2. Diœndria.			
									3 stamens - - - -	3. Triœndria.

									Stamens and pistils in different flowers.	{	perfect and imperfect flowers on the same or different plants	stamiferous and pistiliferous flowers on the same plant - -	21. Monœcia.
stamiferous and pistiliferous flowers on different plants - -	22. Diœcia.												
perfect and imperfect flowers on the same or different plants -	23. Polygamia.												
									- - - -	24. Cryptogamia.			

After these twenty-four classes, the palmi are placed in the way of appendix, because their fructification has not hitherto been sufficiently described.

By attending to these few simple and easy characters, the botanical student may readily find out under what class he is to look for any unknown plant, the name of which he is de-

sirous to learn. He is next to inquire to which order of the class it belongs.

The orders of the first thirteen classes are founded entirely on the number of the pistils; and are called monogynia, digynia, trigynia, &c. from *γυνη*, female, or wife, compounded, as in the names of the classes, with the Greek numerals. The styles

styles are to be counted from the base, and not from the upper part, which is often divided into two or more segments, without destroying the monogynous character of the flower. When the styles are wanting, the number of stigmas determines the order.

In the classes didynamia and tetradynamia, none of the genera have more than one style; the characters of the orders are, therefore, taken from the pericarp.

The class didynamia has two orders; the first is distinguished by its naked seeds, inclosed, till ripe, in the permanent calyx instead of a pericarp. Its name, gymnospermia, is derived from *γυμνός*, naked, and *σπέρμα*, seed.

The second has its seeds in a pericarp, and is called angiospermia, from *αγγείον*, a vessel, and *σπέρμα*.

The class tetradynamia has also two orders, distinguished by the form of the pericarp; the first called siliculosa, from *silicula*, a little pod; the second, siliquosa, from *siliqua*, a pod. See *SILICULA*, and *SILIQUA*.

In the classes monadelphia, diadelphia, and polyadelphia, the orders are denominated from the number of the stamens, triandria, pentandria, &c.

In the class syngenesia, the orders are more complex. They are six in number; the first five are distinguished by the epithet polygamia, intimating that the flowers are compound, and consist of numerous florets, or little flowers, seated on a common receptacle.

In the first order, polygamia æqualis, all the florets are equally possessed of stamens and pistils.

In the second, polygamia superflua, the florets of the disk, or central part of the compound flower, have both stamens and pistils; those of the ray or circumference have only pistils, but the latter, as well as the former, produce fertile seeds.

In the third, polygamia frustranea, the florets of the disk have both stamens and pistils; those of the ray, neither one nor the other, or only abortive pistils.

In the fourth, polygamia necessaria, the florets of the disk have efficient stamens, but abortive pistils; those of the ray, fertile pistils impregnated by the stamens of the disk.

In the fifth, each floret has its own calyx, in addition to that which surrounds the common receptacle, and forms the whole into one compound flower.

The sixth differs from the rest in having only simple flowers, referred to this class on account of the union of their anthers. It has been lately abolished by the general consent of botanists, and the plants formerly included in it have been referred to the class pentandria.

In the classes monœcia and diœcia, the orders have the same names as the preceding classes, and are distinguished by the number of the stamens, or by the union either of the filaments or of the anthers, or by the attachment of the stamens to the pistil.

The orders of the twenty-third class are denominated from the number of houses or plants on which the several kinds of flowers are found.

In the order monœcia, there are some flowers with stamens and pistils, and others that have either only stamens or only pistils on the same plant.

In the order diœcia, they are perfect, and only stamiferous or perfect, and only pistiliferous flowers on two distinct individual plants.

In the order triœcia, the different kinds of flowers are distributed among three distinct individual plants.

The class cryptogamia is divided into four great families:

1. Filices, or ferns.
2. Musci, or mosses.

3. Algæ, which term properly implies sea-weeds; but besides these, it contains several numerous terrestrial genera, which ought to constitute a distinct order.

4. Fungi.

When the order to which a plant belongs is ascertained, its genus is next to be investigated. The characters of the genera are universally taken from some part of the fructification, and are advantageously exhibited in synoptic tables, which will be found under the names of the classes in their proper places.

III. The synonyms of plants; or the names by which they are distinguished in the writings of professed botanists and others, from the earliest times to the present.

It is evident, that a multiplicity of names for the same plant is unavoidable in common life; but it may be thought not likely that scientific men should willingly increase the number. This, however, is the natural consequence of a gradual improvement in knowledge. As genera were formed, and species accurately distinguished, it became necessary to invent generic and specific names. As generic characters were settled with greater precision, former dispositions were necessarily changed, and many plants of course appeared under a different generic appellation. The nomenclature of the early botanists has, therefore, in the natural course of things, become obsolete; and, to avail ourselves of their observations, it is necessary to know what they called the various plants which have since received new names. To form an accurate collection of synonyms is a work of great difficulty and labour, which has exercised the diligence and discernment of all who have entered deeply into the subject, and is still far from complete. It is much to be lamented that the perplexity has been greatly increased by the licentious caprice of even good botanists. Linnæus himself has sometimes departed from the nomenclature of his predecessors, without any good or apparent reason.

In a work like the present, intended for occasional consultation, peculiar attention ought to be paid to this perplexing part of science; and we esteem it incumbent upon us to spare no pains in collecting, not only the synonyms of the most eminent botanists, but also the vulgar English names of indigenous plants, as well as those given by unscientific nurserymen and gardeners to exotics.

IV. The sensible qualities of plants, or the different manner in which they severally affect the organs of sight, smell, taste, and touch.

Of these, colour is the most general and the most striking. The colours of plants are indeed so wonderfully diversified, and so constantly meet the eye, whenever it is directed to the face of nature, that they contribute, more than any other quality, to the beauty of the creation. They are too subject to accidental variation, to be safely employed as specific characters; but they are in many cases so nearly uniform and constant, that they ought not to be entirely neglected. It is not possible, indeed, to do more than express a few leading distinctions. In the description of their minute shades, and gradual approximation to a kindred tint, the powers of language utterly fail. The prevailing colour of vegetables, considered in their appearance as a whole, is green; but this green is not, perhaps, precisely the same in any two species of plants, or in different parts of the same plant, or even in the same part of the same plant, in different stages of its growth. All that can be done is to point it out generally, by stating its relation to white or black, or by fixing upon the colour of some well-known plant, or other natural substance, not as a mark of identity, but as a standard of comparison. Thus we speak of light green, and dark green, of apple green, and olive green, &c.

The colours of plants are divided by Linnæus into Hyaline, with the transparence either of water or of glass.

- White, either cream-coloured or snowy.
- Cinereous, either grey, livid, or lead-coloured.
- Black, either dark or jet black.
- Yellow, either sulphur, flame, or copper-coloured.
- Red, either crimson, flesh-coloured, or scarlet.
- Purple, more or less approaching to violet.
- Blue.
- Green.

It is scarcely necessary to observe, that this enumeration is very imperfect. The different parts of plants have most commonly their appropriate colour. Roots and seeds are frequently black, the pericarp rarely, the corolla scarcely ever. The stem, the leaves, and the calyx are generally green, the corolla very seldom. The filaments and the pistil are often hyaline. The anthers are often yellow, as is also the corolla, especially in autumnal flowers. Vernal corollas and sweet berries are frequently white. Red is common in summer flowers, and subacid berries growing in the shade. Blue is not frequent in corollas.

The prismatic colours afford some fixed points of comparison in the description of colours; but there is no similar natural standard for the discrimination of odours and tastes. However scanty and obscure the vocabulary of the former may be, that of the latter is, therefore, still more so. The sense of smelling and the sense of taste have an evident and intimate connection with each other. Herbs and fruits that are grateful to the palate have almost always a pleasant smell; but the reverse does not equally hold; an agreeable perfume does not, in all cases, warrant the expectation of delicious food. Every plant has an odour and flavour peculiar to itself, and differing from all others in kind as well as in strength. They are discriminated, according to the manner in which they affect the sense, by a few general expressions, which have little or no precise meaning.

Odours are,

- Ambrosiac, or musky, as in sweet woodruff (*asperula odorata*) and musk geranium.
- Fragrant, as in jessamine and violet.
- Aromatic, as in cinnamon, saffras, and cloves.
- Unpleasantly strong, as in garlic and herb robert (*geranium robertianum*).
- Stinking, as in elder (*ebulus*) and stinking may-weed (*anthemis fœtida*).
- Nauseous, or disposing to vomit, as in hellebore, asarabacca, and colocynthida.
- Sharp, as in mustard.
- Faint, as in primrose and lilac.
- Tastes are,
- Sweet, as in sugar-cane and fig.
- Acid, as in tamarind and lemon.
- Fat, or oily, as in fresh almonds and olives.
- Salt, as in falfola, and other maritime plants.
- Bitter, as in wormwood.

Astringent, as in the fruit of the quince. This kind of taste is either austere, partaking a little of the acid, as in unripe fruits, or acerb, rough, partaking more of the bitter, as in the common sloe.

Viscous, as in the fruit of the common jujube (*rhamnus ziziphus*). It produces only a slight sensation on the palate.

Acrid, as in garlic. It is sometimes caustic, as in the berries of daphne mezereon.

Dry and insipid, as in farinaceous seeds, and several kinds of bark.

Watery, as in cucumber and lettuce.

Nauseous, as in tobacco.

Plants affect the touch, as they are fleshy or membranous, soft or harsh, smooth or rough, silky, hairy, or prickly, &c.

V. The anatomy of plants, or description of the different visible parts of which their substance is composed. These are,

1. The *epidermis*, or thin cuticle which invests the whole of the plant.
2. The *cellular*, or *reticular substance*, which appears in the young shoot of a tree after the epidermis is stripped off.
3. The *liber*, inner or true bark.
4. The *aburnum*, or *blea*, improperly called by English dealers in wood, the sap, a ring of imperfect wood between the liber and the true wood.
5. The *lignum*, or true wood, consisting of concentric strata or rings.
6. The *pith*, a spongy substance inclosed in a longitudinal canal, which constitutes the innermost part of the plant.
7. The *medullary productions*, or filaments proceeding from the pith, and crossing the stem in a radiate direction, as far as the cellular substance.
8. The *medullary appendices*, filaments placed between the medullary productions, and reaching no farther than the wood.
9. The *trachea*, or air-vessels.
10. The *sap-vessels*, and
11. The vessels which secrete the peculiar juices of the plant.

VI. The physiology of plants.

A plant, like an animal, is a very compound, organized, living being, in which various operations, both chemical and mechanical, are continually carrying on, from its first production to its final dissolution. It springs from a seed fertilized by the pollen of its parent plant. It takes in foreign substances by its inhaling and absorbent vessels. It elaborates and assimilates to its own substance those parts of them that are nutritious, and throws off the rest. It secretes a variety of fluids by the means of glands, and other unknown organs. It gives that motion to its sap on which the continuance of its life depends. See the articles *PHYSIOLOGY of Plants*, *VEGETABLE*, and *VEGETATION*.

VII. The purposes to which different plants are applied, either as articles of food, ingredients in the composition of medicine, or materials and instruments in the useful and elegant arts; the soil and situation in which they are generally found, and which are most favourable to their growth; the time of the year in which they open their flowers, and ripen their fruit, with many other incidental particulars, are properly within the province of the botanist. But, as a botanist, he is concerned with nothing more than the simple facts. The best methods of cultivating such as are raised in considerable quantities for the special use or amusement of man; the theory of their nutritious or medicinal properties; and the manner in which they are to be prepared, so as to effect the intended purposes; are the province either of the farmer, the gardener, the physician, the chemist, or the artist. But as they cannot, in this work, be conveniently introduced under their respective sciences, they will generally be annexed to the botanical details of each particular plant.

VIII. The history of botany.

In all ages of the world, vegetables have been a principal article of human food. We can, therefore, scarcely doubt, that some intimations of the kinds which are most proper for

this purpose, must have been given to our first parents by immediate revelation from their Creator. Such intimations, however, would be no more than was absolutely necessary, to preserve them from dying by famine, on the one hand, or by the deleterious effects of poisonous plants on the other. They would extend only to a few salutary roots, herbs, and fruits; and agreeably to the general economy of human life, all farther acquisitions in knowledge would be the result of occasional experiments and slow experience. A knowledge of the various species would then gradually increase, and some general distributions would spontaneously offer themselves to notice. A woody trunk would soon be distinguished from an herbaceous stem. A tree and a shrub, an annual and a perennial herb, would not long be confounded with each other. The most striking differences in the form and consistence of the fruit would also be readily observed. Moses, as appears from the first chapter of Genesis, was acquainted with three characteristic divisions: *grasses*, of which the seed was probably for some time overlooked or disregarded; *herbs*, which bear their seed in a dry pericarp or seed vessel; and *trees*, with all other vegetables, which have their seed inclosed in a pulpy or some other eatable substance. And it is worthy of remark, that in the grant of vegetables to man for the purpose of food, only the two latter are mentioned; the first being reserved for "the beasts of the earth, and the fowls of the air, and every thing that creepeth on the earth." Among these a selection would soon be made of such as were most grateful to the palate, and the other senses. Whatever were the *Dudaim* which Rachel begged of the son of Leah, and which our translators have absurdly rendered mandrakes, it is certain, from the song of Solomon, that they were a kind of fruit which gave a pleasant smell. Solomon is celebrated for his knowledge of plants: but all that we know of it is, that he spake of them from the cedar of Lebanon to the hyssop that groweth on the wall. It could not, moreover, be very long before the early race of mankind began to perceive that some vegetable productions are mildly nutritious, and others actively medicinal. In the frequent search after new viands, which the restless curiosity and craving desire of diversified gratification, natural to man, would induce him to make, he would find some that produced violent effects on his bodily frame, and relieved or removed disorders, which are always the "sources of pain, and often the forerunners of death." This would give a new direction to his inquiries, and would present the vegetable creation to him in a more interesting point of view. Pain is, in all cases, so difficult to be borne, that whatever promises to diminish it, is sought for with unwearied assiduity.

The knowledge of medicinal plants was, therefore, regarded as a highly valuable attainment many ages before plants themselves were made the objects of a distinct science. Botany long continued the humble but engaging handmaid of surgery and medicine. The balm of Gilead bore a high price in the estimation of a Jew, because it was strongly and rapidly associated with the idea of a physician. In Homer, Patroclus staunches the bleeding wound of Eurypylus with the juice of a bitter root, the virtues of which he had learned from Achilles, and Achilles from Chiron. The power of the moly, used as an internal antidote against the incantations of witchcraft, is likewise celebrated by the same poet; and the knowledge of it is said to have been owing to the intervention of a god. That great honour was obtained by an acquaintance with the medical properties of plants, in the heroic ages, is evident from the encomium given to the wife of one of the heroes whom Nestor boasts of having slain in his youth:

Ἡ τῶν Φαρμάκων γῆν ὅσα τρέφει εὐρία χθών."

"Who knew the virtues of each earth-born herb."

At a much later period, we shall search in vain for any information concerning the botany of the ancients, except in their medical writers. Hippocrates, the oldest of those of whom we have any remains, and who flourished at the beginning of the Peloponnesian war, of course makes mention of the plants which were then employed in the cure of diseases; but he gives only their names, with their real or supposed sanative qualities. Aristotle, who lived about half a century after, and whose comprehensive genius left scarcely any thing unexplored, could not overlook so obvious and attractive a pursuit: but the two books now existing which bear his name, are of such inferior merit, that they are generally thought to be spurious. Theophrastus, the disciple of Aristotle, is the first professed writer on plants, whose works have incontestably descended to modern times. He was acquainted with about five hundred, and has left descriptions of them, with slight philosophical sketches relating to some of their most prominent distinctions. But his descriptions are so vague and imperfect, that, in most cases, it is difficult, in many impossible, to determine what plant he intended. And he has made only a rude attempt to divide them into grand families, either by their size and texture, as trees, shrubs, and herbaceous plants, or by the uses to which they were then commonly applied.

From the age of Theophrastus to that of Dioscorides and Pliny, there is an interval of 400 years. Dioscorides was a physician, and wrote entirely as such. He has enumerated about 600 plants; but his account of them is so brief and indeterminate, that, in a botanical view, they are of little value. Nor, in this respect, is Pliny entitled to much greater praise.

During the dark ages which succeeded the downfall of the western empire, almost all the knowledge on this side of the Indus was confined to the courts of the Mahometan caliphs. The Arabian and Moorish physicians cultivated the art of medicine with no inconsiderable degree of success, and translated the best Greek writers on the subject into their own language. But in the investigation of plants, they were not much, if at all, superior to their masters. We are, however, indebted to them for the knowledge of senna, cassia fistula, manna, tamarinds, rhubarb, and some other medical drugs, which still keep a place in the *Matena Medica*.

At the revival of literature in the west, the ancients were truly considered as the depositaries of nearly all the knowledge that then existed. It seemed, therefore, as necessary as it was natural, that their writings should, for a time, be exclusively studied. For what steps towards a farther progress could be advantageously taken, till what was already done was clearly ascertained? As a general idea, it was a good one: but its application to natural history was unfortunate. For in this branch of knowledge the ancients had done nothing to much purpose. The lovers of botany, however, buoyed up by vain expectations, devoted themselves diligently to the study of Theophrastus, Dioscorides, and Pliny; and much time was idly spent in endeavouring to find, on the west of the Adriatic, all the plants which have been mentioned by those authors. Commentators succeeded commentators; conjecture superseded conjecture: till at length a few intelligent minds, weary of fruitless attempts, perceived the folly of studying a science in the imperfect remains of two dead languages, when they might have free access to the fair and legible characters of a book always open, and inviting their regard by incontestable marks of unerring knowledge and wisdom.

Gesner, in particular, the greatest naturalist whom the world had seen since the days of Aristotle, cultivated both zoology and botany, with a zeal which has never been surpassed; with a discernment and good sense which till then had never been known. He has the glory of having first discovered the expedience of dividing plants into classes, genera, and species, and the necessity of taking the distinguishing characters of each division from the flower and fruit. He died of the plague in 1565, at the early age of fifty.

Clusius, who was his contemporary, and many years his superior, engaged in the study of plants with equal ardour, but not with equal talents for just arrangement. He distributed them chiefly according to their size, their general habit, and their other sensible qualities.

At this time also flourished Dr. William Turner, who may be accounted the father of English botany. It was he who first gave names to many English plants; and much praise is indisputably due to him for his diligence in examining, and judgment in discriminating, different species: but with respect to arrangement, he was far inferior even to Clusius; for he has disposed his plants in the alphabetical order of their Latin names. The first part of his *Herbal* was printed at London in 1551; the second at Cologne, 1562; and the third, dated Welles, in 1564. It is in the black letter; and contains figures of most of the plants.

In the same period lived Dodonæus, or Dodœus, who began to publish in 1552; and in 1583 collected all his works into one volume, which he quaintly called, "*Stirpium historie sex Pentades*," because each larger division consists of five books.

This work is the foundation of Gerard's *Herbal*, so well known in England, and so long regarded as a standard book by the merely English botanical student. It was published in 1597, and comprizes the whole vegetable kingdom in three books. The first contains the grasses, grain, rushes, reeds, flags, and bulbous-rooted plants; and exhibits a remarkable approximation to the arrangement of a very modern system, founded on natural affinities. It was suggested, however, by a regard not to the monocotyledinous character of the seeds, but to the simplicity and general form of the leaves. The second includes all herbs used for food, for medicine, or for their beauty and elegance. The third is a motley assemblage of trees, shrubs, fruit-bearing plants, reines, gums, roses, heaths, mosses, mushrooms, and sea-plants.

It was left to the judgment of Casalpin to begin to execute what the penetrating mind of Gesner had first conceived; the arrangement of the whole vegetable creation in a regular system. His distinctive characters are taken from the different appearances of the fruit, sometimes modified by the consideration of other parts; and though it cannot boast of being the best in theory, or the most easy in practice, it possesses great merit as the first essay in a difficult and important undertaking. Casalpin is particularly worthy of regard, as the first writer who has distinctly mentioned the true difference of sexes in plants. He died in 1603.

The last of the writers of this period are the two Bauhins. John, the eldest, was the friend of Gesner, and travelled with him into Italy; but, though ardent in his love of plants, he had no turn for systematic arrangement, and added nothing to botany, considered as a science. He wrote a general history of plants, which was published in three folio volumes, but not till 1650, 27 years after his death.

Gaspard, his brother, was much his junior in years, but far exceeded him in the greatness of his conceptions, and the extent of his services to their favourite pursuit. The publi-

cation of his "*Pinax Theatri Botanici*," in 1623, makes a new æra in botany. This immense work, the fruit of forty years' labour, threw over the subject, as it then stood, a clear and conspicuous light, and shewed at one view the information which had been given by a multitude of scattered authors. It afforded a resting-place, a kind of fixed point, from which new excursions were to be made, and new achievements were to be attempted. But though he smoothed and shortened the way for others, it must be acknowledged of him, as well as of his brother, that he added little to what had already been done.

Many accessions were soon after made to the number of known plants, by the labours of Pona and Zanoni in Italy, of Johnston and Parkinson in England, of Hernandez, Pison, and Margrave in south America, and above all, of Rheede, who, in his "*Hortus malabaricus*," brought to light about 800 plants, natives of the East Indies. But botany, as a science, made little progress for nearly half a century; when Morison, Ray, Rivinus, and Tournefort, all nearly at the same time, directed their attention to the classification of plants, and investigated the true principles on which it ought to be formed. Morison, in a second edition of Bruyner's "*Hortus regius Blefensis*," published at Paris in 1669, gave the rudiments of an arrangement, founded on the fruit; and also asserted, that the characters of the genera should be taken from the same part: but in his history of plants, printed at Oxford in 1680, he did not strictly adhere to his own principle. His system was quickly succeeded, and its fame nearly eclipsed, by that of the immortal Ray, the outlines of which were first given, in 1682, in the "*Methodus plantarum nova synoptice in tabulis exhibitâ: cum notis generum tum fuminum tum subalternorum characteristicis*." The principal aim of this great naturalist was to preserve the natural families of plants, as they are connected by a similarity of fructification and general habit. Influenced by the latter consideration, he retained the ancient division of the vegetable kingdom into trees, shrubs, and herbaceous plants; making no alteration, except in classing with the latter what are generally called suffrutices or under-shrubs. This system he afterwards improved and brought nearer to a natural arrangement; but he still left the characters of his genera in a great degree indeterminate, and governed by no fixed principle. The time was not yet come for taking this farther step towards the perfection of the science.

The classification of Rivinus, derived from the structure of the corolla, was first made known to the world in 1690. It is more easy in practice than either of the former, but does more violence to the order of nature. It must, however, be mentioned, to his honour, that he was the first who perceived the propriety of not separating trees from herbaceous plants. They are accordingly blended together in different parts of his system.

As Morison soon yielded in celebrity to Ray, so Rivinus gave way to Tournefort, the glory of France, and equalled only by Ray, the glory of England. His elements of botany, in which the primary divisions are taken from the corolla, and the secondary ones from the fruit, were published in 1694. His arrangement, indeed, is not unexceptionable in all its parts, but its imperfections arise from the defects of his principle; and though he did not define his genera in plain and appropriate terms, it is evident that he had formed just ideas of them in his own mind.

The fame of these two great men, who had done so much in promoting the progress of true scientific botany, obstructed, for a considerable time, its farther advancement. It was vain for botanists to contend, either in England or France,

France, with the established reputation and authority of their respectively favoured countryman. Several other systems were formed about the same time, among whom Boerhaave in particular had great merit; but none of them found many profelytes, or could boast of long duration. The first publications of Linnæus made their way slowly, and with much difficulty. In England, so late as the year 1762, Mr. Hudson was the first who published a national Flora, arranged on the principles of the Linnæan system. In France, owing to the personal antipathy of Buffon, the ideas of the learned Swede met with much greater and more pointed opposition: but they found an early advocate in the duke de Noailles; and, in 1765, the classification was adopted in the "Flora Montpeliciaca," of professor Gouan.

The distinction of sexual parts in plants had been discovered, and pretty generally admitted, before the time of Linnæus: but he was the first who made it the basis of an artificial system. The first sketch of his "Systema Naturæ" was published in 1735; and the "Fundamenta Botanica," in 1736. In 1737 they were followed by the "Critica Botanica," "Genera Plantarum," "Hortus Cliffortiannus," "Flora Lapponica," and "Methodus Sexualis." In 1751 appeared his great and most finished elementary work, the "Philosophia Botanica;" and in 1753, the first edition of the "Species Plantarum," which completed his system, by extending it to the lowest division under which individual plants are collectively arranged. In his "Genera Plantarum," he had given a distinctness and precision to generic characters, which they had never before received; and in this last publication he conferred the same obligation on the species; with the addition of *trivial* names, consisting of a single word, instead of the tedious *specific* names, as they were called, by which the conversation of botanists had till then been burdened and embarrassed. This innovation was at first violently condemned by a few disciples of the old schools, from an apprehension that it would be unfavourable to the recollection of specific distinctions; but its obvious convenience has long gained it universal currency.

Notwithstanding the superlative merit of Linnæus, he found a rival and an opposer in Switzerland, as well as in France. The mighty genius of Haller could not condescend to walk in the trammels of another man. In his history of the plants of Switzerland, styled by the very able and judicious president of the Linnæan society, one of the most excellent and complete Floras the world ever saw, he has adopted a method depending chiefly on the number of the stamens, combined with the divisions of the corolla. But his system is now little talked of, and less studied.

Linnæus devoted the greatest part of his life to the construction and completion of a system confessedly artificial; but he was nevertheless fully sensible, that the perfection of the science requires an arrangement founded solely on natural affinities. The idea of such an arrangement had been conceived, and partly executed, by several of his predecessors. The improved system of Ray, in particular, is a noble essay towards reducing the whole vegetable creation into six natural families. All other distributions are only proofs of the present defective state of knowledge, and are to be employed merely as helps for the attainment of a consummate system. Linnæus has accordingly left what he calls fragments of a natural order, without pointing out their peculiar distinguishing characters; and the substance of his lectures on natural orders has been published, since his death, by his pupil Giseke, in which the omission is, in some degree, remedied; though, at the same time, it is strenuously maintained, that such characters as shall be at once completely comprehensive, and

exclusively discriminating, are, in the nature of things, absolutely impossible.

Adanson, a French traveller in Africa, has also attempted to form natural families of plants, not from the consideration of any particular part, but of all, without exception, from the root to the seed. But, independent of a multitude of other objections, it labours under the insuperable impediment of having the distinctive characters of each family drawn out to the length sometimes of four or five pages, without being capable of an abridgment.

The most successful attempt of this kind is that of Anthony Lawrence de Jussieu, the illustrious nephew of three illustrious brothers, who have been all distinguished for their attachment to botany, and for their eminent services to it. The outlines of this system were struck out by Bernard de Jussieu, demonstrator in the royal gardens at Paris; but owe their present more mature form to the skill and persevering application of his nephew, who succeeded him in his office. It is founded first on the number of the cotyledons of the seed; next, on the insertion of the stamens with respect to the pistil, whether immediately on the receptacle, the calyx, or the pistil itself; or mediately, by the means of the corolla, similarly situated; and so on, from the essential to the non-essential, from the more to the less important parts, in a descending progression, to such as are the most variable and of the least value.

A methodical disposition of plants, from the character of the fruit, has lately been published by Gærtner, a German botanist, who has laboured in this essential part with greater diligence and accuracy than any other writer.

But notwithstanding the acknowledged merit of these essays, the Linnæan still continues the prevailing system, to which all the new genera, constituted for plants since discovered, are regularly referred; and it is to the advantage of the science, that it should, for a long time yet to come, preserve its ascendancy. It is capable, indeed, of many improvements; but such improvements should be slowly and cautiously proposed, always keeping in view an approximation to a natural order. Most of the projects, which have hitherto been formed for this purpose, betray more rashness than acute discernment, more love of innovation than capacity for removing real imperfections. While they seem to acquire greater simplicity, they become actually more artificial, and more violently destroy the connection of natural affinities. The defalcations of the respectable Thunberg have not been generally admitted; the additional ones of Gmelin have been almost universally condemned; and Willdenow, the last and best editor of the Species Plantarum, has restored all the ejected classes. Dr. Smith, with his usual judgment, has only expunged the order *monogamia* from the class *syngenesia*, and retained in the class *polygamia* only such plants as have an essential difference in the structure of their perfect and imperfect flowers.

See the article CLASSIFICATION of Plants, where the different systems will be detailed and examined. See also the Bibliotheca Botanica both of Linnæus and of Haller; La Marek's Preliminary Discourse to the botanical part of the French Encyclopedia; Dr. Smith's Introductory Address to the Linnæan Society; Dr. Pulteney's View of the Writings of Linnæus; and his Sketches of the Progress of Botany in England.

BOTANY Bay, in *Geography*, a capacious bay on the eastern coast of New Holland, so called by captain Cook, who anchored there on the 20th of April 1770, from the great number of plants which were found in its vicinity by sir Joseph (then Mr.) Banks, and Dr. Solander. The land on the sea-coast is moderately high, and nearly level, but in

general higher than it is in the interior parts, and covered with steep rocky cliffs near the sea, which resemble a long island lying close under the shore. The harbour lies about the middle of this land; and, in approaching it from the south, is discovered before the ship comes a-breast of it; but from the north it is not discovered so soon. About the head of the harbour, there are large banks of sand and mud, on which are great plenty of water-fowl, and large quantities of oysters, muscels, cockles, and other shell-fish, which supply the natives, who gather them by means of their little canoes in shoal-water, with the principal means of their subsistence. From the report of Cook, who carefully examined this coast, and took possession of it in the name of the king of Great Britain, it was thought to be a desirable situation for a settlement; and accordingly it was proposed, at the close of the American war, to transport felons thither, who were sentenced to this kind of punishment. This plan was adopted in 1786; and the first ship sailed from Spithead in January, 1787, and arrived thither in the same month of the following year. It appeared, however, from the report of Cook and other navigators, that it was subject to the inconvenience of a great scarcity of water, and on the arrival of the first settlers, that it afforded advantages for the establishment of a colony much inferior to such as they expected to find; the soil being swampy, water scarce, and the bay itself inconvenient for shipping, on account of the shallowness of the water, and its exposure to the easterly winds: and it was therefore resolved by governor Phillip to transfer it to another inlet, about 12 miles farther to the north, called Port Jackson, on the south side of which, on a spot called Sidney Cove, this settlement is now fixed. For a further account of the settlement, and of the country, see *New HOLLAND*. Two French ships, called the *Astrolabe* and *Boussole*, which left France, on a voyage of discovery, under the command of M. la Peyrouse, in 1785, arrived in this bay in the beginning of the year 1788; and during their stay, father La Receveur, who had come out in the *Astrolabe*, as a naturalist, died of the wounds he had received in a conflict with the inhabitants of Masfuna, one of the Isles des Navigateurs, at which they touched. A monument, bearing an inscription, was erected to his memory, but was soon destroyed by the natives. But governor Phillip caused the inscription to be engraved on copper, and nailed to an adjacent tree. Botany bay lies in S. lat.  $34^{\circ}$ , and E. long.  $151^{\circ} 21'$ .

**BOTANY Island**, an island in the Southern Pacific ocean, near the coast of New Caledonia; so called by captain Cook from the number and variety of plants it afforded. S. lat.  $22^{\circ} 26' 40''$ . E. long.  $167^{\circ} 16' 45''$ .

**BOTARGO**, a sort of sausage, made of the milts and roes of the mullet-fish, much used on the coast of the Mediterranean, as an incentive to drink. The manner of preparing botargo, as practised at Martegues in Provence, is described by Mr. Ray. The mullets, *mugiles*, are taken in "burdigoes," which are places in the shallows inclosed with hedges of reeds. The male mullets are called "alltants," the female "boter," of the roes or spawn of which the botargo is made thus:—They first take out the spawn entire, and cover it round with salt for four or five hours; then they press it a little between two boards or stones; then they wash it, and at last dry it in the sun for thirteen or fourteen days, taking it in at night. Ray Trav. p. 396, seq.

The method of making the botargo, in the towns of Koflow and Kassa, in Crim Tartary, on the coasts of the Black Sea, where the mullet abounds, is as follows:—Immediately after the fish spawns, the spawn is put whole into a strong brine, and slightly simmered; when it is thought to be sufficiently done, it is put into pots, and covered with melted

wax, to prevent it from spoiling; and it will then keep for a long while, and may be conveyed to very distant countries.

The people of Provence call it *bou-argues*. The best is brought from Alexandria and Tunis. There is also a manufacture of it near Marseilles. It is much used throughout all the Levant, and usually eaten with olive-oil and lemon-juice.

**BOTARISSAS**, *Strinfos sive Botariffas*, Bell. Aq. one of the synonyms of *gadus lota*, called also *claria fluvialilis* by the same author; by the English, *cel-pout*, or *burbot*. See *LOTA Gadus*.

**BOTATRISSA**, in *Ichthyology*, synonymous with *botariffas*, *cel-pout*, and *gadus lota*. See *BOTARISSAS*, and *LOTA*.

**BOTAURUS**, in *Ornithology*, a species of *ARDEA*, with a smooth black head; body above cinereous and fuscous, variegated; beneath rufous; lore and orbits naked and yellow; throat white, streaked with black, and reddish. Gmel.

This is *botaurus major* of Brisson, and *grand butor* of Buffon; *greater speckled*, or *red heron* of Ray and Willughby; *greater bittern* of Latham.

*Ardea botaurus* is a native of Italy; length three feet nine inches; the bill is yellowish; irides yellow; feathers on the head and breast long and flowing.

**BOTE**, *БОТА*, in our old *Law-Books*, signifies compensation, satisfaction, or amends, for any injury done. See *ESTOVERS*.

Hence *man-bote*, satisfaction due for a man slain. In king Ino's laws it is declared what was the rate ordained for this offence, according to the quality of the person slain.

Hence also *botelsis* (charter of Hen. 1. to Thomas archbishop of York), where no judgment or favour will acquit a man; as, v. gr. for sacrilege, &c. And hence our common phrase *to boot*, speaking of something given by way of compensation.

**BOTE**, *cart*, *fire-bote*, *bay-bote*, *house-bote*, *kin-bote*, *plough-bote*, *sheep-bote*. See the adjectives.

**BOTEFEX**, in *Gunnery*, are sticks two or three feet long, and an inch thick, split at one extremity, to hold an end of the match twisted round it, for firing the cannon.

**BOTENALKAITOS**, a star in the constellation *Cetus*, called also *BATENASTOS*.

**BOTERNHOFEN**, in *Geography*, a town of Germany, in the duchy of Holstein, 9 miles S.S.W. of Nordorp.

**BOTEROIL**, in *Heraldry*, is the tag of a broadsword scabbard, and by the French heralds esteemed an honourable bearing.

**BOTERVIGIE VAN BOER**, in *Zoology*, (*Conus glaucus*, Linn.) is described under this name by Rumphius.

**BOTESCART**, in *Ancient English Writers*, the same with *boatswain*.

**BOTESDALE**, in *Geography*, a market-town of Suffolk, in England, is seated near the borders of Norfolk, on the turnpike road which leads from that place to Bury St. Edmunds. It was formerly called *Botolph's-Dale*, from a chapel dedicated to that saint in a valley. This sacred structure had long continued in a state of dilapidation, but Thomas Holt esq. and some neighbouring gentlemen, raised a subscription, and had it properly repaired and fitted up for its original destination. This town enjoys the advantage of a free grammar school, which was founded and endowed by the eminent sir Nicholas Bacon, who was created the first baronet of England. He also bequeathed other legacies to the town; and the school has been since enriched by the donations of other persons. Botesdale is annexed to the rectory of Redgrave, the church of which is highly interesting to the historian and antiquary, from its inclosing the monuments and

remains of sir Nicholas Bacon and his lady, also another magnificent one for lord chief justice Holt. The latter is said to have cost 1500l., and the former (executed by Nicholas Stone) 200l. Both these illustrious men were successively possessed of the lordship of Redgrave, where the abbot of Bury had previously "his fairest country-seat." The fine old mansion has been succeeded by a modern building; and the place, now possessed by a descendant of chief justice Holt, is considered "one of the finest in the county" of Suffolk.

Boteldale has a weekly market on Thursday, and two annual fairs. It contains only 65 houses, and 536 inhabitants, of which number 222 are employed in manufactures. From Norwich it is 27 miles, and from London 85 miles N.E. Gough's Camden, vol. ii. Magna Britannia, vol. iv.

BOTETOURT, one of the American counties in the state of Virginia, situate between the Alleghany and Blue ridge; its chief town is Fincastle.

BOTH, JOHN, in *Biography*, an eminent landscape painter, was born at Utrecht in 1610, and, after having been the disciple of Abraham Bloemart, went for improvement to Rome, where he resided many years; directing his attention to landscape, in which he attained to high perfection. His model was the style of Claude Lorraine; and some of his performances are mentioned in competition with those of Claude. The warmth of his skies, the judicious and regular receding of the objects, and the sweetness of his distances, afford a pleasure superior to that produced by the works of almost any other artist. His tints are so admirably formed as to express not only the light of the morning breaking from behind hills and woods, and diffusing a warm glow over the whole face of nature, and also the setting of the sun with its tinge in the clouds, but even the different hours of the day. By his colouring he obtained the distinction of being called "Both of Italy." We have also by his hand a set of ten landscapes, which are etched in a slight, free, masterly style. He lost his life by accidentally falling into a canal at Venice in 1650. Pilkington and Strutt.

BOTH, ANDREW, brother of the former, and disciple of Bloemart, accompanied him to Rome, and applied to the study of figures, in which he imitated the style of Bamboccio with great success. The two brothers mutually assisted each other till the death of John; and then Andrew returned to his own country, where he painted sometimes portraits, and sometimes landscapes, in the manner of his brother, and also conversations, and players at cards, in the manner of Bamboccio; and where he died in 1656. Andrew Both also etched some few plates in a free, masterly style, resembling that of Ostade, viz. six small upright plates of "Dutch merry-making," to which he affixed his name; "St. Antony praying with a skull before him," and "St. Francis with a crucifix before him," its companion. Pilkington and Strutt.

BOTH, in *Geography*, a river of Germany, in the circle of Bavaria, which runs into the Inn, near Scherding.

BOTH *subjects* *ast*, in *Sea Language*, expresses the situation of a ship sailing right before the wind.

BOTHAGIUM, BOTHAGE, or BOOTHAGE, customary dues to the lord of the market, for the liberty of pitching and standing of booths.

BOTHENA, BOTHNA, or BORTHNA, in the Scotch *Law*, a park or field wherein cattle are inclosed, and fed. The word is also written *barthena*; formed from the ancient Scottish *buth*, a flock of sheep.

BOTHENA is also used for a barony, lordship, or sheriffdom. In which sense it is ordained by statute, that the king's

moot or court of each bothena, that is, each sheriffdom, shall be held within forty days.

BOTHFELD, in *Geography*, a district of Germany, in the bailiwick of Calenberg, consisting of five villages, of which Bothfeld is parochial.

BOTHMAR, a county of Germany, in the principality of Zell, and 7 leagues W. of it; situate on the Reuse.

BOTHNIA, EAST, *Offer-bottan*, Lat. *Ostro-bothnia*, a province of Sweden, situated on the east side of the gulf of Bothnia, whence it derives its name, is bounded on the north by Swedish Lapland, on the east by Russia, on the south by Finland, to which it properly belongs, and on the west by the gulf of Bothnia. Its extent has not been accurately ascertained; by some it has been computed to be about 90 Swedish miles long, and 40 broad; and by others its length has been estimated at 66 Swedish miles, and its breadth at 12. It is separated from Russia and Finland, properly so called, by a chain of hills, which runs along its east side. These mountains supply large rivers, of which some discharge themselves into the White sea, and others into the gulfs of Bothnia and Finland. The country, especially on the sea coast towards the south, is low and marshy; however, the industry of the inhabitants has made it productive of corn, though the cold and frost often disappoint their hopes, and several tracts of land lie waste. It abounds with wood, and its lakes and rivers yield plenty of fish. Some of the rivers are said to have furnished pearls. The inhabitants derive their chief subsistence from agriculture, grazing, burning lime and tiles, and making pitch and tar. They also employ themselves in fishing and hunting, ship-building, and the manufacture of wooden-ware. Those who inhabit the rocky islands near the sea-coast speak the Swedish language, but those of the inland parts use that of Finland. The number of inhabitants is estimated at about 80,000, who are scattered over 28 parishes, 19 of which are occupied by Finns, and nine by Swedes, and which are under the jurisdiction of the bishop of Abo. The commodities furnished by this country for exportation are timber, butter, cattle, fish, oil, pitch, tar, &c. East Bothnia is divided into three parts or lehns, which are under one governor. Its chief towns are Cajana or Cajaneborg, Utea, Brahestad, Gemla-Carleby, Ny-Carleby, Jacobstads, Wasa, and Chrillinstad.

BOTHNIA, WEST, a province of Sweden, lying on the west side of the gulf of Bothnia, and bounded on the north and west by Lapland, on the south by Angermanland, and on the east by the gulf of Bothnia. That part of this province which is inhabited extends from the frontiers of Angermanland to the church of upper Tornea, and is computed to be about 58 Swedish miles in length, and from 16 to 18 miles in breadth. Off the coast of this province are several pleasant islands, and its interior has several forests, with lakes and rivers. It has also excellent pastures among the mountains, the summit of which supplies the rein-deer with moss. The soil is tolerably fertile, and produces corn, which is sown late, and ripens in six, seven, or eight weeks, but which is often injured by the sudden frosts of July. This province has several mines of copper and iron. The inhabitants are celebrated for their hardiness and valour; they subsist by agriculture, grazing, hunting, and fishing; and even in fruitful years mix their corn with chaff and pulverized pine bark, with which they make their "stampe-brot," or pounded-bread. They traffick in beams, deal-boards, and other timber, shingles, tar, salted and smoke-dried salmon and other fish, wild fowl, venison, common train-oil, tallow, butter, and cheese; and also in fables, and skins of blue and white foxes, ermines, bears, wolves, martens, hyenas, beavers, and rein-deer. These commodities are carried by them, not only to other parts of Sweden,

Sweden, but over the mountains to Norway, and through extensive deserts to Russia. It is divided into four vogtys or inferior governments, contains two provincial jurisdictions, and, with regard to its ecclesiastical state, belongs to the see of Hernosand. The principal towns are Umea, Pitea, Lulea, and Tornea.

**BOTHNIA**, *gulf of*, one of the branches into which the Baltic is divided; the other being the gulf of Finland. The former is separated from the Baltic by the isles of Aland, is bounded on the east, west, and north by the Swedish dominions, and extends between them, from Aland to Tornea, about five degrees and a half in latitude, or about 127 leagues from north to south, and from 18 to 35 in breadth from east to west.

**BOTHNICUS**, in *Entomology*, a species of *CRYPTOPHAGALUS*, *Chrysemela bothnica* of Linnæus. The colour is deep black, with a longitudinal red line on the thorax. Inhabits Sweden.

**BOTHOA**, or **БОТОНА**, in *Geography*, a town of France in the department of the north coast, and chief place of a canton, in the district of Guingamp; the place contains 2021, and the canton 7554 inhabitants; the territory comprehends 207½ kilometres, and 8 communes.

**BOTHWELL**, an ancient barony and parish of Scotland, which includes an area of about 8½ miles in length by 4 miles in breadth. The bridge in this parish, which crosses the Clyde river, is memorable for an engagement fought on the south side of it, June 22, 1679, between the royalists, under the duke of Monmouth, and the presbyterian insurgents. In this fatal conflict the latter were defeated, with the loss of 400 slain, and 1200 taken prisoners. Here are the remains of a castle, which appears to have been formerly of very large dimensions. It is frequently mentioned in the annals of Scottish history. Sir John Sinclair's Statistical Account, vol. xvi.

**BOTI**, in *Geography*, a town of Siberia; 32 miles S. of Orlenga.—Also, a town of Siberia, 76 miles N. E. of Nertheinsk.

**BOTICUM**, in *Ancient Geography*, a town of Asia Minor, in Phrygia, which had a marsh that produced salt. Steph. Byz.

**BOTISAS**, a name given in Spain to a smaller sort of alcarrazas, or vessels used for cooling water; the larger sort being called jarras. See **ALCARRAZAS**.

**BOTISTMENI**, in *Geography*, the name of a mountain in the southern part of the island of Madagascar.

**BOTLAN**, **AL MOKHTAR BEN HASSAN, BEN ABOUN**, or **D'EBN BOTLAN**, in *Biography*, a Christian physician of Bagdat, the contemporary and antagonist of Ebn Rodwan. It is said that Botlan, in order to be personally acquainted with his adversary, made a voyage into Egypt, A. D. 1047. On leaving Egypt, he went to Constantinople, where he lived a year. He is the author of the following works, viz. "Kenafsch," or a compendium of medicine, for the use of the convents; "Instructions how to buy slaves, and to make profit of them;" "Tables of health;" "Of the diseases of physicians;" "Introduction to the art of medicine;" "Devat et athebbai," or the religion of physicians; and "Of the cure of a child who had the stone." D'Herbelot.

**BOTNA**, or **KAUZEN**, in *Geography*, a river of European Turkey, which runs into the Dnieper, near Bender.

**BOTOL**, or **BOTEL** *Tabaco-Xima, Tabaco-Xima*, or *Tabaco-Sima*, the name of two islands in the Chinese seas, situated at the distance of about 5 leagues from the south point of Formosa, and on the same parallel. The great island, at its south-east point, is placed, by captain Marc-

hand, in N. lat. 22° 3'. and E. long. 121° 34'; by Dalrymple's chart, in N. lat. 22° 6' 30". E. long. 121° 50'; by La Pérouse, in N. lat. 21° 57'. E. long. 121° 52'; by Chaval, in N. lat. 22° 3'. E. long. 121° 54'. and by G. Robertson, in his table of positions, in N. lat. 22° 6'. E. long. 121° 41' 45". This island is sufficiently elevated to be seen at a distance of 15 leagues, when the sky is clear; it is about 4 or 5 leagues in circumference; and it is well peopled with inhabitants, as Marchand observed fires blazing during the night; and La Pérouse, on approaching very near to it, distinguished three extensive villages within the space of a league. It is very woody from about one-third of its elevation, taken between the water's edge and its summit, which appeared to be crowned with trees of the largest size. The declivity of the space between these forests and the beach is very rapid. It was covered, says La Pérouse, with the most beautiful verdure, and in many places cultivated, though furrowed by the torrents that descend from the mountains. The small island of the same name, the only one, probably observed by lord Anson, the other being very often covered with fogs, lies to the south by east of the great one, in N. lat. 21° 57', and E. long. 121° 56', on the same parallel with the middle of the great island, according to Dalrymple's chart; but on the parallel of its south-east point, according to that of La Pérouse. It is somewhat less elevated than the larger island, (not half so high, says La Pérouse,) but, however, sufficiently lofty to be seen at the distance of 10 or 12 leagues. These two islands are separated by a channel half a league in width; and both shores, as well as the channel, appeared to Marchand, equally free from rocks or shoals. On the small island La Pérouse perceived some little verdure and a few bushes; but he says, that it is neither inhabited nor habitable. He adds, that if there be any anchorage at the great island, it is extremely near the coast. Marchand's Voyage, vol. ii. p. 60. La Pérouse's Voyage round the World, vol. ii. p. 9. Eng. Ed.

**BOTONE'**, in *Heraldry*. See **CROSS BOTONE'**.

**BOTONTINI**, in *Middle Age Writers*, denotes mounts or hillocks, raised to serve as land-marks, or boundaries of grounds. The word is also written *botontones*, *botones*, and *botones*. Du-Cange Gloss. Lat.

**BOTOTOE**, in *Ornithology*, a name given by the people of the Philippine islands to a beautiful bird of the parrot kind, but of what species is rather uncertain. It is described as being smaller than the common parrot, and the plumage totally of a fine blue colour. It agrees with the blue parakeet of Otaheite, *Pittacus Cyaneus*, and may very possibly be the same.

**BOTOVSKAIA**, in *Geography*, a town of Russian Tartary; 20 miles S. S. W. of Koperik.

**BOTRIA**, in *Botany*, Bose in Nouveau Dictionnaire d'histoire naturelle. Clafs, *pentandria monogynia*. Gen. Char. Cal. perianth, bell-shaped, five-toothed. Cor. petals five, sharp-pointed, fleshy, recurved at the point. Stam. filaments five, flat, attached to the claws of the petals. Pist. germ. superior. Stigma sessile, concave. Per. a berry with one seed.

There is only one species known, which is a climbing shrub, with scattered heart-shaped, three or five-lobed, veined, crenulated, villose leaves; and small reddish flowers on common axillary peduncles, which terminate in tendrils. It is found on the coast of Zanguebar, where it is esteemed a diuretic. Its berries are eaten; and a decoction of its root is given in cases of pleurisy, inflammation, and abscess.

**BOTRO**, in *Geography*. See **BOURTOS**.

**BOTRODUS**, in *Ancient Geography*, a place of Spain in Celtiberia, mentioned by Martial in his epigrams.

**BOTRYITES**, in *Natural History*, a stone of the gem kind,

kind, resembling a branch of young grapes. The word is formed from *βοτρυς*, a grape. In English writers, it is sometimes called the grape-stone.

**BOTRYTES**, or *Botrites*, also denotes a sort of burnt cadmia, found somewhat in the form of a bunch of grapes, adhering to the upper parts of furnaces, where that mineral is calcinated. It differs from the placites, which is that gathered on the lower parts of the furnace; though Schroder gives a different distinction, viz. into botrites, found in the middle of the furnace, placites in the upper, and ostracites in the lower part.

**BOTRYLLUS**, (*botryllus conglomeratus*), in *Zoology*, the name of *alecyonium conglomeratum* of Gmelin in *Gærtn. ap. Pallas Spic. Zool.*

**BOTRYOIDES**, in *Natural History*, a species of *MADREFORA*, having thick, fastigiate, obtuse, clustered branches, with reticulate, craggy undulations. Habitat. unknown. Described in Solander and Ellis's *Corallines*.

**BOTRYS**, in *Ancient Geography*, a city of Phœnicia, near the coast and south of the river Eleutherus, mentioned by Pliny, Mela, and Polybius. According to the latter (*lib. v.*) it was built by Ethbal, or Ithobal, who reigned at Tyre in the time of Ahab, about the year 923, B. C. Stephanus Byz. thinks that this was the city which is called by Joshua (*xxi. 36*) *בֹּטְרַיִם*, *betser*, and by the *LXX βοτρυς*, and enumerated among the 48 cities which were assigned to the Levites. This city, in Christian times, became an episcopal see, and its bishop, Porphyry, assisted at the council of Chalcedon, held A. D. 448.

**BOTT**, among *Bone-lace Weavers*, a kind of round cushion of light matter placed on the knee, whereon they work or weave their lace with bobbins, &c.

Among the French the *bott*, called *oreiller*, is a little square wooden frame or desk, covered ordinarily with green stuff.

**BOTT**, in *Entomology*. See **BOTTS**.

**BOTTENSTEIN**, or *POTTENSTEIN*, in *Geography*, a town of Germany, in the circle of Franconia, and bishopric of Bamberg; 22 miles E.S.E. of Bamberg.

**BOTTER**, HENRY, in *Biography*, a learned physician of Amersfort, professor of medicine in the university of Marburg, published, in 1621, "Epistola de expurgatione empyematis," 4to. and in 1646, "De scorbuto tractatus," 4to. Lubeck. Haller Bib. Med.

**BOTTESDALE**. See **BOTESDALE**.

**BOTTESTANO**, a town of Germany, in the county of Tyrol; 10 miles S. of Bruneck.

**BOTTIA**, or *BOTTIA*, in *Ancient Geography*, a country of Macedonia, in the neighbourhood of Thrace. Its limits are not ascertained by the ancient geographers, who mention it. Herodotus places it at the towns of Ichnæ and Pellæ.

**BOTTLE**, a small vessel proper for holding liquors.

The word is formed from *butellus*, or *botellus*, used in barbarous Latin writers, for a lesser vessel of wine; being a diminutive of *bota*, which denoted a butt or cask of that liquor. It is evidently derived from *butte*, *botte*, *buta*, *buticula*, *buticella*, which occur in the middle ages.

We say a glass bottle, a stone bottle, a leathern bottle, a wooden bottle, a sucking bottle.

Of glass bottles, says Beckmann (*Hist. of Inventions*, vol. ii. p. 124.), no mention occurs before the 15th century: for the "Amphoræ vitreæ diligentibus gypsatæ" of Petronius, (*Sat. c. xxxiv. p. 86.*) to the necks of which were affixed labels, expressing the name and age of the wine, appear to have been large jars, and to have formed part of the many uncommon articles by which the voluptuary Trimalchio

wished to distinguish himself. It is, however, singular, that these convenient vessels were not thought of at an earlier period, especially as among the small funeral urns of the ancients, many are to be found which, in shape, resemble our bottles. Mr. Beckmann conceives, that he discovers the origin of our bottles in the figure of the Syracusan wine-flasks. Charpentier (*Gloss. Nov. i. p. 1132.*) cites, from a writing of the year 1387, an expression which seems to allude to one of our glass bottles; but this, attentively considered, refers merely to cups or drinking glasses. The name *boutiaux*, or *boutilles*, occurs in the French language for the first time in the 15th century; but if it were more ancient, it would prove nothing, as it signified originally, and still signifies, vessels of clay or metal, and particularly of leather. Such vessels, filled with wine, which travellers were accustomed to suspend from their saddles, might be stopped with a piece of wood, or closed by means of wooden or metal tops screwed on them; and such are still used for earthen pitchers. We shall here add, that stoppers of cork must have been introduced after the invention of glass bottles. In 1553, they were little known; and their introduction into the shops of the apothecaries in Germany took place about the end of the 17th century. Before that period, they used stoppers of wax, which were more troublesome and more expensive.

The ancient Jewish bottles were cags made of goats' or other wild beasts' skins, with the hair on the inside, well sewed and pitched together; an aperture in one of the animal's paws serving for the mouth of the vessel. Calmet.

Bottles of this kind are mentioned in scripture, and called *σκυτοί*; and they were used for carrying water through the deserts of Arabia and other countries, where springs and streams are scarce. Such bottles, indeed, have been in common use both in ancient and modern times. They are mentioned by Homer, *Od. Σ. 77. Il. Γ. 246*, and *Od. E. 265*. Sallust speaks of them in *Bell. Jug. 96*, where he says "Ex coriis utres uti fierent curabat;" i. e. He provided bottles made of skins. That the ancient Romans were acquainted with goat-skin bottles is also evident from two lines of Virgil (*Georg. ii. v. 383, 384.*)

— Inter pocula læti  
Mollibus in prætis unctos saliere per utres."

From the circumstances here alluded to we may infer, that these were leather bottles, which were oiled on the outside to make them more slippery, and more likely to occasion the fall of those that hopped upon them. Horace (*l. ii. Sat. ii. v. 68, 69.*) mentions greasy water, which was given to his guests by Nævius, a man of a parsimonious disposition. Thus,

— Neque sicut simplex Nævius, unctam  
Convivis præbebit aquam. Vitium hoc quoque magnum."

This "aqua uncta" has puzzled commentators; but it probably refers to an oiliness, which the water contracted by being fetched in unclean leather bottles. Those, however, to which the same appellation of bottles is applied in our translation of the Old Testament, are expressed by different terms in the original; and they were made of various forms, and consisted of different materials. Thus, in *Gen. xxi. 14*, the "bottle" of water, given by Abraham to Hagar for herself and Ishmael, is in the original *חֶמֶת*, *chemeth*, which denotes an earthen pitcher; and it appears from Habbakuk (*chap. ii. v. 15.*), that they were accustomed to drink out of these *chemeths*. Sir John Chardin, however, supposes that the bottle given to Hagar was a leather one. The "bottle" of wine, which Samuel's mother brought to Eli, (*1 Sam. i. 24.*) is called *בֵּיבֵל*, *nubel*, and was probably an earthen jar or jug; and the same word is also used *1 Sam.*

x. 1. and 2 Sam. xvi. 1. But the term, translated "earthen bottle," in Jerem. xix. 1. is *קַבֵּב*, *lubbē*. A very different word is used in Judges iv. 19. to signify the vessel out of which Jael gave milk to Sisera; it is called *קַבֵּב*, *qabbē*, which, having some reference to mott or onzing, was probably made of goat-skin, or the skin of some animal, and being constantly kept full of milk, was preserved in a phant state. The same word is also used to denote the bottle in which Jesse sent wine by David to Saul, 1 Sam. xvi. 20. *Nud* is also used to express the bottle into which the Psalmist desires that his tears might be collected, Pf. lvi. 8.; and that to which he resembles himself, Pf. cix. 83. He says "I am become like a bottle in the smoke," i. e. like a bottle kept in the tents of the Arabs, blackened with smoke. To the meanness of such a drinking vessel as a goat-skin bottle, as well as to the blackness contracted in the Arab tent, the Psalmist probably refers; and it was a most natural image for him to use, driven from among the vessels of silver and gold in the palace of Saul, to live as the Arabs did, and consequently to be obliged frequently to drink out of a smoked leather bottle. The word used by Job (*ch. xxvii. 19.*) in the plural, is *קַבֵּב*, *qabbē*; and as *קַבֵּב*, *qabbē*, signifies, in general to swell or distend, it is properly used to express a skin bottle, which would be made to swell by the liquor poured into it, and which would be more distended and enlarged, till they would at last burst, if they had no vent, by the fermentation of the liquor as it advanced towards ripeness. Hence we perceive the propriety of putting new wine into new bottles, &c. according to the appropriate allusion in the gospels (Matt. ix. 17. Mark, ii. 22. Luke, v. 37, 38.), which being moist and strong, would resist the expansion, and preserve the wine to due maturity; whereas old bottles of this kind, being dry and more brittle, would be in danger of bursting, and were best adapted to receive old wine, the fermentation of which had ceased. These leather bottles are supposed, by a sacred historian, not only to be frequently rent, when grown old and much used, but also to be capable of being repaired (Josh. ix. 4.). Modern travellers, as well as ancient authors, frequently take notice of these leather bottles. The Arabs, says sir John Chardin, and all those who lead a wandering life, keep their water, milk, and other liquors, in these bottles, the manner of repairing which he also describes. They serve, according to this writer, to preserve their contents more fresh than in any other way. They are made, he says, of goat-skins: when the animal is killed, they cut off its feet and its head, and in this manner they draw it out of the skin without opening its belly. They afterwards sew up the places where the legs were cut off, and the tail, and when it is filled, they tie it about the neck. These nations, and the country people of Persia, never go a journey without a small leather bottle of water hanging by their side like a scrip. The great leather bottles are made of the skin of an he-goat, and the small ones, that serve instead of a bottle of water on the road, are made of a kid's skin. In speaking of the Persians, the same traveller says, that they use leather bottles, and find them useful in keeping water fresh, especially if people, when they travel, take care to moisten them, wherever they find water. The evaporation thus furnished serves also to keep the water cool. He says, that the disagreeable taste of the leather is taken off, by causing it to imbibe rose-water, when it is new, and before it is applied to use. Formerly, it is said, the Persians perfumed these leather vessels with mastic, or with incense. From him also we learn, that they put into these goat-skin and kid skin vessels every thing which they want to carry to a distance in the East, whether dry or liquid; they are thus preserved

fresher than if they were conveyed in boxes or pots; the ants and other insects are prevented from getting among them; and they are thus kept free from dust; and for these reasons butter, honey, cheese, and other such aliments, are inclosed in vessels made of the skins of these animals. Accordingly, the things, particularly the balm and honey, which were somewhat liquid, that were carried to Joseph as a present, (see Gen. xliii. 11.) were probably inclosed in little vessels made of kid-skins. Homer also refers to this mode of preserving various kinds of provision in leathern vessels. Od. B. 354.

The bottles made of skin resemble the "Girba," described by Mr. Bruce, in his Travels through Abyssinia, vol. iv. p. 334. "This," he says, "is an ox's skin squared, and the edges sewed together very artificially by a double seam, which does not let out water, much resembling that upon the best English cricket balls. An opening is left in the top of the girba, in the same manner as the bung-hole of a cask. Around this the skin is gathered to the size of a large handful, which, when the girba is full of water, is tied round with whip-cord. These girbas generally contain about 60 gallons each, and two of them are the load of a camel. They are then all besmeared on the outside with grease, as well to hinder the water from oozing through, as to prevent its being evaporated by the action of the sun upon the girba, which, in fact, happened to us twice, so as to put us in imminent danger of perishing with thirst."

Glass bottles are better for cyder than those of stone. Foul glass bottles are cured by rolling sand or small shot in them; musty bottles, by boiling them.

Bottles are chiefly made of thick coarse glass; though there are likewise bottles of boiled leather made and sold by the case-makers.

Fine glass bottles covered with straw or wicket, are called *flaske*, or *betteés*.

The quality of the glass has been sometimes found to affect the liquor in the bottle. Mem. Acad. Scienc. 1704.

BOTTLE, is also a measure at Amsterdamb, the same with the mingle.

BOTTLE, *blue*, in *Botany*. See CENTAUREA CYANUS.

BOTTLE, *mess*. See SPLACHNUM.

BOTTLE, *sebite*. See CUCUBALUS BEHEN.

BOTTLE-head, a species of whale.

BOTTLE-nose, in *Natural History*, a name given by the English to various animals; the *cachalot* is called the bottle-nose; so also any of the whale tribe distinguished by the gibbosity of their snout. In some parts of England the *anas arctica* of old writers is called the bottle-nose.

BOTTLING, or BOTTELING, the operation of putting up liquors in bottles corked, to keep, ripen, and improve.

The writers on good husbandry give divers rules concerning the bottling of beer, cyder, and the like. The virtues of Spa, Pymont, Scarborough, and other waters, depend on their being well bottled and corked, otherwise they lose both their taste and smell. To preserve them, it is necessary the bottles be filled up to the mouth, that all the air may be excluded, which is the great enemy of bottled liquors. The cork is also farther secured by a cement. Some improve their bottled beer, by putting crystals of tartar and wine, or malt spirits; and others, by putting sugar boiled up with the essence of some herbs and cloves, into each bottle.

Cyder requires special precautions in the bottling; being more apt to fly, and burst the bottle, than other liquors. The best way to secure them, is to have the liquor thoroughly fine before it be bottled. For want of this, some leave

leave the bottles open a while, or open them after two or three days bottling, to give them vent. If one bottle break, through fermentation, it is best to give them all vent and cork them up again. Mean cyder is apter to break the bottles than rich. Some soak the corks in scalding water, to render them more pliant and serviceable. See *Cyder*.

Another particular to be observed is, to lay the bottles so as that the liquor may always keep the cork wet and swelled. Something also depends on the place where the bottles are set, which ought to be such as exposes them as little as possible to the alterations and impressions of the air: the ground is better for this purpose than a frame; sand better than the bare ground; and a running water, or a spring often changed, best of all.

To hasten the ripening of bottled liquors, they are sometimes set in a warm place, or even exposed to the sun, when a few days will bring them to maturity.

**BOTTOM**, the lowest part of a thing as contradistinguished from the top.

Hydrostatical writers speak of the pressure of fluids, on the bottom of vessels; in which case, the law of gravitation is, that the altitude remaining the same, the pressure will be as the bottom. M. Leibnitz has asserted, that a body, in falling through a fluid, does not press on the bottom, that is, does not increase the pressure on it; which is found to be false. *Phil. Trans. N<sup>o</sup> 351. p. 570. A. D. S. an. 1692. p. 16.*

When water boils, the bottom of the vessel is found considerably colder than it was some time before boiling; inasmuch that the hand may bear it in the former case, not in the latter. *Hist. Ac. Sc. ann. 1703. p. 29. See BOILING.*

**BOTTOM**, in *Navigation*, denotes the ground or surface of the earth under the water.

They say, a rocky, sandy, gravelly, clayey bottom; a bottom with good hold, with a bad hold, &c.

The bottom of the sea, Ray observes, is level, i. e. the descent from the shore to the deep is equable and uniform: but the bottoms of some seas are found higher than those of others. Count Marsigli has made divers inquiries into the structure of the bottom of the sea, and its beds of stones, salt, bitumen, &c. Ray, *Wisd. of Creat. part i. p. 84. See SEA.*

Over the natural bottom of the sea is formed an accidental bottom, by the mixture of different matters, sand, shells, mud, &c. strongly compacted by the glutinous quality of the sea-waters, almost to a degree of petrification. These incrustations being necessarily formed in strata, there are some places wherein the fishermen can distinguish the annual augmentations. *Hist. Acad. Sc. 1710.*

**BOTTOM of a Ship**, that part of a ship below the water. This is also called the *quick-work*: and that above the water is called the *dead-work*. As the good or bad qualifications of a ship, with regard to sailing, steering, and staying well, veering, carrying sail, stowing her cargo, carrying her guns, &c. depends, in a great measure, upon the form of the bottom, every attention ought, therefore, to be paid to this particular point; and hence the method of constructing the bottom of a ship, so as to answer any intended purpose, is the nicest and most difficult part of ship-building; to this article the reader is referred.

That a ship may sail well, it is necessary to give her a long floor, with little rising both fore and aft, and the capacity of the fore-body equal, or nearly so, to that of the after-body.

In order to make a ship steer well, the after-part of the bottom must not be full; the wing transom carried pretty high; the fashion-pieces well-formed, and not full below the

load-water line; the midship-frame carried well forward; to draw more water aft than at the stem; a considerable rake forward, but the stern-poll to be nearly perpendicular to the keel; and the upper works to be tight and as low as possible.

That a ship may carry a press of sail, the floor-timber must be flat and long; the lower futtock full; upper futtock nearly straight; the breadth to be thrown out aloft, the main breadth carried high; the upper works light; and hence, the centre of gravity low.

To make a ship keep a good wind, and drive little to leeward, requires a considerable length of keel, with respect to her breadth; a deep hold, and consequently a short floor-timber, with a considerable rising.

In order that a ship may carry her guns well above the water, she must have a long floor-timber, and not much rising; a full midship-frame; a low wing transom, and light upper works.

To obtain the preceding properties, very opposite rules must be followed; and hence it appears to be almost impossible to construct a ship so as to be possessed of them all. The body, however, must be so formed, that as many of these properties may be retained as possible; always observing to give the preference to those which are most required. If it is known what particular employment the ship is wanted for, those qualities then are to be principally adhered to, which are most essentially necessary for that employment.

**BOTTOM, Copper**, a practice now become pretty general in Britain, of covering the bottom with sheets of copper, which accelerates the sailing of a ship, prevents the bottom from being worm-eaten, and keeps it long clean. It is, therefore, necessary, that ships, making long voyages, should be coppered.

**BOTTOM, Double**; a ship of this kind was constructed by sir William Petty in the year 1663; which was found to sail considerably faster than any of the ships with which it had an opportunity of being tried. Her first voyage was from Dublin to Holyhead; and in her return, she turned into that narrow harbour against wind and tide, among rocks and ships, with such dexterity as many old seamen confessed they had never seen the like. This vessel, with seventy more, were lost in a dreadful tempest.

**BOTTOM, Foul**, that is, when the bottom of a ship is covered with shell-fish, weeds, &c. This greatly retards the rate of a ship, and prevents her from steering and working, and, besides, proves sometimes fatal. An instance of this happened to a large built ship from Africa, in this foul condition, that could not be steered into Liverpool, but was lost, entirely owing to her bottom not being scrubbed during the voyage. Every possible means ought, therefore, to be used to keep the ship's bottom clean. For this purpose a cask scrubber has been found to answer with success when at anchor, and in calm weather on the open ocean. This scrubber is made of elm, about an inch thick, and a foot broad, the middle part of the frame just to fit a ten gallon cask, that was lashed to the battons at each end, and the long square spaces on each side of the cask were filled with birch-broom stuff, which projected about six inches without the frame, and wedged fast towards the ends, with long wedges against boards that slide with small tennons at each end in a groove, to keep the birch fast and firm. Two of these were connected together by iron-work, having a joint, that they may the more naturally ply to the curved or rounding parts of the ship's bottom. In using this scrubber, a block was fastened under the bowsprit end, and another on the driver boom, rigged out right aft; a single block is reeved in these blocks, and made fast to the slings, and just long enough

to veer and haul the scrubber along the bottom fore and aft, close to the keel. Another rope is bent to the lower part of the scrubber, and hauled tight under the bottom, and made fast to the inside of the boat's main-bow, the upper part of the scrubber being even with the water's edge, at midships, on the other side. The people are then ordered to walk fore and aft with the rope to the scrubber, till it comes to the water's edge both ways, the boat moving the same way with the scrubber, the people in her helping, by pushing their hands against the ship's side, till the first depth is thought to be clean enough; then the people in the boat haul by their rope the scrubber a depth lower, by which, and the empty casks, it is confined and pressed to the bottom, at the different depths, till it is scrubbed down to the keel; and even the keel itself, by the rope going fore and aft under it.

**BOTTOM**, *Hogged*, a concave keel by which the sheer of the ship is apparently broken. Ships with long straight floors are most liable to this defect, either from accident, in taking the ground, improper stowage of the cargo, or otherwise. To prevent this, Mr. Hutchinson advises to build ships with their floors and bottoms lengthways, to form an arch with the projecting part downwards, which will naturally not only contribute greatly to prevent their taking damage by their bottoms hogging and straining upwards, either aground or aloft, but will, among other advantages, be a help to their sailing, steering, staying, &c. This curved bottom is one of the principal properties of the life-boat.

**BOTTOM** *having several keels*, which, upon account of the very different form of the bottom from the common form, requires a particular description. This is a proposal of Thomas Gordon esq. of Premnay, in his "Principles of Naval Architecture," printed at Aberdeen in the year 1784, in order to unite the several properties of ships, which has hitherto been deemed impracticable; such as to make a ship sail well, draw little water, keep a good wind, &c. For this purpose the bottom, says Mr. Gordon, should be formed quite flat, and the sides made to rise perpendicular from it, without any curvature; which would not only render her more steady, as being more opposed to the water in rolling, but likewise more convenient for stowage, &c., while the simplicity of the form would contribute greatly to the ease and expedition with which she might be fabricated. Though diminishing the draught of water is, *ceteris paribus*, undoubtedly the most effectual method of augmenting the velocity with which vessels go before the wind, yet, as it proportionably diminishes their hold of the water, it renders them extremely liable to be driven to leeward, and altogether incapable of keeping a good wind. This defect may, however, be remedied, in a simple and effectual manner, by proportionally augmenting the depth of the keel, or, as so large a keel would be inconvenient, on many accounts, proportionally increasing their number; as, in place of adding a keel eight feet deep to a vessel drawing six feet water, to affix to different parts of her flat bottom, which would be well adapted for receiving them, six different keels of two feet deep each, at equal distances from each other, with proper intervals between; which will be found equally effectual for preventing these pernicious effects.

Thus then it appears, that a vessel drawing eight feet water only, keels and all, may be made to keep as good a wind, or be as little liable to be driven to leeward, as the sharpest built vessel of the same length drawing fourteen, nay twenty feet or upwards, if a few more keels are added, at the same time that she would be little more resisted in moving in the line of the keels, than a vessel drawing six feet only. These keels, besides, would strengthen the vessel considerably,

would render her more steady, and less liable to be over-set, and thereby enable her to carry more sail, &c. Vessels of this kind would likewise be well qualified for lying in docks and harbours when dry; and though the very quickest sailers of any, might be navigated in the shallowest water; from which latter circumstance many important advantages would result, as running little danger from sand-banks, rocks, &c. being capable of riding in many bays, and entering many harbours, rivers, and creeks inaccessible to others, whether as an asylum, or for the purposes of trade or war; for bombarding, or making descents on an enemy's coast. By enlarging, perhaps doubling, the breadth of ships, and forming their bottoms flat, and well furnished with keels, they must, in the first place, become much steadier, so as to carry their guns well, roll little, if at all, and be enabled to carry greatly more sail, and that in a better direction; at the same time that they would be in no danger of being dismantled or over-set, unless the masts were of a most extraordinary height indeed. Secondly, that they could carry more guns on their bow and stern, would have little or no occasion for ballast; and if any was used, would incur less danger upon its shifting. Thirdly, that there would be much more room upon deck, as well as accommodation below, the breadth being so much increased without any diminution of the height above the load water line, and without occasioning any necessary augmentation in the number of men for working the vessel, &c. These are the principal advantages of a ship of this construction; Mr. Gordon, however, proceeds to enumerate others.

**BOTTOM** *with sliding keels*. See **SHIP** *with sliding keels*.

**BOTTOM**, *fagged*, the keel having a convex curvature. Long straight floored ships are most liable to be fagged, as well as hogged. This defect arises, in a great measure, from loading the ship with a weighty cargo, as lead, iron-ore, stones, &c. and stowing it in the main-body of the ship. This fagging of the bottom has, from experience, been found to increase the velocity; but, on the other hand, the ship is generally in a leaky condition. The principal method of remedying this defect, is to distribute the cargo more equally, so that the upward and downward pressures may nearly counterbalance each other. This may be accomplished by means of a form-gage; for an account of which see that article.

**BOTTOM**, *to prevent from being worm-eaten*. One of the best remedies hitherto discovered for preventing worms from destroying the bottom of a ship, seems to be the coal-tar, invented by the earl of Dundonald, and manufactured at Culross in Scotland. By many comparative trials, by sinking piles of wood for some considerable time in the water, some of which were payed with coal tar, and the others with common vegetable tar; it was found that, in those payed with coal-tar not the least appearance of the worm could be traced, the tar still remaining black and smooth upon the wood, which, on being cut, emitted a strong smell of the tar; whereas the other piles were observed to be full of worms. Some proofs of the efficacy of this tar will be inserted under the proper article.

A mixture of the oil of the cocoa-nut with lime has also been used to pay the bottoms of ships, in order to exclude worms.

**BOTTOM** is also used to denote a whole ship, or rather vessel.

In this sense we say, English bottoms, foreign bottoms. By the act of navigation, certain commodities imported in foreign bottoms, pay a duty called petty custom; from which they are exempt, if imported in English bottoms.

**BOTTOM** is also used for what remains at the bottom of a vessel. In this sense, Paracelsus calls the sediment of urine, *fundus urine*.

**BOTTOM-stone**, a kind of iron-stone, or ore, in the Staffordshire mines.

**BOTTOM nails**. See **NAIL**.

**BOTTOMRY**, in *Navigation and Commerce*, is a contract, in the nature of a mortgage of a ship, on which the owner borrows money, to enable him to fit out the ship, or to purchase a cargo for a voyage proposed; and pledges the keel or bottom of the ship (*partem pro toto*), as a security for the re-payment. It is moreover stipulated, that if the ship be lost, in the course of the voyage, by any of the perils enumerated in the contract, the lender also shall lose his money; but if the ship should arrive in safety, then he shall receive back his principal, and also the interest agreed upon, generally called the "Marine Interest," however this may exceed the legal rate of interest. The person of the borrower, as well as the ship and tackle, if they arrive safe, are answerable for the money lent, and the marine interest. But if the loan is not upon the ship, but upon the goods and merchandize, which must necessarily be sold or exchanged, in the course of the voyage, then only the borrower, personally, is bound to answer the contract; who is therefore, in this case, said to take up money at "*Respondentia*." Bottomry is a loan upon the ship, and respondentia upon the goods. However, in the latter case, the personal responsibility of the borrower is not always the only security of the lender. If the money be lent for the outward and homeward voyage, the goods of the borrower on board, and the returns for them, either in money, or in other goods, purchased with the proceeds of them, are liable to the lender. The money is to be repaid to the lender, with the marine interest, upon the safe arrival of the ship, in the one case, and of the goods, in the other. Such are the leading circumstances that discriminate these two contracts; in all other respects, they are nearly the same, and are governed by the same principles.

This kind of contract by bottomry, or rather respondentia, was known to the Romans; they denominated it, "*nauticum sœnus*," or "*contractus trajectitiæ pecuniæ*;" and it is treated of, both in the Digest, and the Code, "*De nautico sœnere*." They called the sum lent, "*pecunia trajectitia*," perhaps, because the borrower was accustomed to take the money on board with him in specie, in order to employ it in trade, in the course of the voyage; which money was to be repaid, after a fortunate voyage, with a stipulated interest, called "*periculi pretium*;" and sometimes, "*usura maritima*," or "*usura nautica*;" but it was lent on this condition, that if the ship should be lost, by the perils of the sea, in the course of the voyage, the lender should lose both principal and interest.

Bottomry essentially differs from a simple loan: because, in a loan, the money is at the risk of the borrower, and must be paid at all events; but in bottomry, it is at the risk of the lender during the voyage. Accordingly, upon a loan, the legal interest only can be reserved; whereas, upon bottomry, any interest may be legally reserved, which is agreed upon between the parties.

The contracts of bottomry and insurance resemble one another in several particulars; the lender and the insurer are alike liable to the perils of the sea; the former receives the marine interest, and the latter the premium, as the price of the risk, which of course varies, according to the length, and danger of the voyage. The perils to which both are exposed, commence and terminate together. The marine, and also the premium of insurance, are not due, if

no risk be run, though this be prevented by the voluntary act of the borrower. These contracts, however, materially differ in a variety of respects. In bottomry, the lender supplies the borrower with money, to purchase the goods that are risked; but an insurer furnishes no part of the property insured. The lender, in taking on himself the risk of the goods, does not contract any obligation to the borrower; a loss by the perils of the sea does not make him a debtor to the borrower, but only prevents the borrower from becoming his debtor; whereas, in case of loss, the insurer becomes a debtor to the insured, to the amount of such loss, not exceeding the sum insured. In case of shipwreck, the lender, by the general law, has a *lien* on the effects saved, to the extent of the sum lent, and the marine interest, to the exclusion of the borrower; whereas, an insured person has an interest in the effects saved, in common with the insurer, so far as he was uninsured. The lender is not liable for particular average; but the insurer is liable for this, unless he be exempt by express stipulation. By the clause, "free of average," insurers may be exempted from general average; but, in a case where the lender is liable by law to general average, such a clause would be illegal and void. If the voyage be divisible into several distinct risks, the premium of insurance may be apportioned to each, and there may be a return for such as have not been begun; but in bottomry, if the risks be once commenced, and no loss happen, the marine interest must be paid entire.

This contract is eminently useful in a country, where persons in trade have not capital sufficient to carry on their foreign commerce; and by means of it a kind of partnership is formed between the lender and the borrower, in which one supplies money, and the other skill, experience, and a spirit of adventure; in which one risks the perils of the sea, and the other compensates him by a share of the profits of the adventure. But in other respects this contract bears no resemblance to a partnership, as it has no community of capital nor any community of loss.

Formerly contracts of this kind were more common in this country than they are now; because the immense capitals engaged in every branch of commerce supersede the necessity of such loans. On this account money is now seldom borrowed in this manner, unless it be by the masters of foreign ships, who, being in our ports, need pecuniary assistance to refit, to pay their men, to purchase provisions, &c. or by officers and others belonging to ships engaged in long voyages, who are allowed to trade to a certain extent with the prospect of great profit, but without capitals of their own; in this case, though it now seldom occurs in this country, they take up money on respondentia to make their investments.

This contract, required to be always in writing, is sometimes made in the form of a deed poll, called a "*bill of bottomry*," executed by the borrower; sometimes in the form of a bond or obligation, with a penalty. But whatever may be its form, it must contain the names of the lender and the borrower, those of the ship and master; the sum lent, with the stipulated marine interest; the voyage proposed, with the duration of the risk: and it must also specify, whether the money be lent on the ship, or on the goods on board, or on both; together with any other stipulation agreed by the parties to be introduced into the contract. It is also essential to this contract, that the marine interest be expressly reserved in it.

Concerning the parties in this contract we observe, that any person, who is capable of contract, may lend money on bottomry. Any person, who has a vested assignable property

party in a ship or cargo, may borrow money on bottomry or respondentia, to the extent of his interest. The contract itself seems to have originated from the practice of permitting the master of a ship, in a foreign country, to hypothecate the ship, in cases of necessity, for the purpose of raising money to refit; and, indeed, it is necessary for the safety of the ship, and in order to ensure the success of the voyage, that the master, in the absence of the owners, should have this power, implied by the marine law in his appointment. However, with respect to the purposes of this contract, he possesses no such power, till he becomes actually master, or as far as this business is concerned, till after he sets sail. Hence, if he borrow money on bottomry in the place where the owners reside, without their express authority, the act can only concern himself, and affect his own interest on board. In a foreign country, and in the absence of the owners, the master cannot raise any money on bottomry for any debt of his own, but merely for the use of the ship, in cases of necessity; and this necessity must appear in the written contract, or else the lender will have neither a *lien* on the ship, nor an action against the owners; the master alone being liable. Nevertheless the lender is not bound to look to the application of the money, but may have his action against the owners and his *lien* on the ship, without being obliged to prove that the money was properly applied, unless indeed he be an accomplice in any fraudulent misapplication of it; in which case the owners may impeach the contract upon that ground. As an insurance upon any trade with the enemies of the state in time of war is void, the lending of money upon bottomry is illegal.

As to the articles hypothecated, they may be the body, tackle, furniture, and provisions of the ship, the whole or any part of the cargo, or both ship and cargo. On respondentia, indeed, money may be borrowed without hypothecating any thing; and the borrower may take money on board with him in specie, for the purpose of employing it in trade, during the course of the voyage. But it is essential to the nature of the contract, that the money lent, or some equivalent to it, be exposed to the perils of the sea, at the risk of the lender. The same reasons of policy which forbid gaming insurances, equally apply to wagers in the form of bottomry loans. The mischiefs likely to result from this practice have been restrained by our legislature. Accordingly the statute 16 C. II. c. 6. re-enacted and made perpetual by 22 C. II. c. 11. § 12. after reciting "that masters and mariners of ships, having insured, or taken upon bottomry, greater sums of money than the value of their adventure, do wilfully cast away, burn, or otherwise destroy the ship under their charge, to the great loss of the merchants and owners," enacts, for future prevention of the same, "that if any captain, master, mariner, or other officer belonging to any ship, shall wilfully cast away, burn, or otherwise destroy the ship to which he belongs, or procure the same to be done, he shall suffer death as a felon." When this species of gaming came into use in England, and persons borrowed money "on the voyage," as it was called, without any interest in the ship or cargo, which they could hypothecate, the statute 19 Geo. II. c. 37. § 5. directed, that upon East India voyages the money should only be lent on the ship or goods on board, with benefit of salvage to the lender. As many British subjects, in the reign of George I. fitted out ships, and clandestinely traded to the East Indies under colour of foreign commissions, the statute 7 Geo. I. c. 21. § 2. made to restrain these practices, and to protect the monopoly of the East India company, declares, "that all contracts and agreements, made or entered into by any of his majesty's subjects, or any person or per-

sons in trust for them, for the loan of any money, by way of bottomry, on any ship or ships in the service of foreigners, and bound to, or designed to trade in, the East Indies, shall be void." This clause expressly, and in the most unqualified terms, restrains the lending of money on bottomry, on any ship or ships in the service of foreigners. But whether a ship, the property of British subjects, fitted out by them, and laden with their merchandize, can be said to be in the service of foreigners, merely because she is furnished with a commission from a foreign state, is a question upon which there has not yet been any judicial decision. Freight may be both insured and hypothecated upon a bottomry contract. Seamen may borrow money on any goods which they have on board; but with respect to their wages, they can neither insure them nor borrow money upon them.

As to the rate of marine interest, Justinian, who, in ordinary cases prohibited the *centesima*, or one *per cent.* per month, or 12 *per cent.* per annum, allowed it in this contract, and forbade any higher interest. But in modern times, when commerce is carried on between countries remote from one another, it is impossible to fix any precise standard by which this may be regulated. The legality of marine interest, however exorbitant it may seem, is allowed by course both of law and equity; nor can it be deemed usury, provided the money lent be *bonâ fide* put in risk. This interest commences with the risk, and also terminates with it. But if the time of the contract be a fixed period at a stipulated rate, and the voyage be performed within that period, the marine interest for the whole period will be due; but if the voyage exceed that period, the risk of the lender will cease, and the debt become obsolete, though the voyage should not be ended. The risk also will cease, if the ship has been prevented by unavoidable accident from performing her voyage within the time limited. Upon the cessation of the sea-risk, if the borrower delays the payment, common interest begins to run on the principal, exclusive of the marine interest, "*ipso jure*," without any demand.

The perils of the sea, which constitute the risk of the lender, comprehend all those accidents and misfortunes to which ships at sea are liable, and which no human foresight or precaution can prevent. Accordingly contracts on bottomry and respondentia expressly provide, that "if, in the course of the voyage, and within the time prescribed, an utter loss of the ship by fire, enemies, men of war, or any other casualties, shall unavoidably happen," the bond shall be void, and the borrower discharged; so that the perils are nearly the same with those to which the under-writers upon a policy of insurance are liable. A loss by pirates, though not usually expressed in securities of this kind, is included in the risk. Nothing, however, but a total loss will discharge the borrower; and the obligation remains, notwithstanding any damage which the goods may sustain by the perils of the sea; nor is there any deduction on account of such damage. In this respect the lender on bottomry is in a better situation than an insurer, who is obliged to indemnify the insured, to the extent of the sum insured, from all damage arising from any of the perils against which the insurance is made. No capture or detention, that does not amount to a total loss, in a case of insurance, can discharge the borrower. Lord Mansfield, in delivering the opinion of the court, in a case of this kind, said, "It is clear, that, by the law of England, upon a bottomry contract, there is neither average nor salvage." But the lender is not liable for loss proceeding from the internal defect of the thing that is hypothecated, unless by express stipulation, such as the ship's not being sea-worthy, and perishing by age, rotteness, or any such cause, or the goods perishing of themselves, liquors

liquors running out through the defect of the casks, dry goods heating and fermenting by length of time, &c.; nor is the lender liable for the act of the owners or master of a ship, as if the voyage be changed by order of the owners, or if a loss happen by the barratry of the master, or by the misconduct of the merchant. In these cases the borrower is not discharged, except by express stipulation, which shall render the lender liable for every loss not occasioned by the act of the borrower. Nor is the lender liable for any loss by smuggling, which occasions a forfeiture of the ship, and a confiscation of the goods, unless he was privy to it. In England, if the money were lent to be employed in a trade prohibited by law, the contract would be void; and the sum lent could never be recovered from the borrower, even though no loss had happened. The lender, like an insurer, is only answerable for losses that happen within the time and place of the risk, specified in the contract; and, therefore, if the ship deviate from the voyage, without necessity, neither the lender nor the insurer will be liable to any loss that may afterwards happen. (See INSURANCE.) If the ship be pressed into the king's service, this will excuse a deviation; but if the borrower allege a deviation, this must be explicitly denied. A change of the ship, without necessity, discharges the lender. Money is generally lent for the whole voyage, outward and homeward; or for either separately; or for a limited time. The contract usually specifies the commencement and end of the risk; and any misfortune, happening before or after, is at the risk of the borrower. If the voyage be described in the bond, but the time of the commencement and end of the risk be not specified, the risk, as to the ship, shall commence from the time of her setting sail, and continue till she anchors in safety at her port of destination; and as to goods, from the time of their being shipped till they are safely landed. When the loan upon goods is both for the outward and homeward voyages, the lender continues liable to the risk, during the homeward voyage, on the goods by which those have been replaced on which the money was lent.

Between insurance and bottomry there is this difference; that an insurer, independently of previous stipulation to the contrary, is liable to the charge of particular average, whereas, a lender without express stipulation is exempt from it: but, by the general law of merchants, in case of gross or general average, the lender shall contribute to discharge the borrower; and it is maintained by some writers, that the nature and object of the bottomry contracts seem to require, that the lender should be liable for general average. Lord Mansfield, however, as we have already observed, is of opinion, that, by the law of England, there is neither average nor salvage upon such contracts; and in this opinion lord Kenyon concurs. But serjeant Marshall observes, that he has not been able to discover any decided case, or authority in the law, to warrant this doctrine. He also dissents from another learned writer, (Park,) who thinks, that the stat. 19 Geo. II. c. 37. § 5. which provides, that the benefit of salvage shall be allowed to the lender, on East India voyages, conclusively proves, that there was neither average nor salvage upon bottomry contracts at common law. Mr. Marshall is of opinion, that this statute has not introduced any new principle into the law, either of insurance or bottomry contracts; but merely restored them to their original and proper use, from which a spirit of gaming had perverted them. Nor can he admit, that, because the statute gives the benefit of salvage to the lender upon East India voyages, he was not therefore entitled to this at common law. But admitting this to be the case, does it hence follow, that he was not liable to general

average at common law? The statute makes no mention of general average. It has been determined, however, that if an insurance be made in England, upon a respondentia interest, upon a foreign ship, and it appears that the lender is liable, by the law of the country to which the ship belongs, to contribute to a general average, the under-writers upon the policy will be liable for such contribution.

As the statute 19 Geo. II. c. 17. gives the benefit of salvage to lenders on bottomry, and respondentia securities, restricted to East India voyages, it has been a subject of inquiry, whether, before that act, the lender upon any voyage was entitled to the benefit of salvage. By the general law of merchants, the event upon which the borrower is discharged, is the total loss of the ship or goods, upon which the money is lent, in consequence of the perils mentioned in the contract. The borrower is bound to pay principal and marine interest, provided the ship or goods, on which the money is lent, arrive at its destined port, however damaged or depreciated by the perils of the sea; nevertheless, if part should be captured or lost, the borrower is only bound to pay in proportion to what remains. If the ship be lost, and the goods saved, the contract remains in force, and the borrower becomes liable, provided another ship can be procured to convey the goods to the place of their destination. But for the expense of this other vessel, the lender is accountable; and if no other can be procured, the borrower will be discharged, on accounting to the lender for the proceeds of the goods saved. By the law of England, according to the opinion of Lord Mansfield, already cited, "there is neither salvage nor average upon bottomry contracts:" however, without the benefit of salvage, this contract must partake, in a great degree, of the nature of a wager, even when the money is lent upon goods on board, of equal value. In case of a total loss of the ship, the lender loses all, though all the goods are saved. Blackst. Comm. vol. ii. p. 457. Marshall on the law of Insurance, vol. ii. b. ii. p. 632.

BOTTOMRY, *bill of*, is a contract between two persons, the one borrowing, and the other lending a sum of money, by which the borrower, setting forth his intention to make a voyage in a certain ship therein named, acknowledges the receipt of a certain sum of money from the lender, on this condition, that if the ship does happily perform her voyage, without any disaster by enemies or otherwise, then he is to restore that sum to the lender, with an additional sum, therein expressed, for the interest, within a certain time after his return; but that if the ship be lost, or taken by enemies or pirates, then the person of the borrower to be for ever discharged, and the lender to bear the loss. For the form of such a bill by deed, and when the ship is to go to several ports, see Marshall's Treatise on the Law of Insurance, vol. ii. Appendix, p. 718. See BOTTOMRY.

BOTTONI, ALBERTUS, in *Biography*, of an illustrious family, originally from Palma, was born at Padua, in the early part of the 16th century. After passing through the usual school education, in which he distinguished himself, he applied to the study of medicine, took the degree of Doctor, and was soon after advanced to the chair of professor in that faculty, which he filled many years, with singular credit. He died at a very advanced age, in 1596, leaving behind him, Haller says, an immense property. He published, "De vita conservanda," Patav. 1582. 4to. "De morbis muliebribus," 1585, reprinted in the collections of Bauhine and of Spachius. "Methodi medicinales duae, in quibus legitima medendi ratio traditur." Francof. 1595. 8vo. For the titles of other publications by this author, see Haller Bib. Med. Eloy. Dict. Hist.

**BOTTONI, DOMINIQUE**, the son of Nicholas Bottoni, a celebrated philosopher and physician of Lentini, in Sicily, born the 6th of October 1641, received his education under Peter Castello. In 1658, he was admitted to the degree of doctor in medicine, and was soon after made physician to the marquis De Villa Franca, viceroy of Sicily, physician to the royal hospital of Messina, and superintendent of the physicians there, with a pension of 50 crowns per month. He afterwards enjoyed a similar situation under the viceroy of Naples. In 1697, he was made corresponding or honorary member of the Royal Society of London, to which he had previously sent his "Idea historico-physica de magno trinacriæ terræ motu," which is published in their transactions. We have also by this writer "Pyrologia topographica, id est, de igne disertatio, juxta loca, cum eorum descriptione," Neapol, 1692, 4to. "Febris rheumaticæ malignæ, historia medica," Messina, 1712, 8vo. "Preserve salutari contro il contagio malore," Messina, 1721, 4to. He died about the year 1731. Eloy. Dict. Hist.

**BOTTONO**, in *Geography*, a town of Italy, in the duchy of Parma; 9 miles S. S. E. of Parma.

**BOTTRYS**, in *Botany*. See *CHENOPodium*.

**BOTRYTIS**. See *Byssus*.

**BOTTS**, in *Zoology*, bots and horseworms. See *OESTRUS* genus, and species *EQUI, BOVIS, HÆMORRHODALIS, VETERINUS, OVIS*. There are a peculiar kind of grub, found not unfrequently in the stomach of the horse, of a cylindrical figure, pointed at one extremity, and obtuse at the other, and beset every where with numerous rigid spines. There are at least two different kinds inhabiting the stomach of the horse, which at length produce, on their arriving at maturity, a two-winged insect of the fly kind.

Besides those of the horse, there are others of a distinct kind, but belonging to the same family, which live in their grub state under the skin of the backs of oxen, the deer, and the rein-deer; and others, again, occupy for a dwelling the frontal cavities of the head of the sheep, and cells at the base of the horns; and others inhabit also the same situations in the deer. They exit on the pus and lymph they create on these membranes by their irritation; and when full fed, they fall to the earth, and undergo the usual transformations of other insects.

The inaccessible situations of these animals in their larva state, and the impossibility of raising them out of those situations, has been the cause, probably, of their history having so long remained in the greatest obscurity.

They have been generally considered by the vulgar as true worms of the intestines, and similar in their origin to other worms of the intestinal canal, than which nothing can be more untrue.

The following is a concise detail of what is at present known respecting them; the account pursuing nearly the order in which the discoveries have been made. The first who laboured to unveil the hidden and extraordinary economy of these animals was Vallisnieri, an Italian of Padua, and the pupil of Malpighi. Before his time, the most absurd notions prevailed respecting them. The Romans, who had seen them hanging to the extremity of the rectum of the horse, believed them to be pieces of the intestine itself torn away by the worms and animals existing within them; and Vegetius has thus described them; "Hujusmodi passionis signum est (morbus coriaginofus,) cum invenitur humor in ano fabæ coctæ similis: est namque sanies ex illis vulneribus quæ bestiolæ intrinsecus fecerunt." Vallisnieri, in his first essay, described the changes of the *oesstrus bovis*; giving indifferent figures of them, and tracing them from the back of the ox

to the perfect state of a fly. This essay was published soon after the year 1700. Indeed, all that is known respecting them was discovered within the limits of the last century.

The next essay develops the history of the *oesstrus ovis*, or of that insect which is found infesting the nostrils and cavities of the face of the sheep; and in a subsequent volume (ed. Venezia, vol. ii. p. 1633.), he published his observations on the bots of the horse. He was embarrassed by the great difference he found in the appearance of the bots of the stomach; and hardly knew whether to attribute it to a difference of sex, of feeding, or of their being two distinct kinds, which subsequent discoveries have fully confirmed to be the case. His figures of them are very obscure, and ill expressed, so much so that it requires an eye accustomed to the appearance of these insects, at all to identify them. They are, however, without doubt, designed to represent the *oe. equi* and *oe. hæmorrhoidalis*.

The next labourer in this obscure path of natural history, was the celebrated Reaumur, vol. iv. p. 503. of the "Mémoires pour l'Histoire des Insectes." He repeated all the experiments of Vallisnieri respecting the above three species, and fully confirmed all he had said respecting them; accompanying his account with ample details of their appearance and habits, and his descriptions with much better representations of them than his predecessor. Madame de Breauté, an abbess, in whose praises he sufficiently enlarges, at length furnished him with an opportunity of getting the larvæ of the *oe. bovis* from some of the cows belonging to her convent; and on them he made his observations. Among other remarks, in this interesting memoir, he mentions, that by a singular chance he observed a line of small air-bubbles arranged along the side of the insect, and placed opposite to the spiracula, being entangled in the pus, which every where covered its surface, and corresponding in number and position to these openings; which would seem to prove that these spiraculæ are designed, not for the admission of air, as is generally conceived, but in reality for its exit; the air being received by a cartilaginous tube opening at one end of the insect, viz. that extremity which is placed next the external opening of the skin, and which becomes the tail part of the future insect, the larva being, in reality, inverted in the abscess. He very candidly observes, however, that he could not force any air through these apertures, by holding the larva under water, and compressing it with the fingers.

He also noticed, that the opening in the skin, through which the larva breathes and evacuates, is considerably enlarged about the period of its exit, by the animal raising itself in the abscess, and pressing against it; and after some days of this discipline, the aperture being enlarged, he works himself through by successive efforts, and falls to the ground. This excellent observer particularly mentions also their launching themselves from the back of the animal at an early hour of the morning in preference to any other part of the day.

The perfect insect, he observes, could not be induced to take any kind of food or nourishment, though he presented it with a great variety; a circumstance, indeed, that is not so much to be wondered at, since a large share of the insect world appear to pass the last stage of their lives, not only without food, but without organs for receiving it. Generation would appear to be the leading purpose of this state of their existence.

It is particularly worthy of remark, as it may be the means of exciting those who may be possessed of the opportunity to farther research, to make mention of the recitals given by this celebrated observer in another memoir (vol. v.

p. 66.), where he describes the larvæ found in the cavities of the face of the stag; and it is evident that they are widely different from those inhabiting the same place in the sheep, or indeed from any other species at present known. He did not succeed in his attempts to breed the fly from these larvæ; and we are therefore in the dark respecting this insect: and, unless it be the *œstrus nasalis* of Linnæus, which, on several accounts, it does not appear probable that it is, it must be a new species.

Reaumur seems fully to have believed the absurd doctrine of Vallisnieri, that the parent fly entered actually into the nostrils and fauces to deposit its eggs, of which we shall have occasion to speak hereafter more particularly.

Next to the works of Reaumur, in this line of research, follow the writings of baron De Geer, who has followed and confirmed the discoveries of Vallisnieri and Reaumur, without adding any thing of importance to their observations. He seems also to entertain, without hesitation, the opinion of Vallisnieri, that the *œstrus equi* enters the rectum to deposit its eggs. We find, however, that he was aware that Linnæus, under the title *œ. bovis*, had confounded two distinct species.

He also erroneously appears to have considered the *œ. bovis* and *hæmorrhoidalis* as one species, being deceived by the circumstance of their description, which, as to colours, is very similar.

Linnæus next, by the extraordinary conciseness of his writings, seemed to satirize the enormous details in the natural historians of the preceding age, whose works were rapidly becoming too voluminous even for perusal. On most occasions he brought what was important to be known within the narrow limits of a few Latin phrases well expressed. He marshalled, for the first time, the scattered members of this extraordinary race under the common family title of *œstrus*. He, however, was only acquainted with five species, all European; *bovis*, *tarandi*, *hæmorrhoidalis*, *nasalis*, and *ovis*. His specific characters are very appropriate; and we shall have occasion, in enumerating the species at present known, at the conclusion of this general account, to give them nearly as he had done.

Fabricius next added to this family three more species; the *œ. buccatus*, *œ. pecorum*, *œ. trompe*. Describing from cabinets, without entering into their history, has been the source of the greatest confusion. His *œ. vituli* is a mere variety of the *œ. equi*; and the Linnæan *bovis*, which is the commonest species, seems to be altogether omitted in his enumeration.

Gmelin next occurs; and, collating from all quarters, without any acquaintance with the animals themselves, has added three more species, which he believes to be new, from the works of professor Pallas. These are indicated by the names of *antilopæ*, *fasciculosus*, and *hominis*.

The European species, especially those that infest our cattle, horses, and sheep, in Great Britain, being the most interesting, we shall proceed to illustrate the most curious circumstances of their history, and barely mention the names of the rest, and the animals and country they inhabit.

Linnæus, through the whole course of his life, had never met with the true fly produced by the ox-bot, but had constantly taken a very dissimilar one which infests the horse for it. Indeed, this insect is truly rare. Vallisnieri had never seen but one, and that was mutilated. Reaumur, with uncommon pains, had raised two or three to the perfect state of a fly, and informs us, that to effect his purpose more completely, he employed a cow-herd to collect for him, promising him the price of half a day's labour for each he should bring; but out of thirty procured by this means not one

lived. The cow-keeper, no doubt, too eager for his reward, had pressed them with his fingers from their situations under the skin, before they were perfectly ripe and full fed; in which case they would certainly all perish, even though within a day of this period.

There is only one good specimen of this insect that we know of in England, even at this time, which is in the collection of Mr. Thomas Allen, and was taken from the back of a cow near Hampton court. By rare chance we took another of these in the Alps, between Salanche and Bonneville, after observing it to settle on some dung that lay in the road where some cattle had recently passed, and which, on our return through Germany, we presented to the venerable and very respectable professor D. Schreber of Erlang, the intimate friend and pupil of Linnæus, who, we were surprized to find, till that time had not seen it.

Nothing is, however, more easy than to procure these insects by the simple means we formerly used, and the detail of which may not be unacceptable to the public, especially to those who wish to see them from curiosity, or from a desire to procure them for their cabinets. During the latter months of the summer, at which time these larvæ are most frequently found of a mature age, and ready to quit their habitations, which is discoverable by the superior size of the tumor, and by the increased diameter of the external opening in the skin; selecting such as these, the hairs are to be removed with a pair of scissors to some little distance from the tumor, and a piece of leather thickly spread with pitch, through the centre of which a hole is cut, and into this is inserted a small gauze pouch or bag; the pitched leather is now placed on the skin, to which it readily adheres, and the insect, when it falls from the abscess, is caught by the bag, where, as it cannot escape, it remains till removed by the person who looks after them. Three larvæ, procured in this way, produced two flies in very good condition: one fled away during some experiments that we were making with it; the other was given to Mr. Allen, as above stated, after drawings had been made of it for the use of the Linnæan society.

We are now under the necessity of adverting to a small communication sent to the Linnæan society by the writer of this article, in the year 1796, and published in the third volume of their Transactions, p. 289, as this memoir contains some farther observations and discoveries than these which had fallen within the notice of Vallisnieri and Reaumur, we shall briefly extract from them what is new or useful.

Page 291. "The larva of the *œstrus bovis* is very unlike the other larvæ of this genus, so much so that I did not imagine, till I had procured the fly from it, that it was the larva of an *œstrus*. It neither possesses the aculci, the lips, or the marginal setæ, which are the prominent characters of the larvæ of the *œ. equi* and *hæmorrhoidalis*. When young, the larva is smooth, white, and transparent; as it enlarges, it becomes browner; and about the time it is full grown, it is totally of a deep brown colour, having numerous dots on its surface, disposed in transverse interrupted lines passing round the segments. Two distinct and different kinds of lines are seen on each segment; the uppermost of them is narrower, and consists of larger dots. Underneath these there is a broader line, and the dots smaller. The first are easily seen, by using the lens, to be real hooks bent upwards, or towards the tail of the insect; and on examining the broader line of small dots, with a tolerably powerful magnifier, they were found also to be real hooks turned in an opposite direction to the former, that is, downwards in the abscess, and towards the head of the insect. This singular arrangement of hooks round the body of the larva, in this instance, serve the purpose of legs in other larvæ, enabling it to move about

in the abscess at pleasure, and to crawl out of it when ripe, and renders the use of the tentaculæ, observable at the small end in the other species, not necessary in this.

“ These hooks, being erected by the muscles of the skin, according to the series of them used by the larva, it appears to be raised or depressed in the abscess; and by this motion, and the consequent irritation, a more or less copious secretion of pus is produced for the sustenance of the larva. The *chrysalides* continued in that state from about the latter end of June till about the middle of August, when the fly, forcing open a very singular marginated triangular lid, or *operculum*, at the small end, made its appearance.

“ Although its effects on the cattle are so often remarked, yet the fly itself is rarely seen or taken, as the attempt would be attended with considerable danger, if in pursuit of the oxen. The pain it inflicts in depositing its eggs, appears to be very severe. When one of the cattle is attacked by this fly, it is easily known by the extreme terror and agitation of the whole herd. The unfortunate object of the attack runs bellying from among them to some distant part of the heath, or the nearest water. The tail, from the severity of the pain, is held with a tremulous motion straight from the body; and the head and neck stretched out to the utmost. The rest, from fear, generally follow to the water, or disperse to different parts of the field.

“ When the oxen are yoked to the plough, the attack of this fly is attended with real danger to the drivers; since they become perfectly uncontrolable, and will often run with the plough directly forwards through the hedges, or whatever obstructs their way.

“ There is provided, on this account, to many ploughs a contrivance immediately to set them at liberty. The singular scene attending the attack of this fly on the herd, has often been the subject of poetical description; no one has, however, more naturally or elegantly delineated it than the bard of Mantua:

“ ——— Est lucos silari circa ilicibusque virentem  
Plurimus alburnum volitans cui nomen asilo  
Romanum est, oestrus Graii vertere vocantes:  
Asper, acerba, sonans: quo tota exterrita sylvis  
Diffugiunt armenta; furit mugitibus æther  
Concussus, sylvæque, et sicci ripa Tanagri.”

Georg. lib. iii. ver. 146—151.

“ The strongest and healthiest beasts seem constantly to be preferred by this fly; and their possessing them in their backs is considered as a criterion of goodness with the dealers in cattle; and the tanners observe, that their best and strongest hides have the greatest number of bot-holes in them.

“ The whole of this family of insects appear to have a strong dislike to moisture; since the animals find a secure refuge, when they get into a pond or brook, where the other flies which annoy them, follow without hesitation, but the oestrus rarely or never; and during very cold, rainy, or windy weather, they are not to be seen.

“ Among the country-people, the larvæ of this insect are commonly known by the name of warbles, wormuls, or wormuls, or more properly bots.”

We now transcribe from the above memoir what is most worthy of notice respecting the *oestrus equi*, or large horse-bot.

“ These larvæ attach themselves to every part of the stomach, but are in general most numerous about the pylorus, and are sometimes, though much less frequently, found in the intestines. They hang most commonly in clusters; being fixed by the small end to the inner membrane of the stomach, where they adhere by means of two small hooks or *tentacula*. When removed from the stomach, they will attach them-

selves to any loose membrane, and even to the skin of the hand; for this purpose, they draw back their hooks almost entirely within the skin, till the two points of these hooks come close to each other; they then present them to the membrane, and keeping them parallel till it is pierced through, they expand them in a lateral direction; and afterwards, by bringing the points downwards, or towards themselves, they include a sufficient piece of the membrane with each hook, and thus remain firmly fixed, for any length of time, without any farther exertion from the animal.

“ All those bots which feed on the mucous membranes lining the canals of the body, are provided with these tentacula; whilst those which inhabit beneath the skin, will be found universally without them. The oestrus of the sheep has them also, but uses them only in passing over the membranes on which it lives, making them a fixed point to which it draws up its body, and thus secures its passage along those smooth and lubricated surfaces of the nostrils.

“ The larva of this bot, when very young, is of a cylindrical figure, of a pellucid ruby red, and appears without spines to the segments. As it acquires an increase of size, it assumes a more flattened appearance, becomes whiter; and the spines, which are tipped with black, become very visible, being placed in double lines, and are directed towards the tail, or truncated end of the larva.

“ Their food is probably the chyle, which, being nearly pure aliment, may go almost wholly to the composition of their bodies without any excrementitious residue; though, on dissection, the intestine is found to contain a yellow or greenish matter, which is derived from the colour of the food, and shews that the chyle, as they receive it, is not perfectly pure.

“ The slowness of their growth, and the purity of their food, mult occasion what they receive in a given time to be proportionably small; from whence probably arises the extreme difficulty there is found in destroying them by any medicine or poison thrown into the stomach. Opium, tobacco, or the drastic purgatives, which often bring away in abundance the common worms of the intestines, produce little or no effect on these.

“ On opening the body of the bot, and removing the gelatinous matter, the air tubes are seen, and seem of a splendid silvery colour, glittering very beautifully, as though they were injected with the purest mercury; they remain distended by their own inherent elasticity, and are filled with air to their minutest ramifications.

“ Respiration appears to be the office of these air-canals, which are the lungs of the larva; and, considered in this point of view, they are much larger than the respiratory organs of any other animal, which is the more extraordinary, if the respiration of animals be for the production of animal heat; this being unnecessary to larvæ, that are supplied so abundantly with it from the high temperature of their residence in the living stomach. Nor can these organs be formed for the purposes of the future insect, since they cannot be detected in either the chrysalis or fly. One should almost, from this circumstance, be led to suspect that the respiration of animals was more intimately connected with the reception of food, and the converting it into living matter than any other design. Though it would also appear, that the impurity of the air in the stomach, and its casual supply might render these larger reservoirs necessary.

“ The larvæ of the large horse-bot attain their full growth about the latter end of May, and are coming from the horse from this time to the latter end of June, or sometimes later. On dropping to the ground, they find out  
some

some convenient retreat, and change to the chrysalis; and in about six or seven weeks, the fly appears; for the description of which, see the conclusion.

“The mode pursued by the parent fly, to obtain for its young a situation in the stomach of the horse, is truly singular, and is effected in the following manner. When the female has been impregnated, and the eggs are sufficiently matured, she seeks among the horses a subject for her purpose; and advancing on the wing, she holds her body nearly upright in the air, and her tail, which is lengthened for the purpose, curved inwards and upwards. In this way, she approaches the part where she designs to deposit the egg; and suspending herself for a few seconds before it, suddenly darts upon it, and leaves the egg adhering to the hair; she hardly appears to settle, but merely touches the hair with the egg held out on the projected point of the abdomen. The egg is made to adhere by means of a glutinous liquor secreted with it. She then leaves the horse at a small distance, and prepares a second egg; and poizing herself before the part, deposits it in the same way. The liquor dries; the egg becomes firmly glued to the hair; and this process is repeated by various flies, till four or five hundred eggs are sometimes placed on one horse.

“The horses, when they become used to this fly, and find it does them no injury, as the *tabani* and *conopes*, by sucking their blood, hardly regard it, and do not appear at all aware of its insidious object.

“The inside of the knee is the part on which these flies are most fond of depositing their eggs, and, next to this, on the side and back part of the shoulder, and less frequently on the extreme ends of the hairs of the mane. But it is a fact worthy of attention, that the fly does not place them promiscuously about the body, but constantly on those parts which are most liable to be licked with the tongue; and the ova, therefore, are scrupulously placed within its reach. Whether this be an act of reason or instinct, it is certainly a very remarkable one; and one should suspect, if it was the latter, it ought to direct the performance of the act in one way only.

“Whichever of these it may be, it is, without doubt, one of the strongest examples of pure instinct, or of the most circuitous reasoning, any insect is capable of. The eggs thus deposited, I at first supposed were loosened from the hairs by the moisture of the tongue, aided by its roughness, and were conveyed in this way to the stomach, where they were hatched: but on more minute search, I do not find this to be the case, or at least only by accident; for when they have remained on the hairs four or five days, they become ripe, after which time the slightest application of warmth and moisture is sufficient to bring forth in an instant the latent larva. At this time, if the tongue of the horse touches the egg, its *operculum* is thrown open, and a small active worm is produced, which readily adheres to the moist surface of the tongue, and is from thence conveyed with the food to the stomach.

“I have often clipped off with a pair of scissors some hairs, with the eggs on them, from the horse; and on placing them in the hand moistened with saliva, they have hatched in a few seconds. At other times, when not perfectly ripe, the larva would not appear, though held in the hand, under the same circumstances, for several hours; a sufficient proof that the eggs themselves are not conveyed to the stomach.

“It is fortunate for the animals infested by these insects, that their numbers are limited and kept within bounds, by the hazards they are exposed to. I should suspect near a hundred are lost for one that arrives at the perfect state of a fly. The eggs, in the first place, when ripe, often hatch

of themselves; and the larva, without a nidus, crawls about till it dies; others are subject to be washed off by the water, or are hatched by the sun and moisture thus applied together; when in the mouth of the animal, they have the dreadful ordeal of the teeth and mastication to pass through; and on their arrival at the stomach, they may pass, mixed with the mass of food, into the intestines; and when full grown, on dropping from the anus to the ground, a high road or water may receive them; if on the common, they are in danger of being crushed to death, or of being picked up by birds, which so constantly for food attend the footsteps of the cattle. Such are the contingencies, by which nature has prevented the too great increase of their numbers, and the total destruction of the animals they feed upon.”

I have once seen the larvæ of this oestrus in the stomach of an ass. Indeed, there is little reason to doubt their existence in the stomachs of all this tribe of animals.

The perfect fly but ill sustains the changes of weather; and cold and moisture in any considerable degree would probably be fatal to it. These flies never pursue the horse into the water; this aversion, I imagine, arises from the chillness of the atmosphere over that element, which is probably felt more exquisitely by them, than by other flies, from the high temperature they had been exposed to during their larva state. The heat of the stomach of the horse is much greater than that of the warmest climate; being about 102° of Fahrenheit; and in their fly state, they are only exposed to 60°, or from that to about 80°, in very warm weather. Such a change, if suddenly applied, would in all probability be fatal to them; but they are prepared for it, by suffering its first effects in the quiescent and less sensible state of a chrysalis. I have often seen this fly in cloudy weather, and during the night time, fold itself up with the head and tail nearly in contact, and lying apparently in a torpid state, though in the middle of the summer.

I never observed these bots hanging to the extremity of the rectum, previous to quitting it, as the hæmorrhoidales, or small horse-bots, are seen to do.

Whether these bots can at all exist in the stomach of a carnivorous animal, I am not assured. I gave upwards of a hundred eggs, proved by trials to be ripe, and containing a living caterpillar, to a cat in milk at various times; and on destroying her, at the end of two months after the first portion had been given, I could discover no traces of them in the stomach or intestines.

I gave six of the larvæ of the great horse-bot, recently taken from a dead horse's stomach, and perfectly alive, to another horse, in a ball made of meal, in the centre of which they were enclosed: their effects on the stomach were not noticeable by any external indications; 27 of them were the next day exhibited to a horse with the farcy, without their producing any sensible effect.

Of the *oestrus hæmorrhoidalis*, or small horse-bot. The larva, or grub, producing this insect, is in most respects like the former, occupying the same situation also in the stomach of the horse: it is easily distinguished by its smaller size, and being nearly or quite destitute of spines, on leaving the rectum; when full grown, it assumes a reddish green colour, and in about two days becomes a chrysalis.

None of the larvæ of this family of insects appear to change their skin, which at length becomes also the shell of the chrysalis: when squeezed, they forcibly contract themselves into a smaller space, and become very hard. It is probable they in this way resist the violent pressure they must occasionally sustain from the weight of the food, and the actions of the stomach, and in passing through the intestines and the sphincter ani.

After remaining in the chrysalis state about two months, the fly appears. See the description at the conclusion, and the figure of it in the plate.

It seems hitherto to have been universally believed among naturalists, that the female fly enters the anus of the horse, in a very extraordinary manner, to deposit its eggs. Reaumur received the idea of Vallisnieri, and Vallisnieri of a Dr. Galvani, whose observations I should suspect originated from seeing the *hippobosca equina* teazing the horse, as is very commonly seen; and its getting within the rectum was merely, it is probable, supplied by his fancy and imagination. The objections to an idea of this sort are these, admitting there was any good foundation for such a supposition; that the anus is rather closed than opened by any irritation externally applied; that the fly would be crushed in attempting to pass the sphincter of a horse's rectum; and having no means of holding, while depositing its eggs, it would be quickly forced out with the dung; and it is evident, that the whole of the ova, to the amount of some hundreds, must all be deposited in one horse, as it is impossible if the fly survived, it could undergo this punishment a second time; for the heat and moisture of the rectum would at least destroy its wings, and prevent its attaining a second time this situation.

I mention these objections, not as they merely relate to this species, but that it may not be credited of the nasal, or indeed of any of them, that they really enter the body of the animal, to obtain for their young a situation there.

I have not seen any writer who has conjectured the real mode in which this fly deposits its ova; which having discovered by repeated opportunities of witnessing it, I can speak of with certainty.

The part chosen by this insect for this purpose is the lips of the horse, which is very distressing to the animal from the excessive titillation it occasions: for he immediately after its touch rubs his mouth against the ground, his fore legs, or against a tree; or if two are standing together, they often rub themselves against each other.

At the sight of this fly the horse appears much agitated, and moves his head backwards and forwards in the air, to baulk its touch, and prevent its darting on the lips; but the fly, watching for a favourable opportunity, deposits its eggs from the point of the abdomen, and he continues to repeat his attacks on the lip, till the enraged animal endeavours to avoid it, by galloping away to a distant part of the field. If it then continues to follow, or teaze him, his last resource is in the water, where the oestrus is never observed to pursue him.

The teazing of other flies may sometimes occasion a motion of the head similar to this; but it should not be mistaken for it, as it is never in any degree so violent as during the attack of the oestrus.

At other times I have seen this fly get between the legs of the horse whilst he is grazing, and then make his attack on the lower lip. The titillation occasions the horse to stamp violently with his fore-foot against the ground, and he often strikes with his foot as though aiming a blow at the fly. They also sometimes hide themselves in the grass; and as the horse stoops to graze, they dart on the mouth or lips, and are always observed to poize themselves during a few seconds in the air, while the egg is preparing on the point of the abdomen.

When several of these flies are confined in a close place, they have a particularly strong stinky smell, such as we feel when animals are confined in a close place: and I have observed both sheep and horses, when teazed by them, to look into the grass, and smell to it very anxiously; and if

by these means they discover the fly, they immediately turn aside, and harken to a distant part of the field.

The eggs of this species appear of a darker colour than the former, and are provided with a *petiolus*, or foot-stalk from the small end, the opposite being obtuse, and provided with an *operculum*: it is also ribbed in a transverse direction, unlike the eggs of the preceding species.

Our ancestors imagined that poverty or bad food engendered these animals, or that they were the offspring of putrefaction. In Shakspeare's *Henry the Fourth*, part 1st, the ostler at Rochester says, "peas and beans are as dank here as a dog, and that is the next way to give poor jades the bots;" and the miserable nag of *Petruchio* is said to be so "begnawn with the bots." When the animal is kept from food, the bots are also; and, it is natural to suppose, are then the most troublesome: whence arose the idea, that poverty or bad food could engender them.

Of the *oestrus veterinus*. This insect was known to Linnæus, who gave it the name of *nasalis*, from an idea of its entering the nostrils of the horse, and depositing its eggs in the fauces: "Habitat in equorum fauce per nares intrans." Linn. Syst. Nat. 2. p. 969. which as it could not well do without destroying its own wings, is probably as much a fable as the "mirè per annum intrans," of the preceding species. We have seen four *chrysalides* of this fly, which were uniformly found under the dung of horses, which leads to a suspicion that they also inhabit the stomach of this animal. The larva is at present unknown; but if it inhabited the *fauces* of the horse, it would produce such troublesome symptoms as could not easily escape the notice of those whose business it is to attend to the diseases of cattle. Such a disease has, however, never been described; nor after an extensive opportunity, both in the dead and living subject, have I ever seen a bot in the *fauces* of the horse. Perhaps the bots of the stomach, having crawled to the fauces in search of food, after the death of the animal, might have given rise to this idea: they may have even accidentally bred there; for there is little room to doubt, that these animals can live in any part whatever of the alimentary canal, or the passages leading to it. For a figure of this fly, see also the plate of the *oestri*.

Of the *oestrus ovis*. About the middle of June I procured some full-grown larvæ of the *oestrus ovis*, from the inside of the cavities of the bone, which supports the horns of the sheep. They are nearly as large as those of the large horse-bot, of a delicate white colour, flat on the under side, and convex on the upper, having no spines at the divisions of the segments, though provided with two curved hooks at the small end. The other extremity is truncated, with a small prominent ring or margin, which seems to serve the same purpose, though in an inferior degree, as the lips of the *oe. equi* and hæmorrhoidales, by occasionally closing over, and cleaning the horny plate of respiration. When this margin opens, after closing over the plates, a slight snap is sometimes heard, from the sudden admission of air.

When young, those larvæ are perfectly white and transparent; except the two horny plates, which are black: as they increase in size, the segments of the upper side become marked with two brown transverse lines; and some spots are observable on the sides.

They move with considerable quickness, holding with the *tentacula* as a fixed point, and drawing up the body towards them. On the under side of the *larva* is placed a broad line of dots, which, on examination with glasses, appear to be rough points, serving, perhaps, the double purpose of assisting their passage over the smooth and lubricated surfaces

faces of these membranes, and of exciting also a degree of inflammation in them where they rest, so as to cause a secretion of lymph or pus for their food.

"I have mostly found these animals in the horns and frontal sinuses; though I have remarked that the membranes lining these cavities were hardly at all inflamed, while those of the maxillary sinuses were highly so. From this I am led to suspect they inhabit the maxillary sinuses, and crawl, on the death of the animal, into these situations in the horns and frontal sinuses.

"The breeds of these, like the *oe. bovis*, do not appear confined to any particular season; for quite young and full-grown larvæ may be found in the sinuses at the same time.

"When full grown, they fall through the nostrils to the ground, and change to the *pupa* state, lying on the earth, or adhering by the side to a blade of grass. The fly bursts the shell of the pupa in about two months. The figure is given in the plate; and its description at the conclusion.

"The manner in which this species deposits its *ova*, which we have often seen, has not, we believe, ever been described; nor is it easy to see, though standing close to the animal at the time, exactly in what way this is accomplished, owing to the obscure colour and rapid motions of the fly, and the extreme agitation of the sheep; but from the motions of the sheep afterwards, and the mode of defence it takes to avoid it, there is little doubt that the egg is deposited in the inner margin of the nostril.

"The moment the fly touches this part of the sheep, they shake their heads violently, and beat the ground with their feet, holding their noses, at the same time, close to the earth, and running away, earnestly looking on every side, to see if the fly pursues: they also may sometimes be seen smelling to the grass as they go, least one should be lying in wait for them; which if they observe, they gallop back, or take some other direction, as they cannot, like horses, take refuge in the water: to defend themselves against its attacks, they have recourse to a rut, or dry dusty road, or gravel-pits, where they crowd together during the heat of the day, with their noses held close to the ground; which renders it difficult for the fly, who makes his attacks on the wing, to get at the nostril.

"I imagine the nostril, from repeated attacks of the fly, and the consequent rubbing against the ground, becomes highly irritated and sore; which occasions their touch to be so much dreaded by the sheep.

From the difficult and very precarious mode these flies pursue, and also the *hemorrhoidalis*, in depositing their eggs, they cannot succeed in depositing but a few in each sheep; whereas, on the contrary, if they actually entered those cavities of the face to effect it, they must deposit them all, and in one subject, the impossibility of which is already stated.

"*General observations on the oestri.* Having traced these separately through their various changes, and mode of propagation, it may not be improper to consider their good or ill effects on the animals that are subject to them.

"Though the attention of naturalists is at present occupied with the formation of a nomenclature, and descriptions, to every object of natural history, yet this pursuit, though difficult, and highly important, is not so much the ultimate aim of this science, as a knowledge of their economy and properties; as it is from those we are taught the most effectual means of avoiding the consequences of the injurious, and of protecting such as can be usefully applied to the purposes of mankind. If after mature inquiry, the existence of the oestri should be proved, in a greater degree,

injurious, than beneficial, by any service they can afford, their numbers might be considerably reduced, and a total extirpation of some of the species would not, I am disposed to believe, be altogether impracticable in our insular situation.

"The injury derived from their depredations is principally felt by the tanners, whose hides are often so perforated by these animals, as to be considerably damaged; and sometimes the loss of a horse or sheep may be occasioned by the existence of the other species.

"If it were desirable to lessen their numbers, the following, I apprehend, would be the most successful means. The larvæ of the *oe. bovis*, or ox bot, which breeds in the backs of the horned cattle, is so conspicuous, that it is more easily destroyed than the others: the injection of any very corrosive liquor into the sinus would kill it; or by puncturing the larva with a hot needle, through the aperture in the skin, or even by simple pressure, they may be destroyed, afterwards extracting them, or leaving them to slough away, which I have often observed they do, when crushed by a blow from the horn of the beast, or by any other accident, without the least injury to the animal. A man employed for this purpose might, in half a day, destroy every bott on a large common, the beasts being suffered to pass by him one by one.

"In respect to the great and small horse-bot, those who have horses which have been much out to grass the preceding year, in countries where these flies are prevalent, might considerably diminish their numbers, by examining the horses occasionally for the bots, during the summer months; when they will be found hanging to the extremity of the rectum, where they remain, especially the *hemorrhoidalis*, for some days before they fall to the ground.

"The destruction of a single one, at this season of the year, is not only the death of an individual, and its effects, but the almost certain destruction of a numerous family.

"I am induced the more particularly to recommend attention to this circumstance on another account, which is from the necessity there is of preventing the irritation which this animal occasions to the anus of the horse, which at times is highly troublesome. If the horse is used on the road, while the bots are adhering to this part, the irritation becomes particularly distressing, and causes him to move very awkwardly and sluggish, as though tired; and, if severely beaten, he soon relapses again into the same awkward way of going; and as this generally happens during warm weather, it is attributed to mere laziness, and severe correction follows, but to no purpose, of which we have two or three times been an eye witness; but, on the removal of the bot, the cure is instantaneous.

"There is no medicine at present known that will detach them from the stomach, or intestines, though there are not wanting abundance of infallible nostrums for this purpose among the very numerous professors of horse medicine. An easy and effectual mode for the *oe. equi*, is to destroy the eggs which are deposited on the hairs, and are readily seen and removed by a pair of scissors, or a brush and warm water.

"In the sheep, it would be much more difficult to prevent or destroy them by any of these means, particularly if they are situated in the maxillary sinuses; as, in this case, even trepanning them would be insufficient, as they would probably lie concealed in the convolutions of the turbinated bones.

"Perhaps the removal of the sheep to a distant pasture, during the months of June and July, whilst the greatest part of the bots are yet on the ground, in a chrysalis state, and not bringing them on such ground again, till the setting in

of winter, would be the means of destroying them most effectually; and this process, repeated for two or three years successively, in places where they are particularly troublesome, might prove eventually useful to the farmer: the Lapplanders, we learn from Linnæus, migrate annually with their rein-deer, on account of the bot which infests them.

On the other hand, notwithstanding the apparently unecessary existence and cruel effects of the *oesfri*, they are probably not altogether without an use, or were designed by Providence to add, without a recompence, to the numerous sufferings of these laborious and inoffensive animals.

“A physiological view of their effects will perhaps best justify their existence, and save them from such an imputation.

“The larvæ of the *oesfri*, when applied under proper restrictions, and only to a certain extent, may be of greater utility than from our present very limited knowledge of them we are able to discover; but we may venture to remark, that their effect in keeping up a considerable degree of irritation in the membranes, on which they are situated, may perhaps not inaptly be compared to that of a perpetual issue, or blister. Nor is there wanting abundant proof of the utility of local irritations, in preventing the access, as well as in effecting the cure of disorders. We often see a formidable disease quickly removed by blistering the skin, or by irritating the mucous membranes of the stomach, or intestines, by a vomit or purge. The appearance of exanthematous eruptions on the skin, and the formation of local abscesses, from the same cause of partial irritation, often relieve a general disorder of the system.

“The mucous membranes, and the skin, possess this power, when irritated, in a more eminent degree than all the other parts of the body, and it is to these larvæ of the *oesfri* are applied. Irritating the membranes of the stomach, by such means, in other animals, would excite nausea and vomiting; but the horse, not possessing this power, his stomach is peculiarly fitted for the stimulus of such inhabitants.

“How far the access of those dreadful disorders, which sometimes arise of themselves in cattle and horses, and afterwards become contagious, as the murrain, glanders, farcy, &c. may be prevented by these peculiar irritations, it will not be easy to discover, nor whether that singular tendency or disposition in the horse to inflammatory complaints, as the inflammation of the eyes, termed moon-blindness, inflammation of the lungs, and of the bones, &c. may be in any degree subdued by these local stimuli.”

“In confirmation of this suggestion, I may remark, (although I am aware other reasons may be also assigned for it,) that those horses which are not exposed to the bots, more frequently are infected with the glanders, farcy, &c. as those of the army, post coaches, post waggons, and dray horses, these being rarely spared, from the nature of their work, to graze on the commons, and thus be exposed to receive them.”

If, on a more minute search into their effects on the system, the utility of these native stimuli of animals should be established, and, like the leach, or the cantharides, they should be called in aid of veterinary medicine, it would be very practicable to administer them artificially, in any quantity, either by the eggs, or the larvæ themselves.

If the stimulus is considered as of too gentle a nature, it is, in some measure, atoned for by its permanency, and the unlimited power of increasing their numbers; at least by the administration of them, in this way, we might accurately ascertain their real effects, and whether they are so fatal as has been imagined.

There seems also to be a principle existing in nature, of

leaving no space unoccupied that can possibly afford a situation for the convenient increase of animal existence: hence, perhaps, springs one of the causes for the extraordinary occupation of these parts by these animals.

The characters which appear to be general in the structure of this family are, that the *antennæ* have three articulations, the last almost globular, having a bristle or hair in front; and these antennæ are each lodged in a deep excavation of the face. The mouth, a simple aperture, not at all projecting from the head. The *palpi*, or feelers, are two, of two joints, their extremity globose, sunk in a depression on each side the mouth.

All the species of this extraordinary family at present known are,

*Oestrus bovis*, great ox bot fly. Brownish unspotted wings; abdomen with a black band in the middle, and its extremity with orange-yellow hairs.

*Oe. equi*, or great horse bot. Wings white, with a stripe of black, and two small black spots.

*Oe. hæmorrhoidalis*, or lesser horse bot. Wings dark, unspotted, abdomen black, base white, and point orange.

*Oe. veterinus*, or *nasalis* of Linnæus, the red bot fly. Wings unspotted, sides of the thorax, and base of the abdomen, with white hairs.

*Oe. ovis*. The sheep hot fly. Wings transparent, with small spots at the base; abdomen chequered with black and white.

*Oe. tarandi*. The rein-deer bot fly. Wings immaculate, thorax with a black band, abdomen orange, posteriorly yellow.

Larva, &c. In the backs of the rein-deer of Lapland.

*Oe. cuniculi*. The American rabbit bot. Black wings, brown thorax, black beyond the middle, posteriorly, on the sides of the thorax, and the base of the abdomen, with yellow hairs. Larva. In the backs of the hares and rabbits of Georgia. The immense size of this *oesfrus*, which is more than twice as large as the ox bot of this country, would lead us to doubt, whether it might not have been the inhabitant, originally, of some of those immense animals of that continent, which are now lost. See Lin. Society Trans. vol. iii. p. 299.

*Oe. buccatur*. Carolina bot fly. Red-brown, face white, with black spots.

Found in Carolina and Georgia.

*Oe. pecorum*. Wings brown, thorax grey, hairy, abdomen black, base with white hairs. In the intestines of the sheep, says Fabricius, whose species are to be adopted with great caution; perhaps it is only a dark-coloured female, of the *oe. nasalis*. The whole genus has been greatly confused by Fabricius, and not less by his successor, Prof. Gmelin, where three additional species, *antilopæ*, *fasciculosus*, and *hominis*, are probably all spurious. The first of these agrees, in all respects, with the female of *oe. equi*, the habitat being false. The second is a variety of the *oe. nasalis*, and the third is, perhaps, merely an accidental deposit of *oe. bovis*, in the human body, of which there are numerous instances.

*Oe. Georgianus*. Body and wings black, sides of the thorax white, with two black spots.

It is found in American Georgia; the animal it infests is not yet known. From the cabinet of Mr. Francillon. It is twice as large as the *oe. bovis*, and very distinct from any thing yet described.

For the figures of these animals, see the plate of the genus *Oestrus*.

BOTWAR, in *Geography*, a town of Germany, in the circle of Suabia, and duchy of Wurtemberg, seated on a small river of the same name, which runs into the Neckar; 10 miles S. of Heilbronn, and 13 N.N.E. of Stutgard.

**BOTZEN.** See **BOLZANO.**

**BOTZENBURG.** See **BOITZENBURG.**

**BOVA**, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, the see of a bishop, suffragan of Reggio, situate on the brow of a hill, at the foot of the Apennines, near the sea; 20 miles S.E. of Reggio. Being out of the way of trade and thoroughfare, this place can boast neither of wealth nor agriculture. The villagers in its vicinity carry corn, cheese, and cattle to Reggio; but that being a poor mart, has but small demands, and a little circulation of money. Most of the inhabitants are of Greek origin and rise; and emigrated from Albania a few centuries ago. Their common language is Albanese, which is a dialect quite different from the modern Greek and Slavonian languages; and though known in Europe for more than a thousand years, and spoken by all the nations round Albania, still remains without an alphabet, and many of its sounds are not to be accurately expressed either by Latin or Greek letters. Hence it may be inferred, that it is a mixture of the dialects of those Tartarian hordes that overran Macedonia and Greece in the 8th century; to which medley the intercourse with Germans, Italians, and crusaders, has added a variety of foreign terms. The men can speak Calabrese; but the women, who neither buy nor sell, understand no tongue but their own, which they pronounce with great sweetness of accent. Swinburne's Travels in the two Sicilies, vol. ii. p. 241, &c.

**BOUAGE**, a town of France, in the department of the Lower Loire, and chief place of a canton in the district of Nantes; 8 miles S.W. of Nantes.

**BOUALL**, a town of Africa, the capital of Loango, so called by the French.

**BOVATA terra**, in *Ancient Latin Writers*, signifies an oxgate of land, or so much as may be ploughed in a year with one ox; by some reckoned at fifteen acres, by others at eighteen, by others at twenty, and by others at thirteen or twenty shillings yearly rent.

This is otherwise called *bovatus*, and *bovariata terra*.

**BOUATI**, in *Botany*. Rumphius Amb. 2. tab. 41. *Bosc in Nouveau Dictionnaire d'Histoire Naturelle*. Class, *hexandria digynia*.

Gen. Char. *Cal.* perianth small, tripartite, pubescent, caducous. *Cor.* petals three, oblong, pointed, concave, longer than the calyx. *Stam. fis.* *Pist.* germ superior, oval, compressed, villose, dimpled at its summit; stigmas two, sessile, obtuse. *Per.* a capsule nearly heart-shaped, compressed, smooth, sharp-edged, dimpled at its summit, and divided into two cells, each of which contains a single oval seed.

It is a small tree which grows in the East Indies, is extremely bitter in all its parts, and is given with success in fevers. It is also used as a restorative, and an antidote to poisons.

**BOUBI**, in *Ornithology*, the name given by the French navigators to the booby of the English. See **BOOBY**.

**BOUBIL**, the name by which the Chinese at Canton denominate the crying-thrush, *turdus canorus*. In other parts of China, the same bird passes under the title of *wa-mew*. Sonnerat tells us, this is the only singing bird that is known to inhabit the vast empire of China, where it is occasionally kept in cages, for the sake of amusement, by the fair sex. It subsists on rice, worms, insects, &c. The same bird is also called *baniabhou*. See **CANORUS**.

**BOUBIL**, *Boubil de la Chine*, the name given by Sonnerat to the *turdus bubil* of Gmelin, and *chaunting-thrush* of Latham. See **BUBIL**.

**BOUBOU**. Le Vaillant, in his History of the Birds of

Africa, bestows this name on a species of *Turdus*, the male of which has a remarkable peculiar note, resembling the word *boubou*, often repeated. This bird was previously described by Buffon, under the title of *Merle noir et blanc d'Abissinie*: it is also the *turdus ethiopicus* of Gmelin.

**BOUBOUT**, one of the synonymous names of the hoopoe, or hoop, the *upupa epops* of Linnæus. See **EPOPS**.

**BOUC**, in *Zoology*, *Geysser bock*, Gesn. synonymous names of the goat, *capra hircus*. *Bouc d'Afrique*, is *capra depressa*; and *bouc de juda* (of Buffon) is *capra reevesia* of Linnæus; the *whidaw* goat of Pennant.

*Bouc Damoiseau*, the French name of the Linnæan *antilope grimmia*; called also by them *grimmie*, and *Chèvre de grimmie*.

*Bouc-Estein*, or *Bouc-stein*, the names of the wild goat (*capra ibex* of Linn.), in old French writers. The word is of German origin, being derived from *bock*, or *bouc*, and *stein*, a rock or stone; in French, *bouc de rocher*; or, as we should render it, the rock, or mountain goat. Thus also, *bouc des rochers*, *bouquetin*, *bouc sauvage*, &c.

**BOUCANE'GRE**, in *Ichthyology*, one of the synonymous names of *sparus pagel*. See **PAGEL**.

**BOUCARDE**, or **BUCARDE**, in *Conchology*. See **CARDIUM**, the cockle.

**BOUCHAIN**, in *Geography*, a town of France, in the department of the North, and chief place of a canton in the district of Douay, seated on the Scheldt, and carrying on a considerable trade in corn and cattle. The place contains 1,128, and the canton 13,509, inhabitants; the territory comprehends 152½ kilometres and 20 communes. Bouchain is a strong town; it was taken by the duke of Marlborough in 1711, after a siege of 30 days, retaken in the following year by marshal Villars, and invested by the Austrians in 1793, but soon relieved; 3 leagues S.W. of Valenciennes, and 2½ N.N.E. of Cambray.

**BOUCHARDON**, **EDME**, in *Biography*, an eminent French sculptor, was born in 1698 at Chaumont in Bassigny, where his father was a sculptor and architect: and educated at Paris, in the school of Coustou the younger. At Rome, whither he removed as the king's pensioner, to which his merit advanced him, he cultivated, with assiduity and success, his talent for design, by copying the precious remains of antiquity, as well as the works of modern painters. He afterwards settled at Paris, and, notwithstanding his singular simplicity of character, became eminently distinguished, so that he was employed in several works of importance; the principal of which are the fountain in the rue de Grenelle, fauxbourg St. Germain; a statue of Love making a bow of the club of Hercules, with the arms of Mars; and the equestrian statue of Lewis XV. at Paris. In 1736, he was appointed designer to the Academy of Belles Lettres: and, in 1744, he was admitted into the Academy of Painting, of which he was made professor in 1746. Having acquired a decent fortune, by his industry and regularity, and attained high eminence in his art, he died in 1762. His compositions are formed in the style of simple antiquity, and more admired for correctness and good taste, than for force of expression or vigour of imagination. His drawings are highly esteemed; they have furnished various engravings; and a Treatise on Anatomy, for the use of artists, published by Huquieres in 1741, is illustrated with figures by his hand. The chief amusement of this artist was music, which he performed in a masterly style. D'Argenville's Vies de Sculpteurs. Gen. Biog.

**BOUCHARI**, or **POUCHARI**, also *Boutcher*, *Boucherie*, &c. in *Ornithology*. These are the common names of the grey-

grey-backed shrike, *lanius excubitor*, in Burgundy. The words are derived from the English butcher-birds, an epithet applied with us, in a general manner, to all the species of the shrike, or *lanius* genus.

BOUCHE, MARTIN, in *Biography*, an engraver, who flourished in 1680. He was chiefly employed by book-sellers: and portraits were his principal performances. He worked altogether with the graver, in a neat but stiff style; but his portraits, several of which were those of Jesuits who flattered in England about his time, are not destitute of merit. Strutt.

BOUCHE of court, the privilege of having meat and drink at court seat-free.

The word is also written *bouge*, *bouge*, and *budge*: it is mere French, where it signifies *mouth*. The French still use the phrase, *Avoir bouche à la cour*; that is, *to have table or diet at court*.

This privilege is sometimes only extended to bread, beer, and wine: it was a custom anciently in use, as well in the houses of noblemen as in the king's court.

Thomas earl of Lancaster retained sir John de Ewre, to serve him with ten men at arms in time of war, allowing them *bouge of court*, with livery of hay and oats, horse-shoes, and nails. Sir Hugh Merrill had the same privilege for life, on condition of serving king Edward II. Kennet. Gloss. ad Paroch. Ant. p. 378.

BOUCHE d'Argent, in *Conchology*, the trivial French name of a shell of the turbo genus, the mouth, or opening of which is silvery within. Linnæus calls it *turbo argyrostomus*; the English silver-mouth turbo, or silver-mouth.

BOUCHE d'Or, as in the former, a trivial sort of expression among the French collectors for the Linnæan *turbo chryso-stomus*, the mouth of which is of a fine golden hue. This is the gold-mouth turbo of the English.

There are a number of other shells, distinguished in like manner, by the colour of the mouth, to each of which a characteristic epithet is given; but such names are always capricious, and liable to be misapplied, because they are the names in common use among the dealers in shells, and others, who have only a slight acquaintance with the subject of testaceology. It is always better, therefore, to retain the names ascribed to them by Linnæus, and other Latin authors.

BOUCHEMAINE, in *Geography*, a town of France, in the department of the Maine and Loire, and chief place of a canton in the district of Angers; 4 miles S. of Angers.

BOUCHENE', a town of Persia, in the province of Korasan; 20 miles N. of Herat.

BOUCHER, FRANCIS, in *Biography*, a modern French painter of celebrity, was born at Paris in 1706, first educated under Le Moine, and finished his studies at Rome. Upon his return to Paris, where he settled, he obtained, by the style of his painting, the appellation of the "painter of the graces," and the "French Albani." He was advanced to the post of first painter to the king, and that of director of the Academy of Painting, after Vanloo; but he was carried off by a premature old age in 1770. His character was social and frank, without envy or avarice; he was always ready to bestow his works on those who admired them, and liberal in his encouragement of young artists. Of his singular modesty we have an instance, in his refusal to retouch a picture of one of the first Italian masters, alleging, "Such works are holy vessels to me." His works were held in high estimation. He possessed great fertility of invention; but, says Mr. Strutt, he was defective in correctness and grandeur of design. He executed some slight etchings from his own compositions, and those of other masters. Strutt. Nouv. Dict. Hist.

BOUCHER, JOHN, a furious fanatic, was born in Paris, where he became professor of philosophy and theology, and afterwards rector, in 1580. He was also prior and doctor of the Sorbonne, and was made rector of St. Benedict. As a preacher and a writer, he was a leading and active promoter of the league against king Henry III.: the rebels first assembled in his apartments in 1585; and he ordered the alarm-bell to be rung in his church, which contributed to excite the popular insurrection of 1587, the consequences of which were so disgraceful and detrimental to the king. Soon after he published a discourse, entitled, "De justa Henrici III. abdicatione et Francorum regno," Par. 1589; which contained several very infamous charges against the king. Boucher has been charged with instigating James Clement, a Dominican monk, to the assassination of Henry; however this be, he applauded the act after it had been committed. He was a violent opposer to the succession of Henry IV. against whom he declaimed from the pulpit and from the press. Nor did his opposition cease with the king's abjuration; for pretending that he was a feigned convert, and that the pope's absolution was invalid, he published "Nine Sermons" on the subject, which he had preached at Paris in 1593. When the Parisians received Henry into the capital, these sermons were publicly burnt, and Boucher, persisting in the party of the leaguers, fled with the Spanish garrison, in 1594, into the Low Countries. At Tournay he obtained a canonry; and, after a residence of 50 years, he died dean of that chapter, in 1644. Under a feigned name he is supposed to have written an apology for John Chatel, who made an attempt on the life of Henry IV. and also for the Jesuits, who, in consequence of it, were banished from France. So atrocious was his virulence as a partisan, that he justified the conduct of those wretches who had hanged the first president Brisson, and dignified them with the title of martyrs of Jesus Christ, after they had been executed by the duke de Mayenne for that murder. It is said, however, that, towards the close of his life, he regretted living among the enemies of his country, and manifested some signs of repentance for the atrocities of which he had been guilty. Gen. Dict.

BOUCHER, JOHN-JOSEPH, born at Lisle, the 25th of March 1715, was made, in succession, physician to his native city, corresponding member of the Academy of Sciences, and foreign associate of the Royal College of Surgery at Paris. He published, in 1751, "Methode abregee pour traiter la dysenterie regnante a Lisle en 1750," 4to. He also furnished the Journal de Medicine with "Meteorological Observations" made at Lisle, and with other philosophical papers. Eloy. Dict. Hist.

BOUCHER, in *Geography*, a town of Persia, in the province of Faristan, on the north coast of the Persian gulf; 160 miles S.W. of Schiras.

BOUCHOUX, a town of France, in the department of Jura, and chief place of a canton in the district of St. Claude. The place contains 1,890, and the canton 6,094, inhabitants; the extent of the territory comprehends 127½ kilometres and 13 communes.

BOUCLANS, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Befançon; 8 miles E. of Befançon.

BOUCLIER, in *Ichthyology*, synonymous with cycloptère the French name of the *CYCLOPTERUS* genus of fishes.

BOUCLIER d'écaille de tortue, in *Conchology*, the name given by the French collectors to those shells of the limpet genus whose colours, and general form, bear some resemblance to the scale of a tortoise. The most remarkable species of this kind is *patella testudinaria* of Linnæus.

**BOUCLIER**, in *Entomology*, a genus of coleopterous insects in Olivier's arrangement, included in his first section.

The boucliers are distinguished by having two transparent wings under the elytra; body a little depressed; thorax large, dilated, scarcely less than the elytra, and concealing the head of the insect. The antennæ clubbed, perfoliated, somewhat compressed, nearly the length of the thorax, with eleven joints, the first of which is large, elongated, and clubbed, and the last almost oval. The mouth is furnished with horny, simple mandibles; acutely pointed jaws; and four unequal filiform feelers; and lastly, the tarsi are filiform, and composed of five joints.

Insects of this tribe were formerly confounded with those of *castida*, *elophorus*, *sphaeridium*, *microphorus*, *opatum*, and *nitidula*, from all of which they are to be discriminated by the foregoing character of bouclier.

There is another very analogous genus to this, namely, *peltis* of Fabricius. *Peltis* was a name given many years ago by Geoffroy to the insects afterwards called *silpha* by Linnæus. It was again taken up by Illiger, who bestowed it on a new genus of *coleoptera* established by him, in which the Linnæan species of *silpha*, *grossa*, *ferruginea*, *oblonga*, and *limbata*, were comprised. The genus *peltis* is adopted from Illiger by Fabricius, in his last work on coleoptera, *Sytlema Eleutheratorum*. It will be therefore proper to point out exactly in what particulars those two genera differ. The *peltis* has the lower lip truncated and ciliated, while in the boucliers that part is dilated and bifid; there is some dissimilitude in the external character of the two genera, and their habits of life are distinct. See *PELTIS*.

The boucliers exhale a most fetid odour. Commonly they are found feeding upon cadaverous carcases, the dung of animals, or other such filth. There can be no doubt that the stench of these insects affects even the animal matter which they crawl upon, and on which they subsist. When taken in the hand, these beetles spurt from the mouth, as well as from the anus, a drop of liquor of a dark or black colour; the consistency of which is thick, and the stench disgusting. This liquor is not produced by violence or compression; it is voluntarily discharged by the creature, and is, beyond dispute, a secretion prepared by nature to promote the putrefaction of the flesh it may chance to meet with, as is only in that state that the boucliers feed upon it.

Olivier describes only a few species of this family; namely, *le thoracique*, which is black, oval, and depressed; thorax fawn colour; and wing-cases with elevated lines. *Le littoral* is black, long, with three elevated lines on the wing-cases, and a transverse protuberance. *Le raboteux* is black; the wing-cases rugged, with three elevated lines; the thorax rugged likewise, and sinuous behind. *L'atre* is very black, with an entire thorax; the wing-cases dotted, with three smooth, elevated lines. *L'obscur* is black, slightly convex, with the wing-cases dotted, and three elevated lines obscurely marked. *Le quadripunctué* is oval, depressed, and black; the wing-cases of a pale yellow, with two black dots on each. These are all the boucliers mentioned.

**BOUCNASCH**, in *Geography*, a town of Germany, in the duchy of Holstein; 5 miles E. N. E. of Rendfburg.

**BOUCOIRAN**, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzes; 3 leagues W. of Uzes.

**BOUCONVILLE**, a town of France, in the department of the Meuse, and chief place of a canton, in the district of St. Mihiel; 2 leagues E. of St. Mihiel.

**BOUDHA**, in *Indian Mythology*. See *BOODH*.

**BOUDIN DE MER**, in *Zoology*, the name given by

Dicquemare in the *Journal de Physique*, October, 1778, to a sort of marine worm with a sheath, which, it is believed, must appertain to the *nercis* genus; but of which the description is so very incomplete as to render this a matter of uncertainty. The animal inhabits a membranaceous sheath about four inches long.

**BOUDOIR, LE**, in *Geography*, a small island in the southern Pacific ocean, discovered by Quinos, in 1606, by whom it was called "La Dezana;" in 1767, by Wallis, who named it "Ofnaburg;" and in the following year by Bougainville, who gave it the name of "Le Boudoir," or "Pic de la Boudeufe." The natives call it "Maitea," according to the report of captain Cook, who visited it in 1769. See *MAITEA*.

**BOUDRI, or BOUNDRY**, a town and chatelain of Switzerland, in the county of Neuchatel, 6 miles S.S.W. of Neuchatel, near the river Reufe, which runs into the lake of Neuchatel. N. lat. 46° 59'. E. long. 6° 38'.

**BOUDROU, or Boudroun**, the modern name of the ancient "Halicarnassus," (which see,) situate at the entrance of the Ceramic gulf, now called the gulf of Stancho, on the coast of Caria. The fortrefs, which is at the entrance of the present harbour of Boudroun, is the work of the knights of St. John of Jerusalem, who made themselves masters of this place, when, after the first crusades, they had established themselves at Rhodes. They constructed this citadel on the foundations of the magnificent palace of the consort of Artemisa, and named it "Castel San Pietro," or, in Spanish, "San Pedro." Of this the Turks made "Bedro," then "Boudroun," changing the P into B, according to their manner of pronunciation. Coats of arms, sculptured in some compartments of the walls, still shew, as at Rhodes, in whose hands Boudroun was, before it passed into those of the Turks. Its present possessors have, with their customary negligence, suffered the harbour to be choked up, so that there is no longer water enough for large ships: the harbour, however, is safe and commodious, leaving to the wind and sea only a very narrow entrance. N. lat. 36° 59'. E. long. 27° 15'.

**BOUDS**, in *Entomology*, the epithet under which the *weevil* is distinguished in some countries.

**BOVEE**, in *Geography*, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy; 5 leagues S. E. of Bar-le-Duc.

**BOVELLES**, a town of France, in the department of the Somme, and chief place of a canton, in the district of Amiens; 2 leagues W.S.W. of Amiens.

**BOVENA**, the most easterly of the Hieres islands to the east of Toulon, in the Mediterranean, on the coast of France. See *HIERES*.

**BOVENDEN**, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse-Rhinfels; 4 miles N. of Gottingen.

**BOVES**, a town of France, in the department of the Somme, and chief place of a canton, in the district of Amiens; 1½ league S. E. of Amiens.

**BOUEXIERE, LA**, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Vitré; 10 miles N. E. of Rennes.

**BOUFFE**, in *Zoology*, a race of dogs with fine, long, frizzled hair; a cross bred between the barbet and great spaniel.

**BOUFFLERS, LOUIS-FRANCIS**, in *Biography*, duke, peer, and marshal of France, and a celebrated general, was the son of Francis count of Boufflers, and born in 1644. In 1669, he became colonel of dragoons, and served in the conquest of Lorraine under marshal Crequi; and in the war

against Holland he distinguished himself, under Turenne, in several battles and sieges. He afterwards served in Germany, on the frontiers of Spain, and in Flanders; and at length was made general of the army on the Moselle, in 1690. After several services of importance at Mons, Liege, Luttenburg, and Namur, &c. he was advanced in 1693 to the rank of marshal of France; and, in the following year, he was made governor of French Flanders and the town of Lille. In 1695, having held out 63 days against the united forces of the allies under king William at Namur; when the place capitulated, he was arrested prisoner of war; and upon his remonstrance that the whole garrison, which had not been surrendered by the French, according to the articles of war, should have been retained rather than himself, he was answered, by the compliment, "Sir, you are estimated at 10,000 men." He afterwards conducted the conference which terminated in the peace of Ryswick. In 1708, he acquired great glory by an obstinate defence of Lille for four months, when it was threatened with a siege by Marlborough and Eugene. On this occasion he displayed his magnanimity, by his noble declaration to a person who represented to him the facility of killing prince Eugene; "Take him prisoner," says he, "and your fortune is made; but expect the most severe punishment, if you undertake any thing against his life." At the battle of Malplaquet, he conducted the retreat, so as to lose neither cannon nor prisoners. Having established the character of a true patriot, as well as that of a great commander, he died at Fontenoy, in 1711, at the age of 68. "His heart," said madame de Maintenon, "was the last part that died." *Nouv. Dict. Hist. Gen. Biog.*

**BOUFFLERS**, in *Geography*, a town of France, formerly called "Cagri," in the department of the Oise; 7 miles W. of Beauvais.

**BOUFRAMONT**, a town of France, in the department of the Vosges, and chief place of a canton, in the district of Neufchâteau; 2 leagues S. of Neufchâteau.

**BOUGAINVILLE**, JOHN PETER DE, in *Biography*, was born at Paris in 1732, and educated at the college of Beauvais. The first exhibition of his literary character was in a prose translation of "Anti-Lucretius," with a preliminary discourse. Amongst the friends and patrons, procured for him by his distinguished literary talents and amiable qualities, was M. Freret, secretary of the Academy of Inscriptions and Belles Letters, by whom he was introduced into that society, and whom he succeeded in his office. Of the various papers, which he wrote for the Memoirs of the Academy, two of the most considerable are those on the voyages of Pytheas of Marseilles, and of Hanno the Carthaginian. In 1754, he was admitted into the French academy; and appointed censor-royal, and keeper of the antiquities in the Louvre. He also published "a parallel between Alexander and Thamas Kuli Khan; and edited Freret's Chronology. He died of an asthma, to which he had been subject from his youth, at the castle of Loches, in 1763. *Nouv. Dict. Hist.*

**BOUGAINVILLE**, M. D. F. a native of France, and the first person of that country who circumnavigated the globe. His nautical discoveries were very numerous, and he occupies a high rank among those who have extended our acquaintance with distant seas and islands. He was killed by the mob in a tumult at Paris, May 10, 1792.

**BOUGAINVILLE bay**, in *Geography*, lies in the straits of Magellan, on the north side.

**BOUGAINVILLE island**, an island of the South Pacific ocean, adjoining a group of other islands, with which it forms a bay not less than 15,000 toises in extent, seen by M.

Bougainville in 1768, and separated by the straits, called after his name, from the island of Bouka, which see. The high mountains of this island are covered with trees, and appeared to the voyagers in search of La Pérouse to be at least 1200 toises in perpendicular height, and to be distant from the shore above 20,000 toises. It terminates in very low lands, having fine plantations of cocoa-nut trees, and seemed to be very populous. The most southerly point of this island is in S. lat.  $7^{\circ} 4' 50''$ . E. long.  $155^{\circ} 38' 34''$ . The northern point, called point Laverdy, is in S. lat.  $5^{\circ} 34'$ . E. long.  $154^{\circ} 51'$ . See **ARSACIDES** and **SOLOMON islands**.

**BOUGAINVILLE'S straits**, lie in the south Pacific ocean, at the N. W. end of the islands of Solomon; which see.

**BOUGEANT**, WILLIAM-HYACINTH, in *Biography*, a French Jesuit, was born at Quimper, in 1690, and having been educated among the Jesuits, he taught the languages and rhetoric in their seminaries at Caen and Nevers. He afterwards resided in the college of Lewis le Grand at Paris, and devoted himself wholly to literature. Besides the part which he took in the Journal de Trevoux, he was the author of several works; the principal of which are "History of the Wars and Negotiations which preceded the Treaty of Westphalia, in the reign of Lewis XII.;" 2 vols. 12mo. a work of high estimation for its curious facts and elegant style; "Expositions of the Christian doctrine by questions and answers, divided into three catechisms," 4 vols. 12mo.; "Voyage Merveilleux du prince Fan-Ferdin dans la Romanie," 12mo. a performance of fancy for which some orthodox zealots occasioned his temporary exile to La Fleche; "Three Comedies," in prose. He also wrote some controversial pieces on the eucharist, and some critical papers in the Memoirs de Trevoux. After his death, was printed his "History of the Treaty of Westphalia," 2 vols. 4to. a work that is ranked among the best historical productions of France. Bougeant was of an amiable, social disposition; and is thought to have felt much uneasiness from the attacks that were made upon him, which shortened his days. He died at Paris in 1743. *Nouv. Dict. Hist.*

**BOUGH**, in *Antiquity*. Green boughs made part of the decorations of altars and temples, especially on festival occasions. Oaken boughs were offered to Jupiter; those of laurel to Apollo; of olive to Minerva; myrtle to Venus; ivy to Bacchus; pine to Pan; and cypress to Pluto.

**BOUGIE**, in *Surgery*, is a French term, originally denoting a wax taper, but now generally applied to several instruments which are used by surgeons in diseases of the urinary passage, &c. See the articles **CARUNCLE**, **STRICTURE**, **URETHRA**, and **ŒSOPHAGUS**, where an account is given of the disorders in which bougies are principally employed, the subject of the present article being chiefly on the composition of these chirurgic instruments.

Contrivances for dilating the urethra, in cases of obstruction to the flow of urine, were employed even so early as the time of Alucasis, and the Arabical surgeons; but these were not brought to any tolerable degree of perfection until about the middle of the sixteenth century, when the frequent occurrence of strictures in the urethra introduced them into more general use. The first efforts of surgeons, in this particular department of their art, may be perused in the writings of Andreas Lacuna, Amatus Lusitanus, Alphonfus Ferrus, Ambrose Paré, Franc. Arcæus, Theodore Mayerne, John de Vigo, and Fabricius ab Aquapendente.

It is not easy to determine who invented wax candles, or rather

rather who applied them, for these purposes; but, as the name *bougie* is of French origin, it may be the invention of a French surgeon, and perhaps of Guido de Cauliaco, (who flourished before the existence of Syphilis in Europe); for this surgeon, in his chapter "De ulceribus ancharum, &c." Chir. Mag. Traët. IV. Doctr. II. cap. 7. recommends the "Turunda ex cera," to be passed up the urethra.

The materials commonly had recourse to, in the fabrication of bougies, catheters, and sounds, during the sixteenth century, were gold, silver, and lead; but as these metallic rods were not sufficiently pliable and soft for introduction into a diseased urethra, surgeons afterwards used bougies formed of slips of linen or cloth, dipped in melted wax, &c. and rolled into the size of a goose-quill, of sufficient length to pass as far as the neck of the urinary bladder. This kind of bougie was greatly improved by Mr. Daran, of Paris, who, nevertheless, made use of some very ridiculous and useless ingredients in the composition of them; such as sheep's dung, pulverized shoe-leather, port wine, and live pigeons; not to mention various other ingredients, equally needless, though not quite so absurd and preposterous.

As it is now generally admitted by surgeons that bougies act mechanically only, and not medicinally, in curing diseases of the urinary canal, we shall proceed to describe the properties and composition of waxen or plaster bougies; after which we shall notice the elastic bougies, and shall offer a few hints on an invention by Mr. Smyth, of London, who has lately contributed to the revival of metallic instruments, which had almost been wholly laid aside, on account of their wanting due flexibility, &c.

The properties required in a bougie for dilating a contracted urinary canal are, 1. Sufficient firmness to overcome the resistance of the stricture; 2. A degree of flexibility, which shall yield and accommodate itself to the windings or tortuosities of the morbid canal; 3. So much strength, cohesion, or tenacity, as not to be in danger of breaking; 4. Perfect smoothness of surface, that it shall occasion no uneasiness or difficulty in passing; 5. A mildness in its composition, which may ensure its remaining for a sufficient time in the urethra, without exciting pain or inflammation.

That it is possible to communicate a medicinal quality to bougies, cannot be denied; and it having been an old opinion that strictures were usually attended with ulcers or abrasions in the urethra, which required healing, surgeons have frequently employed medicines in the composition of bougies, supposed to possess a power of cicatrizing these ulcers: but of late, both the remedy and the disease have been exploded; we do not any longer suspect venereal ulcers as a concomitant symptom of stricture, and therefore have discontinued what were called cicatrizing applications. Still, however, the idea of employing mercury in this way, is not wholly given up; and there are medical practitioners who prefer bougies containing a large proportion of the specific, believing that it tends to eradicate any venereal taint in the system; but the major part of the profession consider mercury as entirely useless in these cases; because, if there happens to be any venereal taint in the constitution, this mode of administering mercury would not be the most eligible for the cure; and because the addition of such an incongruous article to the other ingredients, has the effect of diminishing the tenacity of the bougies. A prescription formerly in vogue, and which therefore had been received into the last edition of Chambers's Cyclopædia, consisted of Burgundy pitch, two ounces; quicksilver, one ounce; and crude antimony in powder, half an ounce.

The objection against antimony, and such like brittle ma-

terials, will undoubtedly be urged with at least as much force as that we have already made against mercury; and on this account we recommend that no mineral substance shall be employed in such quantity as to lessen the tenacity or cohesive nature of the plaster composition.

The best formed plaster bougies may, without any injury, be varied in the proportion of their ingredients, or in the colouring matter they contain, according to the temperature of the weather, or the intention of the surgeon. They may be coloured red, with a little cinnabar; white, with cerusse; black, with æthiops, &c.; and in warm weather, or a tropical climate, they should be made of a firmer consistence than in a cold country. The basis of all plaster bougies should be wax and oil: the wax may be either yellow or white; the oil, either vegetable or animal; to which may be added, a small proportion of resinous matter, &c. to afford the degree of consistence and tenacity we require. The ingredients should be well boiled and incorporated together, especially when there is the addition (usually made) of litharge or minium in considerable quantity.

The following are among the most simple and approved compositions for plaster bougies:

N<sup>o</sup> I. R. Gum lac, one pound;

Litharge plaster, three pounds;

Dissolve the gum lac in the plaster by slow boiling, and add of yellow wax two pounds. After about three hours more boiling, the whole may be set aside for use.

N<sup>o</sup> II. R. Olive oil, three pounds;

Yellow wax, one pound;

Minium, one pound and a half.

These articles are to be boiled slowly for six hours, or even longer in the winter. If the mass be not of a sufficiently firm consistence, add three or four ounces more of the wax.

N<sup>o</sup> IV. R. Litharge plaster three parts, and

White wax two parts; to which add as much olive oil or hog's lard as will give the consistence required. Boil them as before.

N<sup>o</sup> V. R. Yellow wax, one pound;

Sperma ceti, half an ounce;

Acetated cerusse, from two to eight drams, according to the degree of solidity desired. Small bougies are to be made of a thicker mass than larger, especially for a hot climate.

N<sup>o</sup> VI. R. Yellow wax, four parts;

Oil of olives, three parts;

Sperma ceti, one part.

Boil them gently together for two hours, or until they are properly incorporated.

As prescriptions of this sort may be varied at pleasure, it is unnecessary to increase the number of our formulæ: the above compositions are to be used in a melted state, but not very hot. Slips of soft linen or calico, of a fine texture, and not less than eleven inches in length, are to be dipped into the warm mass, or spread over with some of it by means of a broad spatula; and care should be taken to make the surface of this creeloth as smooth and uniform as possible. Some persons advise that the slips of fine rag shall be of different lengths, from eight to eleven inches, and about three in breadth; these slips are then to be rolled up loosely, and taking hold of one extremity with the left hand, let it fall upon the surface of the plaster, and then draw it out gently. As it is drawn out it will unroll, and take up a quantity of plaster on the surface, equal to the thickness of a wafer or a pence; though, to facilitate the unrolling of the rag, it will be proper to assist its motion with the end of the spa-

tola, or some other instrument. The plaster, however, must be warm enough to soak through, and discolour the rag, otherwise it will not make so good a bougie.

If the cloth be exactly three inches broad, it will make six bougies of a moderate size; but their size may be suited to the occasion. It is generally advisable that the bougie should be smaller at the end which is introduced through the strictures, than at that which is left out at the penis. For this purpose many cut off a part of the oblong square before mentioned, in such a manner as to reduce it almost into the shape of a long right-angled triangle; but as this way of cutting it weakens the bougie exceedingly, and as it is not at all necessary that the bougie should be taper from one extremity to the other, it is much better to cut off a little slope of about an inch and a half long from the end that is to be passed into the urethra, which will lessen it where it is necessary to be small, and leave it strong in the other part, where the diminution is not necessary.

The plaster taken up by the cloth, when dipped, will have little bubbles upon its surface, and not be so smooth as if it had been spread: therefore an iron spatula, a little warmed, may be passed over the plaster before it be cut into bougies, which will render it more compact and even. It is a much more exact and speedy method to cut the bougies off with a knife and ruler than with scissars. When they are rolled up, it must be with that side outward which is covered with plaster; and they must first be rolled by hand as close as possible, before they are rolled upon a board or marble; for upon this circumstance the neatness of the bougie depends.

It seldom happens that a bougie is required to be more than a quarter of an inch in diameter, or three quarters in circumference; but the generality of practitioners are apt to err in using them of too small a size to produce any permanent advantage in overcoming the stricture. There is undoubtedly a great difference in the calibre of the urethra of different persons, and we have known the plaster composition to have been forced off the linen by a patient having used the bougie too large, so as to collect the plaster in a mass within the urinary canal; but we still lay it down as a general rule to employ the instrument as large as can be conveniently introduced, and again withdrawn from the urethra, although by no means so large as to hazard the accident here alluded to.

Some surgeons have very highly extolled the utility of bougies made of catgut, because of the property they possess of becoming dilated by the moisture of the urethra, and thus enlarging the contracted part of the canal. We have, however, been much disappointed in our expectations from catgut bougies; as they did not dilate with sufficient force upon the exact spot in which the disease existed, and therefore swelled generally without advantage: nay, it even happens that the catgut, if it be large, will not come away without difficulty and pain, since it dilates equally beyond the stricture itself, as well as on the contracted part; and if it be not sufficiently large, its softness renders it of no utility whatever. As there is no possible mode in which the catgut can do any good, but by mechanically extending the stricture, and as this can only happen for a few moments while the instrument remains firm, it must be obvious to every reflecting person that this kind of bougie is likely to be even less useful than those made of plaster or cerecloth; and this is precisely what we have observed as the result of our own experience.

Practitioners, being in some respects dissatisfied with the bougies commonly used, have introduced pieces of smooth whalebone, or long slips of leather, for the same purpose:

but we think, upon the whole, they are liable, at least, to as strong objections as any we have already mentioned; and the trials made with them, by several surgeons, have not at all produced a conviction of their superiority. At present, indeed, they seem to be entirely laid aside.

Another species of bougie, which deserves much more attention, is composed of catgut internally, and covered by a thin layer of dissolved elastic gum, or caoutchouc. The manufacture of this elastic vegetable substance is confined to a very few hands. We believe it was first applied in a state of solution to the purposes of surgery, either by Mr. Theden, a Prussian surgeon, or by M. Bernard, of Paris; but bougies of this kind are also made in other countries, especially in Sweden and Germany, and lately by Mr. Walsh, of London. The mode of dissolving and drying the caoutchouc is kept as a secret. It is said, however, to be soluble in æther and in linseed oil: it may likewise be rendered fluid by cutting the substance into slips, and burning them; but the great difficulty is in restoring it to a state of solidity and dryness, so as to render the bougies useful after they are fabricated and covered with caoutchouc. These bougies, when properly made, are not only very flexible and smooth, but may remain a considerable time in the urethra without being greatly injured. When they crack, or become rough on their surface by repeated use, they are unfit for our purpose, and should be exchanged for new ones. See the articles CATHETER and CAOUTCHOUC.

It has formerly been the practice of some surgeons, in using any of the several kinds of bougies already described, to daub their surface over with different stimulating unguents, &c. And it has been imagined that the puriform discharge thus produced from the urethra, had a tendency to dissolve the callosity of the stricture or caruncle, which they supposed to be the occasion of the obstructed urine. Now this is an entire fallacy, founded on a false theory; for neither is there any proof of the existence of such caruncles and callosities in the urethra, nor (if they really did exist) could the suppuration produced by such means afford material advantage. Any stimulating substance introduced into the urethra, for example a common plaster bougie, may produce a discharge of matter, especially in very irritable patients; but this discharge arises from the whole internal surface of the canal to which the bougie has been applied, and not exclusively, or perhaps, not at all, from the obstructed part where the stricture exists: and this suppuration is no more than the common result of the application of a mechanical stimulus, or foreign body, to a delicate secreting membrane. If that portion of the bougie which came into contact with the diseased part be more covered with mucus or pus than any other, this circumstance is probably owing to a greater irritation or increase of action in the secreting arteries of that part, in consequence of its preternatural irritability; but, by introducing a bougie composed of active ingredients, or smearing its surface over with acrid materials, we excite an unhealthy action not only in the morbid part of the urinary passage, but also along the whole extent of the sound surface. The reasoning here employed against so absurd a practice, will apply likewise against the use of what have been called "Medicated bougies," which have been ignorantly supposed to possess some healing or medicinal quality.

The only remaining bougies we intend to notice in the present article, are those which Mr. Smyth, an apothecary of London, has recently fabricated, of a flexible metallic composition. Although he has not published his invention, (if indeed it be a *new compound* of the metals,) we think the

the instruments of Mr. Smyth deserving our consideration. Experience, in a great number of cases, warrants the use of them, and particularly those of a large size; on account of the extreme smoothness of their surface, the yielding or flexible property they have, without breaking, and the length of time which patients may wear the bougies (where it is necessary to retain them in the bladder) with ease to themselves, and without eroding the metal.

We cannot, however, divest ourselves of an objection, which has too much foundation in truth, against the small-sized metallic bougies, viz. that there is great danger of tearing or penetrating the urethra in passing them; so that they can hardly be trusted with safety in the hands of inexperienced persons, or even of young surgeons who may not be adepts in this line of practice. Mr. Smyth has certainly obtained very respectable testimonies in favour of his instruments; but, we think, on perusing his late publication, that the comparative advantages and disadvantages of these bougies are not always detailed with sufficient precision. Some of the objections, which were formerly made by one of the surgeons of the Lock Hospital, in the fourth volume of the London Medical Review, do not apply to the larger sized metallic bougies; and we are assured that, since the period alluded to, the inventor has improved the form of his instruments so much as to have obviated the little difficulties then suggested by Mr. Blair. It was our duty to say this, in justice to the inventor; and we doubt not, that by further trials and observation, it will be found that Mr. Smyth's bougies and catheters are entitled to the patronage of surgeons in general. We do not mean to affirm, that they will exclude the use of all other kinds of bougies and catheters; but only that they are highly serviceable, (and even to be preferred to any others) in some particular circumstances of diseased urethra, or retention of urine, &c.

We reserve the observations we have to make on *caustic bougies* for a future article on the subject of STRICTURE, where the history and treatment of this morbid affection will properly come under consideration. In the interim, we refer our readers to the several publications of Mr. Home and Mr. Whateley; and to a paper, in the 18th number of the London Medical Review, p. 209, vol. iv. entitled "Reflections on the use of caustic substances and metallic bougies in strictures of the urethra, by Mr. Blair, surgeon of the Lock Hospital, &c."

**BOUGIE**, *inlet*, in *Geography*, lies on the coast of North Carolina, between Core Sound and Little Inlet.

**BOUGINESE**, or **BONIANS**, a denomination distinguishing one of the various nations who inhabit the island of Celebes. These and the Macassers are the most known. The Bouginese are at present the most powerful people in this island, though, about a century ago, they were not comparable with the Macassers. They are of a middle stature, strong, and muscular, and of a light brown complexion. Some of them, especially the women, are nearly as fair as Europeans; and they have pleasing countenances, except that their noses are somewhat flattish. The females are ardently addicted to sensual pleasures, and ingenious in every refinement of amorous gratification; and on this account, the Bouginese girls are preferred, throughout the east, for concubines, both by Europeans and by Indians. The Bouginese are generally called by the English *Buggeffes*.

**BOUGLON**, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; 4 miles N. of Castel Jaloux. The place contains 681, and the canton 5,547 inhabitants. The

territorial extent comprehends 162½ kilimetres, and 12 communes.

**BOUGUER**, **PETER**, in *Biography*, a celebrated mathematician, was born at Croisic in Lower Brittany, Feb. 10, 1698. He was the son of John Bouguer, royal professor of hydrography, and author of a complete treatise on Navigation, first printed in 1698, 4to. and re-printed in 1706. In this comprehensive and excellent work, the author correctly delineated the state of navigation at that period. Bouguer, the son, was initiated by his father in the mathematics, at a very early age; and such was his proficiency, that at the age of 11 years, he instructed his regent in the Jesuits' college at Vannes; and at the age of 13, he detected the error of a professor of mathematics, who, mortified at being thus exposed, quitted the country. Although he lost his father at the age of 15, and before he had finished his studies, he was thought competent to be his successor in the office of hydrographer; and he discharged the duties of it with great reputation, even at this early age. In 1727 he obtained the prize, proposed by the royal academy of sciences, for the best method of masting ships; in 1729, that, for the best method of observing the height of the stars at sea; and in 1731, that, for the most advantageous means of observing the variation of the compass. In his piece concerning the best method of observing the height of the stars at sea, he assumes the honour of having been the first person who undertook to give a legitimate solution of the "Solar;" for so he calls the curve, traced by a ray of the sun, in its descent through the atmosphere. But though he did not seem to have known it, Mr. Taylor, in his "Methodus incrementorum directæ et inversæ," had obtained, by an elegant analysis, a fluxional equation, which gave all the points of the curve. However, Bouguer's method was the first that was applied to use for astronomical purposes. Bouguer, in his "Optical essay on the gradation of light," published in 1729, examined the intensity of light, and determined its various degrees of diminution, in passing through different pellucid substances, and particularly that of the sun in traversing through the atmosphere. An extract of this first essay was given by M. Mairan in the *Journal des savans*, for 1730. Dr. Priestley in his "History of light and colours," p. 541, &c. has given a particular account of Bouguer's observations on this subject. At Havre, whither he removed in 1730, he became intimately connected with several members of the Academy of Sciences; in the following year, he was chosen to succeed Maupertuis as associate-geometer; and in 1735 he was promoted to the office of pensioner-astronomer. On the 16th of May in this year, Bouguer left France, on a commission, in which he was joined with Godin and La Condamine, for measuring a degree of the meridian in South America; and he returned to his own country from this expedition in June 1744. Of his various operations, he gave an account to the French academy in November following: and this account was printed in the "Memoirs" for 1744, and afterwards in his treatise "De la figure de la terre." The principal scene of this laborious undertaking, was the Cordilleras mountains; and in the execution of it, Bouguer and his associates made many other important and useful observations, besides those that related to the immediate object of their commission. To Bouguer in particular, we are indebted for many curious remarks on the expansion and contraction of metals, and other substances, by the sudden change of heat and cold, among those lofty mountains; on the refraction of the atmosphere from their summits, and on the singular phenomenon of a sudden in-

crease of refraction, when the star can be observed below the line of the level; on the laws of the different densities of the air at different heights; on the effect of the attraction of the earth upon a plummet; on the method of carrying the error of navigators in computing their course and distance; on the new construction of a log for measuring the ship's way; and on a variety of other particulars; which, with those already recited, will be duly noticed in the course of this work. Of his heliometer for determining the diameters of the larger planets in a telescope with two object glasses, his experiments on the refraction of the parallel, and his method of measuring the force of light, &c. &c., we shall introduce an account in their proper places.

The principal works of M. Bouguer, that have been separately published, are "The figure of the earth, determined by the observations in South America," 1749, 4to.; "Treatise on navigation and pilotage," Paris, 1752, 4to., abridged by La Caille in one volume, 8vo. 1768. "Treatise on ships, their construction and motions," 1756, 4to.; and "Optical treatise on the gradation of light," first published in 1723, and afterwards in 1760, 4to. The following detail of his chief communications to the royal academy, and of the volumes of the "Memoires," in which they may be found, will probably gratify the curiosity, and direct the researches of our mathematical and philosophical readers. Accordingly, we have in the "Memoires" for 1726, a comparison of the force of the solar and lunar light, with that of candles; for 1731, observations on the curvilinear motion of bodies in mediums; for 1732, upon the new curves called the "lines of pursuit;" for 1733, to determine the species of conoid, to be constructed upon a given base, which is exposed to the shock of a fluid, so that the impulse may be the least possible; and a determination of the orbit of comets; for 1734, comparison of the two laws which the earth and other planets must observe in the figure, which gravity causes them to take; on the curve lines proper to form the arches in domes; for 1735, observations on the equinox; on the length of the pendulum; for 1736, on the length of the pendulum in the torrid zone; on the manner of determining the figure of the earth, by the measures of the degrees of latitude and longitude; for 1739, on the astronomical refractions in the torrid zone; observations on the lunar eclipse of September 8th 1737, made at Quito; for 1744, short account of the voyage to Peru by the members of the royal academy of sciences, to measure the degrees of the meridian near the equator, and from thence, to determine the figure of the earth, a communication no less elegantly, than accurately written; for 1745, experiments made at Quito, and divers other places in the torrid zone, on the expansion and contraction of metals by heat and cold; on the problem of the masting of ships; for 1746, treatise on ships, their structure and motions, (see METACENTRE and SHIP); on the impulse of fluids upon the fore parts of pyramidoids, having their base a trapezium; continuation of the short account, given in 1744, of the voyage to Peru for measuring the earth; for 1747, on a new construction of the log and other instruments for measuring the run of a ship; for 1748, of the diameters of the larger planets; the new instrument called a heliometer, proper for determining them, with observations of the sun; observation of the eclipse of the moon, Aug. 8th, 1748; for 1749, second memoir on astronomical refractions, observed in the torrid zone, with remarks on the manner of constructing the tables of them; figure of the earth, determined by Messrs. Bouguer and Condamine, with an abridg-

ment of the expedition to Peru; for 1750, observations of the lunar eclipse, Dec. 13th, 1750; for 1751, on the form of bodies, most proper to turn about themselves, when they are pushed by one of their extremities, or any other point; on the moon's parallax, with the elimination of the changes, caused in the parallaxes by the figure of the earth; observation of the lunar eclipse, Dec. 2d, 1751; for 1752, on the operations made by seamen, called "Corrections;" for 1753, observations on the passage of mercury over the sun, May 6th, 1753; on the dilatations of the air in the atmosphere; new treatise of navigation, containing the theory and practice of pilotage, or working of ships; for 1754, operations, &c. for distinguishing, among the different determinations of the degree of the meridian near Paris, that which ought to be preferred; on the direction which the string of a plummet takes; solution of the chief problems in the working of ships; for 1755, on the apparent magnitude of objects; second memoir on the chief problems in the working of ships; for 1757, account of the treatise on the working of ships; on the means of measuring the light. In the volumes of the prizes, given by the academy, are the following pieces by Bouguer; in vol. i. on the masting of ships; in vol. ii. on the method of exactly observing at sea, the height of the stars, and the variation of the compass; also on the cause of the inclination of the planets' orbits. M. Bouguer was also for 3 years a writer in the *Journal des Savans*, to which he communicated several useful papers.

In his earlier years, M. Bouguer had lived in a state of seclusion from general intercourse with the world, and he had thus acquired a cast of temper, which marked his character in more advanced life. Although he was universally acknowledged to possess superior talents, and to be distinguished by an assiduity and zeal, no less successful than indefatigable, in various departments of useful science; he indulged a degree of suspicion and jealousy, with regard to his reputation, which disgusted some of those with whom he was under a necessity of associating, and which disquieted his own mind. Fully sensible of the importance and utility of his own performances, he was apt to consider others, who were engaged in similar pursuits, as competitors with himself, and to grudge them the reputation which they justly acquired, from an apprehension that his own credit would be thus diminished. Hence arose his disputes with La Condamine, one of the companions of his voyage, and associate in his labours in America; and the mortification he experienced from the public suffrage that seemed to have been bestowed on that academician. It is much to be lamented, that mean jealousies of this kind should fulfil among persons, distinguished by their literature and science; because they are not only disreputable to themselves, but injurious to the advancement of useful knowledge. M. Bouguer, after a course of incessant application, which undermined his health, closed his life on the 15th of August, 1758, at the age of 60 years. Mem. of the French Academy, 1758. *Nouv. Dict. Hist. Montucla*, "Hist. des Mathematiques," by De La Lande, tom. iv. *Gen. Biog.*

BOUHIER, JOHN, a person of eminent literary character, was born at Dijon, in 1673, and first educated at a Jesuit seminary, where his extraordinary talents for languages were carefully cultivated. The peculiar studies of his profession were prosecuted at Paris and Orleans, whence he returned to Dijon, and began the exercise of it in 1673. Here he distinguished himself by his professional practice, and was admitted into the parliament, succeeding his father in the office of president *à mortier*. As he devoted his leisure

leisure hours to literary inquiries, he was well known to the learned, and in 1727, was unanimously elected a member of the French academy. But afflicted with the gout, he was under the necessity of resigning his office of president à mortier; and, in 1746, this disorder, seizing his stomach, terminated his life. He was much respected on account both of his private and public character; and his literary performances, published separately and in the memoirs of different societies, are very numerous. Some of the principal are, "A translation, in verse, of Petronius on the civil war, and of some passages in Virgil and Ovid," with very learned notes; "A translation of Cicero's Tusculan Questions," in connection with the abbé d'Olivet; the 2d and 5th are by Bouhier; and he also annexed learned notes and dissertations to the translations of others of Cicero's works; "Letters on the sect of Therapente;" and "Dissertations on Herodotus." In his own profession his principal work is "The custom of Burgundy," 2 vols. fol. 1746; and a "Treatise on dissolution of marriage on occasion of impotence," esteemed by the curious. *Nouv. Dict. Hist. Gen. Biog.*

**BOUHOURS, DOMINIC**, a learned Jesuit and critic in the French language, was born at Paris in 1628; and having taught for some time in the colleges of the Jesuits, became preceptor to the young prince of Longueville, and to the marquis de Seignelai, son of the famous Colbert. He died in the place of his nativity, in 1702. His first work, which was an agreeable miscellany on subjects of taste, entitled "Les entretiens d'Ariste et d'Eugene," appeared in 1671, and was at first much read. His other principal works are, "Remarques et doutes sur la langue François," 3 vols. 12mo.; "Manieres de bien penser sur les ouvrages d'Esprit," 12mo. much commended by Voltaire; "Penfées ingenieuses des anciens et des modernes;" 12mo.; also, "Lives of the grand-master d'Aubusson, of St. Ignatius, of St. Francis Xavier, of mad. de Bellefond, and translations of some books of devotion, in some of which he manifests his attachment to the Jesuits, though with less credulity than that of others. His manners were polite; but his criticisms, though he was a general apologist, involved him in some literary disputes. *Nouv. Dict. Hist.*

**BOVI-CERVUS** of French authors, in *Zoology*, their *Babale* and *antilope lubalis* of Linnæus.

**BOVIANUM**, in *Ancient Geography*, Boiano, a town of Italy, in Samnium, situate among the mountains. It was taken several times by the Romans; became a Roman colony, and possessed the advantages granted by the Julian law. See **BOIANO**.

**BOUJEAH**, in *Geography*. See **BUGIA**.

**BOUILLAC**, a town of France, in the department of the Upper Garonne; 3 leagues N. W. of Grenade.

**BOVILLÆ**, in *Ancient Geography*, Marino, a town of Italy in Latium, situate at the 10th mile in the Appian way, and built after the destruction of Alba, by the Albani. It became a considerable place, as is indicated by its ruins, among which is a temple dedicated to Augustus. Near this city Claudius was slain by order of Milo; and here they celebrated games in honour of the Julian family.

**BOUILLE, LA**, in *Geography*, a town of France, in the department of the Lower Seine; 3 leagues S. S. W. of Rouen.

**BOUILLÉ Menard**, a town of France, in the department of the Mayne and Loire, and chief place of a canton, in the district of Segré; 2 leagues N. W. of Segré.

**BOUILLEROT**, or *Boullereau*, in *Ichthyology*, common names of several fishes in France, but more especially of *Gobius niger*; the *Cyprinus gobio* and *Bleinnius pholis* bear the same names.

**BOUILLET, JOHN**, in *Biography*, born at Servian, in the diocese of Beziers, the 14th of May 1690, and created doctor in medicine, at Montpellier, in 1717, enjoyed, during the course of a long life, spent in the study and practice of medicine, at Beziers, a considerable portion of reputation. He was, in succession, made professor in mathematics, and secretary to the academy at Beziers; member of the royal society at Montpellier, and corresponding member of the academy of sciences at Paris. He was also author of several ingenious dissertations. "On the properties of Rhubarb," published at Beziers 1717, 4to. probably his "Inaugural Thesis." "Sur la cause de la pesanteur," 1720, 12mo. which obtained for him a prize from the academy at Bourdeaux; "Avis et remedes, contre la peste," Beziers, 1721, 8vo. "On asthma and on the gout," in which complaints he recommends the Venice soap as a powerful auxiliary; "Sur la maniere de traiter la petite verole," Beziers, 1736, 4to. and some years after, "On the best method of preserving the district of Beziers from that disease;" "Recueil des lettres, et autres pieces pour servir a l'histoire de l'Academie de Beziers," 1736, 4to. with several other publications; for the titles, see Eloy *Dict. Hist.* He died in 1770.

**BOUILLET, HENRY NICHOLAS**, his son, was born December 6th, 1729. Treading in the steps of his father, he was made doctor in medicine, at Montpellier, and member of the academy of Beziers. He published, in 1759, in 4to. "Observations sur l'anasarque, le hydropefies de poitrine, des pericarde," &c. Haller. *Bib. Botan.*

**BOUILLEUR DE CANARI**, in *Ornithology*, the provincial name by which the Am bird is known among the creoles and negroes in Guiana.

**BOUILLON**, among *Ferriers*, a lump of excrecence of flesh, growing either on or just by a horse's frush, and making him halt.

**BOUILLON**, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Sedan; the place contains 1,973, and the canton 4,340 inhabitants. The territory comprehends 167½ kilometres, and 17 communes.

**BOUILLY**, a town of France, in the department of the Aube, and chief place of a canton, in the district of Troyes; 7 miles S. of Troyes. The place contains 790, and the canton 9,310 inhabitants. Within the territory are 212½ kilometres, and 28 communes.

**BOVIN**, or *BOVING island*, an island of France on the coast of Lower Poitou, south of the river Loire. It is wholly covered with salt pans.

**BOVINA, AFFECTIO**. See **AFFECTIO**.

**BOVINA**, in *Zoology*, a species of *TÆNIA*, found in the viscera and liver of cattle. This kind is simple, with the vesicle large; body short, with imbricated scales. Barthol. *Hist. Anat. Cent. Goetze, &c.*

**BOVINO**, in *Geography*, a city of Naples, in the province of Capitanata, and see of a bishop, suffragan of Benevento. It stands very high, on the south side of the river Cervaro. It is a duchy belonging to the Guevaras, one of the Spanish families that followed the fortunes of Alphonfus the magnanimous.

**BOVIS**, in *Entomology*, a species of *PEDICULUS*, with which cattle are infested. Linnæus distinguishes it by the eight transverse ferruginous lines on the abdomen. Linn. *Fn. Suec.*

**BOVIS**, a species of *OESTRUS*, with brown, unspotted wings; abdomen black, white at the base, and at the tip fulvous. Fabr. &c. See **BOTTS, GADFLY**, and **OESTRUS**.

**BOUISSE**, in *Geography*, a town of France, in the department

partment of the Aude, and chief place of a canton, in the district of la Grasse; 3 leagues S. W. of la Grasse.

BOVISTA, in *Botany*. See LYCOPERDON.

BOVIUM, in *Ancient Geography*, a place in the second rout of Antonine's itinerary, plied by some antiquaries at Bangor-Monachorum; by others at Boverton, and by Mr. Hartley somewhere near Stretton, at the distance of about 10 miles from Chester. But its true situation is unknown.

BOVIUS, THOMAS, in *Biography*, an empiric of a noble family in Italy, lived in the middle and at the end of the 16th century. He called himself Zephirelem, the name he gave to a tutelar spirit, who, he pretended, watched over and assisted him. He was well stored with general learning, but applied particularly to the study of the law, of medicine, and of chymistry. He wrote against the regular physicians, and boasts of the success of his practice. He contrived an elaborate and concentrated preparation of mercury and gold, first dissolved in a kind of aqua regia, which he called his Hercules. With this he professed to cure malignant and pestilential fevers, the plague, and the lues venerea. He condemned the method used in making the decoction of the woods, by which their volatile parts, in which he contends their virtue reside, were dissipated. He cured epilepsies with a preparation of antimony, and suppressed menses with hellebore. He expelled a tape worm from one of his patients, measuring, he says, fifty yards in length. He condemns bleeding, except in certain aspects of the heavens. He prepared "aurum potable," with which he pretended to have performed great cures. He laughs at Capivaccius, who had dismissed a patient as incurable, whom he afterwards restored to health. He was addicted to alchemy, and acknowledges he was indebted for much of his knowledge to Arnold de Villanova. He pretends to have cured upwards of 7000 patients. But notwithstanding his boasting, Claudius Gellus, who undertook to refute him, in a small tract, since joined to Bovius's works, shews he was no physician, and that he was very little consulted. The titles of his works are, "Flagello contro de medici communi detti rationali," 4to. Venet. 1583; "Fulmine contro de medici putatitii rationali," 4to. Verona, 1592; "Melampygo, ovvero confusione de medici sofisti e del Claudio Gelli," Verona, 1595, 4to. He discovered that a disease, affecting the inmates of a monastery, was occasioned by their cooking their food in copper vessels, not well tinned. His works, which separately passed through several editions, were collected and printed at Venice, in 1626, 12mo. Haller. Bib. Med. Practica.

BOUKA, in *Geography*, an island of the Pacific ocean, so called by Bougainville, from the frequent use of this term among the natives, separated by a narrow channel from Bougainville island. It is sometimes called lord Anson's island. The vast plantations of cocoa-nut trees which adorn its shores, indicate a numerous population. The natives are dextrous in the use of their canoes: they seem to be acquainted with the method of barter; and from the value which they affix to nails and other articles of hard-ware, they indicate a knowledge of the use of iron. They are addicted to gaiety, and passionately fond of music, especially of the most brisk and noisy tunes. The colour of their skin is blackish; they are of a middling stature; and their muscles, distinctly seen as they are naked, indicate great strength. Their figure, though not very agreeable, is very expressive. Their heads are very large, their foreheads broad, like the other parts of their faces, which are very flat; their chins large and prominent, their cheeks full, their noses flat, their mouths very wide, and their lips thin; their ears are loaded with large rings made of shells, by which they are very

much extended. Some have red and white streaks traced upon their bodies; and some have bracelets formed of the fibres of the cocoa-nut hulk. Their hair is curled, thick, and bulky; and they pluck the hair from every other part of the body. They handle the bow with much address; and their industry seems to be particularly directed to the fabrication of their arms. Their canoes are formed of several planks, ingeniously constructed, and adapted for a quick motion. The north point of Bouka is in S. lat.  $5^{\circ} 5' 36''$ , and  $154^{\circ} 29'$  E. long. Labillardiere's Voyage in search of La Pérouse, vol. i. p. 375, &c.

BOULAC, BOULAK, or BULAK, a large, irregular, and pleasant town, about 2 miles long, but not very wide, built on the east side of the harbour of Grand Cairo, and about half a league distant from it. The road leading to it appears to be one of its streets; and the crowd and bustle of the place indicate the entrance of a populous and commercial city. Boulac is the port of Lower Egypt, as well as of Cairo, as Mif-el-Attike is of Upper Egypt; and here all the merchandize is landed which comes from Damietta and Alexandria. It contains magnificent public baths, and large "Okals," which are square buildings, round a great court with a portico, that supports a winding gallery. The ground floor is composed of spacious warehouses; and the next floor contains apartments without furniture and without ornament. These okals are inhabited by strangers, who there deposit their merchandize. One single gate, like that of the citadel, secures them from insult at the time of the revolts. These klans are the only inns to be met with in Egypt. The traveller is obliged to furnish them, and dress his victuals there; for in this country a dinner is not to be had for money. The okal built by Ali Bey the great, and called the Alexandrian okal, is equally extensive and convenient, and chiefly used for goods brought from that city. From all the houses at Boulac thousands of boats may be seen at anchor, of every shape and of every size. Some of them are strong and solid, and have two masts, and are employed in transporting merchandize. These have usually a large chamber for the passengers. Others, lighter and without deck, only serve to convey the people from one shore to the other. Those which are used in voyages of pleasure are adorned with painting and sculpture, and have handsome apartments covered with carpeting, and sheltered from the sun. In these the rich amuse themselves by breathing that cool air, which is incessantly supplied by the Nile. With a favourable wind, and when the sail is spread, these light vessels seem to fly upon the water; but when the wind is contrary, a number of robust men row them with great rapidity. Cleopatra, who knew the charms of these water-parties, and the variety of landscapes which diversify the verdant banks of the Nile, engaged Cæsar in one of them, and carried him even into Upper Egypt. Gardens, occupying the fertile grounds between the houses of Boulac, and between this port and Cairo, afford an ample supply of fruits and vegetables. In the middle of the river, nearly over-against Boulac, is an island, where Murad Bey has a kind of prospect house, or place of retirement, and here are also several gardens. Opposite Boulac, upon the west bank of the Nile, is the small village of "Embabe," or "Embabil," composed of wretched round huts of earth under the sycamore trees, by which they are propped. Some few houses of brick hardened in the sun, and a small mosque, lose themselves at a distance, among the foliage of date and tamarind trees. This village is famous for the excellent quality of its butter, with which it supplies the inhabitants of Cairo; and, indeed, it is the only place in Egypt where butter can be eaten fresh; every where else, in that country,

it is good for nothing. The fertile plains adjacent to Embabe, on the western side, are enriched with several kinds of culture; and in particular they produce a sort of lupins, of the seeds of which there is a great consumption in Egypt. These are boiled with salt and water, and eaten, after being stripped of the thick and hard skin with which they are covered. They are sold ready dressed in the streets and markets. By the Christians in the east, lupins, called "Embabens," from the place of their growth, are eaten as a stimulus for drinking brandy. Flour is also made of them, which is adapted to clean the hands and soften the skin. The flalk, reduced to ashes, is preferred to other charcoal in the composition of gun-powder.

Half a league to the north-east of Boulac is the old castle of "Hellé," so called, probably, from "Heliopolis," not far distant; it is now falling into ruins. Here the Beys, attended with brilliant retinues, receive the new pacha, to conduct him in pomp to the prison, whence they have just expelled his predecessor. In the environs of Hellé are spacious inclosures, where orange, lemon, and pomegranate trees grow luxuriantly, and form, with fycamores and palms, bowers and groves of delicious fragrance and refreshing coolness. Savary. Sonnini. Brown.

BOULAI, CÉSAR-ÉGASSE DU, in *Biography*, register, historiographer, and rector of the university of Paris, was a native of St. Ellier, in Maine, and became, for many years, professor of rhetoric in the college of Navarre. His treatise of rhetoric, entitled "Speculum eloquentiæ," was much esteemed; and he also published, in French, a "Thesaurus of Roman antiquities," fol. Paris, 1650; but he acquired his highest reputation from a "History of the university of Paris," in 6 vols. fol. containing, indeed, many fabulous relations with regard to the early periods of the university, but much curious information concerning the lives and writings of the literati of France, and of other countries. Boulai wrote Latin verses with tolerable ease and purity. He died in 1678. Gen. Dict.

BOULAINVILLIERS, HENRY DE, count de St. Saire, &c. was born at St. Saire, in 1658, and educated in a seminary of the fathers of the oratory. His first profession was that of arms, which he quitted on the death of his father, and an account of the deranged state of his domestic affairs. From this time he ardently pursued his favourite studies of history and genealogy, both for his own amusement, and the instruction of his children. Voltaire, qualifying his commendation by ascribing to him that attachment to system, which perverted his narrations, says of him, that he was the most learned gentleman in the kingdom, with respect to history, and the best qualified to write that of France. But Montesquieu, as well as the president Henault, have entirely rejected his assertions concerning the commencement of the French monarchy; and the former characterizes him as "possessing more wit than understanding, and more understanding than knowledge." Such was his respect for nobility, that he entitles the feudal system, "the matter-piece of human art." Inclined as he was, in some respects, to free-thinking, he had his systematic prejudices, and avowed his faith in judicial astrology. In all his writings, however, his intentions seem to have been those of a good citizen. His works are, "A History of France, to the reign of Charles VIII." 3 vols. 12mo.; "Historical Memoirs on the ancient government of France, to the time of Hugh Capet;" "History of the Peerage of France;" "Dissertations on the Noblesse of France;" "State of France," 6 vols. 12mo.; "Mémorial on the Administration of the Finances." 2 vols. 12mo.; "History of the Arabians and of Mahomet," left unfinished, but published after his death, both at London

Vol. V.

and Amsterdam; in which work, it seems to have been his aim to represent Mahomet as a hero, and an accomplished statesman; but in doing this, he has deviated much from true history. This work subjected him to the suspicion of indifference with regard to Christianity; but the Catholics have endeavoured to adduce attestations to his piety, at the time of his death, which happened in 1722. All his works on French history have been collected in 3 vols. folio. Nouv. Dict. Hist.

BOULAN, in *Geography*. See BULAM.

BOULANCHAIR, a town of Asiatic Turkey, in the province of Aladulia, 20 miles S. W. of Malatia.

BOULANGER, NICHOLAS-ANTHONY, in *Biography*, was born at Paris, in 1721, and devoting himself to the study of mathematics and architecture, he accompanied the baron de Thiers to the army, as engineer. On his return, he was employed in the construction of bridges and causeways, and executed various public works in Champagne, Burgundy, and Lorraine. From contemplating, in the exercise of his profession, the changes which have taken place in the surface of the earth, he was led to extend his views and researches to the changes of manners, government, and religion; and, in order to acquaint himself more accurately and extensively with these subjects, he applied to the revival, or improvement, of his knowledge of Greek and Latin, and to the study of the oriental languages, both ancient and modern; and if his life had been prolonged, he would have become one of the most learned men in Europe. His speculations, however, inclined him to free-thinking; and of this he gave evidence in various publications. Such were, "A Treatise on Oriental Despotism;" "Antiquity Unveiled," published after his death; "Christianity Unveiled," not ascertained to have been written by him; "A Dissertation on Elias and Enoch." He also contributed to the Encyclopædia the articles "Deluge," "Corvée," and "Society." He died in 1759. Nouv. Dict. Hist.

BOULANGER, JOHN, an engraver, who flourished about the year 1657, was a native of France. His first manner of engraving was partly copied from that of Francis de Poilly; but he afterwards adopted a manner of his own, which, though not original, he greatly improved; and, accordingly, he finished the faces, hands, and all the naked parts of his figures very neatly with dots, instead of strokes, or strokes and dots. This style of engraving has been of late carried to a high degree of perfection, particularly in England. Notwithstanding several defects in the naked parts of his figures, and in his draperies, his best prints are deservedly much esteemed. Such are "A Holy Family," from Fran. Corlebet; "Virgin and Child," from Simon Vouet; "The Pompous Cavalcade," upon Louis the XIV. coming of age, from Chauveau; "The Virgin with the infant Christ," holding some pinks, and therefore called "The Virgin of the Pinks," from Raphael; "the Virgin de Passau," from Salario; "Christ carrying his Cross," from Nicolas Mignard; "A dead Christ, supported by Joseph of Arimathea." He also engraved many portraits, and, among others, that of Charles II. of England. He likewise engraved from Leonardo de Vinci, Guido, Champagne, Stella, Coypel, and other great masters, as well as from his own designs. Strutt.

BOULAR, in *Ornithology*. Cotgrave has the long-tailed titmouse, *PARUS CAUDATUS*, under this name.

BOULAY, in *Geography*, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Metz; 4½ leagues N. E. from Metz. The place contains 2,669, and the canton 12,813 inhabitants: its territorial extent comprehends 227½ kilometres, and 37 communes.

R

BOUL-

**BOULCOLACA**, among the *modern Greeks*, denotes the spectre of some wicked person who died excommunicated by the patriarch, re-animated by the devil, and causing great disturbance among the people; of which many strange stories are told. The word is Greek, and is sometimes written βρουκολακος, *broukolakos*; and supposed to be derived from βροκος, or βροκκ, *mud*, and λακος, a *ditch*, on account of the filthiness of the sight.

**BOULDER walls**, in *Building*, a kind of walls, built of round flints or pebbles, laid in a strong mortar; used where the sea has a beach cast up, or where there is plenty of flints.

**BOULUDUC**, SIMON, in *Biography*, an eminent apothecary and chemist of Paris, and for many years demonstrator in Chemistry, and associate in the Royal Academy of Sciences, furnished the memoirs of that society with numerous dissertations, containing analyses of the most popular and valuable vegetable productions used in medicine, which are still valued for their neatness and accuracy. The principal are, the analysis of ipecacuanha and of colocynthis, published in the memoirs of the academy for the year 1701; of jalap, hellebore, and focotrine aloes, in 1708; of catechu, (*terra japonica*) 1709; shewing this substance to be a vegetable production, and not an earth, as it had been esteemed; of rhuibarb and opium, published in 1712; of the cucumis agrestis, in 1719. He made an extract from the wild cucumber, which was a powerful hydragogue, and which might be given in doses of 24 grains, with perfect safety; also an elaterium, the dose of which was six grains. He died, far advanced in years, in 1729. His son,

**BOULUDUC**, GILES FRANCIS, born at Paris, February 20th, 1675, succeeded to his honours and appointments, and continued the same line of research. His essays, containing analyses of several purging salts, and of some mineral waters, were also published in the memoirs of the Royal Academy of Sciences. He died at Versailles, the 17th of January, 1742, much regretted by the king and queen, to whom he had been many years apothecary. Haller Bib. Bot. Eloy Dict. Hist.

**BOULEAU LAKE**, in *Geography*, a lake of North America, in the vicinity of Bear Lake, with which it communicates by rivers and small lakes. This lake might, with greater propriety, be called a canal, as it is not more than a mile in breadth. Its course is rather to the east or north for 12 miles, to Portage de L'Isle. The Bouleau Portage is in N. lat. 54° 50'.

**BOULENE**, a town of France, in the department of the Gard, five miles E. of Pont St. Esprit.

**BOULETERANES**, a town of France, in the department of the Eastern Pyrenées; 12 miles W. of Perpignan.

**BOULEY BAY**, called also Trinity Bay, lies on the N. E. point of the island of Jersey, and E. from Bonnhaven.

**BOULIMY**, in *Medicine*. See BULIMY.

**BOULINIS**, or **BOULIGNIS**, in *Commerce*, a copper coin struck at Bologna, in Italy, equivalent to the BAIOCCO.

**BOULKI**, in *Geography*, a town of Poland, in the palatinate of Lemberg; 16 miles S. E. of Lemberg.

**BOULLOIRE**, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of St. Calais: the place contains 1490 and the canton 9,011 inhabitants: its territory includes 160 kilometres, and nine communes: five leagues E. of Le Mans.

**BOULLONGNE**, LOUIS DE, the *elder*, in *Biography*, a painter, was born at Paris in 1609; and though he was principally distinguished for his ability in copying the works of the most famous ancient painters, and in preserving a

very striking resemblance, he painted historical subjects of his own invention and design; of these there are three in the church of Notre Dame, in Paris, viz. "St. Paul at Ephesus," "the Martyrdom of St. Paul," and "the Presentation of Christ in the Temple." He was painter to the king, and professor in the academy. He died at Paris in 1674.

**BOULLONGNE**, BON DE, son of the former, was born at Paris, in 1649, and acquired the principles of painting from his father, whom he resembled in his talent of imitating the works of the greatest masters, and this he did to such a degree as to deceive the best judges. On his return from Italy, where he continued five years, he was admitted into the academy, of which he became a professor, and employed by Louis XIV. at Versailles and Trianon. He excelled in history and portrait; his designs were accurate, and his colouring good. Industrious in his profession, though lively in his temper; he promoted industry among his pupils, in whose improvement and success he warmly interested himself. Besides his paintings in fresco, in two of the chapels of the invalids, he painted several pieces for the churches and public buildings of Paris; several of which have been engraved. We have also three etchings done by him, from his own compositions, viz. a species of "Almanack;" "St. John in the Desert;" and "St. Bruno in a landscape;" its companion. He died at Paris in 1717.

**BOULLONGNE**, LOUIS DE, the *younger*, brother of the former, was born at Paris, in 1654, and educated under his father, by whose instruction he made such improvement, that he obtained the prize of the academy at 18. His studies were completed at Rome, where he particularly studied the works of Raphael, and from his copies which were sent home, the Gobelin tapestries were executed. After his return he was received into the academy in 1680; and his works in the churches of Notre Dame and the Invalids, and particularly his frescos in the chapel of St. Augustin, were so much esteemed, that Louis XIV. honoured him with his special patronage; allowing him a considerable pension; conferring upon him the order of St. Michael; choosing him designer of medals to the Academy of Inscriptions, after the death of Anthony Coypel; appointing him his principal painter, and ennobling him and all his descendants: The Academy of Painting also chose him first for its rector, and afterwards director, which place he occupied till his death. He chiefly excelled in historical and allegorical subjects. From his performances it appeared, that he had carefully studied the most eminent masters; his colouring was strong, his composition was in a good style, the airs of his heads had expression and character, and his figures were correctly designed. Two of his historical paintings in the church of Notre Dame, are particularly distinguished, viz. "Christ and the centurion," and the "Good Samaritan." His etchings, of which there are a few, are spirited and free, but incorrectly drawn. Among these are the "Scourging of St. Andrew," from Paolo Veronese; the "Martyrdom of St. Peter," and the "Martyrdom of St. Paul," its companion, from his own composition. His regular attendance at the academy, and his advice to the students, commanded respect: and the general mildness and affability of his disposition engaged esteem among those who knew him. He raised a considerable fortune by his profession, and died in 1734. Two sisters of this family, "Genevieve" and "Magdalen," painted well, and were members of the Royal Academy in 1669. D'Argenville. Pilkington. Strutt.

**BOULLONOIS**, in *Geography*, a country of France, so called before the revolution, in the northern part of Picardy, of which the capital was Boulogne.

**BOULOGNE**, or **BOULOGNE-SUR-MER**, a city and sea port of France, lying in a bay of the same name, in the English channel, and chief place of a district, in the department of the Straits of Calais. The city is computed to contain 10,558, and the canton 16,199 inhabitants; the territory comprehends 70 kilometres and 8 communes. Boulogne is divided into the upper and the lower town; the upper, and smaller, is seated on the declivity of the Chalk mountain, and surrounded with walls; the lower town lies nearer to the sea, has no walls, is larger, and contains a greater number of inhabitants than the other. By its connection with the harbour, formed by the river Liane, it monopolizes almost the whole of the trade. Before the revolution it was the see of a bishop, suffragan of Rheims, the seat of a governor, a commandant, a king's lieutenant, &c. The entrance into the harbour is difficult, and defended by a small fort; but ships of war can proceed no farther than the road of St. John, and trading ships can only enter it with the tide. In the road there is good anchorage, sheltered from easterly winds, in five to fifteen fathoms, and a clean hard sand; but to the northward of the village it is foul and stony ground; and there are also some small rocks along the coast, so that ships must not approach too near the fourthward of the road. The English channel, from about Romney in Kent to the bottom of the bay of Boulogne, is about 30 miles wide; and this short distance was formerly favourable to the smugglers of English wool. Boulogne is the "Gesoriacum" of the ancients, and it was denominated "Bononia" under Constantine. The famous pharos, or light-house, at this place, was erected of an octagonal form, about 200 feet in circumference, and 66 feet in diameter, by Caligula, and it was repaired by Charlemagne in 810. In 1545, when the English took this city, they surrounded the ancient structure with towers; and it was thus preserved till the 29th of July 1644, when the whole of it fell, and nothing now remains but rubbish. Mr. Lyon, in his "Observations on the ancient *Portus Icius*," where Julius Cæsar embarked for Great Britain, contends (see *Archæologia*, vol. x.), that this could not have been Calais, nor any place to the eastward of it, but that it was to the westward, and at Boulogne. From a picce or two, which he procured, of the materials of the ancient structure above mentioned, he infers that the pharos was constructed at Boulogne of a petrification called by fossilists topkuz; and that it is of the same kind with that used in the construction of the other light-house, built by the Romans on the hill at Dover, which still exists, though gradually sinking into decay. N. lat. 50° 43' 33". E. long. 1° 36' 33". High-water 10<sup>h</sup> 30'.

**BOULOGNE**, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of St. Gaudens; 4 leagues N. of St. Gaudens. The place contains 1,476, and the canton 10,692 inhabitants; the territory comprehends 247½ kilometres, and 25 communes.

**BOULON**, LE, a town of France, in the department of the Eastern Pyrenées, taken by the Spaniards in 1793, and re-taken in 1794; 4 leagues south of Perpignan.

**BOULTER**, HUGH, in *Biography*, a prelate eminently distinguished by his charity and public spirit, was born in or near London, in 1671, and from Merchant-Taylors' school removed to Christ-church college in Oxford, whence he was elected, together with Addison, a demy of Magdalen college, of which he afterwards became fellow. By the influence of lord Sunderland, he obtained his first ecclesiastical promotion to the parsonage of St. Olave in Southwark, and the archdeaconry of Surry. In this situation he remained, assiduously discharging his pastoral duties, for several years;

but in consequence of having ingratiated himself with king George I., when he accompanied him to Hanover, in 1719, as his chaplain, he obtained, by royal favour, in that year, the bishopric of Bristol, and deanery of Christ-church, vacated by the death of Dr. Smalbridge. In 1724, he was urged by the king's absolute commands to accept the archbishopric of Armagh, and primacy of Ireland; in which trying station he manifested that wisdom and firmness, which were peculiarly suited to the distracted condition of the country. Intent upon promoting the true interests of that country, he pursued every measure which prudence or benevolence could suggest for this purpose. In 1728, and again in 1740, he diverted the horrors of famine, and liberally supplied the necessities of the poor from his own fortune. He also exerted himself in teaching and converting the poor natives, and, with this view, in promoting the establishment of the protestant charter-schools. His popularity, indeed, for some time declined, in consequence of a plan, which ultimately proved beneficial, for remedying the scarcity of silver, by diminishing the value of gold-coin; but it was not long before he regained the public favour, inasmuch that he left behind him a character highly respected and beloved. Nevertheless, he always inclined to the English interest, in opposition to the Irish, and recommended to the English government a steady adherence to it in all their favours and promotions. As Dr. Swift was attached to the contrary interest, he thought unfavourably of him, and represented him to the ministers in England, as a dangerous and mischievous person. However, though the opinions of these great men were discordant, they both probably aimed at the same object, or the good of Ireland. The primate was on no occasion actuated by a party-spirit, but wished by the aid of any connections to do all the good in his power. His whole life was devoted to business; and when he was, for the 13th time, one of the lord's justices of Ireland, he had occasion to visit England, and died here in 1742. He was interred in Westminster abbey, and a splendid monument has been erected to his memory. A collection of his letters to ministers of state, and others, was published at Oxford in 1769, in 2 vols. 8vo. containing much information with regard to Irish politics during his primacy. *Biog. Brit.*

**BOULTINE**, or **BOLTEL**, in *Architecture*, the workman's term for a convex moulding, whose periphery is just  $\frac{1}{4}$  of a circle placed next below the plinth, in the Tuscan and Doric capitals.

**BOULTON**, RICHARD, in *Biography*, a practitioner in medicine and surgery, of the city of Cheller, published "A Treatise on the Causes of muscular Motion," 1697, 12mo. He attributes the action of the muscles to a sort of fermentation, arising from the commixture of the blood and the nervous fluid, in certain glands, which he supposed to exist in the fleshy part of the muscles; a doctrine nearly similar to that held by Borelli. "A System of rational and practical surgery," 1713, 8vo. This is taken principally from the works of Wiseman, of which it is little more than an abridgment. "A Physico-mechanical Account of the Gout, King's Evil, &c." 1715, 8vo. London; and an "Essay on external remedies," published about the same time. *Hall. Bib. Anat. Med. et Chir.*

**BOULUKE**, in the *Military Orders of the Turks*, a body of the janizaries, with an officer in the place of a colonel at their head, sent upon some particular enterprise; they are selected out of the body for this, and, as soon as the business is over, are received again into their former companies.

**BOUNCE**, in *Ichthyology*, a name given by the people of the western parts of England, to a species of the shark

tribe; the *squalus canicula* of Linnæus; *catullus major vulgaris* of Ray and Willughby; *greater dog-fish* of English writers. See CANICULA.

BOUND, in *Dancing*, a spring from one foot to the other, by which it differs from a hop, where the spring is from one foot to the same. It also differs from a half *coupee*, as, in the latter, the body always bears on the floor, either on one foot or the other; whereas, in the bound it is thrown quite from the floor.

BOUND-masonry. See MASONRY.

BOUND, *hide*. See HIDE-bound.

BOUND, *hoof*. See HOOF-bound.

BOUND-bailiffs. See BAILIFF.

BOUNDS of an Eclipse. See ECLIPSE.

BOUNDS of lands. See ARUNTALS.

BOUNDARY COLUMN. See COLUMN.

BOUNTY, in *Commerce*, denotes a premium paid by the government to the exporters of certain commodities, on their taking oath, or, in some cases, giving bond, not to re-land the same in England.

Bounties, as they respect the fisheries, are either *perpetual* or *temporary*. The former are payable on the export of pilchards, or shads, cod-fish, ling, or hake, whether wet or dried, salmon, white herrings, red herrings, and dried red sprats, being of British fishery and curing. Stats. 5 Geo. I. c. 18. § 6. 26 Geo. III. c. 81. § 16. The latter are payable on the tonnage of ships carrying on the British and Greenland fisheries; on the quantity of fish taken in the British and Newfoundland fisheries; on the quantity of oil, head-matter, blubber, and whale-fins, taken in the southern whale-fishery, and on the export of pilchards. See FISHERY, and NAVIGATION *Ad*. The bounty on cordage manufactured in Great Britain, not less than three tons, is 2s. 4<sup>3</sup>d. per cwt. 6 Geo. III. c. 45. 26 Geo. III. c. 85. 31 Geo. III. c. 63.

Bounties have been granted by several statutes on the exportation of corn, when it does not exceed stipulated prices at the port of exportation.

Bounties upon exportation, considered in a more general view of them, are, in Great Britain, frequently petitioned for, and sometimes granted to the produce of particular branches of industry. By means of these our merchants and manufacturers are supposed to be able to sell their goods as cheap or cheaper than their rivals in the foreign market; and a greater quantity, it is said, will thus be exported, and the balance of trade consequently turned more in favour of our own country. They serve, as those who favour them maintain, the purpose of a kind of premium, inducing foreigners to buy our goods, and in this manner to enrich the whole country, and put money into all our pockets by means of the balance of trade. Bounties, it is allowed, says Dr. Smith (*Inquiry into the Nature and Causes of the Wealth of Nations*, vol. ii. p. 261, &c. ed. 6.), ought to be given to those branches of trade only, which cannot be carried on without them. But every branch of trade, in which the merchant can sell his goods for a price which replaces to him, with the ordinary profits of stock, the whole capital employed in preparing and sending them to market, can be carried on without a bounty. Those trades only require bounties, in which the merchant is obliged to sell his goods for less than it really costs him to send them to market; and the bounty is given in order to compensate this loss, and to encourage him to continue, or perhaps to commence, a trade, of which the expence is supposed to be greater than the returns, so that every operation consumes a part of the capital employed in it.

An ingenious author, in his "Tracts upon the Corn-

Trade," has clearly shewn, that since the bounty upon the exportation of corn was first established, the price of the corn exported, valued moderately enough, has exceeded that of the corn imported, valued very high, by a much greater sum than the amount of the whole bounties which have been paid during that period. Hence he infers, that, upon the true principles of the mercantile system, this forced corn-trade is beneficial to the nation; the value of the exportation exceeding that of the importation by a much greater sum than the whole extraordinary expence which has been incurred by the public in its exportation. But Dr. Smith argues, that this extraordinary expence, or the bounty, is the smallest part of the expence which the exportation of corn really costs the society. The capital employed by the farmer should also be taken into the account; and unless the price of the corn, when sold in the foreign markets, replaces, not only the bounty, but this capital, together with the ordinary profits of stock, the society is a loser by the difference, or the national stock is so much diminished. But the very reason for which it has been thought necessary to grant a bounty, is the supposed insufficiency of the price to do this. It has been said, that the average price of corn has fallen considerably since the establishment of the bounty. But, allowing this to be the case, it must have happened, says Dr. Smith, in spite of the bounty, and cannot possibly have happened in consequence of it; and he traces this gradual fall in the average price of corn to that gradual and insensible rise in the real value of silver, which he supposes to have taken place in the general market of Europe, during the course of the last century. In his opinion it seems to be altogether impossible, that the bounty could ever contribute to lower the price of grain. In years of plenty, the bounty, by occasioning an extraordinary exportation, necessarily keeps up the price of corn in the home market above what it would naturally fall to; and this was the avowed purpose of the institution. In years of scarcity, though the bounty is frequently suspended, yet the great exportation which it occasions in years of plenty must frequently hinder, more or less, the plenty of one year from relieving the scarcity of another. In both, therefore, the bounty necessarily tends to raise the money price of corn somewhat higher than it otherwise would be in the home market. It has been thought, however, by many persons, that the bounty tends to encourage tillage; partly, by opening a more extensive foreign market to the corn of the farmer who produces it, and partly, by securing to him a better price than he could otherwise expect in the actual state of tillage. This double encouragement, it is conceived, must, in a long period of years, occasion such an increase in the production of corn, as may lower its price in the home market, much more than the bounty can raise it, in the actual state of the tillage, whatever it may be, at the end of that period. To this reasoning Dr. Smith replies, that whatever extension of the foreign market can be occasioned by the bounty, must, in every particular year, be altogether at the expence of the home market; as every bushel of corn, which is exported by means of the bounty, and which would not have been exported without it, would have remained in the home market to increase the consumption, and to lower the price of that commodity. The corn bounty, as well as every other bounty upon exportation, imposes upon the people two different taxes; viz. the tax, which they are obliged to contribute towards paying the bounty, and that which arises from the advanced price of the commodity in the home market, and which, as the whole body of the people are purchasers of corn, must, with regard to this particular commodity, be paid by the whole body of the people.

This second tax is by much the heaviest of the two; amounting, for every five shillings per quarter of wheat contributed towards the payment of the first tax, to 6l. 4s. towards the payment of the second. This heavy tax, resting upon the first necessary of life, must either reduce the subsistence of the labouring poor, or it must occasion some augmentation in their pecuniary wages, proportionable to that in the pecuniary price of their subsistence. In the one way, it must tend to restrain the population of the country, as it reduces the ability of the labouring poor to bring up their children; and in the other, it must tend to restrain the industry of the country, as it reduces the ability of the employers of the poor to employ so great a number as they otherwise might do, in proportion to the degree of its operation in both respects. "The extraordinary exportation of corn, therefore, occasioned by the bounty, not only in every particular year, diminishes the home, just as much as it extends the foreign market and consumption, but by restraining the population and industry of the country, its final tendency is to stunt and restrain the gradual extension of the home market; and thereby, in the long run, rather to diminish, than to augment, the whole market and consumption of corn."

It has been thought, however, that the enhancement of the money price of corn must necessarily encourage its production, by rendering that commodity more profitable to the farmer. To this plea Dr. Smith replies, "that this might be the case if the effect of the bounty was to raise the real price of corn, or to enable the farmer, with an equal quantity of it, to maintain a greater number of labourers in the same manner, whether liberal, moderate, or scanty, than other labourers are commonly maintained in his neighbourhood. But neither the bounty, nor any other human institution, can have any such effect. It is not the real, but the nominal price of corn, which can in any considerable degree be affected by the bounty. And though the tax, which that institution imposes upon the whole body of the people, may be very burdensome to those who pay it, it is of very little advantage to those who receive it. The real effect of the bounty is not so much to raise the real value of corn, as to degrade the real value of silver, or to make an equal quantity of it exchange for a smaller quantity, not only of corn, but of all other home-made commodities; for the money price of corn regulates that of all other home-made commodities." The money price of corn regulates the money price of labour, and of all the other parts of the rude produce of land, which, in every period of improvement, must bear a certain proportion to that of corn, though the proportion in different periods may be different. In this latter way, it also regulates the money price of the materials of almost all manufactures, and that of manufacturing art and industry. Though in consequence of the bounty, the farmer should be enabled to sell his corn at an advanced price, and to pay his landlord a proportionable advanced rent; yet if, in consequence of this rise of the price of corn, the money thus obtained will purchase no more home-made goods of any other kind, than the lower price would have done before, neither the circumstances of the farmer, nor those of the landlord, will be much mended by this change. The farmer will not be able to cultivate much better; the landlord will not be able to live much better. In the purchase of foreign commodities, this enhancement in the price of corn might give them some little advantage; but in that of home-made commodities, which constitute the whole expence of the farmer, and the far greater part even of that of the landlord, it can give them none at all.

The bounty, as it raises in the home market, not so much

the real, as the nominal price of our corn; as it augments, not the quantity of labour which a certain quantity of corn can maintain and employ, but only the quantity of silver which it will exchange for; discourages our manufactures, without rendering any considerable service to our farmers or country-gentlemen. Although it puts a little more money into the pockets of both, yet if their money sinks in its value, as to the quantity of labour, provisions, and home-made commodities of all different kinds, which it is capable of purchasing, as much as it rises in its quantity, the benefit accruing from it will be little more than nominal and imaginary. There is, indeed, one class of men, to whom the bounty may be essentially serviceable; and this consists of the corn-merchants, the exporters and importers of corn, who are most anxious for the continuance or renewal of the bounty.

Bounties upon the exportation of any home-made commodity are liable to the general objection, that may be made to all the different expedients of the mercantile system, which is that of forcing some part of the industry of the country into a channel less advantageous than that into which it would run of its own accord, and also to the particular objection of forcing it into one that is actually disadvantageous; the trade, which cannot be carried on otherwise than by means of a bounty, being necessarily a losing trade. The bounty upon the exportation of corn is liable to this farther objection, that it can in no respect promote the raising of that particular commodity, of which it was meant to encourage the production. With a view of encouraging the production of any commodity, a bounty upon production would operate more directly than one upon exportation; and it would have the advantage of imposing only one tax upon the people, or that which they must contribute in order to pay the bounty. Bounties upon production, however, have been very rarely granted. The prejudices established by the commercial system have taught us to believe, that national wealth arises more immediately from exportation than from production; and accordingly, it has been more favoured, as the more immediate means of bringing money into the country. It has been also said, that bounties upon production have been found more liable to frauds than those upon exportation. The latter, however, have not been altogether exempt from this charge. A bounty upon exportation has sometimes enabled the merchant and manufacturer to send abroad the surplus goods of an overstocked market, and to keep up the price of what remains in the home-market; and, therefore, instances have occurred, in which the undertakers of particular works have privately agreed to give a bounty out of their own pockets upon the exportation of a certain portion of the goods, in which they have dealt; and this expedient has answered the purpose, by doubling the price of their goods in the home market, notwithstanding a very considerable increase in the produce.

Something like a bounty upon production, however, has been granted upon some particular occasions. Of this nature are the tonnage-bounties given to the white-herring and whale-fisheries. These, it may be supposed, have a direct tendency to render the goods cheaper in the home-market than they otherwise would be. In other respects, their effects are the same as those of bounties upon exportation. By means of them a part of the capital of the country is employed in bringing goods to market, of which the price does not repay the cost, together with the ordinary profits of stock. But though the tonnage bounties on the fisheries do not contribute to the opulence of the nation, yet they may be thought to contribute to its defence, by augmenting the number of its

its sailors and shipping. Dr. Smith suggests, however, that this may sometimes be done by means of such bounties, at a much smaller expence than by keeping up a great standing navy (if such an expression may be used), in the same way as a standing army; and the ingenious author inclines to believe, that in granting at least one of these bounties, the legislature has been grossly imposed upon. On this subject he makes the following observations. First, the herring-bus bounty is too large. Secondly, the bounty to the white herring fishery is a tonnage bounty, and proportioned to the burden of the ship, not to her diligence or success in the fishery; whence it has been too common for vessels to fit out for the sole purpose of catching, not the fish, but the bounty. Thirdly, the mode of fishing, for which this tonnage bounty in the white-herring fishery has been given (by buffes or decked vessels from 20 to 80 tons burden), seems not so well adapted to the situation of Scotland as that of Holland, from which country it seems to have been borrowed. The bounty granted to the bus fishery is necessarily a discouragement to the boat-fishery, which seems best adapted to the peculiar situation of Scotland, intersected by arms of the sea running up a long way into the land, and called sea-lochs, and which, by the operation of the bus bounty, is gone almost entirely to decay. Fourthly, in many parts of Scotland, during certain seasons of the year, herrings supply a great part of the food of the common people; and, therefore, a bounty, which tended to lower their price in the home market, might contribute to very general relief. But the herring-bus bounty contributes to no such good purpose. It has ruined the boat-fishery which is best adapted for the supply of the home market, and the greater part of its produce is sent abroad. Another ingenious writer, Dr. Anderson (*ubi infra*), has pointed out similar defects attending the fisheries of Scotland; and he proposes, for remedying them, that a reasonable bounty should be allowed on every barrel of herrings properly cured; and that the bounty upon buffes per ton should be lowered, and these vessels be prohibited from fishing within a limited distance of the coast. This would allow the natives to fish in their creeks with freedom; and it would likewise allure merchants to come and purchase the fish when fresh caught, and cure them for themselves. But as the most important improvement, he proposes that the herring and Greenland whale-fisheries should be made to go hand in hand, and mutually assist one another. The whale-fishery, he observes, has been greatly retarded by the large size of the vessels which have been usually employed in it, and the mismanagement that always attends public companies in matters of trade. To prevent this, in some degree, for the future, Dr. Anderson proposes, that the bounty should be granted to vessels of a smaller size; and that all restrictions, with regard to the number of hands, provisions, tackle, &c. should be entirely abolished; in lieu of which the vessels should be only obliged to pursue the fishing for a certain limited time (if not sooner loaded), without following any other employment. As these small vessels would be equally proper for the herring-fishery as for that in the Greenland seas; and as in both fisheries the necessary number of hands is nearly the same, it would be easy for these adventurers, on their return from the Greenland seas, to put ashore their loading, with the fishing apparatus, and take on board the tackle, &c. necessary for the herring-fishery, and to proceed immediately to the proper stations in search of that kind of fish. It is further proposed, that instead of fixing the rendezvous for the herring-fishery precisely to the 22d of June and 1st of October, as at present, ships might be entitled to receive the bounty, if they began fishing on any day between the two periods above-mentioned; the ships being obliged to continue three months

from the time of their entry, or to the end of the fishing season following, if they have not sooner completed their lading. By such regulations, the loss of time would be prevented; and adventurers would be induced to fit out small vessels at a time when trade was dead; and they would conduct the business at a less expence, and with greater profit, than large trading companies. See FISHERY.

In particular manufactures that are deemed necessary for the defence of society, and for the supply of which it would not always be prudent to depend upon our neighbours, and that could not otherwise be supported at home, it would not be unreasonable to tax all other branches of industry for their support. Upon this principle the bounties upon the exportation of British made sail-cloth, and British made gun-powder, may both be vindicated. But it can seldom be reasonable to tax the industry of the great body of the people, in order to support that of some particular class of manufacturers. However, in a season of great prosperity, when the public enjoys a greater revenue than it knows well what to do with, it may, perhaps, be as natural to give such bounties to favourite manufacturers, as to incur any other idle expence. "In public, as well as in private expences, great wealth may, perhaps, frequently be admitted as an apology for great folly. But there must surely be something more than ordinary absurdity in continuing such profusion in times of general difficulty and distress."

When a bounty may be considered as a drawback, it is not liable to the same objections with that which is properly a bounty. Thus, the bounty upon refined sugar exported is a kind of drawback of the duties upon the brown and mulcovado sugars from which it is made. That species of refined sugar upon which the bounty is granted is denominated, in the statute-book, "sugar in the loaf and whole, being nett." Upon the export of this sort of sugar the bounty was raised by 5 Geo. III. c. 45. to 14s. 6d.; and a further bounty of 11s. 6d. was granted by 21 Geo. III. c. 16, in consequence of an additional duty of 6s. per cwt. laid in 1781 on raw sugar imported. The whole bounty amounts to 26s. per cwt. When parliament, in 1791, by 31 Geo. III. c. 15. laid a further duty of 2s. 8d. per cwt. on raw sugar imported from the British plantations, making the import duty 15s. per cwt. in the whole, no addition was made to the bounty on the export of refined loaf. But an addition was made of 3s. 4d. to the drawback, on what the statute calls "bastards, and ground or powdered sugar," and also on "refined loaf broken into pieces," and all sugar called "candy." It was proposed in 1791, when the additional duty of 2s. 8d. was moved, to augment the bounty in the usual proportion; but the sugar refiners remonstrated against the measure, as being, according to their statement, beneficial only to the planters. By a subsequent law it is enacted, that, after the year 1792, whenever the average of the prices of brown or mulcovado sugar (taken weekly upon oath before the lord mayor of London, and published in the Gazette) shall exceed, in the six weeks respectively preceding the middle of February, June, and October, the amount of 50s. per cwt. (exclusive of the duty), the drawback on raw sugar exported is immediately to cease for four months, and the bounty on refined is to cease during a like term, but commencing after an interval of one month. From a statement made by Mr. Bryan Edwards (*Hill. of the West Indies*, vol. ii. p. 462.) it appears, that the apparent loss to the revenue, arising from the bounty, is no more than one shilling the cwt. But as every hoghead of sugar loses considerably in weight, after the duty is paid, and before it is either exported or worked up, and the duty is often paid for more than the casks really contain, by the strict regulations re-

specting tare, every hoghead, by a moderate calculation (averaging the good and bad sugars), loses 56 lbs. which, at 15s. per cwt. the import duty, makes 7s. 6d. per hoghead loss to the planter, and a clear and certain gain to the revenue, however the sugar may be disposed of. Thus government is reimbursed for a considerable part of what it appears to lose by the bounty, and the interest which it gains by a deposit of the whole duties on importation makes up the remainder. "The average annual import of raw sugar is about 160,000 hogheads of 12 cwt. nett; now supposing every ounce of this was to be exported, and receive the drawback of 15s. per cwt. yet, from the difference of weight alone in the same sugar, occasioned by an unavoidable waste, government would have received in duties, from this single article, between 50 and 60,000l. per annum more than it refunds in drawbacks and bounties on the same commodity." See DRAWBACK, and SUGAR.

The bounty upon wrought silk exported, is also a drawback of the duties upon raw and thrown silk imported. See SILK.

The bounty upon gun-powder exported is a drawback of the duties upon brimstone and salt-petre imported. In the language of the customs, those allowances are called drawbacks, which are given upon goods exported in the same form in which they are imported. When that form has been so altered by manufacture of any kind, as to come under a new denomination, they are called bounties. Bounties are sometimes called premiums, as drawbacks are sometimes called bounties.

Having given a compendious abstract of Dr. Smith's reasoning against the system of bounties, particularly as it is applicable to the exportation of corn, we shall now advert to the arguments alleged by the advocates of this system in its favour. Among these advocates we may reckon Dr. James Anderson, in his letters entitled "Observations on the means of exciting a spirit of national industry, &c." 4to. 1777, and his "Calm Investigation of the circumstances that have led to the present scarcity of grain in Britain," 8vo. 1801; Mr. Dirom in "An Inquiry into the corn laws and corn trade of Great Britain, &c." 4to. 1796; Mr. Mackie, in a "Supplement" to the last-mentioned work; and Mr. Malthus, in his "Essay on the principle of population, &c." 4to. 1803. Some of the earliest topics, from which arguments were deduced in favour of the bounty, were its great encouragement of British shipping, and the gold it brought home for paying the balance of exported corn. But exclusively of these arguments, the advocates for the bounty urge, that, by forcing a production of corn, greater than the annual consumption of the home market, the bounty provides a reserve against years of deficient crop;—that it secures an adequate profit to the farmer;—that it reduces the prices of corn, which are usually very fluctuating, to a greater uniformity and steadiness;—and that it makes this uniform price rather lower than it otherwise would be. From such considerations, Dr. Anderson, and others on the same side of the disputed question with himself, have inferred, that, setting aside the innumerable beneficial effects of a well regulated and efficient bounty on the exportation, aided by a duty on the importation of corn, with regard to the population, industry, manufactures, commerce, national wealth, public tranquillity, and augmentation of revenue, it is a measure fraught with multiplied advantages; and "that it could not be abandoned," such is the strong language of Dr. Anderson, "without endangering the welfare of the people, and the very existence of this kingdom, as an independent nation." Upon the four preceding propositions it has been observed by an anonymous writer, seemingly well acquainted with the

subject (Edinburgh Review, N<sup>o</sup> IX.), that the promised steadiness in the price of corn must be derived from that surplus of produce which is to be reserved in years of a bad crop; this surplus of the average produce above the annual consumption, must be the result of an enlarged encouragement of tillage; and this encouragement, operating by an augmentation of the profits of the farmer, must ultimately consist in an increase of the price of his commodity. The argument, therefore, so far as it depends upon the first three of the above alleged advantages, resolves itself into this single proposition, viz. that the bounty gives the farmer a real advance upon the price of his corn. When it is stated, as a fourth consideration, that it has likewise the effect of lowering the price of corn to the consumers, it is the money price only that can here be consistently understood; a diminution of which is without doubt compatible with an advance of the real price. Consequently, in an investigation of the effects produced by a bounty upon the commerce and growth of corn, the precise subject of inquiry is the effect of that bounty upon the real price, and upon the money price of corn. Dr. Smith, accordingly, who has decidedly pronounced a very different opinion from that above stated, maintains it, by propositions directly the reverse, already detailed, of which the following is a summary:—that it can have no effect in equalizing prices, because there is no surplus to be reserved in years of scarcity;—that there can be no such surplus, because the bounty gives no additional encouragement to agriculture;—that it can give no such encouragement, because it occasions no advance of the real price of corn;—and, lastly, that its effect is to raise, not to lower, the average money price of that commodity. The anonymous writer above cited, after having illustrated, in a very clear and satisfactory manner, the effect of a bounty, first on the *production*, and then upon the *exportation* of bread-corn, in conformity to the principles and reasoning of Dr. Smith, supplies some defects, and corrects some errors that escaped the notice of this very ingenious and accurate author, in his general argument upon the bounty. By separating the extension of the foreign market, from the enhancement of price to the farmer, and treating them as quite distinct, Dr. Smith seems to have overlooked the necessary connection that subsists between them. In both cases, he appears to have too hastily assumed, that a bounty on exportation would *immediately* occasion a rise of the money-price in the home-market; and this assumption betrays itself explicitly, when he speaks of it as "a very moderate supposition, that a bounty of 5s. per quarter upon exportation, may raise the price 4s. in the home market." From this assumption, he deduces a separate answer to the alleged enhancement of price; but his remarks on this head, which, as far as they extend, are unexceptionable, are not sufficient to warrant his inference, that the bounty can have no effect in raising the real price of corn; because he has overlooked that *interval* which elapses between the enhancement of the money-price of corn, and its communication to the money-price of labour and other commodities. In his separate answer to the alleged extension of foreign demand, he does not expressly deny the fact, but affirms, that, in every particular year, this is at the expence of the home market; and endeavours to shew, that the bounty also restrains the gradual extension of the home market, by its enhancement of the price. But in affirming, that the quantity exported in every particular year, were it not for the bounty, would remain in the home market, he evidently takes it for granted, that this quantity, though there had been no bounty, would still have been grown; now, this is the very question, upon which he undertakes to prove his particular

ticular opinion. In endeavouring to shew, that the enhancement of price, occasioned in the home market by the bounty, must restrain the population or the industry of the country, he proceeds upon the above-mentioned assumption, that the bounty occasions an immediate rise of the money-price of corn; and must, therefore, either reduce the subsistence of the labourers, or, if wages rise, the ability of their employers to give them work. If that rise of money-price, however, is consequent, as the anonymous writer argues, to an extension of demand in the foreign market, it will at first increase the ability of those employers; and though it will likewise reduce at first the subsistence of the labourers, their wages must soon rise to their true rate; and this rise in the money-price of labour, will only reduce the ability of the employers to its former level.

The anonymous writer, after these criticisms on the reasoning of Dr. Smith, proceeds to specify some of the errors into which the advocates for the bounty have fallen, which are of a more palpable kind, and which proceed from an imperfect acquaintance with the principles of political economy. In the *first* place, they have misunderstood Dr. Smith's important doctrine, that the variations of the money-price of corn are communicated ultimately to that of labour, and other commodities. Whilst they insist, that the price of commodities and labour is liable to be affected by many other circumstances, besides the price of corn, they advance a truth, in itself unquestionable, and not incompatible with Dr. Smith's proposition, which merely asserts, that every change which the bounty may occasion in the money-price of corn, will communicate itself, first to the money-wages of labour, and, through them, to the money-price of all other articles; and thus, the real price of corn will be maintained the same, notwithstanding a nominal variation. In the *second* place, they seem very imperfectly aware of the manner in which the principle of competition operates upon profits, and upon exchangeable value: and, on this account, many of their remarks are inconsistent as well as unfounded. They have supposed, with Dr. Smith, that the sum of the bounty is immediately added to the former money-price even in the home-market, and, at the same time, contend, that the average-price in that market will be lowered. It is also their opinion, that the real price of corn will, upon the whole, be rendered cheaper to the consumers, and that the same real price of corn will be maintained permanently higher to the farmer; though these two positions are, in direct terms, contradictory to each other. Mr. Malthus observes, that the bounty greatly lowers the price of corn, by producing a growth considerably above the wants of the actual population; whilst he forgets, that a greater growth can only be occasioned by a greater demand, to which it will be always adjusted; and, keeping the supply and the demand always in the same ratio, will in other words keep the price always at the same rate. But the advocates for the bounty have betrayed a much less pardonable inattention to the necessary action of the principle of competition, when they conceive, as some of very high authority have done (See Reports of the committee of the house of commons respecting the corn trade, ordered to be printed May 14th and June 14th 1804), that the average price of grain in the home market may be so low as not to yield a fair and reasonable profit to the grower. Besides, Dr. Smith and his opponents have pronounced, that, in years of extraordinary abundance, the bounty will prevent the money-price of corn in the home-market from falling quite so low, as it would fall if there were no bounty. Dr. Smith, indeed, is consistent with himself, because he uniformly maintains, that the bounty can have no effect in rendering the annual produce

larger than it otherwise would be. But those who assert this position, and assume that the bounty increases the produce, and occasions a surplus growth above the annual consumption, evidently incur the charge of inconsistency. For this surplus will, in a year of extraordinary abundance, partake of the extraordinary increase; so that over and above the usual home supply, there will, in such a year, be reaped not only the extraordinary increase upon that supply, together with the usual surplus for exportation, but likewise the extraordinary increase upon that surplus. Of these four portions of the crop, therefore, not only the second, but the fourth also, will be thrown as an excess upon the home-market; and the price in that market will consequently be lowered much more by the whole of this excess, than it would have been by the former part of it alone.

The ingenious writer, to whom we are indebted for these remarks, suggests that a bounty upon export may, in a particular manner, afford some temporary encouragement to tillage; and thus, to a certain degree, force the production of a surplus, which may be reserved for the home-market in deficient years. By preventing, in such years, the temporary price from rising so high as it otherwise would, it may be considered as restraining a little on one side the occasional fluctuations of the price of corn; but, by overstocking the home-market in plentiful years still more than it would otherwise be overstocked, it must be considered as giving a still greater range to the fluctuation of the temporary price on the other side. Whilst the bounty has this influence upon the temporary changes of real price, its effects upon the nominal price of corn will be to raise and keep it higher than it otherwise would be. If the encouragement to tillage, derived from a bounty, should be deemed a sufficient benefit to induce a great nation to establish it; it should be remembered, that, though it may indirectly secure a more certain supply of corn, it necessarily retards, upon the whole, the growth of national opulence and industry. It forces a part of the national capital into a branch of trade, which is unavoidably a losing one, and which does not return the whole of the capital that is employed in it; for the whole sum granted in bounties, together with the expences of collecting the tax for defraying them, is a part of the national capital thrown into that trade without any return.

After estimating to its full amount the possible benefit to be derived from such an artificial contrivance as the bounty, we should not only weigh against that, both the immediate sacrifice and all the subsequent disadvantages, but we ought also to consider whether the very benefit proposed, at least in one point of view, might not be better obtained in another way; as by the removal of any exiling impediments to cultivation, to the free commerce of land, the free employment of capital, or the free transference of labour. Besides the sacrifice of capital that is incurred by bounties, there is a disadvantage arising from that constant diminution of the real wages of labour, which is occasioned by the progressive rise of the price of corn in the home market; other disadvantages are incurred from the constant enhancement of the money-price of labour and all other commodities, both in the depreciation of fixed pecuniary returns, and in the injury to domestic manufactures, with regard to their competition against foreign industry. Moreover, another disadvantage, perhaps still greater, consists in the uncertainty and derangement to which interferences of law subject the capital that is vested in the trade of grain, and the obstacle opposed by them to the free enlargement and consolidation of this most important system of commerce. On the other hand, it should be considered, that the encouragement,

agement which any assigned bounty will give to husbandry, must expire after a short interval, or as soon as the money price of corn, in the home market, has risen, which it will inevitably do, so high as to cover the whole advantage, which the bounty had originally given to the exporter in his sales abroad:—and the whole encouragement which, in the mean time, the bounty can give to agriculture, will be found to be very slight, when it is considered in what way it is formed, and that it consists, not in the addition of the whole bounty to the farmer's price, but in that small addition to his price which is occasioned from time to time by the gradual extension of foreign demands. In reference to the present circumstances of this country, it ought also to be recollected, that, when the average price of corn at home is greater than that of the foreign market, the interval of encouragement to tillage, under the same bounty, will be shorter than in the other two cases, and the whole disadvantage of high money prices will be sooner brought to its greatest height. Adverting to the present state of the agricultural produce of our own country, and what has caused an alarm to some of our legislators as well as political writers, we are happy in adopting the opinion of those who think it unnecessary. If, besides being dependent in years of scarcity on very large importations from abroad, we are even in ordinary years dependent upon importation for a certain portion of our necessary supply, it seems, admitting the fact, to be only a temporary and slight inconvenience. It is doubted, whether, in this case, a bounty upon exportation, and the prohibition of importation, furnish the most suitable and effectual remedy: and it is not unreasonably suggested, that an entire freedom of importation, continued with a bounty upon production, augmented from time to time, might have appeared at least a more plausible proposal. Nothing can be more unfounded than the fear, which some advocates for the bounty have expressed, that England may cease to be an agricultural nation; except the lamentations, which others have indulged over the actual decline of its husbandry, since that which has been called the fatal statute of the year 1773. It should be recollected that, from year to year of this period, the husbandmen of Britain have extended their capital, their skill, and their produce, though the commerce and manufactures of the island have in some measure concealed its agricultural grandeur. The bounty seems to have recommended itself to some of its admirers, as a simple expedient for securing, by paying a few shillings at the custom house, such a surplus of annual produce as will equalize the variation of value, and establish even a remedy against the natural inconstancy of the seasons. In this view of it, the bounty is to accumulate, by a kind of mechanical operation, a surplus of produce, for supplying an occasional deficiency; and it is to act as a regulator of the price, against the circumstances that tend to enhance or to depress it. If it is capable of doing so much, it may also do more; and serve to repress, as Mr. Malthus has inferred, the principle of population a little in years of plenty; and to encourage it comparatively in years of scarcity; regulating, in this manner, the population more equally, according to that quantity of subsistence which can permanently be supplied. It is well observed, that a measure can rarely be wisdom for one great state, which may not be permanently followed by all. All cannot, by adopting the bounty, secure to each an export of grain; and the single nation that stoops from the plain high maxims of policy to such an artifice, will ultimately be convinced that the advantage gained by it, if any, must be very inconsiderable. The balance of this trade cannot long be very great to any nation; and it will be naturally possessed by that one, whose capital and skill are in

a condition to furnish the additional supplies most advantageously to all. In this condition, if the exportation is free, it will hold the balance, without requiring the aid of a bounty; nor can a bounty give it the balance, if it be not in that condition.

Having stated, as briefly as possible, the principal arguments on both sides, for and against a bounty, we shall close this article with a short abstract of the history of this commercial institution. The prices of corn had been so variable during the 17th century, and in general so high, the average price of wheat for fifty years before 1650 having been 6l. 8s. 10d. and from 1650 to 1700 3l. 6s. 11d. per quarter, that the attention of the legislature had frequently been directed to this object; and various attempts had been made to revive agriculture, with a view of redressing this evil, by encouraging the exportation, and checking the importation of corn; but none of them had proved effectual. Towards the end of the century, however, the prices had been so uniformly high, and on some occasions so oppressive, as to induce the truly patriotic and judicious administration under William and Mary, immediately after the revolution in 1688, to investigate some method of remedying this evil, and of preventing its future recurrence. With this view, a resolution was adopted of granting a certain bounty upon the exportation of corn, when the crops were so abundant as to reduce the price below the rate which they conceived to be necessary for indemnifying the farmer for his expense and trouble, so as just to enable him to find for it a foreign market; and with a view also of preventing a competition of foreigners in our home market, when the crop happened to be uncommonly abundant, and of guarding against the machinations of corn-dealers, who might, for their own lucrative purposes, occasionally introduce much foreign corn into the home market, so as to lower the price of a moderate crop in Britain below its intrinsic value, they imposed certain duties on corn imported, which rose or fell in proportion to the selling price at the time in our own market, as protecting duties. The aim of the legislature, in these regulations, was to preserve, as much as possible, an equality and moderation of price at all times in the home market. Such were the principles of the corn law, first enacted in the year 1688 by 1 W. and M. and finally completed in 1700 by 11 and 12 W. and M. c. 20. By the law of 1688, a bounty of 5s. was granted for every quarter of wheat exported, when the price was at or under 48s. per quarter; and by the same law, there was payable on importation a duty of 1l. 4s. per quarter, when the price did not exceed 3l. 19s. 3d.; when the price was above that, and not exceeding 6l., the duty payable was 12s. per quarter; and when the price was above 6l., the duty was only 8s. This commercial regulation was much celebrated by the best writers and statesmen of England, throughout the first part of the last century; they always mentioned it with admiration, as an institution that had been wisely planned, and that had completely succeeded; and it was ranked with the art of navigation, the laws for the woollen staple, or queen Elizabeth's provision for the poor, as an inseparable part of that peculiar system, to which England was indebted for her superiority over all other nations. The diminution of the average price, and the progressive increase of exports, within the period at the beginning of which the bounty had been instituted, presented a flattering coincidence; and at a time when the analysis of national wealth was unknown, it was natural enough to believe, that the cause of these curious facts could be no other but that remarkable law which just preceded their appearance. As a protective regulation, Dr. Anderson considers it as one of the highest exertions of

human wisdom; for the beneficial tendencies that have resulted from it in practice, and to which we can now refer as facts to inform our judgment, could be only contemplated by the devisers of that law as plausible probabilities. By the operation of this law, the prices in the home market were reduced, in the course of 50 years, to the consumers in the home market, from 3*l.* to 1*l.* 2*s.* 6*d.* per quarter; and we were enabled by it to export corn till our excess of exports rose by degrees to the amount of more than one million and a half quarters in one year, which brought into the country a sum not much under three millions sterling; being paid for the price of our own best manufactures, and for encouraging the most useful kind of industry that can ever be promoted in any nation. Similar sentiments with regard to king William's corn law were adopted by our admirers upon the continent. The bounty became a theme of paenegyric in all their political treatises. Though a most artificial expedient, it was applauded even by the economists of France, in whose profound writings all devices were reprobated, that might check the spontaneous order of nature. Dr. Smith, however, maintained that the system of laws, which is connected with the establishment of the bounty, seems to deserve no part of the praise which has been bestowed upon it. The improvement and prosperity of Great Britain, which have been so often ascribed to those laws, may very easily be accounted for by other causes. That security which the laws in Great Britain give to every man, that he shall enjoy the fruits of his own labour, is alone sufficient to make any country flourish, notwithstanding these and twenty other absurd regulations of commerce; and this security was perfected by the revolution much about the same time that the bounty was established. The natural effort of every individual to better his own condition, when suffered to exert itself with freedom and security, is so powerful a principle, that it is alone, and without any assistance, not only capable of carrying on the society to wealth and prosperity, but of surmounting a hundred impertinent obstructions with which the folly of human laws too often incumbers its operations; though the effect of these obstructions is always more or less either to encroach upon its freedom, or to diminish its security. In Great Britain industry is perfectly secure; and though it is far from being perfectly free, it is as free, or more free, than in any other part of Europe. Upon the whole, though the period of the greatest prosperity and improvement of Great Britain has been posterior to that system of laws which is connected with the bounty, we must not on this account impute it to those laws. It has been posterior likewise to the national debt; but the national debt has most assuredly not been the cause of it. The sentiments of Dr. Smith were adopted by many philosophical inquirers; and at length they approved themselves to our legislators, and became a subject of parliamentary deliberation. Accordingly the act of 1773, (13 Geo. III. c. 43; see also stats. 31 Geo. III. c. 30. 32 Geo. III. c. 50. 33 Geo. III. c. 3, 65.) which was conducted through the house of commons by Mr. Burke, effected a virtual repeal of the bounty, though it retained the language, and seemed even to confirm the purposes of the former law, in compliance with those prejudices which it was more easy to betray than to conquer. By this statute, the high duties upon importation for home consumption are taken off, as soon as the price of middling wheat rises to 4*s.* per quarter; that of middling rye, pease or beans, to 3*s.*; that of burley to 2*s.*; and that of oats to 1*s.*; and instead of them a small duty is imposed of only 6*d.* upon the quarter of wheat, and upon that of other grain in proportion. With regard to all these different sorts of grain, but particularly with regard to

wheat, the home market is thus opened to foreign supplies at prices considerably lower than before. By the same statute, the old bounty of 5*s.* upon the exportation of wheat ceases so soon as the price rises to 4*s.* per quarter, instead of 4*s.*, the price at which it ceased before; that of 2*s.* 6*d.* upon the exportation of barley ceases as soon as the price rises to 2*s.* instead of 2*s.*, the price at which it ceased before; that of 2*s.* 6*d.* upon the exportation of oatmeal ceases as soon as the price rises to 1*s.* instead of 1*s.*, the price at which it ceased before. The bounty upon rye is reduced from 3*s.* 6*d.* to 3*s.*, and it ceases so soon as the price rises to 2*s.* instead of 3*s.*, the price at which it ceased before. So far, says Dr. Smith, this law seems to be an improvement upon the ancient system; but by this law, a bounty of 2*s.* per quarter is given for the exportation of oats, whenever the price does not exceed 1*s.* No bounty had ever before been given for the exportation of this grain, any more than for that of pease or beans. By the same law, the exportation of wheat is prohibited as soon as the price rises to 4*s.* per quarter; that of rye at 2*s.*; that of barley at 2*s.*; and that of oats at 1*s.* These several prices are, in Dr. Smith's opinion, much too low; and there seems to be an impropriety in prohibiting exportation altogether at those precise prices, at which that bounty, which was given in order to force it, is withdrawn. The bounty ought to have been withdrawn at a much lower price, or exportation ought to have been allowed at a much higher. In these respects the new law seems to be inferior to the ancient system. However, with all its imperfections, Dr. Smith applies to it what was said of the laws of Solon, that though not the best in itself, it was the best which the interests, prejudices, and tempers of the times would admit of; and he adds, that in due time it might prepare the way for a better. Since the passing of this act, and the repeal of the bounty, circumstances have occurred, in consequence of which the prices of corn have risen, and the balance of trade has been turned against us. The prices, according to the statement of Dr. Anderson, in 1801, have risen from 2*l.* 2*s.* 1*d.* to 5*l.* 10*s.* per quarter; and our imports have been advanced to three millions of quarters nearly, in value more than six millions sterling; and this, compared with the sum already stated arising from the exports under the former act, granting a bounty, makes a total balance of trade against us, in this single article, of not less than nine millions sterling per annum. These facts seem to have made a great impression on several ingenious and well informed minds; the bounty has once more found advocates among some political writers of great merit, and among several statesmen; and a statute has been lately passed, which, it is expected, will produce all the beneficial effects that have been ascribed by its advocates to the old bounty. The committee of the house of commons, in their second report, ordered to be printed June 14th, 1804, deliver their opinion in these words: "It appears to the committee, that the price of corn from 1791 to the harvest of 1803 has been very irregular; but, upon an average, increased in a great degree by the years of scarcity, has in general yielded a fair profit to the grower. The usual high prices, however, have had the effect of stimulating industry, and bringing into cultivation large tracts of waste land; which, combined with the two last productive seasons, and other causes, have occasioned such a depression in the value of grain, as it is feared will greatly tend to the discouragement of agriculture, unless maintained by the support of parliament." Accordingly an act was passed July 30th, 1804, (44 Geo. III. c. 109.) to regulate the importation and exportation of corn, and the bounties and duties payable thereon. Without the aid of this new statute, it has been said, that

the farmer cannot be sure of obtaining, even in the home market, a fair and reasonable profit. By those who have disapproved this measure, and who, adopting the general principles of Dr. Smith, are adverse to a bounty, it has been alleged, that, like other sorts of trade, that of the farmer is liable occasionally to the spirit of overtrading, if profits for a time have happened to be greater than ordinary. The late years of dearth and most extraordinary price, they say, rendered the profits of farming, for the time, much greater than ordinary: and the consequence appears to have been a pretty free indulgence of the disposition to trade too much, and to enter into projects disproportioned to the capital that would immediately be invested. In many instances, where farmers came to make a new agreement about rent, they reckoned too confidently upon the continuance of prices which they ought to have considered as unusual; and made the estimate of their future returns too much upon the recent rate of profit, and not upon an average sufficiently and reasonably large. Like other improvident speculators, they were, of course, to suffer for their want of foresight, as soon as prices and profit returned to their ordinary rate. Hence it has happened, that those farmers who had overtraded, and who found it difficult to make good their imprudent engagements, found it almost as easy to persuade other persons as themselves, that prices are much too low. Their landlords, in particular, are not the persons most likely to discover that prices are not too low, but rents a little too high; and they may honestly find it somewhat difficult to be convinced, that the embarrassment of their tenants is owing to that local cause, and not to something that affects the general condition of the country. To this purpose, it is said, in a pamphlet by a member of parliament, entitled, "Curfory Observations on the act for ascertaining the bounties, &c." 1804, that "times, unfortunate in other respects, impressed on tillage a renovated vigour; a vigour which the principles of this act, and those alone, are able to sustain." By this statute it was enacted, that, from and after November the 15th, 1804, so much of the statute 31 Geo. III. c. 30. as regulates the prices at which British corn, grain, malt, meal, flour, and biscuit, may be exported, except to Ireland, and at which foreign corn, grain, meal, and flour, may be imported, except from Ireland, and as fixes the duties and bounties payable thereon, shall be repealed. By this statute it is farther enacted, that the importation and exportation of corn, into and from England and Wales, shall be regulated by the average price of the twelve maritime districts; and into or from Scotland, by the average price of the four districts in Scotland; and that the bounties and duties shall be regulated by schedules, annexed to this act; that whenever the average shall be under the prices at which corn may be importable into Great Britain and Ireland, on the low duties from foreign parts, exportation shall be allowed from Great Britain to Ireland, &c.; and that the importation and exportation of corn, into and from Ireland, shall be regulated by schedules, annexed to this act. The first schedule shews the prices to which the scale of bounty is to attach on the export of corn, &c. and the prices at which the exportation is prohibited. By this schedule, wheat may be exported, when at or under 48s. per quarter, with a bounty of 5s.; rye, at or under 32s. with a bounty of 3s.; pease and beans are exportable without a bounty, till at or under 35s.; barley, beer, or bigg, or malt made of barley, beer, or bigg, may be exported at or under 28s. with a bounty of 2s. 6d.; oats, at or under 16s. with a bounty of 2s.; wheat flour, biscuit, &c. with a bounty of 1s. 6d. per cwt.; wheat meal, with a bounty of 1s. 3d. per cwt.; barley, beer, or bigg meal, with a bounty of 10d. per cwt.; and oatmeal, with a

bounty of 1s. per cwt. But when the price of wheat exceeds 54s. that of rye 35s. that of pease and beans 37s. that of barley, beer, or bigg, or malt made of them, 31s. and that of oats 19s., no export is allowable. The second schedule shews the prices, according to which high or low duties are to take place on importation. When imported from the province of Quebec, or the other colonies or plantations in North America, wheat under 53s. per quarter is subject to the high duty of 24s. 3d. per quarter; at or above 53s. but under 56s. to the first low duty of 2s. 6d.; and at or above 56s. to the second low duty of 6d.; rye, pease, and beans, under 35s. per quarter, are subject to the high duty of 22s.; at or above 35s. but under 37s. to the first low duty of 1s. 6d.; and at or above 37s. to the second low duty of 3d.; barley, beer, or bigg, under 26s. are subject to the high duty of 22s.; at or above 26s. but under 28s. to the first low duty of 1s. 3d.; and at or above 28s. to the second low duty of 3d.; oats under 17s. pay the high duty of 6s. 7d.; at or above 17s. but under 18s. the first low duty of 1s.; and at or above 18s. the second low duty of 2d.; oatmeal, if under 16s. 6d. per boll of 140 lbs. avoirdupoise, or 128 lbs. Scotch troy, is subject, for every boll, to the high duty of 8s.; at or above 16s. 6d. per boll, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. per boll, to the second low duty of 2d. When imported from any other foreign country, wheat under 63s. per quarter, pays the high duty of 24s. 3d.; at or above 63s. but under 66s. the first low duty of 2s. 6d.; and at or above 66s. the second low duty of 6d.; rye, pease, and beans, under 42s. pay the high duty of 22s.; at or above 42s. but under 44s. the first low duty of 1s. 6d.; and at or above 44s. the second low duty of 3d.; barley, beer, or bigg, under 31s. 6d. pays the high duty of 22s.; at or above 31s. 6d. but under 33s. the first low duty of 1s. 3d.; and at or above 33s. the second low duty of 3d.; oats under 21s. pay the high duty of 6s. 7d.; at or above 21s. but under 22s. the first low duty of 1s.; and at or above 22s. the second low duty of 2d.; oatmeal under 20s. per boll pays the high duty of 8s.; at or above 20s. but under 21s. the first low duty of 1s.; and at or above 21s. the second low duty of 6d. The third schedule shews the prices to which the scale of bounty attaches on the export of corn, ground corn, flour or meal, malt, &c. from Ireland, and the prices at which the exportation is prohibited. When exported to any foreign country, wheat, at or under 29s. 5d. per barrel, British, is allowed a bounty of 3s.; rye, and also pease and beans, at or under 20s. 4d. a bounty of 1s. 10d.; barley, beer, or bigg, or malt made of these, at or under 16s. a bounty of 1s. 5d.; oats, at or under 10s. 2d. a bounty of 1s. 3d.; wheat, flour, biscuit, &c. a bounty of 1s. 6d. per cwt.; wheat meal, 1s. 3d. per ditto; rye meal or flour, 9d. per ditto; barley, beer, or bigg flour, 10d. per ditto; and oatmeal, 1s. per ditto. When the price of wheat exceeds 33s. 1d. per barrel, British; of rye, pease, and beans, 22s. 3d.; of barley, beer, bigg, or malt made of them, 17s. 8d.; and of oats, 12s. 3d.; no exportation is allowed. The fourth schedule shews the prices, according to which the high or low duties are to take place on importation into Ireland; for which, and other particulars, we refer to the act itself.

**BOUNTY**, *Queen Anne's*, for augmenting poor livings under 50l. per annum, consists of the produce of the first fruits and tenths, after the charges and pensions payable out of the same are defrayed. A corporation for management of the same was settled, &c. in 1704. See **AUGMENTATION** and **FIRST FRUITS**.

By stat. 44 Geo. III. c. 2. the sum of 8000l. was granted out of the consolidated fund to the governors of queen

Ann's bounty, for the relief of curates deprived of their cures on account of the residence of incumbents, in consequence of the act 43 Geo. III. c. 84. But no curate is entitled to receive any allowance under the act, who shall not produce to the said governors a proper recommendation from the bishop of the diocese in which the cure is situated, and no allowance shall exceed three-fourths of the income lost.

**BOUPER, LE**, in *Geography*, a town of France, in the department of the Lower Pyrenées; 10 miles S. W. of Mauleon.

**BOUQUENON**, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Bitché on the Sarre; 5 leagues S. W. of Bitché.

**BOUQUETIN**, in *Zoology*, the wild goat. See **CAPRA** **IBEX**.

**BOUR**, in *Geography*, a town of Asiatic Turkey, in the province of Caramania; 4 miles S. E. of Akserai.

**BOURAC**, a town in the Arabian Irak; 70 miles S. S. E. of Bagdad.

**BOURBACH**, or *Grand-Bourlach*, a town and castle of Germany, in the circle of Westphalia, and principality of Nassau-Dillenburg, near which is a lead mine; 9 miles W. of Dillenburg.

**BOURBON, NICHOLAS**, in *Biography*, a famous Latin poet in the 16th century, was a native of Vandœuvre, near Langres; and appointed by Margaret de Valois preceptor to her daughter, Jane d'Albert of Navarre, the mother of king Henry IV. He died at Condé whither he had retired, and where he had a benefice, about the year 1550. He wrote eight books of "Epigrams," commended by Erasmus, and a poem on the forge entitled "Ferraria." He was distinguished for his knowledge of antiquity and of the Greek language.

**BOURBON, NICHOLAS**, a celebrated Latin and Greek poet, was nephew of the former, and son of a physician at Bar-sur-Aube, where he was born about the year 1574. He taught rhetoric in the colleges of Paris, and was nominated by cardinal Du-Perron, in 1611, professor-royal in Greek eloquence. He was canon of Orleans and of Langres, and a priest of the oratory, though he declined the title. In 1637, he was admitted by cardinal Richelieu a member of the French academy, without soliciting the honour. He died at the house of the fathers of the oratory in 1644. As a Latin poet, he sustained the highest rank in France, and has been thought, if not superior, equal to any who lived in the two last centuries. In his verses he has combined a considerable portion of poetic fire with elevation of style and sentiment; and he has been charged with making Lucan and Claudian, rather than Virgil, his models; their manner being probably better adapted to the warmth of his conceptions. His master-piece is said to be an "Imprecation against the parricide of Henry IV." His poems were printed at Paris in 1651, 12mo. He also wrote Greek, as well as Latin verses, and in the latter language some pieces of prose. His taste was refined and accurate; and as he was much addicted to the use of wine, he expressed his contempt of the French poetry, by saying, "When I read French verse, I think I am drinking water." Although he was afraid of starving, 15,000 livres were found in his strong box at his death. Bourbon published an edition of St. Cyril's work against the emperor Julian, with a Latin translation. *Nouv. Dict. Hist.*

**BOURBON, ISLE OF**, in *Geography*, lately called *Isle de la Reunion*, an island of the Indian ocean, about 370 miles distant from the coast of Madagascar to the east, and at the distance of about 60 miles to the west of the isle of France, was first discovered by the Portuguese, in 1545, who called it *Maf-*

*carenbas*, after the name of the commander of their fleet; and this appellation was afterwards corrupted into *Mascaraigne*. In 1642, Pronis, the commandant at Madagascar, took possession of the island for the French government; and seven years after, says La Barthe, in his "Annales maritimes et coloniales," but, according to others, in 1654, the new commandant, M. de Flancourt, took possession of it again in the name of his sovereign, and gave it the name of *Bourbon*. He introduced into it domestic animals, which multiplied considerably; and, on account of its fertility, several Frenchmen formed in it settlements. In 1665, two ships of De la Haire's squadron arrived here, and left Renaud, an "officer d'administration," together with 20 labourers. The French, who, in 1671, escaped the massacre at Fort Dauphin in Madagascar, fled to this island; and various sea-faring persons settled in it, and employed themselves in agriculture. From the isle of France to this island, the passage may be performed in a day, but the return often requires a month. It is about 40 miles in length, and 30 in breadth. The shores are exceedingly steep, and cannot be approached except by small vessels, without danger. On this account it has few ports; but round the island there are several good roads where ships may ride securely. The soil is more sandy than that of the isle of France; and at some distance from the shore it is mixed with those smooth stones, which cover the bottom of the sea. In those parts, however, which admit of cultivation, the ground is excellent, and well watered by various streams that are supplied in summer by the melting snow, which in winter covers the tops of the mountains. The soil, thus manured, though not deep, is very fertile, and produces Turkey corn and rice, twice a year, and of the latter a great abundance. The mountains are very high; and the three inaccessible peaks, called the "Salasses," are said to be 1600 toises. In the southern part of the island there is a tremendous volcano, the district round which, called "pays brûlé," is entirely burnt up; and there are many gulleys, the declivities of which are so steep that they cannot be cultivated. The island is divided into four quarters. The first is that of St. Paul, which is the largest and most populous. Their houses are built at the foot of a steep mountain, on both sides of a fresh water lake. Their plantations are on the top of a mountain, which they ascend by a very steep and toilsome passage. On the summit, however, is a spacious plain, divided for the most part into plantations of rice, tobacco, corn, sugar canes, and fruit-trees. The sea at the port of St. Paul is calmer, and the anchoring ground more secure than at St. Dennis; nevertheless, mariners prefer the latter. The quarter of St. Dennis lies 15 miles from that of St. Paul towards the east; and here the governor resides. This district is more pleasant, though less populous, than the other. The chief port in the island is that of St. Dennis, where a draw-bridge, secured by iron chains, has been constructed for the purpose of enabling boats to land. This bridge extends more than 80 feet into the sea, and at the end of it is a ladder of ropes by which people who wish to go on shore must ascend; in all other parts of the island they must jump into the water. At two leagues from St. Dennis, proceeding along the sea-coast, is the quarter of St. Mary's, which is thinly peopled. The last and most fruitful district of the island is that of St. Susanne, four leagues from St. Dennis; the passage from one to the other having been with great labour cut through a wood; but the passage from St. Dennis to St. Paul is only by sea.

The sky in this island is serene, the atmosphere pure, and the water salubrious. Although the climate is hot, the breezes from the mountains are refreshing; and the hurricanes, which

which commonly occur once or twice every year, contribute to purify the air, and to preserve its salubrity. The island, which the French found at their settlement almost a desert, abounds in fruit, grass, and cattle of various kinds; the wild goats and wild hogs have retired to the woods and summits of the mountains; the land tortoises were formerly abundant, but are now found only in the western part, those of the other parts having been exterminated by the crews of ships that have touched upon the island. The rabbits, quails, partridges, and pintades, brought to the island, have none of them increased, except the last. It is said that no venomous animals are found in this island; nor any disagreeable to the sight, except spiders, of the size of a pigeon's egg, which weave very strong nets, capable, as some say, of being rendered as valuable as silk, and a kind of large bats, denominated "Poiseau bleu," which are skinned and eaten as a great delicacy. The rivers are well stocked with various sorts of fish. Among the vegetable productions we may reckon tobacco, sugar-canes, ebony, benzoin, aloes, white pepper, the cotton shrub, abundance of timber fit for ship-building; and several kinds of fruits, such as the guavas, bananas, citrons, tamarinds, lemons, and oranges. On the shores are found ambergris, coral, and many beautiful shells.

In the year 1717, the number of inhabitants in this island was computed at 2000, viz. 900 free, and 1100 slaves; and with regard to their disposition, they are, generally speaking, gentle and quiet, very industrious, and submissive to just and mild authority; but when it is otherwise exercised, apt to associate and unite in rebellion. In 1763, the population amounted to 4627 white people, and 15,149 blacks; the cattle consisted of 8702 bees, 4084 sheep, 7405 goats, and 7619 hogs. Upon an extent of 125,909 acres of cultivated land, they gathered as much cassava as would feed their slaves, 1,135,000 pounds weight of corn, 844,100 pounds of rice, 2,879,100 pounds of maize, and 2,535,100 pounds of coffee, which last the company bought up at about 3d. per pound. Labarthe says, this island produces annually 55,700 weight of corn, 54,300 of maize, and three millions of pounds of coffee. Ever since the French India company became established possessors of this island, they have directed their attention to the improvement of its cultivation; and with this view, they imported into it coffee-trees from Arabia, which have succeeded so well, as to produce an eighth, and according to some, a sixth part as much coffee as is raised in the Arabian kingdom of Yemen, and next to that in quality. The French have also erected forts and batteries, so as to render the island almost inaccessible. When admiral Boscawen appeared before this island with a British fleet in 1748, he found it well fortified both by nature and art, that, after some ineffectual cannonading, he was obliged to pursue his voyage. S. lat.  $20^{\circ} 51' 43''$ . E. long.  $55^{\circ} 30'$ ; which is the longitude of the port of St. Dennis, according to the *Connoissance des Temps*, an. viii.

BOURBON, a small island of Africa, near the coast of Senegal. N. lat.  $11^{\circ}$ . W. long.  $15^{\circ}$ .

BOURBON, a county of America, laid out and organized in 1783, by the state of Georgia, in the S. W. corner of the state, on the Mississippi, including the Natchez country. Having continued under the jurisdiction of the Spaniards ever since their conquest of this part of the country in 1780, it was given up to the United States by the treaty of 1795.

BOURBON is also a county of Kentucky, between Licking and Kentucky rivers, containing 7837 inhabitants, of whom 508 are slaves.

BOURBON, a post town, and capital of the county last

named, stands on a point of land formed by two of the southern branches of Licking river; 22 miles N. E. of Lexington, 21 E. of Lebanon, and 749 W.S.W. of Philadelphia. It contains about 60 houses, a baptist church, a court-house, and gaol. In its neighbourhood are several valuable mills.

BOURBON, *Fort*, lies in the island of Martinico, in the West Indies.—Also, the name given by the French to a principal port in North America, situate on a small island which divides it from Mud-lake; which see.

BOURBON *Parcehaud*, a town of France, in the department of the Allier, which gave name to a country and to the house of Bourbon; celebrated for its hot medicinal waters and baths. It contains two hospitals and about 2000 inhabitants; 4 leagues W. of Moulins. N. lat.  $46^{\circ} 35' 22''$ . E. long.  $2^{\circ} 57' 39''$ .

BOURBON *Lancy*, a town of France, and principal place of a district, in the department of the Saone and Loire, celebrated for its mineral springs. It contains three parishes and two hospitals. Its large bath, encompassed with circular walls, and paved with marble, is a work of the Romans;  $9\frac{1}{2}$  leagues S. W. of Autun. N. lat.  $46^{\circ} 37'$ . E. long.  $3^{\circ} 40' 42''$ .

BOURBONNE *les Bains*, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Langres; the place contains 3136 inhabitants, and the canton 11,978; the territory comprehends  $202\frac{1}{2}$  kilometres, and 16 communes. It takes its name from its hot baths; 6 leagues E.N.E. of Langres.

BOURBONNOIS, a province of France before the revolution, now the department of Allier, bounded on the east by Burgundy, on the north and west by Nivernois and Berry, and on the south by Auvergne; its climate is very temperate, and it produces in great abundance corn, hemp, fruit, wine, pasture, and wood; it has also some mines of coal, and medicinal springs. Its capital is Moulins. This province was erected into a duchy of France by Philip de Valois in 1329, in favour of Louis, son of Robert, the youngest son of St. Louis. This duke had two sons, Peter and James; from the latter of whom descended the house of Bourbon, which was the reigning family in France.

BOURBOURG, a town of France, in the department of the North, and chief place of a canton, in the district of Bergues, seated on a navigable canal which communicates with Calais, St. Omer, Dunkirk, Gravelines, &c.; 3 leagues S. W. of Dunkirk, and 1 S. E. of Gravelines. The town contains 1966, and the canton 9456 inhabitants; the territory comprehends 160 kilometres and 13 communes.

BOURBRIAC, a town of France, in the department of the North coast, and chief place of a canton, in the district of Guingamp; 5 miles S. of Guingamp. The town contains 2977, and the canton 7646 inhabitants; the territory includes 180 kilometres and 7 communes.

BOURCHET, a town of the duchy of Luxemburg; 4 miles N. W. of Diekirch.

BOURCHIEK, BOWSCHYRE, or BOWSER, THOMAS, in *Biography*, archbishop of Canterbury in the successive reigns of Henry VI., Edward IV., Edward V., Richard III., and Henry VII., has no particular claim to notice, otherwise, than as he was the principal instrument in introducing the art of printing into England. By descent, he was related to the noblest families in England, being the son of William Bouchier earl of Hereford in Normandy, and by his mother, the countess of Strafford, great grandson to Edward III. He was born at Hawfield in Essex, one of the family seats of the Bouchiers or Bourchiers, educated at Oxford, and held the office of chancellor of that univer-

city, from 1433 to 1437. After several inferior preferments in the church, he was elected bishop of Worcester, in the former of these years; invested by the king, with the temporalities of this see in 1435, and consecrated in 1436; his age not allowing of its being done sooner. In 1454, he was elected archbishop of Canterbury, and presided over the church during 32 years, in the most distracted period of the English government. He enjoyed the prelate 51 years from the time of his first consecration; an honour of longer duration than any which occurs in the English history, if we except the case of bishop Hough, who was bishop for almost 53 years. He was promoted to the office of lord high chancellor of England in 1455, and resigned it, according to Rymer, in the following year, but according to Dugdale, in 1457. In 1464, he received the red hat from Rome, being created cardinal-priest of "St. Cyriacus in Therinis." Soon after his advancement to the see of Canterbury, he visited his diocese, and instituted several regulations for its government; and he likewise published a variety of constitutions for the reformation of the clergy and laity, and for restraining the excessive abuse of papal provisions. Among his benefactions, it is recorded, that he gave to the prior and convent of Christ-church in Canterbury, the alien priory of Cranfield in Essex, the grant of which he had obtained from the crown, in the time of Edward IV.; to the church of Canterbury, he gave a fine image of the Trinity, of solid gold, adorned with precious stones, and a complete set of sacerdotal vestments; to his successor, he left 2000*l.* in recompence for dilapidations; to the church of Worcester, he gave an image of the Virgin Mary, of gilt silver, estimated at the value of 60*l.*; to the church of Ely, 200 marks for repairing the steeple; and to each of the universities, he bequeathed about 125*l.*, which he ordered to be kept in chests, for the support of poor scholars. The chest at Cambridge, which was united with Billingford's, subsisted in 1601, when 100*l.* was borrowed out of it, for the use of the university; but this fund was afterwards embezzled, through the iniquity of the times. The archbishop also left legacies to several monasteries. Bouchier had the honour of performing the marriage ceremony between Henry VII. and the daughter of Edward IV. Thus, as Dr. Fuller observes, "his hand first held that sweet poeie, wherein the white and red roses were tied together." He died at his palace of Knowle in 1486, and was buried on the north side of the choir, by the high altar, in a tomb of marble, round the verge of which is an inscription in old text characters. To the learning of this prelate, the testimonies are very equivocal; no record of it remaining, if we except some synodical decrees, an inquiry into heresies, and a few letters, instructions, and addresses to his clergy, which appear to have been merely official. The act that does the greatest honour to his memory, and indeed the only one that claims our particular notice, was his introduction of the art of printing into England. Having been informed, that the inventor, Tossan, *alias* John Guttenberg, had set up a press at Haerlem, he persuaded king Henry VI. to commission Robert Tournour, a gentleman of his wardrobe, to go over privately to Haerlem. This person was furnished with 1000 marks, of which the archbishop contributed 300, and accompanied by Caxton, a merchant of London, embarked for Holland. Concealing both his name and business, he went first to Amsterdam, then to Leyden, and to last settled at Haerlem. After spending much time and money, he at length persuaded Frederic Corfelli, one of the compositors, to carry off a set of letters, and to embark with him in the night for London. Upon their arrival, Corfelli was sent down to Ox-

ford, and secured from escaping, before the secret was thoroughly divulged, by setting a guard upon the press. Thus, it is said, the mystery of printing appeared ten years sooner in the university of Oxford, than at any other place in Europe, Haerlem and Mentz excepted. Not long after, presses were set up at Westminster, St. Alban's, Worcester, and other monasteries of note. If this account be just, printing was introduced into England, by the care of archbishop Bouchier, in 1464, the third year of king Edward IV. See PRINTING. Biog. Brit.

BOURDALOUE, LEWIS, a celebrated preacher and reformer of pulpit eloquence in France, was born at Bourges in 1632, and entered at an early age, into the society of Jesuits. Having distinguished himself by his proficiency in the studies immediately connected with his profession, and more particularly by his talents for the pulpit, the society determined to assign him the office of a preacher. The reputation which he acquired in the country, induced his superiors to send for him to Paris in 1669, where his fame increased, and recommended him to the court, so that he preached before Louis XIV., in the advent of 1670. He continued, for many years, the favourite preacher of the king, though he occasionally animadverted on his personal faults. Upon the revocation of the edict of Nantes, he was appointed by the court, to preach the catholic doctrine to the new converts in Languedoc. His talents were peculiarly adapted to this mission, as he was serious and impressive, and, at the same time, mild and insinuating, and capable of accommodating his addresses to persons of every rank and condition. With respect to the style of his eloquence, M. d'Alembert, in his "Eloge de Massillon," represents it as solid and serious, and, above all, strictly logical. Compared with Massillon, he is said to have been the best reasoner, and the latter the most pathetic. It redounded much to the honour of Bourdaloue, that he had, in a great degree, the merit of an original; the pulpit, when he appeared, "rivalling the theatre in buffoonery, and the schools in dryness." Towards the close of his life, he devoted himself to the service of the hospitals, the prisons, and the poor, and to other offices of charity. His conduct, which was exempt from that laxity of morals that was charged on his fraternity, afforded the best refutation of the "Provincial Letters." He died in the midst of his pious and benevolent labours, in 1704. His discourses and other religious tracts have been published in two editions, one of 16 vols. 8vo. and the other of 18 vols. 12mo. The first is the most esteemed. Nouv. Dict. Hist.

BOURDEAUX, or BORDEAUX, in *Geography*, a city and sea-port of France, and capital of the department of the Gironde, including 6 cantons, which contain 112,844 inhabitants, and comprehending 92½ kilometres, and one commune. Bourdeaux is seated on the west bank of the river Garonne, about 40 miles from its mouth; and, before the revolution, it was the capital of the province of Guyenne, and one of the most prosperous and flourishing cities of France, but, in consequence of that event, its commerce has suffered much injury. The tide flows quite up to the city; its port is ample and commodious, and ships of considerable burden may load and unload at its quays. It was not unusual to see 400 or 500 vessels in the harbour at the same time. Its traffic with the West Indies consisted of sugar, cotton, indigo, and other merchandizes; its chief exports were wine and brandy, and particularly the vin de Bordeaux, which we denominate claret; together with vinegar, fruit, resin, paper, honey, cork, &c.; and its imports were woollen stuffs, tin, copper, coals, herrings, leather, salted beef, tallow, drugs, deals, masts for

ships, hemp, pitch and tar. The whale and cod fishery, likewise, formed a considerable branch of the commerce of this city. It had 3 forts, the principal of which is that called "Trompette," fortified by M. de Vauban, and commanding the harbour. The figure of this city is a kind of half moon; and it consists of 3 fauxbourgs, viz. that of "Chapeaux-rouge," that of "St. Surin," and that of "Chartrons," which last is remarkable for its extent, and the beauty of its buildings. Its university was founded in 1441; its academy of sciences and belles lettres was established in 1712, to which belongs a large library; its cathedral is an immense Gothic structure; and its hospital, built without the walls, accommodates a variety of manufactures. The "Place royale," in the fauxbourg of "Chapeaux-rouge," is adorned with several magnificent buildings, and an equestrian statue of Louis XV. in bronze, erected in 1743. Its theatre is the most magnificent in France, and the actors used to receive extravagant salaries; and as much as London exceeds Paris, so much did Bourdeaux, before the revolution, transcend Liverpool. This city has many vestiges of Roman art and grandeur; such as the tower-gate, said to have been constructed in the time of Augustus; the amphitheatre, which formed an oval of 227 feet long and 140 feet wide; the palace of Gallienus, of which remain only some walls, and the 2 gates at the entrance; a temple consecrated to the tutelary deities, whose columns surpassed in elevation the finest buildings of the city, and which subsisted almost entire, till the year 1700, when Louis XIV. demolished it, in order to extend the esplanade of the Trompette castle; the fountain of Auberge, celebrated by Ausonius, and furnishing the city with water, &c. The temperature of Bourdeaux, upon a mean of 5 years, from 1777 to 1781, was 56.8°; and the standard temperature of this latitude is 57.6°. See Kirwan's estimate, &c. p. 87. N. lat. 44° 50' 18". W. long. 0° 34' 49".

BOURDEAUX, a town of France, in the department of the Drome, and chief place of a canton, in the district of Die; the town contains 1181, and the canton 3885 inhabitants. The territory comprehends 132½ kilometres, and 9 communes.

BOURDEILLE, a town of France, in the department of the Dordogne, 3½ leagues N. W. of Perigueux.

BOURDEILLES, PETER DE, in *Biography*, more generally known by the name of *Brantome*, of which he was abbot, was born of an ancient family of Guyenne, in 1527. From his early youth, he devoted himself to the servile offices of a courtier, without deriving any substantial advantage from the character he assumed, and the adventures in which he was engaged. Although he obtained the honorary distinctions of knight of the order of Malta, gentleman of the chamber to the kings, Charles IX. and Henry III., chamberlain to the duke of Alençon, and baron of Richemont in Perigord, he complains of indigence at the approach of old age. He died in 1614, at the age of 87. His memoirs, which have furnished anecdotes and biographical narrations, relative to the time in which he lived, were printed in 10 vols. 12mo.; and the last edition at the Hague in 1741, to which is annexed a supplement, is extended to 15 volumes. These memoirs abound with indecencies and contradictions; and though the anecdotes he has recorded, throw considerable light on the biography and history of the times, his own opinions and observations are entitled to little deference. Brantome, however, is an amusing writer, and his memoirs have had many readers. *Nouv. Dict. Hist.*

BOURDEILLES, CLAUDE DE, the nephew of the preceding, and comte de Montrefor, attached himself to Gas-

ton of Orleans, both whilst he was in favour, and when he lost it; but at length, being disgusted with the tumult and artifices of the court, he withdrew in order to enjoy the sweets of retirement. He died at Paris in 1663. His memoirs, under the name of Montrefor, in 2 vols. 12mo. contain several curious particulars, relating to the history of his time. He divulges without scruple, the projects he formed against the life of cardinal Richelieu.

BOURDELIN, CLAUDE, born at Villa-francha, near Lyons, in 1621, applied early to the study of pharmacy and chymistry, in which he acquired considerable reputation. When the royal academy of sciences was formed in 1666, under the auspices of Mons. Colbert, he was appointed to superintend the chymical department, and, in conjunction with Duclos, made analyses of the principal mineral waters in France. He also furnished the academy with the analyses of numerous other natural bodies, and contrived, or executed the greater part of the chymical experiments, made in the laboratory of the academy, for the space of 23 years. He died in 1699, and was succeeded in his appointment by Mons. Lemery. *Haller. Bib. Botan. Eloy. Dict. Hist.*

BOURDELOIS, in *Geography*, was, before the revolution, the name of a country of France in the province of Guyenne, in the environs of Bourdeaux; bounded on the east by Agenois and Perigord, on the south by Gascony, on the west by the sea, and on the north by Saintonge.

BOURDELOT, JOHN, in *Biography*, a learned French critic, lived towards the close of the 16th, and commencement of the 17th century. Having applied from his youth, to the study of the belles lettres and learned languages, he acquired the reputation, according to Baillet, of being a connoisseur in the oriental tongues, and in the knowledge of MSS. He was also well skilled in the law, and became an advocate to the parliament of Paris in 1627, and was appointed, on account of his merit, master of requests by Mary of Medicis. He died suddenly at Paris in 1638. His notes and emendations upon Lucian were published at Paris in 1615, fol.; his Heliodorus, with notes, in 1619, 8vo.; and his Petronius, also with notes, at Amsterdam in 1663, 12mo. He wrote also, according to Moreri, an "Universal history;" "Commentaries on Juvenal," and many other works which were never published. The abbé Bourdelot, his sister's son, who changed his name from Peter Michon, in compliment to his uncle, was a celebrated physician at Paris, who gained great reputation by a treatise upon the viper, and several other works. He died there in 1685, at the age of 76. *Biog. Dict.*

BOURDIN, in *Conchology*, the vulgar French name of a species of the HALIOTIS genus, found upon the rocks on the coast of France, and in the Mediterranean, the animal of which is eaten. The sort of Haliotis, generally called Bourdin, is the *H. tuberculata*; but the species *friata* also bears the same name. Bellonius gave the title of BOURDIN to the whole tribe of those shells called the sea ears, *auris marina*, &c. See HALIOTIS.

BOURDON, in *Entomology*, the trivial French name of the male insect of the common honey bee, *Apis mellifica*. But, among the naturalists of France, it is applied, in a more especial manner, as a generical title to that family of the bee tribe which Linnæus calls *Apes bombinatrices hirsutissima*. These are called also *Bourdons velus*, or hairy bees, in common. See APIS, BEE, BEE, *wild*, and HUMBLE-bee.

BOURDON, SEBASTIAN, in *Biography*, an eminent painter and engraver, was born at Montpellier, in 1616, and received the first rudiments of his art from his father, who

was a painter on glass. He afterwards studied at Paris, under an artful of no great note, and at the age of 13 years went to Italy, where he very successfully imitated the style of different masters, as Claude Lorraine, Andrea Sacchi, Correggio, and Bamboccio. After his return into his own country, he painted, at the age of 27, his most famous picture, "The crucifixion of St. Peter, in the church of Notre Dame at Paris." But being by religious profession a Calvinist, he was interrupted in the exercise of his profession by the civil wars; and therefore, in 1652, he removed to Sweden, where queen Christina made him her first painter. Here he had an opportunity of exhibiting a singular display of his disinterestedness. Gustavus Adolphus, the father of Christina, had brought some pictures from the pillage of Prague, which had never been unpacked. Christina employed Bourdon to examine these; and upon his making a favourable report of them, especially those of Correggio, the queen presented him with the whole collection. Bourdon declined accepting them, and informed the queen, that they were some of the finest pieces in Europe, and that she ought not to part with them; accordingly Christina, after her abdication, took them with her to Rome, and made them the basis of a collection, which afterwards came into the possession of the regent duke of Orleans.

After Christina's abdication, Bourdon returned to France, and pursued the exercise of his profession with uncommon assiduity; confining himself frequently to his garret, which was his painting-room, for a month together. He painted in a great variety of styles, and succeeded in all; history, portrait, landscape, pastoral, and grotesque. His chief faults, says Mr. Strutt, are want of force in the colouring, though others ascribe to it great force and effect, and of correctness in the outline; but these were amply overbalanced by the beauties of his composition, the lively fertility of his imagination, the animation of his expressions, and the variety and gracefulness of his attitudes. His virgins in particular are much esteemed; and the best of his pieces are those that are the least finished. Bourdon was one of the twelve persons who, in 1648, commenced the establishment of the Royal Academy, of which he became director. A violent fever terminated his life in 1671, much to the regret of all who highly respected his character as well as genius. Some of his daughters painted in miniature, and some of his scholars became eminent. His principal works are in the churches at Paris, in the gallery of the hôtel de Bretonville, at Versailles, Montpellier, and Toulouse. His etchings, which are numerous, are executed in a bold, masterly style; and convey a clear idea of his manner of painting. The lights are broad, the draperies are formed with great taste, and the folds well marked, though sometimes too dark and hard upon the lights; the heads are very expressive; the back-grounds are finely conceived, and executed in a grand style. This master's etchings are held in the highest estimation, of which some of the principal from his own compositions are the following; viz. the "Seven acts of mercy;" the "Flight into Egypt," and the "Return from thence;" several subjects of the "Virgin and child;" in one of which is seen a woman washing linen, hence distinguished by the name of the washer-woman; the "Return of the ark," said to be very scarce; the "Baptism of the eunuch;" "Twelve large landscapes," very spirited and fine prints. D'Argenville. Pilkington. Strutt.

BOURDON, AMELOT, a physician of Cambay, published, towards the end of the 17th century, "Nouvelles tables anatomiques, ou sont représentées toutes les parties du corps humain," large folio, Paris, 1678. Some of the tables are by the author; more from Vesalius. The plates represent-

ing the nerves are from Willis. "Nouvelle description anatomique de toutes les parties du corps humain, et de leur usages," Paris, 1679 and 1683, 12mo. No memorials of the life of this writer are known. Hall. Bib. Med. Eloy. Dici. Hist.

BOURDONNAY, in *Geography*, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Chateau-Salins; 4 leagues N. E. of Lunéville.

BOURDONNE, in *Heraklogy*, is understood of a cross, whose extremities are turned round like the ends of a pilgrim's staff; more frequently called *pomme*, *globatus*.

BOURDONNEUR, or L'OISEAU BOURDONNANT, in *Ornithology*, the same as *Oiparis meucher* and *colibris*, among French naturalists. The birds are so named, because, when flying, they make a strange kind of noise with the rapid motion of their wings, the sound of which Maicgrave compares to that of a spinning wheel.

BOURDOUR, in *Geography*, a town of Asiatic Turkey, in the province of Carmania; 98 miles S. W. of Cogni.

BOUREAU, in *Ichthyology*. The Linnæan *Trisla lyra*, is so named by the inhabitants in the neighbourhood of Bayonne.

BOURTOUTE, in *Geography*, a town of France, in the department of the Lower Seine; 8 leagues N. N. W. of Rouen.

BOURG, a town of the island of Cayenne, in South America.

BOURG, or *Bourg en Bresse*, a city of France, and capital of the department of Ain, seated on the Rhône, in a country somewhat marshy, but fertile. The principal commerce consists of corn, horses, cattle, and white leather. The town contains 6984, and the canton 149,739 inhabitants; the territory includes 297½ kilometres, and 13 communes. Bourg is distant 93 leagues S. E. from Paris. N. lat. 46° 12' 31". E. long. 5° 8'.

BOURG, or *Bourg-sur-Gironde*, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Blaye, seated on the Gironde; 4 leagues N. of Bourdeaux. It has a good harbour, about half a league from the confluence of the Dordogne with the Garonne, and carries on a considerable trade in wine. The town contains 2704, and the canton 13,286 inhabitants; the territory includes 132½ kilometres, and 19 communes. N. lat. 45° 4'. W. long. 0° 45'.

BOURG, *Le*, a town of France, in the department of the Lower Loire; 7 leagues W. of Nantes.—Also, a town of France, in the department of the Charente, situate on the south side of the Charente, opposite Jarnac, and 5 miles E. of Cognac.

BOURG *Saint-Andéol*, a town of France, in the department of the Ardèche, and chief place of a canton, in the district of Privas, and 7 leagues S. S. E. of it. The town contains 3964, and the canton 9492 inhabitants; the territory includes 282½ kilometres, and 9 communes.

BOURG-Argental, a town of France, in the department of the Loire, and chief place of a canton, in the district of St. Etienne, and 4 leagues S. E. from it. The town contains 1068, and the canton 6034 inhabitants; and the territory includes 150 kilometres, and 9 communes.

BOURG *d'Ault*, a town of France, on the sea-coast, in the department of the Somme; 1 league N. of Eure.

BOURG *des Comtes*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Redon; 3½ leagues S. of Rennes.

BOURG *Dieu*, a town of France, in the department of the

the Indre, and chief place of a canton, in the district of Chateauroux, and 1 mile N. of it.

**BOURG Laflig**, a town of France in the department of Puy-de-Dôme, and chief place of a canton, in the district of Clermont, and 8 leagues W. S. W. of it. The town contains 2133, and the canton 5787 inhabitants; the extent of the territory comprehends 215 kilometres, and 10 communes.

**BOURG de Lesfra**, a town of France, in the department of the Ardèche; 6 leagues N. N. W. of Privas.

**BOURG-Maurice**, a town of Savoy, in the department of Mont Blanc, and chief place of a canton, in the district of Montiers; the town contains 2166, and the canton 11,578 inhabitants; and the territory includes 967½ kilometres, and 13 communes.

**BOURG Neuf**, a sea-port town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Paimboeuf, seated on the English channel, at the mouth of the Loire, in a bay to which it gives name, between the isle of Noirmoutier and the continent. It has a safe bay and harbour; and trades chiefly in salt, made from salt marshes in its vicinity; 6½ leagues S. W. of Nantes, and 2 W. N. W. of Machecoul. It contains 2033 inhabitants, and the population of the canton includes 5501; the territory comprehends 187½ kilometres, and 6 communes.

**BOURG d'Oisans**, a town of France, in the department of the Isère, and chief place of a canton, in the district of Grenoble, and 5 leagues S. E. of it. The town contains 2079, and the canton 12,688 inhabitants; and the territory includes 910 kilometres, and 21 communes.

**BOURG de Peage, or de Valence**, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Valence, 1 mile N. of it. The town contains 2339, and the canton 15,113 inhabitants; the territory includes 245 kilometres, and 14 communes.

**BOURG le Réme**, a town of France, and principal place of a district, in the department of Paris, and 4 miles S. of it.

**BOURG le Roy**, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Freney-le-vic; 2 leagues S. of Alençon.

**BOURG-de-Viva**, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban, 8 miles W. of Lauzerte. The town contains 684, and the canton 7,470 inhabitants; the territory comprehends 130 kilometres, and 11 communes.

**BOURGACHARD**, a town of France, in the department of the Eure, and chief place of a canton, in the district of Pont Audemer, and 4 leagues E. of it.

**BOURGANEUF**, a town of France, and principal place of a district, in the department of the Creuse, 5½ leagues W. of Aubusson.

**BOURG DUN, LE**, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Dieppe, and 3 leagues S. W. of it.

**BOURGOIS, LOUISA**, also called *Bourfier*, in *Bio-graphy*, an experienced and intelligent midwife, in great repute, the latter part of the 16th and the beginning of the 17th centuries. Her husband was an army surgeon, as she informs us, and had been educated under Ambrose Paré; from him she received instruction in the more difficult parts of the art, so that she was enabled to deliver in some cases, where the assistance of the surgeon was usually thought necessary. In one case she extracted a stone from the urinary bladder, by means of the forceps. It is no wonder, therefore, that she attained to the height of her profession, and should be employed by the ladies of the highest rank, and at length by the queen of France, whom she de-

livered of six children. Her publications are, "Observations diverses sur la sterilité, perte de fruit, secondité, accouchemens, et maladies des femmes," Paris, 1608, 8vo. This was followed by a second and a third part, containing together, a collection of useful facts and observations on every branch of midwifery. "Recueil des secrets," &c. 1635, 8vo, containing formulae for the composition of a great variety of medicines, for the cure of diseases incident principally to women and children, in which she appears to have had great faith; also for preparing cosmetics, for improving the complexion. "Recit véritable de la naissance de messis, et dames, les enfans de France," containing a register of the births of the children of the queen, with the circumstances attending the labours. It appears that the present made her on the birth of each of the royal infants was, 500 crowns for a male, and 300 for a female child. She had also a pension of 300 crowns per annum, which she was to enjoy during her life. "Instructions a ma fille," Paris, 1641, containing rules for her conduct in practice. These several treatises were collected together and published in 1652, Paris, 12mo. The volume is decorated with portraits of the queen of France, to whom it was dedicated, and of mad. Bourfier. It is also accompanied with copies of verses to the king's physicians, and to mad. B. Haller Bib. Chirurg. Med.

**BOURGER MESTRES.** See *BURGHIER Majlers*.

**BOURGES**, in *Geography*, an ancient city of France, formerly called *Avaricum* and *Bitoriges*, the capital of the department of the Cher, situate at the conflux of the Auron and Eure. Before the revolution it was the see of an archbishop; its university was founded in 1406, by Lewis XI., who was born here, and invested the town with considerable privileges. The college of the Jesuits was a large and magnificent building. It contained 16 parish churches, and many public buildings. The cathedral church is considered as one of the most beautiful Gothic edifices in Europe. The principal manufactures of this place are linen cloth, woollen stuffs, and stockings, which are sold at its annual fairs; exclusively of these its commerce is small. The town contains 15,340, and the district the same number of inhabitants; the territory includes 90 kilometres, and 1 commune. N. lat. 47° 5' 4". E. long. 2° 23' 26".

**BOURGET**, a small town of Savoy, seated on a lake of the same name, about 10 miles long, and from 2 to 3 wide, 6 miles N. of Chamberry. This lake has a fish unknown in other countries, called "Lavalette," which weighs four or five pounds, and which is much valued at Chamberry. Near this lake is an irregular reciprocating spring, which issues from a rock, and is called "La Fontaine de Merveille."

**BOURGET, Le**, a town of France, in the department of Paris; 2 leagues N. of it.

**BOURGNEUF DE LA FOREST, LE**, a town of France, in the department of the Mayenne; 3 leagues N. W. of Laval.

**BOURGOGNE**, a town of France, in the department of the Marne, and chief place of a canton, in the district of Reims, and 6 miles N. of it. The town contains 633, and the canton 11,989 inhabitants; the territory includes 275 kilometres, and 25 communes.

**BOURGOING**, a town of France, in the department of the Isère, and chief place of a canton, in the district of la Tour-du-Pin, and 2 leagues W. of it. The population of the town includes 3595 persons, and that of the canton 15,021; the territory comprehends 175 kilometres, and 11 communes.

**BOURGTHEROUDE**, a town of France, in the department of the Eure, and chief place of a canton, in the district

district of Pont-Audemer, and 5 leagues E. of it. The town contains 865, and the canton 11,257 inhabitants; the territory includes  $107\frac{1}{2}$  kilometres, and 24 communes.

**BOURGUEBUS**, a town of France, in the department of Calvados, and chief place of a canton, in the district of Cien; containing 405 inhabitants; the population of the canton is 9,391; and the extent of the territory comprehends  $147\frac{1}{2}$  kilometres, and 30 communes.

**BOURGUEIL**, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Chinon;  $7\frac{1}{2}$  leagues W. of Tours. The town contains 2810, and the canton 14,969 inhabitants; the territory includes  $142\frac{1}{2}$  kilometres, and 7 communes.

**BOURGUET**, LEWIS, in *Biography*, was born at Nîmes in 1678, and removing with his family, who were protestants, to Switzerland, on the revocation of the edict of Nantes, he pursued his studies at Zurich. Here he distinguished himself by his application to theology, the languages, mathematics, law, antiquities, medals, and more particularly natural history. His attention was more especially directed to geology, for the cultivation of which his situation among the Swiss mountains was peculiarly favourable. He afterwards settled at Neufchatel, and here became professor of philosophy and mathematics. In 1729 he printed, in French, "Philosophical letters on the formation of salts and crystals, and on the generation and organic mechanism of plants and animals," &c. 12mo. In the preceding year he had undertaken, with the assistance of learned colleagues, a periodical work, entitled "Bibliothèque Italique," printed at Geneva, and extended to 16 vols. 8vo. which was esteemed a judicious and useful performance. Bourget had many literary connections, and was a member of several learned societies. Many of his papers were published in the "Journal Helvétique." He died in 1742. Moreri.

**BOURGUIGNOTTE**, a defensive weapon wherewith to cover the head; being a kind of cask, open before, and proof against either pike or musket; its name arose from the Bourguignons, who first introduced it.

**BOURGUIGNONS**. See BURGUNDIANS.

**BOURI**, in *Ichthyology*, the Arabic name of *Mugil cephalus*, Linn.

**BOURIGNON**, ANTOINETTE DE LA PORTE, in *Biography*, an enthusiast of a wild imagination and turbulent disposition, was born at Lille in Flanders, in 1616. Under a pretence of a divine inspiration and commission, she engaged in reviving the true spirit of Christianity, which she represented as extinguished by theological animosities and debates. Her own temper, however, was very different from that truly Christian spirit which she professed to rouse and reanimate. Adverse to marriage, though urged to it by her family, which was opulent, she eloped in order to avoid their persuasions; and, after a variety of adventures, became governess of an hospital in her native town, and assumed the order and habit of St. Augustin. Here, however, her restless and overbearing temper occasioned such disturbances, that, in consequence of the interference of the magistrates, she was obliged to remove to Ghent. One of her converts, named Christian Bartholomew de Cordt, who had been a Jansemit and priest of the oratory at Mechlin, was owner of part of an island in Holstein, called Noordstrandt. Of this patron of her fanaticism she bought an estate in this island, and determined to settle there with her disciples. In the mean while she resided at Amsterdam, and made many proselytes. She also wrote several books, and particularly one, entitled, "The Light of the World," in which she professes to explain her mystical principles. Mosheim suggests, that an attentive reader of her works will perceive,

that her intellect must have been in a disordered state; that most of her divine effusions were borrowed from the productions of the Myltics; and that, by the intemperance of her imagination, she has given an additional air of absurdity and extravagance to the tenets which she had derived from those pompous enthusiasts. The predominant principle of her works is this: "that the Christian religion consists neither in knowledge nor practice, but in a certain internal feeling and divine impulse, that arises immediately from communion with the Deity." Upon the death of De Cordt, who made this female fanatic his heiress, she left Holland in 1671, with a view of settling at Noordstrandt; but she discouraged many of her disciples from attending her, under an apprehension that their attachment was selfish, and that they wished to obtain a subsistence at her expence. She wrote in French, Dutch, and German, with great facility; and printed her numerous works in a press, which she had set up in her own house. Such, however, were both her principles and temper, that they exposed her to a variety of persecutions, which disquieted her mind, and made it necessary for her frequently to change her abode. At length she obtained the direction of an hospital in East Friesland, where her time was devoted to the service of the poor, whilst she retained her money under a notion, that she could find none that were deserving objects of her bounty. After a life of vicissitude and vexation, and suffering many insults on account of her religious fancies, she ended her days at Franeker, in 1680. Whilst she lived her followers were few in number; but after her death, her writings were the means of multiplying her proselytes, who were distinguished by the appellation of "Bourignonists." Amongst these a Cartesian, of a bold and penetrating genius, whose name was Peter Poiret, took the lead; and he dressed out in an artful manner, and reduced to a kind of system, the wild and incoherent fancies of Bourignon, in a large work, entitled, "L'Oeconomie Divine, ou Systeme Universel," which was published, both in French and Latin, at Amsterdam, in 1686, in 7 vols. 8vo. In Scotland her notions occasioned a controversy, in which Dr. Cockburn distinguished himself as the opponent of the Bourignonists. Gen. Dict. Mosh. Ecl. Hist. vol. v. p. 514, &c. 8vo.

**BOURMONT**, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chaumont, and 6 leagues E. N. E. from it, seated on a steep mountain; the population of the town is estimated at 1071, and of the canton at 10,370; the territory includes  $272\frac{1}{2}$  kilometres, and 26 communes. N. lat.  $48^{\circ} 12'$ . E. long.  $5^{\circ} 32'$ .

**BOURN**, a market town of Lincolnshire, in England, stands on the southern side of the county, near the borders of Rutlandshire, at the distance of 97 miles north from London. Here have been a castle and a priory, but both are partly destroyed. The outworks, ditches, and some fragments of the former are left to commemorate the spot; and as the fortified area includes about eight acres of land, we may presume that it was a place of considerable strength and importance. "Very large irregular works," says Mr. Gough, "are on the north and west sides between the two ditches; the earth raised about 20 yards in length, and 10 in breadth, and a ditch between every one of these pointing to the grand moat." These works are said to have been formed by Oliver Cromwell, when he attacked the town. Some of our ancient historians have stated that S. Edmund, king of the East Angles, was crowned at Bourn; but this is confuted by Mr. Gough, who places the scene of that event at Buers in Suffolk; indeed this castle does not appear to be connected with any public event till the time of the Danish invasions.

invasions. Some of these marauders having made an inroad into Lincolnshire, Marcot, lord of Bourn, with his numerous family and attendants trained in arms, and about 250 men from Croyland abbey, marched against them, and met them at Laundon, where a desperate battle ensued, which terminated in favour of Marcot and his party. Bourn, as its name implies, is situated in a valley, and has a stream running through part of it, which turns three mills, very near its source. Here is also a medicinal mineral spring, the waters of which are rather brackish, and are found to be serviceable in some disorders. Here are some tanneries, and one parish church, a chapel, and two alms-houses. The markets are weekly on Saturdays, and here are three annual fairs. Vessels of about ten tons burthen convey articles of commerce, &c. from this place to Spalding, Boston, &c. That distinguished statesman, sir W. Cecil, who was created baron Burleigh, by queen Elizabeth, was born here in 1521, and possessed this manor. At an inn in this town was formerly a curious old portrait of queen Elizabeth, on a pannel. The town-hall was built by the above nobleman. The township contains 282 houses, and 1474 inhabitants.

At Stanefield, a village a little to the north, is a chalybeate spring, and, according to Dr. Stukeley, many Roman coins have been found here. About four miles hence is Grimsthorpe, a seat belonging to the duke of Ancaster. The house, a magnificent structure, stands on a hill in the midst of a large park, which, with its fine woods, and large piece of water, constitute many grand and beautiful scenes. "Grimsthorpe," says Fuller, "I may call an extempore structure, got up on a sudden by Charles Brandon, duke of Suffolk, to entertain king Henry VIII. in his progress into these parts." Since the period of Fuller's writing, this house has undergone many improving alterations, and is now finished and fitted up in an elegant style. Gough's edition of Camden's Britannia, vol. ii. Fuller's Church History of England.

**BOURNASEL**, a town of France, in the department of the Aveyron,  $4\frac{1}{2}$  leagues N. W. of Rhodéz.

**BOURNEVILLE**, a town of France, in the department of the Eure; 2 leagues N. W. of Pont Audemer.

**BOURNEZEAU**, a town of France, in the department of the Vendée; 5 leagues N. W. of Fontenay le Comte.

**BOURNIQUEL**, a town of France in the department of the Lot, and chief place of a caupon, in the district of Montauban, seated on the south side of the Aveyron; 13 miles E. N. E. of Montauban.

**BOURNOU**. See **BORNOU**.

**BOURNOU**, *Great and Little*, two capes at the commencement of the road in the gulf of Salonica. This road, which terminates at a shoal, which is situated at the head of the gulf, affords good anchorage to ships of every size, and a safe retreat to fleets.

**BOURO**, one of the Moluccas or Spice islands in the East Indies, lying between Ceram on the east, and Celebes on the west; its shape is oval, the longest diameter extending east and west; about 90 miles in length by 50 in breadth. This isle was nominally subject to the king of Ternat; but in 1660 the Dutch built a fort in the bay of Cagale, or Cayeli, at the north east end of the island, where the natives who profess the Mahometan religion have a mosque, whose roofs, gradually arising in a regular gradation one above another, present a very agreeable appearance; and though they burned the exterior woods, they seem to have improved the industry of the inhabitants. This island rises suddenly from a deep sea, being encompassed as with a wall. Part of its northern coast is inhabited by a people who are sub-

jects of the Dutch company, and are governed by their "Oran-cayos," who have each a "dap," or deputy under them. The interior parts, which consist of mountains so lofty, that they may be sometimes descried at the distance of 28 leagues, are the haunts of the "Alforek," or wild mountaineers. The south coast is now deserted, on account of the continual invasions of the Papuas. The coast, to the east of the village of Cayeli, is watered by a number of small streams; but to the north-west there is a very considerable river, called by the natives "Aer-Bellar," which discharges itself into the roadstead. This river is very deep, and for some distance from its mouth more than 70 feet broad. On its borders is found the beautiful shrub, known by the name of "Portlandia grandiflora." The pebbles rolled from the mountains by the rivulets are fragments of "quartz," mixed with mica. Birds, especially parrots, are so numerous, that the island probably derives from this circumstance its name, which signifies, in the Malayan language, a bird. The woods afford abundance of deer, goats, and wild boars. The civet weasel is found in this island, and the curious hog called *babiroussa*. A green ebony, and a kind of iron wood, are mentioned among the trees, and several other kinds of wood, proper for inlaid work, much valued by the Chinese, and others useful for dying; and it is not improbable that the clove, and perhaps the nutmeg, defy, in the recesses of the mountains, the wild avarice of man. The sago tree grows here in great abundance, supplying the inhabitants with the principal means of their subsistence, as well as an article of exportation. The "Cayou pouti," of the Malays (*Melaleuca latifolia*) grows in great abundance upon the hills; and from this is obtained, by distillation, a great quantity of the oil of cajeput. According to astronomical observations, made by those who pursued the voyage in search of la Pérouse, at the village of Cayeli, its latitude was  $3^{\circ} 21' 54''$  S. and longitude  $127^{\circ} 21' 6''$  E. The dip of the magnetic needle was  $20^{\circ} 30'$ . Its variation, observed on board, was  $0^{\circ} 54'$  E. The highest point indicated by the thermometer (Reaumur's) on board was  $23^{\circ}$ , and on shore  $25^{\circ} \frac{1}{5}$ ths. The mercury in the barometer varied only from 28 inches 1 line to 28 inches 2 lines. The time of high water on the full and change days was three quarters after eleven; it then rose to the perpendicular height of 6 feet. Voyages in search of la Pérouse, drawn up by M. Labillardiere, vol. ii. p. 308, &c. Eng. ed.

**BOURO**, is also a small island, north of the island of Sumatra; 5 leagues N.E. of Acheen.

**BOURON**, a town of European Turkey, in Romania, the see of a Greek bishop, seated on a lake of the same name, and 15 miles distant from the coast of the Archipelago.

**BOURRE**, in *Ornithology*. According to Salerne, the common or domestic duck is called *bouurre* in Normandy, and the ducklings *bouurret*.

**BOURRE**, in *Zoology*, is also a word in use in France to express the hair of several quadrupeds, such as the ox, the buffalo, the horse, stag, &c. Thus also they have the distinction of *bouurre de laine* for the woolly kinds, and *bouurre de soie* for that of a silky texture.

**BOURKEE'**, Fr. the air of a dance so called, is supposed to come from Auvergne, in which province it is still in use. The tune is in common time, and begins with an odd crotchet. Rousseau.

**BOURRERIA**, in *Botany*. See **EHRETIA**.

**BOURRIQUE**, in *Zoology*, synonymous with *l'antessi*, the she-ass.

**BOURSAULT**, **EDME**, in *Biography*, a French dramatic writer, was born in the province of Burgundy, in 1638; and by singular assiduity, though his education was

altogether neglected in his youth, attended a very accurate acquaintance with the French language. After his settlement at Paris, he was employed by the king in composing a work for the Dauphin, entitled "The true Study of Sovereigns," which was so well received, that the author would have been appointed sub-preceptor to the Dauphin, if he had understood Latin. For a weekly gazette in verse, with which he amused the court, he obtained a pension; but, on account of an imprudent attack upon the Capuchins, a complaint was lodged against him by the queen's Spanish confessor, who belonged to that order, and in consequence of it his gazette and pension were suppressed, and he himself was in danger of being confined in the *baillie*. In a similar gazette he afterwards introduced a satire on the prince of Orange, which political considerations induced the court to suppress. At length, however, he was appointed receiver of the *tailles* at Montlaçon, where he died in 1701. As a writer for the stage, Bouffault was distinguished by his talents for agreeable ridicule, united with good sense, and also by an harmonious versification, as well as a style that was easy and adapted to his subjects. His "Esope à la Ville," and "Esope à la Cour" still retain their reputation on the theatre. An attack upon Boileau, by way of retaliation for some personal reflections in this author's satires, prevented the introduction of his piece in one act, entitled "La Satyre des Satyres," on the stage; but it was afterwards printed with a preface. Some years afterwards, Bouffault, by his polite attention to Boileau, conciliated his friendship, and induced him to insert some other name terminating with *aute*, in his satires. Bouffault also wrote tragedies and operas; and his dramatic works were published in 1746, under the title of "Theatre de Bouffault," in 3 vols. 12mo. His letters, miscellaneous pieces, and romances, are now forgotten. *Nouv. Dict. Hist.*

BOURSE, in *Ichthyology*, in the isles of France and Madagascar, the common name of all the fishes of the *TETRODON* genus. In the French American colonies, *baliste vieille* (*balistes vetula*) bears the same name. Lacepede likewise assigns the word *bourse* as a specific name to a new species of balistes described by Sonnerat, the first dorsal fin of which has three rays; the second is spotted; tail forked; and below the eye a black lunated spot.

BOURSIER, LAWRENCE-FRANCIS, in *Biography*, an eminent theologian and metaphysician, was born at Écouen, in the diocese of Paris, in 1679, and entered into the Sorbonne in 1709, where, in 1711, he obtained the degree of doctor. As he devoted himself to study, he refused several benefices which were offered to him; and, at the age of 31, acquired great celebrity, both as an eloquent writer, and profound reasoner, by a work entitled "The Action of God on the Creatures," or "Physical Premotion proved by reasoning," 2 vols. 4to. and 6 vols. 12mo. This work was highly extolled by the Jansenists; and Voltaire speaks of it (*Age of Lewis XIV.*) as deeply argumentative, learned, and sometimes extremely eloquent. It involved him in a controversy with the famous Malebranche. He was also the author of a memoir presented to Peter the Great by the doctors of the Sorbonne, concerning a proposed union between the Russian and the Latin churches, which originated from a conference held by the author with the czar, on his visit to the Sorbonne. His other works, which were numerous, chiefly related to the disputes that subsisted in the Gallican church. In 1729, he was one of many doctors who were expelled the Sorbonne; and from this time he was under a necessity of securing his personal liberty by living in privacy. He died at Paris, in 1749. *Nouv. Dict. Hist.*

BOURSIRLES, in *Entomology*, the *cancer latro*. *Rocheff. Ant. 1. c. 26.* See *LATRO*.

LOURTANG, in *Geography*, a town and fortress of Groningen; 12 miles S.S.W. of Winschotten.

BOURTH, a town of France, in the department of the Eure; 2 leagues N.W. of Verneuil.

BOURTHES, a town of France, in the department of the Straits of Calais, and chief place of a canton, in the district of Boulogne; 4 leagues S.E. of Boulogne.

BOURTRY, or BOTRO, a village of Africa, in the kingdom of Anta, on the Gold coast, seated on a small river, at the foot of an eminence, on which the Dutch have built an irregular and mean fort, of an oblong form, divided into two parts, each defended by four small pieces of cannon. The fort was built by one Carolus, in the service of the Dutch, who afterwards passed into the pay of France, and obtained that privilege from the king of Anta, on acknowledging his superiority by a slight tribute. This fort is called *Bademlyu*; its batteries command the village of Bourtry, which has no other commerce besides the gold trade carried on with the negroes of Adom. The inhabitants are of a mild and gentle disposition, much attached to the Europeans, whom they consider as their protectors. In 1708, the Dutch concerted a plan for forming sugar-plantations, which alarmed sir Dalby Thomas, then the English governor at cape Coast, who represented to the Royal African company the danger of permitting the Dutch to execute a scheme, which would diminish the value of the British colonies in the West Indies. These sugar-plantations, the plan of which was thus counteracted, never answered the great expectations of the Dutch.

BOURY, in *Zoology*, a species of ox, that inhabits Madagascar. It is of the size of a camel, of a snowy white colour, and, like that animal, has a protuberance on the back. Boury is the name by which this kind is called by the natives.

BOUSCH, or BOUCS, in *Geography*, a town of Upper Egypt, situate about a quarter of a league from the west bank of the Nile, and 4 miles N.E. of Benisouef. The houses are built of brick, and the roofs are elevated in the form of pigeon-houses. The inhabitants occupy the ground-floor, and the pigeons the first; a practice which is general through the rest of the Thebais. These houses, which make some figure at a distance, exhibit on entering them only tokens of wretchedness in the midst of an abundantly rich country. In this town is occasionally held a considerable market for cattle and provisions. The canal of Bousch formerly poured its waters into the river for six months of the year. At present it conveys them through the whole year into the lake Moeris, which does not receive a sufficient quantity by Joseph's canal, half choaked up as it is, to admit of its restoring any to the Nile.

BOUSIER, of the French *Entomologists*. See *COPERS*.

BOUSKAVIR, in *Geography*, a river of Persia, which discharges itself into the Persian gulf, near Bender Kik.

BOUSSAC, a town of France, and principal place of a district, in the department of the Creuse, 6 leagues N.E. of Guéret. The place contains 586, and the canton 7787 inhabitants; the territory includes 337½ kilometres, and 17 communes.

BOUSSANGES, a town of France, in the department of the Herault; 6 leagues N. of Beziers.

BOUSSIÈRE, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Befançon; the town contains 347, and the canton 7015 inhabitants; the territory comprehends 135 kilometres, and 25 communes.

BOUSSU,

**BOUSSU**, a town of France, in the department of Jemappe, and chief place of a canton, in the district of Mons; the town contains 1882, and the canton 13,571 inhabitants; the territory includes  $82\frac{1}{2}$  kilometres, and 13 communes.

**BOUSTROPHEDON**, compounded of *βους*, *bullock*, and *τροφή*, *I turn*, in *Literature*, is used in speaking of the ancient method of writing among the Greeks, wherein the lines were continued forwards and backwards, like the furrows in ploughing.

Pausanias (lib. v. c. 17. Eliaca) mentions several ancient inscriptions written in this manner: the laws of Solon are also said to have been thus written; which, as the author last cited explains it, is when the second line is turned on the contrary side, beginning at the end of the former, thus:

ΕΚ ΔΙΟΣ ΑΡ  
ΒΟΞΗΒΩΧ

Potter, Arch. Græc. lib. i. cap. 26. tom. i.

**BOUT**, in *Ornithology*. Under this name Buffon describes two birds of the *CROTOPHAGA* genus; namely *C. asi.* as *le petit bout de Peau*; and *C. major*, as *le grand bout de Peau*.

**BOUTA**, in *Ancient Geography*, a town of Africa, in Libya Interior, near the source of the river Cinipha, according to Ptolemy.

**BOUTADE**, in *Musick*, an irregular flight or movement without art or study.

The word was also formerly used for a *solo* on the *viol di gamba*, thus called as being supposed to be extemporary.

Richelet speaks of a dance called *boutade*, invented by the famous Bocan, in the reign of Lewis XIII. so called from the brisk humorous manner of its beginning; but now out of use.

**BOUTAEL**, in *Ichthyology*, the local name of a certain kind of fish, that is said to inhabit the lakes, ponds, and standing waters, in the East Indies, where it is also called the *Neegen oogen*. Ray describes it under the name of *lampetra Indica*. It is conjectured that this must belong to the lamprey, or *petromyzon* genus, from the accounts of authors who speak of it; but whether really so, or not, it is difficult to determine.

**BOUTAN**, in *Geography*. See **BOOTAN**.

**BOUTANT**, in *Architecture*. An arc boutant is an arch or buttress, serving to sustain a vault; and which is itself sustained by some strong wall, or massive pile.

The word is French, and comes from the verb *bouter*, to *but*, or *abut*.

A *pillar BOUTANT* is a large chain or pile of stone, made to support a wall, terrace, or vault.

**BOUTE'**, in the *Manege*. A horse is called *bouté*, when his legs are in a straight line from the knee to the coronet; short-jointed horses are most apt to be *bouté*.

**BOUTKOUJA**, in *Geography*, a town of Persia, in the province of Ghilan; 120 miles N.N.W. of Reshd.

**BOUTON**, or **BOOTON**, one of the Molucca or rather Celebesian islands, in the Indian sea; situate about 12 miles to the south-east of Celebes. It is a large and woody island, and is a kingdom of itself, to which the neighbouring islands belong. The king of Bouton is in alliance with the Dutch company, who pay him a yearly sum of 150 rix-dollars, or 22l. 14s. 6d. sterling, in new Dutch coin, upon condition, that he should not only permit the extirpation by the company of all the clove-trees in this and the neighbouring islands, but also assist them in effecting it. For this purpose, the company annually send out a serjeant, who is styled the "extirpator," and who goes through all the woods in the islands, and causes all the clove-trees which he meets with to

be cut down. The king of Bouton is obliged to provide for him guides and interpreters, and also vessels, if he should need them. But as this contract has not been regularly fulfilled, the government in India has thought proper to withhold this pecuniary allowance, at least for one year, in order to induce this prince to adhere more rigidly to his contract, and to be more active in assisting the company to destroy this rich production in his country, for the benefit of Amboyna and Banda. The passage between Bouton and the Toucan-bessis is the second dangerous part of the navigation for ships going to the Moluccas or Spice islands; the other being that of the "Budgeroons." The former channel is, indeed, wider than the latter, being about 4 leagues in breadth from the nearest part of Bouton to the westernmost of the Toucan-bessis; but the danger is of longer duration, on account of the numerous small islands that form the cluster called the "Toucan-bessis;" all of which are either connected or surrounded by rocky shoals, over and between which very rapid currents set strongly to the eastward; besides, a large and dangerous flat, called the "Hoefyzer," or horse-shoe, lies one and a half or two leagues south of them, upon which many vessels of the company have been wrecked. In the narrowest part of the passage is also a bay running into the land, west and north, into which vessels are in danger of being driven by the currents which set in to the bay, if the point opposite Toucan-bessis be approached too near in calm weather. From this bay there is no escape till the west monsoon sets in again; and some of the company's ships have been under a necessity of remaining in it for five or six months. From this circumstance, the navigators have given it the name of "Dwaal," or Mistake-bay. The principal town of this island is Callasufurg, seated about a mile from the sea, on the top of a hill, and surrounded by walls. The inhabitants are small, but well-shaped, and of a dark olive complexion. Their houses are erected on posts; and their religion is Mahometanism. Stavorinus's *Voyages to the East Indies*, vol. ii. p. 300. S. lat. 5°. E. long. 125° 30'.

**BOUTON de Camifille**, in *Conchology*, a trivial name in France for *trochus labis* of Linnæus.

**BOUTON de la Chine**, the Linnæan *trochus niloticus*.

**BOUTON de Rose**, a species of *BULLA*, ornamented with red bands, *bulla opulente* of Linnæus.

**BOUTON terrestre**, the common name of a terrestrial snail, figured by D'Argenville. It is the *helix rotundata* of Linnæus.

**BOUTONNE**, in *Geography*, a river of France, which runs into the Charente, 2 leagues E. of Rochfort; passing by St. Jean de Angely, and navigable to that town.

**BOUTS-RIMES**, a popular term in the French *Poetry*; signifying certain rhymes, disposed in order, and given to a poet, together with a subject, to be filled up with verses ending in the same words, and the same order. The invention of the bouts-rimes is owing to one Du Lot, a poet, in the year 1649. In fixing the bouts, it is usual to chuse such as seem the remotest, and have the least connection.

Some good authors fancy, that these rhymes are of all others the easiest, that they assist the invention, and furnish more new thoughts than any others. Sarasin has a poem on the defeat of the bouts-rimes. The academy of Lanternists, at Thoulouse, have contributed towards keeping in countenance the bouts-rimes, by proposing each year a set of fourteen, to be filled up on the glories of the grand monarch: the victorious sonnet to be rewarded with a fine medal. An instance hereof may be given in the following one, filled up by P. Commire:

Tout

Tout est grand dans le roi, l'aspect seul de son  
 Rend nos fiens ennemis plus froids que des  
 Et Guillaume n'attend que le tems des  
 Pour se voir succomber sous un bras si  
 Qu'on ne nous vante plus les miracles d'  
 Louis de bien regner lui feroit des  
 Horace en vain Pegale aux dieux dans ses  
 Moins que mon heros il etoit sage et

*busle*  
*glaçons.*  
*moissons,*  
*robuste.*  
*Auguste;*  
*leçons:*  
*chançons:*  
*juste, &c.*

**BOUSALLICK**, in *Ornithology*, synonymous with *caulus foetidus*, which see.

**BOUTTONNE'E**, Fr. in *Heraldry*, is applied to the seed of a rose, when represented of a different colour from the flower; which the English call *seeded*: e. g. a rose gules seeded.

**BOUVERET**, in *Ornithology*, the French name of *loxia auranti*.

**BOUVERON**. Under this name *loxia lineola* is described by several French writers. Brisson, however, calls it *petit bouvreuil noir d'Afrique*.

**BOUVIER**, the name of *motacilla nevia*. Salern. Orn.  
**BOUIERA**, in *Ichthyology*, a name given by some writers to a small fresh-water fish, found in the clear streams of France and Germany. The French call it *bowière*. It also bears the name of *bubulea*. This is *cyprinus amarus* of naturalists.

**BOUVIERE**, the common name in France of *cyprinus amarus*.

**BOUVIGNES**, in *Geography*, a town of the Netherlands, in the county of Namur, seated on the Meuse. Near Bouvignes, which was formerly surrounded with a wall, and had a strong castle, are the remains of an ancient city, called "Chivremont," the inhabitants of which committed many depredations, and defended themselves with valour against Charles the Simple in 922, against Otho in 939, and against Bruno archbishop of Cologne, in 960. But it was at length taken and destroyed, in 992, by Notger, bishop of Liege. It is distant four leagues S. from Namur.

**BOUVINES**, or **PONT-A-BOUVINES**, a village of Flanders, seated on the river Marque, 3 leagues S.E. of Lille, where Philip Augustus obtained a great victory over the emperor Otho in 1214.

**BOUVREUIL**, in *Ornithology* (Buffon, &c.), *loxia pyrrhula* of Linnæus and other systematic writers; and *bulwer* of the English. Bouvreuil, in a more general sense, implies all the birds of the *LOXIA* genus.

**BOUXIERES-AUX-DAMES**, in *Geography*, a town of France, in the department of the Menrthe, 1 league N. of Nancy.

**BOUXWILLER**, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Saverne; 6 leagues N.W. of Strasbourg. The town contains 2700, and the canton 12,264 inhabitants; the territory includes 105 kilometres, and 21 communes.

**BOUZANNE**, a river of France, in the department of Indre, which rises near Aigurande, 7 leagues from Argenton, and discharges itself into the Creuse, near Cluseau.

**BOUZDOGAN**, a town of Asiatic Turkey, in the province of Natolia; 24 miles N.W. from Mogla.

**BOUZE**, a town of France, in the department of the Cote d'Or, and chief place of a canton, in the district of Beaune; 1 league N.W. from Beaune.

**BOUZEK**, a town of Asiatic Turkey, in the province of Caramania; 32 miles E.N.E. of Kir-sehr.

**BOUZILLE**, a town of France, in the department of the Mayne and Loire; 1 league S.E. of Ancenis.

**BOUZILS**, a town of France, in the department of Vendée, and in the district of Montaigu; 5 miles south of it.

**BOUZKIR**, a town of Asiatic Turkey, in the province of Natolia; 30 miles S.S.E. of Beishehri.

**BOUZOLS**, a town of France, in the department of the Upper Loire; 1 league S. of Puy-en-Velay.

**BOUZONVILLE**, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville, and 5 leagues S. of it, seated on the Nied. The town contains 1400, and the canton 12,740 inhabitants; the territory comprehends 190 kilometres, and 40 communes.

**BOW**, *Arcus*, a weapon of offence, made of wood, horn, or other elastic matter; which, after being strongly bent, by means of a string fastened to its two ends, in returning to its natural state, throws out an arrow with great force.

The bow is the most ancient, and the most universal of all weapons: and has been found to obtain among the most barbarous and remote people, who had the least communication with the rest of mankind.

Its invention was ascribed by the ancients to Apollo, and was said to have been first communicated to the primitive inhabitants of Crete: Hence, even in latter ages the Cretan bows were famous, and preferred by the Greeks to all others. Some, however, rather chose to honour Perseus, the son of Perseus, with the invention; while others ascribed it to Scythes the son of Jupiter, and progenitor of the Scythians, who were not only excellent at the bow, but by many reputed the first masters of it. (Potter's Arch. Græc. &c.) All these different tales, however, serve but to show that its antiquity must be referred to the remotest periods of history.

The earliest instance in the Old Testament, where the use of the bow is implied, is in that remarkable passage where Hagar and her son, driven from the house of Abraham, wander in the wilderness of Beer-sheba. Of Ishmael it is said (Gen. xxi. 20.), "And God was with the lad, and he grew, and dwelt in the wilderness, and became an archer." The connection of which with the fifth preceding chapter (xvi. 12.) implies an earlier practice with the bow than any that can possibly be adduced from the profane historians. The overthrow of Saul was particularly owing to the Philistine archers. (1 Sam. xxxi. 3.) and (2 Sam. i. 18.) David, we are told, who succeeded him, "bade them teach the children of Judah the use of the bow: behold it is written in the book of Jasher."

The practice of the bow indeed, at this time, appears to have been so general, that it was not infrequently made use of as a figure of speech. Israel, when blessing his sons, (Gen. xlix. 23, 24,) says of Joseph, "The archers have sorely grieved him, and shot at him, and hated him. But his bow abode in strength, and the arms of his hands were made strong, by the hands of the mighty God of Jacob." The companies that came to David at Ziklag (1 Chron. xii. 2.) "were armed with bows, and could use both the right hand and the left." Its earliest application was undoubtedly to the purposes of food: and accordingly, when Isaac sent Esau to the forest, he said, "Take, I pray thee, thy weapons, thy quiver, and thy bow, and go out to the field, and take me some venison."

The fabulous writers of antiquity assert, that Teutarus, a Scythian, first gave Hercules a Scythian bow and arrows (Lycophron. Cassandra, v. 56.); and Theocritus mentions it by the name of the Mæotian bow.

From the Scythians, it was derived to the Grecians, some of whose ancient nobility were instructed by the Scythians in its use, which in those days passed for a most princely education (Potter, Arch. Græc. tom. ii. l. iii. cap. 4. Aquin. Lex. Milit. ii. 260). The Scythian was distinguished

guished from the Grecian *bow*, as well as from that of every other nation, by the singular incurvation of its shape, which was so great as to form a half-moon or semicircle (Amin. Marcellinus, l. xx.); whence the shepherd, in Athenæus, being to describe the letters in Theseus's name, and expressing each of them by some apposite resemblance, compares the third to the Scythian *bow*, meaning not the more modern character of Σ, but the ancient C, which is semicircular, and bears the 3d place in ΘΙΣΕΥC.

Among the ancients, the bow-string, called *τριχωνίς*, was made of horse's hair, and thence called *σπιννα*; though Homer's bow-strings are frequently made of hides cut into small thongs; whence *τοξὸν βοσίου*. The uppermost part of the bow, to which the string was fastened, was called *κορυμή*, being commonly made of gold, and the last thing towards finishing the bow.

The Grecian bows were frequently beautified with gold or silver; whence we have mention of *aureus arcus*; and Apollo is called *αργυροτοξος*. But the matter of which they were ordinarily composed, seems to have been wood; though they were anciently, Scythian like, made of horn, as appears from that of Pandarus in Homer (Iliad. β. v. 105. Potter Arch. Græc. tom. ii. cap. 4.)

Till the second punic war the Romans had no bowmen in their armies, but such as came with their auxiliary forces. (See Potter, ut supra.)

The bows of the Arabians, who attended Xerxes' expedition, were long, flexible, and crooked, (Herodotus Polymn. lxi.) The Bactrians also had their bows and arrows (Ibid. lxiv.); and among the Indians they are still retained.

In drawing the bow, the primitive Grecians did not pull back their hand towards their right ear, according to the fashion of modern ages, and of the ancient Persians (Procopius de bello Perico, l. 1.); but, placing their bows directly before them, returned their hand upon the right breast (Eustathius, Iliad. β. p. 344. &c.). This was likewise the custom of the Amazonian women, who are reported to have cut off their right breasts, lest they should prove an impediment in shooting.

The most barbarous nations often excel in the fabric of the particular things which they have the greatest necessity for, in the common offices of life. The Laplanders, who support themselves almost entirely by hunting, have long had an art of making bows, which we, in these improved parts of the world, have never arrived at.

Their bow is made of two pieces of tough and strong wood shaved down to the same size, and flatted on each side; the two flat sides of the pieces are brought closely and evenly together, and then joined by means of a glue made of the scales of perch, which they have in great plenty, and of which they make a glue superior in strength to any which we have.

The two pieces, when once united in this manner, will never separate, and the bow is of much more force to expel the arrow, than it could possibly have been under the same dimensions, if made of only one piece.

Having thus traced the early history of the bow, and evinced its general use, we now come to its history as principally confined to England. The bows in use have been of two kinds; the common or *long-bow*, and the *cross-bow*: but as the *Saxon bow* appears to have differed from them both, our readers may not be displeas'd to read the description of it separate. Its particular use among the Anglo-Saxons and the Danes has been already mentioned: their skill, however, does not appear to have been extended beyond the purposes of procuring food or pastime: and the representation of a Saxon bow, as given in an ancient MS. of

the tenth century, (MS. Cott. Claud. B. iv.) shews it was made very different from what one might expect in a military weapon: the string not being fastened to the extremities, but suffered to play at some distance from them. In size too it was a mere toy, compared with the *long-bow* of succeeding ages. (Strutt's Sports and Pastimes, p. 39.)

The history of the *long-bow* has been already detailed, under the head of *ARCHERY*. We have here little else to add, than that a variety of acts of parliament, passed in different reigns, tended much to the encouragement of those who used it. In 1482 (12 Ed. IV. c. ii.), four bow-blaves were ordered to be imported, with every ton of merchandize, from Venice; and by other acts, passed in the first of Richard III. the sixth of Henry VIII. and the thirteenth of Elizabeth, ten bows for every butt of malmsey. Malmsey or Tyre wine, at that time came chiefly from Crete, which then belonged to the Venetians; and the price of bows, it appears, had risen from 40s. to 8l. a hundred (Archæol. vol. vii.) In the 38th of Henry VIII. the price of a year-bow was reduced to three shillings and four pence. (Ibid.)

In the ages of chivalry its use was considered as an essential part of the education of a young man, who wished to make a figure in life: and even the ladies, as in later times, partook of the amusement. It is said of Margaret the daughter of Henry the VII. that when she was on her way to Scotland, a hunting party was made for her amusement in Alnwick park, where she killed a buck with an arrow. (Leland's Collect. vol. iv. p. 278.) And the use of the bow was more than once practised by queen Elizabeth. The ladies, however, might probably have used the *cross-bow*.

James I. issued one or two commissions for the prevention of enclosures in the grounds which had formerly been used for the practice of the bow: agreeably to which, the archers' grounds in the immediate neighbourhood of London were reduced to the same state they were in in the beginning of the reign of Henry VIII. (Strutt's Sports and Pastimes, p. 14.)

Among the ancient charters preserved in the British Museum (Rol. ix. 8.), is a petition of the bowyers, fletchers, arrow-head-makers, and string-makers, dated 1635, requesting the king to appoint Richard Adames and Jeffery le Neve to put in force the statute of the thirty-third of Henry VIII. It was referred by the king to the privy council; and a commission, the original of which, with the broad seal annexed, is in the same collection (xii. 68.), was afterwards directed to "Timothie Taylor, John Hobart, Henry Hobart, and Jeffery le Neve for the maintenance of artillery, archerie, and shooting in long-bowes, to enforce an act of the thirty-third of Henry VIII. that all persons under 60 years of age should use and exercise in shooting in long-bowes; and that men children, from 7 to 17 years of age, should be instructed in the same."

This, it seems, was one of the last acts by which public encouragement was given to archery. The great body of the people, from the improvements that had been made in military tactics, were not likely to support the commissioners in what was now proposed: and the troubles which were rising turned the attention of the legislature to more serious objects.

Ascham (Toxophilus. 1571. 4to.) says, it was necessary for the archer to have a *bracer*, or close sleeve, to lace upon the left arm, that the bow string, when loosed from the hand, might not be impeded: to this was to be added a *shooting glove*, for the protection of the fingers. The bow, he tells us, should be made with well-seasoned wood, and formed with great exactness, tapering from the middle towards each

cross-bow were by the name of Brazil, elm, ash, and holly, and that the cross-bow had the sanction from the pope of Avignon.

The composition of the bow in the East Indies were "bamboo, palm, and brass." The bow was a level mark, and required a long arrow with a wood feather. The cross-bow "was a small compass" that certain its distance; and the cross-bow was a "level mark, with a small ring-sized cross-bow, which was a "mark of uncertainty." And thus were they called in the different languages.

Part of the extremities of a bow, to which the string is attached, are called its horns, *cornua*. And the strength of a bow may be calculated on this principle, that its spring, i. e. the power whereby it restores itself to its natural position, is always proportionate to the distance or space it is removed therefrom.

The cross-bow, or *balista*, is an *arcu balista*, i. e. *arcu balista*, a bow with a fixed cord to a level bow, fastened upon a notch, and is discharged by means of a catch or trigger, which probably gave rise to the lock upon the modern musket. Lays, explaining the difference between testimony and argument, thus sums up: "Testimony is like the shot of a cross-bow, which owes its efficacy to the force of the shooter; argument is like the shot of a cross-bow, equally forcible whether discharged by a dwarf or a giant."

The invention of cross-bows is said by ancient writers to have come from the Sicilians. They made both great and small bows. The great ones, drawn on wheels, as our cannon-barrel, threw darts three cubits long; while those of the smaller kind were carried by foot-soldiers, the length of whose arms was scarce a cubit and an half. The larger ones were called *baliste*, of which, as Livy informs us, there were no less than three and thirty at the siege of Carthage, beside fifty-two of a smaller kind (see *BALISTA*); and Josephus mentions forty at the siege of Jerusalem. Vegetius says, that the balista discharged arrows with such rapidity and violence, that nothing could resist their force. And Athenæus tells us, that Agesistratus made one of little more than two feet in length, that shot darts almost five hundred paces. (Rollin's Art and Sciences, vol. ii. p. 52.)

*Cross-bows* were first used in England by the Normans, at the battle of Hastings; and a quarrel, or bar-bolt, from one of them, was the immediate cause of Harold's death. That they were afterwards adopted among our military weapons, is evident from the continual recurrence of *balistarius* in the Domesday Survey. In the reign of Stephen, 1139, the second council of Lateran prohibited their use; and some historians assert, that they were not again used in this country till the reign of Richard I., whose death, occasioned by one, was considered as a judgment on his impiety: but Fitzstephen, who wrote his History of London about 1180, in the reign of Henry II., says, the skaters of the metropolis moved faster than the *pilum baliste*; which seems to imply that both the cross-bow and its use were known. From the death of Richard I. till the splendid victories of Edward III. we hear little of the cross-bow as a military weapon. Its use appears to have been principally confined to the sieges of fortified places and to sea-fights.

In 1346, at the battle of Cressy, a large body of Genoese soldiers, who were particularly expert in the management of the cross-bow, were in the service of the French. At the commencement of the action, a sudden shower wetted the strings, and prevented the archers from doing their usual execution.

But in England, after the reign of Henry III., its use seems to have been studiously discouraged. The English

found the long bow a more effectual weapon; though the French, even in the reign of Henry V., after the English bow had so often proved superior in execution, to the great cool of their countrymen, were still attached to the cross-bow; and Henry V. as duke of Normandy, confirmed the charter and privileges of the *balistarii*, who had long been established as a fraternity at Rouen.

Their use, under our two last Henrys, has been already noticed as frequently forbidden; and by the statute of the 25th of Henry VIII. a penalty of ten pounds was inflicted on every one in whose house a cross-bow might be found. From this time they seem to have been chiefly used for killing deer (see Shakspeare's Henry VI.), till, in 1677, they were again used by the English as a military weapon, in the expedition to the Isle of Rhee. (Gent. Mag. vol. liv. p. 269.)

The cross-bow is of a most inconvenient form for carriage, even with the modern improvements; and in case of rain could not be easily secured from the weather. After the first shot, moreover, it could not be re-charged under a considerable time, whilst the bolts are also heavy and cumbersome. The English long-bow, on the other hand, together with the quiver of arrows, was easily carried by the archer, as easily secured from rain, and re-charged almost instantaneously. It is not therefore extraordinary, that troops, who solely used this most effectual weapon, should generally obtain the victory, even when opposed to much more numerous armies. (Barrington's Obl. on Archery, Archæol. vol. viii.) The reach of the cross-bow was confined; that of the long bow more extensive: although when the armies were opposed at no considerable distance, the quarrels of the former might possibly be poured in with the most regular effect.

**Bow, or STRATFORD-LE-BOW**, in *Geography*, is a village of Middlesex, in England, seated on the river Lea, at the distance of about two miles east from London. The village has no particular claims to public notice, but from its ancient bridge, which crosses the river Lea at this place. This structure is said to have been the first *arched* bridge erected in England. Stowe, Iceland, and some other antiquaries, concur in ascribing its first building to Maud, or Matilda, the queen of Henry I.; and thence some writers coincide in the current tradition of its being the most ancient *arched stone bridge* of this country. The faithful Stowe relates, that Matilda had been "washed in the water, in passing this dangerous forde;" and to provide against such accidents in future, caused this, and another smaller bridge to be erected, "arched like a bow," which, he farther observes, "was a rare piece of worke; for before that time the life had never been *seen in England*." An old bridge of three arches still occupies the place of the original structure. Through this place, and over this ford, passed the ancient Roman road, called Watling-street, from Londinium (London) to Camelodunum (Colchester). From this arched bridge, and the name *Street-ford*, this place evidently derives its name.

At a short distance northward, are the *Temple-Mills*, which anciently belonged to the knights-Templars, and afterwards to the knights of St. John of Jerusalem. In the year 1720, they were used for brass works, but are now appropriated to the manufacture of sheet lead. (Lyson's Environs of London, vol. iii. p. 480.)

**Bow**, a small market town of Devonshire, in England, seated on the banks of one of the branches of the river Taw. Deprived of the advantages of manufacture, and situated at a distance from the great turnpike road, this place is fast sinking into decay, and at present consists of only 162 houses, most of which

which are occupied by the peasantry. Yet here is a small show of a market on Thursday, and it has two annual fairs. A few blacksmiths, carpenters, and shoe-makers, are the principal tradesmen of the place. It is 188 miles W. of London; the parish contains 677 inhabitants.

Bow, an island in Lough Erne, county of Fermanagh, Ireland, on the northern part of the lake, and one of the largest in it, being three miles long, and one and a half broad. It is well-wooded, and contributes much to the beauty of the lake. It is about 15 miles from Enniskillen.

Bow, an island in the South Pacific Ocean, about 10 leagues in circumference. S. lat.  $18^{\circ} 23'$ . W. long.  $141^{\circ}$ .

Bow, a township of America, in Rockingham county, New Hampshire, seated on the west bank of Merrimack river, south of Concord, and 53 miles from Portsmouth; containing 568 inhabitants.

Bow, in *Music*, denotes a machine that serves to play, or give the sound to, viols, violins, and other instruments of that kind, by drawing it gently over the strings thereof.

The bow consists of three parts; the first is the stick, or wood, to which the hair is fastened; the second is composed of about eighty or an hundred horse-hairs, or filaments of silk; the third is the nut, a sort of half-wheel, which serves to keep the hairs in the due degree of tension.

The ancients do not appear to have been acquainted with bows of hair: in lieu of these they struck their instruments with a plectrum; over which our bows have great advantage, for giving long and short sounds, and other modifications, which a plectrum cannot produce.

Bow, in *Trade and Manufactures*, denotes a flexible instrument consisting of a piece of steel or iron, to the two ends of which is fastened a cat-gut, used by smiths, watch-makers, and other artificers, for the piercing and turning of divers sorts of works.

This is more peculiarly called a drill-bow.

It is sometimes also made of wood, whalebone, and the like.

Operators in Mosaic have a sort of bow made of a piece of elastic wood, with a brass wire fastened to the ends of it, which serves to saw hard and precious stones. Letter-casters have also a bow wherewith to keep the matrix even. See *FOUNDERY*.

Bow, among *Builders*, denotes a beam of wood, or brass, with three long screws, that govern or direct a lath of wood or steel to any arch; chiefly used in drawing draughts of ships, and projections of the sphere, or wherever it is requisite to draw large arches.

Bow, in *Navigation*, an instrument formerly used for observing the altitude of the sun, in order to determine the latitude of the ship.

This instrument consists of the five following parts; viz. first, an arch, or portion of a circle, capable of containing upwards of ninety degrees, whence the name of the instrument; second, a straight rod or bar, equal in length to the radius of that circle of which the arch is a portion; and three vanes, called the *sight*, *shade*, and *horizon* vanes.

The arch of the bow is divided into 90 degrees, and numbered from the top downwards; and these degrees are subdivided into halves, quarters, or tenths, &c. according as the size of the instrument will admit; but the common method is to divide the degree into three equal parts, and by means of concentric arches and diagonal lines, the subdivisions may be carried as low as two minutes.

One end of the radius or straight bar is put into a perforation in the arch at 45 degrees; and the horizon vane,

having a narrow slit in it, through which the horizon is to be seen at the time of observation, is to be put upon the other end of the radius. The shade vane, which is sometimes fitted up with a convex lens, is placed on the arch above 45 degrees; and the sight vane, having a small perforation, through which, and the slit in the horizon vane, the sight is to be directed to the horizon, is put on the arch below 45 degrees. These two vanes are moveable upon the arch. The manner of using this instrument is as follows:

1. *To observe the meridian altitude of the sun with the bow.*

With the latitude of the ship by account, and the sun's declination, find the estimate meridian altitude, which will be equal to the sum, or difference, of the complement of the latitude of the ship by account, and the declination of the sun, according as they are of the same, or of a contrary denomination. Then place the shade vane to any whole degree, as much above 45 degrees as amounts to nearly half the estimated meridian altitude, and the sight vane is to be placed as much below 45 degrees. Now let the observer look to the opposite point of the horizon with respect to the sun, and hold the bow vertically, and in such a manner that the horizon may be seen through the slit in the horizon vane, the eye being placed at the sight vane; then, if the bright solar spot, from the lens in the shade vane, is upon the slit in the horizon vane, the sight vane is in its proper place; if not, the sight vane is to be raised or depressed accordingly: continue observing in this manner, until the sun has attained its greatest altitude; and the degrees, and parts of a degree intercepted between the fiducial edges of the two vanes, will be the sun's meridian altitude; and hence the true latitude of the ship may be found as usual.

When the sun begins to fall, that is, when the altitude diminishes, or the sun is past the meridian, the solar spot will appear above the slit in the horizon vane, that slit and the horizon being in one.

2. *To observe the altitude of the sun, when off the meridian, by the bow.*

Let the altitude of the sun, at the time of the observation, be estimated; then place the shade vane to any whole degree, as much above 45 degrees as is about half the altitude by estimation; and move the sight vane upwards or downwards, until the solar spot is upon the slit in the horizon vane, at the same time that the horizon is seen through the vane; and the intercepted degrees and parts of a degree upon the arch, between the sight and shade vanes, will be the altitude of the sun.

Bow, in *Ship-building*, that circular part of a ship in which the stem is in the middle, and its extremes near the foremost part of the fore-chains. A proper form of a bow is of the utmost consequence. A vessel with a sharp bow will, *ceteris paribus*, sail faster in smooth water than one with a full bow; but in a high sea, she will plunge and dive greatly more, and thereby diminish her rate of sailing. A proper medium between these two extremes, consistent with the form of the ship, is, therefore, to be employed. M. Bouguer has paid very particular attention to this subject; and he has given a set of tables, deduced from algebraic formulæ, for the construction of bows that will meet with the least resistance, and that will have the greatest velocity, or of such as will render a ship more capable of carrying sail, and at the same time will divide the fluid with the greater facility; also, of the greater motion which, he says, differs in some cases from that of the greatest velocity. M. Bouguer observes, that it is very doubtful whether that figure, which meets with the least resistance in dividing the water, may be the most advantageous to acquire the greatest degree of velocity; for it is

possible that a bow which meets with a little more resistance may render the ship capable of carrying a proportionable quantity of more sail, although the two bows, which may be distinguished by naming the one that of the least resistance, and the other that of the greatest velocity, should have such an affinity to one another, that one should, in a great measure, partake of the most essential properties of the other. M. Bouguer also observes, that a bow which meets with the least resistance in a direct course, not only meets with the least resistance in oblique courses, but the vessel has also the additional property of driving the least to leeward; which is a double advantage gained, by forming the bow so as to give it that figure which will be the least opposed in moving through any medium.

*Bow, Bold*, a full high bow.

*Bow, Lean*, a sharp bow, having little bearing or support, so that, in a rough sea, a vessel with a bow of this kind is apt to pitch greatly, which retards her rate, and also to ship much water.

*Bow, Starboard*, that part upon the right-hand side of the stem, to a person on deck looking forward; and that part upon the left-hand side is called the *larboard bow*.

*Bow, Weather*, is that part of the bow towards the wind when a ship is close-hauled; and the other part is called the *lee bow*.

*Bow, On the*, an expression used to denote the position of any object, as a ship, the land, &c. appearing in the direction of some particular part of the bow. If the ship is sailing directly towards the object, it is said to be *right a-head*; if not, the object is said to be on the *starboard*, or on the *larboard bow*; or it is said to be on the *weather*, or on the *lee bow*. If the object is in the direction of any particular part of the vessel, with respect to the observer, as the cat-head, &c. it is then said to be right over the cat-head.

The position of an object, with respect to the course of the ship, may be eliminated by the intercepted portion of the horizon between them; and in this case it may be expressed either in points of the compass, or in degrees, but the former is most commonly used. Hence, if from a ship running N. by W. with her starboard tacks aboard, a light or sail was observed to bear N.W. by N. it would be said to bear two points upon the lee bow.

When the angle, contained between the object and the ship's course, is greater than four points, it is usual to express the bearing from the beam; thus, in place of saying that an object bears six points on the larboard bow, it is expressed to bear two points before the beam.

*Bow-bearer*, an under officer of the fore-st, who is to observe and take notice of all manner of trespass against vert or venison; and to attach, or cause to be attached, the offenders in the next court of attachment.

*Bow-compass*. See COMPASS.

*Bow-dye*, a new kind of scarlet-red, superior to madder, but inferior to the true scarlet-grain, for fixedness and duration. It was brought into England, and first practised at the village of Bow, near London, by Kephler, a Fleming, in the year 1643; whence its name.

In the year 1667, another Fleming, named Brewer, invited to England by Charles II. with the promise of a large salary, brought this art to great perfection. These accounts, however, and the names of the persons, are extremely dubious. Anderson's Commerce, vol. ii. p. 77. Beckmann's Hist. Invent. vol. ii. p. 206.

*Bow-legged*, in Surgery. See BANDY-legs.

*Bow-net*, or *wheel*, an engine for catching fish, chiefly lobsters and craw-fish, made of two round wicker-baskets,

pointed at the end, one of which is thrust into the other; at the mouth is a little rim, four or five inches broad, somewhat bent inwards. It is also used for catching sparrows.

*Bow, rain*. See RAIN-bow.

*Bows of a saddle*, are two pieces of wood laid archwise, to receive the upper part of a horse's back, to give the saddle its due form, and to keep it tight.

The fore-bow, which sustains the pommel, is composed of the withers, the breasts, the points, or toes, and the corking.

The hind-bow bears the trousséquin, or quilted roll.

The bows are covered with sinews, that is, with bulls pizles beaten and so run all over the bows, to make them stronger. They are likewise strengthened with bands of iron, to keep them tight. It is on the lower side of the bows that the saddle-straps are nailed; the use of which is to make fast the girths.

*Bow-piece*, a gun, or piece of ordnance placed in the bow.

*Bow-grace*, or *Bow-grafe*, a frame or composition of old ropes, or junks of cables, used to be laid out at the bows, stems, and sides of ships, to preserve them from bodies or fields of ice, when, in high latitudes where these are expected.

*Bow-slaves*. See GARBLING of bow-slaves.

*Bow-saw*. See SAW.

BOWDOIN, in Geography, a township of America, in Lincoln county, and district of Maine, on the north-eastern bank of Androscoggin river: distant from York, north-easterly, 36 miles, and from the mouth of Kennebeck river 6 miles, and 166 N.E. from Boston. It contains 983 inhabitants.

BOWDOINHAM, a township of Lincoln county, and district of Maine, separated from Pownalborough east, and Woolwich south-east, by Kennebeck river. It lies 171 miles N.E. from Boston, and contains 455 inhabitants.

BOWED, in Botany, (*arcuatus*), bent like a bow; a term expressing the direction of filaments, and the figure of a legume. It is employed also by Gærtner, to denote that figure of the cotyledons which is found in some of the leguminosæ and siliquosæ, in cænella, myrtus, cyllus, scorpiurus, &c. and that figure of the embryo which occurs in allium, morea, asparagus, &c.

BOWEL-GALLED, in Farriery, denotes a laceration occasioned by the tightness and heat, or friction, of the girths, just behind the elbows of the fore-legs, and is soon hardened and obliterated by two or three applications of a soft sponge, impregnated with common vinegar.

BOWELLING, *exenteratio*, the act of pulling out the entrails of an animal. Bowelling makes part of the progress of embalming.

BOWELLING is also a part of the punishment of traitors in England, who are to have their bowels ripped open, torn forth, and burnt before them. *Fractioni, suspendio, decollationi, exenterationi, & quaterizationi adjudicavit.* Knight sub. Edw. II. in the sentence of Hugh Spencer.

BOWER, ARCHIBALD, in Biography, a native of Scotland, was born at or near Dundee in 1686, educated in the Scots college at Douay, and admitted, in 1706, into the society of Jesuits at Rome. After some varieties of situation and employment, during the succeeding interval, he at length, viz. in 1723, settled at Macerata, where, according to his own account, he performed the office of counsellor to the Inquisition: conceiving disgust, as he states the fact, at the enormities committed by this tribunal, or, as his enemies

assert, charged with incontinence, he removed, in 1726, to Perugia, and secretly made his escape to England. Of the circumstances attending his escape he has given a very ample account; but his written documents and oral testimony have been found to differ in several particulars from each other, and of course his integrity was not only suspected but reproached. Soon after his arrival, he was introduced by Dr. Aspinwall to Dr. Clarke and to bishop Berkeley, from intercourse with whom, added to his own reading and reasoning, he obtained, as he says, the fullest conviction that many of the favourite doctrines of the church of Rome were not only repugnant to scripture and reason, but wicked, blasphemous, and utterly inconsistent with the attributes of the deity. Under the impression of these sentiments he withdrew himself from the Romish communion, and abandoned the order with which he had been connected. His mind seems at this time, according to his own account, to have been in a state of scepticism and indecision on the subject of religion; and though he continued a Protestant for about six years, he connected himself with no particular denomination of Protestant Christians. At length, however, he conformed to the church of England, alleging that this church was "as free in her service as any reformed church from the idolatrous practices and superstitions of popery, and less inclined than many others to fanaticism and enthusiasm." By the recommendation of Dr. Goodman, physician to king George I., he obtained patronage in the family of lord Aylmer, and was entrusted with the education of two of his lordship's children. By lord Aylmer, he was introduced to lord Lyttleton, who considered him as a kind of religious confessor, and remained his active friend and zealous advocate, even when he was deserted by almost every other person of any distinguished reputation. Whilst he lived with lord Aylmer, he formed a connection with the bookfellers, and was employed, first, in a monthly publication, entitled "*Historia Literaria*," and afterwards in the compilation of the "*Universal History*." The part of this work which he undertook was the Roman history; but in the execution of it he is charged by his coadjutor, George Pfalmanaazas, with having unduly extended it in some parts, and in others, particularly in the Byzantine history, with having injuriously abridged it. By the emolument accruing from his tuition and writings, he accumulated a considerable sum of money, the disposal of which led to discoveries which very materially injured his character, and subjected him to just reproach. According to his own statement, he proposed to purchase a life annuity with this money, amounting to 1100*l.* of old South-Sea annuities; but being disappointed in these views, he negotiated with Mr. Hill, a Jesuit, respecting the loan of it; and obtained from him an interest equal to that which he might have made of it by the purchase of the annuity in which he was disappointed. A very different account of this transaction has been given by those persons who have questioned his integrity; and it must be acknowledged, that it is accompanied with such kind of evidence, as leaves little room for hesitation in admitting the credibility of it. They allege, that being desirous of re-admission into the church, which he had abandoned, he made use of his money in a way which would serve to recommend him to the superiors of the society with which he wished to be re-united. Accordingly, he proposed to father Shirburn, then provincial in England, to deliver up to him, as representative of the society, his whole stock, on condition of their granting him a life-annuity, of 7 per cent. The offer was accepted; and Bower paid at sundry times sums of money, amounting in the whole to 1350*l.* and stipulated by a bond to receive yearly 94*l.* 10*s.* In consequence of this negotiation, Bower was re-admitted,

in a formal manner, into the order of Jesuits, at London, about the end of the year 1744, or beginning of the year 1745. Afterwards he determined, for reasons not satisfactorily ascertained, to separate from the order of Jesuits; and upon leaving them he obtained a return of his money. When a second edition of the "*Universal History*" was in contemplation, the bookfellers, very unfortunately for themselves and for the credit of the work, engaged Bower to revise and correct it; but though he received a considerable sum of money, not less than 300*l.* he published it without any material emendation. In 1747 he announced to the public proposals for a "*History of the Popes*;" the first volume of which was presented to the king in the following year. In recompence of his labour, Mr. (afterwards lord) Lyttleton, obtained for him the place of keeper of queen Caroline's library; and his credit being somewhat revived, he married a niece of bishop Nicholson, with a fortune of 4000*l.* His "*History of the Popes*" was continued, in successive volumes, printed at different periods. In 1754 his unalterable friend, Mr. Lyttleton, appointed him clerk of the buck-warrants, a place which, though of no great emolument, evinced his continued attachment. In this year the first attack was made on his "*History*," which the advocates of popery considered as peculiarly hostile to their church, in a pamphlet printed at Doway, entitled "*Remarks on the two first volumes of the late lives of the popes*," 8vo.; a publication ascribed by Mr. Bower to a popish priest of the name of Butler, one of the most active and dangerous emissaries of Rome in this kingdom. But an event soon happened, which was much more ruinous to the reputation of Mr. Bower, and which sunk him into total disgrace; and this was the divulging of his correspondence with the Jesuits. The charges alleged against him were repelled with spirit by himself; but his veracity, though attested by an affidavit, was questioned; and he had scarcely any friend left besides lord Lyttleton. In the course of this controversy, he was in danger of being exhibited on the stage, as a mock convert of profligate character, by Mr. Garrick, on account of the manner in which he mentioned that incomparable actor and his lady, in his "*Summary of the controversy between the papists and the author*," 4to. But Mr. Garrick, by the mediation of lord Lyttleton, was induced to waive that public chastisement which he had intended. The reputation of Bower's history declined with his own; the fourth volume was published during the agitation which the controversy in which he was engaged had produced; the fifth appeared in 1761; and the sixth and seventh volumes were presented to the public a little time before his death; and whatever may be the estimation in which the preceding volumes deserve to be held, these two are executed with such haste as to deserve very little regard. The whole period from 1600 to 1758 is comprehended in 26 pages! Bower died in 1766, at the age of 80; and he left a will, dated in 1749, which contained no written declaration of his religious principles, agreeably to the practice which very much prevailed in those times, and which, in his peculiar circumstances, might have been reasonably expected. His widow, however, sometime after his death, attested his having died in the Protestant faith. *New Biogr. Dict.* 8vo. 1798.

BOWER, *Lady's*, or *Virgin's*, in *Botany*. See CLEMATIS.

BOWER, in *Gardening*, a shady place, under covert of trees or branches interwoven. A bower differs from an arbour, in that the latter is always built long and arched, but a bower either round or square at the bottom, and made with a sort of dome or ceiling at the top. See ARBOURS.

BOWER-anchors, *best and small*, in *Sea-Language*. See ANCHOR.

**BOWES**, in *Geography*, a town of Yorkshire, England, is more noted for its former than present consequence. During the abode of the Romans in Britain, this place was chosen for one of their military stations; and from an inscribed altar found here, it appears, that, in the reign of Severus, when Varius Lupus was legate and proprator of Britain, the first cohort of the Thracians was in garrison here. Hoisley, in his *Britannia Romana*, says, "there is an old castle here, which, with the church, stand in the north part of the old Roman station, and no doubt have been built out of the ruins of it." About two furlongs south of this station (called Lavatris) runs the river Greta.

Bowes is included in that division of the county of York, called Richmondshire, in the north riding, at the distance of 4 miles from Barnard castle, and 248 miles north from London. The town consists of one long street, running east and west, and contains 120 houses and 670 inhabitants. Here is a weekly market on Fridays, and one fair annually. This parish includes the three townships of Bowes, Boldron, and Gilmonby. The surrounding country, consisting mostly of moors and commons, abounds with coal and lead mines, which, with the royalty, belong to the proprietor of Carlton-hall.

About two miles from Bowes, is a singular natural curiosity, called *God's bridge*, which is formed by a rude arch of freestone. This stretches across the river Greta, the waters of which are precipitated over different ledges of rocks, and soon afterwards sink beneath the surface, and continue through a subterraneous passage of about half a mile, when they again emerge into light through some rocky cavities. Gough's edition of Camden's *Britannia*. Hutchinson's *Tour to the Lakes*, 8vo.

**BOWET**, or **BOWESS**, among *Falconers*, denotes a young hawk when she draws things out of her nest, and covets to clamber on the houghs.

**BOWGE** of *court*. See *BOUCHE* of *court*.

**BOWL**, denotes either a ball of wood for the use of bowling, or a vessel of capacity for holding liquors.

**BOWL-wassel**. See *WASSEL-bowl*.

**BOWLDER-stones**, a species of small stones, of an indeterminate texture and figure, generally roundish, found on the shores of the sea and banks of rivers. Bowlders, or bowlder-stones, are only lumps and fragments of stones or marble, broken from the adjacent cliffs, and rounded by being bowled and tumbling to and again by the action of the water; whence the name bowlder-stones, as being formed by an action like that of a bowl, and thereby reduced to the shape of one. Neither the bowlders nor rubble-stones are ever invested with an exterior strong crust or skin: it is plain from the manner of their formation they cannot. This is one mark by which they are distinguished from flints, pebbles, or the other native nodules, which were formed before the subsiding of the matter of the strata, and are always covered with such a crust or skin, unless it has been worn off.

**BOWLE, JOHN**, in *Biography*, rector of Idminstone near Salisbury, was a descendant of Dr. John Bowle, bishop of Rochester in the 17th century, born in 1725, and being admitted of Oriel college, in the university of Oxford, took the degree of master of arts in 1750. He had the honour of being, according to Dr. Douglas's account, the original detector of Lauder's forgeries, for the purpose of injuring the reputation of Milton. He was the author of a "Letter to Dr. Percy," and editor of *Don Quixote* in Spanish, and of *Marston's Satires*, and some old poetry in English. He died in 1788. *New Biog. Dict.*

**BOWLESIA**, in *Botany* (named after Bowles, author of *Travels in Spain*). *Flora of Fern.* pl. 34. *Bosc* in *Nouveau*

*Dictionnaire d'Histoire Naturelle*. Class, *pentandria digynia*. Nat. Ord. *umbellifera*.

Gen. Char. *Umbel* of three flowers. *Invol.* none. *Fruit* tetragonal. *Seeds* two, externally concave.

**BOWLINE**, in *Sea-language*, a rope fastened near the middle of the leech, or perpendicular edge of the principal square sails, by three or four subordinate parts called *bridles*, and leading forward towards the bow, and hence its name. It is always used when the wind is so unfavourable that the sails must be all braced sideways, or *close-baul*ed to the wind: in this situation, the bowlines are employed to keep the weather or windward edges of the principal sails tight forward and steady, without which they would be always shivering, and rendered incapable of service. Neither the sprit-sail, nor sprit-sail top-sail has bowlines, as there is no place forward to which they could lead, and therefore these sails cannot be used when the vessel is upon a wind. The bowlines of the fore-sail, fore-top-sail, and fore-top-gallant-sail, lead to the bowsprit. Those of the main-sail, main-top-sail, and main-top-gallant-sail lead to the foremast; and the mizen-top-sail, and top-gallant bowlines lead to the main-mast.

To *check* or *ease* the bowline, is to slacken it, when the wind becomes large, or more aft; and when the wind comes more a-head, or the ship lies nearer to it, so that any particular sail is shivering, or nearly so, it then becomes necessary to get the weather-leech of that sail more forward, that the sail may stand, or be kept full; and the order for this purpose is to *haul taught*, or *take a pull* of the weather bowline belonging to that sail.

**BOWLINE-bridles**, the ropes by which the bowline is fastened to the leech of the sail.

**BOWLINE-knot**, a particular kind of knot which will not slip, by which the bowline bridle is fastened to the cringle. See *KNOT*.

**BOWLING**, the act or art of throwing bowls. Bowling, among us, is chiefly the name of a game or exercise, practised either in open places, as bays and bowling-greens, or in close bowling-alleys. The skill of bowling depends much on a knowledge of the ground, and the right choice of a bowl suitable to it: for close alleys the flat bowl; for green swards plain and level, the bowl as round as a ball is preferred.

The terms used in bowling, are, to *bowl wide*, which is when the bias does not hold, or is not strong enough; *narrow*, when it is too strong, or holds too much; *finely bowled*, is when the ground is well chosen, and the bowl passes near the block, even though it goes much beyond it; *bowling through*, or a *yard over*, is done in order to move the block; an *over-bowl*, that which goes beyond it; a *bowl laid at hand*, is that put down within the gamster's reach, to be in the way of the next bowler, and hinder his having the advantage of the best ground; *bowling at length*, neither bowling through nor short; a *dead length*, a just or exact one; *throwing* or *flinging*, is discharging a bowl with a strength purposely too great for a length, in order to carry off either the block or some near bowl; *bowl-room*, or *missing-wood*, is when a bowl has free passage, without striking on any other; *get off*, is when a bowl being narrow, is wanted to be wider; *bowl best at block*, that nearest the block; *drawing a cast* or *bowl*, is to win it by bowling nearer, without stirring either the bowl or block; a bowl is said to *rub*, when it meets with some obstacle in the ground which retards its motion, and weakens its force; *it is gone*, when far beyond the block. *Block* signifies a little bowl laid for a mark, also called a *jack*. *Mark*, is a proper bowling distance, not under so many yards; and being at least a yard and a half from the edge of the green. *Ground*, a bag or hand-

handkerchief laid down to mark where a bowl is to go. *Lead*, the advantage of throwing the block, and bowling first. *Cast*, is one best bowl at an end. *End*, a hit, or when all the bowls are out. The *game*, or *up*, is five casts, or best bowls.

**BOWLING-GREEN**, in *ornamental Gardening*, is a spacious plat laid evenly with turf in pleasure or other grounds, designed for the purpose of ornament, as well as amusement, in the summer season, in bowling upon.

These sorts of compartments should mostly be formed as near the houses or habitations as possible, being laid out on the back fronts so as to serve by way of lawns to such parts as they may be situated in; as at the termination of walks or avenues. They may also be contrived amidst detached contiguous plantations, or wilderness quarters, to serve as portions of sward ground, or as openings to such places, and should always, if possible, have tall trees so situated on the boundaries, as to afford shade, especially in the afternoon. The dimensions must vary according to circumstances; but where there is scope of ground sufficient, they should not be less than from half an acre to an acre. The most common form is that of a square moderately extended; but some are made oblong, others circular, though, to suit the general plan or figure of the ground, they may be of any other form, so as to avoid the garden-ground. Their boundaries may also be spacious planted borders of either the straight or serpentine kind. The plane or surface of the greens should be perfectly level, and as high, at least, as the general level of the adjoining ground, so as that it may be always preserved from stagnant moisture.

In forming these plats, the surface should be levelled in the most exact manner, and laid with the finest grass turf that can be procured from a close pasture, common, or down. See **TURF**. The extent and proper levels of the greens are then set out with stakes placed round the extremities or boundaries, at fifteen or twenty feet distance, on which should be marked the determinate levels of the ground, and from which, on the opposite sides, levels in other crossways at the same distance should be made; and then, according to these levels, proceed by line and spade to form the ground to a proper surface, making it up firmly in lines from stake to stake; the panels or spaces between being made up equally firm and regular, so that no part may sink in a hollow afterwards. The whole should then be raked level, and finished off evenly and smooth. Two or three inches deep of light sandy soil, or any light dry poor earth may then, if necessary, be laid evenly over the surface, as equal in quantity as possible, as by that means the turf or grass will form a most fine, regular, and even sward.

The grassy surfaces should always be formed by laying them with fresh cut turf, as being much superior to the method of only sowing them with grass seeds. The turfs should be cut each a foot wide, a yard long, and about an inch thick, and laid with exactness, closely joining them edge to edge, then beating them well down with large wooden beaters, repeatedly rolling them with a large heavy iron roller.

The best season for performing work of this sort is the autumn, or very early in the spring; but the first is to be preferred when it can be conveniently done, as the turf has time to establish itself well before the hot season sets in.

In order to keep bowling-greens neat after being thus formed, they require frequent mowing in summer, probably once or twice a week, or oftener, in order to keep the grass sufficiently fine and short for bowling, as well as occasional rolling to preserve the surface firm and even. When wormy casts are much thrown up over their surfaces, they

should be poled occasionally to break and scatter them, and then well rolled with a wooden roller, to which the scattered earthy particles may adhere, and the surface be thereby made more clean. See **POLING GRASS**. Where coarse weeds, as the dock, dandelion, &c. present themselves, they should be wholly eradicated, to prevent their seeds from being dispersed over the surface, and new plants thereby raised which would prove injurious, and render the turf unfit for the purpose of bowling upon.

**BOWLING-GREEN**, in *Geography*, a village of Virginia in America, situated on the post-road, 22 miles S. of Fredericksburg, 48 N. of Richmond, and 25 N. of Hanover court-house.

**BOWNESS**, in *Geography*. See **BORROSTOWNNESS**.

**BOWSE**, in *Sea-language*, an order to all the people employed in hauling upon any particular rope, to pull together. *Bowse away*, that is *pull away*, and all at the same instant.

**BOWSPRIT**, a large boom or sprit projecting from the bow of a ship, over the stem, and hence its name. The bowsprit makes an angle with the keel, which is various, according to the fancy of the builder; being, in general, between twenty degrees, and three points or upwards, as the height of the bowsprit at the cope, above a horizontal line at the keel, extends from one third to one half of its length. According to Mr. Chapman, the elevation of the bowsprit of a merchant ship ought to be three-sevenths of its length, and in ships of war four-sevenths. This elevation of the bowsprit is called its *steering* or *living*. Mr. Gower is a strong advocate for diminishing the steering of bowsprits, and upon this subject he expresses himself as follows: "As every position of the rudder, except a middle one, takes from the speed of the vessel, it should be preserved as much amidships as possible. Almost every ship under full sail, with a side wind, carries a weather-helm; to counteract which, it is recommended to lower the steering of the bowsprit to one angle of five or ten degrees with the keel, and to increase the jib-boom in stoutness, that a large jib of strong canvas may be carried in most weathers. With the bowsprit lowered, it will be better without a spritsail yard; and let the jib boom be secured from the cat-heads and stem, by a standing and travelling guy on each side, and a standing and travelling martingale." In cutters, schooners, luggers and shallops, the bowsprit is nearly parallel to the keel.

The length of that part of the bowsprit which is without the stem, is generally equal to the extreme breadth of the ship. In trading ships, the celebrated Mr. Chapman makes the length of the bowsprit to be equal to the sum of the extreme breadth, and one-tenth of it; and in ships of war, it is equal to the sum of the extreme breadth, and three-twentieths of the same. Thus, if the extreme breadth of a ship is 32 feet, the length of that part of the bowsprit beyond the stem will be 35.2 for a merchant ship, and 36.8 for a ship of war.

The diameter of the bowsprit is equal to half the sum of the diameters of the main and fore-masts.

As the safety of the fore-mast depends greatly upon the bowsprit, every precaution, therefore, is used to have this last well secured. The keel is firmly fastened to the decks; that part of the bowsprit at the stem is strongly fastened thereto by several turns of a rope, which is called the *gammeling of the bowsprit*; and the hoblay connects the lower part of the stem or cutwater with that part of the bowsprit at the forestay.

**BOWYER**, WILLIAM, in *Biography*, an eminently learned printer, the son of a printer of the same name, was born in London, December 17th 1699; received his grammatical education under Mr. Ambrose Bonwicke, a non-juring clergyman

clergyman of acknowledged piety and learning; and was admitted, in 1716, as a sizar at St. John's college, in the university of Cambridge, where he continued for six years, and probably took his degree of bachelor of arts. Although his disposition was naturally reserved, yet he cultivated, during his residence at college, an intimate acquaintance with several respectable members of the university, and particularly with Mr. Markland and Mr. Clarke, with whom he maintained through life a regular correspondence, which furnishes a valuable treasure of polite literature and sound criticism. When he left Cambridge, he officiated as a school-master for the benefit of the family of Mr. Bonwicke, who died in 1722; and thus testified his gratitude for the assistance he had received from him in his education, at a time when the whole property of his father was destroyed by a fire. Having performed this act of kindness and of gratitude, he joined his father in the printing business; and began with a correct and complete edition of Selden's works by Dr. David Wilkins, in 3 vols. fol. As he read the proof sheets, he drew up an epitome of the treatise "De Synedris." This work was followed by an admirable sketch of William Baxter's Glossary of the Roman Antiquities; in which Bowyer sufficiently evinced his literary talents. In 1729, he was appointed printer of the votes to the house of Commons, which office he held for nearly 50 years. It is hardly necessary to mention the part taken by him, in 1731, in a controversy which is now sunk into oblivion. It produced, however, on his part, a pamphlet entitled "The traditions of the clergy not destructive of religion; being remarks on Mr. Barmau's sermon, exposing that gentleman's deficiency in Latin and Greek, in ecclesiastical history and true reasoning." In the same year he printed, and is supposed to have translated, Voltaire's Life of Charles XII. of Sweden. In 1736, he was admitted a fellow of the Society of Antiquaries, of which he was an assiduous and useful member. His translation of "Trapp's Latin lectures on poetry," with additional notes, was published in 1742; and about the same time he corrected and formed anew an useful school-book, entitled "Selectæ ex profanis scriptoribus historię." We should far exceed the bounds of this article, if we were to mention the prefaces, notes, and various additions, which he contributed to the works that issued from his press. We shall content ourselves with noticing some of the principal of this kind. In 1744, he wrote, as it is supposed, a small pamphlet on the present state of Europe, chiefly taken from Puffendorf; and, in 1746, he published the "Life of the emperor Julian," translated from the French of M. Bletterie, with curious notes, and a genealogical table. In 1750, he annexed a prefatory critical dissertation, and some valuable notes, to Kuster's treatise, "De vero usu verborum mediorum," which was published, with further improvements, in 1773. About the same time he wrote a Latin preface to Leedes's "Veteres poetæ citati, &c." and soon after improved an edition of col. Bladen's translation of Cæsar's commentaries. In 1751, he wrote a long preface to Montesquieu's "Reflections on the rise and fall of the Roman empire;" translated the dialogue between Sylla and Socrates, and improved the edition by several corrections from the baron's "Spirit of Laws," as well as by his own notes. Of this work a new edition, with additional notes, was printed in 1759. In the same year (1751) he published the first translation that was made of Rousseau's paradoxical oration, which gained the prize of the academy at Dijon, in 1750; and thus he first announced that singular genius to the attention and admiration of Europe. To Mr. Bowyer we are indebted for the notes signed (B) in the 9th 4to. volume of Swift's works, extracted from letters, which

were printed but never published. His "Remarks on the speech made in common council, on the bill for permitting persons professing the Jewish religion to be naturalized, so far as prophecies are supposed to be affected by it," was intended for the purpose of allaying the ferment occasioned by the Jew-bill in 1753, and of shewing, that whatever political reasons might be alleged against the bill, Christianity would in no degree be prejudiced by the indulgence proposed to be granted to the Jews. In this year also appeared his notes, annexed to bishop Clayton's translation of "A journal from Grand Cairo to mount Sinai, and back again." In 1761, Mr. Bowyer was appointed printer to the Royal Society; and he had the honour of retaining that office till his death. Without mentioning other publications, in which he was concerned either as a writer or as an editor, we shall proceed to notice an excellent edition of the Greek Testament, in 2 vols. 12mo., which appeared in 1763, under the following title; "Novum Testamentum Græcum, ad fidem Græcorum solum codicum MSS. nunc primum impressum, adhibente J. J. Wettienio, juxta sectiones Jo. Alberti Bengelii divisum; et nova interpretatione sæpius illustratum. Accessere in altero volumine emendationes conjecturales virorum doctorum undique collectæ." This edition was sold with great rapidity; and the conjectural emendations were well received by the learned. These were separately published, with very considerable enlargements, in one volume, 8vo., in 1772. A new and correct edition of this Greek Testament, with the conjectures, in 4to. much enlarged from the margin of Mr. Markland's Testament, and by new communications from bishop Barrington, professor Michaelis, M. Stephen Welton, Dr Goffet, &c. was printed by Mr. Nichols, in 1782 and 1783, under the inspection of the learned Dr. Owen, with his remarks. At the request of Thomas Hollis, esq. Mr. Bowyer wrote, in 1765, a short Latin preface to Dr. Wallis's "Grammatica Linguae Anglicanae;" a larger English preface, written by him, and intended for that work, is communicated to the public in his "Miscellaneous Tracts," published by Mr. Nichols in 1785, 4to. In 1766, he formed a partnership with Mr. Nichols, who had been trained by him to the profession, and had assisted him several years in the management of business. This connection with a person, whose disposition was amiable and communicative, and who resembled himself in his solicitude, by literary researches and publications, to promote the cause of literature, ensured the prosecution of views and plans similar to his own; and warranted a confidence which enabled him to withdraw, in the declining state of his health, from the fatigues of active employment. It also afforded him greater leisure for indulging his own studious inclination. Accordingly, in this year (1766) Mr. Bowyer wrote an excellent Latin preface to "Joannis Harduini, Jesuitæ, ad censuram scriptorum veterum prolegomena," in which he gives an account of the nature of the work, and of the manner in which it had been preserved. About the same time were published Mr. De Milly's remarks on the extraordinary production of the celebrated Jesuit, in a Latin letter to Mr. Bowyer. In 1767, he was appointed, by the recommendation of the earl of Marchmont, to print the journals of the house of Lords, and the rolls of parliament. In this year he printed Mr. Clarke's learned work, entitled "The connection of the Roman, Saxon, and English coins," with notes by himself, together with a dissertation on the Roman sesterce, which was partly his own production, and an excellent index of his own compilation. In 1771, the late Matthew Raper, esq. communicated to the Royal Society a very ingenious "Inquiry into the value of

of the ancient Greek and Roman money," which was printed in the Philosophical Transactions; and Mr. Bowyer published, "Remarks," on this dissertation, which he intended as an appendix to Mr. Clarke's treatise on coins. Three small tracts were published by him in 1773, under the title of "Select Discourses; 1. of the correspondence of the Hebrew months with the Julian, from the Latin of professor Michaelis; 2. of the Sabbatical years, from the same; and 3. of the years of jubilee, from an anonymous writer in Maffon's *Hilloire Critique de la Republique des Lettres*;" and in 1774, he corrected a new edition of Schrevelius's Greek lexicon, to which he added a number of new words, collected in the course of his studies. Of his critical skill in the learned languages he left in MS. many evidences, which appear in the additions made by him to the lexicons of Hederic and of Buxtorf, the Latin ones of Faber and of Littleton, and the English dictionary of Bailey; and also in the corrections and enlargements of Leigh's "Critica Sacra," and Dugard's "Lexicon Græci Testamenti alphabeticum;" together with his notes on Middleton's Life of Cicero, Duncan's and Bladen's Cæsar, Theocritus, Horace, and Pope, and an astonishing number of critical remarks on the Old and New Testament. In 1774 was published "The origin of Printing, in two essays: 1. The substance of Dr. Middleton's dissertation on the origin of printing in England. 2. Mr. Meerman's account of the invention of the art at Haerlem, and its progress to Mentz; with occasional remarks, and an appendix." Of this work the original idea was Mr. Bowyer's; but it was completed by Mr. Nichols. A second edition of this work, which was well received both at home and abroad, was published, with very considerable improvements, in 1776. In 1777, he closed his literary career, with a new edition of Dr. Bentley's "Dissertation on the epistles of Phalaris," with additional notes and remarks by himself and others. On this occasion he was much indebted to the friendly assistance of Dr. Salter, late master of the charter-house, and Dr. Owen.

Mr. Bowyer had been always subject to a bilious colic, and for the last ten years of his life he was afflicted with the palsy and the stone: and yet he retained, to a great degree, a remarkable cheerfulness of disposition; and his faculties, though somewhat impaired, enabled him to derive great satisfaction from the conversation of his literary friends, to pursue a course of incessant reading, which was his principal amusement, and to correct the learned works, especially the Greek books, which were printed at his press. Within a few weeks before his death he sunk under his maladies and the progress of decay, and at length terminated a life of singular reputation and usefulness, on the 18th of November, 1777, in his 78th year. His numerous publications afford ample evidence of his talents and learning, and he was honoured with the friendship and patronage of many of the most distinguished ornaments of the age in which he lived. As a learned printer he had no rival for more than half a century; and he was no less distinguished by his moral qualities than by his mental abilities and literary attainments. Of his regard to religion, both in the principles and practice of it, his whole life afforded unquestionable evidence; his probity was inflexible; the promptitude with which he relieved every species of distress marked the benevolence of his mind; and his modesty in endeavouring to conceal his benefactions reflects great honour on his memory. Although his literary avocations and natural temper induced him to seclude himself very much from the world, and from intercourse with any persons besides men of letters, he was reckoned to possess an excellent talent for discriminating the real characters of man-

kind. In the decline of his life, and in his testamentary arrangements, he seems to have been influenced by a regard to two great objects; one was to repay the benefactions which had been conferred on his father at a time when he peculiarly needed assistance, and in this respect he manifested a very amiable disposition; his other object was to be himself a benefactor to the meritorious in his own profession. A transcript of his will, if our limits would admit of it, would bear ample testimony to the laudable views by which he was actuated; and we have been induced to enlarge in our account of him from real respect to his memory. After liberally providing for his only surviving son, by his first wife, (for he was twice married,) and allotting various bequests to his relations, executors, private friends, and his father's benefactors; he appropriated several sums to "the benefit of printing," particularly with a view to the relief of aged printers, compositors or pressmen, and to the encouragement of the journeyman compositor, whom he particularly describes, and who is required to be capable of reading and construing Latin, and at least of reading Greek fluently with accents: these latter bequests he committed to the direction and disposal of the mauler, wardens, and assistants of the company of stationers. Mr. Bowyer was buried, agreeably to his own direction, at Low-Layton, in Essex, and a neat monument was erected, at the expence of his successor Mr. J. Nichols, to his father's memory and his own, upon which is a Latin inscription written by himself. A bust of him is placed in Stationers' hall, with an English inscription annexed to it, in his own words; and besides this there are also a good portrait of his father, and another of his patron Mr. Nelson; all presented to the company by Mr. Nichols. Biographical and literary anecdotes of William Bowyer, printer, F. S. A., and of many of his learned friends," by John Nichols, his apprentice, partner, and successor. 4to. 1782.

**BOWYERS**, artificers whose business is to make 'bows.

In which sense, bowyers stand distinguished from fletchers who made arrows.

The bowyers' company was incorporated in 1620, and consists of a master, two wardens, twelve assistants, and thirty on the livery. See COMPANY.

**BOX**, in its most general acceptance, is used to denote a case for holding things; of which there are several kinds, as a salve-box, *pyxis unguentaria*, that used by surgeons to carry with them.

Box is sometimes also used for a kind of measure, though variable according to the commodity. Thus the box of quicksilver contains from one to two hundred weight; of prunellas, about fourteen hundred; of rings for keys, two gros, &c.

Box, in *Botany*. See **BUXUS**.

Box, *African*. See **MURSINE**.

Box, *coach*, a place under the coachman's seat, wherein he puts what may be wanted for the service of the coach or horses.

Box, *dice*, a narrow deep cornet, channelled within, wherein the dice are shaken and thrown. This answers to what the Romans called *fritillus*; whence *crepitantes fritilli*, and, in Seneca, *resonante fritillo*. The same author also uses *concutere fritillum* figuratively for playing. Besides the *fritillus*, the Romans, for greater security, had another kind of dice-box, called *pyrgus*, and sometimes *turricula*. It was placed immoveable in the middle of the table, being perforated or open at both ends, and channelled also within: over the top was put a kind of funnel, into which the dice were cast out of the *fritillus*; whence descending, they fell through the bottom on the table; by which all practising

on them with the fingers was effectually prevented. For want of some contrivance of this kind, our sharpers have opportunities of playing divers tricks with the box, as palming, topping, flabbing, &c. Hyde. Hist. Nerdilud. § 2. p. 27, 28.

**Box room**, a kind of case wherein the heaters are enclosed for ironing linen.

**Box-money**, at *Hazard*, is that which is paid the box-keeper, or him who furnishes the box and dice. Bettors have the advantage over casters, as they have no box-money to pay, which at long run would beggar the most fortunate player. Hence some gamblers will never cast, to save the expence of box-money.

**Box of a plough**, a name by which the farmers call that cross-piece in the head of the plough, through which the spindle of the two wheels passes, and to which are fastened the two cross-staves, serving, by their holes, to regulate the height of the beam, the tow-chain below, the flake which supports the bridle-chain above, and the gallows behind, into which are fixed the wilds with the crooks of iron, for the drawing of the whole plough along. This part of the plough is placed cross-wise with the beam, and stands much below it, and not far from the ground. See **Plough**.

**Box of a rib-saw**, two thin iron plates fixed to a handle; in one of the iron-plates is an opening to receive a wedge, by which it is fixed to the saw.

**Box, strong**, a coffer of iron, or of thick wood, secured with iron plates, and a lock with several bolts, difficult either to be opened or forced; chiefly used for putting money in.

**Box the compass**, in *Sea-language*, to repeat the opposite points of the compass alternately. Thus, N. S. N. by E. S. by W. N.N.E. S.S.W. &c.

**Box of the compass**, the square wooden box which contains the mariner's compass; in the construction of which, no iron work is to be used.

**Box of a watch**, the case or cover.

**Box of a wheel**, the aperture wherein the axis turns.

**Box-puceron**, in *Entomology*, among old writers, the *coccus hesperidum*, an insect that infests the box, in common with various other evergreens. See **HESPERIDUM**. The word puceron, and bastard puceron, appears to have been formerly applied indiscriminately to several distinct genera of insects that infest plants, as those of the *cynips*, *aphis*, *thrips*, and others.

**Box-thorn**, in *Botany*. See **LYCIUM**.

**Box-tree**, *sand*. See **HURA**.

**Box-hauling**, in *Seamanship*, a particular method of veering a ship, when the swell of the sea renders tacking impracticable, or when there is not room to veer by the common method of filling the head, and shivering the after-sails. This operation is performed by putting the helm hard a-lee, which brings the ship's head to windward; the after-sails, particularly the main-sail, mizen, and mizen stay-sail, are to be hauled up; as soon as the sails begin to shake, haul in the weather-head braces, and the lee-fore, and fore-top bowlines; the ship's head will then fall off, which, together with the action of the water upon the rudder, by the sternway she has acquired, will bring her round until the wind is right aft; when her sternway will have ceased, and then the helm is to be put hard a-weather: in the mean time the after-sails are to be braced up, which will greatly assist in bringing the ship round; the main-sail, mizen, and mizen stay-sail are to be set, the head-yards braced up, as the ship comes to the wind, and the helm shifted to its proper position.

**Box-hill**, in *Geography*, near Dorking, in Surrey, England, received its name from the great number of box-trees

which ornament its shelving sides and summit. Many of these are said to have been planted on the south side of it by the celebrated earl of Arundel, in the reign of Charles I. Since that period they have proved highly beneficial to the proprietor, and to the public. "Formerly," says Mr. Gilpin, "the ships from the Levant brought such quantities of this wood in ballast, that the trees on this hill could not find a purchaser; and not having been cut in 65 years, they were growing in many parts cankered. But the war having diminished the influx of it from the Mediterranean, several purchasers began to offer for this native wood; and in the year 1795, Sir Harry Mildmay put it up to auction, and sold it for the immense sum of twelve thousand pounds." This hill, and the neighbouring eminences, on which the box-tree flourishes in such profusion and perfection, should be considered as making a part of the natural history of Britain. The extensive prospects commanded from this place, combining with its singular and beautiful scenery, frequently excite the attention and admiration of travellers. In its immediate vicinity are several elegant villas, and the river Mole, which runs under ground for some distance, winds its slow waters beneath the precipitous sides of this hill. Gilpin's *Observations on the Western Part of England*, 8vo. 1798. Manning's *History of Surrey*, fol. vol. i. 1804.

**BOXBERG**, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and the Palatinate; 34 miles E. of Heidelberg.

**BOXBOROUGH**, a township of America, in Middlesex county, and state of Massachusetts, containing 412 inhabitants; 30 miles N. W. from Boston.

**BOXERS**, a kind of *athletes*, who combat or contend for victory with their fists. See **ATHLETE**.

Boxers are the same with those who, among the Romans, were called *pugiles*. The ancient boxers contended with such force and fury, that they frequently dashed out one another's teeth, broke their bones, and killed each other.

The strange disfigurement these boxers underwent were such that frequently they could not be known, and rendered them the objects of many railleries. In the Greek anthology, there are four epigrams of the poet Lucilius, and one of Lucian, wherein their disfigurements are pleasantly enough exposed. Anthol. Græc. lib. ii. Ep. 1, 2, 3, 10, 14.

**BOXES**, in a play-house, are little apartments behind and aside of the pit. We say, the front boxes, the stage-boxes, &c.

**BOXES of the pump**. See **PUMP**.

**BOXFORD**, in *Geography*, a small township of America, in Essex county, Massachusetts, seated on the east side of Merrimack river; 7 miles W. of Newbury port, and containing 925 inhabitants.

**BOXHORNIIUS**, **MARK ZUERIUS**, in *Biography*, an eminent philologist, the son of James Zuerius, was born at Bergen-op-Zoom, in 1612, and assumed the name of his maternal grandfather, Henry Boxhorn, a convert from popery, and minister of Breda. At Breda, where he was educated, his proficiency in literature was such, that at the age of 17 years he published some Latin poems that were well received, and at the age of 20 he was editor of some learned works. In 1632, he became professor of rhetoric in the university of Leyden. Declining to accept the invitation of queen Christina to an honourable office in Sweden, he succeeded Daniel Heinsius in the professorships of politics and history, both which departments he occupied with great honour to himself and benefit to his auditors. His literary career, however, was terminated by death, in 1653. His works were numerous and curious. He published, in addition to his juvenile labours as an editor,

notes upon Justin, Pliny's Epistles, and Tacitus, and a "Commentary upon the Life of Agricola," by the last-mentioned author. In a work written by him on the invention of printing, he endeavoured to establish the claims of Haerlem in opposition to those of Mentz. He also wrote a Latin account of the siege of Breda. Among his political pieces are enumerated his defences of the liberty of navigation claimed by the Dutch, a short account of the Dutch constitution, and a vindication of the rights of Charles II. to the English throne. He wrote "Critical and historical dissertations on the antiquities of Gaul and Scythia;" and "Sacred and profane history from the birth of Christ, to the year 1650," in one volume 4to. His account of learned women never appeared. His letters, and his Latin and Greek poems, were printed after his death. Gen. Dict.

**BOXING**, the exercise of fighting with the fists, either naked, or with a stone or leaden ball grasped in them: in which sense, boxing coincides with the *pugillatus* of the Romans, and what, on our amphitheatres, is sometimes called trial of manhood. When the champions had *σφαίρα*, or balls, whether of lead or stone, it was properly denominated *σφαίρομαχία*, Potter, Arch. Græc. lib. ii. cap. 21. vol. i. The ancient boxing differed from the *pugna castuum*, in which the combatants had leathern thongs on their hands, and balls, to offend their antagonists; though this distinction is frequently overlooked, and fighting with the *castrus* ranked as part of the business of the *pugiles*. We may distinguish three species of boxing; viz. where both the head and hands were naked; where the hands were armed and the head naked; and where the head was covered with a kind of cap called **AMPHOTIDES**, and the hands also furnished with the *castrus*, which see.

Boxing is an ancient exercise, having been in use in the heroic times, before the invention of iron or weapons. Accordingly, we find in the Latin and Greek poets, several descriptions of this rudest, and most dangerous of the gymnastic combats. In Homer, we have that of Epeus and Euryalus; in Theocritus, that of Pollux and Amycus; in Apollonius Rhodius, an account of the same battle; in Virgil, that of Dares and Entellus; and in Statius, and Valerius Flaccus, are relations of several other combatants. Dioscor. Idyl. 22. Argonautic. l. 2. Æneid. l. 1. Theocritus, l. 6. Argonaut. l. 4.

Those who prepared themselves for it, used all the means that could be contrived to render themselves fat and fleshy, that they might be better able to endure blows; whence corpulent men or women were usually called *pugiles*, according to Terence: "Siqua est habilior paulo, pugilem esse aiunt." M. Burette has given the history of the ancient pugilate, or boxing, with great exactness. Mem. Acad. Inscrip. tom. iv. p. 353, &c.

The *athletæ* sometimes came immediately to blows, and began with charging in the most furious manner. Sometimes, whole hours passed in harassing and fatiguing each other, by a continual extension of their arms, rendering their mutual blows ineffectual, and endeavouring by this mode of defence to keep off their adversaries. But when they fought with the utmost fury, they aimed chiefly at the head and face, which parts they were most anxious to defend, by either avoiding or catching the blows that were aimed at them. When a combatant threw himself with all his energy upon another, they had a surprising address in avoiding the attack, by a nimble turn of the body, which caused the incautious adversary to fall, and deprived him of the victory. Notwithstanding the ferocity with which the combatants contended, they were sometimes so exhausted

by the duration of the combat, as to be under the necessity of making a truce, upon which the battle was suspended for some minutes, which were employed in recovering from their fatigue, and rubbing off the sweat with which they were bathed. They then renewed the fight, till one of them, by letting fall his arms through weakness, or by swooning away, indicated that he could no longer support the pain and fatigue, and desired quarter, which was conceding himself vanquished.

This art, adapted, as one might conceive, only to a period of barbarism, has in modern times been almost appropriated by the English; and about half a century ago, it formed a part of the exhibitions at places of public amusement. It was encouraged by the nobility, and even tolerated by the magistrates. Before the establishment of Broughton's amphitheatre, a booth was erected at Tottenham court in London, the proprietor of which, Mr. Geo. Taylor, invited the professors of the art of pugilism to display their skill, and the public to attend their performances. The entrance money, amounting sometimes to 100 or 150l., was shared among the performers, in such proportion, that the victorious champion had two thirds of it, and the vanquished one third; and in some cases, both had an equal share. When complaints were made by the nobility and gentry of the inconvenience attending the exhibitions in Taylor's booth, they prevailed on Mr. Broughton, at that time of rising fame in the class of pugilists, to build a place better adapted for the purpose. A subscription was raised, and, in 1742, a building was erected behind Oxford-road, and denominated "Broughton's new Amphitheatre." In this building, there were, besides a stage for the combatants, seats corresponding to the boxes, pit, and galleries in other theatres. In process of time, the public taste was refined and improved, so that exhibitions of this kind ceased to be popular, and sunk into neglect. At a later period, the death of one of the combatants served to render them still more disreputable, and unworthy of any patronage and encouragement. Instances, however, are often occurring of the renewal of these contests; but they are now so disgraceful in the public estimation, and so much restrained and prohibited, by the interference of the magistrates, that they are attended by few persons above the lowest class of the community, whenever, by eluding notice, they happen to take place.

**BOXING**, an operation in sailing, somewhat similar to box-hauling. It is performed by laying the head sails a-back, to receive the greatest force of the wind in a line perpendicular to their surface, in order to bring the ship's head back into the line of her course, after she had inclined to windward of it, by neglect of the person at the helm, or otherwise. But should a ship be taken flat a-back, or through neglect in not timely boxing her off, it should cause the wind to be broad upon the other bow, and it should be the wish of the officer to have her upon the same tack as before, then furl the helm over to that side, which just before was the weather; brail up the mizen, and mizen stay-sail; raise the main-tack and sheet, and square the after-yards. In this situation of the helm and sails, she will pay round off upon her keel; and when she has brought the wind ast, and gathered head-way, shift the helm. The wind round upon the other quarter, haul ast the mizen and mizen stay-sail sheets, brace up the after-yards, get on board the main tack, and hawl ast the sheet. As she comes to, right the helm, and trim sharp as before.

**BOXING**, in *Ship-building*, the projection left on the haufe-pieces, in the wake of the haufe-holes, where the planks do not run through.

BOXING is also used for the tapping of a tree, to make it yield its juice.

The boxing of maple is performed by making a hole with an ax or chisel into the side of the tree, about a foot from the ground; out of it flows a liquor from which sugar is made. Phil. Trans. N<sup>o</sup> 364. See MAPLE, BLEEDING-BIRCH, and SAP.

BOXMEER, in *Geography*, a town of Germany, situated on the west side of the Meuse, on the frontiers of the duchy of Gueldres; 8 leagues E. of Bois-le-Duc, and 4 S. S. W. of Cleves.

BOXTEHUDE, a town of Germany, in the circle of Lower Saxony, and duchy of Bremen, seated on the river Eite or Este, navigable for boats to the Elbe. It is subject to the Danes; 14 miles W. of Hamburg. N. lat. 53° 40'. E. long. 9° 35'.

BOXTEL, a town of Brabant, seated on the Dommel, and furnished with sluices; 5 miles S. of Bois-le-Duc. N. lat. 51° 30'. E. long. 5° 15'.

BOY-BISHOP, in *Antiquity*. See BISHOP.

BOY, *St.* in *Geography*, a town of Spain in the province of Catalonia; 6 miles S. W. of Barcelona.

BOYAR, or BOIAR, a term used for a Russian lord, or grandee. According to Becman, boyars are what, in other countries, are called the upper nobility: he adds, that the czar of Muscovy, in his diplomas, names boyars before waywodes.

It has not yet been satisfactorily determined, what the ancient boyars were; whence they derived their descent; and how they maintained their dignity; and whether this dignity was conferred by the sovereign; whether it attached to birth, or whether it sprung from the rank and importance which they brought with them into the country. If we consider them as the privy counsellors of the sovereign, then their precedence arises merely from their office, or they must have possessed it by their birth. But it has been likewise affirmed, that the boyars, now in general the most considerable of the Russian nobility, came from abroad, were sprung from foreign ancestors, and brought their nobility into the empire with them. However, future researches are necessary for obtaining satisfaction, with regard to these questions. During the Tartarian and Mongolian sovereignty, no trace of them is found; and even during the reign of czar Ivan Vassillievitch I. no such title appears, though it seems to have arisen at that time, or very soon after it: for, under the czar Ivan Vassillievitch II., the boyars had already endeavoured to collect a considerable force; but were much overawed by that monarch. In the succeeding period of distraction, occasioned by the aspiring views of the patriarch and his superior clergy, the boyars seized the favourable opportunity of extending their power. It is also probable, that persons of respectable birth from other countries, who occupied high stations in Russia, and on this account, as well as from the privileges brought with them, enjoyed great authority; and hence all boyars, i. e. the superior officers, might take occasion to assume a consequence, which they afterwards, as opportunities occurred, endeavoured to enlarge. Although the boyars are always mentioned in history as persons of distinction, yet the same history also informs us, that they received their dignity from the sovereign alone, that it was entirely personal, and that it was not transmitted by inheritance from father to son. Accordingly, it depended on the will of the monarch, whether he would have many or few boyars: and, therefore, they can never be considered as native privileged deputies of the people, nor as persons who could restrain the power of the sovereign, or

resist him in the undue exertions of it. In some cases, however, they usurped an authority to which they had no just pretensions, and then brought great distress upon the empire. At the drawing up of the uloshenie, or old law of the land, they, as well as the clergy, were consulted: but probably only as privy counsellors, under which description they were generally noticed in the ukasses. However, in order to prevent any further usurpation and mistakes, an order was issued in 1701 by Peter I., that they should no longer be mentioned at all in the ukasses. From the authority they possessed, and with a natural desire of extending it, it may be reasonably presumed, that they took a lead in the elections of the sovereign princes, if they were not the prime managers of them; they without doubt thought themselves the first personages after the sovereign and the privileged representatives of the people, especially of all the rest of the nobility; and this seems to be the reason why the latter are not named among the electors. The boyars, in early times, when wars were frequent, besides having a share in the election, were commanders of the army, as well as the ministers and counsellors of the prince. The directing senate in the Russian government, instituted by the emperor Peter I. about the year 1711, and raised to the rank of the supreme college of the empire, consisted at first of 9 boyars; and seems to have been created in the place of the old boyars. The boyars before his time sat at the helm of state in the capital, and officiated as viceroys in the provinces, deciding, commanding, and acting, according to their own humours. But he abrogated the court of boyars, called "Boyariskoi dvor," which had hitherto constituted the ministry of the czar or tzar, and without whose consent nothing could be enacted, inasmuch, that all the decrees of government began with these words, "By command of the tzar, and with the approbation of the boyars;" and substituted the senate in its room. Writers are not agreed as to the precise meaning of the word "boyar" or "boyarin." In the dictionaries it is made to denote a lord, a person of quality, or a nobleman. Sometimes it peculiarly denotes a soldier. In the Russian language, "boyarin" signifies a gentleman, a person of distinction, or a master of a family; and the Russian peasant usually styles his nobleman, even though he has neither rank nor estate, boyarin, or contractedly, barin, and his spouse, boyarina. Hence the task-service, performed by the boors to their lord, is called "boyarschtschina." Tooke's view of the Russian empire, vol. ii.

BOYAU, in *Fortification*, a branch of the trenches; being a ditch covered with a parapet, which forms a communication between two trenches; it runs parallel to the defensive works of the body of the place, and serves as a line of contravallation, to hinder the sallies of the besieged, and also to secure the miners. When it is a line or cut, that runs from the trenches to cover some spot of ground, it is drawn so that it may not be enfiladed, that is, that the shot from the town may not scour along it.

BOYCE, DR. WILLIAM, in *Biography*, organist and composer to his majesty, was a musician to whom our choral service is greatly indebted, not only for his own excellent choral works, but for the well selected, correct, and splendid edition of our cathedral music, which he published in three volumes large folio, upon the plan, and at the recommendation of his master and predecessor, Dr. Greer, to whom he served an apprenticeship.

This eminent professor (Boyce) was born at Joyner's hall, in the city, of which his father was housekeeper, and with whom he resided during celibacy. When he became a family-man, his residence was in Chancery-lane, to the end of the

reign of his late majesty George II., about which time he removed to Kensington Gore, where he ended his days in 1779. He was educated at St. Paul's school, and began his musical career as a chorister in that cathedral. When he lost his treble voice, he was bound apprentice to Dr. Greene, then organist of the metropolitan church. The master and scholar seemed worthy of each other, living in the utmost cordiality and friendship; the master loving the pupil, and the pupil honouring and respecting the master, to the end of their lives.

In 1734, he was a candidate for the place of organist of St. Michael's church, Cornhill, with Froud, Young, James Worgan, and Kelway. But though he was unsuccessful in this application, Kelway having been elected, yet he was appointed, the same year, to the place of organist of Oxford chapel; and in 1736, upon the death of Weldon, when Kelway, being elected organist of St. Martin's in the Fields, resigned his place at St. Michael's Cornhill, Boyce was not only elected organist of that church, but organist and composer in the chapel royal.

The same year he set "David's Lamentations over Saul and Jonathan," which was performed at the Apollo Society. About the year 1743, he produced his *serenata* of "Solomon," which was not only long and justly admired, as a pleasing and elegant composition, but still affords great delight to the friends of English music, whenever it is performed. His next publication was "Twelve Sonatas or Trios for two Violins and a Bass," which were longer and more generally purchased, performed, and admired, than any productions of the kind in this kingdom, except those of Corelli. They were not only in constant use, as chamber music, in private concerts, for which they were originally designed, but in our theatres, as act-tunes; and public gardens, as favourite pieces, during many years.

In 1749, he set the ode written by the Rev. Mr. Mason, for the installation of the late duke of Newcastle, as chancellor of the university of Cambridge, at which time he was honoured with the degree of doctor in music by that university. Soon after this event he set the "Chaplet," a musical drama, written by the late Mr. Mendez, for Drury-lane theatre, which had a very favourable reception, and long run, and continued many years in use among the stock pieces for that theatre. Not long after the first performance of this drama, his friend Mr. Beard brought on the same stage the secular ode, written by Dryden, and originally set by Dr. Boyce for Hickford's room, or the Castle concert, where it was first performed, in still life. This piece, though less successful than the "Chaplet," by the animated exertions of Mr. Beard, was many times exhibited before it was wholly laid aside. These compositions, with occasional single songs for Vauxhall and Ranelagh, disseminated the fame of Dr. Boyce throughout the kingdom, as a dramatic and miscellaneous composer, while his choral compositions for the king's chapel, for the feast of the sons of the clergy at St. Paul's, and for the triennial meetings at the three cathedrals of Worcester, Hereford, and Gloucester, at the performances in all which places he constantly presided till the time of his death, established his reputation as an ecclesiastical composer and able master of harmony.

Dr. Boyce, with all due reverence for the abilities of Handel, was one of the few of our church composers who neither pillaged nor servilely imitated him. There is an original and sterling merit in his productions, founded as much on the study of our own old masters, as on the best models of other countries, that gives to all his works a peculiar stamp and character of his own, for strength, clearness, and

facility, without any mixture of styles, or extraneous and heterogeneous ornaments.

On the decease of Dr. Greene, in 1757, he was appointed master of the king's band, and, in 1758, on the death of Travers, organist of the chapel royal; of which he had succeeded Weldon, in 1736, as composer; so that he enjoyed three honourable appointments at once, which used to be supplied by three several professors. The gout put an end to the exultance of this worthy man, and excellent composer, at the age of 69. He was succeeded in the chapel royal by Mr. (afterwards Dr.) Dupuis, and, as a master of his majesty's band, by Mr. Stanley.

BOYD, MARK ALEXANDER, a descendant of the ancient family of this name in Scotland, was born in Galloway, in 1562, and placed for education at Glasgow, under the care of his uncle, the archbishop. But being of an ungovernable and turbulent temper, he quarrelled with his preceptors, destroyed his books, and renounced the pursuits of literature. He then fought to push his interest at court; and when all the endeavours of his friends to serve him in that situation proved ineffectual, they sent him in a military capacity to the wars of the United Provinces, with a view of restraining the violence of his temper. From hence he soon removed to Paris, and lost his whole stock of money by gaming. The distress that ensued seems to have brought him to reflection, and he determined to apply to literary studies. Accordingly he repaired to Bourges, and attended the lectures of the famous civilian Cujacius. To this eminent professor he recommended himself by peculiar attention and respect, and by adopting his taste in Latin poetry; and thus he acquired a fondness for the antiquated style of Ennius, and of the older Latin poets. From Bourges he was driven by the plague to Lyons, and thence to Italy. On the renewal of the civil wars in France, he removed thither, and bore arms with reputation in the royal cause; and after a variety of adventures he returned to his native country, where he died in 1601. The talents and performances of Boyd have been much over-rated; and he has been represented as another "admirable Crichton." But though he possessed a vigorous and versatile genius, he never acquired, probably on account of his indolence and dissipation, any kind of distinguished excellence. Besides several manuscripts which he left behind him, on political, critical, and poetical topics, his "Epistolæ Heroidum," and his "Hymni," were published in the "Deliciæ Poetarum Scotorum," printed at Amsterdam, in 2 vols. 12mo. 1637. His "Epistolæ" were inscribed to James VI. of Scotland, or James I. of England, whom he represents as superior to Pallas in wisdom, and Mars in arms. As to the character of his poetry, it consists in an imitation of the worst manner of Ovid; and his hymns, which have no tincture of devotion, are poems to which he has annexed the title of some flower or herb, the qualities of which he has described. Bishop Tanner informs us, that, besides his epistles and hymns, he published two books of "Epigrams." *Biog. Brit.*

BOYDELL, JOHN, a liberal patron of the arts, and an honour to his country, was born at Dorrington, in Shropshire, on the 19th of January 1719. His father, who was a land-surveyor, intended his son for his own profession; and, had it not been for one of those little accidents which often determine the path that men are destined to walk, he had wasted that life, which has been so honourable to himself, and beneficial to this nation, in measuring and valuing the acres of Shropshire squires, and the manors of Welch baronets. Fortunately for himself and the arts, a trifling incident gave a different direction to his mind, and led him to aim at the delineation of scenes more picturesque than the ground-

plans of houses, boundaries of fields, or windings of obscure roads. While he was yet very young, chance threw in his way "Baddeley's Views of different Country Seats;" and among them was one of Hawarden castle, Flintshire; which being the seat of sir John Glynn, by whom he was then employed in his professional capacity, and in the parish of which his father was an inhabitant, naturally attracted his attention. An exact delineation of a building that he had so often contemplated, afforded him pleasure, and excited an astonishment earlier to be conceived than described. Considering it as an engraving, and reflecting that from the same copper might be taken an almost indefinite number of impressions, he determined to quit the pen, and take up the graver, as an instrument which would enable him to disseminate whatever work he could produce, in so much wider a circle. This resolution was no sooner made, than it was put in execution; for, with that spirit and perseverance which he manifested in every succeeding scene of life, he, at twenty-one years of age, walked up to the metropolis, and bound himself apprentice for seven years to Mr. Toms, the engraver of the print which had so forcibly attracted his attention. These, and accidents equally trifling, sometimes attract men of strong minds into the path that leads direct to fame, and have been generally considered as proving that they were born with some peculiar genius for some peculiar study; though, after all, genius is perhaps little more than what a great moralist has defined it:—"a mind with strong powers accidentally directed to some particular object." Sir J. Reynolds had the first fondness for his art excited by the perusal of "Richardson's Treatise on Painting;" and, as we have before observed, Mr. Boydell was induced to learn the art of engraving, by a coarse print of a coarse artist, representing a mis-shapen Gothic castle.

His conduct, during his apprenticeship, was eminently assiduous. Eager to attain all possible knowledge of an art on which his mind was bent, and of every thing that could be useful to him; and impelled by an industry that seemed inherent in his nature, he, whenever he could, attended the academy in St. Martin's lane to perfect himself in drawing; his leisure hours in the evening were devoted to the study of perspective, and to the learning of French without the aid of a master. After very steadily pursuing his business for six years, and finding himself a better artist than his teacher, he bought from Mr. Toms the last year of his apprenticeship, and became his own master; and the first use that he made of his freedom was to return into his own country, where he married a very deserving young person of a most respectable family, to whom he had an early attachment, and with whom he lived many years in great felicity.

In the year 1745, or 1746, he published six small landscapes, designed and engraved by himself. This publication, from his having, in most of the views, chosen a situation in which a bridge formed part of the scenery, was entitled "The Bridge-Book," and sold for a shilling. Small as this sum was, he sometimes spoke with apparent pleasure of a silversmith in Duke's-court, St. Martin's-lane, having sold so many, that when he settled his annual account, he thought it would be civil to take a silver pint mug in part of payment, and this mug he retained until his dying day. He afterwards designed and engraved many other views, generally of places in and about London, and published the greater part of them at the low price of one shilling each. But, even at this early period, he was so much alive to fame, that after having passed several months in copying an historical picture of Coriolanus by Sebastian Concha, he so much disliked his own engraving, that he cut the plate to pieces. Beside these, he engraved

many prints from Broeking, Berchem, Salvator Rosa, &c. The manner in which many of them are executed is highly respectable; and, being done at a time when the artist had much other business to attend to, displays an industry rarely to be paralleled, and proves, that had he devoted all his time to engraving, he would have ranked high in the profession. His facility of execution, and unconquerable perseverance, having thus enabled him to complete 152 prints, he collected the whole in one port-folio, and published it at five guineas. He modestly allowed, that he himself had not at that time arrived at any eminence in the art of engraving; and that those prints are now chiefly valuable from a comparison of them with the improved state of the art within the last 50 years. In fact, there were at that time no eminent engravers in England; and Mr. Boydell saw the necessity of forcing the art by stimulating men of genius with suitable rewards. With the profits of the folio volume of prints above mentioned, he was enabled to pay very liberally the best artists of his time, and thus presented the world with English engravings from the works of the greatest masters. The encouragement that he experienced from the public was equal to the spirit and patriotism of his undertaking, and soon laid the foundation of an ample fortune. He used to observe, that he believed the book we have alluded to was the first that ever made a lord mayor of London; and that when the smallness of the work was compared with what had followed, it would impress all young men with the truth of what he had often held out to them, "that industry, patience, and perseverance, if united to moderate talents, are certain to surmount all difficulties." Mr. Boydell, though he never himself made any great progress as an engraver, was certainly the greatest encourager of the art that this country ever knew. English engravings, which were before considered as extremely inferior to those of foreign nations, began from that time to be highly prized; and the exportation of them soon became a valuable article of commerce. On the 5th of August, 1782, Mr. Boydell was chosen alderman of London, for the ward of Cheap, in the room of alderman Crichton, deceased.

Having been so successful in promoting the art of engraving in this country, he resolved to direct his next efforts to the establishing of an English school of historical painting; and justly conceiving that no subject could be more appropriate for such a national attempt, than England's inspired poet, and great painter of nature, Shakspeare, he projected, and just lived to see completed, a most splendid edition of the works of that author, illustrated by engravings from paintings of the first artists that the country could furnish, and of which the expence was prodigious. These paintings afterwards formed what was termed "The Shakspeare Gallery," in Pall Mall; and we believe there are few individuals, possessed of the least taste, or even curiosity, who have not inspected and been delighted by them.

In the year 1790 Mr. Boydell was chosen lord mayor of London; an office, of which he discharged the duties and the honours with a diligence, uprightness, and liberality, that may be equalled, but will rarely be exceeded.

After having expended, in his favourite plan of advancing the fine arts in England, no less a sum than 350,000*l.* this worthy and venerable character was necessitated, by the stoppage of his foreign trade during a dozen years of war, to apply to parliament, in the beginning of 1804, for permission to dispose of the Shakspeare gallery, and his other collections of pictures and prints, by way of lottery. His letter to sir John William Anderson, bart. on the occasion of his introducing a petition for that purpose to the house of commons, is preserved in most of the respectable periodical

cal publications of the time, and will at once inform, instruct, and deeply affect the feelings of the reader. It is, however, too long for insertion in this place; and, indeed, the facility of reference to the Gentleman's, the European, the Monthly Magazines, &c. render it little necessary.

[A coincidence that may be just worth mentioning here is, that by mere chance this article came under the writer's hand on the very day which, by the result of the lottery, transferred the property of this valuable collection to Mr. Tassie, an artist of Leicester Square, the nephew of a late well known imitator of ancient cameos and intaglios.]

Mr. Boydell's death was occasioned at last by a too scrupulous attention to his official duties. Always early in his attendance on public business, he arrived at the Sessions-house in the Old Bailey, on Friday the 7th December 1804, before any of the other magistrates, and before the fires were lighted. Standing near a grate while this was done, the damps were drawn out, and he took a cold; this produced an inflammation of the lungs, which terminated his life on the Tuesday following. He was interred, with great civic pomp (the spontaneous result of private friendship and public respect), on the 19th of the same month, in the church of St. Olave, Jewry; leaving behind him, for the instruction of mankind, a striking example to what heights of fame and fortune men may attain by the united efforts of persevering industry, prudent enterprize, and honourable dealing. We have shown how Mr. Boydell's 152 plates, engraved by himself, laid the foundation of his fortune. We understand, however, that he was also the means of making Mr. Woollet's genius known to the public, by employing him to engrave the Niobe and the Phaeton, from pictures by Wilson. For the first of these he agreed to give Woollet 50 guineas, and when it was completed, paid him 100. The second the artist agreed to engrave for 50 also; but Mr. Boydell paid him 120. The two prints were published by subscription at 5s. each; and proof impressions have since been sold at public auctions for ten and sometimes eleven guineas each!

BOYER, ABEL, was born at Castrès in 1664, and on occasion of the revocation of the edict of Nantes, he became a refugee, and finally settled in England, where he became a considerable writer. His "French and English Dictionary," 4to. has been often published, and is well known; and so is his "French and English Grammar." His "Political State" was a monthly publication, commenced in January 1710, and continued to November 1729. He also wrote the "History of king William," 3 vols. 8vo.; "Annals of queen Anne," 11 vols. 8vo.; a French translation of "Addison's Cato;" "Letters French and English;" an English translation of "Telemachus;" "State Trials to that of the Earl of Oxford," and several other works. He died at Chelsea, in 1729. *Moreri. Gen. Biog.*

BOYER, JOHN BAPTIST NICHOLAS, was born at Marseilles, August the 5th, 1693. His father, intending to bring him up to business, gave him a suitable education, and, at a proper age, sent him to Constantinople, to his uncle, who was consul there; but finding him inclined to literature, and to the study of medicine, he sent him, on his return from the Levant, to the university at Montpellier. In the year 1717, he took the degree of doctor, and gave for his inaugural thesis, "A Dissertation on Inoculation of the Small Pox," which he had seen practised at Constantinople. On the plague breaking out at Marseilles, in 1720, he was sent there with five other physicians; and his practice, or his conduct on that occasion, having been approved, he was rewarded by the king with a pension, and was made physician to a regiment of guards. He was some years after invited to Hunspruche, a town in the bishopric of Treves, where an

infectious fever was making great ravages, and, in 1742, to Paris, on a similar occasion. His success at these places occasioned him to be sent for to Beauvais, in 1750, where by his judicious management he prevented the spreading of an infectious fever, infesting that country. For these services he was honoured by the king with letters of nobility, and invested with the order of St. Michael. He died Jan. 1768. His works are "Methode indiquée contre la maladie epidémique qui vient de regner à Beauvais," Paris, 1750, 4to. It consists of only ten pages. "Methode a suivre dans le traitement de différentes maladies epidémiques qui regnent le plus ordinairement dans la generalité de Paris," 1761, 12mo. He wrote, in 1745, a "Memoir" on the disease infesting the cattle at that time. It was sent to the Royal Society in London, and procured him a place in the list of their foreign members. He also gave a new edition of the *Codex medicamentarius*, seu "Pharmacopœia Parisiensis," 4to. a very useful and well digested work. *Eloy, Dict. Hist.*

BOYER'S Bay, in *Geography*, lies at the N.W. end of the island of St. Kitts, in the West Indies.

BOYER, in *Navigation*, a kind of Flemish sloop, or small vessel of burden, having a bolt-sprit, a castle at each end, and a tall mast; chiefly fit for the navigation of rivers, and, in many of its parts, resembling a smack.

The hoyer has a double bottom, and a forked mast, that it may run better with the bowling-line, without driving.

BOYERA, in *Geography*, a village of Africa, in the kingdom of Anta, on the Gold coast, situate between Bourry and Tokorari, and wholly inhabited by fishermen and labourers, who carry on a considerable trade with their neighbours by exchanging the fruits of the earth and fish for the produce of other countries. This village, and an adjoining one, called "Pandos," of the same description, are known at sea by a large pointed rock that lies before the coast.

BOYES, an order of American priests or magicians, used by the savages for calling up their gods, either to be revenged on those who have done them any injury, or to be cured of some disease, wherewith they are infested, or to drive out some devil. They are also consulted with regard to the event of their wars. Each boye has his peculiar duty; who is invoked by certain forms of words, sung in a quaint tone, accompanied with the fumes of tobacco.

BOYEUPECANGA, in *Zoology*, the name of a very large serpent, distinguished by this name on account of certain prominences on its back. It is a very large and remarkably thick serpent, and of very fatal poison. *Ray.*

BOYLE, RICHARD, in *Biography*, an accomplished statesman, generally stiled the "Great earl of Cork," was the descendant of an eminent and honourable family in Herefordshire, and the second son of Roger Boyle, a younger brother, who settled at Canterbury, where he was born in 1566. Having pursued his studies for some time at Bennet college in the university of Cambridge, he removed to the Middle Temple with a view to the profession of the law; but he soon changed his destination, and entered into the service of sir Richard Manwood, chief baron of the exchequer. This situation presenting to him no prospect of speedy advancement, he went to Dublin in 1588; and, though his whole wealth amounted only to 27l. 3s. he had good recommendations, which, together with his own talents, introduced him into connection with the principal persons employed in the government, to whom he rendered himself eminently useful. The business in which he was engaged afforded opportunities of acquiring a comprehensive and accurate knowledge of the kingdom, and of the state of public affairs, which he did not neglect duly to improve. His marriage also, in 1595,

with a lady possessing 500*l.* *per annum* of landed property, fixed to accelerate his advancement. By several advantageous purchases, at a time when land was of precarious tenure, and consequently cheap, he laid the foundation of his future ample estate; and the office of clerk of the council, under sir George Carew, in the province of Munster, to which he was appointed by queen Elizabeth, served to give him additional importance. His constant attendance on sir George in all his expeditions against the Irish rebels, offered him various opportunities of singular service to the state, and of justifying the confidence that was reposed in him. Accordingly, after the battle of Kingsale, A. D. 1601, in which the Irish and their Spanish auxiliaries were totally routed, he was dispatched by his patron, the president of Munster, to communicate the news of the victory to the queen; and he executed this commission with such dispatch, and so much to the satisfaction of sir George, that he was employed in another embassy to England, in order to obtain the queen's permission for the president's return to his own country. In consequence of the advice of his patron, Mr. Boyle purchased, at a low rate, sir Walter Raleigh's estate in Ireland, consisting of 12,000 acres, in the counties of Cork and Waterford, which he so cultivated and improved as very much to enhance their value. In 1603 he married the daughter of sir Geoffrey Fenton, and in the same year received the honour of knighthood from his friend and patron sir G. Carew, then lord deputy of Ireland. The next step of his progressive advancement to the high honour and ample fortune, which he afterwards acquired, was the office of privy-counsellor for the province of Munster, to which he was appointed by king James in 1606; and as he had considerable estates in this province, he was enabled, by this promotion, to pay due attention, at the same time, to his own interest and to that of the public. With a view to both these objects, he took care to let his estates to English protestants only, and to erect several towns and boroughs, as well as some castles, for their security. His conduct was so much approved, that in 1612 he was promoted to the dignity of privy-counsellor for the kingdom of Ireland, and in 1616 to the rank of peerage, by the title of baron of Youghall, in the county of Cork, and in 1620 to that of viscount Dungarvan and earl of Cork. By his active and unremitting exertions for promoting the security and prosperity of the English and protestant interest in Ireland, and improving the arts and manufactures of the country, he conciliated the favour of king Charles I., and obtained for his sons, even in their infancy, several titles of distinction. As they grew up he settled them in separate estates, and formed connections for his daughters with the best families in the country. At the castle of Lismore, the centre of very ample domains, which on this account he chose for his own residence, he lived in a style of princely splendour. In 1629 he was appointed one of the lords justices of Ireland; an office of high dignity and influence, which he held for many years; and in 1631 he was appointed lord treasurer of the kingdom, accompanied with the unprecedented circumstance of hereditary succession in his family. But it has not continued in the sole line of the house of Boyle; for, on the death of the last earl of Burlington, in 1753, the office was conferred by his late majesty, on the then marquis of Hartington, who was not of the Boyle family; and it is now enjoyed by his son, the present duke of Devonshire, who descends from a female branch. In the exercise of the powers with which he was invested, he assiduously executed the rigorous laws of queen Elizabeth against the papists; and for the more effectual suppression of the popish religion and worship, he shut up several mass-houses both in Dublin and in the country.

He was also active in providing a regular and competent subsistence for the army; and in transplanting a multitude of barbarous Irish "septs," or "clans," out of the fertile and well cultivated province of Leinster, into the wilds and deserts of the county of Kerry. He also took great pains in endeavouring to procure a mint to be settled in that county. Upon the arrival of lord Wentworth, who was appointed lord-deputy of Ireland in 1633, the high powers possessed and exercised by the earl of Cork excited jealousy and opposition; and the cold civilities which at first passed between them terminated in open and avowed hostility. This hostility continued for several years; very much to the mortification and disquietude of both parties. However, when the earl of Strafford was impeached before the house of lords in 1641, the earl of Cork, who was then in England, had an opportunity of retaliating by giving evidence against him. Soon after this event, and just before the commencement of the fatal rebellion in that country, he returned thither; and assuming a military capacity, exerted himself with all the ardour of youth, and collected an army among his tenants and dependants, at his own expence, which he committed to the command of his four sons, distributing them through various parts of his extensive domains, so as to secure them, in a great degree, against the depredations of the superior forces of the Irish, and to gain many advantages over them. In this contest he lost one of his sons, who fell at the battle of Lisecarrol in 1642; nor did the earl himself, whose active exertions overpowered a constitution already impaired by age, long survive. In September 1643 he closed his honourable career of private advancement and public service, and was interred in his own chapel, in the parish church of Youghall, near the noble monument he had erected for his family. How well he deserved the title of the "Great earl of Cork," under which appellation he is always mentioned, even among the native Irish, the historians of the interesting period in which he lived have amply testified. "The noble earl of Cork, lord high-treasurer," says sir Richard Cox, an intelligent and impartial writer, in his introduction to the 2d volume of his History of Ireland, "was one of the most extraordinary persons, either that or any other age hath produced, with respect to the great and just acquisitions of estate that he made, and the public works that he began and finished, for the advancement of the English interest and the protestant religion in Ireland, as churches, alms-houses, free-schools, bridges, castles, and towns, viz. Lismore, Tallow, Cloghnakilty, Imiskeen, Castletown, and Bandon, (which last place cost him fourteen thousand pounds,) inasmuch that when Cromwell saw these prodigious improvements which he little expected to find in Ireland, he declared "that if there had been an earl of Cork in every province, it would have been impossible for the Irish to have raised a rebellion." And whilst he was carrying on these solid works, he lived in his family at a rate of plenty that exceeded those who consumed great estates in the lavish ways of ill-ordered excess. His motto, "God's providence is my inheritance," shews from whence he derived all his blessings, the greatest of which was the numerous and noble posterity he had to leave his estate unto." By his second lady he had fifteen children, of whom many survived him, and rose to great eminence. *Biog. Brit.*

BOYLE, ROGER, earl of Orrery, fifth son of the great earl of Cork, was born in 1621, and created baron Broghill, of the kingdom of Ireland, at the age of seven years. At Dublin, where he received his education, he was distinguished by his genius and application; and, in 1636, he set out on the tour of France and Italy. Upon his return from his travels, he found the country in great confusion; and

and having married the daughter of the earl of Suffolk, they landed in Ireland on the day when the rebellion in that kingdom broke out, viz. October 23, 1641. On this occasion the post which his father assigned him was the defence of the castle of Lismore, in which he behaved with equal prudence and valour: after the cessation of the contest between the protestants and popish parties in Ireland, he visited England, and paid his respects to king Charles I. at Oxford; to whom he communicated information concerning the true state of Ireland; and he returned with a commission to lord Inchiquin, and instructions to act against the rebels, in which service he assisted that nobleman to the utmost of his power; and he continued his service, as the only means of promoting the protestant interest, under the commissioners named by parliament, till the king's death. When this event took place, he left his country and retired to Marlton in Somersetshire, where he remained for some time in close retirement; but here he formed a scheme of crossing the seas, under a pretence of visiting the Spaw, on account of his health, and of applying to Charles II. for a commission to raise forces in Ireland, for the restoration of his majesty and the recovery of his own estates. The committee of state, however, were apprized of his design; and Cromwell, wishing to avail himself of his talents and influence, proposed an interview with him. In this interview he was informed, that the committee of state knew the object of his leaving the kingdom, and that they had determined to make an example of him, if he himself had not interposed and diverted them from their purpose. Lord Broghill, finding that it was vain to dispute, and that Cromwell had copies of several letters which his lordship had sent to those in whom he had confided, and which he put into his hands, returned Cromwell thanks for his protection against the committee, and solicited instructions how he was to act in his peculiarly delicate and embarrassed circumstances. Cromwell assured him of the high opinion he entertained of his merit and character; and, as he had been appointed lord lieutenant of Ireland, he informed him, that he had obtained leave of the committee to offer his lordship the command of a general officer, if he would serve in the war for reducing the country; pledging himself at the same time, that no oaths or engagements would be imposed upon him, and that he should not be obliged to draw his sword against any but the Irish rebels. Whilst his lordship was hesitating about accepting an offer so generous and unexpected, Cromwell urged the necessity of an immediate resolution; as the committee, who were then sitting, determined, if he refused the offer, to send him to the Tower. Lord Broghill, apprehending danger both to his liberty and life, and overpowered by the apparent frankness and generosity of Cromwell's conduct, gave him his word and honour, that he would faithfully serve him against the Irish rebels. Accordingly he directed him to repair immediately to Bristol, where he would find a supply of forces, and a sufficient number of ships to transport him into Ireland. Having accepted Cromwell's commission, he served under him with great military skill and vigour in his Irish campaigns. After Cromwell's assumption of the protectorate, lord Broghill became his constant companion and confidential counsellor; and it has been said, that he proposed a matrimonial connection between the exiled king, Charles II. whom he had founded upon it, and whom he found not altogether averse from the project, and Frances, the daughter of the protector, who was not inclined to adopt it. It has also been said, that he advised Cromwell to restore the old constitution, and to assume the title of king. The measures he recommended, whilst he enjoyed the confidence of the protector, were mild and lenient; and by these he equally served both Cromwell

and the nation. In parliament he opposed and defeated the detestable measure, proposed by some party-men, which was that of a law for decimating the royal party. In 1656, lord Broghill accepted, on conditions previously stipulated, a commission to govern Scotland for one year with absolute authority; and in the execution of it he gave great satisfaction both to the Scots and to Cromwell. It redounds much to the credit of his lordship's judgment, that, notwithstanding the number and influence of his enemies, and their frequent access to the protector, he retained his confidence to the last, and possessed some of the most distinguished posts under his government, being a general officer in the army in Ireland, a member of both parliaments, a lord of Oliver's creation, and one of his confidential council. After the death of Cromwell he adhered faithfully to his son Richard, as long as he had any prospect of maintaining his power; but as soon as he had dissolved the parliament, he thought the government subverted, and himself absolved from all obligations of attachment to the Cromwell family, considered as that of a prince. He, therefore, determined, for his own security, to withdraw to Ireland, and to assume his command in the province of Munster. Availing himself of the advantages which his situation afforded him, he was eminently useful in restoring and re-establishing the king's authority in Ireland; and soon after his arrival, he came over to England, and farther ingratiated himself with his majesty, by giving him full information with regard to the state of parties in Ireland. For the services that were rendered by him on this occasion, he was advanced, in 1660, to the dignity of earl of Orrery, and appointed one of the lords justices for Ireland. Having drawn up the act of settlement for that kingdom, and thus secured the protestant interest, he withdrew in 1662, upon the appointment of the duke of Ormond to the lieutenantancy, to his local jurisdiction in the province of Munster. In this situation of subordinate authority, and comparative retirement, and though he was occasionally afflicted with paroxysms of the gout, he took an active part, when opportunity offered, in public affairs. He is said to have had the seals offered him, when he made a visit to England in 1665, but he declined accepting them. On his return to Munster, he found ample employment for his talents during the progress of the Dutch and French war. Besides other services of an important nature which he performed, he put the town and harbour of Kinsale into such a state of defence, as to relieve the people amidst their alarms and apprehensions, and to render abortive the scheme for seizing it projected by the admiral of the French fleet. To him it was owing, that this port became afterwards a commodious refuge in time of war, both for our East and West India fleets. Notwithstanding all his labours and services for the safety of the kingdom, an unhappy dispute arose in 1667 between him and the duke of Ormond; so that he was deprived of his presidential power in Munster, and a charge of high treason was preferred against him in parliament, but it produced no effect. He still retained the king's esteem and confidence; though he was incapable of rendering him any essential service. Accordingly he determined to spend his latter years in Ireland, and to devote himself to literary pursuits, to the improvement of his estates, to the encouragement of manufactures, and to the support of the protestant interest. He closed his life, much respected by his domestics and tenants, and generally esteemed, October 16, 1679. As a statesman and soldier the earl of Orrery appeared with singular advantage; but though he was ambitious of obtaining the reputation of a writer, and published a great number of works, in prose and verse, tragedy, comedy, and romance, &c. none of them

them have escaped oblivion. As a patron and encourager of literature, he has been mentioned with respect and applause. *Biog. Brit.*

BOYLE, ROBERT, an eminent philosopher, illustrious by birth, learning, and virtue, was the 7th son of Richard, earl of Cork; and born at Lismore in the county of Cork, February 23th, 1726-7. In his infancy he was committed to the care of a country nurse, with instructions to bring him up hardily, as if he were her own son; and he thus acquired a strong and vigorous constitution, which was afterwards enfeebled by too tender treatment. About the age of 3 years, he lost his mother, whom he mentions with great respect; and whilst he was under the care of his nurse he acquired, by imitating some children of his own age, a habit of stuttering, which was never entirely cured. In his father's house he was taught to write a fair hand, and to speak both French and Latin; and at this early period he manifested a docility and an invariable regard to truth, which very much endeared him to his father, and formed distinguishing features of his character in the progress of his life. In 1635, when he was about eight years of age, he was sent to Eton college, of which sir Henry Wotton was then provost, and placed under the care of Mr. Harrison, to whose attention and judicious mode of instruction he acknowledged himself indebted for those habits of assiduous investigation in which he afterwards excelled. At Eton he was afflicted with an ague, which rendered it advisable to divert his attention from the course of study which he was pursuing, and to allow him to seek that kind of amusement, which the perusal of romances might afford him; but though he was only 10 years old, he was sensible of the injury produced by this kind of desultory reading; and as soon as he regained his health, he sought a remedy for this evil in the severer studies of mathematics and laborious calculations. After having spent between 3 and 4 years at Eton, he was placed under private tuition for the recovery of his knowledge of the Latin language which he had nearly lost; and in 1638 he accompanied his brother Francis on his foreign travels, under the care of Mr. Marcombes. In their route they passed from Dieppe to Rouen, Paris, and Lyons, and at length settled at Geneva, where they were directed to remain and to pursue their studies. The principal objects of Mr. Boyle's attention were mathematics, in the prosecution of which he found great pleasure; but besides these, he employed himself in the study of rhetoric, logic, and political geography, and in acquiring the external accomplishments of fencing, dancing, &c. At this time some incidents happened, which concurred with his naturally serious disposition to direct his thoughts to the subject of religion; and in examining the evidences of the christian revelation, he obtained full satisfaction, notwithstanding the doubts and difficulties which had occasionally perplexed his mind; and was confirmed in his belief of its truth and importance. Having remained a year and three quarters at Geneva, he left it in September 1641, and traversing various parts of Italy and Lombardy he arrived at Venice; and from Venice he proceeded to Florence, where he spent the winter. During his residence in this city, he acquired a knowledge of the Italian language; and employed a great part of his time in reading modern history; and in acquainting himself with the new discoveries of Galileo, who died in the vicinity of Florence at the period of Mr. Boyle's abode in this city. Towards the end of March, 1642, he commenced his journey to Rome, visiting the most remarkable places in his route thither; and from Rome, where his stay was short, he returned to Florence, and from thence he passed to Leghorn, and afterwards to Genoa. Having travelled through the

country of Nice, and crossed the sea to Antibes, he proceeded to Marseilles, where he expected bills of exchange; but, to his great mortification, he found a letter from his father informing him and his brother, that the rebellion had broke out in Ireland, and that it was with considerable difficulty that he had been able to procure for them a remittance of 250l. in order to defray their expences in their return to their own country. But through the negligence of the person, to whom the remittance was entrusted, they received no part of this money, and were, therefore, left in a destitute condition. At Geneva, whither they were enabled to proceed by the assistance of Mr. Marcombes, their governor, they waited two years without receiving any supplies; and by the disposal of some jewels which they took up on his credit, as they proceeded on their journey homeward, their travelling expences were defrayed, and they arrived safe in England about the middle of the year 1644. On their arrival they received the news of their father's death; but Mr. Boyle was amply provided for by the bequest of the manor of Stalbridge in England and other estates in Ireland; and yet on account of the confusion of the times, he was for some months unable to procure any money. However he was relieved on his arrival by his sister the lady Ranelagh; and by her interest, and that of his brother lord Broghill, his English and Irish estates were secured for him. He also obtained leave to go to France; and having settled his accounts with Mr. Marcombes, he soon returned. In March, 1645, he retired to his manor of Stalbridge, and for 5 years devoted himself to various kinds of literary and scientific pursuits in this place; and more particularly to the study of natural philosophy and chemistry. During this period of retirement, when he was about 20 years of age, he commenced that extensive correspondence with the principal persons of his time, which he maintained, with distinguishing reputation to himself and benefit to the world, till near the close of his life. In the list of his first literary friends and correspondents, we may enumerate Mr. Francis Tallents, afterwards known to the world as the author of the "Chronological Tables;" Mr. Samuel Hartlib, whom he greatly esteemed, and who is mentioned with peculiar commendation by Milton in his "Tractate of Education;" Dr. William Petty; Mr. John Beale, besides many others. At this early age he manifested his zeal for religion, as well as his candour and christian charity, by favouring the designs of Mr. John Drury, for effecting a reconciliation between the Lutherans and Calvinists. He was likewise one of the first members of that learned body, which, after the restoration was incorporated under the title of the *Royal Society*. Notwithstanding the disease of the stone, with which he was afflicted, and numerous avocations which his various connections imposed upon him, his application to study was assiduous and indefatigable; and before he had attained the age of 20, he had completed three treatises, viz. "Seraphic Love," "Essay on mistaken Modesty," and "the Swearer silenced," or "Free Discourse against swearing." Mr. Boyle was distinguished as a promoter of literature and science, by his patronage of others engaged in similar pursuits, as well as by his own labour and writings. Accordingly in 1651, Dr. Nathaniel Highmore, an eminent physician, dedicated to him his "History of Generation," which was a work at that time much esteemed. Whilst he was unwearied in his chemical and philosophical inquiries and experiments, he was no less attentive to the subject of religion; and with this view he applied to the study of the scriptures in their original languages. About the year 1652 he began his "Essay on Scripture;" and he continued it during frequent interruptions, occasioned by his journeys to Ireland at this period. Ireland, however, where he spent a great part of

two years, from 1652 to 1654, did not afford favourable opportunity for prosecuting the researches to which he was devoted; and, therefore, he employed the time of his continuance there principally in anatomical dissections, with the assistance of his friend Doctor, (afterwards Sir William) Petty. Upon his return to England in 1654, he settled at Oxford, where he had the advantage of pursuing his experiments, and where he enjoyed the society of many learned friends, who occupied different situations in the university. It was during his residence at Oxford, that he invented, or rather improved, the construction of the air pump (See *AIR-pump*); an instrument, by the use of which he was enabled to perform a variety of experiments, relating to the gravity and elasticity, and other qualities, of the air, which entitled him to rank amongst the first philosophers of any age. He had at this early period of his scientific career renounced the philosophy of Aristotle, as a system of words instead of things; and attached to the only just and effectual mode of pursuing philosophical researches by experiment, and fearing lest his mind should acquire any improper bias from the ingenuity of the author, he declined the perusal of the works of Des Cartes, whose philosophy was held by many in high estimation. Mr. Boyle did not restrict himself, whilst he continued at Oxford, to the study of philosophy; but he availed himself, in the prosecution of sacred criticism, of the assistance of those great orientalis, Dr. Edward Pococke, Mr. Thomas Hyde, Mr. Samuel Clarke, and Dr. Thomas Barlow, afterwards bishop of Lincoln. His correspondence was also at the same time very extensive; and was carried on for the purpose of the promotion of science with Mr. Henry Oldenburgh, afterwards secretary to the Royal Society, Dr. John Beale, John Evelyn esq. Dr. John Pett, and Dr. John Wallis, who honoured him with the dedication of his excellent treatise "*De Cycloide, et corporibus inde genitis.*"

In 1659, as soon as he was made acquainted with the distressed circumstances of Dr. Robert Sanderson, afterwards bishop of Lincoln, who had been deprived of his preferments on account of his attachment to the royal cause, he settled upon him an annuity of fifty pounds a year; a favour which was respectfully acknowledged by the doctor in his dedication of "*Ten lectures on cases of conscience,*" delivered in Latin in 1647, and printed at Oxford in 1659.

After the restoration in 1660, Mr. Boyle was treated with great respect by the king, and also by the lord-treasurer, lord Southampton, and lord-chancellor Clarendon; and by the latter he was urged to enter into holy orders. Having considered the proposal with due attention, his pious scruples determined him to decline the clerical office. In this year he published his "*New experiments touching the spring of the air;*" which involved him in a controversy with Francisus Linus and Mr. Thomas Hobbes, and to which he annexed a defence in the edition of 1662; and also his discourse "*On seraphic love.*" Mr. Boyle's reputation had at this time extended itself to foreign countries; so that the grand duke of Tuscany communicated to him by Mr. Southwell, then resident at Florence, his wish to correspond with him on philosophical subjects. In 1661 he published his "*Physiological essays, and other tracts;*" and soon afterwards his "*Sceptical chymist.*" Other treatises, to which he refers in this publication, and which were in great forwardness, were unfortunately lost at the time of the great fire of London. In 1662, a grant of the forfeited impropriations in Ireland was obtained from the king in his name, but without his knowledge; and they were applied by him to the promotion of religion and learning. He was also appointed governor of the corporation for propagating the gospel in New England; and in this office he was active and

successful in restoring an estate, of which they had been deprived by col. Bedingfield, a papist, although they had given him for it a valuable consideration. In the conduct of the concerns of this institution he was, in other respects, eminently useful. When the royal society was incorporated in 1662, Mr. Boyle was appointed one of the council; and as he may justly be regarded as one of the founders of this society, he continued through life one of its most useful and industrious members. In the following year he published his "*Considerations on the usefulness of experimental philosophy;*" his "*Experiments and considerations upon colours,*" with "*Observations on a diamond that shines in the dark;*" and "*Considerations on the style of the holy scripture,*" extracted from a larger work, entitled "*An essay on scripture,*" published after his death by Mr. Peter Pett, attorney-general for Ireland. In 1664, Mr. Boyle was elected into the company of royal miners; this new connection, and other engagements of a benevolent and public nature, prevented his publishing any treatises, either on religion or philosophy, in this year. But the year 1665 produced his "*Occasional reflections on several subjects;*" to which is prefixed, "*A discourse concerning the nature and use of such kind of writings.*" This piece, which had been written by Mr. Boyle in his youth, and at various intervals, was ludicrously attacked by Dr. Swift in his "*Pious meditations upon a broomstick,*" in the style of the honourable Robert Boyle." How far Mr. Boyle possessed in his youth, or acquired in his maturer years, a correct taste and style of writing, particularly in works of imagination, it is now needless to inquire; it is sufficient to observe, that no attack on the part of Dr. Swift can affect the fame of this distinguished person, either as a man or a philosopher. In this year Mr. Boyle, besides some communications to the Royal Society, printed in the *Philosophical Transactions*, published "*Experiments and observations relative to an experimental history of cold, with several pieces thereunto annexed;*" a work well received at the time, and containing a variety of observations and facts that have been useful to those who, in more modern times, have directed their attention to this interesting subject. Towards the close of this year, his majesty appointed Mr. Boyle provost of Eton college; but he declined accepting this honourable and lucrative office, because he did not wish his studies to be interrupted, and because he thought it more suitable to a person in holy orders.

About this time Mr. Valentine Greatraks, an Irish gentleman of good family and competent fortune, and of a serious disposition inclining to melancholy, persuaded himself that he possessed the power of curing diseases by stroaking. In some cases he succeeded, but in others he failed. His performances, however, were so extraordinary, that they excited very general attention; and an account of them was published, by Mr. Henry Stubbs, in a letter entitled "*The miraculous conformill, &c.*" and addressed to Mr. Boyle. To this letter Mr. Boyle replied; but his answer was not published till eighty years afterwards, in Dr. Birch's account of his life. Nevertheless, the sentiments and reflections contained in it were probably communicated to his friends; and though they were expressed with a caution, candour, and judgment, that did him great honour, they were thought to countenance what some persons deemed a deception, or the mere effects of enthusiasm, and they produced a controversy of some continuance. As far as Mr. Boyle was concerned in this business, it will be sufficient to observe, that, firmly believing the actual exercise of those miraculous powers which attested the truth and divine origin of christianity, and admitting, in consequence of the extent and variety of his

researches into the operations of nature, the reality of facts, which he could not immediately reconcile by analogy to the small aggregate of human acquisition, the letter, hastily written by him in reply to Mr. Stubbs, did not at all derogate from his character as a philosopher, or as a man of rational piety. He neither denied nor admitted the existence of the miraculous power ascribed to Mr. Greatraks; but allowing the facts, he proposed a variety of inferences and queries, which demanded discussion; and in the whole of this controversy he conducted himself in such a manner as to avoid personal censure from any of the disputants. See *STROASING*.

In 1660 Dr. Wallis addressed to Mr. Boyle "An hypothesis about the flux and reflux of the sea," printed in N° xvi. of the Philosophical Transactions; and Dr. Sydenham dedicated to him his "Methodus curandi febres, probris observationibus superstructa." His own publications in this year were "Hydrostatical paradoxes;" "The origin of forms and qualities, according to the corpuscular philosophy, illustrated by experiments;" and several papers communicated to the Royal Society, and printed in the Philosophical Transactions of that period. In the dispute that occurred in the establishment of the Royal Society between the adherents to the Aristotelian or old philosophy, and the advocates for the new method of philosophizing by experiments, Mr. Boyle took a decided part with the latter; but without incurring censure or reproach from the most violent of the opposite party. About this time Mr. Boyle removed to London, where he afterwards resided, very much to the advantage of the Royal Society, which he countenanced by his personal presence and philosophical communications; as well as of the cause of science in general.

In 1669, he published his "Continuation of new experiments touching the weight and spring of the air," to which he annexed "A discourse of the atmospheres of consistent bodies;" and also "A discourse of absolute rest in bodies;" together with other hydrostatical pieces subjoined to his larger works: and in the same year he revised several of his former tracts, which had been translated into Latin for the benefit of foreigners. In the following year appeared his treatise "Of the cosmical qualities of things," containing a variety of interesting facts and observations; and several papers, communicated to the Royal Society. At this time his studies were interrupted by a stroke of the palsy, the effects of which were removed by a strict attention to a proper regimen; so that he soon returned to his labours. In 1671, he published a second volume of "Considerations touching the usefulness of experimental philosophy," and "Tracts of a discovery of the admirable rarefaction of the air, &c.;" and in 1672 appeared his "Essay concerning the origin and virtue of gems," 8vo.; his "Tracts, containing new experiments touching the relation between flame and air, and various other interesting subjects chiefly relating to the statical action of fluids;" and, in the Philosophical Transactions, "Observations on shining flesh," and a paper on the effects of the varying pressure of air. In 1673 he published "Essays on the strange subtlety, great efficacy, and determinate nature, of effluvioms;" "Experiments on the weighing and coercion of fire and flame," 8vo.; and "A letter concerning ambergris," communicated to the Royal Society. In 1674 appeared a collection of "Tracts on the saltness of the sea; on a statical hygroscope; on the natural and preternatural state of bodies, and on the positive or privative nature of cold," 8vo.; "The excellency of theology compared with natural philosophy," 8vo.; "Tracts, containing suspicions about the hidden qualities of the air: animadversions upon Hobbes's problem concerning a va-

enum; and a discourse of the cause of attraction by friction," 8vo.; and in this year he communicated to the editor of the Philosophical Transactions, "An account of the two sorts of Helmontian laudanum." In 1675 he published "Some considerations about the reconcileableness of reason and religion," by T. E. a layman; to which is annexed, by the publisher, "A discourse of Mr. Boyle about the possibility of the resurrection," 8vo. T. E. are supposed to be the final letters of his own name, as both these tracts are ascribed to him. In this year he communicated to the Royal Society four papers, which appear in the Transactions: "On the air-bladders of fishes;" "A new essay instrument;" "New experiments touching the spring of the air, &c.;" and "An experimental discourse of quicksilver growing hot with gold." In 1676 he published "Experiments and notes about the mechanical origin of particular qualities," in which he treats of alkalis and acids, heat and cold, tastes, odours, volatility, fixity, corrosive action, precipitation, magnetism, and electricity; and he also communicated to the Royal Society two papers on the configuration of the surfaces of fluids in contact with each other.

Mr. Boyle, having been for several years an active and useful director of the East-India company, wished to avail himself of his office for propagating the gospel in those remote parts to which their commerce extended: and with this view he caused 500 copies of the four gospels and acts of the apostles to be printed at Oxford, in the Malayan tongue, under the direction of Dr. Thomas Hyde, and to be sent abroad at his own expence. For similar purposes of piety and benevolence, he had transmitted, about three years before, several copies of Grotius's treatise "De veritate Christianæ religionis," translated into Arabic by Dr. Edward Pococke, into the Levant.

In 1677 a miscellaneous collection of his works, defective, and badly arranged, was printed in Latin at Geneva. In the following year he communicated to Mr. Hook a "Short memorial of some observations made upon an artificial substance that shines without any preceding illustration," which was published in that philosopher's "Cutlerian lectures:" this substance was the phosphorus of urine. In this year he also published his "Historical narrative of a degradation of gold made by an anti-elixir," 4to.; and he received a tribute of singular respect, in a letter from the great Newton, laying before him his sentiments concerning an ethereal medium, which he afterwards proposed, in his Optics, as the mechanical cause of gravitation. In the year 1680, he published "The aerial noctiluca," 8vo.; and "An account of a new lamp," in Hook's Philosophical Collections; and he improved the second edition of his "Sceptical Chymist." Some persons have very unwarrantably asserted, that Mr. Boyle assumed to himself the invention of phosphorus, after having purchased the secret of Kraft. This calumny is refuted by his own narrative, in which he discusses the claims of Brand, Kunckel, and Kraft, and acknowledges the advantage which he derived, in the prosecution of his inquiries, from the information communicated to him by the latter, that the shining substance was obtained from a matter belonging to the human body. From the narrative it appears, that the aerial noctiluca was an aqueous solution, or diffusion of phosphorus, obtained by distillation from putrid urine in an experiment where his retort failed; and which did not prove altogether successful. At the annual election of officers for this year, Mr. Boyle was elected president of the Royal Society; but having objections of delicacy with regard to the official oaths that are required, and for some other reasons, he declined accepting the honour. At this  
time

time he contributed very liberally to the publication of Burnet's History of the Reformation, as the author acknowledges in his preface to the second volume. It was probably about the beginning of the year 1681, that he exerted himself for promoting the propagation of the gospel among the Indians; as his letter on this subject was a reply to one from Mr. John Elliot, of New England, dated Nov. 4, 1680. From this letter, which is preserved by Dr. Birch, it appears that he was a declared enemy to persecution on account of religious opinions. In this year (1681) he published his "Discourse of things above reason;" and in the following year, "New experiments and observations made upon the icy noctiluea," 8vo.; and also a "Continuation of new experiments physico-mechanical, touching the spring and weight of the air, with a large appendix." It appears that his icy noctiluea was the solid phosphorus, which at first he found some difficulty in making; but from a paper left with the secretary of the Royal Society, to be opened after his death, which was nevertheless communicated to his friend Dr. Beale during his life, we find that he evaporated urine by distillation till it acquired the consistence of syrup, then mixed it with siliceous sand, and distilled by a strong heat into a reservoir containing water. See PHOSPHORUS. In 1683 he wrote a letter, sanctioning and encouraging an undertaking of Mr. Fitzgerald for rendering sea-water fresh; and in the following year, he published his "Natural history of human blood," and his "Experiments and considerations about the porosity of bodies," both in 8vo. From a letter addressed to Mr. Boyle in 1684 by the learned Dr. Cudworth, it appears how highly he appreciated his talents and labours. After recommending a collection of his several treatises, he concludes in these terms: "You have much outdone Sir Francis Bacon in your natural experiments; and you have not insinuated any thing, as he is thought to have done, tending to irreligion, but the contrary." The year 1685 produced his "Short memoirs for the natural experimental history of mineral waters," and an "Essay on the great effects of even languid and unheeded motion;" to which is annexed an "Experimental discourse of some hitherto little regarded causes of the salubrity and insalubrity of the air," 8vo. In the course of that year appeared in the Philosophical Transactions, "An account of a strangely self-moving liquor," which was a compound of oils and bitumens, the ingredients of which, though known to himself, he has not specified: and also a distinct treatise "On the reconcileableness of specific medicines to the corpuscular philosophy, to which is annexed, a discourse about the advantages of simple medicines," 8vo. Besides these philosophical tracts, he presented the world in this year with a theological treatise, entitled, "Of the high veneration man's intellect owes to God, particularly for his wisdom and power," 8vo. The only work that appeared in 1686, was his "Free inquiry into the vulgar and received notion of nature." This treatise was much admired by the advocates for pure religion and sound philosophy; it was translated into Latin, and reprinted in the following year in 12mo. In this year, 1687, he published a work, written in his youth, entitled "The martyrdom of Theodora and Dydimia," and five decades of "Choice remedies," to which when the work was reprinted in 1692, five more were added. In 1688 appeared "A disquisition about the final causes of natural things; wherein it is inquired whether, and if at all, with what caution, a naturalist should admit them; to which was subjoined, by way of appendix, "Some uncommon observations about vitiated light." About the beginning of this year our author found it expedient to apprise the public, by way of preface to his mutilated and

unfinished writings, and as a general apology for the state in which they appeared, that some of his papers had been stolen from him, and that others had been destroyed by corrosive liquors. The decay of his health, and the derangement of his affairs in Ireland, obliged him to diminish the number of his communications to the Royal Society, and induced him to resign the office of governor of the corporation for propagating the gospel in New England. From other arrangements with regard to his private affairs, his papers, and the number of visits which he received, it appeared that he was not without apprehensions of an approaching change. The time, however, which he thus reserved to himself, he industriously improved; as he availed himself of it for collecting various elaborate processes in chemistry; which, as we are informed in a letter preserved by Dr. Birch, "he left as a kind of hermetic legacy to the studious disciples of that art." This collection he committed to the care of a friend, enjoining him to impart it to the public faithfully, and without envy, verbatim in his own expressions. This friend is unknown, and the work was never published. From many circumstances, however, we are led to conclude, that Mr. Boyle concurred, with many other ingenious alchemists of the age in which he lived, in believing, what is now rejected as a groundless opinion, the possibility of transmuting the baser metals into gold; and hence, probably, he was led to take pains in procuring, in 1689, the repeal of the statute of the 5th of Henry IV. against the multiplying of gold and silver.

In 1690, he published his "Medicina hydrostatica, or hydrostatics applied to the materia medica," 8vo. with the promise of a second volume, which never appeared; and "The christian virtuoso, shewing, that by being addicted to experimental philosophy, a man is rather assisted, than indisposed to be a good christian;" a second part of which was published in an imperfect state, after his death. In 1691, he communicated to M. de la Croze, "An account of some observations made in the great congregation of waters, by lowering down bottles into the sea 600 feet from the surface," which was printed by that author in the "History of learning." Mr. Boyle's last work, published by himself, was his "Experimenta et observationes physicae;" to which is added "A small collection of strange reports," 8vo.

In July of this year, Mr. Boyle executed his last will, and in the succeeding months his health rapidly declined. On the 23d of December, he lost his sister, lady Ranelagh, to whom he was affectionately attached, and within a week afterwards, viz. on the 30th of December, 1691, he departed this life, in the 65th year of his age, and was interred at the upper end of the south side of the chancel of St. Martin's in the fields, near the remains of his sister, with whom he had lived for the greatest part of 47 years. His funeral sermon was preached by Dr. Burnet, bishop of Salisbury.

Mr. Boyle's posthumous works are as follow: 1. "The general history of the air, designed and begun," 1692, 4to.; 2. "Medicinal experiments, or a collection of choice remedies, for the most part simple, and easily prepared," 1692, 12mo; 3. "General heads for the natural history of a country, great or small, drawn out for the use of travellers and navigators," 1692, 12mo.; 4. "A paper of the honourable Robert Boyle's, deposited with the secretaries of the Royal Society, Oct. 14, 1680, and opened since his death; being an account of his making the phosphorus, &c. Sept. 30, 1680;" 5. "An account of a way of examining waters, as to freshness or saltness;" 6. "A free discourse against customary swearing, and a dissuative from cursing;" 1695, 8vo. 7. "Medicinal experiments, or a

collection of choice remedies, chiefly simple and easily prepared, used in families, and fit for the service of the country people;" the 3d and last volume published from the author's original MSS. A collection of all Mr. Boyle's works was published in 1744, in 6 volumes folio, with a life prefixed, by Dr. Birch; and in 6 vols. 4to. in 1772.

Mr. Boyle, as to his person, was tall and slender, and of a pale and emaciated countenance. His constitution was so delicate, that he regulated his cloathing by a thermometer: and he was occasionally subject to such debility of body, such painful paroxysms of the stone, and such depression of spirits, that we may be well astonished at the number and variety of his scientific and literary performances. However, to the simplicity of his diet, and the strict temperance which he observed, we may reasonably ascribe the degree of health which he enjoyed, and the length to which his life was protracted. His speech was slow and deliberate, and subject to hesitation; in his conversation he was unassuming, never dictating his own opinions, or urging his objections to those of others with confidence, but rather proposing them as topics of inquiry and discussion; and in his manners he was singularly mild and courteous. Although he was a favourite at court, and indulged in free intercourse with three successive sovereigns, viz. Charles II. James II. and William III., he never disguised his sentiments with regard to public men and measures; but he took no active part in the politics of the eventful times in which he lived, preferring the pursuits of philosophy, and the retirement which best suited his infirm frame and religious temper. To the rank of a peerage he never aspired, but refused it whenever it was offered to him. One of the most prominent features of his character, was his sincere and unaffected piety. This was exemplified in all his writings, and in the whole course of his life. Of his firm attachment to Christianity, and of his solicitude for vindicating its truth, and extending the knowledge and influence of it, he exhibited many substantial proofs, both whilst he lived, and at his death. Besides the translation of the gospels and book of acts into the Malayan language, and of Grotius's treatise concerning the truth of the Christian religion into Arabic, which we have already mentioned, and which was conducted at his own expence, he proposed an impression of the New Testament in the Turkish language; and when the Turkey company undertook it, he liberally contributed towards accomplishing it. A translation and edition of the Bible in the Irish language cost him 700l.; and he defrayed a considerable part of the charge attending an impression of the Welsh Bible, and of the Irish Bible for Scotland. He gave, during his life, 300l. towards propagating the Christian religion in America; and as soon as he heard that the East India company were projecting a similar design in the East, he sent a donation of 100l. by way of example and encouragement in the prosecution of the scheme. Of the impropriations belonging to his estates he ordered considerable sums to be given to the incumbents in these parishes, and even to the widows of those who had died before this distribution of his bounty. This he did twice during his life to the amount of 600l., and he ordered another distribution as far as his estate would bear, by his will. In other respects, his charities were so numerous and extensive, that they amounted, as bishop Burnet informs us, from his own knowledge, to upwards of 1000l. per annum. The annuity established by his will for providing a series of lectures in defence of Christianity, affords further evidence of the benevolence of his temper, and of his concern for promoting the interests of religion. See *BOYLE'S Lectures*. His zeal in the cause of religion, though it was

ardent and active, was free from the least tincture of bigotry and intolerance. Whilst he adhered to the established church, he entertained the most undissembled charity towards all who differed from him in opinion: nor did he ever express himself in stronger terms, and with a greater degree of indignation, than when he condemned every kind of severity and persecution in the province of religion. Burnet in his funeral eulogy informs us, that his knowledge comprehended Hebrew and the other Oriental languages, the writings of the most eminent fathers, commentaries on the scriptures, religious controversies, and the whole body of divinity. He represents him as being acquainted with the whole compass of the mathematical sciences, and as well versed even in the most abstruse parts of geometry. Geography, navigation, and books of travels he had recourse to for the relaxation of his mind, and the amusement of his intervals of leisure. Of his knowledge with regard to subjects of natural history, chemistry, and experimental philosophy, his various researches and discoveries, recorded in his numerous publications already recited, afford ample evidence. Mr. Boyle, indeed, possessed in an eminent degree those qualities, which justify his being ranked among the first philosophers of any age or country. He was distinguished by the comprehension of his views, and the extent and variety of his researches, by indefatigable diligence and invincible perseverance in his collection of facts and investigation of their causes, by a total freedom from any preconceived attachment to theories and systems, by candour in discussing the opinions of others, and by fidelity, modesty and perspicuity in the narration of his own performances. Mr. John Hughes might well say of him (*Spectator* N<sup>o</sup> 554), after observing that he was born the same year in which lord Bacon died, that he was the person designed by nature to succeed to the labours and inquiries of that extraordinary genius. It would be endless to recount the testimonies in commendation of him, that might be collected from the writings of the most illustrious foreigners, and of the best judges of his merit in our own country. It will be sufficient to say, that he is uniformly ranked with Bacon and Newton; that his researches and experiments have led the way to many modern discoveries, both in philosophy and chemistry: and that his writings will ever be held in high estimation by every friend of science. "They cannot be read," says one of his biographers, "without improvement; and in these alone, if no life of Boyle had ever been written, the reader would behold a man truly deserving of the affection, the esteem, and the admiration of succeeding ages." Boyle's account of himself, under the name of Philocetus. Birch's life of Boyle, prefixed to his works. Burnet's funeral sermon. *Biog. Brit.* Birch's *Hist. of the Royal Society*. *Phil. Transf.*

*BOYLE, CHARLES*, fourth earl of Orrery, and baron Marlton in England, was the second son of Roger, second earl of Orrery, and was born at Chelsea in 1676. At the age of 15 he was entered at Christ-church college in the university of Oxford, where his tutors were Dr. Atterbury, afterwards bishop of Rochester, and Dr. Freind. His application and proficiency were so distinguished, that he was styled by Dr. Aldrich, the dean, "the great ornament of our college," and deputed to prepare an edition of some classic author, for his annual publication. The book recommended by the dean was the "epistles of Phalaris," of which a splendid edition appeared in 1695. This publication gave rise to a controversy, the particulars of which have been already detailed under the article *Bentley*. We shall here add, that from a letter of bishop Atterbury to Mr. Boyle, written in 1698, (see *Epistolary Correspondence*,

ence, &c. published by Mr. Nichols, vol. ii.) it appears, that the former laid the design of the celebrated book, in answer to Bentley's dissertation, wrote above half of it, revised a good part of the rest, and transferred the whole. Upon the death of his father, Mr. Boyle quitted the university and entered into public life. He was chosen as a member of the house of commons in 1700; and when his brother Lionel died in 1703, he succeeded to the title of the earl of Orrery. For his services in the army, he was elected, in 1705, one of the knights' companions of the most ancient order of the thistle; and as a major-general, to which rank he was advanced in 1709, he distinguished himself at the battle of the Wood in Flanders. He afterwards resided for some time at Brussels, as the queen's envoy to the states of Brabant and Flanders: and for his faithful discharge of this trust, he was raised to the dignity of a British peer. On the accession of George I. he received additional honours; but during the absence of the king at Hanover in 1716, his regiment was taken from him: upon which he resigned his post of lord of the bed-chamber, and withdrew from public affairs. When Layer's plot broke out, he was suspected by the government, and committed to the tower, whence, after being confined 6 months, he was first liberated by bail, and at length discharged. From this time he amused himself with his library and philosophical apparatus, till his death, which happened in August 1731. He was much esteemed for his domestic and social qualities; and respected for his talents and literary attainments. He was the author of a comedy, entitled "As you find it," and also of some songs and occasional poems; but his favourite studies were of a different kind. The astronomical instrument called an "orrery," and first invented by Rowley, whom he patronized, derived its name from his title. See ORRERY. Biog. Brit.

BOYLE, JOHN, earl of Cork and Orrery, only son of Charles, fourth earl of Orrery, by lady Cecil, daughter of the earl of Exeter, was born in 1707, and for his early education entrusted to the care of Mr. Fenton, the poet. From Westminster school, whither he had been sent at a proper age, he removed to Christ-church college, Oxford. As an instance of his filial piety, which does him honour, it is related, that when his father was committed to the Tower, he earnestly intreated to be confined with him; but this indulgence was refused. Soon after the completion of his 21st year, in 1728, he married lady Harriet Hamilton, the youngest daughter of George, earl of Orkney. A dissension which occurred between the two earls produced a temporary misunderstanding between the earl of Orrery and his son. This misunderstanding is said to have originated in lord Boyle's refusal to suffer his wife to sit at table with his father's mistresses. However this be, the son's conduct on the occasion, and in a situation peculiarly delicate and trying, reflected great honour on his judgment and temper. Although a reconciliation had been effected between the father and the son, yet the latter found reason to regret their dissension: for under the influence of a prejudice hastily conceived, the earl had made his will, and bequeathed his valuable library, consisting of above 10,000 volumes, with the exception of the journals of the house of peers, and books relating to the English history and constitution, bequeathed to his son, and a fine collection of philosophical instruments, to the college of Christ-church. After their reconciliation, he determined to alter his will, and had sent for his attorney with this view; but the suddenness of his decease prevented the execution of his just design. The young lord, however, behaved on the occasion with a filial piety and generosity, which entail singular honour on his memory. For though his father had

died considerably in debt, and had left legacies to a large amount to persons who were no relations, he took his debts upon himself, paid the legacies, and sent the books and mathematical instruments, within the limited time, to Christ-church. The loss of his father, aggravated by the circumstances now recited, made a deep impression upon his mind, and was succeeded by a fit of illness, which endangered his life. Of the acuteness of his feelings we may form some judgment by the following lines addressed to a friend, in return for a consolatory letter received by him at Bath, and enclosing a copy of verses, which exhorted him to dispel his grief by poetry, and to shew that Bath could inspire as well as Tunbridge, where, in the preceding year, he had written some humorous verses.

"Nor Bath, nor Tunbridge, can my lays inspire,  
Nor radiant beauty make me strike the lyre;  
Far from the busy crowd I sit forlorn,  
And sigh in secret, and in silence mourn:  
Nor of my anguish ever find an end;  
I weep a father, but I've lost a friend."

Upon the recovery of his health and spirits, he took his seat in the house of peers in January 1732, and distinguished himself by his opposition to sir Robert Walpole's administration, and particularly by his speech against the mutiny bill, and a standing army, which was much applauded. However, the delicacy of his health, his love of retirement, and the necessity of occasional residence in Ireland, precluded him from a regular attendance on his parliamentary duty. During his residence in Ireland, he became acquainted with dean Swift, who professed a high regard for him, and introduced him to the friendship of Mr. Pope. Upon his return to England, in 1733, he retired to his seat at Marlton in Somersetshire, and amused himself in building, planting, and improving both his estate and his library. In 1737 he took a house in town, for the convenience of superintending the education of his sons at Westminster school. Having lost his first lady in 1732, he married a second wife in 1738; and with both he enjoyed the most uninterrupted state of domestic felicity. In 1739 he published a new edition, in 2 volumes 8vo. of the dramatic works of his great grandfather, Roger, earl of Orrery, and, in 1742, his state letters in one volume folio. The first of his own performances, which was *Imitations of the first and fifth odes of the first book of Horace*, with remarks on the peculiar excellencies of this poet, and on the translations of Dacier and Sanadon, appeared in 1741, fol. In 1743 his lordship was presented, by the university of Oxford, with the honorary degree of doctor of civil law, and he was likewise elected a fellow of the Royal Society. In 1746 he removed to Caledon in Ireland, where he resided, with little intermission, till the year 1750; employing his intervals of leisure in laying out gardens and plantations, and in various substantial and ornamental improvements. On his return to Marlton, he pursued those alterations and improvements which he had begun at a former period. In the mean while, the employment of his winter-evenings was his "Translation of the Letters of Pliny the Younger, with observations on each letter, and an essay on Pliny's life," which was published at London in 1751, in 2 volumes 4to. and since reprinted in 8vo. This work was well received, and established the reputation of the author as a polite scholar; and it would have still retained its character as a standard work of the kind, if it had not suffered by the superior elegance of Mr. Melmoth's translation. In the same year appeared his "Remarks on the life and writings of Dr. Swift;" in a series of Letters addressed to his second son; which, abounding with popular anecdotes, met with a very rapid sale, though it gave occasion to many strictures and attacks, on

account of the freedom with which it represented the defects as well as the excellencies of the character of his old friend. The portrait it exhibits is, however, deemed more faithful than several others of a more flattering kind. In 1753 lord Orrery succeeded to the Irish titles of Richard the third earl of Burlington and fourth earl of Cork, who died without male issue. His lordship continued to amuse himself and the world by occasional writings; and communicated several papers, chiefly of the humorous kind, to the periodical publications, entitled, "The World," and "The Connoisseur;" the former conducted by Mr. Moore, and the latter by Mr. Norton and Mr. Colman. In 1754, he set out on a tour to Italy, and resided nearly a year at Florence, where he acquired universal esteem, and where he collected materials for his history of Tuscany, which he proposed to publish in a series of letters; but of these he only finished twelve, which were published after his death in 1774. From Italy he returned to Marston in 1755; but the last years of his life were rendered peculiarly distressing to him by the loss of his wife and his eldest son, and by frequent and severe paroxysms of the gout. These trials, however, he bore with a fortitude and resignation which did honour to his principles and character, both as a philosopher and a Christian. In his distress he sought refuge, like Pliny, in his studies; and amused himself by publishing, in 1759, from an original MS. "Memoirs of the life of Robert Cary, earl of Mountmouth," with a preface, explanatory notes, and a tender dedication to his youngest son. He also, in the same year, wrote a preface to Mrs. Lennox's translation of Brumoy's Greek theatre; and he translated "The Discourse upon the theatre of the Greeks," "The original of tragedy," and "The parallel of the theatres." Some smaller pieces, written by his lordship, are dispersed in the periodical publications of his time. His last work, which was posthumous, is his "Letters from Italy," written in the years 1754 and 1755, and published in 1774, by the Rev. John Duncombe, who hath prefixed a life of his lordship. In his last illness he is said to have burnt many MSS. and, among them, the continuation of his letters from Italy, on account of their not being corrected and fairly transcribed. It is also apprehended, that his Florentine history underwent the same fate. At length this truly accomplished and amiable nobleman fell a sacrifice to an hereditary gout, at a comparatively early period, in November 1762, in the 56th year of his age; and his remains were interred near to those of his second lady, in the burial-place of his family in Frome church. He was succeeded as earl of Cork and Orrery by Hamilton, his second son by his first countess; and on his death the titles and estate of the family devolved on Edmund, his son by his second lady, who became the seventh earl of Cork and Orrery.

From the tribute of just respect paid to his memory by the writer of his life, we learn, among other particulars, that "in every domestic and social relation, in all the endearing connections of life, as a husband, a father, a friend, a master, he had few equals. The lustre which he received from rank and title, and from the personal merit of his family, he reflected back, unimpaired and undiminished; and though the post of honour, which he chose and preferred, was "a private station;" though he was neither a statesman nor a soldier, like the first lord Cork, the first lord Orrery, and his own father; the rival of Pailadio, like the late lord Burlington; or the rival of Bacon, like Mr. Robert Boyle; yet, in a general taste for literature, and, as they are commonly called, polite studies, he was by no means inferior to his ancestors."—"He loved truth even to a degree of adoration. He was a real Christian; and, as such, constantly hoped for a better life; there trusting to know the real causes of those effects, which

here struck him with wonder, but not with doubt." Mr. Duncombe proceeds to exhibit, in several instances, the striking resemblance between the earl of Orrery and Pliny, his favourite Roman. With regard to religion, his sentiments were rational, and his moral conduct as irreproachable and exemplary, as his manners were elegant and accomplished. His political principles were those of a disinterested patriot, and an ardent lover of liberty. His sentiments and feelings on this latter subject are admirably displayed in the following lines, extracted from one of his pieces annexed to his "Translation of Pliny," and expressing the love of Britons for liberty:—

"With native freedom, as with courage blest,  
Chains, and each mark of thralldom we detest.  
'Tis heaven's high gift, 'tis nature's great decree.  
That none be slaves, whom God himself made free.  
Revere we ought those powers which we entrust,  
But to ourselves be resolutely just:  
Scorn base corruption, nor, like slaves, disown  
The laws that fix'd our monarch in his throne:  
For well we know, by Truth's eternal rules,  
Where slaves are subjects, subjects must be fools.  
Exert but reason, liberty will reign,  
And tyranny exalt her impious head in vain."

Biog. Brit.

BOYLE, in *Geography*, a market and post town of the county of Roscommon, and province of Connaught, Ireland, sometimes, but improperly, called *Abbey-Boyle*. It is situated on the river Boyle over which it has two stone bridges. In 1786, it contained about 200 families, and has probably increased; its linen markets having of late become considerable from the improved state of the yarn and linen manufactures in its neighbourhood. This town had a castle, which was of great strength, having held out during the civil war of 1641. It was one of the new corporations in the reign of James I. and continued to send two members to parliament until the act of union deprived it of that privilege. In the neighbourhood, and at present inclosed within the demesne of lord Kingston, is the ruin of the abbey of Boyle, finely situated near Lough Key, from which the town derived its name, and probably its existence. It belonged to the Cistercian monks, and was founded in 1161, after three or four other places had been tried, and not found sufficiently agreeable. The monastic records mention several noble converts who took the habit of the order, and probably enriched it with considerable benefactions; and they also mention some instances of sacrilegious plunder, in the wars which for so long a time distracted Ireland. When the dissolution took place, the property of the abbey was found to be very considerable, and was granted to sir John King ancestor of the earl of Kingston, by James I. in 1603, in reward of his services. The remains of this ancient erection are sufficient to shew its former magnificence, and deserve the attention of the antiquarian. The architecture is Gothic, and the arches are esteemed for their noble elevation and grandeur; and are of so firm a texture as to have withstood the severest shocks. Boyle is 84 miles N. W. of Dublin. N. lat. 53° 58'. W. long. 8° 13'. Beaumont—Monasticon Hibernicum.

BOYLE, or BUELLE, the name of a river which, rising in the county of Mayo, flows into a romantic sheet of water called Lough Gaza; thence meandering through woods and dales, it enters Lough Kee, or Kingston lake, a beautiful piece of water, interspersed with several islands, some of which are adorned with old castles and ruins; others in the state of nature, wooded with lofty timber trees; and some highly improved without a tree to be seen, but the

more

more pleasing prospect of everlasting verdure. The river again emerges out of the eallern side of this lake, as it were by constraint, and then glides on to pay its tribute to the Shannon, which it joins a little above Carrick.

BOYLE'S *Lectures*, a course of eight sermons or lectures, preached annually, set on foot by the honourable Robert Boyle, esq. by a codicil annexed to his will in 1691; the design of which, as expressed by the institutor, is, to prove the truth of the Christian religion against infidels, without descending to any controversies among Christians; and to answer new difficulties, scruples, &c.

For the support of this lecture, he assigned the rent of his house in Crooked-lane to some learned divine within the bills of mortality, to be elected for a term not exceeding three years, by the late archbishop Tennison, and others. But the fund proving precarious, the salary was ill paid: to remedy which inconvenience, the said archbishop procured a yearly stipend of 50 pounds, for ever, to be paid quarterly; charged on a farm in the parish of Brill, in the county of Bucks.

To this appointment we are indebted for many elaborate defences both of natural and revealed religion. A collection of these sermons from the year 1691, to 1732, was printed in 1739, under the title of "A defence of natural and revealed religion," in 3 vols. fol.; and those of several of the preachers have been printed and published in distinct volumes. An abridgment of these lectures in 4 vols. 8vo. was published by the Rev. Mr. Gilbert Burnet, vicar of Coggeshall, in Essex, who died in 1746.

BOYLING. See BOILING, and EBULLITION

BOYLSTON, in *Geography*, a township of Worcester county, in the state of Massachusetts, America, 10 miles N. E. of Worcester, and 45 N. W. of Boston. It was incorporated in 1786, and contains by survey 14,356 acres of land, of rich soil and well watered, and 839 inhabitants.

BOYNE, the name of a considerable river in Ireland, supposed to be the *Bubinda* of Ptolemy. It takes its rise in the bog of Allen, in the county of Kildare, and having separated that county from the King's county, and the southern part of Meath for several miles, it enters the latter county at Clonard, and flowing N. W. divides it nearly into two equal parts, forming the general civil division of the county, and constituting a boundary to every barony touching its banks. The scenery of this river has been much celebrated, and there are few situations adapted to the purpose of mill machinery that are not occupied. In its course within the county of Meath alone, there are six extensive bowling mills, besides several grist and cloth mills; and one for the manufactory of cotton was erecting in 1802. The Boyne navigation, between Drogheda and Navan, runs along the course of the river, and has considerably increased the trade of both those towns. At Navan, it receives the Blackwater, and having passed by Slaine and Drogheda, it flows into the Irish sea, a few miles below the latter town, to which it is navigable. The fishery of this river is valuable, and the salmon in particular is highly esteemed. The Boyne, however, is not so noted for any circumstance as for the victory gained by William III. over that infatuated prince James II. on the 1st of July, 1690. The place where the battle was fought is between Drogheda and Slaine, and is marked out by an obelisk, founded on a rock, which rises boldly from the river. The advantage of situation was in favour of James's army; and if he had not himself fled before the battle was decided, the event might have been very different. The brave duke Schomberg lost his life on this occasion, and William was

often in great danger. It was long customary to celebrate the anniversary of the day on which this battle was gained; but as it served no purpose but that of perpetuating party animosity, the observance begins to be neglected; and it is to be hoped that the different sects will become so united in attachment to their common country, as almost to forget that they were ever enemies. Thomson's Meath, &c.

BOYSE, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Pithiviers; 2 leagues S. E. of Pithiviers, and 7 N. E. of Orleans.

BOYSE, or BOIS, JOHN, in *Biography*. See BOIS.

BOYSE, JOSEPH, a protestant dissenting minister, was born at Leeds, in Yorkshire, in January, 1659-60. After early instruction under the care of his parents, he received the first part of his education for the ministry at the private academy of the Rev. Mr. Frankland, near Kendal, in Westmorland, and completed it under the tuition of the Rev. Mr. Edward Veal, who kept a private academy at Stepney, near London. Having continued in these seminaries five years, and availed himself of the opportunities which he enjoyed in the latter situation of attending on the preaching of many able divines, both conformists and non-conformists, he entered on the exercise of his ministry about the year 1680. In 1683, finding that he could not discharge the duties of his function in England without molestation, he accepted an invitation to be joint-pastor with Mr. (afterwards Dr.) Daniel Williams, in Dublin; and had afterwards for his co-adjutor the Rev. Mr. Thomas Emlyn, so well known for his writings and his sufferings. This connection subsisted for more than ten years with mutual friendship and uninterrupted harmony; but it was at length dissolved in consequence of Mr. Emlyn's sentiments concerning the doctrine of the Trinity. On this occasion the zeal of Mr. Boyse for the orthodox led him to take some steps that were thought injurious to his former colleague, and inconsistent with the friendship that had subsisted between them; though he disapproved the prosecution which Mr. Emlyn suffered, and behaved towards him with a greater degree of kindness than any of the other dissenting ministers of Dublin. The latter years of Mr. Boyse's life were embittered by hostile disorders and straitened circumstances. His funeral sermon was preached in December, 1728; but the precise time of his death is not known. He was considered as a pious, learned, and useful divine; assiduous in the exercise of his ministry, and in his conduct generally esteemed. He had a principal concern in promoting the act of toleration in Ireland. His works were published in 1728, in 2 vols. fol. The *first* contains 71 sermons, 6 dissertations on the doctrine of justification, and a paraphrase on those passages of the N. T. which chiefly relate to that doctrine. The *second* volume contains several pieces, of which the principal is a "Vindication of the true deity of our blessed Saviour," in answer to Mr. Emlyn's "Humble inquiry into the Scripture account of Jesus Christ, &c." As Mr. Boyse's answer was published at the time when Mr. Emlyn was under prosecution for his sentiments, his conduct did not escape censure; and was thought not to be candid, liberal, and ingenuous. Biog. Brit.

BOYSE, SAMUEL, the son of the former, was born in 1708, and having received the rudiments of his education in a private school at Dublin, was sent, at the age of 18 years, to the university of Glasgow, probably with a view to the office of a minister. Before he had attained his 20th year, he imprudently married; and this connection, in addition to the natural extravagance of his temper, involved him in pecuniary difficulties, which obliged him to quit the university

university before he had finished his studies, and to seek relief for himself, his wife, her sister, and family, from his father at Dublin. Notwithstanding the assistance he received, very much to the injury of his father's circumstances, his own conduct, which was marked by indolence and dissipation, and that of his wife, who was dissolute and vicious, contributed to increase his distress, and to accelerate his ruin. After the death of his father, all his resources failed, and he was under a necessity of repairing to Edinburgh, where his poetical talents procured for him a considerable degree of patronage. In 1731, he published a volume of poems, to which were annexed a translation of "The tablature of Cebes;" and "A letter upon liberty;" which had been printed in the Dublin journal, in 1726. This publication gained him reputation, and recommended him to the patronage of the countess of Eglinton, to whom it was addressed. Upon the death of the viscountess Stormont he wrote an elegy, entitled "The tears of the muses," for which he received a handsome present from her husband, lord Stormont. These tokens of favour, on the part of his lordship, and of the countess of Eglinton, served to procure for him the patronage of the duchess of Gordon, who employed her interest in obtaining a place for him in the customs at Edinburgh, but he lost the intended benefit by his own negligence. Having reduced himself by his own imprudence and indolence to extreme poverty and distress, he was under a necessity of leaving Edinburgh; and with recommendatory letters to Mr. Pope and sir Peter King, then lord chancellor of England, as well as to other persons of rank, fashion, and influence, obtained from the duchess of Gordon, and from lord Stormont, he removed to London. But his own indiscretion defeated the kind design of these recommendations, and he again experienced the distress of indigence, without making any attempt to extricate himself, besides writing a variety of mendicant letters. These served to procure him a temporary supply, which he soon expended by the most unaccountable and inexcusable extravagance. About the year 1740, his penury and wretchedness were so extreme, that he pawned his apparel, and even his bed-cloaths, and confined himself in his lodgings and his bed, with no other covering besides a blanket. Wrapped only with this covering he sat up in bed, having cut a hole through it large enough to receive his arm; and placing the paper on his knee, he scribbled in the best manner he could the verses he was obliged to make. When he was under a necessity of appearing abroad, he occasionally supplied the want of a shirt by slips of white paper round his wrists, and neck. In this state he remained for several weeks, without any other subsistence except what he could obtain by writing verses for the magazines, and from benefactions procured by the most abject supplications, and by the meanest arts of deceit. When he was employed in translating from the French, it was his constant practice, after sending a sheet to the press, to pawn the original, and to repeat this as often as it was redeemed during the course of his work. After passing through various scenes of a wretchedness that is scarcely paralleled in the records of human misery, in the vicissitudes of spunging-houses, garrets, and ale-houses, he resided at Reading, in 1745, where, having lost his wife, he was employed in compiling an historical work, entitled "An historical review of the transactions of Europe, from the commencement of the war with Spain in 1739, to the insurrection in Scotland in 1745, &c." and published in 1747 in 2 vols. 8vo. This work, for which the author was paid at a very low rate, is not destitute of merit, and contains much useful information respecting the history of that period. After his return from Reading, he married a second wife of

low condition, but he assumed a more decent behaviour, and some hopes were entertained of his reformation. He was employed by a bookseller to translate Fenelon's "Demonstration of the being of a God." At this time his appearance was very different from that to which he had been accustomed, and he seemed to pay some regard to his character. Towards the close of his life, and during a lingering illness which preceded his dissolution, the principles which he had imbibed, contrasted against the licentiousness and profligacy of his conduct, produced a degree of remorse and self-reproach, which he could not evade or suppress. So deep, indeed, and so permanent were the impressions of his good education, that his whole life was a kind of conflict between his vicious inclinations, and his sober reason. It was, as it is said, from the experience of this mental struggle, that he wrote his poem, entitled, "The recantation." He died in indigence and obscurity in London, in the month of May 1749, and was buried at the expense of the parish. Few instances occur, in which distinguished talents have been more lamentably perverted, than in the case of Mr. Boyse. Besides his genius for poetry, he possessed a taste for painting, music, and heraldry; and if his powers had been diligently cultivated and exercised, he might have acquired a higher degree of excellence than he ever attained; and he would certainly have escaped the ignominy and wretchedness, which were the consequences of his misconduct. His poetical effusions, if they were collected from the periodical works in which they were inserted, would make several volumes. Two volumes were published in London during his life. The most celebrated of his poetical productions was his religious poem, entitled "Deity," and published about the year 1741. This poem received the public commendation of two very different writers, viz. Hervey, in his "Meditations;" and Fielding in his "Tom Jones;" and it was so popular, as to have passed through three editions in 1752. Of this piece, Mr. Boyse said, that Mr. Pope, upon being asked if he was the author of it, disclaimed the work, but at the same time acknowledged, that there were many lines in it, of which he should not be ashamed. The best of Mr. Boyse's productions are admitted into Dr. Anderson's collection of the poets of Great Britain, printed at Edinburgh. In Ogle's Canterbury tales of Chaucer modernized, several appear under Mr. Boyse's name, and are executed with spirit. His ode entitled "Albion's triumph," was written on occasion of the battle of Dettingen in 1743, and published without his name. Cibber's lives of the poets, vol. v. Biog. Brit.

BOYSERSTEIG, in *Geography*, a calcareous mountain of Germany, near Stutgard, the capital of the duchy of Wurtemberg.

BOYUANA, in *Zoology*, the name of an American kind of serpent, of a long and slender form, the colour entirely black. It is related of the boyuana, that it has exactly the smell of a fox, but so strong, that no one can endure to be near it. The particular species, or even genus is uncertain. Several of the serpent race have an offensive scent; that of some of the boa tribe is known to be intolerable, when they have seized upon their prey, and begin to anoint it with their saliva, preparatory to swallowing it.

BOZE, CLAUDE GROS DE, in *Biography*, an eminent antiquary, was born at Lyons, in 1680, and after first applying himself to jurisprudence, devoted his whole attention to antiquities and medals. In this study he was encouraged by the chancellor Pontchartrain, Bignon, Vaillant, and Hardouin, who became attached to him on account of both his amiable character and extensive erudition. In

1705, he was admitted into the academy of inscriptions and belles lettres, and in the following year appointed perpetual secretary. He became a member of the French academy in 1715; and in 1719, he was appointed keeper of the royal cabinet of medals, the treasures of which he augmented by his journey to Holland in the ensuing year. Upon his return to Paris, he devoted himself wholly to his academical and official duties, except that he contributed also some occasional papers to the "Journal des Scavans." He died, much esteemed for the gentleness and politeness of his manners, in 1754.

His publications are, the 15 first volumes of the "Memoirs of the Academy of Inscriptions, &c." to which he added the historical eulogies of its members, published separately in 2 vols. 12mo., and much valued as elegant and judicious compositions, particularly the latter of them; the second edition of the "Medallic history of Lewis XIV." brought down to that king's death, 1723, fol.; "The history of the emperor Tetricus, illustrated by medals;" and several dissertations on medals and other subjects of antiquity, in the academical memoirs. A catalogue of his valuable library was published in 1745, and is highly prized by bibliographers. Another was published after his death, Paris, 1753, 8vo. Moreri. Nouv. Dict. Histor.

**BOZE**, in *Geography*, an island and river in the island of Sardinia. The town is on the south side of the river, which falls into the ocean on the west; and the island of this name lies off the west to the south, between the mouth of that river and another situate to the south of it.

**BOZEN**. See **BOLZANO**.

**BOZENTIN**, a town of Poland, in the palatinate of Cracow, seated at the foot of Kaleberg mountain, and surrounded with a wall and rampart.

**BOZIN**, **BOSING**, **BASINECK**, **BAZINGA**, or **BAZINIUM**, a small, but handsome, free royal city of Lower Hungary, in the upper outward district, seated on a rising ground. The inhabitants are industriously employed in the cultivation of vineyards, trade, and handicrafts. In 1605, 1620, and 1655, this place was laid in ashes.

**BOZOCK**, or **BZOWIK**, a small town of Hungary, with a castle, in a district of the same name.

**BOZOULS**, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rodés, or Rhodéz, and 10 miles N. E. of it. The town contains 2,306, and the canton 6,427 inhabitants; the territory comprehends 237½ kilometres, and 12 communes.

**BOZRAH**, in *Ancient Geography*. See **BOSTRA**.

**BOZRAH**, in *Geography*, a town of America, in New-London county, and state of Connecticut; 36 miles E. from Norwich.

**BOZZASOTRA**, **ANTHONY**, in *Biography*, a celebrated professor of medicine in the university of Naples, his native country, flourished the early part of the 16th century. His works are "Quæsitus de calido innato," Neapoli, 1542, 4to. "De veneficatione in utero gerenti, adversus negantes hujusmodi auxilium pro cautione abortus," Romæ, 1545, 4to. The author shews that the prohibition of Hippocrates, to the bleeding of pregnant women, arose from the rude custom of bleeding ad deliquium; but that blood might be drawn in small quantities from women in that state, not only safely, but with advantage. "Tractatus quatuordecim medendi methodi, ex Galeno." Neapoli, 1549, 8vo. He died Jan. 15, 1557. Haller, Bib. Med. Eloy. Dict. Hist.

**BOZZOLO**, in *Geography*, a town and small principality of Italy, in the duchy of Guaitella, adjoining to the Cremonese, formerly belonging to the duchy of Mantua,

from which it was separated. The town was fortified in 1734. It is situate 15 miles W. of Mantua, and 20 E. of Cremona.

**BRA**, **HENRY DE**, in *Biography*, commonly called *Henry a Bra*, a physician of considerable eminence, born at Dockum, in West Friesland, the 25th of September, 1555, was initiated into the study of medicine by his father, who was pensionary physician to the town. To improve him in knowledge his father sent him to visit the different universities in France, Italy, and Germany. After spending eight years, he returned by Basle, where he took his degree of doctor in medicine, under John Bauhine, the elder. He now went to Kempen, where he practised about eight years, but was at length invited to Zutphen, and made pensionary physician, and there continued to the end of his days. His works, which were in request in his time, are "Medicamentorum simplicium et facile parabilium ad icterum, et hydropem, catalogus, et quomodo iis utendum," Leid. 1590, 8vo. "De curandis venenis per medicamenta simplicia, et facile parabilia," Arnhem, 1603, 8vo. with others of a similar kind. "De novo quodam morbi genere, Frisii et Westphaliæ peculiari," published in the works of Peter Forestus. Haller, Bib. Med. Eloy. Dict. Hist.

**BRA**, in *Geography*, a town of Italy, in the principality of Piedmont, including 3 parish churches; 10 miles S. E. of Carmagnola, and 2 N. W. of Cherasco.

**BRAAN**, a river of Scotland, which runs into the Tay, near Dunkeld, in the county of Perth.

**BRAAWICKEN**, or **BRÄVICKEN**, a gulf of East Gothland, on the west side of the Baltic sea, about 30 leagues S. W. from Stockholm, into which the river Motala discharges itself near the town of Nordkiöping.

**BRABANÇIONES**, in *Middle Age Writers*, a kind of Netherland soldiery, infamous for rapine, being little better than commissioned banditti, who hired themselves to fight for any that could pay them best.

The word is variously written by the historians of those days; all given them from the country of Brabant, which was the chief nursery of those troops. They are also frequently confounded with the *Routiers*, *Roturiers*, *Ruptarii*, *Ruterarii*, *Coteraux*, &c. Daniel. Hist. de la Mil. Franc. liv. iii. chap. 8.

Towards the close of the 12th century, when the government in all the states of Europe was relaxed, and it was almost impossible to enforce any general execution of the laws, troops of banditti under these denominations were emboldened to disturb the public peace, to infest the highways, to pillage the open country, and to brave all the efforts of the civil magistrate, and even the excommunications of the church, which were fulminated against them. Some of these troops were occasionally enlisted in the service of one prince or baron, and others in that of another; they often acted in an independent manner, under leaders of their own; the peaceable and industrious inhabitants, reduced to poverty by their ravages, were frequently obliged to betake themselves to a like disorderly course of life; and a continual intestine war, pernicious to industry, as well as to the execution of justice, was thus carried on in the bowels of every kingdom. These mercenary ruffians formed a kind of society or government among themselves, which set at defiance the rest of mankind. The greatest monarchs were not ashamed, on urgent occasions, to have recourse to their assistance; and as their habits of war and depredation had given them experience, hardiness, and courage, they generally composed the most formidable part of those armies, which decided the political quarrels of princes. Accordingly Henry II. enlisted numerous troops of them in his service; and the situation of

his affairs was such as to tender even such banditti the only forces on whose fidelity he could repose any confidence. We read also of soldiers under this and similar denominations in the subsequent reigns of Richard I. and John. Hume's Hist. vol. i. and vol. ii.

**BRABANCON**, in *Geography*, a town, with the title of principality, in the county of Hainaut; 4 leagues E. of Manbeuge.

**BRABANDERKOEK**, a small island of Denmark in the duchy of Sleswick, and prefecture of Husum, called also Nordstrand, which see.

**BRABANT**. **DUCY OF**, a province of the Netherlands, bounded on the north by Holland and Guelderland, on the east by Guelderland and the principality of Liege, on the south by Namur and Hainaut, and on the west by Flanders and Zealand. The circumference is estimated at about 80 leagues, and it contains twenty-six walled towns, besides several others of inferior importance; the principal cities are Louvain, Antwerp, and Brussels. It was first erected into a duchy in the 7th century, and formerly belonged to the Frankish monarchy; but it afterwards became a fief of the German empire. The last duke of Brabant, of the race of Charlemagne, was Otto, on whose death, in 1005, it came to Lambert I. count of Louvain, who married the sister and heirs of Otto. By his posterity it descended to Philip II. duke of Burgundy; and from him in the line of his family to the emperor Charles V., and by him to Philip II. king of Spain. In the 17th century the republic of the United Netherlands took possession of the northern part of the duchy of Brabant, which it retained at the peace of Westphalia. This comprehended the quarter of Bois-le-Duc, (which see,) and a part of the quarter of Antwerp, and was called Dutch Brabant. Charles III. afterwards known by the title of the emperor Charles VI., after the battle of Ramillies, in 1706, took possession of the Austrian part of this duchy, consisting of the town and quarter of Louvain, those of Brussels, and those of Antwerp. A small part towards the south was known by the name of Walloon Brabant. When the French passed the Rhine they established themselves in Brabant; and by the new partition of their territories and conquests, in consequence of the third article of the treaty of Campo Formio, in 1797, and the second of the treaty of Luneville, in 1801, which ceded the Austrian Netherlands to the French, the eastern part of Brabant was formed into the department of Deux Nethes, and the southern part into that of Dyle. The air of Brabant is good, and its soil is fertile. It produces a great quantity of flax, and is watered by several rivers, of which the chief are the Dommel and the Demer, which, after receiving the smaller rivers of Ghute, Dyle, Secne, and Nethc, takes the name of Rupel, and discharges itself into the Scheld. The religion of this country is the Roman catholic. Mr. George Foster, who travelled through this country in 1790, gives a very unfavourable account of it. See his travels, vol. iii. In no place, he says, has ignorance ever established her dominion so firmly, nor diffused so palpable a darkness, as over the minds of the Brabanters; and no where has the iron yoke of implicit faith so deeply degraded the human understanding. Never, he adds, since they were deluged with blood by Philip and Alva, have these provinces attracted the notice of mankind, except when foreign armies made them the theatre of war, or when, like an absolute property they were transferred from one princely family to another. Nothing can be a greater proof of the stupidity and insensibility to which the people were sunk, than the indifference shewn by the Brabanters, and the opposition made by the Flemings, to the design of the emperor

Joseph II. to open the navigation of the Scheld. Indeed the picture which he gives of the decayed state of their manufactures, of the wealth and power of the church, of the insolent spirit of the nobles, and of the superstition which prevails among all ranks, is sufficient to convince us that the inhabitants of these countries were so exceedingly degraded by civil and religious tyranny, that they were become totally insensible to every thing that can dignify human nature. Of the people, however, he observes, that their good qualities are their own, but that their faults are derived from their teachers. They are remarkably phlegmatic, but humane, good natured, and friendly; even amid the violence of passion, they are neither cruel nor implacable. The measures which Joseph II. concerted, however arbitrary in their first appearance, imprudent in their arrangement, and precipitate in their execution, were designed for restraining the power of the insolent priests, and for abolishing the grosser absurdities of popery. But the insurrections occasioned by them, and the revolution in which they terminated, were attended with consequences which the people had reason to lament. By throwing off their allegiance to the emperor, they fell under a heavier yoke, and groaned under the most intolerable of all despotism, that of an absolute aristocracy. How far their condition has been improved since their country has been made a part of Belgium, by the extension of the French conquests, time must determine, and their own experience may clearly in some measure be able to testify. See NETHERLANDS.

**BRABEIUM**, in *Botany*, from *βραβείον*, a sceptre, *Lin.* gen. 160. Reich. 1262. Schreb. 1580. Mant. 137, 332. Jussieu 79. Class, *polygamia monœcia*. Species plantarum & systema naturæ. Ed. 12. *tetrandria monogynia*. Nat. Order not determined by Linnæus. *Protes* Jussieu. Gen. Char. *Cal.* ament pubescent, with ovate, obtuse, three-flowered scales. *Cor.* monopetalous, deeply divided into four oblong, obtuse segments, rolled back at top. *Stam.* filaments four, inserted into the base of the segments; anthers oblong, attached to the inner side of each filament, so as scarcely to reach its summit. *Pist.* germ very small, villose, style filiform, longer than the stamens; Stigma simple, Martyn (two upright and oblong, *Lin.* La Mark, and Bosc.) *Per.* a dry drupe, somewhat pear-shaped, villose. The male flowers on the same tree agree with the above, with the exception of an abortive pistil. *Seed*, nut globular.

*Essen.* Char. Scale of the ament. *Cor.* with four revolute segments. *Stam.* four. *Pist.* one. *Drupe*, somewhat pear-shaped. *Seed*, globular.

Species. B. *Stellatifolium*, (*Syst. Nat.*) *Stellatifolium*, (*sp. plant.*) Breyn. Cent. 1. pl. 1. Pluk. 47. pl. 265. La Mark, pl. 847. African almond. A native of the country about the Cape of Good Hope, where it grows to a tree of a moderate size, but in Europe it seldom grows above eight or nine feet high. *Stem* straight, soft, full of pith, covered with a brown bark, throwing out horizontal branches at each joint, which gradually diminish from the bottom to the top so as to form a sort of pyramid. *Leaves* lanceolate, of a deep green on their upper, and a pale russet colour on their under side, reticularly veined, with a few blunt serratures at their edges, and growing in whorls on short peduncles, round the joints or knots of the branches, from five to seven in a whorl. *Aments* axillary, growing also in whorls, a little shorter than the leaves. The fruit is called, at the Cape of Good Hope, the wild chestnut, and is greedily eaten by the wild boars.

The foregoing generic character and description have been drawn up from a careful comparison of Linnæus, Martyn, La Mark, and Bosc, who all agree in calling the bra-

beium an amentaceous tree. But Linnæus must have used the term in a lax and improper sense; he would otherwise have placed the genus in his natural order of amentaceæ, and not among those whose natural character he deemed dubious. When La Mark wrote his description in the Encyclopédie Methodique, he had in his possession only a dried specimen without flowers, brought to Europe by Sonnerat; he consequently described the fructification from preceding authors. Where he obtained the figure published afterwards, and how he would now describe the plant, is not known, the letter-press to that part of the work not being yet published; but certain it is that the fructification, as it is there delineated, has not the appearance of an ament. It corresponds much better with the following natural character by Jussieu. (The corolla of other authors.) *Cal.* small, four-cleft, at first connivent, afterwards revolute, the segments bearing the stamens at their base. *Stamens*, four, anthers oblong, attached to the inner part of the filaments. *Stigmas*, one or two. *Drupe*, villose, one-seeded. *Leaves* (of the *Theophrasta*) nearly in whorls; flowers in axillary spikes, fascicled, the fascicles consisting of three or more flowers connected with a single bractea, (the scale of the ament, of other authors.) The calyx sometimes five-cleft, with five stamens, and a greater number of masculine flowers.

Whether what Jussieu calls *B. theophrasta* be a new species, we have not at present the means of ascertaining; but the inflorescence in La Mark's figure we should rather call a raceme than a spike.

The *Brabyta capensis*, Mantissa, 1, 137, is judged by professor Martyn to be probably the same tree bearing hermaphrodite flowers. La Mark pronounces it to be so without hesitation. Bosc makes no mention of it, either under brabeium, or in a separate article. Linnæus says, that though it resembles the brabeium, its fructification is altogether different. His description of it in Mant. 1. is as follows: *Branches*, rigid, purplish, striated, subvillose. *Leaves*, seven in a whorl, petioled, lanceolate, rather rigid, a hand's breadth long, smooth above, reticulated underneath. *Petioles*, erect, pubescent. *Aments*, oblong, cylindric, petioled, round, erect, lateral, often two within each leaf, shorter than the leaves, rather rigid, two inches long, imbricate. *Scales*, ovate, acute, pubescent, many-flowered. *Corollule*, funnel-shaped, five-cleft. *Stamens*, five. *Style*, one.

*Propagation and Culture.* This tree is propagated in Europe only by layers, and that with difficulty. The layers should be made of the former year's shoots, and slit at a joint, as is practised in laying carnations. The best time is in April, when the plants are beginning to shoot; but they will often be two years before they produce roots strong enough to be taken from the old plants. They must have little water given them, especially in winter. The plants must be placed in a good green-house in winter, but in summer should be set abroad in a sheltered situation. See Martyn's Miller's Dict. The brabeium does not occur in the Hortus Kewensis.

**BRABUTES**, or **BRABUTA**, formed from βραβύτης, *prize*, or *reward*, in *Antiquity*, an officer who presided at the public games, and decreed the prizes to the victors. The Latins called him *designator*, and *munerarius*. The generality of writers confound the brabutes with the agonotheta, between whom there however appears to have been this difference, that the former presided at the gymnic combats, the latter at the sacred ones. The number of brabutes was not fixed; sometimes there was only one, but more commonly there were nine or ten.

**BRABONIACUM**, in *Ancient Geography*, a place of Britain, mentioned in the Notitia Imperii, and supposed by Mr. Horsley to be the same with Bremstonacis.

**BRABORG**, in *Geography*, a town of Sweden, in East Gothland; 24 miles E. of Nordkiöping.

**BRABYLA**, in *Botany*. See **BRABEUM**.

**BRAC**, or **CALAO D'AFRIQUE**, of Buffon, in *Ornithology*, the African Hornbill; *Buceros Africanus* of Gmelin.

**BRACARA AUGUSTA**, in *Ancient Geography*, *Braga*, a town of Spain, in the territory of the Callaici, situate above Nebia, and occupying the rank of "Conventus." See **BRAGA**.

**BRACCAS**, in *Geography, an island of America, near that of Cuba; one of those called Caymans.*

**BRACCATA**, in *Entomology*, a species of *VESPA*, of a black colour: the thorax without spots; lip silvery; base of the antennæ in front, and the fore legs yellow; thighs above black. Linn. Inhabits Europe.

**BRACCATA**, a species of *TENTHREDO*, of a black colour; thighs rufous; base of the four posterior shanks, and three last joints but one of the antennæ white. Linn. A native of Europe.

**BRACCATUS**, an European species of *ICHNEUMON*, of a black colour, with the mouth, antennæ, and thighs at the base yellow; abdomen ferruginous, and black at the base; four anterior legs yellow. Linn. &c.

**BRACCIANO**, in *Geography*, a small town of Italy, in the state of the church, and patrimony of St. Peter, and capital of a duchy of the same name, in which are warm medicinal baths. The duchy surrounds a lake, called "Lago di Bracciano." The town is situated at the distance of 2 leagues from the Mediterranean, and 15 miles N. W. from Rome.

**BRACCIO**, *Ital.* the arm, in *Musie*, as *Viola da braccio*, a tenor-viol, that rests on the shoulder, to distinguish it from the base-viol, which rests on the leg. See **VIOLA DI GAMBA**.

**BRACCIO Di Mania**, called also *Tzakonia*, in *Geography*, a district of the Morea in European Turkey, comprehending the ancient Arcadia and Laconia.

**BRACCIOLINI**, FRANCIS, in *Biography*, an Italian poet of noble extraction, was born at Pistoia, in 1566, and admitted into the academy of Florence, where he devoted himself to the pursuits of literature. Having accompanied the cardinal Maffeo Barberini to France, he returned after the death of Clement VIII. to his own country; but upon the accession of Barberini to the papedom, under the title of Urban VIII. he re-visited Rome, and became joint secretary with the pope's brother, cardinal Antonio. He was also allowed the honour of taking a surname from the arms of the Barberini family, which were "Bees," and from this circumstance was denominated Bracciolini dell' Api. During his continuance at Rome, he frequented the most illustrious academies, and obtained great reputation for his literature, but was reproached for his sordid avarice. After the death of Urban VIII. he retired to his native country, where he died in 1645. Bracciolini was a copious writer in various kinds of poetry, epic, dramatic, pastoral, lyric, and burlesque. The most noted of his poems is his mock-heroic, entitled "Sclerno degli Dei," ridiculing the heathen mythology; which, though confessedly inferior to Tassoni's "Secchia rapita," disputes with it priority of date. Of his heroic poems, the most celebrated is the "Croce Racquillata," Paris, 1605, 12mo. ranked by some next to the great works of Ariosto and Tasso. He celebrated the elevation of his patron Urban VIII. in 23 books, and he must therefore have written verses with great facility. His dramatic pastoral, entitled "L'Amoroso sdegno," is esteemed one of the best productions of that age; and some of his tragedies gained applause; particularly his "Evandro." Tiraboschi. Gen. Biog.

**BRACCIOLINI**, POGGIO, one of the revivers of literature in Italy in the 15th century, was the son of Guccio Bracciolini,

ciolini, and born in 1380, at Terranuova, a small town of the republic of Florence, not far from Arezzo. Deriving from his father no hereditary advantages of rank or fortune, he sought emolument and distinction in the course of literary pursuits. Having acquired a competent knowledge of the Latin and Greek languages at Florence, where his studies were directed by Manuel Crisoloras, he removed to Rome about the year 1402; and here his literary reputation introduced him to the notice of Boniface IX. who took him into his service, and promoted him to the office of writer of the apostolic letters. At the period immediately preceding the admission of Poggio into the pontifical chancery, the Italian states had been convulsed by war and faction; but a treaty having been concluded, just before his arrival, between Boniface and the Florentine republic, the Roman court, relieved from its distraction and anxiety, was become a scene of luxury and dissipation. Poggio, however, resisted the temptations which presented themselves to his lively fancy and ardent constitution; and as the emoluments of his office afforded only scanty means of gratification, he devoted himself the more assiduously to the prosecution of his studies, and to the cultivation of an acquaintance with those whose conversation might lead to the improvement of his mind. Literary pursuits were now become fashionable, and the character of the scholar was often found united with that of the man of the world. To this circumstance it is natural to ascribe the union of learning, politeness, and knowledge of the human heart, which shines so conspicuously in the writings of Poggio. In 1404 he sustained a considerable loss by the death of his patron, Boniface; but his distinguished merit recommended him to the favourable notice of the successor to the papal see, Innocent VII.; who continued him in his office, and treated him with particular kindness and respect. During the distractions of the Roman court, which succeeded the death of Innocent in 1406, Poggio exchanged the intrigues and dissensions of the pontifical palace for the tranquil delights of friendship, which he enjoyed at Florence in the society of his literary acquaintance, and particularly in the patronage and cordial esteem of the celebrated Niccolò Niccoli. He seems, however, to have retained his situation in the pontifical chancery; and having acted as apostolical scribe to Alexander V. he occupied the same office in the household of John XXII. that pontiff's successor. At the council of Constance, in 1415, the death of Manuel Crisoloras, the instructor of his youth, afforded him an opportunity of celebrating his praises in a funeral oration, and of dedicating to his memory an appropriate and elegant Latin epitaph. Upon the deposition of John at this council, and the consequent dispersion of the pontifical household, Poggio remained at Constance, and employed his intervals of leisure in studying the Hebrew language, under the direction of a Jew who had been converted to the Christian faith. But in this language he seems to have made no great progress; nor, indeed, was he desirous of providing himself, by a knowledge of the oriental tongues, with the weapons of religious controversy. As he was not disposed to call in question the prevailing creed, he was inclined to think that St. Jerome's translation of the Jewish Scriptures was amply sufficient for all the purposes of his Christian faith. Biblical studies seem not to have suited his taste and inclination; and therefore his proficiency in them was not very considerable. The vigour of his mind might likewise have suffered some relaxation from the precariousness of his situation, and the gloomy and discouraging prospects which presented themselves with regard to his future preferment. Finding no amusement in varying or extending his literary pursuits, he altogether suspended his studies; and in

the spring of the year 1416, he availed himself of the leisure afforded him, by the termination of his functions as secretary to the deposed pontiff, to make an excursion to the baths of Baden. On his return to Constance he was present at the trial of Jerome of Prague; and of this trial and the last end of Jerome he gave a very circumstantial and interesting account, in a letter to his friend Leonardo Aretius. "He stood undaunted and intrepid," says Poggio, "not merely contemning, but, like another Cato, longing for death. He was a man worthy to be had in everlasting remembrance. I do not commend him for entertaining sentiments hostile to the constitution of the church; but I admire his learning, his extensive knowledge, the suavity of his eloquence, and his ability in reply. But I am afraid that all these endowments were bellowed on him by nature, in order to effect his destruction." He thus concludes; "He may have been heretical in his notions, and obstinate in persevering in them, but he certainly died like a philosopher. I have rehearsed a long story, as I wished to employ my leisure, in relating a transaction which surpasses the events of ancient history. For neither did Mutius suffer his hand to be burnt so patiently as Jerome endured the burning of his whole body; nor did Socrates drink the hemlock as cheerfully as Jerome submitted to the fire." The feeling manner in which he describes the trial and execution of Jerome, evinces a heart, which daily intercourse with bigotted believers and licentious hypocrites could not deaden to the impulses of humanity. The manifested interest which he took in the fate of a man, who was held up by the church as an object of unqualified abhorrence, awakened the fears of Leonardo on his account; and he advised him to exercise a greater degree of caution.

During the vacancy of the pontifical throne, Poggio improved his leisure by an expedition of no small importance to the interests of literature. Having received information that many ancient MSS. of classic authors were scattered in various monasteries, and other repositories in the neighbourhood of Constance, he determined to rescue them from the hands of those who, ignorant of their value, were suffering them to perish. In the monastery of St. Gall he found, among other MSS., a complete copy of Quintilian, buried in rubbish and dust; and also the three first and one half of the fourth books of the Argonautics of Valerius Flaccus, and Asconius Pedianus's comment on eight of Cicero's orations. In a monastery of the monks of Clugny, in the town of Langres, he found a copy of Cicero's oration for Cæcina; and in his other researches he discovered the following orations of the same author, the loss of which had been long deplored by the learned: viz. "De lege Agraria contra Rullum, lib. i. et lib. ii." "Contra legem Agrariam ad populum;" and "In L. Pisonem." A copy of these orations is preserved in the abbey of Sta. Maria at Florence, with a memorandum ascribing the discovery of this and also of three others, viz. "Pro C. Rabirio Pifone;" "Pro C. Rabirio perduellionis reo;" and "Pro Roscio comædo," to Poggio; but the three last are torn from the volume. To him also, in concurrence with Bartolomeo di Montepelciano, we are indebted for restoring to light the poem of Silius Italicus, Lactantius's treatise, "De ira Dei et officio hominis," Vegetius "De Re militari," Nonius Marcellus, Ammianus Marcellinus, Lucretius, Columella, and Tertullian. Poggio likewise added to the eight comedies of Plautus, known before his time, twelve more; and by the assiduity of his own researches, and those of others employed by him, he discovered a fragment of Aulus Gellius, a copy of Julius Frontinus, "De aquæductis," and eight books of Firmicus's treatise on the mathematics. From Cologne he procured the fifteenth book of Petronius Arbiter; and to his exertions we

owe the entire work of Columella, the preservation of Calpurnius's *Bucolic*, and the recovery of the works of Manilius, Lucius Septimius, Caper, Euty chius, and Probus.

After the deposition of John XXII. Poggio remained for some time in suspense with regard to his future destination; and it does not appear that he held any office under Martin V. who was elected to the papal see, although, after the dissolution of the council of Constance in 1418, he travelled in the suite of the new pontiff to Mantua. At this time he paid a visit to England, in consequence of an invitation from Beaufort, bishop of Winchester; but disappointed in his expectations of preferment, adequate to his views and wishes, he impatiently waited a favourable opportunity of returning to his native country.

At length, viz. in 1420, when the dissensions respecting the pontificate were finally settled, and Martin V. was recognized as the true successor to the papal throne, Poggio arrived at Rome, and accepted the office of secretary, to which he was recommended by the cardinal of St. Eusebius. A quarrel having taken place between his two friends Leonardo Aretino and Niccolò Niccoli, he interposed as mediator, and succeeded in accomplishing a reconciliation. In 1429 he availed himself of an interval of tranquillity, in presenting to public notice his first literary production, which was a "Dialogue on Avarice," and which seems to have possessed considerable merit. In this dialogue he took occasion very severely to satirize those Franciscan friars, who were distinguished by the title of "Fratres Observantia," a new order founded by Bernardo of Siena. This was followed, at a more advanced period of life, by a "Dialogue on Hypocrisy," a composition which abounds in the keen sarcasms of polished wit, and in acute observations on the human character. In both these dialogues he boldly expresses the contempt he entertained for those ecclesiastics, who adopted the religious habit as a convenient cloak for the concealment of indolence or luxury; and who, by the mere appearance of extraordinary sanctity, endeavoured to attain that worldly honour which at the same time they affected to despise. The freedom with which he exposed the vices not merely of individuals, but of whole classes of religious hypocrites, manifested a great degree of virtuous resolution, and merited no mean praise. After the accession of Eugenius IV. to the papal throne, a contest occurred between him and the council of Basil, which terminated in the deposition of the pontiff, and his flight to Florence; and Poggio, in attempting to follow him thither, was captured, and for some time detained in confinement. However, by the payment of a ransom, which his pecuniary circumstances rendered very oppressive, he was set free, and finally accomplished his retreat to Florence. During his residence in this city, he had an opportunity of testifying his ardent attachment to the house of Medicis, by entering into a literary contest, or rather a kind of lampoon war, with Filelfo, an avowed enemy of that family, in which they seem to have vied with each other in inventing falsehoods of the most atrocious kind, and in disgracing their pages by the most malevolent and indecent calumnies. This contest between two of the most learned men of the age was conducted in a manner, which, however it might have contributed to the amusement of their contemporaries, entails lasting disgrace on both parties, in the judgment of posterity. Poggio, soon after the termination of this contest, determined to fix his permanent residence in the Tuscan territory, and with this view he purchased a villa in the pleasant district of Valdarno. The Tuscan government favoured his purposes of retirement, and passed a public act, which exempted him and his children from the payment of all public taxes.

Foggio's fortune was inconsiderable; but he contrived to render his humble mansion an object of attention to the lovers of the liberal arts, by the treasures of his library, and by a small collection of statues, which he disposed in such a manner as to constitute a principal ornament of his garden, and the appropriate furniture of an apartment which he intended to dedicate to literary conversation. His attention seems to have been long engaged by the study of ancient sculpture; nor was he less assiduous in rescuing its relics from obscurity, than in searching for the best writers of antiquity. With this view he made a diligent survey of the ruins of ancient Rome, and inserted in the proemium to his dialogue, "De Varietate Fortunæ," a catalogue of the relics of Roman architecture, which has been introduced by Mr. Gibbon in the 71st chapter of his "Decline and Fall of the Roman empire." Poggio's researches extended beyond the precincts of Rome, and his zeal for the restoration of the monuments of ancient sculpture induced him to visit Crypta, Ferrata, Tusculum, Ferentinum, Alba, Arpinum, Alatrium, and Tiburtum; and by means of friends he directed his researches to Rhodes, Greece, and other countries. Whilst he was occupied in collecting ornaments for his rural residence, he was employed at the request of a friend, Scipio of Ferrara, in composing a dissertation on the comparative merits of Cæsar and Scipio; which he closes with the following general statement of his opinion, "that the youth of Scipio was distinguished by the purest morals, whilst the early years of Cæsar were rendered infamous by his vices; that the former, inspired with the spirit of patriotism, by his splendid military achievements rescued his country from destruction; and that the latter, prompted by ambition, too successfully exerted his extraordinary talents to effect the subversion of the commonwealth; that consequently, whilst Scipio was by no means inferior to Cæsar in the fame of his military exploits, he was greatly his superior in virtue, which alone constitutes the character of a truly great man." Soon after the termination of a controversy which this publication occasioned, an event occurred which, in all the circumstances that attended it, reflects no great honour on the character of Poggio. At the age of 55, he married a young lady of a wealthy and honourable family in her 18th year; and to this alliance he sacrificed a mistress, by whom he had had 12 sons and 2 daughters, and, moreover, set aside a bull of legitimacy which he had procured for them, in order that they might be enabled to inherit his fortune. Not long after this event, in 1437, his friend Niccolò Niccoli died, and Poggio composed and published his funeral eulogium, in which are several traces of eloquence and pathos. Although Poggio devoted much of his attention to domestic duties, and to the improvement of his Tuscan villa, he found leisure to renew his disgraceful literary contest with Filelfo; and to compose a work, which redounded much more to his honour, entitled "A Dialogue on Nobility," and published in 1440. This was followed by his "Dialogue on the unhappiness of princes," in which he dwells with so much energy on the vices of exalted rank, as to afford room for suspicion, that resentment and indignation had at least as much influence in its composition as the suggestions of philosophy. However, the effusions of moroseness that occur in this dialogue are interspersed with precepts of sound morality, and the historic details with which it abounds are both entertaining and instructive.

In 1444 he lost Leonardo, the sole surviving companion of his youthful years; and on this occasion he published a funeral oration, which was at once dignified and pathetic.

Poggio, though he had held the office of apostolic secretary

tary under seven pontiffs, had never been promoted to any of the superior departments of the Roman chancery. But when Nicholas V. ascended the pontifical throne, his prospects were brightened; and he indulged the hope of spending the remainder of his days in a state of independence, if not of affluence. With a view of improving his interest with the new pontiff, he addressed to him a congratulatory oration, which was recompensed by very liberal presents. This was succeeded by a dedicatory epistle, introducing to his patronage a dialogue "On the vicissitudes of fortune," the most interesting of Poggio's works, and inculcating maxims of sublime philosophy, enforced by a detail of splendid and striking events. Confiding in the pontiff, he also published the dialogue "On hypocrisy," already mentioned. At the request, and under the patronage of Nicolas, he also contributed to the illustration of Grecian literature, by a Latin translation of the works of Diodorus Siculus, and the *Cyropædia* of Xenophon. During the plague, which raged in various parts of Italy in 1450, Poggio visited the place of his nativity; and availing himself of this interval of relaxation from the duties of his office, he published his "Liber Facietiarum," or collection of jocose tales, containing anecdotes of several eminent persons who flourished during the 14th and 15th centuries. This work acquired a considerable degree of popularity, and was read, not only in the native country of its author, but also in France, Spain, Germany, and Britain. In 1451 he dedicated to the cardinal, Prospero Colonna, his "Historia disceptativa convivialis." In 1453 Poggio was elevated to the chancellorship of Florence; and, at the same time, he was chosen one of the "Præfidi degli atti," or presidents of the trading companies. These offices he held till his death, which happened on the 20th of October, 1470. Notwithstanding the multiplicity of his business, and the advances of age, he prosecuted his studies with his accustomed ardour; and published a dialogue "De miseria humanæ conditionis," and a version of Lucian's "Æls," with a view of establishing a point of literary history, which seems to have been till that time unknown, namely, that Apuleius was indebted to Lucian for the stamina of his "Ælius aureus." The last literary work in which he engaged, was his "History of Florence," divided into eight books, and comprehending the events in which the Florentines were concerned from the year 1350, to the peace of Naples in 1455. This history was translated into Italian by Jacopo, the son of Poggio; but the original was published by Recanati, and has been republished in the collections of Greuvius and Muratori. Poggio concluded his career in the possession of universal respect, and in the tranquil enjoyment of social and domestic comforts. His remains were interred with solemn magnificence in the church of Santa Croce at Florence; and his fellow citizens testified their respect for his talents and virtues, by erecting a statue to his memory on the front of the church of Santa Maria del Fiore. As the citizen of a free state, which he deemed a high honour, he improved every opportunity that occurred for increasing and displaying the glory of the Tuscan republic. Although he was honoured by the favour of the great, he never sacrificed his independence at the shrine of power, but uniformly maintained the ingenuous sentiments of freedom. The licentiousness which disgraced the early period of his life, and the indecent levity which occurs in some of his writings, were rather the vices of the times than of the man; nor did they deprive him of the countenance of the greatest ecclesiastical dignitaries, or cause him to forfeit the favour of the pious Eugenius, or of the moral and accomplished Nicolas V. To those with whom he maintained a personal intercourse, he recommended himself by

the urbanity of his manners, the strength of his judgment, and the sportiveness of his wit. As a scholar, Poggio is entitled to distinguished praise. By assiduous study, he became a considerable proficient in the Greek language, and intimately conversant with the works of the Roman classic authors. In selecting as his exemplar in Latin composition, the style of Cicero, he manifested the discernment of true taste. When compared with the works of his immediate predecessors, the writings of Poggio are truly astonishing. "Rising to a degree of elegance, to be sought for in vain in the rugged Latinity of Petrarca and Coluccio Salutati, he prepared the way for the correctness of Politiano, and of the other eminent scholars whose gratitude has reflected such splendid lustre on the character of Lorenzo de' Medici." Shepherd's life of Poggio Bracciolini. 4to. 1802.

BRACE is commonly taken for a couple, or pair; and in this sense is applied by huntsmen to several beasts of game; as a brace of bucks, foxes, hares, &c.—They also say, a brace of greyhounds.

BRACE, in *Architecture*, denotes a piece of timber framed in with bevel-joints; serving to keep the building from swerving either way. When a brace is framed into a king-piece, or principal rafter, it is called by some a *strut*.

BRACE, BRACCHIO, or BRASSE, in *Mensuration*, denotes a foreign long measure, answering to our FATHOM.

BRACE is also used for a measure taken from the length of the arm when extended, and is used in divers cities of Italy, in lieu of the foot or yard. Its length is various; the brace of Bergamo, according to Scamozzi, is nineteen Paris royal inches, and a half; according to M. Petit, sixteen inches two-thirds; the brace of Bologna is fourteen inches; that of Bresse, seventeen inches seven lines and a half, according to Scamozzi; and according to M. Petit, seventeen inches five lines; the Mantuan brace is seventeen inches four lines; that of Milan, twenty-two inches; that of Parma, twenty inches one-third; of Sienna, twenty-one inches two-thirds; of Florence, twenty inches two-thirds, according to Maggi; twenty-one inches four lines and a half, according to Lorini; twenty-two inches two-thirds, according to Scamozzi, and twenty-one inches one-third, according to Picart.

BRACE, in *Writing*, a term used to signify a crooked line, (as } ) made at the end of two or more articles in an account, the amount of which is usually placed in the centre of the brace. It is also used in printing, to enclose an entire passage, as in a triplet, &c.

BRACE the yards to, in *Sea-language*, signifies to move them, by means of the braces, to any direction required. To brace about, is to brace the yards round for a contrary tack. To brace sharp, is to brace the yards in a position, in which they will make the least possible angle with the keel, for the ship to have head-way. To brace to, is to ease off the lee-braces, and round-in the weather braces, to assist the motion of the ship's head in tacking. See the next article.

BRACE, a rope at each extremity of all the yards of a ship, except the mizen yard, which is provided with ropes called *wangs*, for the purpose of bringing the yard in a proper position, that the sail may be full, whether the ship is sailing by, or large. All braces ought, if possible, to lead aft, for the greater security of the masts; in ships, therefore, the braces of the yards belonging to the fore and main-masts lead aft; but in square-rigged vessels with two masts, those, only, of the yards belonging to the fore-mast, lead aft. The braces of the yards of the after-mast of a square rigged vessel, lead forward. The braces of the principal yards are double, being reeved through blocks,

blocks, at the ends of the yards, or at pendants seized to the yard-arm. The braces of the top-gallant, and sprit-sail top-sail yards, are single.

**BRACED**, in *Heraldry*, is used in speaking of chevrons which are intermingled. He bears azure a chief or, and three chevrons *braced*, in the base of the escutcheon, by the name of *Fitz-Hugh*. See **BRAZED**.

**BRACELET**, an ornament usually worn round the wrist. The word is French, *bracelet*; which Menage derives further from *braceletum*, a diminutive of *bracile*, a word occurring in writers of the Justinian age; all formed from the Latin *brachium*, *arm*. It amounts to the same with what was called by the ancients, *armilla*, *brachiale*, *occulus*; in the middle age, *boga*, *bauga*, *armispatha*.

Among the ancient Romans, the men as well as the women, wore bracelets; but the latter, it is to be observed, never wore them till they were betrothed.

In the times to which the Scripture history refers us, the bracelet seems to have been an ensign of royalty; and this accounts for Saul's wearing this ornament at the time of his death, and also for the Amalekite's bringing the bracelet which he found on Saul's arm, together with his crown, to David. 2 Sam. i. 10. It is well known, that the bracelet has been in much later times used in the East as a badge of power. D'Herbelot informs us, that when the caliph Caiem Bemrillah granted the investiture of certain dominions to an eastern prince, which his predecessors had possessed, and among the rest of the city of Bagdad itself, this ceremony of investiture was performed by the caliph's sending him letters patent, a crown, a chain, and bracelets. Although Grotius, referring to Num. xxxi. 50. observes, that the bracelet was an ornament used by the men as well as women of those nations; yet it does not seem to have been so common as some writers have supposed: for though the word bracelet frequently occurs in our translation, the original word in this text is found only in two other places; and as the children of Israel found one or more of these bracelets among the spoils of Midian, so they killed, at the same time, five of their kings. Num. xxxi. 8. In the other passage, Is. iii. 20. mention is made of female ornaments; but allowing the word to be the same, might not the women of that age wear an ornament which, from its likeness to one of the ensigns of royalty, might be called by the same name. We read in Gen. xxiv. 22. that the bracelets of Rebekah weighed ten shekels, or about five ounces; a weight which some have thought to be very extraordinary. But Sir John Chardin assures us, that ornaments as heavy, and even heavier, were worn by women of the East when he was there. He says, with a reference to the ornaments of Rebekah, that "the women wear rings and bracelets of as great weight, through all Asia, and such as are much heavier. They are rather manacles than bracelets. There are some as large as the finger; the women wear several of them, one above the other, in such a manner as sometimes to have the arm covered with them from the wrist to the elbow. Poor people wear as many of glass, or horn. They hardly ever take them off; they are their riches."

Bracelets were at first properly military ornaments or rewards, frequently conferred among the ancients, by generals and princes, on those who behaved gallantly in fight. They became afterwards arbitrary decorations, assumed at pleasure; and are sometimes said to have been worn for health as well as ornament; and particularly as amulets, to break the force of charms and fascinations. Among the Romans we meet with divers species and denominations of bracelets; as the *brachiak*, which covered the whole length of the arm; the *dextrale*, or *dextrocherium*, only the wrist, and that only

of the right arm; *viria*, or *viridia*, peculiar to the male sex; *spinther*, to the women, being worn on the left arm; *verax*, used as an amulet; *amphidion*, worn either on the arm, or about the neck; *calbeum*, or *galbeum*, worn by generals in their triumphs. Pitisc. Lex. Ant. tom. i. & ii. Du-Cange. Gloss. Lat. tom. i. & ii. Kenact. Rom. Ant. Not. P. II. lib. iv. cap. 16.

Bartholin has a treatise on the bracelets of the ancients. The northern people used also to swear on their bracelets, to render contracts more inviolable.

Bracelets are still much used by the savages of Africa and America, made of metal, glass-beads, shells, and the like. In civilized countries they form a common part of the ornament of the ladies.

**BRACELET** is also used, in *Anatomy*, to denote the circular ligament which invests the *carpus*, called also *ligamentum annulare*.

**BRACELETS**, in some *Ancient Law Books*, denote beagles, or hounds of the smaller kind.

**BRACES**, in *Geography*, are two sand-banks lying across the entrance into the channels for the river Hughly, at the bottom of the bay of Bengal.

**BRACES**, in *Ship building*, that security to the rudder which is fixed to the stern-post, and bottom of the ship, and to which the rudder is hung.

**BRACES** of a *coach*, denote the thick and strong straps of leather on which it hangs.

**BRACHERIUM**, or **BRACHERIOLUM**, a kind of steel bandage worn about the hips, and used for the retention and cure of ruptures. Du-Cange Gloss. Lat.

**BRACHIÆUS**, or **BRACHIALIS**, *internus, musculus*, in *Anatomy*, is the deeper situated flexor of the elbow joint. It arises fleshy from the middle of the os brachii, and from all the lower and fore part of the bone. It passes over the joint, and adheres firmly to the ligament. It is inserted by a strong short tendon into the coronoid process of the ulna. Its use is to bend the fore arm, and to prevent the capsule of the joint from being pinched.

**BRACHIAL NERVE**. See **NERVES**.

**BRACHIALIS**, *coraco*. See **CORACO-BRACHIALIS**.

**BRACHIATE**, in *Botany*, a term applied to branches when they grow opposite to each other, one on each side of the stem, and when each pair points in a different direction, so as to make a right angle with the pair above or below it.

**BRACHIOBOLUS**, a name given by Allioni to a genus of plants formed for such species of silybrium as have a short silique. It corresponds with Haller's radícula. See **SISYMBRIUM**.

**BRACHION**, in *Ancient Geography*, *Gerba*, an island in the Mediterranean sea, situate on the coast of Africa, 15 leagues S. E. of Tacapé. Scylax.

**BRACHIONUS**, in *Zoology*, a genus of *Vermes infusorie*, having the body contractile, covered with a shell, and furnished with ciliate rotatory organs at the head. The species of this genus Linnæus includes in his genus *Vorticella*, from which they are distinguished by modern naturalists by the shelly covering of the body; the vorticellæ being destitute of a shell.

The species of this genus are *ureolaris*, *patella*, *striatus*, *cirratus*, *tripus*, *uncinatus*, *mucronatus*, *cernuus*, *calyciflorus*, *tubifex*, *quadridentatus*, and *patina*, which see.

**BRACHITÆ**, in *Ecclesiastical History*, a branch of **MANICHEES**, who appeared in the third century.

**BRACHIUM**, the *arm*, in *Anatomy*, is that part of the upper extremity which intervenes between the joints of the shoulder and elbow.

**BRACHIUM**, in *Botany*, a term employed by *Linnaeus* as a measure of plants. It denotes the distance from the armpit to the base of the middle finger in a middle sized man, and is about 24 inches.

**BRACHIUM moventium secundus**, in *Anat. ny.* a name given by *Vesalius*, and other of the old writers, to the muscle now generally called *deltoideus*.

**BRACHIUM movens quartus**, the name by which *Vesalius* calls the muscle now generally known under the name of *brachialis dorsi*. *Fallopianus*, and many others, have also called it *genuus humeri*.

**BRACHII tertius**, a name given by *Vesalius* and others to a muscle since called, from its shape, *teres major*, and *rotundus major*.

**BRACHIURE**, in *Zoology*. an epithet given by the French naturalists to many animals that have short wings, the word being derived from the Greek as in *Brachytera*, &c.

**BRACHLERCHE**, *FRISCH*, in *Ornithology*, *ALAUDA CAMPESTRIS*, the meadow lark.

**BRACHMANS**, a branch of the ancient *Gymnosophists*, or philosophers of India, remarkable for the severity of their lives and manners. See *GYMNOSOPHISTS*.

The Greeks usually give them the name *Gymnosophists*; but among ancient authors, both Greek and Latin, we find different accounts of these Indian sages. *Ptolemy* considers them as distinct from the *Gymnosophists*; and he places the *Brachmans*, whom he calls *Magi*, in a southern district of India, between the rivers *Solenus* and *Chaberus*, not far from the sea; whereas he assigns to the *Gymnosophists* a situation in the north-eastern part of that country, near the western bank of the *Ganges*. On the other hand, *Megasthenes*, cited by *Strabo*, (*Geog. tom. ii. p. 1038.*) asserts, that the *Gymnosophists* were divided into two branches or sects, viz. the *Brachmans* and the *Germanes*. *Diodorus Siculus*, in one place, represents the philosophers of India, who were the *Brachmans* of *Megasthenes*, as equivalent to the priests of other nations; but, in another passage, he considers them as a separate nation, sect, or body of men, settled in one particular part of India. *Arrian* (*De Exped. Alexand.*) fixes the *Brachmans* among the *Malli* and the *Musciani*; and *Pliny* (*Nat. Hist. l. 6. c. 17.*) says the appellation *Brachman* was applied to many nations, and intimates, that it did not denote a distinct class or order in society. *Porphyry* (*De abst. l. 4.*) asserts, that the *Gymnosophists* were divided into two sects, the *Brachmans* and the *Sama-neans*; and that of the *Brachmans*, some lived in a mountainous tract, and others about the *Ganges*. *Arrian*, *Apuleius*, *Clemens Alexandrinus*, and *Plutarch*, differ in several particulars relating to these Indian sages; though they all seem to agree in celebrating their love of divine wisdom, their knowledge, their abstemious way of life, their singular temperance, and their contempt of all the good, as well as evil things of this world, so much desired or dreaded by the bulk of mankind. Upon the whole, it seems to be evident from various records, concerning the ancient *Brachmans*, that they were not so much a distinct nation, or particular class of philosophers, as a tribe or body of men, or rather a numerous family, descended from one common ancestor, who existed at some remote period, and who was different from the progenitors of the people among whom they lived. They deduced their origin from *Brahma*, the first of the three beings whom God created, and whom he afterwards employed as his agents in forming the world. Some have supposed that this *Brahma* was the Supreme being; but others have rejected this supposition as absurd and incredible. It has been a generally received

opinion among some of the best Jewish writers, adopted by *Sharefiani*, an Arabian author of great repute, and sanctioned by the authority of the learned *Dr. Hyde* (*De rel. vet. Persarum, p. 31, 52.*) who has offered some ingenious conjectures in defence of this notion, that the progenitor of the *Brachmans* was the patriarch *Abraham*, whom in their language they call *brachma*, or *brama*.

*Positellus* (*In comment. ad Jezir.*) takes these *Brachmans* to have been descended from *Abraham* by his wife *Keturah*, whence he calls them *Abrachmans*; and believes that the true religion prevailed long among them; and, indeed, from the accounts given of them by the ancients, it seems to appear, that they acknowledged one supreme being, and a future state of rewards and punishments. It also farther appears, that some of them worshipped this supreme being with great fervency and adoration, spending the greatest part of the day and night in singing hymns in honour of the deity, praying and fasting almost incessantly, and despising every thing in this world for his sake. Hence, some have derived their name from the Hebrew *barach*, to *lift* or *prize*, because this was their principal occupation. Most of them lived in solitude, without marrying, or possessing any estates; and from this circumstance of their retiring into the country and living in deserts, *F. Thomasin* deduces the original of the appellation by which they are distinguished; supposing it to have been derived from the Hebrew *barach*, to *fly* or *escape*. These *Brachmans*, according to the accounts of *Arrian* and *Porphyry*, were held in great veneration in their own country, enjoying perfect liberty and total exemption from taxes, and officiating, not only as the priests of the Indians, but likewise as the principal counsellors of their princes. Thus they served their country, both in a civil and religious capacity, as the *Magi* did among the Persians. They assisted at the public sacrifices; and if any person desired to sacrifice in private, one of them must be present, otherwise the Indians were persuaded they would not be acceptable to the Gods. It was their peculiar province to consult the stars, and to practise divination. According to *Strabo's* account, they believed that the world had a beginning, and that it will have an end; that its form is circular; that it was created by God, who pre-fides over, and fills it with his majesty; and that water is the principle of all things. With regard to the immortality of the soul, and the future punishment of the wicked, they followed the doctrine of *Plato*; intermixing it, like that philosopher, with some fictions, in order to express or describe those punishments. The *Brachmans* are celebrated all over the ancient world for their wisdom, the austerity of their lives, and their invincible fortitude and patience. Their food consisted altogether of herbs, roots, and fruits, and their drink was water. They wholly abstained from the flesh of animals, and thought themselves defiled by touching them: they thought it highly criminal to deprive the most inconsiderable animal of life; and as they held the doctrine of the *Metempsychosis*, they supposed that the souls of men transmigrated into those of brute animals. *Pythagoras* is said to have studied their doctrine and manners, and to have received his notion of the transmigration of souls, or *Metempsychosis*, from them. Persuaded that it is below the dignity of a man to wait calmly for death, when he finds himself oppressed by age or sickness, they earnestly wish for the moment when the soul shall leave the body, and hold it to be glorious and laudable to preclude the approach of their last hour, and to burn themselves alive. Among them, no honours were paid to those who died merely of old age; and they conceived, that their funeral pile, and the fire that was to reduce them to ashes, would

be polluted if they did not move to it with a firm and quick step, and ascend it with fortitude and animation. Cicero, in his *Tusculan Questions*, (l. v. n. 78.) expresses his admiration of the invincible patience, not only of the Indian sages, but also of the women of that country, who used to contend for the honour of dying with their common husband. This privilege was reserved for that wife to whom the husband was most affectionately attached; and it was decided in her favour by the sentence of persons appointed for that purpose, who never pronounced judgment till they had made a strict examination, and heard the allegations on all sides. The wife, who was ultimately preferred, ran to meet death, and ascended the funeral pile with incredible firmness and joy; whilst the surviving wives withdrew with the most depressing regret and sorrow, and with their eyes bathed in tears. Some of the Brachmans, however, lived in cities, and associated with their own species; and so far from considering suicide, or a premature surrender of themselves to death, as a virtuous and brave action, they looked upon it as a weakness in man not to wait patiently the stroke of death, and as a crime to anticipate the will of the Gods. The Brachmans were all of one tribe; and in this respect, they differed from the Gymnosophists, and particularly from the Samanæans, who might have belonged to any family or Indian tribe. They formed the first and principal of the four casts that subsisted from time immemorial among the Hindoos, and that were supposed to be derived from Brama. See **CAST**.

In ancient times it should seem, that the Brachmans were not hereditary, or a distinct Levitical tribe; but that any member of the other casts might enter into this order, which was of course deemed inferior to the chief secular or military cast. But in latter times the case has been very different; for the meanest Bramin will not now condescend to eat with his sovereign. The Brachmans from the time of their birth were put under guardians; and as they grew up, had a succession of instructors. They were in a state of pupillage till 36 years of age; after which they were allowed to live more at large, to wear fine linen and gold rings, to live upon the flesh of animals not employed in labour, and to marry as many wives as they pleased. Others of them submitted, through their whole lives, to a stricter discipline, and passed their days upon the banks of the Ganges, with no other food besides fruits, herbs, and milk. The rigours practised by the Brachmans are almost incredible, and would hardly be believed, if they were not attested by the best authority, and by the reports of modern travellers concerning the cruelties, penalties, and even tortures, which are commonly practised without scruple by the Indian Bramins. Pliny relates, (N. H. l. vii. c. 2.) that some have stood with their eyes stedfastly fixed upon the sun from morning to night, and that others have remained, in one and the same painful posture, upon the burning sands, for whole days. For a further account of the tenets and practices of the ancient Brachmans, see **GYMNOSOPHISTS** and **SAMANÆANS**.

Among those Brachmans, that are mentioned with particular respect by the Greek writers, who treat of the time when Alexander visited India, and particularly by Strabo, (Geog. l. xv.) are Mandanis and Calanus. The former is celebrated for the boldness with which he censured the intemperance and licentiousness of Alexander and his army, in a conference which he held with Onesicritus. The latter, when he saw Alexander's messengers clothed with fine linen garments and elegantly adorned, laughed at their effeminaey, and requested them, if they wished to hold any conference with the Brachmans, to lay aside their ornaments, and, like them, recline naked upon the rocks. Of him, it

is also related, that when he found the infirmities of age coming upon him, he devoted himself to voluntary death, and ascending the funeral pile, said, "Happy hour of departure from life, in which, as it happened to Hercules, after the mortal body is burned, the soul shall go forth into light!"

The modern Bramins of Hindostan derive their name from the ancient Brachmans, and pretend to derive their doctrine and practice from the same origin. In several particulars, the resemblance is manifest; and although much inferior, both as philosophers and men of learning, to the reputation of their ancestors, as priests their religious doctrines are still followed by the whole nation, and as preceptors they are the source of the greatest part of the knowledge which exists in Hindostan. However, sir William Jones, and several other intelligent authors on that subject, caution us against confounding the ancient Brachmans with the modern Bramins. The religion of Bouddha, (see **BOODH** and **BIRMAN empire.) still retained by the Birmans and other adjacent nations, it is said, was the real ancient system of Hindostan; but the artful Bramins have introduced into it many innovations, in order to increase their own power and influence. If the conjectures of sir William Jones, relative to the inscriptions found at Mongueer, and on the pillar at Buddal, (*Asiat. Researches*, vol. i. p. 123, &c. 8vo.) be well founded, it appears that the governing power on the banks of the Ganges, as late as about the time of the birth of Christ, belonged to the sect of Bouddha. Although the Bramins had then introduced themselves into Hindostan, and had obtained lands, and even the rank of prime minister to the great Rajah; they had not persuaded him to change his religion, a change which, when accomplished (says Dr. Buchanan, *Asiatic Ref.* vol. vi. p. 165.) proved equally destructive to the prince, and to the people. He adds, "however idle and ridiculous the legends and notions of the worshippers of Bouddha may be, they have been in a great measure adopted by the Brahmins, but with all their defects monstrously aggravated: rajahs and heroes are converted into gods, and impossibilities are heaped upon improbabilities. No useful science have the Brahmins diffused among their followers; history they have totally abolished; morality they have depressed to the utmost; and the dignity and power of the altar they have erected on the ruins of the state, and the rights of the subject. Even the laws attributed to Menu, which, under the form in use among the Burmas, are not ill suited for the purpose of an absolute monarchy, under the hands of the Brahmins have become the most abominable and degrading system of oppression, ever invented by the craft of designing men." From the account which Mr. William Chambers has given of the sculpture and ruins at Mavalipuram, (*Asiat. Ref.* vol. i. p. 160, 161.) we have very good reason for believing, that the worship of Bouddha once extended over all India, and that it was not rooted out by the Bramins in the Decan so late as the 9th, or even the 12th century of the christian era. Dr. Buchanan observes, (*As. Ref.* vol. vi. p. 163.) that this opinion of the late introduction of the superstition now prevailing in Hindostan is not contradicted by the almost singular remain of the Hindoo history; the only one which has escaped the destructive research of the cunning Bramin; i. e. the history of Cashmere presented to the sultan Akber on his first entrance into that kingdom. We are told, (*Ayeen Akbery*, ii. 173.) that the Sultan caused this book to be translated, and of this translation Abul Fazil has given an abridgment. This informs us, that when Cashmere was freed from an inundation, by which it had been covered, a certain Kushup brought the Bramins to inhabit the new land; that, after a long time, a general**

assembly of the inhabitants was called, who elected a man celebrated for his virtue to be their king; and that from thenceforward monarchy was established in that delightful region. The name of the first successor to this king, that is mentioned, is Owngund, contemporary with Kishen; referred by Dr. Buchanan to the year before Mahommed 870, or B. C. 248. These Bramins, whom Kishup brought to Cashmere, could not, our author apprehends, be the Bramin sect of priests, as they cultivated the earth, and were the only inhabitants of the country; but they must have been one of the Brachman nations, several of which, according to Pliny, were dispersed over India; and these again, he conjectures, are the same with the Biamma of the Rāhāns, supposed by them to have been the first inhabitants of the earth. "That this must be the meaning of the history of Cashmere (he says) seems plain; as we are told, rajah Jenek the 45th prince, and who, according to my theory, must have lived about the year of Christ 202, established in his reign the Brahmeny rites. His successor Jelowk, the most powerful of the princes of Cashmere, tolerated the doctrine of Bowdh; and in that delightful valley it was not till the reign of Nerkh, the 59th prince, A. D. 342, that the Brahmins got the better of the followers of Bowdh, and burned down their temples." In process of time, as the Rāhāns, or priests of Godama in the Birman empire, were entirely prohibited the study of astrology, and as the people were much addicted to all kinds of divination, the Bramins availed themselves of their credulity, and established themselves in considerable numbers all over India beyond the Ganges. It does not seem, however, that they have any concern in the religion of these countries; but they are merely employed about the courts, and in the houses of the great, as the Chaldeans were about the kings of Persia, as sooth-sayers and wisemen. They annually compose Almanacks; they perform incantations, under the throne of the king, before an audience is given on solemn occasions; they are consulted in all matters of importance, for determining the fortunate hour or season in which these ought to be undertaken; and they bestow on their protectors, amulets, charms, and such trifles. By such means the Bramins have rendered themselves important and useful in the Birman empire, and have obtained many privileges, confirmed even by the written law of the kingdom. However, their introduction into the Birman kingdom is a very recent event. The knowledge of the Birman Bramins is chiefly confined to astrology, and, it is said, that they are very ignorant of astronomy; in so much that, when they attempt to calculate eclipses, they do not pretend to ascertain either the hour of their commencement, or the extent of the obscuration. It is also asserted that the Bramins of Hindostan are not much farther advanced in science than those of Amarnapura, notwithstanding the improvements they have introduced from time to time, as they were able to procure information from their conquerors, Mahomedans and Christians. The lunar zodiac, in use among the Bramins, has been exhibited by sir William Jones, (*As. Res.* vol. ii. 291, &c.) and is supposed by him to have been communicated to the Birmans from Chaldæa by the intervention of the Bramins; nor is it unreasonable to imagine that the Bramins have derived astronomical knowledge from the Greeks and Arabs.

The religion of the Bramins, according to the opinions maintained by Paulinus and sir William Jones, is essentially the same with that of the Egyptians; and M. Anquetil du Perron concurs with the latter in supposing that Egypt was the source from whence the Bramin worship has been spread over a great part of the Eastern world. The Bramin priests

in India adopted and extended it, and, as we have already observed, gained a superiority over the priests of Bouddha about the time of Christ; and about 900 years afterwards, they totally overthrew his doctrine in its native country. The Vedas, which are the oldest books of the Bramins, are inferior in antiquity to the time of Bouddha, because they mention the name of that personage. Against the Egyptian origin of the Braminical worship, the cosmography of the Bramins has been adduced: this is nearly the same with that of the Rahans, and seems to have been framed in the north of Hindostan. However, we may reasonably suppose the Bramins to have been a colony of Egyptians, who formed their first establishment in the vicinity of Bombay; as the images in the cave at Elephanta (which see) seem to be those of the gods of the Bramins. By degrees they engrafted their superstition on the ignorance of the Hindoos, adapting the African deities and mythical philosophy to the Asiatic fables and heroes, and carefully introducing the Egyptian cast and ceremonies, with all their dreadful consequences. Some have supposed, that the religion of the Bramins was introduced from Egypt into India as early as the time of Sesostris; but to this opinion it has been objected, that the object of his military expeditions, if indeed we allow their reality (see *SESOSTRIS*), appears to have been plunder, and the capture of slaves, rather than the propagation of religion or philosophy. The persecution of the Egyptian priests by Cambyfes is an event more likely to have produced an extensive migration into India; nor is it improbable that the Egyptians, who before this time traded to India, might have communicated some knowledge of their science to the Hindoos.

Whatever was the precise æra of the introduction of the Bramins into India, it seems to be unquestionable, that, in the usual course of human affairs, a contest arose, at some period or other after their settlement, between the regal and ecclesiastical powers. The latter, instead of being subdued, as in China and Japan, acquired the superiority, as in Thibet. But in Hindostan, from a most refined and cunning policy, the priesthood asserted the divine institution of the several casts (see *CAST*), and, in the natural progress of their power, pronounced their own to be the supreme, and possessed of innate and hereditary sanctity. It seems to be allowed that Boodh was a deified philosopher; and it is also probable, that Brahma was the sophist who invented the new casts, and was not only deified, but placed in the first rank of the gods, by the grateful priesthood, which assumed the sole direction of the national mythology. The chief modern deities of the Bramins are Brahma, Vishnu, and Siva, i. e. the creator, the preserver, and the destroyer, corresponding to the three characters under which the Greeks represented their Zeus or Jupiter. But the fundamental principle of the whole fabric of Indian mythology, conformable to the universal system of the east, was the belief in a supreme creator, too ineffable and sublime for human adoration, which was therefore addressed to inferior, but great and powerful divinities. The names and attributes of the gods and goddesses (for the voluptuous Hindoos delight in female divinities), are very numerous, and, as human ideas and wants are almost universally the same, correspond in many instances with the Greek and Roman polytheism. The chief divinities of the Hindoos are well represented in Sonnerat's decorated publication; and we have an elaborate account of them in a tract "On the Gods of Greece, Italy, and India," published in the first volume of the Asiatic Researches, p. 221—275.

The Bramins of Hindostan constitute the first and chief body of the four orders or casts (see *CAST*) into which the whole of the people is distributed. Their order is deemed the

the most sacred; and to them belongs the province of studying the principles of religion, performing its functions, and cultivating the sciences. They have been for a long time, whatsoever be their origin, and whether it be more ancient or more modern, the priests, the instructors, and the philosophers of the nation. Such is the superiority of their cast or order, even to that of the monarchs of India, with regard both to rank and sanctity, that they would deem it degradation and pollution, if they were to eat of the same food with their sovereign. Their persons are sacred, and even for the most heinous crimes they cannot be capitally punished; their blood must never be shed. On important occasions, it is the duty of sovereigns to consult them, and to be directed by their advice, as was the case with respect to the ancient Brachmans. Their admonitions, and even their censures, must be received with submissive respect. From some accounts preserved in India of the events which have happened in their own country, we find, that princes, who violated the privileges of the casts, and disregarded the remonstrances of the Bramins, have been deposed by their authority, and put to death. The discoveries of modern times, procured and furnished by those who have visited India during the course of the three last centuries, afford us a considerable degree of authentic information concerning the state of science among the Bramins. The distinction between matter and spirit appears to have been known at an early period by the philosophers of India; nor can any description of the human soul be more suited to the dignity of its nature than that given by the author of the "Mahabarata," an epic poem, in high estimation among the Hindoos, composed, according to their account, by Kreesna Dwyipayen Veias, the most eminent of all their Bramins, above 3000 years before the Christian æra. This poem consists of more than four hundred thousand lines. Mr. Wilkins has translated above a third part of it; but only a short episode, entitled "Baghvat-Geeta," is published. "Some," says the author, "regard the soul as a wonder; others hear of it with astonishment; but no one knoweth it. The weapon divideth it not; the fire burneth it not; the water corrupteth it not; the wind drieth it not away; for it is indivisible, inconsumable, incorruptible; it is eternal, universal, permanent, immovable; it is indivisible, inconceivable, and unalterable." With regard to the knowledge of logic and metaphysics, for which the Bramins have been celebrated, we learn from Abul Fazil's compendium of the philosophy of the Hindoos in the Ayeen Akbery (vol. iii. p. 95, &c.); from the specimen of their logical discussions contained in that portion of the SHASTER, published by colonel Dow (Dissertation, p. 39, &c.); and from many passages in the Baghvat-Geeta; that the same speculations which occupied the philosophers of Greece had engaged the attention of the Indian Bramins; and the theories of the former, either concerning the qualities of external objects, or the nature of our own ideas, were not more ingenious than those of the latter. That sceptical philosophy, which denies the existence of the material world, and asserts nothing to be real but our own ideas, seems to have been known in India as well as in Europe; and the sages of the East, as they were indebted to philosophy for the knowledge of many truths, and were able to define with accuracy, to distinguish with acuteness, and to reason with subtlety, were not more exempt than those of the West from its delusions and errors. To the subject of ethics the Bramins had directed particular attention; and their sentiments seem to have been various; so that, like the philosophers of Greece, they were divided into sects, distinguished by maxims and tenets often diametrically opposite. From several passages that occur in the Baghvat Geeta we may infer, that

the distinguishing doctrines of the Stoical school were taught in India many ages before the birth of Zeno, and inculcated with a persuasive earnestness nearly resembling that of Epicæctus. From India the western world derived their knowledge of the modern mode of notation by 10 cyphers or figures, which have been universally adopted, and found so convenient for performing every operation in arithmetic with the greatest facility and expedition. (See ARITHMETIC.) The astronomy of the Indians affords a proof still more conspicuous of their extraordinary progress in science. To M. de la Loubere, on his return from an embassy to Siam, A.D. 1687, we are indebted for an extract from a Siamese MS. which contained tables and rules for calculating the places of the sun and moon. The epoch of these tables corresponds to the 21st of March, A.D. 638. Another set of tables was transmitted from Chirnaouram, in the Carnatic, the epoch of which answers to the 10th of March, A.D. 1491. A third set was brought from Narfapour, the epoch of which is between the 17th and 18th of March, A.D. 1569. The fourth and most curious set of tables was published by M. Le Gentil, who received them from a learned Brahmin of Trivalore, on the Coromandel coast. The epoch of these last tables is very ancient, and coincides with the beginning of the celebrated æra of the Collee Jogue, which, according to the Indian account, commenced 3102 years before the birth of Christ. The calculations of M. Bailly, founded on these four sets of tables, have been verified by Mr. Playfair, who has also illustrated and extended his reasonings, in a learned dissertation published in the Transactions of the Royal Society of Edinburgh, vol. ii. p. 135. From the inquiries, reasonings, and calculations that relate to Indian astronomy, it has been inferred, that the motion of the heavenly bodies, and more particularly their situation at the commencement of the different epochs to which the four sets of tables refer, are ascertained with great accuracy; and that many of the elements of their calculations, especially for very remote ages, are verified by a surprising coincidence with the tables of the modern astronomy of Europe, when improved by the latest and most nice deductions from the theory of gravitation. The Indian Bramins annually circulate a kind of almanack, which contains astronomical predictions of some of the most remarkable phenomena in the heavens, such as new and full moons, the eclipses of the sun and moon; and they seem to possess certain methods of calculation, that involve a very extensive system of astronomical knowledge. M. Le Gentil, while in India, had an opportunity of observing two eclipses of the moon, which had been calculated by a Bramin; and he found the error in either to be very inconsiderable. The method of calculating eclipses, adopted by the Bramins, is very different from that which was practised among rude nations in the infancy of astronomy, and founded on an analysis of the motions of the sun and moon, which indicate a considerable acquaintance with these motions. Indeed, the modern Bramins, though they are guided in their calculations by scientific principles, do not understand them; nor are they acquainted with the method of constructing the tables, to which they recur in their computations. Of course the ancient Bramins, who constructed the tables and rules now in use, must have possessed an extensive and tolerably accurate acquaintance with the elements of geometry, and also with the principles of plain and spherical trigonometry. See BENARES.

With regard to the religious institutions of the Bramins, they seem to be artfully contrived with a view of extending their own authority, and maintaining their influence over the people. They form, indeed, a regular and complete system of superstition, strengthened and upheld by every circumstance that can excite the veneration, and secure the attach-

ment of the multitude. The temples consecrated to their deities (see PAGODA) are magnificent, and highly ornamented with the most exquisite work in painting and sculpture; the rites of their worship are pompous and splendid, and the performance of them constitute an essential part of the more momentous transactions of common life; and the Bramins themselves, who are the ministers of religion, and preside in all its functions, are of an order elevated above all others, acknowledged to be sacred, and, by a gradation of rank among themselves, adapted to maintain subordination in their own class, and to give them a more absolute dominion over the minds of the people. This dominion they are enabled to support by having a command of the immense revenues, with which the liberality of princes, and the zeal of pilgrims and devotees, have enriched their pagodas. The number of their deities, the attributes and characters they ascribed to them, and the various rites by which they celebrated their worship, are such as indicate their origin in the rude age of society, and such as are adapted, in their nature and design, to answer the purposes of their introduction and establishment. The manners of the Indians, though distinguished, from the time when they became known to the people of the West, for mildness, seem, in a remoter period, to have resembled those of other nations. Accordingly, several of their deities were fierce and awful in their nature, and were represented in their temples under the most terrific forms. By the known influence of superstition we shall be able to account for the establishment of a ritual of worship suited to the character of such deities, among a gentle people. Every act of religion, performed in honour of some of their gods, seems to have been prescribed by fear; and a variety of mortifications and penances was introduced among them, the recital of which is accompanied with horror. Although it is repugnant to the feelings of an Hindoo to shed the blood of any creature that has life, many different animals, not excepting the most useful, such as the horse and the cow, were offered up as victims upon the altars of some of their gods; and their pagodas were even polluted with human sacrifices, as well as the temples of the West. But religious institutions, and ceremonies of a less severe kind, were more adapted to the genius of a people, formed, by the extreme sensibility of their mental and corporeal frame, to an immoderate love of pleasure. Accordingly, there is no part of the earth, in which a connection between the gratification of sensual desires and the rites of public religion is displayed with more shameful indecency than in India. In every pagoda a band of women was set apart for the service of the idol honoured there, and devoted from their youth to a life of pleasure, for which the Bramins prepared them by an education, which added so many elegant accomplishments to their natural charms, that what they gained by their profligacy often brought no inconsiderable accession to the revenue of the temple. It is the office of these women, in every service performed in the pagoda, and in every public procession, to dance before the idol, and to sing hymns in his praise; and it is difficult to say, whether they trespass most against decency by the gesture which they exhibit, or by the verses which they recite. The walls of the pagoda are covered with paintings in a style no less indelicate; and in the innermost recess of the temple is placed the "Lingam," an emblem of productive power, which it would be improper to explain.

If we advert to the theology of the Bramins, we shall find that, amid all their polytheism and superstition, they acknowledge and reverence one Supreme Being, the creator of all things, and from whom all things proceed. "They all," says Abul Fazil (Ayeen Akbery, vol. iii. p. 3.) "believe in the unity of the godhead; and although they hold

images in high veneration, it is only because they represent celestial beings, and prevent the thoughts of those who worship them from wandering." To the same purpose, the Pundits, who translated the "Code of Gentoo laws," declare, that "it was the Supreme Being, who by his power formed all creatures of the animal, vegetable, and material world, from the four elements of fire, water, air, and earth, to be an ornament to the magazine of creation; and whose comprehensive benevolence selected man, the centre of knowledge, to have dominion and authority over the rest; and having bellowed upon this favourite object judgment and understanding, gave him supremacy over the corners of the world." These refined sentiments the modern Bramins derive from the writings of their ancient Pundits, to which they are also indebted for the wisdom which the most learned members of their order now possess. The most profound mysteries of the Hindoo theology, which had been long carefully concealed by the art of the modern Bramins from the body of the people, have been unveiled by the translations from the Sanscrit, or SHANSKRIT language lately published. The principal design of the Baghvat-Geeta, already cited, seems to have been to establish the doctrine of the unity of the godhead, and, from a just view of the divine nature, to deduce an idea of that kind of worship which will be most acceptable to a perfect being; and we find in this poem descriptions of the Supreme Being, equal in sublimity to any which we derive from the Greek philosophers. Dow, in his "Dissertation," (p. 40.) quotes a passage from one of the sacred books of the Hindoos, from which we may infer what were the general sentiments of the learned Bramins concerning the divine nature and perfections: "As God is immaterial, he is above all conception; as he is invisible, he can have no form; but from what we behold of his works, we may conclude, that he is eternal, omnipotent, knowing all things, and present every where." To men capable of forming such ideas of the deity, the public service in the pagodas must have appeared to be an idolatrous worship of images, by a superstitious multiplication of frivolous or immoral rites; and they must have perceived, that it was only by sanctity of heart, and purity of manners, men could hope to gain the approbation of a Being perfect in goodness. This truth is sedulously inculcated in the "Mahabarat;" but, at the same time, with the prudent reserve and artful precautions natural to a Bramin, studious neither to offend his countrymen, nor to diminish the influence of his own order. We find, however, a very lamentable mixture of ignorance and error in all the theories of the Bramins, in common with the fables of other countries, concerning the perfections and operations of the Supreme Being. As they held that the system of nature was not only originally arranged by the power and wisdom of God, but that every event which happened was brought about by his immediate interposition; and as they could not comprehend how a being could act in any place in which it was not present, they supposed the deity to be a vivifying principle diffused through the whole creation, an universal soul that animated each part of it. Every intelligent nature, particularly the souls of men, they conceived to be portions separated from this great spirit, to which, after fulfilling their destiny on earth, and attaining a proper degree of purity, they would again be re-united. In order to efface the stains with which a soul, during its residence on earth, has been defiled, by the indulgence of sensual and corrupt appetites, they taught that it must pass, in a long succession of transmigrations, through the bodies of different animals, until, by what it suffers and what it learns in the various forms of its existence, it shall be so thoroughly refined from all pollution, as to be rendered meet for being absorbed into the divine essence, and returns like a drop into that un-

bounded ocean, from which it originally issued. These doctrines of the Bramins concerning the deity, as the soul which pervades all nature, giving activity and vigour to every part of it, as well as the final re-union of all intelligent creatures to their primeval source, coincide with the tenets of the Stoical school. In the errors also of their theological speculations we may discover a great similarity. As it was maintained by many among the Greek and Roman philosophers, that the vulgar and unlearned had no right to truth, the Bramins of India adopted similar ideas, and they regulated their conduct in the same manner with respect to the great body of the people. To their order belonged the exclusive right of reading the sacred books, as well as of cultivating and teaching science; and therefore they had it in their power more effectually to prevent all who were not members of the order from acquiring any information beyond what they were pleased to impart. Hence it happened, that, like many of the sages of Greece, the Bramins of India carried on, with studied artifice, a scheme of deceit, and, according to an emphatical expression of an inspired writer (Rom. i. 18.), they *detained* the truth in unrighteousness. Whilst they themselves knew and approved what was true, they laboured among the rest of mankind to support and perpetuate what was false.

The Bramins of Hindoستان have a language peculiar to themselves, which they call Sanserit or Shanferit (which see); and in this language they have ancient books written, as they allege, by their great prophet and founder Brahma; such as the *Beda*, or *Vedam*, delivered, as they say, to their lawgiver, Brahma, by the Deity; the *Shaster*, or *Shastah*, which is their bible; and *Puran*, or *Pourane*, a history which they deem sacred, and which they pretend to have been dictated by God himself, containing also the explanation of the *shaster*. For an account of these books, see each of these terms. These sacred books are kept in close custody by the Bramins; nor do they suffer their contents to be communicated to their own laity, much less to strangers. The *shaster* contains a summary of their moral and ceremonial laws, together with the distribution of mankind into tribes and classes, and an account of the rules of conduct appropriated to each. (See SHASTAH.) From this book, on the precepts of which the Bramins profess to found their practice, it appears, that their religion, and particularly the ceremonial part of it, consists in frequent ablutions in their rivers, and more especially in the Ganges, muttering over divers prayers under green trees, and in their temples, accompanied with processions, tinkling of bells, offerings to images, unctions, and similar rites, the observance of fasts and festivals, pilgrimages, invocations of saints, and divers strange and unaccountable penances. From their *Vedam* they pretend to derive several privileges, peculiar to their own order; such as those of celebrating the feast called "Iagam," at which they kill animals, and eat flesh, and offer a beast for sacrifice, which they strangle, in order to avoid shedding its blood; of teaching the Kutteries the manner of celebrating this feast; of reading the *Vedam*, and of teaching it to their own tribe, and that of the Kutteries; of demanding but not of giving alms; and of never being punished with death, even for the most enormous crimes. Their office is to teach others not only reading, writing, and arithm etc, but the principles of their religion. As a recompence for their time and labour, the kings, or rajahs, assign for their support the revenues of certain villages, and they also receive contributions from the inhabitants of the several countries in which they reside. They are also allowed to officiate as merchants, and to practise physic, but are strictly forbidden to employ themselves in tillage, or any handicraft trade; or to perform any

servile office, even for the king. An offence of this kind would incur degradation and expulsion from their tribe; however, they are permitted to act as secretaries, ambassadors, or counsellors to their sovereigns, and, indeed, they almost wholly engross these honourable offices to themselves. The birth, baptism, and education of the Bramins are attended with circumstances and ceremonies peculiar to themselves. At their baptism, they are not only washed with water, but anointed with oil, which rites are accompanied with prayers and benedictions. At an early age, they are invested with a small cord, which is hung on the left shoulder, and descends low on the right side; and which they retain as an essential article of their attire. The Bramins never contract marriage out of their own tribe, and that they do at a very early period of life. On this occasion they receive a second little cord, resembling the first, and to this also they usually annex a third, which serves instead of an upper garment. When the Bramins arrive at maturer and more advanced age, they are allowed to take wives out of the other tribes; but they never marry their children to near relations, as incest is deemed by them one of the five mortal sins which is scarcely ever to be forgiven. Among the Bramins polygamy is indulged to great excess; and as an apology for it, they allege, that the *Vedam* has not forbidden it. For concubinage and adultery they have no punishment; but a Bramin who finds his wife to be inconstant, confines her and supplies her with food while she lives; and if he is much attached to her, he requires her to serve at a feast, to which he invites several of his tribe, and after the guests have received victuals from her hand, she is regarded as an honest woman. Their diet, like that of the ancient Brachmans, is simple and temperate, and consists solely of rice, roots, fruits, and herbs, and their drink is water and milk. They never use any intoxicating liquor; for they abhor drunkenness, and reckon it among their mortal sins. Although the Bramins decline eating flesh, because they deem the slaughter of animals for this purpose to be a great sin; they are, however, charged with inconsistency by the Kutteries and Soudras, who eat fish and flesh, as they dislodge many souls from their bodies by plucking up roots and plants, which, upon their system of transmigration, are endued with souls as well as animals.

The Bramins, as we have already observed, are priests both secular and regular, and have amongst them an established hierarchy, composed of several orders, that are variously distinguished in the several provinces of Hindoستان. The learned Bramins constitute two classes; the first of which is called "Kuru," and belongs to the priesthood; the second, denominated "Sastriar," or "Shastriar," comprehends the professors of the different systems of theology. Besides these two classes of learned Bramins, there are many others, not much inferior to them in wisdom and erudition, whose chief business is to instruct youth in those points which relate to the ceremonies used in public worship, and solemn festivals. The ministerial function of the Bramins consists in praying with the people, and reading their law. To them it also belongs to educate the young persons of the same tribe, who advance by various gradations to the priestly office. When they are set apart to this office, they are enjoined not to change their tribe; to observe all things contained in the law of the Bramins; and not to communicate the mysteries of their religion to any of a different persuasion.

The Bramins are divided into six sects; viz. Weistnouwa, Seivia, or Aradheya, Smartu, Shauvakka, Pafenda, and Checktea, who are distinguished by certain differences in their tenets, and ceremonial practices. For a further account of the

the doctrines, worship, character, customs, &c. of the Bramins, we may refer to the *La Porte Ouverte* of M. Roger, chaplain to the Dutch factory at Poohcat on the coast of Coromandel; the travels of Bernier and Sonnerat; the *Dissertations* of Orme, Dow, sir William Jones, &c. &c.; the *Code of Gentoo Laws*; the *Asiatic Researches*; Robertson's *Dissertation* concerning India, &c. See also the articles above referred to, and also **BENARIS**, **HINDOOS**, **HINDOSTAN**, &c. in this dictionary.

Robert de Nobili, an Italian Jesuit, and one of the Indian missionaries, in the beginning of the seventeenth century, in order to secure success to his mission, assumed the title and appearance of a Brachman, and at length persuaded the credulous people, that he was, in reality, a member of that venerable order. He forged a deed in the ancient Indian characters, shewing that the Brachmans of Rome were older than those of India, and that the Jesuits of Rome descended in a direct line from the god *Brahma*. He farther declared on oath, that he derived his origin from this Indian deity. By this imposture he profelyted twelve eminent Brachmans, whose influence proved very favourable to his mission. After his death, the Portuguese Jesuits carried on the imposture with very considerable success. These missions, however, were suspended and abandoned, in consequence of a papal mandate, issued out in the year 1744, by Benedict XIV. who declared his disapprobation of the artifices that had been used in the conversion of the Indians. Mosheim's *Eccles. Hist.* vol. iv. p. 211, &c. 8vo. edit.

**BRACHMANUS**, in *Ancient Geography*, a river of India, on the other side of the Ganges, between this river and Catabeda.

**BRACHME**, **CANJE-VARAM**, a town of India, in the peninsula on this side of the Ganges, according to Ptolemy. It was situated in the interior of the country, at an equal distance from the eastern coast of the peninsula and the town called *Arcatis*, and occupied by the people denominated by Ptolemy "Brachmani Magi."

**BRACHODES**, the name of a promontory in the Mediterranean, on the coast of Africa. Ptolemy. Strabo calls it "Ammonis promontorium," and Procopius "Caput-Vada."

**BRACHSEN**, in *Icthyology*. See **BRAMA CYPRI-NUS**.

**BRACHVOGEL**, in *Ornithology*, the name given by Frisch to the *stelopax arguata*, or common curlew.

**BRACHURI**, in *Zoology*, a term applied by Dr. Hill to a genus of animalcules of a roundish figure, with tails shorter than the body. The vermes of this description have undergone of late years much accurate investigation, especially by Müller, the result of which is, that the genus of *brachuri* is exploded by modern writers on the *animalcula infusoria*.

**BRACHYACANTHUS**, in *Entomology*, an insect of the *ICHNEUMON* genus found in Europe. The colour is black; spots on the head and thorax; small line on the scutell, and tip of the abdomen white; sting very short; shanks fuscous, whitish at the base. Linn. &c.

**BRACHYACANTHUS**, a species of *ICHNEUMON*, the colour of which is black; antennæ fuscous; abdomen and legs yellow; sting very short. Linn. Inhabits Europe.

**BRACHYCOLON**, from *βραχυς*, short, and *κολον*, member, is when one member of a period is shorter than another.

In which sense, the word stands contradistinguished from *isocolon*, where the members are equal, or consist of the same number of syllables.

**BRACHYLOTTIS**, in *Botany*, (from *βραχυς*, short,

and *γλωττις*, a tongue.) Forster Nov. gen. Jussieu 181. La Marek pl. 677. Class, *syngenesia polygonia superflua*. Nat. Ord. *Composita radiata*. *Corymbifera*. Jussieu. Gen. Char. *Calyx* common, oblong, cylindrical, simple; scales linear, equal, cottony. *Cor.* compound, radiate. *Corrollules* of the *disk*, hemaphrodite, funnel-shaped, a little longer than the calyx, with a five-cleft upright, border; of the *ray*, ligulate, few, very short. *Seeds* oblong; down sessile, plumose. *Recep.* naked.

*Ess.* Char. *Flowers* radiate. *Corrollules* of the *ray* few, short, recurved, three-toothed. *Calyx* polyphyllous, connivent, cylindrical, equal. *Down* plumose.

Species, 1. *B. repanda*. Leaves ovate, repando-finate. 2. *B. rotundifolia*. Leaves nearly round, very entire. Forster.

**BRACHYLOTTIS**. See **CINERARIA**.

**BRACHYGRAPHY**, (from *βραχυς*, short, and *γραφω*, scribo, I write,) denotes the art of short-hand writing, called also **TACHYGRAPHY**. See **SHORT-HAND**.

**BRACHYLOGY**, from *βραχυς*, short, and *λογος*, expression, in *Rhetoric*, brevity, the expressing any thing in the most concise manner. This, so far as consistent with perspicuity, is a virtue and beauty of style; but if obscurity be the consequence, which is often the case, it becomes a blemish and inexcusable defect. Quintilian gives us an instance of brachylogy from Sallust: *Mithridates, corpore ingenti perinde armatus*: Mithridates, as it were armed with the hugeness of his stature. *Int.* Or. lib. viii. cap. iii.

**BRACHYOTOS**, in *Ornithology*, a species of **STRIX**, or **OWL**, of the horned kind. It is specifically distinguished by having the horn-feather or tuft very short; the body is fuscous above; feathers edged with yellow; beneath pale yellow, longitudinally streaked. Forst. Penn.—Donov. Brit. Birds. &c.—Buffon calls this kind of owl *chouette*, or *grande chevêche*. It is the short-eared owl of English ornithologists. The length is fourteen inches. Found in America as well as Europe.

**BRACHYPNŒA**, in *Medicine*, a term expressing short breathing, a symptom which occurs in various affections of the lungs, both acute and chronic, from *βραχυς*, short, and *πνέω*, I breathe. See **DYSPNŒA**.

**BRACHYPOTÆ**, a term applied to persons labouring under acute diseases, who drink but little, and with difficulty; from *βραχυς*, short, and *πότης*, a drinker. This term has been applied by some modern physicians to persons labouring under hydrophobia.

**BRACHYPTERA**, in *Entomology*, a species of **MANTIS**, found by Pallas in Russia. The colour is cinereous; thorax dentated; wings half the length of the abdomen. Haunts sandy deserts.

**BRACHYPTERA**, in *Ornithology*, the name of a genus of birds of the rapacious kind, in Willughby's System. The birds of this genus he distinguishes by the shortness of the wings, the word being derived from *βραχυς*, short, and *πτερον*, a wing; these, when folded, not reaching so far down as the extremity of the tail. Of this genus were the *goshawk*, *sparrow hawk*, and three kinds of *butcher-bird*. Neither the general term, nor the discriminating character laid down for it are recognized by modern ornithologists.

**BRACHYPTERUS**, in *Entomology*, a species of **CIMEX**, described by Linnæus, the colour of which is pale; body linear; wing-cases a third part the length of the abdomen. Inhabits Europe.

**BRACHYPTERUS**, a species of **GRYLLUS**, (*Tettigonia*, Fab. *Locusta*, Gmel.) Inhabits the north of Europe. This kind feeds upon the grass; it is of a greyish fuscous colour, and is distinguished further by having the wings, and wing-cases

*cases* half the length of the body, a circumstance to which its specific name alludes.

**BRACHYPYRENIA**, from *βραχυς*, *short*, and *πυρην*, *nucleus*, in *Natural History*, a genus of fossils of the class of *SEPTARIÆ*. The brachypyrenia have a short roundish nucleus, inclosed by, and contained within, the body of the mass.

**BRACHYTELOSTYLA**, the name of a genus of crystals.

The word is derived from *βραχυς*, *short*, and *τελος*, *perfect*, and *στυλος*, a *column*, and expresses a perfect crystal, with a short intermediate column.

The bodies of this genus are crystals composed of a short hexangular column, terminated at each end by an hexangular pyramid. Of this genus there are six known species. Hill's *Hist. Fossils*, p. 163.

**BRACHYURA**, in *Ornithology*, a species of *FRINGILLA*, that inhabits Italy. It is briefly described as being entirely yellowish.

This is the short-tailed sparrow, and short-tailed Italian sparrow of English writers. Brisson names it *passerculus bononiensis*.

**BRACHYURUS**, in *Entomology*, a species of *ICHNEUMON*, that inhabits Germany. The colour is fulvous: scutell fulvous; thorax, eyes, and abdomen, (which is linear at the base,) black. Schrank.—Abdomen and head testaceous; legs yellow.

**BRACHYURUS**, in *Ornithology*, a species of *LANIUS*, described by Pallas. The head above is ferruginous grey; eye-brows whitish; a black band from between the eyes to the ears; body above greyish, cinereous; beneath yellowish white; tail rounded.—This is the *short-tailed srike* of Latham. Found but rarely in Hungary.

**BRACHYURUS**, the short-tailed crow, a species of *CORVUS*, of a green colour; beneath tawnyish, and lined on the head with the same colour; wings with a white spot.

This bird inhabits the islands of the Indian ocean. The species admits of no less than seven distinct varieties, according to some writers, of which number Gmelin describes three, *corvus Philippinensis*, *corvus Bengalenfis*, and *corvus Madagascariensis*.

**BRACIEUX**, in *Geography*, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Blois, 3 leagues N. E. of Blois. The place contains 706, and the canton 10,250 inhabitants; the extent of the territory comprehends 345 kilometres and 14 communes.

**BRACKE**, a town of Germany, in the circle of Westphalia, and county of Oldenburgh; 18 miles N.N.E. of Oldenburg.

**BRACKE**, or **BRAKE**, a town of Germany, in the circle of Westphalia, and county of Lippe; one mile S. E. of Lemgow.

**BRACKENWITZ**, a town of Germany, in the circle of Upper Saxony, and middle mark of Brandenburg; 3 miles S. of Treuenbrietzen.

**BRACKET**, in *Building*, denotes a kind of wooden stay, in form of a knee or shoulder, serving for the support of shelves, &c. or a cramping-iron, which serves as a stay in timber work. The word is also written *braget*, and seems derived from the Italian *brachetto*, a diminutive of *brachio*, *arm*. Modillions are a sort of *brackets* to the *corona* of an entablature.

**BRACKETS**, in *Artillery*. See *CHEEKS of a Mortar*.

**BRACKETS**, in *Ship-building*, small knees serving to support the galleries, and commonly ornamented with carving. Also, the timbers fixed under the galleries and frame of a ship's head to support the gratings.

**BRACKISH water**, a mixture of fresh and salt water.

**BRACKLEY**, in *Geography*, an ancient borough town of Northamptonshire, England, consists of the two parishes of St. James's and St. Peter's, and a hamlet called Old Brackley. Leland states, that this place consisted of many streets, in his time, and that it was a flourishing town during part of the Saxon dynasty, till the Danes "raided it." Edward the III. made it a wool staple, and gave it a corporation; but it was not invested with borough privileges till the last parliament of Henry VIII., when two members were returned. "There was a fair castle," says Leland, "in the south-west end; the site and hill where it stood is evidently seen, and beareth the name of the Castle Hill, but not any piece of wall standing." Here were also three ancient catholic crosses, one of which, says this respectable antiquary, "was decorated with divers tabernacles, with ladies and men armed. Some say the staplers of the town made it; but I rather think some nobleman, lord of the town." This cross, 28 feet high, was taken down in 1706, by the duke of Bridgewater, to build the handsome town-house in its place. Robert Bossu, earl of Leicester, founded an hospital here in the time of Henry III. John, son of lord chancellor Ellesmere, was created viscount Brackley 14th James I., earl of Bridgewater the following year, and marquis, afterwards duke of Bridgewater, 6 George I. On Bayard's Green, between Brackley and Mixty, was held a famous tournament in 1249; and another was held here about the same time. The river Ouse rises near this town, and supplies it with water. Here are a weekly market on Wednesday, and five fairs annually. It is 13 miles from Northampton, and 63 N. W. from London. The two parishes and hamlet contain 183 houses, and 1495 inhabitants, of whom 533 are employed in manufactures. Gough's edition of Camden's *Britannia*; Bridge's history of Northamptonshire, folio.

**BRACKWADE**, a town of Germany, in the circle of Westphalia, and county of Ravensberg; 4 miles S. E. of Bielefeld.

**BRACLAW**, or **BRACKLAU**, a city of Poland, and capital of a palatinate of the same name, called also Lower Podolia, seated on the river Bog.

**BRACTEA**, a thin flake or spangle of any substance; it is used by many authors in the same sense with the word *lamina*, but usually in a sort of diminutive sense, expressing a small plate.

**BRACTEA**, **BRACTE**, in *Botany*, a name given by the Latins to very thin plates of gold, silver, or other metal, and applied by Linnæus to the floral leaves of a plant, first distinguished and described by himself. They consist of scales, or of small leaves, which differ from the other leaves of the plant generally in figure, and often in colour. They are placed sometimes on the peduncle, and always near the flower, so that in some cases they are liable to be mistaken for a perianth: they may, however, be distinguished from it by their continuing as long as the proper leaves; whereas the perianth withers as soon as the fruit becomes ripe. Good examples of bractæ may be found in *tilia* (linden or lime-tree), *melampyrum* (cow-wheat), *monarda* (oswego balm), &c.

According to the physiology of Linnæus, and his immediate pupils, they are formed in the bud, by a kind of anticipation, and become proper leaves of the new shoot or branch in the second year, if the state of inflorescence be not hastened on by the force of the medullary principle: but when that takes place, as in certain circumstances it naturally does, part of the nourishment which they would otherwise have received, being diverted to the use of the fructi-

fructification, they do not acquire their full vigour, and in consequence, dwindle into floral leaves. In proof of this theory, it is alleged, that if the fructification be prematurely destroyed by insects, or purposely cut off, they regain sufficient sustenance, and assume the form and size of perfect leaves. See the introduction to the second volume of the *Syſtema Nature*, and two dissertations, entitled *Prolepsi Phytarum*, published in the *Amoenitates Academicæ*.

The bractæ are placed by Linnæus under the head of what he fancifully calls fulera, props, or supports, from an idea that they sustain or strengthen either the whole plant, or some of its parts. In the *Syſtema Nature* they are distinguished according to their duration, into *caducous*, falling off before the end of the summer; *deciduous*, falling off at the end of the summer; and *perſiſtent*, remaining beyond the end of the summer: but it does not appear how the criterion laid down in the *Philosophia Botanica*, to discriminate a bractæ from a perianth, is to be applied to those that are caducous. They are styled *comose*, when they shelter the flowers in the form of a crown, tuft, or coma (head of hair) as in the *fritillaria imperialis* (crown imperial), *bromelia aanas* (pine-apple), &c.: but in this case they do not very happily correspond with the generic appellation *fulcrum*. They have the character of *imbricate*, when they are placed among the flowers so close to them and to one another, as to form a kind of spike or head, as in *prunella* (self-heal), and *origanum* (marjoram).

Bractæ not only afford excellent specific differences, but are sometimes admitted into the generic character, as in many genera of the natural order, umbelliferæ, and in some of the class didynamia; and are there said by Linnæus to constitute an involucreum; one of his species of calyx. They are, however, truly bractes; and would, doubtless, have been so considered by him, if, under that denomination, they had not interfered with the established principle, that generic characters are to be taken solely from the parts of fructification.

BRACTEA, in *Entomology*, a species of PHALÆNA of the noctua family, the wings of which are variegated, and in the middle of each of the anterior pair is a large shining golden spot. Fabr. &c. Found in England, though very rarely: more common in the south of Europe.

BRACTEARIA, in *Natural History*, the name of a genus of fossils of the talc class; the characters of which are, that they are composed of small plates in form of spangles, and each of these, naturally very thin or fissile, into very thin ones.

The word is derived from the Latin *bractea*, a *spangle*, or small and thin glittering particle of any thing.

There are many species of this genus denominated from the variety of their colours; as *MICA aurea*, or gold-glimmer, and *MICA argentea*, silver-glimmer, cat's-silver, &c.

BRACTEATA, in *Entomology*, a species of CICADA (*membracis*, Fabr.) of a small size, that inhabits Cayenne, the thorax of which is green, and without spots.

BRACTEATED, among *Antiquaries*, denotes a coin covered over with a thin plate, or leaf of some richer metal. See MEDAL.

Bracteated coins, or medals, *nummi bracteati*, are usually made of iron, copper, or brass, plated over, and edged with gold or silver leaf, and then stamped with the hammer or mill.

Medallists find some bracteated pieces even among the truly ancient coins. The French call them *fourrées*.

BRACTEATUS, in *Entomology*, a species of MONOCULUS, the shell of which is orbicular and unarmed. Mill. The shell of this kind is very pellucid; antennæ and legs furnished with bristles: eyes not conspicuous. Inhabits pure fresh water.

BRACTON, HENRY DE, in *Biography*, a celebrated English lawyer and judge of the 13th century, was, according to Prince (Worthies of Devon), a native of Devonshire; and having gained distinguished reputation by his study of both the canon and civil law at Oxford, he was appointed by king Henry III. one of his judges itinerant about the year 1244, and afterwards, as some say, lord chief justice of England. In the exercise of this office he conducted himself with exemplary integrity; but his fame is principally owing to his excellent treatise on the laws of England, generally entitled "De legibus et consuetudinibus Angliæ;" though he himself gave it the title of "Brito," whence many mistakes have occurred in writing his name. This work has always been esteemed one of the most accurate and methodical treatises on our laws. It was first printed at London, in 1569, in folio; and reprinted, in 1640, in 4to., from a collection of various manuscripts for the amendment of the text. Some inconsistencies have been charged on Bracton from the citation of different passages in his book; in some he seems to discover too great an attachment to the authority of the pope; and in others he gives such various representations of the regal authority in this kingdom, as seem to favour sometimes the extension, and at other times the restraint and limitation, of the royal prerogative. These inconsistencies, however, have been ascribed by candid writers to the unsettled times wherein he lived, in which the power of the king and that of the barons were alternately prevalent, and charters of liberty were no sooner signed than violated. The time of his death is not precisely ascertained: but he probably survived his master, and died in the reign of Edward I. Biog. Brit.

BRAD, in *Geography*, a town and capital of a district of the same name, in the county of Weissenburg, in Transylvania.

BRADDOCK'S *field*, a place in America, situate on Turtle creek, on the N. E. bank of Monongahela river, 6 miles E. S. E. from Pittsburg, and rendered memorable by the defeat of general Braddock, who with 1400 men, the first division of his army, fell into an ambuscade of 400 Indians, by whom he was defeated and mortally wounded, July 9th, 1755. The American militia, disdainfully placed in the rear, continued unbroken, and served as a rear-guard; and under col. Washington, afterwards president of the United States, preserved the regulars from being entirely cut off.

BRADDOCK'S *bay* lies on the south side of lake Ontario, 42 miles west from Great Sodus, and 65 east from fort Niagara.

BRADFIELD, a market town of England, in the county of Essex.

BRADFORD, JOHN, in *Biography*, a protestant martyr, who flourished in the reign of queen Mary, was born at Manchester, in the early part of the reign of king Henry VIII. Having received a good education, not only in the Latin tongue, but particularly in writing and accounts, he was recommended to sir John Harrington, treasurer, pay-master of the forces, and principal engineer at Boulogne, and was employed by him as his clerk. In this employment, for which his education had eminently qualified him, he continued many years, approving himself to his principals, and deriving from his office considerable emolument as well as honour. In the discharge of his trust, however, he seems to have availed himself of his acuteness and dexterity, as an accountant, in a manner that rendered him uneasy in his own mind, more especially after he had heard a sermon from Latimer on the subject of "Restitution;" and he immediately determined to procure an adjustment of his accounts with the crown, and to apply to his master,

for John Harrington, for this purpose; for John demurred and delayed, and thought Bradford conscientiously precise and scrupulous. This incident gave a new direction to his views and pursuits; and though for some time he pursued the study of the law at the Inner Temple, he resolved to remove to Cambridge, and to devote himself to the profession of a divine. In this new situation he applied to his studies with singular diligence, and first took his degree of M.A.; and was afterwards elected fellow of Pembroke hall. During this time the recollection of his former misconduct oppressed his spirits, nor was he able to recover the tranquillity of his mind till, by successive payments, as his circumstances would allow, he had discharged the full sum of 520l. 10s. as a restitution to the king. By this act of just retaliation, performed voluntarily on his own part before the king and council knew of the offence, did he give the most unequivocal proof of the sincerity of his repentance, and lay the surest foundation of that reputation and usefulness for which he was afterwards distinguished. Having thus pacified the accusations of his conscience, he proceeded in his studies with unabated vigour; and his character for piety was likewise so eminent, that bishop Ridley, in 1550, sent for him to London, induced him to receive deacon's orders, gave him a licence to preach, and soon after appointed him one of his own chaplains. Mr. Bradford acquired great popularity as a preacher, both at St. Paul's Cross in London, and in his native county; and continued the exercise of his ministry with unintermitting ardour and singular success until the close of king Edward's reign, and after the commencement of that of queen Mary. But with the change that took place on this occasion, he, as well as many others, suffered the severity of persecution. His undaunted resolution and zeal exposed him to peculiar danger; and his popularity as a preacher, which afforded him an opportunity of preserving the life of a popish priest, who, by a furious declamation against the late king, and in favour of popery, had incensed the multitude that formed his auditory at St. Paul's Cross, was interpreted by his enemies into an occasion of offence; and in consequence of this act of humanity and kindness, for which he merited recompence even from the powers that then prevailed, he was arrested by order of the queen's council and bishops, and committed to prison under a charge of sedition and heresy. During his close confinement, for about a year and a half, in various prisons, he manifested an invincible attachment to the principles of the reformation; and exerted himself by private admonitions and epistolary addresses, for which he availed himself of every opportunity that occurred, in representing the delusions of popery, and in confirming those who were wavering in their adherence to the protestant faith. Many of his letters and discourses are extant; and they abound with expressions of the most fervent piety and unshaken constancy. In the beginning of the year 1554, he was brought before a commission specially appointed for his examination; but, as he persisted in an undiminished avowal of his opinion, he was finally condemned. After his condemnation, he was remanded to prison, where he remained near half a year longer; manfully resisting every attempt that was made with a view of inducing him to abandon the cause to which he was devoted, and recommending himself to mild treatment on the part of those who had the custody of him, by the gentleness of his temper and manners. During the successive intervals of his confinement, he preached constantly, and was allowed to receive the visits of his friends, who resorted in great numbers to enjoy the benefit of his discourses. So irreproachable and exemplary, indeed, was his conduct, and to such a degree did he attach the esteem, and interest the humanity of those who had access to him,

that many papists were induced to express their wishes for the preservation of his life. To his fellow prisoners he communicated salutary counsel and pecuniary assistance, as their several circumstances required; and he was eminently useful in reclaiming the erroneous, and in reforming the vicious and profligate. At length, however, the day of his execution arrived; and when it was announced to him, he lifted up his eyes to heaven, and said, "I thank God for it; I have looked for it a long time; therefore it comes not suddenly, but as a thing waited for every day and hour; the Lord make me worthy of it." On the 11th of July, 1555, he was brought to the stake at Smithfield, in company with a Yorkshire youth, named John Lyefe, then an apprentice in London, whom he animated to constancy by his example of calm and undaunted fortitude; and having kissed a faggot and the stake, he pulled off his cloaths, and prepared for the last tremendous scene. At the stake, he exclaimed aloud, with his hands and face lifted up towards heaven, "O England, England, repent thee of thy sins; beware of idolatry, beware of Antichrists, lest they deceive you:" and then forgiving, and intreating forgiveness of all the world, he comforted his companion, and embracing the flaming reeds that were near him, uttered these words, the last which were distinctly heard; "Strait is the way, and narrow is the gate," &c. and thus expired. Biog. Brit.

BRADFORD, *East and West*, in *Geography*, townships of America, in the county of Chester, and state of Pennsylvania.

BRADFORD, a township of Essex county in the Massachusetts, seated on the south side of Merrimack river, opposite to Haverhill, and 10 miles west of Newbury port. It has two parishes, and contains 1371 inhabitants. In this place is a manufacture of leather shoes for exportation, and some vessels are built in the lower parish. Several streams fall into the Merrimack river from this town, which support a number of mills of various kinds.—Also, a township in Hillsborough county, New-Hampshire, containing 217 inhabitants, incorporated in 1760; 20 miles E. of Charlestown.—Also, a township in Orange county, Vermont, on the west bank of Connecticut river, about 20 miles above Dartmouth college, having 654 inhabitants. In this township is a remarkable ledge of rocks, about 200 feet high, which appears to threaten the passing traveller; the interval between it and the river is scarcely wide enough for a road.

BRADFORD, a market and manufacturing town in Wiltshire, in England, 100 miles W. from London, and 7 N. E. from Bath. Its name appears to have been derived from the Saxon term *Bradensford*; so called from the broad ford which formerly crossed the river at this place. Though not a town of large extent, it has acquired considerable importance from the great quantities of fine broad cloth manufactured here, as from ten to twelve hundred pieces are sent away annually. One manufactory alone employs nearly fifteen hundred persons, and the number of clothiers is between sixty and seventy. Its situation is peculiarly romantic, being principally built on the declivity of a hill, and consists of three streets rising one above the other. These are narrow and irregular, yet many good houses present themselves to the eye of the passenger. The church, a plain stone building, with a square tower and small steeple, is situated at the foot of the hill, and consists of a nave, N. aisle, chancel, and a small chapel on the S. side. In the chancel are several large and handsome monuments, and the church is ornamented with two windows of modern stained glass, which were given by John Ferrott, esq. a native of Bradford; who also left a donation of ten pounds to be laid out in bread, and distributed among the poor monthly. Near the church is a free-school for boys, and in the town are two charitable

establishments for old men and women. The river, distinguished by the name of the Lower Avon, passes through, and divides the town into two parts, respectively termed the New and Old Town. These are connected by two stone bridges, one of three arches, the other of four. The markets, which are on Mondays and Saturdays, are well supplied with meat and vegetables. It has also two fairs for cattle, &c. Bradford formerly sent two members to parliament, who were summoned the twenty-third year of Edw. I. but discontinued the next year. The town was greatly damaged by fire on the 20th April 1742. The houses are 1288, and the inhabitants 7322, of which number 4648 are employed in the manufactory. By a notice in the Saxon chronicle, it appears that a battle was fought near this town in 652, between Kenewaleh, a west Saxon king, and the Britons, who were defeating the counties of Somerset, Devon, and Cornwall from Saxoa dominion; but their efforts proved unsuccessful, and Kenewaleh drove them farther westward. A nunnery was founded here by Aldhelm, bishop of Sherborne, about the year 706, which was totally destroyed in the Danish wars, and never afterwards restored. This lordship, with the parsonage, were given to the nunnery of Shaftsbury by king Ethelred in the year 1010. About 2 miles N. E. from Bradford is the village of Holt, noted for a medicinal spring which was discovered in the year 1718. Four miles N. W. is Monkton Parley, the seat of the duke of Somerset. About 3 miles S. W. are the mouldering ruins of Farley Castle, formerly one of the residences of the Hungerford.

BRADFORD, an ancient and considerable market and manufacturing town in the West Riding of Yorkshire, in England; is situated between Leeds and Halifax; 10 miles from the former, 8 from the latter, and 176 N. W. from London. It is an extensive parish, containing several subordinate hamlets, scattered cottages, and farms. The prosperous state of the clothing trade, and the augmentation of its manufactures since the general application of machinery, have conspired to increase considerably the buildings and population of this part of the country. In 1801 the houses of this town were estimated at 1368, and its inhabitants at 6323; about 1500 of whom were directly employed in manufactures. Though worsted stuffs are the staple trade of the place, yet some broad and narrow cloths, wool cards, combs, and leather boxes are also made here. For the convenience and accommodation of the tradesmen of the town, a public structure has been erected, called the Piece-hall, wherein various manufactured articles are exhibited and sold. In the vicinity of Bradford is a spacious iron foundery, with forge, &c. which is advantageously supplied with its coal and iron ore, on the spot: here have lately been cast some pieces of cannon for government. Three large iron-founderies are also established in this town; also a very spacious still-house, for the distillation of aquafortis and spirits of vitriol. By a cut from the Leeds and Liverpool canal, the manufactures of the place are cheaply conveyed to the great marts of commerce; and other merchandizes and materials are brought back in return. Bradford has a weekly market (Monday), and two principal fairs annually. The church is a large well proportioned structure, dedicated to St. Peter; and has under it the chapels of Thornton, Wibsey, and Haworth. The adjacent land is all inclosed, possessed by small proprietors, and mostly occupied by the manufacturers of the town. It is chiefly kept in pasture for the support of cows; but a small portion is ploughed, and appropriated to oats. At the commencement of the civil war in 1641, Bradford was besieged and ransacked by the earl of Newcastle's army.

At Pulfey, 4 miles from Bradford, is a large religious house, belonging to the Moravians; and consists of a chapel, refectory, dormitory, school, &c. See MORAVIANS. Aikin's Description of the country round Manchester, 410.

BRADING BAY, lies in the Isle of Wight, at the east end of the island, almost opposite to Portsmouth, and not far from St. Helen's road. It is generally dry at low-water, and when the tide is in, has only a narrow channel for small vessels, on account of a bar at the entrance.

BRADLEJA, in *Botany*, (in honour of Richard Bradley, F. R. S. the first professor of botany at Cambridge.) Schreb. 1474. Gærtner, 632. Glochidion, Forster. Clafs, *monocia monadelphia*, (Schreb.) *Monocia hexandria*, (La Marek.) Nat. Order, *Euphorbia*.

*Male Flowers.*

*Calyx*, none, (Schreb.) five or six leaves, persisting (Gærtner.) *Corol.* petals six, ovate, concave, spreading, nearly equal. (Schreb.) none, (Gært.) *Stam.* filaments three, very minute; anther cylindrical, erect, consisting of three united, didymous anthers, tipped with a sharp-pointed appendage. (Schreb.) six, (Gært.)

*Female Flowers.*

*Cal.* none. *Cor.* one-petalled, six-parted, inferior, three of the segments interior, (Schreb.) *Cal.* and *Cor.* as in the male, (Gært.) *Pijl.* germ globose, six-furrowed, superior; style, none: stigmas, from six to eight, very small, converging, (Schreb.) style thick, six-parted above, stigmas simple, obtuse, (Gært. from the papers of Solander.) *Perianth.* capsule depressed, with twelve furrows, six cells, and six valves, dehiscent. *Seeds*, solitary, roundish, (Schreb.) two in each cell, (Gært.)

Species 1. *B. juica*, (La Marek. illust. pl. 772. 2. branch in fruit,) a shrub. *Leaves*, alternate, lanceolate, veined. *Flowers*, axillary, single, peduncled. 2. *B. zeylanica*. A shrub. *Calyx*, monophyllous, six-parted, (Gært.) Flowers more than one on a peduncle, (La Marek.) 3. *B. Glochidion*, (Philippica, Cavanilles, pl. 371.) A tree. *Leaves*, alternate, lanceolate, smooth, axillary, very small and numerous.

Bradleja is nearly allied to phyllanthus; but the structure of the seeds is so singular, that it ought to be made a distinct genus.

BRADLEY, JAMES, in *Biography*, an eminent astronomer, was born at Shireborn, in Gloucestershire, in the year 1692, and received the first rudiments of education at a grammar school in North-Leach. He was admitted a commoner of Balliol college, in the University of Oxford, March the 15th, 1710-11; and took the degree of B. A. October the 24th, 1714, and that of M. A. January the 21st, 1716-17. In 1719, he was ordained deacon and priest; and preferred in the same year by the bishop of Hereford, who had made him his chaplain, to the vicarage of Bridftow in Herefordshire. The sinecure rectory of Landewy Welfry in Pembrokefhire was also procured for him soon after, by the honourable Mr. Molyneux. With such patronage he might have indulged reasonable expectations of more considerable preferments, and of attaining to eminence in the church; but his predilection for mathematical and astronomical studies gave a different direction to his views and pursuits. In these he was assisted and encouraged by his uncle, Dr. James Pound, who then resided at Wanstead in Essex, where our astronomer was curate, and where he commenced those observations that laid the foundation of his future fame.

On the 31st of October, 1721, he succeeded Dr. John Keil, as Savilian professor of astronomy at Oxford; and determining to devote himself to astronomy, so congenial to his

his taste and talents, he resigned his preferments in the church. In 1724, he communicated to the Royal Society his observations on a comet, which had appeared towards the close of the preceding year; and, in 1726, he communicated to the same body, of which he had become a member, a paper containing a comparison of some observations made at Lisbon, with those made by himself at Wanstead, on the eclipses of the first satellite of Jupiter, and published in the Philosophical Transactions, No. 396. (See Abr. vol. vi. pt. i. p. 412.) These communications were followed by his celebrated theory of the aberration of the fixed stars, the discovery of which was announced in 1728, and published in the Philosophical Transactions, No. 406. (See Abr. vol. vi. pt. i. p. 129.) For a particular account and illustration of this theory, of the principles on which it is founded, and of the important purposes to which it is applicable, see the articles *ABERRATION*, *LIGHT*, and *STAR*.

Our author's theory, established by the most accurate observations, was approved by the most eminent mathematicians; and whilst the publication of it served in a very high degree to advance his reputation, it was the means of introducing him to the acquaintance and friendship of the earl of Macclesfield, sir Isaac Newton, Dr. Halley, and several other persons of the most distinguished character.

In 1730 Mr. Bradley was appointed lecturer of astronomy and experimental philosophy in the University of Oxford; the duties of which office he performed till within a few years of his death. His observations on the comet that appeared in the beginning of the year 1737, were published in the Philosophical Transactions, No. 446, and an abstract of them may be found in the Abridgment, vol. viii. pt. i. p. 210. About this time Dr. Halley, who was then the astronomer royal, and who had conceived a very high opinion of Mr. Bradley's talents and attainments, formed a design of resigning in his favour; but his death prevented the accomplishment of his purpose. However, after that event, he obtained the appointment in February 1741-2; and was, at the same time, honoured with the degree of doctor of divinity by a diploma from Oxford. He was now in a situation peculiarly favourable for the prosecution of his favourite science; and he lost no opportunity of cultivating it by the number and accuracy of his observations. Accordingly, in 1747, he announced to the Royal Society his important discovery of the nutation of the earth's axis; which was published in the Philosophical Transactions, No. 485; and is preserved in the Abridgment, vol. x. pt. i. p. 32. For a particular account of this discovery, see *NUTATION*. The Royal Society, duly apprized of its value, conferred on Dr. Bradley their annual prize medal. By means of the excellent instruments, constructed by Mr. George Graham, Dr. Bradley, who knew how to use them, and what allowance ought to be made for the errors to which they were subject, was enabled to observe celestial phenomena, which had escaped the notice of former astronomers; and to the vigilance and accuracy of his observations we are indebted for the above-mentioned discovery. Sensible, however, of the importance and utility of good instruments, our excellent astronomer availed himself of the yearly visit of the Royal Society to the Royal Observatory at Greenwich, to recommend an attention to this business; and he succeeded in obtaining, by the interposition of the society, in 1748, a grant of 100*l.* from his majesty George II. to be laid out under his direction for the improvement of the astronomical apparatus. Mr. Graham and Mr. John Bird assisted him in the accomplishment of this object. To him the world is peculiarly indebted for the new naval quadrant, as well as for those other instruments which were set up in the Royal Observatory.

What use he made of them will further appear in the sequel of this article.

In 1748, Dr. Bradley was chosen a foreign member of the Royal Academy of Sciences at Paris; and about the same time he became entitled to bishop Crew's benefaction of 30*l.* a year to the lecturer in experimental philosophy at Oxford. In the year 1751, on occasion of a vacancy in the valuable living of Greenwich, it was thought to be conveniently situated for the Royal Observatory, and offered, on the part of the king, to Dr. Bradley. But he alleged that the duty of a pastor was incompatible with his other studies, and necessary engagements; and from the most conscientious and laudable motives declined accepting this valuable preferment. The king, however, determining that he should not lose by his integrity, granted him a yearly pension of 250*l.* (Feb. 15, 1752); which was continued till his death by his present majesty, and has since been regularly paid to the astronomer royal.

In 1752, Dr. Bradley was elected one of the council of the Royal Society; in 1754, he was appointed a member of the Academy of Sciences at Peterburg, by diploma from the whole body; and in 1757, he was admitted into the Academy of Sciences at Bologna; and he was also a member of the Prussian Academy of Sciences and Belles Lettres at Berlin. His observations on the comet of 1757, were published in the Philosophical Transactions, vol. i. part 1. p. 408.

Dr. Bradley prosecuted his studies and observations with unabated vigour and assiduity, till within about two years of his death; when, probably, as the effect of his intense and little varied application, his spirits began to be depressed, and he was disquieted by an apprehension that he should survive his rational faculties; a calamity, however, which he never experienced. Nevertheless, in 1760, his bodily strength declined; and about the end of June, 1762, he was attacked with a total suppression of urine, in consequence of an inflammation of the kidneys, which terminated his life, at Chalford in Gloucestershire, on the 13th of July, in the 70th year of his age. He was interred at Mitchin Hampton, in that county, in the same grave with his mother, and his wife, whom he married in 1744, and by whom he had one daughter, who survived him.

"The public character of Dr. Bradley," says one of his biographers, "as a man of science and discernment, is well established by his works. His private character was in every respect estimable. Temperate in his enjoyments, mild and benevolent in his disposition, indifferent to the calls of wealth, distinction, and even of fame; he was indebted to his uncommon merit alone for the friendship and regard of the most eminent men of his time. His manner was engaging and communicative, and his language in conversation clear, impressive, and fluent, though he was rather more disposed to listen than to speak. That he published so little may perhaps be ascribed to his scrupulous accuracy which rendered him diffident, or more probably to the calm and placid temper of his mind, which did not strongly urge him to solicit that attention he could at pleasure command." His observations made at the Royal Observatory during 20 years, comprized in 13 fol. and two quarto volumes, unfortunately for the interests of science, were taken away at his death by his representatives, who, upon preparations being made by government for recovering them by process of law, (and an actual commencement of a suit for that purpose,) presented them to lord North, by whom they were transferred, in 1776, to the university of Oxford, of which he was chancellor, on condition of their printing and publishing them. In June, 1791, fifteen years after the Obser-

vations had been given to the university on this condition, and nearly thirty years after the death of Dr. Bradley, the Board of Longitude, seeing no prospect of their being published, passed several spirited resolutions, respecting the public right to these Observations, and the importance of the publication of them, which were transmitted to the vice-chancellor of the university; after considerable delay, in March, 1792, the Board was informed that the delegates of the press in the university were proceeding with the work. About the same time in the following year the Board renewed its application to professor Hornsby, under whose direction the Observations were to be published; and he, in reply, engaged that the first volume should appear on or before March 2d, in the following year. At length, however, after long delay and renewed application, and successive interruptions occasioned by the ill health of Dr. Hornsby, the first volume was published in 1798, in a splendid form, more worthy indeed the magnificence of a great university, than suitable to the use of the practical astronomer; under the title of "Astronomical Observations made at the Royal Observatory at Greenwich, from the year 1750, to the year 1762," folio: the price in sheets being five guineas. Dr. Hornsby, after having stated in a preface the causes of the delay attending the publication, proceeds to give some account of the instruments used by Dr. Bradley. The tables contained in this volume are "Observed transits of the sun, planets, and fixed stars over the meridian;" "Meridional distances of the sun, planets, and fixed stars from the zenith, southward;" "Meridional distances of the fixed stars from the zenith, northward;" "With zenith sector;" and likewise "Apparent right ascensions;" the whole comprising 757 pages. Biog. Brit. Gen. Biog. Proceedings of the Board of Longitude in regard to the recovery of the late Dr. Bradley's Observations, &c. 1795, folio.

BRADLEY, RICHARD, professor of botany, in the university of Cambridge, fellow of the Royal Society of London, and foreign associate of the Academy of Sciences at Paris. He appears to have been indefatigable in his researches, and to have possessed no less ingenuity than zeal for the promotion of his favourite study; yet no memoirs have been published of his life, and we only know the time in which he lived from the date of his several publications. "Historia plantarum succulentarum," published in five parts, in 1716, 1717, 1725, 1727, and 1728, 4to.; they were afterwards published together in 1734, with figures. "A new improvement of planting and gardening, both philosophical and practical," first also in parts, and then collectively, in 1731, 8vo. In this he gives the anatomy of plants, and their sexes. He demonstrates the circulation of the sap, from the progress of a disease of the branch, downward to the root. He also brings, as a further proof, an experiment on the lime-tree, which being planted inverted, with the branches downward, produced leaves and flowers from the roots. "The virtues and use of coffee, with regard to the plague and contagious diseases," 1721, 8vo. with an engraved figure of the plant. "Philosophical account of the works of nature." He here also contends for the double sexes in plants. He gives an historical account of the principal gardens in Europe, and gives the preference to the public garden at Amsterdam. "New experiments relative to the generation of plants," 1724, 8vo. "Treatise concerning the manner of sowing ground, raising of grass seeds, and training of line and lemp," 1724, 4to. "Survey of ancient husbandry and gardening, collected from the Greeks and Romans," 1725, 8vo. with many other similar works; also "Dictionarium botanicum," 8vo. 1728, in

which he gives the medical properties and the countries from which the plants were originally brought. See Haller Bib. Botan. for a complete catalogue and account of his works.

BRADNINCH, in *Geography*, an ancient corporate and market town in Devonshire, England, is situated on the banks of the river Collumb, in the great road from Exeter to Bath, 8 miles from the former, 2 from Collumpton, and 16; W. from London. This barony belonged, in the time of Edward the Confessor, to Bricnoth, a Saxon: and at present it is vested in his royal highness the prince of Wales. Bradninch sent members to a parliament holden at Westminster, the sixth year of Edward II. and likewise to another at Windsor in the following reign; but on account of the trouble and expence, the members were excused from further attendance.

The original charter of incorporation was granted by Reginald, earl of Cornwall, (natural son of king Henry I.), who gave his seal to be used by them, which is still continued; the corporation consists of a mayor, recorder, twelve alders, a town-clerk, and two serjeants at mace.

The town consists principally of one irregular street, nearly a mile in length; the houses, in general, indifferently built, and covered with thatch, are estimated at 253, and the inhabitants 1187, who are nearly equally employed in agriculture and manufactures; of the latter, paper-making is the chief, there being, within two miles of the town, five mills constantly at work.

Here are a market on Thursdays, and two fairs. The church dedicated to St. Denis, is an ancient edifice; the body and south aisle appear to have been built in the end of Edward III.'s reign, or early in that of Richard II. On the breaking out of a rebellion in the north of England, in the 28th year of Henry VIII., this town was appointed the head-quarters for the troops under the command of the marquis of Exeter, who was employed to act against the rebels.

BRADS, in *Carpentry*, a slender kind of nail, used in building, having no spreading heads as other nails have.

Of these, some are called *joiners brads*, and are for hard waincoats; others, *batten-brads*, for soft waincoats; and some *bill-brads*, or *quarter-heads*, used when a floor is laid in haste, or for shallow joists subject to warp to.

BRADSBERG *Lebu*, or *fief*, in *Geography*, a district of Norway, in the diocese of Christiania, containing the district of Tillemarken. The inhabitants are distinguished for their hardiness and valour, and have been always accounted the most warlike people of Norway. In this district are several iron founderies.

BRADWARDINE, THOMAS, in *Biography*, denominated the "profound doctor," was born at Hatfield, in Suffolk, (according to Godwin), or at Hartfield, in Suffex, (according to Bale,) towards the beginning of the 14th century, and educated at Merton college, in the university of Oxford, of which he was professor, in 1325, and where he took the degree of doctor in divinity. He was introduced to court under the patronage of Stratford, archbishop of Canterbury, and became confessor to Edward III. canon of Lincoln, and chancellor of St. Paul's cathedral in London. He accompanied the king in his warlike expeditions to France, and to his sanctity and prayers the superstition of the age ascribed the victories of this monarch more than to the bravery of the soldiers, or the skill of their general. In 1348, he was elected by the chapter of Canterbury, to succeed Stratford as metropolitan; but, in deference to the king and pope, who preferred John Ulford, he surrendered to him the archiepiscopal chair, but upon his death he was again

again elected, and confirmed by the king and pope. His consecration took place at Avignon, but his premature death prevented his being enthroned. As a theologian, and also as a mathematician and philosopher, he gained great reputation, and his character for an attention to the duties of his elevated station is highly commended. His works are lectures delivered at Merton college, and entitled "De causa Dei, et de veritate causarum contra Pelagium," libri iii. published by Henry Savile, in London, in 1618, fol.; "Geometrica Speculativa," and "Arithmetica Speculativa," printed together at Paris, in 1512; and "Tractatus Proportionum," Venet. 1505. Mosheim, probably referring to the first of the works above recited, says, "the learned Bradwardine, an English divine, advanced many pertinent and ingenious things towards the confirmation of Christianity, in a book upon Providence." Cave, Hist. Lit. t. ii. p. 429. Mosheim's Eccl. Hist. vol. iii. p. 367.

BRADY, ROBERT, a learned English historian and physician, was a native of Norfolk, and admitted, in 1643, into Caius college, at Cambridge, where he took his degree of bachelor of physic, in 1653, and that of doctor in the same faculty, by royal mandate, in 1660. By the same mandate he was also elected master of his college. About the year 1670 he was appointed keeper of the records in the Tower of London, and some time after he was chosen regius professor of physic, in the University of Cambridge. A letter to Dr. Sydenham, written in 1679, and proposing certain questions, which were answered in Sydenham's "Epistolæ responsivæ duæ," is his only performance in the line of his profession. His practice was probably inconsiderable, as he employed himself chiefly in historical investigation, and was one of the representatives for the University, in the Oxford parliament of 1681, and in that of James II. in 1685. He was, however, physician in ordinary to the king. He, among others, attested the birth of the prince of Wales in 1688. He died in 1700. His principal historical works are, "An introduction to the old English history," and "A complete history of England, from the first entrance of the Romans unto the end of the reign of king Richard II." in 3 vols. fol. The first work was printed in one volume in 1684, and the substance of it may be comprised in the three following propositions, viz. 1. That the representatives of the commons in parliament were not introduced till the 49th of Henry III. 2. That William duke of Normandy made an absolute conquest of the nation. 3. That the succession to the crown of England is hereditary, and not elective. The second work was printed in two volumes; the first in 1685, and the second in 1700. The principal aim of Mr. Brady is to shew, that all the English liberties are derived from the crown by way of concession from the princes; and he adduces a collection of copious materials, chiefly epitomised from Matthew Paris, in order to prove that the Normans imposed on the English nation their own system of laws and customs. The system adopted by Brady, in consequence of some bias resulting from his obligations to the crown, and his personal attachments, and ably supported, is the basis of the general doctrine maintained in Hume's history. To this purpose it is observed by the learned Dr. Gilbert Stuart, (View of Society in Europe, p. 327,) that "Mr. Hume, struck with the talents of Dr. Brady, deceived by his ability, disposed to pay adulation to government, and willing to profit by a system formed with art, and ready for adoption, has executed his history upon the tenets of this writer. Yet, of Dr. Brady it ought to be remembered, that he was the slave of a faction, and that he meanly prostituted an excellent understanding, and admirable quickness, to vindicate tyranny, and to destroy the rights of his nation." Besides his three volumes of history, Dr.

Brady also wrote, "A treatise on Burghs," in a thin folio. Biog. Brit.

BRADY, NICOLAS, an episcopalian divine, was lineally descended from Hugh Brady, the first protestant bishop of Meath in Ireland, and born at Bandon in the county of Cork, in 1659. At the age of 12 years he was removed from Ireland to Westminter school, and from thence elected student of Christchurch at Oxford. After remaining in the University about four years, he went to Dublin, where his father resided; and in the University of that city he obtained the degrees of B. A. and M. A. and, afterwards, in a manner peculiarly honourable, he received the degree of D. D. His first ecclesiastical preferment was to a prebend in the cathedral of St. Barry, at Cork, and to the parish of Kinaglarchy, in the county of Cork, to which he was collated by bishop Wettenhall, to whom he was domestic chaplain. His attachment to the revolution, and his zeal in promoting it, exposed him to much suffering; and, such was his interest with M<sup>c</sup>Carty, king James's general, that in 1690, when the troubles broke out in Ireland, he thrice prevented the burning of his native town. Having been deputed by the people of Bandon to come over to England, for the purpose of petitioning parliament for a redress of some grievances which they had suffered, while king James was in Ireland, he resigned his Irish preferments, and settled in London. In this country he was much esteemed for his pulpit talents, and obtained several preferments, amounting in the whole to 600l. per annum; the last of which was the rectory of Clapham in Surrey, which he held, together with Richmond, to the time of his death. He was also chaplain to their majesties, king William and queen Mary, and afterwards to queen Anne. He died May 20, 1726, in the 67th year of his age. His works are a translation of the "Æneids of Virgil," published by subscription in 4 vols. 8vo.; "Three volumes of sermons, published by himself; and "Three other volumes," published by his son, in 1730; and "A new version of the psalms," in which he was assisted by Mr. Tate. This version was licensed in 1696; and is now used in most churches of England and Ireland, instead of the old and obsolete version by Thomas Sternhold and John Hopkins, made in the reign of king Edward VI. Biog. Brit.

BRADYPE, in *Zoology*, (in French) synonymous with BRADYPUS, the sloth.

BRADYPEPSIA, in *Medicine*, a term signifying slow digestion, from βραδύς, slow, and πέψις, concoction. See DYSPEPSIA.

BRADYPUS, in *Zoology*, the first genus of animals in the order *bruta*, the character of which stands thus in Gmelin: no fore-teeth; grinders in each jaw six, obliquely truncated, cylindrical, the two anterior ones longest, and far distant; body covered with hair. The species are *tridactylus* and *didactylus*, which see.

Dr. Shaw defines the general character of the sloth, or *brachypus* genus, in a manner somewhat different from the preceding. He observes that there are no cutting-teeth in either jaw; that the canine teeth are obtuse, single, longer than the grinders, and placed opposite; grinders, five on each side, which are obtuse; fore-legs much longer than the hind; and the claws very long. The two species *tridactylus* and *didactylus* are retained by this writer, under their old Linnæan names; a third species is also added, the ursine sloth, *bradypus ursinus*, the uriform sloth of Pennant, and petre sloth of Catton.

It should be observed, that the immense fossil skeleton, of which Monf. Cuvier has given an accurate description under the name of *megatherium*, in the opinion of that writer, must have belonged to an animal much more nearly allied to the

genus *bradypus*, or sloth, than to any other at present known. The skeleton alluded to was found in the vicinity of the river La Plata in a fossil strata, a hundred feet beneath the surface of a sandy soil. It is 12 French feet long, and six in height. The original is at Madrid.

**BRÆ-MAR**, in *Geography*, a mountainous district of Scotland, in Aberdeenshire, 27 miles N. W. from Aberdeen. In this territory the last earl of Mar began to raise a rebellion in 1715.

**BRÆ-Murray**, a mountainous and woody tract of land, lying on the shores of Elgin and Nairn in Scotland.

**BRAG**, a name given to a game at cards, from the nature of it; the principal stake being won by him who brags with most confidence and address; i. e. who challenges the other gamblers to produce cards equal to his. In this game a pair of aces is the best brag, a pair of kings the next, and so on: and a pair of any sort wins the stake from the most valuable single card. The knave of clubs pairs with any other card in hand: but a hand of cards of less value in this game has sometimes gained the stake from one of superior value, by the confidence and art of bragging: the contest being given up on the part of the latter through fear of losing. One stake is gained by the highest card that is turned up in dealing, three cards being dealt round to each person, and the last turned up; the highest card is the ace of diamonds: the other stake is won by the person who first makes up the cards in his hands one and thirty; each dignified card passing for ten, and drawing from the pack. Each gambler deposits three stakes, one for each card.

**BRAGA**, in *Geography*, the *Bragara* of Antonin's Itinerary, a city of Portugal, and capital of the province of Entre-Douro-e-Minho, is situated in a broad open vale, cultivated and shaded by trees, near the small river Cavado. It is subject to the archbishop of the place, who has a revenue of above 100,000 crusades, and appoints judges and two tribunals, the one spiritual and the other temporal; so that this is the only city where the king does not appoint a corregidor, or a juiz de fora. In the contos, or privileged places round the town, his sentence is final in criminal affairs, but not on the inhabitants of the town. Braga contains about 13,000 inhabitants, 5 parishes, and 7 monasteries. Several of the streets are wide and open, but most of the houses are small. Among the objects of curiosity in this town, we may reckon the large old Gothic cathedral, with its antiquities and treasures; and also the church and monastery of St. Fructuoso, with its treasures and relics, and standing very conspicuously on a hill without the town. Braga claims a very ancient origin. The Romans called it *Augusta Braccara*, and Roman coins are often found in the neighbourhood. Although it has much declined from its former importance, it has a hat-manufacture, which supplies a great part of Portugal with hats for the common people; and it has also an inconsiderable manufacture of knives. It exhibits signs of industry and activity; and the women are every where seen knitting, sewing, or making linen. The rich inhabitants are reckoned more reserved and unsocial than their neighbours in the other towns of Minho; and they are accused of being quarrelsome, fond of scandal, and of disagreeable manners. N. lat. 41° 26'. W. long. 8° 17'.

**BRAGA, HA**, is now called Fort Dauphin, in the island of Cuba.

**BRAGA**, the name of a liquor brewed in Russia from wheat, which, as well as the buse, that is brewed only from millet, is turbid, foaming, affecting the head, and drunk only by the common people. On the Terek, a sort of beer is brewed, called "teriskaia braga," by soaking millet in warm

water; and when it is swollen like malt, it is bruised, boiled soft, and so poured upon malted-rye and barley. By the malt the brewage is tepid, and in this state oats are added; it is then left to ferment, and the husks being strained from the drink, it is fit for use. It is of good colour, always turbid, rather clammy, disgusting to the taste and smell, and very intoxicating.

**BRAGANTIA**, in *Botany*. Loureiro. Flor. Coch. Clat's, *gynandria hexandria*.

Gen. Ch. *Calyx* none. *Corol.* one-petalled; tube globular, with ten furrows; border divided into three, equal, obtuse, recurved segments. *Stam.* anthers six, sessile, oblong, adhering to the middle of the style. *Pist.* style thick; stigma concave; germ linear, inferior. *Pericarp* long, quadrangular, four-celled, four-valved. *Seeds*, many.

There is only one known species, a shrub about five feet high. *Leaves* large, alternate, lanceolate, very entire, veined. *Flowers* in racemes, axillary, brown red. It grows on the mountains of Cochinchina.

**BRAGANZA**, in *Geography*, a city of Portugal, and capital of a duchy of the same name, in the province of Tra-los-Montes, seated on a spacious plain near the river Fervença. It consists of a city, fortified with towers and a castle; and a town, defended by a fort. Braganza contains two parish churches, two hospitals, four convents, and about 2700 inhabitants. It is one of the most ancient towns in the kingdom, and is said to have been built by Augustus. Its manufactures consist of silk stuffs, velvets, and program. It was erected into a duchy by Alphonso V. in 1542. John II. its eighth duke, was crowned king of Portugal by the name and style of John IV.; and it confers the ducal title on the present reigning family. N. lat. 41° 57'. W. long. 6° 48'.

**BRAGANZA**, a small town on the frontiers of the marche of Trevisano, in the territory of the republic of Venice.

**BRAGGOT**, derived from the old British word *brag*, which signifies *malt*, and *gots*, a *honey-comb*, a sort of drink made in some parts of England, of malt, with honey, spices, and other ingredients.

**BRAGNAS**, or **BRÆGNERZ**, in *Geography*, a town of Norway, in a district of the same name, in the diocese of Christiania, seated on the side of the river Dramme, opposite to Stromsøe and Tanger. These three towns lie in a fertile vale, at small distances from each other, at the bottom of some rugged rocks, and on the margin of a bay. They are distinguished by the general name of Dramme, because they are situated on that river. Each of them has its own church, and separate jurisdiction. The inhabitants are industrious, and carry on a considerable trade. The principal exports are timber and planks. The imports are chiefly corn, and lead from England for smelting the silver ore at Kongberg. In the district of Bragnas-lehn are several iron-works, and also a glass-house. N. lat. 59° 45'. E. long. 10° 22'.

**BRAGOS**, a river of Spain, in Catalonia, which runs into the Segre, 6 leagues N.E. of Balagner.

**BRAGU POINT**, lies at the mouth of the great river Ava (see **AVA**); and is supposed by M. Gosselin (*Geography of the Greeks analysed*) to be the "Magnum Promontorium," which M. d'Anville concludes to be cape Romania, at the extremity of the peninsula of Malacca.

**BRAGUZ**, a town of Germany, in the county of Tyrol; 27 miles W. of Trent.

**BRAHE**, **ТУСНО**, in *Biography*, a celebrated astronomer, was the descendant of a noble family of Sweden, settled in Denmark, and born December the 19th, 1546, at Knudstorp, a small lordship near Helsingborg in Scania or Schonen. His father,

father, Otto Brahe, having a large family, the charge of his education was undertaken by his uncle, George Brahe, who adopted him as his heir. This was a fortunate circumstance for Tycho, as his father thought literature inglorious, and wished all his sons to follow the military profession. After a course of private instruction in the Latin language, his uncle sent him, in 1559, to study philosophy and rhetoric at the academy of Copenhagen; where he was casually incited to the study of astronomy by an eclipse of the sun, which happened August 21st 1560, at the precise time predicted by astronomers. Hence he was led to regard that science as divine, which accurately described the motions of the celestial bodies, and predetermined their relative positions. From this time he devoted himself to the study of astronomy, and by means of the tables of Stadius, which he purchased, he acquired a knowledge of the theory of the planets. In 1562 he was sent to study the civil law at Leipzig, in which he made a very considerable proficiency; but, notwithstanding the remonstrances of his tutor, and the application with which he was required to prosecute the study of the law, his predominant inclination led him to perfect himself in astronomy. With this view he expended the money that was allowed him for his private expences, in the purchase of books, the difficult passages of which were explained to him by his private tutor Scultens; and by means of a small celestial globe, and nightly observations of the heavens while his preceptor was in bed, he became acquainted, in the course of a month, with the names and positions of the constellations, and the apparent motions of the celestial bodies. Inspired with the same ardent zeal in the prosecution of his favourite science, he acquired a competent knowledge of mathematics, without the assistance of a master, and invented several mathematical instruments. Having passed three years at Leipzig, it was his intention to have pursued his travels through Germany; but the death of his uncle in 1565, and the estate which was bequeathed him, required his return to his native country. Discouraged, however, in his favourite pursuits by his relations, he made the necessary arrangement of his affairs; and before the expiration of a year, he abandoned his country, and set out on his travels. Accordingly he first went to Wittenberg, and on occasion of the plague, which broke out in this town, he removed, in 1567, to Rostoc, where an accident occurred that endangered his life. At a wedding-feast to which he was invited, a dispute arose between him and a Danish nobleman, on some subject of mathematics, which terminated in a duel; and having lost his nose in the conflict, he contrived to supply the defect so completely, by an artificial composition of gold, silver, and wax, that it could hardly be distinguished from the natural organ. From Rostoc, Tycho continued his travels through the principal towns of Germany and Italy, and in 1569 he repaired to Augsburg, where he formed an acquaintance with the celebrated Peter Ramus, who admired his skill in the science of astronomy. After his return to Copenhagen, in 1571, he was favoured by his maternal uncle, Steno Billes, with a convenient retreat from the ceremonies of the court, and the intrusive visits of the capital, at his castle of Herritzvold near Knudtorp; which also afforded him a commodious situation for the construction of an astronomical observatory, and a chemical laboratory. During his residence with his uncle, Tycho, besides his astronomical researches, prosecuted, with his natural ardour, the study of chemistry, or rather of alchemy, to which he seems to have had an early inclination, with the chimerical view of obtaining the philosopher's stone, that he might amass wealth sufficient to enable him to settle in some foreign country. At Herritzvold he observed, in 1572, a new star in the constellation Cassiopeia. Soon after

this period he incurred the resentment of his relations by marrying a beautiful country girl, whose name was Christina, and who was the daughter of a neighbouring peasant. Although he offered various reasons in justification of his choice, the connection with a person so far below his rank alienated his family from him; and they refused to hold any intercourse with him, until Frederic II. interposed, and authoritatively effected a reconciliation. Tycho himself seems not to have repented of his choice; but found in his Christina, to whom affection had attached him, a grateful companion, and an obedient wife. In 1574, he commenced his lectures at Copenhagen, by the express desire of the king; and in these lectures he took occasion to explain the theory of the planets, introducing his explanation by a learned oration on the history and excellency of astronomy and the sister-sciences, with some remarks in favour of judicial astrology, a study no less congenial to the times than to the inclinations of Tycho himself. Disgusted by the conduct of his relations, and with his countrymen in general, our philosopher determined to quit Denmark and settle abroad. After travelling through Germany and Italy, he at length formed a purpose of fixing his residence at Basle, to which he was induced by the salubrity of the air, the cheapness of living, the celebrity of the university, and the opportunity this situation would afford him of maintaining a correspondence with the astronomers of France, Germany, and Italy. With this view he returned to Denmark; but whilst he was preparing for his removal, he received an unexpected message from the king. Frederic, secretly apprised of his intentions, was unwilling that Denmark should be deprived of so great an ornament; and in order to retain him in his dominions, offered him protection, and, with a liberality which did honour to the monarch, as well as to the philosopher, presented him with the island of Huen, and promised to erect the buildings and to provide the apparatus necessary for his scientific pursuits. He also settled on him a pension of 2000 crowns a year, and gave him a fief in Norway, and a canonry of Roschild, which produced a thousand more.

This liberal offer Tycho gratefully accepted; and repairing to Huen, he was present, on the 8th of August, 1576, at the laying of the first stone of a magnificent house, which he afterwards called Uraniburg, or the Castle of the Heavens. This was a building 60 feet square, containing a spacious suit of apartments, an observatory, and a subterraneous laboratory; for the erection of which the king supplied 100,000 rix-dollars (20,000*l.*), and Tycho himself expended no less a sum. He afterwards constructed a detached-building for his observatory, which he called Stiernberg, or the Mountain of the Stars. In this retreat he passed 20 years, and, by his observations and study, greatly contributed to the improvement of the science of astronomy. He maintained ten or twelve scholars, whom he instructed in mathematics and astronomy, and whom he employed as his assistants in his observations. His retreat was not, however, that of an hermit, who secluded himself from society; but he lived in a sumptuous and hospitable manner, affording free access and liberal entertainment to all visitors. Among these were persons of the highest rank, such as Ulric, duke of Mecklenburgh, with his daughter Sophia, queen of Denmark; William, landgrave of Hesse-Cassel; and James VI. king of Scotland, and afterwards James I. of England, on occasion of his repairing to Copenhagen in 1590 for the purpose of concluding his marriage with the princess Anne. James remained with Tycho eight days; and, on leaving him, made him a handsome present, granted him a royal licence for the publication of his works, accompanied with an honourable testimony to his talents and learning, and composed

some

some Latin verses in his praise, more expressive of esteem and admiration, than remarkable for classic elegance. In 1592 Tycho had the honour of a visit from his own sovereign, Christian IV., then in the 15th year of his age; who expressed great satisfaction in examining his astronomical and chemical apparatus, and proposed to him several questions on various points of mathematics and mechanics, and particularly on the principles of fortification, and the construction of ships. He was also highly delighted with a gilt tin globe, which represented the face of the heavens, and being turned on its axis, exhibited the rising and setting of the sun, together with the motions of the planets and heavenly bodies. The king, upon being presented with this curious machine, acknowledged the favour by the donation of a gold chain, and by an assurance of inviolable protection and encouragement. Notwithstanding these assurances, the enemies of Tycho, jealous of his merit, or offended by the violence of his temper, and the severity of his satire, contrived, in 1596, under various pretences, to divert the young king's attachment, and to induce him to deprive the astronomer of his pension, his see, and the canonry of Roschild. Thus deprived of the means of supporting his expensive establishment at Uraniburg, Tycho was reduced to the necessity of quitting his favourite residence, and repairing to Copenhagen, where for a short time he continued his observations. But the malevolence of his enemies pursued him; and therefore, after having transported from Uraniburg all those parts of his apparatus which could be removed, he departed from Copenhagen with his wife and family, landed at Rostoc, and remained a year at Wansbeck, with his learned friend Henry Rantzau.

About this time he published his astronomical treatise, intitled "Astronomia instaurata mechanica;" and having dedicated it to the emperor Rodolphus II., who had a taste for mechanics and chemistry, he received from him an invitation to settle at Prague, whither he removed, towards the close of the year 1598. The emperor granted him a magnificent house, assigned him a pension of 3000 crowns, and promised him a fee for himself and his descendants. Here he seemed to have obtained a fixed settlement for himself, and his sons, and his scholars, among whom was the famous Kepler; but he did not long enjoy the advantages of this situation. About a year before his death, he felt symptoms of declining health, occasioned, probably, by his intense application, and by the chagrin he had suffered on his removal from Uraniburg; to these he was himself conscious, though he concealed them as much as possible from his friends. But the immediate cause of his decease was a strangury, brought on by drinking more than he was accustomed to do, at the table of a lord named Rosenberg, and by an imprudent retention of urine; and attended with excruciating torments, which occasioned a violent fever, and a temporary delirium; in the paroxysms of which he was heard frequently to exclaim, "Ne frustra vixisse videar;" i. e. that I may not seem to have lived in vain. When the fever subsided, and he recovered his senses, he was well apprised of his approaching end. In the prospect of it he gave necessary orders with composure and resignation, amused himself with composing an extempore copy of verses, sung various hymns, offered up prayers to the Supreme Being, recommended to his family and friends piety and submission to the divine will; charged his sons, that none of his works should be lost; exhorted his pupils to persevere in their studies, and conversed with Kepler on the abstruse parts of astronomy, and requested him to complete the Rodolphine tables which he had constructed for regulating the motions of the planets. Thus employing his last moments,

he expired so quietly, that he was neither heard nor seen by any of those who were present, to breathe his last. He died October the 24th, 1601, in the 55th year of his age; and was very magnificently interred in the principal church at Prague, where a noble monument was erected to his memory. His wife, two sons, and four daughters, survived him.

Tycho Brahe was a man of moderate stature, with light red hair, and a countenance that was rather handsome. As to his mental powers, he combined energy and activity; and thus endowed, he was admirably qualified for arriving at those eminent attainments by which he was distinguished. His merit as an astronomer is unquestionable; for though he rejected the simple and beautiful system of Copernicus, and endeavoured to reconcile the absurdities of the Ptolemaic hypothesis, he formed a system conformable to the more obvious phenomena, but which did not require any motion of the planet which we inhabit. To this system (for an account of which, see SYSTEM) he was so zealously attached, that, in his last moments, he desired his favourite scholar, the great Kepler, to follow his hypothesis rather than that of Copernicus. For a further account of his discoveries, as well as for a concise abstract of his history, see ASTRONOMY. As a poet, Tycho wrote some Latin verses, which are not altogether destitute of classic elegance. He had also a taste for building; he drew the plan of the castle of Cronberg, and sketched the design for the noble mausoleum of Frederic II., which was executed in Italy, and erected in the castle of Roschild. As a medical practitioner, he was fond of being consulted, and gave his advice and medicines gratis; he invented an elixir, which he calls an infallible remedy for epidemic disorders, and of which he published the recipe in a letter to the emperor Rodolphus. He was likewise a good mechanic, and constructed several automata, which he took delight in exhibiting to the peasants; and in his apartments at Uraniburg he had several contrivances, which were calculated to deceive and astonish those who came to visit and consult him. He was also very much devoted to the study of chemistry; and expended as much on the terrestrial astronomy, as he styled it, as on the celestial; but he has left no writings on this subject. Indeed, his researches in this department of science, like those of his contemporaries, were directed to the visionary desiderata. To judicial astrology he was addicted to a degree that is truly astonishing; and he manifested a proneness to credulity and superstition, very unsuitable to his learning and judgment. He was an attentive observer of good and bad omens; insomuch, that if he met an old woman on first leaving his house, or a hare crossed him upon his journey, he would instantly return home. He took pleasure in being consulted as a fortune-teller; and pretended, that his knowledge of the heavenly bodies enabled him to observe horoscopes, and to foretel future events. At his house at Uraniburg, he kept an insane person, who sat at his feet during the time of dinner, and whom he fed with his own hand; and he noted down any incoherent expressions which were uttered by this person, under a persuasion, that the mind, in a state of emotion, was capable of predicting future events; and he even believed, that, if any inhabitant of the island was taken ill, this idiot could predict his recovery or decease.

As to his natural disposition, it was irritable, impetuous, morose, and inflexible; and he indulged a humour for raillery, to a degree that gave offence; but while he rallied others without reserve, and becoming caution, he was easily provoked by the raillery of others. If, however, we divert our attention from the unfavourable to the brighter parts of his

his character, we shall be justified in adopting the eulogy of his panegyrist Joffenus, in his "Funeral oration;" who observes concerning him, that "His studies were life; meditation, delight; science, riches; virtue, nobility; and religion, his constant guide." Gallendus, in his "Equitis Dani Tychonis Brahe Astronomorum Coryphæi vita," gives the following list of his principal writings:

1. "An account of the new star which appeared Nov. 12th, 1572, in Cassiopeia," Copenhagen, 1573, 4to.
2. "An oration concerning the mathematical sciences, pronounced in the university of Copenhagen, in 1574;" published by Conrad Assac, of Bergen, in Norway.
3. "A treatise on the comet of the year 1577, immediately after it disappeared." Upon revising it nine years afterwards, he added a 10th chapter, printed at Uraniburgh, 1589.
4. "Another treatise on the new phenomena of the heavens;" in the first part of which he treats of the restitution, as he calls it, of the sun, and of the fixed stars; and in the second part, of a new star which had then made its appearance.
5. "A collection of astronomical epistles," 4to. Uraniburgh, 1596; Nuremberg, 1602, and Francfort, 1610. It was dedicated to Maurice, landgrave of Hesse; because it contains a considerable number of letters of the landgrave William, his father, and of Christopher Rothmann, the mathematician of that prince, to Tycho, and of Tycho to them.
6. "The mechanical principles of astronomy restored," Wandersburg, 1598, folio.
7. "An answer to the letter of a certain Scotchman concerning the comet in the year 1577."
8. "On the composition of an elixir for the plague; addressed to the emperor Rodolphus."
9. "An elegy upon his exile;" Roitock, 1614, 4to.
10. "The Rodolphine tables," revised and published by Kepler, according to Tycho's desire.
11. "An accurate enumeration of the fixed stars, addressed to the emperor Rodolphus.
12. "A complete catalogue of 1000 of the fixed stars, which Kepler has inserted in the Rodolphine tables."
13. "Historia cælestis; or, a history of the heavens, in two parts;" the first containing the observations he had made at Uraniburg, in 16 books; the latter containing the observations made at Wandersburg, Wittenberg, Prague, &c. in 4 books.
14. "An epistle to Casper Puccr," printed at Copenhagen, 1663.

The apparatus of Tycho Brahe, after having been transported from place to place, during his life, was, after his death, purchased of his heirs by the emperor Rodolphus for 22,000 crowns of gold. The persons to whose custody he committed them, concealed them from inspection; and thus they remained useless till the time of the troubles of Bohemia, when the army of the elector palatine plundered them, breaking some of them, and applying others to different uses. The great celestial globe of brass was preserved; carried from Prague, and deposited with the Jesuits of Neysa in Silesia, whence it was afterwards taken, about the year 1633, by Udalric, son of Christian, king of Denmark, and placed in the hall of the royal academy at Copenhagen. Gallendi, ubi supra. Moreni. Coxe's Travels in Denmark, &c. vol. v. p. 191, &c. Svo. Gen. Dict.

**BRAHELINNA**, in *Geography*, a town and royal demesne of Sweden, in the province of Savolax.

**BRAHESTAD**, a town of Sweden, in the province of East Bothnia, built by count Peter Brahe in 1652, and invested with the privileges of a town. It has a commodious harbour.

**BRAHLOW**, or **BRAILA**, a town of Walachia, seated on the Danube, near the confines of Moldavia, opposite to Silistria. N. lat. 45°. E. long. 27°. 14'.

**BRAHIN**, a town of Lathuania; in the palatinate of Minsk; 48 miles E. of Mozyr.

**BRAILLER**, *Fr.* to scream and roar in singing vulgarly, like country psalmodists and parish clerks.

**BRAILS**, in *Sea language*, a general name given to all ropes which are employed to haul up, or collect to their yards, the bottoms, lower corners, and skirts of the great sails, for the more ready furling them whenever it becomes necessary. In particular, it is applied to ropes, fastened at different places on the aftmost ridge of the mizen, and passing through blocks on the mizen mast, for the purpose of bringing or brailing up the sail to the mast; boats with either gaff or sprit-sails have generally brails attached to these sails. The operation of thus drawing them together, is called *brailing them up*, or *hauling them up in the brails*.

**BRAIN**, in *Anatomy*. The brain is a soft and somewhat white substance, situated in the cavity of the skull, and corresponding in form to that cavity. Its parts are supported by a firm membrane, called the *dura mater*, and its substance is immediately invested by a more delicate membrane, named the *pia mater*. The Greeks termed these membranes simply *meninges*, whilst the Latin writers gave them the name of *matres*, from the supposition, that they were the origins of the other membranes of the body. We shall first describe the dissection of the brain; which will comprehend an account of its membranes, of its general divisions, and of the appearances found in the interior of the organ.

It may not be improper to premise a few general observations. The structure of the brain is remarkably constant and uniform, very seldom deviating from the accustomed standard. Varieties in formation occur not unfrequently in most other parts of the body; but the parts of the brain preserve an almost invariable relation of form, position, magnitude, and connection, which seems to prove, that the right performance of the functions of this organ requires an exactness in the structure of individual parts. The brain is symmetrical; all its parts are double; even those which being situated in the middle, appear on superficial examination to be single, will be found, by more attentive investigation, to consist of two symmetrical portions, e. g. the *corpus callosum septum lucidum* and *medulla spinalis*. The weight of the brain, according to Soemmerring, varies from 2½ 5½ oz. to 3½ 5¾ oz. (*De corpus humani fabrica*, tom. iv. § 23.) Out of two hundred brains which he has examined, none weighed four pounds, whereas Haller states its weight generally at five pounds. This error must of course affect the account, which that author gives, of the proportion between the weight of the brain, and that of the body. The weight of the brain, compared with that of the body, is in an inverse ratio to the age of the subject. It is soft and almost fluid in young subjects, becomes of a more solid consistence with increasing age, and is firmest in old persons.

*Dissection of the brain.* An incision should be made from ear to ear through the scalp, which is to be reflected from the cranium forwards and backwards. The cranium is next to be sawn through in a circular manner, as low down as convenient.

In lifting off the top of the skull, it is torn from the *dura mater*, which is closely connected to it by vessels and cellular substance. The *dura mater* may be, therefore, regarded as the perosteum of the internal table of the skull, as well as the membrane which invests and supports the brain. The surface of the membrane is covered with bloody points, which are the orifices of the torn vessels that connected the *dura mater* to the inner table of the bone. There are more numerous in the course of the futures than elsewhere, but abundant in every part. This is manifest from the pores observable in the internal table of the skull; and there can be no doubt but that more blood is sent into the bone for

its nutrition, from the dura mater, than from the pericranium.

The dura mater, which is a very strong, dense, and elastic membrane, consists of two layers, intimately connected in general, but separated from each other at particular parts, so as to leave vacancies between them called sinuses, into which the veins of the brain pour their blood. (For an account of the sinuses, see VEINS, *distribution of*.) Its structure is obviously fibrous; the fibres not following any regular distribution, but intersecting each other in every direction. After being macerated for some time in water, it is resolved into a firm tendinous kind of cellular texture. The sides of the membrane are covered by the ramifications of the arteria meningea media, which are very conspicuous on the mere removal of the skull cap, each branch being accompanied by two veins. (For the description of this artery, see ARTERIES, *distribution of*.) In the middle of the superior surface of the membrane is a depression, extending from the lower part of the os frontis to the tentorium, which denotes the situation of the superior longitudinal sinus.

We also observe, on the upper part of the dura mater, clusters of little white granular bodies, termed glandulae Pacchioni. These vary in number and situation; sometimes they rise in little heaps on the side of the longitudinal sinus, and are lodged in considerable cavities formed in the bone for their reception. In other instances the clusters of these glands are so small and few in number, that they may escape observation. In dissecting the brain, we are in the next place to cut the dura mater round on a level with the bone which we have sawn, except in front and behind, where the falx is situated. We are then enabled to reflect it on either side from those membranes which immediately invest the brain. Its inner surface is smooth and shining, and has no connection with the pia mater, except at the upper part, near to the longitudinal sinus. The connection at this part is of two kinds; one by means of large veins, which, coming from the surface of the brain, pass between the layers of the dura mater to terminate in the longitudinal sinus: the other by means of clusters of glandulae Pacchioni, which adhere equally to the under layer of the dura mater, and surface of the membranes, which more immediately invest the brain. These glands are found not only in the outer and inner layers of the dura mater, but frequently they communicate and make one cluster through an opening in the membrane. They are also found attached to the inner surface of the longitudinal sinus. The use of these glands, as they are called, is not known.

The internal layer of the dura mater forms, by its reflexion from the outer, processes for the support of the brain: the principal of these are, one which descends perpendicularly between the hemispheres of the cerebrum, and is called the falx cerebri, from the shape of its lower edge; and one which proceeds transversely, supporting the back lobes of the cerebrum, and separating them from the cerebellum. As this is stretched across over the cerebellum, it is called the tentorium cerebelli. The falx is a duplicature of the internal layer of the dura mater, which begins to recede from the external at the ethmoid bone, and incloses the crista galli of that bone. It proceeds in like manner from the spine, and from the middle of the os frontis, from the sagittal suture of the parietal bones, and from the upper half of the perpendicular ridge of the occipital bone, and it terminates behind in the tentorium, gradually increasing in breadth to its termination.

The arteria meningea media is the principal source of the arterial supply of the dura mater: it receives some small branches in front from the internal carotid, ophthalmic, and

pharyngeal arteries: behind from the occipital and vertebral vessels. Its veins open into the nearest sinuses. The accurate researches of Lobstein and Wrisberg have shewn that no nerves can be traced to this membrane. (See Comment Gottingens: an. 1777. Ludwig collect. scriptor. neurol. minor. tom. 1.)

After the connection of the dura mater with the subjacent membranes is broken, the front of the falx is to be divided from the crista galli, and that process is to be turned back from between the hemispheres of the brain. Then the brain and its immediate investing membranes become fairly exposed to our examination. These membranes were considered as one, and called the pia mater, till Ruysch demonstrated that they were two. The outer one is uniformly spread over the visible surface of the brain, is of a pale white colour, yet in some degree transparent, very thin, devoid of evident vessels, and is named the tunica arachnoidea. It is seen most distinctly where it passes between the two lobes of the cerebellum: in most other parts of the brain it adheres very firmly to the pia mater. Although the tunica arachnoidea has in its natural state no visible vessels, yet, when it is inflamed, its vessels become enlarged and evident, and there can be no doubt but that it contributes at all times to secrete its share of that liquor which preserves it separate from the dura mater. In inflammation of the pia mater and tunica arachnoidea, it is common to have a turbid and sometimes puriform fluid effused between it and the dura mater, which is doubtless secreted by the inflamed membrane.

The membrane which lies beneath the tunica arachnoidea is called the pia mater; it covers the whole surface of the brain, sending down processes between all its convolutions. It is extremely vascular, and a great portion of the blood, which the brain receives, is spread out upon its surface in minute vessels: from these others proceed capable of admitting very subtle injections. From the great number of vessels, which ramify on this membrane, Soemmering calls this membrane, membrana vasculosa cerebri. Its vessels are fewer and smaller where it covers medullary parts, than where it is in contact with the cortex. The processes which pass from its inside no where touch medullary matter. The outer surface is tolerably smooth; the inner universally villous, from the torn orifices of innumerable vessels which entered the substance of the brain.

The membranes of the brain having been examined, may be removed; and then the surface of the cerebrum is brought into view, which appears convoluted, so as to resemble the windings of the small intestines. These convolutions do not in general penetrate more than one inch, or one inch and a half, into the substance of the cerebrum. A very deep fissure is however observed extending itself obliquely upwards, and backwards, from the ala of the sphenoid bone; and this is called the fissura magna Sylvii.

The encephalon or brain is divided into the cerebrum, cerebellum, and medulla oblongata.

The cerebrum is the uppermost portion, and by much the largest, and that which first claims our attention in dissection. It rests upon the tentorium and petrous portions of the temporal bones behind, and upon the sphenoid ale, and the orbitary processes of the frontal bones in front. Its superior surface presents a regularly convex oval, narrower in front than behind. This oval is divided into two equal parts named hemispheres, by a deep longitudinal fissure, into which the falx cerebri descends. The depth of this cleft being greater than the breadth of the falx, the opposed plane surfaces of the hemispheres are loosely united below the inferior edge of the falx, by vessels and cellular sub-

stance.

stance. The hemispheres are conjoined below, and the part which unites them can be perceived at a considerable depth from the surface, by distracting the hemispheres from each other. It is about three inches in length, and is called the corpus callosum. (In a singular instance, which occurred to Mr. Carlisle, the falx was deficient, and there was no division into hemispheres. See Transactions of a Society for the improvement of medical and chirurgical knowledge, vol. i. p. 212.) Each hemisphere is divided into two lobes. This subdivision is the consequence of the projection of the transverse process of the sphenoid bone, which divides the bottom of it into two surfaces; and it is from this division that the fissura Sylvii commences. All that part of the hemisphere which is in front of the fissura Sylvii, and which rests on the orbit, is called the anterior lobe; and all that which is supported by the sphenoid alæ, by the petrous part of the temporal bone, and tentorium, is called the posterior lobe. Such is Haller's division of the cerebrum, which has been generally adopted by anatomists. Some authors, however, divide the posterior or great lobe into two parts; calling that portion of it, which rests in the middle fossa of the basis cranii, the middle lobe of the brain; and that which is supported by the tentorium, the posterior lobe.

As there are no distinguishable parts in the upper portions of the hemispheres of the cerebrum, so in dissection it is customary to pare all these away, nearly to the level of the corpus callosum, in order that we may be able more easily to open, and more particularly to examine, certain cavities which are situated on either side of that body, and which are called the lateral ventricles. On making a section of the brain we perceive that it is composed of two substances, an exterior one which is of a grey colour, and an interior one which is white. These are termed simply the cineritious and white substances, or substantia cinerea and alba; or, from the former surrounding the latter, as the bark does the wood of a tree, they are named in contra-distinction, the cortical and medullary substances of the brain. The cortical part receives so great a supply of blood, that after a successful injection it appears almost composed of vessels; the medullary substance on the contrary has very few vessels. In the crura cerebri is a small portion of a black substance, named by Soemmerring locus niger; and, in some places, a fourth substance, partaking of the appearances of the cortical and medullary matter, is described, as in the under surface of the posterior lobe, and is named by Soemmerring portio intermedia.

When the substance of the two hemispheres has been removed by repeated horizontal sections, as low as the surface of the corpus callosum, we see the greatest extent of medullary matter, that can be demonstrated in the brain. The medulla of the two hemispheres is united by the corpus callosum. The margin alone is grey; all the rest is white. This appearance is the centrum ovale of Vieussens; the maximus medullæ orbis of Soemmerring: a more complete view of the corpus callosum is now obtained. This part is overlapped by the edges of the two hemispheres, in such a manner that it is completely hidden, until the hemispheres are either held asunder, or removed by dissection. Its length is equal to that of one half of the hemisphere, and it is placed in such a situation, that a space equal to one third of its own length is left, between its anterior extremity and the front of the cranium, and another twice as long between its posterior part and the back of the skull. The breadth of this part is about  $\frac{3}{4}$  of an inch, but less in front. Its upper surface is convex. It turns downwards in front and behind, so as to form two rounded extremities, which are the

bourrelets anterior and posterior of Vicq d'Azyr. Two prominent lines run through the whole length of the corpus callosum, with a depression between them, which is called the raphe. Transverse lines proceed from these on both sides at right angles.

The two lateral ventricles (ventriculi tricornes of Vicq d'Azyr) are situated in the substance of the brain, by the side of the corpus callosum, (one in either hemisphere,) and should be opened by an incision along the margin of that body. The roof of the ventricle being dissected off, its course becomes apparent. The cavity begins in the front lobe of the brain, as far forwards as the commencement of the corpus callosum. This portion of the ventricles, which is formed between the front of the corpus striatum and the medullary matter of the front lobe, turns rather outwards, and is distinguished by the name of cornu anterius. The ventricle then runs from before backwards, in a direction parallel to that of the corpus callosum, and diverging from the opposite one. Afterwards it bends downwards, something like the turning of a ram's horn, and returns obliquely from behind forwards, to terminate almost under its superior extremity, being situated however behind that, and more externally. This is the cornu inferius, or descendens, or reflected horn of the ventricle. At the place where the ventricle bends in order to run downwards, there is a particular elongation passing into the posterior lobe, forming a triangular pointed cavity, terminating in a cul de sac, with its point turned inwards. This is the digital cavity or cornu posterius of the lateral ventricle. Its length and size vary considerably in different subjects and often are very dissimilar in the right and left sides of the same brain. It sometimes extends quite to the posterior part of the back lobe, and at others is barely demonstrable. This part of the ventricle is peculiar to the human subject and simia. These ventricles, and some other cavities, which will be presently described, are lined with a smooth membrane, and contain a small quantity of a watery fluid, which serves to preserve the parietes of the ventricle separate and distinct from each other, and to fill up the spaces which are left between the convexities which constitute the sides of the cavity. The disease of hydrocephalus is a morbid increase of quantity in this fluid, which accumulates sometimes to the amount of some pounds, distending and dilating the ventricles enormously. The learned Soemmerring, who may justly be esteemed the first of modern anatomists, places the sensorium commune in this fluid. He has traced all the nerves of the brain to the sides of the ventricles; and concludes, that impressions made on these nerves will be transmitted to the water of the ventricles, which he considers as the organ of the soul. (See his dissertation ueber das organ der seele, Berolini, 1796, 4to.)

The two lateral ventricles are separated by a perpendicular partition, which descends from the inferior surface of the corpus callosum to the fornix. This septum, which is broad in front, grows gradually narrower behind, and, at the posterior part of the ventricles, does not exist at all; the corpus callosum and fornix being there continuous. It is composed of two thin layers, separated above and uniting below at an acute angle, so as to leave between them a triangular cavity, called the fifth ventricle of the brain, or ventricle of the septum lucidum. The corpus callosum may be cut off from the septum lucidum, so as to shew the two layers and intervening ventricle.

The fornix is composed of two crura, which arise in front of the brain, from the corpora subrotunda. These, which are round in shape, converge, and unite to form the fornix, which lies between the two corpora striata, and on the upper surface

(See of the thalami nervorum opticorum. It separates behind into two posterior crura, which are thin, broad, and flat, and pass into the reflected horns of the ventricles, where they run along the front of the hippocampus major, and soon terminate. Their posterior margin is connected to the hippocampus; the anterior is loose and floating, and forms the bandelette de l'hippocampe of Vicq d'Azyr. The triangular space left between the posterior crura fornicis, where they diverge to enter the reflected horns of the ventricles, is filled up by medullary matter marked on its under surface by several oblique lines; it is called trigonum psalterium, or corpus psalteroides. It may be regarded as the under surface of the corpus callosum. The origin of the fornix in the front of the brain is situated at some distance from the corpus callosum; it rises gradually in an arched manner, until it reaches the under surface of the corpus callosum, before its separation into the posterior crura. On this circumstance depends the different breadth of the septum lucidum in the front and back part of the ventricles. Under the anterior part of the fornix is a small slit-like opening, by which the two lateral ventricles communicate. This aperture is just in front of the thalami nervorum opticorum, and precisely over the foramen commune arterius. It becomes considerably enlarged, in cases of great accumulation of fluid in the ventricles. The communication between these cavities would be much more extensive, did not the fornix behind this aperture adhere to the choroid plexus and velum, which intervene between its under surface and the optic thalami. The thin edge of the fornix, and of its posterior crus, receives vessels from this vascular membrane. The fornix should now be cut through opposite to the communication just described. By turning up the anterior part of this body, its origination by two distinct crura becomes clearly seen, which would not be satisfactorily made out on the upper surface. By reflecting the posterior part, the psalterium, the separation of the posterior crura, their course, flat shape, extenuated margin, and pointed termination on the hippocampus, will be clearly exposed.

In this stage of the dissection, the situation and connection of the choroid plexus may be traced. This is a production of the pia mater, containing a vast number of tortuous, arterial, and venous ramifications, entering the reflected horn of the ventricle, and ascending into the superior part of the cavity. It is broader and larger below, diminishes in size, as it proceeds along the upper part of the ventricle, and terminates just at the opening of communication between the two lateral ventricles, by joining the opposite plexus. The right and left plexuses are joined together by a middle expansion under the fornix, which is the velum, five plexus choroideis interpositus of Haller, or the rete, or tela choroidea of Vicq d'Azyr, who has illustrated these parts by the most beautiful coloured plates which have ever been published on any anatomical subject. (See particularly *Tab. 7*, also *Tab. 5*, and *8*.) The two plexuses, with the intervening velum, cover the hippocampi majores, the pineal gland, and upper surface of the optic thalami. They support the fornix and psalterium, intervening between them and the optic thalami, and giving blood-vessels to all the parts just enumerated. When successively injected, these plexuses resemble a mere network of blood-vessels. They contain numerous little glandular bodies, which are often enlarged, so as to resemble hydatids. The veins of the choroid plexus form a large trunk situated in the middle of the velum, and named the vena magna Galeni. This, passing in the angle of connection of the falx and tentorium, constitutes the torcular Herophili. The choroid plexuses and velum should now be reflected, to expose clearly the

eminences which form the sides of the lateral ventricles. We now see, in the middle of the under surface of the velum, a small and narrow portion of plexus, which was first described and represented by Vicq d'Azyr under the name of plexus de la glande pineale ou du troisieme ventricule. (*Tab. 7. fig. 4. p. 21.*) The anterior and superior eminence in each lateral ventricle is oblong, smooth and grey on its surface, but composed internally of a striated mixture of cortical and medullary substance, whence it derives the name of corpus striatum. The more deeply we cut into this body, the more complicated does its striated texture appear. The corpora striata are large, convex, and near to each other in front; they diminish in size, and diverge behind, being separated by the optic thalami, and presenting on the whole a pyriform appearance. The posterior eminence of the lateral ventricle is called the thalamus, or colliculus nervi optici. It is found behind, within, and rather below the former. Its surface is white, but the interior of the body is formed of a striated intermixture of cortical and medullary matter; in shape, it is nearly hemispherical, except that it is surmounted above by a more or less prominent oval tubercle, which extends from before backwards. The convexities of the optic thalami are turned towards each other, and are connected by a cineritious union, which is called the middle commissure of the brain, or soft commissure of the optic thalami. This union, which is naturally of a soft and delicate nature, is torn by the mere weight of the parts, when the brain has been kept a few days before it is used for dissection. Hence some anatomists have denied its existence altogether. This is the opinion of Sabatier, derived, as he says, from the most exact observation and very numerous dissections. (*Traité d'Anatomie*, tom. ii. p. 32.) The careful examination of a recent brain will shew the error of this celebrated anatomist; and if authority be required on a point which can be made the subject of demonstration, it will be sufficient to cite the names of Vieussens, Winslow, Morgagni, Soemmerring, and Vicq d'Azyr. These bodies separate from each other below, and form a cavity, which is the third ventricle of the brain. The thalamus nervi optici is separated from the corpus striatum, by a whitish, fibrous, and flat cord, which is broader in front than behind. This arises from the front of the third ventricle, and following the posterior margin of the corpus striatum, was named by Willis limbus posterior corporis striati. It descends into the inferior horn of the ventricle, and terminates on the upper surface of that cavity. This part is the centrum geminum semicirculare of Vieussens, the tænia semicircularis of Haller, bandelette striée of Vicq d'Azyr, and stria cornea of Soemmerring. The posterior and reflected horns of the ventricle contain certain eminences, which are named hippocampi. The posterior margin of the corpus callosum mixes on either side with the medullary matter of the brain, and produces in the digital cavity one or more small projections, corresponding in direction to the course of the cavity, and named colliculus, or unguis cavæ posterioris ventriculi lateralis (Pergot, or hippocampus minor of Vicq d'Azyr).

In the descending horn a very large and conspicuous medullary body is seen, extending to the termination of the ventricle, where it forms a bulbous extremity divided by three or four fissures, in such a manner as to bear an obscure resemblance to the foot of an animal. The eminence is named hippocampus major, or cornu Ammonis (processus cerebri lateralis Soemmerring de corporis humani fab. tom. iv. § 36.), and its termination pes hippocampi.

It is necessary to remark in this place, that the hippocampi are continuations of the medullary matter, which forms the corpus callosum; and that the corpus callosum itself,

itself, the septum lucidum, fornix, and pſalterium, are parts of one continuous medullary body. To underſtand clearly the relative poſition and connections of theſe parts, it is abſolutely neceſſary to reſort to the proper ſource of all anatomical deſcription, diſſection of the parts, which will ſhow how inadequate a notion of theſe circumſtances is obtained from the beſt deſcription.

An oval opening is ſeen between the optic thalami in front, named the foramen commune anterius, which leads into the third ventricle. As it is ſituated under that part of the fornix, which is not adherent below, it opens by means of the ſlit above mentioned, as forming the communication between the two lateral ventricles, into each of theſe cavities. Hence they communicate with the third by means of this aperture. The foramen commune poſterius, which opens alſo into the third ventricle, is a triangular ſpace left between the optic thalami at the poſterior part, and only expoſed when the choroid plexus and velum have been reflected.

On drawing aſunder the thalami, and ſeparating their ſoft commiſſure, we expoſe a conſiderable oblong cavity, which is named the third ventricle. In front of this a round medullary cord appears juſt under the anterior crura of the fornix, which paſſes tranſverſely between the two hemiſpheres, and is continued in a diſtinct form, for the ſpace of an inch, into the ſubſtance of the brain on each ſide, as will be beſt ſeen by a tranſverſe ſection. A ſimilar body is ſeen at the back part of the ventricle, which is not however produced into the hemiſpheres like the anterior one; theſe are the anterior and poſterior commiſſures of the brain. There is a round aperture under the anterior commiſſure, beyond which the ventricle terminates by a pointed and conical extremity, from which a ſmall and ſhort cylindrical proceſs is continued to the pituitary gland, under the name of the infundibulum. It is a matter of diſpute among anatomists, whether or not this proceſs be hollow. The foramen commune anterius leads through the third ventricle into this opening. Juſt before the poſterior commiſſure a round opening is found leading through a ſhort canal, in front of the tubercula quadrigemina, into the fourth ventricle. The canal of communication is named canalis medius, iter ad quartum ventriculum, or aquæductus Sylvii.

The pineal gland, or conarium, is found at the back of the optic thalami. Its ſize is about that of a ſmall horſe-bean; its colour a reddiſh grey; its ſhape moſt frequently conical. Two ſmall medullary cords connect it to the poſterior commiſſure and to the optic thalami; they are inſerted in the convex part of the thalamus, and form a diſtinguiſhable prominent line, extending quite to the front of that body, as is very beautifully repreſented in the 8th plate of Vicq d'Azyr. This gland is covered by the velum, and has immediately over it the two ſmall plexuſes, which have been already deſcribed under the name of plexus de la glande pineale. In the ſubſtance of the pineal gland, or in the medullary matter, which connects it to the optic thalami, there is found a ſmall quantity of a gritty matter nearly reſembling ſand. It conſiſts of a number of little ſemitransparent and light yellow grains. Soemmering, who firſt diſcovered that this was a part of the healthy ſtructure of the brain, calls it the acervulus of the pineal gland. (*Diſſertatio de lapillis intra vel prope glandulam pinealem ſitis, in Ludwig. collect. ſcriptor. neurol. minor. tom. iii.*)

The pineal gland reſts on a ſquare portion of the brain, which is ſeen behind and below the optic thalami, and below the level of the tentorium. The ſurface of this is divided into four projections or tubercles, and hence it has acquired the name of corpora quadrigemina. Of theſe bodies the two ſuperior are larger and more plane; the inferior more

convex. From the lower bodies a medullary production extends to the upper part of the crura cerebelli. Vicuffens deſcribed this part by the name of the valvula magna cerebri, ſuppoſing it to perform the office of a valve to the fourth ventricle. Vicq d'Azyr, whoſe incomparable plates throw new light on this as well as on every other part of the ſubject, calls it the "lame medullaire du cerveau." The lateral portions of this production conſtitute pretty ſtrong medullary bodies, which are the "procellus a cerebello ad teſtes" of Haller, "les pedoneales ou colonnes de la lame medullaire" of Vicq d'Azyr. The interval between theſe is filled by a very thin medullary plate, the velum interjeſtum of Haller, which is the part commonly known as the valve of the brain. This valve forms the roof of the fourth ventricle; therefore, if air be impelled into that cavity from the canalis medius, the valvula cerebri is elevated, and we can perceive the fourth pair of nerves ariſing from it; the origin of this nerve evidently projecting from the ſurface of the valve.

On liſting up the poſterior lobes of the cerebrum, a tranſverſe production of the dura mater, called the tentorium, comes into view. This is attached to the internal tranſverſe ridge of the occiput, and poſterior angle of the parietal bones behind, and to the ſharp margin of the petrous portion of the temporal bone in front, as far forwards as its connection to the body of the ſphenoid bone, where it terminates in a pointed form. This proceſs therefore ſeparates the cavity, which holds the cerebellum, from that part of the cranium which contains the cerebrum. The vacancy left in its anterior part, oppoſite to the baſilar proceſs of the occiput, tranſmits the commencement of the medulla oblongata. The middle of the tentorium, which has the termination of the falx fixed to it, is elevated; the lateral portions of the proceſs are rather ſloping.

The tentorium ſhould be divided on either ſide, in order to expoſe the cerebellum, which then appears lying in the poſterior foſſæ of the occiput. This is divided into a right and left lobe by the falx cerebelli, which is a ſmall proceſs of dura mater, attached to the lower part of the perpendicular ridge of the occiput.

The reſt of the encephalon ſhould now be removed from the cranium, that the fourth ventricle and baſis of the brain may be conſidered. In doing this, we liſt up the anterior lobes, and detach the different nerves as they go out of the cranium, cutting them near to the brain on one ſide, and near to the apertures by which they quit the ſkull on the other. The pituitary gland is to be ſcooped out of the ſella turcica, and the medulla ſpinalis to be cut acroſs as low down as poſſible.

The part which has been taken out ſhould be laid on a plate, in the ſame ſituation which it held in the cranium, that the fourth ventricle may be demonſtrated. This cavity is formed between the upper and poſterior part of the medulla oblongata, and the middle anterior part of the cerebellum. It extends laterally to a conſiderable diſtance in the crura cerebelli; a groove runs along the middle of the medulla oblongata, which conſtitutes the front of the ventricle, and terminates in the end of the cavity in a point. From the lateral productions, and the pointed termination of the cavity, it has been named the calamus ſcriptorius. Its ſhape indeed bears conſiderable reſemblance to a pen, except that it is much larger. To deſcribe its boundaries more accurately, we may ſtate, that it has four ſides or parietes. The ſuperior is formed by the valvula cerebri, the lower and anterior by the back of the medulla oblongata, the two lateral by the crura cerebelli, and in part by the thick portions of the valve, which unite the crura cerebelli

to the corpora quadrigemina. It opens above into the third ventricle, by means of the canalis medius; its termination would open below towards the back of the medulla spinalis, were it not closed by pia mater. The brain may now be turned over to expose the basis. The lower and anterior part of the third ventricle is closed by a ciceritious substance of a conical form, which extends from the anterior commissure and crura cerebri to the junction of the optic nerves, where its apex is continued, under the name of infundibulum, to the pituitary gland. This body is lodged in the sella turcica, the upper aperture of which is contrasted by a fold of the dura mater. Its superior surface is plane; its inferior convex. Its substance is harder than that of the brain. Immediately behind the infundibulum are seen two small convex medullary eminences, named the corpora subrotunda, caudicantia, or mamillaria, from which the anterior crura fornicis and the pedunculi of the pineal gland commence. The crura cerebri (processus medullæ cerebri of Soemmering) are two large medullary processes, having a fibrous appearance externally, which come from the middle and convex part of the hemispheres. They are separated above and in front, approach below and behind, and meet together just before they terminate in the medulla oblongata. There is seen therefore a depression, or hollow, between these crura in front, from which the third pair of nerves arises, and which is called by Vicq d'Azyr la fosse des nerfs oculo-musculaires.

The cerebellum is lodged in the posterior and inferior fossa of the basis cranii; it is situated therefore under the cerebrum, in a peculiar cavity, formed chiefly by the occipital bone, the posterior surface of the petrous part of the temporal bone, and the tentorium. Its upper surface is nearly flat; the under and posterior are convex. It forms in front some prominences named appendices vermiformes. It is divided into a right and left lobe, by a fissure which does not extend very deeply, and which lodges the falx cerebelli. The cerebellum consists, like the cerebrum, of an intermixture of cortical and medullary matter; but they have not the same relative arrangement as in the cerebrum. The surface of the cerebellum is marked by several horizontal lines, not disposed concentrically, into which the pia mater descends to a considerable depth, and from which other divisions containing also processes of pia mater commence. The cerebellum has, therefore, a much more extensive surface than an equal bulk of cerebrum; and the cortical matter is more abundant than the medullary. On a vertical section we see a thick cord of medullary matter sending off processes, from which other branches proceed, and all of which are surrounded by cortex; this is the arbor vitæ. An horizontal section discovers several parallel curved portions of cortex and medulla succeeding each other alternately. The trunk of the arbor vitæ constitutes the crus cerebelli on each side, which joins the medulla oblongata.

The medulla oblongata is a large protuberance occupying the lower and middle part of the cranium, and resting on the basilar process of the occiput. It is formed by the crura cerebelli and cerebri, which have been already described. Its surface has an irregular and fibrous appearance. It is divided into a right and left portion by a groove, which contains the basilar artery. This body is named the crura Varolii, tuberculum annulare, or nodus cerebri. A medullary cord passes from its posterior part through the foramen magnum occipitale, and enter the spinal canal under the name of medulla spinalis. It is separated from the pontic Varolii by a circular contraction. The medullary cord forms a bulb or dilated upper part of this medu-

part, which is divided into four convexities, of which the two superior are named corpora olivaria, the two inferior corpora pyramidalia. For the most ample and satisfactory information on the anatomy of the brain, we refer the reader to the *Encefalotomia Nuova universale di Vincenzo Mala carne*, Torino, 1780; the *Traité d'Anatomic of Sabatier*, vol. ii.; the fourth volume of Soemmering's work "*De corporis humani fabricâ*;" and his dissertation "*Ueber das organ der Seele*." Above all, however, the "*Traité d'anatomic, et de physiologie, avec des planches coloriées*," Paris, 1786, folio, of Vicq d'Azyr, requires the greatest commendation. In this superb work all the parts of the brain are represented of their natural colour, with such fidelity and beauty as render it, beyond dispute, the grandest book, which has ever been published in illustration of the human frame.

We shall subjoin to this description of the brain, a brief account of the anatomy of the medulla spinalis, and nerves. Thus, we shall include in one article, the structure of the sensorium, of the organs which transmit impressions to it, and convey the determinations of the will from it; which are only to be considered as parts of one circle of actions.

#### *Structure of the Medulla Spinalis.*

This part is a continuation, as we have already mentioned, from the medulla oblongata, which is formed by the union of the medullary appendices of the cerebrum, and cerebellum. The bulbous portion, which we have before described as forming the corpora pyramidalia and olivaria, is the commencement of the medulla spinalis; although, as it is contained in the cranium, the term of spinal marrow cannot, with strict propriety, be applied to it.

The medulla spinalis consists externally of medullary matter; on making a transverse section, we find a portion of ciceritious substance in the centre, consisting of two stripes, which cross each other, thus X. When covered by its membranes, it is of a firmer consistence than the brain; but it speedily dissolves when laid bare. Its form is nearly cylindrical, but it is compressed before and behind. A groove extends along its anterior and posterior flat surface, and these impressions seem to divide it into two cords. It is larger in the bottom of the neck, and towards the lower part of the back, than in the intermediate spaces. It contracts in the lumbar region into a conical form, and terminates by a small filament, which is fixed to the bottom of the sheath of dura mater.

It sends off a pair of nerves at each interval between the vertebrae, which are named cervical, dorsal, lumbar, or sacral, according to the region in which they arise. These nerves are produced by two fasciculi of fibres, one of which comes from the front, the other from the back of the cord. These are separated by a membrane, which will be presently mentioned, and penetrate the dura mater by two distinct holes, after which they unite to form a ganglion. The arteries of the dura mater are derived from many sources; the vertebrae furnish an anterior and posterior one. The others are derived from the cervical, intercostal, lumbar and sacral arteries, which enter at the openings, through which the nerves go out, and communicate with the spinal branches of the vertebrae, so as to keep up their size to the end of the medulla spinalis. The veins, which are also numerous, pour their blood into two longitudinal sinuses, formed in the dura mater, which lines the vertebral canal, and extending the whole length of that canal. These communicate together by transverse portions at the intervals of the vertebrae. They communicate in the neck with the vertebral veins; in the back, with the intercostals; and below, with the lumbar and sacral veins.

The spinal marrow is covered externally by a production of dura mater, which extends from the great occipital foramen to the bottom of the sacrum, connected throughout to the vertebral canal, by a loose cellular and adipose substance; and at the intervals of the vertebræ by the conical process, which it attaches to the commencement of the nerves. The tunica arachnoidea is much more loosely connected to the vascular membrane, than it is in the brain. The pia mater surrounds the spinal marrow very closely, in so much that, in making a transverse section, the medullary matter protrudes from the cut surface. The medulla spinalis is connected at the side to the dura mater by small portions of membrane, which are found between the anterior and posterior origins of the nerves, and are inserted in a pointed manner into the dura mater: it is called ligamentum dentatum. For descriptions and representations of the medulla spinalis, the reader may consult Huber de medulla spinali, Goetting. 1741, which is also contained in the Icones of Haller; Monro's observations on the nervous system, and Fratscher descriptio medullæ spinalis cum icones, Erlang. 1783.

*Structure of the nerves.*

The nerves are soft, white and fibrous chords, nearly of a cylindrical shape, arising from the brain, or medulla spinalis. When they leave the brain, the pia mater collects the fibres into larger or smaller fasciculi, which can be seen without any previous preparation, by making a longitudinal or transverse section of a pretty large trunk. Where the nerves penetrate the dura mater, they are firmly connected to the margin of the opening, and have been supposed to receive an external coat from that membrane; this, however, is only true of the optic nerve. The medullary filaments of the nerves are covered by a vascular membrane called by Reil neurilema, which detaches processes from its inner surface, to surround and invest the smaller divisions and fibres of the medullary substance. By immersing a nerve in alkali, the medulla of the nerve is dissolved, and the contained membranous tubes formed of neurilema are left. Acids dissolve the neurilema, and leave the medullary fibres. These organs receive a considerable supply of blood from vessels which ramify on the neurilema, as those of the brain do on the pia mater. The cellular texture, which constitutes the vascular membrane of the nerve, is resolved on its surface into a loose substance, which connects the nerve to the surrounding parts. By maceration in water, and careful dissection, a nervous trunk may be separated into numerous threads; and each of these, when examined in a microscope, seems to be an assemblage of proportionally smaller fibres. Greater magnifying powers shew those fibres, which before appeared single, to be still composed of smaller threads; and it is doubtful, whether the ultimate nervous fibre can be discovered. All that is said, therefore, of the form, course, &c. of these ultimate fibres, is wholly conjectural. Microscopical observations, however, shew many transverse striæ in the substance of nervous trunks, of a more lucid appearance than the rest, which disappear on stretching the nerve, and are restored by again letting it loose. This appearance characterizes the smallest perceptible fibres, and enables us to distinguish them from muscle, tendon, &c. Fontana probably alludes to this circumstance, when he calls the nervous fibres, waving cylinders. The fibres do not proceed in a straight uninterrupted course, but join frequently with each other, so that, according to the expression of Monro, they form a plexus in each nervous trunk. The experiment of Reil, of immersing the nerve in nitric acid, to dissolve its membrane, shews this, as well as microscopical observations. A nerve, when divided

in the living subject, retracts: the medulla is expressed from its extremities by the contraction of its membranes, in the form of globules, more copiously, according to Prochaska, from the upper, than the lower end. This protrusion of the medullary matter takes place in a less degree in the dead subject. If a nerve be cut in a living animal, and he be killed at some period after the operation, it will be found, that the divided extremities have swollen into a small tubercle, and that they are connected by a new formed matter. Anatomists have disputed greatly, whether or not this were real nerve, whether it was a regeneration of medullary matter. As it would not probably be very easy to decide this question, by merely anatomical testimony, from our ignorance of the minute structure of these organs, it appears most philosophical to inquire, whether the new matter will perform the functions of a nerve; and this has been completely proved by the experiments of Dr. Haighton, in the first part of the Philosophical Transactions for the year 1795. In some parts of the nervous system, little tubercles or knots, called ganglia, are found in the course of the nerve; and are usually formed by the concurrence of several branches. These bodies are of various figures, but generally flattened. They partake more of the red colour, than the trunks of the nerves on which they are formed, as they possess more numerous blood-vessels. They contain several nervous fibres, distinguished by their peculiar characteristics, and surrounded by a pretty firm vascular substance. The fibres communicate in these bodies, and each nerve which goes from a ganglion, is said to possess some fibres of every other nerve which joins it. For a further account of the structure of nerves, the following works may be consulted: Reil Exercitationes Anatomicae; Prochaska de Structurâ Nervorum; Monro's Observations on the Structure and Functions of the nervous System; Arneman versuche an lebendigen Thieren; Fontana Traité sur le Venin de la Vipère, &c.; Haase de gangliis nervorum; Scarpa Annotationes Academicæ.

*BRAIN, Physiology of the.* Having described the anatomy of the brain and nerves, we proceed in conformity to the arrangement adopted in this book, to speak of the functions or physiology of these organs. The first circumstance which it appears necessary to discuss in this intricate and interesting subject, is the inquiry respecting the place in which sensation exists. There could scarcely be any thing more difficult than to convince a person who has never thought on this point, that feeling resided solely in the brain, and that his belief, that it existed in the tangible extremities of the nerves, is a deception; and yet there is nothing of which men of the strongest minds, and who have most attended to the subject, are more perfectly convinced. The circumstances which have induced them to entertain this belief are, 1st. that if the continuity of the nerve between the extremity which receives impressions from the objects of sense, (and which we shall, therefore, call the tangible extremity of the nerve,) and that extremity which terminates in the brain, (which is usually denominated the sensorial extremity,) be by any means intercepted, both feeling and voluntary motion are suspended. 2dly, The false judgment which the percipient forms of corporeal disorders, confirms this opinion. If a nerve be irritated at the mid-space between its origin and termination, severe pain is supposed to be felt in those parts to which it is distributed; and if it supplies muscles, they become convulsed. If a disease forms about the hip-joint, or in the loins, the patient frequently complains of violent pain on the inside of the knee, without adverting to the real seat of the disorder. And people who have had their limbs taken off, can scarcely

ly believe that they are removed from their bodies, in consequence of the pains and sensations which they seem to feel in them. In either of these cases a motion is produced in the middle of a nerve, which being transmitted to the brain, is attributed by the percipient to a disordered state of the parts, from which it had been accustomed to receive impressions. Again, if a certain degree of pressure be made on the brain, all sensation and voluntary motion are interrupted. As these circumstances have been so well explained by Haller, we shall not enlarge on this subject, but proceed to consider the means, by which this transmission of motion from one end of the nerve to the other, is probably effected.

From the earliest times in which men contemplated the animal economy, reflecting persons imagined, that they perceived some subtle invisible agent, which operated in the performance of the animal functions. Hippocrates attributed actions, which he could not otherwise account for, to something which he called nature; Paracelsus, to the operation of an archæus; Stahl, to different animæ; and Harvey seems to have had an idea of a vital principle. But if any merit is due to such opinions, the credit of first decidedly teaching that a subtle invisible matter was diffused throughout living bodies, and was the cause of many phenomena occurring in them, belongs to Mr. Hunter. This opinion he has endeavoured to prove by experiments, which will be noticed under the article LIFE. The most conclusive arguments in favour of this opinion will probably be given under the *physiology* of MUSCLES, in discussing the cause of muscular motion, and to these the reader is referred.

It has been customary to consider matter as passive, and to denominate the active power which puts it in motion, by the name of spirit; but we relinquish the pursuit of the primary cause of the motions of matter, because we know nothing of the substances which we usually denominate matter or spirit. These appellations have been given to them from their properties, which we do know. We know nothing of matter, but some of the properties which different species of it possess. Of that matter, which, for the most part, presents itself to our notice, when collected together in such quantity as to be cognizable to the eye and touch, we know that it possesses a property, called by Sir Isaac Newton inertia, an indisposition to move, unless impelled to it, and a propensity to continue in motion, unless retarded. But there are other substances in the universe which are usually considered as material, such, for instance, as electricity and magnetism the motions of which do not seem to be regulated by the same laws, and which are cognizable neither to the eye nor touch, but of the existence of which reason furnishes us with the most indisputable testimony. Of these kinds of subtle and mobile matter, we know that they frequently act upon, and put in motion that which is more gross and inert. We see magnetism move even ponderous pieces of iron, and electricity displace and disperse the most stable substances which oppose its passage. The reasons for entertaining the opinions of Mr. Hunter, that there is a subtle, mobile, and invisible species of matter connected with the evident structure of living bodies, as magnetism may be superadded to iron or electricity to various substances, will be detailed under different articles in this book. At present, we claim permission to employ this explanation of the phenomena of life, because there appears nothing improbable in it, or inconsistent to present philosophical notions; and it is a supposition, which appears, not only verifiable, but adequate to account for the phenomena which occur in living bodies. By employing this mode of accounting for the

actions of life, we avoid all inquiry into the primary cause of the motions of matter; we contemplate only a secondary cause, such as takes place in electrical and magnetic experiments, in which a subtle species of matter puts in motion that which is more gross and inert.

If it be admitted, that sensation exists in the brain, and volition proceeds from that part, it necessarily follows, that a motion must be transmitted along the nervous cords, whenever these effects take place. It was formerly supposed that these cords were passive, and might be made mechanically to vibrate; but their want of elasticity and tension, and their pulpy origins and terminations, are circumstances which rendered this supposition inadmissible. Physiologists were, therefore, induced to suppose, that the nervous fibrils were tubular, and that they contained a subtle fluid, by means of which such motions were transmitted. Haller's opinion of the nervous fluid appears sensible and accordant to the philosophical opinions of his time. He says, "Si vero cogitata nostra de ipsa natura spirituum proferre juberemur, activum ad motum a voluntate et a sensu concipiendum aptissimum celerissimum omne ferissimum acie subtilissimum, tamen hæc igne et æthere et electio, et magnetica mater hæc assidue facere elementum, ut et contineri vas et vinculis coerceri aptum sit, et denique manifestum ex cibis nasci et reparari queat." But, at present, no one will doubt the possibility of a subtle and mobile fluid inhering in cords, and moving along them without being contained and confined in tubes. Does not electricity move along a wire? and is it not probable that a subtle fluid may where in a substance, in consequence of an attraction which it possesses to it, and more particularly, if the substance which attracts it is surrounded by others, which may be regarded as non-conductors. The celerity with which motions are transmitted from the tangible extremities of those nerves which are most distant from the brain, and the celerity with which volition is transmitted to muscles in consequence of sensations thus occasioned, are sufficient to convince us that these effects must be produced by the medium of a very mobile matter. It is not necessary to suppose, when motions of a subtle matter are transmitted along the nervous cords, that an evident motion of the visible matter of those cords should take place. This opinion, that sensation is caused, and volition directed through the medium of a subtle, invisible matter, inhering in the nervous cords, is so like the opinion of Hartley, of the phenomena of the nervous system being produced by the vibrations of an æther, that it is not necessary, in this place, further to prosecute the subject. We rather refer the reader to his work, for a more ample illustration of this theory.

Formerly it was supposed, that the motions of the nerves, which cause sensation, were the mere effect of an impulse made on their tangible extremities by the bodies which we feel. It seems to be an improvement in modern physiology, to impute the nervous motions to an action begun in them, in consequence of the stimulation which they suffer from such impulses. This opinion is contended for by Doctor Darwin, in his paper on "Ocular Spectra", inserted in the Philosophical Transactions; and Mr. Home has further shewn, in the Croonian Lecture for the year 1801, inserted in the Philosophical Transactions, that nerves have an irritability resembling that of muscles, which produce a contraction in them when they are divided. This opinion assists us in understanding how our sensations may be very vivid from the slightest impulses; such as, for instance, take place from the application of the particles of odour to the olfactory nerves, for it is not the impulse, but the consequent action, that is transmitted to the sensorium; and why

we may have no sensation from the most violent impulses, for such we cannot but suppose to take place when a limb is removed by a cannon ball, a circumstance which has happened without the consciousness of the person to whom it has occurred.

These hypotheses appear to us adequate to explain all the circumstances that have been noticed relative to the functions of the nervous system. To review the circumstances, even with the greatest possible brevity, would render this article too extensive. Yet, there are some particulars which the reader may expect that we should advert to. Of these, it is right to mention, that the disposition of the nerves to act, is increased, as the causes exciting their action is diminished. This circumstance has been expressed, we can scarcely say explained, by the late Doctor Brown, in his "*Elementa Medicinæ*," by saying, that the excitability of the nerves is accumulated in proportion to the deficiency of the exciting causes. This fact is productive of consequences which appear particularly beautiful and useful; it furnishes a power of accommodation in our senses to the varying circumstances of life. Thus, for instance, a person confined in the dark, shall receive the impression of light from a very small quantity of light, and his eyes would even be injured by the common day-light. The reverse of this is equally true: that a person shall live in a strong light, till his eyes become so accustomed to it, that a less quantity shall not produce a proper impression; or a person, who has long been in a still and silent place, shall hear the slightest sound, such as would be imperceptible to one whose auditory nerves had, for some time, been accustomed to the forcible impressions of the air, made by loudly sounding bodies. This power of accommodation does not only belong to particular senses, but it will bear a more universal application. A person, living a luxurious life, who avoids every sensation which gives him the least uneasiness, and who attends only to the gratification of his pleasures, renders his nervous system too sensible: he shrinks at the cold wind, he is startled at a loud noise; and every rough impression, which would not disturb another, owing to his ill-judged indulgence, distresses him. Let us remark the contrast in a hardy seaman, who has indured the inclemency of the weather, who has sustained fatigue and pain: if the winds blow, or the cannon thunder, he hears the one, and feels the other, but they do not much affect him; and from being habituated to sensations, at first painful, he is afterwards unaffected, even by those impressions which would hurt a man living in the medium between these two extremes.

It seems also right here to remark, that a great similarity appears to exist between the supposed irritable actions of the nerves, and those of the muscles. The facility, accuracy, and celerity of the actions of nerves are improved by use, as is exemplified in the correct and quick sensations of those persons who are accustomed to exercise their auditory nerves in attending to musical sounds.

A train or succession of nervous actions having taken place, they become concatenated, and are liable to recur in succession, if one of these actions is accidentally induced.

Both the nerves and muscles seem to require temporary respites from action, and both appear to be refreshed by sleep.

The supposition of actions occurring in the nerves, explains many circumstances connected with diseases. Vehement actions may be begun independent of impulses in the tangible extremities of nerves, and thus occasion severe pains. This seems to happen in the disease called *tic douloureux*. Ordinarily, actions begun in the tangible extremities of the nerves, are regularly transmitted to the brain; but in cases of nervous pains, the action seems to begin in the middle of the nerves.

It is also probable, that actions may take place in the sensorial extremities of the nerves producing illusory sensations, and thus exciting ideas.

The next subject which claims our attention, is the part of the brain to which all the nervous motions, produced by external impressions, tend, and from which all the motions arising from volition begin. Physiologists have agreed to call this part the sensorium, and have supposed it to be situated in various parts of the brain; but there is no part of the brain to which this importance has been ascribed, which has not been occasionally found diseased, without sensation and volition being impeded. Of late, Soemmering has affirmed, that he can trace all the nerves to the ventricles of the brain, in which he therefore supposes the faculty of sensation and volition to reside. All our senses may be gratified at the same time, and we may give a preference to the pleasure which we receive from one of them, above that which we derive from the others; which circumstance seems to prove the unity of that which perceives and determines. Haller, after considering the subject, thus concludes: "*Nunc quidem in univcrsum observamus, non debere angustiore animæ sedem poni, quam sit conjuncta omnium nervorum origo; neque particulam aliquam pro ea sede offerri, nisi ad quam omnes nervos ducere possimus. Facile enim intelligitur, debere a sensorio communi nullum ullius particulæ corporis animati sensum abesse.*" &c. *Elem. Physiol.*

If it be admitted that sensation and volition exist in the brain, it must also be granted that motions must be produced in the sensorial extremities of the nerves by the objects of sense, and that reflected motions must take place in the nerves, by which the mandates of the will are transmitted to the muscles.

If all that has been said were to be ascertained, the extent of our knowledge would, in that case, only lead to this conclusion, that motions of a subtle substance took place in the sensorium, and from such motions we esteem it impossible to account for sensation. We can conceive no varieties in these motions but those which relate to degree or duration. We feel it impossible to believe that sensation can be the result of such motions, or that ideas can arise from any succession or train of them. We therefore conclude, with many celebrated physiologists, and men of the soundest understanding and greatest reflection, in the natural belief, that sensation, remembrance, comparison, judgment and volition are properties of a distinct substance.

The conclusion to be drawn from this examination of the functions of the brain and nerves, and from that of the other animal functions, seems curious and interesting. We perceive an exact correspondence in the opinions we obtain from physiological researches, and those which arise so naturally from the suggestions of reason, that they have been considered as intuitive. For most reflecting persons in all ages of the world have believed, and it is, indeed, natural to believe, what modern physiology teaches, that in the human body there exists an assemblage of organs, formed of common inert matter, such as we see in the dead state, a principle of life and motion, and a sentient and rational faculty, all intimately connected, yet each distinct from the other.

*BRAIN, Chemical Analysis of.* Though the analysis of this most important organ can throw no light on its peculiar functions, it is in itself sufficiently remarkable to be detailed somewhat at length.

It is needless to give all the conjectures on the nature of brain, made before chemists had acquired a tolerably accurate and just method of analyzing animal matter. The experiments of real importance are chiefly those of Fourcroy, in 1790, with some subsequent additions by Fourcroy.

thrust through the inner end of it; one of which resting across two cheeks or ears, in the upper end of the pump, serves as a fulcrum for the brake, supporting it between the cheeks. The other bolt connects the extremity of the brake to the pump spear, which draws up the box, or piston charged with the water in the tube. See PUMP.

**BRÄKEL**, in *Geography*, a town of Germany, in the circle of Westphalia, and bishoprick of Paderborn, formerly a city of the empire, 3 miles E. of Paderborn.

**BRÄKENBURG**, **REINER**, in *Biography*, a painter of landscapes and conversations, was born at Haerlem in 1649, and studied first under Mommers, and afterwards, according to Houbraeken, under Bernard Schendel. His subjects were like those of Brouwer; and he resembled him, not only in his genius, and style of composition, but in the dissoluteness of his morals. In some of his pictures, he seems to have been desirous of imitating Ostade. His figures were designed after nature, and represented in the habit and fashion of the times. His subjects were the feasts of boors, the amusements of the villagers, dances, and frequently conversations, in which love and wine were always introduced. His compositions are ingenious, and full of variety; though the forms of his men and women are the same, and selected without elegant taste from low nature. His colouring is strong and natural, his touch lively and fine, but he is deficient in taste of design. Pilkington.

**BRÄLIN**, in *Geography*, a town of Silesia, in the principality of Qels; 7 miles E. of Wartenberg.

**BRÄLIO**, a mountain in the country of the Grisons, separating the valley of Munster from the county of Bormio, and being a part of the Alps, which is supposed to be the same with that mentioned by Tacitus, under the appellation of "Juga Rætica." The first source of the river Adda lies near the summit of this mountain. Over the Brälio is a road, which, though very indifferent, was formerly the principal passage for the merchandize, sent from the Tyrol, through the Valteline, into the Milanese: at present, it is much less frequented.

**BRÄM**, a river of Germany, which runs into the Stoer, 10 miles above Itzchoe, in the duchy of Holstein.

**BRÄMA**, or **BRÄHMA**, in *Mythology*, a pagan deity among the Brahmins in the East Indies. See **BRÄCHMANS**.

**BRÄMA**, in *Ichthyology*, a species of **CYPRINUS**, known with us by the name of Bream, and which is distinguished by having the fins brown, and in the anal fin twenty-seven rays. The bream is found in lakes and rivers, or in the sea. It grows to the length of two, or even almost three feet. The food of this fish is herbs, worms, and smaller fishes. This is esteemed a coarse fish for the table, but to the angler it affords excellent sport. The best time of angling for the bream is from St. James's day to Bartholomew tide, being then in the highest perfection.

**BRÄMÆ**, in *Natural History*, a species of **ECHINORHYNCHUS**, that infests the intestines of the bream. The neck is filiform, and the proboscis armed with very minute prickles. Gœz. Gmel.

**BRÄMÆ**, a species of **FASCIOLA**, found in the intestines of the bream and sticklebacks. The form is oblong, round, tapering, and obtuse at the base; neck round and somewhat incurvated. Mull. Zool. Dan.

**BRÄMAGUM**, or **BROMAGUM**, in *Ancient Geography*, a town of Italy, in the route from Rauracum to Augulla Prætoria. Antonin. Itin.

**BRÄMANT**, in *Geography*, a small town of Savoy, in the valley of Maurienne, seated on the river Arc. N. lat. 45°. E. long. 4° 15'.

**BRÄMANTE**, **LAZZARI**, in *Biography*, a famous Italian

architect, was born at Castel-du-Sante, in the territory of Urbino, in 1444. His first views were directed to the profession of a painter; but architecture being better adapted to his taste and talents, he devoted himself wholly to the attainment of excellence in the art. For this purpose he went to Milan, about the year 1470, and afterwards to Rome, and other cities of Italy, availing himself of instruction from the best masters, and from a diligent examination of the architectural remains of antiquity. At Naples he was employed by cardinal Caraffa in re-building the convent della Pace; and the reputation he thus acquired recommended him to pope Alexander VI., in whose service he executed many designs. Under Julius II. he was employed, as superintendent of his buildings, in accomplishing the grand project of joining the Belvidere with the Vatican, by means of two galleries extended across a valley. In 1504 he accompanied pope Julius to Bologna, and was engaged in fortifying the town; and during the war of Mirandola, he had several opportunities of exercising his talents in the military art. After his return to Rome, he adorned the city with many fine buildings; and at length undertook to demolish the cathedral of St. Peter's, and to supply its place with another edifice suited to the capital of the Christian world. His plan for this purpose was adopted; and before the death of the pope, in 1513, the new structure was advanced as far as the entablature; and at the time of his own death, in 1514, the four great arches for the support of the dome were erected. The original design was abandoned by the architects who succeeded him, not without injury to the structure; but the prosecution of the work was entrusted with Michael Angelo, who praised his plan, and conformed as much as possible to his ideas. Bramante was no less estimable for his general character than for his extraordinary talents as an artist. Obliging in his disposition, he took pleasure in encouraging young persons of the profession; and he invited the celebrated Raphael, who was his cousin, to Rome, instructed him in architecture, and procured for him employment in the Vatican. He was also skilled in poetry and music, and composed extemporaneously for his harp. To him is ascribed the invention of constructing arches by casting in wooden moulds a mixture of lime, marble dust, and water, supposed to be a revival of the stucco of the ancients. His poetical works were printed at Milan, in 1756. The knowledge and practice of the art of engraving may also be added to his other accomplishments. This art he probably acquired at Milan, and his execution of it exactly resembles the style of Andrea Mantegna, that is, with the strokes running from one corner of the plate to the other, without any crossing. He died in 1517. Tiraboschi. Strutt.

**BRÄMBAS**, in *Botany*, a name given by the people of Guinea, and some other parts of Africa, to a peculiar species of lemon-tree. The leaves of this are of a deep green, and of an admirable fragrantcy, when rubbed between the hands. The fruit is very small, and has a remarkable thin skin. The juice is used in dying. Phil. Trans. N° 108.

It has not been taken up as a distinct species, either by Linnæus or any other systematic botanist. In the Abridgment of the Philosophical Transactions it is passed over without notice.

**BRÄMBER**, in *Geography*, is an ancient borough town of Sussex, in England. This place, though now reduced to only 25 houses, still possesses the privilege of sending two members to the English imperial parliament, and the borough of Steyning, which unites with this, also returns two members. (See **STEYNING**.) From 1298 to 1472 the writs for electing burgeses to serve in parliament were directed jointly

to these two places; but since that period each has been separately represented, and each governed by its respective charter. This borough is the joint property of two persons, who, in the year 1786, strongly opposed each other, for the exclusive power of possessing the whole. In this struggle, it is stated on authenticated authority, that a tenant of one of the poor cottages had the fortitude and integrity to resist the present of 1000*l.* which was offered for his vote. Here is neither market nor fair, and its whole population only amounts to ninety-one persons. It is 51 miles south from London. History of the Boroughs of Great Britain, 8vo. vol. iii.

**BRAMBLE**, in *Botany*, the common English name for the black-berry and dew-berry bushes, *Rubus fruticosus* and *cæsius*.

**BRAMBLE**, *Brambling*, *Bramble-finch*, in *Ornithology*. See *FRINGILLA montifringilla*. **BRAMBLING**, greater. See *FRINGILLA lapponica*. Ray calls the tawny bunting, *Emberiza mystellina*, the brambling or sea lark.

**BRAMBLE-galls**, in *Entomology*. See *GALLS of the Bramble*.

**BRAMBLE-net**, otherwise called *ballier*, is a net used by bird catchers, of several sizes.

**BRAME**, Martin Brame of Sonnerat, in *Ornithology*, *Turdus pagodarum*, the pagoda thrush.

**BRAMER**, LEONARD, in *Biography*, a Flemish historical painter, was born at Delft in 1596, and acquired the art of painting in the school of Rembrandt, whose manner in small he imitated. At the age of 18 years, he went to Rome for further improvement, but could never wholly divest himself of the Flemish goût. With a fine taste of design he combined an expression generally good, and occasionally noble. His pencil is delicate, and his colouring very peculiar in the tints, and by great skill in the management of the chiaro-scuro, light, bold, and full of lustre, particularly in the vases, which he was fond of introducing, and to which he gave a rich and fine relief. To his pictures he was accustomed to give a great degree of transparency, by painting with a very thin body of colour, especially in the brown and shadowy parts. His name was famous, not only at Rome, but in several other cities of Italy, and his works, out of Italy, are scarce; but when they occur in an undamaged state, they fetch high prices. Among his most capital pictures are the "Raising of Lazarus," exhibiting a charming contrast of light and shadow; his "Denial of St. Peter;" both executed in his best manner, and preserved at Rome; and, particularly, a small picture on copper, representing the "Story of Pyramus and Thisbe." Pilkington.

**BRAMIA**, in *Botany*. Rheede, Hort. Malab. tom. x. tab. 14. Clafs, *dichynamia angiospermia*. Gen. Char. *Cal.* five-leaved, rather unequal. *Stamens*, four, two longer. *Pist.* style filiform; stigma simple; germ superior. *Pericarp*, capsule conical, one-celled. *Seeds*, numerous, attached to a linear, central receptacle.

There is only one known species. *Stems*, cylindric, tender. *Leaves*, opposite, oblong, obtuse, succulent. *Flowers*, axillary, single, blue. It is a native of moist situations in the East Indies.

**BRAMHALL**, JOHN, in *Biography*, an eminent prelate of Ireland, was born at Pontefract in Yorkshire, about the year 1593, and admitted into Sidney college in Cambridge, in 1608, where he took his degree of B. A. in 1612, and that of M. A. in 1616. Having taken orders, he was preferred to a living in the city of York; then to the rectory of Elvington in the same county, and afterwards to the prebends of York and Rippon. In these several situations he engaged such a degree of esteem and confidence,

both by his abilities as a preacher and by his general conduct, that he had very considerable influence in all public transactions. As one of his majesty's high commissioners, to which office he was appointed, he was very assiduous, and, as some have said, severe in the discharge of his duty. In 1623 he took his degree of B. D. and in 1630 that of D. D. on which latter occasion the subject of his Latin thesis was "The Pope is the Author, or Maintainer of all, or at least, of the chief Controversies in the Christian world," in the support of which he displayed great learning. Soon after he was invited to Ireland by lord Wentworth, deputy of that kingdom, and sir Christopher Wandesford, master of the rolls; and in 1633, having resigned all his English preferments, he removed into that country. From the archdeaconry of Meath, which was his first preferment, he was advanced in the following year to the bishopric of Londonderry. In these stations of dignity and influence he was eminently active and useful in passing several important acts in the parliament of 1634, in reforming the doctrine and discipline of the church, and in the improvement of its revenues. In pursuance of the first of these measures he abolished the fee-farms that were charged on the lands of the church; in accomplishing the second, it was his object to effect a more entire union between the churches of Ireland and of England, and for this purpose he obtained a canon in the convocation, holden at that time, which expressed an approbation of the 39 articles of the English church, and which denounced excommunication against those who affirmed, that "any of them are in any part superstitious or erroneous;" and with a view to the improvement of the revenues of the church, he adopted various means, which, in the space of four years, gained an accession to them, of 30 or 40,000*l.* a year. In the conduct and execution of these measures, however, he excited much opposition and obloquy, and he incurred the charge of being inclined to popery and arminianism. In March 1640-41, articles of high-treason were exhibited by the house of commons to the house of lords in Ireland against him, and several of the ministers of state, in which they were charged with a conspiracy for subverting the fundamental laws of the kingdom, and for introducing an arbitrary and tyrannical form of government. Instead of securing himself by flight, agreeably to the advice of his friends, he determined to repair to Dublin, and to appear before his enemies in the parliament house, where he was arrested, and from thence conveyed to prison. After a rigorous examination, in the course of which he cleared himself from all selfish and sinister views in recovering the patrimony of the church; and when his accusers were proceeding to fix upon him the charge of subverting the laws of his country, he obtained, by the interposition of the primate Usher, then in England, a letter from the king to stop the prosecution of the suit. Accordingly he was set at liberty, though not publicly acquitted. Finding it unsafe to reside at Londonderry, he removed to England; and settled in Yorkshire, where, by his influence and activity, he did great service to the royal cause; but, after the battle of Marston-moor, when the king's affairs became desperate, he embarked with several persons of distinction for Hamburg, in 1644; and from thence he went to Brussels, where he molly resided, and exercised his ministry till the year 1648. In that year he visited Ireland, but was soon obliged to withdraw again to the continent; and he remained abroad until the restoration. Upon this event he was recompensed for his loyalty, by being translated, in January 1660, to the archbishopric of Armagh, the primacy and metropolitan see of Ireland. Soon after his promotion he visited his diocese, and by prudence, moderation, and firmness, allayed the dif-

contents that prevailed in it, removed several prejudices that were very generally entertained, both against himself and the church, and gained over many adherents to the cause of conformity. In the parliament of 1661 he was chosen speaker of the house of lords; and as a further evidence of the high estimation in which his character was held, both houses concurred in expunging from their records every charge both against himself and the earl of Strallford. In this parliament he also obtained many substantial advantages for the church. Whilst he was meditating other plans for the benefit of the church and its ministers, he was disabled from prosecuting them by a second stroke of the palsy; and this was succeeded by a third fit which terminated his life, in June 1663. His works were collected and reprinted at Dublin in 1667, in one volume, folio, which was divided into four series or parts. The *first* contains his discourses against the Roman Catholics; the *second* consists of various pieces against the English sectaries; the *third* includes his writings against Mr. Hobbs, which have been deemed very valuable; and the *fourth* comprehends his controversies about the Sabbath and the Lord's day, single sermons, and occasional tracts. Mr. Granger observes, "that Dr. Bramhall was one of the most learned, able, and active prelates of the age in which he lived, an acute disputant, and an excellent preacher." Although his conduct in the Irish convocation of 1634 be not entitled to any very extravagant applause, and the latter part of the canon, which is said to have been procured by his arguments, be totally inconsistent with a proper respect for free inquiry, or any just sentiments of religious liberty; and although he coincided in many respects with Laud, and more especially in his principles of civil government, he possessed much greater moderation in religious matters. The temper and prudence, likewise, with which he conducted his designs, for the interest of the established church, were far superior. Whilst he approved himself a firm friend to the church of England, he manifested a great degree of charity towards persons of different persuasions; and, accordingly, he distinguished between articles necessary for peace and order, and those that are necessary for salvation; often declaring, "That the church was not to be healed but by general propositions." Biog. Brit.

**BRAMICIDE**, the crime of killing a bramin, reputed in the East Indies one of the five most enormous sins.

**BRAMINS**. See BRACHMANS.

**BRAMNEE**, in *Geography*, a river of Hindostan which runs into the bay of Bengal, 40 miles S. of Balasore.

**BRAMPOUR**. See BURHANPOUR.

**BRAMPTON**, a market town in Cumberland, England, is situated in a deep and narrow vale, 31 miles N.W. from London. Camden supposes it to have been the Roman Bremeturacum, "where the Cuneus Armaturarum were in garrison on the decline of the Roman empire;" and from its general appearance, it seems to have been of much greater importance than at present. At the east end is a vast conical mount, called the Moat or Castle-hill; which is about 360 feet in perpendicular height, and its acclivity very steep. Near the summit are a trench and rampart, which entirely surround the hill, the crown of which has been formed into a plain, about forty paces in diameter, and defended by a breast-work. Brampton principally consists of one spacious street, irregularly built; but a few modern houses, and a good inn, have been lately erected. Its chief support are a large weekly market (Tuesday), and two annual fairs, for which the grant was obtained in the reign of Henry the Third, by Thomas de Multon, lord of Gillsand. The houses are 346, and the inhabitants 1682, who are not well employed, there being no manufacture of any extent in

the town: it appears, however, to be improving; and a railed waggon-way, which the earl of Carlisle has lately made from his collieries at Tindalefell, will probably conduce to the augmentation of its trade. Religious worship is performed in a chapel, which was consecrated in 1789, having been built with the materials of the church, which stood about a mile from the town, on a bold eminence, near the banks of the river Irthing. The chancel yet remains, and the burial-service is generally read there, most of the inhabitants preferring to be interred in the ground that had entombed their ancestors.

About two miles distant, on the face of a rock overhanging the river Gelt, is the celebrated Roman inscription, noticed by Camden, and almost every antiquary since his time. The rock is of an angular form; and, from its exposed situation, the letters have been partially obliterated, but less so than could have been expected from the storms of fifteen centuries.

Near the junction of the rivers Irthing and Gelt is Edmond-Castle, the seat of Thomas Graham, esq. beautifully situated; but greatly improved by the plantations, and other tasteful and judicious alterations of the present proprietor. Near this mansion, on a rising ground, is a mound of earth, called Castle-Hill, raised about twelve feet from the adjacent land, hollow on the top, and upwards of thirty yards in diameter. Between one and two miles north-west from Edmond-Castle, is Watchcros, the fourteenth station ad lineam Valli, and supposed to have been the Aballaba of the Notitia. It is situated on the summit of an eminence, of an easy ascent, and commanding a very extensive prospect. On the south side are several irregular lines and breast-works, and the site of the Prætorium is still distinct. The military way, which generally accompanied the Prætenturæ, runs in this part of the county at some distance, in order to avoid the marshes and bogs through which both the walls of Severus and Hadrian were carried. Its comparative direction, therefore, from Carr-voran to Stanwix, is that of a string to a bow; and hence it passes this station, which is several hundred yards south of the wall.

**BRAMSCHE**, a town of Germany, in the circle of Westphalia, and bishopric of Osnabruck, on the Hase; 5 miles S.W. of Vorden.—Also, a town in the circle of Westphalia, and county of Lingen; 5 miles S.S.E. of Lingen.

**BRAMSTEDT**, or **BRAHMSTEDT**, a town of Germany, in the circle of Lower Saxony, and duchy of Holstein, situated on the river Bram, and having near it a medicinal spring discovered in 1681; 21 miles N. of Hamburg.

**BRAN**, the skins or husks of corn, especially wheat, ground, separated from the farina or flour, by a sieve or boulder.

Of wheat bran it is that starch-makers make their starch, which is nothing else but the *fecula* remaining at the bottom of the vessels, wherein the bran has been steeped in water.

Bran is held detergent, and, on that account, is of some medicinal use in gargarisms and glysters. It is also a chief ingredient in the composition of cataplasms. Some apply it hot against the pleurisy; boiled, it purges scurf and dandriff, and cleanses the hands in lieu of soap. Among the ancients, it was also used as an erotic, to excite love.

Bran has been given to horses; but it has been observed that those of bakers and mealmen, which have principally subsisted on this article, with the addition of a few split beans or peas, have become purfivè and thick-winded, then asthmatic, and lastly, dull, heavy, and inactive; and when they have died at 9 or 10 years old, a large ball, or mealy concretion, of different sizes in different subjects, has been found

found in the stomach and intestinal canal, impenetrably hard, and about 10 or 12 pounds in weight. However, bran, though an improper food for horses in its dry state, is an useful ingredient in mashes with meal, and serves to prevent the fatiating richness of that article alone; and also in common mashes with oats, when a horse is under a course of physic; and with a proper impregnation of honey in the mashes for colds, during the severity of the winter season. Taplin.

Dyers rank bran in the number of non-colouring drugs; because it yields no colour of itself. It serves for the making of their sour waters, used in preparing stuffs to take the dye. This water is made by boiling wheat bran, and into the decoction putting a little leaven.

BRANA, in *Ancient Geography*, a town of Spain, in Bœtica. Pliny.

BRANAW, in *Geography*, a town of Bohemia, in the circle of Koniggratz, in which is a manufacture of coloured cloth; 11 miles N. W. of Glatz, and 29 N. E. of Koniggratz.

BRANCA URSINA, J. Bauh. in *Botany*. Bear's breech. See ACANTHUS.

BRANCA Ursina Germanica, J. Bauh. See HERACLEUM *Sphondylium*.

BRANCA, in *Geography*, a small island in the Atlantic, being one of the Cape de Verde isles, near the coast of Benin, in Africa.

BRANCA, in *Middle Age Writers*, the paw, or extreme part of the foot of a wild beast, or bird of prey. Duncange.

BRANCA, or BRANCHIA, also denotes a right of lopping or cutting off branches of trees in the forest for firing. Duncange.

BRANCALEO, JOHN FRANCIS, in *Biography*, a Neapolitan physician, published, in 1534, "De balneis, quam salubria sint, tum ad sanitatem tuendam, tum ad morbos curandos. Dialogus adversus neotericos," Rome, 8vo. He defends bathing against the objections of his contemporaries, on the authority of Galen, and from his own experience recommends the practice in intermitting fevers, and as an assistant in the cure of the lues venerea. He reproves his brethren for their too frequent use of purgative medicines, the common resource, at that time, against most diseases. The work has been several times reprinted. Haller Bib. Med. Pract.

BRANCALEONE, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra; 9 miles S. E. of Bova.

BRANCAS, Sr. a town of France, in the department of the Indre and Loire; 4 leagues S. of Tours.

BRANCH, in *Botany*. Branches are the divisions of a stem or trunk, which are found on many herbaceous plants, but are chiefly noticed on shrubs and trees. The primary branches spring immediately from the trunk; the secondary ones from the primary; and so on in a regular subordination, till they terminate in slender twigs. They consist of precisely the same anatomical parts as the trunk, and with the exception of a root, are in fact little trees, which if separated from their parent stock, and planted in the earth under favourable circumstances, would throw out roots, and become independent plants. They proceed from buds formed within the surface of the trunk which interrupt the parallelism of its fibres, and form knots in the wood. These knots afford a point of support, and centre of motion to the growing branches, and are sunk more deeply in the wood in proportion to their age.

The lower branches are often nearly parallel to the horizon at right angles with the trunk: those above them make

angles more and more acute, as they are placed nearer the summit; but these angles differ in different species, and in every individual tree are subject to numerous varieties, from the influence of external causes. Some branches produce only leaf, and new branch buds: others produce only flower buds. The former are smooth in their surface, pliable and tough, with close straight fibres, easily separable from each other: the latter are wrinkled at their base, have their fibres less compact, and break short when struck. There are also branches which pierce the bark without a bud, and form what is commonly called false wood. These, as they are often luxuriant in their growth, and rob the more useful branches of their due nourishment, are carefully pruned away by the skilful planter and horticulturist. They have a rough bark, and produce only a few blackish buds.

BRANCH, in *Vegetable Anatomy*. Almost every plant or tree, when arrived at a certain period of its growth, exhibits at its superior part, more or less of a divided or ramified appearance. The mode of increase by means of branches has been observed so generally amongst vegetables, that it was formerly considered the exclusive distinction of that class of beings; but it is now well known that a numerous tribe of animals multiply themselves by branches, and therefore this mode of propagation is not quite peculiar to the vegetable kingdom.

On a superficial inspection, the branches appear as so many divisions and sub-divisions of the tree, in the formation of which the main trunk is disposed of or expended; but a more accurate examination proves, that the trunk loses none of its substance in the production of the branches; that both trunk and branches take their origin, and continue to increase precisely in the same manner; that, in fact, every branch should be considered as a lesser trunk, differing only from the parent stem, in the circumstance of not deriving its sustenance immediately from the earth.

The branches are the product of the buds in which they enjoy, for a certain period, a species of foetal existence, as the embryo of the trunk did originally in the seed. See the articles SEED, FRUIT, TRUNK, BUD, and BULB.

The kind of attachment which continues to subsist between the trunk and the branches affords additional proof of the individuality of the existence of the latter: although the external form of a tree would lead to the supposition, that the branches were formed by different detachments of the fasciculi composing the original trunk, in the same manner as one separates into several portions the fibres of a rope; yet, to exhibit the contrary, it is only necessary to make some sections of the branches where they are implanted into the trunk. Thus, suppose a tree, which divides into two primary branches, be cut transversely about a foot above the bifurcation, the section will be found to represent that of two distinct trunks, each composed of concentric circles of woody fibres. (See Plate II. in *Vegetable Anatomy*, fig. 1.) If a transverse section be then made of the same branches, at the place where they first appear to separate from the trunk, the concentric layers corresponding to each branch will be perceived as before, but they will be found surrounded by several circles of the woody layers belonging to the trunk. (See Plate II. in *Vegetable Anatomy*, fig. 2.) If a transverse section be again made similar to the last, but a few inches lower down, the circles of woody layers which compose the branches will be seen diminished in number and size, while the concentric layers of the trunk have become in the same proportion more numerous. (See Plate II. in *Vegetable Anatomy*, fig. 3.) If, lastly, similar sections to these described be repeated at short distances from each other, it will be found, that the number of woody circles which

appertain

appertain to the branches, continue regularly to decline, in proportion as the sections are performed lower upon the tree, until they disappear altogether, there being at last exhibited only the appearance of the divided circles of the layers of wood, which constitute the main trunk. The connexion of the branches with the trunk is, therefore, by means of a cone, of which the apex is directed towards the centre of the tree, and the base corresponds with the superficies. *Fig. 4. of Plate II. in Vegetable Anatomy*, represents the arrangement of the ligneous fibres, by means of which the origin of the branches is rendered of a conoid form.

When a branch is forcibly torn from the stem, it is commonly observed to bring with it a portion of a cone or pyramid, which leaves a corresponding depression at the part from whence the branch has been removed. This arises from the woody fibres being most easily ruptured, where they are reflected into the angle, which forms the line of junction between the branch and the trunk.

The small or secondary branches have precisely the same kind of origin and connexion with respect to the large or primary branches, which these latter have with regard to the trunk. Hence every branch may be considered as a parent stem sustaining others, which in their turn give origin to new branches, and these again to others, as long as the vegetable continues to grow.

Branches acquire bulk by the addition of successive layers of wood, in the same manner as the trunk. See *fig. 5. of Plate II. in Vegetable Anatomy*, which is copied from the design of Duhamel, to illustrate the growth of branches. The entire figure is supposed to represent a tree of four years of age, furnished with several branches in the order in which they might naturally occur. The woody cone, N<sup>o</sup> 1, having developed a bud towards *a*, a branch would exist in the fourth year possessed of four layers of wood, as represented by *a b*. If another bud were formed upon the ligneous layer of the second year, N<sup>o</sup> 2. 2, its branch in the fourth year would be composed of three layers, as seen in *c d*. Admitting further, that in the third year a bud was produced from the branch *a b* towards *f*, a little branch would be formed which could only have two layers; and lastly, if in the fourth year, when the ligneous layer N<sup>o</sup> 4. 4, is deposited, another bud were to grow towards *g*, the branch to which it would give origin would be made of only one layer of woody fibres, as shewn by *g b*. Thus, the number of woody layers which compose any branch being ascertained, its age becomes known, and the relation which this bears to the age of the parent trunk is discovered by finding the woody layer upon which the apex of the ligneous cone of the branch is implanted; or, in other words, observing the point where the parallelism of the longitudinal fibres of the trunk is first interrupted.

It is asserted by Parent, "Histoire de l'Academie," 1711, that the branches are nourished by the pith or medulla, but nothing can be more erroneous: the medulla of the branch does not even communicate with that of the trunk, although the ligneous cone of the branch is most frequently implanted upon the innermost layer of the woody fibres, or those which immediately incase the medulla.

Du Hamel has remarked, that the longitudinal fibres, whether woody or cortical, take the direction of the chief current of the sap: thus, if the sap be propelled in the direction of the trunk, (which happens when either the branches have been originally inconsiderable, or have been early lopped off,) the cortical and woody fibres preserve nearly a perpendicular position, only separating to give passage to the branches and immediately after recovering their parallelism. See *Plate II. in Vegetable Anatomy. Fig. 6.*

exhibits a portion of a thick trunk, from the side of which had proceeded a small branch. If a large branch arises from a trunk, it necessarily attracts a great portion of the sap, and, in this case, the inclination of the cortical and woody fibres is obliquely towards that branch, as it is represented by *fig. 7. of Plate II. in Vegetable Anatomy*. This effect is still more remarkable in trees, which have been topped immediately above the origin of a young branch; for then, all the sap being obliged to pass towards the branch, the fibres pursue the same direction, and hence, if a tree be examined in the spring, after having been thus deprived of its top the preceding winter, the new ligneous fibres will be observed to cross the others, as appears in *fig. 8. of Plate II. in Vegetable Anatomy*.

The course of the ligneous fibres determines the nature and quality of what is called the grain of wood. In proportion as the fibres preserve the parallel direction the grain is smooth and equal, and the wood tractable in the hands of the workman, and accordingly those trees which furnish but few or small branches, such as the different *firs*, are most used in carpentry: whilst *mahogany* and several *fruit trees* are preferred for making furniture, on account of the various disposition of the fibres, and the number of large knots, which produce the beautiful diversity of colours observed in these woods.

The branches occasion that appearance in wood, known by the name of a *knot*: the longitudinal fibres being diverted from their course, and subjected to compression, at first by the eruption of the bud, and afterwards by the growth of the branch, acquire a degree of solidity and compactness unlike any other part of the vegetable body. The ligneous cone of the branch itself generally acquires more or less of the knotty texture; the conversion of the origin of the branch into a knot is influenced however by several accidental circumstances, the habit of the tree, &c. which are pointed out in another place. See *KNOT*.

The branches of the vegetables with one seminal leaf differ from the dicotyledons in this particular, that they are not produced by buds, but by the longitudinal fibres turning aside, and prolonging themselves in a diagonal course, until they penetrate the bark.

After the description which has been given of the origin and growth of the branches, it is almost unnecessary to add, that they possess the same anatomical structure as the trunk; all the parts which compose the one are met with in the other, and are disposed with perfect similarity in each, as the epidermis, the parenchyma, the cortical layers, the wood, and the medulla.

The form of the larger branches is most frequently cylindrical, but the slender ones have several sides, or exhibit in the transverse section more or less of a polygon figure. The section of the branches of the *alder* and the *orange-tree* is triangular, that of the *Virginian poplar* is square, and in the *plum-tree* and *willow* it is pentagonal.

The general appearance of a vegetable, which botanists have termed the *habitus*, depends chiefly upon the position which the branches and their ramifications obtain with respect to each other, and the different directions they assume. The branches like the leaves arise in various orders: sometimes they are opposed to each other, as in the *hazel*, *oak*, and *coffee trees*; at other times they succeed one another alternately, as in the *pear* and *apple trees*, &c. They are arranged in a circle round the stem in the *protea argentea*: in some instances the branches are widely scattered on the tree, while in others, they are so thickly set, that they conceal from view the trunk and one another. The various situations of the branches depend upon that of the buds from

from whence they originate; and being constant in each species, more particularly with regard to the secondary branches, it furnishes a botanical character, of which Adanson has taken advantage. The branches, as well as the leaves, are strongly attracted by the light; they avoid even the shade caused by the foliage of the adjoining branches of the same tree, and hence it is, that those which are next the ground extend in a horizontal direction, in order to escape from the shadow of the superior branches, and that the latter, in proportion as they approach the summit of the tree, assume more of an erect position. The lesser ramifications observe a similar position. The economy of some trees renders the direction of their branches somewhat peculiar: thus, in the *poplar*, they are nearly vertical, whilst in the *sweeping willow* they bend towards the earth, and in the *fig-tree* they are curved towards the root; but in these instances also the lowest branches are still the most prominent, in order that all may be equally and fairly exposed to the light.

Du Hamel has made a number of experiments, to determine the proportionate thickness of the trunk to the primary branches, and again of these to the secondary branches: his experiments tend to prove, that the squares of the circumferences of the first branches exceed those of the trunk, in the proportion of 5 to 4; and in comparing the squares of the circumferences of the primary and secondary branches, he found that the latter fell short of the others in the proportion of 100 to 101 in one instance, and in another of nearly 50 to 51; the primary branches, therefore, not only exceed in quantity the trunk, but those of the second order also, which are nevertheless so much more numerous. Du Hamel explains this curious circumstance, by supposing that the smaller branches are most liable to be destroyed, in which case they would not only suffer diminution themselves, but their loss would tend to make those from which they spring more vigorous, and consequently larger.

The Abbe Schabol distinguishes in fruit trees five sorts of branches: the first kind are smooth on the surface, their fibres are straight and closely applied to each other, but easily separated; they are pliant, and break with difficulty; it is upon these branches the wood buds are found. The second sort sustain the fruits; they are wrinkled at their base; their fibres appear to be more interwoven; they are supposed to be endowed with numerous vessels and pores; they contain a thick sap; and when bent are readily broken. The third kind of branches resemble those which become the wood, but are not produced from buds; they arise from the bark, and, as they never become hard, they are called the *branches with false wood*. The fourth set are very broad at their base; their bark is brown and rough; their buds are black and not numerous; these branches, like the last, are produced by the bark; they grow rapidly and soon perish; they are injurious to the tree, in depriving more useful branches of their due proportion of nourishment. The fifth sort are small branches which abound upon unhealthy trees; they exhaust feeble trees, and are useless upon the most vigorous; they die before they acquire any magnitude.

There is a remarkable relation between the branches and the roots; upon these parts mutually depend the ascent and descent of the sap; they must, therefore, act in harmony and in proportion to each other: hence, if a tree be deprived of some of the principal branches, the corresponding roots perish; or, if the small branches be clipped to form the tree into any particular shape, the roots gradually assume the same figure; if the summit of the trunk be cut off, the lateral branches become more vigorous; in the same manner

the lateral roots acquire strength, by the removal of the extremity of the principal root. The fine fibres of the root perish at the fall of the leaf; and lastly, experiment has shewn, that the tops of the branches, when covered with the earth, will produce roots; and that the roots, when exposed to the air, will put forth leaves.

BRANCH, in *Mythology*. Anciently branches were carried in the hands at the processions and ceremonies of the gods; whence the *thallophori*, or branch bearers. The Thespians adored a branch. The olive-branch was the symbol or ensign of peace. The natives of the islands of the South Seas use green boughs, &c. for the same purpose at this day.

BRANCH is also applied to the parts or ramifications of divers other bodies, which, in respect hereto, are considered as stems. Thus chemists speak of the branches of their metalline vegetation, branches of the *arbor Diana*, *arbor Martis*, &c. Phil. Trans. No. 286. Mem. Acad. Sc. 1692. 1710.

BRANCH, in *Anatomy*, denotes a division of a vein, artery, or nerve. All the veins in the body are only branches of the *vena cava*.

BRANCH is also used in the *Military Art*, in speaking of trenches, mines, and their several ducts, ways, returns, and the like, between one well and another. See GALLERY.

BRANCH is also used in speaking of the veins in mines of gold, silver, or other metals, which divide like the veins in the body.

BRANCH, in *Genealogy*, is applied to the several lines or successions arising out of the same stock or origin. In which sense, branches amount to much the same with cadets.

BRANCH also denotes a complex metalline kind of candlestick, contrived for the reception of a number of candles. These, in ancient writers, are called *phari*, *canthara*, *jesse*; when made of glass, *lustres*; the richer sort, *girandoles*.

BRANCH of the trenches, in *Fortification*. See BOYAU.

BRANCH-stand, in *Falconry*, signifies to make a hawk leap from tree to tree, till the dog springs the partridge.

BRANCH, in *Scripture*, is an appellation peculiarly given to the Messiah, as being of the branch or house of David.

BRANCHES of vaults, are sometimes used to denote the arches of them.

BRANCHES of arches, denote several portions of arches springing all from the same summer.

BRANCHES of ogives, in *Architecture*, the reins or arches of Gothic vaults; which traversing from one angle to another, diagonal-wise, form a cross between the other arches which make the sides of the square, whereof those arches are diagonals.

BRANCHES of a bridle, in the *Manege*, are two crooked pieces of iron which support the mouth-bit, the chain, and the curb: and which are fastened on one side to the head-stall, on the other to the reins; serving to keep the horse's head under command.

What way soever the branches of the bit incline, the horse's mouth goes to the contrary. The duke of Newcastle is very particular on the head of branches; explaining their several kinds and their effects, which are reducible to those of a lever. The branch is always to be accommodated to the design, either of bringing in, or raising a horse's head, and to the necessary degree: accordingly, we have strong and hardy branches, gentle branches, rude branches, &c.

With regard to their form and structure, branches are either straight, in form of a pistol, for young horses to form their mouth; or, after the contable of France's fashion, for hofses that already carry the head well: others are in a form of a

gigot, or leg; others of a bent knee; others in the French fashion, &c.

These are the laws in the *Mange*: 1. That the farther the branch is from the horse's neck, the more effect it will have. 2. That short branches, *cæteris paribus*, are ruder, and their effects more sudden, than those of longer. 3. That the branch is to be proportioned to the length of the horse's neck.

That part of the branch of a bridle, whereby we judge of its effects, and which discovers its strength or weakness, is called the *line of the banquet*. A strong and hardy branch is that whose sevil-hole, at the lower-end of it, is placed on the out-side of the line of the banquet. A gentle branch is that, the sevil-hole of which is set on the inside of the said line. A rude and hardy branch will bring in a horse's head, proportionably as it is more or less hardy; whereas a gentle branch, by diminishing the effect of the bit-mouth, makes a horse more easily to bear the pressure thereof, who before could hardly endure it. See BITS.

BRANCHED velvet. See VELVET.

BRANCHIER, among *Fowlers* and *Falconers*, denotes a young bird well fledged, which, having quitted the nest, is not yet in a condition to fly far, or shift for itself, but still keeps in the bushes or branches about its native dwelling, where it is fed by the dam.

The branchiers of hawks are also called *ramage falcons*; those of nightingales, *pushers*: because, as some say, they are thrust out of the nest by the old ones. Canary birds of the first year are called branchiers; when just flown, and unable to feed themselves, *pushers*.

BRANCHERY, in the *Anatomy of Vegetables*, denotes the vascular parts of divers fruits, as apples, pears, plums, and berries. In which sense the branchery stands contradistinguished from the skin, pulp, &c.

The branchery of an apple is only the ramifications of the ligneous body through all the parts of the *parenchyma*; the greater branches being likewise, by the insensations of the lesser, united together. Grew. *Anat. of Plants*, lib. i. cap. 6. § 2.

BRANCHIA, in *Ichthyology*. See GILLS.

BRANCHIADÆ, in *Ancient Geography*, a people who are placed by Quintus Curtius towards the Oxus, and by Strabo in Sogdiana, the adjacent country.

BRANCHIALE, in *Natural History*, a name given by Mr. Lhuyd to a peculiar species of FUNGITÆ, which being of a deeply striated texture, is supposed to resemble the gills of a fish.

BRANCHIDÆ, in *Antiquity*, priests of Apollo serving in his temple at Didyma, near Miletus; which was famous for its oracle. The temple of the Branchidæ, or, as it was afterwards called, of Apollo Didymæus, together with the oracle, were seated on the promontory called Posideum, at the distance of 18 or 20 stadia from the shore, and 180 from the city of Miletus; and both are recorded as occupying this spot before the Ionic migration. The appellation "Branchidæ," was derived from a very noted family, so called, which continued in possession of the priesthood till the time of Xerxes, deducing its pedigree from the real or reputed founder, and original proprietor, "Branchus." Several of these sacred tribes flourished in Greece, and intermixed, as the Branchidæ did, fable with their genealogy; and with a view of conciliating from the people a greater respect for their progenitor, raised him far above the level of common humanity. The story of the Branchidæ is too ridiculous to be recited; and we shall, therefore, refer for the relation of it to Varro. By some, however, this name is derived from Branchus, a Thessalian youth, beloved by

Apollo, who received him into his own temple, and commanded that divine honours should be rendered him after his death. Steplianus Byzantinus informs us, that this oracle was sacred to Jupiter, as well as to Apollo; and probably both these deities, as well as Branchus, were honoured in this temple. Whatever be the origin of the oracle, it is certain, that it had acquired a very early and extensive reputation by Branchidæ; and it was particularly consulted by Cræsus, who was profusely munificent upon these occasions, dedicating his choicest treasure to a vast amount, in the same manner as at Delphi.

The Persians, under Xerxes, the son of Darius, afterwards despoiled this temple and oracle of all their wealth, and then destroyed it by fire. The Branchidæ, who had betrayed this temple and oracle into the hands of the Persians, became, on the miscarriage of Xerxes the voluntary companions of his flight, in order to avoid the punishment of their treachery and sacrilege, and settled among the Bactri, in a region far remote from Greece. However, the descendants of those who had fled with Xerxes, were cruelly extirpated by Alexander the Great; thus visiting the sins of the fathers on the children, in a manner which will for ever reflect the greatest odium on the memory of the perfidious tyrant, who, after receiving their submission, put them all to the sword, and erased even the vestiges of their towns: so that the city remained a bare solitude and barren waste.

Although the Milesians were too much impoverished and depressed to attempt an immediate restoration of their temple, after the conclusion of the Persian war, they exerted themselves at a subsequent period, not precisely ascertained, in rearing the fabric from its ruins; and the architects employed by them for this purpose, were Peonius, an Ephesian, and Daphnis, of Miletus. With what magnificence and prodigious spirit this new edifice was designed, may in some measure be inferred from its present remains. Strabo has termed it, "The greatest of all temples;" adding, that it continued without a roof, on account of its magnitude. Pausanias mentions it as one of the wonders peculiar to Ionia; and Vitruvius numbers this among the four temples which had raised their architects to the summit of renown. In this temple was the famous statue of Apollo, formed by Canachus, a Sicyonian, who had been a scholar of Polykletus the Argive; it was carried away by Xerxes, and restored by Seleucus Nicanor. It is said, that the oracle of this Milesian temple became silent, when it was deserted by the Branchidæ, and that it afterwards resumed its prophetic and oracular faculties. After Paganism began to decline, this oracle continued in some repute; and the emperor Julian was very solicitous to reinstate the god in the full possession of his Ionian territory; which, however, he was constrained to yield up to Christianity, soon after the death of the royal apostate. Strabo, *Geog.* tom. ii. p. 517—624—814. Pausanias, *Græc. Descript.* p. 533, 694, ed. Kuhnii. *Ionian Antiquities*, by Chandler, Revett and Pars. 1769.

BRANCHIER, ST. in *Geography*, a town of Swisserland in the Valais, seated near the river Drance. N. lat. 46° 5'. E. long. 7° 3'.

BRANCHING, the *ramification* or *sprouting* of the horns of deer, &c. which bears an analogy to the vegetation of plants. *Phil. Trans.* N° 227.

The hair at the ends is apt to *branch*, or split and divide into whole brushes, which are easily visible by a microscope.

BRANCHIOPODA, in *Entomology*, a genus of crustaceous insects established by late continental naturalists to include those species of the Linnæan *cæcæri*, and *gammari* of Fabricius, which have four simple, setaceous, unequal antennæ; the body oblong, and destitute of feet, but in lieu

of which each side is furnished with either a single, or a double series of oblong, ciliated, branchiollegous appendages, which are formed for swimming; and the tail naked, jointed, long, and forked at the extremity.

The two species of this new genus, described by Herbert, Duchesne, and Bose, are le branchiopode flagnal, which is cancer stagnalis of Linnæus, and a second form delineated by Herbert, called le branchiopode paliudeux.

BRANCHIOSTEGA, in *Zoology*, a kind of CORYPHENA, having for the aperture of the gills a transverse cleft, or opening. It inhabits the Asiatic seas.

BRANCHIOSTEGI, in *Ichthyology*, a term employed for that natural order of fishes which have gills destitute of bony rays. The genera of branchiollegous fishes are, *mormyrus*, *ostracion*, *tetrodon*, *diodon*, *syngnathus*, *pegasus*, *centrisrus*, *balistes*, *cyclopterus*, and *lophius*.

BRANCHUS, in *Medicine*. The hoarseness which accompanies a catarrh is so called from  $\epsilon\gamma\chi\alpha\varsigma$ , to be moist. See CATARRH.

BRANCHUS, or *branchæ*, also denotes a kind of glandular tumor in the *fauces*, resembling two almonds, which render the breathing and hawking difficult.

BRANCION, in *Geography*, a small town of France, in the department of the Saone and Loire,  $1\frac{1}{2}$  league W. of Tournus.

BRANCO, an island in the gulf of Mexico, and bay of Campeachy, between cape Coudecedo, or point Delgado, and Vera Cruz.

BRANCOVAN, a town of European Turkey, in the province of Walachia; 28 miles N. of Nicopoli.

BRANCOURT, a town of France, in the department of the Aisne; 10 miles W. of Laon.

BRANCZYCE, a town of Lithuania, in the province of Novogrodek; 10 miles N. of Sluck.

BRAND, in *Agriculture*, the name of a disease to which corn, and some other grasses, are subject. "It is a sort of fungus, which derives its nourishment from the vegetable. Of these fungi, there are several species. One of them is named by Dr. Withering (Bot. Arrang. vol. iv. p. 388) "*Reticularia Segetum*;" and in a pamphlet upon Brand, by the Rev. Henry Bryant, entitled, "A particular inquiry into the causes of that disease in wheat commonly called Brand, &c.;" Norwich, 1783, it is called "Dust Brand." In other places its usual name is "Smut," or "Burnt Corn." This species is common to wheat, oats, barley, and rye. The scilicet fruitans, and other grasses, are also affected by it. It is destitute of scent, and consumes not only the farinaceous part of the grain, but even the arillus and chaff, dispersing itself entirely before the corn is cut; so that the injury occasioned by it is confined to the quantity of grain destroyed by it, which is not very great in any season. The ear is often affected by this *reticularia* before it emerges from the folium vaginans, or hofe; but about the root there is no appearance of disease. Barley and oats are more frequently attacked by it than wheat; which circumstance may be accounted for by the latter being usually *druffed* for sowing. Mr. Lathbury examined the dust of this fungus under a powerful magnifier, and thus found, that it consisted of a number of minute particles, uniform in shape and size, much smaller and blacker than those of the "pepper brand," and less easily separable; and they seemed to be contained in little irregular cells. This dust, or seed, is the food of a small, shining, black dermestes, the "*Dermestes ater*," of Marsham. Another species which Mr. Bryant distinguished by the name of, "pepper brand," is also called simply "brand," or "bladders." This species does not eat through the arillus, consuming

only the farinaceous part of the grain. The ears affected by it are easily discovered by their external aspect; for the chaff opens as if unnaturally distended, the germen becomes shorter and rounder, and exhibits the appearance of swelling, and a sort of inflammation; the grain assuming in this state a deep and dingy hue, easily breaking when rubbed, and furnishing a sooty powder, which soils the fingers, and emits a very fetid scent. This species is very prejudicial to the farmers; because it is carried with the corn into the barn, and when broken under the flail it discolours and otherwise injures the sample, so as to render it unsaleable, or to reduce its price. For the prevention of this evil, farmers generally dress their seed-wheat with various preparations: some use a lixivium of wood-ashes and water; others, salt and water only, or sea-water, when it can be easily procured; others, they from the soap-boilers; others again, urine and cheese-whey; and others, it is said, have infused arsenic for this purpose. All, as Mr. Kirby believes, dry their seed with fresh slacked lime. From this practice we may infer, that the disease is supposed to originate from the adhesion of the dust or seed of the brand to the seed of the wheat; and these methods are adapted for the purpose of washing it off, or destroying it. The ultimate cause of this distemper has been variously assigned. Mr. Bryant (*ubi supra*) strenuously maintains, that it is occasioned by an injury which the antheræ receive by too great constriction, when the ear emerges from the folium vaginans; and therefore he condemns the common practice of dressing the seed, as not only useless, but destructive of the grain. Some take the dust for the eggs of insects; and others adopt the opinion, with which Mr. Kirby coincides, that this evil is occasioned by a minute vegetable of the order of "Fungi." Mr. Bryant's method of accounting for this disorder, is acknowledged by this ingenious naturalist to be plausible; but he conceives that it is founded upon no arguments which can convince one who is in search not of theories, but of truth. From a variety of experiments made by the Rev. Peter Lathbury, F.L.S., and recited by Mr. Kirby, (*ubi infra*) together with other facts that occurred within his own knowledge, he concludes, without hesitation, that the practice of dressing the seed previous to sowing, in the way above-mentioned, is a very effectual prevention of the brand.

Rejecting Mr. Bryant's hypothesis, and also that of the brand's being produced by insects, Mr. Kirby proceeds to establish the third opinion, that the disorder is occasioned by a vegetable substance. The fact, established by the experiments which he recites, that the dust of brand, carried into the field with the seed-wheat, like other vegetables, propagates itself, gives (he says) the highest degree of probability to this opinion. It is further confirmed by the recital of an experiment of Mr. Lathbury, of sowing it, as it were, upon its native soil (especially in the case of wheat taken from a clean sample), which seems to have occasioned the destruction of three-fourths of its produce. Besides, this dust, when placed under a powerful magnifier, exhibits every appearance of minute seed. As to the manner in which these seeds vegetate and ascend from the seed with the growing plant, till they reach the heart of the grain, it is a subject of inquiry that may be extended to a great number of the fungi, which without impropriety may be denominated "subcutaneous" vegetables. With regard to the brand in particular, it is suggested, as a probable conjecture, that the uncommonly minute seeds of this fungus may attach themselves either to the "plumula," and so pass through the air-vessels into the plant; or else to the "rostellum," which seems most likely; and in that case they may be propelled through the sap-vessels with the sap,

till they at length arrive at their final seat, the heart of the germen. See observations upon certain fungi, which are parasites of the wheat, by the Rev. William Kirby, F. L. S. in the *Linnæan Transactions*, vol. v. page 112. &c.

BRAND, in *Geography*, a town of Germany, in the circle of Erzgebirg, chiefly inhabited by miners; 2 miles S. of Freyberg.

BRAND-SUNDAY, *Dimanche des Brandons*, in *French Ecclesiastical Writers*, denotes the first Sunday in Lent; which is thus called on account of an ancient practice in the Lyonnais, where the peasants, in the night of this day, walked about their orchards, gardens, &c. with torches lighted, or fire-brands in their hands; in which plight they visited every tree, and addressing themselves to them one after another, threatened that if they did not bear fruit well the ensuing season, they should be cut down to the ground and burnt. This is evidently a relic of paganism; the like of which was practised by the ancient idolaters in the month of February; hence called *Februarius, à februando*. Menellr. *Hist. de Lyon*. p. 279. Menag. *Orig.* p. 126. & Du Cange *Gloss. Lat.* tom. i. p. 610.

BRANDAN, in *Geography*, a town of the East Indies, in the island of Java, belonging to the king of Sourahaya.

BRANDANO, a river of Italy, which runs into the gulf of Tarento, 10 miles S. of Castellanetta, in the kingdom of Naples.

BRANDARIS, in *Conchology*, a sort of MUREX, common in the Mediterranean and Adriatic sea. The shell is somewhat ovate, and surrounded with straight spines; beak moderately subulate, straight, and obliquely furrowed with spines. Gmelin, &c.

Many varieties of this shell are described by writers; generally the colour is white, whitish, cinereous, or brown, with a triple row of spines, or sometimes with only a single row.

BRANDEIS, in *Geography*, a town of Bohemia, in the circle of Konigingratz, seated on the river Orlitz; 21 miles S.E. of Konigingratz.

BRANDEL, PETER, in *Biography*, a painter of portrait and history, was born at Prague, in 1660; and having spent about four years in the school of John Schroeter, principal painter at that court, a kind of jealousy of his rising merit was excited in the mind of his master, so that Brandel resented the ill-treatment. He removed from him; and at the age of about 19 years, quitted his school, and commenced a master himself. Most of the churches at Prague and Breslau are embellished with his works; and the prince of Hatzfeld is said to have given 100 ducats for one picture of St. Jerome at half length. He spent most of his time at Prague, where the wealth which he acquired was dissipated by profusion and irregular conduct; so that he died poor, and was buried by charitable contributions. The Jesuits and monks, however, honoured his memory by appointing for him a solemn funeral procession, in which 300 tapers of wax were carried by ecclesiastics. Brandel was distinguished by a ready invention, an expeditious manner of painting, and natural colouring, except that his shadows were sometimes too black. His pencil was broad, easy, and free. Pilkington.

BRANDEN, in *Geography*, a bay lying on the east coast of China, in the Indian ocean, north of Harling's bay.

BRANDENBURG, MARK, or MARQUISATE OF, a country of Germany, bounded on the north by Mecklenburg and Pomerania, on the east by Poland, on the west by the duchies of Magdeburg and Lunenburg, and on the south by Silesia, the Lusatias, the electorate of Saxony, the principality of Anhalt, and part of the duchy of Magdeburg. Its greatest extent from west to east is about 200 miles, and from north to south about 110 miles. The country is gene-

rally level, and the soil sandy and barren, but by the industry of the inhabitants rendered productive of several sorts of grain. They find, however, that the only very profitable crop upon these sands is buck-wheat, which they sow in large quantities, and which yields a product equal to that of the best soils applied to that grain. When a piece of land has been managed with greater care than ordinary, it will yield a good crop of rye; but wheat and barley are rarely to be seen. In some parts the inhabitants cultivate millet and flax; in other parts, potatoes and turnips; and again in others, tobacco and woad for dyeing. By various improvements of modern times, the waste lands and the large morasses, which have been drained, are become fertile. From their woods they derive an ample supply of fuel for their domestic use, and for their glass and iron furnaces, charcoal, tar, wood-ashes, and large quantities of timber for house and ship-building, part of which is exported to Hamburg, Holland, France, and other places. Their breed of cattle, and especially their sheep, are objects of particular attention; from the latter they are supplied with wool, which has enabled them to establish several woollen manufactures; and with a view to the improvement of their breed of sheep, king Frederic II. caused rams to be imported from France and England. The culture of silk is also carried on with industry and with increasing success; and besides their silk and woollen manufactures, they have others of linen, cotton, and leather. At Berlin, and Potsdam in particular, they have also excellent painters, statuaries, and engravers. By means of these manufactures and arts they not only preserve in the country large sums, but they also import an accession from other countries to which their productions are exported. The country also furnishes good clay, and fine porcelain earth, together with iron-stone, amber, salt-petre, alum, colour-earths, and medicinal springs. The principal rivers are the Elbe, the Oder, the Prignitz, the Havel, the Warte, the Spree, and the Dosse. The Spree and Oder are united by a canal, begun in 1662, and finished in 1668. The Havel and Oder are joined by the canal of Fiacow, which king Frederic II. caused to be begun in 1743, and completed in 1746, with thirteen sluices. By these canals navigation is facilitated; and from their rivers and lakes they draw a supply of various kinds of fish. In the electoral mark they reckon 84 cities, 19 market-towns, about 1917 royal and noble villages, 2027 ancient villages, 44,749 hides of land liable to taxes, and 8421 hides of the nobility, 26,000 hearths in the towns, and 68,000 in the country, 1971 Lutheran churches, and 80 Calvinistical churches. The population of Brandenburg, according to the statement of Hoeck, consists of 755,577 persons. The states consist of the nobility and towns, whose house of assembly is in the Spandau street at Berlin, and who still enjoy some small remains of their ancient privileges. The hereditary offices of the marquisate are, a marshal, chamberlain, cup-bearer, purveyor, sewer, treasurer, and ranger. The religion of the country is Lutheran, which was adopted by Joachim II., elector of Brandenburg, in 1539; but the king of Prussia, who is also elector of Brandenburg, and those of his court, are Calvinists. The churches of both persuasions are well endowed; and the laity jointly employed by the government. The Roman catholics are also tolerated; and every inhabitant enjoys liberty of conscience and a free exercise of his religion. For the education of youth, and the advancement of learning, this electorate, besides Latin schools and gymnasia in several places, has an university at Frankfort on the Oder, and an academy of sciences at Berlin.

The whole country of Brandenburg is divided generally into the Electoral Mark and New Mark. The Electoral Mark

Mark is again subdivided into the Old Mark, the Vor-Mark, or Mark of Prignitz, the Middle Mark, and the Ucker Mark.

The *Old Mark*, extending from east to west about 9 German miles, and from north to south about 11 miles, is separated, towards the east, by the Elbe from the Prignitz and the duchy of Magdeburg, and bounded also by the latter to the south and likewise, in part, to the west, but in other parts by the duchy of Lunenburg. It contains 13 cities, of which the capital is Stendal. Its taxable lands are 858 hides.

The *Vor-Mark*, or *Prignitz*, is terminated by the Elbe and Havel, the duchy of Mecklenburg, and the circles of Ruppin and Havelland in the Middle Mark, and is  $10\frac{1}{2}$  German miles in length, and  $7\frac{1}{2}$  in breadth. It contains 20 towns, the principal of which is Perleberg. The hides of land that pay taxes are 5211.

The *Middle Mark* is bounded by the Prignitz, the duchies of Magdeburg, and the electorate of Saxony, the Lower Lusatia, the New Mark, the Ucker Mark, and the duchy of Mecklenburg. The most fertile part lies near the Oder, in the circles of Havelland and Ruppin; the marshes having been drained, and the inhabitants cultivating millet, madder, and buck-wheat, producing also wine, and breeding silk-worms, and having manufactures of alum and vitriol, and some medicinal springs. Among its cities and towns, which are reckoned 48, the chief are Berlin, Brandenburg, and Potsdam; and its hides of taxable land are 24,901.

The *Ucker Mark* terminates to the south and west on the Middle Mark and the duchy of Mecklenburg, from the latter of which it is principally separated by the Havel; and to the north and east on Pomerania and the New Mark, being mostly separated from the former by the Welse and Rando, and from the latter by the Oder. Its greatest extent is about 13 German miles in length, and 11 in breadth. This province was anciently called the Ucker, or Uckerland, from the river and lake of that name; and the title of the Ucker Mark was first applied to it towards the latter end of the 15th century. If we except a narrow slip, which runs along the Middle Mark, from the frontiers of Mecklenburg towards the Oder, it consists of a very good soil, which, by the industry of the inhabitants, has been so much improved, that the province annually exports great quantities of grain, and more particularly supplies Berlin. It also produces a great number of sheep, fruit, honey, hops, and tobacco. The inhabitants are Lutherans, but not without a mixture of French and German calvinists. The whole territory is divided into the two circles of Ucker-Mark and Stolp, and contains 15 towns, of which the capital is Prenzlö. The hides of land that are taxable are 6379.

The *New Mark* is a long narrow tract of land, separated to the west from the Middle and Ucker Marks by the Oder, terminating to the north on Pomerania, and eastward on Pomerania, Poland, Silesia, and the Lower Lusatia, and extending about 40 geographical miles in length, and in breadth 10 miles. Although the soil is generally sandy, this province has some good corn lands, and near the rivers luxuriant pasture grounds and marshes, the grass of which is coarse and rushy. It abounds in wood, and supplies fruits, fish, and game. The incorporated circles produce wine, and yield great quantities of iron ore. The New Mark, properly so called, extends from the river Rega to the river Warte; and contains, according to the statement of Hoeck, 279,584 inhabitants. It appears to have been in the possession of the margraves of Brandenburg as early as the year 1257; it was transferred by Otho the Tall to the knights of the Teutonic order in 1286, but soon redeemed. In 1429, it was wholly ceded to the same order;

and in 1443, the cession was confirmed at Franckfort, by the elector Frederic II. But in 1455, their circumstances required the sale of it, and it was purchased by the said elector; and since that time it has remained in the house of Brandenburg, under the appellation of the New Mark. It has a regency of its own, courts of justice, and other colleges. It consists of Cultrin, or Kustrin, which is the capital, seven original circles, and four incorporated circles. Its cities are reckoned to be 39; its hides of taxable land 16,738; and the value of the estates is estimated at one million of dollars.

The ancient inhabitants of Brandenburg are said to have been the Suevi, of whom there are several subdivisions. As the Romans pursued their conquests as far as the Elbe, about the commencement of the Christian æra, they were probably acquainted with this country. However, the Vandals checked their further progress in this direction; but, about the fifth century, they repaired more to the south, abandoning their own country to the Wendi, Veneti, or Heneti, who, being too much confined by the Vistula, occupied the territory which the Vandals had abandoned, and, possessing themselves of the whole country along the southern side of the Baltic, formed there a new nation, known by the general name of Sclavi or Slavonians, who were a barbarous people of very extensive migration, and inveterate enemies to the Christian religion. With these the kings of the Franks, and especially Charlemagne, had frequent wars, and his successors were indefatigable in their endeavours to subdue them. At length, Henry, surnamed the Fowler, succeeded, about the beginning of the 10th century, A. D. 927, in the conquest of them, and planted Christianity in the country. He then conferred it on his brother-in-law Sigefrid, a Saxon count, with the title of margrave or lord-warden of the marches or borders; and he, with his successors, new planted and peopled it from the Netherlands, Westphalia, Franconia, and Saxony. At first this title was conferred by the emperor according to his own arbitrary pleasure; and it did not become hereditary till the time of Albert, surnamed the Bear, the first prince of the race of Anhalt, who was made margrave by Conrad II., and afterwards raised to the dignity of an elector by Frederic Barbarossa, about the year 1100. When this family became extinct in 1332, several others succeeded; and, in 1373, the emperor Charles IV. assigned Brandenburg to his second son Sigismund, who, in 1415, being then emperor of Germany, sold this margravate and electorate to Frederic, burgrave of Nuremberg, for four hundred thousand ducats. Frederic, the ancestor of the present reigning race, received the investiture of Brandenburg, in 1417, at the diet of Constance, from the hands of the emperor Sigismund, who, two years before, had conferred upon him the dignity of elector and archchamberlain of the holy Roman empire. This Frederic was the first elector of the house of Hohenzollern, which some German genealogists have traced to Thassilo or Tassilon, who lived in the beginning of the 9th century. From Frederic the electorate descended, through different branches of the family, to Joachim II. who, in 1539, embraced the Lutheran religion, and who, whilst the war of religion desolated Saxony, and the neighbouring countries, maintained his electorate in peace; having declined to enter into the union which the Protestants concluded at Smalkald: nor did he agree to the interim published by the emperor Charles V. In 1618, the elector, John Sigismund, received from the king of Poland, the investiture of Prussia for himself and his descendants; and resigned the electorate in favour of his son George William, who, in 1640, was succeeded by his son, Frederic

Frederic William, surnamed the Great, born at Berlin in 1620, and educated in the camp of Frederic Henry, prince of Orange. When he came to the government, he found a desolated country in possession of his enemies, allies in whom he could repose no confidence, few troops, and almost no resources of supplies. Nevertheless, he compelled the king of Poland, in 1656, to declare Prussia an independent state, which had been formerly held of the Polish sovereigns: and closing a reign, which has been much celebrated, was succeeded, in 1688, by his son Frederic III. born at Konigsberg, in 1657, who, supporting the emperor in the contest for the Spanish succession, was by him acknowledged as king of Prussia, in 1700, and in the following year crowned by the emperor at his native place. This elector has been usually distinguished by the title of Frederic I. He died in 1713; when his son Frederic William II. ascended the throne. By him the city of Potsdam was founded in 1711; but he was chiefly distinguished as the father of that great prince Frederic II. who ascended the throne in 1740, and died in 1786, after a long and glorious reign; the most memorable and permanent event of which was the acquisition of Silesia from the house of Austria, in 1742. The short reign of his nephew is well known; during which the failure of the Prussian tactics in France and Poland, convinced Europe, that the great Frederic had been the soul of the machine. However, these checks were counterbalanced by the completion of the Prussian acquisitions in Poland. Of the reign of his son, the present monarch, it is sufficient now to say, that it has been marked by caution and prudence more than by enterprise. See PRUSSIA.

The elector of Brandenburg possesses the seventh place among the electors of the empire; and in the council of the princes of the empire he has five voices. As arch-chamberlain, he carries the sceptre before the emperor at his coronation, and brings him water to wash with in a silver basin. For the government of Brandenburg, and the administration of justice, there are several supreme colleges and tribunals.

BRANDENBURG, an ancient city of Germany, in the circle of Upper Saxony, and the marquisate to which it gives name; seated on the Havel, which separates the old town from the new, and the castle from both, and likewise environs the new town to the left with a particular trench, on which a sluice has been erected. Both these towns have, ever since the year 1714, been under the government of the same magistrates; and each of them contains two churches; the number of inhabitants does not exceed 6000. It was erected into an episcopal see by the emperor Otho I. in 949, but the see was abolished at the reformation, in 1563. Manufactures of cloth, fustian, and canvas have been established in this place by the French Calvinists; and the navigation of the Havel affords it a considerable trade. The fort appears like a suburb, and contains, besides the cathedral church, and residences for the members of the cathedral, a riding school for the instruction of young noblemen. The members of the chapter, which still subsists, and which is composed of a Lutheran provost, dean, senior, sub-senior, and three other canons, are distinguished by a cross of gold, enamelled with violet, and terminating in eight points: an honour conferred by Frederic II. in 1755. In the vicinity is a mountain, on which Henry I. in 928, erected a church in honour of the Virgin Mary, from which time the mountain had the name of "Marienberg." The church has been destroyed, and its site planted with vines. Near the old town is a lake, about two German miles long. Brandenburg is 31 miles W. from Berlin. N. lat. 52° 25'. E. long. 13°.

BRANDENBURG, NEW, a town of Germany, in the circle of Lower Saxony, and duchy of Mecklenburg, seated on

a small rivulet, which loses itself in a neighbouring lake. The town is flourishing, and has two churches, a grammar-school, and a superintendenty. Hops are much cultivated in its environs; 48 miles W. of Stettin, and 60 N. of Berlin.

BRANDENBURG, a town of Prussia, in the province of Natangen, near the Frische-Haff, chiefly inhabited by fishermen; 12 miles S. W. of Konigsberg.

BRANDER1, in *Entomology*, a species of CIMEK, that inhabits Barbary, the snout of which is bent; thorax somewhat six-spined; wing-cases with three white dots. Gmel. — Obs. This is of the middle size, gaseous beneath, testaceous, and has the antennæ rufous.

BRANDERIANA, a species of PHALÆNA, (*Tortrix*) described by Linnaeus in Fa. Sued. The first wings are testaceous, luscous, and without spots. A native of Europe.

BRANDERIM, in *Geography*, a town of France, in the department of Morbihan; 1 league E. of Hennebont.

BRANDEUM, in *Ecclesiastical Writers*, a linen cloth or veil put over the tombs of the apostles St. Peter and St. Paul, and left there for some time: by which it is supposed to acquire a degree of sanctity, so as to be worshipped as a relic; and for that purpose frequently sent by the pope as a present to some prince. In this sense, brandeum amounts to the same with what was otherwise called *sanctuarium*, *judarium*, *orarium*, and *velum*. The use of brandea was introduced as a means of diffusing and propagating the virtues and influences of relics, without moving or any way impairing the substance of them; the translation of relics in early days being forbidden. Fleur. H. E. l. 35. Du-Cange, Gloss. Lat. t. i. p. 909.

BRANDGANS, in *Ornithology*, the name given by Cluſius and Frisch to the sheldrake or burrough duck, *anas tadorna*, Linn.

BRANDGUTH, in *Geography*, a town in Germany, in the circle of Upper Saxony, and country of Erzgebirg; 4 miles N. E. of Lauterstein.

BRANDHIRSCH, in *Zoology*. See CERVUS HIPPELLAPHUS.

BRANDI, GIACINTO, in *Biography*, an Italian painter of history, was born at Poli, about 20 miles from Rome, in 1623, and first instructed by Algarde, and afterwards, by Giacomo Sementa of Bologna, who painted after the manner of Guido. Upon quitting the school of Sementa, he became a disciple of Lanfranc; and having exercised his art in several of the churches and palaces at Rome, he rose to such reputation, that he became head of a school, and was made president of the academy of St. Luke. He obtained the patronage of several persons of rank, and especially that of the pope, who created him a knight of the order of Christ; but less attentive to fame than fortune, and more remarkable for avarice than excellence, although he had a lively genius and free pencil, he was often very incorrect, and his colouring was feeble. He seldom associated with persons of his own profession, of whom he generally expressed an unfavourable opinion; but took pleasure in low company, dissipating by profusion and pleasure the wealth which his industry acquired. He died in 1691. His works are chiefly at Rome, Verona, Milan, and Gæta. The daughter of this painter was married to the celebrated Rosa da Tivoli, of whom Giacinto conceived a mean opinion, because he painted only beails. By this contemptuous behaviour Rosa was so incensed, that he collected all the clothes belonging to his bride, on the morning after marriage, and sent them back to her father, with a message, "that his daughter's person was fatter enough to make her husband happy; and that a good painter of beails was as likely to become rich, as a bad painter of men." Argenville. Pickington.

BRAND.

**BRANDING** in the face or hand, denotes a punishment inflicted by law on various offences, by burning with a hot iron, after the offender has been once admitted to benefit of clergy.

By 4 Hen. VII. c. 13. a distinction was established between mere lay scholars, and clerks in orders, by directing, that also laymen, who are allowed the privilege of clergy, should be burnt with a hot iron in the brawn of the left thumb. This distinction, however, was abolished for a time by 28 Hen. VIII. c. 1. and 32 Hen. VIII. c. 3. but it is held to have been virtually restored by 1 Edward VI. c. 12. After this burning, the laity, and before it the clergy, were discharged from the sentence of the law in the king's courts, and delivered over to the ordinary to be dealt with according to the ecclesiastical canons. But the trial in the ecclesiastical courts, and consequent purgation, were attended with such perjuries and abuses, that the statute 18 Eliz. c. 7. enacts, that after the offender has been allowed his clergy, he shall not be delivered to the ordinary; but, upon such allowance and burning in the hand, he shall forthwith be enlarged and delivered out of prison; with proviso, that the judge may, if he thinks fit, continue the offender in gaol for any time not exceeding a year. Thus the law continued for above a century; except only that the statute 21 Jac. I. c. 6. allowed, that women convicted of simple larcenies under the value of 10s. should be burned in the hand, and whipped, stocked, or imprisoned for any time not exceeding a year. And a similar indulgence by the statutes 3 & 4 W. & M. c. 9. and 4 & 5 W. & M. c. 24. was extended to women guilty of any clergyable felony whatsoever, who were allowed to claim the benefit of the statute, in like manner as men might claim the benefit of clergy, and to be discharged, upon being burned in the hand, and imprisoned for any time not exceeding a year. The punishment of burning in the hand, being found ineffectual, was also changed by statute 10 & 11 W. III. c. 23. into burning in the most visible part of the left cheek, nearest the nose; but this provision was repealed by statute 5 Ann. c. 6. It was farther enacted by the same statute, that when any person is convicted of any theft or larceny, and burnt in the hand for the same according to the ancient law, he shall also, at the discretion of the judge, be committed to the house of correction or public work-house, to be there kept to hard labour for any time not less than six months, and not exceeding two years; with a power of inflicting a double confinement in case of the party's escape from the first. It was also enacted by 4 Geo. I. c. 11. and 6 Geo. I. c. 23. that when any persons shall be convicted of any larceny, either grand or petit, or any felonious stealing or taking of money or goods and chattels either from the person or the house of any other, or in any other manner, and who by the law shall be entitled to the benefit of clergy, and liable only to the penalties of burning in the hand or whipping, the court, in their discretion, instead of such burning in the hand, or whipping, may direct such offenders to be transported to America, (or, by statute 19 Geo. III. c. 74. to any other part beyond the seas) for seven years. See **TRANSPORTATION**. It is also enacted by the same statute, 19 Geo. III. c. 74. that, instead of burning in the hand, the court in all clergyable felonies may impose a pecuniary fine, or (except in the case of manslaughter,) may order the offender to be once or oftener, but not more than thrice, either publicly or privately whipped: which fine or whipping shall have the same consequences, as burning in the hand; and the offender, so fined or whipped, shall be equally liable to a subsequent detainer or imprisonment. See *Benefit of Clergy*.

**BRANDIS**, in *Geography*, a town of Germany, in the

circle of Upper Saxony, and territory of Leipfick; 9 miles E. of Leipfick.

**BRANDLECHT**, a town of Germany, in the circle of Westphalia, and county of Bentheim; 3 miles S. S. E. of Northorn.

**BRANDMULLER**, GREGORY, in *Biography*, a painter referred by the Germans to the first rank of artists, was born at Basle in 1661; and, in consequence of having discovered a genius for his art, and of having acquired a knowledge of design by studying and copying some good prints in his father's possession, he was placed under the tuition of Caspar Meyer. From Basle he removed to Paris, and was admitted into the school of Le Brun, whose esteem and preference he acquired by his proficiency in his profession to such a degree, that he became the object of jealousy to others, and was under a necessity of retiring into his own country; having first obtained the prize in the Royal Academy at Paris. He excelled in history and portrait; and resembled Le Brun in the fire, elevation, and grandeur of his subjects. His design is correct; his expression just and animated; and his method of colouring good, so that it retained its original strength and beauty without fading. He died in 1691. Pilkington.

**BRANDO**, in *Geography*, a small island in the gulph of Bothnia, containing 6 or 7 villages, a church, some arable land, and small woods.

**BRANDO**, a town in the island of Corfica, 6 miles N. of Bastia.

**BRANDOLINI**, AURELIO, in *Biography*, an eminent Italian poet, divine, and polite writer, was born of a noble family at Florence in the 15th century, and surnamed "Lippus," on account of a defluxion from his eyes, which, at an early age, had nearly deprived him of his sight. Notwithstanding this misfortune, he acquired great eminence in various kinds of literature; and he found in these, sources of consolation, amidst the afflictions occasioned by a defect of sight, and the loss of his fortune. Among other excellencies for which he was distinguished, he was singularly ready in his poetic compositions; and this talent he possessed in so eminent a degree, that he is said to have put into very elegant verse, without premeditation, all the topics of Pliny's 37 books of Natural History. Corvinus, king of Hungary, hearing of his fame, invited him to his court; and employed him, for several years, in teaching rhetoric at Buda and Gran. After the death of that king, in 1490, he returned to Florence, and assumed the habit of the friars of St. Augustin. In this new profession, he applied assiduously to the exercise of his ministry, and preached, with great applause, to crowded auditories in several parts of Italy. As to the character of his sermons, it is said, that they were distinguished, not only by ingenious illustrations of the Scriptures, but also by a strain of sublime philosophy derived from the ancients. After residing for some time at Naples, where he had for his scholar Giammaria del Monte, afterwards pope Julius III., he settled at Rome, and died there of the plague in 1498. The most valuable of his numerous works were his 3 books, "De Ratione Scribendi," containing the precepts of good writing, and written with singular learning and elegance; his two books, entitled "Christiana Paradoxa," first printed at Basil in 1543, 8vo; "De Humanæ Vitæ Conditione, et tollenda Corporum Ægitudine." These, with some others, were printed at Basil in 1498. He also published, in heroic verse, the histories of the O. and N. T., a commentary on St. Paul's epistles, a treatise "De Lege," some orations, and some Latin and Italian poems; and left, several treatises in MS. on political and historical subjects. Tiraboschi. Gen. Dict.

**BRANDON**, in *Geography*, a market-town of Suffolk, England, is pleasantly situated on the banks of the lesser Oule, which is navigable from Lynn to Thetford, and forms part of the boundary between the counties of Suffolk and Norfolk. By the navigation of this river, various articles of trade and commerce are imported to, and exported from the town. An ancient bridge is thrown across the river, upon which there was a hermitage in 1406, belonging to the bishop of Ely. Upon the decay of this structure, that prelate granted 40 days' pardon to all persons who contributed towards the repairs, and to the hermit, a pardon for three years. This town gives the title of duke of Brandon to Archibald Hamilton, which title was first conferred by queen Anne in 1711.

Simon Eyre, lord mayor of London, who built Leaden-hall, was a native of this town. Here are a weekly market on Thursdays, and four fairs annually.

In the vicinity of Brandon, are some very extensive rabbit warrens, which supply the London markets with vast numbers of this animal.

Brandon is 78 miles N. of London, and contains 203 houses, with 1148 inhabitants. Gough's Edition of Camden's Britannia, vol. ii.

**BRANDON**, a township of America, in Rutland county, Vermont, situate on both sides of Otter Creek, containing 637 inhabitants; about 60 miles N. of Bennington. Here Brandon Creek discharges itself into Otter Creek, from the North East.

**BRANDON**, a harbour on the N. side of Long Island, New York, 9 miles W. of Smithtown, and at the same distance from Hempstead plain.

**BRANDON**, ST. the name of an islet or rock lying in the Indian ocean, to the N.E. of the islands Bourbon and Mauritius. S. lat.  $16^{\circ} 45'$ . E. long.  $64^{\circ} 48'$ .

**BRANDON**, a mountain in the county of Kilkenny, Ireland, below which the river Barrow flows; it is the last of the granite chain which takes its rise in the county of Wicklow, and though its elevation is not considerable, it commands a very extensive prospect.—Also, a very high mountain in the county of Kerry, Ireland, which is seen at the distance of 15 leagues, and is an important land-mark for mariners. Its summit is generally covered with clouds: and it is esteemed a certain token of fine weather when its top is visible. It received its name from St. Brandon, who had an oratory, or chapel, near its summit.

**BRANDON Bay**, a bay on the western coast of Ireland, near Tralee bay, in the county of Kerry. On the west it has Brandon mountain, and, on the east, a flat low land called Maghericbeg, off which is a cluster of small islands. This bay is open to the north, and has neither safe anchorage nor tolerable shelter. Smith's Kerry.

**BRANDON Head**, a cape of Ireland, forming the western extremity of Brandon bay, and projecting from the lofty Brandon mountain. It is about 15 miles west of Tralee, and 10 north of Dingle. N. lat.  $52^{\circ} 17'$ . W. long.  $10^{\circ} 1'$ . Beaufort.

**BRANDRITH** denotes a trevet, or other iron stand, whereon to set a vessel over the fire.

**BRANDRITH**, among *Builders*, denotes a fence, or rail, about the mouth of a well.

**BRANDT**, GERARD, in *Biography*, an eminent historian, was born at Amsterdam, in 1626, and, after a course of preparatory study, commenced his ministry with a congregation of remonstrants at Nieukoop. Having married a daughter of the celebrated Gaspard Barleus, he removed first to Hoorn, and finally to Amsterdam in 1667. His principal works are, "A short account of the Reformation in the Low Countries, and the War with Spain," 1658: "History of the Refor-

mation, and other particulars concerning the Church of the Low Countries," 4 vols. 4to. 1671, &c. This work, written in Dutch, contains a faithful and accurate representation of the important event, concerning which it treats; and so highly was it esteemed, that pensionary Fagel told bishop Burnet that the perusal of this alone would amply recompense the trouble of learning the Dutch language. We have an English translation of it by Chamberlayne, and it has been abridged in French, in 3 vols. 8vo. 1730. Brandt also wrote "A History of the Town of Enkhuyzen;" "Life and Exploits of Admiral Ruyter;" "Account of the Proceedings against Barneveldt, Hoogerbeets and Grotius;" "Poems," &c. He died in 1685. Moreri.

**BRANDT**, NICHOLAS, or, as some call him, *Selbstian*, a German chemist, much addicted to the fanciful researches of the period in which he lived, was born in 1458, and died in May, 1521. Leibnitz, in the *Melanges de Berlin* for 1710, cited by Chaptal, in his "Elements of Chemistry," vol. iii. p. 350, mentions Brandt as a chemist of Hamburg, who, during a course of experiments upon urine, with a view of extracting a fluid proper for converting silver into gold, discovered phosphorus in 1667, or, as others say, in 1669. He communicated his discovery to Kraft, who imparted it to Leibnitz, and, as it is pretended, to Boyle. (See BOYLE.) Leibnitz, says Chaptal, introduced Brandt to the duke of Hanover, before whom he performed the whole operation; and a specimen of it was sent to Huygens, who shewed it to the Academy of Sciences at Paris. It is said, that Kunckel had associated himself with Kraft to purchase the process from Brandt; but Kunckel having been deceived by Kraft, who kept the secret to himself, knowing that urine was made use of, set to work, and discovered a process for making the substance; and hence it has been called Kunckel's phosphorus. See PHOSPHORUS.

**BRANDY**. This valuable spirit is produced by the distillation of wines of all kinds, and, properly speaking, by no other fermented liquor, though, as we have explained fully, under the article ALCOHOL, the purely spirituous part of all fermented vinous liquors, procured by distillation, is essentially the same, and, therefore, an infinite variety of imitations of the intermediate products of distillation may be produced by adding flavouring and colouring matters to any kind of pure spirit.

Brandy is prepared in many of the wine countries of Europe, and, with particular excellence, in Languedoc, in Anjou, whence the well-known Cogniac brandy, and other parts of the south of France.

The general mode of preparing it is extremely simple, being nothing more than a well-regulated distillation of wine from suitable vessels. This manufactory is technically termed, in France, *Brulerie*, and the makers, *Bruleurs d'eau de vie*.

Though every wine will give a certain portion of brandy, by distillation, it is not every kind that can be used with advantage. In general, the strong heavy wines are to be preferred. Those that do not yield a sixth of their quantity of spirit, are not worth the expence of working.

The apparatus is composed of three parts, the *alembic*, or boiler, the *capital* fitted on the top of the boiler to receive the spirituous vapour, and the serpentine, or *worm*, a convoluted pipe fitting to the beak of the alembic, and immersed in water, in which the vapour is condensed, and flows out at the bottom, in the form of distilled spirit.

The alembic is a cylindrical copper boiler about 30 inches (French) high, and 24 in diameter, flattened at the bottom to present a greater surface to the fuel, and drawn out into

into a neck at the top, about 2 inches high, and only 9 or 10 in diameter. The capacity of this alembic is about 320 quarts. The capital, which fits on the neck of the alembic, is somewhat in the form of a very flattened cone, with the apex downwards, and truncated where it joins the alembic. Its diameter here is of course a trifle more than that of the neck of the alembic over which it fits; above, its diameter is about 7 or 8 inches more. A tube, or beak, projects laterally from the lower part of the capital, to convey the vapour into the pewter serpentine or worm, which makes six or seven turns before it reaches the bottom of the large tub of water in which it is immersed. The diameter of the worm is about an inch and a half at the upper part, where it joins the beak of the capital, and lessens gradually to one inch towards the bottom.

The alembic is built into brick-work, which lines the whole, except the bottom, and a few inches below the neck. Beneath the alembic is the fire-place, made so that the flame of the fuel (generally wood) immediately touches the flat bottom of the alembic, and furnished with an ashpit, flue, and registers, or dampers.

In distilling, the alembic is first filled to about five-sixths of its capacity, with wine, (which, in the above dimensions, is from 5 to 6 quintals,) and the fire kindled beneath. When the wine is near boiling, the capital is put on, and all the joints luted with clay and ashes, and presently a thin stream of brandy begins to fall from the lower extremity of the worm, into a large cask set to receive it. The fire is kept up, and the distillation continued, till all the spirit is got from the wine; after which, the fire is let out, and the remaining contents of the alembic are drawn off by a cock at the bottom, and thrown away as useless.

In distilling, care should be taken not to urge the fire too much at first, otherwise the wine boils up into the capital, and comes over into the worm, mixing with, and fouling the spirit. In general, the slower the process, and the smaller the stream of spirit from the worm-pipe, the finer and better is the brandy. The distillers make a distinction between the former and the latter runnings of the spirit. What first comes over has the strongest, richest, and highest flavour, and this is gradually lessened, and the spirit becomes more and more watery to the end. Therefore, when the brandy becomes weak, the portion already distilled is set apart, and the remainder is collected in a separate vessel, and is called *seconds*, or *petite eau*, or *feints*, in the term of British distillers, and is not immediately fit for use, but is redistilled with fresh wine, in the next process, being still too valuable to be lost. It is obvious, that the precise point at which this distinction is made, must be arbitrary, and, therefore, it is determined, in some countries, by the proportional quantity of spirit obtained, to the wine put into the alembic; and, in others, by a certain specific gravity; in Spain and Portugal, (as with rum in the West Indies,) the sipping of olive oil in the spirit is the established proof. The wine is known to be entirely exhausted of its spirit by taking a small quantity of the liquor at that time distilling over, laying it on the heated part of the alembic, and putting a lighted match to it. If the steam which it gives, takes fire, burning with a blue flame, it is still spirituous; if not inflammable, the liquor is little else than water. It takes about nine or ten hours to run off the quantity above mentioned, in which time about 60lb. of coal is used, when this is the fuel.

Brandy is naturally clear and colourless as water; for the different shades of colour, which it has in commerce, arise partly from the casks in which it is kept, but, chiefly, from the addition of burnt sugar, Saunders wood, and other co-

louring matters that are intentionally added by the manufacturer, and which appear to do neither good nor harm to the quality of the spirit.

There are several ways of judging of the strength of the spirit. Many are mentioned under the article *ALCOHOL*. The following is also much used by the dealers: a phial is filled three quarters with the brandy, stopped with the thumb, and suddenly knocked, with some force, against the knee, to prevent breaking it. This raises a froth on the surface, and, by the size and durability of the bubbles, a good idea may be formed of the strength of the liquor by those who are in the constant habit of examining samples. This is, however, as liable to error as the trial with gunpowder, burning, &c.; for it is well known, that certain additions may be made to brandy which will very much alter the frothing. After all that has been done, it is still a difficult problem to determine, with perfect accuracy, the strength of all kinds of made spirits, by any shorter method than that of distillation, though the improved *hydrometers* answer most of the purposes of trade and revenue.

The strength of the spirit, of course, depends on the strength of the wine from which it is made, and this, again, depends on the quantity of saccharine mucilage contained in the must or grape-juice, and the perfection of the fermentation. Generally speaking, the wines of hot climates furnish much more spirit than those of colder; and sweet, rich, well-ripened grapes give much more than the cold, sour, watery fruits. The richest wines furnish as much as a third of spirit; and the general average of the wines in the south of France and Spain is stated to be, by Chaptal, about a fourth. On the other hand, some of the northern wines (though perfect as wine) give no more than a fifteenth of spirit.

The principal differences in the quality of brandies are *strength*, or quantity of alcohol, and *flavour*, which last is given, apparently, by several principles contained in the wine. There appears to exist in wine a peculiar aroma, or flavouring principle, which is imparted (somewhat altered, indeed, by distillation) to the brandy procured from it. This, whatever it is, is lessened by every subsequent rectification of the brandy, and is entirely lost when the alcohol or purely spirituous part is extracted. There are also several unpleasant flavours found in different kinds of brandy, and which greatly impair its excellence and delicacy for the table. The flavour of *emphyreuma*, or *burning*, is the commonest. This is properly so termed, since it is scarcely ever found in the very first portions of any distillation, but increases as the process continues; when the wine, therefore, has undergone a longer impression of heat, and when, from the decreasing strength of the spirit, a higher temperature than at first is required to keep the wine boiling in the alembic. This burnt flavour is also more prevalent where the construction of the still is such as to require a longer continuance of the boiling, and may, at any time, be given, by raising the heat much at the end of the process. Though this flavour is disagreeable to the finest judges of brandies in the wine countries, it has become, through the caprice of fashion, an excellence in some exported brandies, and must, accordingly, be given by the manufacturer.

Chaptal, with great probability, attributes this burnt taste, in a great measure, to the presence of the malic acid in the wine, which also appears, in some degree, in the spirit distilled from it. He observes, that the thin or ill-fermented wines contain much of an acid which, by its forming insoluble salts with lead, silver, and mercury, and lime, and by other chemical tests, is proved to be the *malic*, and it also appears in great abundance in cyder, perry, and other such

harsh wines. All these, when distilled, yield a spirit which is of bad quality, acid, empyreumatic, especially in the last-distilled portion, and even contains a sensible quantity of the same acid which has passed over in distillation. The addition of chalk, alkali, or lime water to the wine does indeed keep down the acid, and prevents it from passing into the spirit, but with a very remarkable diminution of the quantity yielded, and even then, the empyreumatic odour remains. On the other hand, the richer wines are those that are the most free from this acid.

Another substance, which gives a very strong, and molly, unpleasant flavour and smell to brandy, appears to be an essential oil of peculiar nature, which is found in the spirit of some of the richest and fullest bodied wines. The exact nature of this oil is not known, nor can it be well ascertained, whether it is different from the common flavouring principle, or aroma of wines, except in being so abundant, as to be in part altered by distillation, and changed thereby from a grateful to a nauseous substance. When spirit, charged with this oil, is rubbed in the hands till dry, a strong ungrateful smell is left by this oil, resembling, in some degree, the breath of drunkards. Sometimes this oil is in such a quantity as to separate, in part, from the spirit as it cools, and is found in the capital, as a concrete, fetty oil, strongly nauseous to the smell and taste. Brandy distilled from this oily wine is, in fact, a saturated solution of this essential oil in alcohol. It is much improved by a second rectification, with the previous addition of pure water, which immediately renders the spirit milky, separates it from a great part of its oil, and, by very careful redistillation, the spirit rises much more pure than before. Any artificial solution of an essential oil in alcohol may be rectified, and the oil separated in the same manner.

The manufacture of brandy, in other countries, very closely resembles the French process which we have just described. Thus, in Spain, the still is filled to four-fifths of its contents with wine, the capital luted on, a fire kindled, and, in about an hour and a half, the spirit begins to come over. About a fifth of the entire quantity of wine is proof-spirit, in which olive oil sinks, and comes over fit to be used, without farther process; and, as much of inferior and weaker spirit comes over afterwards, which is redistilled and rectified. When the wines are old, heavy, and oily, and a fine clear spirit is wanted at once, water is added to the wine before distillation, to keep down the oil. The principal distilleries in Spain are in Catalonia.

In Portugal, the olive-oil proof is also established, and the wines are there also so heavy and oily, as often to require the addition of water, which, however, is not added to the wine, but only to the brandy before rectification.

An inferior kind of brandy is made from the *marc* of grapes, or the residue of the grapes after the juice has been pressed out. This still retains enough of the grape-juice to be readily brought into fermentation, when properly arranged, and, therefore, to be capable of yielding afterwards a spirit by distillation. In Switzerland, it is thus performed: Wine-casks are filled with the fresh marc quite full, and pressed down by trampling, to make it lie close, and prevent it from moulding; the casks are then headed, and the bung-holes and joinings are closed up with clay. In two or three days, fermentation begins, the marc heats, and when the first working has subsided, and it has got an agreeable vinous smell, (which happens in from two to four or five weeks,) it is fit for distillation. The alembic may be filled quite to the top with the fermented marc, and just water enough is added to wet it thoroughly. The fire should be very slack, and kept up very moderately in the

process, otherwise, the marc, nearest to the bottom, will burn, and give a very unpleasant taste to the brandy. Thirty-two cubic feet of fermented marc will give about ten gallons of spirit. If not wanted immediately, the marc will keep without spoiling in the barrels, if well closed, for two, three, or even four months. This spirit should be rectified over ashes or lime-water to become very drinkable.

M. Beaumé, in his experiments, found, however, that he could obtain a very good spirit from the marc, by a single distillation, either by immersing the alembic in a water-bath, and thus regulating the heat, or by making a kind of wicker cradle within the alembic, raised an inch or two from its bottom, and letting the marc rest upon it, so as to be prevented from coming in contact with the bottom, where the heat is strongest, and adding water, as before, and distilling with a slow fire. By this contrivance, all the burnt flavour was avoided, and the spirit rose at first very pure and good.

Various improvements have been proposed, and partly adopted, in the construction of the alembics and distillatory apparatus, the chief of which, with other observations relating to the general art of preparing DISTILLED SPIRITS, will be described under that article. See also WINE and ALCOHOL.

Encycl. Meth. (Art. Alcool et Distillateur liquoriste) Beaumé et Rozier, in Jour. de Phys. tom. xii et xviii. An. Chim. Tom. xxxvii.—Report to the H. of Commons on the Scotch Distilleries.—Chaptal, &c. For the laws relating to brandy; see SPIRITS.

BRANDY-*Cherry*. See CHERRY.

BRANDY-*Pots*, in *Geography*, the name given to islands, in the river St. Lawrence, 46 leagues below Quebec.

BRANDYWINE, a township of America, in Chester county, Pennsylvania.

BRANDYWINE *Creek*, a creek of America, which falls into Chribiana creek from the northward, at Wilmington, in the state of Delaware, about 25 miles from its N. and N. W. sources in Chester county, Pennsylvania. This creek is famous for a battle, fought on the 11th of September 1777, and terminating with considerable loss by the British troops. In consequence of this battle, Philadelphia was taken possession of by general Howe on the 26th.

BRANE, a river of South Wales, which runs into the Towy, near Llanidoverly, in the county of Carmarthen.—Also, a river of South Wales, which runs into the Usk, 3 miles W. of Brecknock.

BRANFORD, a township of America, in the county of New Haven, and state of Connecticut, lying on the south side of a river of the same name, which runs into Long Island Sound, 10 miles E. of New Haven, and 40 S. of Hartford. It is considerable on account of its iron works.

BRANG, a town of Poland, in the palatinate of Volhynia; 44 miles S. W. of Lucko.

BRANGES, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Louhans, half a league N. W. of Louhans.

BRANITZ, a town of Silesia, in the principality of Oppau; 4 miles S. E. of Jagerndorf.

BRANITZY, a town and district of Russia, in the government of Moscow, seated on the Moscva, between Moscow and Kolomna.

BRANK, in *Botany*, polygonum fagopyrum, buck-wheat.

BRANK. See SCOLDING BRIDLE.

BRANKER, or BRANCKER, THOMAS, in *Biography*, an eminent English mathematician, was born in Devonshire, in 1636, admitted butler of Exeter college, Oxford, took the degree of B. A. in 1655, and that of M. A. in 1658, and

and became a preacher. Upon the restoration, objecting to conformity to the established church, he resigned his fellowship at Oxford in 1662, and retired to Cheller; but changing his mind with respect to conformity, he was episcopally ordained, and was appointed minister of Whitegate. By his attention to mathematics and chemistry, in the study of which he employed his intervals of leisure, he obtained the patronage of lord Brerewood, who gave him the rectory of Tillston. Being afterwards appointed master of the well-endowed school at Macclesfield, he spent the remainder of his life in that place, and died there in 1676. His mathematical writings were "A Piece on the Doctrine of the Sphere," in Latin, published at Oxford in 1662; a translation of Rhonius's algebra, entitled "An Introduction to Algebra," 4to. Lond. 1668, in which he liberally acknowledges the assistance of Dr. Pell. He also corresponded on subjects of mathematics with Collins, and other eminent men. Hutton's Dict.

BRANKYRKA, in *Geography*, a town of Sweden, in the province of Sudermania.

BRANLE, *Fr.* a kind of dance, very gay, brought hither from France in the time of Charles II.

BRANLIN, in *Ichthyology*. See SAMLET.

BRANNE, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Libourne; 2 leagues S. of Libourne. The town contains 544, and the canton 10,726 inhabitants: the territory includes 155 kilometres, and 21 communes.

BRANNOGENIUM, in *Ancient Geography*, a town of the Ordovices, in Ptolemy's description of Britain, placed by Camden and Baxter at Worcester, supposing that some transcriber had committed a mistake in assigning it to the Ordovices, from which territory Worcester is too remote. Mr. Horsley places it near Ludlow, which might belong to the Ordovices.

BRANNOVII, a people mentioned by Cæsar, who were under the protection of the Ædui, and who furnished him with troops. They are placed in a small canton of Burgundy in France, called the "Briennes," to the west of Maçonnois.

BRANNY, in *Botany*, furfuraceous, covered with branny scales; a term applied to the stipes, or stalks of some species of fungi.

BRANODUNUM, in *Ancient Geography*, one of the nine forts, subject to the command of the count of the Saxon shore in Britain; garrisoned by the equites Dalmatiæ, and seated on the Sinus Metaris; now Brancaster in Norfolk, on the washes.

BRANSEE, in *Geography*, a small island of Denmark, in the Little Belt; 5 miles W. N. W. from Assens.

BRANSK, a town and district of Russia, in the government of Orcl, situate on the Desna.—Also, a town of Poland, in the palatinate of Bielsk, 16 miles W. of Bielsk.

BRANSKA, a town of Transylvania, seated on the Marish. N. lat. 46° 0'. E. long. 23° 15'.

BRANSON, a town of Switzerland, in the Valais, north of the Rhone, and about 2 miles N. E. of Martigny. N. lat. 46° 11'. E. long. 6° 57'.

BRANT, a river of North Wales, in the isle of Anglesea, which runs into the Menai, about 3 miles S. from Newburgh.—Also, a town of Germany, in the archduchy of Austria; 8 miles E. of Zwettl.

BRANTA, BRENTA, and BRENT-GOOSE, in *Ornithology*, synonymous names of *Anas Bernicla*, the common brent goose of the English.

BRANTA TORRIDA, is the name given by Scopoli to *Anas torrida*. Gmel.

BRANTA ALBIFRONS Scopoli, *Anus albicans*, Gmel.

BRANTHOME, in *Geography*, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Perigueux; 3½ leagues N. of Perigueux. The town contains 2461, and the canton 10,765 inhabitants; the territory comprehends 265 kilometres, and 12 communes.

BRANTOME, in *Biography*. See BOURDEILLES.

BRACQUE, and BRACQUE DE BENGALE. Buff. *Canis avicularius*, the spaniel.

BRARUP, in *Geography*, a small island of Denmark, in the gulf of Schley; 10 miles E. N. E. of Sleswick.

BRAS, a town of France, in the department of the Var, and district of the Brignolles; 4 miles E. N. E. of St. Maximin.

BRASCHEN, a town of Germany, in the circle of Upper Saxony, and duchy of Crossen; 5 miles S. S. E. of Crossen.

BRASCHEVSKOI, a fortress of Siberia, on the Irutsh; 50 miles E. of Semipolatoi.

BRASCHI, in *Biography*. See PIUS VI.

BRASENIA, in *Botany*. Schreb. 938. Class, *polyandria decagynia*.

Gen. Char. *Petal* one-leaved, six-parted, permanent; segments lanceolate, curved, obtuse, coloured; three of them interior, alternate, a little longer and narrower than the others. *Cor.* none. *Stam.* filaments from eighteen to twenty-five, capillary, erect, attached to the receptacle, shorter than the calyx; anthers oblong, erect. *Pistl.* germs from five to ten, oblong, compressed, attenuated at the apex; styles erect, bent inwards towards the top, pubescent, shorter than the stamens; stigmas obtuse. *Pericarp.* as many capsules as germs, oblong, compressed, the outer side flat, the inner gibbous, acuminate, rather fleshy, one-celled, without valves. *Seeds* two or three, oval, compressed. *Obf.* Calyx, before flowering, erect, green. Allied to *nectris*. In both genera the pericarp might, perhaps, be more properly called a berry. Only one seed often comes to perfection.

Bosc, in *Nouveau Dictionnaire*, gives the same generic character, except that he considers the three inner segments of the calyx as a corolla. He gives no farther description of the plant, nor does he mention any habitat. The genus is not taken up by Willdenow, nor is there any figure of it in La Mark's illustrations.

BRASIDAS, in *Biography*, a famous Lacedæmonian general, who distinguished himself, on a variety of occasions, in the Peloponnesian war, which began in the 431st year before Christ. Having gained the reputation of one of the greatest generals of his time, he received a mortal wound in the action between the Lacedæmonians and Athenians, near Amphipolis, in which the former proved victorious, B. C. 422. See ATHENIANS. Brasidas, no less distinguished by his modesty than by his prudence and bravery, wrote a letter from Thrace to the Ephori, which closes with this heroic declaration: "Whatever the honour of the state requires, I will perform or die;" and he fulfilled his promise. Plutarch (*Apothegm.*) records, that having caught a mouse among some figs, he let it go after having bitten his fingers, observing to those who attended on the occasion; "That there is no creature so contemptible as not to be able to free itself from a foe, if it exerts all the power it possesses." Public honours were decreed to his mother for the speech uttered by her on occasion of his death (see ATHENIANS); and a monument was erected to Brasidas at the expence of the public. See the next article.

BRASIDIA, in *Antiquity*, anniversary feasts held at Sparta in honour of Brasidas, famous for his great achievements

ments in favour of that state, at Methone, Pylus, and Amphipolis.

The *Brasilia* were celebrated with sacrifices and games, at which none were allowed to contend but free-born Spartans. To be absent from these solemnities is said by some to have been held criminal, and punished with fines. Meurs. Græc. Ferial. Potter. Arch. Græc. lib. ii. cap. 20.

BRASIL, or BRAZIL, in *Geography*, an extensive and opulent country in South America, belonging to the Portuguese, and of such importance as to be almost essential to the existence of their monarchy. It derives its name from the wood which is so called, mentioned by Chaucer, and known many ages before his time. It is bounded on the north by the river of the Amazons and the north Atlantic ocean, on the east by the south Atlantic ocean, on the south by the mouth of the river La Plata, and on the west by a multitude of morasses, lakes, rivers, and mountains, which separate it from the dominions of the Spaniards; and extends from the frontier of Dutch Guiana, N. lat. 3°, to Port St. Pedro, S. lat. 32°, including 35° of latitude, or 2100 geographical miles, and in breadth from Cape St. Roque, to the farthest Portuguese settlement on the river of Amazons, called St. Paul de Omaguas, comprehending at least the same number of miles. Some have ascribed the first discovery of Brasil to Martin Behem, in 1484 (see *BEHEM*); but this, however, has been more generally allowed to Pedro Alvarez Cabral, who, being entrusted with the command of a powerful fleet, designed by the king of Portugal not only for the purposes of trade, but also of conquest, set sail in 1500; and in order to avoid the coast of Africa, where he was likely to be retarded in his voyage by variable breezes or frequent calms, he stood out to sea, and kept so far towards the west that he found himself, to his surprise, upon the shore of an unknown country, in the 10th degree beyond the line. He first thought that it was some island in the Atlantic ocean that had not been before observed; but proceeding along its coast for several days, he was led gradually to believe, that a country so extensive formed a part of some great continent. This country proved to be that called by its discoverer "St. Croix," but now known by the name of Brasil. Here he landed; and having conceived a high idea of the fertility of the soil, and the agreeableness of the climate, he took possession of it for the crown of Portugal, and dispatched a ship to Lisbon, with an account of that event, which appeared to be no less important than it was unexpected. The Portuguese, however, notwithstanding the flattering report of Cabral, entertained, for some time, no very favourable opinion of this country; because they found, after a survey of its harbours, bays, rivers, and coasts, that it afforded neither gold nor silver; and accordingly they sent thither none but condemned criminals and abandoned women. Two ships were annually sent from Portugal for this purpose, and they returned with parrots, and woods for the use of the dyers and cabinet-makers. In 1548, when the Jews were persecuted by the inquisition, they were plundered of their possessions and banished to Brasil. But receiving encouragement from some of their mercantile friends in different nations, with whom they had formerly been connected, they were enabled to procure sugar canes from the island of Madeira, and to establish sugar plantations. The court of Lisbon, perceiving that the mother-country might derive considerable advantage from this colony, although it furnished them neither gold nor silver, sent thither, in 1549, Thomas de Souza to regulate and superintend it. This governor, notwithstanding the talents which he possessed, found it very difficult to reduce those who had been accustomed to anarchy to due

subordination, and to induce the natives, who were dispersed through the forests and plains, and who had no settled habitations, to associate with one another, and to submit to the yoke which the Portuguese seemed desirous of imposing upon them. A dissatisfaction ensued between both parties, which at length terminated in war; nor was the force that had accompanied Souza sufficient to bring it to a peaceful termination. This was in some measure effected by the establishment of a kind of central and rallying point for the colony at St. Salvadore, which was built in 1549, on the bay of All-Saints, and which was the first Portuguese settlement in the country; but the object was chiefly accomplished by the address of the Jesuits, who, dispersing themselves among the Indians, contrived to engage their esteem and attachment, and thus to extend the influence of the Portuguese, and to insure, as well as to augment, the advantages which the mother country derived from this settlement. The Indians, instructed by the Jesuits and employed by them, distributed among the savage natives hatchets, knives, and looking-glasses with such effect, that they were induced to regard the Portuguese as an inoffensive and humane people. The increasing prosperity of the colony became gradually known in Europe; and excited the envy of the French, Spaniards, and Dutch successively. The latter, however, were the principal enemies with whom the Portuguese had to contend in their new settlement. In 1624 the Dutch admiral Willekens was detached with a powerful squadron, and a considerable number of soldiers and marines for Brasil; and having cast anchor before St. Salvadore, the capital of the country, and the residence of the Portuguese viceroy, he landed his forces, expelled the inhabitants, and took possession of the town. After having plundered it of its wealth, he appointed colonel Van Dort as governor, and left with him a strong garrison for his support. His first act was the publication of a manifesto, in the name of the States, allowing liberty of conscience to all who were willing to take an oath of fidelity to the republic of the United Provinces. When an account of the success of Willekens arrived in Holland, it was received with great satisfaction, and it was concluded, without hesitation, that the entire conquest of Brasil would ensue. Upon the return of Willekens to Europe, the Spaniards were prepared with a squadron of 56 sail, under Frederic de Toledo, which was destined to drive the Hollanders out of Brasil. The fleet was manned with 12,000 soldiers and marines, who, immediately upon their arrival, laid siege to St. Salvadore, which, after an obstinate resistance and the loss of its governor Van Dort, was obliged to capitulate. When the affairs of the Dutch at home assumed a more favourable aspect, they dispatched admiral Lonche, in 1630, with a strong armament to the South American sea, and he arrived on the coast of Pernambuco, or Fernambucco, one of the most considerable and best fortified provinces in Brasil, and, after several obstinate engagements, succeeded in reducing it. He left behind him troops which reduced, in the years 1633, 1634, and 1635, the three provinces of Temeraca, Paraiba, and Rio Grande. These four provinces furnished annually a large quantity of sugar, wood for dyeing, and other commodities, which supplied the Hollanders with such an accession of wealth, that they determined to conquer the whole country; and entrusted Maurice of Nassau with the conduct of the enterprise. After resisting many well-conducted efforts for self-defence on the part of Albuquerque, Banjola, Lewis Roca de Borgia, and Cameron of Brasil, idolized by his people, and himself devoted to the interest of the Portuguese, the Dutch took possession of the provinces of Siara, Serengippe, and the greatest part of that of Bahia. Having

thus acquired seven out of the fourteen provinces into which Brasil was divided, they expected soon to conquer the other seven, when Portugal recovered its independence by the elevation of the family of Braganza to the throne. The Dutch, then, as enemies to the Spaniards, became friends to the Portuguese, who were likewise the enemies of the Spaniards. They agreed, therefore, to leave that part of Brasil which they had not conquered to the king of Portugal, who also agreed to leave that part which they had conquered, as a matter not worth disputing about with such good allies. But the Dutch government soon began to oppress the Portuguese colonists, who, instead of amusing themselves with complaints, took up arms against their new masters, and by their own valour and resolution, with the connivance, indeed, but without any avowed assistance from the mother-country, drove them out of Brasil. The Dutch, therefore, finding it impossible to keep any part of the country to themselves, were contented that it should be restored to the crown of Portugal; to which it has since belonged, giving title to the presumptive heir.

Geographers are not agreed as to the number of provinces or captainships into which Brasil is divided. Some have distributed it into three grand divisions: 1. The northern, containing eight provinces, viz. Para, Maragnon, Siara, Patagones, Rio Grande, Paraiba, Temara, and Pernambuco. 2. The middle division, comprehending five captainships, viz. Seregippe, Bahia, or the bay of All-Saints, Illicos, Porto Seguro, and Spirito Sancto. 3. The southern division, including three captainships, viz. Rio Janeiro, St. Vincent, and Del Rey. Others reckon fifteen provinces, viz. Para, Maragnon, Siara, Rio Grande, Paraiba, Temara, Pernambuco, Seregippe, Bahia, Porto Seguro, Spirito Sancto, Rio de Janeiro, Angra, St. Vincent, and Del Rey. By others again the whole of the Brasils is divided into eight independent governments, beside that of Rio de Janeiro, of which the governor retains the name only of viceroy of the Brasils. The others are those of Para or Amazons, Maragnon, Pernambuco, Bahia, Santo Paulo, Matto Grosso, Minas Geraes, and Minas Goyaves. The rest are fiefs granted to some of the nobility, in recompence of their extraordinary services, who do little more than acknowledge the sovereignty of the king of Portugal, and his representative the viceroy of Peru, who acts both in a civil and military capacity, and maintains the state and grandeur of a sovereign prince in the city of St. Salvador. Formerly Bahia dos Todos os Santos, or St. Salvador, was the principal seat of government and chief mart for commerce in the Brasils; but the discovery and improvement of the gold and diamond mines, within about 100 leagues of Rio de Janeiro, and communicating immediately with it, gave a decided superiority to the latter. On the coast are three small islands, where ships touch for provisions on their voyage to the South Seas; viz. Fernando, St. Barbaro, and St. Catherine's. The bays, harbours, and rivers, are the harbours of Pernambuco, All-Saints, Porto Seguro, the port and harbour of Rio de Janeiro, the port of St. Vincent, the harbour of St. Gabriel, and the port of St. Salvador, on the north shore of the river La Plata. "All the provinces of Brasil," says sir George Staunton (*Embassy to China*, vol. i. p. 180.) "are growing fast into opulence and importance. They manufacture of late several of the most necessary articles for their own consumption; and their produce was so considerable, that the balance of trade became to be already in their favour; and remittances of bullion were made to them from Europe, in return for the overplus of their exports beyond their imports." It appears, from the account of this

writer, that the Portuguese settlers have manifested repeated symptoms of revolt from the parent country. It appears also, that during the administration of the marquis de Pomal, so long prime minister in Portugal, these colonies were delivered from some monopolies and restraints, which had contributed to depress them; and, moreover, that the project of removing the seat of the Portuguese government to the Brasils was once, in fact, seriously in contemplation with this minister, when that country was invaded by the Spanish forces in 1761, and that calculations were made, and precautions taken, as to the number of vessels necessary to transport across the Atlantic the royal family, with the principal officers of the court, and their several attendants. But the project vanished with the danger that occasioned it; and the Brasils continued to be considered as a colony, destined, exclusively, to enrich the parent state.

The climate of Brasil has been described by two eminent naturalists, Piso and Margrave, who observed it with philosophical accuracy, as temperate and mild, when compared with that of Africa. This they chiefly ascribe to the refreshing wind, which blows continually from the sea. The air is not only cool, but chilly through the night, inasmuch that the natives kindle fires every evening in their huts. Nieuhoff, who resided long in Brasil, confirms their description. The rivers in this country annually overflow their banks, and, like the Nile, leave a sort of slime upon the lands; so that the soil, especially in the vicinity of the rivers, is extremely rich. The northern provinces are subject to heavy rains and storms; but those of the south are more temperate and fertile. Among the vegetable productions of this country, we may reckon Indian corn, wheat, rice, manioc, sugar canes, coffee, cocoa or chocolate, indigo, pepper, cactus, on which is bred the insect furnishing cochineal, and the noted Brazilian tobacco. The red or Brasil wood, imported into this country, for the purpose of dyeing, is the property of the crown. To the class of esculent plants, we may refer those that are common to all the tropical regions of America, such as, besides the cocoa and chocolate nut, the plantain, the banana, palms, the yam, potatoe, casava, together with many species of melons and gourds. The principal fruits are the pine apple, the mango, and the tamarind. The warm aromatic plants found here in a truly indigenous state, and much used by the inhabitants as condiments to their food, or as the basis of various drinks, are the oranges and limes, the grapes, ginger, the turmeric, several species of pepper, American coffee, capsicum or Guinea pepper, and the wild cinnamon, (*laurus canella*.) Several medicinal plants of high estimation grow here spontaneously, and in great abundance, such are the contrayerva, the Indian pink, the mechoacan, the jalap, the amyris which yields the gum elemi, and the guaiacum. Besides the Brasil wood, this country furnishes for ornamental use, or for the purpose of dyeing, logwood, suttic, mahogany, ebony, rose wood, satin wood, and many others. Among its ornamental plants are the Brazilian myrtle, the scarlet fuschia, and the amaryllis formosissima. Brasil abounds with horned cattle, which are hunted merely for their hides, of which 20,000, it is said, are annually sent to Europe. These cattle are taken and killed, more for the sake of their hides and tallow than their flesh; though great quantities of the latter are applied to the use of such ships as sail from Pernambuco, Bahia, Todos os Santos, and Rio de Janeiro, to Guinea. The places which are chiefly frequented for procuring these cattle, are Rio Grande and Rio Paraiba, lying to the northward of Pernambuco; and they are inhabited by Indians, called Tapanuyes; many of whom send annually large droves of cattle, through

through the Tupique nation, which extends from the source of Rio St. Francisco in S. lat. 8° to that of Rio Doce in S. lat. 20°, to Bahia Todos os Santos, and Rio de Janeiro, where they sell them for 3 or 4 crusadoes a piece, (a crusado being in value about 2s. 8d. sterling,) or exchange them for knives, hatchets, &c. or coarse baize, for a yard of which they will give a good beast. Among its animals, we may reckon several species of the armadillo or dasypus, the cat or felis kind, the otter or lutra, the weasel or mustela, the opossum or didelphis, the porcupine or hystrix, the cavy, the squirrel or sciurus, the hare or lepus, the musk or moschus, the deer or cervus, the hog or sus, &c. Among the fishes found on its coasts, and in its rivers, are some species of the cachalot or physifer, and the globe-fish, beset with spikes like a hedge-hog, &c. Many of its birds are curious and beautiful, particularly some of the parrot or psittacus kind, the toucan or ramphalos, the motmot or momotus, the palamedea or aninga, with a strong nail or spur at each flexure of its wings, and a horn about 6 inches long growing from its forehead. The size and vivid line of the flowers in the forests, and the gaudy plumage of the birds, are very striking. Brasil breeds a variety of serpents and venomous reptiles; among which are the Indian salamander, an insect with 4 legs, whose sting is said to be fatal; the ibiboboca, a species of serpent, about 7 yards long and half a yard in circumference, (see BOIGUACU); the rattle snake of enormous size; and the hboya, or roe-buck snake, which is said to extend to the length of between 20 and 30 feet, and to be 2 or 3 yards in circumference, and which is capable, as some authors have reported, of swallowing a roe-buck whole. The hissing noise of this large and formidable snake sets the hearer on his guard, and they seldom, without provocation, advance to an attack.

The gold and diamond mines of Brasil were first opened in 1681; and our information concerning them is imperfect. The former are situated in the mountains, from which flow various streams north and south, which discharge themselves on one side into the river Tocantin, and on the other into the Parana; but there are mines of gold, as far inland as the river Cuyaba, which runs into the Paraguay, and even near the river Ytenas. Others are near the river Paixe and Sagucinonha, the Riacho-Fundo, and Guarapara in St. Paul's. One fifth of the gold is exacted by government, and the people of Rio are prohibited from working up even the gold of their own mines, and the tools and instruments used for that purpose are seized and confiscated.

The diamond mines are near the little river of Milho Verde, not far from Villa Nova de Principe, in the province of Serro de Frio, S. lat. 17° according to La Cruz, and W. long. about 44°. These diamonds of Brasil are not of so fine a water as those of Hindostan; being of a brownish and obscure hue; and, supposing the weights to be equal, they are sold 10 per cent. cheaper than those of the east. One of the largest diamonds that has been known, was sent from Brasil to the king of Portugal. It weighed 1680 carats, or 12½ ounces; and it has been valued at 56,787,500l. Some skilful lapidaries, however, have suggested, that this supposed diamond is only a topaz. All the diamond mines belong exclusively to the crown. The mines of gold and silver are said to have yielded above five millions sterling annually: those of diamonds have been usually farmed at about 30,000l. yearly, which is thought to be scarcely a fifth of their actual produce.

The trade of Brasil, notwithstanding the restraints and impositions to which it is subject, is very extensive, and continually increasing. This commerce is of such

importance to the parent state, that it could not subsist without it. The confluence of people who resort to the Brasils from Portugal, and from other countries, has much augmented the imports of gold, and, what is much more important to Europe in general, the exportation of the manufactures of this hemisphere. Great Britain supplies Brasil with a variety of woollen manufactures; such as fine broad medley cloths, fine Spanish cloths, scarlet and black cloths, serges, duroys, druggets, sagathies, shalloons, camblets, and Norwich stuffs, black Colchester bays, says, and long ells, hats, stockings, and gloves. Holland, Germany and France, have chiefly exported thither, fine holland, bone-lace, and fine thread; silk manufactures, lead, block tin, and other articles are also sent from different countries. England likewise trades with Portugal for the use of the Brasils, in copper and brass, wrought and unwrought pewter, and all kinds of hard ware. By this extension of its trade, Portugal, instead of 12 ships usually employed in the commerce with Brasil, employs at least 100 fail of large vessels, which are perpetually passing from one country to the other. Brasil also carries on a considerable trade with Africa in slaves, and thus Portugal occupies a great number of ships. All these ships, employed in different branches of trade, go and return at appointed seasons, under the direction of government, and under-convoy of a certain number of men of war; nor can a single ship clear out or depart, without the fleet, except by a special licence from the king, which is seldom granted. By these restrictions, however, as well as by the infatuated policy of the country, it fails to derive that advantage from this extensive commerce, which it is adapted to afford. The fleets sail in the following order, and at the following stated periods: that destined for Rio de Janeiro sets sail in January; the fleet to Bahia, in February; and the third fleet to Pernambuco, in March.

The duties which the agents of Portugal levy upon the importation of goods from Lisbon and Oporto at Rio de Janeiro are 12 per cent., upon the value of each article. The chief duties paid at Lisbon, on the commodities of the Brasils, are as follow: upon gold, 1 per cent.; coffee, 8 per cent.; sugar, rice, and skins, 10 per cent.; indigo, 12 per cent.; planks, 17 per cent.; and rum, 4 dollars for every pipe of 180 gallons. All large ship timber, as well as the Brasil wood, is claimed as the property of the crown. Yet, notwithstanding all monopolies, prohibitions, and heavy taxes, the whole revenue from the Brasils is said not to be equal to a million sterling, of which the expence of their government consumes about a third part. The taxes are severely felt, especially in the interior provinces, where the carriage and transit duties increase the price of every article so enormously, that a bottle of port wine, for instance, costs 10s. sterling to the consumer. The hardships thus imposed by the mother-country, excite a spirit of general dissatisfaction and revolt. Hence it happens, that those officers, both civil and military, who are natives of Portugal, and also the ecclesiastics, soon change their original affection for the parent state, into an attachment to that where they are likely to spend their days, and are sometimes tempted to sacrifice to their own interest that of their employers. It is observable, that whatever difficulties the Portuguese may be likely to encounter, in securing their American possessions against internal enemies, they seem to have taken no mean precautions against any foreign attack. See RIO DE JANEIRO.

The population of this extensive country has not been accurately ascertained. Some have reckoned the Portuguese and their descendants at half a million, and the natives at 3 or 4 millions. According to sir George Staunton's ac-

count, (*Embassy to China*, vol. i. p. 172.) all the whites are computed at about 200,000, and the number of slaves, born in Africa, or descended from such, is estimated at 600,000. Probably, the natives do not exceed one million. Labour is chiefly performed by slaves, of whom about 20,000 are annually imported, and of these, about 5,000 are usually sold every year at Rio. In the harbour of Rio, at a place called Val Longo, are warehouses for the reception and preparation for sale of the slaves, that are imported thither, chiefly from Angola and Benguela. This spot is appropriated to the purpose of cleansing, fattening, rendering sleek and saleable, and concealing the defects of this class of beings, who, it is said, seem little sensible of the humiliation of their condition. The average price on importation is about 28l. sterling each. Before they are shipped from Africa, a duty of 10,000 reis a head is paid to the queen of Portugal's agent there; the whole amounting to about 60,000l. a-year, which goes into her privy purse, and is not considered as part of the public revenue. The plantation slaves in the Brasils are allowed two days out of seven for their own purposes, which is a greater interval than that which is granted in the West India islands. They are upbraided for being addicted to stealing and lying; their disposition seems to be gay and active, and easily reconciled to their situation. They seldom recur to intoxication as a relief against any feelings of distress; and they are fond of music and dancing. Many of these slaves are the property of the crown, and of these, about 10,000 are employed in the diamond mines; and several of them are attached to convents. The Benedictines alone had 1000 upon their plantations; some of these fathers observed, that the offspring from the connection between the blacks and whites were generally endowed with much intelligence and ingenuity. Some of them they bred up carefully, and instructed with such success, that they thought themselves under no necessity of sending persons to the universities of Portugal for a liberal education: one of this mixed breed, as they boasted, having been promoted to a learned professorship at Lisbon.

The European settlers, in all classes of society, are much addicted to gaiety and pleasure; and though at Rio, in particular, there are three convents for men, and two for women, the austerity and self-denial intended by their original institution are little practised. Although the conquest of the country was at first professedly undertaken for converting the natives to Christianity, and ample endowments have been granted for this purpose, yet none of the friars now engage in the troublesome, unsafe, and, perhaps, hopeless enterprise. No inquisition or tribunal of the holy office has been established in the Brasils. Nevertheless, the ceremonies of religion are regularly observed, and even multiplied at Rio. During the day-time, bells, and sometimes sky-rockets announce, at every hour, the performance of some solemnity in the churches; after sunset the streets are crowded with processions; and at every corner is stuck up, in a glass-case, the image of the Virgin Mary, which receives regular homage from passengers. Men of the lower classes generally wear cloaks when they walk abroad; and those of the middle and higher ranks never appear without swords. The ladies wear their hair hanging down in tresses, tied with ribbands, and adorned with flowers; their heads being uncovered. In their visits to the churches, both at matins and vespers, they are very regular; at other times, they are generally seated at their balconies or windows. Many of them have fine dark eyes, and animated countenances. In the evenings, they amuse themselves with playing on some kind of musical instrument, chiefly the harpsi-

chord or guitar. Among the more innocent pleasures of both classes, are operas, plays, and masquerades, and assemblies in a public garden. In Brasil, the convents and monasteries are numerous, but the manufactories more rare.

The original inhabitants of the Brasils have been found incapable of being reduced to a state of slavery, or even to the domestic habits of civil society. Children of these natives have been taken into Portuguese families, and pains have been taken, from motives of curiosity, or of humanity, to domesticate and instruct them; but their nature, it is said, is so intractable, that they constantly return to their original habits of savage life, without retaining any of the principles which might restrain their passions or caprices. These people, though poor, seldom offer themselves for hire, and are as seldom coveted by the Portuguese, except for rowing their boats, in which practice they are remarkably expert. In their persons they are generally somewhat under the middle size, muscular, stout, and active, of a light brown complexion, black, strong, uncurling hair, with very little beard; and large dark eyes, which discover no mark of imbecility of intellect; their aspect, upon the whole, indicates no trace of meanness or vulgarity; but their looks and expressions are intelligent and distinct. Their chief pleasure seems to consist in boundless freedom; and whilst they cherish an hereditary and implacable antipathy to the invaders of their country, they withdraw from the considerable settlements of the Portuguese, and massacre individuals, without remorse, wherever they are found dispersed and unprotected. The coast between Rio and Bahia is still very much inhabited and frequented by them; and this prevents any regular communication by land, between these two places. The language of the indigenous Brasilians has not been invelligated by the Portuguese; but that which is most widely diffused is the Quarania, or that of the Guarani. They have no books in their own language.

As to the government of the Brasils, each province has its respective chief, under the viceroy, but they receive their instructions from the court at Lisbon. They are usually appointed for three years, but continued at pleasure. Each district has a particular judge, from whose sentences an appeal lies to the superior tribunals of Rio Janeiro or Lisbon.

**BRASIL, OR BRAZIL-WOOD.** Fernambouc Wood.—Span Wood. The tree which bears this important wood is the *CÆSALPINIA Crista*. Linn. This wood is very hard, takes a high polish, and is so heavy as to sink in water. When chewed, it has a sweetish taste. It resembles in appearance red sanders; but is distinguished from it readily, by giving out its colour to water, which sanders-wood does not.

Brasil wood is valuable for the beautiful orange and red colour in various shades which it furnishes to the dyer, and its analysis is of some importance. Boiled in water for some time, the wood furnishes a fine red decoction. The residue appears black, but alkalies will still extract much colour from it. Spirit of wine and ammonia also readily extract a colour which is of a deeper red than the preceding.

When sulphuric acid is added slowly to a fresh watery decoction of brasil wood, a small quantity of red precipitate falls down, and the clear liquor now assumes a yellow. Nitric acid produces a similar change, but the liquor is more of an orange. Most of the other acids also produce a red precipitate, and leave the liquor of various shades of yellow and orange. The alkalies restore the colour of the liquor, but with a tendency to crimson and violet-brown.

The action of the solutions of tin and of alum is the most important. Alum gives a fine red precipitate in great abundance,

dance, inclining to crimson, and subsiding slowly. The supernatant liquor also retains the original colour of the decoction, but a further crimson precipitate is yielded on adding alkali enough to decompose the alum in solution. In this way, a fine crimson LAKE and CARMINE are sometimes prepared, which therefore consist of alumine, united intimately with the natural colour of the wood, a little heightened.

Nitro-muriat of tin, added to the decoction, separates the whole of the colouring matter, which falls down in great abundance, united with the oxyd of tin, and the liquor remains colourless. Even when the decoction has first been made yellow by an acid, as above-mentioned, the solution first restores the original colour, and then precipitates it, as with the simple decoction.

The solutions of iron blacken brasil wood, shewing the presence of gallic acid.

Many of the other metallic solutions act similarly to that of tin, forming a precipitate of the metallic oxyd with the colouring matter.

The colour of Brasil wood, though very beautiful, is fugitive, and has the additional disadvantage of being readily darkened and rendered purple by alkalis, and therefore by soap. The colour is made permanent by acids, but is then changed to the shades of yellow; but it is peculiarly distinguished from kermes and madder, by having the original crimson restored by solutions of tin, after being altered by acids. Accordingly, the best practical dyers have employed acids and tin in their attempts to fix this beautiful colour. For further particulars as to its use, see the article DYEING.

BRASILIA, in *Ornithology*, a species of *TANAGRA*, of a scarlet colour, having the wings and tail black. Gmel. Inhabits Brasil, and other parts of South America. The synonymous names under which this beautiful bird is described by different authors are numerous; it is called Cardinal by Buffon, *Cardinalis*, Brisson. *Merula brasiliica*, &c. Aldr. Tye piranga, Maregr. Chilotl, Hern. Mex, &c. Latham names it the Brazilian Tanager. Its size is that of the common sparrow. It is conjectured, that *Cardinalis navius*, and *Cardinalis torquatus* of Brisson, are varieties of the first-mentioned species.

BRASILIANA, in *Conchology*, a species of *VENUS*, that inhabits the shores of Brasil. The shell is lentiform, of a yellowish brown colour, with thin transverse distant striz; anterior depression, broad and blueish; posterior one of the same colour, and heart-shaped. Bonan.

BRASILIANA, in *Ornithology*, a species of *STRIX*, the Brazilian owl of Latham. The body above is pale and ferruginous, brown spotted with white: beneath white, with ferruginous brown spots. Gmel. This is of the size of a thrush: bill, irides, and the feet (which are short) together with the toes, yellowish. Called by Brisson *Asio brasiliensis*.

BRASILIANA, a species of *PROCELLARIA*, the Brazilian petrel of Latham, Puffin de Brésil of Buffon; and majague of Ray. The colour is blackish: throat yellow.

BRASILIANA, a species of *CERTHIA*, described by Latham under the name of the black and violet creeper. The colour is black, with the crown of the head golden green: rump, chin and throat, violet: breast purple, inclining to chestnut. Gmel. &c. Length of this bird  $3\frac{1}{2}$  inches. This is Le Guit-guit noir et violet, of Buffon. Inhabits Brasil.

BRASILIANORUM, in *Entomology*, a species of *APIS*, that inhabits America. This kind is hairy, and blueish black: thighs at the base black. Fabr. Obs. The beak is conic, or rather subulate: eyes black; antennæ above fuscous, beneath testaceous: jaws black, and bidentated: thighs testaceous, glabrous, and compressed: shanks, and soles of the feet, with testaceous pile.

BRASILIANUS, a species of *CERAMBYX*, the thorax of which is spinous and ferruginous: wing-cafes pointed, testaceous, with three little glabrous yellow lines. Fabr. Inhabits Brasil.

BRASILIANUS, a species of *SCARABÆUS*, found in the dung of cattle in Brasil. The colour is deep black: shield of the head emarginate: wing-cafes striated.

BRASILIANUS, in *Ornithology*, a species of *CAPRIMULCUS*, of a blackish colour, varied with small white spots, and yellow: beneath, varied with black and white. This bird inhabits Brasil. The wings and tail are equal: area of the eyes yellow: bill and eyes black: legs white. Brazilian goat-lucker of Latham.

BRASILIASTRUM, in *Botany*, false Brazil wood. Aubl. Guian. Pl. 390. Class, *diazia*. Gen. Char. Male flowers unknown. Female flowers. Cal. villous without, deeply divided into five pointed segments. Corol. petals five, lanceolate, a little longer than the calyx. Pisl. germ. superior, ovate, smooth; style none; stigma two lobed, pubescent. Pericarp, drupe, soft, pulpy, shaped like an olive, but rather smaller, coral-red, slightly acid.

Sp. 1. *B. hirsutum*, a shrub, from eight to ten feet high. Stem straight, near two inches in diameter, with a brownish grey bark, finely wrinkled. Branches alternate, growing near the summit of the stem. Leaves in tufts, near a foot and half long, pinnate with an odd one, on a pubescent reddish petiole. Folioles from fifteen to nineteen, about three inches long, on short petioles, oval-pointed, entire, or slightly angular, smooth, green, and shining above, villous at their edges. Flowers in terminal, branched racemes, very small, of a dull red colour. It is a native of St. Domingo, Jamaica, and Guiana, and, like the true Brazil (*Cæsalpinia*) is used for dyeing red, but does not produce so fine a colour. Aubret relates, that its leaves bruised when fresh communicate to cotton a green colour, which soon becomes violet. It is said by Plumier, that its stem, if wounded, yields a caustic juice, which fixes an almost indelible spot upon whatever part of the human body it happens to fall. Described by La Marek from a dried specimen without flowers. 2. *B. glabrum*, differs from the preceding in being smaller, less proper to be used in dyeing, and in having its leaves perfectly smooth. It is a native of St. Domingo. A single female plant has been cultivated in the royal garden at Paris, which flowered in the beginning of November.

BRASILIENSIS, in *Entomology*, a species of *CICADA*, (*Membracis* Fabr.) The thorax of this kind has two horns, is spotted with white, and is produced behind beyond the length of the abdomen. Inhabits Brasil.

BRASILIENSIS, a sort of *GRYLLUS* (*Acheta*), that inhabits Brasil. Its general colour is fuscous; wings tailed and longer than the elytra; back pale; tail ascending, and the length of the body. Fabr. &c.

BRASILIENSIS, in *Ornithology*, a species of *FALCO*, with yellow feet; body rufous, varied with white and yellow dots; tail variegated with white and fuscous. Gmel.

Willughby and Latham describe this under the name of the Brazilian kite, being found in Brasil, where, we are informed, it is highly destructive to the domesticated poultry. It is as large as our common kite. The beak and claws are long, very sharp, and black; eyes with the irides yellowish. Buffon has described it by the name of *caracara*. The same bird is *circus brasiliensis* of Brisson.

BRASILIENSIS, a sort of *PSITTACUS*, or parrot, that is found in Brasil. It is of the size of a pigeon, of a green colour, with the face red, the temples blue, and the orbits of the eyes cinereous. Gmel. Whether it be distinct from the lesser green parrot of Edwards (*psittacus autumnalis* of Latham),

tham), remains doubtful. It is the same bird as Buffon calls *crick à tête bleue*.

**BRASILIENSIS**, a species of **ALCEDO**, the plumage of which is variegated with rufous, chestnut, fuscous, and white; beneath white; greater quill feathers and tail rufous, with transverse spots. Gmel.

This bird is of the size of the common European king's fisher: the bill and eyes are black; band across the eyes, with the legs and claws, brown. Buffon calls it *gip-gap*. It is *ispida Brasiliensis* of Brisson; and the *Braslian king's fisher* of English writers.

**BRASILIENSIS**, a species of **MEROPS**, of a fine red colour, variegated above with fuscous and black; wings and tail pale blue. Gmel. &c.

This is the *Braslian bee-eater* of Latham; *merops rouge et bleu* of Buffon; *apiafer Brasiliensis* of Brisson; and *pica Brasiliensis* of Seba. The length of this bird is nine inches. As the name implies, it is an inhabitant of Brasil.

**BRASILIENSIS**, the species of **ANAS**, called by English writers the *mareca duck*. The colour of its plumage is fuscous; beneath cinereous and glossy; between the eyes and beak is a yellowish or ochraceous spot; chin white; tail wedge-shaped and black. This is a native of Brasil.

**BRASILIENSIS**, a species of **ARDEA**, with a smooth head; body blackish, dotted with yellow; quill and tail feathers, with the bill and legs, blackish. Gmel. Briss.

This is a bittern of large size, measuring two feet eight inches. Brown, in his Natural History of Jamaica, calls it the *clucking hen*. It is named *foco* by Maregraave; by Buffon, *onore des bois*. Inhabits Brasil and South America in general.

**BRASILIENSIS**, a species of **EMBRIZA**, described specifically by Gmelin, as having the crown, collar, and body beneath yellow; back, wings, and tail greenish, variegated with fuscous and yellow.

Inhabits Brasil; its size that of the common sparrow. Latham names it the *Braslian bunting*. Ray has it under the title of *guirnegat beengata*. It is the *guirnegat* and *bruant du Brasil* of Buffon.

**BRASILIENSIS**, a species of **TURDUS**, of a black colour, beneath rusty yellowish; rump ferruginous; tail somewhat wedged, and having the outer feathers totally white, and the rest white only at the tips. Gmel. *Obs.* Across the wings is a white stripe; legs brown.

This is the yellow-bellied thrush of Latham.

**BRASILIENSIS**, a species of **TANAGRA**, of a small size, being about six inches in length, that is found in Brasil. The general colour is black, beneath white; throat and rump blueish; face and breast black. Gmel.

*Obs.* The beak is blackish; head blueish. Called by Latham *turquoise tanager*. Maregraave has it under the name of *guira-genoia*; and Buffon, those of *turquin* and *tanagra bleu du Brasil*.

**BRASILIENSIS**, in *Zoology*, a species of **RANA**, or toad of a yellowish ash colour, with waved red spots; beneath glabrous. Laur. Inhabits Brasil.

**BRASLAW**, in *Geography*, a city of Lithuania, in the palatinate of Wilna, on the side of a lake, which communicates with the Dwina; 76 miles N.N.E. of Wilna. N. lat. 55° 36'. E. long. 27° 22'.

**BRASMA**, in the *Medical Writings of the Ancients*, a name given by Dioscorides and others to a light, empty, and good for nothing kind of black pepper. This was no peculiar species of pepper, but, as John Bauhine has well observed, it was the same with the pepper we now frequently meet with, which has decayed upon the plant. Diosc. lib. ii. cap. 189.

VOL. V.

**BRASPARS**, in *Geography*, a town of France, in the department of Finistère, and chief place of a canton, in the district of Châteaulin, 8 miles N.E. of Châteaulin.

**BRASS**, or **LATTEN**, *Lait n Jaune*, Fr.; *Messing G.* This very important alloy is a mixture of copper and zinc in various and uncertain proportions, so intimately united as to form a homogeneous malleable yellow metal, applicable to a vast variety of purposes in the arts, and capable of being wrought in various ways with the greatest facility.

Mere fusion will scarcely produce a perfect union between copper and zinc; for the latter metal, being highly volatile and combustible, readily takes fire, and burns off at a heat necessary to melt the copper; and hence, when the metals are simply melted together, before an uniform alloy can be obtained, the proportion of zinc is every moment lessening by its volatilization, and would continue to fly off in this manner, by the continuance of the fusion, till at last scarcely any thing but the copper would be left behind. In order, therefore, to combine copper with as much zinc as it can take up, so as to retain its malleability, the very ingenious process of *dry cementation* has been resorted to in the manufacture of brass, which is performed by strongly heating small pieces of copper in close vessels with zinc in the state nearly of vapour, whereby it is thoroughly penetrated with the zinc, and unites with it into a perfect alloy.

Zinc being a volatile metal, it can only be procured from its ores by sublimation; and the process of obtaining it (which will be described at length under that article), is to heat strongly a mixture of the native oxyd with charcoal in a close vessel, with no other exit for the vapour than a tube dipping its further end in water. As soon as the charcoal reduces the oxyd to the metallic state, the zinc rises in vapour, passes through the tube, and is condensed in the water. A similar reduction takes place in brass-making, only, instead of conveying the vapour of the zinc out of the crucible, in which it is formed, copper is inclosed in the same vessel, which being then thoroughly heated, readily absorbs the zinc as soon as reduced to the metallic state, fixes it, contracts a very intimate union with it, and the result is perfect brass.

Brass is made in many countries, but no where more extensively and better than in England, in which both the materials are in great abundance. The ores of zinc are several species of *calamine*, and of *blende* turned by the miners *black jack*, which are found abundantly in Devonshire, Derbyshire, and North Wales, accompanying the lead ores, and in other places. These are chiefly oxyds or carbonated oxyds of zinc, and require a previous calcination before they are fit for brass-making. At Holywell, in Flintshire, the calamine, which is received raw from the mines in the neighbourhood, is first pounded in a stamping mill, and then washed and sifted, in order to separate the lead with which it is largely admixed. It is then calcined on a broad shallow brick hearth, over an oven heated to redness, and frequently stirred for some hours; or, in some places, a conical pile is composed of horizontal layers of calamine alternating with layers of charcoal, and the lowest layer is of wood in large pieces, with intervals left for the draught of air through the centre of the pile, to maintain the combustion thoroughly.

The calamine being fully calcined is then ground in a mill, and mixed at the same time with about a third or fourth part of charcoal, or in some places with pit-coal, which last, however, injures the malleability of the brass. This mixture is then put into large cylindrical crucibles, along with alternate layers of small bits of copper, consisting either of the clippings of copper plates, or of copper shot, made by melting any refuse pieces of this metal, and pouring it into

cold water, which divides it into very small rounded shot-like fragments. Powdered charcoal is put over all, and the crucibles are covered and luted up. The brass furnace has the form of the frustum of a hollow cone, or a cone with the base downwards, and the apex cut off horizontally. At the bottom of the furnace is a circular grate, or perforated iron plate, coated with clay and horse-dung, to defend it from the action of the fire. The crucibles stand upon this circular plate, forming a circular row with one in the middle. The fuel, which in England is coal, is thrown round the crucibles, and is thrown into the furnace at the upper part of it, or the truncated apex of the cone. A perforated cover, made of bricks or clay, and kept together by iron bars, is fitted to this opening. This cover serves as a regiller to regulate the heat; so that when it is to be increased, the cover is to be partly or entirely removed, and a free draught admitted to the external air, which passes along an underground vault to the ash-hole, through the holes in the circular grate betwixt the crucibles, and through the upper mouth, along with the smoke and flame, into an area, where the workmen stand, which is covered by a large dome with a chimney to conduct the smoke out of doors. To diminish the heat, the regiller cover is put on the mouth of the furnace, leaving thereby no other exit for the smoke and flame than the holes of the cover. The time requisite for heating the crucibles varies considerably in different works, being determined chiefly by the nature of the calamine or other ore of zinc employed, and also by the size of the crucibles. In the great way, at least ten or twelve hours are required. At Holywell about twenty hours are employed.

During the process, and especially towards the latter end, part of the reduced zinc which escapes, being absorbed by the copper, finds its way in vapour through the crucible lids, and burns around them with the beautiful blue flame and white smoke peculiar to this volatile metal.

The heat required for brass-making is somewhat less than what is necessary to melt copper, for brass is more fusible than copper, and the zinc is able to penetrate copper when kept at a full red heat. When the brass is judged to be made, the heat is increased to fuse the whole down into one mass at the bottom, and the crucibles are then removed, and the melted brass poured out into moulds. At Holywell, six crucibles are used to one furnace; and the quantity of brass procured from them all is sufficient to fill one of them. This makes a single large brass plate, which is manufactured in the same way as copper plate. Or, more accurately, from forty pounds of copper and sixty pounds of calamine, about sixty pounds of brass are obtained, besides that a considerable quantity of zinc burns off in the process above-mentioned.

The above is the usual process of making brass in most parts of England, and is essentially the same wherever this alloy is manufactured, but with some variation as to the choice of ingredients, their proportions, the time of fusion, and other smaller circumstances. In Goslar in Saxony, instead of a native calamine, the *cadmia*, or sublimed oxyd of zinc is used, which is collected in a particular part of the chimneys of the reverberatory furnaces, in which the lead ores and blends are roasted. The proportions of the ingredients also vary considerably. According to Swedenborg, they are, in Goslar, 30 parts of copper, 40 to 45 of cadmia, and twice the volume of charcoal; in many of the manufactories in France, 35 of copper, 35 of old brass, 40 of calamine, and 20 to 25 of charcoal; in Sweden, 30 of copper, 20 to 30 of old brass, and 46 of calamine, with charcoal sufficient; or 40 of copper, 30 of old brass, and 60 of calamine; in this country, generally about 40 of cop-

per, and 60 of calamine. The product of brass varies also; but it seems to be in few places so great as in some of the works of England, where, as already mentioned, 40 pounds of copper increase to 60 pounds of brass. This superior quantity is ascribed to the smallness to which the copper is previously reduced by pouring it melted into water, which, it seems, is not always practised elsewhere, and probably too to the goodness of the calamine.

At Stolberg, near Aix la Chapelle, where brass is made to a very great extent, the furnaces are cylindrical, and each contains eight crucibles arranged in two tiers of four each. The crucibles are fifteen inches high, twelve inches deep, and eight or nine wide. The proportions are 40 pounds of copper, 65 of calamine, and double its volume of charcoal. After the fire has been kept up for twelve hours, a workman takes off with an iron trowel all the scum and charcoal which swim upon the liquid, and when cooled form a mass called *arkelst*. This, examined by a glass, is found to consist of calamine and copper particles cohering together, but not completely united. The brass resulting from this first process is coarse, brittle, and unequal in texture, and requires a second fusion, before it is fit to be wrought. For this purpose the same crucibles are again employed, and are filled, first with three handfuls of the mixture of calamine and charcoal, over which are put two or three pounds of the impure brass broken in pieces, then more calamine and charcoal, with a piece of the *arkelst*, and over all the calamine and charcoal powder. They are then heated strongly for two hours, after which the brass is fit to be cast into plates.

A single fusion, where the fire is kept up long enough, and the materials are good, is certainly sufficient to make good malleable brass; but it is probable, that the finest sorts undergo a second operation with fresh calamine and charcoal. Some secrecy is, however, observed by those individuals who have the reputation of making the very finest article.

In the laboratory, by way of experiment, brass may be made in a much shorter time by using the same materials, that is to say, copper-shot buried in a mixture of calamine and charcoal, putting the crucible in a wind furnace, and heating slowly for half an hour, till the zinc begins to burn off in blue flame round the cover of the crucible, and then raising the fire, and heating briskly for an hour longer. This process of cementation of copper is also shewn very neatly by a somewhat different management, as given by Cramer. Put the mixture of calamine and charcoal into a crucible; cover it with a thin layer of clay, over which, when dry, lay a thin plate of copper, and cover the whole with fine charcoal powder, and a luted cover to the crucible. Apply heat gradually, and the vapour of the reduced zinc will rise through the floor of clay, will penetrate the red-hot copper above it, and convert it gradually into brass, which, at the end of the operation, will be found lying melted upon the stratum of clay; and the increase of weight, which the copper will be found thus to have gained, will afford a good practical test of the goodness of the calamine, and its fitness for brass-making in the great way.

Brass is wrought into plates by casting and laminating. At Stolberg the plates are first cast into a mould formed of two blocks of hard granite five feet long, three and a half broad, and eight inches thick. These are placed one above the other, and the upper one is raised by a pulley, and smeared with cow-dung previous to casting. To give the plate the requisite thickness, hoops of iron of different dimensions are adapted to the under stone, so as to confine the melted metal, and regulate its thickness. The stones

are gently inclined before the metal is run into them. These plates are afterwards laminated and manufactured in a thousand different ways.

The most important properties of brass, compared with copper, are the following: its colour is much brighter, and more approaching to gold; it is more fusible than copper, as is seen from the circumstance, that less than a copper-melting heat is sufficient for the making of brass; it is less subject to rust, and to be acted on by the vast variety of substances which corrode copper; and lastly, it is equally malleable when cold, and more extensible than either copper or iron; and hence is peculiarly fitted to be made into wire. Brass, however, is only malleable when cold. By hammering, brass is found to become magnetic, perhaps only from the particles of the iron hammer which may have been beaten into its surface; but this makes it necessary to use unhammered brass about compass-needles, and similar magnetic apparatus. The expansion of brass has been very accurately determined, as this metal is most commonly used for mathematical and astronomical instruments, where the utmost precision is required. Mr. Smeaton found that 12 inches in length of cast brass at  $32^{\circ}$ , expanded by  $180^{\circ}$  of heat, (or at the boiling point of water,) 225 ten thousandth parts of an inch: brass wire in the same circumstances expanded 232 parts; brass 16 parts, with one of tin, expanded 229 parts. The expansion of hammered copper is only 204 parts, but that of zinc is 353; so that brass holds a middle place in this respect between its two component metals.

The zinc is readily separated from brass by fire. When brass is heated strongly in open vessels to at least a copper-melting heat, the zinc of the brass takes fire, and slowly burns away. If this is continued long enough, little else is left but copper, though still retaining a small portion of zinc, which no further continuance of the heat will entirely separate.

Some kinds of very fine brass, it is said, are not made by cementation in the way already described, but by a more speedy and direct union of copper and zinc, care being taken to prevent the access of air to the materials while in fusion. Very fine brass may also be made in the small way, (and doubtless also in manufacture,) by mixing the oxyds of copper and zinc, and reducing them together. This plan is ingenious, and the intimate mixture of the two metals, the great object in brass-making, is probably more accurately obtained in this way than even by the common process of cementation. The following experiment on this plan is given by Sage: Mix together 50 parts of oxyd of copper, remaining after the distillation of verdigris (which is a very pure oxyd) with 100 parts of lapis calaminaris, 400 parts of black flux, and 30 parts of charcoal powder; melt together, till no longer any blue flame is seen to burn round the top of the crucible. When cold, a fine button of brass is found beneath the scoria, weighing a sixth more than the copper obtainable from the oxyd of this metal reduced in the same way, but without the calamine. This brass has a very fine colour, like gold. On this experiment M. Sage observes, that a sixth increase of weight gained by the copper, is the proportion which constitutes the finest brass, and that which copper will always retain, however long kept in fusion, provided the access of air is prevented, as in this case, by the alkaline scoria. When the copper retains a fifth of zinc, the colour is not so fine; and any quantity above a sixth will be expelled by the heat, even when the alloy is covered; and, on coming to the air, the zinc will burn. Hence the cessation of the zinc flame is in this experiment the proof, that the copper now retains no more than a sixth of zinc, and is fine brass.

The analysis of brass is a point of some consequence, and several modes have been proposed, some good, others defective.

Brass may, in some degree, be analysed by strongly heating in an open vessel, as above mentioned. The zinc then burns off, and when no more flame is given out, the copper is supposed to be pure. But Dizé has found that this mode is very uncertain; so that no two assays of the same sample correspond, for it is not easy to tell when all the zinc is burnt off that can thus be volatilized; and the increase of weight, caused by the oxidation of part of the copper, throws a further uncertainty on this method.

Neither will a simple solution of brass in the sulphuric, or any other acid, and crystallization, answer the purpose; for, though much of the crystallized sulphat of copper may readily be picked out from the sulphat of zinc, the perfect separation of the two kinds of crystals is impracticable, and at last one species becomes mixed with a portion of the other, even in the respective crystals.

M. Dizé proposes the following methods:

1. Dissolve the brass in nitric acid, which takes up the copper and zinc, and leaves any tin with which it is often alloyed. Decompose the clear nitrated solution by pot-ash, redissolve the precipitate in sulphuric acid, and add a piece of clean bright iron to the solution, previously diluted with six parts of water. The copper is thus precipitated in the metallic state, and the solution now holds sulphat of iron, and sulphat of zinc. These M. Dizé proposes to separate by gallic acid, which slowly precipitates the iron, and leaves the zinc. Lastly, the sulphat of zinc may be decomposed by a carbonated alkali, and the quantity of zinc in the carbonat may be estimated according to proportions, which will be presently mentioned.

This method is useful, but the separation of the iron from the zinc by the gallic acid, is excessively tedious. Sulphuretted hydrogen gas would be much shorter, and to be preferred.

2. Dissolve brass in nitric acid, dilute with six parts of pure water, and immerse in the solution a cylinder of bright clean lead. The copper speedily separates in the metallic state round the lead, which last takes its place in the solution. As this advances, the liquor loses its blue colour; and when all the copper is separated, it becomes slightly yellow. To determine, however, whether all the copper is separated, add a fresh clean piece of lead, and boil the solution for some time. This now contains nitrat of lead, and nitrat of zinc. Sulphuric acid will precipitate thence the lead in the form of an insoluble sulphat, and the nitrated zinc may then be decomposed by a carbonated alkali. On this precipitation, however, there are some observations to be made. Copper, when dissolving in nitric acid, absorbs nearly  $\frac{1}{100}$  of its weight of oxygen; but lead, under the same circumstances, absorbs only  $\frac{1}{160}$ . Hence (as Vauquelin remarks on this subject of the analysis of brass) 100 parts of copper dissolved in nitric acid would require, for their disoxygenation, (which takes place whenever one metallic oxyd in solution is precipitated in a metallic form by another metal immersed in it,) full 250 parts of lead, which last is of course oxidated in proportion as the copper precipitates in the metallic form. But this large quantity of oxyd of lead cannot be held in solution by the nitric acid, except this is largely in excess; and this explains why, as M. Dizé has observed, a portion of oxyd of lead is apt to form at the latter end of the process, and to mix with the copper, so as to require a subsequent operation to get the copper free from it. Nor will an excess of acid ensure the purity of the precipitated copper; for M. Vauquelin finds that

if 50 grains of pure copper are dissolved in nitric acid to excess, and then precipitated by metallic lead, of which about 220 grains are requisite, the cupreous precipitate weighs 138 grains instead of the original 50 grains, and therefore is not pure copper, but an alloy of this metal, with a very large proportion of lead. This method, therefore, of analysing brass is highly erroneous, unless the supposed copper precipitate be separately treated, in order to free it from the large proportion of lead with which it must be alloyed.

The following methods are given by Vauquelin :

3. Dissolve a given quantity of brass in nitric acid, put it in a well-closed bottle, and add caustic pot-ash to excess, so that there shall be a sensible alkaline taste in the liquor; shake the mixture well, and keep it a short time in digestion. By this simple process the oxyd of copper is precipitated by the alkali, but the oxyd of zinc is re-dissolved in it; and if the liquor be now filtered, the alkaline solution of zinc passes through clear, and the oxyd of copper is left behind. This oxyd is brown, and nearly metallic in appearance. When thoroughly washed, and gently dried, it contains 65 per cent. of metallic copper. If one is assured by a previous assay, that the brass only contained copper and zinc, when the quantity of copper is thus obtained, that of the zinc may be inferred from the difference between the copper, and the weight of the brass employed; or else the alkaline solution of zinc may be supersaturated with sulphuric acid, so as at first to precipitate, and afterwards to re-dissolve the zinc, after which this metal may be precipitated as a carbonat, by adding carbonat of pot-ash or soda. A very trifling quantity of copper passes into the alkaline solution of the zinc, occasioned by a small portion of ammonia formed by the nitrated metals when the caustic alkali is added, which takes up this atom of copper. If necessary, the copper might be again precipitated by heating the alkaline solution, so as to expel the ammoniac; but not to boiling, otherwise some of the zinc would separate from the alkali, and cause a greater error.

4. Dissolve brass in sulphuric acid, dilute with 20 times as much water, and immerse a stick of zinc exactly weighed. The copper soon precipitates completely in the metallic state, which is to be well washed and weighed. The solution now contains only the zinc of the brass, and the zinc dissolved out of the stick of metal immersed. By weighing the undissolved stick of zinc, and precipitating the whole by carbonat of pot-ash or soda, an easy calculation will give the portion of zinc belonging to the brass: or, more simply, this may be inferred from the copper obtained, and the quantity of brass originally employed.

It only remains, on the subject of analysis, to give the metallic contents of carbonat of zinc. Dizé dissolved 100 parts of zinc in nitric acid, precipitated it by carbonated soda, and this product, well washed and dried, now weighed 180 parts. Hence 100 parts of carbonat of zinc thus obtained, contain 55.5 of metallic zinc.

On the other hand, Vauquelin found that carbonat of zinc obtained from the sulphat by carbonated pot-ash, well washed and calcined in a crucible to expel all the carbonic acid, contained 69 per cent. of metallic zinc. Hence the carbonat obtained by Dizé, it is obvious, must only have been dried at a low temperature, probably that of boiling water; and from either of the above data the quantity of zinc may be estimated: or else the carbonat or oxyd may be mixed with charcoal, and strongly heated in an earthen retort, without the access of external air, by which the zinc will be reduced, and will distil over, and condense in the cool neck of the retort in the metallic state.

Analysis shews a vast variety in the proportions of the different species of brass used in commerce; nor is it easy to determine whether the perfection of this alloy depends on any certain proportion of the two metals, or the mode of manufacture. In general, the extremes of the highest and lowest proportion of zinc are from 12 to 25 parts in the hundred. Even with so great a quantity of zinc as 25 per cent., the ductility of brass is not injured, provided it be manufactured with care, though zinc itself is scarcely malleable. In proof of this, Dizé analyzed a specimen of a remarkably fine brass, which is made at Geneva for escapement wheels, and other nicer parts of watch-making. This metal unites great beauty of colour to a high degree of ductility; and the bars that are perfect fetch a very high price with the watch-makers of this town, so celebrated for this delicate manufacture. This brass was found to consist of 75 of copper, and 25 of zinc. Probably, too, the copper was Swedish, or of some other very superior kind. The common brass of Paris appears to contain no more than about 13 per cent. of zinc. The English, probably, contains more zinc.

The use of brass is of very considerable antiquity; but from the inaccuracy of the ancient descriptions, and their ignorance of the true nature of zinc and its ores, much uncertainty prevails on this subject. Most of the genuine relics of antiquity of this kind are composed of various mixtures of brass, with tin and other metals, and are rather to be termed *bronzes*. For this and the other yellow alloys of copper, see *COPPER*.

Keir, in a note to the article brass in Macquer's dictionary; Watson's Essays; Sage in J. Phys. vol. xxxviii.; Dizé in ditto, vol. xlvi.; Repertory, vol. xiv.; Vauquelin in An. Ch. vol. xxviii.; Encycl. Meth.; Original, &c.

BRASS, in *Antiquity*. See *ÆS*.

BRASS, in a more extensive sense, includes copper, and all the mixtures or alloys of copper with other minerals. In which sense, brass amounts nearly to the same with the Roman *æs*, and the French *airain*.

BRASS-lumps, or BRASSES, in *Minerology*, a common name among the colliers for the masses of pyrites that are found to accompany, more or less, the different kinds of coal.

BRASS d'Or, in *Geography*. See *CAPE BRETON*.

BRASS, ST. Bay of, lies east by north from cape d'Aguillas, on the east side of the cape of Good Hope. S. lat. 34°.

BRASS island, one of the smaller Virgin islands, situate near the N. W. end of St. Thomas's island, on which it is dependent.

BRASS town, a town of America, in the state of Tennessee, situate on the head waters of Hiwassee river, about 100 miles south from Knoxville. Two miles S. from this town is the "Enchanted mountain."

BRASS wire. See *WIRE*.

BRASSA. See *BRESSAY*.

BRASSAC, a town of France, in the department of Puy-de-Dôme, and chief place of a canton in the district of Issoire, seated on the Allier; 3 leagues S. of Issoire.

BRASSAC de Belfourtas, a town of France, in the department of the Tam, and chief place of a canton in the district of Castres; 4 leagues E. of Castres. The town contains 1149, and the canton 4190, inhabitants; the territory includes 195 kilometres and 5 communes.

BRASSAU. See *CRONSTADT*.

BRASSAVOLA, ANTONIO-MUSA, in *Biography*, professor in medicine and philosophy at Ferrara in Italy, who flourished in the early part of the 16th century, was a diligent investigator into the properties of medicines, both simple and compounded. He was educated under Manardi and Leoncini,

Leoncini, two celebrated professors at Ferrara, but finished his studies at Paris. On his return, he was made physician to Hercules II. his sovereign, to whose daughter he dedicated one of his works. As he soon came into great request in his profession, and had acquired considerable knowledge in botany, and other parts of natural history, to which he had, in a particular manner, turned his attention, he was able, from his own experience, to correct several errors of his teachers, on the nature and qualities of drugs. The first work by which he became known, is "Examen omnium simplicium medicamentorum, quorum usus in publicis officinis est," Romæ, 1536, fol. This work has been frequently re-printed. In the course of it he examines the qualities of some poisonous drugs, and their effects on dogs, and other animals. He twice saw a cartilage, he says, of the form of a cross, in the hearts of two stags. He had received manna from Syria, but preferred the Calabrian. He shews that calcined mercury had been early given in the cure of the lues venerea, though then disused. "De medicamentis tam simplicibus, quam compositis, quæ unicuique humori sunt propria," Tiguri, 1555, 8vo.; containing many valuable observations, principally from experience, on the effects of various purging medicines. He effected the cure of a maniacal complaint, in a person of rank, by the use of black hellebore, which had been many years disused and proscribed. "Examen omnium syruporum, quorum publicus usus est," Lugduni, 1549, 8vo. This, as well as several other of his works, is written in the form of a dialogue, between himself and an apothecary. In the commencement, the apothecary gives an account of his manner of treating his wife, from whom he exacts the same implicit submission that Petruccio requires from Catherine, on their wedding-day. When retired to their chamber, he says, he threw a pair of breeches on the ground, and giving his bride a stick, similar to one he held in his hand, insisted on her contending with him who should thereafter wear them; and having then conquered her, he had taken care to keep up his authority. The doctor reproves his guest, and gives him some good rules for his future conduct. He afterwards, and in succession, published "Examinations of the compositions of electuaries, pills, loochs, trochises, &c." besides "Commentaries on parts of the works of Hippocrates," "A Complete list of Galen's works," "A Treatise on the venereal disease, on the use of China root, guaiacum, &c." in all of which he has many original observations. He died, according to Carrere, in 1554. His son,

BRASSAVOLA, JEROM, published, in 1590, "De officiis medicis libellus," 4to. Ferrara. In this he treats largely on the duties of physicians, on their conduct in consultation, on the signs from which the prognostics in diseases may be drawn; also, "In primuni Hippocratis aphorismorum librum expositio," 4to. Ferrara. Haller. Bib. Med. Botan. Eloy Dict. Hist.

BRASSBRIDGE, THOMAS, of Northampton, published, in 1578, "The poor man's jewel," "A treatise of the pestilence, and a declaration of the virtues of the herbs carduus benedictus, and angelica," 8vo. London. Haller. Bib. Botan.

BRASSE, in *Icthyology*, a species of PERCA.

BRASSI, in *Geography*, a town of France, in the department of the Nièvre, and chief place of a canton in the district of Clamecy; 10 miles E. of Corbigny.

BRASSICA, in *Botany*, is derived by C. Bauhine from βραχμα or βρασσα, which he says signifies to devour, because it is eagerly eaten by cattle; but this is a sense in which the Greek word does not appear to be used by ancient writers. Linnæus derives it from the same word, and rightly rendering

it to boil, supposes the plant was so called from its being a common pot-herb. Scaliger conjectures that it was originally written βραχμας from βραχμα, a divination or garden. But as the word was not known to the Greeks who first called the plant from which Linnæus has derived the genus βραχμας, and afterwards κρουβη, it is probably of Latin origin. By Varro and Feilius it is derived from bratica, on account of its being cut off from the stem. This seems forced, and the etymology must be allowed to be altogether uncertain. Lin. gen. pl. 820. Reich. 884. Schreb. 1096. Just. 238. Gært. 434. Tab. 143. La Marek Pl. 565. Smith Flor. Brit. 311. Clafs, *tetradynamia siliquosa*. Nat. ord. *siliquosa* or *cruciferae*. *Cruciferae*, Just.

Gen. Char. *Perianth* four-leaved, erect, a little converging. *Leaves* lanceolate-linear, concave-channelled, gibbous at the base, erect, parallel, deciduous. *Cor.* four-petalled, cruciform. *Petals* subovate, flat, expanding, entire, gradually lessening into claws about the length of the calyx; nectariferous glands four, ovate, one between each of the shorter stamens and the pistil, and one between each of the longer stamens and the calyx. *Stam.* Filaments six, awl-shaped, erect, of which two opposite to each other are the length of the calyx, and four longer. *Authers* erect, acuminate. *Pist.* germ, columnar, the length of the stamens; style short, the thickness of the germ; stigma capitate, entire. *Pericarp.* siliques long, rather round, but flattened on each side, and in some species quadrangular, two-celled; partition prominent at the apex, two-valved, valves shorter than the dissepiment. *Seeds* many, globular.

Esf. Char. *Cal.* erect, a little converging. *Seeds* globular. Dissepiment prominent. Nectariferous glands four.

It is distinguished from sinapis by its firm and close calyx, and from raphanus by its siliques not being articulated. Its distinctive character is however very obscure, and some of its species might be referred to other genera.

\* *Siliques* slender, four-angled, with a very short permanent style.

Sp. 1. *B. orientalis*, Lin. *perfoliata*, La Marek. "Stem leaves cordate, embracing the stem, smooth; root leaves, rough, very entire." *Root* annual, spindle-shaped, small, white. *Stem* generally branched at the base, about a foot high, round, smooth, glaucous. *Leaves* glaucous, very entire, obtuse: root leaves obovate: stem leaves alternate: flowers small: petals white or yellowish, narrow: siliques very long, erect. A native of Spain, France &c. and rarely in England on the coasts of Suffolk, Essex and Suffex. 2. *B. austriaca*, Jacquin Aust. Tab. 283. "Leaves cordate, embracing the stem, very entire, smooth. *Siliques* deeply furrowed." Distinguished from the foregoing by its furrowed siliques and yellow flowers. Willden. Dr. Smith deems it only a variety of the former. Corn-fields in Austria and Thuringia. 3. *B. campestris*, Linn. "Root and stem slender, leaves cordate-acuminate, embracing the stem; lower leaves lyrate, toothed, somewhat hispid." Smith. *Root* annual, spindle-shaped, small. *Stem* erect, branched, round, smooth, rather glaucous: *upper stem leaves* alternate, very entire, smooth; *lower* a little toothed, *lowest* and especially the root ones, lyrate, toothed, and waved, hispid beneath at the veins; all glaucous, and paler beneath. *Leaves of the calyx* scarcely cohering, a little spreading. *Petals* yellow, three times larger than those of the orientalis. *Siliques* erect, round, obsoletely quadrangular, reticularly veined, torulose, with an awl-shaped beak, quadrangular at the base, striated. A clearly distinct species. Smith. A native of Europe, and plentiful in some parts of England. La Marek considers both the campestris and the austriaca as varieties of the orientalis. 4. *B. arvensis*, Linn. Mant. "Leaves embracing

entire of the stem, spatulate, waved, the upper ones cordate, entire." *Root* perennial. *Stem* a foot high, smooth, branched, zigzag, perennial near the root. *Leaves* smooth, very obtuse, a little fleshy. *Calyx* clove, smooth, often a little coloured. *Flowers* spreading, emarginate, violet, with purple veins. South of Europe in corn fields. 5. *B. alpina*. "Stem leaves heart-arrow-shaped, embracing the stem; radical leaves ovate; petals erect." Lin. Mant. *Root* perennial; *stem* about two feet high, not branched, with few leaves; *leaves* linear, petioled, entire; *flowers* small, white. Switzerland, Germany, Dauphny, and Spain.

\* *B. q.* with a cylindrical, rather obtuse style.

6. *B. Nap.* Rap. or Navew. Linn. "Root caulescent, spindle-shaped; leaves smooth, upper ones cordate-lanceolate, embracing the stem, lower ones lyrate, toothed." Smith. *Root* perennial, calyx spreading, allied to napais. *Flowers* yellow; *siliques* finally spreading, torulose. Corn fields; and ditch banks in England and other parts of Europe. 7. *B. Rapa*. Turnip. Linn. "Root caulescent, orbicular, depressed, fleshy; radical leaves lyrate, rough; stem leaves very entire, smooth." Smith. *Root* biennial; *stem* erect, branched, round, smooth. *Root leaves* unequally toothed, deep green; *stem leaves* cordate-lanceolate, embracing the stem, a little glaucous; *flowers* yellow; *siliques* cylindrical. La Marck makes the Napus and Rapa one species under the trivial name asperifolia, and alleges that the Linnean specific characters drawn from the root afford no real distinction. Ditch banks in England &c. 8. *B. oleracea*. Linn. Cabbage. "Root caulescent, round, fleshy; all the leaves smooth, glaucous, waved or lobed." Smith. *Root* biennial, from a span to a foot long, scarred. *Flowers* large, lemon-coloured. *Siliques* torulose. 9. *B. richeri*. Villars. Allioni. "Leaves petioled, oblong, a little toothed; root caulescent." Willd. *Root* perennial; *stem leaves* very entire. Mountains of Dauphny and Piedmont. 10. *B. cretica*. Willd. "Stem shrubby; leaves roundish, crenate, petioled, smooth." La Marck. *Root* perennial. *Stem* about a foot high and an inch thick. *Leaves* glaucous, a little fleshy, from three to four inches long, and from two to three broad. *Petioles* channelled, from one to two inches long. Discovered by Tournefort in Crete and the islands of the Archipelago. 11. *B. suffruticosa*. Willden. "Stem somewhat shrubby; leaves glaucous, a little fleshy, very entire, ovate-oblong, attenuated at the base." *Root* perennial; *stems* branched, erect, smooth, round, a foot high. *Leaves* smooth, petioled, obtuse. *Flower* violet, reticularly veined; *siliques* slender, erect, smooth, round, allied to *B. arvensis*, but differs in the shrubby stem, and petioled leaves, attenuated at the base. On arid mountains in the north of Africa. 12. *B. chinensis*, Linn. Amæn. "Leaves oval, nearly entire, floral ones embracing the stem, lanceolate; calyx longer than the claws of the petals." *Root* biennial; *lower leaves* large resembling those of cynoglossum, but smooth. *Flowers* yellow. *Siliques* a little flattened. China. 13. *B. violacea*. Linn. "Leaves lanceolate-ovate, smooth, undivided, toothed." *Root* biennial. *Leaves* tough, not esculent. China. 14. *B. subhastata*. Willd. "Radical leaves smooth, runcinate; stem leaves lanceolate, very entire, somewhat hastate." *Root* annual; *stem* erect, branched. *Racemes* with few flowers; *flowers* yellow; *siliques* slender, round, erect. Islands of the Archipelago. 15. *B. polymorpha*, Murray. "Lower leaves linear-lanceolate, pinnatifid-toothed; upper awl-shaped, entire." Willden. *Root* perennial. 16. *B. teretifolia*. Willden. "Leaves fleshy, round, smooth, pinnate; pinnules distinct." *Root* long, branched, crooked; *stem* smooth, branched, a foot high; *leaves* glaucous, smooth; *foot pinnules* unequal. *Flowers* in racemes pedicelled. *Calyx*

coloured; leaves close, linear. *Corol* large, violet; laminae obovate, entire; *siliques* slender, smooth, two inches long, many-seeded. Moist sandy ground in the north of Africa.

\* *Erucæ*. *Siliques* with a sword-shaped style.

17. *B. Tournefortii*, La Marck. "Leaves runcinate, hispid; stem hispid; siliques torulose, smooth, spreading, with a very long beak." Gouan. *Root* annual, small, fibrous. *Stem* slender, generally simple, almost naked near the top. *Leaves* oblong; upper ones almost linear. *Flowers* small, pale yellow, in racemes. *Siliques* peduncled. Cultivated in the royal garden at Paris, and supposed to come from Spain. 18. *B. Erucastrian*, Linn. "Leaves runcinate-pinnate; stem hispid at the base; flowers without veins." La Marck. *Root* annual, spindle-shaped. *Stems* several, about a foot and half high, a little branched, slightly striated. *Root-leaves* prostrate on the ground. *Stem-leaves* alternate, one to each branch, a little decurrent, glaucous, often with a few hairs; petioles furrowed above. *Flowers* in a loose, terminating raceme. *Peduncles* alternate, one-flowered. *Corollas* yellow. *Siliques* spreading, obtusely quadrangular. Barren places and walls in the south of Europe. 19. *B. Erucæ*, Linn. "Leaves lyrate; stem hairy; flowers pale, with coloured veins." La Marck. *Root* annual. *Stem* two feet high, angular, branched. *Leaves* green, petioled. *Calyx* erect; claws of the petals erect, long; laminae broad, roundish. *Siliques* on short peduncles, pressed to the stem. South of Europe. 20. *B. pinnatifida*, Willden. "Leaves pinnatifid, segments ferrate, siliques cuspidate, four-sided." *Stem* a foot and a half high, smooth, sometimes hispid at the base. *Flowers* pale yellow, nerved. *Siliques* smooth, acuminate. North of Africa. 21. *B. elongata*, Willden. "Leaves petioled, the lower sinuate, pinnatifid, hispid, the upper smooth, toothed; siliques torulose, four-sided, cuspidate." *Root* biennial. *Stem* smooth. *Racemes* very long, loose. *Siliques* little longer than the peduncle; valves half as long as the dissepiment. Waldsteir. Barren land in Hungary. 22. *B. Cheiranthus*, Willden. "Leaves petioled, pinnatifid, dentate, hispid; siliques torulose, with a flat beak." *Root* biennial; siliques one-seeded. Dauphny and Piedmont. 23. *B. vesicaria*, Linn. "Leaves runcinate, siliques hispid, covered with a swelling calyx." *Root* annual, spindle-shaped. *Stem* hairy, branching. *Leaves* lanceolate, toothed, smooth above. *Racemes* erect, terminating. *Flowers* yellow, with darker veins. *Calyx* at first cylindrical, afterwards inflated. *Siliques* short, oval, or elliptic, hispid backwards. 24. *B. lyrata*, Willden. "Leaves hispid, the root ones lyrate, stem ones toothed; siliques oblong, compressed." *Stems* half a foot high, simple or branching, several rising from the root, with few leaves. *Stem-leaves* small, oblong, petioled. *Flowers* violet, veined. *Siliques* short, hispid. Sandy deserts in the north of Africa. 25. *B. crassifolia*, Willden. "Leaves pinnatifid, segments linear." Vahl. In Egypt, about the pyramids; found by Forskal.

The first five species are cultivated merely for curiosity. They should be sown early in the spring, on a bed of light earth, and when they are sufficiently grown, thinned, but not transplanted. They will flower in June, ripen their seeds in August, and afterwards sow themselves, requiring no farther care except weeding. Those species that are cultivated in the garden or field, for the use of the kitchen or cattle, or for other purposes, are the *B. Napus* or *Navew*, under the name of coleseed or rape, (see COLESEED); a variety of the *B. rapa*, or TURNIP, (which see); the cabbage; and cauliflower; and broccoli; the turnip cabbage and turnip-rooted cabbage. We may here observe that the cabbage has been reclaimed from its wild state, and cultivated as a valuable esculent vegetable, from the remotest antiquity. It was well known to Theophrastus, and is mentioned

tioned by all the succeeding Greek and Latin authors who have written on the natural history of plants, or on subjects of rural economy; but, like all other cultivated plants, it has gradually undergone so many changes, and assumed so many permanent varieties, that it is not easy to form a description which will apply to the whole. We may, however, observe in the general, says Duchesne, who has written a particular treatise on it, that it has always a fleshy, cylindrical, ascending caudex; a branched, smooth, and leafy proper caulis or stem; alternate, smooth leaves more or less green, or tinged with red or violet; the lower ones petioled, runcinate at their base, and more or less sinuate; the upper ones simple, smaller, and often embracing the stem; and flowers rather large, yellow or nearly white, in upright, loose, and terminating racemes, succeeded by nearly cylindrical siliques.

The numerous varieties are divided by Mr. Miller into three grand families. 1. Those which grow in a natural way, without forming the leaves or stalks into a head, comprehending the wild colewort, the green colewort, the borecoles, and the turnip cabbage. 2. Those which form their leaves into a head, and to which the English gardeners exclusively apply the term cabbage. 3. Those which form their stalks into a head, as the cauliflower, and the different kinds of broccoli.

Duchesne throws them into six divisions. 1. The wild colewort, unaltered by cultivation. 2. The improved kinds, which do not form a head, or undergo any remarkable change in the stalk or root. 3. The proper cabbages. 4. The cauliflower. 5. The turnip-cabbage. 6. The turnip rooted cabbage.

I. The wild colewort unaltered by cultivation.

Our English botanists agree in considering the sea cabbage, the *maritima arborea seu procerior ramosa maritima* of Morison and Ray's Synopsis, as the parent stock. But Duchesne places this plant under his second division; though surely with little propriety, for he allows, at the same time, that it grows wild on the coasts of England and France. Notwithstanding this inconsistency, the arrangement is implicitly adopted by La Marek and Bose. Ray asserts that the sea cabbage is perennial, and supposes (Hist. Plant.) that the *brassica rubra vulgaris* of John Bauhin is only a land variety of it. Hudson, Robson, Withering, (1st edit.) and even Dr. Smith make it biennial. Miller, who, according to Mr. Martyn, seems to confound it with the napo-brassica or turnip-cabbage, says, that it grows naturally on the sea-shore near Dover; that it has a perennial branching stalk, in which it differs from all the others; that the leaves are inclining to a purple colour, and are placed alternately on the branches, (exactly agreeing in this respect with the description given by J. Bauhin.) He insists that it is a distinct species, having always found the seeds to produce the same plant, with this difference only, that in good ground the stalks will be much stronger than in poor; and adds, that the young shoots, after they are much frozen, are very sweet and good, but at other times are strong and stringy. He observes, afterwards, that the perennial colewort is little cultivated in the gardens near London, as not being so good for the table, unless in very hard frost; though it is very hardy, will grow two years before it runs up to seed, and will afterwards produce many side shoots, continuing in poor land three or four years, but in rich soil not so long. La Marek and Bose, adopting the description of Duchesne, confirm the opinion of Ray and Miller. In France several other kinds have been grafted on this stock; and though the produce has not been of long duration, it has always been very remarkable. Upon the whole, it seems

probable, that the perennial colewort of Miller is the only improved variety of the sea-cabbage, and that the French botanists are right in seeking for another origin of our common cultivated biennial kinds.

The plant which Duchesne thinks the parent of the common garden colewort, the borecoles, true cabbages, &c. is what he calls *brassica oleracea arvensis*, which he describes as growing from a small, fibrous tap-root, about 15 or 18 inches high when wild, but rising to the height of four or five feet when cultivated, and having a branched stem, with small sinuated leaves more or less deeply divided; the lower ones lyre-shaped, the stem ones heart-shaped, elongated and sessile. It is much cultivated in the Netherlands, and especially about Lille, for the use of cattle, and for the sake of an excellent oil compressed from its seeds, which must not be confounded with the oil of the navew, or rape oil of England. It is sown in July, should be transplanted about the middle of September, and ripens its seeds about the middle of the July following. If designed for cattle, it should be sown in June, and the leaves may be plucked in November; but as it is hardy, it is better to preserve it till other kinds of green forage begin to fail. After winter, if its stem be cut some inches above the ground, it will produce a second crop of leaves for spring use.

II. Of the cultivated improved kinds which do not form a head, or undergo any remarkable change, either in the stalk or root, the principal are the common green colewort, or Dorsetshire kale of the English gardeners; and the borecoles or curled coleworts. The common green colewort is cultivated in France, and in some parts of England, to feed milk cattle and sheep, but is not used in the kitchen till it is tendered by frost. It is nearly superseded in the gardens about London by the sugar-loaf cabbage plants, which, from December to April, are the sweetest greens yet known. The borecoles are more esteemed than the common colewort, as being more delicate and equally hardy; but like it they are tough and bitter, till they have been exposed to frost. (See the next article.)

III. The proper cabbages, whose leaves form a head.

The effect of cultivation upon this variety is confined to the lower leaves, which are large, roundish, and nearly entire; and are set so close together, that they lie upon each other like the scales of a bulb; and increasing in compactness as they increase in size, prevent, for some time the development of the flowering stem, and its branches. (See the next article.)

Cabbages were a favourite esculent vegetable with the Romans; and as the late excellent Mr. White has observed, must have been known, in some of their varieties, to our Saxon ancestors, since the month of February was called by them *sprouteale*. They are still in universal use, but are often productive of flatulence and indigestion. The winter cabbages are most wholesome, especially when they have been tendered with frost. They are said to be improved in this respect at an earlier season, by being kept some time after they are gathered, and suffered to wither a little before they are dressed. An agreeable pickle is sometimes made of them, by cutting them into six or eight pieces, according to their size, putting them for a few moments into boiling water, and then plunging them in vinegar, which, especially at first, should be occasionally changed, throwing in a little salt each time. In this form they are an excellent antiscorbutic, and are found a valuable sea-store. The Germans and other northern nations have a still more salutary and pleasant preparation, which they call four-croot. With an instrument made for the purpose, they cut the head of a large variety (*brassica capitata maxima*) into small shreds,

and then lay them on a cloth to dry in the shade. They afterwards put these shreds into a common cask open at one end, and if it has contained wine or vinegar, it will be more favourable to the necessary fermentation: otherwise the inside should be rubbed with a little leaven of old four-croût. The cover of the open end should be strong, that it may sustain a large weight, and should have a handle fixed in the middle that it may be readily put on and taken off. A quantity of very fine sea salt should be procured, in the proportion of two pounds to twenty cabbages. A layer of this salt is first evenly spread at the bottom of the cask; on this is placed a layer of the shreds six inches thick. A man in strong boots, well washed and very clean, then gets into the cask, and treads down the mass till it is reduced to the thickness of three inches. Similar layers of salt and shreds of cabbage are put in and trodden down in their turn, till the cask is nearly full, but the last layer must be of salt. Some large fresh cabbage-leaves are then laid on, and covered with a wet cloth; and on the cloth is put the cover of the cask pressed down by heavy weights, to prevent the croût from swelling and rising during the time of its fermentation. A seasoning either of juniper berries, or, which is much better, of caraway seeds, is mingled with the cabbage, but not with the salt, and an empty space of about two inches is left at the top. The shreds are soon deprived of part of their vegetable juice by the pressure. This fluid, which naturally rises to the top, is green, turbid, and fetid, and is drawn off by means of a cock placed two or three inches below it. A new brine is then added, which also soon becomes foul, and is drawn off in the same manner. After these operations have been continued twelve or fifteen days, more or less, according to the temperature of the place, the liquor will remain clear and sweet: but care must be taken that there be always about an inch of brine at the top, and that no space be left between the cover of the cask and the cabbage, which will otherwise acquire a putrid offensive smell. Sour-croût, well made, and well kept, has a very-pleasant acid taste, especially if it be washed after it is taken from the cask, and mixed, before it is served up, with a little vinegar. It has been found highly serviceable in long voyages, as a preservative from the sea-scurvy. For the IVth, Vth, and VIth divisions, see the next article.

BRASSICA, in *Gardening*, comprehends cabbage, borecole, turnip cabbage, cauliflower, Broccoli-cole, or rape, and turnip; and of course affords some of the best esculent vegetables of the kitchen garden.

The species chiefly cultivated are such as follow; viz the *B. oleracea*, or common cabbage, which has a biennial root, and upright, fleshy stalk, of oblong roundish leaves, which in some varieties closely cabbage into large compact heads; but in others they spread loose and open.

The varieties of this are the common heading cabbage, with a roundish, oblong, closely cabbaged head, of roundish or oblong, plane, entire leaves; the Savoy cabbage, with a roundish and oblong closely cabbaged head, of roundish, crumple-curled leaves; the fimbriated open cabbage, or borecole, having a tall stem, crowned by an open loose head, of oblong cut, fimbriated-curled leaves, spreading open but never cabbaging; the Siberian borecole, Scotch cole or kale, with a strong stem, crowned by a large open head, of oblong, roundish, broad, thick, cut, curly leaves, not cabbaging; the green, common, open colewort, having a short stem, crowned with an open head of oblongish plane leaves, not cabbaging; the turnip-cabbage, with the stalk and root swelling, turnip-shaped, being crowned by a head of open oblongish leaves, never closing to cabbage; the clustered

brassica, or cauliflower, with an upright shortish stalk, crowned by an open head of oblong, narrow, plane, entire leaves, not cabbaging, but having a large clustered flower-head in the centre; and the Italian cabbage called broccoli, having an erect robust stalk, crowned by a large open head of oblong, dark, and light-green plane leaves, not cabbaging, but affording a clustered flower-head in the centre, in the manner of a cauliflower.

*B. Napus*, navew, rape, or cole, has a spindle-shaped biennial root, and oblong, lyre-shaped, deeply divided, sinuated, smooth leaves, not cabbaging; the stem leaves being oblong and cordate. This is seldom cultivated in the garden, but is valuable as a field crop; the culture, application, and use of which will be described hereafter. See *COLLE*.

*B. Rapa* or turnip, produces a large round fleshy annual root, crowned with oblong, cut-sinuated, rough leaves.

As these plants are mostly considered among gardeners as different, and as requiring different modes of culture, they may be treated of under separate heads.

Of the *B. capitata* or common heading cabbage the varieties are numerous, and all denominated cabbages, from the circumstance of their inner leaves turning in closely over one another, till by degrees they form a large, compact, globular, or oval head, some of them attaining a very large size. And as some of them are in perfection in summer, and others late in autumn, they are sub-divided into summer and autumn cabbages.

Of the early summer kind the varieties are the small, roundish, early cabbage, and the larger, oblong, early cabbage. The first comes early in May, and the second about the middle, or latter end; both of them soon become very hard, and crack; and, therefore, no considerable quantity should be raised, where the use of the family is only regarded.

Of the sugar-loaf kind the varieties are the early dwarf sugar, the large, and hollow sugar loaf. The first is a small, longish, pyramidal cabbage, which comes in early in June, and is very sweet while young; but soon grows hard. The second is a large, pyramidal, hollow cabbage, that comes in about the end of June, and is in full perfection in July and August, seldom growing hard or cracking. It is a fine family and market cabbage.

The early Yorkshire cabbage is a roundish, oblong, heading cabbage of a moderate size, growing close, hearting quickly, and cabbaging early in summer, as in May, June, or July, &c. It is an exceeding good, tender-boiling, sweet-eating cabbage, proper to cultivate with the large sugar-loaf kind, &c. as a principal, early, and general summer crop, and for autumn and winter use as young light cabbages.

The early Battersea cabbage is a roundish-oval-heading, rather smallish cabbage, that heads quick, comes in early, and is excellent for use while moderately young, or of middling light growth, before it becomes very hard.

The early Russia cabbage is a small roundish cabbage that comes in about June and July, heads very fast, and soon grows hard; but if used while young and hollow is very sweet and tender.

Of the autumn and winter kinds the principal sorts are the common round white cabbage, which is a large middle-sized, roundish, very white cabbage, that is in perfection about August and September, and which gradually acquires a degree of hardness. It is hardy enough to endure the winter.

The long-sided cabbage is a large, oval, and roundish hollow cabbage, which never grows hard, is exceedingly sweet and tender, and in high perfection in August, or September and October.

The drum-head, or great flat-topped cabbage, is a very large spreading cabbage, generally very broad, and flat at top, and pretty close and firm. It is in perfection in September, and will continue till Christmas, or longer.

The hollow cabbage is a large, roundish-oval, hollow cabbage, which seldom grows hard, is sweet tasted, and comes into perfection from August to October.

The musk cabbage is a middle sized, roundish, hollow, very tender, crisp-eating cabbage, of a musky scent. It is in perfection from August or September till Christmas.

The giant, or great Scotch cabbage, is an admirable, large, roundish cabbage, heading very close and hard, arrives to perfection in September and October, and will continue all winter. It is principally valued as a field cabbage for feeding cattle; but eligible also occasionally for family use.

The American cabbage is a very large roundish cabbage, principally for field culture.

The Devonshire cabbage is an exceedingly large very good cabbage, eligible both for the purposes of the two last sorts, and as a profitable domestic cabbage, about the end of autumn and in winter.

The red cabbage is a middle-sized, roundish, thick-leaved cabbage, heading very hard, the whole of a red colour; the darker the red, and the more thick and fleshy the leaves, without any white in the ribs and veins, the more valuable. It is in perfection from autumn until the end of winter, as well as all the spring months till May; esteemed principally as a choice pickle, and to eat raw as a salad.

All these sorts or varieties of cabbage are biennial, being raised from seed, and attaining perfection the first year; and the second shooting up into stalk, to flower, and seed, soon after wholly perishing.

Both the summer and winter kinds are raised from seed sown annually in beds of common earth, from which they must be afterwards transplanted. The chief periods of sowing are autumn and spring; those plants raised in the autumn arrive at perfection early the following summer; and the spring-raised plants cabbage the same year in summer and autumn, and attain full perfection. But the larger autumn sorts, sown in the spring, do not in general cabbage so soon in autumn, or to so large a size as the autumn-raised crop, planted out chiefly in the latter-end of that season or the beginning of winter, or partly early in the following spring, but will be cabbaged in good perfection in August and September. It is of course always proper to sow some in both the autumn and spring seasons.

#### *Method of culture in the summer kinds.*

In the culture of these plants, for the early and first general summer crops, the proper sorts are the dwarf and other small earlier kinds, which it is necessary to observe should only be sown in small portions; larger supplies of the Battersea, or, which is probably better, the large sugar-loaf, and Yorkshire, being put in, the former to come in early as in April and May, and the others to succeed them in June and July. Some of the early Russia cabbage may also be provided.

Thus the autumn sowing serves for the early and first main spring and summer crops of the following year, and the spring sowing for succession crops in summer and autumn. Where the autumn sowing has been omitted, care should be taken to put some seed in as early in the spring as the weather will permit, as the beginning or any time in February, or early in March, in a warm situation for the purpose of early cabbages.

In order to raise an early and general summer crop of any or all of these sorts, a suitable quantity of good fresh seed should

be sown precisely about the first or second week in August: as if sown earlier, the plants are apt to run up to seed in spring; and if sown much later, they do not acquire due strength before winter.

For this purpose a spot of rich ground in an open exposure is to be carefully prepared, by digging it nearly one spade deep, and dividing it into four feet wide beds; sowing the seed immediately, each sort separately, and raking it in evenly. If the season proves showery, the plants will rise in ten or twelve days; but if dry weather prevail, it is necessary to water the beds frequently, both before and after the plants appear, and to keep them clean from weeds. When the plants have leaves of an inch or two in breadth, it is proper to prick out a quantity of the larger plants from the seed-bed into nursery-beds, in order that they may acquire due strength, previous to their being planted out for good in October, and the following spring. In this intention, dig over an open spot of the best ground, and divide it into beds as before, raking the surface smooth; then prick out the plants in rows six inches distant, and three or four inches apart in the lines, giving them a full watering, which, if dry weather succeeds, must be repeated occasionally.

The plants may remain in this situation, some till October or November, and the principal part till February, March, or April in the following year, at each of which periods a quantity of the stoutest should be transplanted into the places where they are to remain to cabbage; good ground in an open exposure being allowed them, which if well dunged, and dug in about a spade deep, will be the better. The plants are mostly put in by line and dibble, in rows: the small early kinds at two feet distant, and about one and a half in the lines; but the large sugar-loaf and Yorkshire kinds should be set two feet and a half distant every way. A double quantity of these sorts should be planted, for the supply of a family; as the small early kinds seldom continue long before they grow hard.

But in planting crops of early or summer cabbages, either in autumn or spring, some may occasionally be planted closer than these distances advised for the principal standing crops, in order to admit of thinning out for use, by degrees, in young small growth, and a portion also planted in rows at only eighteen inches, as under, by a foot in the row.

It is necessary to observe that, as the autumn plantings sometimes suffer by the severity of frost or other causes in winter, the deficiencies should be made good occasionally from the plants in the nursery beds.

Those that have remained in these beds all the winter should be planted out in February, if the weather be temperate and open, where they are to remain, though, if much cut by the winter frost, it is better to let them remain until March or April to become strong. When the winter happens to be so severe as to cut off most of the autumn-raised plants, recourse must be had to an early spring-sowing in February or March; the sooner the better.

Where constant successions of perfectly young cabbages are required through the summer and autumn seasons, it is necessary to perform spring and summer sowings, to succeed those of the autumn-raising. Some seed of the large sugar-loaf and Yorkshire cabbage should be sown in February, March, or the beginning of April, and smaller portions in May, managing them as already directed, which will furnish supplies of young cabbages in July, August, and September, &c. A small crop may also be sown in June, or early in July, to plant out for successions of small young cabbages, or good cabbage coleworts, in the latter end of autumn and early part of winter.

All the culture cabbage crops require, after being planted

out where they are to grow, is hoeing the ground over occasionally between them in dry weather, to destroy weeds, and hoisting the surface of the earth, in order to encourage the growth of the plants; and when they have advanced a little, drawing some earth once or twice about the bottoms of their stems, to strengthen the plants and forward them; as in forward spring the earliest sorts will often make efforts for heading the latter end of April or early in May; if anxious to have them as forward as possible, some of the best may be assisted, by tying their leaves moderately close together with an osier twig, or piece of baw, which promotes their cabbaging, whitens them internally, makes them more crisp and tender, and causes them to be ready for use a week or ten days earlier. In cutting summer cabbages it is proper to permit some stalks to remain to produce crops of sprouts, which they afford abundantly. These may either be gathered while young and green, or some left to stand for forming little heads, either of which are in many instances preferred to other summer greens; for this purpose sugar-loaf and Yorkshire cabbage-stalks should be preferred.

*Method of culture in the autumn kinds.*

In the culture of these sorts it is necessary to consider those of the white or green kinds, and the red separately. These sorts are adapted principally for autumn and winter use, as they rarely attain any degree of perfection before August; and some of the larger kinds not till September and October, but continue in excellent condition till Christmas, or sometimes till the end of winter, some of the sorts arriving at a great bulk. When used while young, or before they grow hard, they are excellent for culinary use. The season for sowing all the late kinds is, as has been observed, either autumn or April; but to have a large succession, it is necessary to sow some seed at both seasons, those sown in autumn and the first week in August arriving at perfection early in the following autumn, as August and September; and the spring sowing coming in about the beginning or middle of September, or towards Michaelmas, though they seldom attain any tolerable perfection till the end of October. They are very fine in November and December, but rarely attain so large a growth as the autumn-raised plants.

The same method of putting the seed in, and pricking out the plants, is to be observed, as in the summer kinds. The time for planting out the autumn-raised plants is, for a few October or November, but for the principal part February, or early in March; and for the spring-raised plants, May and June. All of them must have an open exposure of well dug ground, and the plants set in rows two feet and a half at least distant; and for the larger kinds, a yard distant each way should be allowed.

All the culture they need is that of hoeing, to extirpate weeds, and drawing earth about their stems, which is an essential piece of culture in the whole cabbage tribe of plants.

The red cabbage is principally valued for pickling, and occasionally for being shred small and eaten as salad, sometimes also for stewing. It attains perfection in autumn and winter.

The culture which it requires is nearly the same as in the former sorts. The seed may be sown in autumn and spring; but as it is a late cabbage, the spring-raised plants do not require the full size so soon in the proper season as those sown and raised in the preceding autumn; though it is generally proper to sow some seed in both these seasons, in order to obtain a longer succession.

It is most advisable to sow the main crop in autumn, or in the beginning of August, as in that case the young plants will be fit to prick out in September or October in nursery-beds. They should stand four or five inches asunder, and be

watered if the weather be dry. The plants are to remain till they acquire a proper growth for planting out where they are to grow, some either the same year in November or beginning of December, and the rest in the spring following; or the whole till that season, as February or March. In either case, it is necessary to allot an open situation of good mellow ground, which should be well dug over and manured with dung; a quantity of the strongest plants being then drawn from the nursery-bed, should be planted out in rows at not less than two feet and a half distance every way. After being thus planted out where they are to stand, they only require the culture of occasional hoeing in their advancing growth in spring, and beginning of summer, to destroy the rising weeds, and loosen the surface of the ground, and at the same time drawing a little earth about the lower parts of their stems. They will by this means advance in their growth in a spreading open manner at first and towards autumn, gradually form closing hearts in the centre, and increase to large cabbaged-heads in full perfection in September and October, &c. continuing firm for six months or more, being hardy enough to resist the severest frosts. Not only a spring sowing is necessary to have a succession to the autumn sown main-crop ready, if wanted in winter, and the following spring, but also to continue longer in the latter season before they shoot for seed. If the sowing for a main-crop in autumn has been omitted, some seed must be sown in the spring, as in February or early in March, but not later than that month.

The young plants may be pricked out in April or beginning of May four inches asunder, and occasionally watered, continuing a month or five weeks to gain some tolerable strength, and then planting them out two feet and a half asunder, where they are to grow, giving them the necessary culture of hoeing, as in the former-mentioned crops. They cabbage in moderate heads about September and October, and continue increasing in size during November, if the weather be open, and are proper for use in that season, and continue good late in the spring till April and May.

In order to obtain a spring sown crop as forward as possible for finally planting out, some seed may be sown in February, in a moderate hot-bed, and the young plants pricked out in March or beginning of April, in a warm situation, or in a frame, if an unkindly season happens, to have occasional protection, with glasses, &c. in cold nights and sharp cutting weather, to continue them forward in proper growth for setting out in April or beginning of May, and thereby they not only cabbage sooner but in greater perfection and size in autumn.

For the field culture and modes of application of this plant in feeding cattle, see CABBAGE.

*Method of culture in cabbage coleworts.*

Cabbage coleworts are almost generally substituted in place of common green coleworts, which, though valuable on account of their hardiness in being proof against frost, yet, as table greens, are apt to boil tough and be rank tasted, being greatly inferior to the former. What were formerly understood by coleworts were such cabbage-greens as never closed or cabbaged, but always remained quite open and green to the heart, and were raised for autumn, winter, and spring use as open greens; but at present cabbage plants, while they continue open and green, or just forming little central hearts, are mostly denominated coleworts, and are the most sweet and tender greens that can be cultivated for autumn and winter eating, continuing fine all the spring till summer cabbages are ready. For winter and spring supplies, a considerable quantity of these coleworts should always

be raised in autumn, and occasionally in spring and summer, for summer and autumn coleworts, such as some of more early and close-growing, quick-heating cabbage kinds, as these, even in their young state, will generally have small closing hearts; and what are not used in their young colewort growth may be permitted to stand to grow to proper full headed cabbages. For this purpose, any of the smaller or moderate sized sorts of white or green heading cabbages may be cultivated, though it is most advisable, as just observed, to fix upon some of the early or summer kinds, as being of a more close hearting growth, more tender, and sweeter than the larger sorts. The most eligible of these are the sugar-loaf, Yorkshire, and Battersea cabbages, though the sugar-loaf kind generally surpasses all the other sorts for eating.

The proper time for sowing the seed in this view is any time in July, for the autumn and winter crop; but to have them continue, without running for spring drawing, some should also be sown the beginning of August, as in cabbages, as by this means the plants will continue in a colewort state all the spring months till May, when such as remain advance in growth to heading cabbages, either to cut young in small hearts, or to stand and form proper cabbaged heads as may be required. But where a succession of coleworts is wanted all summer and autumn, it is proper to sow some of the same sorts also in the spring, in February, March, or beginning of April, and in June and July to plant out at different times, and thus provide coleworts and small hearted young cabbages throughout the summer months.

In raising these different crops of coleworts, some seed for each should be sown in an open situation, moderately thick, raking it in evenly; and when the leaves of the plants are two or three inches broad, the plants should be set out where they are to stand, in rows a foot asunder, and half that distance in the rows: all the culture they afterwards require is, to have the ground occasionally hoed to destroy the weeds, and loosen it about the plants. When the plants are as large as a full grown coss lettuce, they are of proper size to be drawn as coleworts.

In drawing them for use, especially the spring crops, where there is a large quantity, every other row may be taken, permitting the intermediate ones to stand to cabbage, cutting for use also every other plant in the remaining rows, according as they form little hearts, leaving the others to cabbage more perfectly.

#### *Method of culture in the Savoy kinds.*

The Savoy is a variety of the cabbage, which, with care, always retains its difference from seed; it admits of some varieties, all of which have crumpled curled leaves, and head or cabbage to a large size. The principal varieties are the common green Savoy, the large green Dutch Savoy, the yellow Savoy, the round headed Savoy, the oval headed Savoy, and the sugar loaf Savoy, which are all excellent for autumn and winter use.

They are propagated by seeds sown at two or three different times, from the beginning of February till the middle of April; and for the very early autumn crop, a sowing may be made in August. Each sowing should be made in an open situation, and the seed raked well in. When the plants have leaves an inch or two broad, and stand thick in the seed bed, it is proper to prick out a quantity of them on separate beds three or four inches distant, to acquire strength against the time of planting them out finally. Some of the autumn raised plants may be set out in October or the following months, if the weather be open, and wholly in the beginning of spring; and those raised from early spring sowings should be planted out finally as soon as the plants are of proper

growths. The general crops of the later spring-raised plants may be planted out occasionally, as ground is cleared, from May till August: those planted out early being set two feet and a half distant every way, and the next crop about two feet; but the latter plantings need not be planted at more than a foot and a half distant.

It is sometimes customary to plant out the summer crops of these plants between rows of forward beans, peas, kidney-beans, cauliflowers, early cabbage, and other plants, tho' stand distant in rows and are soon to come off the ground, as by this practice some ground is gained; but the plants are generally stunted when they are planted out in a clear open spot of ground, previously well dug over for their reception. In performing the summer plantings it is of much advantage to chuse moist weather for the work, otherwise watering must be practised several times till the plants have stricken fresh root.

All the culture that is afterwards required is, to hoe them well, to destroy the weeds, and to draw a little earth up to their stems occasionally.

#### *Method of culture in the borecole kind.*

In the borecole varieties of cabbage, the plants are open, never closing to form a head or cabbage. They possess a peculiar degree of hardiness, so as almost to bid defiance to the severest winter. The sorts mostly cultivated are the green curled borecole, the red curled borecole, the thick-leaved curled borecole, and the finely fringed borecole. They mostly rise with a thick stalk a yard or more in height, surmounted by a large head of thick leaves; in some spreading horizontally every way, being finely fringed and curled; but there are others that grow more contractedly. In all the sorts the stems produce numerous fine sprouts early in spring, closely surrounding them for some length, and which, as well as the principal or main top heads, boil exceedingly green and tender. The main heads come in for use in autumn and winter, and the sprouts early in the spring.

They are raised by sowing seed annually from March to the middle of April, for the main crops; and a smaller portion, in the beginning of May, for a succession. They should all be sown in open situations, not too thick, and the seed raked in. A quantity of the plants, when the leaves are an inch or two broad, should be pricked out on beds four or five inches asunder, to remain five or six weeks, so as to obtain a proper degree of strength for the late crops to be selected out finally in June and July for the main crops, in rows two or three feet and a half asunder; and for the late crops, early in August, placing these in rows two feet apart and eighteen inches in the rows. Moist weather should, if possible, be chosen for this purpose.

A small crop may also be sown in autumn, or about the beginning of August, to stand the winter in young growth, and be planted out early in the spring, in order to be of the largest full size in the following autumn.

For the field culture of these plants, and their application as the food of cattle, sheep, &c. see BORECOLE.

The Siberian borecole, or Scotch cole, is a sort, some of which grow with very tall stems and large open heads; others more robust, with shorter stems and larger heads of broad curly leaves; in some sorts, spreading; in others, standing erect. These sorts are not so generally esteemed as the common borecoles to cultivate in the garden in any considerable crops; they, however, boil tolerably tender and good in the winter, and the stems furnish young sprouts after the main tops are gathered; so that they might be cultivated for winter and spring use. They also answer well in the field. See BORECOLE.

There are some perennial varieties of the borecole kind,

with variegated leaves, which are cultivated as plants of ornament and curiosity. There are others also of a somewhat perennial shrub by nature, rising with tall branching stems, furnished with leaves all the year round; of which some are curiously variegated, the plants continuing several years. Those with variegated leaves make an highly ornamental and curious appearance.

These sorts are propagated and continued principally by planting the off-sets, slips, and slips of the side shoot, in the spring or summer seasons, watering them till they become well-rooted.

The common or green colewort is a hardy biennial plant of the open-headed kind, with a short stem producing a head of largish, oblong, plane, entire leaves, generally of a green colour. It is a very hardy plant, and was formerly cultivated for winter greens, but, till severely pinched by frost, is tough, rank-tailed, never boiling so fine and tender as the cabbage coleworts, for which reason it is rarely cultivated now for the table. They may be raised for winter use by sowing the seed in July, as directed for cabbage coleworts.

The Anjou cabbage or colewort is a plant of the borecole kind, which grows tall, and produces very large open heads. It is raised as the preceding kinds, but must be planted out at a much greater distance.

Brussels' sprouts, or *chou de Milan*, is a dwarf, perennial, open colewort, very productive of sprouts all the year round. It is raised by seeds, as in the other open coleworts, and by the perennial roots, the smallest bit of which will grow and increase very fast.

#### *Method of culture in the turnip cabbage kinds.*

This is a singular variety of cabbage, having its stalks swelled globularly, like a great turnip, and crowned by a large tuft of leaves, which never close or cabbage. The sorts are the turnip cabbage, with the turnip above the ground; and the turnip cabbage, with the turnip under the ground. The plants rise and grow for some time, as in the common open colewort kind, till they form bulbs. It is the globular or turnip-part of the plant that is used, being sometimes sliced in soups, and by some used as common turnips; but unless employed when quite young, they are rank and unpalatable. They are much recommended for culture in fields, as a green food for cattle and sheep; their chief merit is their hardiness, as they are capable of withstanding the hardest winter. See TURNIP CABBAGE. These plants are propagated by seed sown annually in March, April, and June, being set out in an open situation, in rows two feet asunder, keeping them clean from weeds, and throwing a little earth about the bottom of the stems occasionally. The turnip part will be fully grown by Michaelmas, and continue all winter for use. They may likewise be sown where the plants are intended to remain, and be hoed out to proper distances. This last is probably the best method of cultivating field crops.

#### *Method of culture in the cauliflower kind.*

The cauliflower is supposed to be a variety of some of the sorts of common cabbage, brought up to its present improved state by diligent culture. Mr. Miller insists that the cauliflower is specifically distinct from the common cabbage; because, in a course of fifty years' experience, he could never find the least appearance of one approaching the other; because they are so different in their leaves, when the plants are young, as to be easily distinguished; and because the common cabbage puts out one upright stem from the centre, which afterwards divides into several branches; whereas the cauliflower sends out many flower stems from the part that is eaten, which is a compact collection of the heads of these

stalks, dividing afterwards into so many stems, and branching out into many spreading shoots, so as to form a large spreading head when in flower, but never rising pyramidically like the cabbage. Bose, however, asserts, that though in a well cultivated soil it may be kept from degenerating, by being properly watered, it will become a common cabbage, if neglected. It was first brought to England from the island of Cyprus, and, in the course of the last century, has been so much improved in our kitchen gardens, that most parts of Europe are now supplied with English seeds.

The varieties are the early cauliflower and the late cauliflower, which are alike in their growth and size, only the early kind comes in about a week before the other, provided the true sort can be obtained, of which, however, there is no certainty, unless by sowing the seed from the earliest sorts, as is the practice of the London kitchen gardeners, who are always in possession of an early and a late kind of the former, of which they are very careful. Both the varieties are of a delicate nature, being generally too tender to resist the cold of the winter season, without the occasional aid of glasses or other means. Those who are curious in the culture of the cauliflower, have generally three or four crops in the year; as an early summer crop, a main summer crop, a late summer crop, and an autumn or Michaelmas crop.

The proper season for sowing the above crops are, for the early summer-crop, about the middle of August; the plants which rise in the same season are to be pricked out, and preserved through the winter, under bell glasses, hand glasses, frames, or other conveniences, which, being planted out in spring, arrive at perfection the ensuing summer, from May to July and August. For the late summer crop to succeed the above, the seed must be sown in February, or early in March, but not later than the first week in April, the plants being set out in May to come in for use in August and September. And for the Michaelmas or autumn crop, the sowing should be performed about the middle of May, the plants being set out in July. These are ready after Michaelmas, and the following month, come to perfection gradually in October, but are never so large, fair, or perfectly headed as the summer crops.

In the culture of the early and main summer crops, great attention is necessary to procure good seed, such as is not more than a year old, and which has been saved from the best sorts. For the purpose of raising them in the greatest perfection, a bed of the richest light earth, in the full ground, in a free exposure, is to be prepared at the proper period, by digging it well over neatly, one spade deep, and breaking the surface fine, then, either sowing the seed on the surface, and raking it in evenly and lightly; or first, raking the surface smooth, and then sowing the seed, sifting light earth over it to a quarter of an inch in thickness. When the weather is dry, gentle waterings, in the evening, are necessary, both before and after the plants appear; and if very hot, dry weather, it is adviseable to shade the bed moderately with mats in the heat of the day. The plants generally appear in a week or ten days. All the culture necessary afterwards, is occasional watering and weeding, until towards the latter end of September, when their leaves will be an inch or two broad; a quantity of the best plants should then be pricked out, in four feet wide beds of rich earth, in rows three or four inches distant, rejecting all crooked and black-shanked plants. As soon as they are planted, a moderate watering should be given, which, when dry weather prevails, should be moderately repeated. The plants must remain there till about the end of October, when they should be transplanted into their winter quarters, some being planted out under hand or bell glasses for the earliest crops; others

others into garden frames, to be occasionally protected by glasses till planted out in the spring.

The plants intended to be wintered in frames may also, occasionally, be pricked out from the seed bed at once into the frames to remain. For the plants to be cultivated under glasses, a proper bed of the richest mellow ground should be provided in the best defended and warmest part of the garden, in a free exposure to the full sun, being well dunged with the best rotten dung, such as that of old cucumber or melon beds, or any other of similar quality, spreading it equally over the ground at least three or four inches thick, and the whole then regularly trenched in one good spade deep, burying the dung equally, then forming the ground into beds a yard wide, with foot-wide alleys for the convenience of going in to raise, and set off and on the glasses, &c. The plants are then to be put in, allowing three to each glass, though the London gardeners often plant more; but two of the best are enough to be left to come to perfection. At the time of planting them, a quantity of the handsomest, straight, clear-stemmed plants should be chosen, which being ready, a line should be stretched along the middle of the beds, and at every yard distance, and three plants put in a triangle, six or seven inches apart; a little water being given afterwards, and the glasses put on, which should be kept close about ten or twelve days. When the plants have taken fresh root, prop them up on the sunny side, about three inches high, with forked sticks, pieces of brick-bat, or wooden pegs, fifteen inches long, three or four notches being made an inch or two above one another to receive the edge of the glass, sticking them in the ground. The glasses, by this means, may be readily propped higher or lower, or on any side as occasion may require. During winter the glasses should be kept almost constantly over the plants, only keeping them tilted on the props in mild weather, on the warmest side, for the admission of air; but in fine, mild, dry days they may be set quite off, which if the plants be forward in growth, should be practised at all opportunities, lest by too constant glassing they be drawn up to flower in their small winter growth, and be rendered useless. The glasses must always be put over the plants at night; and when cutting winds or frosty weather prevail, they should be kept as close down as possible, and long litter laid down close about the lower part of each glass, raising it higher as occasion may require.

In their spring culture, they must be thinned out, about the beginning or middle of March, to one stout plant or two at most under each glass, though in large bell-glasses the market gardeners frequently leave more, for the sake of having the advantage of the glasses, to bring as many as possible to early perfection. The others should be planted out into another place, as a piece of rich, well-dunged ground, the plants being raised with the point of a trowel, to preserve the fibres of the roots, being planted two feet and a half distant each way, water being given to settle the earth about them.

The plants under glasses should have the earth directly made good about them, and a little mould drawn up about their stems, continuing to cover them occasionally with the glasses, which must now be raised considerably on props, in proportion to the advanced growth of the plants, not omitting to let them have the benefit of the full air in mild days, and that of warm showers, by occasionally setting the glasses wholly off. But the glasses are to be continued occasionally over the plants until the middle or latter end of April, or longer, if it be necessary. When the plants are so far advanced that their leaves press against the glasses, they should be raised, by forming a border or ridge of earth round each

hole of plants, three or four inches high, on which ridge of mould the glasses should be set, continuing to prop up one edge occasionally as before, and according as the plants advance in growth, raising them on every side three or four inches in height; as the length of the days and warmth of the weather now increase, the plants grow freely, and require as much free air and scope to grow in as it is possible to allow them; at the same time being careful to continue to expose them occasionally to the full air in fine days and moderate warm showers, always carefully defending them in the nights, and in cold rains or boisterous weather, until the weather becomes warm, and the plants are grown too large for the glasses; then they should, by degrees, be fully exposed night and day, so that by the middle or latter end of April they may be wholly discontinued. At this period, if the weather be not hot and dry, moderate waterings will be of utility in promoting the progress of the plants, as well as increasing their size and strength. Towards the latter end of May some of the forwardest plants may probably shew flower, at which period they should be examined daily; and whenever a flower appears to be advanced in growth, turn down some of the inward leaves over the head, to screen it from the sun's rays, rain, and full air, in order to preserve it more white and close, as when fully exposed to the weather it generally changes the fine white colour to a yellowish hue, and occasions the head to open before it acquires perfection. The excellence of the cauliflower consists not only in size but in the whiteness, and compact curdy-like growth of the head; such as have a frothy, loose appearance being inferior in value. It is in its utmost perfection of growth when the outward parts of the head begin to open and expand, after which the whole soon divides and shoots up to flower and seed.

In gathering or cutting cauliflowers, the flower head should mostly be cut off with some inches of the stalk, together with most of the surrounding leaves, which should be trimmed down nearly equal to the circumference of the head, especially when for present use; but if required to keep a few days, and such as are intended for market, should have the full leaves to continue, and be trimmed off as wanted. As the stalks of these plants never produce sprouts as in those of the cabbage kind, they should be moved as soon as the head is cut.

In the culture of the plants for the main summer crop, which have been preserved in frames or other places during the winter, in order to be planted out in the spring, it is necessary to observe that the plants should, during the winter, be every day in mild, open, dry weather, exposed fully to the free air by showing the glasses entirely off, but they should always be drawn on again towards the evenings, and in excessive rains; though if this happen in the day, and the weather be mild, one end of the glasses may be raised on props three inches high, for the admission of plenty of fresh air, as the plants must not be kept too close in mild weather, as they would run up weakly and tender, or be forwarded too much in growth, and forced into small button-flowers. They only need protection from frost and immoderate rains while in the frames, their decayed leaves being picked off, and search made for slugs, which often attack the plants in frames and hand glasses. When the weather is very frosty, the glasses should always be kept close, to protect the plants; and, if very severe, the additional protection of covering them at night with dry, long litter or garden-mats, should be attended to, being laid round the outsides of the frames.

In open, mild weather, as the spring approaches, the plants should be inured by degrees to the full air, by taking the glasses off entirely every day, and gradually leaving them

fully exposed at night in the more advanced part of the spring, to larden them for their removal into the places where they are to remain. From the latter end of February to the beginning of April, according to the weather and condition of the plants, all those which have been wintered either in frames or other ways should be planted out where they are to remain. An open spot of the best ground should be chosen for this purpose, which should be previously dunged, and dug over, as directed for the early crop; the plants being put in by a line, two feet and a half distant every way, watering them at planting, and in dry, warm weather, repeating it two or three times, till they have taken fresh roots.

In planting this crop, it is sometimes the practice of market gardeners, who have occasion to make every advantage of their ground, to sow a thin crop of radish and spinach between the rows of cauliflower plants; but the practice is not much to be recommended. In May and June, when the plants have attained considerable growth, the ground should be well hoed, to cut down all weeds, drawing earth about the stems of the plants; and when the latter month proves very hot and dry, occasional waterings may be of great utility, bafons being formed round the plants for that purpose. In July this crop will be in full perfection, continuing in succession until the middle of August, when it will be succeeded by the late summer crop.

In order to the culture of the late summer crop, it is necessary to raise a proper supply of plants in spring, to be planted out in April or May, to arrive at perfection in August and September, in time to succeed the autumn rated crops. The seed for this crop may be sown any time in February, but not later than the first week in March; and, in order to forward the plants as much as possible, it is proper to sow the seed on a slender hot-bed, made for one light box eighteen or twenty inches in depth, of hot dung, covered with light, rich earth, four or five inches in thickness. The seed should be sown on the surface, and covered a quarter of an inch deep with fine mould; the glass being then put on occasionally, and light sprinklings of water given, raising the glass daily for the evaporation of the steam and admission of free air. The plants will rise in a few days, at which time admit the air freely, by tilting the glass, and by taking it wholly off in fine warm days, and when there are moderate showers. In dry weather, give frequent light waterings. When the plants have leaves an inch broad, prick them out; and if some of them are put upon another moderate hot-bed, it will forward them considerably. From the end of April to the middle of May, some of the forwardest plants may be fit to plant out, which should be in an open spot of rich, well-dunged ground, as in the former crops, and in dry weather they should have frequent waterings, till they have taken good root. The necessary culture afterwards is only occasional hoeing to destroy weeds; and when the plants are somewhat advanced in growth, drawing the earth about their root-stems.

In the culture of the Michaelmas crop, some seed must be sown about the middle of May, on a bed of common earth; and when the plants have leaves an inch or two broad, they should be pricked out three or four inches asunder, to remain until the middle or latter end of July, then planted out as in the other crops, supplying them occasionally with water till rooted. They begin to shew heads towards the end of October, which will continue a great part of December, or sometimes in mild weather till Christmas. But this crop depends greatly on the state of the autumn after Michaelmas, which, if moderately dry and warm, tolerably large, handsome cauliflowers are often

produced in November; but if wet and cold, the heads are mostly small, irregular, and ill-coloured.

*The method of culture in the broccoli kind.*

This is another supposed variety of the common cabbage, which has different sorts, that in their growth, habit, and eatable parts, much resemble the cauliflower, all of them forming roundish heads in the centre of their leaves, composed entirely of a compact collection of numerous buds or ends of advancing shoots.

They are annual-biennial plants, as they attain perfection in the same year, in the early sown crops; but in the later sowings, stand all the second season, when, after producing heads, they shoot up into stalk, ripen, seed, and wholly perish.

They are cultivated principally for autumn, winter, and spring use, these being the seasons of their production in the best perfection, being obtained in the different crops by a spring and summer sowing in March, April, and May; those of the former months generally furnishing heads in autumn and winter, and that of the latter principally after Christmas, and all the spring months, in which they are commonly rather superior to the foregoing in the production of larger and more perfect heads. They are so hardy as to resist the cold of an ordinary winter, though very severe frost often affects such as are weak, or grow in exposed cold soils, especially the sort called cauliflower broccoli. The chief sorts and varieties are the early-purple, which is a moderate growing darkish green plant, producing smallish purple heads, but earlier by a fortnight or more than the others; and of which there are the purple, the green, and the blue, often rising from seed of the same plants. This sort is proper for the first crop, which, if sown the latter end of March, or more generally in April, and a succession crop in May, and planted out in June and July, comes in for use from Michaelmas till Christmas; and when their heads are gathered, the stalks produce plenty of fine sprouts.

The late purple is a large robust-growing darkish green plant, producing a large purplish head like a cluster of buds, being generally much larger, and more perfectly headed than the former sorts, and very delicate eating; of this there are the common purple headed, the dwarf purple, the blue broccoli, the brown broccoli, the green broccoli, and the yellowish broccoli; all of which frequently rise from the same seed, though that of the true purple kind is superior both in size and perfectness of heading, as well as delicacy of eating; and with care in sowing the seed, the sorts may be continued. This and all its varieties, by sowing in April, May, and beginning of June, and planting out the plants in July and August, may be obtained for use from about Christmas until the beginning or middle of May, but they are always in the greatest perfection, in regard to size, in February, March, and April; and after the main head is cut, the stalks produce abundance of side shoots, or sprouts, terminated by small heads, which eat as sweet and tender as the principal ones. The white, or cauliflower broccoli, is a curious variety. The plants are of robust growth, and lightish green colour, each forming a close white head in the centre, sometimes as large as a middling cauliflower, and greatly resembling them in every state of growth, and for delicacy of eating, they are equal to the finest summer cauliflower. This sort admits of no varieties, except in degrees of whiteness, though the whitest generally assumes somewhat of a yellowish hue. By sowing the seed in March, April, or May, and planting out the plants in June, July, and August, may be obtained heads for use all winter and spring; but those that appear about March, and beginning or middle of

April, are considerably the largest and fairest heads. The black broccoli is a tall growing plant, of a blackish green colour, which for the most part produces smaller and less perfect heads, being somewhat open and seedy like, but possesses the property of being so hardy as seldom to be injured by the severest frosts. There are of this black or dark-headed, the brown and the blue, all sometimes from the same seeds. They are proper for cultivation to stand the winter by way of reserve to serve for spring use, sowing the seed early in May, and planting out the plants in June, and beginning of the following month. All the different sorts or varieties are raised from seed sown in the open ground. The principal season for sowing the main crops of all the varieties, is March and April for the autumn and winter productions, and May and the beginning of June for the principal successive crops to come in for the spring supplies. Some may be occasionally sown so early as February, or beginning of March, of the cauliflower broccoli, as also any of the purple kinds, in order to obtain an earlier autumn production of small heads in the latter end of August, or beginning of September, and beginning of October. The seed should be sown in an open exposure, where the plants rise much stronger than on narrow borders under walls. Each sort should be sown separately, moderately thick on the surface, and raked in lightly; the plants appear in ten or twelve days, occasional waterings being given them in dry weather; and when the plants have leaves an inch or two broad, it is proper to prick them out in a nursery bed three or four inches apart, giving them water as soon as planted, and occasionally till they have taken root, in which bed let them remain a month or six weeks, where they may acquire due strength; by this means they are short, and of robust growth, and will be considerably better prepared for transplanting where they are to stand, than those which remain in the seed bed. The time of transplanting them where they are to remain, is June, July and August, and beginning of September, according to the time they were sown, or are desired for use. The plants should have an open situation, and as good ground as the garden affords; which, if it have the addition of dung, will be advantageous, digging it in neatly one good spade deep, and directly putting in the plants, for which work a moist time is beneficial. They are to be planted in rows two feet and a half asunder, and two feet distant in the lines; but for those that are planted late in August and September, two feet at most are sufficient, and eighteen inches distant in the row. As soon as planted, they should be watered; and if dry weather prevail, the watering should be repeated every other day, till the plants have got root. After the plants have taken root, their further culture is to keep them clear from weeds, by hoeing the ground occasionally; and when they have advanced a little in growth, to draw some earth, or hoe about their stems, which, if repeated once or twice, will be of great advantage in promoting their growth. In gathering broccoli for use, attention must be had that the heads have attained their full growth, but they should be cut while they remain close, and before they begin to divide, and assume a seedy-like appearance, and with about six inches of the main stalk to each head, as the upper part of the stalks eats exceedingly sweet and tender, but, previously to its being dressed, it must be peeled, or divested of the outer rind.

*Saving seed in all the sorts.* In order to have good and perfect seed of any of the above sorts of plants, some of the best of each kind should be selected, and left to run up to seed. In the cabbage sort, this is effected either after their heads have been cut, or by letting them remain without being cut. In the first way the stems which have the

strongest shoots may be left to seed where they stand, or be planted up to the necks in good earth in an open sunny exposure in the autumn, or beginning of winter; and in the latter, the same methods may be pursued. And when the plants have seeded, great attention should be bestowed to support them well with sticks till the seed is perfectly ripened, which is generally the case about the end of July, or in the following month.

Where seed of the different varieties is wanted, the plants for this purpose of the different sorts should be cultivated at as great distances as possible from each other, in order to continue them perfect without degenerating.

When the seed begins to ripen, it should be gradually collected by cutting off the ripened stems, to prevent the birds from devouring it. These, after they have been exposed a little to the sun, may be threshed to get out the seed, which sufficiently dried, should be put up in bags, and marked.

In the cauliflower kinds, some of the best and most perfect plants of the earliest crop should be left to run up to seed in the situations where they stand, being supported as in the cabbage sort, and occasional waterings given when the season is dry, to prevent the mildew. The seed should be collected and managed in the same manner as above. It is mostly in a state to be gathered about September. Fresh seed should be gathered annually, as it cannot be depended upon when old.

In the broccoli kinds, the best plants of the early spring crops must be selected, and left to stand with their heads perfect, the side shoots being only taken off. The seedling plants of the different varieties should be at considerable distances from each other.

*Method of culture in the turnip kind.* All the varieties of the turnip are annual-biennial; as if sown early in spring they attain perfection, run up to flower, ripen seed, and totally perish the same year; and when sown in summer and autumn, they also attain perfection the same seasons, and stand without running to stalk till next spring; then wholly run up for seed, and finally terminate their growth in the autumn following.

The sorts chiefly cultivated are the early Dutch turnip, which is an orbicular, moderate-sized, handsome, white turnip, coming early to perfection, very sweet and tender when young, and a very fine garden turnip for the early and summer crops; though when it is old, it is apt to become stringy.

The early white stone turnip is a round, moderate-sized, neat, white turnip, that comes in early, and is very good in its young and middle growth. It is very proper for garden use as an early and first general crop. Of this sort there are the large later turnip, and the early red stone turnip.

The white round turnip is globular and large, being proper for the garden and the field, to succeed the two former sorts.

The green topped turnip is large, round, and remarkable for having its outer coat green at top, and a great part of the root growing above ground. It is excellent for a general crop in gardens, to draw for the table when of middling growth; and also valuable in the field.

The red topped turnip is large, and of a globular form, having its outer skin red at top. From its very large size, it is also adapted to field culture.

The yellow Dutch turnip is moderately large, and frequently oblong, the skin and flesh being of a yellow colour.

The oblong white turnip is largish, and strikes considerably into the ground.

The tankard turnip is large, oblong, and cylindrical, of quick growth, the root generally standing above ground. It is a good field turnip, but not proper for the garden.

The large Norfolk turnip is large and round, but mostly cultivated in fields.

The hardy Russian turnip is middle sized, dark coloured, very hardy, and continues long in spring without running. It is proper for sowing as a moderate garden crop for winter and spring.

The long rooted French turnip is long, small, and spindly rooted, but of little merit. The purple turnip is roundish, small, early, and purple coloured, but grown mostly for curiosity. In general use the early Dutch turnip is the best for the early and first general summer crops, as it generally arrives to perfection a fortnight, at least, sooner than most of the other sorts; and, by an early sowing in spring, may be obtained by the beginning of May. Next to this is the early stone turnip for an early and first general summer crop, and the common round white turnip to sow for a main summer crop, all of which may be continued in perfection the whole summer and autumn, by performing three or four different sowings from March until July, so as to have crops regularly succeeding one another.

For the autumn and winter crops the white round, the green topped, and the red topped kinds, are the hardiest. From their magnitude they are to be preferred to all others for field culture.

These roots may be obtained for use eight or ten months in the year, as from about the middle of May till the beginning or middle of March; after which time they begin to shoot into stalk for seed.

The method of propagation in all these sorts, is by sowing the seed in situations where the plants are to remain, as they do not admit of being transplanted with success. The common season for sowing is any time from the beginning of March, until the latter end of July; but to have a long and regular succession, it is necessary to make four or five different sowings at proper intervals, from the latter end of February till the middle of August. The most proper soils for the culture of this root are those of the more light and mellow kinds; as on strong land the roots frequently acquire a stringy texture, and rankness of taste. In garden culture, the necessary space of ground to sow at a time, for the supply of a family, is from about two to six, eight or ten rods, according to circumstances; the proper quantity of seed for each sowing may be from one to two or three ounces; but for large field crops, the common allowance is about two pounds to an acre. The ground should be prepared for the seed by digging it well over, one spade deep, and breaking it as fine as possible on the surface, the seed being sown while the ground is fresh stirred, especially when there is hot or dry weather. A moist season for sowing is of great importance. In this culture the seed is mostly sown broad cast, scattering it moderately thin, with a regular cast and evenly spreading hand, afterwards raking it evenly in. It is of much advantage, when the weather is hot, to keep the seed a few hours in water before it is sown, as by that means it germinates more quickly, and there is less danger of the plants being destroyed by the fly. See FLY and TURNIP.

In the after-culture of the turnip, all that is requisite is, when the plants have two or three leaves, or are about a month old, to thin them out to six, eight, ten or twelve inches distance, and clear them from weeds, which is most effectually done by the hoe, and is best performed in dry weather. At the same time the weeds should be removed,

and the surface earth well stirred, as this will prove highly beneficial to the growth of the crops. The very earliest crops need not be thinned to more than five or six inches distance, especially if it is intended to begin drawing the roots as soon as they begin to turnip. In three or four weeks after hoeing, the plants will mostly begin to turnip; and in five or six weeks some may be fit to draw for use. In the markets these roots are exposed clean washed, and neatly bunched up, in number from twelve to fifteen or eighteen, according to their size in each bunch, and disposed of to the retailers by the dozen of bunches.

The field culture of these plants, and their different applications in the feeding and supporting different sorts of live stock, will be given hereafter. See TURNIP.

*Saving seed.* To obtain good seed, some of the best roots of the autumn and winter crops must be left to run up to stems, which mostly produce ripe seed about July, or the following month. It should be collected and managed in the same manner as in the cabbage sorts. And in order to obtain seed of the different varieties as perfect as possible, the plants of such varieties should be at considerable distances from each other.

BRASSICA *Brassiliana*, C. Bauh. Pinax. See ARUM *esculentum*.

BRASSICA *Marina*, J. Bauh. &c. See CONVULVULUS *Soldanella*.

BRASSICA *Maritima*, C. Bauh. Pin. See CRAMBE *maritima*.

BRASSICA *Monensis*, Hudson and Withering. See SYMBRIUM *monense*.

BRASSICA *Muralis*, Hudson and Withering. See SYMBRIUM *tenuifolium*.

BRASSICA *Spinosa*, C. Bauh. Pin. See BUNIAS *Spinosa*.

BRASSICA *Sylvestris*, Boccone. See ARAEIS *Turrita*. C. Bauh. Pinax. See TURRITIS *Glabra*.

BRASSICÆ, in *Entomology*, a species of CHRYSOMELA, that inhabits Germany. The prevailing colour is deep black; wing-cases pale, testaceous with all the margin, and a band in the middle black. Fabricius, &c.

BRASSICÆ, a species of STAPHYLINUS, of a ferruginous colour; head and body black; wing-cases punctated; antennæ very thick and hairy. Scopoli. Found on the cabbage in Europe.

BRASSICÆ, a species of PHALÆNA (*noctua*), the wings of which are clouded with cinereous; a black hook connected with the first spot. Linn. Fabr. &c.

BRASSICÆ, the species of APHIS, that infests the common cabbage. Linn. Fabr.

Obs. It is *Pediculus brassicæ* of Frisch.

BRASSICARIA, a South American species of PHALÆNA, of the *noctua* section; the wings of which are indented, variegated, and marked with a common gold testaceous spot; posterior wings white.

BRASSICARIA, an insect of the genus MUSCA, the colour of which is black: abdomen cylindrical; second and third segment rufous. Fabr.

This is *Musca cylindrica* of Degeer. A variety of this species is mentioned by Fabricius, which has the abdomen ferruginous, with a black dorsal line at the base. Donov. Brit. Inf. &c.

BRASSIDELIC ART, a term used by Paracelsus, to denote a method of curing wounds by the application of the herb *brassidella*, or *opbioglossum*, on the fresh wound.

BRASSIOLIS, in *Entomology*, a species of PAPILIO (*Heliconius*), that inhabits Surinam. The wings are fuscous; anterior ones spotted with yellow; posterior pair radiated beneath

beneath with sanguinous. Fabr. *Papilio bellona* of Cramer. Inhabits Surinam.

BRATENBRUNN, SZELES-KUT, in *Geography*, a walled and well-inhabited town of Hungary, in the circle below the Danube, and district of Odenburg, under the jurisdiction of the Esterhazy family.

BRATHYS, in *Botany* (*Brathys*, or *Βραθυσ*, the name of a plant in Dioscorides), a genus instituted by Linnæus the son for a plant found by Mutis in New Granada, and taken up from him by Schreber (937), Jussieu (254), and Mr. Martyn, but referred by Dr. Smith (Plant. icon. 41.) to the genus *hypericum*, in which he has been followed by La Marck, Bosc, and Willdenow. See *HYPERICUM Brathys*.

BRATSKOI, in *Geography*, a town of Siberia, in the province of Irkutsk, and the circle of Ilimsk, on the river Angura; 140 miles N.E. of Nishnie-Udinsk.

BRATSKOW, or BAKOW, a town of European Turkey, in Walachia, situate in a fertile and pleasant country, and the residence of a Roman catholic bishop.

BRATTELEN, a plain of Switzerland, near Basle, where, in the year 1444, 1500 Swiss withstood the whole army of France, consisting of 30,000, till they were all cut to pieces, except 16 who escaped, and 30 who were found alive on the field of battle. See *BASLE*.

BRATTLEBOROUGH, a considerable township, and post town of America, in Windham county, Vermont; having 1589 inhabitants, seated on the west bank of Connecticut river, about 28 miles E. of Bennington, 61 N. of Springfield in Massachusetts, and 311 from Philadelphia. N. lat. 42° 52'.

BRAVA, one of the Cape de Verde islands, on the coast of Africa, the land of which is high and mountainous, producing, however, oranges and lemons in great abundance, and furnishing excellent wine. The inhabitants are somewhat more than 500, and they cultivate maize, gourds, figs, water-melons, and potatoes; they also breed horses, cows, asses, goats, and hogs. This island yields a considerable quantity of saltpetre, and the mountains are supposed to be rich in metallic ore, especially copper, as there are several vitriolic springs. The coast abounds with fish. The circuit of the island is about 4 leagues; and it is about the same distance W.S.W. from Fuego. We learn from sir George Staunton's account (Embassy to China, vol. i. p. 136.) that this island is a better and safer place for ships to be supplied with water and provisions than the island of St. Jago, as it has three harbours, one called Puerto Furno on the east side, from which vessels must warp, or be towed out by boats; the Puerto Fajendago to the west; and the Puerto Ferreo to the south, which is the best for large ships, and into which runs a small river. N. lat. 14° 54'. W. long. 24° 45'.

BRAVA, a sea-port town of Africa, on the coast of Zanguebar, being the capital of a small republic or aristocracy, founded within the kingdom of Magadoxo, and at its southern limit, by seven Arabian brethren, who fled hither from the tyranny of their king Lacab, one of the petty monarchs of Arabia Felix. Here they found a convenient and delightful situation, bounded on each side by a river, whence some have assumed it to be an island. This district does not extend far from the coast, as it chiefly depends on the commerce of the capital, which is situated on a bay, formed by the mouth of the northern branch of the river, about the distance of somewhat less than one degree from the equator. Brava, which is now a small town, was once large and populous, and carried on a considerable trade in gold, silver, silk, cotton, and other cloths, elephants' teeth, gums, and other drugs, particularly ambergrise, with which this coast abounds.

The houses were large and well-built, in the Morecco style; and the town was strong and fortified, and accounted one of the most celebrated and frequented marts on the Habeshan coast. The people were mostly Mahometans, but under the protection of the kings of Portugal, to whom they annually paid a small tribute. This payment, however, they refused; upon which Trilbran de Cugna, admiral of the Portuguese fleet, bound for India, having set on shore at Melinda three ambassadors sent by king Emanuel to the emperor of Abyssinia, proceeded to Brava, situate about 200 leagues northward of Melinda; and, after some previous negotiations, assaulted the city. After a severe conflict between the besiegers and the garrison, consisting of 4000 men, the latter retreated into the city, and shut the gates against the enemy. The siege was prosecuted, and the city was at length taken and plundered of a large and valuable booty. Many of the besieged were slain and wounded, and many taken prisoners; but most of them were released. The Portuguese, on this occasion, perpetrated many atrocious acts of cruelty; and Cugna, having plundered the city, set it on fire, and it was quickly reduced to ashes. After this Brava became tributary to its destroyers; but it was never able to recover its pristine grandeur and liberties. Brava appears to have been the Essina of Ptolemy, which was only 1 degree from the line. N. lat. 0° 45'. E. long. 44°.

BRAVA *Pavina*. See *PEREIRA Brava*.

BRAUBACH, in *Geography*, a town of Germany, in a prefecture of the same name, in the circle of the Upper Rhine, and principality of Hesse-Darmstadt, seated on the Rhine opposite to Rees; 10 miles W. of Nassau, and 18 N.W. of Mentz. Near this place is a very valuable salmon-fishery.

BRAVINIO, in *Ancient Geography*, a town of Britain, in the twelfth route of Antonine's Itinerary; supposed to be Ludlow.

BRAULIO, in *Geography*. See *BRALIO*.

BRAULS, in *Commerce*, Indian cloths with blue and white stripes; otherwise called "turbants," because they serve to cover those ornaments of the head, particularly on the coast of Africa.

BRAUN, GEORGE, in *Biography*, Lat. *Braunius*, archdeacon of Dortmund, and dean of Notre Dame in gradibus at Cologne, lived to the beginning of the 17th century, and published a "Latin oration against the fornicating priests," 1566; the "Life of Jesus Christ," and that of the "Holy Virgin," and "A Controversial Treatise against the Protestants," printed at Cologne in 1605, 8vo.; but his chief work is the "Theatrum Urbium," comprised in several folio volumes. Gen. Dict.

BRAUNAU, in *Geography*, a town of Bohemia, in the circle of Koniggratz, belonging to the abbey of Benedictines of the place.

BRAUNAW, a fortified town of Germany, in the circle and duchy of Bavaria, seated on the river Inn. It was formerly the residence of the elector palatine of Bavaria; but ceded to the house of Austria by the treaty of Teschen in 1779; 8 leagues S.W. of Passau. N. lat. 48° 10'. E. long. 13° 3'.

BRAUNECK, or BRAUNEGG, a town of Germany, in the Tyrol, and bishopric of Brixen; 16 miles N.E. of Brixen.

BRAUNER-GEYER, in *Ornithology*, Cramer's name of the Austrian kite, *falco austriacus*.

BRAUNER-MALDERGEYER of Cramer, is the black kite, *falco nax*.

BRAUNFELS, in *Geography*, a town of Germany, in the circle of the Upper Rhine, belonging to the count

Solms, with a castle fortified in the ancient manner; five miles east of Wetzlar.

**BRAUNSBURG**, a town of Prussia, in the bishopric of Ermland, seated on the Passarge, which, at a little distance, discharges itself into the bay called Fische-baf. It was built in the year 1275, and derives its name from Bruno, bishop of Prague. In 1461, the inhabitants expelled the Polish garrison, and afforded an asylum to the bishop of Ermland, who had declared for the knights of the Teutonic order. It was formerly one of the Prussian great cities, and sent representatives to the senate or council of state; but it is now under the jurisdiction of the bishop. It is large and populous, and carries on a good trade. Braunsberg is divided into the Old and New Town; 32 miles S.W. of Konigsberg. N. lat. 54° 20'. E. long. 20° 7'.

**BRAUNSBURG**, a town of Germany, in the circle of Westphalia, and county of Wied Runkel; 4 miles N.E. of New Wied.

**BRAUNSDORF**, a town of Germany, in the circle of Upper Saxony, and circle of Erzgebirg; 11 miles N.E. of Freyberg.—Also, a town of Germany, in the archduchy of Austria; 6 miles E. of Meillau.

**BRAUNSELFFEN**, a town of Moravia, in the circle of Olmutz, 16 miles N.N.E. of Olmutz.

**BRAUNSWIG**, a town of Germany, in the circle of Lower Saxony, and duchy of Holstein, serving as a faux-bourg to Kiel, and one mile north from it.

**BRAVO**, JOHN, in *Biography*, a native of Castile, practised medicine at Salamanca, the latter part of the 16th century, with distinguished reputation; he was also professor in medicine there, and much resorted to and esteemed by his pupils. His works are “De hydrophobis natura, causis, atque medela,” Salam. 1571, 8vo.; “De saporum et odorum differentiis, et causis,” 1583, 8vo.; “De curandi ratione per medicamentis purgantibus exhibitionem,” 1588, 8vo.; “De simplicium medicamentorum delectu,” 1592, 8vo. He also published, agreeably to the fashion of the times, commentaries on the works of Galen and Hippocrates.

**BRAVO**, JOHN, professor of medicine and surgery, in the university of Coimbra, in Portugal, published in 1605 “De medendis corporis malis per manuales operationem,” 12mo.; “De capitis vulneribus,” fol. 1610. He died in 1615.

**BRAVO**, GASPARD, of Aguilar del Campo, in Old Castile, physician to Philip IV. and to the Inquisition, took his degree of doctor in medicine at Valladolid, where he taught medicine and surgery the middle of the 17th century; and was author of “Resolutio medicarum circa universam totius philosophiæ doctrinam,” 1649, Lugduni, fol.; “Consultationes medicæ, et tyrocinium practicum,” Coloniae, 1671, 4to.; “Operum medicinalium, tomus tertius,” Lugduni, 1674, fol. The author treats in these volumes of the physiology and the pathology of fever; of the effects of bleeding, purging, and of sudorifics; of the use of the Peruvian bark, lately introduced into practice, which he commends: and, among his consultations, he gives an account of the disease and death of Philip IV. of Spain. Haller. Bib. Med.

**BRAVO RIO**, called also *Del Norte*, or of the northern star, the principal river of Spanish North America, which, as far as its sources can be conjectured, has a course of about 1000 British miles; but its whole circuit probably exceeds that of the Danube. It discharges itself into the gulf of Mexico. N. lat. 25° 40'. E. long. 97° 30'.

**BRAVO!** Ital. a word which needs no explanation. It is an Italian exclamation of applause, which all Europe has adopted.

If, in a theatre, the Italians approve a musical composition, and dislike the singer, though they hiss the performer,

they afterwards cry out *bravo pure il maestro*; and on the contrary, when they hiss the composer, immediately after they discriminate, if the singer is a favourite, and exclaim *bravo Marchese*, or *brava la Banti*; and if a composer is a plagiarist from the well-known works of a favourite author, the critics cry out *bravo Pasello!* or *bravo Cimarosa!*

**BRAURONIA**, in *Antiquity*, a feast held every fifth year in honour of Diana, surnamed *Brauronia* from *Brauron*, a village near Athens, where the famous statue of that goddess, brought from Scythia Taurica, was preserved till it was taken away by Xeixes.

The ceremony of the Brauronia was managed by ten men, from their office called *ἱερόποιαι*; the victim offered was a goat, and it was customary for certain men to sing one of Homer's Iliads during the service; other ministers at the solemnity were young virgins, from five to ten years of age, habited in yellow, and consecrated to Diana, under the denomination of *ἄρκτοι*, i. e. bears, which they derived from this circumstance. A bear, having become tame and tractable, was admitted to eat and play with the Phlenidæ, the inhabitants of a borough in Attica; but a young maid being too familiar with it, the bear tore her to pieces, and was afterwards killed by the brethren of the damsel. Hence a fatal pestilence ensued, for slaying which an oracle advised them, in order to appease the anger of Diana, occasioned by the destruction of the bear, to consecrate virgins to her in memory of it. The Athenians obeyed the mandate of the oracle, and enacted a law, that no virgin should be married till she had undergone this ceremony. Potter. Arch. Græc. lib. ii. cap. 20.

**BRAVUM**, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the Tarragonensis, in the country of the Murboges.

**BRAVURA**, Ital. is a musical term, as *Aria di Bravura*, implies a style of air, with which in modern times Miss Davies *Ingleterica*, the Gabriel, the Agujari, Madame Le Brun, Madame Mara, and Mrs. Billington, have made us perfectly acquainted. M. Ginguiné, in the Encycl. Meth. has described and apologized for *execution*, with much taste and feeling. “We admire (says he) the warbling of birds, in tones which we cannot appreciate or understand; the nightingale, blackbird, thrush, canary bird, and lark, charm us with their divisions; the measured intervals and varied melodies exquisitely performed by sweet and flexible voices, supported and enriched by harmony, may afford a delight of a superior kind, in human tones, which can insinuate themselves into the inmost recesses of the heart, to which words can never penetrate, however impassioned, or tuned by numbers.”

**BRAUWEILER**, in *Geography*, a prefecture and abbey of Germany, in the circle of the Lower Rhine, and electorate of Cologne; 7 miles W.N.W. of Cologne.

**BRAUWER**, or **BROUWER**, ADRIAN, in *Biography*, a Flemish painter of great eminence, was born of obscure parents at Oudenarde, as some say, or, according to Houbraken, at Haerlem, in 1608, and obtained instruction in his art from Francis Hals for the profit of his labour. In this situation he manifested such superior powers, that Hals employed him in a garret apart from his other scholars, assigning to him hard labour and a scanty diet, and selling his performances for high prices. From this state of close confinement and harsh treatment he eloped, and went to Amsterdam, where his works were known and esteemed. Having become master of 100 ducatoons, which he received for a single piece, he became frantic with joy, and spent it at a tavern in ten days. From this time his usual abode was a public house; and he worked only when he was urged to

it by necessity. As soon as he had finished any piece, he offered it for sale; and if it did not produce a stipulated price, he burnt it, and began another with greater care. Possessing a vein of low humour, and engaging, both sober and drunk, in many droll adventures, he removed from Amsterdam to Antwerp, where he was arrested as a spy, and committed to prison. This circumstance introduced him to an acquaintance with the duke d'Arenberg, who, having observed his genius, by some slight sketches drawn with black lead while in custody, requested Rubens to furnish him with materials for painting. Brouwer chose for his subject a group of soldiers playing at cards in a corner of the prison; and when the picture was finished, the duke himself was astonished, and Rubens, when he saw it, immediately pronounced that it was the performance of Brouwer, and offered for it the sum of 600 guilders. The duke, however, retained it, and gave the painter a much larger sum. Upon this, Rubens procured his release, and received him into his own house; but, uninfluenced by gratitude to his benefactor, he stole away, and returned to the scenes of low debauch, to which he had been formerly accustomed. Being reduced to the necessity of flying from justice, he took refuge in France; and, having wandered through several towns, he was at length constrained by indigence to return to Antwerp, where he was taken ill, and obliged to seek relief in a hospital; and in this asylum of self-procured poverty and distress he died in his 32d year. Rubens lamented his death, and procured for him an honourable interment in the church of the Carmelites.

Such were the talents of Brauer, that, in the course of a dissipated life, he attained to distinguished excellence in the style of painting which he adopted. His subjects were taken from low life, and copied after nature; such as droll conversations, feasts, taverns, drunken quarrels, boors playing and disputing at cards, or surgeons dressing the wounded. His expression, however, is so lively and characteristic; the management of his colours so surprizing; and truth was united with exquisite high finishing, correctness of drawing, and wonderful transparence, to such a degree, that his paintings are more valuable, and afford higher prices, than many works of the most eminent masters. Some of his best works are found at Duffeldorp. His drawings are dispersed in the various cabinets of Europe. Several of his designs have been engraved; and we have some few etchings by himself of subjects usually represented in his pictures, which are signed with the initials of his name, H. B.; Adrian being spelled with an H. Pilkington. Strutt.

**BRAUX**, in *Geography*, a town of France, in the department of the Ardennes; 5 miles N. of Charleville.

**BRAWALLA**. See **BROWALLA**.

**BRAWN**, in the *Culinary Art*, signifies the flesh of a boar, boned, rolled up, or collared, boiled, and lastly pickled, for the winter's use.

The method of preparing it is as follows:—After the flesh has been sprinkled with salt, and the blood drained off, it is to be salted a little, and rolled up as hard as possible. In this state, it is to be boiled in a copper or large kettle till it is so tender as to admit of a straw's being run through it; and then set by thoroughly to cool. When it is cold, it is to be put into a pickle, prepared by adding to every gallon of water a handful or two of salt, and as much bran of wheat; boiling these ingredients together, and then draining the bran as clear as possible from the liquor. When the liquor is quite cold, the brawn is to be put into it.

Brawn is made only of the slices, without the legs; the oldest boars are chosen for this use; it being a rule, the older the boar, the more horny the brawn.

There is also brawn of pig, which is made by scalding, drawing, and boning the beast whole, except the head; then cutting it in two collars, soaking it in brine, seasoning, rolling, putting it into a cloth, binding it up, boiling it, and when boiled, hooping it up in a frame.

**BRAXEY**, in *Veterinary Science*, a disease of sheep, which is distributed into the dry, collic, and watery braxey. The dry braxey seems to be cold and inflammation in the bowels, owing to the taking in with the food some hoarfrost, or to a change in the blood arising from the removal of the animals from a poor to a rich keep. The collic braxey is merely the colic, from obstructed intestines. The watery braxey is supposed to be the "red water," as it arises from the usual cause, and is attended with the similar symptom of suppression of urine. In this latter case, instead of using turpentine and other strong diuretics, the surest and safest course is to puncture the bladder, without wounding the guts, and thus to draw off the urine, afterwards covering and healing the wound.

**BRAY**, SIR REGINALD, in *Biography*, an English politician and ingenious architect of the 15th century, was the second son of sir Richard Bray, one of the privy council to king Henry VI., and descended from an ancient family, who accompanied William the conqueror into England, and flourished in the counties of Northampton and Warwick. In the first year of Richard III., Reginald obtained a general pardon, probably, on account of the part he had taken from personal and hereditary attachment to Henry VI.; and he was recommended as a person of sober and prudent policy, to those who favoured the advancement of the earl of Richmond, afterwards king Henry VII., to the throne. In the service of this prince, both before and after his accession, he was steady and active; and his zeal was recompensed by a variety of honourable appointments. He was made a knight banneret, probably at the battle of Bosworth, a knight of the bath at the king's coronation, and afterwards a knight of the garter. He was also constable of the castle of Oakham in Rutlandshire, joint chief justice with lord Fitzwalter of all the forests south of Trent, high treasurer, chancellor of the duchy of Lancaster, high steward of the university of Oxford, and a member of the privy council. In the 16th year of the king's reign, he had a grant for life of the isle of Wight at the annual rent (says Camden) of 300 marks. He received many other marks of the royal bounty and favour; and died August the 5th 1503, possessed of a very great estate; and his remains were interred in the chapel at Windsor. Notwithstanding the wealth he acquired, and the activity with which he officiated as minister during 17 years, under a sovereign, who was suspicious in his temper, and extorted large sums of money from his subjects, historians concur in giving him an excellent character. They represent him as the father of his country, a sage and grave person, a fervent lover of justice, and one who would often admonish the king when he did any thing contrary to justice or equity. His piety and charity were also conspicuous in the usual exercises of the times, in which he lived.

Of his skill in architecture, he gave sufficient evidence, in building the chapel of Henry VII. in Westminster abbey, which was conducted under his direction, and in completing the chapel of St. George at Windsor, to which he was a liberal benefactor. As he died without issue, he bequeathed the bulk of his fortune to Edmund, the eldest son of his younger brother John, who was summoned to parliament in 1530, as baron of Eaton Bray; and he also left considerable estates to Edward and Reginald, younger brothers of Edmund. From Edward, the manor of Shire Vachery

and Cranley in Surry, which was given to sir Reginald upon the execution and attainder of lord Audley, descended to the Rev. Geo. Bray, who possessed it in 1778. Reginald settled at Barrington in Gloucestershire, where the male line of that branch became extinct, about fifty years ago. Biog. Brit.

BRAY, THOMAS, a learned and pious divine of the 17th century, was born at Marton in Shropshire in 1656, and after finishing his school education at Oswestry, was admitted into Hart hall, in the university of Oxford, where he made considerable proficiency in those studies, which were adapted to the ecclesiastical profession, for which he was intended. Being under a necessity of leaving Oxford, on account of his circumstances, soon after he had commenced bachelor of arts, he entered into holy orders; and by his assiduity in discharging the duties of his profession, as well as by his exemplary behaviour, he obtained the patronage of lord Digby, who presented him to the living of Over-Whitacre in the county of Warwick, generously augmented for his sake, by the addition of the great tithes, and in 1692, to the rectory of Sheldon, which he retained till within a quarter of a year of his death. In 1693, he took his degree of master of arts in Hart-hall, Oxford. At Sheldon, he composed his "Catechetical lectures," published in 1696, which were not only well received by the public, but the means of recommending him to Dr. Compton, bishop of London, who fixed upon him as a proper person for modelling the infant church of Maryland in America, and establishing it upon a solid foundation. In 1696, he was appointed commissary for this purpose, with a salary of 400*l.* per annum. Determined on active and useful service, whatever present sacrifices might attend it, he intimated his readiness to accept the office, on condition of being encouraged and aided in providing parochial libraries for the ministers who were to be sent to the churches of this colony. This scheme of parochial libraries he extended to all the colonies and plantations in America and the West Indies, and also to the factories in Africa; and he connected with it another design, which was that of establishing lending-libraries in every deanery throughout England and Wales, out of which the neighbouring clergy might borrow books; and where they might have an opportunity of consulting them, with regard to all matters that pertained to literature in general, and to their own office in particular. The plan became popular, and many libraries were founded, both at home and abroad. With a view of promoting the utility of these libraries, and of directing the missionaries in the prosecution of their theological studies, Mr. Bray published two books, one entitled, "*Bibliotheca parochialis, &c.*" and the other, "*Apostolic charity,*" a discourse upon Daniel xii. 3. preached at St. Paul's at the ordination of some protestant missionaries, intended for the plantations; to which is prefixed, "*A general view of the English colonies in America, &c.*" About this time, viz. in 1696, Mr. Bray took the degree of doctor in divinity, though his circumstances would hardly allow of the expence attending it; thinking that this title and honour would give authority to his advice, and serve to promote the benevolent purposes which he wished to accomplish. In 1698, he made some unsuccessful exertions in order to procure a public fund for the propagation of the gospel in foreign parts; but failing in his main design, his efforts were availed for the purpose of forming a voluntary society, which was afterwards incorporated by royal charter. See SOCIETY. Ever since his appointment to the office of commissary for Maryland, he had received no emolument from it; but he had expended his time and money in promoting those important objects, to which he was zealously devoted; and,

therefore, some of his friends endeavoured to dissuade him from prosecuting his design of going abroad, and to accept of two valuable preferments which were offered to him at home, which were those of sub-almoner and the donative of Aldgate in London. But persisting in his purpose, and finding that his presence was necessary, he set sail for Maryland in 1699, and arrived thither in March of the following year. He immediately applied to the object of his mission, visited the province, and took measures for the re-establishment of the church, which had been for some time in a very unsettled state. Having obtained a bill from the assembly for this purpose, he came over to England to solicit the royal assent; and, notwithstanding the objections that were urged by those who were to be thus compelled to contribute towards the maintenance of a clergy, from whose services they were to derive no benefit, he succeeded in procuring a law, framed according to his wishes. Dr. Bray, after his return in 1701, published his "Circular letters to the clergy of Maryland." In 1706, he accepted the donative of Aldgate, which was again offered to him; and, in 1712, he published his "Martyrology, or papal usurpation," fol.; a work consisting of extracts from the treatises of celebrated authors, arranged and digested into a kind of regular history. He had provided materials for a second volume; but being obliged to lay aside the prosecution of his design, his martyrological memoirs, both printed and MS. were bequeathed by his will to Sion college. Such was the zeal of Dr. Bray for the conversion of the negroes in the West Indies, that he took a voyage to Holland to solicit king William's encouragement of the design; and on this occasion, he was introduced at the Hague to an acquaintance with a M. d'Allone, whom he interested in the execution of his object, to such a degree, that he left a considerable legacy towards its completion. Dr. Bray, having met with great success in his establishment of parochial libraries, devoted much time to this business; and for the purpose of impressing the minds of those who are designed for the ministry, with a due sense of the importance of Christian knowledge, he reprinted the excellent treatise of Erasmus, entitled "*Ecclesiastes.*" In 1727, he made a casual visit to Whitechapel prison; and so much was he affected by the contemplation of the wretched state of those who were confined in it, that he exerted himself in procuring contributions for their relief, and that of other prisoners; and he represented their deplorable condition with such effect, as to induce the house of commons to institute inquiries, which were very important and beneficial. To the suggestions and exertions of Dr. Bray, always directed by a pious and benevolent spirit, many charitable institutions in the metropolis and in other places were much indebted; particularly the society for the reformation of manners, that for founding charity schools, and that for the relief of poor profelytes. Having entrusted the accomplishment of his various charitable and public spirited plans to proper managers, this good man, happy in the review of a life, that had been devoted to important and useful purposes, and animated by a well founded hope, with regard to futurity, closed his course of service, February the 15th 1730, in the 73d year of his age. Mr. Whitton bears honourable testimony to Dr. Bray, of whom he says, "that he esteemed him, though not as one of the greatest abilities, as by far the most useful clergyman, and the most indefatigable promoter of religion, and of the pious designs and societies which conduce to it, he ever knew; that he always honoured and assisted him, both in the review of his catechetical lectures, and his many other charitable and Christian attempts; and, that he heard him comforting himself near his

his death, with those numerous good works he had so heartily promoted." "Dr. Bray's opinion," says one of his biographers, "that civilizing the Indians must be the first step, in any successful attempt for their conversion, is a proof of his good sense, and of the just ideas he entertained on the subject." *Bioç. Brit.*

BRAY, SOLOMON DE, a portrait painter, was born at Haerlem in 1597, or, according to Descamps, in 1579, and is reckoned among the good artists of his time. He died in 1664. Pilkington.

BRAY, JACOB DE, a historical painter, the son of the former, was born at Haerlem, and is said by Descamps to have died some weeks before his father, in 1664; but other writers affirm, that he was alive in 1680. He distinguished himself by his drawings, as well as his paintings. At Amsterdam, there is a picture by this artist, in which David is represented playing before the ark; that is much commended. The colouring is so well managed, that it appears as fresh as if it had just come from the easel. His drawings on vellum and paper, finished in red and black chalk, are very fine and highly valued. Pilkington. Strutt.

BRAY, in *Geography*, a sea-port and post town of the county of Wicklow, Ireland, situated on the confines of the county of Dublin, from which it is separated by a small river of the same name, that abounds with excellent trout. It has two fairs, at which are sold great quantities of frieze and flannel, with sheep and black cattle. Here are an old castle, a church and chapel both newly built, and a barrack. In the neighbourhood are many fine seats that attract visitors; and it is also frequented for sea bathing, and for drinking goats' whey. Distance from Dublin, 10 miles S. by E. N. lat. 53° 13'. W. long. 6° 6'.

BRAY-bank, a narrow bank of sand on the east coast of Ireland, opposite to Bray-head, at the distance of from six to seven miles from the coast, and extending about eight miles N. by E. The least water found on it was nine feet.

BRAY-head, a cape on the east coast of Ireland, near the town of the same name, which is steep, and the highest land upon that part of the coast. It is 12 miles north of Wicklow-head, and 5 miles south of Dalkey, the south point of the entrance into the bay of Dublin. N. lat. 53° 12'. W. long. 6° 4'.

BRAY *sur Seine*, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Provins, 3 leagues S. of Provins. The town contains 2030, and the canton 10,582 inhabitants; the territory comprehends 272½ kilometres, and 23 communes.

BRAY *sur Somme*, a town of France, in the department of the Somme, and chief place of a canton, in the district of Péronne, 3 leagues W. of Péronne. The place contains 1065, and the canton 9645 inhabitants; the territory includes 145 kilometres, and 20 communes.

BRAZEY, a town of France, in the department of the Côte-d'Or, 2 leagues from Dijon.

BRAZED, in *Heraldry*, the same as *Braced*, is used to express such charges as are folded or interlaced.

BRAZEEL *parfis*, in *Botany*, (Petiver). See SPI-  
GELIA ANTHELMIA.

BRAZEN *age* is used by the poets to express the third age of the world. See AGE.

BRAZEN-*dish*, among *Miners*, is the standard by which the other dishes are gauged, and is kept in the king's hall.

BRAZEN *laver*, in *Jewish History*, one of the utensils of the court of the tabernacle, described in the 30th chapter of Exodus, and conveniently situated between the east end

of the tabernacle and the altar of burnt-offerings. Neither its shape nor size is mentioned by Moses; but it was probably of considerable capacity, as it served for the use of all the priests to wash their hands and feet, before they performed their ministry. It is said (Exod. xxviii. 8.) that Moses "made the laver of brass, and the foot of it of brass, of the looking-glasses of the women, who assembled at the door of the tabernacle of the congregation." Such were the ancient mirrors, made of polished brass or other metal; which gave but a dark or obscure image, in comparison of glass mirrors. Hence, it is said, we read (1 Cor. vii. 12.) of "seeing through a glass darkly;" or rather "in, or by a glass," as *ὁ θεοῦ* signifies. Some have supposed, that an error has crept into the text, or an exchange of one letter for another like it, as of  $\beta$ , instead of  $\gamma$ ; and that it should be rendered, "he made the laver and its foot of a brass like the looking-glasses of the women that crowded about the door of the tabernacle;" by which we are to understand, that he made them either of the same metal, or that he gave them the same degree of brightness or smoothness. And, if what an ancient father tells us be true, with regard to the Egyptian women, that they used to go into the temple with a looking-glass in one hand, and a timbrel in the other, it will serve to illustrate the practice of the Hebrew women's wearing such an ornament when they came into the tabernacle. Tremell. in loc. Cyril. Alexand. de Adorat. in Spirit, &c. tom. i. l. 2. p. 64.

BRAZEN, or *molten sea*, an utensil in the temple of Solomon, for the size and construction of which, see 1 Kings, chap. vii. and 2 Chron. chap. iv. The water contained in it served for the washing of the sacrifices, and of the priests and Levites, before they performed the several services assigned them; and for this purpose it was drawn out by pipes and conduits. It was filled with water by the Gibeonites, who were afterward called Nethinims.

BRAZEN *serpent*, a figure of the fiery serpent or saraph, which Moses was instructed to form and to elevate upon the top of a pole, promising the Hebrews, that all who were bitten by serpents, and should look towards this image, should be healed; as the event provid. Numb. xxi. 9. Our Saviour compares the lifting up of this serpent on the pole to his elevation, or crucifixion, upon the cross. Joh. 3. iii. 14. John, xii. 32. This brazen serpent was preserved among the Israelites till the time of Hezekiah, who, being informed that the people paid a superstitious worship to it, ordered it to be broken in pieces, and by way of contempt gave it the name of "Nehushtan," i. e. a brazen bawble or trifle. 2 Kings, xviii. 4.

BRAZIER, an artificer who makes and sells pans, pots, kettles, and other kitchen utensils and brass ware.

Itinerant braziers, who go about with their tools and knapsacks, are called *timbers*; by the French, *braziers of the whistle*, *chouderoniers au sifflet*.

BRAZIL-wood, in *Botany*. See CÆSALPINIA, and BRASIL-wood.

BRAZING, the folding or joining of two pieces of iron by means of thin plates of brass, melted between the two pieces to be joined.

If the work be very fine, as when the two leaves of broken saws are to be joined, it is to be covered with beaten borax, moistened with water, that it may incorporate with the brass dust, which is here added; and the piece is exposed to the fire, without touching the coals, till the brass be observed to run. To braze with a still greater degree of meety, they use a folder made of brass, with a tenth part of tin; or another, one-third brass, and two-thirds silver; or borax and rosin: observing, in all these ways of brazing, that

that the pieces be joined close throughout; the solder only holding in those places that touch.

The method of brazing, among smiths, farriers, &c. is by beating the two pieces, when hot, over one another; this is more properly called *welding*.

**BRAZZA**, so called from the town of *Brazza*, in *Geography*, an island in the gulf of Venice, about 10 leagues long, and 3 broad, near the coast of Dalmatia, opposite to Spalatro, and subject to Venice. N. lat. 43° 45'. E. long. 16° 10'.

**BRE'**, a river of Denmark, which runs into the North sea; 6 miles S. W. of Tondern.

**BREA**, a small island in the Pacific ocean, near the west coast of North America. N. lat. 16° 38'. W. long. 59° 1'.

**BREA head**, a cape on the south-west coast of Ireland, being the south-west point of Valentia island, in the county of Kerry. N. lat. 51° 50'. W. long. 10° 16'.

**BREACH**, in a general sense, denotes a break or rupture in some part of a fence or inclosure, whether owing to time or violence. The word is formed from the French *breche*, which signifies the same; formed of the German *brechen*, to break.

Inundations, or overflowings of lands, are frequently owing to breaches in the dikes, or sea-banks. Dagenham breach is famous; it was made in 1707, by a failure of the Thames wall, in a very high tide. The force wherewith it burst in upon the neighbouring level, tore up a large channel or passage for water a hundred yards wide, and in some places twenty feet deep, by which a multitude of subterranean trees, which had been buried many ages before, were laid bare. Phil. Trans. N° 335. p. 478.

**BREACH**, in the *Military Art*, is an extensive aperture, gap, or opening made in any part of the works of a town, either by battering the walls with artillery or springing mines, in order to storm the place, or carry it by assault. They say, *make good the breach, fortify the breach, make a lodgment on the breach, &c.* To clear the breach, is to remove the ruins that it may be the better defended.

The ancients were not provided with means so effectual as our artillery to batter down the walls of fortified places. The catapultæ and balistæ, redoubtable as they were in the open field, or the attack of a camp, were not competent to this effect. With the Greeks, the Romans, and other nations of antiquity, it was necessary to advance close under the walls before they could make use of the ram, their principal instrument of assault. All the other operations of a siege; the construction of their aggeres or terrasses, the moving turrets, the testudoes, galleries, and vineæ, were only directed towards this principal object, that of favouring the approach of the ram towards the town. So long as the besieged maintained themselves in possession of their walls, it was not possible to make use of this formidable weapon. Most of their machines, especially such as tended to avert the effect of the ram, were disposed upon the parapet of the front attacked; and mailers of their battlements, they galled the besiegers with incessant showers of darts and arrows, large stones, entire beams, burning pitch, melted lead, and every kind of missile arms. They directed their principal machines against the ram, whose force was useless the instant its equilibrium was disturbed. But as soon as the catapultæ and balistæ of the assailant had cleared the walls of the place, and the besiegers, protected by their terrasses, had filled the ditch, no obstacle remained to prevent the application of the battering ram. Its effect was inevitable the moment the vibration of the machine was undisturbed and free. The place was then reduced to the last extremity;

and if the garrison had rashly held out until the ram had struck the wall, "si aries murum tetigisset," no capitulation was afterwards granted, unless upon the severest terms.

The ram generally approached the place under the protection of the testudo, a kind of covered gallery, within which it was either suspended in equilibrio, or rested on a base, and worked by a considerable number of hands. In this situation, no tower or wall of masonry, however thick, could for any length of time resist the tremendous shock which accompanied its blows. The ram, however, was not always the method used by the ancients to effect a breach. They sometimes employed their *orgmata*, subterraneous passages, or mines, which, having carried completely under the front of the place attacked, they sustained the walls by enormous beams, until the space undermined was judged sufficient, and then setting fire at the same time to all these beams, their fall infallibly brought along with it great part of the fortification, and opened a wide breach for the assailants to mount over.

Among the ancients, the art of defence, the moment that the besiegers had filled the ditch, planted their machines, and brought the battering ram up to the foot of the wall, bore no proportion to that of attack. Several means, however, were invented to prevent or lessen the effect of this last terrible machine, particularly at the siege of Platea, in the Peloponnesian war. The besieged made use of nooses or pincers, with which they caught the head of the ram, and either drew it up to the walls, or at least disturbed its equilibrium for a considerable time, and spoiled the effect of its stroke. They also made use of a large beam, hung horizontally, by heavy iron chains, to two immense wooden levers, planted upon the battlements. This, when they beheld the ram about to commence its action, they elevated to a great height, and letting it fall suddenly upon the machine, it caused the head of the ram to plunge, and thus considerably deadened, if not entirely destroyed, the impetuosity of its blow. Even when the breach was made, the diligence of the garrison sometimes provided the means of a new defence. During the siege, it was customary to build a new wall, in form of a crescent, behind that against which the enemy directed their principal efforts. This much disheartened the besiegers, who, when they flattered themselves with having overcome all resistance, and holding the town at their mercy, were thus often obliged to recommence the prodigious labour of their aggeres, vineæ, and other machines, against the re-entering wall: a new labour equally difficult and dangerous, as in the process their flanks were laid open to the darts, stones, and other missiles of the enemy. The celebrated sieges of antiquity afford many instances of this method of protracting a defence. The sieges of Platea, by Archidamus; of Halicarnassus, by Alexander the Great; and of Rhodes, by Demetrius Poliorcetes, are the most remarkable in the Grecian history. On the latter occasion, the town was preferred by the construction of a second wall, when the machines of the Macedonians had overthrown the first, and made a very practicable breach. At Athens, when besieged by Sylla, in his war against Mithridates, the same expedient was made use of; but without the same success. But ancient history affords no example of a siege where this mode of defence was carried to so great a length as at Saguntum, when attacked by Hannibal. Several walls were repeatedly raised one after another, to protect those parts of the town in which the Carthaginians had not got footing; and by dint of these successive inclosures, the inhabitants maintained a bloody resistance for nearly eight months: The fatal consequences of this obstinacy are sufficiently known. moires Milit. tom. ii. Cæsar de B. G. lib. ii. Thucyd. Hist. lib. ii. Arrian de exp. Alex. lib. i. Diodorus Sic. Hist. lib. xx. Plutarch in Sylla. Appian. de Bel. Mithrid. Livius Hist. lib. xxi. Polyb. de Polard. Rollin Hist. Ancienne.

In modern warfare, breaches are sometimes effected by battering the place with cannon, sometimes by springing of mines, and oftentimes by a combination of both. In the former case, batteries for making a breach in the body of the place, and ruining the defences, are generally erected upon the covert way, after the besieged have been driven from all their exterior fortifications. As the ravelin is to be attacked first, and is flanked or defended by the faces of the bastions opposite to its ditch, the first batteries erected are to ruin the defence of the ditch, and to make breach in the ravelin. Each of these batteries should contain four or five 24 pounders at least. Sometimes the batteries raised against the ravelin are also used to batter the faces of the bastions; but as this cannot be done without breaking the wall of the ravelin too near the salient angle, it will be much better to erect batteries for that purpose, although if the faces of the protecting bastions were well enfiladed by the guns of the first parallel, firing à ricochet, there would be no occasion for any others. Whilst these batteries are erecting, fresh ones must be made to ruin the flanks of the bastions, of as many guns as can be placed opposite to them, as also some to play against the opposite faces. The best place for effecting breaches, both in the ravelin and bastions, is about 15 fathoms from the salient angle; so that battering on both sides of the angle the breach will become spacious and large; whereas, on the contrary, were the breach made too near the angle, it would become too small and incommodious.

All these batteries are made on the ridge of the glacis, within three fathoms of the covered way, which interval serves to construct the parapet or epaulement; and as the guns which are to effect a breach should fire as low as the bottom of the ditch, the embrasures must be made sloping downwards accordingly. The guns intended to make breach should always fire together, or in salvo's, and as nearly in the same place as possible, and continue so till the wall is quite pierced, which may be known by the earth's falling. They must begin firing at first as low as they can, and batter the wall nearly in an horizontal line, as far as the breach is intended to be made; afterwards fire something higher, in the same manner as before, and continue so to do till the wall tumbles down; for should they fire at first too high, the rubbish would cover the lower part of the wall, so as not to be broken afterwards, and the breach thus become impracticable. The wall being broken down as far as is necessary, the counterforts must be beat down likewise, which, as they advance farther into the earth than the wall itself, will be soonest demolished by firing at them obliquely.

The other, and the shortest way to make a breach, is to pierce the wall with guns, so as to make a hole for two or three miners to lodge themselves in, who are sent over the ditch as soon as it is dark (in boats, if the ditch is full of water), and make three or four small mines under the parapet, which, when sprung, will at once open a breach sufficiently large, and wanting nothing but to be cleared in order to give an assault. The breach effected by battering, however, certainly costs less men than that accomplished by mines, because, in case of a dry ditch, the necessary establishments there to sustain the miner are avoided; and, if the fossé is filled with water, the ruins of the breach partly choak it up.

The breach being made, and the effects of the mine clearly distinguishable, however practicable it may appear, it is not prudent to hazard a general assault immediately after the mine has been sprung. It is necessary that it should be well examined by hardy and resolute men, who should, if possible, gain the top of the breach, reconnoitre the posture of the garrison, and discover what precautions they may have taken in different places, to counteract the effects of a storm. All breaches made in the body of a place, or in the more important outworks, should be widened as much as the ground will admit of, so as to oppose to the enemy a greater front than that by which he can advance to drive out the besiegers. A practicable breach ought to be fifteen or twenty fathoms wide. This, once made, and the ground levelled, with all materials and tools at hand, the troops destined to mount the breach disposed ready for the assault, and others drawn up to support them in case of need, the guns and mortars should begin to fire briskly on all the defences of the place which flank the front attacked, both directly, and enfilading them by the ricochet batteries; and a great number of shells and stones should be thrown into the ravelin or bastion, and its defences. This having continued for some hours, the signal is given for ceasing to fire; and the troops marching to the assault, charge the garrison vigorously, and oblige them to retire. After this, the workmen, headed by an engineer, advance to make a lodgment on the upper part of the breach, which, when partly done, the troops retire behind it, ready to repulse the besieged if they should return, which they will not fail to do as long and as often as they can. But when this lodgment is once so far advanced as to be in a condition of receiving a good number of troops, the besieged will have it no longer in their power to disturb them by open force, and therefore they will make use of their mines, as the last resource left them, if they have not been prevented beforehand, either to blow up the lodgment, or any other place where they perceive a body of men.

When the inner intrenchments have not been ruined by the bombs or mines, which may be the case when they are furnished with revêtements, or have not been sufficiently reconnoitred, other proceedings become necessary. Lodgments should be carried on by saps along the parapet, to get possession of the traverses, if the besieged have made any to shelter themselves from the ricochet batteries. These lodgments must themselves be well traversed, from the enfilades to which they are unavoidably exposed, and joined by others across the work, which serve as a sort of parallels to dislodge the garrison from their intrenchments. If the besieged are retrenched upon the two flanks of the bastion, or at its gorge, which, it is to be presumed, is the case, when the explosion of the mines does not entirely drive him out of the work, it will be expedient to make capacious lodgments on the breach, extend it by means of fourneaux and small mines, and render its access practicable and easy, even for heavy artillery, which it may be necessary to mount in battery on the top of the breach, in case that the bombs fail in driving the garrison out of their retrenchments. If there should be any pallisades placed either round these retrenchments, or serving for retrenchments themselves, they must be broken down with the guns from some battery that can play upon them; or, if this cannot be done, small mines must be carried underneath to blow them up.

These are necessary precautions against the obstinacy of a governor or garrison, who are determined to defend themselves to the last extremity, and which, on such an occasion, must never be neglected. For an assault given hastily and inconsiderately after springing a mine, and which a prudent  
and

and wife governor only withstands when he finds himself enabled to do so without much risk of being forced, always collecting a general some of the best and bravest soldiers in his army, and frequently deters the rest from subsequent hazardous attempts, especially if the destruction from the countermines and souldiers has been considerable. When the breach is to be carried sword in hand, it is indispensibly necessary that all the defences of the work should be ruined; the breach itself very practicable, and that, both before and during the attack, an incessant fire of cannon, musquetry, and mortars should be poured upon, and into the works enfilading that, the immediate object of the assault. The front of the attack should sustain and embrace the whole extent of the work; for, under these circumstances, the superior depth and number of the besieger's column of attack, must necessarily, as at Oezakow, Bender, Valenciennes, &c., overbalance the inefficient resistance which can be opposed by a garrison. It was from a neglect of all these precautions, that the grand attack of the confederates upon the castle of Namur in 1695, entirely failed. The columns destined to mount the different breaches began their march from too great a distance, and, although protected by a prodigious fire of bombs and artillery, the most forward never penetrated further than the middle of the breach; and they retired after sustaining a serious loss. In fact, it is almost impossible to mount a breach by assault, while any works remain, whose fire is either directed upon, or enfilades the attack.

But, on the other hand, it is equally rash in a governor to resist a storm, or hazard the lives of his garrison in fruitless attempts to maintain possession of the breach, after these works have all been destroyed, and the breach is reduced to its own defences. A place thus obliquely holding out is in danger of being taken by assault, and the garrison put to the sword, or obliged to surrender at discretion. Retrenchments, indeed, may sometimes serve to protract an unavailing resistance; but their construction should not be delayed, as is generally the case, till after a breach has been made in the body of the place, with the sole view of obtaining a better capitulation. When the siege is once formed, much time is lost in their formation; and the loss of men by the bombs thrown into the bastion is very great, besides the considerable fatigue which the soldiers experience. In the ravelins, horn-works, crown-works, lunettes, and other detached fortifications, they are of greater service, especially when the ditches are dry; and the communication with the body of the place easy; for, then it becomes impossible to carry them by the gorge. And when they have revêtements, and a fossé, the besiegers will be reduced to the necessity of bringing up artillery upon the work to batter them in breach, or to try the effect of his bombs. If the enemy adopt the method of a blinded sap, he must be very careful to cover himself from the fire of the curtain, and the faces of the bastions; and in every one of these cases, much time is lost before he can approach the body of the place.

The breach itself may also be defended to advantage. When the enemy are ready to mount, a great quantity of all kinds of combustibles are thrown at the foot of the breach, to be fired, and constantly supplied with fuel. While they are mounting, a great number of grenades must be thrown among them; sacks, glass, or earthen bottles filled with powder, and burning matches twisted round them; crow-feet, harrows, and large timbers, with long iron spikes fastened with chains, so as not to be removed, as also shells, so confined, as not to roll out of the breach. A great quantity of loose powder may also be scattered about, and fire set to it at the approach of the enemy. This being well executed, and fire arms, both great and

small, well served, together with the mortars for throwing shells and stones, will do them infinite damage, and sensibly retard the taking of the work. When the defence is exhausted, and the enemy at last are masters of the breach, the mines are fired, to destroy, if possible, their lodgment, with all the men established in it. Should this succeed, the besieged may return immediately, and clear the breach, so as to render it impracticable. Several mines should be made under one another, if the ground will allow of it, that the breach may be destroyed several times, which will sometimes dishearten the enemy's troops, put them out of all patience, and may eventually contribute to make them raise the siege, as was the case at Maastricht, when besieged by the prince of Orange in 1674.

BREACH of *close*, in *Law*. See CLOSE.

BREACH of *covenant*, denotes the non-performance of any covenant expressed or implied in a deed; or the doing of an act, which the party covenanted not to do. See COVENANT.

BREACH of *duty*, denotes the non-execution of any office, employment, or trust, &c. in a due and legal manner. See ASSUMPSIT.

BREACH of *peace*. See PEACE.

BREACH of *pound*. See POUND.

BREACH of *prison*. See PRISON.

BREACH, *to batter in*, *batre en brèche*. See BATTERING.

BREACH, *mounting the*. See MOUNTING.

BREAD ordinarily is made of the flour or meal of some farinaceous vegetable ground, and kneaded with water and leaven or yeast.

In describing the process of making bread, it is natural, in the first place, to advert to the substance or material of which it principally consists. This is the flour obtained from farinaceous vegetables, principally wheat or rye, or a mixture of both these, called in many parts of the kingdom bread-corn, converted into meal by trituration, or grinding in a mill, and separated from the husk or bran by sifting or bolting. This is composed of a small quantity of mucilaginous saccharine matter, soluble in cold water, and separable from it by evaporation, much starch, which is scarcely soluble in cold water, but capable of combining with that fluid by heat, and an adhesive grey substance, called gluten, insoluble in water, ardent spirit, oil, or ether; and in many of its properties resembling an animal substance. When flour is kneaded with water, it forms a tough paste, containing the constituent principles of flour, with very little alteration, and not easily digested by the stomach. By heat the gluten, and probably the starch, undergoes a considerable change, and the compound is rendered more easy of mastication, as well as of digestion. When this dough is kept in a warm place, it swells up, becomes spongy, and filled with a number of air-bubbles, disengages at length an acidulous and spirituous smell, tastes sour, and in this state is called "leaven," from the French word "lever," to raise. Whilst the dough, or paste, is left to undergo a spontaneous decomposition, in an open vessel, the various component parts are differently affected; the saccharine part is convertible into an ardent spirit, the mucilage tends to acidity and mouldiness, and the gluten probably verges towards a state of putridity. By this incipient fermentation, the mass is rendered more digestible and light; that is, it becomes much more porous by the disengagement of elastic fluid, which separates its parts from each other, and much enlarges its bulk. The operation of baking puts a stop to this process, by evaporating a great part of the moisture which favours the chemical

chemical attraction, and probably also by still further changing the nature of the component parts. Bread, however, in this state, will not possess the requisite uniformity; because some parts may be mouldy, while others are not yet sufficiently changed from the state of dough. In order to promote an uniform fermentation, a small portion of leaven is intimately blended with a quantity of other dough; and this, by its union with the mass, and the aid of a gentle heat, accelerates the fermentation, and diffuses it through the whole mass at the same time; and as soon as the dough has acquired a due increase of bulk from the carbonic acid gas, which endeavours to escape, it is judged to be sufficiently fermented, and fit for the oven; the heat of which checks the fermentation by exsiccation, or the subtraction of its water. It is obvious, that by the fermentation of the dough united with leaven, a quantity of carbonic acid gas is extricated from the flour, but remains confined in it by the tenacity of the mass, where it is expanded by the heat, and by that expansion effects the "rising" of the dough. This is also the efficient cause of the porosity and sponginess in baked bread. The fermentation by means of leaven is thought to be of the acetous kind, because it is generally so managed, that the bread has a sour flavour or taste. This bread, raised by leaven, is usually made of a mixture of wheat and rye not thoroughly cleared of the bran, and is distinguished by the appellation of brown bread; and the practice of making leavened bread appears, from the histories of the earlier nations, and particularly from the scriptures, to be very ancient. But yeast or barm, which is the mucilaginous froth that rises to the surface of beer in the first stage of its fermentation, seems to be of modern date. This vinous ferment is used for the finer kinds of bread, commonly denominated white bread. When this is mixed with the dough, it produces a much more speedy and effectual fermentation than that obtained by leaven, and the bread is accordingly much lighter, and scarcely ever sour. The fermentation by yeast seems to be almost certainly of the vinous or spirituous kind.

Bread, if well prepared and properly baked, is materially different from flour and other farinaceous cakes; it no longer forms a tenacious dough with water; nor can starch and gluten be any more separated from it; and hence, most probably, its good qualities result.

The Greeks, in the first ages, are said to have subsisted upon acorns and berries, and were for a long time unacquainted with the art of ploughing the earth for corn; although, according to Hesiod's description of the golden age (*Oper. l. i. v. 116.*), the earth produced corn without cultivation. When this age expired, the earth, as they imagined, became unfruitful, and men lived in a state of extreme ignorance and barbarity, till Ceres taught them the art of agriculture. The invention of making and baking bread was ascribed to Pan; and, according to Pliny (*Nat. Hist. l. xviii. c. 7.*), barley was used, before any other sort of corn, as the food of men; but in more civilized ages, barley-bread was only appropriated to the use of beasts. However, it afterwards was used only among the poor, who could not obtain any other provision. Among the Greeks their loaves were baked either under the ashes, or in the oven; and they had a kind of bread, called *μυζα*, which was made with a coarser flour, salt, and water; to which they sometimes added oil. The art of making bread was not known at Rome until A. U. C. 580. The Roman armies, on their return from Macedonia, brought Grecian bakers into Italy. Before this time the Romans (see Pliny, *Hist. l. xviii. c. 8. and 11.*) prepared their flour into a kind of pap, or soft pudding; for which reason Pliny calls them eaters of pap.

VOL. V.

Among the ancients, we find various denominations of bread; such as 1. *Panis filigineus*, called also *mundus*, *athleticus*, *ifungia*, *coliphis*, and *robys*, corresponding to our white bread; being made of the purest flour of the best wheat, and only used by the richer class of persons. 2. *Panis secundus*, or *secundarius*, called also *smilaceus*, or *smilagineus*, the next in purity; being made of fine flour, from which all the bran was not sifted. 3. *Autopyrus*, called also *syncomastus*, and *confusianus*, made of the whole substance of the wheat, without retrenching either the finer flour or coarser bran; corresponding to our household bread. 4. *Cacabaceus*, seeming to be the same with that otherwise denominated *frigidus*, as being given to dogs; *furfuraceus*, *fufureus*, or *jurfurativus*, because it consisted mostly of bran; and, in the middle age, *biffus*, on account of its brownness; and sometimes also *leibo*.

There were other kinds of bread, denominated either from the uses to which they were applied, or the manner in which they were made; such as, 1. the *militaris*, which was prepared in camp by the officers and soldiers with their own hands; for which purpose some had hand-mills, and others pounded the corn in a mortar, and baked it on the coals. 2. *Clibanites*, that baked in an oven, by way of contradistinction from that baked on the hearth, or under the embers. 3. That called *subcineritius*, or *sub cinere coctus*; sometimes also *reversatus*, because it was to be turned in the baking. 4. *Nauticus*, answering to our sea-biscuit, and denominated *bis coctus*. See BISCUIT.

Other kinds of bread were denominated from certain qualities belonging to them; such as, 1. *Panis ficcus*, that which had been long baked; such was the *bis coctus*, naval and buccellated bread. 2. *Madidus*, a sort made of rye or bear, sometimes also of fine flour, with which they smeared their faces, by way of a cosmetic, to make them smooth. 3. *Acidus*, or sour bread, which was acidulated with vinegar. 4. *Azymus*, unleavened, or unfermented bread.

The French have also many varieties of bread; as queen's bread, alamode bread, bread de Segovie, de Gentilly, quality bread, &c. all prepared in peculiar ways by the bakers at Paris. The bread de Gonesse excels all others, on account of the waters at Gonesse, about 3 leagues from Paris; it is light, and full of eyes, which are marks of its goodness. *Pain de ménage* is that which each family bakes for itself. Spice-bread, *pain d'épice*, denotes bread baked and iced over with the scum taken off sugar in refining houses; it is also sometimes made with honey, and other sorts of seasoning, and answers to what the ancients call *panis militis*.

Among us, bread is chiefly divided into *white*, *whole*, and *household*; differing only in degrees of purity. In the first, all the bran is separated; in the second, only the coarser: in the third, none at all; so that *fine bread* is made only of flour; *whole bread*, of flour, with a mixture of the finer bran; and *household*, of the whole substance of the grain, without taking out either the coarser bran or fine flour. *Stat. 8 Ann. cap. 18.* We also meet with *lymel* bread, *manchet* or roll bread, and French bread; which are only so many denominations of the finest or whitest bread, made of the purest flour; except that in roll bread there is an addition of milk, and, in French bread, of eggs and butter also. To which may be added, *ginger-bread*, made of white bread, with almonds, liquorice, aniseed, rose-water, and sugar or treacle; and *maslin-bread*, *panis mixtus*, made of wheat and rye, or sometimes of wheat and barley.

The process of making household bread among us, is thus: to a peck of meal they add a handful of salt, a pint of yeast, and three quarts of water, cold in summer, hot in winter, and temperate between the two; the whole being kneaded

## B R E A D.

in a bowl or trough by the fire in winter, from it in summer, will rise in about an hour; they then mould it into loaves, and put it into an oven to bake.

For unleavened bread, part of the flour intended for it being made into dough with warm water and a little salt, is laid in the rest of the flour an hour or more, in which time it rises to three times the bulk; then they mix and knead the whole with more water, till it be brought into a stiff dough; which being formed into loaves, is baked in the oven; though the more usual way is to take a piece of dough kneaded and leave it in the tub till next time, when they break it small and mix it with the meal, adding some yeast. Hought. Collect. tom. i. N<sup>o</sup> 90. p. 241.

For French bread, they take half a bushel of fine flour, ten eggs, and a pound and a half of fresh butter, into which they put as much yeast, with a manchet; and tempering the whole mass with new milk, pretty hot, let it lie half an hour to rise, which done, they make it into loaves or rolls, and wash it over with an egg beaten with milk; care is taken the oven be not too hot.

In Lancashire, and several other northern counties of England, the people have several sorts of oaten-bread: as, 1. The *bannock*, which is an oat-cake, kneaded only with water, and baked in the embers. 2. *Clap-bread*, which is made into thin hard cakes. 3. *Bitcheines-bread*, which is made of thin batter, and formed into thin soft oat-cakes. 4. *Riddle-cakes*, which are thick and four, and very little different from the hand-hover bread, which has but little leaven, and kneaded stiff. And, 5. *Jannock*, which is oaten-bread made up into loaves.

In Scotland they have pease-bread, consisting either wholly of the flour of pease, or of this and oatmeal mixed; the dough, sometimes leavened, and sometimes made only with water, is formed either into bannocks or cakes, and baked over the embers; or into what they call *baps*, i. e. a kind of flattish rolls, and baked in the oven.

In the statute of assize of bread and ale, 51 Hen. III. mention is made of waitel-bread, cocket-bread, and bread of trett; which answer to the three sorts of bread now in use, called *white*, *wheaten*, and *household-bread*.

In religious houses, they heretofore distinguished bread by the names, esquires-bread, *panis armigerorum*; monks-bread, *panis conventualis*; boys-bread, *panis puerorum*; and servants-bread, *panis famulorum*, or *panis servientialis*. A like distribution obtained in the households of nobles and princes; where, however, we find some other denominations, as messengers-bread, *panis nunciis*, that given to messengers, as a reward of their labour; court-bread, *panis curialis*, that allowed by the lord for the maintenance of his household; elemosynary-bread, that distributed to the poor in the way of alms. Du-Cange Gloss. Lat. tom. iv.

Bread is usually made of the seeds, sometimes also of the roots, and even the pith of plants. The first bread is supposed to have been made of the plant "lotus." In some countries they make bread of acorns. See ACORNS. In the islands of Banda and Amboyna, they make a kind of bread called "faegem," or "fagoe," of the pith of a farinaceous tree, which yields a white mealy substance, that, being kneaded with water, fermented, and baked on the coals, serves the poor for bread. See SAGO. In the Caribbee islands, &c. they make bread of the root of a poisonous plant called "Manioc;" probably the same with the Cassada bread, which is made of the root of the Yucca Mexicana. See MANIOC, and CASSADA. To the denomination of bread, made of roots, may also be added potatoe-bread, frequent in Ireland, and turnip-bread, used occasionally in some parts of England. Potatoes, previously peeled,

cut into thin slices, and put between folds of paper, will dry in a heat somewhat less than 35° of Reaumur's thermometer, and, when thus dried, will preserve their white colour. In this process they lose about two-thirds of their weight, and they may be then reduced to a fine powder, which indicates the presence of an amylaceous matter, and has the smell and taste of wheat. It is also nutritious, and may be kept for a long time. From these circumstances, M. Parmentier was led to attempt the making of bread with the meal of wheat, and that of potatoes, mixed in different proportions. By combining one-fourth, one-third, one-half, and two-thirds of the potatoe meal with the flour of wheat, and adding a little salt and yeast, he obtained bread that was well tasted, but which had fermented little, was brown, and covered with hard brown crusts. Bread made from the meal of potatoes alone, with the addition of salt and yeast, was eatable, but heavy, unfermented, and very brown; and apt to crumble into powder. In order to give it greater adhesion, M. Parmentier mixed with the meal a decoction of bran, or a mixture of honey and water, either of which made it lighter and more fermented; it thus also obtained a crust of a golden colour, and became well tasted, and sufficiently adhesive. He obtained also well fermented bread, of a good colour and taste, from a mixture of raw potatoe-pulp with mealy wheat, or potatoe-meal, with the addition of yeast and salt. Upon the whole, he recommends, after various trials, the mixture of potatoes, in times of scarcity, with the flour of wheat, instead of employing rye, barley, or oats, which has frequently been done; when grain is altogether wanting, he recommends the use of bread made from a mixture of the amylaceous powder of potatoes and their pulp, fermented with leaven or honey. The meal of this root, diluted with hot water, acquires a tenacious and gluey consistence. This meal, however, gives a grey colour to bread made by mixing it with the flour of wheat; but a mixture of the pulp of potatoes with the flour of wheat does not produce brown-coloured bread. M. Parmentier made bread very much resembling that of wheat, by mixing four ounces of amylaceous powder of potatoes, one dram of mucilage extracted from barley, one dram of the bran of rye, and 1½ dram of glutinous matter dried and powdered. See POTATOE.

M. Parmentier also recommends the use of the horse-chestnut for the purpose of making wholesome bread. With this view he advises taking off the skin, and pressing out the juice, and reducing the fruit into a paste, which, being diluted with water, and strained through a sieve, will yield a milky-coloured liquor, that, on being left to stand, deposits a fine powder. This powder, when dried, has neither smell nor taste, and is very fit for aliment; the mass from which it is procured retaining the bitterness of the fruit. The roots of the bryony, he says, treated in the same manner, yield a similar white powder. By the same treatment, fine, white, insipid, inodorous powders may be procured from the roots of the iris, gladiolus, ranunculus, fumaria, arum, dracunculus, mandragora, colchicum, filipendula, and helleborus; plants which grow spontaneously, and in great abundance. The roots of the gramen caninum arvense, which some naturalists have considered as the original species from which all our grain is produced, are sweet-tasted; and in order to their being prepared for bread, it is merely necessary to cleanse them, to cut them small, and to dry and pound them. The powder, he observes, does not dissolve in cold water or spirits, but is dissolved in boiling water, which it renders thick and cloudy; and, upon cooling, the whole mass obtains a gelatinous consistence. Upon a chemical analysis, it yields an acid empyreumatic oil, which possesses a singular odour, resembling that which is perceived on burning the plant

plant. The spongy residuum, calcined in the air, gives a fixed alkali. From these properties, he infers, that it contains an amylaceous matter, similar to that of grain, which appears to be the nutritive part of vegetables. This amylaceous matter, formed into a jelly, and diffused in water, keeps for a long time without suffering any change. It then turns acid, and at length putrefies. M. Parmentier gives an account of the bread which he obtained from the amylaceous powders of the different vegetables above-mentioned, with the addition of potatoes and a small quantity of common leaven of grain. This bread appeared in general to be well fermented; it was of a good white colour, and free from any disagreeable odour; but to the taste it was somewhat insipid, which he supposes might be corrected by the addition of a proper quantity of salt. In order to guard against a season of scarcity, when some of these plants may not be procured, he proposes a method of preserving the matter thus obtained.

For this purpose, he advises, that bread prepared in the manner above-mentioned should be carefully dried, reduced to powder, and kept in a close cask. By this means he thinks it may be preserved for a very long time, and be always ready to make an agreeable and wholesome panada, with the addition of a little butter and salt. In order to determine the degree of nourishment which this alimentary powder was capable of affording, he tried its effect upon himself; and he found that three ounces of it for dinner, and as much for supper, made into panada with water, was a sufficient quantity of aliment for a day. From his discharge by stool, while he used it, he had reason to believe, that it is almost totally alimentary. He concludes with recommending it not only as useful in times of scarcity, but as a proper substitute to sea-biscuit, and as a kind of food well adapted for armies and hospitals. *Examen Chymique des Pommes de Terre, &c. Memoire sur les vegetaux qui pourroient suppléer en temps de disette à ceux que l'on employe communement à la nourriture des hommes. &c.*

In order to make bread of turnips, the following method is recommended in the "*Musæum rusticum et commerciale.*" When turnips are plentiful, a number of them should be pulled, washed clean, pared, and boiled. When they are soft enough for being mashed, the greatest part of the water should be pressed out of them, and they should then be mixed with an equal quantity in weight of coarse wheat meal. The dough may then be made, in the usual manner, with yeast or barm, salt, water, &c. It will rise well in the trough; and after being well kneaded, it may be formed into loaves, and put into the oven to be baked. The person who made this experiment had other bread made with common meal in the ordinary method. The turnip-bread was baked rather longer than the other. When they were drawn from the oven, a loaf of each sort was cut; and, upon examination, the turnip-bread was sweeter than the other, not less light and white, with a slight, but not disagreeable, taste of the turnip. When it was tasted 12 hours after, this taste was scarcely perceptible, and the smell was quite gone off. After an interval of 24 hours, it could not be known that it had any turnips in its composition, although it still had a peculiar sweetish taste. After 24 hours, it appeared to be rather superior to bread made only of wheat flour; it was fresher and moister; and, after a week, it was still very good.

Rice will serve the purpose of making very good bread; and the method practised in Carolina is as follows: The grain is first washed by putting it in a vessel and pouring water upon it, then stirring it; and changing the water until it is sufficiently cleansed. The water is then poured

off, and the rice placed in an inclined position to drain. After being sufficiently drained, it is put, while damp, for the greater facility of pulverization, into a mortar, and beaten to powder; it is then completely dried, and passed through a common kitchen hair-sieve. The rice flour, thus obtained, is kneaded with a small proportion of Indian corn-meal, and boiled into a thickish consistence; or it is sometimes mixed with boiled potatoes; and a small quantity of leaven and salt is added to the mass. When the fermentation has been sufficiently excited, the dough is put into pans, and placed in an oven to be baked. By this process a light wholesome bread is made, which is not only pleasing to the eye, but agreeable to the taste. See *RICE*.

In Norway, they have bread made of barley and oatmeal, baked between two stones: and Bartholin says, that it keeps 30 or 40 years, and that the older it is, the more agreeable. For their great feasts they use the oldest bread; and at the baptism of a child, they have bread, which had been baked probably at the baptism of the grandfather.

Dr. Townson, in his "*Travels in Hungary,*" has described the mode of making excellent bread without yeast, as it is practised at Debretzin in that country. The ferment used for this purpose is made in this manner: Two good handfuls of hops are boiled in four quarts of water; this is poured upon as much wheaten bran as it will moisten; and to this are added four or five pounds of leaven. When the mass is warm, the several parts are well mixed by being worked together. It is then deposited in a warm place for 24 hours, and afterwards divided into small pieces, about the size of a hen's egg, or a small orange, which are dried by being placed upon a board and exposed to a dry air, but not to the sun; when dry they are laid by for use, and may be kept half a year. The ferment thus prepared, is applied in the following manner.

For a baking of six large loaves, six good handfuls of these balls are dissolved in seven or eight quarts of warm water; and this water is poured through a sieve into one end of the bread-trough, and after it three quarts of warm water, the remaining mass in the sieve being well pressed out. The liquor is mixed up with flour sufficient to form a mass of the size of a large loaf: this is strewed over with flour, the sieve with its contents is put upon it, and the whole is covered up warm, and left till it has risen enough, and its surface has begun to crack: this forms the leaven. Then fifteen quarts of warm water, in which six handfuls of salt have been dissolved, are poured through the sieve upon it, and the necessary quantity of flour is added, and mixed and kneaded with the leaven; this is covered up warm, and left for about half an hour. It is then formed into loaves, which are kept in a warm room for half an hour; and after that they are put into the oven, where they remain two or three hours, according to the size. The great advantage of this ferment is that it may be made in large quantities at a time, and kept for use; and on this account, it might be useful on board of ships, or in camps for armies in the field.

The quantity of bread allowed a soldier for his day's subsistence is called a ration.

For armies the bread is either baked in the park of provisions in the camp, or in the town nearest the army; for the conveniency of ovens, an army ought always to have at least four days bread before-hand. In some cases, the distance of the places from whence bread is to be had; or the army's march from one country to another, obliges the general to distribute bread for six, or even for eight days; a thing never done without absolute necessity, by reason of the abuse which some soldiers make of it, who sell their bread without regard to future subsistence. For long marches

through an enemy's country, they sometimes, instead of bread, make biscuit.

BREAD, in *Domestic Economy*, serves as a nutritive aliment, in all countries where it can be obtained. The farinaceous vegetables are distributed so universally over the face of the earth, and have become to such a degree the objects of culture, that they are very generally made into bread; and as generally a portion of them is taken into the mouth along with almost every morsel of other food. By fermentation it acquires a more spongy texture, and becomes more friable, and of course more easily miscible with the saliva, and our other aliments, during the progress of mastication, which it necessarily retards, and whilst the operation of digestion is performed in the stomach. To these purposes it is adapted by being bulky without too much solidity, and by being firm without too great difficulty of solution. The best aliment of this kind is bread, made of the flour of good wheat, well fermented, thoroughly baked, with a little salt; whereas that which is not thoroughly baked, well kneaded, and without salt, is reckoned hurtful and unwholesome, as are also unleavened bread and cakes baked under the ashes. In general, the lighter the bread the better and more agreeable it is; coarse and barley bread is detestive, commonly purgative, at least to those who are not used to it. "We are willing to own," says Dr. Cullen, in his discussion of this subject, "that a farinaceous substance, formed by fermentation into a perfect bread, is the most wholesome condition in which farinaceous matters can be employed as a part of our food; and we are ready also to allow, that the unfermented farinacea, taken in immoderate quantity, especially at a certain period of life, or in dyspeptic stomachs, may be the cause of disease: but all this seems to have been exaggerated; for the morbid effects of unfermented farinacea are truly rare occurrences; and, indeed, the same unfermented farinacea are for the most part very well suited to the human economy. However considerable the use of fermented bread may be, the use of unfermented farinacea is still very great and considerable amongst almost every people of the earth. The whole people of Asia live upon unfermented rice; and I believe (says he) the Americans, before they became acquainted with the Europeans, employed, and for the most part still employ, their maize in the same condition. Even in Europe, the employment of unfermented bread, and of unfermented farinacea in other shapes, is still very considerable; and we are ready to maintain, that the morbid consequences of such diet are very seldom to be observed. In Scotland, nine-tenths of the lower class of people, and that is the greater part of the whole, live upon unfermented bread, and unfermented farinacea in other forms; and at the same time I am of opinion (says this writer) that there are not a more healthy people any where to be found." In opposition to this fact it has been alleged, that this kind of diet is only safe, when used by robust and labouring people: but Dr. Cullen says, "We give it in this country not only to the farmer's labouring servants, but to our sedentary tradesmen, to our women, and to our children; and all of the latter live and grow up in good health, except a very few dyspeptics who are not free from complaints, which these also are liable to who live on fermented wheaten bread."

It is hardly necessary to say any thing of bread in reference to its medical use; however, decoctions, creams, and jellies of bread have been directed in some dispensaries. Bread, well baked, and infused or lightly boiled in water, imparts to it a deep colour, and a highly agreeable refringent taste. This liquor, used as common drink, has been sometimes beneficial in a weak lax state of the stomach and

intestines; and in bilious vomiting and purging, or the cholera morbus; of which instances occur in the Edinburgh essays, in which no other medicine was used. The use of bread, as an external application, is well known. Mr. Boyle assures us (*Phil. Works Abr.* vol. i. p. 34. 39.) that he derived a menstruum from bread stronger than aqua fortis, and which would act even upon glass itself. See farther concerning bread in the writers on food and cookery; especially in Hen. Nicolai, *Traët. de Pane*, Dantisc. 1651. *Fabr. Bib. Antiq.* c. 19. §. 6. *Cullen's Mat. Med.* vol. i. p. 283.

BREAD, *bonpournichole*, or *bonpournickel*, the name of a very coarse bread eaten in Westphalia, and many other places. This bread of the Westphalians still retains the opprobrious name once given it by a French traveller, of *bonpournichole*, good for his horse Niebole, but is by no means a contemptible kind. It is far from being peculiar to this age or country: it has been known in distant places, and in different ages, and was called by the ancients *panis furfuraceus*, or *panis impurus*, from its not being so thoroughly cleaned from the husk or bran, as the fine sorts of bread are. The wrestlers of old eat only this sort of bread, to preserve them in their strength of limbs; and we may learn from Pliny, that the Romans for three hundred years knew no other bread: and it has been said, that this coarse bread nourishes more, alluages hunger better, and generates humours less subject to corruption than the white.

The inhabitants of Westphalia, who are a hardy and robust people, and capable of enduring the greatest fatigues, are a living testimony to the salutary effects of this sort of bread; and it is remarkable, that they are very seldom attacked by acute fevers, and those other diseases which arise from an ebullition of the humours, and a malignant colliquation of the blood, and of the humours of which it is composed. It is certain that a less strong diet is more proper to weakly constitutions, and people of sedentary lives, than this; but for those who will use the necessary exercise with it, it is easy to see that it is preferable to all other kinds of bread; since it remarkably restores strength, and has another salutary effect, which is, that it renders the belly soluble: this was a quality remarked in coarse bread, and highly commended in it, so early as in the days of Hippocrates.

The Germans make two sorts of waters by distillation from this bread; the one with, the other without, the addition of a spirituous liquor: to both which great virtues are ascribed. That without any thing spirituous, is made of the juice of craw-fish, May-dew, rose-water, nutmegs, and saffron, distilled from a large quantity of this bread. This is esteemed a great restorative, and given in hectic habits. The other is distilled from this bread and Rhenish wine, with nutmegs and cinnamon. This is given in all the disorders of the stomach, vomiting, and loss of appetite, and other complaints of the same kind; and besides these, there is a spirit distilled from it by the retort, in the dry way, which, when separated from its fetid oil, is esteemed a powerful sudorific, and very valuable medicine, in removing impurities of the blood. Hoffman.

BREAD, *horfe*, is made of wheat, oats, and beans, to which sometimes are added aniseed, gentian, liquorice, fenugreek, eggs, and ale; and sometimes rye and white wine are used.

For race-horses, three sorts of bread are usually given with success, for the second, third, and fourth fortnights feeding; they are all made of beans and wheat, worked with barm, the difference consisting chiefly in the proportion of the two former. In the first kind, three times the quantity of beans is used to one of wheat; in the second, equal

# B R E A D.

quantities of both; in the third, three times the quantity of wheat to one of beans.

**BREAD, sacramental,** in the protestant churches, is common leavened bread, agreeable to the ancient practice. In the Romish mass, *azymus*, or unleavened bread, is used, particularly in the Gallican church, where a sort is provided for this purpose, called *pain a chanter*, made of the purest wheaten flour, pressed between two iron plates, graven like wafer-moulds, being first rubbed with white wax, to prevent the palte sticking. See **AZYMUS**.

Ecclesiastical writers enumerate other species of bread, allotted for purposes of religion: as, 1. *Calendarius*, that anciently offered to the priests at the calends. 2. *Prebendarius*, the same with *capitularis*, that distributed daily to each prebendary or canon. 3. *Benedictus*, that anciently given to catechumens before baptism, in lieu of the eucharist bread, of which they were incapable of partaking. 4. Consecrated bread is a piece of wax, palte, or even earth, over which several ceremonies have been performed with benedictions, &c. to be set up in an *agnus dei*, or a relic box, and presented for veneration. 5. Unleavened bread, or *azymus*. The Jews eat no other bread during their passover; and exact search was made in every house, to see that no leavened bread was left. The usage was introduced in memory of their hasty departure from Egypt, when they had no leisure to bake leavened bread. 6. *Shew* bread was that offered to God every Sabbath-day, being placed on the golden table, in the holy of holies.

**BREAD of St. Hubert, St. Genevieve, St. Nicholas, &c.** denote cakes sanctified with certain prayers and invocations of those saints, held by the superstitious to be of great efficacy in the cure of hydrophobias, agues, and other diseases.

**BREAD** is also used to denote certain foods made of animal, or even mineral matters, serving to supply the place of bread. In divers parts of the North, we read of fish-bread, particularly in Iceland, where dried cod is used for bread, being first beaten to powder, and made up into cakes. The like obtains among the Laplanders, whose country affords no corn; and even among the Crim Tartars. Phil. Trans. N<sup>o</sup> 102. p. 35. Sheff. Hist. of Lapl. chap. 14. In the lordship of Moscow in Upper Lusatia, a sort of white earth is found, of which the poor, urged by the calamities of the wars which raged in those parts, make bread. This earth, dug out of a hill where they formerly worked at salt-precree, when warmed by the sun, cracks, and small globules proceed from it like meal, which ferment when mixed with meal. Some persons have lived upon it for some time. Some of this meal has been kept for more than six years. A similar earth is said to be also found near Geronne, in Catalonia. Germ. Ephem. 1764.

**BREAD**, in a more extensive sense, includes all the necessities of life, as food, raiment, lodging, &c.

Hence the sabbath is sometimes called, in ancient writers, the *day of bread*, by reason the eucharist was then administered every Lord's day.

In this comprehensive sense the term bread seems to be used in the petition of the Lord's prayer. Matt. vi. 11. In this passage *ἐπιβσιος ἀγίος*, denotes "sufficient bread," or a competency. The word *ἐπιβσιος* is one of the *ἀπαξ λεγομενα*, and is found in no Greek author prior to the Evangelist. The composition is of *ἐπι* and *βσιος*, *q. d.* proper, or sufficient for support; and it is not improbable, that *ἐπι βσιου* should by degrees have coalesced and become *ἐπιβσιος*, as it now stands in the MSS. The petition exactly corresponds to that in Agur's celebrated prayer, in the O. T. *יִתְּנֵה לִּי אֱלֹהִים*: Prov. xxx. 8. Compare Gen. xlvii. 22. with Luke xv. 12. The Syriac ver-

sion has "the bread of our need." See Mede's works, vol. i. Diff. xxviii. p. 168.

**BREAD, assise, or assize of.** The price and weight of bread are regulated by the magistrates according to the price of wheat; and the assise of bread, beer, ale, &c. is granted to the lord mayor of London and other corporations. Stat. 51 Hen. III. St. 1.; and 51 Hen. III. St. 6. See also 2 & 3 Ed. VI. c. 15. But the statute of 31 Geo. II. c. 29. containing regulations concerng the assise of bread, and for preventing adulteration, repeals so much of stat. 51 Hen. III. entitled "Assisa panis et cerevisie," as relates to the assise of bread, and the stat. 8 Ann. c. 18., and all amendments by subsequent acts; and re-enacts the same with additions and amendments. This statute enacts, that the assise be set, in all places to which the right of so doing extends, with a regard to the price of the grain, meal, or flour, in the adjoining markets, and with a reasonable allowance to the bakers for their charges, labour, and profit. In order to direct the magistrates in making this allowance, they are to take notice, that the peck loaf of each sort of bread is to weigh, when well baked, 17 lb. 6 oz. avoirdupois weight, and the rest in proportion; and that every sack of meal, or flour, is to weigh two hundred weight and two quarters, neat; and that from every sack there ought to be made, at an average, twenty such peck loaves of bread. By 38 Geo. III. c. 62. it is enacted, that the magistrates, before they set the assise of bread, shall add to the average price, per quarter of wheat fit for making wheaten bread, 5d. on account of the additional duty on salt, so as to increase such average price 5d. per quarter; and in settling the assise, they shall use such increased average price as if it were the real average price of wheat, so long as such additional salt duty shall continue. By 31 Geo. II. c. 29. s. 3. no person shall make or sell, in any place where the assise is set, any sort of bread, except wheaten and household (otherwise brown) bread, and such sorts of bread as shall be allowed in the assise; and the offender against this part of the statute, upon conviction by his own confession, or the oath of one witness, before any magistrate or justice within the limits of their jurisdiction, shall forfeit, not exceeding 40s. nor less than 20s.

In every place where an assise is set, the assise and weight of the several sorts of bread there made are set according to tables, calculated for the purpose.

By the preceding table, if the price of wheat is 5s. a bushel (Winchester measure) and the allowance of the magistrates to the baker, for baking, is 1s. 6d., the weight and price of the several loaves will be found opposite to 6s. 6d. in the first column. The weight of loaves of any size may be estimated from that of the penny loaf by simple addition; e. g. the six-penny loaf weighs six times as much, &c.; and the wheaten loaves are three-fourths of the weight of the household loaves; and if the magistrates allow any of the white loaves of the price of one penny or twopence, they are to weigh three-fourths of the weight of the wheaten loaves of the same price. The prices of the household loaves are always three-fourths of the prices of the wheaten loaves.

The persons authorized to set the affise weight of bread, when wheat is above the price of 14s. 6d. the highest price of a bushel of wheat, together with the baker's allowance in the table, should observe, that the respective weights of the several affised loaves will decrease in the same proportion as the prices of the bushel of wheat, together with the allowance for baking, increases; and that such weights may be deduced from the present table as in the following examples: 1. Required the weight of the twelve-penny wheaten loaf, when the price of the bushel and baking is 16s. The weight in the above table opposite to 8s. estimated in the mode above directed, is 5lb. 11oz. 8dwts. But the price of the bushel and baking being now twice as much, the weight of the loaf can only be half what it then was, viz. 2lb. 13oz. 12dwts. 2. Required the weight of the twelve penny wheaten loaf, when the price of a bushel of wheat and baking is 16s. 3d. The weight, when the price of the bushel and baking, is 16s. is 2lb. 13oz. 12dwts.; and the weight, when the price of the bushel and baking is 16s. 6d. is 2lb. 11oz. 14dwts. and these two added together give 5lb. 9oz. 10dwts. and, therefore, one half the weight at 16s. 3d. is 2lb. 12oz. 13dwts.

For the price of the peck loaf, and its subdivisions, it should be observed, that the price increases in the same proportion as the price of the bushel of wheat, together with the allowance for baking, e. g. 1. Required the price of the peck loaf wheaten bread, when the price of the bushel and baking is 16s. The price of such loaf by the table, when the bushel and baking is 8s. is 3s. 0 1/2 d.; consequently at 16s. it must be double or 6s. 1d. 2. Required the price of the peck loaf when that of the bushel and baking is 16s. 3d. The price when that of the bushel and baking is 16s. is 6s. 1d.; at 16s. 6d. 6s. 4d.; and adding these, we have 12s. 5d. one-half of which, or 6s. 2 1/2 d. is the price at 16s. 3d. See 39 and 40 Geo. III. 74.

The affise is to be set in avoirdupois weight; and the prices of grain, meal, or flour, allowed to be made into bread in London, shall be determined by the public sale in the London markets during the whole market, and certified on oath before the court of mayor and aldermen, on some certain day in every week, by the meal-weighers or persons appointed by the said court; and entered in writing, under their hands, in some book provided by the city, and kept at the town-clerk's office. On the next day after such price shall be certified, the affise and weight of all forts of bread for sale, and also the price, shall from time to time be set by the said court, or mayor, and remain in force until a new affise in London shall be set. As soon as it can conveniently be done, the affise so set shall be made public in the manner directed by the said court. But before any advance or reduction shall in any week be made by the said court or mayor in the price of bread, the meal-weighers or persons duly appointed shall return the prices of grain, meal, and flour, in writing, to the common hall of the company of bakers, so that the said company may, on the morning of the next day after every such return and entry, and before any affise be set, have an opportunity to offer to the said court or mayor their objections against any proposed advance or reduction. In other cities and towns corporate this business shall be conducted and settled by the court of mayor and aldermen, if there be any, or by the mayor, bailiff, or chief magistrates, or by two justices in such towns and places which have no such mayor, bailiffs, aldermen, or chief magillrate. In places within counties at large, two justices are authorized to set the affise. Bread of different denominations, such as six-penny, twelve-penny, and eighteen-penny loaves, and peck, half-peck, and quarter of a peck loaves,

loaves, shall not be allowed to be made or sold at the same time in the same place, under a penalty of forfeiting not more than 40s. nor less than 20s. at the pleasure of the magistrate, upon conviction of the offender. After the assize has been set, no alteration shall be made in it till the price of corn alters 3d. a bushel. Officers appointed to make returns, and offenders against the due execution of this act, shall forfeit a sum not exceeding 5l. nor less than 20s. : and dealers in corn refusing to disclose the real prices of grain, meal, or flour, publicly sold, or knowingly giving a false price, shall, on conviction by confession, or the oath of one witness, forfeit not more than 10l. nor less than 40s. Bakers of bread made of other grain besides wheat, according to order, are required to conform to the assize, on pain of forfeiting not more than 5l. nor less than 40s.

The statute 36 Geo. III. c. 22. contains regulations for making mixed bread, and enacts that persons in any place whatsoever, whether any assize of bread has been set or not, may make and sell peck, half-peck, quartern, and half-quartern loaves, made of the whole produce of wheat, deducting only 5lb. of bran per bushel; or made of any sort of wheaten flour mixed with meal, or flour of barley, rye, oats, buck wheat, Indian corn, pease, beans, rice, or any other kinds of grain, or potatoes, in such proportions and of such prices as the maker or seller shall deem reasonable. Every loaf of such mixed bread shall have upon it a mark. It is required by 31 Geo. II. c. 29. § 21. that the several sorts of bread made for sale shall be well made, and no alum, or mixture in which alum is an ingredient, or any other ingredient or mixture whatever, (except only the genuine meal or flour, which ought to be put therein, and common salt, pure water, eggs, milk, yeast, and harm, or such leaven as is allowed by those who set the assize, or by any magistrate or justice within his jurisdiction,) shall be used in making any dough or in the preparation of bread, on pain that the offender (other than a servant or journeyman), upon conviction by confession, or the oath of one witness, shall forfeit not more than 10l. nor less than 40s. or be committed to prison or house of correction for any time not exceeding one calendar month, nor less than 10 days, at the pleasure of the magistrate. A servant or journeyman, upon conviction, shall forfeit not more than 5l. nor less than 20s. or be committed to prison as aforesaid. The magistrate before whom such offender has been convicted, may apply the money forfeited for causing the offender's name, place of abode, and offence, to be published in some news-paper, printed or published near the place where the offence shall have been committed. The adulteration of meal, or knowingly exposing it to sale, incurs a forfeiture of not more than 5l. nor less than 40s. If bread sold, or exposed for sale, be deficient in weight according to the assize, the offender, formerly liable to the pillory, shall now forfeit not more than 5s. nor less than 1s. for every ounce wanting; and for every defect less than an ounce, not more than 2s. 6d. nor less than 6d. such bread being complained of, and weighed before a magistrate within 24 hours after the same shall have been baked or exposed to sale, within the bills of mortality, or within 3 days in any other place. It has been observed, that bread loses weight by keeping: so Bartholine concludes from some experiments that the diminution was nearly one fourth in six months. Bakers are obliged under a penalty, not more than 20s. nor less than 5s. to mark their wheaten bread with a large Roman W, and their household bread with an H. No person shall sell bread for a greater price than that ascertained by the assize, or refuse to sell such bread at the stipulated price, under a penalty of forfeiting for every such offence not more than 40s. nor less than 10s. By 2 and 3 Edw.

VI. c. 25. if a baker shall conspire not to sell bread but at certain prices, every such person shall forfeit 10l. for the first offence; and if not paid within 6 days, he shall be imprisoned 20 days, and have only bread and water for his sustenance; for the second offence, 20l. or the pillory; and for the third offence, 40l. or the pillory, and loss of an ear, and becoming infamous. Bread inferior to wheaten shall not be sold for a higher price than household bread, under a penalty of 20s. By 31 Geo. II. c. 29. and 32 Geo. II. c. 18. magistrates may grant warrants for searching houses, in order to examine bread deficient in weight, or uncomfortable in any respect to the statute and assize, and for seizing the same; and also, upon information given on oath, for searching mills, and other places, where adulterated meal is concealed, and for seizing the same. Every miller, baker, &c. who has in his possession unlawful ingredients for the purpose of adulterating meal or bread, shall forfeit not more than 10l. nor less than 40s.; and out of the forfeiture may be published the name of the offender, his place of abode, and his offence in some news-paper, printed or published in or near the place where the offence was committed. Persons obstructing such search and seizure shall forfeit not more than 5l. nor less than 20s.

By a general clause in the act 31 Geo. II. c. 29. § 34. all penalties and forfeitures, when recovered, shall be paid to the informer; and by 32 Geo. II. c. 18. one moiety of such penalties as are not particularly disposed of shall be given to him who shall inform and prosecute; and the other moiety, together with all penalties and forfeitures incurred in the weighing, trying, or seizure of any bread by any magistrate, shall be applied, for the better execution of the act, according to the pleasure of the magistrate. Prosecutions under this act are limited within 7 days after the commission of the offence, by 33 Geo. III. c. 57. The statute 3 Geo. III. c. 11. contains certain regulations and provisions in case no assize is set. By 13 Geo. III. c. 62. a standard wheaten bread was ordered to be made of such flour as is the whole produce of the grain, the bran or hull only excepted, and to be marked S.W. This bread is made and sold, though no assize be set, of the weight and in the proportions following: viz. that every standard wheaten peck loaf shall weigh 17lb. 6oz. avoirdupois; every half-peck loaf 8lb. 11oz. and every quartern loaf 4lb. 5½oz.; and every peck loaf, half-peck loaf, and quartern loaf shall always be sold as to price in proportion to each other respectively; and that when wheaten and household bread, made as the law directs, shall be sold at the same time, together with this standard wheat bread, they be sold in proportion to each other as follows: viz. that the same weight of wheaten bread which costs 8d. shall of this standard wheaten bread cost 7d. and the same weight of household bread shall cost 6d.; or 7 standard wheaten assized loaves shall be equal in weight to 8 wheaten assized loaves, or to 6 household assized loaves of the same price, as nearly as possible. The magistrates may, when they think proper, fix the assize of this standard wheaten bread, according to tables calculated for the purpose. The bakers and sellers of it shall be liable to all the penalties of the former acts. See the tables 39 and 40 Geo. III. c. 18. and c. 74. Barn's Justice, vol. i. and iv.

BREAD, *Indian, or Cassava.* See *JATROPHA MANIHOT.*

BREAD, *St. John's.* See *CERATONIA SILIQUA.*

BREAD, *swine, panis porcinus,* a denomination given to truffles.

BREAD, *sow's,* a name applied to the herb cyclamen.

BREAD-ROOM, in a ship, that which is set apart to hold the bread. The boards of the bread-room should be jointed and caulked, and also lined with tin plates, for the greater preservation

preservation of the bread. It is also proper to warm it well with charcoal for several days before the bread is put into it, since nothing is more injurious to bread than moisture.

BREAD, *fruit-tree*, in Botany. See ARTOCARPUS.

BREAD, *nut-tree*. See BROSIMUM ALICASTRUM.

BREADALBANE, or BRAIDALBIN, in *Geography*, a district of Perthshire, Scotland, including a tract of country measuring about 32 miles from E. to W. and 13 in its broadest part from N. to S. This mountainous country forms part of the Grampian hills, and is supposed to have been anciently called Albania; whence the Highlanders still denominate themselves Albinich; and the duke of York receives his title of Albany from this place. The name Braid-Albainn, in the Gaelic tongue, signifies the highest part, which corresponds with this portion of country, as some rivers that take their rise here, run partly into the eastern and partly into the western oceans. Flax is the principal article of cultivation. Some years back, when premiums were offered for the greatest crops, from 80 to 120 hogheads of linseed were annually sown; and each peck yielded two stones of dressed flax. Next to this, oats and potatoes are mostly cultivated; and from the latter some strong spirit has been distilled, which is found to be cheaper than that made from grain. Bread and starch are also made from this root. Corcar, or the lichen omphaloides, an article of commerce, is obtained in abundance from the rocks, and is sold mostly to dyers. Pennant's Tour in Scotland, 4to. vol. iii.

BREADTH. See LATITUDE, DIMENSION, AREA, &c.

BREADTH, *Hair's*. See HAIR.

BREADTH, *Finger's*. See FINGER.

BREADTH, *Hand's*. See HAND.

BREADTH, in *Ship-building*, the breadth of a ship at any particular place, as the *extreme breadth*, which is the greatest breadth, being at the main frame, the *top-timber breadth*, the *breadth at the main or wing transom*, &c. The breadth and curvature of all the frames are laid down on the body plan, or plane of projection; those of the fore-body being on the right hand side of the middle line, and the frames in the after-body being on the left hand side of the same line; from whence the frames are transferred to the mould loft. See BODY-PLAN, and SHIP-BUILDING.

BREADTH-SWEEPS. Of these there are two; the *lower* and *upper*. The centre of the lower breadth-sweep is in the line that represents the height of the extreme breadth of the timber. If there is a part of the timber straight, the centre of the sweep will be in the lower line. From this centre extend to the point that limits the half breadth of the timber in the same line; and with that radius describe a circle downwards, till it comes near the floor sweep. The centre of the upper breadth-sweep is in the line that represents the extreme upper height of the breadth of the timber; from which a circle must be described to pass through the point that limits the half-breadth of the timber in the same line, and produced upwards at pleasure to form the top-timber.

*Half BREADTH of the Floor*, is the distance of the centre of the floor sweep from the middle line in the body plan at the main frame; which will always be less than the distance between the point where the straight line, drawn from the side of the keel to touch the back of the floor sweep, is from the middle line. This last may be called the true half-breadth of the floor, which in sharp ships will be above the rising line.

*Half-BREADTH Plan*, or *Floor Plan*, or, as it is frequently called, the *horizontal plan*, contains the several half-breadths

of every frame of timbers at different heights; ribbands, water-lines, &c. are also described on this plane.

*Height of BREADTH lines*, are two lines named the *upper* and *lower* heights of breadth. These lines are described on the plane of elevation to determine the height of the broadest part of the ship at each timber; and being described in the body plan, limit the height and breadth of each frame at its broadest place. One line serves for both in the half-breadth plan.

*Main half-BREADTH*, is a section of the ship at the broadest place, perpendicular to the sheer plan, and represents the greatest breadth at the outside of every timber.

*Top-timber half-BREADTH*, is a section of the ship at the height of the top-timber line, perpendicular to the plane of elevation.

*Half-BREADTH Staff*, a rod about an inch square, and of any convenient length. Upon one side of this staff are set off, from one end, the several half-breadths of all the timbers in the after-body; and those of the fore-body are set off upon the other side. On the other two sides are set off the several heights of the sheer; the after-body on one side, and the fore-body on its opposite. Two sides of the staff are marked *half-breadths*; and the other two sides, *heights of the sheer*.

BREAK, in *Agriculture*, denotes, in Norfolk, land ploughed or broken up the first year after it has lain fallow in the sheep-walks.

In *Architecture*, it denotes a recess, or giving back of a part behind its ordinary range or projection. In which sense, they say, a break of pediment: a break of entablatures, whereby it shrinks, as it were, between the columns, is reputed a fault.

BREAK, *Cape*, in *Geography*, lies on the east coast of Newfoundland, and forms the east point of the entrance into Trinity bay, about 10 leagues south-east from cape Bonaventure.

BREAK-SEA ISLAND, lies without the new passage or north entrance into Dusky bay, on the west coast of the southern island of New Zealand.

BREAK-IN, among *Carpenters*, is when they break a hole in brick-walls with their ripping chisel.

BREAK-NECK, *Brise-cou*, in *Building*, a fault in a stair-case, as when a step is made higher or lower than the rest, and landing-place too narrow, or the like.

BREAK-WATER, in *Sea-Language*, the hull of an old ship, or vessel, sunk at the entrance of a small harbour, to break the force of the waves in their passage to the vessels moored within. Jetties, however, where practicable to be built, are employed for this purpose. A break-water is also a sort of a small buoy fastened to a large one in the water, when the buoy rope of the latter is not long enough to reach from the anchor, lying at the bottom, to the surface of the water. The use of this break-water is, therefore, to shew where the buoy swims.

BREAKERS, a name given to those billows that break violently over rocks lying under the surface of the sea. They are distinguished both by their appearance and sound, as they cover that part of the sea with a perpetual foam, and produce a hoarse and terrible roaring, very different from what the waves usually have in a deeper bottom. When a ship is unhappily driven among breakers, it is hardly possible to save her; as every billow that heaves her upward, serves to dash her down with additional force, when it breaks over the rocks or sands beneath it.

BREAKERS' POINT, in *Geography*, is the south-east point of

of Hope bay, on the north-west coast of North America. N. lat. 49° 15'. W. long. 126° 40'.

**BREAKING**, in *Agriculture*, denotes the ploughing up of grounds, especially such as have lain some time fallow.

**BREAKING Bulk**, the commencement of the discharge of the cargo of a ship.

**BREAKING *beer*** is applied to a ship at anchor, when she is forced by the wind or current from that position in which she keeps her anchor most free of herself, and most firm in the ground, so as to endanger the tripping of her anchor.

**BREAKING up a ship**, stripping off the planks, and taking her to pieces, when she becomes old and unserviceable.

**BREAKING ground**, in the *Military Art*, the beginning of works for carrying on the siege of a place; more especially the beginning to dig trenches, or approaches.

**BREAKING the angles of a battalion**, denotes a military evolution, whereby the four angles turn, and make so many fronts towards the enemy; so that the battalion, which before was only a square, becomes an octangle, and can fire on all sides. This is otherwise called blunting the angles of a battalion; by the French, *emousser les angles d'un bataillon*.

**BREAKING of measure**, in *Fencing*, denotes a moderate retiring, or giving of ground, in order to avoid the adversary's thrust. Breaking of measure differs much from going back, and losing or yielding of ground; the latter being reputed a great reproach, the former a mark of judgment and adroitness. Some pretend, that a man retiring is obliged to forbear, if his adversary call him to stand.

**BREAKING of the sea**, **BREAKING of a wave**, or the like, on a rock, a bank, or the like, are a sufficient indication to the pilots, that it is not safe mooring there.

Divers machines and structures have been contrived for breaking the force of wind, the stream of water, and the like.

**BREAKING** is also used for the taming of animals, or reducing them from a wild to a tractable state.

**BREAKING of a horse to the saddle**. See **BACKING**, and **TRAVICE**. To break a horse for hunting, is to make him acquire the disposition and habit of running. It is a great fatigue to run horses full speed before they are broken.

**BREAKING herd**, among *Sportsmen*, denotes a deer's quitting the herd, and running by itself: or singling it out from the herd for chase. In which sense, the word stands opposed to herding. A deer when close pursued, is luth to break herd. When a hart breaks herd, and draws to the thickets and coverts, he is said to harbour or take hold.

**BREAKING up a deer**, signifies the opening or cutting it up. This term is applied to the act of cutting open the deer after the chase, that the perquisites of blood and garbage may be given to the hounds.

**BREAKING of prison**. See **PRISON**.

**BREAKING the legs**, *crucifragium*, was an appendage of crucifixion, used no where but among the Jews. See **CROSS**.

**BREAKING of hemp**. See **BRAKE**.

**BREAKING of bread**, is sometimes used in *Ecclesiastical Writers*, for celebrating the **EUCCHARIST**.

**BREAKING of wine**, among *Vintners*.—Wine is said to *break*, when being left some time in the air, in an open glass, it changes colour; an indication that it will not keep. This is the usual method of trying the goodness of wine, among the merchants and vintners of Paris.

**BREAKING** is also used in trade, for a person's failing or stopping payment. See **BANKRUPT**. Breaking betimes, while there is something left to pay withal, is a mark of

honesty; and, generally, entitles the unhappy person to compassion and gentler usage from his creditors, saves his credit, and facilitates his retrieving. A late sensible writer on trade takes great pains to inculcate this precept, *break early*. Compl. Eng. Tradesman, vol. i. p. 77, 80, &c.

**BREAKNECK**, in *Geography*, the name of a hill in America, opposite to Butter-hill, at the northern entrance of the high lands, in Hudson river, about 60 miles N. of New York. The rocks on the southern side of the hill are so situated as to give a tolerable idea of a human face, with a nose, mouth, and double chin, without a forehead.

**BREAKSPEAR**, **NICHOLAS**, in *Biography*. See **ADRIAN IV.**

**BREAL**, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Montford; 2 leagues S. E. of Montford.

**BREAM**, *head and bay*, lie on the east side of the north island of New Zealand; the head is the north point of the bay. S. lat. 35° 46'. It has some small islands before it called the "Hen and Chickens." The name of this bay is derived from the sea-bream, with which it abounds.

**BREAM**, in *Ichthyology*. See **BRAMA CYPRINUS**.

**BREAM, to**, in *Sea Language*, to burn off the filth, such as grafs, ooze, shells, or sea-weed, from a ship's bottom, that has gathered to it in a voyage, or by lying long in a harbour. This operation is performed by holding kindled furze, fagots, or such materials, to the bottom, so that the flame incorporating with the pitch, sulphur, &c. that had formerly covered it, immediately loosens and throws off whatever filth may have adhered to the planks. After this, the bottom is covered anew with a composition of sulphur, tallow, &c. which not only makes it smooth and slippery, so as to divide the fluid more readily, but also poisons and destroys those worms which eat through the planks in the course of a voyage. Breaming may be performed, either when the ship lies aground after the tide has ebbed from her, or by *docking*, or by *careening*. See these articles.

**BREAST**, *Mamma*, in *Anatomy*. The breasts, which are two in number in the human subject, occupy the anterior and middle part of each side of the chest, and are therefore situated over the pectoralis major muscle. Each of these bodies consists of a gland, to which anatomists give the name of mammary, surrounded by cellular and adipous substance, and covered by the common integuments. In men, and in young girls, these bodies are small; they enlarge in the female subject very considerably at the time of puberty, assuming an hemispherical shape, and pretty firm consistence, which, however, is lost, as the subject advances in years.

The skin which covers these parts is white and soft to the touch, except in the middle, where there is a circular portion of a reddish brown colour, called the areola. From the centre of this projects the nipple, in the form of a cylindrical prominence, with a rounded end, similar in colour to the areola, and covered, like that part, by a more delicate continuation of the skin, which is somewhat wrinkled and irregular on its surface. Both the areola and the nipple are furnished with numerous sebaceous glands, which may be clearly seen through the integuments. The fluid which these secrete, preserves the parts from the excoriation, which they might otherwise suffer from suckling. Under the integuments, we find a considerable quantity of fat and cellular membrane, which surrounds and envelops the mammary gland, connecting it to the skin in front, and to the pectoral muscle behind, and penetrating into its substance, so as to separate the different portions of the gland from each

other. It is this that gives to the breasts of a well-formed female their beautiful external form.

The substance of the mammary gland presents a flattish body, of a circular form, bearing obscure marks of a division into smaller portions, which cannot be completely separated from each other. It is composed of a vast congeries of small tubes, convoluted and accumulated on each other, and known by the technical name of *tubuli lactiferi*, or galactophori. These unite together, gradually forming larger and larger trunks, which approach from all sides towards the nipple. The trunks become very much contracted at the areola, and in this state pass through the nipple, connected by a dense and shining cellular substance, to terminate on its surface by open orifices, whose size is about sufficient to admit a hog's bristle. The number of these openings is said by Röllin and Sabatier, to be constantly fifteen: the smallness of some of the apertures, and the consequent difficulty of finding them, have led some anatomists to state their number as less than this. Mekel has found, that when the lactiferous tubes, arising from one of the openings on the nipple, were fully distended, the mercury would pass into other sets of tubes by anastomosing branches. Some anatomists, in the number of whom is our countryman Mr. Cruikshank, have contended for the existence of acini in the mammary gland, which are supposed to afford origin to the lactiferous tubes. The description just given is drawn from subjects, who have died while suckling, or near the time of parturition: at these periods the gland is called into action, its parts are developed, and their structure may be unravelled without difficulty. At other times, the lactiferous vessels become so small as to be imperceptible.

The arterial supply of the breast comes from the internal mammary, and the thoracic arteries: the veins terminate in the thoracic trunks: the nerves are derived from the dorsal pairs: the lymphatics, which may be injected with facility from the lactiferous tubes, pass into the axillary glands in their course to the thoracic duct on the left side of the body, to the right lymphatic trunk on the right side. Sometimes, however, according to the researches of Mekel, they terminate separately in the subclavian veins. On the subject of this article, the reader may consult Haller's Elem. Physiol. tom. ii. Sabatier's Traité d'Anatomie, tom. ii. Rolpin de Strucura Mammarum, 4to. 1764.

The mammary glands secrete the milk, the nutriment of the young animal: for an account of the properties of this fluid, the reader is referred to the article MILK.

**BREAST, diseases of the, in Surgery.** See EXCORIATION. **ABSCESS, SCIRRHUS, and CANCER:** these are the chief morbid affections to which the breasts are liable; but they may occur likewise in various other parts of the body, and require to be treated on the same common principles, allowing for the different seat of the disorder.

**BREAST,** applied to the correspondent parts of other animals, is more properly called *udders, dugs, ubera, &c.*

**BREAST** also denotes that cavity or region of the body by anatomists more frequently called **THORAX.** Though, in propriety, the breast is rather restrained to the anterior part of the thorax where the ribs meet; called also sternum, and pectus; in English, popularly, the bosom.

We say, a flat, a narrow, a strait breast; a broad breast, not high, is ranked among the signs of longevity. Desfluxions on the breast and lungs are dangerous.

Coughs, catarrhs, asthma, phthises, peripneumonics, &c. are also diseases of the breast. See **COUGH,** and **ASTHMA.**

Physicians also speak of a dropsy of the breast, *hydrops pectoris.* See **DROPSY.**

Medicines for disorders of the breast are called pectorals. See **PECTORAL.**

Smiting the breast is one of the expressions of penitence. In the Romish church, the priest beats his breast in rehearsing the general confession at the beginning of mass.

**BREAST-bone.** See **STERNUM.**

**BREAST** of a chimney, denotes the fore-part under the mantle or chimney piece, commonly made inclined.

**BREAST-fall,** a Sea Term, a sort of hawser, or large rope, employed to confine a ship side-ways to a wharf or key, or to some other ship; as the head-fall confines her forward, and the stern-fall, abaft.

**BREAST-hooks,** in Ship-building, are thick pieces of timber, incurvated into the form of knees, and used to strengthen the fore-part of the ship, where they are placed at different heights directly across the stem, so as to unite it with the bows on each side. The breast-hooks are strongly connected to the stem and hawse-pieces by tree-nails, and by bolts, driven from without, through the planks and hawse-pieces, and the whole thickness of the breast-hooks, upon whose inside those bolts are fore-locked, or clinched, upon rings. They are usually about one third thicker; and twice as long as the knees of the decks which they support. The fore-side of the breast-hooks, which is convex, is formed so as to correspond with the place in which it is stationed; that is to say, it conforms exactly to the interior figure of that part of the bow where it ought to be fayed; accordingly, the branches, or arms of the breast-hooks, make a greater angle, as they are more elevated above the keel, whilst the lower ones are more incurvated. As it is not necessary that the inner, or concave side of these pieces should retain a regular form, the artificers frequently let them remain as thick as possible, to give additional support to the fore part of the ship, where it sustains the whole shock of resistance in dividing the fluid, or in plunging down into it. It is evident, that the connexion and solidity of the ship in this place, will be reinforced in proportion to the strength and extent of the breast-hooks, so that they may cover a greater number of the head timbers.

**BREAST-pain,** called by the Italians *grandezzo di petto*, is a distemper in horses proceeding from superfluity of blood and other gross humours, which being dissolved by some extreme and disorderly heat, resort downward to the breast, and pain them extremely.

The signs of the breast-pain are, stiff, staggering, and weak-going with his fore legs, besides that he can hardly, if at all, bow his head to the ground.

**BREAST-plate,** in Antiquity, a piece of defensive armour, wherewith to cover the breast.

The breast-plate is said to be the invention of Jason. It was originally made of leather, afterwards of mail, and lastly, of a brazen or iron-plate. When made of this last matter, it is more particularly called *clibanus*, by the moderns *cuirass*; when made of brass, with a Gorgon's head in the middle, it is denominated *ÆGIS.*

The breast-plate, called also by the Romans *pectorale*, is frequently confounded with the thorax and lorica; from both which it ought to be distinguished, as being properly a half-thorax, or half-lorica, covering only the breast; whereas the thorax invests the body.

As the whole thorax might be a temptation to the soldiery to turn their backs, when equally guarded with their breast, the thorax was thrown away, and the hemi-thorax, or breast-plate, only retained. Polyæn. Stratag. lib. vii.

**BREAST-plate,** in Jewish Antiquity, one of the priestly vestments anciently worn by the high-priests. It was a folded piece of the same rich embroidered tissue with that of the ephod, having set upon it twelve precious stones in gold, on

each of which was engraven the name of one of the tribes. These were fet in four rows, three in each row; and the whole was fastened at the four corners; those at the top to each shoulder-piece by a golden hook or ring, at the end of a wreathed chain; and those below to the girdle of the ephod, by two blue strings or ribbands, which had likewise two rings and hooks; so that the whole might be tied fast to the garment, without danger of falling off; for they were never to be severed. The Jews say, that if the high priest did, at any time, either through inadvertency, or wilfully, put on one without the other, he was to be punished: hence this ornament was called the *memorial*, to put him in mind how dear those tribes ought to be in his estimation, whose names he wore over his breast. This is also called the breast-plate of judgment, because it had the divine oracle fastened to it. Thus, however, most interpreters have understood the command of God to Moses of adjoining the urim and thummim to the breast-plate. The stones of the breast-plate were divided from one another by the golden partitions into which they were fet, and were ranged in the following order, to which the Hebrew names are added, together with the tribe that was engraven on each of them:

1.	Odem.	Sardius.	Reuben.
2.	Phiterah.	Topaz.	Simeon.
3.	Barketh.	Carbuncle.	Levi.
4.	Nophek.	Emerald.	Judah.
5.	Saphur.	Sapphire.	Dan.
6.	Jabalom.	Diamond.	Naphtali.
7.	Leshem.	Ligure.	Gad.
8.	Shebo.	Agate.	Asher.
9.	Achlamah.	Amethyst.	Isshachar.
10.	Tarshish.	Beryl.	Zebulun.
11.	Shohem.	Onyx.	Joseph.
12.	Yaphpe.	Jasper.	Benjamin.

**BREAST-plate**, in the *Manege*, denotes a leathern strap running from one side of the saddle, cross the horse's breast, to the other; intended to keep the saddle from slipping backwards in mounting up rising-grounds. It is otherwise called *tee*; sometimes the *poitrail*.

**BREAST-plate**, among *Artificers*, denotes a drill-plate, against which to set the blunt end of the drill.

**BREAST-plough**, in *Agriculture*, a small plough so constructed, that a man may push it before him. It consists of a cutting-iron about eight or nine inches long, with one of its sides turned up to cut the turf, which is fixed to a pole about five or six feet long, forked at the upper end, with a cross handle. It is used in the operation called *burn-taking*.

**BREAST-rail**, in *Sea-Language*, the upper rail of the balcony, or of the breast-work on the quarter-deck.

**BREASTS of a fiddle**, are part of the bow, being the two sides of it down from the arch or upper part.

**BREAST-work**, in the *Military Art*, is an elevation thrown up around a fortified place or post, to conceal or protect the garrison, and which is at the same time so strong that the enemy's shot cannot pierce through it.

The terms *breast-work* and *parapet* are frequently used indiscriminately; but the former is more applicable in a general sense, a parapet implying more immediately that breast-work which is raised upon the rampart of a fortified town. See **PARAPET**.

A breast-work is usually formed simply of earth, not only because it may be procured with the greatest ease, and with the least expence, but also because it is liable to fewer objections and difficulties than such as occur in the use of other materials; for if the breast-work was made of stone or wood, the garrison would be liable to have more men killed

and wounded by the splinters struck off by the enemy, than by his shot. The stiffer the earth, the better it is for the formation of a breast-work; a stiff soil adhering well together, and destroying the force of the balls which penetrate it better than any other. A soil of loam or clay is, therefore, to be preferred to all other kinds of earth. In rocky or marshy ground, a covering may be formed of wool-lacks, dung, brush-wood bound together, or fascines.

With respect to the height of a breast-work, it should be such that a soldier, standing behind it, cannot be seen by the enemy. If, therefore, the garrison and the enemy are on the same level, the height of six feet is sufficient to cover the defenders; but if the enemy is on higher ground something must be added; and, in this case, the principles of geometry will easily determine how much it must be augmented in each particular instance, according to the distance of the enemy from the breast-work, the space behind it in which the garrison is to be covered, and the elevation of the ground on which the enemy is posted. If the garrison stands on higher ground, the breast-work need not be six feet high, and the more the garrison is elevated, the lower the work may be. It is here also easy to determine the necessary height, by only considering the intention of the breast-work, which is at all times to shelter the soldiers placed behind it from the fire of the enemy's cannon and small arms. A breast-work should be so strong that the enemy's shot cannot entirely penetrate it. To resist the most powerful attack of field artillery, the thickness should be at least 18 feet of good soil, and from 22 to 24 feet in bad. This is the case in actual fortification; but in works cast up in the open field, often in the greatest haste, and where we expect to be assaulted only by field pieces, a thickness from 10 to 12 feet is perfectly sufficient. If it is intended only to hold out against musquetry; or if the work is erected only for the purpose of concealing the troops behind it, from three to six feet is an ample thickness.

If the breast-work is formed of earth, each side must make an acute angle with the horizontal base of the work, otherwise it would soon fall down. These oblique surfaces are called the interior and exterior *slope* or *talus* of the breast-work. As good earth will stand firmer than bad, the base of the slope need not be so large in a clayey as in a sandy soil. Experience shews that good earth will stand when the base of the slope is only equal to half the height; but that bad earth requires a slope equal to the whole height; therefore, when other reasons do not render it necessary to vary from this rule, it may be looked upon for earth-work in general, that if the soil is very good it should be equal to half the height; if middling, to two thirds; and if very bad, the base must be equal to the height. The interior slope should be kept as small as possible, for the convenience of the troops posted behind the breast-work. It is, therefore, usual to make the base only one-sixth of the height; and to retain the interior side from falling, a revêtement of fascines, hurdles, fods, or even a stone wall, may be made use of. Of these, fascines and hurdles, from the ease with which they are procured and constructed, are the most advantageous in the open field. In a permanent fortress, the inner side of the parapet should be formed of fods. As for revêtements of boards or stone, they should never be used in the field, because the former become soon rotten, and the splinters of the latter might greatly annoy the garrison. The exterior slope, being more exposed to the enemy's fire, is sooner liable to fall, and requires therefore a larger base; but the smaller this is kept, the more difficult it is for an enemy to climb. For this reason, it should always be as narrow as the nature of the soil will allow. If it has a revêtement, the rules

given for the interior slope apply equally to this, except that boards and stone are not here so dangerous to the garrison.

That the troops thus protected by the breast-work may be enabled to fire on the enemy without obstruction, an elevation of earth, called a *banquette*, is made immediately behind it, which the soldiers mount when they are to fire. This should be raised until the height of the breast-work above is about four feet two inches, that the soldier standing upon it may make use of his arms properly, and fire conveniently over. If the height of the breast-work is six feet, that of the banquette will accordingly be one foot two inches; and if the breast-work is higher, the banquette must also be raised. To render the ascent perfectly easy, its slope should be very broad, at least equal to, or even double its height. The breadth of the banquette should be three feet or more, according to the number of ranks in which the men are drawn up. The upper surface, summit, or crown of the breast-work, must be made with a declivity towards the country, otherwise when the enemy is advanced within a short distance, he cannot be hit from behind the work. The difference in height between the slopes depends on the thickness of the work. If this is 24 feet, the exterior talus may be two feet lower than the inner; if the breast-work is weaker, the difference must be proportionably lessened. If on an eminence, it will be necessary to give the superior slope a greater declivity. Its proper inclination may be easily determined, only taking care that the fire regulated by it is not confined to a single point on the ground, but extends as much as possible. When the breast-work has no exterior slope, but the summit is continued outwards until it meets the surface of the ground, it is a perfect *glacis*. In this case the base must be much broader than that of a common breast-work; otherwise the work would be too weak, and the slope so steep, that the fire acting in that direction instead of grazing, would bury itself in the ground. Two advantages are derived from this glacis: every point in front of it is exposed to the small arms of the garrison, which is not the case in any other kind of breast-work; and it cannot be destroyed by the enemy's shot, which only strikes into it, the loose earth remaining in its proper place; but it is attended with this disadvantage, that it may be mounted without difficulty.

When cannon are planted behind a breast-work, they may either fire *en barbette*, or through embrasures. In the former case, instead of a banquette, an elevation of earth is formed sufficiently large to contain guns mounted on their carriages, and of such a height that their muzzles may reach above the summit. This elevation must be carried to within two and a half, or three feet from the top of the work, and sufficiently broad to afford convenient room for the gun and men attached to it. About ten or twelve feet are allowed for each piece of cannon. The length should be from twelve to eighteen feet, according to the gun, that space may be left behind to prevent its running down in the recoil. An easy slope, called a *ramp*, is made to every battery of this nature, that the guns may be run up without difficulty. This method, however, is only safe when the enemy cannot bring artillery against the breast-work, or when posted on an eminence; and even then we should endeavour to cover the artillerymen with gabions or sand-bags placed upon the work, leaving an opening of  $1\frac{1}{2}$  or 2 feet between them for the mouth of the cannon. If two or more rows of gabions are placed one before the other, the opening must increase in width towards the front, that we may be enabled to point the gun to either side, as well as directly forwards. When the guns, and men who serve them, are much exposed to the enemy's fire, *embrasures* are to be cut for them. When several pieces of

cannon are placed behind a work, their distance asunder should be from 12 to 20 feet. The piece of the breast-work which remains standing between every two is called a *merlon*. As it is to be expected that the enemy will direct his principal fire against the batteries, the merlons ought to be very strong, and constructed with attention; and as musketry are not used behind them, they may, for the better security of the gunners, be made eight or nine feet high.

To procure the earth for the formation of the breast-work, a ditch is made on the outside of it, by which the enemy has an additional obstacle to overcome in his attempts to approach. In some cases the ditch is behind the work; as, for example, on a very steep hill, where a fosse in front would not render the enemy's endeavours to climb it more difficult, and it is more convenient to make use of the earth within the breast-work. The ditch is made sloping on both sides. The inner slope is called the *scarp*, and the outer the *counter-scarp*. The width of their bases is determined by the nature of the soil; but to give the enemy all possible trouble in getting in and out of the ditch, both slopes should be as steep as the tenacity of the ground will allow. If the scarp forms one continued surface with the exterior slope of the breast-work, the enemy has the greatest difficulty in gaining the summit; but as the scarp in this case sustains too great pressure, it would soon give way, and a considerable part of the work with it. Even should the scarp stand firm, the earth must constantly fall from the breast-work into the ditch, and fill it up to our great disadvantage. To prevent this, the breast-work is thrown up at a small distance from the edge of the ditch, thereby leaving a free passage between them, called a *berme*. This certainly facilitates the enemy's mounting the breast-work; but to diminish this disadvantage, it should be made as narrow as possible. The size of the ditch is regulated by that of the breast-work. The requisite quantity of earth may be procured equally, whether the ditch is wide and shallow, narrow or deep; but the removing it is easier by the latter mode, and the enemy will also have greater difficulty in crossing the ditch. In low ground, however, this cannot always be done; and the ditch must at all times be sufficiently broad not to be leaped across. It is usually 10 or 12 feet wide, and, wherever the situation allows, at least six feet deep; but if those dimensions will not furnish the necessary quantity of earth, an augmentation must be made either of the width or depth, and sometimes of both.

A breast-work, constructed according to the foregoing rules, covers our garrison against the fire of an enemy, and enables us to fire on him with tolerable security during his march towards it. Notwithstanding this, if he is resolute, and not to be deterred by the loss of a few men, and as there is no particular difficulty in surmounting the ditch or breast-work, we have ultimately no superiority over him, and must therefore have recourse to other obstacles to impede his progress. These are natural and artificial. Certain natural obstacles render the access to a place extremely difficult; such as when the breast-work is behind a river, canal, or morafs, too deep for the enemy to wade through; or when it is situated in rocky ground, or on a high and steep hill which cannot well be climbed by a body of men in any regular order. Here there is no absolute necessity for a ditch; and provided the breast-work covers us from the enemy's fire, it may be considered as perfect. Artificial obstacles are, 1. *Palisades*, which may either be fixed in the open field in front of the ditch, or in the ditch itself, sometimes in two rows, or lastly upon the banquette, where they occasion excessive inconvenience to the enemy, and afford essential protection to the garrison. 2. *Fraises*, hurried in the exterior slope of the breast-work, their points inclining a little downwards. Where there is also a row

of palisades upon the banquette, these occasion much obstruction to the enemy in his endeavours to mount. 3. *Chevaux de frize*, planted along the middle of the ditch, where they render the passage extremely difficult, especially if they stand behind a row of palisades. 4. An *abbatis* of trees cut down and arranged on the outside of the ditch, along the whole front of the work. When the branches are well intermingled, and the trunks buried obliquely in the earth, or fastened down by strong pickets, they cannot be removed without great difficulty. The *abbatis* should lie under the fire of the breast-work, and therefore ought not to be more distant from it than 200 or 250 yards. 5. *Trous de loup* placed chequerwise in front of the work, about 16 or 20 feet from the counter-scarp. Three rows of them present at all times a formidable obstacle, as they cannot be passed except by each man singly, which causes the enemy to remain a long time exposed to the fire from the breast-work, and to form under it at a great hazard. 6. *Crows' feet* scattered along the bottom of the ditch, or in the ground in front of it; or, where they are wanting, a number of stakes, capped and pointed with iron, may be driven into the ground. 7. An *advanced ditch* about 30 yards in front of the first. This, if filled with water, or enfiladed from the breast-work, presents a considerable obstacle; but, otherwise, only affords the enemy a place of shelter, where he may rest some time in security, and from thence make the remainder of his way to the work in great haste, so that it becomes a detriment instead of an advantage. 8. An *artificial inundation* of the country in front of the work, effected by means of dams. This, if five or six feet deep, and properly under the fire of the garrison, is an amazing and obvious advantage; but the work is so laborious, and requires such a combination of circumstances to render it effectual, that it is rarely executed in the field. 9. *Fougasses*, or *small mines*, placed about eight or twelve yards from the ditch, and sprung when the enemy is marching over them towards the breast-work. These occasion great disorder; and as soldiers have a great dread of mines, and anxiously avoid an attack upon any spot they conceive undetermined, are an excellent security against the attacks of a superior enemy.

Previous to the elevation of the breast-work, its entire plan must be traced or marked out upon the ground, in such a manner that the workmen may afterwards be enabled to calculate the thickness of the work and breadth of the fosse. In computing the length of the breast-work, two feet are allowed for each file of men; and as troops are usually formed two deep for its defence, the length will be equal to the number of men; ten feet are allowed for a small gun, and fourteen or sixteen for a larger. Thus the length of a breast-work for 250 men, and four field-pieces, should be 290 feet. In excavating the ditch, three workmen are allowed to every eight feet in length; and when in a clayey or gravelly soil, to every three men with shovels, one with a pick-axe should be reckoned, to loosen the ground. The breast-work itself, and every thing immediately belonging to it, should be erected entirely by the troops. A work with a revetement of fods may in general be completed in a day, provided there is a sufficient number of workmen. But if it is to be formed with fascines, or palisaded, it will require two days; and if there are likewise to be fraises, fougasses, trous de loup, &c. three may not be sufficient. Under the articles RAMPART, FOSSE, REVETEMENT, FASCINES, FOU GASSES, PALISADES, &c. the reader will find the construction of the different parts of a breast-work more fully explained.

In *Plate IV. Fortification, fig. 1.* *a, b, c,* is the banquette; *c,*

*d,* the interior slope or talus; *d, e,* the summit of the breast-work; *e, f,* the exterior slope or talus; *f, g,* the berm; *g, h,* the scarp; *i,* the fosse; *k, l,* the counter-scarp; *l, m,* the glacis.

*Fig. 2.* is a breast-work fraised and palisaded, seen in profile; *a,* is a row of palisades planted upon the banquette; *b,* another of fraises, buried in the exterior talus of the breast-work; *c,* chevaux de frize in the middle of the ditch behind *d,* a row of palisades, fixed at the foot of the counter-scarp; *e,* trous de loup; *f,* abbatis of trees, seen in profile.

*Fig. 3.* is a plan of the breast-work; *a,* is the slope of the banquette; *b,* banquette; *c,* interior talus; *d,* breast-work; *e,* exterior talus; *f,* berm; *g,* scarp; *h,* fosse; *i,* counter-scarp; *k,* trous de loup in three rows; *l,* abbatis.

**BREAST-WORK**, a *Sea-term*, a set of framing composed of staunchions and rails, with moulding, and sometimes sculpture. It terminates the quarter-deck and poop at the foremost end and the after-end of the fore-castle.

**BREATH**, the wind or air which is received and expelled by the mouth and nostrils, in the act of respiration. In which sense, the word amounts to the same with the Greek *πνευμα*, and Latin *spiritus*.

A stinking breath is one of the symptoms usually preceding the access of an intermittent fever. In some persons, a stinking breath is an indication of the menses being at hand. It is disputed among the civilians, whether a stinking breath, called *scabro*, owing to rotten teeth or gums, should be reputed a disease. Calvin. Lex. Jur.

**BREATH** is more particularly used to denote a strength of lungs, whereby a man is enabled to hold out without taking wind so often. In this sense, we say, a long, a short breath. The ordinary term of holding the breath does not exceed one third of a minute. Bacon, Hist. of Life and Death. Ap. Works, tom. ii. p. 176.

For the pearl-fishery they choose slaves who have the best breath, or can continue the longest under water without fetching their breath. Pechlin has a dissertation express on living long without breathing. J. Nic. Pechlin De Aeris & Alimenti Defectu, & Vita sub Aquis diuturna, Meditatio ad Joel Langelot, 1676. The ancients were very watchful over the last breath of dying persons; which the nearest relations, as the mother, father, brother, or the like, received in their mouths. Pitisc. Lex. Antiq. voc. *Spiritus*.

**BREATH** is also sometimes extended to the odorous effluvia of plants, and even exhalations of minerals.

**BREATHING**. See **RESPIRATION**.

Fighting a cock to breathe him, is called **SPARRING**.

To breathe a running horse, and bring him to his wind, they gave him a **HEAT**.

**BREATHING, exsufflatio**, a ceremony in **BAPTISM**.

**BREATHING, short**. See **ASTHMA**.

**BREATHING, difficulty of**. See **DYSPNEA**.

**BREAUTE'**, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Le Havre, 3½ leagues N.E. of Montivilliers.

**BREBES, BREBERS, or BERBERES**, a denomination that distinguishes an ancient tribe of Africans, who are settled in and about the greater and lesser Atlas, and who inhabit different parts of Algiers, Barbary, and Morocco. Some suppose that they are descended from the ancient Sabæans, who migrated thither from Arabia Felix, under the conduct of one of their princes; others believe them to be some of the Canaanites, whom Joshua drove out of Palestine. But their origin is uncertain. It is probable, however, that they were very ancient inhabitants of the country, and that they were

were compelled by the Arabs or Saracens, who overran the eastern parts of Africa, about the middle of the seventh century, to seek a safe retreat among the vast ridges of almost inaccessible mountains which extend through several parts of the immense country. Whatever be their origin, they are dispersed over Barbary, to which they are supposed to have given its name (the BARBARY), and divided into a multitude of tribes, under their respective chiefs; most of them inhabit the mountainous parts; some of them range from place to place, and live in tents or portable huts, others in scattered villages, avoiding, generally, all intermixture with other nations. These are reckoned the richest of all the various inhabitants of the country; and they carry on a much larger traffic of cattle, hides, wax, honey, iron, and other commodities; they have likewise some artificers in iron, and weavers. The Brebes and the Moors form the two principal classes, comprehending the different tribes that people the empire of Morocco. The Brebes, as well as the Moors, adopted, without doubt, the Mahometan religion, analogous as it was to their manners and prevalent customs, on the first invasion of the Arabs; but they are ignorant, and pay little regard to any of the precepts of their religion, except to that which inspires them with a hatred for others of a different profession. Mahometanism, however, has not effaced the ancient habits and prejudices of these people; for they eat swine's flesh, and, in those places which have vineyards, drink wine; alleging, as an apology, that it is of their own manufacture. In the southern parts of mount Atlas, they preserve it in earthen jars, and in barrels made of the trunks of hollow trees, the buttends of which they spread over with pitch, thus keeping it in caverns, and even in water. In the province of Rif, toward the north, they give it a slight boiling, which deprives it of its fumes, and makes it less intoxicating; and, perhaps, they also think, that it is thus rendered congenial to the spirit of the Koran. Bred in their mountains, the Brebes maintain their resentment against the Moors, whom, confounding with the Arabs, they regard as usurpers. In these asylums they contract a ferocity of character and strength of body, which render them more proper for war and labour than the Moors of the plain generally are; and the independence they profess imparts more of character to their countenance, which is visible to those who reside long among these nations. Although they are subject to the emperors of Morocco by religious prejudices, they set aside his authority whenever they think proper; and, intrenched in their mountains, it is difficult to attack and vanquish them. The Brebes have a language of their own; and they never marry but among one another. They have tribes or castles among them, which are exceedingly powerful, as to both their number and courage. Such are those of Gomera on the borders of Rif, of Gayrasan towards Fez, of Timoor extending along mount Atlas from Mequinez to Tedla, of Shavoya from Tedla to Duquella, and of Mishboya from Morocco to the south. The emperor of Morocco retains the children of the chiefs of these tribes at court as hostages for their fidelity. The Brebes have no distinction of dress; they are always clothed in woollen like the Moors; and, though they inhabit the mountains, seldom wear caps. These mountaineers, as well as their wives, have very fine teeth, and exhibit signs of vigour, which distinguish them from the other tribes. They commonly hunt lions and tigers; and the mothers have a custom of decorating their children with a tiger's claw, or the remnant of a lion's hide on the head, thinking that they thus acquire strength and courage. Similar superstition, without doubt, induces young wives to give their husbands the same sort of amulets. The Brebes and the Shellu, having a language common to them-

selves, and unknown to the Moors, must both have had the same origin, notwithstanding the difference that subsists in their respective modes of life. The Shellu live on the frontiers of the empire towards the south; their population is by no means so great as that of the Brebes, nor are they so ferocious; they do not marry with other tribes; and, though they practise many superstitious rites, they are faithful observers of their religion. The Brebes count the days of the week in the same manner with the Moors, and both of them employ Arabic words. The Shellu enumerate the days after the same method, but in their own language. Both the Brebes and Shellu denote the months of the year like the Moors and the Arabs, and date from the same æra, or the year of the Hegira. The Koran, and books of prayer of the Brebes and Shellu, are in Arabic; and so are their acts and title-deeds, which are written by their Talbes, or learned men. Chenier's Morocco, vol. i.

BREBEUF, GEORGE DE, in *Biography*, a French poet, was born at Torigny, in the Lower Normandy, in 1618, and studied polite literature at Caen and Paris. During his residence at Rouen, where he lived several years, he published, in 1656, a parody on the 7th book of the *Æneid*, and the first book of Lucan travestied, which latter work was intended as a satire against the titled vanity of great lords, and the servile baseness of their flatterers. He afterwards laid the foundation of his celebrity by a translation of Lucan's *Pharfalia*, which first appeared in 1658. Although this performance was censured on account of its dazzling and hyperbolical sentiments, and inflated language, and of its consequent tendency to corrupt the taste of young persons, it possessed the attractions of a rich style and sonorous versification, and became fashionable even at court, where cardinal Mazarin excited the hopes of the author by various promises, which his death prevented from being fulfilled. Disappointed in his expectations from other patrons, he retired to Venoix near Caen, where he died in 1661. His character was modest and gentle; and the last years of his life were spent in pious exercises, of which we have a specimen in his "Eutretiens Solitaires," a collection of religious poems, inferior in merit to his other performances. A collection of his posthumous works was published in two volumes, containing, among other pieces, 152 epigrams, written in consequence of a wager on the single subject of a lady's painting. He was likewise the author of "Poetical Eulogies," and a "Defence of the Romish church." *Nouv. Dict. Hist.*

BREBIETTE, PETER, a painter and engraver, who flourished in 1625, was born at Monte upon the Seine, in France, and acquired some eminence as a painter; but as an engraver he is well known. His etchings, which are spirited, evince genius, and great fertility of invention. His compositions abound with figures, which, though not correctly drawn, are well grouped, and executed in a masterly manner. Among others are the following: "St. George's Martyrdom," from Paulo Veronese; "Paradise," from old Palma; "A holy family, with St. John, whose foot is upon the cradle," from Raphael; the "Virgin kneeling by the side of Christ," attended by two angels, from a design of his own; the "Battle of the Lapithæ," and the "Death of the Children of Niobe," from his own designs." *Strutt.*

BREBINCE, or BOURBINCE, in *Geography*, a river of France, in the department of the Saone and Loire, which issues from the lake of Longpendu, in the district of Montcenis, and joining the Arroux, discharges itself into the Loire, near Digoin.

BRECCA, from the Fr. *breche*, in some ancient deeds, is used to denote a breach or decay. See BREACH.

BRECCIA,

**BRECCIA, BRÉCHE.** The term breccia was invented by the Italian statuary and builders, to denominate those varieties of marble which are composed of angular fragments cemented together by calcareous spar, or any other natural calcareous cement of a different colour from the fragments. Some French mineralogists have adopted the word, but have considerably extended its meaning. By brèche they understand any mineral aggregate composed of angular fragments, cemented together into a compact mass, and divide it into sub-species from the nature of the fragments; hence they have calcareous breccia, siliceous, argillaceous, magnesian, &c. The brèche, therefore, of the French differs from porphyry in the compacted pieces not being crystals, but merely casual fragments, and from pandingues (a term borrowed from our pudding-stone), in the pieces being angular instead of rounded.

**BRECEY**, in *Geography*, a town of France, in the department of La Manche or the Channel, and chief place of a canton in the district of Avranches. The town contains 2097, and the canton 9061 inhabitants. The territory includes  $137\frac{1}{2}$  kilometres and 17 communes.

**BRECHEN, LOWER**, a small town of Germany, in the circle of the Upper Rhine, and electorate of Treves, surrounded with walls, and made a town in 1369: 16 miles W.S.W. of Wetzlar, and 78 E.N.E. of Treves.

**BRECHIN**, an ancient and large town of Forfarshire, Scotland, is seated on the declivity of a hill, and consists of one large, two smaller streets, with a detached row of houses at the foot of the hill. This royal burgh, in conjunction with four others, sends one member to parliament. It was formerly a rich bishopric, founded by David I. about the year 1150, and at the reformation its revenues in money and kind amounted to 700l. a year. The Culdees had a convent-house, whose abbot witnessed the grant made by king David to his new abbey at Dumfermline. Some ruins of this house still remain, in a place called the College Wynde. An hospital was founded here by William de Brechin in 1256, of which some fine ruins were standing in the time of Mr. Pennant. Here was also a cathedral church, which has suffered much dilapidation, but its southern aisle is converted into the parish church. At its north-western angle is a handsome square tower with a short steeple, and near the southern side is a singular round-tower. This ancient structure corresponds with many similar buildings in Ireland; and it is remarked by antiquaries that they are peculiar to that island and Scotland, though only two remain in the latter country. Their origin and appropriation have never been satisfactorily accounted for, though many ingenious dissertations have been written on them by different learned antiquaries. The height of this at Brechin, from the ground to the roof, is eighty feet; the inner diameter, near the bottom, eight feet; and the thickness of the walls seven feet two inches. At the top its diameter is seven feet eight inches, and its circumference forty-eight feet. The top has been covered in, and terminated with a small spire, which has four windows. Near the top of the tower are also four original windows, and towards its bottom are two arched recesses, ornamented with religious sculptures; among which are the Crucifixion, with figures of the virgin Mary, St. John, &c. See *TOWER, round*. Archæologia, vol. ii. 83. Ledwich's Antiquities of Ireland.

Brechin had formerly its baronial castle, which was built on an eminence a little south of the town. It underwent a long siege in the year 1303, when it was gallantly defended against the English under Edward III. by its brave governor Sir Thomas Maule, who, after twenty days resistance, was slain by a stone cast from an engine, and the garrison imme-

diately surrendered. This town is also remarkable for a battle fought here in the great rebellion in 1452.

The trade of this place consists principally in linen and yarn, which gives employ to many of the poor women. Here is also a bleach-field, and a considerable tannery. Brechin is 64 miles N.E. from Edinburgh. Pennant's Tour in Scotland, vol. iii.

**BRECHT**, a town of the eastern part of Brabant, now the French department of the Deux Nettes, and chief place of a canton, in the district of Amers or Antwerp. The town contains 3428, and the canton 8800 inhabitants; the territory comprehends  $257\frac{1}{2}$  kilometres, and 7 communes.

**BRECKBERG, or BIRKHEYDEN, JOHN**, in *Biography*, a painter of landscapes, conversations, and portraits, was born at Haerlem in 1637, according to Houbraken, but, according to Descamps, in 1643, and studied after nature on the borders of the Rhine, where he sketched those views which he proposed to introduce into his landscapes. Having made himself a competent master in this style, he studied and practised the painting of figures, taking his models from nature. His subjects, however, were of the lowest kind, such as boors, husbandmen, shepherds, and inn-keepers, introduced into his landscapes, and represented also at their feasts, dances, or conversations, which he composed in the manner of David Teniers. His pictures were well handled, and agreeably coloured; and some of them were much esteemed. Ambitious of visiting the court of the elector palatine, who had been represented to him as a magnificent patron of persons of his profession, he accompanied his brother Gerrard thither; but being at a loss for a proper introduction, he and his brother finished two pictures, in which they painted the portraits of the elector, and of his principal attendants, which were striking resemblances, as they had observed them in the chace; and they then prevailed with an officer of the household to place them in a gallery, through which his highness always passed on his return from hunting. The stratagem succeeded; as the prince observed them with surprise and satisfaction; and the artists were ordered to be brought to court, where they were honourably received, paid liberally for their works, and presented, among other donations, with two medals of gold: Job died in 1698. Pilkington.

**BRECKBERG, or BIRKHEYDEN, GERRARD**, brother of the preceding, was born at Haerlem in 1645, and painted many pictures in concurrence with his brother; but his usual subjects were views of churches, convents, noblemen's houses, and magnificent structures, which he adorned with small figures designed after nature, and intended for his compositions. His works were much esteemed; but as he was advancing to reputation, he was unfortunately drowned in a canal on his return home from an evening party of friends. This event happened in 1693. Pilkington.

**BRECKERFELD**, in *Geography*, a town of Germany, in the circle of Westphalia, and county of Marek; 26 miles N.N.E. of Cologne.

**BRECKNOCK**, a township of America, in Lancaster county, and state of Pennsylvania.

**BRECKNOCK, or BRECON**, is the principal and county town of Brecknockshire, South Wales. It is situated in a most romantic part of the country on the banks of the rivers Usk and Hodny, whence its ancient name was Aberhodny. During the days of chivalry and papacy here were a castle and a monastery, both of which appear to have been extensive and important. They were built in the reign of Henry I. by Barnard de Newmarck, a Norman lord, who obtained great possessions in this part of the country, and perpetuated his name by founding several religious houses. This town was particularly distinguished by

by his institutions; among which were two priories appropriated respectively to Benedictines and Dominicans. One of these was converted into a college by Henry VIII., and the principal building of the other is now a parish church. The remaining fragments of the castle prove that it has been an extensive and grand pile of building. Part of the keep, and a tower called Ely-tower, still remain. The latter is so named from Dr. Morton, bishop of Ely, who was confined here by order of Richard III., where, in conjunction with his keeper, the disappointed duke of Buckingham, they planned the union of the two houses of York and Lancaster, and the succession of Henry VII. Their plan was completely digested, and eventually brought to a successful termination, though the projectors of it experienced very opposite fates. The duke, who was the most active in this transaction, was detected, seized, and executed; but the more fortunate bishop escaped from the castle, kept quiet, and lived to become, in the ensuing reign, a privy counsellor, and was further advanced to fill the metropolitan see of Canterbury. The castle is divided from the town by the river Hodny or Houdy. Its main body, with all the principal parts, are still to be traced, though the tower just mentioned is the only large mass of building that remains to characterize its architecture and gloomy dignity.

Brecknock was formerly surrounded with an embattled wall, and entered by four gates, named, according to their respective situations, East-gate, West gate, High-gate, and Water-gate. There was also another gate in the suburb, called Portherne S. Mariæ. The town consists, at present, of three principal spacious streets, and, according to Mr. Malkin's statement, "is one of the best built in Wales," though some of the smaller streets, occupied by poor inhabitants, are "miserably deficient in general arrangements." The trade, though not very considerable, is progressively increasing since the completion of its canal; and some manufactories of woollens and hats are established on a respectable scale. "Brecknock," observes Mr. Malkin, "appears in most respects to be a very desirable residence, and is much inhabited by clergy and gentry of independent fortunes. The number of spacious and modern-built houses is greater, in proportion to its size, than perhaps in any town of Wales. The markets are well, but not very cheaply, supplied. The broken summit of the mountainous ridge, continued into Monmouthshire in irregular lines; the dismantled towers of Aberhodny, with its mouldering walls in wild and various ruins, while the unpicturesque compactness of the modern buildings is favourably concealed, render this one of the most striking situations, near any town in the principality." The situation of the priory and castle, with the secluded and interesting walks formed near these ruins, are peculiarly delightful, and invariably attract the attention and admiration of all strangers. Brecon is a borough, and returns one member to parliament.

Here were buried the three bishops of St. David's, Mainwaring, Lucey, and Bull. In the town and its vicinity have been found several Roman antiquities, with coins, &c. and some large intrenchments are to be seen on the neighbouring hills; but the most remarkable fortification is Y-Gaer, about two miles N.W. from the town. This was probably occupied, if not made, by the Romans. It is seated on a gentle eminence, overlooking the river Usk; parts of its walls remain; and within the area of the camp some Roman bricks have been found, similar to those at Caerleon, with the inscription LEG II AUG. Contiguous to the camp, in the middle of a highway, is a rude carved pillar, about six feet high, called *Maen-y-Morinion*, or the Virgin's Stone. Another fragment of Roman antiquity is a sepul-

chral pillar, noticed by Gibson and Gough, standing upright by the road-side, with a defaced inscription, of which only the word VICTORINI is legible.

Brecknock consists of three parishes, and contains 540 houses, and 2576 inhabitants. It is 171 miles west from London, and has two weekly markets on Wednesdays and Saturdays, and four fairs yearly. Evans's Cambrian Itinerary, 8vo. 1801. Malkin's Scenery, Antiquities and Biography of South Wales, 4to. 1804. Gough's Edition of Camden's Britannia, vol. ii.

BRECKNOCK Canal, in *Inland Navigation*, joins that from Monmouthshire, eight miles and a half from Newport, and about one from Pontypool. It crosses the river Avon, and passes the high ground by means of a tunnel 220 yards long, and, inclining towards the river Usk, passes Abergavenny. It then runs parallel with the Usk to the town of Brecknock; making a course of nearly thirty-three miles, with sixty-eight feet rise. A rail-road extends from Abergavenny to the canal, one mile in length; and from the canal at Cwm Clydach to the coal and iron works at Wain Dew, four miles and three quarters. Another rail-road, from the canal to Llangroiney, crosses the river Usk, and is in length one mile and a quarter. The rates of carriage for all kinds of merchandize, materials, horses, cattle, &c. are particularly specified by the act of parliament. Philips's History of Inland Navigation, 4to.

BRECKNOCKSHIRE, deriving its name from Brecon, a distinguished character in legendary story, who succeeded to it about the year 400, one of the counties of South Wales, is bounded on the north and east by Radnorshire, having the river Wye for its natural division. A small part of Herefordshire also attaches to its eastern limits; on the south-east and south the county of Monmouth forms its boundary; and a small part of Glamorganshire, with Caermarthenshire and Cardiganshire, bound its western and south-western extremities. The length of this area, north and south, is estimated at twenty-nine miles, and its breadth at the southern basis about thirty-four miles, making nearly 900 square miles, and containing about 600,000 acres. This district is divided into the six hundreds of Bulth, Crickhowel, Deunnoch, Merthyr, Penkelly, and Talgarth, and contains 4 towns, and 67 parishes. These, with the hamlets, are populated by 31,633 persons, and contain 6794 houses.

This county is described in the following terms by Giraldus Cambrensis, who wrote at the latter end of the twelfth century, and was archdeacon of St. David's, in which diocese this county is included.

"Brechiniane (says he, in his Itinerary of Wales) is a county abounding with corn; and if ever any deficiency happens, it is plentifully supplied from its neighbour, England. It is rich in pastures and woods, deer and herds, and abounds also with river-fish in the Usk on one hand, and the Wye on the other; both yielding salmon and trout in plenty, but the Wye greater quantities of the excellent fish called *umbra*. It is enclosed on every side, except the north, by high mountains; having on the west the mountains of Canterbochan; on the south the southern hills, the chief of which is Cader-Arthur, or Arthur's chair, from its two summits (it being *δινοειδης*, *double-topped*) resembling a chair; and this chair, being on a high and steep place, is by the vulgar ascribed to the greatest and most sovereign monarch of Britain, Arthur. On the top of this hill rises a spring, deep like a well, but square; and though no stream runs out of it, they find trout in it. These mountains, forming a barrier to the south, keep out the sun, while cool breezes, and the native salubrity of the air, render the country extremely temperate. On the east stretch the Tolgar and Ewias hills."

Previous to the reign of William Rufus, this county appears to have been villed in its native princes; but in this reign Barnard de Newmarch, a Norman of great spirit, combined with prudence, assembled a considerable body of English and Normans, with whom he invaded this territory, and subdued the inhabitants. To secure his newly acquired possessions, he built castles, and assigned different parts of them to his principal associates. This policy further induced him to marry Nelt, grand-daughter of Gruffyth ap Lhwelin, who, proving to be of a most revengeful and abandoned spirit, involved her lord in much trouble, and occasioned her son to be disinherited, by falsely swearing to King Henry I. that he was a bastard. The lordship progressively passed to Milo, earl of Hereford, and his sons, next to Humphry de Bohune, to Philip Bruce, to Thomas Plantagenet, sixth son of Edw. III., and afterwards to the dukedom of Buckingham, till an attainder vested it in the crown. Brecknockshire was the seat of war in 1217, and afterwards in 1233, when Lhwelin came with an army, and destroyed nearly all the towns and castles in the county. At the restoration James Butler, afterwards duke of Ormond, was created earl of Brecknock.

The general aspect of the county is mountainous and grand, affording a sublimity of scenery, interspersed with large plots of cultivation, that attaches to it a peculiar character among the strongly marked divisions of South Wales. It is distinguished from Glamorganshire by more level and extensive vales; its mountains are also more continuous, more lofty, and presenting an appearance of hill piled upon hill. Its woods are commonly in very large masses, and the banks of its rivers are luxuriously clothed.

The principal river of this county, next to the boundary one of the Wye, is the Usk, which, taking its rise in the Black mountain, on the border of Caermarthenshire, flows through a fine valley, in its progress to Brecknock.

Agriculture, in this county, is much improved within the last twenty years. Being contiguous to Herefordshire, the good husbandry of which is deservedly noted, many English farmers have purchased estates here, and introduced, with themselves, new and more approved principles of agriculture.

The principal remains of Roman antiquities are in and near the town of Brecknock. Among these are a causeway running nearly at right angles with the Usk, and leading probably to the great Roman camp in the neighbourhood. Another Roman road has been discovered near the bridge of Capel Rhyd y Briw, and another on the top of the most unfrequented mountains. A Roman hypocaust has also been discovered in a field near the county town. Malkin's Tour in South Wales, 4to. 1804. Gough's edition of Camden's Britannia, vol. ii. Barber's Tour in South Wales, 8vo. 1803.

BREDA, VAN, or BREDALE, PETER, in *Biography*, a painter of landscapes and cattle, was born at Antwerp in 1630; studied landscape after nature, and adorned his designs with figures, correctly drawn and judiciously grouped. His scenes are generally enriched with elegant Roman buildings, fountains, monuments, and ruins. His style, though inferior, resembled that of John Brueghel. He died in 1681. Pilkington.

BREDA, VAN, JOHN, a painter of history, landscape, and conversations, was born at Antwerp in 1683, and instructed by his father Alexander Van Breda, who was much esteemed as an artist, with whom he continued, profiting by good example and advice, till he was 18 years of age. Among the capital paintings in the possession of John de Wit at Antwerp, Breda selected those of Velvet Brueghel, which he successfully copied; and he employed 9 years

in copying also the pictures of several other great masters, which he did so exactly as to puzzle good judges in distinguishing the originals from the copies. Having established his reputation in Holland, he accompanied Rysbrack the sculptor to London, where he was highly esteemed and obtained considerable patronage, and particularly that of the earl of Derwentwater, who was belaboured for rebellion in 1715. In London he was much employed by the court and nobility, and was hardly able to supply the demands made upon him for his performances. From London, after a residence of five years, he returned to Antwerp, much enriched; and in 1746, when Louis XIV. visited that city, he honoured this master by purchasing four of his pictures; viz. "Christ at the sea of Tiberias," "Christ performing miracles," and "two landscapes," with figures so exquisitely finished, as not to be easily distinguished from those of Brueghel. This master and Wouvermans were the models which he imitated; and he approached nearer to them than any other artist of his time. His landscapes are in the style and taste of the former; and his conversations, historical figures, fairs, and battles are in the manner of the latter. His colouring is good, his touch neat, his skies and distances natural and beautiful; and his taste of design agreeable. He had as much fire in his composition, and perhaps more genius than Brueghel; and, upon the whole, he is a painter of such rank, that the value and estimation of his works must always increase. He died in 1750. Pilkington.

BREDA, in *Geography*, a city of the Netherlands, the capital of Dutch Brabant, situated at the confluence of the rivers Aa and Merck, in a marshy country which may be overflowed by means of these rivers. The former of these streams, being, a little before its arrival at the town, augmented by the Byloop, is here rendered navigable, so as to form a communication with the German ocean. Breda was formerly large, populous, and well fortified, and was reckoned one of the strongest places in the Dutch frontiers. But its fortifications have sunk into decay, so that it is unable to stand a long siege; its circumference is estimated at about 4000 paces, and it is said to contain about 2200 houses, which are in general well built. Its citadel is environed with a moat; and its figure is triangular, having at every angle a gate constructed with brick; and its ramparts planted with elms. The great church is a magnificent structure, and remarkable for its tower, built in 1666 and afterwards rebuilt, the height of its spire being 362 feet. In this church are several monuments of the ancient lords of Breda; of which the principal are those of Engelbert I. who died in 1442; of John, who died in 1473; and of Engelbert II. who died in 1504; but they are not well preserved. The town-house is large, and its apartments regular and sumptuously furnished. Its woollen manufactures and commerce were formerly prosperous; but they have long since very much declined.

Breda is the capital of an ancient barony or free lordship, which comprehends several considerable villages, and the woods of Liesbosch, Maibosch, and Ulverhoutbosch. The former of these woods is intersected with walks and villas; and the second, consisting of six trees, is about 1½ league in length, and half a league in breadth. This barony includes good corn land and pastures, interspersed with many heaths and morasses. It was wrested from the county of Stryen, to which it formerly belonged, about the year 1100, by the duke of Brabant; in 1212 it pertained to Godfrey of Berg, as a fief of Brabant; in 1284 John I. duke of Brabant conferred the lordship of Breda on Raso von Gavre; and in 1306 it was sold to John III. duke of Brabant, who parted with it, in 1351, to John von Polanen,

whose grand-daughter Joanna transferred it to her consort Engelbert of Nassau, whom she married in 1404. In consequence of this alliance it remained in the house of Nassau, till William III. of England, dying without issue, caused it to be left in abeyance. The old castle was begun by Henry of Nassau in 1530; but about the year 1680, William prince of Orange, afterwards king of England, erected the new one, which is a magnificent structure, surrounded by the waters of the Merck. Breda suffered exceedingly in the wars of the 16th century. In 1507 it was annexed to the domains of the king of Spain, by the duke of Alva, on account of the rebellion of William of Nassau, prince of Orange. In 1575, the emperor Maximilian having offered his mediation for peace, a conference was held at Breda, but it terminated without an agreement between the Spaniards and the Confederates. In 1577 it was delivered up by the garrison to the States; but in 1581 it was retaken by Claude de Berlamont, and fell into the hands of the Spaniards. In 1590 prince Maurice took it by a stratagem, having sent a party of select men concealed in a boat loaded with turf, by which means the prince was admitted, and the city surrendered. In 1625 it was invested by Spinola, who, well knowing the strength of the place, determined to reduce it by famine, and for this purpose drew trenches round it for the space of four miles, erecting forts and redoubts at certain intervals; the siege was prosecuted by Spinola with the utmost diligence and vigour; and the place was defended, amidst the calamities of famine and disease, with a sagacity, steadiness, and valour, which did honour to the talents of the governor, Justin de Nassau, the natural son of William prince of Orange. A negotiation at length took place between the besiegers and the garrison; and the result was, that two capitulations were drawn up, one for the garrison and the other for the city, both of which were the most honourable and advantageous that could be devised. These were accepted; and the garrison marched out, after having sustained a siege of 10 months, and having lost two-thirds of their number and an equal number of the inhabitants. Spinola drew up his army to salute them, and, surrounded by his field officers, paid particular compliments to the governor, and commanding officers. He also distributed money among the soldiers, ordered the sick and wounded to be tenderly treated and taken care of; and in the regard paid to the valour and merit of his enemies he displayed all the sentiments of a hero. On the citizens also he poured out a profusion of civilities; manifesting his admiration of their constancy and fidelity to a degree, which even alarmed the States-General. In 1637 Henry, prince of Orange, determining to recover Breda, laid siege to it on the 23d of June, and obliged the governor, Omer de Fourbin, a very distinguished officer, to surrender, the 20th of October following. The governor and soldiers on this occasion, were, by the prince's generosity, allowed all the honours of war; and the officers of the city placed on the same footing as in the year 1625, before it was reduced by Spinola. Fourbin paid his compliments, sealed in a letter, to the prince; he was received graciously, loaded with praises and honours, and dismissed with valuable presents, reflecting equal credit on the generosity of the prince and the valour of the governor. After this event the Dutch considerably augmented the fortifications; and yet, though they have been reckoned among the most complete in the Netherlands, Breda surrendered to the French, on the 24th of February 1793, after a short siege of 10 days. However, on the 20th of March following, it was again delivered up to the Dutch by capitulation, and the soldiers were permitted to return to France with safe conduct.

Breda was rendered famous in 1667 by the famous congress which was held there for a general peace; first, between Louis XIV. king of France, and Charles II. king of England, concluded the 21st of July, by the mediation of the king of Sweden; secondly, between the king of England, and the States-General on the 31st of July, one article of which peace was the cession of the province of New York to the English; and thirdly, on the same day a peace was ratified between the king of England and Frederick III. king of Denmark. Breda lies 46 miles south of Amsterdam, and 22 S. S. E. of Rotterdam. N. lat. 51° 37'. E. long. 4° 45'.

BREDE, LA, a town of France, in the department of the Gironde.

BREDEMERYERA, in *Botany*, Willden. 1314. Class, *diadelphia obovata*. Essential Char. *Calyx* three-leaved; *Cor.* papilionaceous; standard two-petalled; drupe with a two-celled nut.

Species. *B. floribunda*. A shrub from five to eight feet high. *Leaves* nearly alternate, oblong-lanceolate, smooth, veined, two or three inches long, with short petioles. *Flowers*, small, yellow, terminating, panicled. *Panicle*, much branched, pyramidal, many-flowered. *Bractes*, linear-subulate, at the base of the pedicels. A native of Caracas in the margins of woods.

BREDENBORN, in *Geography*, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn, 4 miles E. of Neheim.

BREDERODE, an ancient feignory of Holland between Beverwick and Haerlem; the lord of which was one of the principal persons who presented a petition to Margaret of Austria, against the inquisition and other innovations in the year 1566. The title is extinct.

BREDEWIG, or BREEDVIC, a sea-port town in Norway, in the diocese of Aggerhuus, and district of Bradsberg-lehn, 44 miles S. S. W. of Christiania.

BREDEWITE, in *Ancient Law Writers*, an amerceement arising from some default in the assise of bread.

BREDIN, in *Conchology*, the French name of the common limpet, *PATELLA VULGARIS*.

BREDL, in *Geography*, a town of Bohemia, in the circle of Boleslaw; 6 miles N. E. of Turnau.

BREDON, the name of a hill in England, that divides the vale of Tewksbury from that of Evesham; from the summit of which the prospect is extensive, commanding the cities of Gloucester and Worcester, and a considerable number of towns and villages.

BREDSTEDT, an ancient and populous town of Denmark, in the duchy of Sleswick, and capital of a district of the same name, two Danish miles in length and as many in breadth, containing a considerable number of acres of marshland, and subject to the prefect of Flenburg; 21 miles N. N. W. of Sleswick.

BREDYDT, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves; 11 miles E. of Treves.

BRE'E, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Ruremonde. The town contains 1184, and the canton 5493 inhabitants; the territory includes 162½ kilometres and 11 communes.

BREECH, in *Ship Building*, the angle formed by a knee timber, the inside of which is called the *throat*.

BREECH of a gun, in *Artillery*, denotes the distance from the hind part of the base ring to the beginning of the bore, and is always equal to the thickness of the metal at the vent. See AC, *fig. 1. Tab. Gunnery*.

Engineers have contrived a sort of cannons, which are charged by the breech.

**BREECH-mouldings.** See **MOULDINGS.**

**BREECH presentation,** in *Midwifery*, a species of preternatural or cross birth, which see; in which the nates of the fœtus present to the uterine orifice, at the commencement of labour, instead of the head.

When on the bursting of the membranes, the part of the fœtus about to enter the os uteri feels soft, and of a globular figure, the accoucheur will generally be right in pronouncing, that it is the breech of the child that presents; particularly, if during the pains, the meconium, or feces of the child are forced away.

Though both nates may be perceived presenting, when the child enters the pelvis of the mother, yet one of them always comes down, through that passage, before the other, and in that manner comes into the world.

When the pelvis of the mother is of the usual form and dimensions, and the child is not disproportionably large, this species of labour requires very little more attention, on the part of the assistant, and usually terminates, equally safely to the mother and child, though not so speedily, as a natural labour.

When, on account of the disproportion between the bulk of the child, and the pelvis of the mother, or through the rigidity of the soft parts of the mother, the breech of the child is very much pressed, and straightened in its passage, the scrotum, if it be a male, will be much swelled, and black. This blackness and swelling, however, usually soon subsides, or they may be dispersed, by fomenting the part with warm water, applying afterwards, some elder, or other cooling ointment.

In this kind of labour no manual assistance will be necessary in ordinary cases, until the breech of the child is thrust down so low by the pains, as to press upon the external orifice. The accoucheur may then pass a finger up the vagina, and round the groin of the child, and assist in drawing it down, during each pain. This will contribute much towards facilitating and expediting the birth of the part. Or if, on account of the disproportion between the size of the child, and the capacity of the pelvis of the mother, the breech of the child should not descend so low as to enable the accoucheur to assist with his finger, a blunt hook may be passed round the groin, and used in the same manner. This will give a better purchase, and enable him to exert much more force than he could use with his finger; but great caution is necessary in extracting in this way, lest the head of the thigh bone of the child be broke off with the instrument. To prevent this accident, it will be necessary that the accoucheur keep two or three of his fingers pressed strongly against the thigh, on the side the instrument is applied, keeping the thigh close to the body of the child.

When, by either of these means, the breech of the child is delivered, the accoucheur must attend to the position of the child, and if its belly be placed opposite to the pubes of the mother, he must turn it round to the sacrum, and then complete the delivery in the manner directed under the article, **LABOUR Preternatural.**

If flooding or convulsion should come on, during a labour of this kind, before the breech of the child has entered, or made much progress in the pelvis, the accoucheur must pass his hand slowly and gradually up into the uterus, until he reaches, and can take a firm hold of one or both the feet of the child, which he must bring down through the vagina, withdrawing his hand in the same slow and cautious manner as he had introduced it. See **CONVULSIONS** and **FLOODING** during parturition.

**BREECHES**, a garment worn by males, reaching from the girdle to the knees, and serving to cover the hips, thighs, &c.

The ancient Romans had nothing in their dress answering

to our breeches and stockings; instead of which, under their lower tunics and waistcoats, they sometimes bound their thighs and legs round with silken scarves, or *fasciæ*, called *tibialia* and *fenoralia*. Salmuth. ad Panciroli. p. i. 161. Kennet. Rom. Ant. Not. p. ii. lib. v. cap. 8. Breeches appear to be a habit peculiar to the barbarous nations, especially those inhabiting the colder countries of the North; whence Tacitus calls them *barbarum tegmen*. We find mention made of them among the ancient Getae, Sarmatæ, Gauls, Germans, and Britons; they also obtained among the Medes and Persians, as being a people of Scythian origin: they also afterwards got footing in Italy, some pretend as early as the time of Augustus; but without much foundation, that emperor's breeches, mentioned by Suetonius, being apparently only swaths tied over his thighs. Tacit. Hist. lib. ii. cap. 20. Pers. Sat. iii. ver. 51. Ovid. Trist. lib. v. Eleg. 11. Suet. in August. cap. 82.

However this be, breeches were at length received into Italy, and grew so highly into fashion, that it was thought necessary, under Honorius and Arcadius, to restrain them by law, and expel the *braccarii*, or breeches-makers, out of the city; it appearing a thing unworthy, that a nation, which commanded the world, should wear the habit of barbarians. We find frequent mention of *bracæ*, *braccæ*, or *bracchæ*, in classic writers, but the form of this habit is not agreed on: some will have it to have been a rough party-coloured coat.

**BREECHING**, in *Sea Language*, a rope used to secure the gun of a ship, and to prevent it from recoiling too much in the time of action. It is thus named, because it is made to pass round the breech of the gun. This rope is fixed by fastening the middle of it to the hindmost knob, or case-bell of the gun, which, by sailors, is called the pomigion, or pummelion; the two ends of it are afterwards inserted through two strong rings on the sides of the carriage, and fastened to other bolts in the sides of the ship. The breeching is of sufficient length to allow the muzzle of the gun to come within the ship's side to be charged.

**BREED**, in *Rural Economy*, a term applied to any particular sort of any kind of domestic animal, which is known and distinguished from all others by certain characteristic marks, or in the technical language of the breeder, *points*. Thus, in the horse kind we have the *race breed*; the *heavy black cart*, or *Leicestershire breed*; the *Cleveland bay*, or *Yorkshire breed*; the *Suffolk Punch breed*; the *Clydesdale*, or *Scotch breed*; the *Welsh*, or *pony breed*, &c. And in neat cattle, the *long-horned*, or *Lancashire breed*; the *middle-horned*, or *Devonshire breed*; the *short horned*, *Dutch*, or *Holdernefs breed*; the *Welsh breed*; the *Suffolk dun breed*; the *Galloway*, or *polled breed*; the *Highland*, or *Kilos breed*; the *Lowland*, or *Wiltshire breed*; the *Alderney breed*; the *Wild breed*, &c. In the sheep kind, the *new Leicester*, or *Dishley breed*; the *Lincolnshire breed*; the *Teeswater breed*; the *Romney Marsh breed*; the *Dartmoor*, or *Devonshire mitt breed*; the *Exmoor breed*; the *Dorsetshire breed*; the *Herefordshire*, or *Ryland breed*; the *South Down breed*; the *Norfolk breed*; the *Heath breed*; the *Herdwick breed*; the *Chesnut breed*; the *Dunfaul breed*; the *Shetland breed*; the *Marino*, or *Spanish breed*, &c. In the swine kind, there are likewise several breeds, as of the large sort, the *Berkshire breed*; the *Hampshire breed*; the *Spratsford breed*; the *Gloucestershire breed*; the *Herefordshire breed*, &c. and of the smaller sorts, the *Chinese breed*; the *robust*, or *stomach-bread breed*; the *prick eared breed*; the *scowling-tailed breed*, &c.

The different properties and qualities of the various breeds of these different kinds of domestic animals, will be fully described and explained when we come to speak of the means of improving live stock. See **CATTLE** and **LIVE STOCK.**

Much of the success of the grazing farmer depends upon a correct knowledge and judgment in selecting and choosing those breeds of different kinds of animals that are the most adapted to the nature, circumstances, and situation of his land. See GRAZING and STOCKING PASTURES.

In the smaller kinds of domestic animals, there are likewise different breeds, which will be described in considering their particular applications and uses in the practice of the farmer.

BREED'S HILL, in *Geography*, an eminence, near Boston in America, where the Americans withstood the attack of the British troops at the commencement of the American war, and where the former lost five pieces of cannon and 139 men, and the latter lost 1054 men, among whom were nineteen officers who were killed, and seven wounded. This battle is commonly called "the battle of Dunker's Hill," from the name of another hill near Breed's Hill. It happened on the 17th of June, 1775.

BREEDBAND, in *Natural History*, one of the synonyms of *ECHINUS SAXATILIS*, which see.

BREEDING, in a general sense, is used for the care of rearing or bringing up the young of divers animals.

BREEDING, in a moral sense, denotes a person's deportment or behaviour in the external offices and decorums of social life. In this sense, we say, well-bred, ill-bred, a man of breeding, &c. Good breeding amounts to much the same with what is otherwise called *politeness*, among the ancient Romans *urbanity*. Good breeding is nearly allied to virtue, and will, of itself, lead a man a great part of the way towards the same; it teaches him to rejoice in acts of civility, to seek out objects of compassion, and to be pleased with every occasion of doing good offices. Lord Shaftesbury compares the well-bred man with the real philosopher: both characters aim at what is excellent, aspire to a just taste, and carry in view the model of what is beautiful and becoming. The conduct and manners of the one are formed according to the most perfect ease, and good entertainment of company; of the other, according to the strictest interest of mankind; the one according to his rank and quality in his private station, the other according to his rank and dignity in nature. Horace seems to have united both characters.

"Quid verum atque decens curo et rogo, et omnis in hoc sum."

Shaftes. *Character*. vol. i. p. 64. vol. ii. p. 242. vol. iii. p. 161. *Hor. lib. i. Ep. ver. 12.*

BREEDING, in *Midwifery*. Immediately after having conceived, a woman is said to be breeding, and this stage of pregnancy continues for the space of three or four months, or to the time of quickening, after which she is said to be young with child, and at seven or eight months, great or big with child. These stages, not of themselves of importance enough to be noticed, are here mentioned on account of some symptoms, peculiar to each of them. The most remarkable of these, and which frequently attacks women almost immediately after conception, is nausea and vomiting, particularly in a morning, and as soon as they rise from their beds; though in some cases, it continues through the whole of the day, scarce suffering them to retain any part of their food. It is usual to attribute this symptom to nervous irritation, occasioned by the distension of the minute vessels of the uterus, the stomach sympathizing with the part. As it is so general an attendant on breeding, perhaps, by the shock it gives to the frame, it may be intended to assist in unfolding those vessels. Whatever may be the cause, vomiting in pregnancy is rather a troublesome than dangerous symptom, and the violence of it may usually be mitigated, though it cannot be entirely quieted, by a moderate and slender diet; and by taking small doses of rhubarb and magnesia, by losing three

or four ounces of blood from the arm, or by going for a short time into the country. It usually ceases soon after quickening, though in some women it continues through the whole time of gestation. Cardialgia or heart-burn, which see, another frequent attendant on this stage of pregnancy, is equally untractable and lasting, and only to be alleviated by remedies and management similar to those recommended for nausea and vomiting. Colliveness, to which women in this state are also subjected, is perhaps occasioned by the loss of the bile, which is thrown up by vomiting, instead of going down through the intestines, where, by its stimulus, it is supposed to keep up the peristaltic motion of the bowels, and thence to facilitate the descent, and discharge of the feces. Magnesia and rhubarb, fenna, manna, Epsom, and glauber's salts, in small doses, are the most convenient and efficacious remedies for obviating this complaint. When the stomach is so weak as to reject these remedies, recourse may be had to aloes, of which four, five, or six grains, in the form of pills, may be given at night going to bed. The custom of giving women a larger portion of food, while breeding, which by the common people is thought to be necessary, as they have then two to support, if not the most frequent cause of the inconveniences here noticed, as attendant on pregnancy, certainly tends to increase and aggravate them, as the stomach is at that time generally very weak and delicate, particularly in the last months, when the uterus has acquired such a bulk as to press on and straiten the bowels, and consequently to impede the passage of the food.

A moderate diet, air, and exercise, are necessary in every stage of pregnancy. Those women therefore err exceedingly who live at such times too sedentary a life, particularly those who spend much of their time in crowded rooms, at the card-table, &c. as besides the injury done by sitting too long in one posture, which they always find troublesome to them, they breathe an impure and noxious air, whence proceed head-achs, sickness, faintings, and a train of nervous symptoms, which not unfrequently lead on to abortion.

BREEDING, in *Rural Economy*, the art or science of raising different sorts of live stock, in the best and most perfect manner. This is a branch of the art of husbandry, on which great attention has lately been bestowed, but which probably depends on principles and circumstances that are not yet fully investigated or understood. Much improvement has, however, been effected in the raising of almost every kind of live stock, since the nature and means of its support have been better known and more abundantly provided. The greatly increased demand for the animals, either in consequence of their usefulness for the purposes of labour or those of supplying the food of mankind, has probably had much effect in promoting this sort of improvement, as rendering it more an object to the breeding as well as grazing farmer. It has been well remarked by the author of "Practical Agriculture," that notwithstanding much has been done in different districts, in bringing different breeds of different sorts of live stock to a greater state of perfection, much still remains to be effected; and that it is probably far from having reached that point to which it is capable of being carried, by the judicious combination of the best and most appropriate breeds of domestic animals, with the improvements in the cultivation of herbage, or other sorts of green food for their support. To fully explain the means of accomplishing such improvements in every sort of stock, many additional facts and experiments are, however, necessary. All that can be done at present is, perhaps, that of presenting the farmer with a few hints and directions, which may serve as guides in conducting the business.

In pursuing attempts of this nature to any extent, Mr. Middleton

Ston has justly observed, great care should be previously taken, that there be a sufficient degree of shelter, shade, and warmth, and at the same time a high state of fertility in the land, with suitable drainage; as it is only by the richness and abundance of food that such changes or improvements can be made in the most advantageous manner, or the stock be carried to any high state of perfection.

Different modes of practice have been followed in the improving of live stock, but the principal are those of crossing the different breeds, so as to supply the imperfections and defects of the one by the merits and perfections of the other; and of uniting the valuable qualities or perfections of the same kinds by continuing to breed and selecting the most perfect animals in the same line or family. The former of these methods has been long known and employed; but the latter has, only within these few years, been fully introduced to the notice of the farmer, and is not, probably, yet so much attended to as it would seem to deserve.

It has been commonly supposed, that the practice of crossing the breeds of domestic animals possesses various other advantages, as well as those of preventing the decrease and degeneracy of the stock, on account of the animals being kept from becoming too nearly related to each other. There are many facts, however, which shew that the supposition of the degeneracy of animals in consequence of the nearness of their relationship is not so well founded as has been commonly imagined. The complete success of the contrary practice in the management of Mr. Bakewell, who reared his best stock by the nearest affinities, not only without degeneracy in any respect whatever, but with a continued improvement and amelioration, makes strongly against the opinion; as well as the circumstance of cattle in the wild state, in particular situations, remaining for centuries without the least alteration taking place in their form, or change in their colour or other properties. It has, notwithstanding, been asserted, that in this system of breeding, young stock decrease rapidly in size. If, however, such a circumstance was really apt to occur, it could hardly have been overlooked or disregarded by the very expert and intelligent breeder just mentioned, in his long and very extensive experience of raising various kinds of live stock, by coupling the most perfect animals of the same line or family.

There cannot be any doubt, however, but that by the method of crossing the breeds of animals much advantage may be derived, especially in what relates to size, and some other properties noticed below; yet it is obvious, that it must require the nicest care, and the greatest circumspection, in order to suit the animals in the most exact manner to the nature of the improvement that is intended, otherwise injury, instead of advantage, may be the consequence. Indeed, from the injudicious and random method in which improvements of live stock, on this principle, have, in general, been undertaken, it does not seem improbable but that injury may often have been produced instead of benefit, by uniting such breeds, as, from the great dissimilarity of their forms, qualities, or other properties, could not have any chance of effecting the purpose with utility. Besides, in almost every district of the kingdom, where the breeding system is pursued to much extent, useful breeds of domestic animals are asserted to have been injured by the practice of injudicious crossing, as may be seen in the various reports that have been published by the Board of Agriculture: and lord Somerville, in his excellent view of the system of the Board of Agriculture, has very pertinently remarked, "that to the mountebank doctrines of crossing dissimilar breeds, whom nature in its infinite wisdom had set asunder, we are indebted for much confusion and mismanagement." It cannot, however, be

disputed, but that by pursuing this method with judgment and proper attention, great advantages may often be obtained, especially in regard to bone or size, and the hide or coat, as well as in the improvement of particular parts or points, and probably in what relates to the movement or speed of the animals. The author of "Practical Agriculture," has observed, "As it is in some measure a principle founded in physiological science, and countenanced by the observation and experience of ages, that animals are somewhat endowed with the faculty of not only propagating an offspring that has, in a considerable degree, the properties, dispositions, and resemblances of themselves, but that it, in some measure, subject to a similarity of disease; it would appear, that although there may be occasional deviations, the most certain method, and that which has the best foundation in the nature and economy of the animal, in so far as the particular qualities and other properties, besides those that have been just mentioned, are concerned, is to breed in the same line, and, perhaps, in the same family; as by a careful procedure in this way, the expert breeder may not only have the greatest security for attaining that improvement which he is anxious to produce, but run the least risk of deterioration." The success of this practice, it is contended, "has not merely been shewn in the breeding of the farmer's stock, but also in that of the sportsman, as it has been found that pointers and game cocks have been bred with the greatest perfection and superiority in this mode:" and that "it is by the same means that the valuable properties of the race-horse are perpetuated and preserved." "The same thing likewise," it is added, "takes place in the vegetable economy, the finest and most perfect productions of this sort being propagated by sowing seed selected from the best and most perfect plants of the same kind, and taking the buds or offsets from the best and most perfect trees of the same species." "There is also another circumstance," continues the same author, "that seems to shew the propriety and superior advantage of this method of proceeding in the breeding of domestic animals, which is that, however much the breeds of live stock may be altered by climate, pasture, and other causes, in what respects their colour and other trifling particulars, their specific characters remain invariably the same. No causes of these kinds have ever been capable of changing any one of the distinct breeds, whether of neat cattle, sheep, horses, or hogs, in such a manner as to have the characteristic distinctions of those of any of the others."

On these principles it is therefore concluded that "by having recourse to occasional crossing in the above intentions, and the careful selection of the most perfect animals of the same breed or kind, with due attention to constant good feeding, the improvement of live stock may be carried to the greatest perfection."

"But as the principal object of the breeding farmer must constantly be that of obtaining such animals as will afford him the largest profit, it may be necessary to ascertain the nature and term of the animal that may be most advantageous in this view, or which pays the best for the food that is consumed, as by this means it will be seen what points are the most desirable or useful in a breed or variety, and what circumstances ought to be attended to, so as to justify its introduction in preference to any other."

The properties which seem the most particularly to interest the breeder, in his attempts to improve the different sorts of live stock, are principally those of form or shape, size, disposition, hardiness, quick maturity, nature of flesh, fattening property, milk, hide, aptitude for labour, and the quality of the breed, or, in the language of the art, *blood*.

With regard to *form*, the notions of breeders have been consider-

considerably at variance; but it would seem that there can only be one perfect form, which must be that which approximates the most to exactness in the shape and proportion of the different parts. This should, therefore, be the principal aim of the improver, whatever the nature or breed of the animal may be.

The writer, mentioned above, conceives, that "in this view a perfectly formed animal should have an exact proportion and consistency in all the different parts; the head neat and compactly formed, being neither too large nor of too great length; the eyes bright and prominent; the neck not of too great length, but somewhat thin, gradually narrowing from the breast towards the head, to which it should be neatly attached; the chest round, wide, full, and of deep girth; the length of the legs well proportioned to the size; the fore ones straight and clean, the hind ones forming an angle at the hock so as to stand well under the loins; the distance between the feet in the different extremities equal; the feet round and even; the hoofs straight; the back and loins straight and broad; the belly firm and capacious; the quarters deep, full, and well fleshed downwards." This would seem to constitute that "utility of form," which is the chief aim of the most enlightened modern breeders: and it has been suggested as probable, that such a form may be the most adapted to the principal object of the grazier, that of taking on and sustaining flesh in the process of fattening; as where animals greatly exceed or fall short of such just proportions of parts, there must be disadvantage either in their being weak and less disposed to fatten, of course requiring a larger proportion of food, and more time in finishing the business; or in their being deficient in the general weight and value of the meat, from their not being sufficiently fattened on the best parts. Mr. Young has indeed observed, in his Eastern Tour, that it has been the constant practice of Mr. Bakewell to procure such animals, whether of the cattle or sheep kind, as were capable of weighing the "most in the most valuable joints," as "there is a great difference between an ox of fifty stone carrying thirty in roasting pieces, and twenty in coarse boiling ones, and another carrying thirty in the latter, and twenty in the former." The utility of attending to this circumstance cannot be disputed; and it may likewise, in particular cases, be of much benefit to consider the nature of the consumption, in relation to the form of the animal, as where some parts are more in demand than others in the market, and of course sell at higher prices, that should be taken into the account of the breeder, and that shape which is most favourable in this view more particularly attended to.

It is supposed probable, that improvement in these as well as many other points of importance depends upon a just proportion and symmetry of parts in the animals made use of for the purpose. And it is conceived not improbable but that the "excellence of the most valuable points in all the different sorts of live stock may, in some measure, bear a proportion to the goodness of the form in the animal."

The fine fulcra of shape usually distinguished by the breeder under the term "beauty of form," has been considered as very different from that of "utility of form," and to consist in a greater roundness of the parts, with a less bony protuberant appearance.

Though it cannot but be a matter of much advantage to bring the shape of domestic animals to as high a state of perfection as possible, yet utility, or what may be termed profit, ought to be more particularly regarded as being the main object of the breeding farmer.

In regard to the second property, that of *size*, the question does not seem to be yet decided, whether large or small

animals pay the bill for the food they consume, nor does it appear capable of being easily ascertained, as it must obviously be influenced by a variety of causes. It is a property that may, however, be desirable where the chief object of the grazier is that of feeding to a great weight, especially where the supply of food is rich and abundant, but in other circumstances, it is perhaps not so necessary to be attended to. It is the difference in the quantity of meat afforded by large and small animals, in proportion to the extent and value of the food which they differently consume, that is to be considered. The experience of graziers would appear to rather favour smallness of size, from the animals fattening with more expedition, and paying them better. And the judgment of Bakewell is in support of the same conclusion, as he found that the "smaller the bone, the truer the make of the beast, and the quicker in fattening." Mr. Young has also observed, in respect to the large sized breeds of cattle, as the Lincolnshire and Holderness, that, though large, their size lies in their bones, they may be fattened with loss, but can never pay so much for a given proportion of grass as the small-boned long-horned sort.

Mr. Knight, an intelligent observer, however, contends that large animals are the most profitable, on the ground that they do not consume food in proportion to their weight, as on putting the question to different breeders, in different parts, he found they were uniformly of opinion, "that the same quantity of food was given to the smallest and the largest beasts of the same age; that the largest, even when not malar of the food, often kept itself in the best condition; and that every thing depended on the disposition to fatten, and very little on the size of the animal." His own experience is likewise in support of the same position. It is notwithstanding allowed that a limited number of large cattle will generally consume more than an equal number of small. This has been clearly shewn by the practice of graziers in most places, as they have found, that with small animals they can often stock nearly in the proportion of two to one. But in the consumption of food a great deal must also depend on the state of the stomach and digestive organs of the animals. There is another circumstance that is necessary to be regarded as being in some measure connected with size, which is that of the quality of the flesh. This is, in general, allowed to be the finest and most delicate, in the smaller sorts; which would seem to be really the case from the grain or muscular fibre being smaller, and of course finer. The taste of the epicure also affords a further proof of the same thing, in constantly preferring the meat of small-sized animals of different kinds. On this account it has been commonly supposed that the meat of small-sized animals, is worth more, for a given quantity, than that of large ones. Mr. Knight, however, contends, "that if the animal be taken as it stands in the pasture or stall, the contrary is the truth; but when the butcher merely buys what are termed the valuable parts, and receives the offal into the bargain, he will unquestionably, for obvious reasons, give more for two cows of twelve stone each a quarter, than for one of twenty-four. The offal is of much greater value, besides a considerable advantage in the hides. The difference between the weight of the animals, when living, and of the four quarters, when dead, is always in an inverse proportion to their sizes, when their forms and merits are equal; but the bones will then be in proportion to the living weight, and therefore, it is concluded, small animals must be, in this case, most disadvantageous to the consumer." However, as the flesh of large animals, from the greater size of their muscles, would appear to be more coarse in the grain; it is probable, that upon the whole, it must sell at a lower price in the market. It has likewise been supposed

supposed to be an advantage on the side of large animals, that the meat, when preserved, retains the juices more perfectly, and that is there less waste in out-sides.

On the supposition that small sized animals are in general more hardy than large ones, Mr. Knight remarks, "that if it be meant merely that they are capable of subsisting on shorter herbage, it is right; as a large animal, though it may have exactly the same form as the small one, necessarily requires more time for rest. It feeds and removes itself with greater labour; and notwithstanding it may be as strong again, as having double the weight, it will still, in relation to itself, be a weaker animal. Its head and neck will be as heavy again, and from their greater length, the weight will recede farther from the centre of motion in the shoulder, consequently increase in power in proportion to the distance: and the same thing holds good in respect to the whole of the limbs." But that "in the stall or the fold, where large oxen are mostly fed, these disadvantages are of no consequence, as the food is received without the trouble of looking for it; and if the necessity of a better pasture does not proceed from the large animal consuming much more, but from less power in collecting food, the consequence will be, that it must afford the largest weight of flesh with the smallest consumption of grass."

With regard to the injury done to the ground by poaching, being greater in large than small sized animals; the same writer observes, "that the question is not, whether the feet of the former be wider in proportion to their weight, but whether the feet and mouths of two small animals will not injure the herbage more than those of one large one." In favour of the latter it is contended, that small sheep do not produce any mischief at all in this way, yet that a score, weighing a ton in the aggregate, will do more harm to a rich pasture in forty-eight hours, than an ox of the same weight in a week. But though this may, in some degree, be true, there cannot be any doubt, but that small stock may be kept longer in the pastures in the autumn, than large, without mischief by poaching, which is a great advantage in many cases to the farmer.

In milking stock the advantage is allowed to be on the side of small size, as such animals give, individually, nearly the same quantity of milk as those of the large kind, and are capable of being supported on shorter herbage, without injuring the land in the same degree.

There are likewise advantages in the small sized animals, in their being capable of being wholly fattened on grass without the aid of other more expensive kinds of food, and on inferior pastures, as well as in their being procured by the grazier with greater facility; being more adapted to the conveniences of different situations, and the loss being less, in case of accidents.

It is evident, therefore, that as each size of stock has advantages, under particular circumstances, the breeder should be chiefly regulated in his conduct by the nature of his pastures, and the command he has of other sorts of food.

In respect to the *disposition* of animals, there can be little doubt but that it must be advantageous to the farmer to have them tame and gentle without their being sluggish or too dull, as they will be not only less disposed to ramble, but be fed, reared, and fattened with less trouble, and with a smaller proportion of food. That this property is much influenced by the mode in which the animals are reared is fully seen by the facility with which they were managed in the practice of Mr. Bakewell.

The quality of *hardiness* is likewise extremely desirable and interesting to the grazing farmer, in most cases, but particularly in bleak and exposed situations, as such sorts of stock constantly succeed better, and keep themselves in more per-

fect condition, than those in the contrary circumstances. It is probable that this property depends in a considerable degree on the nature of the breed, and the manner in which the animals have been reared. It has often been supposed to be denoted by a darkness of colour, and a roughness in the hair; but to these there are numerous exceptions.

*Quickness of arriving at maturity* is another quality that greatly interests the breeding farmer, as his profits are obviously much influenced by it. And it is likewise of much importance to the public, as the abundance of supply must obviously be much connected with it. The length of time that different sorts of live stock may be kept with advantage, under different circumstances, has, however, not been yet well ascertained, but neat cattle may generally, it is supposed, be kept longer with profit to the farmer than sheep. It is obvious, however, that the method in which the animals are treated in respect to food must greatly influence the matter, as where they are abundantly supplied at all times, and of course constantly preserved in a thriving state, they will, without doubt, arrive much earlier at a state of maturity, than when the contrary is the case. In all sorts of stock this must invariably be the consequence. It has, indeed, been well observed, by sir John Sinclair, that where the animals are constantly well fed, a greater progress will be made in three years, than in the common pinching mode can be made in five. The necessity and advantage of not suffering live stock of any kind to be restricted, especially in their more early growth, from the want of due care, food, and warmth, are therefore sufficiently clear, and should never be disregarded by the breeder in rearing of his stock.

In addition to the observations that have been already made on the *nature of the flesh* of animals, it may be remarked, that its goodness probably in a great measure depends on the breed being a quality inherent in the muscular substance. Mr. Marshall has indeed observed, in the Rural Economy of the Midland Districts, that there "the grain is clearly understood to depend wholly on the breed, and not, as has been heretofore considered, on the size of the animal." Experiments are wanting to show how far the flavour and colour of the flesh of different animals may depend on or be influenced by the nature and quality of the food on which they are fed, and on the breed. The common notion of its being in some degree connected with the colour of the skin of the animal, is most probably without any real foundation. The great deviations that have sometimes been observed in the flesh of animals from the natural appearance, can only be accounted for on the supposition of their being diseased. It is remarked in a late work on practical agriculture, that "in the living state the proofs of good flesh are a mellow, elastic, rather firm feel, without any degree of harshness, and in the dead condition a similarity of feel, with a fine grain and marbled appearance. There may likewise be some difference in the quality of the flesh of animals in proportion as they are more old or young, being in the former case more hard and less tender and juicy than in the latter. The fineness of the grain may also vary according as the animal is male or female, being in general coarser in the former than the latter.

The *disposition to fatten* readily while young is another property which has some relation to that just noticed; and which greatly interests the profits of the grazing farmer, as where it does not occur, a large proportion of food must often be consumed to little or no advantage. It is well known, that some animals of different kinds, and some particular breeds of different sorts of animals, become readily fat with but a trifling consumption of food, while others that consume in a vastly increased proportion have not the least

least appearance of attaining such a state; but the principle on which this depends has not been yet fully ascertained. From the little knowledge that has been obtained on the subject, it would seem to be a quality some way or other connected with the smallness of bone. In the experience of Mr. Birkwell and some other intelligent breeders, it was found to depend much upon the goodness of form and the breed. But whether it depends on these, or is the consequence of some particular state or structure of the digestive and internal organs, it is evidently of great importance to the farmer to have such animals as not only fatten readily, but in many cases, as can be supported on the inferior sorts of food. The opposition that has been made to the utility of this quality on the score of the over-fattening of animals, and the supposition that such fat meat is less useful, as well as less economical in the consumption, is probably without any foundation in truth or just observation, as the grazier has no other means of increasing the quantity of lean meat in his feeding flock, but through the medium of the fattening property. This quality should of course be constantly kept in view by the breeder in raising of his stock, whatever the kind may be.

The state of the *hide or skin* is likewise a circumstance that should be attended to in the breeding of animals, as showing, in some degree, their disposition to become fat. When it has a soft silky feel there is mostly a disposition in the animal to fatten in an expeditious manner, and it is supposed to have an advantage in being more distensible, and of course more adapted to admit a large increase of flesh. Thick hides may, however, have advantages in cold exposed situations, where warmth is more particularly necessary to the animals.

The quality of furnishing a large supply of *milk*, with the least possible expenditure of food, is another property in animals that ought not, by any means, be overlooked by the breeding farmer. How far a separate and distinct breed should be provided for this purpose, or one partly adapted to this use, and partly to that of the butcher, be employed, is a point that has not yet been determined; but as it is well known, that such cows as have much tendency to fatten seldom or ever afford any large quantity of milk; there should probably be a breed exclusively for the purpose of the dairy. Sir John Sinclair has, however, suggested it as probable, "that, by great attention, a breed might be reared, the males of which might, in every respect, be well calculated for the shambles; and the females, when young, produce abundant quantities of good milk, yet, when they reached eight or nine years of age, be easily fattened." It is supposed that this would be the most valuable breed that could be produced, and that some of the Scotch breeds have nearly attained such a state of perfection.

The capability of performing *labour* in an easy and proper manner is another property, that, in many cases, demands the attention of the breeder, especially in neat cattle and horses; but in respect to the former sort of stock, it has not yet been, by any means, decided, whether there be any advantage in the increase of meat by working the animals, or whether there may not be some disadvantage in their growth being retarded by the practice. It cannot, however, be disputed, but that where cattle are made to undergo much labour, they must be a greater length of time before they can be in a proper state to be brought to the market; and it would seem that the growth of the animals must also be lessened; however, as they are capable of being reared and kept at a much cheaper rate than horses, a breed well calculated for this use may, in many instances, be an object of great consequence to the farmer.

The inherent property of a breed, or what is usually termed *blood*, is likewise a quality that has engaged the attention of the breeder in the raising of live stock. This is mostly shown in the external appearance, and of course may serve to guide the judgment of the grazier in choosing such animals as may be the best suited to such improvements as he may have in contemplation.

Such are the principal points to which the attention of the breeder should be directed in his attempts at improvements of this nature, as well as the means by which they are chiefly to be accomplished. And it has been remarked by Dr. Dickson, in his *System of Practical Agriculture*, that "the success of his endeavours, to whatever species of excellence his attention may be directed, must obviously, in a great measure, depend upon the accuracy and correctness of his judgment in choosing those breeds, of whatever sort of live stock they may be, that are most adapted to his circumstances; and in selecting such individuals, both male and female, of such breeds, as are the most perfect and exact in their different parts and properties; cautiously continuing to breed from them, without ever suffering the least intermixture by the admission of those of inferior qualities; advancing in this way, with the nicest attention to such faults or defects, however trifling, as may arise, so as to alter and correct them by appropriate pairing in the succeeding generations. And as an indispensable assistant in this arduous undertaking he must constantly have recourse to the aid of good and abundant keep at all seasons, with suitable degrees of shelter and warmth for both the old and young stock; so that they may never decline in flesh or be checked in their growth." This, continues he, "would seem to constitute the great secret of the important art of breeding live stock, which the superior discernment and unwearied perseverance of a single individual raised to a degree of notice and perfection that has had the happiest effects in bringing the improvement of our domestic animals to a state of excellence perhaps unequalled in any other country." See **CATTLE** and **LIVE STOCK**.

*BREEDING of fish.* See **FISH-pond**.

*BREEDING of horses, dogs, &c.* See **HORSE**, &c.

**BREEF-cards**, denote a kind of false cards, either longer or broader than the rest, whereby they may be known and distinguished.

**BREEN**, *G. V.* in *Biography*, an engraver of some merit, whose time is not ascertained, who worked entirely with the graver, and imitated the style of James de Gheyn, from whom he probably received his first instructions; though he never equalled his master, either in correctness of design, or mechanical execution. Strutt.

**BREENBERG**, **BARTHOLOMEW**, called **BARTOLOMEO**, a painter and engraver, was born at Utrecht in 1620, and went, at an early period, for improvement to Rome; where the society of Flemish painters, called "Bentvogels," distinguished him by the appellation of Bartolomeo. Among the superb ruins and beautiful objects, in and about this city, he acquired an elegant taste; and he peculiarly excelled in landscapes, which he enriched with historical subjects. The figures and animals, which he introduced, were elegantly disposed, and executed with spirit and freedom: especially when they were not larger than the final size, in which he usually painted them. His manner, particularly with respect to colouring, gradually improved; his touch is light and spirited, his tone of colouring very pleasing, his taste altogether of the Roman school, and his pictures are distinguished both by force and delicacy. The draperies of his figures, which are gracefully proportioned and designed, are easy and ornamental, and in his smallest figures, the expression

pression is lively, sensible, and natural. His pictures are exceedingly rare, and highly valued. We have of his etching a set of 24 views, and landscapes, ornamented with ruins, &c. from his own designs. He died in 1660. Pilkington and Strutt.

**BRESEBACH**, in *Geography*, a river of Germany, which runs into the Unstrut, 4 miles S. of Weissenfee, in the circle of Upper Saxony.

**BREEZE**, a shifting wind, blowing from the sea and land alternately, during certain hours of the day or night; only sensible near the coasts.

The sea-breeze, Dampier observes, commonly rises in the morning about nine, proceeding slowly in a fine small black curl on the water towards the shore: it increases gradually till twelve, and dies about five.—Upon its ceasing, the land-breeze commences, which increases till twelve; and is succeeded in the morning by the sea-breeze again. The sea-breezes rule by day, and the land-breezes by night; so that, dividing their empire, they remain as constant as the seasons of the year, or course of the sun, on which they seem alone to depend; not but that they appear sooner or later, stronger or weaker, in some places than others, and vary the alternative according to the several latitudes, situations, soils, mountains, vallies, woods, and other circumstances of the countries where they are found.

In some countries, the sea-breezes appear only to be efforts of the general or trade-wind, as at Barbadoes, and in many places between the tropics, where the general wind, if not impeded by mountains or islands, blows fresh in the day time, but, after sun set, the terrestrial exhalations becoming precipitated, produce a new wind, which is not only able to make head against the trade-wind, but to repel it from their coasts.

The sea-breezes do not all come from the same point of the compass, but from different points as the land lies.

In Brazil, and many of the Caribbee islands, they have no land-breeze, especially if the shores lie low, as at Barbadoes, where the general or eastern wind blows from one end of the isle to the other, and serves instead of the land-breeze. In other places they want the sea-breeze, especially between the tropics, in coasts which lie westerly, as in the western kingdoms of Africa.

If either the easterly or westerly winds blow fresh, they hinder both the land and sea-breezes in the Mediterranean; of which those are always found the weakest which rise latest. In England, in very hot days, and when no other winds are stirring, the like alternation of land and sea-breezes may be observed on our coasts, though with little certitude, any where to the northward of Portugal.

Breezes are more constant in summer than in winter, and more between the tropics than in the temperate zone.

The general cause of those alternate breezes which set on and off the coasts in hot countries, is the greater rarefaction of the air by reflected heat, and by fermenting exhalations over the land than over the water: the denser air from the water becomes a sea-breeze in the day; but this air, condensed again, by the cold of the night, may then occasion a land-breeze.

The cause of this alternation of sea and land-breezes may be familiarly illustrated by placing a common pewter water-plate in the middle of a large vessel, and filling the former, first with hot water, and the latter with cold, and holding a taper just blown out at the edge of the plate; in which case, the smoke will be observed to gather over the plate which has heated, and of course rarefied the superincumbent air; but if this experiment be inverted, and the plate filled with cold water, whilst the larger vessel is filled with hot water, the smoke of the taper, held near the plate, will be

seen to move towards the rarefied air that rests over the hot water in the larger vessel.

Breezes differ from *efise*, or trade-winds, as the former are diurnal, or have their periods each day; and, besides, they are only perceived near the shore or coast; whereas the latter are anniversary, and blow at a distance from land. Phil. Trans. N<sup>o</sup> 183, p. 158. See WIND.

**BREEZE**, in *Brick making*, are small ashes and cinders sometimes made use of instead of coals, for the burning of bricks. But as this does not so well answer the end, the use of it was prohibited by 12 Geo. I. cap. 35. but allowed by 3 Geo. II. cap. 22. 10 Geo. III. cap. 49.

**BREEZE-fly**. See OESTRUS and GAD-fly.

**BREFFNY**, in *Geography*, the name of an ancient district of Ireland, which included the present counties of Cavan and Leitrim, with part of Longford. It was divided into east and west, and is frequently mentioned in the history of Ireland, as it was not divided into counties until the reign of James the II.

**BREG**, a small town of Switzerland, in the Valais, near the river Bronx. N. lat. 46<sup>o</sup> 7'. E. long. 7<sup>o</sup> 16'.

**BREGANCON**, a fortress of France, situate on a small island in the Mediterranean, near the coast between Toulon and St. Tropez.

**BREGANZA**, a small place of Italy, in the territory of Vicenza, famous for a luscious wine produced in its neighbourhood.

**BREGE**, a small river of Germany, in the circle of Swabia, which joins the Bribach, below the town of Doneshingen.

**BREGENTZ**, or **BREGENZ**, in Latin, *Comitatus Brigantius*, a county of Germany, in the circle of Swabia, but annexed to the circle of Austria, bounded on the north by the territory of Wangen, on the east, by the bishopric of Augsburg, and the county of Tyrol, on the south, by the counties of Pludentz and Montfort, and on the west, by the Rhine and the lake of Constance. It anciently belonged to the counts of Montfort: but in 1451, part of it was sold to the archduke Sigismund for 35,592 Rhenish florins; and in 1523, the other part was sold for 50,000 Rhenish florins, to the archduke Ferdinand. The capital of the same name is situated at the east end of the lake of Constance; it has several iron works in its vicinity, and an adjoining citadel seated on a mountain, and named Pfannen-berg. To the south of the town is the "Bregenz-claus," which is a strong pass. This town was taken by the French on the 9th of August 1796. It lies 60 miles E. N. E. of Zurich. N. lat. 47<sup>o</sup> 31'. E. long. 9<sup>o</sup> 50'. The river Bregenz runs into the lake of Constance near the town.

**BREGLIO**, in *Geography*, a small town of Piedmont, in the county of Nice, seated on the river Rodia.

**BREGMA**, or **FONTANEL**, in *Anatomy*, is a space left between the parietal or frontal bones in the fetus, in which the pulsation of the brain may be felt. There is frequently a similar vacancy between the parietal and occipital bones which is termed the posterior frontal. See CRANIUM.

**BREGNANO**, in *Geography*, a small town of Italy, in the duchy of Milan, seated on the river Sevese.

**BREGNO**, **VALDI**. See BRENNA.

**BREHAL**, a town of France, in the department of the Channel, and chief place of a canton, in the district of Coutances, 3 leagues S.S.W. of Coutances. The town contains 1373, and the canton 14,251 inhabitants: the territory comprehends 197½ kilometres, and 16 communes.

**BREHAN LOUDEAC**, a town of France, in the department of Morbihan, 6 miles N. of Josselin.

**BREHAR**, or **BRER**, the name of one of the Scilly islands, lying about 50 miles directly west of the Land's End

in Cornwall, N.W. of St. Mary, and W. of Trefcaw, two other islands. It is mountainous and rocky, contains several barrows and monuments of the Druids, and is inhabited by 30 families. It abounds with sea and land fowls, excellent famphire, and a variety of medical herbs. N. lat. 50° 2'. W. long. 10° 47'.

**BREHEMONT**, a town of France, in the department of the Indre and Loire; 4 leagues W. of Tours.

**BREHNA**, a small town of Germany, in the circle and electorate of Upper Saxony, and in the prefecturate of Bitterfeld, having both seat and voice at the provincial diets; 12 miles E.N.E. of Halle.

**BREHONS**, in *Antiquity*, hereditary judges belonging to the inferior provincial kings, and also to the nobles or chieftains, among the ancient Irish, by whom justice was administered, and controversies decided.

These sages were a distinct tribe or family, to whom competent lands were allowed in inheritance. One of these seems to have belonged to each sept or tribe; and they sat to try causes in the open air, either on the summit of a hill, or on its acclivity, as had been the custom of the Druids; and in such places the Irish continued also to hold their provincial assemblies, where all differences or complaints between district and district, and even private causes of extraordinary importance or difficulty, were heard and determined. To these meetings they came armed, some on horseback, and some on foot, as was usual among all the ancient colonies of the Celts in their public consultations. *Brehons'* chairs, or mounts, which are supposed to have been appropriated to this purpose, are found in many parts of Ireland. Dr. Ledwich has given a view of one of them, seated on the hill of Kyle, in the Queen's county. Campion speaks of such lawyers in 1570, who, after the custom of the country, determined and judged causes; to which Stanhurst adds, that they were entirely unacquainted with the English, the canon, and civil law; that their determinations were founded on no solid rules, but on precedents sanctioned by time and usage; and that these were kept profound secrets, by which they acquired admiration, and maintained their influence. An old man, the principal brehon in the part now called Monaghan, is mentioned by sir John Davies, attorney-general of Ireland in the reign of James I. (see his *Tracts*), as being summoned before the lord chancellor, himself, and some others, when on a tour through the north, in 1606; and on a solemn promise of its being returned to him, he produced a roll out of his bosom, written on both sides in a fair Irish character, but worn and defaced with time and ill-keeping. Of the rules of the law by which the brehons determined causes, sir John Davies delivers this opinion: "If we consider the nature of the Irish customs, we shall find that the people which doth use them must of necessity be rebels to all good government, destroy the commonwealth wherein they live, and bring barbarism and desolation upon the richest and most fruitful land of the world. For, whereas by the just and honourable law of England, and by the laws of all other well governed kingdoms and commonwealths, murder, man-slaughter, rape, robbery, and theft, are punished with death; by the Irish custom, or brehon law, the highest of these offences was punished only by fine, which they called an "ericke." He thus describes the mode of imposing it: "For offences and matters criminal, none was of so heinous a nature, that it was capital; for treason against the chief lord, and murder, were fineable; the fine they called an "ericke," which was assessed by the lord and his brehons. In case of treason, the lord had all the fine; in case of murder, the lord had one moiety, and the kindred of the party slain the other moiety; so as they never forfeited their possessions or their lands for any offence. Howbeit their lands were seized by the lords

for their fines, until the same were levied thereupon, and then restored. Rape was fineable in like sort; but theft deserved praise and reward, if the stealth were brought into the country, because the lord had a share, and the country thereby became the richer. But the theft being committed in the country and carried out, if the thief were apprehended before his friend made offer of his fine, he was commonly punished with death. But the lord, in that case, might take an "ericke," if he would. The brehons, assisted by certain scholars, who had learned many rules of the civil and canon law, gave judgment in all causes, and had the eleventh part of the thing adjudged for their fee; and the chief's lord marshal did executions." Having described the Irish customs of tanistry and gavel-kind, he thus concludes: "These are the principal rules and grounds of the brehon law, which the makers of the statutes of Kilkenny did, not without cause, call a "lewd custom;" for it was the cause of much lewdness and barbarism. It gave countenance and encouragement to theft, rapine, and murder; it made all possessions uncertain; whereby it came to pass, that there was no building of houses and towns, nor education of children in learning or civility, no exercise of trades or handicrafts, no improvement or manuring of lauds, no industry or virtue in use among them; but the people were bred in looseness and idleness, which hath been the true cause of all the mischiefs and miseries in that kingdom."

*BREHON-LAWS* denote the general maxims, or rules of law, observed by the brehons, and having the force of law throughout all the provinces of Ireland, previously to the settlement of the English.

Several fragments of the *leges brehonicæ* are still extant in public and private libraries. The most complete collection is that belonging to the duke of Chandos, containing twenty-two sheets and an half, close written, full of abbreviated words, and not very legible. This collection, falling into the hands of sir J. Sebright, was given by him to the university of Dublin, and forms 28 volumes. These laws resemble those of other ancient people, in the order of succession called tanistry, and in appointing fines for murder and other heinous crimes. From the resemblance of some of them to those of Asiatic countries, general Vallancy has endeavoured to strengthen his arguments in favour of the oriental origin of the Irish; whilst Dr. Ledwich urges the similarity of the same laws to the laws and customs of the ancient Germans and the northern tribes, in favour of the truth of Spelman's assertion, that the Irish are "Germanorum nepotes," of German origin. Dr. Ledwich asserts, that "the Irish erics are plain transcripts of the Salic and other weregilds in Lindenbrog's German codes." The reader, who is desirous of further satisfaction in this inquiry, will find most that has been said respecting the origin of the brehons in Dr. Ledwich's "Antiquities of Ireland," and in the "Collectanea de rebus Hibernicis," and other works of general Vallancy. The latter gentleman has published a translation of some parts of the code, in the 10th number of the "Collectanea."

At the time of the conquest of Ireland by king Henry II. A.D. 1172. the Irish were governed by the brehon law; but the laws of England were then received and sworn to by the Irish nation, assembled at the council of Lismore. King John, in the 12th year of his reign, carried over with him into Ireland many able sages of the law; and there by his letters patent, in right of the dominion of conquest, is said to have ordained and established, that Ireland should be governed by the laws of England; which letters patent sir Edward Coke (1 Inst. 161.) apprehends to have been then confirmed in parliament. But to this ordinance many of the Irish were averse from conforming, and still adhered to their

their brehon law; so that both Henry III. (A. R. 30.) and Edward I. (A. R. 5.) were obliged to renew the injunction; and at length, in a parliament holden at Kilkenny, 40 Edward III. under Lionel duke of Clarence, the then lieutenant of Ireland, the brehon law was formally abolished; it being unanimously declared to be indeed no law, but a lewd custom crept in of later times; and it was enacted, that no English subject shall submit to a trial by this law, on the penalty of high treason. And yet, even in the reign of queen Elizabeth, the wild natives still preserved their brehon law, which is described by Edm. Spenser (State of Ireland), to have been "a rule of right unwritten, but delivered by tradition from one to another, in which oftentimes there appeared a great shew of equity in determining the right between party and party, but in many things repugnant quite both to God's laws and man's." As to the prevalence of this law among the Irish, this writer further observes, that "dwelling as they do, whole nations and septs of the Irish together, without any Englishman amongst them, they may do what they list, and compound, or altogether conceal, amongst themselves, their own crimes." Some writers have spoken of these laws, as if they were peculiar to the Irish, and an evidence of their barbarity; not duly considering, that when they were established, many other nations had similar laws; and that if the English had taken proper pains to introduce their improved institutions, and to settle the country under any kind of regular government, they would, in all probability, have been able, though not without difficulty, to effect it. The civilization and improvement of Ireland seem, however, to have engaged little attention till the reign of James I.; who "proceeded in this work," says Hume (Hist. of Great Britain, vol. vi. p. 58.), "by a steady, regular, and well-concerted plan; and in the space of nine years, according to sir John Davies, he made greater advances towards the reformation of that kingdom, than had been made in the 440 years which had elapsed since the conquest was first attempted." The legislative union, reserved for the reign of George III. affords a prospect, under regulations prescribed by wise, moderate, and salutary counsels, and enforced by suitable sanctions, of further improvements, conducive to the remedy of the peculiar disorders of Ireland, and to the promotion of the real interests of both countries. See UNION.

**BREIDDYN-HILL**, in *Geography*, lies on the border of Shropshire, and occupies a large space between Montgomery and the vale of Severn. It consists principally of a coarse argillaceous schistus, blended in some places with small rhomboidal crystals and a calcareous spar. The summit of this hill, near the pillar erected in honour of admiral Rodney, affords a very extensive and delightful prospect, extending over the vales of the Severn, Fyrnowy, and Taned, as far as Plinlimmon, Cader-idris, and Aran-ben-llyn, whose pointed tops agreeably diversify the line of the horizon. This was a favourite situation of Llewelyn the Great, about the year 1240.

**BREIDEMBACH**, a town of France, in the department of the Moselle, 5 miles north of Bitche.

**BREISCH**, a town of Germany, in the circle of Upper Saxony, and duchy of Crossen; 8 miles S. of Crossen.

**BREITENBACH**, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg, seated on a small river of the same name, in the midst of woods, fields, hills, and vallies, with two churches and 400 houses; 14 miles S. of Erfurt. On the river, in its vicinity, is a mine yielding sulphur, alum, and vitriol.

**BREITENBURG**, a lordship and parochial village of Germany, in the duchy of Holstein, and circle of Itzehoe, seated on the river Stor, 2 miles S. of Itzehoe.

**BREITENECK**, a town of Germany, in the circle of

Bavaria, which gives name to a lordship, situate in the upper palatinate, and contributing to each Roman month 25 florins, and to each chamber term 35 six dollars. The fief estates of this seignory belong to the elector of Bavaria, and the allodial to the counts of Montfort, in which is the town, which has a citadel, and is distant 3 miles N.E. from Dietfurt.

**BREITHORN**, and **BREITLAUENEN**, peaks of the Jungfrau, or Virgin, in the canton of Bern, in Switzerland.

**BREITKOPF**, JOHN GOTTLÖB IMMANUEL, in *Biography*, an ingenious printer, letter-founder, and bookseller of Leipzig, was born in that city, Nov. 23, 1719. In early life he manifested a strong attachment to the sciences, and acquired a considerable acquaintance with the languages, particularly the modern ones. When he joined his father in business, he commenced the study of mathematics; and after the perusal of a work of Albert Durer, in which the shape of the letters is deduced from mathematical principles, according to which the first printing types were formed, he made the improvement of the art of printing a principal object of his attention. Accordingly, he began with delineating the forms of types mathematically; and he endeavoured to fashion them according to the most beautiful models, which he could procure by an extensive research among the English, French, Dutch, Flemish, and Italians. By his ingenuity and diligence, employed in this way, he obtained new and improved figures of characters, and had them cast in matrices cut for the purpose. Thus his printing-office and letter-foundry acquired very high reputation, as being the most complete in the world, not excepting those of the society "de propaganda" at Rome, and containing punches for 400 alphabets, with an equal number of matrices, and a very copious assortment of ornaments. Whilst he was assiduous in prosecuting every mode of improvement, he indulged no mean jealousy in contemplating the inventions of others in a similar way; but, on the contrary, he employed the types of Baskerville, and duly appreciated the value of those of Didot. Breitkopf found by his various and extensive researches, that engraving in wood had given birth to printing; and that the latter had contributed to the improvement of engraving. He was thus led to transfer some particulars, in the province of the engraver, to that of the printer; and with this view he made his first experiment on musical notes, and contrived to represent, by the typographic art, all the marks and lines which occur in the modern music, with no less accuracy than that with which they are represented by engraving. Recurring to mathematical principles, he succeeded, in 1755, in bringing this art to its present degree of perfection. He proceeded to print maps with moveable types, and, in 1776, accomplished, after encountering many difficulties, the object at which he aimed. This, however, he considered as a matter of mere curiosity; and such was also another attempt, which was that of copying portraits by moveable types. In 1793, he directed his attention to another object of greater utility; which had long been considered as impracticable, and on which large sums had been expended without avail. This was that of printing, with moveable types, the Chinese characters, which are, in general, cut in pieces of wood, so that a whole house is often necessary to contain the blocks employed for a single book. After some trials he at length succeeded; and having sent specimens to the pope, he returned him thanks in the politest manner by cardinal Borgia. His next attempt was that of printing mathematical figures in the same manner; but though he surmounted all obstacles by his persevering exertions, his numerous engagements prevented the completion of his design. Breitkopf directed his attention to the improvement of type-metal, particularly by giving it that degree of hardness, which has been a desideratum in founde-

ries of this kind. He discovered likewise, a little before his death, which happened on the 26th of January, 1794, a new method of facilitating the process of melting and casting; but this he concealed for the benefit of his heirs. From his foundery, which employed 12 furnaces, and 39 workmen, types were sent to Russia, Sweden, Poland, and even America. He introduced also several improvements in his presses, which were freely presented to the inspection of those who visited his printing-house.

Besides his mechanical inventions, which occupied much of his time and attention, his researches into the origin and progress of the art of printing were very considerable, and furnished the materials of a history, which he left behind in manuscript. Of this larger work, he published, in 1774, an account, in a small treatise, containing, among other particulars a refutation of the opinion of those who pretend that printing was first employed at Florence, Witzsburg, or Antwerp. In 1784, he published the first part of a work, entitled, "An Attempt to illustrate the origin of playing-cards, the introduction of paper made from linen, and the invention of engraving on wood in Europe." The latter part of this work was finished, but not published, before his death. His last publication was a small "Treatise on Bibliography, &c." published in 1793, and containing extracts from his larger works, with his reasons for retaining the present German characters, and a refutation of some assertions respecting typography. Breitkopf was distinguished by his assiduity and perseverance; and devoted his whole life to studious and useful employment, with the interruption of only 5 or 6 hours in the 24, which he allowed for sleep. Schlichtegroll's *Necrology*. *Gen. Biog.*

**BREITZENHEIM**, in *Geography*, a lordship of Germany, in the circle of the Lower Rhine, on the Nahe, near the town of Creutznach, and deriving its name from an old castle now in ruins. In the matricula of the empire it is assessed at six florins, in that of the circle at 8, and pays to the chamber of Wetzlar 3 rix-dollars, 13½ kreutzers. Its inhabitants are partly Roman catholics, and partly Lutherans.

**BRELADE'S, Sr.**, a bay on the south coast of the island of Jersey, which takes its name from a village, 5 miles W. from St. Helier.

**BRELANDS**, a town of Norway, 7 miles W.N.W. of Christiansand.

**BRELLES**, a town of France, in the department of Finisterre, and district of Brest; 3½ leagues N.W. of Brest.

**BREM.** See **PREM.**

**BREMA**, a town of Italy, in the Milanese, near the conflux of the Sessia and Po, on the frontiers of Montferrat; 28 miles W. of Pavia.

**BREMBO**, a river of Italy, which rises on the frontiers of the Valteline, and discharges itself into the Adda, about 8 miles from Bergamo.

**BREME**, a cape which forms the south-eastern side of the mouth of Oroonoko river, opposite to cape Araya, in South America.

**BREMEN**, a duchy of Germany, in the circle of Lower Saxony, bounded on the north by the German sea and the Elbe, on the east by Holstein, Lunenburg, and Verden, on the south by Verden, Hoya, and Diepholz, and on the west by the Weser, Oldenburg, and the German ocean. Its greatest length is about 60 miles, and breadth about 40. The face of the country is level, and it is almost surrounded by the Elbe and the Weser. The air is cold; but the country is fertile and well-peopled. The Elbe, Oite, and Weser, are bordered with very rich marsh lands; those on

the Elbe produce plenty of grain and fruit; those on the Oite are also very productive of grain, and yield a clay for vessels, and a kind of free stone; the soil on the borders of the Weser, besides being fertile in grain, supports likewise large breeds of cattle. Between Bremen and Stade, the country is either a barren sand, or a morass. In order to guard the lands against the inundations of the rivers, dykes and dams have been erected, and are kept in repair at a great expence; and yet in winter they are frequently so much overflowed; that the inhabitants are obliged to make use of long poles to leap over the ditches and other waters, in passing from one place to another; and the inundations of the Weser in particular are such, that cities and villages appear like so many islands in the midst of a sea. The champaign country has, in some parts, good corn land; the heaths are covered with sheep; and the culture of bees is an object of particular attention. On the moors are dug great quantities of turf, which is exported to Bremen and Hamburg, and used in brick-kilns, the glass-house, and as fuel in private houses. This country yields likewise much flax. The inhabitants likewise, by their situation between navigable rivers, have been induced to turn their thoughts to trade. They have the reputation of being good soldiers; but on account of the marshes and inundations of the country, they are subject to agues and fevers, and are hence led to indulge the habit of drinking much brandy. Reisbeck describes them as yellow-skinned, soft-fleshed, and full of wrinkles; and their small round figures form a striking contrast with the tall Germans of the southern parts. Few rosy cheeks are observed either among men or women.

The duchy of Bremen was formed out of an archbishopric, which was originally a bishopric, founded by the emperor Charles the Great in 787 or 788, of which Willehad, an Englishman, was the first bishop. In 858, the see was incorporated with Hamburg, as the archbishopric of the northern nations; and the archbishops gradually got into their hands the counties within the diocese of Bremen, and acquired the sovereignty over it. But after the death of the archbishop Roden in 1511, the chapter elected archbishops out of princely families; in 1644, the Swedes made themselves masters of Bremen; and, in 1648, at the peace of Westphalia, it became a duchy and fief of the empire. In 1675, the duke of Brunswick and Lunenburg, in conjunction with the bishop of Munster and some Danish forces, overran this duchy as far as Stade, which place was taken in the following year by the Lunenburg troops. The conquerors first thought of sharing the duchies of Bremen and Verden between them; but Sweden kept the whole to herself, except some small part of it, which was restored to the dukes of Brunswick and Lunenburg, at the peace of Nimeguen in 1679. During the northern war, the Danes, in 1712, reduced the duchies of Bremen and Verden; and in 1715, Frederick IV. transferred them to the elector of Brunswick, in lieu of the sum of 700,000 rix-dollars. In 1719, by the peace of Stockholm, they were ceded by the crown of Sweden for ever to the elector of Brunswick, together with all their rights and appurtenances, in the same manner as they had been granted to Sweden by the treaty of Osna-bruck; for which renunciation the elector paid Sweden a million of rix-dollars. In 1732 the elector obtained the emperor's investiture for Bremen and Verden. The elector of Brunswick, as duke of Bremen, possesses in the college of princes, the sixth seat on the bench of temporal princes, and in the diet of Lower Saxony, exclusively of a vote, is alternately director with Magdeburg. The assessment of the duchy to a Roman month, is 24 horse and 100 foot, or 688 florins, which is also its contingent to the matricula

of the circle; and to the imperial chamber at Wetzlar, it pays 108 rix-dollars, 22½ kreutzers. The duchies of Bremen and Verden are jointly under the following colleges; viz. the regency, consisting of three counsellors, and subordinate to the privy-council at Hanover; and the chancery, composed of the three counsellors of regency, a director, and certain judiciary counsellors, and taking cognizance of criminal and executive cases. In the high court of justice sit all the members of the chancery, with seven assessors, nominated by the states of each duchy; viz. three by the Bremen nobility, two by Stade and Buxtehude, one by the nobility of Verden, and one by the town. The chief branches of the sovereign's revenue are those of the demesne bailiwicks, districts, and jurisdictions, with the regalia; certain payments arising from the subjects, as excise, and the monies for the maintenance of the high court of appeal at Zell, for furnishing forage, &c.

In the whole duchy there are but two cities, viz. Bremen and Stade, and 12 market towns. The states of Bremen consist of the nobility, and the deputies of the towns of Stade and Buxtehude, whose privileges are the same with those of Verden. An assembly of all the states, or a diet, cannot be held without the knowledge and consent of the regency; but the nobility may assemble twice a-year at Basdal, without giving any previous notice to the regency. All the inhabitants, except those who belong to the free states, and who have a right to sit and vote in the diets, are taxable; and the number of taxable hearths is 22,276. The established religion is Lutheranism; the number of Lutheran churches is 118, under the superintendency of more than this number of pastors; and the supreme inspection of the churches of this duchy and of the principality of Verden is vested in a general superintendent. The Calvinists form seven congregations, with a like number of pastors. The doctrine and institutions of the reformed church were introduced into the republic of Bremen in the 16th century. An attempt for this purpose was made so early as the year 1556, by Albert Hardenberg, the intimate friend of Melancthon; but it did not succeed till towards the close of this century, when no measures, either of prudence or force, were sufficient to prevent the church of Bremen from modelling its faith, worship, and government, after that of Geneva. The manufactures of this country, exclusively of cordage and linen, are those of cloth, flannel, kerseys, and other woollen stuffs, at Scharenbeek. Ammund, in the district of Lessum, has a sugar refinery, and a porcelain manufacture. The principal rivers of the duchy, besides the Elbe and the Weser, are the Oste, the Schwinge, the Luhe or Aua, the Gesste, and the Lesum.

BREMEN, an imperial city of Germany, and capital of the duchy of the same name. This city lies on the banks of the Weser, which divides it into the Old and New town; joined by a large bridge, and another smaller one over a little branch of the same river. The streets of the Old town are very narrow; the houses, which are rarely more than two stories high, are, in general, old-fashioned and inconvenient, nor are the more modern built with great taste. The exchange, however, the Lutheran orphan-house, and a few other edifices, are in a much better style. The houses, both of the Old and New town, which are numbered, inclusive of the suburbs, are 5105; and Hoeck estimates the number of inhabitants at 40,000. The Old town is the largest and most populous, and is divided into four parishes. Most of the magistrates and principal merchants have their winter habitations in this town; but their gardens and summer residences are in the other. In the Old town stands the cathedral, which is an ancient Gothic structure, and which

belongs to the Lutherans. Under its choir is the "Bleekeller," or lead-cellar, so called because the lead, with which this building is covered, was cast there. It has the singular property of preserving from putrefaction the dead bodies which are put in it, and thus resembles the vaults of the Cordeliers and Jacobins in Toulouse. This city is governed by a council, that consists of four burgomasters, who preside by turns, each for six months, two syndics, and twenty-four senators, some of whom are jurists, and the rest merchants. The whole body is distributed into four courts, each consisting of a burgomaster and six senators. These magistrates elect their new colleagues, without consulting the citizens; but none can be chosen who are nearly related to any already in office. They may make any arrangement they think fit, with respect to the police; but they cannot enact any new law, nor alter any part of the constitution, nor impose any tax, without assembling the citizens; nevertheless, no resolutions of these latter are of any effect, unless approved by the council. The management of all public money is committed to deputies, appointed by the citizens, who act under the orders of the council, and must lay their accounts before their constituents. Their taxes are moderate; they who possess property exceeding 3000 dollars, pay a foot or tax on what they are worth, in which each is left to estimate his own possessions, and to ascertain the sum which he thinks he ought to pay. In doing this, the citizens are, in general, so conscientious and public-spirited, that most of them really contribute more than could strictly be demanded from them; but they are well satisfied that the revenues of their little state are wisely and frugally administered; and not wasted in supplying the extravagances of princes, nor in diffusing corruption among the people and their representatives. The police of this city, it is said, is excellent; and not a beggar is to be seen in or near it; the magistrates taking care to furnish the poor with an opportunity of gaining a subsistence by industry. To the Jews, however, they are less tolerant and equitable; for they will not permit any of them to reside in the city, nor even to enter it, except during the fair. The predominant church at Bremen is the reformed, or Calvinist. Of this persuasion are the magistrates; though the Lutherans are not, by any law, excluded from the regency. Formerly they were sometimes chosen into these offices; but since the Calvinists have had undisturbed possession of the government, they have taken care to keep out all that are not of their own sect. This city was formerly an archbishopric; but so early as the 13th century, frequent disputes occurred between it and the bishops and chapter. Frederic, the last archbishop of Bremen, was frequently at variance with the city, opposing its appearance at the diet, though formally summoned to it; and in 1639 he conferred the cathedral on the Lutherans, which had been shut up ever since the year 1568. But in 1640, Bremen was summoned to the diet, and allowed a seat and vote on the Rhenish bench in the college of Imperial cities. In 1648, at the peace of Westphalia, both the city, its dependencies, and vassals were confirmed in their state-freedom, rights, and privileges, ecclesiastical as well as civil; and though disputes afterwards arose, the house of Brunswick and Luneburg, in 1731, voluntarily granted to the city that freedom which had been contested, and all disputes were brought to an amicable termination. In 1757, the French got possession of this city; but in the following year hastily abandoned it and were succeeded by a body of Hanoverians. In the diet of the empire it possesses the eighth seat on the Rhenish bench in the college of Imperial cities. Its matricular assessment is 320 florins, and its contingent to the chamber at Wetzlar 148 rix-dollars, 67½ kreutzers. The king of Great Britain, as elector of Brun-

wick, &c. claims all the authority which the prelate and chapter formerly enjoyed. He appoints the pastor of the cathedral, which belongs to the Lutherans; who, as such, are immediately dependent on the electoral government.

Bremen is supplied with water from the Weser by means of a wheel turned by the stream, which raises it into a reservoir, whence it is conveyed to the several houses by subterranean conduits, at a very small expence. On the building which contains this machine is the following inscription:

“Volve Pater, Civi tradam tua dona, Vifurgis!”

Provisions of all kinds are much cheaper at Bremen than at Hamburg, or even in Hanover; and yet neither the commerce nor the wealth of Bremen is inferior, in proportion to its size, to those of the other Hanse towns; but the expensive luxury, which prevails in many trading places is unknown here, and the manners of the inhabitants are plain and frugal; of which one great cause is, that the town is very little visited by strangers. In this city there are many manufactures, exclusive of a very considerable trade. This trade consists in iron, flax, hemp, and linen, exported to England, France, Spain, and Portugal, and in returns of various other articles with which it supplies Westphalia, and the countries about Hanover. It is also a considerable gainer by its fisheries, and particularly the trade of blubber with the south of Germany. Bremen is famous for Rhenish wine; the sale of which is monopolized by the city, and it can be bought only at the public vaults. In one of these, as we are informed by baron Knigge in his “Letters written on a Journey from Lorraine to Lower Saxony,” published in 1793, that wine is kept so very old, that if, to the prime cost, the accumulating interest of the money, the filling up, and other expences, were added, a bottle of it would amount to above a thousand dollars; but the baron does not vouch for the truth of this report. This precious liquor is only used by the magistrates on rare and grand occasions, and it is sometimes administered, by order of the president, to the sick.

The character of the inhabitants of Bremen, says this author, has been unjustly treated with contempt by travellers; and they have been represented as a plodding, stupid people, without genius or taste. He observes, on the contrary, that though the citizens of Bremen have not that exquisite taste for the comparatively trifling arts of luxury and amusement, nor that studied polish of manners which result from an habitual want of more serious employment, and from frequent intercourse with foreigners, whose sole object is pleasure; they have in general good natural abilities, improved by a judicious education; and with respect to useful knowledge, whether literary or scientific, more information may be obtained by conversation in Bremen, than in many places in which more pompous pretensions are set forth. They are obliging, frank, and hospitable; and their numerous and excellent institutions for the education of orphans, and for other charitable purposes, which are supported by voluntary contributions, reflect honour on their generosity and public spirit. This city has lately afforded M. Olbers an opportunity of forming an association of opulent merchants, who have established a museum, a physical cabinet, and an observatory, with professors, among whom M. Olbers, the discoverer of the new planet called PALLAS, is the professor of astronomy. Bremen is situated 52 miles S.W. of Hamburg. N. lat. 53° 30'. E. long. 9°.

BREMENIUM, in *Ancient Geography*, a town from which Antoninus begins his first journey in Britain. It was one of the towns belonging to the Otadeni. Dr. Gale places

it at Brampton, on the river Bremish in Northumberland; others place it at Brampton in Cumberland; but the altar that has been found at Riecheffer, or Ruchester, near the head of the river Read in Northumberland, with the name Bremenium upon it, demonstrates that this was its real situation. Baxter (Gloss. p. 46.) derives its name from the British words Bre man iu, which signify a town upon a hill near a river, which is agreeable both to its situation and present appellation. Horley, Brit. Rom. p. 243.

BREMERVORDE, in *Geography*, a large village and bailiwick of Germany, in the duchy of Bremen, in which was formerly the palace of the archbishop. It has municipal privileges and two burgomasters; 30 miles N. of Bremen, and 10 S.W. of Stade. N. lat. 53° 58'. E. long. 8° 35'.

BREMETONACIS, in *Ancient Geography*, a place of Britain, in Antonine's tenth rout, from Glanoventa to Mediolanum, between Galacum and Coccium, or Appleby and Ribchester; supposed to be Overborough.

BREMGARTEN, in *Geography*, a town of Switzerland, and one of the free bailiages, formerly subject to the cantons of Zurich, Bern, and Glarus, from the year 1712, and united by the French division of 1798, to Baden, which forms a part of the department of Argovie or Aargow, according to the French constitution of 1801. The inhabitants of this bailiage are Roman catholics. Its regency, previous to the French conquest, consisted of the little and great council; the former being composed of 12 members, and the latter of 40. The town is seated on the Reufs, about 8 miles S. of Baden; and has a wooden bridge over the river, forming a communication between the cantons of Zurich and Bern. It is divided into the Upper and the Lower town; the former situate on an eminence, and the latter on the bank of the river. N. lat. 47° 14'. E. long. 8° 12'.

BREMIS, a town of Switzerland, in the Valais, situate fourth of the Rhine and near it; 4 miles E. S. E. of Sion. N. lat. 46° 16'. E. long. 7° 16'.

BREMONT LA MOTTE, a town of France, in the department of Puy-de-Dôme, 10 miles from Clermont.

BREMPT, a small town of Germany, in the electorate of Treves, seated on the Moselle.

BRENAS, a range of mountains in the southern part of Africa, towards the Cape of Good Hope, which, according to Barrow, in his “Travels,” 1801, p. 298, passes N. W. and S. E. about lat. 32° or 33°. This great range, says Paterson, p. 125, runs E. and W. at the distance of about 4 days' journey from the mouth of the Orange river; probably the inmost terrace of the Table land of southern Africa, which seems to be pervaded by the Jagas, a wandering nation like the Tartars.

BRENCKHAUSEN, a town of Germany, in the circle of Westphalia, belonging to the abbey of Corvey, 4 miles N. W. of Corvey.

BRENDOLO, a small sea-port town in the canals of Venice, between Venice and the mouth of the Po.

BRENET, a picturesque lake of Switzerland, in the valley of the lake of Joux, upon that part of the Jura chain of mountains called Mont Joux, in the bailiage of Roman Motier. From this small lake descends a stream, which is lost in a hollow gulph called “L'Entounoir,” or the funnel, in which several mills are turned by the force of the current. About 2 miles further, on the other side of the mountain, the river Orbe bursts forth, and is probably produced by the stream here ingulphed.

BRENETS, LES, a village and mayoralty of Switzerland, in the Valais, containing about 1000 inhabitants; 10 miles N.W. of Neuchatel. It is seated near the river Dou. N. lat. 47° 5'. E. long. 6° 27'.

BRENNA,

**BRENNÀ, BREGNO, or BLENZO, VAL DI**, one of the bailliages of Switzerland, which formerly belonged to the cantons of Uri, Schwitz, and Underwalden, but referred by the French constitution of 1801, to the 17th department. It lies N. of the Bellinzona and Riviera, and between Val Leventina and the river Tessino, on the west, and Val Calanca on the east. It is about 7 leagues long, and half a league broad. Its principal resources are its pastures and its chestnuts. See **BELLINZONE**.

**BRENNAGE**, *Brennagium*, in *Middle Age Writers*, a kind of tribute paid, in lieu of bran, or bran itself, which the tenants were obliged to furnish for support of the lord's hounds. The word is also written *brenage*, *brenagium*, and *brenage*, *brenagium*, *brenaticum*, and *brenneticum*. Du-Cange Lat. Gloss.

**BRENNAU**, in *Geography*, a town of Lower Bavaria, situate on the river Ilum, meanly built and sinking into decay; 92 miles from Munich, and 23 miles from Passau.

**BRENNE**, the name, before the revolution, of a small district of France, that lies between Berri, Touraine, and Poitou, and of which the chief town was Mezzieres; forming now a part of the department of the Indre.

**BRENNE**, a town of France. See **BRAINE**.

**BRENNER, HENRY**, in *Biography*, a learned Swede, was born in 1669, in the parish of Kronoby in West Bothnia. Having finished his education at Upsal, he accompanied, in 1697, Lewis Fabricius, his Swedish majesty's ambassador, to Persia; and as he had acquired, in this journey, an extensive knowledge of the eastern languages, he remained in that country for the purpose of assisting the Persian envoy, Sarung Chan Beg, in his mission to Sweden. On their way through Russia in 1700, a war having taken place between Charles XII. and Peter I. Brenner was arrested at Moscow, under a suspicion of some political intrigue, and confined in prison till the peace of Nyttad. This journey, however, produced a learned epistolary correspondence with Elias Brenner, Gripenhielm, Gavelius, Benzelier, and Lilienstedt, part of which has been published; and the history of Moses Armenus Choronensis, under the title of "Epitome Commentariorum Moyse Armeni de origine et regibus Armenorum et Parthorum, cum notis et observationibus," Stockholm, 1723. The Armenian original of this work, written about the middle of the 15th century, in the Armenian language, was printed at Amsterdam in 1695; and another translation of it was printed at London in 1736 by the sons of the celebrated Whiston. In 1722 Brenner communicated to the royal college of the chancery his observations on the cause of the expedition undertaken by Peter I. against the Persians; of which Justus Rabner has availed himself in his history of that prince. In the course of these observations, he announced his intention of giving an accurate description of the Caspian sea, and of the river Daxia in the country of the Nezetzu Tartars, which he supposed to be the ancient Jaxartes; but a copy of it was inserted, without acknowledgment, in the "Memorabilia Orientalis partis Asiae." Whilst Brenner occupied the office of librarian to the royal library at Stockholm, to which he was appointed in 1722, he enriched it with more than 30 volumes of MSS. which treat of the ecclesiastical history of Sweden. But his health having been impaired by his long confinement in Russia, he died in 1732. Gen. Biog.

**BRENNER**, in *Geography*, the modern denomination of the Rhetian Alps, which pass through the Tyrol, between Inffruck and Störzing, over which the high road is extended through an interval of 4 leagues. These mountains rival the grand Alps of Switzerland in numerous glaciers, and, like other grand chains, present exterior barriers; that

on the north being distinguished by the name of Spitz, and that on the south by the appellation of Vedretta. The primitive or greatest elevations arise to the north of Störzing, whence streams proceed towards the river Inn on the north, and to the Adige on the south; and the Eisac descends, as a precipitous torrent, amidst masses of granite, petrified, and marble, while the avalanches become dangerous to travellers. The naked and rugged peaks of the mountains Lorenzen, Fartschel, and Tschafatsch, raise their towering heads towards the N.W., and on the S.E. are those of Glander, Schlofs, Pragles, and Pallanfer. Their summits are entirely bare, and seem to be composed of granite. The glacier most easy of access is that of Stuben, the centre of which presents many Alpine plants; and the granite and porphyry are frequently covered with calcareous stone. The glacier of Stuben is 4622 feet above the level of the sea, and exhibits the usual phenomena of such scenes, with beautiful pyramids of azure, which in sunshine reflect a blaze of light. The mountain, particularly called Brenner, is, according to Beaumont (*ubi infra*) only 5109 feet above the level of the sea. The town of Steinach is placed nearly in the centre of the Tyrolese chain; towards the east, from the midst of a long course of glaciers running N.E. and S.W. rises the grand mountain Gefron, a mass of granite covered with snow, and one of the highest peaks of the Rhetian Alps; on the west is Habichpiz, of smaller height; but to the S.W. is Tributaan, another stupendous peak of the great Brenner chain. Bock-kogo (which see) is another. The Brenner, or burning hill, says Beaumont, is so called on account of the frequent thunder-storms. Beaumont's Rhetian Alps, Lond. 1792. Pinkerton's *Geog.* vol. i. p. 362, &c. See **ALPS**, and **TYROL**.

**BRENNING**. See **BURNING**.

**BRENNKIRCHEN**, in *Geography*, a small town of Lower Austria, on the frontiers of Hungary, not far from the Danube.

**BRENO**, a town of Italy, in the Bressano, seated near the Oglio, between Bormio and Brescia; 32 miles N. of Brescia.

**BRENOD**, a town of France, in the department of the Ain, and chief place of a canton, in the district of Nantua; 5 miles S. of Nantua. The town contains 879, and the canton 6959 inhabitants: the territory includes 215 kilometres and 11 communes.

**BRENSCHEN, or BREUNSCHEIN**, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz; 7 miles S. of Militenberg.

**BRENT, MISS**, in *Biography*, afterwards Mrs. Pinto, the first singer who performed the part of Mandane in Dr. Arne's *Artaxerxes*. In her bravura singing she had considerable merit; her execution was neat, distinct, rapid, and unrivalled at the time (1763); but has been greatly surpassed by subsequent female singers. This performer died in 1802, oppressed by age and indigence. Her history, if detailed, might furnish a useful lesson to female favourites of the public, possessed of greater vocal powers than human prudence.

**BRENT**, in *Geography*, a river of England, which runs into the Thames at Brentford in Middlesex.

**BRENTA**, a river which has its source in the Tyrol, about 7 miles E. from Trent, passes by Padua, and runs into the Adriatic, a little to the south of Venice.

**BRENTA**, in *Ornithology*. See **BRANTA**.

**BRENTFORD**, in *Geography*, a market-town of Middlesex, England, stands on the northern banks of the river Thames, at the distance of seven miles W. from London. This place is particularly distinguished in the page of history as the scene of warm contention, in the strongly contended elec-

elections for the county of Middlesex. It derives its name from a rivulet called Brent, which passes through it in its course from Hendon to the Thames. The town is divided into two parts called New and Old Brentford, and belongs to two distinct parishes: the former being mostly within the boundary of Hanwell parish: whilst the latter is situated in that of Great Ealing, to which village its chapel is subordinate. This is a modern structure, and was rebuilt in 1744. Exclusive of continual passage of travellers through the town, it derives considerable profits from the different mills and manufactures established here. Large quantities of malt, corn, flour, pottery, bricks, and tiles, are annually sent hence to the metropolis. Here are a weekly market on Tuesdays, and two annual fairs for swine, sheep, &c. The town is composed of one very long street, occupying the sides of the great western road, and its houses are mostly inhabited by shop-keepers and tradesmen. In 1801, the population amounted to 1443, and the houses to 287.

In the civil wars between Charles I. and his subjects, this town was rendered a scene of conflict and slaughter. The king, after defeating the rebels at Edge-hill, marched his forces to Brentford, where he was opposed by those of the parliament. A battle ensued, and the latter were vanquished, when their captain was killed, and above 500 were taken prisoners. The earl of Forth, having greatly signalized himself in this engagement, was first made general of the king's forces, and afterwards created earl of Brentford; which title became extinct at his death in 1651.

About one mile West of Brentford stands Sion-house, a stately ancient mansion of the dukes of Northumberland. It takes its name from a monastery founded here by Henry V. in 1414. Edward VI. gave it to his uncle the protector, Edward Seymour, duke of Somerset, who, about 1547, began to build a magnificent structure here; but being afterwards executed for felony, this property was confiscated. Passing through different proprietors, James II. at last settled it for ever on the Northumberland family. The house stands in a spacious park on the bank of the Thames, and is composed of a large square with towers at the corners, and an open court in the centre. It is built of white stone, and embattled all round.

On the opposite banks of the river are the beautiful royal gardens of Kew. They were begun by the late prince of Wales, afterwards much improved by the dowager princess, and completed under the direction of his present majesty. This monarch has also commenced the building of a magnificent castellated palace, under the superintendance of Mr. James Wyatt, architect. See KEW, et seq. Lyson's Environs of London, vol. ii. Gough's edition of Camden's Britannia, vol. ii.

BRENTIUS, or BRENTZEN, JOHN, in *Biography*, one of the earliest Lutheran divines, was born at Wil, in Suabia, in 1499; and having pursued his studies with great reputation at Heidelberg, he obtained a canonry of Wittenberg, and took holy orders. Although, at an early period of the reformation, he became a convert to the opinions of Luther, and taught them publicly, he retained a great part of the popish doctrine of the real presence, and attempted to explain and defend it by the notion of the ubiquity of Christ since his ascension, whence the appellation of "Ubiquitarians" has been applied to a class of Lutherans. On the subject of baptism he had also peculiar notions, and he maintained, in the extreme, Luther's opinion concerning justification. In the assemblies of Worms and Ratibon, he distinguished himself as an ardent disputant; and he was charged with promoting the religious war of 1546, which rendered him particularly obnoxious to Charles V. After

the death of Luther, he assumed a considerable lead in his party. He was twice married; and in 1570 died at Tübingen, where he was theological professor, leaving behind him a numerous progeny. His works have been published in 8 volumes, fol. Moreri.

BRENTOLA, or BRENDOLA, in *Geography*, a small town and district of Italy, in the Vicentin, at a small distance from Vicenza.

BRENTON'S reef, the southernmost point of Rhode island, in America, about three miles from Newport, lies 2 miles E. of Beaver-tail; forming with it the mouth of Newport harbour.

BRENTONEGO, a town of Germany, in the Tyrol; 12 miles S.S.W. of Trent.

BRENTUS, in *Entomology*, a genus of COLEOPTEROUS insects, having the head projecting into a very long, straight, cylindrical snout, beyond the middle of which the antennæ, which are moniliform, are inserted. Fabr. &c. The species of this genus are *aneborago*, *assimilis*, *barbicornis*, *lifrons*, *cylindricornis*, *dispar*, *druryanus*, *hastile*, *monilis*, *nafutus*, and *semipunctatus*, which see.

BRENTWOOD, in *Geography*, is a large chapelry in the parish of South-Weald, in the county of Essex, England, situated 18 miles E. from London, on a commanding eminence. It is a considerable thoroughfare, and contains many inns and public-houses. The Crown Inn is of very ancient foundation; and even in Salmon's time was reputed to have had that sign for 300 years. The county assizes were once held here; and in the High-street are the remains of a town-hall and prison, inhabited by a farrier and other persons, who are bound to put them in repair when the assizes shall be again removed hither. Here is a good grammar-school, endowed by sir Anthony Brown in 1537. The chapel, a small ancient structure, was founded about the year 1221, at the intercession of David, prior of St. Osyth, for the use of the tenants of a manor belonging to that monastery. This township contains 182 houses, and 1007 inhabitants. Camden supposed the Cæsaromagus of the Itinerary to have been in the neighbourhood of Brentwood. At South-Weald is a circular camp, single-ditched, including about seven acres, supposed to have been a castra exploratorum near which the Roman way, called Watling-street, passes. Morant's History of Essex, 2 vols. fol.

BRENTWOOD, a township of America, in Rockingham county and state of New Hampshire, containing 971 inhabitants, distant 7 miles from Exeter, and 19 from Portsmouth. In its vicinity is found a stone in which vitriol and sulphur are combined.

BRENTZ, a river of Germany, which rises in Wirtemberg, and discharges itself into the Danube, near Laugingen.

BREPHOTROPHIUM, from *βρεφο*; infant, and *τροφον*, I nourish, an hospital for foundlings, or a place wherein children, exposed by their parents, are brought up at the public charge.

BREREWOD, EDWARD, in *Biography*, first professor of astronomy at Gresham-college in London, to which office he was chosen in 1596, was born in the city of Chester in 1565; and having completed his course of grammar learning in his native place, was admitted, in 1581, of Brazen-Nose college, in the university of Oxford. Here he acquired the character of an assiduous student, and took his degree of master of arts in 1590. Failing in his attempt to obtain a fellowship, for which he was a candidate, he removed to St. Mary's hall. After his election to the professorship of Gresham college, he seems to have had no wishes of further preferment; but devoted himself to the pursuit

pursuit of knowledge, and passed the remainder of his life in retirement. He died of a fever, Nov. 4th 1613; and was buried in the chancel of St. Helen's church, without any monument or other memorial. From his works on a variety of subjects, which were printed after his death, we may conclude that he was a very general scholar. These are as follow: 1. "De ponderibus et pretiis veterum nummorum, eorumque cum recentioribus collatione," lib. i. Lond. 1614, 4to. printed also in the "Critici Sacri," vol. viii. and in the Apparatus of the "Biblia Polyglotta." 2. "Enquiries touching the diversity of Languages and Religions through the chief parts of the World," Lond. 1614, 23, 25, 4to.; 1647, &c. 8vo. To this was prefixed a learned preface by his nephew and heir, Robert Brerewood. 3. "Elementa logicæ, in gratiam studiosæ juventutis in academia Oxoniensi," Lond. 1614, 1615, &c. 8vo. 4. "Tractatus quidam logici de predicabilibus, et predicamentis," Oxon. 4to. 1628; and 1637, &c. 8vo. 5. "Tractatus duo; quorum primus est de meteoris, secundus de oculo," Oxon. 1631, 1638, 8vo. 6. "A Treatise of the Sabbath," 1611; Oxf. 1631, 4to. 7. "Mr. Byfield's Answer, with Mr. Brerewood's Reply," Oxf. 1631, 4to. 8. "A second Treatise of the Sabbath," or "An explication of the fourth Commandment," Oxf. 1632, 4to. 9. "Commentarii in Ethica Aristotelis," Oxon. 1640, 4to. 10. "A Declaration of the Patriarchal Government of the Ancient Church," Oxf. 1641, 4to.; Lond. 1647; Bremen, 1701, 8vo. Ward's Lives of the Professors of Gresham College, p. 74, &c.

**BRESANY, or BREZAN,** in *Geography*. See **BRZEZANY**.

**BRESARGIA,** a small town of Sardinia, in the north part of the island denominated "Capo di Lugatori."

**BRESCIA, or IL BRESSANO, or BRESCIANO,** a country of Italy, formerly a part of Lombardy, but now belonging to the Cisalpine republic, is bounded on the north by the county of Bormio, on the north-east by the Trentin, on the east by the Veronese, from which it is separated by the lake Garda, on the south by the Mantuan and Cremonese, and the small lake of Idro, and on the west by the Bergamasco, from which it is in a great part divided by the lake Isco. Brescia, though mountainous, is fertile in wine, oil, and maize, and has excellent pasturages, and some mines of copper and iron, and also manufactures of silk, paper, &c. The air is wholesome, and the country populous. Its principal rivers are the Adige and the Oglio. It became a province of the Venetian states in 1517; but Brescia, its capital, was taken by the French under Bonaparte, in 1796, and it formed a part of the Cisalpine republic by the 5th article of the treaty of Campo Formio in 1797, confirmed by the 12th article of the treaty of Luneville in 1801.

**BRESCIA,** in Latin *Brixia*, the capital of the above province, is situated on a beautiful plain on the small river Garza. It is large, being reckoned about a league in circumference, well fortified, having a castle on a hill, and is said to contain about 50,000 inhabitants, some of whom are rich and noble, and others are ingenious and diligent in carrying on several manufactures of linen, and particularly fire-arms, swords, knives, and other cutlery wares. It is encircled with walls, in which are five gates; the streets are handsome and clean, most of them being watered by little streams from the river, and the buildings are good. It has several public squares, the largest of which is surrounded with piazzas, and in the centre of it stands the town-house. The palace, where public business is transacted, is a magnificent stone structure, built from the ruins of a temple of Vulcan, and remarkable for its architecture and paintings in fresco. Besides the cathedral, this city has 19 parish-churches, 30 convents, a general hospital, and several chari-

table foundations. The cathedral is a modern edifice, to the rearing of which cardinal Quirini, once bishop of this city, contributed liberally; and he also presented the city with a library; in acknowledgment of which the magistracy, in 1750, erected two marble statues to his honour, one in the church, and the other at the entrance of the library. In the cathedral is exhibited the famous standard of Constantine: and this, as well as several of the churches, are adorned with beautiful statues and paintings. The magistracy, before the revolution, consisted of 600 citizens, divided into inferior councils, under a noble Venetian, who presided as governor, or podestat. This city was the see of a bishop, suffragan of Milan. Brescia is said to have been built by the Cenomani, commanded by Belovefus; and as others affirm, by Brennus; and it afterwards became a Roman colony. It was burnt by Radagastus, king of the Goths, in 412, and re-established by Attila in 452. It was afterwards possessed by the Lombards. Charlemagne, having defeated king Didier in 771, entered Brescia, and built the church of St. Denis. In 1426, after having suffered much by the troubles occasioned by the duke of Milan, it surrendered itself to the republic of Venice. Gaston de Foix, general of Lewis XII. took it in 1512 from the Venetians, and abandoned it to pillage, with the exception of the house inhabited by Chevalier Bayard: but in 1517, it was restored to the Venetians. It was visited by a plague in 1478, which swept away 25,000 persons; and again by a similar calamity in 1524. Brescia was the birth-place of Tartaglia, the famous mathematician, and of Gambarà, the poet, who died in 1596. It is distant about 44 miles E. of Milan, and 32 N. W. of Mantua. N. lat. 45° 31'. E. long. 10° 5'.

**BRESCICATI,** in *Commerce*, a kind of bays, which supplies the negroes between the river Gambia and Sierra Leona. The best sorts for this trade are the blue and red.

**BRESCOU,** in *Geography*, a small island of France, with a fort upon it, in the gulf of Lyons, near the coast of Languedoc, or Herault, about a league S. of AGDE; which see.

**BRESELLO.** See **BERSELLO**.

**BRESINI,** a small town of Poland, in the palatinate of Lenciez.

**BRESINS, or BRESONS,** a small island of the Atlantic, near the south-west coast of England.

**BRESK, or BRESKAN,** a town of Africa, in the kingdom of Algiers, seated on the sea coast, at the bottom of a bay in the Mediterranean; 50 miles W. S. W. of Algiers. N. lat. 36° 50'. E. long. 2° 30'.

**BRESKENS,** a town of Flanders, in the island of Cad-fand; 10 miles N. of Sluys.

**BRESLAU, or WRATISLAW,** a principality of Silesia, bounded on the N. and N.E. by that of Oels, on the S.E. by that of Brieg, on the S. and S.W. by those of Brieg and Schweidnitz, and on the W. by those of Lignitz and Wollau. This district forms a kind of long square, about 25 miles in length, by 16 in breadth. The country is very level; and the parts of it near the rivers, are either sandy or swampy. It is, however, an excellent corn country, and not destitute of rich pasturage ground; it abounds with sheep and cattle; and near the capital, the cows are of an uncommon size, and yield a proportionate quantity of milk; and this part of the country produces great quantities of madder. Wood is every where scarce, except in the circle of Namslau; and the roads are so bad, as to be in some places impassable; but this inconvenience is remedied, particularly in the vicinity of Breslan, by dykes and canals, which are kept in repair at a great annual expence.

On the partition of Silesia in 1764, among the sons of Uladslaus II. Breslan fell to the share of Boleslaus Altus; but

but disputes occurring among his successors, it was sold by one of them, viz. Henry VI., to John, king of Bohemia, who, after the death of Henry, in 1335, incorporated it with the crown of Bohemia, endowing the city, at the same time, with divers important privileges; and the kings of Bohemia always appointed governors over that principality. In 1337, king John assigned the government to the city of Breslau; and, in 1505, king Wladislaus transferred the jurisdiction of the whole principality to the same city: so that the chief magistrate occupied the part of governor until the year 1635, when both the government and jurisdictions were surrendered to the emperor Ferdinand III.; and in this state it continued, till it was united to Prussia. It is divided into four circles: viz. those of Breslau, Neumarkt, Canth, and Namslau; and, together with the district of Glogaw, it includes 53 cities, 108 towns, 14 market-towns, and between 5 and 6 thousand villages, 2000 catholic churches, 605 protestant churches, 20 abbeyes, 91 convents, and 39,000 hearths in the cities. The principal river of this principality, of which the property and jurisdiction belong to the king, is the Oder, which, in its course through the country, receives the inferior streams of Ohlau, Lohe, Weyda, and Weilitz.

BRESLAU, or BRSLAW, the capital of the above-described principality, and of the whole duchy of Silesia, is situated on the south side of the Oder, which receives the Ohlau after its winding course through Old Breslau. This place, the antiquity of which is uncertain, was set on fire by the Tartars in 1241, and was formerly environed by the Ohlau, as with a moat; and all without the Ohlau to the walls in their present position, were additions made by the emperor Charles IV. The Neustadt is more modern, and, since the year 1529, has been included within the fortifications, which are now, indeed, of no great importance. The whole town, both old and new, including the suburbs, is of great extent, being no less than two German miles in length. It is reckoned one of the most beautiful cities in Germany; and has several large regular squares, broad streets, and stately edifices, both public and private. The Roman catholics have several churches and convents; the Lutherans have seven churches within the walls, and two without, and two gymnasia; the Calvinists and the Greeks have, each of them, one church; and the Jews have two synagogues. The popish university is a noble edifice; and the exchange, adjoining to the council-house, is an elegant structure. Several of its monasteries and convents are magnificent buildings: and it has some good public libraries, with two armouries, a college of physicians, and a mint. Breslau holds the third rank, next to Berlin and Konigsberg, among the cities of Prussia. It is the centre of all the trade of Silesia, and its manufactures are considerable and various. The number of its inhabitants is estimated at about 52,000: and as it has several annual fairs, it is much frequented by Hungarian, Bohemian, Polish, and other merchants. The magistracy, which is Lutheran, consists of a town-court and a council; and its consistory is likewise Lutheran. This city was taken by the king of Prussia in 1741; compelled to surrender to the Austrians in 1757; and retaken by the Prussian army at the close of the same year, after a signal victory over the Austrians in its vicinity. In the last siege, several of its churches were much damaged, the library of St. Mary Magdalen was destroyed by the bursting of a bomb, and its suburbs were considerably injured. N. lat. 51° 3'. E. long. 17° 8' 45".

BRESLE, a town of France, in the department of the Oise, and district of Beauvais; 7 miles S. E. of Beauvais. —Also, a river of France, which rises near Aumale, and

separates the department of the Somme, from that of the Eure, till it falls into the sea at Treport.

BRESMA, in *Ichthyology*, a name given by Hildegard, and several others, to the Bream, *CYPRINUS BRAMA*, which see.

BRESMAL, JOHN FRANCIS, in *Biography*, a physician at Liege, was born in the year 1660. After studying some years at home, he went to Paris, where he was admitted doctor in medicine, in 1689. In the course of his travels, he had turned his attention, in a particular manner, to investigating the properties of the most celebrated mineral springs, of which, on his return to Liege, he published analyses, giving also accounts of their virtues in the cure of diseases. The titles of his works are, "La circulation des eaux, ou l'hydrographie des minerales d'Aix, et de Spa." Liege, 1699, 12mo. "Description, seu analyse de fontis, S. Aegidii, prope Tunyros," 1700, 12mo. He cites a description of this spring from Pliny. "Parallele des eaux minerales chaudes et froides du diocese de Liege. Avec un avis au public, pour le preserver de la peste, &c." 1721, 8vo. For the titles of other works by this writer, on the subject of mineral waters, see Eloy. Dict. Hist.

BRESSAN, in *Geography*. See BRESCIA.

BRESSAY, or BRASSA, one of the Shetland islands of Scotland, about 4 miles long, and 2 broad, separated from the main land of Shetland by a narrow sea, called "Bressay sound," forming a spacious harbour, in which a thousand ships may ride at the same time. In this harbour, the Dutch vessels, employed in the herring fishery, assemble about the middle of June. The inhabitants of Bressay fit out about 26 large fishing boats. The mountains supply slate for building, and peat for firing. N. lat. 60° 20'. W. long. 0° 50'.

BRESSE, a country of France, so denominated before the revolution, from a forest called "Brescia," situate in the province of Burgundy, and bounded on the east by Savoy, on the south by Viennois, on the west by Lyonnais and Dombes, and on the north by Franche Comté. It is estimated at 40 miles from north to south, and 23 from east to west. It is fertile in corn and hemp, and has fine pastures and several lakes, abounding with fish. For some time, it was an earldom subject to the dukes of Savoy, who added it in 1601 to France, in lieu of the marquise of Saluzzo. The principal towns are Bourg, the capital, Beauge or Bauge, Coligny, Montrenil, Loge, and Pont de Vaux.

BRESSICI, or BRESTE. See BRZESC.

BRESSOLES, see BREZOLES.

BRESSUIRE, a town of France, in the department of the two Sévres, and chief place of a canton, in the district of Thouars. The town contains 630, and the canton, 5911 inhabitants: the territory includes 290 kilometres, and 13 communes.

BRESSUS, or BREPUS, in *Ancient Geography*, a town of Asia in Armenia Major, situate near the Euphrates, according to Ptolemy.

BREST, or BREAST, in *Architecture*, a term used by some, for that member of a column otherwise called the *Tore*.

BREST-SUMMERS, or BRESSUMERS, in *Building*, are pieces of timber designed for the support of the brick-work in the front or rear wall of a building, for carrying arches, &c. In the inner parts of a building, the pieces into which the girders are framed are called SUMMERS.

BREST, in *Geography*, a sea port town of France, and principal place of a district, in the department of Finisterre. The number of inhabitants in the 3 parts, into which it is divided, is estimated at 27,000; the first canton contains 13,000, and includes 52½ kilometres, and one commune;

the second contains 17,275 inhabitants, and comprehends  $2\frac{1}{2}$  kilometres, and 5 communes; and the third canton includes 14,408 inhabitants,  $22\frac{1}{2}$  kilometres, and one commune. Brest is seated on the declivity of a hill on the side of its port; and its streets, which are few in number, are narrow and inconveniently contrived. It has two parish churches, a marine seminary, and a court of admiralty; but it is principally famous for its spacious road and harbour, which are reckoned, (if we except Toulon), the largest and the safest in the whole kingdom, and capable of containing 500 ships of war, in 8, 10, and 15 fathoms, at low water. Its entrance from the west south-west, called the "Gullet," is narrow and rocky, and the passage is difficult and dangerous, on account of the funken rocks on both sides of the shore. The entrance is also guarded by a strong castle seated on a rock on the sea-side, and defended on the land-side by a large ditch and other fortifications. On one side of the port is a large quay, more than a mile long, and 200 paces broad, covered with store houses for various kinds of merchandize; and, on the other side, there is also a quay, for the warehouses, and the fine church of Notre Dame; and in a suburb, about half the size of the city, there is a strong tower opposite to the castle at the entrance of the harbour. At the bottom of the harbour, to which the range of magazines on the quay nearly extend, there are two docks for the building of ships, adjoining to which are the shops and houses of the workmen; and one of these docks separates the rope walks from the city. The arsenal of Brest is a very large and magnificent building, plentifully supplied with different kinds of naval stores. This was entirely consumed by fire in the year 1744. In 1694, an attempt was made by lord Berkeley, who commanded a fleet of twenty-nine ships of war, with a number of fire ships and bomb-ketches, and general Talmache, who had the command of twelve regiments of infantry, and two of marines, to seize on Brest. But whilst the sailing of this expedition was delayed by counter-intrigues, the king of France dispatched marechal Vauban to repair the old, and to raise new fortifications, and a large body of troops to defend them. When the English armament arrived, the French were prepared in great force to repel it; and, therefore, the attempt, though conducted with singular resolution, was defeated, with the loss of 900 British soldiers, and 400 seamen, and of general Talmache, who died of his wounds, and who, in the agonies of death, complained, that he had fallen by the treachery of his countrymen. N. lat.  $49^{\circ} 22' 55''$ . W. long.  $4^{\circ} 30' 50''$ .

BREST, *bay of*, an American bay on the coast of the Western ocean in New Britain. N. lat.  $52^{\circ} 10'$ . W. long.  $52^{\circ} 30'$ .

BRET, *Cape*, lies in the Pacific ocean, on the east coast of the north island of New Zealand, within about 7 leagues of several small islands, close under the main, called "Cavalles". S. lat.  $35^{\circ} 7'$ . E. long.  $173^{\circ} 52'$ .

BRET, in *Ichthyology*, a name which the people on the coast of Lincolnshire give to the common turbot, a fish extremely common with them, and taken in vast abundance. The way of catching them is in a net, trailed it is said upon the ground by two horses; the one going up to the middle of his body in the water, the other on the shore. The turbot is known by the name of Bret among the fishermen, on many of our sea coasts, but most commonly, the smaller turbot only are distinguished by that title; when they have attained to a moderate size for the table, they are called turbot. It should be further observed, that the pearl, *Pleurocetes Rhombus*, likewise obtains the name of bret in some parts of the country. Bret is the name of the turbot almost throughout the north of Britain.

BRETACHIAE, in *Middle Age Writers*, denote wooden
